The novelty of this paper is in developing a reliable solution for paddy cultivation using IoT system by investigating the problems in placing the sensor to monitor the paddy field. Due to harsh environmental conditions in the paddy field, like very loose soil, the constant presence of water etc. It is very difficult to employ the method of using multiple sensor nodes to monitor the soil state. Placing multiple sensor nodes will be very difficult for the sensor to be maintained properly in the harsh condition of the constantly wet paddy field. It would also cause a lot of difficulties while harvesting the paddy field because the sensors must be removed whenever the crop is harvested by big machinery [24]. This paper also aims to develop the solution with the help of UGV so that it reduces the manpower required for irrigation thereby overcoming the problem of shortage of workforce in the agricultural sector.

The paper is divided into sections, where Section 3 deals with the methodology adopted in solving the problem. Later, the result is discussed in Section 4, followed by conclusions and future work in Section 5.

III. Methodology

Maintaining an optimum level of water and irrigating the paddy field with the right amount is very important to increase the yield of paddy. To perform this task a smart irrigation system for paddy field is important. The main challenges in developing a smart irrigation system for the paddy field are as follows.

- Collection of sensor data.
- Implementing the irrigation solution in the paddy field.

A. Collection of Sensor Data

Collection of data such as real-time field water level, rain status, temperature, humidity in the paddy field has many challenges because of the harsh condition in the paddy field. The method of placing a network of sensors as done in nurseries [25] will not work in particular to the paddy field, as the paddy field is exposed to heavy machinery for ploughing, transplanting, harvesting etc. Placing a network of a wireless sensor for measuring water level, rainwater, humidity, temperature, the light intensity is a big challenge. Instead of reducing the labour cost, this will lead to more cost of labour because the sensor nodes must be removed and placed each time when heavy machinery is used on the field. To solve this problem, the method adopted here is to divide the paddy field into sections and use a UGV which carries sensors on it, to move around in the paddy field collecting data. This not only solves the problem of placing sensor but also reduces the number of sensors needed, thereby reducing the cost, and making this method more feasible and reliable. The description of the sensors used is listed in Table I.

TABLE I. Sensors used in IoT Paddy Irrigation System

SN	*Name*	*Description*
1	DHT22	This sensor uses thermistor and capacitive humidity sensor to measure the temperature and humidity of the surrounding air respectively.
2	LDR	It is a light-sensitive device whose resistivity is a function of the incident electromagnetic radiation.
3	Water level sensor	This sensor gives an analogue signal that depends on the conductance which varies with the water level. Its outputs value varies between 0 to 1024.
4	Raindrop sensor	In this sensor, as the raindrops fall on the circuit board, it creates a path of parallel resistance which is measured using op-amp.

B. Implementing the Irrigation Solution in the Paddy Field

The method implemented here is developed to reduce the required manpower in paddy cultivation and thereby reducing the cost and thus helping the farmer. Paddy irrigation is labor-intensive, as it requires the farmer to constantly check the water level in different sections of the paddy field and maintain the optimal water level in each section, by operating the valves in each section. These works can be achieved by adopting a mobile application-based method and by using an independent cloud-based method.

1) Mobile application-based method: In this method, a mobile application acts as one place switch to monitor the paddy field water level. The mobile application is used to regulate the water level in the field by remotely operating the valves in different sections. Thereby, greatly helping the farmer by reducing the time for operating the valves and directing the water flow in the paddy field. A flow chart representing the mobile application- based method is shown in Fig. 1. In this, the farmer first inputs the login credentials in the mobile application. After logging in, the farmer will be given the option of controlling either the UGV or the water valve. In the UGV control screen, the farmer can control the UGV to move left, right, forward, backward. The UGV moves as instructed and sends the sensor data to the mobile application, where the farmer can see the water level at that location. In the water valve control screen, the farmer can switch the valve on or off.

2) Independent cloud-based method: A flow chart representing the independent cloud-based method is shown in Fig. 2. In this method, the cloud acts as the central system coordinating with the local server and pushing notifications to the mobile application for farmers. The UGV carrying the sensors will be controlled by a local server, the local server then collects the data from the UGV, processes the data and stores it. The local server then updates the variables in the

cloud database, based on this the cloud platform will switch the valve on or off. Thereby, maintaining an optimal level of water at all times. At the end of each day, the local server also pushes the day's sensor data to the cloud storage.

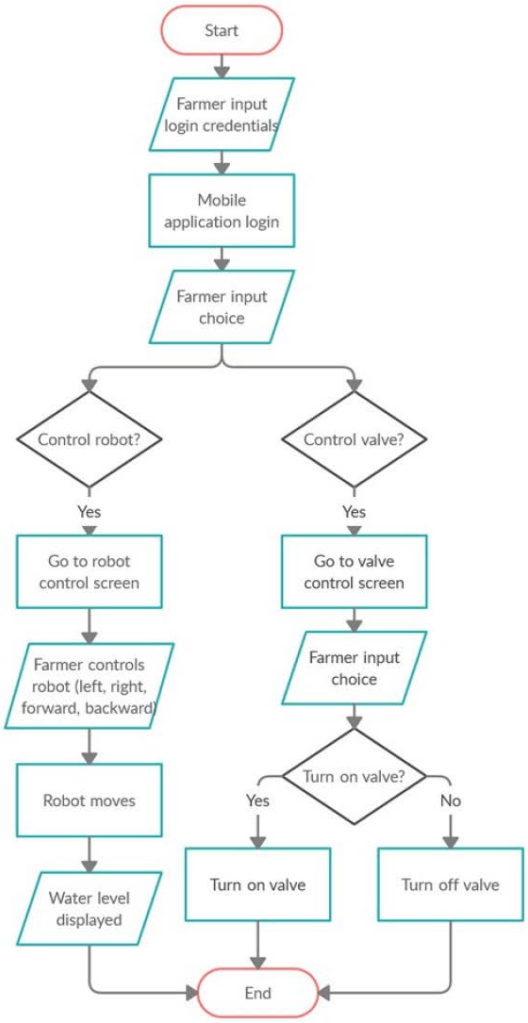

Fig. 1. Flowchart of the Mobile Application-based Method.

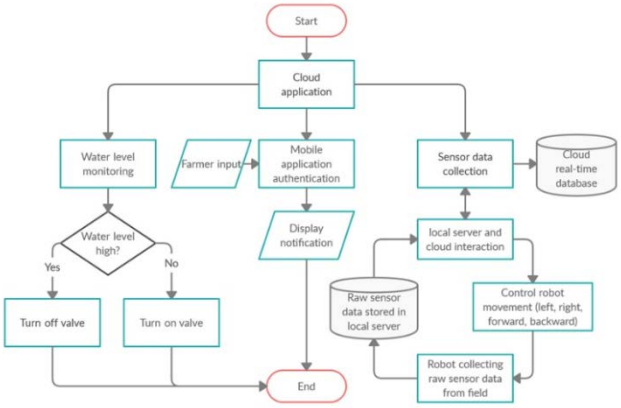

Fig. 2. Flowchart of the Independent Cloud-based Method.

IV. Result and Discussion

To develop an IoT solution for the problems faced by the farmers in paddy cultivation. It has been identified that the key to increasing the paddy crop yield, is to closely monitor the water level in the field and irrigate the land with the correct amount of water at various stages of the paddy growth. As a result, the authors have primarily focused on five main components to achieve this goal and they are listed below:

- Water level monitoring system.
- Water Valve system.
- Unmanned Ground Vehicle.
- Mobile application-based solution.
- Independent cloud-based solution.

On the road to developing a solution, some more hardware components that were used are listed in Table II. The description of each component of the solution that was developed is discussed in the following sub-sections.

TABLE II. Some more Components used in IoT Paddy Irrigation System

SN	*Name*	*Description*
1	Arduino UNO	It is a microcontroller having 6 analogue input pins and 14 digital input/output pins.
2	Raspberry Pi 3 Model B+	It is a single-board computer with wireless, LAN and Bluetooth connectivity.
3	Node Microcontroller Unit (Node MCU)	It is a microcontroller having low-cost open-source firmware and board based on the eLua project.
4	ESP8266	It is a low-cost Wi-Fi microchip with microcontroller capability and a full TCP/IP stack.
5	L293d IC motor driver	It is a Motor Driver module which can control the speed and direction of two motors simultaneously.
6	Relay Module	It can be controlled with low voltage. It is an electrically operated switch which allows the current to pass through when turned on.
7	Solenoid valve	It is an electromechanically controlled valve which consists of a solenoid and a movable ferromagnetic core in its centre.

A. Water Level Monitoring System

Water is a very important natural resource; water is the lifeline for any agricultural activity. The scarcity of water resources in many countries has forced everyone to look for means of utilizing the water resource with utmost care [26]. To utilize the water resources fruitfully, it is necessary to provide the right amount of water for agricultural activity, especially for the cultivation of water demanding crops like paddy, which calls for the need of good water management system for paddy cultivation. The best way to have good water management system is to have a good water level monitoring system.

In paddy cultivation, water plays a vital role in proper yield, as water can both be constructive (i.e., more yield) and destructive (i.e., poor yield). Too less water may lead to dying of crops and cracking of land. Very high water may lead to a poor yield of paddy, it may also lead to the soil nutrients being washed out and causes soil salinity. Therefore, water level

monitoring is crucial for paddy cultivation. The paddy cultivation always requires standing water. This standing water needs to be at different levels in different stages of the paddy life cycle which is obtained from [27]. Therefore, it is very important to check the paddy field water level at various stages of its life cycle.

To monitor the paddy field, the water level sensor is used. The water level sensor is connected to the Arduino UNO via an analogue input pin. The sensor measures the water level and gives output in the form of analogue signals which varies from 0 to 1024, which is mapped to 0 to 5 centimeter of water level in the Arduino using proportionality relation (1). This measurement is then taken consecutively for 20 times in one location and then averaged to get the most accurate value of water level at that location. In this way, the water can be monitored most accurately. Fig. 3 gives the pictorial representation of the water level monitoring system.

$$water\ level(cm) = \frac{analog\ pin\ input * 5}{1023} \quad (1)$$

B. Water Valve System

Valves are very important for the controlled flow of water. In the agriculture field, valves are vital for controlling, stopping, and directing the water flow for irrigation. Valves play the role of end actuator by working as the output device for the input from a water level monitoring system. The water level monitoring system acts as the sensing system in the irrigation of paddy fields.

As paddy fields are very large, it is usually divided into many small sections by constructing bunds. Water is then directed to each of the sections by opening a small portion of the bunds when the required level of water is reached. The portion of the bunds is closed, and other sections are irrigated in the same way. This involves a lot of manpower and wastage of precious time of the farmers. This can otherwise be directed to other important agricultural activities such as weeding, fertilizing process etc., it also leads to excess or low water being irrigated which may lead to a lower yield of paddy. Hence this loss of time and money the farmer and the poor yield can be prevented by using a valve system that is remotely operated either by mobile application or by cloud services.

To develop this valve system a low-cost solenoid valve is used. This valve is connected to the Relay module which is controlled by Node MCU as shown in Fig. 4. Node MCU receives a signal from either the mobile application or cloud platform to switch on or off the valve, and then the MCU switches the relay module which then leads to the opening or closing the valve. In this way, the exact level of water given by [27] in the paddy field is maintained.

Fig. 3. Pictorial Representation of the Water Level Monitoring System for Paddy Cultivation.

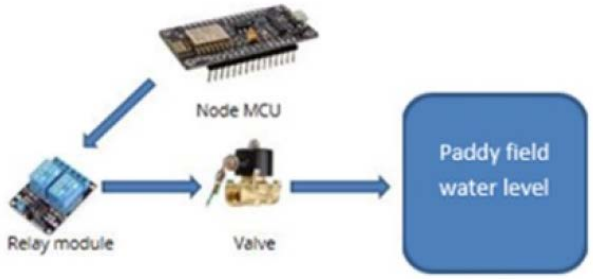

Fig. 4. Pictorial Representation of the Valve System for Paddy Cultivation.

C. Unmanned Ground Vehicle

Paddy field has harsh conditions that are not suitable for sensors, hence the sensors must be protected, it also poses the challenge of placing the sensors in the right locations, to get an accurate reading. Placing the sensors on the ground at a different location to monitor water level, temperature, humidity etc. will not be suitable for paddy field because of various difficulties involved. Hence, there is a need for a robot to carry sensors. As our primary objective is to measure the water level, aerial robots will not serve the purpose, as it is not possible to measure the water level on the paddy field from air. Hence a UGV was developed for this purpose.

The UGV was designed to face the challenges in the paddy field. The design procedure consisted of first identifying the difficulties the UGV would face such as muddy, slippery soil, water standing up to a level. Then various sensors that the UGV must carry was considered, motor's speed to drive the UGV, the battery size, the weight of all the components were considered. The chassis of the UGV was designed considering all these factors. The material was assigned as aluminum because of its lightweight property, as the weight was a major factor in design. As the weight increases, the motor size increases, and the battery size should have to be increased. The wheel of the UGV was decided to be a tracked wheel since it provides a large surface area. Computer-Aided Drawing (CAD) software 'Solid Edge' was used to visualize each part of the chassis. Later all the parts were assembled in the CAD software, shown in Fig. 5. Then based on the CAD software visualization, a model was built.

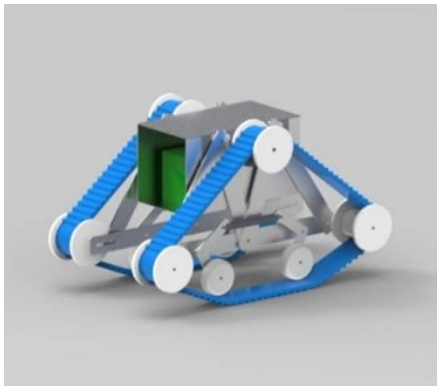

Fig. 5. Picture of UGV Assembled in CAD Software Solid Edge.

The UGV is driven by two DC motor, with the help of L293d IC motor driver which is controlled by Arduino UNO. The UGV carries sensors DHT22 (Humidity and temperature sensor), water level sensor, raindrop sensor, LDR. The pictorial representation of all the sensors carried by the UGV is shown in Fig. 6 and the model of the UGV after fabrication is shown in Fig. 7.

D. Mobile Application-based Solution

The smartphone industry is a growing market in the world, with more and more smartphones penetration into developing country like India, it is expected to reach a user base of 442 million by 2022 [28]. Hence, it has been identified that mobile application-based solution to be a feasible solution for the problem of irrigation [29].

There are lots of work involved in irrigating a paddy field such as, constantly checking the water level in different sections of the paddy field, making sure that the water is maintained at the correct level in each section, opening and closing the valves and directing the water to all the sections. This may not be a big problem for a very small field, but for a very large field, it is very time consuming and may even require a separate full-time worker just for performing these tasks. Employing a separate worker just to perform these tasks incurs additional expenditure to the farmer which can otherwise be prevented by employing technology. Hence the use of a smartphone with a mobile application to perform these tasks will help reduce the unwanted expenditure in employing workers.

The mobile application is a web-based application which is hosted by Google's Firebase. It has three functionalities they are,

- Operate the UGV that carries the sensor.
- Switching on or off the valves.
- Receive any notifications from the cloud platform.

The mobile application has a login screen which requires an email id and password to log in. The credentials are authenticated by the Google firebase's authentication, where it assigns Unique Identification (UID) for each user hence the details of the farmers are stored securely. It has a screen for receiving the notification regarding updates on the field and other related news such as government schemes, which is shown in Fig. 8, firebase has the option of pushing a user-specific notification by using UID that is assigned to each user.

The mobile application has a screen for operating the UGV, where there is information regarding the water level at the current location of UGV and it has buttons for maneuvering the UGV left, right and to move forward, backward and stop. It also has a button for switching the mode of the UGV control to the mobile application-based method or independent cloud-based method. It has another screen which has buttons for switching the valves on and off, this is shown in Fig. 9.

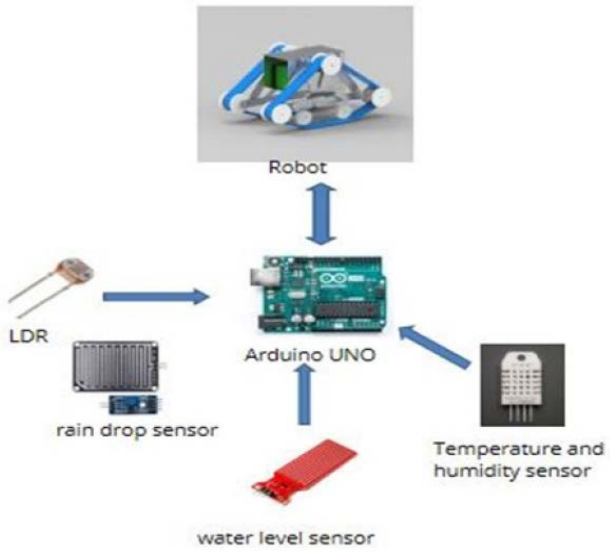

Fig. 6. Pictorial Representation of all the Sensors Carried by the UGV.

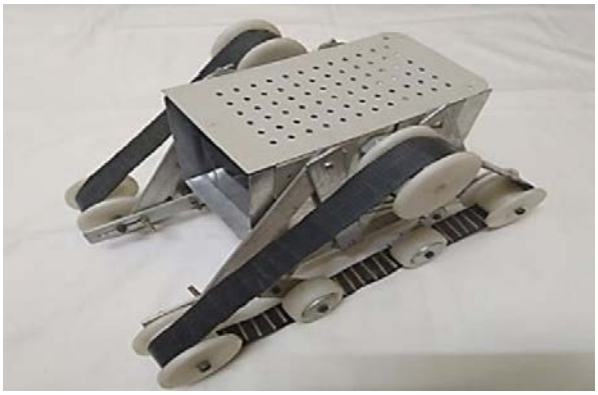

Fig. 7. The Model of the UGV after Fabrication.

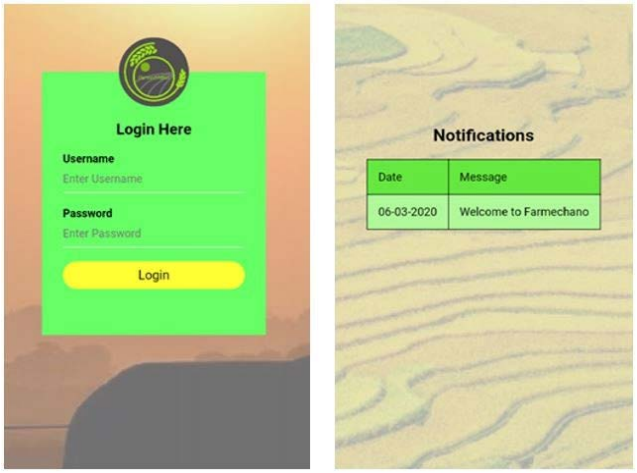

Fig. 8. Snapshot of Login Screen towards Left and Notification Screen towards the Right of Mobile Application.

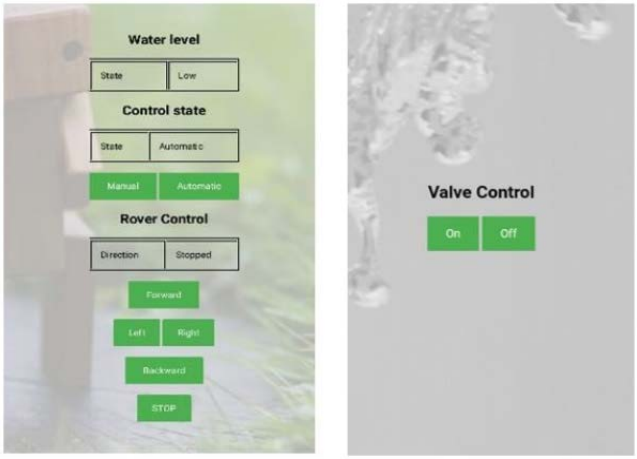

Fig. 9. Snapshot of the Screen for UGV Control in the Left and Screen of Valve Control in the Right in the Mobile Application.

A pictorial representation of a mobile application-based control system is shown in Fig. 10. In this when the buttons in the mobile application are pressed, the corresponding variable of the UGV in Google's Firebase real-time database is updated. These variables, which is constantly being monitored by the local server (Raspberry Pi) as well as the Node MCU of the valve control system receives the command. The local server then sends this command to the UGV using Wi-Fi as the channel for communication. The UGV receives this command with the help of ESP8266 connected to the Arduino Uno. Based on the command, the Arduino controls the driving motor, on the other hand, the Node MCU of the valve control system controls the valve based on the command.

E. Independent Cloud-based Solution

Paddy cultivation is labour intensive, a decrease of workers available for agricultural activity has become a major problem in recent years. As more and more agricultural labourers are migrating to cities in search of better livelihood, financial and social status [30]. This has risen an alarm in the agricultural sector, as farmers are not getting sufficient labourers to carry out agricultural activities. The poor income of farmers and the rising cost of labourers for agricultural activities, has also become a concern. Hence this problem can be solved by bringing in automation in the cultivation of paddy field and integrating with the cloud to develop an end-to-end IoT solution.

The main objective of an independent cloud-based system is listed below:

- To monitor the water level of the paddy field
- To control the UGV for collecting paddy field data
- To control the water level of the paddy field
- To store the collected sensor data

The pictorial representation of the independent cloud-based control system is shown in Fig. 11. In this Raspberry Pi is employed, which is the local server placed in the storeroom next to the paddy field which is considered as the control room. The local server further divides the sections of the paddy fields created by constructing bunds into small pieces virtually, it then instructs the UGV which carries the water level monitoring system on it, to move towards each of these sections and carry out the reading, the water level monitoring system along with various other sensors attached to the UGV (as discussed in section IV C) sends the readings to the local server through Wi-Fi. The local server then processes these raw sensor data and stores the values in the local variables such as water level, temperature, humidity, light intensity, rain. The local server then compares the values for water level with the predefined values which are recommended by the Tamil Nadu Agricultural University (TNAU) where the optimal level of water for different stages of the paddy crop growth can be obtained for different ecosystems [27]. The value of variable water level (wat lev) in each section of the paddy field, temperature (temp), humidity (hum), rain, light intensity (LDR) of the field as processed and displayed by the local server is shown in Fig. 12.

The local server then logs all the processed sensor data in a local file of .CSV format which has columns of time, water level, LDR, rain, humidity, temperature, for every one-hour. This .CSV file is then uploaded to Google firebase's Fire-store at the end of each day, which can later be used for checking the health of various sensors.

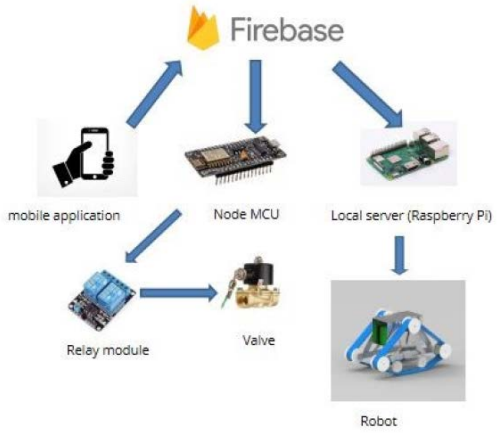

Fig. 10. Pictorial Representation of the Mobile Application-based Control System.

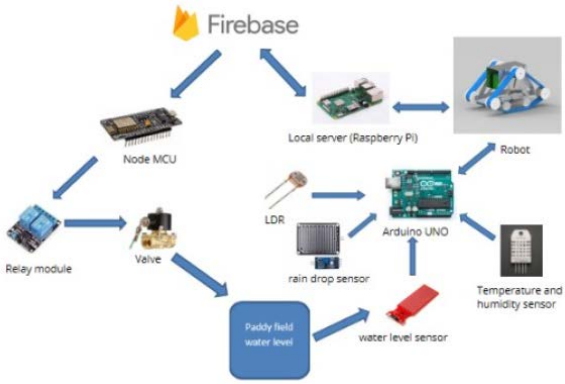

Fig. 11. Pictorial Representation of the Independent Cloud-based Control System.

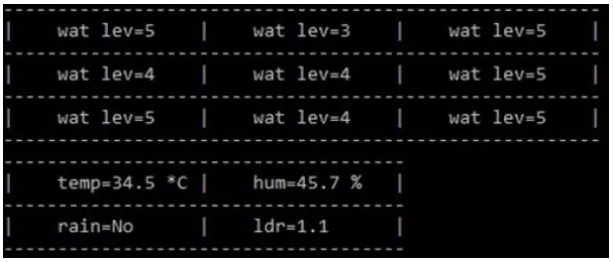

Fig. 12. Snapshot of the Local Variable Values of Water Level for each Section of the Paddy Field along with Temperature, Humidity, Rain Status, Light Intensity (LDR) as Processed and Displayed by the Local Server.

The water level and rain status are updated on the respective variable in Google's firebase real-time database. Based on the water level and rain status the firebase updates the variable 'valve' in the firebase Realtime database. This variable 'valve' being monitored by the valve system controls the valves for various sections of the paddy field. Thus, the independent cloud-based solution can monitor and control the water level of the paddy field.

As mentioned earlier, to increase the paddy crop yield monitoring the water level and irrigating the paddy field with the right amount of water at a different stage of the paddy growth is important. First, the water level that was maintained in a paddy field by following the traditional method of irrigation, where farmers direct the flow of water to different sections manually and maintain water level by eye judgment was recorded, for each hour of the day from 06:30 Hrs. to 18:30 Hrs. Then water level that was maintained in the paddy field by following a mobile application-based solution was recorded for each hour of the day from 06:30 Hrs. to 18:30 Hrs. Then water level that was maintained in the paddy field by following independent cloud-based solution was recorded for each hour of the day from 06:30 Hrs. to 18:30 Hrs. Then the water level values that were collected by using all three methods were plotted against time of the day as shown in Fig. 13. The optimum water level is represented by a constant line in the graph.

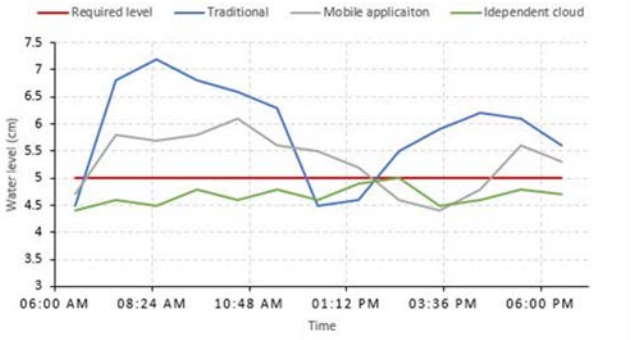

Fig. 13. A Plot of Water Level in cm vs Time for various Methods followed for Paddy Cultivation.

From the graph, the independent cloud-based solution could maintain the water level in the paddy field at a near-constant required level when compared to the mobile application-based solution and traditional method. It was observed that in the traditional method, farmers tend to use more water than recommended since they have no means to measure the exact level of water and just go by eye perspective, whereas when using the mobile application-based solution, there is means to know the water level, thereby the water level is fairly close to the recommended level but there are large deviations a time, as it is still operated by a human.

V. Conclusion and Future Work

A novel solution for irrigation of paddy field was presented with Unmanned Ground Vehicle (UGV) and Internet of Things (IoT) by investigating various problems arising in placing sensors in the paddy field. This solution enables maintaining the water level in the paddy field in the optimal level which is an important parameter for a good yield of paddy crop, throughout the growth cycle in the most cost-effective manner. The solution presented in this paper is feasible to integrate into the present paddy field with ease. It also helps in saving the time and manpower required for paddy cultivation. The solution presented here can be used in places where water resources are scarce and stringent monitoring of water is required. It minimizes the wastage of water and thereby conserving the precious water resources. The UGV can further be modified to carry and spray pesticides, fertilizers etc. making it a multirole UGV for use in paddy field. The path planning for the UGV can be made more dynamic by implementing machine learning and artificial intelligence. The solution developed here can be modified and tested for use in other type of crops.

Adaptive Trajectory Control Design for Bilateral Robotic Arm with Enforced Sensorless and Acceleration based Force Control Technique

Nuratiqa Natrah Mansor, Muhammad Herman Jamaluddin, Ahmad Zaki Shukor
Faculty of Electrical Engineering, Universiti Teknikal Malaysia Melaka (UTeM), Durian Tunggal, Melaka, Malaysia

***Abstract*—This study offers an approach for tackling the issue of instability on the computed force generated on a joint of a robotic arm by improving the model of a bilateral master-slave haptic system with an adaptive technique known as Reaction Force Observer (RFOB). The purpose of recommended modelling is to correct unsought signals coming from the employed standard controller and the surroundings produced within the moving joint of the articulated robotic arm. RFOB is employed to adjust the signal interference by modifying its position response to obtain the desired final location. The investigation and observation were carried out in two separate tests to evaluate the outcomes of the recommended integration technique with the former system that only enforced Disturbance Observer (DOB). Generated feedbacks produced from the organised experiments are measured inside a simulation platform. All numerical records and signal charts illustrate the durability of the proposed method since the system integrated with acceleration-based force control is more precise and quicker.**

***Keywords*—Force and position controller; reaction force observer; bilateral control robotic arm; sensorless; system response**

I. Introduction

A bidirectional master-slave industrial robotic arm manipulator system is a revolutionary technology that was beyond imagination a century ago. It permits explorers and adventurers to reach the places unavailable to them. The places might be inaccessible, harmful or isolated. By the time this research is studied, there have been many applications in multiple fields, including surgical operation, exploration in the deep ocean and outer space operations, and coping with volatile or high emission activities [1]. Robots are programmable machines. It can cope in a different environment with unique features, mobile and easy to manoeuvre. Therefore, this study utilised a youBot made by German robots' manufacturer, KUKA, as the device to showcase and operate as a bidirectional haptic system.

According to prior studies conducted by researchers all around the world, old traditional approaches had technical limitations. The techniques focus on enhancing the control system itself through the use of premade and essential equipment such as a keyboard, joystick, data glove, basic manipulator connection, and the use of force sensors [2]. Common force sensors appear to have several restrictions and disadvantages for the system. The system has particular uncertainty, instability, and delays [2-4]. On an actual industrial robot arm, not much of the previous study uses contemporary control techniques to enhance the system feedback. It is impracticable and wasteful not to use these strategies, which have been shown to improve responses on control systems in multiple previous studies [3,5]. The combination of force control and position control into the design of bilateral robotic arms should be emphasised to discover the disparity, uniqueness, and uncommon industrial task handled by the arm manipulator with other ordinary and smaller haptic devices [6,9].

Therefore, it is a refreshing attempt to build and model a bilateral control system on industrial robots. In the past 40 years, haptic technology has evolved across engineering studies and many other research areas, including arts and design. Several researchers have studied its control system, auxiliary, communication and wearable devices, as there is a diversity of many possibilities, opening doors for incoming haptic technology [6-7]. For instance, [7,8] discovered that control action and response inside the said system might increase as far as 90% accuracy compared to the conventional approach that did not utilise any adaptive control technique. The standard system without the adjusted controller parameters needs to battle around 25% to attain the controller goal [4]. Following the deployment of DOB and RFOB, it acquired efficacy and simultaneously avoided any infallibility on the control process. With the facts, the integration of both adaptive techniques to the new design of the control system should be commissioned and emphasised. The benefits of implementing these stated observers into a system are projected to boost the feedback of bilateral haptic inside the system. It is also to eliminate all unwanted signals and disturbances that occur while operating.

The main objective of this study is to be set and incorporate a type of sensorless force control into the robotic arm simulation and observe the most acceptable parameters to arrange for the robot to operate and work optimally in a bilateral way. The outcome reported in this article is focused on employing two versions of robust control tools to increase the efficacy and discover the capability of the system to adjust its operation to obtain the optimal potential mode of operation [6-8]. The second section will delve into the robust acceleration control and the block diagram of acceleration-based force control, review the series of steps of procedures and methodologies performed on each experiment. In the following section later, all recorded data and information observed from every experiment are tallied and illustrated in

Zamalah Scheme, Universiti Teknikal Malaysia Melaka (UTeM).

graph version. Next, Section III will discuss the feedback of the aforementioned master-slave manipulator control system recorded from the simulation. Meanwhile, Section IV summarises the essential findings and conveys the recommendations to acknowledge the limitations and improve future work.

II. Methodology

A. Control Design based on Disturbance Compensation

The fundamental purpose of this project is to employ a software simulation for constructing a model of a haptic robotic arm to work in bilateral master-slave interaction. As being discussed in the introduction part, system response in normal circumstances carries noise and suffers constraints during operation. The constraints can be in the bandwidth of the filter due to the wide frequency range or internal stability. Hypothetically, there are concerns and limitations to achieving the robustness as it is generally mediocre and tough to maintain the system. One of the solutions to handle the challenge is introducing a control tool into a control system [8]. This control structure can boost system infallibility by erasing uncertainties and undesirable information within the system. The role of this inner-loop output-feedback controller is to discard outer disturbances and make up the outer-loop baseline controller resilient against the plant's uncertainties [7].

Employing force sensors in a machine or equipment brings several significant drawbacks, although it is responsible for measuring the force acting on a specific object. The conventional sensors are not exceptionally durable, expensive, and restricted capability to detect the bandwidth. This observer can be enforced into a system loop to replace the traditional instruments for estimating force measurement and remain sensorless [5]. Moreover, the developed system is suitable to perform navigation and task manipulation in a connected teleoperation setup. The dynamic characteristics of DOB can improve the restrictions and inadequate ability encountered by standard basic controllers. Compared to the other two controllers, such as Proportional and Integral controllers (PI) and Proportional Integral Derivate Controller (PID), Proportional and Derivative Controller (PD) is well matched to pair with the observer to construct a new design of closed-loop control system for the master-slave robotic arm.

Incorporating DOB in the design system can measure disturbance force, F_{dis}, and give compensating current, $I_{cmp,}$ achieving robust motion control in unstable plants. The proposed tool is another notable technique for measuring force-producing and estimating disturbances. Consequently, filtered data by the observer paired with a fed-back input signal will be utilised to nominalise the inner loop, satisfy causality, and adjust motion control. Therefore, it will deliver high precision readings for precise position tracking. Whereas the equation is equivalently illustrated into block diagrams as shown in Fig. 1 and Fig. 2.

Systematically, the integrated technique supports the system to predefined performance criteria and achieves firm acceleration control. Fig. 2 summarises the schematic of the acceleration-based position control block diagram.

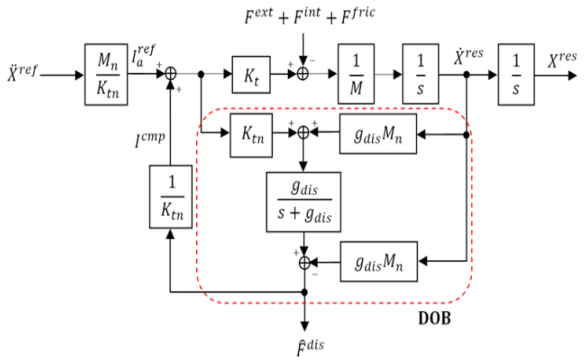

Fig. 1. A Block Diagram for a DOB based Open-loop Control System.

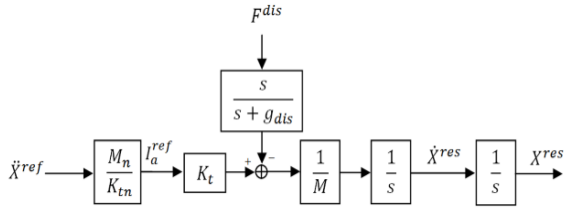

Fig. 2. Robust Acceleration Control.

The open-loop sensitivity and the co-sensitivity transfer function is derived in equation (1) below to denote uncertain and nominal plant models. The following transfer functions are the components of *Fdis*:

$$F_{dis} = F_{ext} + F_{int} + F_{fric} + (M - M_n)\, s^2 X_{res} + (K_{tn} - K_t)\, I_a^{ref} \quad (1)$$

The force-induced consist of modelling errors of nominal mass, M_n and nominal thrust coefficient, K_{tn} in overall is represented as disturbance force, F_{dis} equation. Meanwhile, Interactive force, F_{int} components are the Coriolis term, centrifugal term, and also gravity term. A low pass filter (LPF) and the inverse of a nominal plant model are required to shape the DOB model. The disturbance force F_{dis} is approximated as the following equation:

$$F_{dis} = \frac{g_{dis}}{s+g_{dis}} F_{dis} \quad (2)$$

The equation for position controller, C_p in differential mode is derived from summation of both position gain, K_p and velocity gain, K_v.

$$C_p = K_p + sK_v \quad (3)$$

Then, the corresponding position response, x_{res}, is expanded into:

$$x_{res} = \frac{C_p}{s^2}(x_{cmd} - x_{res}) \quad (4)$$

Where x_{res} in (4) has been rearranged and translated into (5), as seen below:

$$\frac{x_{res}}{x_{cmd}} = \frac{C_p}{s^2 + C_p}$$

$$\frac{x_{res}}{x_{cmd}} = \frac{sK_v + K_p}{s^2 + sK_v + K_p}$$

$$\frac{x_{res}}{x_{cmd}} = \frac{2\xi\omega_n s + {\omega_n}^2}{s^2 + 2\xi\omega_n s + {\omega_n}^2} \quad (5)$$

From the above equation, the damping ratio value, ξ, can be tuned to 1.0 to obtain a critical damping effect, whereas natural angular frequency, ω_n is a substitution of $\sqrt{K_p}$ or ½ K_v.

B. Control Design based on Reaction Force Estimation

Aside from the original purpose of DOB, it can be employed with RFOB to estimate the reaction force. Past studies have shown that the RFOB can estimate a wider band and excellent range of situations (Mansor et al., 2017). Consequently, force sensors are replaceable to be employed in bilateral manipulator's systems. The component of estimation also requires the identification of friction force F_{fric} and the interaction force F_{int}. Furthermore, the design of RFOB is competent to estimate the exterior force given out by the disturbance of the components in the type of acting force or force response [4-5]. To describe the process of this control loop technique and arrangement within the loop system, outlined block diagrams is illustrated in Fig. 3 and Fig. 4, respectively.

The cut-off frequency, g for RFOB, is similar to the DOB. Thus, the computed external force $\hat{F}_{ext}$ is equate as follows:

$$\hat{F}_{ext} = \frac{g_{dis}}{s+g_{dis}} F_{ext} \tag{6}$$

As the value for force controller, C_f is associated with the force gain, K_f, hence the estimated force response, F_{res} is described as follows:

$$\hat{F}_{res} = \frac{C_f Z_c g_{dis}}{s^2(s+g_{dis})}(F_{cmd} - \hat{F}_{res}) \tag{7}$$

Which can be transformed into (8):

$$\frac{\hat{F}_{res}}{F_{cmd}} = \frac{1}{\frac{s^2(s+g_{dis})}{C_f Z_c g_{dis}}+1} \tag{8}$$

C. Design of Bilateral Master-Slave System with Adaptive Control Technique

Fig. 5 displays the whole close-loop bilateral control system following the employment of both control loop techniques into the system. The observers' data will merge and feed back into the input signal for every passing process. The generated feedback will correct any internal modelling error or interruption and emerge into one input.

There are two modes in the bilateral control system, which are Differential Mode, $\ddot{x}_{dif}$ and Common Mode, $\ddot{x}_{com}$. The first mode is the product of position controller, C_p with the difference between the position of the master-slave system, and the latter is the product of force controller, C_f with the differences between the forces computed in master-slave. The equation for both modes follows the equation (9) and (10) below.

$$\ddot{x}_{dif}^{ref} = C_p(s)(x_s^{res} - x_m^{res}) \tag{9}$$

$$\ddot{x}_{com}^{ref} = C_f(s)(f_s^{ext} - f_m^{ext}) \tag{10}$$

D. Procedures for Work Simulation

This study's analysis and experiment are carried out through a simulation platform inside a robotic simulation software called Virtual Robotic Experimentation Platform (VREP). The software has a built-in KUKA youBot in its library and is ready to be integrated with various programmable tasks and coding languages. Furthermore, simulation scenes, models, and object characteristics are simple to manage as it has formed a plethora of choices and functionalities. The first task to be considered to prove whether the proposed system is ideal must follow the law of action and reaction in bilateral communication. After the system works according to the law, the experiment will be carried out to analyse the system with adaptive techniques. All starting values for each parameter and setting are presumed to be related to the real-time experiment. To construct the bilateral way of communication inside the KUKA youBot, the controllers, input and output arrangement are shown in Fig. 6.

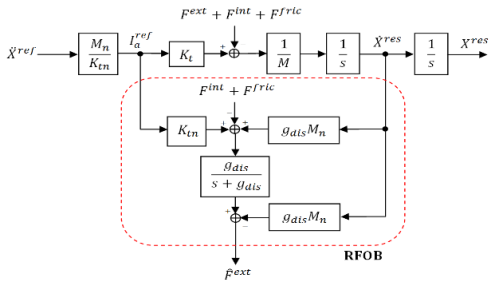

Fig. 3. A Block Diagram for RFOB based on an Open-Loop Control System.

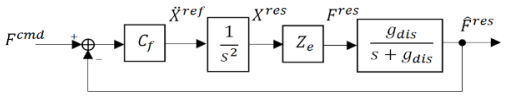

Fig. 4. Acceleration based Force Control System Block Diagram.

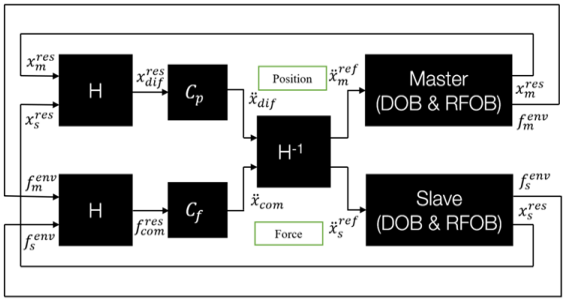

Fig. 5. A Simplified Block Diagram of Master-Slave Bilateral Control System with Proposed Tools.

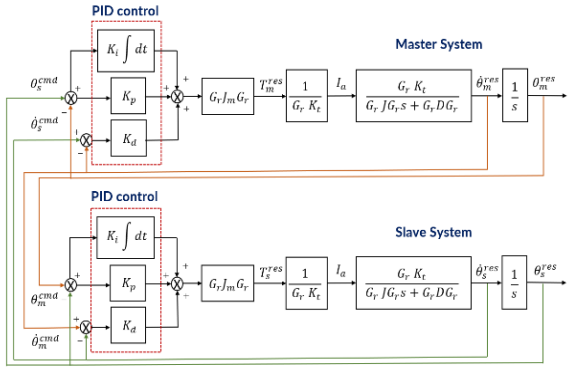

Fig. 6. General Block Diagram for a Bilateral Robotic Arm with Two Separate Subsystems.

The remote Application Programming Interface (API) function will be used to communicate between both robots with the programmed environment. To simplify the study work, only reading in a single joint are monitored even though the robot has 5 degrees of freedom (DOF) and multiple operatable joints, as indicated in Fig. 7 below. This joint on the waist part is labelled as 'Joint0' (located at the first joint on the lower robot component).

The reason to focus on a single link of the manipulator is to reduce the complexity of managing the trajectory control and operating successive joints and degrees of freedom during tests. The environment and setup for all experiments are modelled in VREP. To illustrate the simulation processes, the steps are outlined in Fig. 8 and shown in the following Fig. 9a and Fig. 9b.

In summary, this section explained the methodology to carry the experiment, general block diagrams for every proposed design of bilateral control system and introduced observer, modelling equations and pictorial illustration of the robot operating in simulated software. Detail procedures and control setup have been described to explain every test that has been carried out.

III. Results and Analysis

This section discusses the proposed system's outcome, and output feedback gathered after running separate tests. All findings from experiments have been acquired and assembled into table form and constructed into graph form to observe the disparity between all versions of control systems. Each experiment has been conducted according to the parameters and variable setlist. For every refreshed assessment set, all steps are repeating for three times to compute the mean values before being illustrated in the graph version. These independent variables of K_p and K_d values are presented in Table I below. For RFOB, the priority is to validate the Differential Mode Law of the bilateral master-slave telerobotic arm manipulator system. The test is to verify that the system abiding by the law of subtraction between master and slave for position reading is equal to zero. The test also demonstrates that the integration of two types of different observers is capable of enhancing the system response and lowering the noise value within the internal system. The selected gain values are based on the experimental validation approach. Numerous trials have been performed on an extensive range of variables to determine appropriate lowest and highest values that work compatibly with the proposed system.

TABLE I. IDENTIFIED SET OF CONTROLLER GAIN VALUES

ω_n	$K_p(\omega_n)^2$	$K_d(2\omega_n)$
1	1	2
2	4	4
5	25	10
10	100	20
20	400	40
50	2500	100
100	10000	200
200	40000	400
500	250000	1000

A. Evaluation on Force Control

The first analysis is performed with RFOB is paired to the inner loop output feedback of the working system. The proposed control loop is implemented to monitor the force reaction happening in the system. The recorded force reading generated on both subsystems is displayed in Fig. 10 to Fig. 18, respectively.

Entire graphs from Fig. 10 to Fig. 18 shows the feedback in forces for master and slave youBot in a different set of settings, corresponding to every value of ω_n as listed in Table I. There are two types of forces produced in every graph. The first generated formed in blue colour signifies the torque reading yield from the master; meanwhile, the second line in orange represents the torque induced from the joint at slave robot. It should be noted that the maximum torque for Joint0 for both subsystems is set at 8N.

Referring to graphs in Fig. 10 to Fig. 14, when the force in the master began to grow into 8Nm after being pushed by the external manipulator, the reading value in the slave varied and generated a series of gradual increments in force reading. At this point, the slave did not move and remained in its original position at 0˚. This is because the gain values of K_p and K_d are too small and insufficient to increase the controller's sensitivity in the proposed bilateral control system. Although the force reading in the master climbed up for a certain period after being pushed, the feedback and data circulated from the master subsystem were considered ignored by the slave. This is because the slave cannot read the exact information passed through its subsystem. Force generated on the said joint is collectively unstable and fluctuating.

Nevertheless, as exposed in Fig. 10 to Fig. 12, force reading on both systems is restored to zero after the external manipulator returned to its early position, stopping it from pushing the master youBot arm ahead. There are some instabilities traced in force reading of master and slave as shown in Fig. 13 and Fig. 14 after the value of K_p and K_d is increased up to K_p = 100, K_d = 20 and K_p = 400, K_d = 40. At this point, force reading became unstable and wavering, evidently referred to the current scenario in the simulation workspace. Both robots attempt to identify each other's final pose when the slave robot quakes after being in contact with the obstruction block.

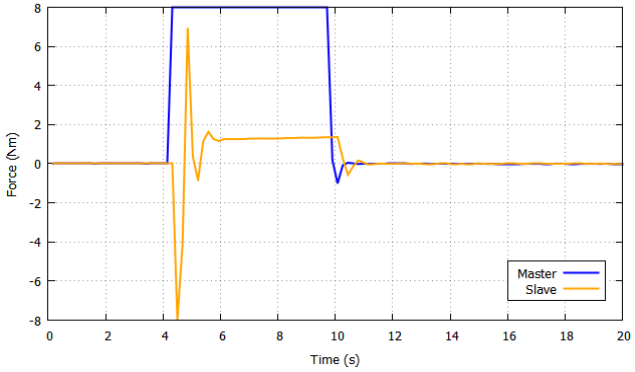

Fig. 10. Generated Force on both Subsystems across Period for ω_n = 1.

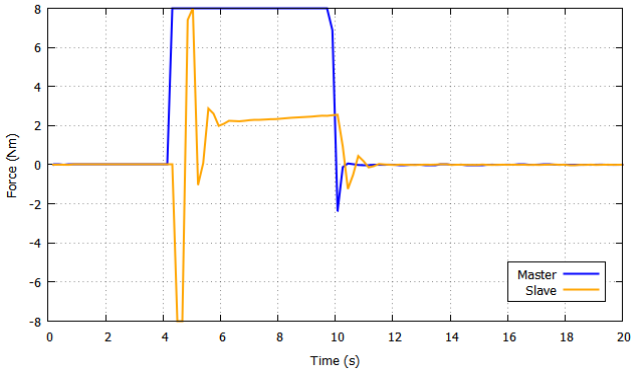

Fig. 11. Generated Force on both Subsystems across Period for ω_n = 2.

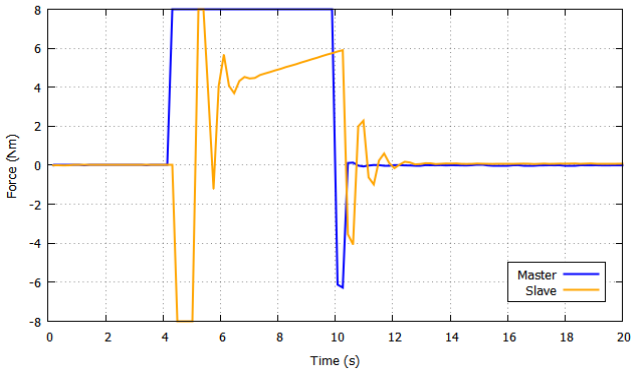

Fig. 12. Generated Force on both Subsystems across Period for ω_n = 5.

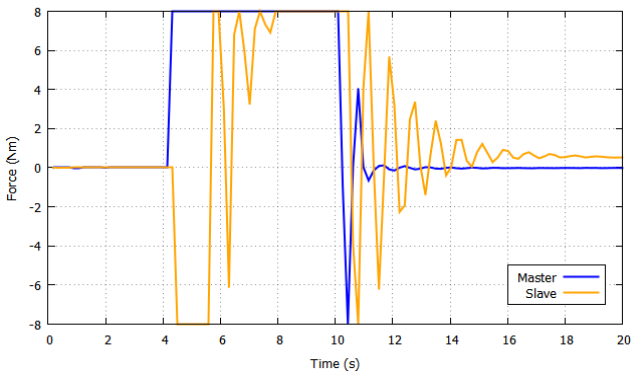

Fig. 13. Generated Force on both Subsystems across Period for ω_n = 10.

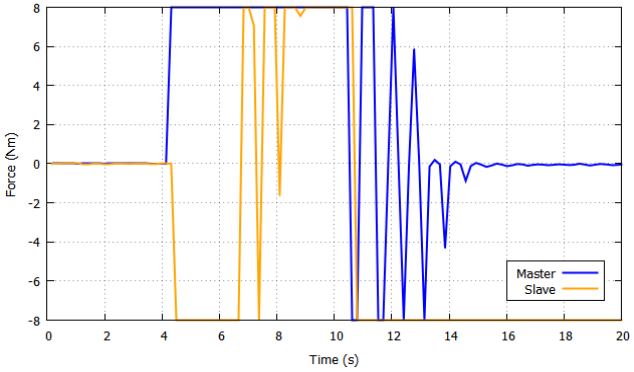

Fig. 14. Generated Force on both Subsystems across Period for ω_n = 20.

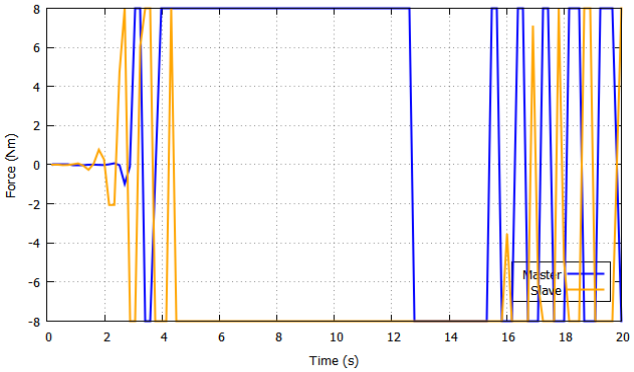

Fig. 15. Generated Force on both Subsystems across Period for ω_n = 50.

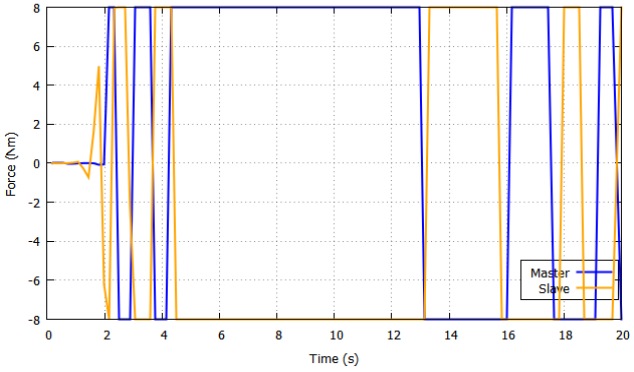

Fig. 16. Generated Force on both Subsystems across Period for ω_n = 100.

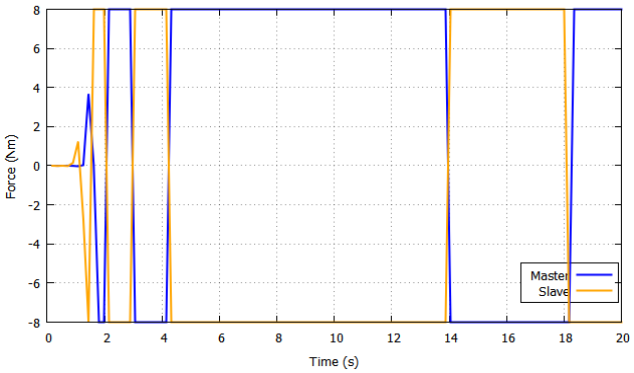

Fig. 17. Generated Force on both Subsystems across Period for ω_n = 200.

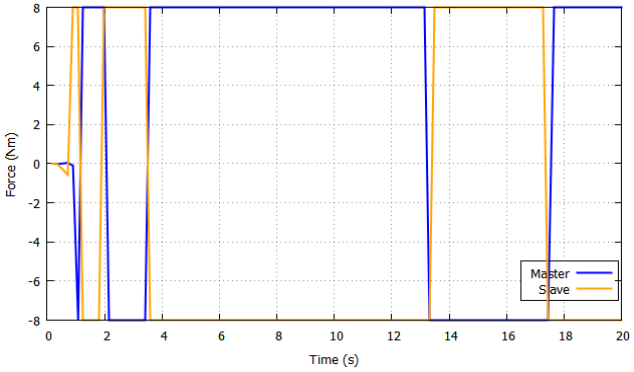

Fig. 18. Generated Force on both Subsystems across Period for ω_n = 500.

Whereas in Fig. 15 to Fig. 18, force reading at slave's joint shows a finer trend of the desired output and corresponds to the reading in master's joint compared to the prior. The gain value for each parameter has been more extensive. At t > *3.5s*, the external arm began to press on the surface of the master youBot. After receiving information from the partner identified as master youBot, the slave youBot will detect the same applied force and proceed ahead. When the block stopped the slave, it instantly applied a counterforce response and attempted to move forward. The shape of the graph can describe this condition in Fig. 15 to Fig. 18. Graphs revealed that the master youBot arm used its maximum torque of +8N to go further. However, the slave youBot arm attempted to withstand greater force coming from the block, resulting in -8N of torque reading in the experiment. The greater the gain values of K_p and K_d were thrust to the system, the greater the connection between the magnitudes of the input signal and the magnitude of the output signal in a steady state. In short, force reading in blue showed that the master youBot arm delivered a maximum torque valued at +8N to move. In contrast, the slave youBot arm tried to counter the enormous force from the block, which resulting -8N of opposing torque value in the experiment. After t > *12s*, the external manipulator returned to its original position and ceased to exert 8N of torque for pushing the master youBot arm. At this moment, there is no outside force acting on the master youBot to propel it forward. Nonetheless, the force reading can be traced on both sides of master and slave as these two are swinging back and forth before settling on their initial position, which is at 0˚. Taking the force reading from the graph and simulation of the system, the robots oscillated for a short time as they strive to settle and eradicate the value of the disturbance before returning to the position in proceeding.

B. Evaluation of Position Control

The second experiment aimed to recognise position control for both single links of the youBot arm (at Joint0) when RFOB is implemented to enhance and operate the system. Thus, all graphs from Fig. 19 to Fig. 27 display the position readings of Joint0 for each master and slave robotic arm.

Every graph from Fig. 19 to Fig. 27 above depicted the position feedback of the single joint in master and slave youBot in a separate set of parameters ranging from ω_n = 1 to ω_n = 500, associated to a list of ωn determined in Table I. The blue line indicates the reference angle, also known as step

input, while the green line in the graphs indicates the joint position of the master, and lastly, the red line signifies the joint position of a slave.

Initially, both Joint0's master and slave manipulator positions are set at 0°. Referring to graphs in Fig. 19 to Fig. 20, the reading for the position of Joint0 in master youBot reached its peak time at around t > *9.5s*, and the situation was maintained until t = *20s*. The position of slave youBot touched the highest at 15° in Fig. 21, 5° in Fig. 20 and 2° in Fig. 19. In comparison, the position of a slave has minimally increased after t > *5s*, although it did not have much difference compared to the original position. The position of the master reached its peak time values around 70° at *9.5s*, as portrayed in Fig. 19 to Fig. 21, while *10s* for Fig. 22 to Fig. 23 and 78° at *13.5s* in Fig. 24.

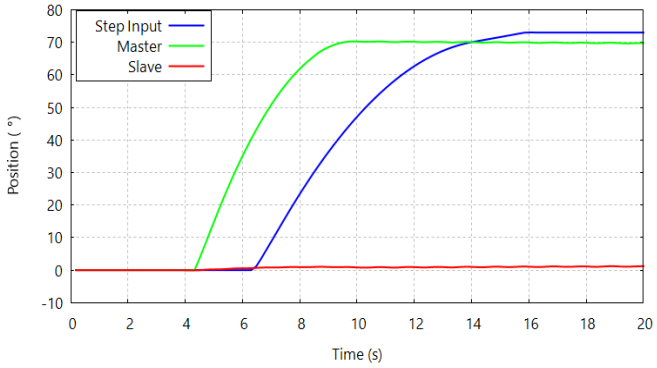

Fig. 19. Position Tracked on both Subsystems across the Period for $\omega_n = 1$.

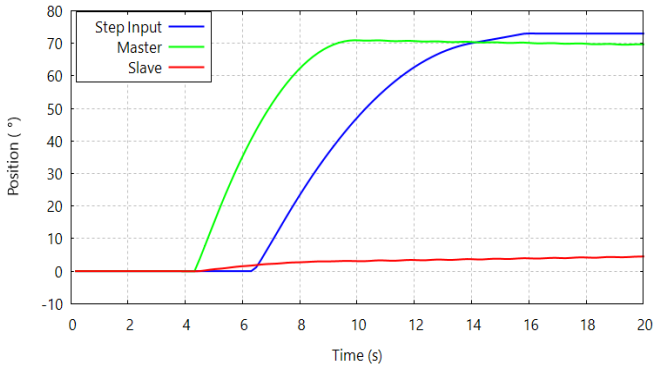

Fig. 20. Position Tracked on both Subsystems across the Period for ωn = 2.

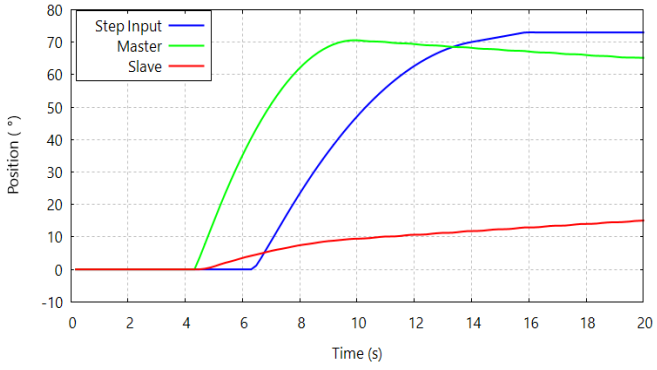

Fig. 21. Position Tracked on both Subsystems across the Period for ωn = 5.

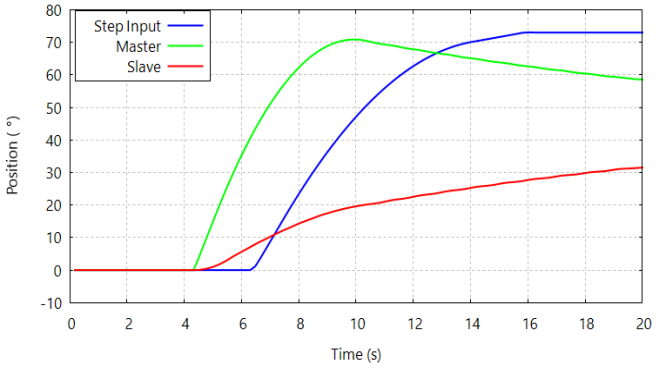

Fig. 22. Position Tracked on both Subsystems across the Period for ωn = 10.

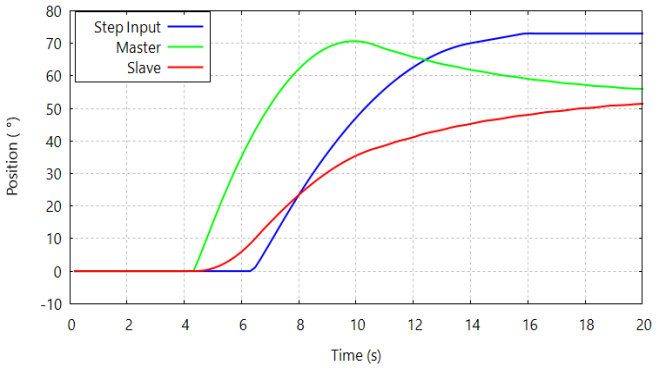

Fig. 23. Position Tracked on both Subsystems across the Period for ωn = 20.

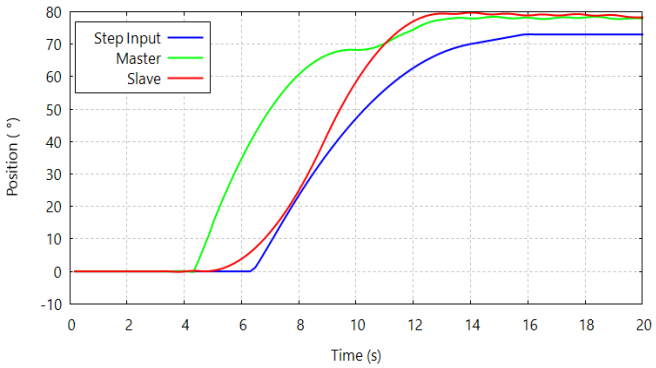

Fig. 24. Position Tracked on both Subsystems across the Period for ωn = 50.

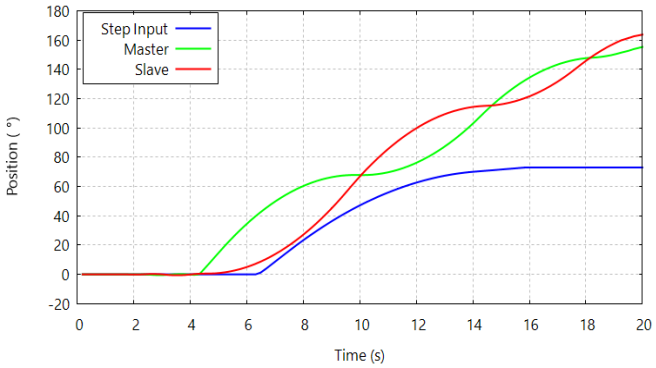

Fig. 25. Position Tracked on both Subsystems across the Period for ωn = 100.

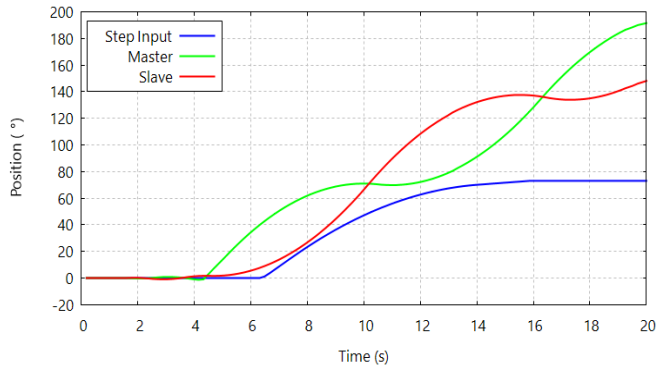

Fig. 26. Position Tracked on both Subsystems across the Period for ωn = 200.

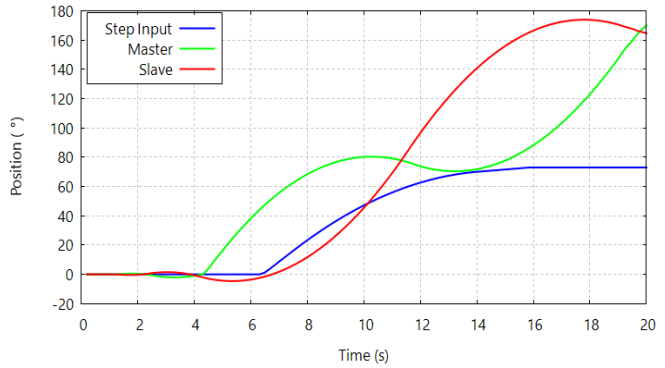

Fig. 27. Position Tracked on both Subsystems across the Period for ωn = 500.

While for Fig. 25 to Fig. 27, both master and slave alternately swing while gradually increasing on its position. The reading from the graphs kept going up because the master arm received an external force that made it move forward. However, the position of the slave according to Fig. 19 until Fig. 21 changed in minimal value compared to the master arm robot because the gain value is not adequate, having neither effects of the percentage of overshoot nor settling time. Referring to Fig. 24 and Fig. 27, when the value of gain is increased, the angle of position in the slave robot started to have changed, moved further and stretched at the top position, recorded at 80° for stable condition and 178° for unstable condition. On the other hand, the reading for the master's position began to drop, similar to the slave's position reading, as shown in Fig. 24. Following the graphs in Fig. 25 until Fig. 27, it can be demonstrated that slave youBot was trying to move further to track the position of master and master concurrently trying to catch the latest post of the slave.

Nevertheless, delays are noticed during the communication process of the two subsystems, thus making the position reading fluctuate until the end of the experiment. The position value of master and slave surpassed the reference angle when the value of ω_n is 50 until the value of ω_n was set at 500. Graph reading in Fig. 24 also presented that the differences in the value of error between the position of master and slave with reference angle are the lowest compared to others which are noted at -6° to -7°, and the most significant error is observed from the graph in Fig. 19 with the value of -70°. Based on the output reading, the percentage of accuracy for each design control is computed and tabulated into a table form. Table II below shows that control systems using RFOB have achieved greater accuracy compared to other systems, while Table III organised the transient response of various frequencies.

TABLE II. ACCURACY RECORDED IN EVERY DESIGNED SYSTEM

ω_n	$K_p(\omega_n)^2$	$K_d(2\omega_n)$	Accuracy *(%)*
1	1	2	1.78
2	4	4	6.49
5	25	10	23.09
10	100	20	53.79
20	400	40	91.82
50	2500	100	98.94
100	10000	200	99.54
200	40000	400	92.66
500	250000	1000	95.31

TABLE III. COMPARISON OF TRANSIENT RESPONSE FOR VARY FREQUENCIES

ω_n	Peak Position (°)		Peak Time (s)		Delay (s)	
	Master	Slave	Master	Slave	Master	Slave
1	70	2	9.5	20.0	4.5	6.0
2	70	5	9.5	20.0	4.5	5.0
5	70	15	9.5	20.0	4.5	5.0
10	70	32	10.0	20.0	4.5	5.0
20	70	52	10.0	20.0	4.5	5.0
50	80	80	13.5	13.5	4.5	5.0
100	158	162	20.0	20.0	4.5	5.0
200	190	170	20.0	20.0	4.5	5.0
500	170	178	20.0	17.5	4.5	7.0

From nine designed systems, six of them achieved more than 90% of accuracy. The system achieved the most accuracy with ω_n = 50, steadily at 99.78%, followed by ω_n = 500 and ω_n = 20, with each of them reaching more than 95% accuracy. Meanwhile, the system with the most negligible accuracy for differential mode law is recorded at 3.56% when the value of ω_n = 1. Therefore, the best design of the proposed system to acquire the most satisfactory position control is ω_n = 500. This is because master and slave robots attained the same final position after 15s, had a minor steady-state error, and achieved critical damping. For common mode law, the ideal design for the controller is when ω_n = 50. As prove, the summation of torque reading observed at both joint of master and slave system revealed to be equal to zero and experienced more minor disturbance as seen in Fig. 19.

IV. DISCUSSION AND CONCLUSION

To sum up, the outstanding response derived from all analyses for both experiments, the results are outlined in Table IV accordingly. The most satisfactory outcome is highlighted as the best parameter for each mode law.

TABLE V. RESPONSE IN BOTH LAW OF BILATERAL CONTROL SYSTEM

	Common Mode	**Differential Mode**
Compatible	K_p=250000 and K_d=1000	K_p=2500 and K_d=100
Incompatible	K_p=1 and K_d=2	K_p=250000 and K_d=1000
Delay and overshoot		-0.5s, from 11s to 15s
Accuracy		99.78%
Total equation	Summation of forces between master and the slave is zero	Position difference between master and slave is almost zero
Force pattern	Fewer vibrations, more stable	

According to the above summary in Table II, K_p=2500 and K_d=100 are considered as the best gain for the integrated system. Once RFOB is employed into the system, six systems achieved greater than 90% accuracy, compared to only five systems that reached more than 90% accuracy without the RFOB. Above all, the form of noise produced at Joint0 in the second experiment is much more refined than in the first experiment. This proves RFOB has advantages in improving the system stability and eliminating periodic oscillation. Furthermore, the recommended technique is intended to remove unwanted signals such as Coriolis forces, F_c, viscous damping friction, and gravity forces produced internally, especially on the motor located at a specific link. To achieve an accurate estimation of forces to be delivered to the operator, the dynamical effects within the force signal must be adjusted.

The RFOB experiment required around 11s to 15s to attain an overshoot in terms of the time delay. In RFOB configuration, the settling time generated by slave youBot is considerably better and sharper. Furthermore, the amplitude of the curve formed is relatively constant and persistent until the target joint reaches its final position. Nevertheless, the system is underdamped for a moment before it progressively climbs to reach overshoots and peak times. For the record, underdamped is a condition in which the system oscillates slower at a low-frequency rate and takes longer to get a steady-state. This situation occurred whenever the value of the PD controller increased. As a result, the stability of the control system may be derived to be conditional, based on the value of gain and threshold. In overall, the proposed designs can reach stability in a certain level of gain levels but can deteriorate when the gain value is unsuitable.

The main objective to validate a master-slave control system with DOB and RFOB implementation abiding by the law of bilateral control system has been successfully confirmed. The stated target is justified by running several sets of parameters and collecting the output response for the analysis. The suggested technique has met the capacity in enhancing the whole system performance. This study also demonstrates that a control system can be sensorless to measure dimension when active reacting forces are in contact with the system. The proposed technique is also applicable to multiple applications of industrial robots aside from position and force tracking. Using the observers to replace old-style force sensors on a device or equipment increased the system reaction and improved internal uncertainty across the system.

In conclusion, few analyses are performed to determine every single type of common controller response, rankings in the percentage of accuracy, overshoot, settling time and delay. The best kind of controller was chosen based on its performance in all three studies. This conclusion is backed by the fact that both robots oscillated at a reduced angle for a time in a control system without applying the DOB approach before they stabilised and came down to remain in a single spot. Whereas the idea for introducing RFOB into the system will remove the unwanted disturbances and errors that arrive before being feed at the DOB loop. Different experiments with diverse parameters have been conducted to oversee the system's latency after applying DOB and RFOB as part of the control loop technique. This work also assesses the system reaction for each suggested design of the bilateral system with a varied set of controllers. Indirectly, the primary purposes of this study were successfully attained.

Several analyses were performed to determine each controller's performance, standings in the accuracy, time-delay, and settling time. The best controller was chosen based on its performance in all three studies. This conclusion is supported by the fact that both robots oscillated at a smaller angle for a while in a control system without employing the DOB technique before they stabilised and came down to remain in a single place. Whereas the method to add RFOB into the system will subtract the uncertainties coming on the input of DOB. To observe the potential and advantage of applying DOB and RFOB onto the system response, separated tests with different parameters have been performed to examine and evaluate the system reaction for each proposed controller design. Indirectly, the second and third objectives of this study were successfully achieved.

Several proposals may be offered and studied in the near future research to enhance the system and make it more resilient. First, video and visual input and recording might be implemented by putting a high-speed camera at the tip of the robot arm as an added sensor for tracking. The extracted data from raw images and videos will undergo image processing technique into a type of visual force to suppress the signal error and remove the unwanted noise [10]. Besides, the relevant data gained from the pictorial records will be utilised to increase the coordination of the system's trajectory [11]. The visual data feeding into the reaction force estimation loop system will be used for the soft navigation system. Assuredly, the research should be undertaken on actual hardware and real interaction to assess the response and stability in a real-time experiment.

Additionally, this project can be one of the working mobile robots dispatched to risky or work in remote regions due to its versatility. Aside from that, a specific experiment is recommended to execute by employing image processing technology on Linux based operating system with a robot operating system (ROS) connected to the entire robotic arm. The information processed from visual data can be fed into the system for more outstanding object tracking and positioning accuracy. The limitations of executing the current technique on a simulator and virtual platform would lower the capacity of the produced feedback and overall system performance. This control procedure is likely to be more responsive in

actual ROS communications. It is easy to track any unaligned output tracking or missteps while executing the robot's task. Not just that, implementing a real-time based system for subsequent study can boost the time responsiveness on the machine and actively doing force and position tracking.

ACKNOWLEDGMENT

The authors would like to acknowledge the funding supplied by Universiti Teknikal Malaysia Melaka (UTeM) under the Scheme of Zamalah to perform the study. The authors would also like to convey our credits to the Robotics and Industrial Automation research group within the Faculty of Electrical Engineering.

***Abstract*—The purpose of this research is to build an application that is used for project evaluation and provide recommendations on project performance in local government agencies. In this study, project evaluation was carried out using the Group Decision Making (GDM) model based on the Group Decision Support System (GDSM) concept. The project output and outcome parameters used by the Decision Maker (DM) use a hybrid of the Multi-Criteria Decision Making (MCDM) and Project Management Body of Knowledge (PMBOK) methods to reduce subjectivity in scoring qualitative data and to determine project ratings from all DMs. Copeland Score voting method. The results of application computing on the implementation of Group Decision Support System (GDSS) and MCDM indicate that the project ranking process will be faster and more accurate. The results of the sensitivity test show that two criteria have a great influence on project performance so that they have a very important role in project evaluation.**

Keywords*—Group Decision Making (GDM); Group Decision Support System (GDSS); MULTI-CRITERIA DECISION MAKING (MCDM); Project Management Body of Knowledge (PMBOK); local government

I. INTRODUCTION

Projects in government agencies are part of the program, and consist of a set of actions to mobilize resources, either in the form of personnel (HR), capital goods including equipment and technology, funds, or a hybrid of some or all of these types of resources as inputs to produce outputs. in the form of goods/services. Measurement of project performance in government agencies, including the current project, has a weakness because it does not reflect the project evaluation that is generally carried out, which is only based on the percentage of achievement of the planned level of achievement of each project performance indicator as determined through the successful realization of the indicators in question [1].

The calculation of the percentage of achievement of the planned level of activity achievement used is based on the absorbed funds and the realization of output between the realization and the plan, which is stated in the administrative document of the Government Agency Performance Accountability Report (LAKIP). There can be no correlation between the output produced and the expected outcome. In the current LAKIP measurement method, including project evaluation, the criteria used to measure organizational performance are only limited to quantitative criteria, namely timeliness of implementation and effectiveness in the use of financial resources. Research conducted [2] developed a description of how to determine KPIs in ICT projects to get ideas and solutions in evaluating ICT projects.

Based on the problems an institutional decision-making system is needed which is an activity that can be carried out by individuals, groups, or organizations. Also, special steps need to be taken so that the group's decisions can be agreed upon and binding on the various parties involved. According to the viewpoint of software engineering, instances of existing applications that utilize notoriety as well as trust approaches incorporate shared, peer to peer (P2P) communications, internet business, e-advertising, multi-specialist frameworks, web search tools and Group Decision Making (GDM) situations [3][4]. The decision is the result of an evaluation of the selection of the best alternative, which involves the relevant parties. With the number of considerations and desires that must be considered, decision-making needs to listen to the considerations of many people.

One solution that is widely offered in making decisions using computing is the Group Decision Support System (GDSS). The model was made with various approaches, one of which used an approach to GDSS [5]. This model is formulated regarding social choice theory. The model is structured using a voting mechanism, in such a way that it allows each decision-maker to express their choice. Research shows that this model can accommodate Multi-Criteria Decision Making (MCDM). In modeling, the choice (vote) of the DM is considered. MCDM has played a role as an instrument for many individuals to choose candidates or alternatives. From its meaning, multi-criteria decision-making (MCDM) is used to determine the best alternative from several alternatives based on certain criteria [6].

There have been many previous studies using this method such as [7][8][9][10][11][12]. One of the popular methods used for this is the Analytic Hierarchy Process (AHP). This method uses human perception input and can process qualitative data, resulting in a comprehensive decision-making model. This is because AHP can solve multi-objective and multi-criteria problems based on the comparison of preferences of each element in the hierarchy. However, the AHP method has a weakness because the main input is in the form of perception so that it involves subjectivity, this will be a problem if the DM gives a wrong assessment. Another popular method used within the project scope is the Technique for Order Preference by Similarity to Ideal Solution (TOPSIS). This method is used because it is closely related to the benefits (benefits) and costs (costs) in a project. This method is based on the concept that the best-chosen alternative not only has the shortest distance

from the positive ideal solution (benefit) but also has the longest distance from the negative ideal solution (cost). The main weakness of the TOPSIS method is that it does not provide elicitation of weights and check the consistency of the assessment [13].

This study will create a new model to facilitate the achievement of consensus among DM while respecting different preferences, interests, and values. GDSS is expected to expand DM capabilities, but not to replace DM assessment. What is to be realized is "a new decision model that is implemented in a computer-based system that supports a group of people who are members of the same task or goal and have one particular tool that functions to interconnect the people in the group". This is known as the Group Decision Support System (GDSS) [14].

The purpose of this research is to develop a Group Decision Support System (GDSS) model for project evaluation, which not only fulfills administrative or normative needs but also provides a more objective evaluation. In this study, assessment criteria will be used that can represent the assessment in the scope of project evaluation, especially evaluation of projects in local government agencies. Considering aspects of the applicable legislation, Decision Makers (DM) are involved, namely: Government Institution Executives, Project Management Work Units, Business Process Owners Units, and the Community represented by DPRD, to provide assessments and evaluations of project implementation in institutions local government. Then, in the evaluation process, a GDSS concept was used. The GDSS concept can overcome inconsistencies that may occur in decision making because with GDSS decisions are made based on a mathematical calculation model. Project evaluation is carried out by DMs on output and outcome parameters, using a hybrid MCDM method based on the established criteria. In the weighting of the criteria used weighting techniques in the AHP method. Furthermore, the weight of the resulting criteria is used as input for the TOPSIS method to generate project rankings for each DM. At this stage, scoring of project qualitative data is carried out based on the Project Management Body of Knowledge (PMBOK) to reduce DM subjectivity. As the last step, to determine the project ranking of all DMs, the Copeland Score voting method was used.

II. Literature Review

The appraisal process is an important step in evaluation because it underlies the successful evaluation of a project. Through a systematic literature review, several project evaluations models have been identified and analyzed. The results show that the effectiveness and efficiency of evaluation are increasingly important for a project [15]. In this regard, several researchers have implemented MCDM methods, both in the DSS or SPKK [16][8][9][10]. Many organizations realize the importance of the MCDM method because the use of the MCDM method increases effectiveness in decision-making. As in the research conducted [8], it is stated that the first step to reducing the risk of project failure is to choose the optimal project. The effectiveness of the criteria in selecting the most optimal project was identified and defined by the MCDM approach, using the AHP and TOPSIS methods. The use of the proposed model can help companies facilitate a systematic approach in making the right project selection decisions.

Effective and efficient project selection has an important meaning in every organization because the decision-making process to assess the feasibility of a project is very complex [16]. The method used in this research is AHP and Moora. Modeling is based on various types of logic, considering the existence of various criteria, the objectives of the decision-maker, and the nature of the complexity of the evaluation process. According to him, the main advantage of MCDM is that it provides decision-making by analyzing complex problems, can aggregate criteria in the evaluation process, and provide scope for decision-makers to actively participate in the decision-making process.

Research [9] proposes the application of the MCDM framework to monitor and measure ongoing project performance. Linear Programming (LP) and MCDM methods are used to evaluate decision-making on the selection of project priorities. An MCDM approach is also proposed [17] to evaluate Product Development (PD) effectively. After the criteria hierarchy is built, the weight of the criteria is calculated using the AHP method. The Vikor method is used to rank the results at a later stage. The results of the sensitivity analysis show that the AHP-Vikor integrated model can accommodate the evaluation of the criteria weights. And the results of empirical studies show that the proposed evaluation framework can solve the problems that arise.

The Project Management Body of Knowledge (PMBOK) was developed by the Project Management Institute (PMI), an organization in America specializing in project management development. PMBOK is a guide that contains knowledge in project management and is always updated within a certain time. Project management is the application of knowledge, skills, tools, and techniques in project activities to meet project needs. PMBOK generally develops 9 (nine) areas that must be understood in project management, namely: Project Integration Management, Project Scope Management, Project Time Management, Project Cost Management, Project Quality Management, Project Human Resource Management, Project Communication Management, Project Risk Management, Project Procurement Management [18]. According to [19], managing ICT projects is seen as a challenging activity, because it involves a balanced portion of tangible and intangible resources. Various studies of independent institutions in America and Europe say that more than 70% of ICT projects are considered a failure, in the sense of not meeting the targets set previously at the planning stage. One of the causes of this failure is due to the indiscipline of stakeholders who are directly involved with ICT projects in complying with the standard project implementation and control methodologies that have been outlined.

Copeland Score is one of the voting methods whose technique is based on reducing the frequency of wins with the frequency of defeats from pairwise comparisons [20]. group decision-making to determine gene abnormalities in cancer.

III. METHODOLOGY

This research will use program/activity data in districts/cities of South Sumatra Province, Indonesia. This study builds a project evaluation GDSS model in local government agencies in determining the best project ranking, using a hybrid method of MCDM and PMBOK. The framework of this research can be seen in Fig. 1.

A. Proposed Model

The proposed model is a Group Decision Making (GDM) model based on the GDSS concept, using the methods in Multi-Attribute Decision Making (MADM) to determine the best project from several alternatives based on several predetermined criteria. Then the MADM combination method in the SPKK will be developed based on the Analytical Hierarchy Process (AHP) method, Technique for Order Preference by Similarity to Ideal Solution (TOPSIS), and Copeland Score, each of which has its role.

Based on Fig. 1, to determine the weight of the criteria, the weighting technique contained in the AHP method is used, then the results of the weighting of these criteria will be input in the TOPSIS calculation which is used to determine the ranking as a result of evaluating the performance of these activities. At the scoring stage, project qualitative data is based on the Project Management Body of Knowledge (PMBOK) to reduce DM subjectivity.

From the TOPSIS calculation, the project ranking for each DM is generated, and to unify the differences in preferences between DMs, the Copeland Score method is used as a voting method to determine the best project ranking from all decision-makers. Fig. 2. is a GDM model for the evaluation of ICT projects in government agencies.

In the GDM component, each component plays a role in the decision-making process as described. Each DM performs a weighting against the assessment criteria it has. The next stage is that each DM assigns a score to the alternative (ICT project) so that the project ranking of each DM is generated. The final step is to rank projects from all DMs using the voting method as a result of group decisions. Fig. 3. describes the decision-making process carried out individually and in groups in the GDM model.

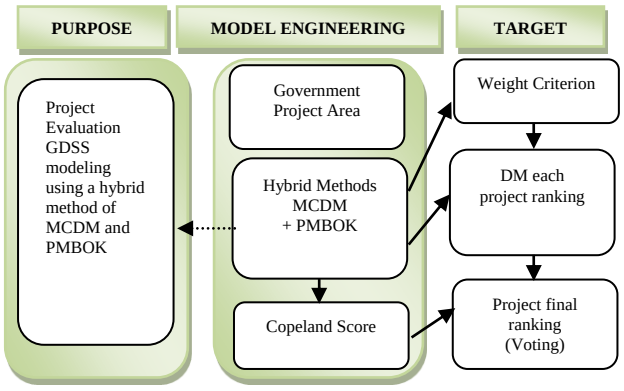

Fig. 1. Framework.

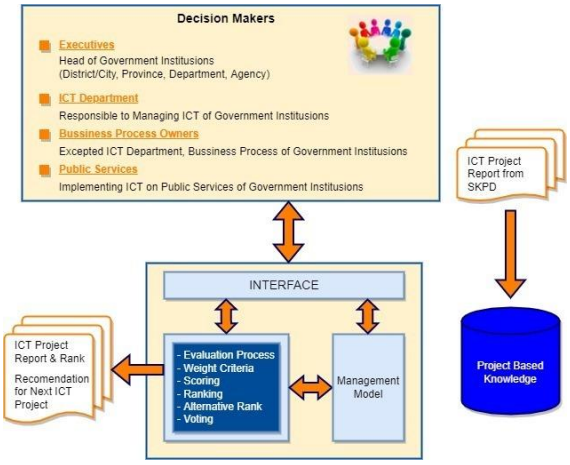

Fig. 2. GDM Model for Evaluation of the Proposed Local Government Information and Communication Technology (ICT) Project.

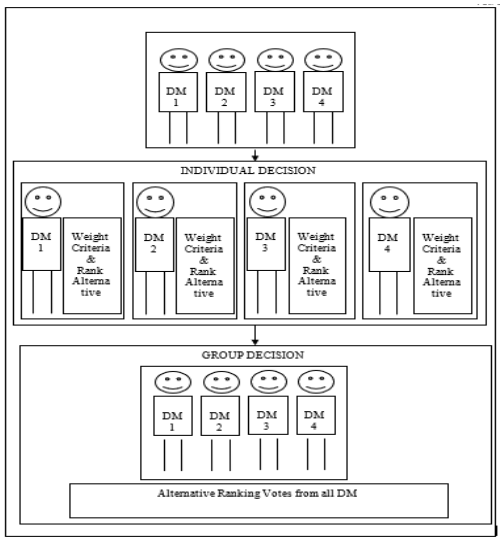

Fig. 3. Individual and Group Decision Making Process in GDM Model.

B. Calculating Weight Algorithm

In this section, a combination of the AHP and TOPSIS methods is carried out with the preparation of a pairwise comparison matrix and weighting the criteria, with the goal of determining whether matrix A is consistent or not as shown in Fig. 4.

1) Each Decision Maker (DM_i) has its assessment criteria (C_{ij}).

2) In process two, matrix A is squared, and in-process three matrix B is calculated. Matrix B is the sum of the elements in the same row of matrix A. Based on Matrix B, the eigenvectors are calculated so that Matrix E is obtained, described in process four.

3) The process of five, six, seven, and eight is to calculate the consistency of the index by deriving a matrix C, which is the product of matrix A and matrix E. Based on matrix C, it is determined whether matrix A is consistent. If it is consistent then the weight of the matrix A is calculated by calling the Algorithm for Calculating the Weighted Normalization Value.

4) The output of this algorithm is the Criteria Weight (Wk) for each DM.

Calculating Weight Criteria Algorithm

Input:
DM_i = {DM $_i$ | i = 1,2, 3..., n};
C_{ij} = {Cij | j= 1,2, 3...};
Output: W_k;
Process:
Begin
1. A[i,j] ;
2. A^2[i,j] = A[i,j] * A[i,j];
3. for k = 1 to i
B(k,1) = $\sum_{i=1}^{i=j} A2(k,l)$;
End
4. for k = 1 to i
E(k,1) = B(K,1)/$\sum B(:,1)$
End
5. C [k,1] = A[i,j] *E[k,1] ;
6. λ max = 1/k * ($\sum_{k=1}^{k=i} \frac{E[k,:]}{C[K,:]}$)
7 C1 = $\frac{\partial - k}{k-1}$
8. if C1 < 10%
W = Bobot (A)
Else
Comparison value evaluation
pairwise comparison on A[i,j]
End
End

Fig. 4. Calculating Weight Criteria Algorithm.

C. Algorithm for Calculating Normalization Value

This algorithm explains the calculation of the normalized value of all alternatives for each criterion and calculates the normalized value of its weight as shown in Fig. 5.

1) The Decision Maker scores all ICT alternatives (projects) based on the assessment criteria it has so that after being converted based on the assessment rating, the results are in the form of a Scoring Matrix (SC).

2) Process 2 calculates the normalized value of all alternatives for each criterion (Matrix X) and process 3 calculates the weighted normalized value (Matrix Y).

Algorithm for Calculating Normalization Value

Input: Matriks Scoring (SC)
W = weight matrix of each criterion
Output: Normalized Scoring Matrix (R)
Normalized Scoring Matrix_Weight (Y)
Process:
Begin
1. i = size (SC,1); j=size (SC,2) // i,j is the dimension of the DM scoring matrix, i is the row representing the number of alternatives (projects) and j is the column representing the number of criteria
2. for k = 1 to i
for l = 1to j
R (k,l) = SC (k,l)/($\sum SC(k,l;)$)
End
End
3. for k = 1 to i
for l = 1to j
Y [k,l]= R [k,l] * E[1,l]
End
End
End

Fig. 5. Algorithm for Calculating Normalization Value.

IV. Design and Implementation System

A. Design

This study continues the research conducted by [21] who has not yet carried out the process of making web-based applications, so this study designs a Web-based GDSS Model Prototype [22] for Project Evaluation in Local Governments. The prototype is built based on a review of research results as described in the Literature Review, which relates to MCDM methods that can be applied in the scope of evaluating a project.

B. Implementation

This system is designed with several stages of implementation to produce an assessment that is used as the basis for making decisions on a project. The results of the application implementation are shown in Fig. 6 to 12.

Fig. 6 is a representation of the login page on the government project evaluation. On the page, the user and password fields are displayed, then the submit button. The home page contains display information regarding login access for users. In this case the user is an administrator who works in the government of the Province of South Sumatra. Users can login with User Name: admin and Password: admin, then press the login button, if the login is successful, it will go directly to the main menu.

When the user successfully logs in, they will immediately go to the main page (Dashboard) of the government project evaluation application. On the main page of the application, there are several menus and a comprehensive list of government projects as shown in the following image.

On the dashboard display from the Fig. 7, there are two menu sections located on the left side of the dashboard display and the upper right corner of the dashboard display. In the menu display on the left side of the dashboard, there are several menus, namely, Dashboard, Activities, Criteria, SKPD, Region, DM, Menu and Users.

From the Fig. 8 shown the activity page, all project activities that are being carried out will be displayed, to add activities, it can be done by selecting the add menu which is in the upper right corner of the activity page display. On the Add Activities page, the Add Activities form will appear, while the data that must be filled in this form include the name of the activity, the activity ceiling, volume and budget year.

Fig. 6. Login Page.

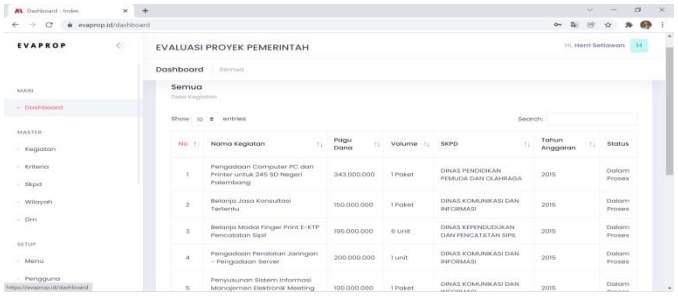

Fig. 7. Dashboard.

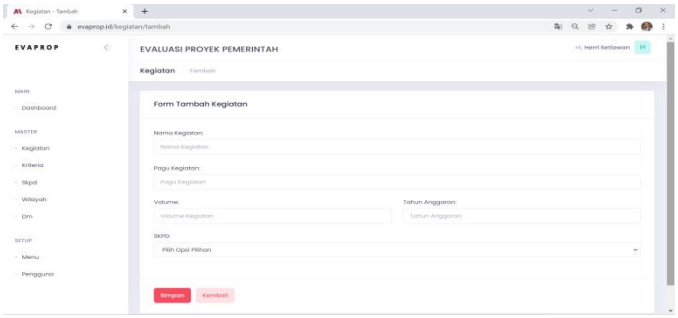

Fig. 8. Activity Setting.

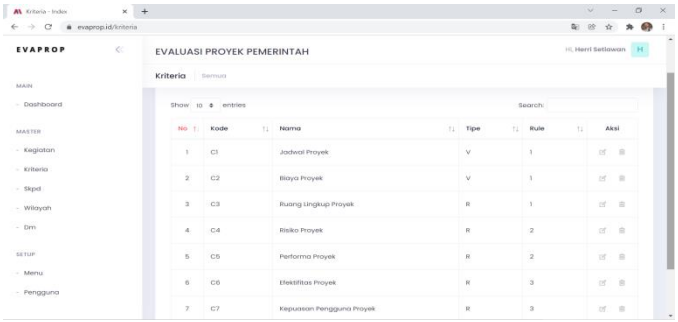

Fig. 9. Criterion Setting.

On the criteria page from Fig. 9, all the assessment criteria used will be displayed, adding criteria can be done by selecting the add menu which is in the upper right corner of the criteria display. On the Add Criteria page, the Add Criteria form will appear, which must be filled in, among others, criteria code, criteria name, criteria type and criteria rule. To save the newly added criteria can be done by selecting the save menu on the added criteria form.

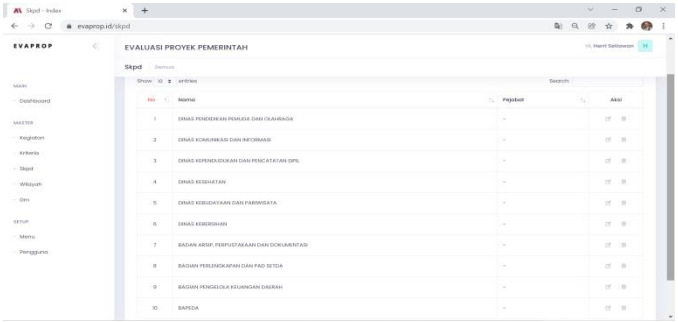

Fig. 10. Setting SKPD.

To fill in the SKPD on the added activity form, choose according to the list of available SKPD, to save new activities, select the save menu on the added activity form. On the Add SKPD page, the Add SKPD form will appear. To add a new SKPD, you must fill in the names of the SKPD and SKPD officials on the Add SKPD form. After all data is filled in, it can be saved by selecting the Save menu on the Add SKPD form.

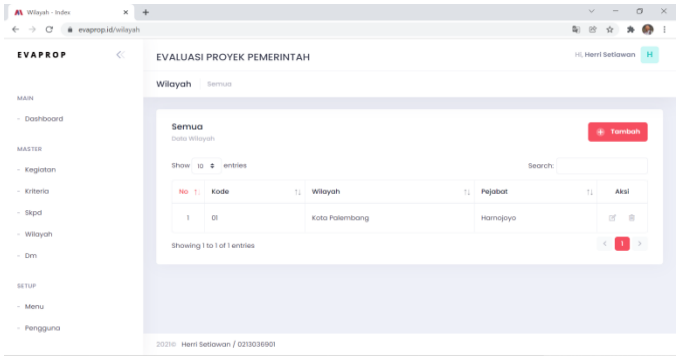

Fig. 11. Area Configuration.

In the regional menu, a regional data page will be displayed, to add regional data, it can be done by selecting the add menu in the upper right corner of the regional page. The Add Region menu will display the Add Region form. To add new area data, you must fill in all the required data on the Add Region form, including area code, area name and official name. After all data is filled in correctly, the data can be saved by selecting the save menu in the Add Region form.

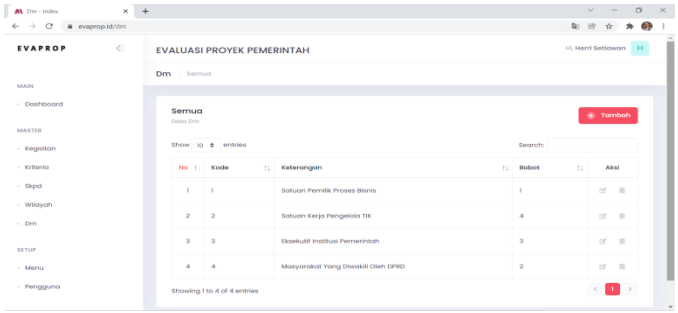

Fig. 12. Decision Maker.

Fig. 12 shows the Decision Maker (DM) page which is the result of weighting for codes 1, 2, 3, and 4 based on the criteria page, each weighting being measured is the Business Process Owner Unit, ICT Management Work Unit, Government Institution Executive, and Communities Represented By the Council. The weighting in each of these categories will be measured based on the criteria that have been determined on the criteria page.

V. Result and Analysis

In the implementation, DM1 will evaluate each alternative (project) based on 3 (three) criteria C= {C1, C2, C3), DM2 will evaluate each alternative based on 2 (two) criteria C= {C4, C5}, DM3 and DM4 will evaluate each alternative based on 2 (two) criteria C= {C6, C7}.

DM1 determines the relative importance between the criteria of Project Schedule (C1), Project Cost (C2), Project Scope (C3). The assessment uses the weighting standard with a scale ranging from 1 to 9 and vice versa, the values of these criteria, according to a DM1 pairwise comparison matrix, are as follows:

	C1	C2	C3
C1	1	0.5	0.3
C2	2	1	0.5
C3	3	2	1

(1)

This stage calculates the priority weighting by finding the eigenvector value of the A matrix through the following process. Squaring the A matrix.

$$\begin{vmatrix} 1 & 0.5 & 0.3 \\ 2 & 1 & 0.5 \\ 3 & 2 & 1 \end{vmatrix} \text{ X } \begin{vmatrix} 1 & 0.5 & 0.3 \\ 2 & 1 & 0.5 \\ 3 & 2 & 1 \end{vmatrix} = \begin{vmatrix} 2.9 & 1.6 & 0.85 \\ 5.5 & 3 & 1.6 \\ 10 & 5.5 & 2.9 \end{vmatrix}$$

The next process is to add up the elements of each row of the A2 matrix so that a matrix is obtained. Then arrange matrix B, and add up all elements of matrix B with the following values below.

$$B = \begin{bmatrix} 5.3500 \\ 10.1000 \\ 18.4000 \end{bmatrix} \quad (2)$$

From the B matrix that has been obtained in the above step, then normalization is carried out on the B matrix to obtain the eigenvector value of the B matrix.

$$E = \begin{bmatrix} e1 \\ e2 \\ e3 \end{bmatrix} \quad (3)$$

e_1=5.3500/(5.3500+10.1000+ 18.4000)=0.1581.

e_2=10.1000/(5.3500+10.1000+ 18.4000)=0.2983.

e_3=18.4000/(5.3500+10.1000+ 18.4000)=0.5436.

$$E = \begin{bmatrix} 0.1581 \\ 0.2983 \\ 0.5436 \end{bmatrix} \quad (4)$$

The three processes above are repeated and at the end of each iteration, the difference between the eigenvector matrix E values obtained and the previous eigenvector matrix E values is sought until a number close to zero is obtained. The matrix E obtained in the last step shows the priority of the criteria indicated by the coefficient of the eigenvector value so that the eigenvector matrix E obtained is:

$$E = \begin{bmatrix} 0.1638 \\ 0.2972 \\ 0.5390 \end{bmatrix} \quad (5)$$

To measure the consistency of the matrix, the first thing to do is to calculate the Consistency Index (CI) by calculating the weighted vector number. The product of the matrix A on the Eigenvalue (matrix E).

$$\begin{bmatrix} 1 & 0.5 & 0.3 \\ 2 & 1 & 0.5 \\ 3 & 2 & 1 \end{bmatrix} X \begin{bmatrix} 0.1638 \\ 0.2972 \\ 0.5390 \end{bmatrix} = \begin{bmatrix} 0.4921 \\ 0.8941 \\ 1.6248 \end{bmatrix}$$

quotient above by the number of elements present, the result is called max (λmax)

λmax = 1/3 * (0.4972/0.1638) + (0.8943/0.2972) + (1.6248/0.5390)

λmax = 3.0092 (6)

So that the value of the Consistency Index

(CI) = (3.0092-3) / (3-1) = 0.0066 (7)

The matrix has 3 (three) elements, so the IR value is 0.58. So the value of CR is 0.0066/0.58=.0.0079. Because the CR value is less than 10%, the data judgment is correct. It can be concluded that matrix A is quite consistent.

From the values that have been tested in this study, sensitivity analysis was carried out by changing the weight of the criteria. Changes in the weight value of each criterion are carried out by lowering or increasing the weight to see whether the alternative ranking results (projects) tend to change or not. The trial weight changes were increased or decreased from the initial values of 10%, 20%, and 30%. Sensitivity analysis was performed against all criteria. Sensitivity analysis on criteria C1 (Project Schedule) Based on the graph of the results of sensitivity analysis against criteria C1 (Project Schedule) as shown in Fig. 13, test for changes in the weight of the criteria there is a change in the value of the alternative (project schedule).

Fig. 15. Sensitivity Analysis on Criteria C3 (Scope of the Project).

VI. Conclusion

This study resulted in a GDM model for evaluating ICT activities in local government agencies in Indonesia using the GDSS concept. DM involved consists of 1) Executive government institutions, 2) ICT Management Unit, and 3) Business Process Owner Unit, and the community represented by DPRD. From the values that have been tested in this study, sensitivity analysis was carried out by changing the weight of the criteria. Changes in the weight value of each criterion are carried out by lowering or increasing the weight to see whether the alternative ranking results (projects) tend to change or not. The trial weight changes were increased or decreased from the initial values of 10%, 20%, and 30%. Sensitivity analysis was performed against all criteria.

Determination of the best ICT project from several alternatives using several determining qualitative and quantitative parameters and criteria. In the project output parameters, the criteria used in the assessment are project schedule, project cost, project scope, project risk, and project performance. While the outcome parameters are projected effectiveness criteria and project user satisfaction. With the guidance of the Project Management Body of Knowledge (PMBOK), the provision of qualitative data scoring projects has an assessment basis to reduce the subjectivity of DM.

At the main stage of this study, we concluded that the method succeeded in parsing the draw voting process by developing it by adding a winning gap (distance) between alternatives during the pairwise contest and then multiplying the existing gap by the weight or population of DM. the results of the model trial case study, the voting results of all DMs on ten (10) ICT projects in the Palembang city government, it was found that and also the results of the sensitivity test against the three criteria affected project evaluation. In the future, we will try a ranking system to get results that can determine transparent winners in a project in government.

***Abstract*— Today, due to their interactive, participatory and entertaining nature, the Serious Games set themselves apart from other learning methods used in teaching. Much progress has been made in the design techniques and methods of Serious Games, but little in their evaluation. In order to fill this gap, we had proposed in our previous work an evaluation tool capable of helping practitioners to evaluate Serious Games in different training contexts. This evaluation tool for Serious Games is designed around four dimensions, namely the pedagogical, technological, ludic and behavioral dimensions, which are measured by clearly defined criteria. During this process, it was highlighted that the human factor (evaluator) influences considerably the result of the weightings through the choice to weight the evaluation dimensions of the Serious Games. In order to reduce this influence during the evaluation process and to keep the correlation between the variables of our evaluation system, we present in this paper, an improvement of our evaluation tool by equipping it with an intelligent supervised self-learning algorithm allowing self-regulation of the weights according to the context of use of the Serious Game to be evaluated. Thanks to the experimental verification of the optimization results, the root mean square error and the coefficient of determination are 0.016 and 98.59 percent respectively, indicating that the model has high precision which guaranteed better predictive performance. A comparison was made between this intelligent model and the models presented in our previous work; the results obtained indicated the same order of the four dimensions, and this by reducing the influence of the human factor during the Multi-Output Support Vector Regression weighting process.**

Keywords*—Serious game; evaluation tool; multi-output support vector regression

I. INTRODUCTION

Serious Games are increasingly present in any innovative educational strategy aimed at effective and motivating learning [1]. However, before endorsing a serious game in any training, it is essential to evaluate it in addition to evaluating its impact [2], [3].

In [4], we have presented a serious game evaluation tool based on four dimensions, {Pedagogical (P), Technological (T), Ludic (L) and Behavioural (B)}, that a serious game must satisfy in order to perform the task for which it was designed. In addition, given that the importance of one dimension compared to another depends on the context in which the serious game is used, the fuzzy multi-criteria decision making methods fuzzy AHP, fuzzy TOPSIS, and fuzzy ELECTRE have been used [5], to validate the choice of the weighting of these dimensions.

In conclusion of this work, it is demonstrated that the human factor has a significant influence on the result of weightings when choosing weights for the serious game evaluation dimensions. This is done by favouring, during the weighting process, a higher value of one dimension over another.

Indeed, depending on the context of use of the serious game to be evaluated, the evaluator favours one or more dimensions deemed to be more important. For example, in a Context where the order of the dimensions is as follows P>T>L>B, the evaluator can assign, to the dimensions, all possible percentages satisfying the order of the chosen context of use and this while ensuring that their sum equals 1.

And so, to reduce this human influence in the serious game evaluation process through the choice of weightings of the evaluation dimensions, we present in this paper an improvement of our evaluation system, by endowing it with an automatic algorithm intelligent supervised learning, allowing self-regulation of the weightings according to the context of use of the serious game to be evaluated.

Thus, the Multi-Output Support Vector Regression (M-SVR) will analyze the context data of use of the serious game to allow the evaluation system to build its reasoning system without having to impose a program beforehand. In this learning phase, the algorithm is based on several examples of data to find the existing patterns in the data allowing it to build a model that will be evaluated subsequently in order to estimate its general predictive accuracy for future data.

In this paper, we advocate the use of an intelligent supervised machine learning algorithm to self-regulate weights according to the serious game context of use, to minimize this human influence in the serious game evaluation process.

This paper is divided into four sections. In Section 1, the problem, the formalization and the postulated hypotheses are presented. The description of the proposed model is illustrated in Section 2. Section 3 presents the modeling process steps carried out, together with the obtained results. In Section 4, a general conclusion is provided.

II. Problem - Formulation and Hypotheses

As mentioned above, this work is based on the findings made in our previous work that can be summarized in the following points.

A. Influence of the Human Factor (the Evaluator) in the Choice of Weightings of the Serious Game Evaluation Dimensions

As shown in Fig. 1, the evaluator participates in the serious game evaluation process by choosing the ordering of the evaluation dimensions according to the context of use of the serious game to be evaluated.

For example, if the serious game is used in a purely formative context, the evaluator will consider the pedagogical dimension as dominant over the other dimensions.

However, if the evaluator errs in his judgment of the adequacy between these choices of ordering of evaluation dimensions and the context of use of the serious game, then the entire evaluation system will be biased.

B. Existence of Correlation between the Variables of our Evaluation System

By analysing our evaluation system, we note the existence of dependency relations between its variables. Thus, we note that there is a relationship between the weighting variables expressed by their sum, which must be equal to 1. Likewise, there is a direct relationship between the evaluation dimensions' variables (P, T, L, B) and the serious game context of use. Fig. 2 presents four main cases of serious game context of use classified according to their main dominant factor: Pedagogy (Fig. 2(a)), Technology (Fig. 2(b)), Ludic (Fig. 2(c)), and Behaviour (Fig. 2(d)).

In each major type of the serious game context of use and according to the ordering of the other dominated factors, we obtain a finite number of serious game contexts of use (branches of the tree).

We also note that in each tree branch, we have an infinite number of possible serious game contexts of use. For example, take the serious game context of use (P > T> L> B) (Fig. 2(a)) where each branch (P > T) or (T > L) or (L > B) will be interpreted, as a weighting value (y_1(P) > y_2(T)), (y_2(T) > y_3(L)) and (y_3(L) > y_4(B)) respectively. With (y_1, y_2, y_3, y_4) varying between 0 and 1 that generates an infinite number of possibilities.

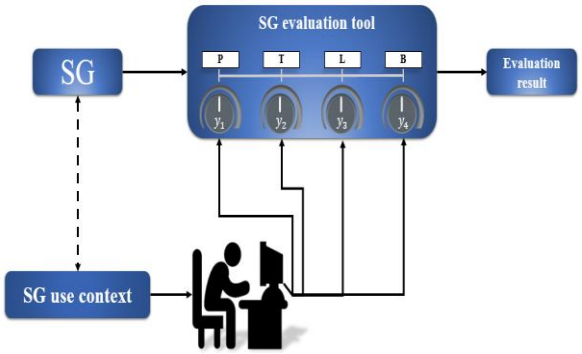

Fig. 1. Serious Game Evaluation Process.

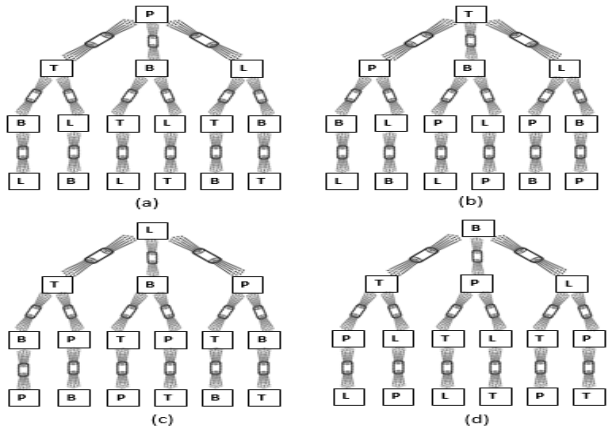

Fig. 2. Possible Serious Game use Contexts.

The Serious Game context of use is represented by the vector $X = \{x_1, x_2, x_3, x_4, x_5, x_6\}$. It is assumed that the serious game type to be evaluated corresponds to its context of use. The number of elements of this vector is deduced from the pair-to-pair comparison of the four dimensions of the evaluations with $(x_i) \in]0, 9]$ Table I.

TABLE I. Example of Representation of Context of Serious Game use

Dimensions Pairwise comparison	Vector X
(P, T)	x_1 =5
(P, B)	x_2 =7
(P, L)	x_3 =8
(T, B)	x_4 =3
(T, L)	x_5 =4
(L, B)	x_6 =0.5

Likewise, the weighting vector represented by $Y = \{y_1, y_2, y_3, y_4\}$, respectively determines the weighting of each dimension {P, T, L, B}. With $(y_i) \in]0, 1]$ is considered as a continuous dependent variable.

III. State of the Art

In order to minimize the evaluator influence during the choice of dimension weights in serious game evaluation process and keep the correlation between the variables of our evaluation system, we believe that it is wise to use the supervised machine learning algorithms power to self-regulate the weightings according to the serious game context of use to be evaluated. Among the machine learning algorithms that can meet our need, there are multi-output regression algorithms [6]. These algorithms, using a single model, aim to simultaneously predict several continuous variables when a common collection of input variables is given [7]. This takes into account not only the underlying relationships between the input variables and the corresponding targets, but also the relationships between the correlated targets [8]. This guarantees better predictive performance [16].

This algorithm type has received a lot of attention from the machine learning science community. It has already proven itself in a wide variety of real life applications [9] such as

health [10], [13], wind speed [11], heating load in buildings. Energy efficiency [12], natural language processing [14] and bioinformatics [15].

Among the multi-output regression algorithms, we opted for the multi-output support vector regression (M-SVR) algorithm proposed by Pérez-Cruz et al. [19]. This choice was dictated by:

- The infinite number of input vectors of our system, which represent the evaluation of serious game context of use and the number of output vectors, which represent the weighting, values of the dimensions of evaluation.
- Its ability to predict with high certainty multiple correlated outputs as shown in [24], [25].

IV. Proposed Model

The model proposed in this paper is an intelligent evaluator of serious game that can be adapted to any type of serious game depending on its context of use. As shown in Fig. 3, our evaluator system will be endowed with an intelligent supervised self-learning algorithm.

Therefore, the M-SVR will make it possible to simultaneously self-regulate the weightings $\{y_1, y_2, y_3, y_4\}$ of each dimension according to the serious game context of use to be evaluated $X = \{x_1, x_2, x_3, x_4, x_5, x_6\}$, by capturing all existing dependencies and internal relationships, in order to give better performance (Fig. 4).

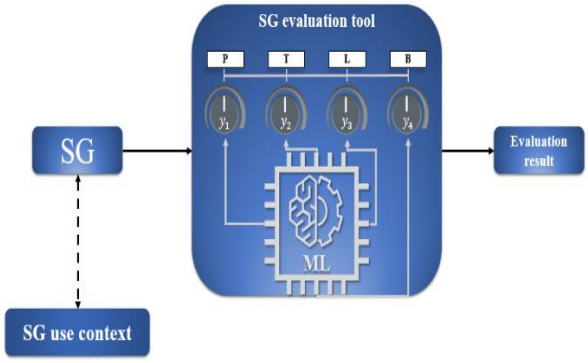

Fig. 3. Intelligent System of Weightings of the Serious Game Evaluation Dimensions.

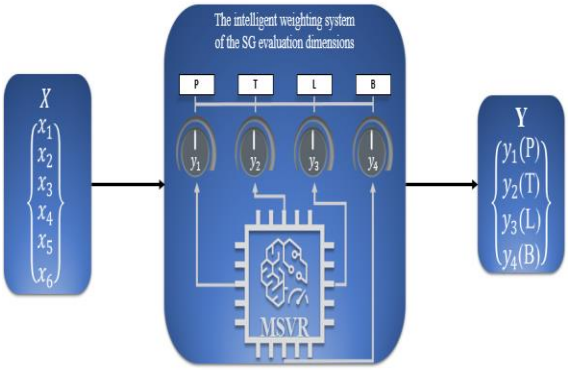

Fig. 4. M-SVR as Intelligent System Implemented in an Evaluator Tool.

A. Algorithm Description

As presented in [19], the M-SVR goal is to find the regressor w^j and b^j (j = 1,…., m) for each output which minimizes the following function (1):

$$\min_{W,b} L_p = \frac{1}{2}\sum_{j=1}^{m}\left\|w^j\right\|^2 + C\sum_{i=1}^{N} L(u_i) \quad (1)$$

Where:

$$u_i = \|e_i\| = \sqrt{e_i^T e_i}\,, e_i^T = y_i^T - \varphi(x_i)^T W - b^T$$

$W = [w^1, \dots, w^m]$: Vector of coefficients of the multiple outputs,

$b = [b^1, \dots, b^m]^T$: The constant vector representing the bias of each output,

C : The regularization parameter that balances the complexity of the model and the approximation precision,

$\varphi(.)$: Denotes a nonlinear mapping of n-dimensional input space to m-dimensional feature space, $\mathbb{R}^n \to \mathbb{R}^m$.

$L(u)$ is an ε-insensitive quadratic cost function, defined by the following equation:

$$L(u) = \begin{cases} 0, u < \varepsilon \\ u^2 - 2u\varepsilon + \varepsilon^2\,, u \geq \varepsilon \end{cases} \quad (2)$$

When ε = 0, in equation (2), this problem boils down to an independent regularized kernel least squares regression for each component.

For ε ≠ 0, it will take into account all the outputs to build the regressors for each individual, to then produce a single support vector for all the dimensions, in order to obtain more robust predictions. To solve equation (1), an iterative method called iteratively re-weighted least squares (IRWLS) [21] was used in [20], [22].

V. Steps Carried Out in the Modelling Process

The machine learning goal, implemented in our evaluation system, is to allow the multi-output regression algorithm (M-SVR) to learn a correspondence between the input vector (X) $X^{(i)} = \left(x_1^{(i)}, \dots., x_n^{(i)}\right)$ and the output vector (Y) $Y^{(i)} = \left(y_1^{(i)}, \dots, y_m^{(i)}\right)$ from the training data set (D) $D = \left\{\left(X^{(i)}, Y^{(i)}\right)\right\}_{i=1}^{N} \subset \mathbb{R}^n \times \mathbb{R}^m$ for N samples. Therefore, find a function h, which relates the input vector X to the output vector Y, $h(X) = Y$.

And so, for a given new input vector $\hat{X}$, the model will be able to predict an output vector $\hat{Y}$. $\hat{Y}$ = h ($\hat{X}$) which best approximates the real output vector Y.

Fig. 5 shows the process of machine learning algorithm like M-SVR, which consists of three main steps:

In our experiment, we used the implementation of the M-SVR algorithm with the programming language Python, using the machine-learning library Scikit-Learn [23]. The initial setup was done with the kernel = 'rbf', γ = 0.001, ε = 0.001 and C = 40.

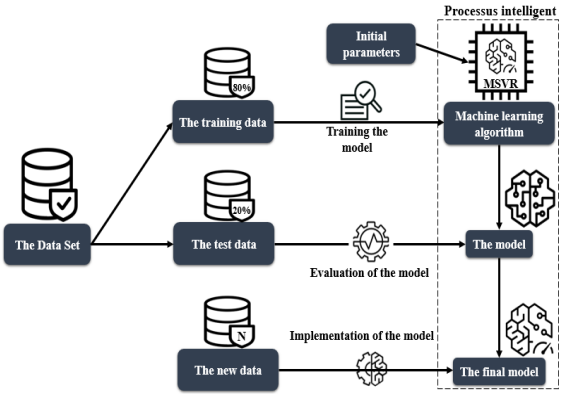

Fig. 5. Steps carried out in the Modelling Process.

A. Model Training

In the training phase of the model, we used the training data from the set (D). $D = \{ (X^{(i)}, Y^{(i)}) \}_{i=1}^{N}$. With N = 2500 knowing that the complexity of the adjustment time is more than quadratic, which makes it difficult to adapt the M-SVR to data sets of more than 10000 samples. Table II shows an example of the pair of training vectors (X, Y) used in this step.

The input vector (X) $X^{(i)} = (x_1^{(i)}, \dots, x_n^{(i)})$ and the output vector (Y) $Y^{(i)} = (y_1^{(i)}, \dots, y_m^{(i)})$ with n = 6 and m = 4.

We followed the recommendations mentioned in the scientific literature of Machines Learning, taking 80% of the learning data as model training data and 20% of the training data as model evaluation data.

TABLE II. TRAINING DATA

Input vectors: serious game contexts of use's						**Output vectors: evaluation dimensions weightings'**			
x_1	x_2	x_3	x_4	x_5	x_6	y_1	y_2	y_3	y_4
0.5	3	0.2	0.2	0.5	0.5	0.135	0.133	0.154	0.578
7	1	7	3	5	3	0.508	0.234	0.196	0.062
5	1	3	7	9	5	0.387	0.371	0.182	0.06
3	5	5	0.142	7	7	0.514	0.134	0.307	0.045
7	3	0.125	5	3	5	0.307	0.293	0.189	0.212
7	3	3	5	7	0.333	0.527	0.279	0.076	0.118
0.333	5	0.125	3	0.142	1	0.138	0.214	0.104	0.544
0.2	1	0.2	1	0.2	3	0.100	0.223	0.290	0.386
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮
0.5	3	0.2	5	0.2	0.5	0.128	0.247	0.076	0.549
3	5	7	5	5	7	0.540	0.293	0.124	0.043

B. Model Evaluation

After the training phase, the evaluation data is used to evaluate the performance of the model based on the statistical measure R^2.

This statistical measure represents the quality of the regression model adjustment. The closer the value of R^2 is to 1, the more accurate the regression model [18].

$$R^2 = \frac{SS_{reg}}{SS_{tot}} = 1 - \frac{SS_{err}}{SS_{tot}} \quad (3)$$

Where SS_{reg} the sum of squares is explained by the regression, SS_{tot} refers to the total sum of squares and SS_{err} is the sum of the squared error.

In addition, the root mean square error (RMSE) [17] is calculated to have the standard deviation of the errors that occur when a prediction is made on a data set. The closer the value is to 0, the less error the model produces.

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N} \|y(i) - \ddot{y}(i)\|^2}{N}} \quad (4)$$

Where N is the number of data items, $y(i)$ is the ith measure, and $\ddot{y}(i)$ is its corresponding prediction.

The results in Table III give a value of RMSE = 0.016 and R^2 = 98.59%. From these values, we can deduce that the accuracy of the prediction model is acceptable and, therefore, we can proceed to the exploitation of the model.

C. Model Exploitation

Once the model is trained, tested and validated, we were able to exploit it by introducing new input values $\hat{X}_i$ characterizing contexts of use of possible serious games for the prediction of the weighting values of the weighting dimensions evaluation of serious game $\hat{Y}_i$. Table IV shows an example of the operating values of the model.

TABLE III. MODEL TEST

TABLE IV. PREDICTION OF DIMENSION WEIGHTS

New Input Vectors						Model output vectors			
$\hat{x}_1$	$\hat{x}_2$	$\hat{x}_3$	$\hat{x}_4$	$\hat{x}_5$	$\hat{x}_6$	$\hat{y}_1$	$\hat{y}_2$	$\hat{y}_3$	$\hat{y}_4$
3.3	3	5	3	5	3	0.500	0.283	0.163	0.056
5	3	5	3	2	3	0.543	0.181	0.160	0.119
1	5	3	5	7	3	0.350	0.483	0.107	0.060
5	3	1	3	2	3	0.351	0.180	0.179	0.291
1	3	3	7	7	3	0.295	0.527	0.116	0.060
2	1	2	7	7	6	0.271	0.471	0.192	0.063
5	3	1	3	2	7	0.345	0.198	0.242	0.217

We also tested our evaluator model with the M-SVR model using the same evaluation context proposed in [4], where the context of use of the serious game is purely educational, with an academic and scientific target audience.

The vector X = {3,5,7,3,5,3} represents the context of use and the corresponding output vector generated by the M-SVR model is Y = {0.557,0.270,0.123,0.052}. The serious game to be evaluated is "Leuco'war", Fig. 6 illustrates the results obtained which confirm those obtained in [4].

According to the results obtained, we note that the use of the M-SVR algorithm at the centre of the weighting process of the chosen dimensions has provided our serious game evaluation tool the ability to self-regulate with an acceptable precision the weights of the dimensions in different Serious Game evaluation contexts. This allowed us to respond to the observations noted during the experimental studies conducted in [4], [5]. Indeed, M-SVR, using a unique predictive model of several continuous variables, guaranteed a better predictive performance confirmed by the values of RMSE and R^2 respectively equal to 0.016 and 98.59 per cent. This by taking into consideration the underlying relationships between the context variables of use of the Serious Game and the weights of the corresponding dimensions, and their correlated relationships. Likewise, the comparison of the results obtained by this evaluation model confirms, with a notable reduction in the influence of the human factor in the process of weighting of dimensions, the same order of its last obtained in [4], [5].

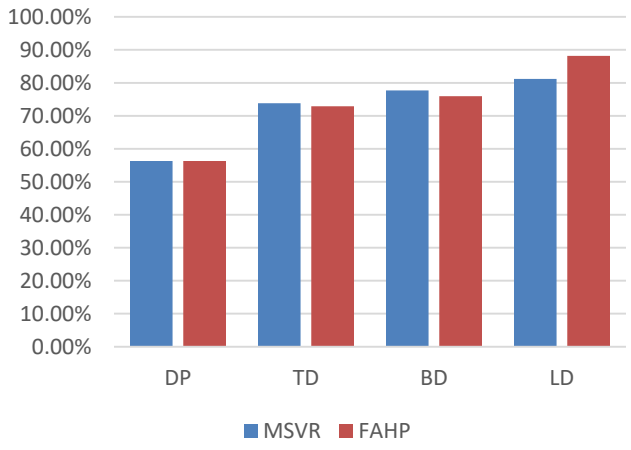

Fig. 6. Serious Game "Leuco'war" Evaluation Results.

Finally, we note that the most important added value of the use of the M-SVR multi-output supervised machine learning algorithm is its ability to adapt the weightings of the serious game evaluation dimensions to the very large number of possible contexts of use.

VI. CONCLUSION

By introducing a smart process such as M-SVR into our serious game evaluator system, we were able to reduce the subjective evaluation introduced by the human factor by having automatic weighting values according to the context of use of the chosen serious game. In addition, the values of the test parameters RMSE and R^2 equal to 0.016 and 98.59% respectively testify to an acceptable performance of the algorithm used. However, we noticed an instability of the algorithm when we used a very large dataset volume. Thus, we plan to compare the results obtained with M-SVR with another other algorithms of the same type that is more stable with respect to the volume of the data set of more than 10000 samples, because the complexity of the adjustment time is more than quadratic. Likewise, we plan to place an intelligent process in our system linking the serious game context of use and the corresponding serious game.

***Abstract*—This article consider two main local network topologies. Based on the basic DFS protocol, a mathematical model has been developed for a new method of multipath routing and traffic engineering in data centers with a ramified topology. This method was developed with the features and benefits of SDN in mind. Also, the simulation of the developed method was carried out on two local topologies considered earlier.**

***Keywords*—Local networks; traffic engineering; SDN; DCN; DFS; Mininet**

I. Introduction

The successful operation of the enterprise in a dynamic market and competition is largely determined by the ability to make quick decisions. Timely and high-quality decision-making is possible only if the reliable and productive operation of the company's IT infrastructure. In turn, modern IT systems are evolving dynamically: there are more and more different business applications and automated workplaces, increasing the amount of information, requires continuous provision of IT services.

The basis of building the company's IT infrastructure is the Data Center (DC). The main task of the DC is to ensure guaranteed trouble-free operation of the enterprise's IT infrastructure. In this case, we are talking not only about the automation of business processes, but also about the most reliable data storage and guaranteed constant access to them. Databases can be upgraded by adding computing resources when implementing new business applications, as well as increase the amount of data storage, which means the ability to quickly adapt to changing business requirements.

First of all, data centers are in demand by large organizations, such as banks, insurance and trading corporations, mining companies, telecommunications companies (billing systems, hosting, various Web-services and social services). They all use complex business applications, and their activities depend on the reliability of the IT infrastructure.

The most important advantages of creating a DC are the consolidation of computing power and storage systems. As shown in [1], It is known that centralized management of IT infrastructure and information systems is more efficient than in the case of a distributed heterogeneous solution. In addition, it is easier to provide surveillance of a single complex and protection against possible failures.

At the same time, the growing needs of business must be met in conditions of limited resources: more data must be stored in the allocated space, this will prevent consumption or allocation of too much energy so calculations will be faster, to transmit more information through existing channels of communication, to ensure maximum readiness operated IT systems. And all this with limited funding. In such conditions, the competent design of the DC is a key link to achieve efficient operation of the enterprise, and these limitations determine the choice of technologies and equipment used.

It is known that in the field of high-availability IT systems, the situation is constantly and rapidly changing. The lack of a unified approach to the organization of DC, standards for the design and operation of various processing centers and server rooms pose the problem of developing a systematic approach to infrastructure implementation, as well as developing methods and models of DC to a new level. The emergence of experience in the form of standards, models and methods will unify the implementation and simplify changes in its infrastructure, thereby contributing to the replication and scalability of solutions.

In the absence of such experience, it is easy to be tempted and prefer the latest developments. Obviously, it is a rational choice, justified from the economic and technological point of view of the infrastructure that would provide long-term investment protection and allow the company to perform current tasks and develop. The amount of information in the future will only grow. Further growth of such sectors of the Internet related to business applications as e-commerce, payments, communications require an appropriate infrastructure. It is necessary to make sure that in the future there is an opportunity to ensure cost-effective growth and expansion of diabetes, because disruptions in electronic services can have significant economic consequences, both for individual enterprises and for government agencies and sectors of the economy.

The above indicates the relevance of the study of ways to effectively design traffic in networked data centers with a branched topology, taking into account open standards, which helps to minimize the problems of interaction when scaling the DC [2].

Improvement of quality of service (QoS) of traffic and reduction of it's design time can be hold by using multipath routing in SDN for centralized formation of multiple paths [3],

unlike known methods that have high time complexity. So a modified method was proposed in which formation of multiple paths has less complexity compared to known methods.

This paper considers the modeling proposed in article [4] mathematical model of a modernized method of constructing traffic in networked data centers with a branched topology, focused on software configuration of the network. This method, by taking into account the peculiarities of the organization of SDN, in particular due to the presence in the network of a central controller, reduces the time of formation of many routes of access to network resources [5], [6], [7], [8] and [9].

II. Algorithm Modification

In terms of routing, we are usually only interested in optimal routes. This applies to both one-path routing (search for the shortest route) and multi-path (search for a set of non-ordinary, partially ordinary routes). However, applying this method to this model is ineffective, because the controller requires a rapid response to changes in the state of communication channels, which leads to changes in the metric. Therefore, it is unwise to list the paths to find the shortest path.

For example, consider dynamic routing protocols such as OSPF and IS-IS [10]. These protocols are similar and designed for dynamic routing and take into account the state of the channels when constructing routes. These protocols use the Dijkstra algorithm to find the shortest route. In time, the complexity of the algorithm is $O(n^2)$. From this we can conclude that as the number of nodes increases, the time of finding the shortest path increases quadratically. With frequent updating of the status of communication channels, this approach is ineffective.

In the proposed method, the network topology rarely changes, therefore, it is advisable to consider a one-time calculation of all possible paths and the calculation of the next route to form new connections. Therefore, if it is necessary to find the optimal route, it is not necessary to calculate the route using the adjacency matrix; it is enough to list metrics and to choose an optimum line on the basis of the available information on a condition of knots and channels. This method can be used for different types of metrics. In the model used, the speed of information transmission along the route is used as a metric, so the controller will choose the path at high speed and send it to the first vertex along the route to the router [11].

Using the algorithm of passage of the graph in width makes it possible to identify all possible paths between the vertices. Ideally, this method will be applied once for each pair of vertices, while lists with calculated routes will be stored in the controller.

The method of constructing a route is based on the use of recursive steps. As a result, a set of all possible routes from the final to the initial vertex is formed. To do this, the extreme vertex is selected in each path and, starting from it, new routes are formed, which includes the already formed sub-route from the final vertex to the current one with the inclusion of one of the neighboring vertices. The algorithm terminates for this subroute if a new neighboring vertex is already in the route or the current vertex is the last. The procedure is complete if all routes have reached the initial peak.

However, a new route will not be formed if the adjacent vertex is already on the desired path. As mentioned, this step is recursively repeated for all routes until the next peak on the way is final. In the case of the formation of new links in the network, the already formed routes are supplemented as follows:

1) Select all paths that include vertices connected by a formed channel;

2) For each selected path, a sub-route is created from the vertex that participates in the new connection;

3) The vertex, which is located on the other side of the new connection, is added to the received sub-routes.

4) Recursive steps described for the formation of all routes, starting with the corresponding sub-route, are repeated.

Consider forwarding a packet to the next node on the way to its destination.

In high-load networks, the state of communication lines is constantly changing. These changes are difficult to predict because there are a number of reasons that can cause an unexpected load on a connection that was lightly loaded and guaranteed data transfer while maintaining a high level of service quality.

The packet forwarding algorithm used (MPLS VC) calculates the path during the traffic generation phase and stores the intermediate node labels in the packet headers. This algorithm using a virtual data channel does not allow timely response to changes in the state of communication channels in the network, because the intermediate nodes on the data route are stored as labels in the packet. Therefore, it is possible that the intermediate nodes stored in the packet header will not create the optimal path for the current time. This situation is likely to lead to some delays in data transmission for both the destination node and those nodes along which the routes intersect with the considered.

The proposed modernized method is based on the traditional approach to the routing table. These tables are updated after a certain period of time, each of the paths is updated independently of the others, just when you want to use it, or the time until the next update of the current route. After a request from the router, the controller calculates indicators if the paths for the destination node are already formed, generates these paths, and then sends them to the router, which sent a request to update the path with the number of the next node on the optimal path now.

Consider an unmodified width search algorithm (DFS) [12],[13]. It is based on a recursive stroke of the graph's vertices, through the tour, visited and non-visited nodes were marked. In the start point, some nodes are visited. The visited node is the one that receives the control packet and analyze information about neighboring nodes. After that the packet is transmitted to one of the neighboring unlabeled nodes. Otherwise, the control packet will pass back, if there is no unmarked neighboring nodes related to this node.

The disadvantages of main algorithm come from the ignorance of:

1) Channels communication capacity.
2) Network features topology.

Strategies for channel selection:

- Worst .Fit: In which the highest available bandwidth channel is selected.
- First Fit: In which any available bandwidth Chanel fits the requirements is selected.
- Best Fit: In which the available bandwidth Chanel that best fit the requirements

Taking in account, when DFS method is used to create multiple paths in DCN, the most effective strategy is Worst Fit. Moreover, the efficiency of aeration of many paths using DFS method is increased in association with the peculiarities of the DCN hierarchical organization and the communication channels bandwidth between the nodes of the network [14].

The DFS method is dependent on the centralized routing method. In this method all the information that are required to generate routes are found in the central controller, which contains information about network topology and capacity of communication channels, which is used to select the communication channel at a higher level or return to a lower level in the tree. Following the next path formation the communication channel with the allowable bandwidth for the selected path is reduced by a given value.

Based on that the network topology information is found in the central controller, the first step that is determined by the algorithm is the sender and recipient topology level where the nodes are unified. The modes are connected directly, if the path have many switches to pass through, their number is determined by the nodes relative location.

If the connection level of nodes is determined, routing will be facilitated, there for eliminating the unnecessary transitions between levels.

Fig. 1 shows the sequence of operations for modified DFS algorithm:

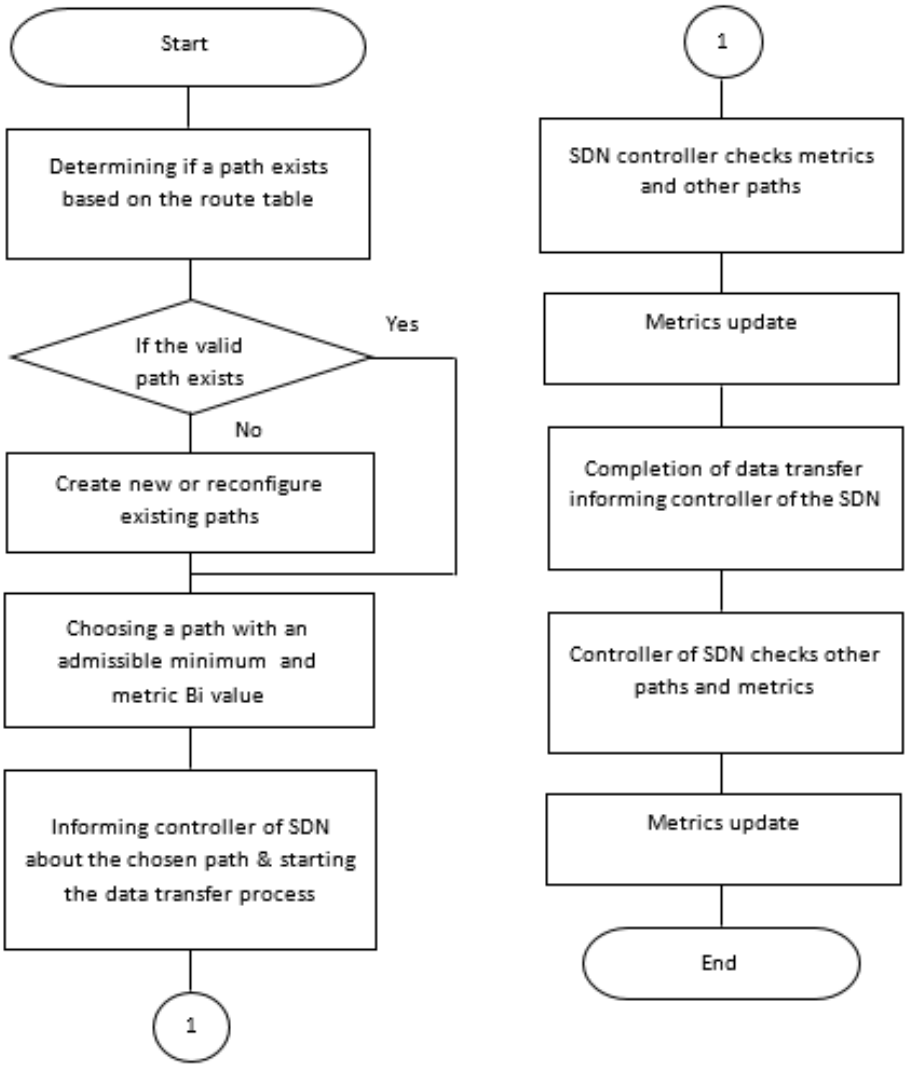

Fig. 1. Modified DFS Algorithm.

An advantage of SDN is that the network organization and management at the software level is carried out by virtual switches [15].

The Open Flow standard, [16], [17] and [18] in which the SDN concept is based, defines the network traffic management flow principles. The implementation of multi-threaded traffic routing in a software - configurable network is proposed due to the ability to configure the route of each individual traffic at the level of software-configurable SDN switches.

Streaming algorithms for multibeam routing have a minimal time complexity with known algorithms [19].

A set of continuous paths can be formed in the presence of centralized SDN control based on a network controller, by organizing counter - flows between sender and recipient nodes. Finding paths task is to find the tree's points of connections from the start and end vertices. As in [20], for a route similar to the modified wave algorithm, as the next for a certain path, a vertex with a smaller external degree is selected. So, a divergent paths formation is ensured.

Path trees are built until all the intersecting paths between the start and end vertices are built. Forming a set of disparate paths algorithm is illustrated below.

Define nodes set $X_1 = \{U_n\}$;
B_i=0;
J=0;
for $j = j + 1$ step 1, create a nodes set X_j+1 ={U_i| i=1,…n} adjacent to the set nodes of Y_i {U_n, U_l, N_i,c, b_i}, where n is the power's sum of the set of node X_{j1} ={U_i| i=1,…n};
if $X_{j+1} = \varnothing$ then go to 10 do
for i=1 step 1 to n calculate
Y_i {U_n, U_l, N_i,c, b_i}
if $b_j > B_i$ then $B_i = b_j$
end;
go to 4

end.

In the centralized formation of a set of independent paths, complete information about the formed paths and the trees that generated them is found in the central controller SDN. This gives us the chance to optimize them in the process of forming paths in accordance with the specified indicators.

III. Modeling

The Mininet environment was used to demonstrate the operation of the algorithm. Mininet is a computer network emulator. It allows you to quickly set up a network on a personal computer. This network will be almost indistinguishable from the real one, it will just not be able to send pings to external IP addresses.

To model the proposed method of traffic design, you need to build and configure the topologies considered in article [4], namely the double extended star and the double ring.

Two (2) controllers, 6 switches and 12 hosts were used to build the Double Extended Star topology (Fig. 2).

Before the simulation begins, the controllers form a model of the constructed topology. To do this, they build an adjacency matrix and store nodes and connections. As a result of the correct start of modeling of controllers on the console the list of all nodes and their connections will be deduced. The console displays basic information about the nodes and the connections with other nodes, namely the actual node name, bandwidth and channel load (delay). In this step, each connection has a bandwidth of 100Mbit, i.e. it does not contain any load. This message is displayed only once during the initial initialization, then when the topology changes, the network model is updated by the controller without messages of this type.

To simulate the operation of the algorithm, it is necessary to initiate traffic between hosts h7 and h14. To demonstrate, execute the command to compile the dump and start the traffic between hosts h7 and h14 (Fig. 3).

As you can see from the results, the routing table that was created at network startup and updated periodically, controllers immediately know the optimal route for traffic. In our case, we can see in the logs, which are collected during the transmission of the packet, a complete description of the route, and the time of passage of the packet between nodes. We also obtain the IP and MAC addresses of the sending and receiving nodes, which simplifies the analysis of the collected data and allows easy packet routing.

To demonstrate the effective operation of the developed method of traffic design for this topology, a original DFS algorithm was simulated.

As you can see in Fig. 4 the execution time of the first packet transmission takes 0.11 ms, which is 0.058 ms more than the modified one. This is because before the transmission begins, complete information is collected about the state of the nodes and communication channels in the topology, which takes some time. If the topology was static (nodes are always working, communication channels have a constant non-variable load) then a slightly longer time to send the first packet did not play an important role, but because it is not possible and the topology is dynamic (nodes fail or topology is supplemented by new, in communication channels are constantly changing the load or they break off altogether) then each time to collect new information about the state of the topology before sending the packet is quite time-consuming operation.

To obtain more detailed information about the operation of the modified method of traffic design, simulations were performed with different numbers of packets (Graph 1 and Table I).

Four (4) controllers, 8 switches and 12 hosts were used to build the Double Ring topology (Fig. 5).

In this simulation, the situation is the same as described earlier. A topology model is formed due to the adjacency matrix and information about nodes and connections between them.

IV. CONCLUSION

This paper simulates the operation of a modified method of constructing traffic in networked data centers with a branched topology, which, given the peculiarities of the organization of SDN, reduces the time of forming a set of routes to access network resources and simplify the procedure for changing the route.

Topology data using this method [6] allow to virtually eliminate the delay or loss of packets in the process of traffic reconstruction. At the same time, the more paths formed in the topologies, the less likely it is that packets will be delayed or lost.

The results, based on the two most popular topologies for large businesses, showed a 30-50 percent acceleration of packet transmission between nodes due to the collection of information about communication channels by controllers and the construction of a contiguity matrix. As'ad et al [21], [22], [23] and [24] enter new concept on networks and computer science which it bipolar intuitionistic fuzzy sets and he used it in many of his articles.

Computer Science Department, University of Nigeria, Nsukka, Enugu state, Nigeria[1, 3]
National Board for Technology Incubation, Abuja, Nigeria[2]

***Abstract*—The advancement in Information Technology permits high volume of data to be generated in databases of institutions, organizations, government, including Law Enforcement Agencies (LEAs). Technologies have also been developed to store and manipulate these data to enhance decision making. Crime remains a severe threat to humanity. Criminals currently, exploit highly sophisticated technologies to perform criminal activities. To effectively combat crime, LEAs must be adequately equipped with technological tools such as data mining technology to enable useful discoveries from databases. To achieve this, a Real-time Integrated Crime Information System (RICIS) was developed and mobile phones were used by informants (general public) to capture information about crimes being committed within Southern-East, Nigeria. Each crime information captured is being sent to the LEA responsible for the crime type and the information is stored in the agency database for data analysis. Thus, this study uses data mining algorithms to analyze crime trends and patterns in Southern-Eastern part of Nigeria between 2012 and 2013. The algorithms adopted were Classification and Rule Induction. The data set of 973 were collected from Eleme Police station, PortHarcourt (2012) and Nsukka Police station (2013). The analysis enables identifications of some trends of crimes and criminal activities from various LEAs databases, enhancing crime control and public safety.**

Keywords*—*Information technology; law enforcement agency; data mining; crime; classification and rule induction

I. Introduction

Technology advancements have made the world a better place including access and manipulation of huge volume of dataset in virtually all fields of life [1]. Criminology is an important area for applying data analysis and it is a practice aimed at discovering crime characteristics [2]. Crime is of immense concern in our world today. Crime ranges from simple violation of civic duties (e.g., illegal parking) to internationally organized crimes (e.g., the 9/11 attacks) [3]. Crime has negatively impact both developed and developing nations because of its emotional, economic and social disruptive tendencies. It threatens the quality of life, human rights and poses severe challenges to any society [4][5]. The motivation of this study is to understand the trend, pattern and the prevalence of each crime type in different parts of the South-East, Nigeria. This properly advises the Law Enforcers (LEs) on the most effective approach on crime management. Criminals today, use sophisticated technological tools [6] not just to commit crimes but also to avoid being detected. Unfortunately, most of the Nigeria LEAs are still using paper-based information systems to capture and store crime data, leading to delay in crime information flow and inefficient crime data analysis. The work aims to analyze crime data generated from the implemented RICIS model to assist the LEAs perform their operations.

Crime control and prevention are fundamental to the welfare, stability and development of any society. Though, Government and communities have been making effort to improve on security standard of the public (through establishing different LEAs and community policing), more effort should be done to equip the LEAs with current technologies (e.g. crime analytic tools) for effective crime management. Timely access to relevant information is also of utmost necessity in day-to-day business of LEA, especially in crime investigation and detection of criminals [7].

Data mining is a tool that enables efficient extraction of useful information and patterns from complex and large datasets [6][8][9][10]. It is primarily aimed at uncovering hidden relationships in data warehouse with the aid of artificial intelligence method [11][12]. Data mining has been applied in the areas of crime analysis and prediction to assist the LEs in crime decision making [13].

Crime analysis is a task that includes exploring and detecting crimes and their relationships with criminals to assist security personnel in planning the deployment of available resources for the prevention and suppression of criminal activities [14].

A crime analysis should be able to identify crime patterns quickly in an efficient manner [7]. Some areas of data mining applications include supermarket, hospitals, banks, insurance companies, airline, governments and many other fields of life [15]. Data mining has been used to solve some challenges such as detection and prevention of fraudulent activities in telecommunication services, criminal's activity, etc.

Some data mining algorithm for knowledge discovery in databases include Classification, Rule induction, Association rules, Clustering, Forecasting, and Visualization, etc. Most times, researchers combine data mining techniques to achieve more precise and accurate extractions. Some software packages (built in mining tools) [16] [17] [18] designed for implementation of these techniques for data analysis include: Waikato Environment for Knowledge Analysis (WEKA), KNIME, ORANGE, etc. PHP and other programming tools were used to implement the algorithms (classification and Rule induction) for data analysis. The research will help LEAs and as well the government in improved decision-making and public safety.

The remaining sections are organized as follows: Section 2 discusses literature review; Section 3 deals with the analysis, design and method; Section 4 is on implementation, analysis and results, and finally Section 5 discusses conclusion.

II. Review of Literature

This section deals with the data mining basic concepts, the imperatives for crime analysis and review of some existing literatures in the related areas.

A. Data Mining and Imperatives for Crime Analysis

Three steps involved in data mining include: exploration, pattern identification and deployment [1]. Exploration means to clean and transform data into a new form, then important variables and nature of data are determined based on the problem; Pattern Identification means to identify and choose the patterns which make the best prediction. Deployment organizes the patterns for desired outcome [1]. According to [16], [19], [15], crime data analysis provides summary statistics, general and specific crime trends to LEs in timely manner to enable understanding on crime and criminal behaviour. This assists LEAs to be proactive in crime detection and prevention while managing their limited resources effectively.

B. Types of Crime Analysis and Data Mining Tasks

The crime analysis types include:

1) Tactical crime analysis generates information on where, when, and how crimes take place to assist officers and investigators in identifying and understanding specific and immediate crime problems.

2) Strategic analysis examines long term changes in crime, known as “crime trends”. Administrative Crime Analysis provides summary statistics, and general trend information.

3) Criminal investigative Analysis involves profiling suspect and victims for investigators based on analysis of available information. One may analyze to find out the type of person committing a particular crime series.

4) Intelligence analysis focuses on organized crime, terrorism, and supporting specific investigations with information analysis and presentation.

5) Operations analysis examines how LEA is using its resources. It focuses on such topics as deployment, use of grant funds, budget issues, etc. [15].

Two stages of data mining Tasks include:

a) Data collection phase: The researcher collects the training dataset from a defined source.

b) Data Pre-processing Phase: Processing the collected data to get it suitable for analysis through data cleaning, integration, transformation, reduction and discretization [16].

C. Types of Data Mining Techniques

Classification deals with discovering and sorting crime data into groups or predefined classes such as type, location, time, etc. based on certain attributes/criteria discovered from databases [20][21]. Classification is the process of learning a function f that maps each attribute of a set $X=\{x1, x2, \dots, xn\}$ to a predefined class label y ***[21]***. The goal is to build a model to predict future outcomes. Data classification helps to predict how new individuals or events will behave based on the classification criteria [17]. Classification has been used to detect email spamming and find authors who send out unsolicited emails [11], [18].

Rule induction is a machine learning technique in which through observations, rules are extracted from a dataset. These rules may possibly denote a scientific model of a dataset or signify a pattern in the dataset. A rule is conveyed with “if-then statements”. Rule-based algorithm takes training dataset as input and generates rules by dividing the table with cluster analysis.

Association rules are generating rules from crime dataset based on frequent occurrence of patterns [16]. Association Rule searches for relationship between data that exist together in a given record to uncover crucial information. In [18], association rule detected suspicious e-mails by identifying unusual and deceptive communication in e-mails.

Clustering techniques is used to automatically associate different objects (such as persons, organizations, vehicles) that are similar to one another and dissimilar to objects of another group in crime records. Clustering is based on finding relationships between different Crime and Criminal attributes having some previously unknown common characteristics [15]. In crime analysis, cluster analysis is used to identify areas with high concentration of a particular crime type. By identifying these crime "hot spots" i.e. where a similar crime has happened over a period of time helps to manage law enforcement resources more effectively [3].

Forecasting deals with discovering patterns and data that may lead to reasonable predictions. It estimates the future value based on a record's pattern. It deals with continuously valued outcome. Visualization enables miners to rapidly and efficiently locate vital information that is of interest within the data [17].

D. Review of Related Literature

Data mining technology has been adopted by organization improve on business strategies through performing different knowledge discoveries [1]. Authors in [11] reviewed data mining techniques and presented four case studies of their crime data mining project as follows: entity extraction for police narrative reports, detecting criminal identity deceptions, authorship analysis in cybercrime and criminal network analysis. According to [16], a model was proposed for crime and criminal data analyzes using clustering and association rules algorithm. The work tends to help LEs in discovering crime patterns and trends, making forecasts and as well identifying possible suspects. The intension was to assist the Libyan Government on strategic decisions to reduce the high increase on crime rate.

In [19], k-means clustering algorithm was used to perform data analysis to assist LEs in crime reduction. The goal was to extract useful information from crime dataset to enable LEs to identify and analyze crime patterns for effective crime control and prevention. WEKA and Microsoft Excel were used for analysis. Data mining and machine learning tools such as the

Additive Regression, Linear Regression were used to conduct a comparative study between the violent crime patterns from the Communities and Crime Unnormalized Dataset provided by the University of California-Irvine repository and actual crime statistical data for the state of Mississippi provided by neighborhoodscout.com. The researchers implemented the three selected tools using the same finite set of features on the Communities and Crime Dataset and found that the linear regression algorithm performed best in predicting violent crime patterns [17].

A concise review on Data mining techniques and its applications on over 100 different areas on crime analysis were presented in chronological order [18]. In [22], clustering algorithm was used for crime data analysis to detect crime patterns and speed up the process of solving crime issues. The aim was to formulate crime pattern detection as machine learning task and using data mining to support LEs in crime struggle. The modeling technique was able to identify the crime patterns from the crime data. Research on [3], presented a detailed overview of clustering technique, its types and some of its application areas.

In [2], data clustering method and artificial neural networks were adopted to unsupervisely classify crimes and crime pattern recognition respectively. This research finally proposed a method for crime matching processes. In [23], binary clustering and classification techniques were used to analyze criminal data and was aimed to potentially discover a criminal based on the witness/clue at the crime spot. An auto correlation model was used to validate criminals on the process. Researchers in [24] focused on property crime and explore the best approach to reliably predict the location, time, and/or likelihood of future residential burglary. The work adopted classification model to perform the crime forecasting.

Authors in [13] studied data mining technologies used in criminal investigation, highlight the approach adopted in crime data analytics and summarizes some challenges arising during the analysis process**.** A machine-learning classification algorithms, such as boosted decision tree and K-Nearest Neighbour (KNN) were adopted to create a model that will perform crime prediction on Vancouver dataset collected for a period of 15 years (2003-2018). It is recorded that prediction accuracy between 39% and 44% was achieved [25].

III. Design and Methods

A. Methodology

Data collection and the research output adopted quantitative method. The 973 primary data were collected from Eleme police station PortHacourt (2012) and Nsukka police station (2013) in the South-East Nigeria. Subsequently, data for analysis will be collected from the RICIS developed. To get the desired outcome, the data collected passed through three stages of data mining: exploration, pattern identification and deployment. The data were pre-processed using different pre-processing techniques (cleaning, missing values and removing inconsistency). The pre-processed data were used to find different crimes, criminal trends and behaviour. The crimes and criminals were grouped into clusters according to their important attributes. The data mining algorithm adopted were classification and Rule Induction. The Psuedocode of the two techniques is presented in section 3.3.

B. Conceptual Framework of the Study

The framework of the proposed research presents the summary of the research in a block diagram as shown in Fig. 1. This gives details of the processes of the mining from data collection to the final report (result). The work aims to analyze crime data generated from the implemented RICIS model shown in Fig. 2, to assist the LEAs perform their day-to-day operations, though, data currently used for analysis in this study was collected from two different Nigerian Police stations as mentioned in Section 3.1.

C. Analysis of the RICIS System

The RICIS is a crime reporting system developed to capture crime information from informant as shown in Fig. 2. The components of the RICIS as shown in Fig. 2 include an informant who reports crime, a mobile phone for crime report, an application for directing crime information to the appropriate agency, a middleware to enable data exchange among the agencies, individual agency's databases for their data autonomy, a centralized database for data analysis and backup, internet to enable communication and finally the bidirectional arrows indicating the direction of information flow.

This system enables LEA to collaborate by sharing resources such as one agency searching for the existence of a criminal's information in any of the participating agency or LEAs redirecting a crime information wrongly sent to any of them to the appropriate agency for instant responses. The system also enables LEAs substitute the traditional paper-based crime reports systems with an electronic system. The system provides instant response to crime and generate huge amount of crime data for data analysis. The reported crime provides data such as location codes, crime type, where, when, and how crimes happens (short crime details), information about suspect (if identified) and the victim. These information enables the law enforcement officers to offer a just-in-time response to crime scene and have quick access to the right data.

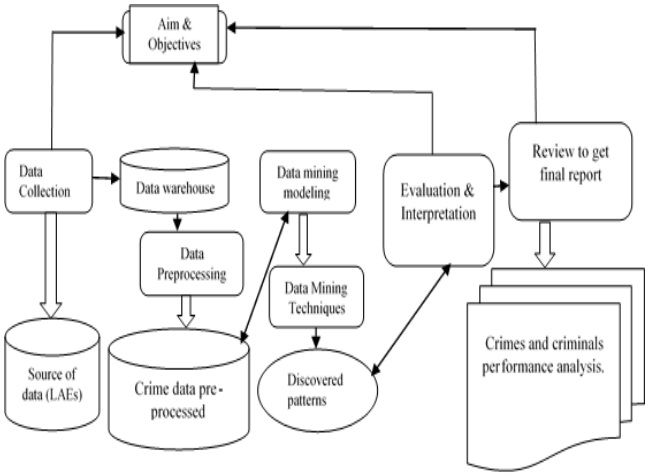

Fig. 1. Conceptual Framework of the Data Mining Process.

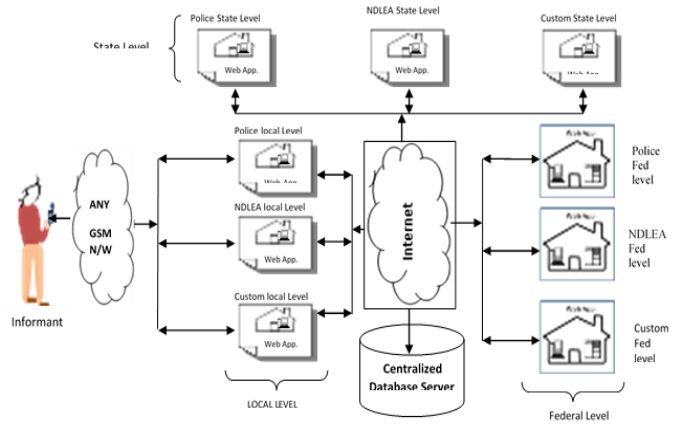

Fig. 2. The RICIS Model.

Mining the crime data on RICIC extract some crime pattern and relevant information such as: most prevalent crime in the country, state with highest number of criminals or crimes, age range of criminals with highest crime rate, location with highest crime rate, the class of people that commit most crimes (literate, illiterate, married, single, jobless etc.), time of the day crime usually occur in a particular place and which week of a month or month of the year or year with highest number of crime, etc. The results from this system can provide statistics of crimes handled in an agency in a specified time (e.g. number of crime incident investigated and handled in a year, etc.). This will to a great extent help LEs to manage their limited resources effectively and improve on the security standard of the nation.

D. Data Mining Algorithm

This section shows the algorithms (Pseudocode) of the data mining techniques (Classification and Association rule) used. The pseudo code shows the sequential steps taken in the implementation of these techniques. The analysis done is a modified algorithm that combines both classification and association rule. Association rule is a learning algorithm based on rule or adaptation [26][27]. The algorithm must be provided with TrainingSet already been classified in order to generate a list of classification rules.

Rule Induction algorithm

1.0 Input data
1.1 let the ClassificationRuleList be empty
2.0 Perform classification
2.1 repeat
2.1.1 let the ConditionalExpressionSet be empty and let the BestConditionExpression be nil
2.1.2 Repeat
2.1.2.1 Let the TrialConditionalExpressionSet be the set of conditional expressions, {x and y where x belongs to the ConditionalExpressionSet and y belongs to the SimpleConditionSet}.
2.1.2.2 Remove all formulae in the TrialConditionalExpressionSet that are either in the ConditionalExpressionSet (i.e., the unspecialized ones) or null (e.g., big = y and big = n)
2.1.2.3 for every expression, F, in the TrialConditionalExpressionSet
2.1.2.3.1 If F is statistically significant and F is better than the BestConditionExpression by user-defined criteria when tested on the TrainingSet then replace the current value of the BestConditionExpression by F
2.1.2.4 While the number of expressions in the TrialConditionalExpressionSet > user-defined maximum
2.1.2.5 Remove the worst expression from the TrialConditionalExpressionSet
2.1.2.6 Let the ConditionalExpressionSet be the TrialConditionalExpressionSet
2.1.3 until the ConditionalExpressionSet is empty
2.1.4 if the BestConditionExpression is not nil then let the TrainingSubset be the examples covered by the BestConditionExpression
2.1.5 Remove from the TrainingSet the examples in the TrainingSubset
2.1.6 Let the MostCommonClass be the most common class of examples in the TrainingSubset
2.1.7 Append to the ClassificationRuleList the rule 'if ' the BestConditionExpression ' then the class is ' the MostCommonClass
2.2 Until the TrainingSet is empty or the BestConditionExpression is nil

3.0 return the ClassificationRuleList [28].

The classification algorithm classifies data based on rules. The algorithm goes thus:

1.0 Input data
1.1 Convert continuous values to categorical values.
1.2 Set all classified to false (all classified is a variable that checks if all the data values are totally classified or not)
1.3 Set n = 0
1.4 Initialize classified dataset to empty
2.0 Repeat
2.1 pick the value of an attribute
2.2 generate rule for the combination (inserting value into a classified dataset)
2.3 classify the value of the attribute
2.4 set n=n+1
2.5 if n = total number of data in raw dataset then set all classified to true, go to 3.0
2.6 else repeat from step 2.1 until all classified = true

3.0 return classified data.

In the combined algorithm, there are key things to note:

1) Attributes – these are the field names.

2) Instances – these are the rows(records) in a dataset.

3) Class – this is the value of attribute (data stored in a field).

4) Subclass – this is the node of a class.

The task here is to loop through all the instances, pick the classes and classify them according to their respective attributes. In each classification, there is also a sub classification. Each classification has inner classifications which are based on the original criteria for mining the data. These are said to be sub attributes. The algorithm employs statistical method in forming a rule. Basically, the system used these techniques to display the crime type that is most committed, location with highest crime, age group with highest crime, state/LGA with highest crime, etc. Sorting rule is used to form this assertion. When an array is sorted in descending order, those elements at the beginning of the array are the ones with highest frequency, therefore to form the rules from the sorted array becomes easier. The data mining algorithm goes thus:

1.0 Input data
- *1.1 Input data mining criteria (select attribute)*
- *1.2 read data from the database and store in unclassified dataset*
- *1.3 initialize sub-attributes*

2.0 Manipulate data
- *2.1 convert continuous values to categorical values*
- *2.2 set classified dataset to empty*

3.0 LOOP through the unclassified dataset
- *3.1 Pick a class from an instance based on selected attribute*
- *3.2 Search through the Classified Dataset for the class*
  - *3.2.1 If class is not found then add a new node of the class to the classified dataset*
    - *3.2.1.1 Loop through the sub attributes*
    - *3.2.1.2 Pick a subclass from the instance*
    - *3.2.1.3 Add the subclass as a sub node to the class node*
    - *3.2.1.4 Repeat from 3.2.1.2 until all the sub attributes are treated*
  - *3.2.2 Else update the node where the class is found in the dataset*
    - *3.2.2.1 Loop through the sub attributes*
    - *3.2.2.2 Pick a subclass from the instance*
    - *3.2.2.3 Search for the subclass in the parent class node in the classified dataset*
    - *3.2.2.4 If subclass is not found then add the subclass as a sub node to the class node*
    - *3.2.2.5 Else update the subclass sub node in the class node*
    - *3.2.2.6 Repeat from 3.2.2.2 to 3.2.2.5 until all the sub attributes are treated*
- *3.3 Repeat from step 3.1 to 3.2.2.5 until all data are classified*

4.0. Generate Rules for the manipulated data
- *4.1 Sort the classified dataset in descending order*
- *4.2 Set n = 0*
- *4.3 Loop through the nodes of the classified dataset*
  - *4.3.1 Pick a class at node n*
  - *4.3.2 If n = 0 and the number of occurrence of class in node n is greater than the class in node n+1 then the rule follows that the class in node n is the best fit for the test. Go to step 4.4*
  - *4.3.3 Else if n > 0 and the number of occurrence of class in node n is greater than the class in node n+1 then the rule follows that all the classes from node 0 to n are the best fit for the test. Go to step 4.4*
  - *4.3.4 Else set n = n + 1*
  - *4.3.5 Repeat from step 4.3.1*
- *4.4 Return the results*

5.0 Print results
- *5.1 Display the results node by node*
- *5.2 End*

IV. System Implementation

These sections document the implementation and the results of the proposed system. Fig. 3 shows list of all reported cases that are yet to be investigated. To display this, simply login and select state and the LGA where the crime was committed.

Fig. 4 displays the investigated crimes (centralized database) where one can mine data. In mining crime data, the following 13 different parameters were used: Person, Sex, Age, Marital Status, Occupation, Educational Status, State, LGA, Crime Location, Crime Date, Crime Time, Crime Type and Tribe. If a parameter is selected, the program analyzes the crime data based on that parameter. Fig. 5 shows mining by age range. Data mining results on classification based on age showed that out of 973 crime data collected in 2013, criminals within the age range of 31-40 committed the highest number of crimes with 263 cases. In each analysis, there are always sub-analysis which re-analyzes the crime cases using all other parameters except the selected one.

Fig. 3. List of Crime Cases Yet to be investigated.

Fig. 4. List of Investigated Crimes.

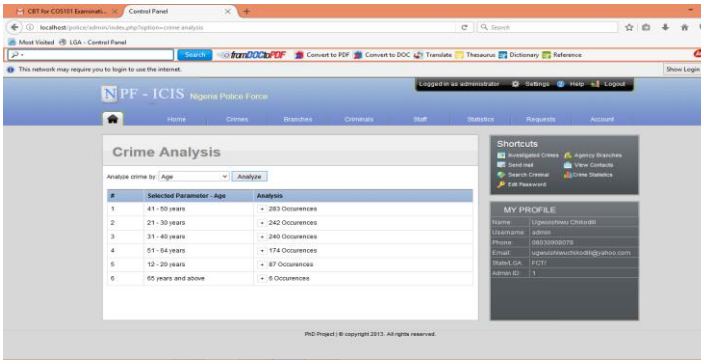

Fig. 5. Crime Analysis by Age Range.

Table I shows a clearer picture of the result in Fig. 5. The sub-analysis of the result on Fig. 5 is shown on Fig. 6. Result from Fig. 6 shows that Beach Junction Nsukka is a location with the highest number of crimes.

Table II shows a comprehensive crime statistics of all crime types committed in 2013 based on the collected. The result is presented state by state and the total occurrence of each crime type within the year is given. This crime distribution is based on the state of origin of the criminals i.e. citizens of the country that committed crime in Enugu state. Data mining results on classification showed that out of 973 crime data collected in 2013, Anambra state has the highest number of criminal cases with 192 crimes. It may also interest a reader to note that because this research was carried out in the Eastern part of the country, the concentration of these criminals' states of origin was spread mostly in the South eastern part of the country.

TABLE I. THE CRIME ANALYSIS RESULT BY AGE RANGE AS SHOWN IN FIG. 5

#	Age Range	Analysis
1	41 - 50 years	228 Occurences
2	21 - 30 years	229 Occurences
3	31 - 40 years	263 Occurences
4	51 - 64 years	168 Occurences
5	12 - 20 years	83 Occurences
6	65 years and above	2 Occurences

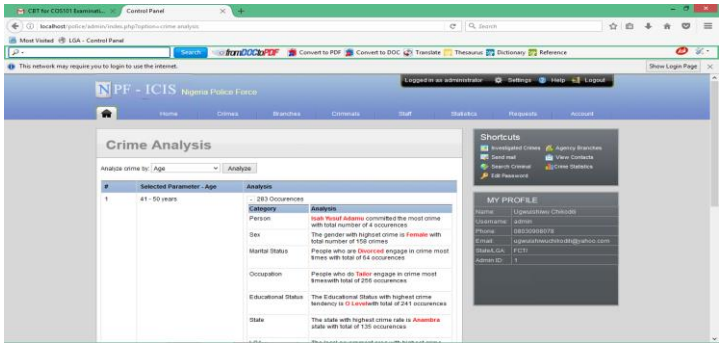

Fig. 6. The Sub-Analysis of the Result shown in Fig. 6.

TABLE II. CRIME STATISTICS FOR 2013 BASED ON THE CRIMINAL'S STATE

V. CONCLUSION

A Real- Time Integrated Crime Information System was developed and data analysis performed. It is intended that when this application is fully deployed, data analysis should be done on crime data available in the RICIS centralized database. This work used classification and Association rule algorithms to identify useful crime trend and patterns. These machine learning algorithms (Psuedocode) were implemented using PHP and other programing language tools. The results of this data mining will support LEAs in effective decision making, management of their limited resources and will considerably reduce crime rate and increase the security standard of the nation.

A. Limitations of the Study

There was a big challenge during data collection because most of these Nigerian LEAs do not have electronic crime data. The data I got was manually picked into a table format one after the other and this made things difficult. Nigeria Custom Services, Nigeria Police and NAFDAC offices were visit by the researcher but data were collected from only two police stations – Eleme Police station and Nsukka police station, the major reason being that there was no electronic database to access.

B. Recommendations

The system is used by virtually every citizen of the country to fight against crime. Specifically, this application is meant for Nigerian LEAs to manage societal crime issues. LEAs of any country, other governmental agencies, private and public organization can equally use this system with a little modifications. Government can use this application to determine the efficiency of LEAs on crime management by taking the statistics of crime handled within a specified time.

WEKA and other mining software tools may be considered in the data analysis instead of developing new mining application, increase in the data size and mining parameters, and as well data mining techniques such as clustering and linear regression may be may be adopted for a more improve analysis.

Comments: The data collected are not sufficient to make for conclusive evidence. How does this provide for privacy of persons under investigation? The supposed ‘criminals’ are suspects, or have they been convicted by a court of competent jurisdiction?

Human Face Recognition from Part of a Facial Image based on Image Stitching

Osama R. Shahin, Rami Ayedi, Alanazi Rayan, Rasha M. Abd El-Aziz, Ahmed I. Taloba
Department of Computer Science, College of Science and Arts in Qurayyat, Jouf University, Saudi Arabia

***Abstract*—Most of the current techniques for face recognition require the presence of a full face of the person to be recognized, and this situation is difficult to achieve in practice, the required person may appear with a part of his face, which requires prediction of the part that did not appear. Most of the current forecasting processes are done by what is known as image interpolation, which does not give reliable results, especially if the missing part is large. In this work, we adopted the process of stitching the face by completing the missing part with the flipping of the part shown in the picture, depending on the fact that the human face is characterized by symmetry in most cases. To create a complete model, two facial recognition methods were used to prove the efficiency of the algorithm. The selected face recognition algorithms that are applied here are Eigenfaces and geometrical methods. Image stitching is the process during which distinctive photographic images are combined to make a complete scene or a high-resolution image. Several images are integrated to form a wide-angle panoramic image. The quality of the image stitching is determined by calculating the similarity among the stitched image and original images and by the presence of the seam lines through the stitched images. The Eigenfaces approach utilizes PCA calculation to reduce the feature vector dimensions. It provides an effective approach for discovering the lower-dimensional space. In addition, to enable the proposed algorithm to recognize the face, it also ensures a fast and effective way of classifying faces. The phase of feature extraction is followed by the classifier phase. Displacement classifiers using square Euclidean and City-Block distances are used. The test results demonstrate that the proposed algorithm gave a recognition rate of around 95%, to validate the proposed algorithm; it compared to the existing CNN and Multibatch estimator method.**

Keywords*—Face recognition; image stitching; principal component analysis; Eigenfaces distance classifiers; geometrical approach

I. Introduction

Image stitching is the method used for consolidating various photographic images with an overlapping manner of view to get a sectioned display or high-resolution image. Most regular methodologies of image stitching require correct covers amongst images and indistinguishable exposures to create consistent results. Moreover, by using image stitching in computer vision and PC design applications, some digital cameras can stitch their photographs together internally [1]. Arrangement of the images may comprise at least two digital images taken of a solitary scene in various circumstances, from various sensors, or various perspectives. Image stitching strategies are classified into two general methodologies: feature-based techniques and direct techniques [2]. Feature-based techniques expect to identify a connection between the images through unmistakable features separated from the prepared images whereas direct techniques were dealing with all pixels of the parts of the image stitched. The feature-based strategy has the advantage of being more robust against direct techniques, and it can naturally find interlinkages between disorganized arrangements of images. Image stitching comprises three stages: Image Acquisition, Image Registration, and Image Blending.

Face recognition has wide applications in security, validation, surveillance, and distinct forensic evidence. Regular identification strategies such as ID cards and passwords are not considered as reliable as previously thought due to the various methods of hacking secret keys and others. As an option, biometrics, which is characterized by being a physical identification mark or belonging to a specific person, is not the same as others. The distinction between different individuals in the Known person database is the focal point of face recognition. In the future, face recognition is expected to oversee unlimited frameworks, such as access control for aircraft station security, smart home applications, structures, and faces, as well as for checking and monitoring buildings and vehicles and intelligent human-PC collaboration. In recent years, confrontational recognition has created limitless application fields from acknowledged assertion and proof to collaboration and correspondence between human devices and computers through video applications based on face recognition. Face recognition algorithms are regularly classified into three categories, which are comprehensive methods, feature-based methods, and hybrid methods.

The holistic methods category symbolizes the entire facial region as a high-dimensional vector that contributes to a classifier. Principle Component Analysis (PCA) is a successful agent technique for all-encompassing face recognition strategies, including Linear Discriminant Analysis (LDA) and Independent Component Analysis (ICA). Local methods, on the other hand, extract neighborhood characteristics from facial territories; for example, the eyes, mouth, nose, and cheeks. These features are utilized to characterize faces. Finally, in the hybrid method, both the holistic and local methods are utilized to perceive and distinguish a face [3]. The essential challenge confronting any calculation for facial recognition is the deficit in the appearance of the face that is expected to perceive. The motivation behind this work is to construct complete face images by utilizing the stitching image algorithm.

II. Related Work

Over the last two decades, numerous analysts have proposed and executed different display image stitching frameworks. In the authors have introduced new systems on image stitching based on the histogram-matching algorithm [4]. Histogram coordinating is utilized for image adjustment, so the images stitched have a similar level of brightness. At this point, the paper embraces the SIFT algorithm to separate the key features of the images and plays out the harsh coordinating procedure. This work followed by the RANSAC algorithm for fine matches finally ascertained the most suitable scientific mapping model between the two images and as indicated by the mapping relationship, a straightforward weighted normal algorithm was utilized for image blending.

Authors in [5] provided a specialized examination for the fast image stitching calculation based on SIFT. Firstly, the images are separated into squares. The component sorts these neighborhood image squares and is resolved. The element purposes of the nearby image squares are removed utilizing diverse streamlined techniques adaptively. Secondly, we utilize coordination to achieve the changed framework and the RANSAC algorithm connected to expel incorrect coordinating point sets. Finally, the stitched image can be achieved by image blending.

Another proposal [6] has provided a new approach for image stitching techniques using (DTW). This work proposes a novel technique that uses the Dynamic Time Warping (DTW) algorithm to coordinate sets of images for image stitching. They additionally perform a measurement-reducing plan that shrinks the computational multifaceted nature of the standard DTW algorithm without influencing its execution. The viability of their proposed technique is shown in the stitching of 50 sets of restorative X-beam images and its execution contrasted with those of standardized cross-relationship (NCC), minimum average correlation energy (MACE) channels, total of-square-contrasts (SSD), and the entirety of absolute-contrasts (SAD). Their technique likewise beats two generally utilized stitching programs accessible on the web called Hugin and Auto-stitch.

The work in [7] gives an in-depth review of the current image mosaicing algorithms by ordering them into a few classes. For each class, the principal ideas will be clarified, and afterward, the adjustments made to the fundamental ideas by various analysts clarified. Moreover, this paper additionally discusses the focal points and burdens of all the mosaicing classes. Several previous investigations have led the field of face detection and recognition in settled images through a different scheme of frameworks. Shahin and EL-SAYED proposed a face recognition system based on the Geometrical Approach. The geometrical approach consists of two phases, namely, the detection phase and the recognition phase. The edge of the tested face is detected in the first phase after some pre-processing operations have occurred on the tested image. The second phase attempts to identify the angles of the face outline. After calculating the angle vector of the tested face, it will compare with the training set angles vectors via a neural network to identify the face [8].

Recognizing the weaknesses and strengths of machine learning techniques is critical for real life applications as well as being a prerequisite for determining extensive research and development requirements. Papers on intense analysis model can be found in literature as part of either job that specifically focuses on the attributes of deep models, or ii) work which explores the attributes of deep models as component of that other participation. Papers in the first collective, like ours, typically investigate different models and current legal findings that address a variety of deep models as their main contribution, whereas papers with in second category introduce a new classification model and then analyze its attributes.

This work proposed a discriminative feature-learning approach to recognize the face using convolution neural networks (CNNs) [9]. The proposed center loss algorithm is needed for the task of face recognition. In this algorithm, they train robust CNNs to obtain the deep features with two key learning objectives, intra-class compactness, and inter-class dispensation, as much as possible, which are necessary to the process of face recognition. Kasar et al [10] proposed a strategy for face recognition using artificial neural networks (ANN). They examined the face recognition methods proposed by numerous specialists utilizing ANN, which are used as a part of the field of pattern recognition and image processing.

Furthermore in [11] proposed a strategy for face detection and recognition based on (PCA) – (LDA) and square Euclidean distance with the Viola-Jones algorithm. Their proposed strategy is based on the appearance-construct features that concentrate on the whole face image as opposed to neighborhood facial features. The initial phase in the face recognition framework is face location. The Viola-Jones' face location technique equipped for handling images to a great degree while accomplishing high identification rates is utilized. Feature extraction and measurement-reducing strategy connected after face recognition. The principal component analysis (PCA) technique is generally utilized as a part of pattern recognition. The Linear Discriminant Analysis (LDA) technique, used to overcome the disadvantages of PCA, has effectively connected to face recognition. It is accomplished by projecting the image onto the Eigenface space by PCA and then applying unadulterated LDA over it. Subsequently, Square Euclidean Distance (SED) was utilized. This distance classifier is required to identify the similarity between the tested face images with those located in the training set.

Finally, conducted a comprehensive survey on pose-invariant face recognition [12] (PIFR). They discussed the intrinsic challenges in PIFR and exhibited a complete audit of built-up systems. They characterized the current PIFR strategies into four classes, namely, pose-robust feature extraction methodologies. They described and assessed the inspirations, systems, geniuses/cons, and the execution of agent approaches.

The key contributions of the proposed work are summarized as,

- Initially, the face images dataset is trained in a system.
- At first, an input testing image is taken from the dataset.

- Consequently, image stitching process operation is performed to determine the missing part of the face.
- Moreover, feature extraction is done through the Eigen face approach through PCA and geometrical method.
- Finally, the displacement classifier that utilizes Square Euclidean and City- block distances is used for categorizing the faces.

III. Methodology

The proposed system developed in this paper is divided into two phases. The first phase is stitching the face image for the face that needs to recognize, while the second phase is face recognition. Fig. 1 illustrates the scheme of the proposed system.

Initially, the input face image was taken from the dataset. The image undergoes a face-stitching operation to find the missing part of the face. Through this, the complete face image is obtained, as the human faces are symmetrical on either side. After the image stitching operation, the features extraction is accomplished to classify the face image. Using the selected features, the face image is categorized as either known or unknown face by a distance classifier, which utilizes the Eigen-face approach with PCA and geometrical method.

A. Image Stitching

Image stitching is the method utilized for obtaining a more extensive field of perspective of a scene from a succession of halfway perspectives. It is an alluring exploration zone given its extensive variety of applications, including movement identification, determination upgrade, checking worldwide land use, and face insertion. These procedures can be classified into two groups: direct techniques and feature-based systems as shown in Fig. 2.

In a direct technique, every pixel located in the image is compared with each other, which is an exceptionally complex method. The direct way to perform an alignment between two images is to shift one image that corresponds to another by comparing pixels of the two images under testing. This comparison will depend on the rows or columns of each image and the mean square error (MSE) for each row or column will be calculated and will take as a reference to compare the given images. However, MSE is an example of the error metric. The [13] principal obstacle of direct methods is that they have a constrained scope of union.

The direct method utilizes data from all pixels. It iteratively refreshes a gauge of homography with the goal that a specific cost of work is limited. To speed up the error metric search process, hierarchical motion estimation is used. In hierarchical motion, an image pyramid is first [14] created and a search process over a fewer number of discrete pixels will perform at coarser levels.

Thirdly, Fourier-based [15] stitching depended on performing a convolution in the spatial domain resembles the summation of one signal with its conjugating of the other. In a parametric motion, a single constant translation vector with a correspondence map will be used. Finally, due to the feature points that may not be accurately located, an incremental motion refinement algorithm can calculate a more accurate matching score. However, incremental motion refinement needs more calculations than other algorithms [16], so they consider time-consuming, which reflects a decrease in its performance.

In contrast, feature-based systems are progressively more prominent and broader in mosaicing. This is particularly the result of the quality of new calculations and types of invariant features that have evolved over recent years. In Schmid represent a survey on key points detection and implements an experimental comparison to determine the repetitive features of detectors [17] and the information content available at each detected key point. The feature matching process will occur after detecting the features and key points. In addition [18] the feature matching process will determine which feature comes from locations in different images. The fundamental qualities of strong locators incorporate invariance to image scale invariance, interpretation invariance, and turn changes [19].

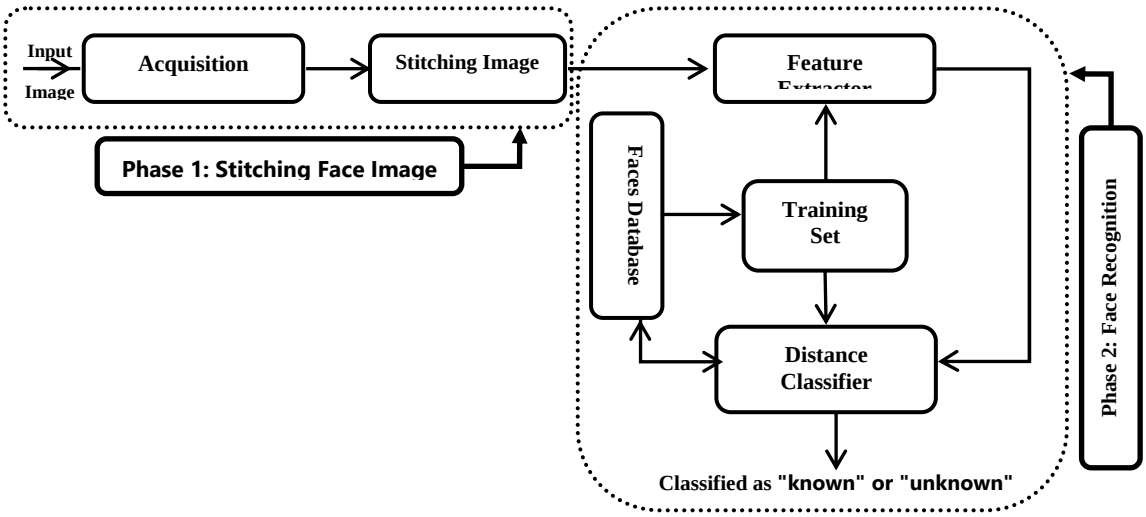

Fig. 1. Outline of the Typical Face Recognition System.

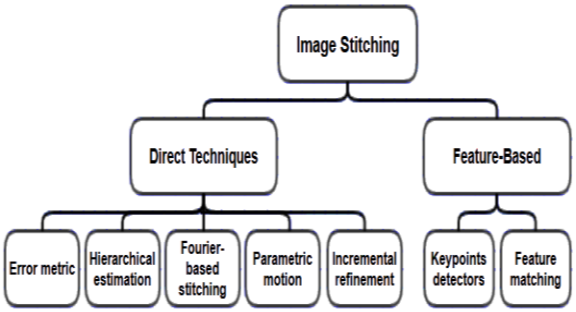

Fig. 2. Images Stitching Methodology.

Phase 1: Stitching the Face Image.

In this phase, the process of stitching the face image will be accomplished and completed according to the steps summarized in Table I.

TABLE I. PROPOSED FACE STITCHING APPROACH

1: Tested Image Acquisition: the image of the face to identify is processed. The facial image in this work assumed an incomplete face, which represents the main challenge in any face recognition system.

2: Nose Area Detection: the human face is symmetric around a certain line. To find such a line, the process of the nose detector is required. Here, the Viola-Jones Nose Detection Algorithm [20] was used. Then the centroid of the nose region is equivalent to the centroid of the rectangle that surrounds it. The centroid lies at the intersection point of the rectangle diagonals. The diagonals intersect at height $(\frac{h}{2})$ from reference y-axis and at width $(\frac{b}{2})$ from reference x-axis.

3: Vertical Line Drawn: A vertical line is drawn perpendicular to rectangle width (b) passing through the centroid. The whole face is symmetric around this vertical line.

4: Cropped Image: The image of the uncompleted tested face image cropped to obtain a cropped image I_1. The dimension of the cropped image I_1 from a pixel that has coordinate $x = 0$ to width equals $(x_0 + \frac{b}{2})$ from reference x-axis and from a pixel that has coordinate $y = 0$ to height equals the height of the vertical line that drawn in the previous step, which is equal to the height of the original tested image from reference y-axis. Whereas (x_0, y_0) represent the origin, i.e., [21] coordinate of the first pixel in the cropped nose detector image.

5: Flipped Image: A horizontal reflection of I_1 is performed to generate the missing part of the face, this part will be denoted as I_2.

6: Stitched Image: The first step is to calculate the relative positions of the obtained images and to produce a vacant set of images in the computer memory where these images will be assigned. The following stage is identifying the purpose of best correlation, which is performed by sliding contiguous image edges in the two headings until the point where the best match of edge features is found. The normalized cross-correlation coefficient for the case above is defined as in equation (1):

$$\text{Cross Correlation} = \frac{\sum_{x=0}^{L-1}\sum_{y=0}^{K-1}(w(x,y)-\bar{w})\left(f(x+i,y+j)-\bar{f}(i,j)\right)}{\sqrt{\sum_{x=0}^{L-1}\sum_{y=0}^{K-1}(w(x,y)-\bar{w})^2}\sqrt{\sum_{x=0}^{L-1}\sum_{y=0}^{K-1}\left((f(x+i,y+j)-\bar{f}(i,j)\right)^2}} \quad (1)$$

Where $w(x, y)$ represents a pixel value of the image to place; $\bar{w}$ is the mean value of all pixels included in the selected – cropped -box area $f(x + i, y + j)$ represents a pixel value of the composite image inside the box area. However, $\bar{f}(i, j)$ are the mean value of all pixels of the composite image within the box area and parameters K, L represents the box dimensions in the number of pixels included [21].

7: Image Blending: After all the input images had aligned with each other, we will use a multi-band image blending approach to produce seamless panoramic views by choosing a suitable compositing surface.

Fig. 3 depicted the outline of the image stitching process. Fig. 3(a) depicts the input test image. To find the symmetric line of the face, the nose detection technique is used and the nose-detected image is shown in Fig. 3(b). In addition, the centroid point of the nose is shown in Fig. 3(c) and the vertical line through that point is given in Fig. 3(d). The image is cropped through that vertical line to obtain the cropped image and it is shown in Fig. 3(e). Now, the image flipped to obtain the reflected part of the cropped image. It is shown in Fig. 3(f). The search area of the stitch is shown in Fig. 3(g). After face stitching is done, the complete face image would be obtained and it is shown in Fig. 3(h) and Fig. 3(i) is the final face image after the image blending operation is performed.

B. Face Recognition Techniques

Face Recognition has been an interesting topic for many computers science engineers who deal with artificial intelligence. The computer first detects the face and then for recognition, a step will be performed. Face recognition is considered a pattern recognition task performed precisely on human faces [8]. The outcome of this process is to classify either a face as "known" or "unknown" which compares the given unknown faces with stored known faces. The face image must be with a uniform background to avoid problems concerning the background complexities. However, it may be affected by the change in facial expressions. For example, laughter and crying change the mouth and eyes opening size, and aging also plays an important role as the face detail changes. Much research in computer recognition of faces has focused on identifying individual face features such as the nose, eyes, head outline, and mouth. The closest match between stored data and face image achieves recognition.

PCA is a standard technique used to distinguish patterns and signal processing. It is a statistical method employed to reduce data dimensions and extract features, which is an essential step in facial recognition. The analysis of basic compounds involves a mathematical procedure that converts several interrelated variables into several non-interrelated variables called basic components. These components are linked to the original variables by orthogonal transformation and are defined in such a way that the first primary component has the highest variance and the second fundamental component has the second-highest contrast and so on. Go back to Osama Shahin [8] present a face recognition approaches that depend on the geometry of the head which is done by calculating the angles for the head circumference and then storing these readings in a vector that describe a given face and will be used for comparison with other vectors that represents other cases.

Phase 2: Face Recognition Algorithm

The idea of the proposed system is to identify human faces if they are recorded in the database of the system as well as categorize individuals whose images are not recorded in the database as unqualified or as strangers through the process of automatic identification [22] and identification of persons. In this phase, Eigenfaces for recognition algorithm and Geometrical Approach for Face Detection and Recognition [8] will be used.

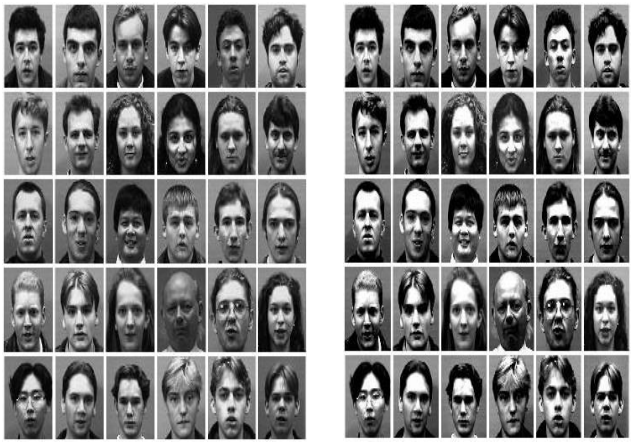
IV. Experimental Results

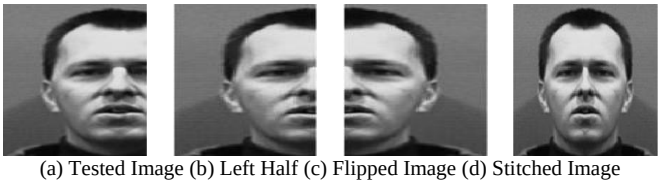
The system was tested on database FACES94. The training dataset contains a total number of 3080 images of 123 individuals grouped and classified into three categories (male, female, and male staff) taken with a little variation in head position. The image had a resolution of 180×200 datasets [23]. The training sample of face images is shown in Fig. 4(a). These training sample images normalized to minimize blunders caused by lighting conditions. The normalized face images as shown in Fig. 4(b).

Fig. 5 shows the test image that is fed into the proposed system for classification. The quality of the image stitching process is located by observing the seam lines between the stitched images.



(a) (b)

Fig. 4. (a): Initial Training, (b): Normalized Training Image Set.



(a) Tested Image (b) Left Half (c) Flipped Image (d) Stitched Image

Fig. 5. Tested and Stitched Image.

As previously mentioned, the experiments were performed on the FACES94 database with various numbers of training images. The percentage of discrimination calculated using the method of analyzing only the basic compounds in the extraction of properties and neural networks in discrimination and depending on the mainframe. The percentage of the recognition rate [24] is dependent on the number of Eigenfaces with the highest value of Eigenvalues. When 100 Eigenfaces were taken, the recognition rate was 94.2% with the Euclidean distance classifier and was equal to 92.3% when the City-Block classifier is used. When taking 150 Eigenfaces, the recognition rate rose to 94.6% with the Euclidean distance classifier and 93.1% with the City- Block classifier. This percentage then dropped to 92.2% and 91.8% respectively and then to 91.7% and 90.4% with the Euclidean and City-Block classifiers respectively when 200 and 250 Eigenfaces were taken. On taking 300 Eigenfaces, the percentage increased again to 95.1% and 93.7% respectively when Euclidean and City-Block classifiers were used. Fig. 6 and Table II show the result of the recognition process using Eigenfaces.

A comparative recognition error rate for glasses-persons is wearing glasses – and no glasses – persons are not wearing glasses – recognition using the eigenfaces and geometrical approaches methods are depicted in Table III.

Recognized Image Input Image

Fig. 6. Correct Face Recognition Result for FACES94 Database.

TABLE II. RECOGNITION RATES FOR THE PROPOSED ALGORITHM

No. of Eigenfaces	Recognition Rate % Euclidean Distance	Recognition Rate % City-Block Distance
100	94.2	92.3
150	94.6	93.1
200	92.2	91.8
250	91.7	90.4
300	95.1	93.7

TABLE III. A COMPARATIVE RECOGNITION ERROR RATES

Approach	Error rate % for glasses	Error rate % for no glasses
Eigenfaces approach	45.2	20.2
Geometrical approach	25.5	7.7

After the process of the recognition is performed, the calculation of Image Quality Metrics (IQM) between the stitched image and the original one is needed. In this work, MSE and CR [25] were chosen as quality factors. Table IV shows the advantages and disadvantages of several existing face detection techniques.

TABLE IV. ADVANTAGES AND DISADVANTAGES OF VARIOUS EXISTING FACE DETECTION TECHNIQUES

Methods	Advantages	Disadvantages
Feature face detection	More precise and low execution time	Maximum learning time
Geometric face detection	Effective approach and easy to implementation	Low precise and more false alarm
Haar like feature face detection	Feature extraction has been improved, and there are very few false alarms now.	Maximum execution time and implementation difficulty

A. Mean Square Error (MSE)

MSE is needed to measure image quality. Mean Square Error must be zero in a perfect case because it is the difference between the original images and the stitched ones. However, in a practical case the smaller the value of MSE, the better the quality of the stitched image.

$$\mathrm{MSE} = \sum_{i=1}^{m} \sum_{j=1}^{n} \frac{\mathrm{OI}(i,j) - \mathrm{SI}(i,j)}{m * n} \quad (2)$$

Where "OI" is the original image, "SI" is the stitched image, "M" & "N" is the numbers of rows and columns in both images respectively.

B. Correlation Coefficient (CR)

CR was used in measuring closeness between the original image and the stitched one. The correlation Coefficient should equal 1 in a perfect case. However, in a practical case value of CR near one is a significant figure.

$$C_r = \frac{\sum_m \sum_n (Xi - \bar{X})(Yi - \bar{Y})}{\sqrt{(\sum_m \sum_n (Xi - \bar{X})^2)(\sum_m \sum_n (Yi - \bar{Y})^2)}} \quad (3)$$

Where "$\bar{X}$" & "$\bar{Y}$" is the original image & stitched image average values respectively, "M" & "N" are the numbers of

rows and columns in both images respectively. Table V depicted MSE and Cr, the calculations for a sample of stitched and original images.

The accuracy and error rate comparison of the existing and proposed mechanism is shown in Fig. 7(a) and (b).

From the above figure, it is clear that the proposed method achieves higher accuracy of 99.78% and a reduced error rate of 0.22% compared to the existing CNN [9] and Multibatch estimator method approaches [26].

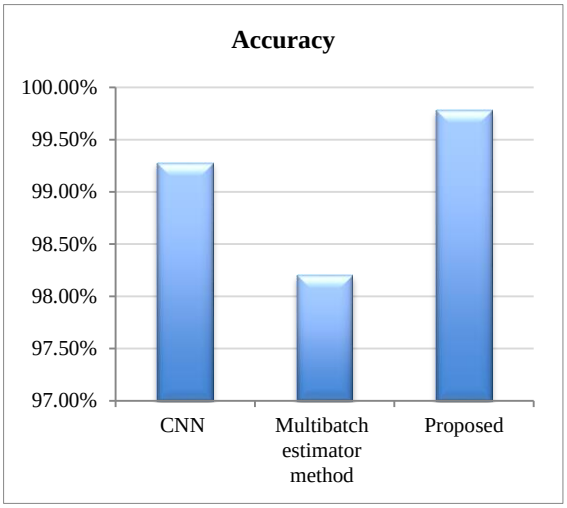
TABLE V. MSE AND CR ARE CALCULATIONS FOR A SAMPLE OF STITCHED AND ORIGINAL IMAGES

Cases		MSE	Cr
Stitched Image	Original Image		
		7.2011	0.9902
		13.2465	0.9734
		12.3301	0.9855
		9.3312	0.9977
		8.2135	0.9924

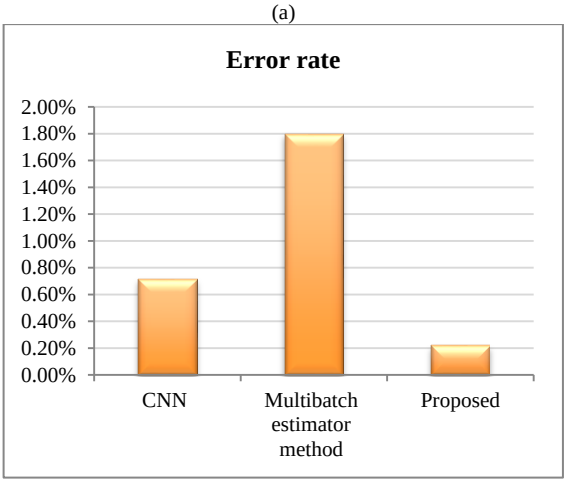
The proposed image stitching approach with Eigen-face and geometrical approach is compared with the existing CNN [9], Voting, and Random Subspace with Random Forest approaches [26]. The comparison of proposed and existing face recognition mechanisms is framed in Table VI.

TABLE VI. COMPARISON OF PROPOSED AND EXISTING FACE RECOGNITION METHODS

Parameter	Accuracy	Error rate
CNN	99.28 %	0.72 %
Multibatch estimator method	98.20 %	1.80 %
Proposed	99.78 %	0.22%



(a)



(b)

Fig. 7. (a) Accuracy Comparison of Existing and Proposed Methods, (b) Error rate Comparison of Existing and Proposed Methods.

V. CONCLUSION

This work proposes an improved algorithm for human face recognition by using two approaches: Eigenfaces and geometrical methods from part of a facial image, which is based on image stitching. The geometrical approach was accurate especially when the person wears glasses than Eigenface, but the Eigenface approach is quick and simple for the face recognition problem. Face recognition from the perspective of PCA connected on two distance classifier systems with a certain training dataset. The training dataset contained a total number of 3080 images of 123 individuals are grouped and classified into three categories (male, female, and male staff) and was taken with a little variation in head position. The test results identified that PCA gave the best results with the squared Euclidean distance methodology, with a recognition rate of 95.1%, which was more noteworthy than the city-Block distance strategy. The recognition rate also varied with the number of Eigenfaces used in the experiment. In future development, much improved methods can be ready for improved performance. With a larger data set, a greater number of pixels could be learned. Components that are less expensive can be suggested.

Comparative Heart Rate Variability Analysis of ECG, Holter and PPG Signals

Galya N. Georgieva-Tsaneva, Evgeniya Gospodinova
Institute of Robotics, Bulgarian Academy of Sciences, Sofia, Bulgaria

***Abstract*—The article presents a demonstrative software system with included procedures for input, preprocessing and mathematically based analysis of cardiac data. The created program has the ability to work with the following signals: ECG, holter recordings, PPG signals. The presented system uses real cardiological data from patients and obtained with modern medical devices - electrocardiography, continuous holter monitoring, photoplethysmography device and others. The presented system allows mathematically based study of cardiac records through the use of linear, nonlinear, fractal and wavelet based methods. A comparative analysis was made of the results obtained in the evaluation of the HRV parameters in the three types of signals used. The difference between HRV time series (cardiac intervals and HRV analysis) obtained by examination of individuals diagnosed with heart failure and healthy individuals is graphically presented. The findings indicate that studies of heart rate variability on ECG, Holter and PPG records can be used to support the cardiac practice of physicians.**

***Keywords*—Heart rate variability; cardiovascular diseases; mathematical analysis; holter records; software system**

I. Introduction

The research conducted in recent years has unequivocally shown that heart rate variability (HRV) reflects an individual's health status. HRV [1] presents the variation in time between successive heartbeats (time intervals between heart beats), which variation depends on internal and external conditions. Internal conditions include the work of the physiological systems of the human body, their effective interaction and the general health of man as a result. External conditions include the impact of external circumstances (temperature, weather, emotions, stress, etc.) on the body. HRV is the ability of the human body and in particular of the heart to adapt to constantly changing external circumstances through compensatory reactions.

Usually high values of HRV parameters are an indicator of good health and excellent regulation of the autonomic nervous system. Low values of HRV parameters are an indicator of deteriorating health and disorders in the regulation of the body. The study of many quantitative characteristics of HRV makes it possible to assess how the variability in the parameters of the cardiac series [2] reflects the response of the human body to internal and external factors affecting its physiological and mental health.

HRV can be used to assess the regulation of the autonomic balance of the human body, the work of the heart system and the condition of blood vessels, blood pressure, the work of the digestive system, the nervous system and others.

Heart rate variability can be measured by various mathematically based methods: linear and nonlinear methods, methods based on fractal and wavelet theory, Detrended fluctuation analysis (DFA), Poincare method, methods for estimating the Hurst parameter and many others.

The article uses 3 types of cardiac signals: holter recors, write down from monitoring device for continuous observation; photoplethysmographic (PPG) and electrocardiographic (ECG) recorded with PPG device, capable of simultaneous recording of ECG and PPG signals. When recording the input data, the holter device works in parallel with the PPG device.

In ECG and Holter recordings, heart rate variability parameters are evaluated on RR intervals (determined by the input values of ECG and Holter recordings, R is the maximum point in QRS), and in PPG signal evaluations are performed on PP intervals (P peaks - maximum amplitude deviations of input signal).

The purpose of this article is to present the results of the project "Investigation of the application of new mathematical methods for the analysis of cardiac data", funded by the Research Fund, obtained with a demonstration software system for research and mathematical analysis of cardiac signals and data (obtained by Holter device, and developed demonstration device for write down of ECG and PPG signals). The paper presents the results obtained in time analysis, frequency analysis, DFA and calculation of the Hurst parameter of heart rate variability on three investigated types of real cardiac signals: ECG, Holter records and PPG.

The aim of the article is to present research on the cardiovascular system, made by means of a PPG device developed by the authors and a software system for processing and analysis of cardio data. The software system is designed to work with 3 types of cardio data: PPG, ECG and Holter records, performing preprocessing in accordance with the specific type of cardio data.

The article raises and seeks a solution to the following questions:

- Are the use of the three types of examined cardio (ECG, PPG and Holter records) equally effective in the assessment of HRV and in the analysis of the parameters of HRV data of healthy and sick individuals.
- The problem with the difference of HF parameters in patients with heart failure from those of the studied control healthy group was studied.

- Can PPG, ECG and Holter records be used to differentiate between healthy and sick individuals (and in particular patients diagnosed with heart failure)?

The rest of this document is organized as follows:

Section II provides an overview of related research in the scientific literature on heart rate variability. Section III focuses on the Methodology, HRV data analysis procedures used in this paper (performing mathematical analysis in time domain, frequency domain; fractal analysis and wavelet analysis). Section IV presents the results of the performed experimental analyzes in numerical and graphical form. Finally, Section V presents the conclusions drawn from the results obtained and Section VI presents the direction of future work and perspectives.

II. Review of HRV Studies

Healthy individuals are characterized by good heart rate variability, which results from the body's internal forces to adapt to environmental challenges (physical and psychological). The functioning of the cardiovascular system of a healthy human body can be described by complex mathematical models based on variability in the action of the heart.

HRV is a method for determining the work of the heart, which has been the subject of extensive scientific research over the last two decades on both healthy and diseased individuals. Despite numerous publications on this subject, the method for mathematically based analysis of heart rate variability has not yet been well studied. New methods for the study of HRV are emerging, which need extensive research before being adopted in the daily practice of cardiologists and to be standardized. Particularly valuable in this regard are the findings made on the studied real cardiac records of patients with various heart diseases.

The authors of [3] emphasize the importance of the age and sex of the subjects and the duration of the records made for the results of the HRV analysis.

The research, conducted by Murthy et al. [4] by spectral analysis on PPG records of 5 patients (with atrial fibrillation and myocardial infarction) and 5 healthy individuals showed that PPG signals can be used in the analysis of heart disease. PPG signals were recorded from the earlobes from the earlobes of the subjects.

In publication [5] the authors record and analyze ECG and PPG signals, the recording of which (within 5 minutes) is done simultaneously in time. HRV estimates were performed in the time and frequency domains, and nonlinear mathematical analyzes were performed. However, the recording of the signals is made in ideal conditions (without movement of the studied individuals).

The study done in [6] proposes to improve the efficiency of localization of the maximum deviations in the photoplethysmographic signal through a probabilistic approach based on Bayesian training.

The authors of [7] propose an algorithm based on continuous wave transform (CWT) to detect the maximum deviations of the PPG signal. The algorithm also uses a combination of functions obtained from the applied wavelet transform and indicators evaluating the self-similarity of PPG signals to detect damaged areas of the studied signal.

Studies in [8] compare PPG and ECG signals in terms of determining the HRV time series and accuracy when working with both types of signals. The authors propose a modified algorithm for detecting PP peaks in PPG signals. The obtained results show low statistical errors in determining the HRV time series for both types of studied signals.

Fractal methods for HRV analysis are used by the authors of [9], studying patients with congestive heart failure (CHF) and healthy subjects. The data used are taken from a public database (Physiobank).

The effect of artifacts in cardiac signals (obtained with PPG sensors) caused by movement on HRV and its evaluation using the statistical parameters SDNN and RMSSD was studied in [10]. The authors examined cardiac data obtained from devices worn on the wrist by 22 young and healthy individuals.

A study on 50 healthy young volunteers was presented in [11]. The HRV study was performed on simultaneously recorded photoplethysmographic and electrocardiographic signals using a mobile device. The presented HRV results were obtained using popular public Kubios software.

III. HRV Data Analysing Procedures

The procedures used in the paper for pre-processing and mathematical analysis of the input cardiac data are presented in Fig. 1. The preprocessing includes:

- ✓ Reduction of signal interference, noise and so on;
- ✓ Determination of maximum deviations (R peaks (QRS complexes) in ECG and Holter signals, and P peaks in PPG signals);
- ✓ HRV time series obtained;
- ✓ Determination of normal to normal (NN) intervals from RR intervals time series or PP intervals time series.

The detection of the main points in the cardiac signals - the points with maximum amplitude deviations (R peaks in ECG signals and P peaks in PPG signals) [12] is the starting point in the HRV analysis.

Normal NN intervals are obtained by excluding abnormal strokes such as ectopic strokes from RR/PP intervals (outside the right atrium’s sinoatrial node).

Each of the three types of signals studied in the paper (Holter records, ECG, and PPG signals) has its advantages and disadvantages compared to other ways of recording the activity of the heart. Therefore, each case of treatment and prevention of a patient should be considered separately and to determine which method of HRV testing is most appropriate.

ECG signals are obtained in a non-invasive, popular, and widespread way. Electrocardiograms (in cases when they are recorded in an inpatient setting in a polyclinic or hospital) require the placement of several electrodes on the human body in specific places and each of them must be firmly fixed. This

is uncomfortable with frequent use of this method (for example, for daily measurements or if several measurements per day are required).

Long-term monitoring of the heart (if you need 24 hours of records and longer for a continuous monitoring of heart activity in risk groups of individuals) is appropriate to perform with a Holter device [13].

Photoplethysmographic signals are an alternative to ECG signals, they are easier to record, PPG devices [14, 15], through which these signals are recorded, are light and comfortable for longer carrying. PPG sensors are small and can be easily integrated into various lightweight and easily portable devices, smart phones and smart watches. In the last few years, with the improvement of the technology for production and miniaturization of PPG sensors, PPG technology enters the daily life of more and more people and becomes an integral part of it. Photoplethysmography determines the time between heartbeats by continuous monitoring of changes in blood volume in part of the peripheral microvasculature [16]. This non-invasive method for measuring pulse waves can also be the basis for HRV analysis.

Determining the health status of an individual is an issue that more and more people are interested in today. Advances in technology have led to an increasing miniaturization of digital sensors, which has led to an increase in the possibility of more accurate and easy continuous monitoring of individuals (eg blood pressure monitoring [17], a parameter that is crucial for the development of a number of diseases) if necessary with the help of mobile devices.

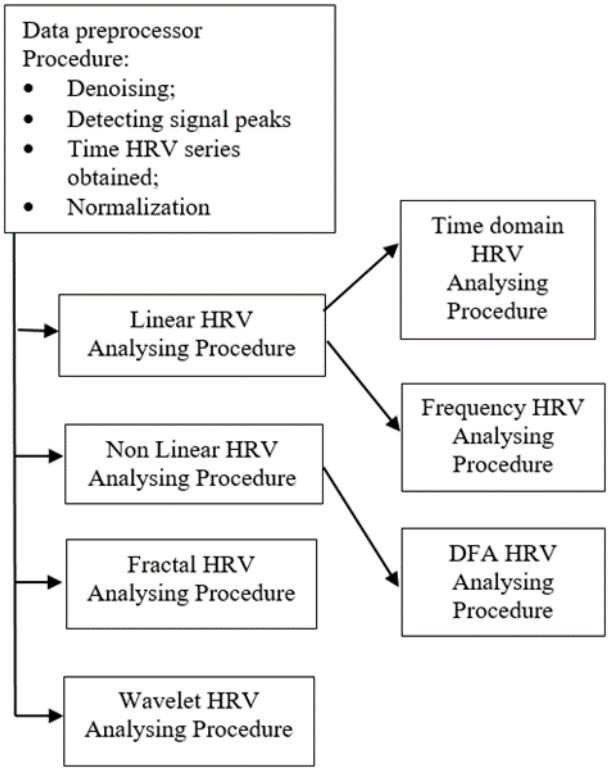

Fig. 1. HRV Analysing Prosedures.

One of the disadvantages of PPG signals is their influence by artifacts [18], which are obtained during the movement of the studied individual. This may adversely affect the HRV score if inaccuracies are found in the localization of the peaks in the PPG signal. In addition, the physiological processes carried out with the help of the heart and the influence of human skin (which may have different characteristics in individual individuals) make it difficult to study HRV in PPG signals.

In this paper, studies of the three types of signals (ECG, Holter, PPG) for recording heart activity were made in terms of assessing heart rate variability.

The article examines HF on short-term cardiac records (2 to 24 hours). Short-term HRV is affected by the cardiovascular system, central nervous system, respiratory system, baroreceptors (blood pressure sensors) and others. Nonlinear estimates of HRV quantify the unpredictability of cardiac time series.

A. HRV Time Domain Analysing Procedure

The parameters in the time domain give numerical expression of the quantitative characteristics of HF for time periods from 2 to 24 hours [19]. The following statistical parameters in time domain were examined in the present study [20]:

- Mean RR (Mean PP) - the mean value of RR and PP intervals;
- SDNN - standard deviation (sd) of normal RR (PP) intervals;
- SDANN - standard deviation of the average normal RR (PP) intervals for each 5 min segment of a 24 h record;
- RMSSD - square root of the mean squared differences between successive RR (PP) intervals;
- SDindex - mean of the standard deviation of all normal RR (PP) for each 5 min segment of the whole record.

The calculations of the presented parameters are performed using the HRV time domain analyzing procedure of the demonstration software system.

B. HRV Frequency Domain Analysing Procedure

The parameters in the frequency domain provide a quantitative assessment of the complexity of the model and the low ability to predict the values of the cardiac series.

The signal energy (Power) in the respective frequency band is determined by the HRV frequency domain procedure. Measurements in the frequency domain show the distribution of absolute power (in ms^2) and relative power (in normal units (nu)) in the studied three frequency bands (Very Low Frequency, Low Frequency and High Frequency).

Frequency domain parameters are based on spectral analysis for the following three components (for short-term records) presented in Table I.

The sum of the three powers (VLF, LF and HF) for short-term recordings gives the total signal power [21].

TABLE I. HRV PARAMETERS IN FREQUENCY DOMAIN

Power [ms^2]	Frequency range [Hz]	Interaction with the systems of the human body
Very Low Frequency (VLF)	0.003-0.04	Sympathetic nervous system
Low Frequency (LF)	0.04-0.15	Sympathetic and parasympathetic nervous system
High Frequency (HF)	0.15-0.4	Parasympathetic nervous system and respiratory sinus arrhythmia.
LF/HF	-	Gives an assessment of the sympathetic balance

The ratio (LF/HF) between LF and HF band powers, known as the sympathetic balance index, assesses the ratio between the activity of the two parts of the nervous system (sympathetic and parasympathetic).

C. HRV Fractal Analysing Procedure

The fractal properties of the three types of studied cardiological data in this paper are determined by analyzing the fluctuations in the time series through the parameters Alpha1, Alpha2 and Hurst.

Detrended fluctuation analysis examines the correlations between RR (PP) interval series in different time scales. DFA defines two parameters: Alpha1 (α_1) – describes short-term fluctuations, Alpha2 (α_2) - provides information on the long-term fluctuations of the studied signal.

The traditional R/S statistical method, most often used in the scientific literature, is used to determine the Hurst parameter in the studied cardiological data [22, 23].

D. HRV Wavelet Analysing Procedure

In the present study, wavelet-based method are used to determine the Power Spectral Density (PSD) of heart rate variability. A graphical method was chosen for the study of global PSD, which allows for visual comparison of the spectral properties of the analyzed signals.

To account for the differences between the HRV parameters determined on the time series of the studied three types of signals, the root mean square error (MSE) is calculated:

$$MSE = \sqrt{\sum_{i=1}^{N}(x_i - y_i)^2}, \quad (1)$$

Where: x – time series of one signal;

y - time series of the second signal;

N- the number of intervals.

IV. RESULTS

Twenty-four individuals diagnosed with Heart Failure were studied (10 men and 14 women aged 52.8 ± 1.6). Records were also made of 12 healthy volunteers without cardiac disease.

The following recordings were made: ECG, Holter and PPG signals of the subjects. Holter recordings are made with a holter monitoring device purchased for the purposes of the research project. ECG and PPG signals are recorded with a multisensor device created according to the scientific project. The created demonstration software determines the RR intervals in the ECG signals and the PP intervals in PPG signals.

In Fig. 2 shows the RR intervals obtained from an ECG signal recorded using a multifunctional PPG device of an individual diagnosed with Heart Failure.

In Fig. 3 presents the RR intervals obtained from the Holter record recorded using the Holter Heart Failure Patient Monitoring Device.

Fig. 4 shows the PP intervals obtained from a PPG signal recorded using the portable PPG device of an individual diagnosed with Heart Failure.

Fig. 5 shows the PP intervals obtained from a PPG signal (via a PPG device) of a healthy individual. The comparison of Fig. 4 and Fig. 5 shows greater variability in the determined PP intervals, which is also proved by the calculated values of the HRV parameters using the methods used in the study (presented in Table II).

All made records of the three types of cardiac signals shown in the figures and participating in the present study were two hours.

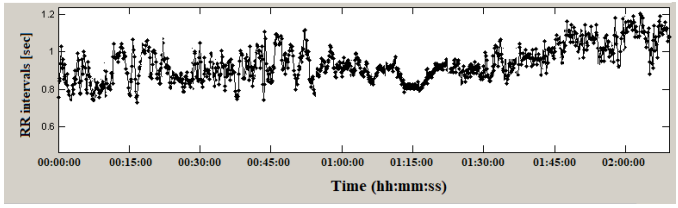

Fig. 2. RR Intervals (ECG Signal, Heart Failure).

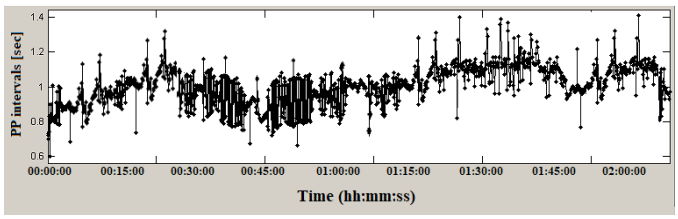

Fig. 5. PP Intervals (PPG Signal, Healthy Individual).

TABLE II. HRV PARAMETERS FOR ECG, HOLTER AND PPG

Parameters		Group 1 ECG (mean± sd)	Group 2 Holter (mean± sd)	Group 3 PPG (mean± sd)
Time Domain Analysis	MeanRR(PP) [ms]	684.22 ±214.68	661.33 ±189.13	692.11 ±223.83
	SDNN [ms]	124.08 ±16.88	118.77 ±24.32	132.66 ±32.09
	SDANN [ms]	98.56 ±34.21	112.01 ±35.43	104.67 ±31.08
	RMSSD [ms]	28.18±8.65	26.35 ±14.15	31.06 ±18.98
	SDindex [ms]	61.33 ± 26.11	64.07 ±22.18	63.88 ±26.44
Frequency Domain Analysis	Power VLF [ms^2]	3098.51 ±654.22	3127.06 ±487.34	2995.78 ±586.39
	Power LF [ms^2]	688.22 ±183.06	691.89 ±243.99	704.05 ±433.01
	Power HF [ms^2]	586.23 ±204.55	582.99 ±244.13	602.33 ±212.03
	Power LF [nu]	0.54±0.19	0.54±0.16	0.53±0.87
	Power HF [nu]	0.46±0.23	0.46±0.43	0.47±0.68
	LF/HF ratio	1.17±0.78	1.19±0.81	1.17±0.93
DFA	Alpha1	1.22±0.24	1.18±0.19	1.23±0.48
	Alpha2	1.28±0.27	1.21±0.22	1.17±0.31
R/S method	Hurst	0.72±0.26	0.74±0.71	0.68±0.14

Table II presents the obtained results of the HRV analysis in Time Domain, Frequency Domain, DFA and hurst parameter (R/S method) obtained from a study of Heart Failure Individuals (n=20).

The results presented in Table II show lower mean values for all three types of cardio signals examined on the frequencies in the Low Frequency band in Power in the indicators of patients diagnosed with Heart Failure compared to the values of healthy patients (691.89 ± 243.99 ms^2 for Holter records versus 1170 ± 416 ms^2 normal values (for healthy people) given in the HRV Standard [20]). The Power HF values for the three types of cardio signals tested were also lower than those recommended in the HRV Standard for Healthy Individuals (582.99 ± 244.13 ms^2 for Holter records versus 975 ± 203 ms^2 normal values given in [20].

The calculated LF/HF ratio, giving information about the balance between Low Frequency band and High Frequency band, has a value of 1.19 ± 0.81 (against 1.5-2.0 recommended value for healthy people [20]).

In the time domain, the following studied parameters show lower values than those recommended for healthy individuals according to [20]: SDNN (max 132.66 ±32.09 ms for PPG against 141±39 ms in [20]); SDANN (max 112.01 ±35.43 ms for Holter records against 127±35 ms in[20]).

Fig. 6 shows the DFA results for Heart Failure Individual. The two studied parameters are alpha1 (shown in cyan color) and alpha2 (shown in red color). The obtained parameters for short correlation values are alpha1=1.26 and for long correlation alpha2=1.28. Fig. 6 shows that alpha1 and alpha2 have similar values in diseased individuals. This shows that in heart disease there is a tendency for short-term and long-term correlations in the HRV series to equalize.

Fig. 7 shows the DFA results for a Healthy Individual. The obtained values for the short correlations are as follows: alpha1 =0.87 and long correlations alpha2=1.24. Fig. 7 shows higher values for the alpha2 parameters relative to alpha1.

Fig. 8 presents a global PSD, drawn using a wavelet-based graphical method of one of the studied Heart Failure Individual (on a record of cardiac data made with a Holter device). The graph shows relatively low values of signal power in all three studied frequency bands (VLF, LF and HF).

Fig. 9 presents a global PSD, drawn by means of a wavelet-based graphic method of one of the examined volunteers without disease (the cardiological record was made with a Holter device). The graph shows high values of signal power in each of the three frequency bands (VLF, LF and HF).

The comparative analysis of the presented global PSDs, shown graphically in Fig. 8 and Fig. 9 shows a decrease in the power of the studied cardiac signal in the studied three frequency bands. This is an indicator of reduced heart rate variability in individuals with Heart Failure.

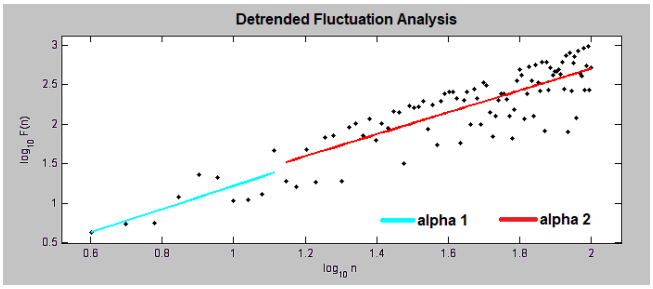

Fig. 6. DFA for Heart Failure Individual.

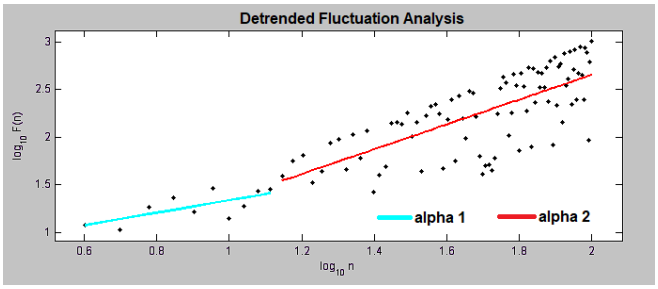

Fig. 7. DFA for an Individual without Disease.

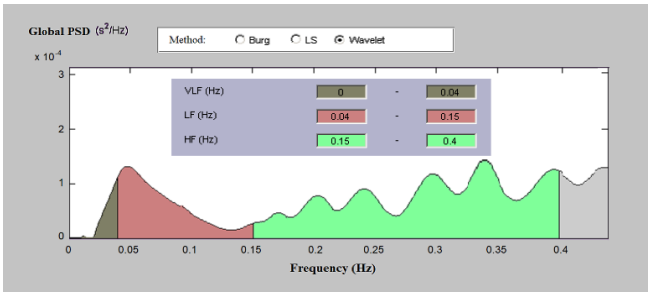

Fig. 8. PSD for Heart Failure Individual.

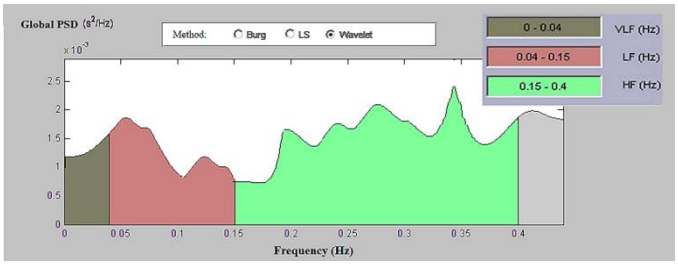

Fig. 9. PSD for an Individual without Disease.

Table III shows the mean squared error calculated by formula (1) for the signals ECG-Holter (MSE_{G1-G2}), ECG-PPG (MSE_{G1-G3}) and Holter-PPG (MSE_{G1-G3}). The smaller the MSE parameter show the closer the two studied time series have values, from which it follows that the two studied methods for determining the cardiac interval give similar results.

TABLE III. RELATIVE ERROR BETWEEN ECG, HOLTER, PPG RECORDS

Parameters		MSE_{G1-G2} **[%]**	MSE_{G1-G3} **[%]**	MSE_{G2-G3} **[%]**
Time Domain Analysis	MeanRR(PP) [ms]	1.34	3.31	0.6
	SDNN [ms]	0.64	1.47	0.88
	SDANN [ms]	1.49	0.69	0.83
	RMSSD [ms]	2.27	3.13	5.27
	SDindex [ms]	4.01	3.18	3.58
Frequency Domain Analysis	Power VLF [ms^2]	2.96	4.92	5.93
	Power LF [ms^2]	3.04	4.07	1.69
	Power HF [ms^2]	4.33	6.71	2.78
	Power LF [nu]	0.04	1.65	1.97
	Power HF [nu]	0.1	1.37	2.06
	LF/HF ratio	0.49	0.08	1.02
DFA	Alpha1	2.44	1.36	3.9
	Alpha2	0.88	1.11	0.82
R/S method	Hurst	0.67	1.03	0.94

From the comparative analysis of the studied data pairs it follows that the relative errors for all examined parameters are less than 4.33% for the ECG-Holter pair, less than 6.71% for the ECG-PPG pair and less than 5.93% for the Holter-PPG pair. The calculated relative errors are small and we can assume that the results obtained in the study of heart rate variability through the three types of signals studied are similar and reliable.

The presented numerical and graphical results are obtained through a demonstrative software system created in the MATLAB software environment.

V. DISCUSSION AND CONCLUSION

The article aims to consider the possibility of interchangeable use of three types of cardio signals in the study of heart rate variability. To solve this problem, MSE errors were determined between the evaluation parameters of each of the three studied types of cardio signals. The results (Table III) show low values of the calculated MSE errors (maximum value 6.71 for MSE_{G1-G3} in determining of Power HF), which is an indicator of the ability to use for correct research each of the three types of cardio signals (ECG, PPG, Holter records). This conclusion is of practical importance, as it proves the possibility of using PPG signals, which have recently become more and more common in human everyday life, for correct analyzes for health purposes.

The other purpose of the article is to examine the possibility of distinguishing healthy individuals from sick cardiovascular patients (more specifically, patients diagnosed with heart failure). The results presented in Table II show that the indicators Power LF, Power HF and LF/HF differ significantly from the corresponding indicators given in the HRV Standard, which is an indicator of the ability to differentiate between healthy controls and patients with heart failure.

The graphical representation of the alpha1 and alpha2 indicators obtained from the application of DFA visually show that these two parameters have similar values in diseased individuals (Fig. 6). The graphical representation of these parameters in Individual without disease (Fig. 7) shows higher values for the alpha2 parameters relative to alpha1. This finding was confirmed for all 24 individuals in the study diagnosed with Heart Failure.

The graphical representation of Global PSD shows low values of global PSD for Heart Failure Individuals (Fig. 8) compared to the values of this parameter in Individuals without disease (Fig. 9). Studies have therefore shown the possibility of graphically distinguishing patients from healthy individuals.

The article presents software procedures for determining heart rate variability, based on mathematical methods for studying three types of signals: ECG, Holter records, PPG. The presented software procedures perform a study of the parameters of heart rate variability in the time domain, frequency domain, apply DFA and determine the hurst parameter of the studied time series.

The parallel analysis of the studied three types of signals shows similar results in the study of heart rate variability and therefore the three methods for HRV analysis can be used equally. The choice of the specific method can be made according to each specific individual case.

The obtained numerical and graphical results show reduced variability of heart rate in the studied individuals with Heart Failure (for example for Holter records Power LF is 691.89 ±243.99 ms^2, Power HF is 582.99 ±244.13 ms^2) compared to healthy individuals. The coefficient showing the state of balance between LF and HF (1.19 ± 0.81) also has lower values in patients with arrhythmia compared to this coefficient in healthy people (1.5-2.0).

The studies in this paper were made on real cardiac records (three types of data were taken: ECG, Holter and PPG) of patients diagnosed with heart failure by a cardiologist as well as on several healthy volunteers.

The use of PPG signals to assess HRV and continuous monitoring of cardiac activity in patients with heart disease in need of long-term monitoring has the following advantages: easy, patient-friendly measurement; efficient signal processing and HRV, use of measuring devices that have increasingly popular and affordable hardware and software solutions; low price and convenience in their use.

VI. Future Work

Procedures for mathematical analysis of the three types of studied HRV signals are to be created with other nonlinear methods, as well as with wavelet-based methods for determining and detailed study of numerical parameters. The results of this study indicate the possibility of a study of HRV parameters in patients with other heart diseases (myocardial infarction, ischemic heart disease, syncope) and creation of an information database for patients.

Multistage Relay Network Topology using IEEE802.11ax for Construction of Multi-robot Environment

Ryo Odake, Kei Sawai, Noboru Takagi, Hiroyuki Masuta, Tatsuo Motoyoshi
Graduate School of Engineering, Toyama Prefectural University
Toyama, Japan

***Abstract*—This paper describes an information gathering system comprising multiple mobile robots and a wireless sensor network. In general, a single robot searches an environment using a teleoperation system in a multistage relay network while maintaining communication quality. However, the search range of a single robot is limited, and it is difficult to gather comprehensive information in large-scale facilities. This paper proposes a multistage relay network topology using IEEE802.11ax for information gathering by multi-robot. In this multi-robot operation, a mobile robot carries wireless relay nodes and deploys them into the environment. After a network is constructed, each robot connects to this network and gathers information. An operator then controls each robot remotely while monitoring its end-to-end communication quality with each mobile robot in the network. This paper proposes a method assuming the end-to-end throughput with multiple mobile robots. The validity of the proposed method is then inspected via an evaluation experiment on multi-robot teleoperation. The experimental results show that the network constructed with the proposed topology is capable of maintaining the communication connectivity of more than three mobile robots.**

I. Introduction

After a disaster, disaster reduction activities are performed in the affected area to prevent the damage from spreading. In the implementation of disaster reduction activities, information should be gathered to determine the damage status [1-2]. Helicopter aerial photographs, existing infrastructure (such as surveillance cameras), and rescue teams can be used to gather such information [3-6]. However, in enclosed spaces, such as tunnels and underground malls, it is difficult to gather information using helicopters. In some cases, existing infrastructure cannot be used due to malfunction or lack of power supply. Moreover, there is a risk of injuring humans or inducing secondary disasters during information gathering by rescue teams. Therefore, the use of mobile robots is widely considered to gather information in enclosed spaces after disasters [7-11].

Two communication methods are adopted for mobile robots: wired and wireless. Wired communication maintains a stable communication quality and power supply from cables [12]. However, cables may be disconnected and communication with the mobile robots can be interrupted when cables become tangled with obstacles or the wheels of the mobile robot. Wireless communication offers high runability, as there is no physical restriction by cables [13-14]. However, in wireless communication, mobile robots may become isolated when radio waves are hindered by obstacles. Therefore, in an enclosed space after a disaster, it is necessary to use the communication method that best matches the purpose and the situation of the disaster area [15-16]. This paper discusses a method for gathering information using wireless communication in environments where it is difficult to operate a mobile robot using wired communication.

Robot wireless sensor networks (RWSNs) involve the teleoperation of mobile robots using wireless communication [17-19]. In an RWSN system, a mobile robot expands its search range by deploying a relay node called a sensor node (SN) in its path (Fig. 1). In a network using a multistage relaying such as RWSNs, the communication quality decreases as the number of relays and the distance between nodes increase. Therefore, it is difficult to maintain the communication connectivity of mobile robots in a multistage relay network, and single robots are mainly operated. Moreover, the search range of a single robot in a large-scale facility is limited. This paper proposes a multistage relay network topology for constructing a multi-robot environment. The experiment in this paper constructed a multistage relay network with the proposed topology and measured the communication quality to confirm the validity of the proposed topology for constructing a multi-robot environment. This experiment used a bandwidth compression throughput to measure the communication quality at the packet level.

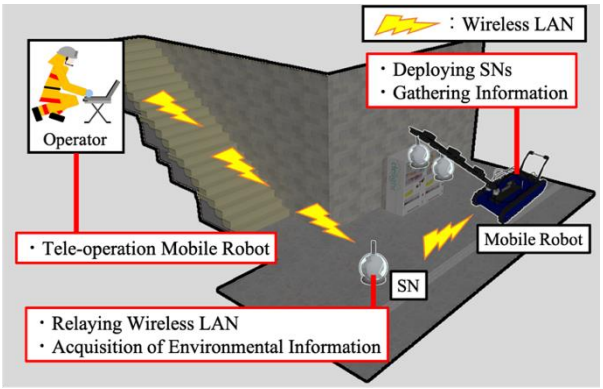

Fig. 1. RWSN.

II. Teleoperation Method for Mobile Robots using Multistage Relay Network

In the teleoperation of mobile robots by wireless communication, the search range is limited due to radio-wave damping. Therefore, wireless communication is not effective for gathering information in large-scale facilities. An RWSN relays SNs to expand the search range of a mobile robot. It also extends the network construction range by teleoperating the mobile robot with each node relayed in advance (Fig. 2). This allows the operator to teleoperate the mobile robot without the risk of a decrease in communication quality due to the increase in the number of relays. An RWSN deploys SNs in consideration of the communication quality between nodes, thereby constructing the network flexibly according to the environment. Therefore, RWSNs have scalability and flexibility, which make them effective for searching in environments with many obstacles.

However, in a multistage relay network, such as an RWSN, packets are processed for transfer within the SN. Hence, the transmission rate decreases and the packet reception interval become misaligned as the number of relays and the distance between nodes increase. Consequently, the mobile robot becomes less operable; it can become isolated due to moving out of the communication range by mistake or failing to maintain communication connectivity. Therefore, in an RWSN, it is common to operate a single robot to maintain the communication quality required for its teleoperation with the mobile robot. However, a single robot encounters limitations in searching and gathering comprehensive information in large-scale facilities. Given the importance of multi-robot systems for solving the problem of using RWSNs in large-scale facilities, and the paper aims to construct a multi-robot environment using a multistage relay network. The next section shows the flow of the multi-robot system using a multistage relay network and the requirements for the network to teleoperate multiple robots.

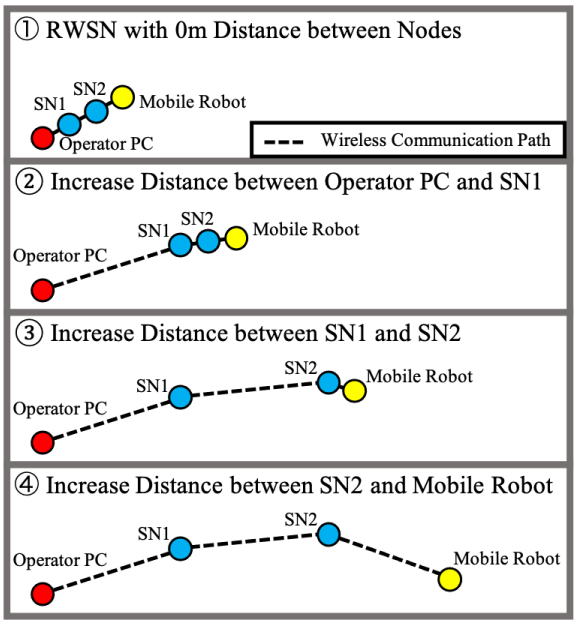

Fig. 2. Increasing Distance between Nodes while Maintaining Communication Connectivity in RWSNs.

III. Requirements of Multistage Relay Network

Let mobile robot <1> be the mobile robot that deploys the SN. The flow from the construction of the network to the operation of the mobile robots is shown in Fig. 3.

- The construction range of a multistage relay backbone network is expanded with the mobile robot <1> as shown in Fig. 2.
- Multiple mobile robots are connected to the constructed backbone network.
- Mobile robot <1> and the other mobile robots search within the network construction range while switching the nodes to be connected.

The requirements of the multistage relay backbone network for multi-robot operation are as follows:

1) Remote control of a total of three or more mobile robots
2) A throughput of 20.0 Mbps or higher in the communication path between each operator PC and each mobile robot.

About three mobile robots with five cameras each are needed to search 100 m of an enclosed space. Therefore, in requirement (1) set the number of teleoperated mobile robots to three. Moreover, the mobile robot used for searching in the nuclear power plant damaged by the Great East Japan Earthquake gathered information based on five camera images and required a throughput of 20.0 Mbps. Therefore, in requirement (2), the throughput required for the teleoperation of a single mobile robot is set to be 20.0 Mbps or higher.

Many wireless teleoperation systems for mobile robots are based on TCP/IP protocols. TCP/IP is highly suitable for the communication of mobile robots because most of the control system of a mobile robot involves a PC. Therefore, socket communication is often adopted for mobile robot communication, and information communication by packet transmission and reception is typical. Therefore, RWSNs adopt wireless LAN as their communication method. However, the theoretical value of IEEE802.11b/g used in RWSNs is 54 Mbps, which is an insufficient throughput for multi-robot operation. This study constructs a network using IEEE802.11ax, which has a theoretical value of about 1,200 Mbps. The next section describes the proposed multistage relay network topology, which takes into account the abovementioned requirements.

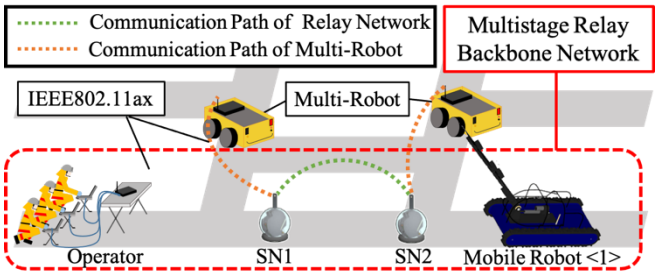

Fig. 3. Gathering Information by Multi-robot using Multistage Relay Network.

IV. Proposed Network Topology

A network topology is a form of connection that shows how devices such as operator PCs are connected to each other. From the flow of the multi-robot operation in Section 3, the multistage relay part of the proposed topology should be a static network and an RWSN to prevent any change in communication quality due to the dynamic communication path change. The proposed network topology for a multi-robot system is shown in Fig. 4. The devices of each node are in Fig. 5, and Fig. 6 depicts how the nodes are connected. In this network topology, each node in the multistage relay network is equipped with an access point (AP) and an adapter device; this creates a communication path between the operator PC and the mobile robot <1>. Then, the multi-robots are equipped with adapter devices, which are connected to the APs installed in each node of the multistage relay network to construct a communication path between each operator PC and each mobile robot. In this topology, a network is constructed for each node, and each robot can comprehensively search within the network construction range while switching the AP to which it is connected.

In case of SN failure or battery power insufficiency, it is necessary to replace the SN and reconstruct the multistage relay network. In this topology, the communication path between the operator PC and mobile robot <1> can be reconstructed with the same topology as that before the communication interruption by connecting the newly deployed SN to the AP of the node on the upload side that is still functioning.

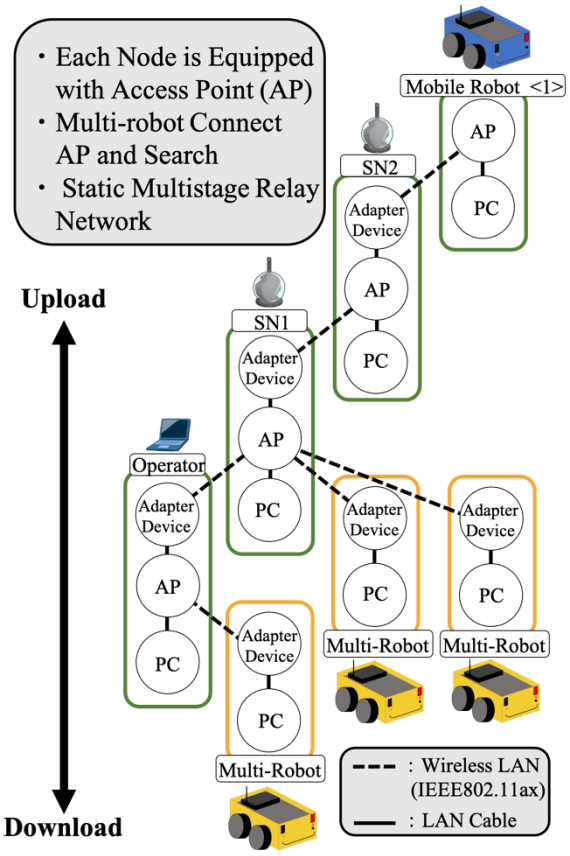

Fig. 4. Proposed Topology for Constructing a Multi-robot Environment.

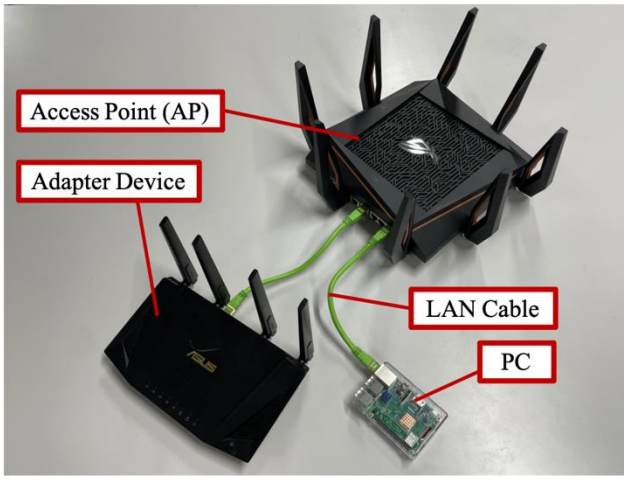

Fig. 5. Device of a Node Constituting the Multistage Relay Network.

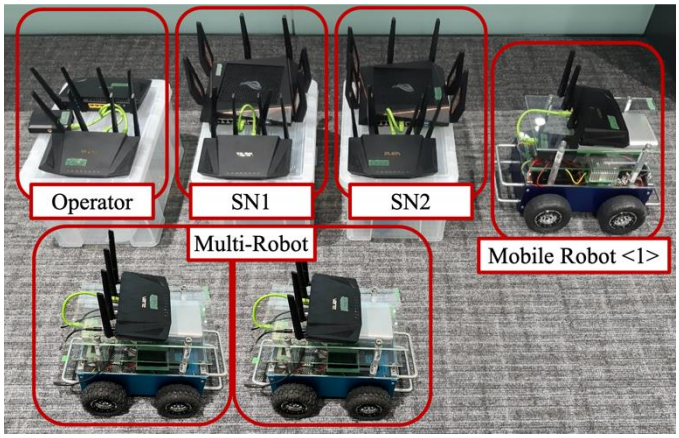

Fig. 6. Multistage Relay Network and Robots.

V. Evaluation of Communication Quality using Bandwidth Compression Throughput Measurement

This section define the communication quality characteristics that should be evaluated when teleoperating a mobile robot and explain how to measure them.

The operator receives packets containing camera and sensor information acquired by the mobile robots, and teleoperates the mobile robots (Fig. 7). Therefore, the transmission speed between the operator PC and the mobile robots should be monitored to maintain stability of the teleoperation of the mobile robots. This paper evaluates the transmission speed in a TCP/IP-compliant communication path as the throughput at the packet level. Throughput (bps) indicates the transmission speed received by the receiving PC per second. This system is expected to send a large amount of sensed information from the mobile robots. Therefore, this paper uses a band compression throughput measurement that can determine the upper limit of the transmission speed.

Bandwidth compression throughput represents the maximum number of data receivable per second by transmitting a large number of measurement packets from the transmitting side. Additionally, this measurement method send as many packets as the computer can process to measure the upper limit of the throughput accurately. The packet size of the

transmission packet is set to 1,400 bytes, which is the upper limit. In this system, the bandwidth compression throughput is calculated assuming that the packet size is *B* (byte), the total number of received packets is *n*, and the time required to complete the measurement is *t* (s). Then, the band compression throughput, *Th* (bps), can be expressed by the following equation:

$$Th = \frac{8Bn}{t} \quad (1)$$

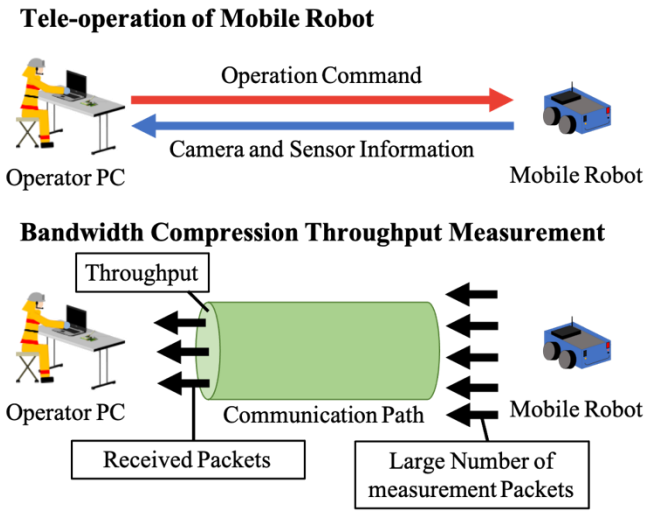

Fig. 7. Evaluation of Communication Quality of Teleoperation of Mobile Robots.

VI. Possibility of Constructing a Multi-robot Environment with Proposed Multistage Relay Network

A. Experiment on Increasing Distance between Nodes

This experiment examined the change in throughput with increasing distance between nodes to confirm whether such distance can be increased during network construction. This experiment measured the bandwidth compression throughput to determine the change in throughput with increasing distance between nodes. The distance between SN1 and SN2 was increased from 0 m to 5 m at 5 m intervals until communication was lost, and the bandwidth compression throughput was measured 10 times in both directions at each point. Then, this experiment loaded the network by sending 50,000 packets of 1,400 bytes. The upload direction was from SN1 to SN2, and the download direction was from SN2 to SN1, as shown in Fig. 4. A straight, paved 250 m road was used (Fig. 8). Furthermore, this experiment used a Raspberry Pi 4 Model B as the PC, ASUS RT-AX3000 as the router, and a CAT8 LAN cable.

Fig. 9 and 10 show the experimental results in the upload and download directions, respectively. The figures state the minimum, average, and maximum throughput values at each point. After the bandwidth compression throughput measurement in the download direction at the 230 m point, SN1 lost connection to the AP of SN2, so the upstream direction could be measured to the 225 m point and the download direction to the 230 m point. Thus, the distance between nodes can be extended, so this experiment constructed a multi-robot environment with a multistage relay network, as explained in the next section.

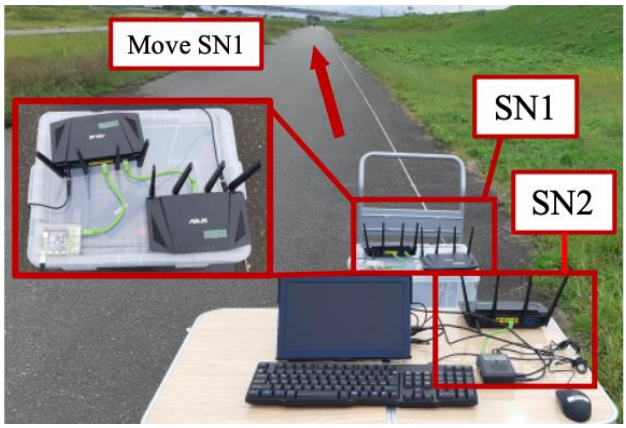

Fig. 8. Experimental Environment; Increase in Distance between Nodes.

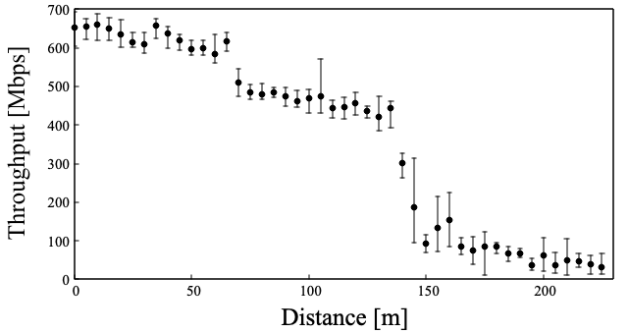

Fig. 9. Throughput of Upload; Increase in Distance between Nodes.

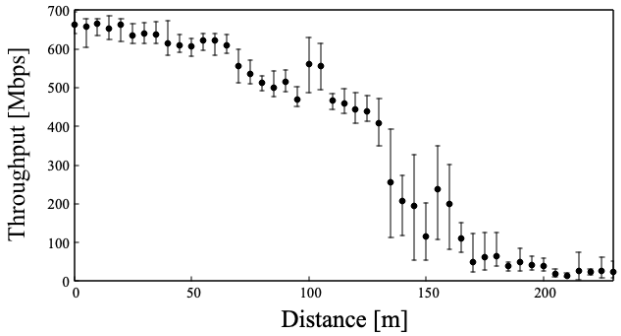

Fig. 10. Throughput of Download; Increase in Distance between Nodes.

B. Construction of Multi-robot Environment using Proposed Multistage Relay Network.

The purpose of this experiment is to confirm whether it is possible to construct a multi-robot environment that satisfies the requirements of the proposed network topology. This experiment measured the bandwidth compression throughput to confirm whether the constructed network can maintain the throughput required for multi-robot teleoperation. First, the distance between each node between the operator PC and mobile robot <1> in the proposed topology was increased from 0 m to 90 m at 10 m intervals. Then the bandwidth compression throughput was measured five times in both directions between the operator PC and the mobile robot <1> at

each point. A mobile robot was connected to the constructed network (the distance between each node was 90 m) and teleoperated, and bandwidth compression throughput measurement was performed five times in both directions between the operator PC and the mobile robot every 10 m. This experiment used a Raspberry Pi 4 Model B as the PC, ASUS RT-AX3000 and GT-AX11000 as the router, and a CAT8 LAN cable.

Fig. 11 shows the experimental environment of this section. This experiment was performed indoors with a straight 90 m line, so the operator PC and SN2 were deployed at the 0 m point, and SN1 and mobile robot <1> were moved to increase the distance between each terminal in the fold. A mobile robot connected to the constructed network switched the nodes to which it was connected is the following manner:

- The mobile robot was teleoperated by connecting to the operator's AP from the 0 m point to the 90 m point (point where SN1 was deployed).
- The mobile robot was teleoperated by connecting to the AP of SN1 from the 90 m point to the 180 m point (point where SN2 was deployed).
- The mobile robot was teleoperated by connecting to the AP of SN2 from the 180 m point to the 270 m point (point where mobile robot <1> was deployed).

Fig. 12 and 13 show the throughput values between the operator PC and mobile robot <1> during the expansion of the network construction range. Fig. 14 and 15 show the throughput values between the operator PC and the mobile robot during the teleoperation of the mobile robot. Fig. 12–14 shows the minimum, average, and maximum throughput values at each point. As stated in Fig. 11 and 12, the range of the multistage relay network was expanded to a distance of 90 m between each node (270 m in total), and the throughput was maintained at more than 60 Mbps in both directions. Fig. 13 and 14 also show that the throughput between the operator PC and the mobile robot remained over 60 Mbps.

These results indicate that a multistage relay network constituted by the proposed topology can maintain the required throughput for multi-robot teleoperation. Therefore, the robots connected to the multistage relay network constructed in this experiment could operate stably.

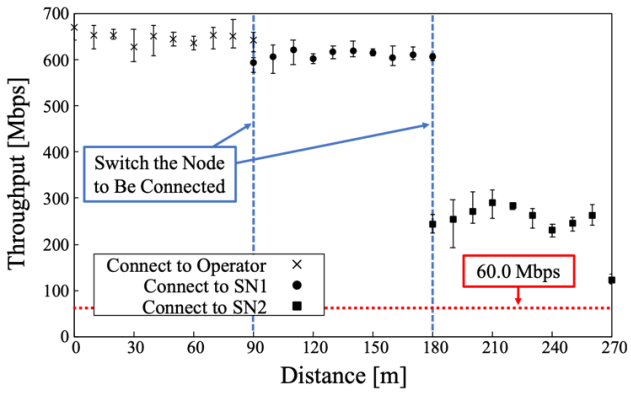

Fig. 15. Throughput of Download between Operator PC and Mobile Robot during Mobile Robot Teleoperation.

VII. Discussion

As the distance between nodes increased, the throughput between the operator PC and mobile robot <1> was measured up to the 225 m point. Fig. 9 and 10 show the throughput decreased by more than 100 Mbps when the distance between nodes was about 140 m. This decrease in throughput was deemed to have been caused by fallback, which decreases throughput in relation to a decrease in electric field strength. In the transmission and receiving of data between nodes, a delay or disconnection occurs if the amount of communicable data is exceeded. Furthermore, in wireless LANs, communication connectivity between nodes is maintained by fallback, which sets an upper limit on the transmission speed according to the electric field strength [20]. Therefore, the experiment of Section 6 assumed that the decrease in throughput at 140 m was due to the decrease in electric field strength caused by the increase in distance between nodes. This result suggests that it is necessary to monitor not only the throughput but also the electric field strength in a multi-robot system.

The multistage relay network was expanded to 270 m, maintaining a throughput of more than 60 Mbps. Therefore, more than three mobile robots could be teleoperated at 270 m in the network constructed in this experiment. A comparison between Fig. 9 and 10, and Fig. 12 and 13 indicates that the multistage relay network provided a larger search area. Moreover, in the teleoperation of the mobile robot, a throughput of more than 60 Mbps was maintained between the operator PC and the mobile robot after the construction of the multistage relay network. Thus, more than three mobile robots could be teleoperated when connected to any node of the network constructed in this experiment.

An RWSN cannot maintain the required throughput for multi-robot teleoperation, but the proposed method can ensure stable communication connectivity for multi-robot operation. The proposed topology is also effective in intricate environments because it can be used to construct a multistage relay backbone network with a high throughput.

VIII. Conclusion

This paper proposes a multistage relay network topology for constructing an environment with mobile robots for information gathering in large-scale facilities. Teleoperation of a mobile robot using a multistage relay network is effective for exploring in intricate environments and obstacle spaces due to its flexibility and scalability. However, in a multistage relay network, the communication quality decreases due to the increase in the distance between nodes and the number of relays, so a single robot is typically operated to maintain communication connectivity. As the search range of a single robot is limited, this paper considers the importance of operating a multi-robot system in a large-scale facility. A multistage relay network consisting of the proposed topology can connect multiple mobile robots to each node. These robots change the search range by switching the nodes to which they are connected. The experiment of Section 7 connected a mobile robot to a multistage relay network consisting of the proposed topology and confirmed its effectiveness by measuring the throughput. Findings indicated that this topology is effective for constructing a multi-robot environment in a large, enclosed space.

The proposed topology is effective for the teleoperation of multi-robot systems; however, there is a communication time loss when a mobile robot switches between connected nodes. Additionally, the mobile robot may become isolated if it fails to maintain the communication quality required for teleoperation in the communication path after changing nodes. Therefore, the future aim to develop a method of changing the communication route while maintaining the communication connectivity of a mobile robot.

Use of Value Chain Mapping to Determine R&D Domain Knowledge Retention Framework Extended Criteria

Mohamad Safuan Bin Sulaiman, Ariza Nordin, Nor Laila Md Noor, Wan Adilah Wan Adnan
Faculty of Computer and Mathematical Sciences
Universiti Teknologi MARA (UiTM)
Shah Alam, Malaysia

***Abstract*—Implementing a knowledge retention (KR) strategy is crucial to overcome the loss of expert knowledge due to employee turnover and retirement. The knowledge loss phenomenon caused organizations to face enormous risks which affect performance. KR frameworks and models are made available beyond research and development (R&D) organizations, to address knowledge retention strategies for administrative, operational, and manufacturing organizations. For research-intensive portfolios within R&D organizations, using the available KR frameworks requires fitting. The difficulty to address knowledge loss due to the uniqueness of the R&D organization's knowledge artifacts requires an extended KR framework. Before designing the extended KR framework, it is crucial to determine the framework's additional criteria. The paper reports the use of value chain mapping to determine the extended criteria of the KR framework fit for R&D organizations. The value chain mapping method identifies the knowledge activities in the R&D using Porter Value Chain (PVC) as the reference model. The output is a Knowledge Chain Model (KCM) that defines the critical points of knowledge loss in the R&D value chain. These critical points are project-based expert critical knowledge focus, project-based tacit knowledge transfer, and project-based knowledge repository which are nominated extended criteria of the KR Framework fit for R&D organizations.**

Keywords*—Knowledge retention framework; research and development; porter value chain; knowledge management; knowledge loss; research intensive portfolio; knowledge chain model

I. Introduction

Knowledge loss is a phenomenon that undeniably brings risk to organizational sustainability. The knowledge loss is spurred by either aging experts leaving the organization for retirement or expert or knowledgeable workers leaving for better job offers in other organizations. Knowledge loss is critical drawing much attention from the organizational knowledge management teams and risk managers to overcome the phenomenon using solutions pertaining to retention of critical knowledge loss. Despite having excellent KM practices in place, organizations still have a slimmer chance of facing critical knowledge loss [1].

Most of the studies of retention of critical knowledge loss were conducted on small and medium enterprises (SMEs), oil and gas, education, and manufacturing sectors [2,3,4]. These studies were more focused on the operational knowledge of the organizations. To address the critical knowledge loss in the organization, this research specificity focused on the critical knowledge loss in the research and development (R&D) organizations. Like other organizations, R&D organizations also face knowledge loss when their expert or knowledgeable researchers leave the organization. The loss indefinitely affects the performance of the R&D organization since the absence of expert researchers' knowledge hinders the completion of remaining or future R&D projects. The need to understand knowledge loss in an R&D organization is important since R&D is a strategic investment to produce better and newly featured products of technology either in a business or government. Overlooking knowledge loss in R&D organizations may be a strategic loss for the economic growth of a country. The current literature reported limited studies conducted for R&D organizations to address the critical knowledge loss of R&D activities.

The paper reports on a study to determine extended criteria required to fit the KR framework for an R&D organization. The use of value chaining mapping is elaborated to define criteria that are synthesized from the R&D and knowledge chain analysis. This study used the Porter value chain (PVC) model as the basis to develop the R&D value chain and knowledge chain model (KCM) to identify the knowledge activities in the R&D value chain.

II. Literature Review

Knowledge Retention (KR) is one of the important KM and organizational strategies to minimize critical knowledge loss [5]. Many KR Frameworks and models were proposed to overcome the knowledge loss but there is a lack of focus being given to KR for R&D organizations. The literature review of this study consists of four parts. The first part discusses frameworks and models for retention of critical knowledge loss to help understand the issues and context of the existing setup of managing critical knowledge loss.

The second part focuses on the R&D organizations to show the uniqueness of the organizations as compared to the operational-based organizations. The third part reviews the Porter Value Chain (PVC) model that is used in this study as the basis for synthesizing the R&D value chain. The fourth part reviews the knowledge chain model that is used to map the

knowledge activities with the R&D value chain. These reviews are towards the objective of identifying criteria that will be used as the foundation for the development of the KR framework for R&D organizations.

A. Frameworks and Models for Retention of Critical Knowledge in Organization

Several frameworks related to KR were reviewed for this purpose. This study has reviewed the frameworks and models proposed by Arif, Egbu, Alom & Khaflan [6], Boyles, Kirschnick, Kosilov, Yanev & Mazour [7], Doan & Rosenthal-sabroux [8], Levy [1] and Wamundila and Ngulube [9]. The summary of the frameworks is shown in Table I.

Early work on the KR model [6] for the construction organizations is based on a case study performed at construction companies in the United Arab Emirates (UAE). This model proposed a method to assess the KR capabilities of an organization and suggests opportunities for improvement. The model emphasizes a four-stage KR process that covers socialization, codification, knowledge construction, and knowledge retrieval.

Similarly in the same year, Boyles, Kirschnick, Kosilov, Yanev & Mazour [7] proposed a comprehensive cycle of retention processes in the case of retirement implemented in nuclear industries that emphasized several important stages that included (1) Conduct of risk assessment, (2) Determination and Implementation of the plan, (3) Monitoring and evaluation. Each process has sub-processes that further elaborate the retention of critical knowledge in detail. In addition, Boyles, Kirschnick, Kosilov, Yanev & Mazour [7] suggested a dedicated and separate self-assessment process in the case of employees who are leaving and transferring to other organizations or departments.

Continuing work on KR is seen in the work of Levy [1] who proposed a retention framework that is based on case studies performed in Israel between 2007 and 2010. The case studies were performed in seven organizations in banking, ministerial- level of a government department, national services, and defense industries. The model consists of three main stages for retention, which focused on the implementation stage for vertical knowledge transfer and eliminates assessment stage. The stages include (1) Scope, (2) Transfer, and (3) Integration. In the context of the organization, Levy [1] has underlined three types of organizational response to the phenomena of knowledge loss which include (1) Avoidance, (2) Engagement, and (3) Reaction. In this context, Knowledge retention is in the need for Engagement and Reaction-type of organizations because of inappropriate KM practice at the organizational level.

Wamundila and Ngulube ([9] proposed a retention framework for higher education institutions which the case study was performed at the University of Zambia (UNZA). The proposed framework has focused on (1) Identifying KR challenges at the organizational level, (2) Acknowledge the need and purpose for KR at the organizational level, (3) Preparedness of tacit and explicit knowledge integration, (4) Understanding the dimensions of KR which primarily encompasses knowledge assessment, acquisition, and transfer.

TABLE I. SUMMARY OF COMPONENTS IN EXISTING KR FRAMEWORKS

Authors	Components of the Framework
Arif et al. (2009) [6]	1. Personalization/Socialization (Individual knowledge) 2. Codification/ Externalisation (Conversion - Tacit to Explicit) 3. Combination (Organizational Memory: knowledge saved in IT/ Support Systems) 4. Internalisation (Retrieval - Explicit to Tacit: Retrieving Knowledge for Reuse)
Boyles et al. (2009) [7]	1. Conduct Risk Assessment 2. Determine and Implement Plan 3. Monitor and Evaluate
Doan et al. (2011) [8]	1. Top Management Support 2. ICT Tools 3. Knowledge Retention Process 4. Critical knowledge (Initiation, 5. Implementation and evaluation) 6. Business Process Focus 7. Human Resource Practices 8. Knowledge Retention Strategy 9. Learning Culture
Levy (2011) [1]	1. Initiating the process 2. Scope 3. Transfer 4. Integration 5. Structured Process 6. Structured Result
Wamundila and Ngulube (2011) [9]	1. Identify knowledge retention challenges 2. Acknowledge need and purpose for knowledge retention 3. Integrate tacit and explicit knowledge 4. Dimensions of knowledge retention (knowledge assessment, acquisition, and transfer)

Doan & Rosenthal-Sabroux [8] proposed a reference model of knowledge retention for Small and Medium-Sized Enterprises (SMEs). The model consists of several elements that are believed to be critical for an effective KR implementation. Doan & Rosenthal-Sabroux [8] suggested the model can be used as a starting step of the KR initiative and as a template to assess the KR maturity level.

Based on the summary in Table I, all frameworks and models have variations of components which some have similar, and some have their unique components. In addition, data that have been acquired to propose the frameworks are mainly from operational-based organizations. Whilst an analysis by Sulaiman [10] has underlined several issues on the applicability and completeness of KR frameworks for knowledge-intensive organizations which found such limitations in the existing frameworks that lack of technology used to help the assessment process during the implementation of KR and lack of study had been done in R&D organization and remain as recommendations for future exploration. These limitations have motivated this study to be conducted.

B. Research and Development (R&D) Organizations

Research and development (R&D) organization is an example of a knowledge-intensive organization where KR is deemed to be important. Before further discussion it is good to clarify the definitions of R&D. Research is defined in a few categories which includes.

1) Basic research that its objective to gain more complete knowledge of the studied subject without a specific application in mind with the advancement of scientific knowledge without working for long-term economic or social benefits and with no positive efforts to apply it (pure basic research) and produce a broad base of knowledge to form the background to the solution of problems (oriented basic research) without a specific commercial goal (oriented basic research) [11,12].

2) Applied Research is the acquisition of knowledge to determine the means to achieve a specific and recognized need by discovering new scientific knowledge that has specific commercial objectives concerning products, processes, or services [11,12].

Development is defined as the systematic use of the knowledge or understanding gained from research, directed toward the production of useful materials, devices, systems, or methods, including the design and development of prototypes and processes. [11]. It is also called experimental development which means a systematic work, drawing on existing knowledge gained from research and practical experience that is directed to producing new materials, products, and devices; to installing new processes, systems, and services; or to improving substantially those already produced or installed [12].

R&D is found to be the most important component in any part of modern businesses that creates new, robust, and better products, processes, and the way people do things. Elements of R&D in the organizations and firms have a strong influence on the success rate in their business and help them gain a competitive advantage over other firms [13].

R&D also plays important role in the economic sector in a nation, making a profit in business enterprise, effective in technology-based governmental agencies (e.g., the US Department of Defence), and the higher investment in R&D activities by a nation ($355 billion in the United States in 2007), [14]. Korea is one of the many examples, where R&D spending is on more advanced industries that foster productivity growth and proven that the productivity impact of R&D is stronger in more high-tech industries and during economic downturns [15].

R&D organizations are different from other organizations based on four elements 1) People, 2) Ideas, 3) Funds and 4) Culture [14]. Managing an R&D organization is not simple and good management of research is not only the critical difference among the organizations, but the research itself is the most difficult to manage as compared to other functional activities [14].

The importance of R&D and the uniqueness of R&D organizations due to their people, ideas, funds, and culture raise the need to further explore KR in R&D organizations. This agrees with the findings from Sulaiman [10] who also suggested the need to further explore KR in the R&D organization. As a first step, it is necessary to identify where critical knowledge loss could occur in R&D organizations before addressing the KR of R&D organizations. For this purpose, the Porter value chain (PVC) and knowledge chain model (KCM) analyses can be used to identify the critical knowledge loss in R&D organization value chain activities. PVC and KCM are further elaborated in the following sub-sections.

C. Porter Value Chain (PVC)

Porter [16] introduced the value chain concept to describe a set of activities that an organization carries out to add value to its customer. The concept is now formally known as the Porter value chain (PVC) and is an established mechanism to understand the value chain in operational, business, and manufacturing organizations. Various authors have used the PVC in their research settings ever since. Relating to the knowledge value chain, the PVC has been used by Holsapple and Singh [17] for mapping a proposed knowledge chain model and Jordan et al. [18] used PVC as the basis for the product value chain in his framework for evaluating R&D impact and supply chain.

The PVC model consists of nine value-adding activities with five primary and four secondary activities toward competitive advantage as illustrated in Fig. 1.

The primary value-added activities consist of inbound logistics, operations, outbound logistics, marketing and sales, and service and are defined as in Table II.

The secondary activities (Table II) involve corporate infrastructure, human resource management, technology development, and procurement. In the primary activities, that PVC shows the important value-added at each stage starting from input materials until the finished product that can be marketed. While secondary activities are in support of the whole range of primary activities.

The mapping of PVC to specific organization activities highlights the value-added at each phase of the organization's primary activities and identifies the organization's competitive advantage. The mapping of PVC activities to organizational value chain was used by Tomasevic and Stojanovic [19] and Sobotka [20] for educational institutions and Rapcevi [21] for public sectors.

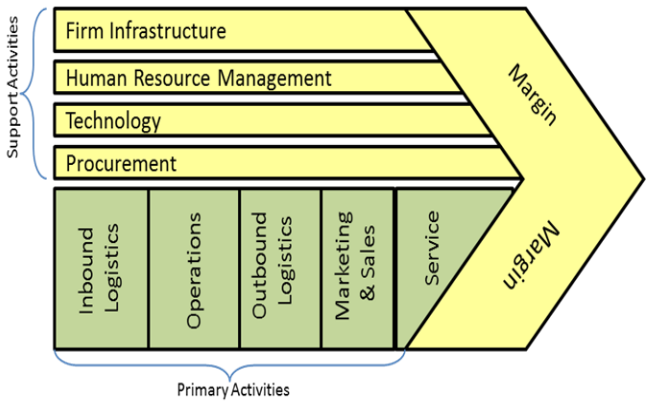

Fig. 1. Porter Value Chain (PVC) Model.

TABLE II. DEFINITION OF THE PVC ACTIVITIES

Activity	Definition
Primary	
1. Inbound Logistics	Receiving, storing, and distributing materials to manufacturing premises.
2. Operations	Transforming inputs into finished products
3. Outbound Logistics	Storing and distributing products
4. Marketing and Sales	Promotion and sales efforts
5. Service	Maintain or enhance product value through post-sale services
Secondary	
1. Corporate Infrastructure	Support for the entire value chain including general management, planning, finance, accounting, legal services, government affairs, and quality management
2. Human Resource Management	Recruiting, hiring, training, and development of employees
3. Technology Development	Improving product and manufacturing process
4. Procurement	Purchasing input

D. Knowledge Chain Model (KCM)

The KCM was proposed by Holsapple and Singh [17] and was based on a descriptive KM framework developed via a Delphi study involving an international panel of prominent KM practitioners and academicians [22]. The model has five primary and four secondary KM activities in the KCM as in Fig. 2 [23].

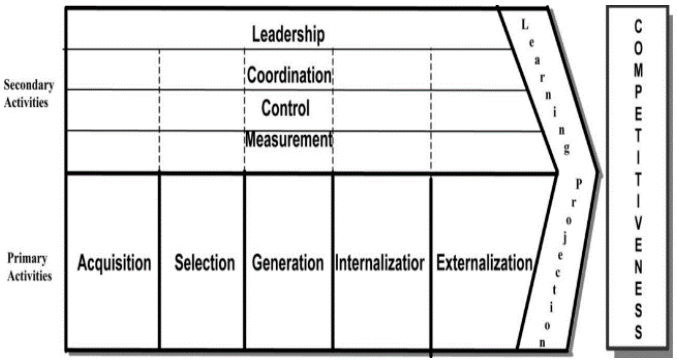

Fig. 2. Knowledge Chain Model (KCM).

Five primary KM activities include Knowledge acquisition, selection, generation, internalization, and externalization, and four secondary KM activities include knowledge leadership, coordination, control, and measurement. The definition of the primary and secondary KM activities is in Table III.

The reviewed KR frameworks from previous works are different from one another. The differences have shown the gaps between the frameworks. A small but important gap has shown that a lack of data was acquired from R&D organizations as the basis of producing the existing KR Framework. Therefore, the importance and unique characteristics of R&D organizations are reviewed and have shown some differences between operational-based and R&D organizations. The reviewed PVC model has shown the useful technique to derive the R&D organization value chain activities as been used in the operational-based organization as well as another mapping for the organizational value chain. While KVC is reviewed, to address important knowledge activities at the organizational level that might lead to critical knowledge loss.

TABLE III. DEFINITION OF THE PRIMARY AND SECONDARY KM ACTIVITIES

Primary Activities	Secondary Activities
Knowledge Acquisition: Acquiring knowledge from external sources and making it suitable for subsequent use. Knowledge Selection: Selecting needed knowledge from internal sources and making it suitable for subsequent use. Knowledge Generation: Producing knowledge by either discovery or derivation from existing knowledge. Knowledge Internalization: Altering the state of an organization's knowledge resources by distributing and storing acquired, selected, or generated knowledge. Knowledge Externalization: Embedding knowledge into organizational output for release into the environment.	Knowledge Leadership: Establishing conditions that enable and facilitate fruitful conduct of KM Knowledge Coordination: Managing dependencies among KM activities to ensure that proper processes and resources are brought to bear adequately at appropriate times Knowledge Control: Ensuring that needed knowledge processors and resources are available in sufficient quality, subject to security requirement Knowledge Measurement: Assessing values of knowledge resources, knowledge processors, and their deployment

III. METHODOLOGY

The research method employed is a two-step procedure that focused on (1) the PVC mapping on R&D processes to produce R&D organization value chain activities and (2) the knowledge chain model mapping on R&D organization knowledge chain activities to identify possible loss of critical R&D knowledge.

The PVC mapping on R&D processes was conducted based on the R&D processes as described by several kinds of literature that include the work of [23-29]. An interpretive analysis based on PVC is then used to map the operational-based organization with the R&D organization value chain. This analysis is purposely to identify the differences between operational-based and R&D organizations and produce the R&D organization value chain.

In the next step, the knowledge chain model by Holsapple and Singh [17] is used to map each R&D organization's value chain activities with knowledge activities. The result of the mapping is used to identify knowledge activities at each R&D value chain activity that might lead to the possible loss of critical R&D knowledge.

By knowing the critical point of R&D knowledge loss from the findings of those mappings, several criteria for retention of critical knowledge loss would be suggested for KR Framework in R&D organizations.

IV. Data and Analysis

The mapping of PVC onto the R&D organizational process is mainly used in R&D standard processes [26]. The R&D standard processes are well-structured and similar to the PVC structure [26].

Standard R&D processes into two levels: the organizational level and the project level [26]. The organizational level contains organizational processes such as R&D Planning, Portfolio Management, Idea Management, Intellectual Property Management, Infrastructure Management, Human Resource Management, Organizational Performance Management, and Quality Management The structure of the standard R&D processes at the organizational level is shown in Fig. 3.

The project level contains support processes and fulfillment processes. Support processes consist of Project Planning, Project Monitoring, Gate Assessment, Collaboration Mgt. and Risk Mgt. while, fulfillment processes consist of Concept Modelling, Business Feasibility, Specification Definition, Design, Development, Prototype, Market Test, and Market Launch. The standard R&D processes at the project level are shown in Fig. 4.

Besides standard process mapping [26], some other R&D processes are also considered in the mapping includes [27,28,28] to support the works from Yoon, Lee, Lee & Yoon [26] and some have additional perspectives [28] Table IV shows the summary of R&D processes, used in this mapping.

Fig. 3. Standard R&D Processes at the Organizational Level.

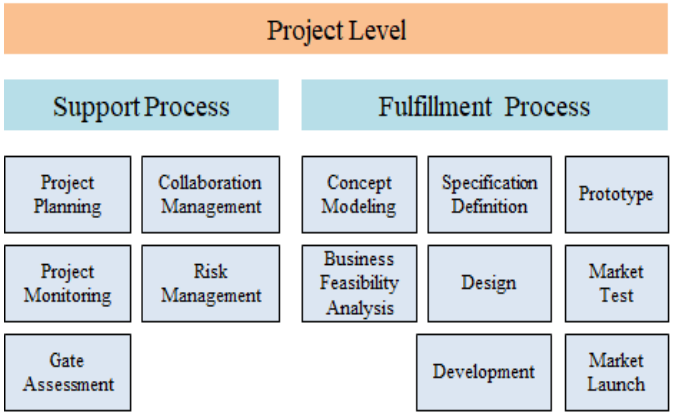

Fig. 4. Standard R&D Processes at the Project Level.

TABLE IV. Summary of R&D Components and Processes

Authors	R&D Components/ Processes	/Processes
Yoon, Lee, Lee & Yoon. (2015) [26]	• Organizational Process • Support Process • Fulfillment Process	• R&D Planning • Portfolio Mgt. • Idea Mgt. • Intellectual Property Mgt. • Infrastructure Mgt. • Human Resource Mgt. • Organizational Performance Mgt. • Quality Mgt. • Project Planning • Project Monitoring • Gate Assessment • Collaboration Mgt. • Risk Mgt. • Concept Modeling • Business Feasibility • Spesification Definition • Design • Development • Prototype • Market Test • Market Launch
Martin (2014) [28]	• Foster Ideas • Focus Ideas • Develop Ideas • Prototype And Trials • Regulatory, Marketing, And Product Development Activities • Launch	
Kalypso (2018) [27]	• R&D\Strategy	• Portfolio Management • Innovation • Project Management • Ip Management • Sourcing • Talent Management • Regulatory Compliance • R&D Operation
Rousselon Saadn & Erickson (1991) [29]	• Priority Setting • Portfolio • Management • Project Management • Strategic Planning	• Program Analysis • Portfolio Analysis • Portfolio Adjustment • Portfolio Assignment • Project Planning • Project Budgeting • Manpower/Resource Planning • Scheduling • Active Monitoring • Project Analysis • Technology Forecasting • Strategic Planning • Market Forecasting

Based on some similar structures that exist in secondary activities on PVC and R&D standard processes [26], this study focused the analysis on the primary activities (PVC) and R&D standard processes at the project level. Each R&D process in Table III is grouped based on the PVC activities. However, the mapping of the R&D processes into PVC activities is rather difficult because the definition of inbound logistics, operations, and outbound logistics is more focused on the product. Therefore, some adjustments on the terminology of the value chain activities and definitions are suggested because R&D standard processes are more focused on the research project rather than the product itself. For Inbound Logistics, Operations, Outbound Logistics, and Marketing and Sales, new terminology of the value chain activities for R&D are R&D Inputs, R&D Work Processes, R&D Outputs, and Realization respectively. The result of the mapping is shown in Table IV and the adjustment on the definition is suggested as follows:

- R&D Inputs: Inputs to the research project that is needed to conduct Research Activities such as project team member, planning, and funding.
- R&D Work Processes: Activities needed to achieve the objective of the research project such formulation of the research project, development of ideas, data collection, development of concept, model, theories by utilizing the research input.
- R&D Outputs: The output of the research project such as patents, Innovations, products, and publications acquired from research activities.
- Realization: Established and tested R&D output such as products and processes are packaged to be marketed and applied to targeted industries and commercialize the application of the Research Output to many industries.
- Service: Activities of maintaining the R&D output such as marketed product and processes or usually called after-sales service.

Table V indicates the mapping of the R&D processes onto the PVC components and is based on the above definitions. Mapping Inbound Logistics onto R&D Inputs include business feasibility, specification definition, portfolio analysis, portfolio adjustment, portfolio assignment, and sourcing.

R&D Work Processes include project monitoring and analysis, concept modeling, design, development, scheduling, active monitoring, R&D operation, fostering and developing ideas, prototype and trials, product development activities, and gate assessment.

R&D Outputs include Innovation and Intellectual Property and mapping Marketing & Sales onto Realization include market launch, test, and forecasting, launch, and marketing.

Based on the mapping analysis, it can be understood, Inbound Logistics can be mapped with Research Inputs, Operations with R&D Work Processes, and Outbound Logistics with Research Outputs and Marketing and Sales, with Research Realization [30].

TABLE V. MAPPING R&D PROCESSES ONTO PORTER VALUE CHAIN (PVC)

Primary Activities (*Project Level*)				
Inbound logistics *(R&D Input)*	**Operations (*R&D Work Processes)***	**Outbound logistics *(R&D Output)***	**Marketing & Sales *(Realization)***	**Service**
Business Feasibility	Project Monitoring	Innovation	Market Launch	
Specification Definition	Concept Modelling	Intellectual Property	Market Test	
Portfolio Analysis	Design		Market forecasting	
Portfolio adjustment	Development		Launch	
Portfolio assignment	Prototype		Marketing	
Sourcing	Scheduling			
	Active Monitoring			
	Project Analysis			
	R&D Operation			
	Foster Ideas			
	Focus Ideas			
	Develop Ideas			
	Prototype and trials			
	Product dev. activities			
	Gate Assessment			

None of the R&D processes could be mapped onto the service activities because it is not part of R&D processes and usually under the technical department after the technology has been transferred within a period. The result of the mapping is shown in Fig. 6.

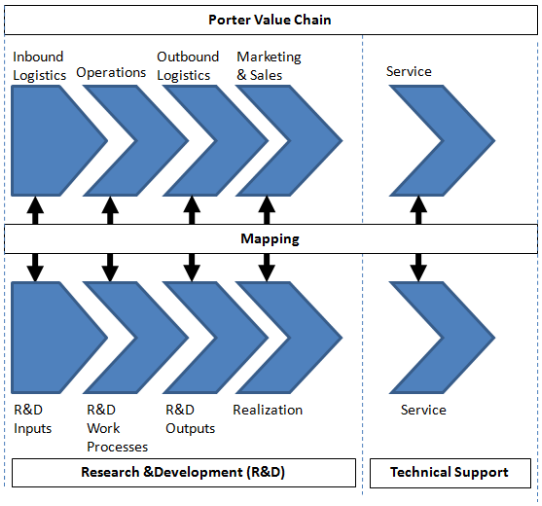

Fig. 5. Result of the PVC Mapping onto R&D Processes.

As referred to Fig. 5, four primary value chain activities for the R&D value chain were identified which include R&D inputs, R&D work processes, R&D Outputs, and Realization. Whilst Service is more towards technical support and was not considered as part of R&D processes. As a result, the proposed R&D value chain is as in Fig. 6.

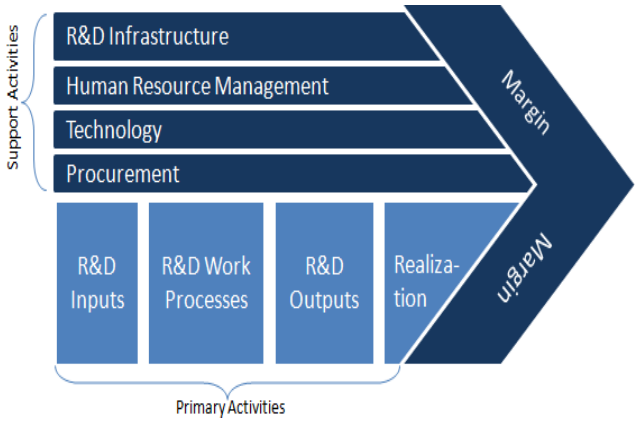

Fig. 6. The R&D Organization Value Chain.

The primary activities in the R&D organization value chain as in Fig. 6 are then mapped with the knowledge chain model to identify the point of critical R&D knowledge loss. The knowledge chain model (KCM) of Holsapple and Singh [17] is used in this study to identify knowledge chain activities in each of the R&D value chain activities. The definition of each primary knowledge chain activity is suggested by Holsapple and Singh [17] as in Table III.

From the definition of primary knowledge chain activities, it is understood, each R&D value chain has at least one knowledge chain activity. Knowledge acquisition and selection occur at R&D Inputs, knowledge generation and internalization occur at R&D Work Processes Activities, knowledge generation and externalization occur at R&D Outputs and knowledge externalization occurs at Realization. The result of the mapping of knowledge value chain activities on R&D value chain activities is shown in Fig. 7.

At this stage, each R&D value chain activity has knowledge activities and at some R&D activities, it produces and generates new knowledge.

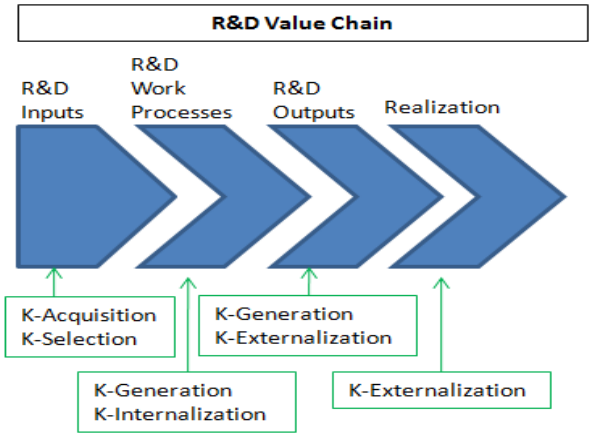

Fig. 7. R&D Value Chain and Knowledge Chain Activities.

V. Discussion

As this study is focusing on the criteria for knowledge retention framework, further discussion on the context of knowledge aspects for retention of critical knowledge in R&D organization which is based on the R&D value chain and knowledge activities is relevant.

From the analysis of mapping PVC onto R&D Processes, it is discovered that the R&D organization's value chain has different primary activities with similar support activities. These can be seen in the adjustment of the definitions at the primary activities as well as the absence of the R&D process at Service activity. The differences proved that R&D and operational-based organization is different obviously at the primary activities which perhaps the existing KR framework is not fit for R&D organizations.

From the KCM mapping onto primary R&D value chain activities, it is found that knowledge activities occur in each R&D value chain activity. It is also believed that each knowledge activity such as knowledge acquisition, selection, generation, internalization, and externalization has intensively and extensively occurred from the beginning until the end of the R&D projects.

R&D Project team which is considered as R&D knowledge workers play an important role in each R&D and its knowledge activities. In addition, an expert in the project team plays a more significant role in the R&D project. According to Joe, Yoong & Patel [31], "experts are a powerful source of value creation within organizations and are people who have deep specialized knowledge of a subject, who are tested and trained, especially by experience. Expert demonstrates higher levels of efficiency, performs tasks with greater accuracy and cost-effectiveness and holds subject-specific knowledge, such as on methods and procedures, including knowledge of how to deal with problems and new situations". Expert knowledge is also a valuable organizational resource [32]. To a certain extent, the experts often do not realize that they possess unique valuable knowledge, and for cognitive reasons, they are not able to express this knowledge [33]. In the situation, if an expert suddenly leaves the organization during the development of a prototype, where the knowledge generation is just started to be implemented and no one has the capability similar or nearly like the expert, it is critical and affects the project progress as well the performance of the R&D organization. This implies that an R&D expert is one of the critical points to be seriously considered for the criteria of KR in R&D organizations.

By looking into the R&D value chain and its knowledge activities, the tacit and explicit knowledge of each R&D project team will possibly accumulate over time and at each R&D value chain activity. The knowledge of the team gradually and proportionally increased over time and chain activities. It means that knowledge accumulated at R&D Outputs activities is more than knowledge accumulated at R&D Inputs. The knowledge accumulated over time and value chain activities is an asset to the organization. Losing experts or project team members at the final stage of the R&D value chain activities are more critical than at the earlier R&D stages because more efforts and resources must be invested to make the project progress as planned. Therefore, the accumulated

knowledge over time and R&D chain activities is found to be important to be seriously considered where some strategic action could be possibly done to capture the knowledge as it progressed.

From the above arguments, expert knowledge and accumulated R&D project knowledge are two important factors to be seriously considered for the criteria setting of KR Framework for R&D organization based on the following findings:

- R&D organizations are expertise-oriented and not solely product-oriented organizations. Therefore, in the context of retention of critical knowledge loss, more focus should be given to expert knowledge instead of knowledge of the product and innovation of the R&D projects at every R&D value chain activity.
- Each R&D project must have project team members that manage the accumulated R&D project knowledge at each R&D value chain activity. The accumulated knowledge in each R&D value chain is important starting from the R&D Inputs until Realization activities and it should be easily stored and transferred.
- Each project team consists of several persons that might have specific and diversified knowledge of the working R&D projects and come from different generations. Transfer and sharing activities of tacit knowledge between members should be_done as early as at the R&D Inputs to prevent knowledge loss.
- Each R&D value chain activity has its knowledge activities which might hold the critical point of losing R&D knowledge due to retirement, aging, and turnover factors. Therefore, each R&D project shall have documentation at every R&D value chain activity and stored in organizational memory to prevent the loss of explicit knowledge.

VI. Proposed Criteria for KR Framework

Based on the previous findings derived from the PVC and KCM analyses in Section V, this study underlines several criteria on the perspective of critical R&D knowledge loss to be used as the basis of developing the KR Framework for R&D organizations. Details of the criteria are as follows:

- Focused on the KR should be given to the retention of the R&D expert knowledge and potential project team that might leave the organization. Therefore, the KR Framework for R&D organization should have a thorough assessment component and shall be focusing on the critical R&D expert knowledge so that the potential leaving critical experts or members of the project team and a successor could be easily identified and risk of losing the critical knowledge of the project team could be minimized and retained as early as possible. It is also recommended to use some technology [34], to assist the preparation of the assessment process and prevent the waste of organizational resources [10].
- For expert knowledge transfer, the minimum knowledge gap between an expert and a successor and within the R&D project team would be a possible chance of easy transfer of critical knowledge. Therefore, the KR framework for R&D organizations should consider mapping and binding experts and successors for tacit knowledge transfer. In the case of the expert and successor have multiple R&D projects. The transfer shall be based on the project's point of view.
- For accumulated R&D project knowledge, each knowledge activity in R&D value chain activities should retain the R&D project as it's progressed to minimize critical knowledge loss due to retirement and employee turnover. Therefore, the KR framework should consider a mechanism for easy transfer, store and retrieve R&D project knowledge as the project progressed. It is also important to consider the use of technology so that knowledge stored procedure would be easily reinforced, and the organizational memory would be easy and well-structured, and organized.

VII. Conclusion and Future Work

Most studies on KR frameworks are based on operational-based organizations and a lack of focus had been given to R&D-based organizations. As a first step towards KR frameworks for R&D organizations, the first part of this study used mapping of PVC onto R&D processes to identify the differences between both organizations. From the mapping analysis, the differences were found at primary activities of both organizations and proposed an R&D organization value chain. The second part of this study used the mapping of KCM onto the proposed R&D organization value chain to identify knowledge chain activities in the R&D value chain. From the KCM mapping analysis, expert and accumulated R&D knowledge factors were identified as a critical point of potential R&D knowledge loss. Several criteria used as a basis for the development of the KR framework for R&D organizations were proposed which were based on several findings from the result of the mapping analyses.

Some empirical study is suggested for future works to further extend and examine the findings and streamline the recommended criteria of the KR framework for R&D organizations.

***Abstract*—This paper proposes a deep learning based predictive model for forecasting and classifying the price of cryptocurrency and the direction of its movement. These two tasks are challenging to address since cryptocurrencies prices fluctuate with extremely high volatile behavior. However, it has been proven that cryptocurrency trading market doesn't show a perfect market property, i.e., price is not totally a random walk phenomenon. Based upon this, this study proves that the price value forecast and price movement direction classification is both predictable. A recurrent neural networks based predictive model is built to regress and classify prices. With adaptive dynamic features selection and the use of external dependable factors with a potential degree of predictability, the proposed model achieves unprecedented performance in terms of movement classification. A naïve simulation of a trading scenario is developed and it shows a 69% profitability score a cross a six months trading period for bitcoin.**

Keywords*—Computer intelligence; cryptocurrency; deep learning; market movement; recurrent neural network; timeseries forecasting

I. Introduction

Cryptocurrency, or digital currency, is a virtual currency used for the exchange and transfer of assets. When compared to traditional currencies, which rely on central banking institutions, cryptocurrencies are built on the idea of decentralized control. As a result, a cryptocurrency is used to send money electronically without the involvement of a central or governmental authority. Within the last few years, and due to its uncontrollable and untraceable character, there has been a growing interest in cryptocurrency trading. The industry has grown tremendously for financial transactions and trading throughout the world. It also shows a continuing and growing trend for the near future. The market is expected to rise from 1.8 billion to 2.2 billion USD by 2026 according to https://coinmarketcap.com/charts/" (accessed Jul. 18, 2021). Moreover, when compared to traditional state-issued currencies, cryptocurrencies are extremely volatile. Their exchange rates cannot be assumed to be independently and identically distributed phenomena [1]. In a short period of time, the cryptocurrency sector has experienced exponential development and global popularity. Such increase in popularity received significant media attention, attracting more investors, researchers, regulators, and speculators to the field as promising booming business. Such increased popularity necessitates study into their dynamics and how they affect the financial sector and economies of countries in general.

The following sections discuss in short the intrinsic characteristics of cryptocurrency systems that relate to the problem statement addressed, and what are challenges, gaps and research questions of this work.

A. Cryptocurrency Characteristics

The value of each cryptocurrency is determined by its volume of transactions and price movements. Moreover, each cryptocurrency has its own ecosystem and operates differently from the other ones in terms of value variations, transaction speeds, usages, and volatility. Such independence makes forecasting cryptocurrencies prices a challenging task.

Another characteristic is that despite the massive bitcoin meltdown at the start of 2018, with a lot of volatility, people's interest in it has remained relatively steady. In response, in recent years, academics have presented a variety of approaches for predicting and modelling the price of cryptocurrencies as well as analyzing the volatility of the crypto market. Also, it is difficult to say exactly what drives the price of cryptocurrencies over time. However, P Katsiampa used the *asymmetric Diagonal BEKK* model to investigate the volatility dynamics of four main cryptocurrencies in this extensive analytical work that had been published in 2019 [2]. The conditional variances (the variance of a phenomenon given the value(s) of one or more factors in econometrics) of all four cryptocurrencies are strongly impacted by both prior squared errors and past conditional volatility, according to the study. Furthermore, big news has been proven to affect volatility dynamics. Finally, the crypto industry as a whole is known for its price fluctuations and trading volumes. With the growing interest in cryptocurrencies and their importance in the financial sector, extensive research and forecasting of cryptocurrencies' volatility dynamics is needed [3].

Also, because of the exponential growth in speculative activities, cryptocurrency markets are increasingly vulnerable to price fluctuations and degradation. It's still unclear if the biggest price fluctuations in cryptocurrencies are unpredictable or predictable over time. In other words, is it follows the Efficient Market Hypothesis (EMH) or not?

According to [4], markets are regarded as totally effective when they follow a random (weak-form) model in which future returns on the basis of prior data cannot be forecasted. Many recent studies have been conducted to investigate the efficiency and volatility characteristics of cryptocurrency prices. According to Palamalai et al. [5] the returns from the top cryptocurrencies show a persistency impact, indicating market inefficiency, i.e., not a random-walk process. Their findings have immediate ramifications for cryptocurrency market speculation. For example, the idea that bitcoin history data retains some degree of predictability about future values is correct. Another approach to figuring out predictability for the bitcoin problem is to see whether external elements may be integrated as additional features. Besides these, there are prediction strategies that are already in-use by traders. Most of them are based on heuristics and empirical conclusions, such as "Engulfing Pattern" and "Evening Star". Furthermore, some studies have also shown that social media sentiment analysis, particularly tweets about trading activities, have considerable prediction potentials, check Fig 1for factors that may contribute to the cryptocurrency pricing.

Based upon this discussion, prediction of price's value and movement direction (whether goes up or down) is a task that plays a vital role in the cryptocurrency economy. Even though the efficiency of the forecasting models has been improved in recent years, most improvements have been achieved by minimizing the error between predictions and real readings. However, due to high fluctuations rates, predicting the next exact value turned to be not that useful for trading purposes more than predicting whether it will go up or down. However, a review of relevant studies reveals that the majority of research activities have exclusively focused on the forecasting model's accuracy. Nonetheless, it is possible to further address the actual goal (which is increasing trading profitability) by setting the focus on the price movement directions rather than, or with addition to, the price values.

With this goal in hand, this work seeks to address the following research questions: 1) Are cryptocurrency prices predictable? And if so, is that due to inherent features of the pricing data? or, alternatively, because of external influences? 2) Which is more important in terms of profitability: forecasting the price value or predicting the price movement direction (increase or drop)? 3) What additions that deep learning algorithms potentially provide in this regard? Whether it's forecasting the price or deciding the price change's direction?

B. Organization of the Paper

The rest of the paper is organized as follows: Section II outlines various related and recent work in this new field with emphasis on deep learning models. Section III is devoted to this work; the dataset involved in the study, the features engineering, the proposed model architecture. Section IV shows the experiments setup, findings, and results. Finally, Section V concludes the study and discusses suggested future work.

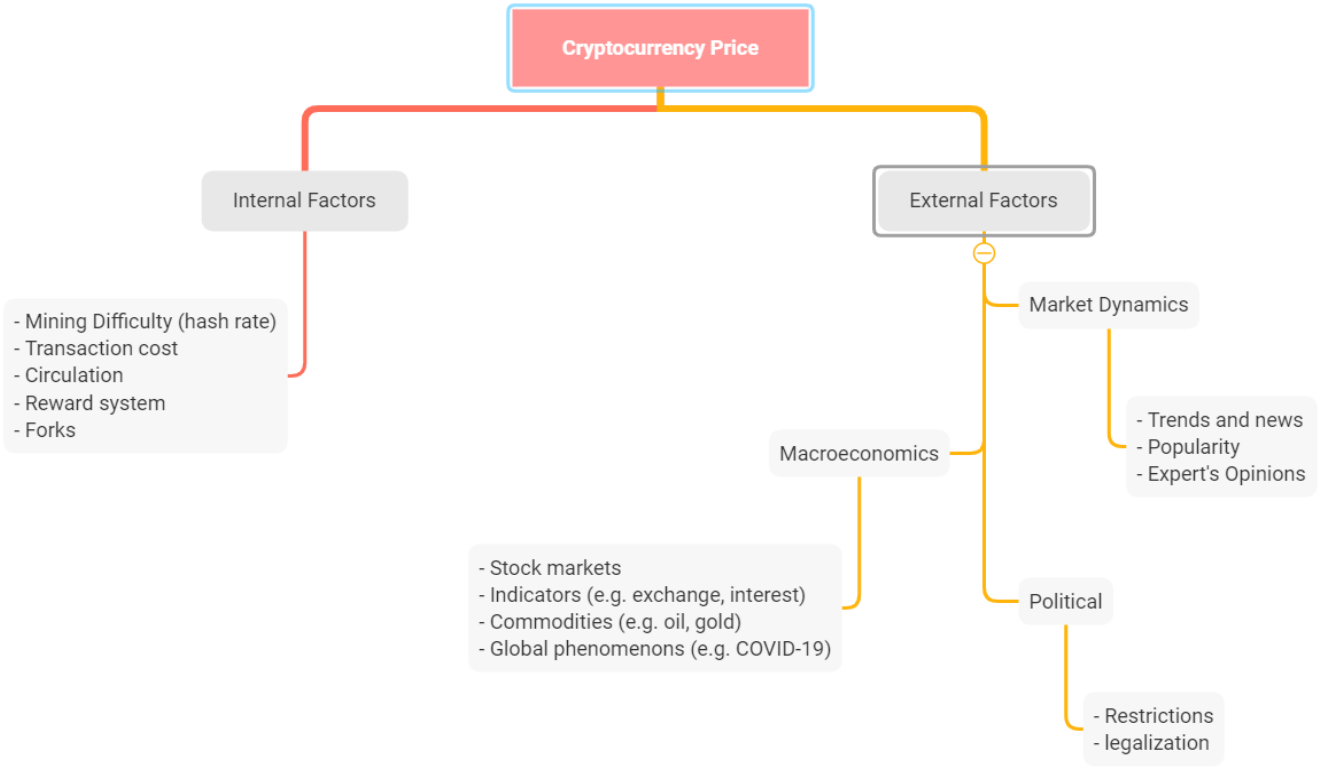

Fig. 1. Factors Affecting Cryptocurrency Prices.

II. Related Work

Over the last several years, there has been a significant surge in research interest in the subject of cryptocurrencies. Since 2015, the number of publications in this field has been increasing, and this trend is expected to continue in 20201, attributed to the growing popularity of cryptocurrencies and their widespread attention as an emerging financial sector. The field of cryptocurrency price prediction is still relatively new, with not much papers having been published; however, it is a very important topic that deserves to be explored because of the impact it is having on the financial system. Also, research trends are mostly focused on forecasting price.

A. Statistical and Traditional Techniques

A recent study by Palamalai et.al [5] evaluated the weak-form market efficiency of a top ten cryptocurrencies. They used random-walk testing with parametric and non-parametric methods which are resistant to "unknown structural breakdowns" and "asymmetric effects". The results confirmed the cryptocurrencies' weak-form inefficiency, and that it refuted the random-walk hypothesis. In essence, the results said that there is potential predictability within the cryptocurrency trading process. Their findings were consistent with which earlier research in 2017 (Hayes et al [3]) that demonstrated the impact of external factors on cryptocurrency predictability.

Holt-Winters exponential smoothing is a classic linear method for time-series forecasting that is commonly used. It splits the input data into several trend components. These components are used to forecast targets that have seasonal characteristics. Peng [6] argued that such traditional linear methods cannot be used to accurately predict cryptocurrency prices because they lack seasonality.

Chu et.al, [1] developed a GARCH method-based models. They investigated the log returns of exchange rates. The maximum likelihood method was used to fit the data. The models were evaluated based on several criteria, and the best-fitting models with the best forecasting performance were selected. Recently, Malladi et.al, [7] investigated the relationships between both Bitcoin and Ripple renderings and volatility, the authors used the Autoregressive Mobiles Average Exogenous Input (ARMAX), the Autoregressive Generalized Conditionally Heteroscedastic (GARCH) model, the Vector Autoregression (VAR) model, and Granger causality tests and showed that the Bitcoin crash of 2018 might have been described by these time series approaches. They also discovered that global stock and gold returns do not cause Bitcoin's returns, but Ripple's returns have a direct impact on Bitcoin pricing.

The impact of the three factors on cryptocurrency value was studied by Hayes et al [3] using cross-sectional data from 66 of the most commonly used cryptocurrencies. The factors are competition levels in the producers' network, production rates of the unit, and the algorithm difficulty used to mine crypto-monetary activity. The authors demonstrated that the three factors have shown a significant impact on price. Blau et.al, [8] used the regression to analyze the impact of the speculative trading, a 5-day bitcoin return, a 5-day volume sale, excess bitcoins, and a volatility estimate on the price of bitcoin of a number of other cryptocurrencies. The results showed that speculative trade has no impact on bitcoin prices. Speculative trade is the trade in future contracts, without obtaining the commodity that underlies it in reality. These traders buy or sell future contracts to re-sell it before their settlement date.

Another early proposition is described in [9] that applied autocorrelation and partial autocorrelation functions. The authors found that the first difference in the Bitcoin exchange rate is a weak-stationary time-series dataset. They created an ARIMA model to forecast future prices. They showed that ex-post forecasting's mean absolute percent error is 5.36 percent. In this work and in related references [14] it was investigated multiple variables that affecting the values of four cryptocurrencies (Bitcoin, Ethereum, Dash, litecoin, and Monaro). It has been shown that using weekly data and the enhanced Dickey–Fuller unit-root test and bound testing technique from 2010 to 2018. Market exchange, trading volume, and volatility all have an influence on the values of all four cryptocurrencies in the short and long run. This research used ARIMA as a forecast model.

Recently, Akcora et al. [10], [11], [12] have introduced a novel concept of chainlets, or blockchain motifs, to create a complex network of financial interactions on the blockchain that can be used to investigate link between bitcoin risk investing and different blockchain network aspects. Chainlets allow researchers to examine the influence of the blockchain's local topological structure on Bitcoin and Litecoin price development and evolution.

The authors in [13], [14], [15] described a strategy for forecasting changes in Bitcoin and Ethereum values using Twitter data and Google Trends [16]. Twitter is rapidly being utilized as a news source, alerting users about the currency and its rising popularity, affecting purchasing decisions. They discovered that tweet volume is a better predictor of price direction than tweet sentiment, which is always positive regardless of price direction. They were able to properly forecast the direction of price fluctuations using a linear model that takes as input tweets and Google Trends data. Aside from that, Shen et al. [17] argued that the number of tweets from Twitter, rather than Google trends, is a better indication of attention from more knowledgeable investors. They notice that the quantity of tweets has a substantial impact on the trade volume the next day.

Mohapatra et.al, [18] developed a novel KryptoOracle, a unique real-time and adaptable bitcoin price prediction engine based on Twitter emotions. The platform's integrative and modular design includes a Spark-based architecture for durable and fault-tolerant handling of massive amounts of incoming data, as well as real-time natural language processing including sentiment analysis, and an online learning-based prediction approach. Based on the accessible and ever-increasing volume and diversity of financial data, the experimental assessment indicated that the suggested platform may assist in the acceleration of decision-making, the identification of new possibilities, and the supply of more timely insights.

Bhambhwani et al. [19] used the dynamic ordinary least-squares approach was used to study the underlying determinants of cryptocurrency prices (Bitcoin, Ethereum, Monero, Litecoin, and Dash). The values of various currencies have been revealed to be influenced by their mining computer power and network connection. In [20], the authors looked into the correlation between Bitcoin market volatility and volatility in other traditional markets including gold, currencies, and stocks. On a daily, weekly, and monthly basis, they used data. Recent data shows a small but positive correlation between changes in Bitcoin volatility and changes in the trade weighted USD currency index volatility, according to correlations and regressions. Furthermore, a greater positive link between Bitcoin volatility and search demands on Bitcoin-related terms on Google has been observed. Furthermore, a VAR-analysis demonstrated that the volatility of the USD currency index, which is the lone driver of future Bitcoin volatility, is to some extent predictive of future Bitcoin volatility.

Vector autoregression method was investigated by Giudici et.al, [21]. The authors introduced partial correlations and correlation networks. The model assisted in determining the dynamics of cryptocurrency prices in various crypto exchange markets and allowed one to understand its correlation with other traditional market prices. The use of VAR correlation networks also allowed for the development of a model for predicting bitcoin price that makes use of the information contained in various correlation patterns among various exchange prices. Dos Santos et al. [22] investigated the dynamic behavior and predictability of bitcoin price dynamics (high and low). They used the fractionally cointegrated vector autoregressive (FCVAR) model to analyze bitcoin and dollar price patterns. The empirical analysis was carried out between January 2012 and February 2018. They compared fractionally cointegrated VAR to various other algorithms, and the results showed that fractionally cointegrated VAR performed better.

In [23] The authors utilized a modified Binary Auto Regressive Tree model to develop a short-term bitcoin price forecasting model (BART). BART is a hybrid method which mixes autoregressive models from the classification and regression trees (C&RTs). A short-term prognosis was made of the three most important cryptocurrencies, Bitcoin, Ethereum, and Ripple (from 5 to 30 days). The suggested technique has been identified in the prediction of crypto-currency time slower (fall) and transitional dynamics more accurately than ARIMA-ARFIMA models (change of trend). In RMSE according to the predicted horizon, the suggested model obtained 2,5 to 4,9 percent.

As reported by [15], sentiment analysis can be used as a computational tool to forecast the prices of bitcoin and other cryptocurrencies over various time intervals. The fact that currency prices fluctuate based on people's perceptions and opinions, rather than institutional money regulation, is a key feature of the cryptocurrency market. As a result, examining the relationship between web search and social media is crucial for projecting cryptocurrency prices. Because these social media platforms are used to influence purchasing decisions, this study forecasted the short-term prices of the major cryptocurrencies using Google Trends and Twitter. The study adopts and interpolates a novel multimodal approach to investigate the impact of social media on bitcoin pricing. The findings demonstrate that the psychological and behavioral views of people have a substantial influence on such highly speculative cryptocurrency values.

B. Machine Learning Techniques

Cryptocurrency is a highly volatile asset. Researchers were inspired to apply DL and ML paradigms to cryptocurrency issues as a result of this. The use of stock market price prediction techniques can help to improve precision. Because of its ability to identify the general trend and fluctuation, machine learning has become one of the most researched approaches in cryptocurrency price prediction in recent years.

One of the early work using machine learning techniques showed in [24], the authors used an SVM, an ANN, linear regression, and logistic regression to predict bitcoin price using blockchain data. The highest price accuracy was 55% for a NN classifier with two hidden layers, followed by logistic regression and SVM. In addition, the study mentions the use of several tree-based models and K-nearest neighbors in its analysis. In this study, only blockchain data was used for training and prediction, which resulted in limited predictability. According to the findings, using features directly extracted from bitcoin exchanges, such as financial flow features, would likely improve the accuracy of bitcoin price prediction. Hitam et.al, [25] forecasted the cryptocurrency future price using an optimized Support Vector Machine (SVM) based on Particle Swarm Optimization (PSO). The results of forecasting using basic SVM algorithms were found to be unreliable. Meanwhile, PSO's optimized version of SVM shows that it can accurately forecast future cryptocurrency prices, outperforming single SVM algorithms.

Mohanty et al. [26] used LSTM for bitcoin future price prediction. and Twitter data was used to predict public mood. This method selected some key features from the blockchain that had a significant impact on bitcoin demand and supply, and then used them to train a model that improved bitcoin price prediction in the future. The model demonstrated high precision and accuracy. Mittal *et al.* [27], identified the correlation between bitcoin price and Twitter and Google search patterns using machine learning techniques such as linear regression, polynomial regression, recurrent NN (RNN), and long short-term memory (LSTM)-based analysis. Tweet sentiment analysis performs the worst out of Google Trends, tweet volumes, and tweet sentiments. When LSTM, RNN, and polynomial regression were used to analyze Google Trends and tweet volume, the accuracy of the results improved.

Atsalakis *et al*, [28] proposed PATSOS, a neuro-fuzzy controller for predicting bitcoin's daily price change trend. The scheme outperformed two other computational intelligence models, the first of which was created using a simpler neuro-fuzzy approach and the second of which was created using artificial neural networks (ANNs). They also stated that the PATSOS system's performance was stable enough to be used for other cryptocurrencies.

The results obtained by applying hidden markov models in [29] to the historical cryptocurrency movements, and using LSTM to predict future movements suggested that the proposed approach had the lowest MSE, RMSE, and MAE when compared to traditional time-series prediction models, ARIMA, and conventional LSTM, demonstrating its effectiveness. This hybrid approach's parameters were further optimized using a genetic algorithm. This model did not account for the internal details of bitcoin transactions. As a result, they planned to consider additional features for future work in order to provide more information about the blockchain.

Radityo et.al, [30] showed for the next-day prediction, four variants of ANN were used to use the bitcoin exchange rate (closing price) on the American dollar. They Studied variety of ANN methods to predict the market value of one of the most used cryptocurrencies, Bitcoin. The ANN methods will be used to develop model to predict the close value of Bitcoin in the next day (next day prediction). This study compares four ANN methods, namely backpropagation neural network (BPNN), genetic algorithm neural network (GANN), genetic algorithm backpropagation neural network (GABPNN), and neuro-evolution of augmenting topologies (NEAT). The methods are evaluated based on accuracy and complexity. The result of the experiment showed that BPNN is the best method with MAPE 1.998 ± 0.038 % and training time 347 ± 63 seconds. Maiti et.al, [31] proposed a forecasting approach based on the chaotic co-movement of seven major cryptocurrencies, non-linear forecasting models have been proposed and implemented. For lags 0 and 0-3 the LSTM outperforms the ANN, while for large lags 0-7 the ANN outperforms the LSTM. Further research confirms that forecasting using variables like volume is ineffective in any case. In [32], As machine learning techniques, the authors used ARIMA, *FBProphet*, and XGBoosting for time series analysis. Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and R2 are the parameters they used to evaluate these models. They tested these three techniques, but time series analysis revealed that ARIMA was the best model for forecasting Bitcoin price in the crypto market, with an RMSE score of 322.4 and an MAE score of 227.3.

III. METHODOLOGY

We use a new approach that achieves two convergent tasks: forecasting the price and classifying the price movement. The intuition is that the focus is not only on the next point's prediction value, but also on the price movement direction whether it's going up or falling down. The determination of whether prices will rise, or fall is critical, particularly for traders. The proposed method focuses on utilizing LSTM layers' ability to extract useful knowledge by learning the internal representation of cryptocurrency features as well as correlation with external factors features. LSTM layers are used to identify short and long-term dependencies between time-series data, which are then used to predict the next point value and answer the question of whether price will fall or rise. Next sections discuss the underlaying hypothesis, the data used in the experiments and the proposed model architecture.

We formulate the price movement direction problem as follows; let T be the time divided into a timestamp $t = T/N$ where N is number of observations over T. t length maybe in minutes, hours, days, or any interval. Suppose $\mu \in \mathbb{R}$ is the price change value from t_{k-1} to t_k, where μ sign indicates the direction of change. The goal is to build a data-driven model to achieve two objectives; 1) classify μ_k sign at time t_k, and 2) predict the cryptocurrency price value at tine t_k , given observations of multiple timeseries features within time interval $\{t_0 - t_{k-1}\}$.

A. Cryptocurrency Performance Metrics

For point forecast, standard RMSE and MAPE are both used. For price direction detection, standard classification metrics are used. In this study, we use roc-auc and accuracy (which could be interpreted on a time range simulation into profitability measure).

B. Raw Datasets

The top popular cryptocurrencies with the highest market capitalizations are: Bitcoin ($577.36), Ethereum ($212.79), Tether ($62.00), and Binance Coin ($47.29) in Billions of dollars "https://coinmarketcap.com/all/views/all/" at the time of this writing. **Error! Reference source not found.** presents further information about datasets in hand.

TABLE I. TOP-TRADED CRYPTOCURRENCIES

Crypto	Data date range	Samples
Bitcoin (BTC)	7/18/2010 to 7/7/2021	4000
Ethereum (ETH)	3/10/2016 to 7/7/2021	1947
Tether (USDT)	4/14/2017 to 7/7/2021	1546
Binance Coin (BNB)	11/9/2017 to 7/7/2021	1338

1) Bitcoin (BTC): Market cap: Over $641 billion. Is the first cryptocurrency, founded in 2009 under the alias Satoshi Nakamoto [33]. Bitcoin's value has soared as it has grown in popularity. Five years ago, a Bitcoin could be purchased for around $500. A single Bitcoin was worth more than $32,000 in June 2021. This equates to a 6,300 percent increase. Plotting on Fig 2 visualizes Bitcoin data since its inception in 2010. In 2018, the price rose briefly before dropping dramatically in which is now known as bitcoin bubble (also known as the Bitcoin crash and the Great crypto crash). And in 2021, a much increasing tendency emerged.

2) Ethereum (ETH): Market cap: Over $307 billion. Ethereum, which is both a cryptocurrency and a blockchain platform, is a favorite among programmers due to the potential applications it offers, such as smart contracts that execute automatically when certain conditions are met and non-fungible tokens (NFTs). Ethereum has also exploded in popularity. Its price increased by more than 22,000 percent in just five years, from around $11 to over $2,500.

3) Tether (USDT): Market cap: Over $62 billion. Tether, unlike some other types of cryptocurrency, is a stable coin, which means it is backed by *fiat currencies* such as US dollars and the Euro and theoretically maintains a value equal to one

of those denominations. In theory, this means that Tether's value should be more consistent than other cryptocurrencies, and it is preferred by investors who are wary of the extreme volatility of other coins.

4) Binance Coin (BNB): Market cap: Over $56 billion. The Binance Coin is a type of cryptocurrency that can be used to trade and pay fees on Binance, one of the world's largest cryptocurrency exchanges. Binance Coin has grown beyond simply facilitating trades on Binance's exchange platform since its inception in 2017. It is now possible to use it for trading, payment processing, and even booking travel arrangements. It can also be traded or exchanged for other cryptocurrencies like Ethereum or Bitcoin. It was only $0.10 in 2017; by June 2021, it had risen to over $350, a gain of about 350,000 percent.

Each cryptocurrency dataset comprises of 5 indicators: open, low, high, close and volume. All data are acquired from https://www.investing.com API webservices via python library "investpy". investing.com is a global platform that delivers financial market analyses and news from across the world.

Besides historical cryptocurrencies datasets, other external factors datasets are used as shown in **Error! Reference source not found.**. Factors investigated in this study include:

1) Gold and Brent oil daily prices (open and volume values).

2) NYSE Bitcoin (NYXBT) index; the bitcoin index on the New York Stock Exchange. NYXBT indicates the US dollar value of one bitcoin unit based on actual transactions on selected bitcoin exchanges that have been assessed and meet NYSE quality criteria. The NYSE Bitcoin Index integrates data from Coinbase Exchange, the largest bitcoin exchange in the United States, in which NYSE has a minority investment [34].

3) The Standard and Poor's 500 or (SPX). SPX is a stock market index that tracks the performance of 500 big firms that are listed on US stock exchanges. As of December 31st, 2020, more than $4.6 trillion has been invested in assets tied to the index's performance.

4) The Bitcoin and Ethereum Energy Consumption Index (PWR) is a measure of how much energy is consumed by the cryptocurrency mining in a certain time period available at "https://digiconomist.net". The data found online only available for Bitcoin and Ethereum.

5) Google Trends, https://trends.google.com/ . The daily historical data for two specific keywords: ("bitcoin", "Ethereum", "Tether", "Binance Coin", and "cryptocurrency") obtained from Google API webservices via the "pytrends" python module. Google Trends examines the popularity of top search queries in Google Search across several countries and languages. The website makes use of graphs to compare the search volume of various queries over time.

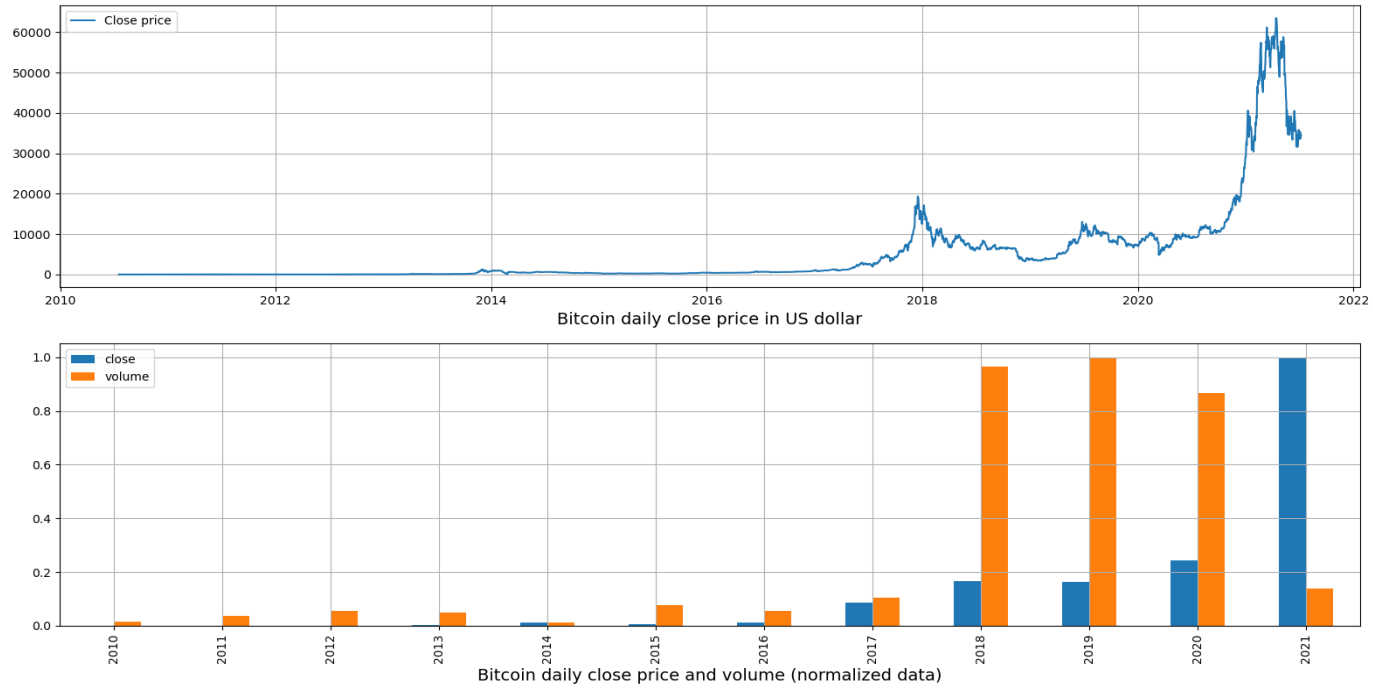

Fig. 2. Bitcoin Dataset Properties.

TABLE II. EXTERNAL FACTORS

Features	Description
gold_close	Gold commodity material daily price
oil_close	Brent oil daily price
nyxbt	NYSE Bitcoin index
spx	Standard and Poor's 500
pwr, pwr_min	Bitcoin Energy Consumption Index (expected estimation and minimum).
gtrend_bitcoin	Google Trends for the cryptocurrency name keyword
gtrend_crypto	Google Trends "cryptocurrency" keyword

C. Features Engineering

In this work, the strategy is to leverage the availability of various data sources as predictors for cryptocurrency price fluctuations and forecasting. In terms of which features are chosen for training, the features selection method is adaptive. The most important fundamental requirements are to find the right balance between training time and prediction accuracy. The proposed work dynamically infers the prediction power for each feature by using *predictive power scoring (PPS)* and *correlation coefficient* methods. PPS is an asymmetric, data-type agnostic tool for detecting linear and non-linear correlations between two columns. Values range from 1 (full predictive power) to zero (complete absence of predictive power). Asymmetric here in the sense that correlation between A-to-B is not the same as B-to-A. PPS uses a decision tree regression algorithm.

1) Features selection (Phase I): We use PPS, as a first phase filtration, to disregard features that have not much significance to the target prediction as PPS has the ability to detect non-linear relations.

2) Data preprocessing: We begin data preprocessing by normalizing the features. Normalization method is done by squashing the data from its original numerical scale to $[0, 1]$ range. We make use of "*MinMaxScaler*" found in *sklearn* library. Normalization is essential step for neural networks innerworkings as unscaled data with higher values tend to wrongly dominate when calculating derivates by the optimizer. Also, normalization prevents some activation functions from getting numerically saturated. For detailed information please check [35]. Second, we devise a set of new fabricated features as following:

Crossing original features.

Encoding date minutes information.

Time lagging features.

3) Features Selection (Phase II): We continue the feature selection process by computing the linear statistical relationship between the target and candidate predictor variables with measures such as Pearson, Kendall, and Spearman. Pearson Correlation Coefficient (PCC) is used, which produces a value between [-1, 1], where an absolute value of one shows perfect correlation, the sign indicates whether the correlation is positive or negative, and zero indicates no linear dependency at all [36]. Fig 3 illustrates PPS and PCC analysis for bitcoin external features datasets. The target is the "close" price.

We think that the forecasting possibility may changes over time in a market as volatile and inefficient as cryptocurrency trading. To overcome this difficulty, it's necessary to adopt flexible features selection approach. We use an adaptive features selection strategy in where it selects the prospective features that have the best chance of being a good predictor throughout time.

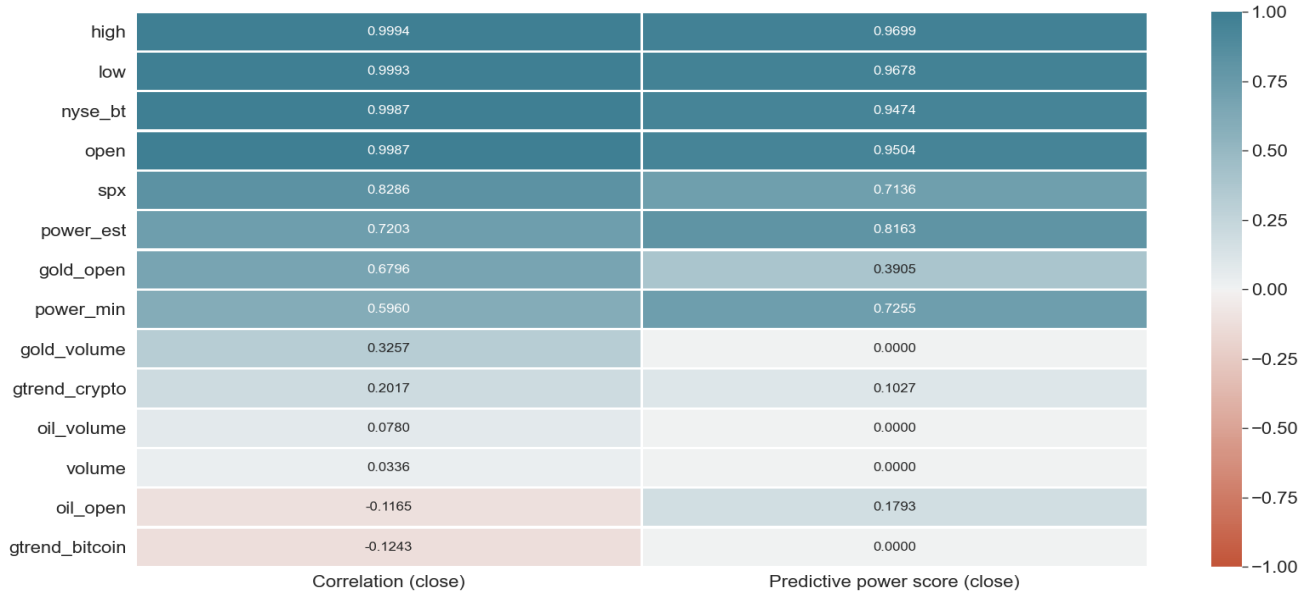

Fig. 3. Heat Map shows Correlation Coefficient and Predictive Power Scoring (Bitcoin External Features).

D. Proposed Model Architecture

The proposed model is built around a deep learning engine that receives two tensors from a preprocessed multivariate timeseries datasets as input ($X_p and\ X_d$) where $X_p = \{x_1^p, x_2^p, \dots, x_n^p\}$ and $X_d = \{x_1^d, x_2^d, \dots, x_n^d\}$, n is the number of training samples. The target variables ($Y_p and\ Y_d$) are the cryptocurrency closing price value and direction μ which is encoded as (1, -1) for up and down respectively. The prediction output vector $o = \{\hat{y}^p, \hat{y}^d\}$ where $\hat{y}^p \in \mathbb{R}$ is inferred from the learned reference distribution $p(Y^p)$. $\hat{y}^p$ is a value which when scaled back to its original scale represents the forecasted closing price. $\hat{y}^d$ is further marginalized by a threshold ε to label the closing price direction:

$$\mu^{sign} = \begin{cases} up \ \ if\ \hat{y}^d \geq \varepsilon \\ down\ if\ \hat{y}^d < \varepsilon \end{cases}$$

The proposed model consists of two stacks of layers for each input tensors $X_p and\ X_d$: 1) X_p stack consists of three GRU layers with 256 neurons each. Followed by MLP layer and an MLP output layer. 2) X_d stack consists of three LSTM layer with 256 neurons each. Followed by MLP layer, dropout layer and an MLP output layer. As shown in Fig 4, output of X_p stack GPU layer concatenates with X_d stack LSTM layer and feeds the X_d MLP layer. Layer counts, number of neurons per layer, batch sizes, training epochs, and other model hyper-parameters are set empirically.

The training algorithm works as the following steps:

1) Step 1: the PPS values are computed for all raw inputs to identify n factors with the largest predictability score. The target variable here is price "close".

2) Step 2: preprocessing features by normalizing data in range $[0, 1]$ and devising new cross features.

3) Step 3: computing PCC values and further filter features to the selected n features.

4) Step 4: train the neural network model on data.

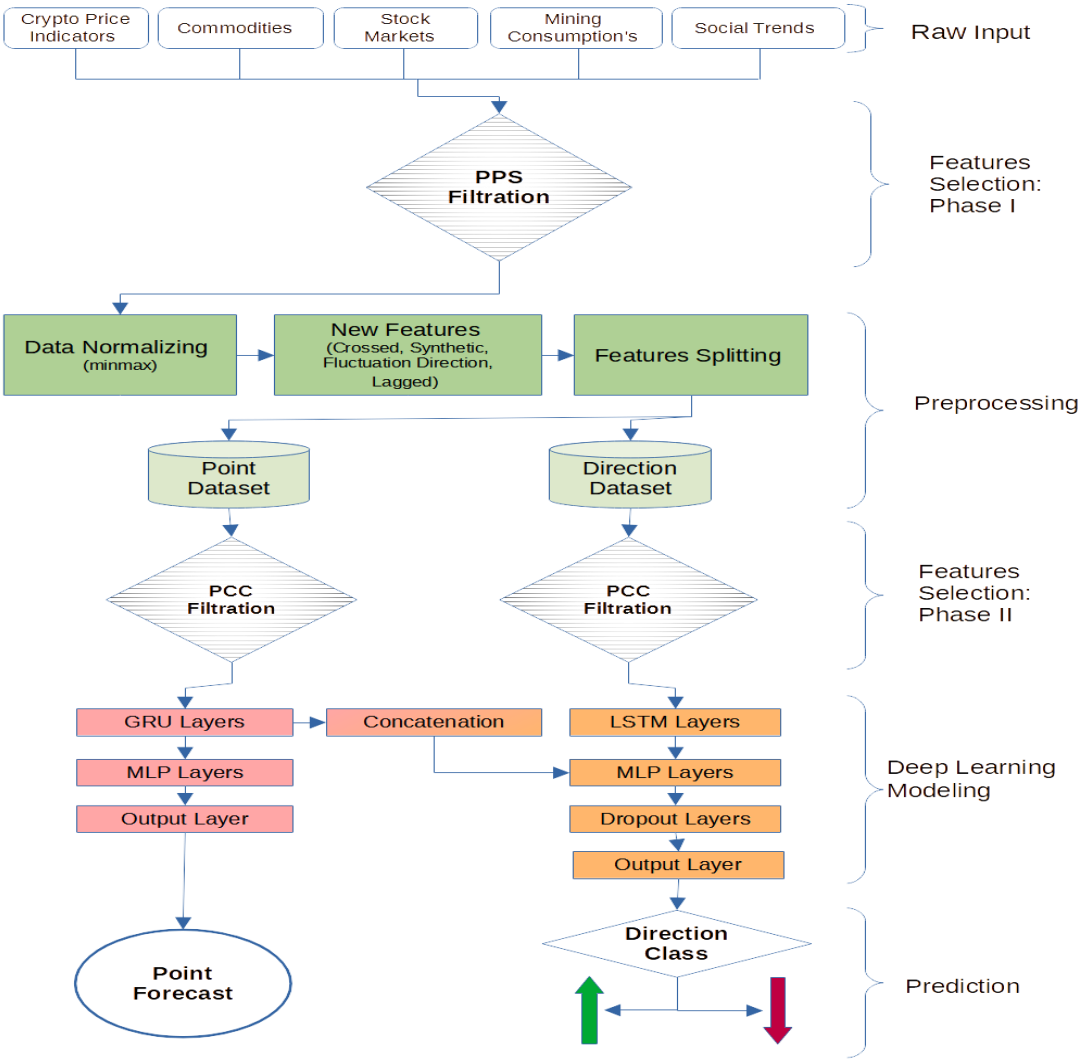

Fig. 4. System Diagram for the Proposed Cryptocurrency Model.

IV. Experiments and Results

A. Experiments Setup

We implemented the proposed model on python 3.8 platform. The deep learning library is Keras on top of TensorFlow. Hardware consists of nVidia GTX 1660Ti (6GB dedicated RAM), 16GB RAM and i7 10th generation 2.6GHz processor. Results shown are the highest of multiple trials with different combination of configurations. Average training time within range 65^{+}_{-} seconds with GPU accelerated computations. We split datasets in training /testing as 80% ratio.

For regression task, the model forecasts the price value of the next point. The regression branch of the model consists of two cascaded GRU layers of 256 neurons. Experiments show no benefit from applying recurrent dropouts. For the classification task of price movement direction, we trained the model with a list of two types of features: original and devised features.

B. Results and Findings

Results about bitcoin attained 92% accuracy score. We define accuracy as the overall proportion of correct predictions among the entire number of instances investigated. For regression, the proposed model achieved a score of 2.4 MAPE for bitcoin data. The overall performance metrics results are summarized in **Error! Reference source not found.**. Best classification achieved occurred with bitcoin data. As shown, the direction is successfully classified for all cryptocurrencies. Tether regression metrics are on top.

We can deduce no unique patterns or circumstances that are connected to the direction classification from the data. Fig 5 compares the classification of price movement direction to real data. The test data is shown in sub-figure (a) for the time period 3-2019 to 7-2021, with hits in blue circles and misses in red crosses. The data in sub-figure (b) is zoomed in to reveal one-month details. The true pricing data is shown by the green line.

TABLE III. Results Summary in Terms of MAPE and PR-AUC

Cryptocurrency		Regression		Classification	
	Mean ($)	**RMSE ($)**	**MAPE (%)**	**Accuracy**	**PR-AUC**
Bitcoin (BTC)	6690.87	850.8	2.28	92.1%	0.981
Ethereum (ETH)	425.6	82.03	3.17	90.26%	0.930
Tether (USDT)	0.999	0.0045	0.230	85.3%	0.853%
Binance Coin (BNB)	56.4	26.7	3.100	63.29%	0.743%

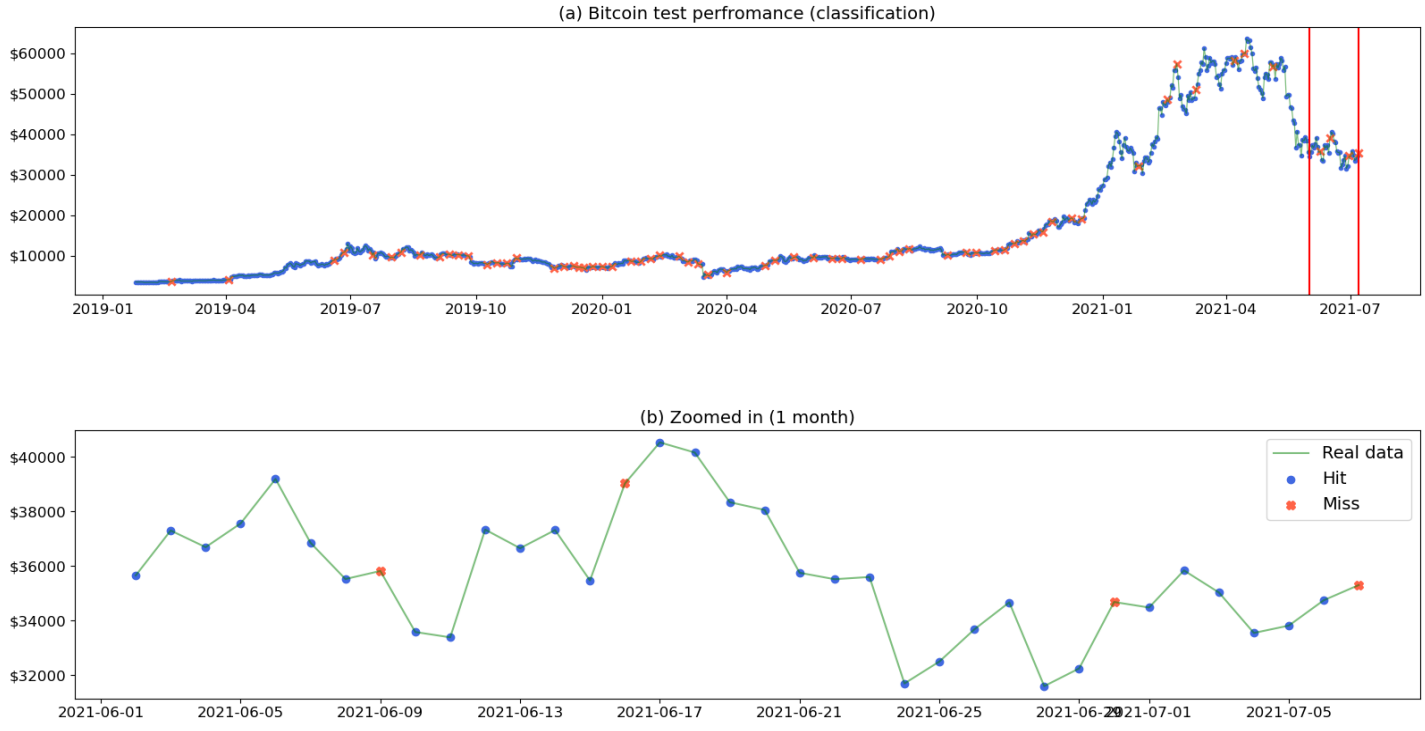

Fig. 5. Cryptocurrency Price Movement Classification Test Results (Hits and Misses).

Regression results shown in Fig 6 are in orange color. RMSE for bitcoin is 850.8. considering the scale of the bitcoin price which is extremely volatile from several thousands to tenth of thousands of dollars. RMSE don't reveal much about how good the regression results are. We can claim that MAPE is better representing the performance. In sub-figure (b), a one month zoom-in plotting illustrates the proposed model which performs a good job generalizing on unseen test data. In addition to forecast the next point, we forecast the 90% and 10% quantiles as a confidence boundaries (in sub-figure (b) as grey lines enclosing the real and forecasted values).

C. Comparison with Related Work

A Comparison with a three related deep learning work to the problem of interest reveals that the proposed model achieves highest accuracy in terms of classifying the next day price movement. From our perspective, adaptive features selection is a major contributor the results.

D. Profitability Simulation

We understand that traders must earn a profit at the end of the day. We use a basic trading algorithmic method to determine the projected profitability. We also use python code to implement it. The simulation method is naive since we simply want to illustrate how to utilize the anticipated results to prove the suggested model's profitability. Simulation results are shown as a waterflow chart in Fig 7. The simulation is based on the results of the tests (895 samples for bitcoin). The trade epochs were divided into 60 days period. The number of epochs is 15, with the first one beginning on March 3, 2019, and ending on July 7, 2021. The simulation resulted in 9 profits and 6 losses. The profit was 199038 dollars, with a return of 68.24 percent, on a maximum investment of 291690 dollars. Over time, the volume of profit and losses represents the rising and diminishing volatility of cryptocurrency trading prices and volumes, with the biggest earnings and losses accompanying the most spectacular jumps and falls, respectively.

E. Final Discussion

The predictive power score (PPS) method is used in Phase I of the feature selection procedure to exclude features that have little potential for cryptocurrency prediction. When using PPS, there are two variables to consider: 1) the threshold, which is the PPS score value used to determine if a feature is acceptable or not. 2) The effective sample size, which is the number of samples needed to compute the PPS score, or the cryptocurrency time period over which we are looking for the best predictors. The effect of these two factors on MAPE and accuracy is depicted in Fig 8. When we ignore predictors with a score of less than 0.3, as shown in sub-figure (a), the least regression MAPE value happens. In sub-figure (b), a score of 0.5 results in the most accurate price movement direction classification. When we limit the effective sample size to the last 500 samples of the training data in (c), we get the lowest MAPE value, and when we increase the size to 1000 samples, we get the maximum accuracy as shown in (d).

TABLE IV. COMPARISON WITH RELATED WORK

Model	Technique	Accuracy
RNN-based ensemble [37]	RNN-based ensemble with decision tree classifier	62.91%
CNN-BiLSTM [38]	Convolutional-based bidirectional LSTM	55.43%
Bayesian optimized LSTM [39]	Bayesian optimization LSTM	76.83%
The proposed model	RNN-based with adaptive features selection	**93.1%**

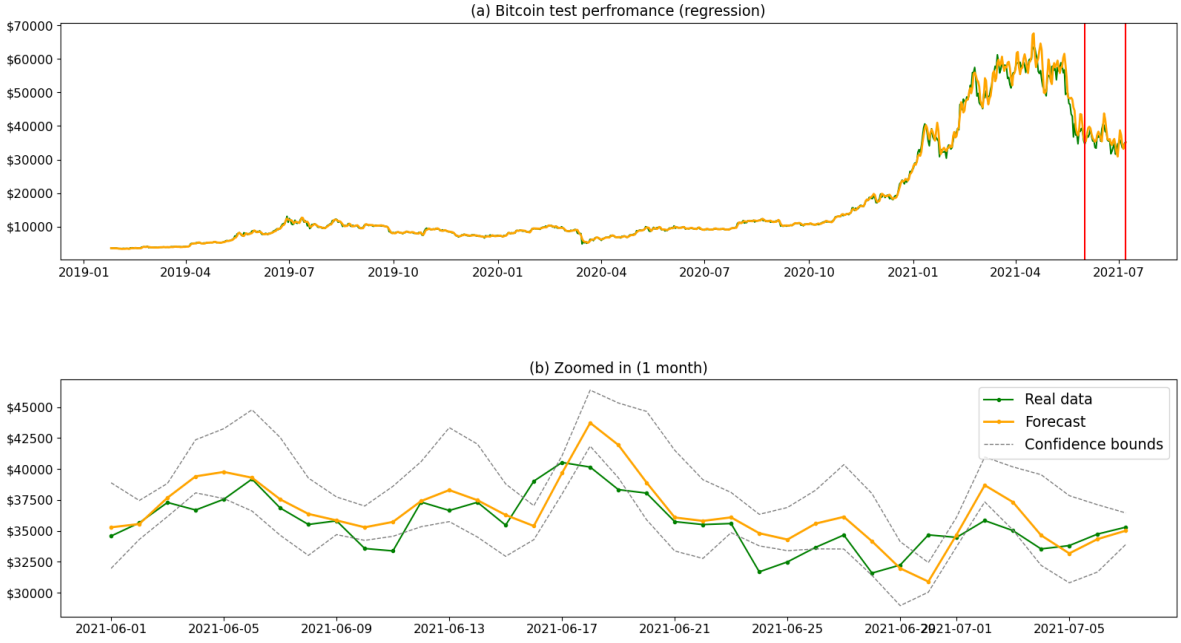

Fig. 6. Cryptocurrency Price Forecast Results (Next Point Forecast).

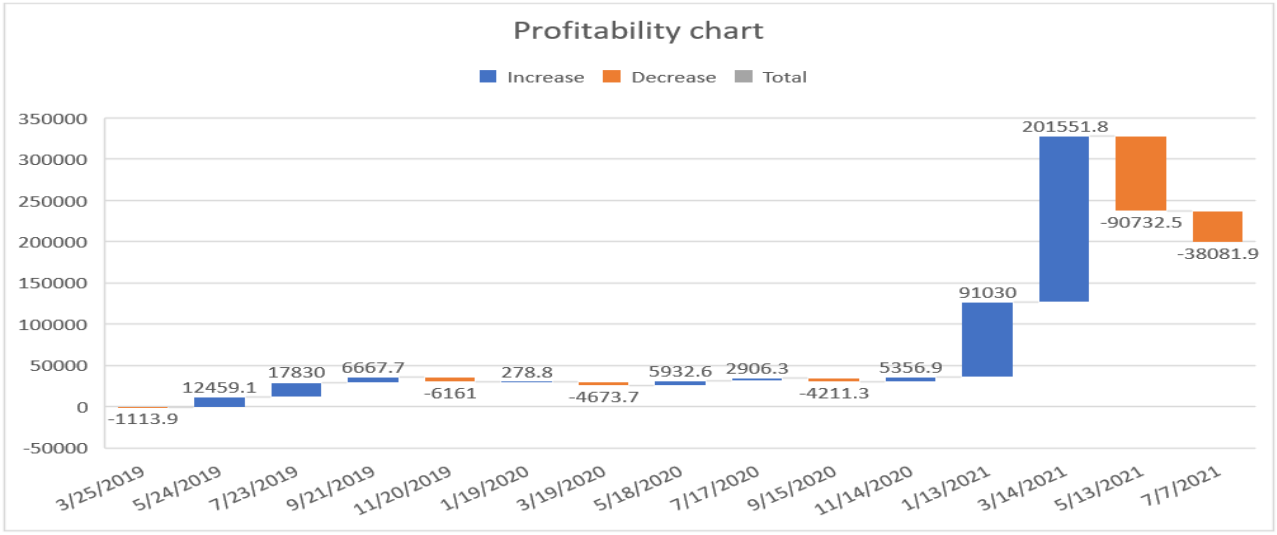

Fig. 7. Profitability Simulation Results.

The model's ability to forecast and classify accurately is influenced by the values of recurrent timesteps. Formally, the model needs to learn the probability of a sample y_{i+1} at time $i+1$, given the context $x_{i-t:i}$ of earlier t input features samples: $p(y_{i+1}|x_{i-t:i})$. RNN (LSTM, GRU, and other recurrent neural network variants) incorporate past data in addition to the current data point, which is the timestep parameter t passed to the RNN layers. Contextual-based prediction increases model performance. We may consider that point inside the problem of interest as follows: we use the earlier n days to properly forecast the price value and direction of the next day. $\widehat{y_i} = model(X_{i-t}^{i})$, where $\widehat{y_i}$ is the model prediction at point i, X_{i-t}^{i} input vector of t number of samples prior to i time, $t \in \mathbb{N}$ is the timesteps parameter. Sub-figures (a) and (b) shows model behavior with different timesteps values. Apparently, a timestep value of "7" gives lowest MAPE and highest accuracy.

The predictors vector is shifted back into the time domain using time lags. $lag_l = x_{t-l}$, where $l \in \mathbb{N}$ is the lag value, t is the time point. As an example, $lag_1$is using the previous day $t-1$ to predict the coming day t. $lag_2$is using the day before $t-2$ to predict the coming day t. Usually in seasonal data with high stationarity, autocorrelation function (ACF) analysis computes which time lag is best to be used as a predictor. In addition, in timeseries forecasting lags could be looked in as the forecast horizon. However, in case in hand, the situation is different since cryptocurrency timeseries data is a random walk and non-stationary, i.e., no seasonality, no steady statistical moments values and high variability. Augmented Dickey Fuller Test (ADF Test) on bitcoin "close" data give a p-value of "0.738698" which can be interpreted as *strong non-stationarity* property ($p-value > 0.05$). Fig 9 shows time lags from "1" to "7", lag_1 gives best performance. also, we notice accuracy keeps above 60% till lag_5, that means profitability still possible till forecasting horizon of 5-days (we limit the scope to daily data, forecasting long-term periods such as months requires a different data frequencies and different strategies).

In deep learning, hyper-parameters tuning task requires a lot of hands on efforts, and sometimes the task is automated [40]. Fig 10 depicts two model hyper-parameters: neurons per recurrent layers and dropouts. As we can notice, for regression layers, a "128" gives least MAPE and for classification, a "256" neurons give highest accuracy. For both tasks, a dropout of 0.1 is enough to have a positive impact on the predictions.

: 1) Are cryptocurrency prices predictable? And if so, is that due to inherent features of the pricing data? or as a result of external influences? 2) Which is more important in terms of profitability: predicting the next price value or predicting the future price direction (increase or drop) over a forecasting horizon? 3) Can deep learning algorithms accurately forecast the price of cryptocurrencies?

We have presented applied research to address both problems in cryptocurrency prices fluctuations, the next point forecast and next price movement direction classification. We have included several features grouped into cryptocurrency indicators ("open", "close", "low", "high" and "volume") and external factors gathered from various sources, including "SPX", "NYCE_BT", "GTrends_CRYPTO", and others.

The results of the experiments and the profitability simulation done in this study show that we can develop predictive model for two tasks using deep learning methods, particularly, recurrent neural networks algorithms: regression of the future pricing values and classification of the direction of price movement. A careful features selection strategy is mandatory to successfully identify good predictors and how to include them in learning process. Such results answer the third research question: "Can deep learning methods accurately forecast the price of cryptocurrencies and classify its movement direction?"

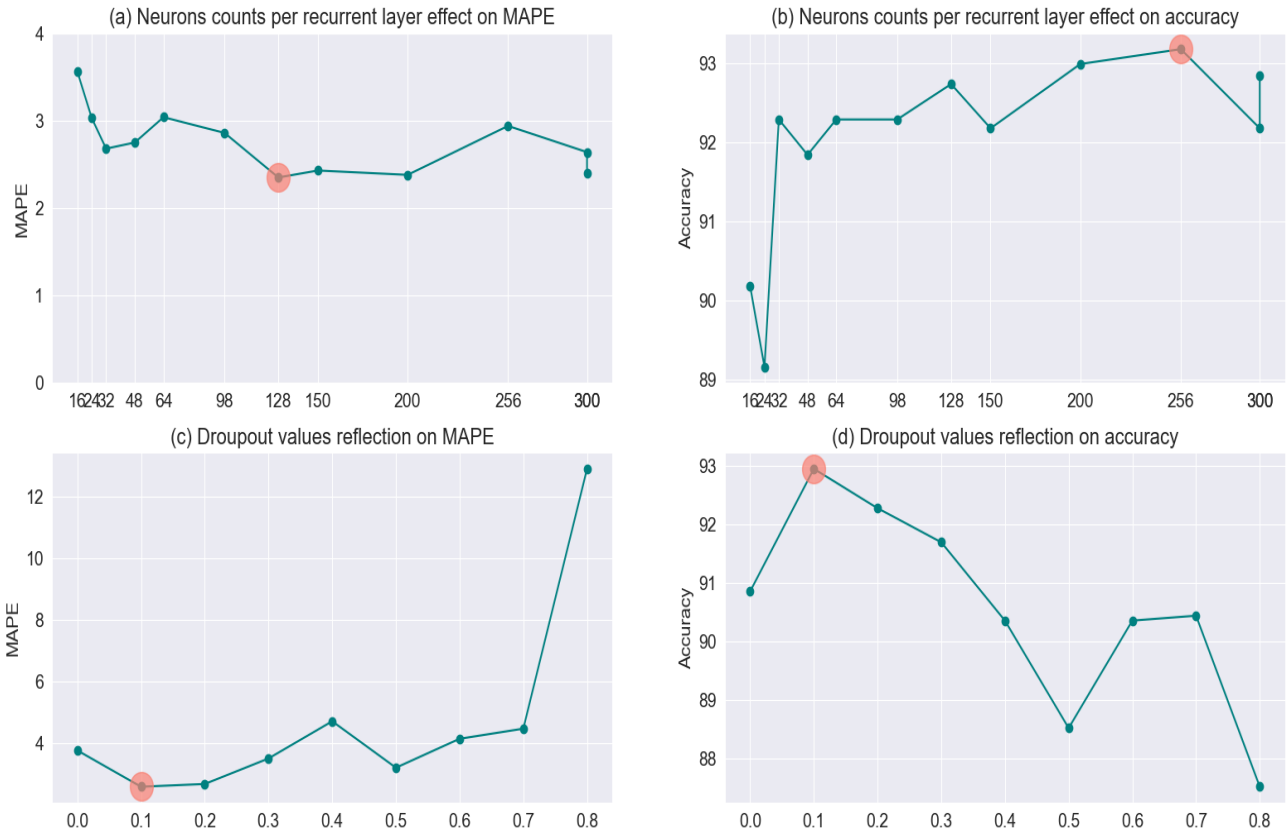

Fig. 10. Units and Dropouts Parameters Effect on Performance.

V. Conclusions and Future Work

This research presents a deep neural network model for bitcoin price/movement prediction based on a multi-input architecture. To determine which variables to include, a two-phase adaptive feature selection process is applied. As a result of this method, the data provided to the neural network has the maximum predictive power for the price. The results suggest that using an adaptive feature selection technique to improve classification performance has a significant influence. Future study could consider using more advanced deep learning architectures, such as attention mechanisms, to focus on key patterns in data. Another idea is to look at generative adversarial architectures for various speculative scenarios with varying levels of confidence. In addition, other external elements that correlate or have a degree of predictability with the bitcoin price movement should be included.

***Abstract*—Human Activity Recognition has been a dynamic research area in recent years. Various methods of collecting data and analyzing them to detect activity have been well investigated. Some machine learning algorithms have shown excellent performance in activity recognition, based on which many applications and systems are being developed. Unlike this, the prediction of the next activity is an emerging field of study. This work proposes a conceptual model that uses machine learning algorithms to detect activity from sensor data and predict the next activity from the previously seen activity sequence. We created our activity recognition dataset and used six machine learning algorithms to evaluate the recognition task. We have proposed a method for the next activity prediction from the sequence of activities by converting a sequence prediction problem into a supervised learning problem using the windowing technique. Three classification algorithms were used to evaluate the next activity prediction task. Gradient Boosting performs best for activity recognition, yielding 87.8% accuracy for the next activity prediction over a 16-day timeframe. We have also measured the performance of an LSTM sequence prediction model for predicting the next activity, where the optimum accuracy is 70.90%.**

***Keywords*—Machine learning algorithms; activity recognition; gradient boosting; next activity prediction; LSTM sequence prediction model**

I. Introduction

Rapid advancement in machine learning addresses a significant area of research, recognition, and human activity prediction. Predicting the next activity ahead of time can have a substantial impact on shaping and designing future technologies. A system needs to know the daily activities of a human to predict the next activity, which requires activity recognition. Recognition of an activity depends on capturing the movements and gestures made by different body parts. It is pretty challenging to correctly detect daily activities from a whole bunch of body movements. Again, the same activity can be performed in different ways. So, activity recognition has gained increasing interest in research in the past years. Activity prediction is the next step into the advancement of technology. From the recognized activities, a system would be able to predict what is going to be the next activity. It would be a massive leap towards reshaping the future, and the promise of such systems and technologies motivated this work to contribute to this field.

Activities are parts of Human behavior. An Activity consists of Actions. Three important terminologies are to be considered: Action, Activity, and Behavior [1]. Actions are a more straightforward form of conscious body movements like moving hands up and down, which form a specific action such as eating, running, walking, etc. All the actions a human performs in daily life contribute to creating his behavior, a complex structure of activities with a hidden pattern. Action data is needed to be captured by using different sensors for recognition of Activity. It can also be done from a video feed. Thus, we have two approaches for activity recognition- vision-based and sensor-based [1]. The vision-based activity recognition approach often turns into privacy concerns, so sensors get more attention in research and thus our area of interest.

In recent years, the consumer electronics industry has made a considerable investment in wearable technology. Companies produce many different wearable devices: fitness trackers, smartwatches, connected headsets, smart glasses, wrist bands, etc. Despite wearable devices not being new, the development of mobile technologies and the quantified-self movement related to fitness and sports activities have led to their explosion [2], [3]. Among the wide variety of wearable devices, wrist-wearables such as smartwatches and wrist bands seem to have become mainstream. Estimations indicated that by 2019 [4], wrist wearable devices would reach 1 million sold units, while all the other wearable devices together will achieve just 7.3 million units. In addition to other features associated with their reduced size and comfortable use, wrist-wearable devices include many sensors providing continuous data about vital signs (e.g., heart rate, skin temperature, acceleration) and environmental variables (e.g., movements). Such advancements in wearable technology create opportunities to study further by analyzing the data and developing new applications, technologies, and solutions.

Different context-aware systems such as personalized assistants, home automation, health monitoring, security management systems, etc., can benefit from activity data. The anticipation of the following activity will empower such systems to interact and perform more efficiently with users to improve context-aware experiences.

Predicting the next activity of a user requires previous activity data. So, a system that recognizes activity and stores activity information (e.g., activity name, timestamp, etc.) can be used for activity prediction. For activity recognition, it requires data for training a machine learning model. Our work includes data collection using a wearable device to build a recognition model to recognize the activity. Then the predictor model predicts the next activity from the sequence of recognized activities. We will focus on the following facts:

1) Collecting sensor data for building a machine learning model.

2) Deploying a machine learning model that best recognizes activity from collected data.

3) Storing activity information in a log file for creating an activity sequence.

4) Build another machine learning model to learn patterns in the activity sequence for predicting the next activity.

We intend to record sensor data generated from body movements and use the data to train Machine Learning Models to recognize activities. Further, the detected activities will be used for predicting the next activity for a specific user. There are different sensors available to collect required data, and these sensors can be positioned in various body parts. Sensor position is an essential factor in HAR (Human Activity Recognition) [5]. They can also be attached to home entities (e.g., bedroom doors, kitchen doors, refrigerators, washing machines, etc.) in a smart home setting. Some sensors are integrated into smartphones and smartwatches/fitness trackers. We propose to record data from a wrist wearable device because wrists are engaged in most activities in daily life, and the position is ideal for collecting data for activity recognition purposes [5]. Choosing the suitable machine learning model for this task requires effort [6]. In our proposed work, the prediction of the next activity depends on the recognized activity sequence. Though activity recognition is a widespread research interest, activity prediction is still moderately new and challenging. Several approaches have been adopted to predict activities which include Hidden Markov Models (HMM) [7], Recurrent Neural Networks (RNN), Long-Short Term Memory (LSTM) [5], etc. In this work, we intend to collect data from sensors positioned at the wrist, recognize activity and predict the next possible activity of a specific user in the nearest future by implementing machine learning models. This paper contributes to the following sectors:

1) We derive three new features from collected data and build an Activity Recognition Model that performs moderately well based on a reduced dataset.

2) We propose a novel approach to predict activity by converting the sequence prediction problem into a supervised learning problem.

3) We also explore an LSTM sequence prediction approach for the next activity prediction.

The study schemes to propose a model to recognize human activity from the data collected by the sensors of a wrist-wearable device and then predict the next possible activity from the sequence of previous activities. Section 2 contains a brief discussion about Activity Recognition and Activity Prediction and prior works related to these fields. The Architecture and System Workflow of our proposed model is described in Section 3. The evaluation of our work and results are covered in Section 4. Section 5 includes an insightful discussion of our findings.

II. Literature Review

Activity recognition is the process of recognizing an activity performed by a human. It is a machine learning approach to detect activity by analyzing data given as input to a machine learning model built on a machine learning algorithm. It is a way to teach a machine to recognize an activity.

It is a fundamental and challenging problem to track and understand agents' behavior through videos taken by various cameras—the primary technique employed in computer vision. Vision-based activity recognition has found many applications such as human-computer interaction, user interface design, robot learning, and surveillance. In vision-based activity recognition, a great deal of work has been done. Researchers have attempted many methods such as optical flow, Kalman filtering, Hidden Markov models, etc., under different modalities such as single-camera, stereo, and infrared. In addition, researchers have considered multiple aspects of this topic, including single pedestrian tracking, group tracking, and detecting dropped objects. Recently some researchers have used RGBD cameras like Microsoft Kinect to detect human activities. Depth cameras add an extra dimension, i.e., the depth which a regular 2d camera fails to provide. Sensory information from these depth cameras has been used to generate real-time skeleton models of humans with different body positions. This skeleton information provides meaningful information that researchers have used to model human activities, which are trained and later used to recognize unknown activities.

Despite the remarkable progress of vision-based activity recognition, its usage for most actual visual surveillance applications remains a distant aspiration. Conversely, the human brain seems to have perfected the ability to recognize human actions. This capability relies not only on acquired knowledge but also on the aptitude of extracting information relevant to a given context and logical reasoning. Based on this observation, it is proposed to enhance vision-based activity recognition systems by integrating commonsense reasoning and contextual and commonsense knowledge.

Sensor-based activity recognition integrates the emerging area of sensor networks with novel data mining and machine learning techniques to model a wide range of human activities. Mobile devices (e.g., smartphones) provide sufficient sensor data and calculation power to enable physical activity recognition to estimate energy consumption during everyday life. Sensor-based activity recognition researchers believe that these computers will be better suited to act on our behalf by empowering ubiquitous computers and sensors to monitor agents' behavior (under consent). Sensor-based activity recognition is a challenging task due to the inherently noisy nature of the input. Thus, statistical modeling has been the main thrust in this direction in layers, where the recognition at several intermediate levels is conducted and connected. At the lowest level where the sensor data are collected, statistical learning concerns how to find the precise locations of agents from the received signal data. At an intermediate level, a statistical inference may be concerned about recognizing individuals' activities from the inferred location sequences and environmental conditions at the lower levels. Furthermore, at the highest level, a significant concern is to find out the overall goal or sub-goals of an agent from the activity

sequences through a mixture of logical and statistical reasoning.

Activity Recognition can be done in various ways. Some AR works include only accelerometer data. Fernando G.D Silva [8] designed a recognition system for simple human body movements using a tri-axial accelerometer sensor integrated with a sports watch. Min-Cheol Kwon and Sunwoong Choi built a system for recognizing activity using accelerometer and location data generated from a wrist-worn smartwatch using an Artificial Neural Network. Their approach is location-specific; a user can only perform certain actions in a specific location. An activity recognition model based on a wavelet using one or more accelerometers was proposed by Mannini and Sabitini [9]. Casale et al. [10] used a wearable device for collecting accelerometer data for human activity recognition. Some works include multiple accelerometers. Chung, Lim, Noh, Kim, and Jeong [11] built a testbed to collect motion data using a tri-axial accelerometer, gyroscope, and magnetometer by attaching eight Inertial Measurement Units (IMU) devices on different parts of the human body. They trained that dataset using the Long Short-Term Memory (LSTM) network to recognize a few Activities of Daily Living (ADLs). Foerster and Fahrenberg [12] collected data using five accelerometers and proposed a hierarchical model to classify different body postures and movements. Beddiar, Nini, Sabokrou and Hadid [13] surveyed numerous vision-based human activity recognition research papers to describe the method of HAR. They featured three essential components of this approach, which are video frame segmentation for activity recognition, action representation of the body postures and motions and ML algorithms to recognise activities by learning process. Bao and Intille [14] used five biaxial accelerometers worn on other body parts to monitor 20 types of activities using C4.5 and Naive Bayes classifiers. Wallace [15] Ugulino proposed another ML-based recognition classifier to detect five different activities (sitting, standing, sitting down, standing up, and walking) using body-worn accelerometer data collected from 4 participants. Krishnan et al. [16] collected data from ten participants using three accelerometers to detect lower body motions. Samad Zabihi [17] used transformation of the accelerometer data (x, y, z) to a spherical coordinate system (r, Ø, θ) for activity recognition and extracted features from transformed data. Zhen-Yu [18] used tri-axial accelerometer data to build an autoregressive model to detect human activity. Different activities (run, still, jump, and walk) were classified using AR coefficients feature extraction. Huawei Wang [19] used Principal component analysis to reduce the dimensionality and selected 3 out of the 12 features of a dataset. Magnetic-induction based communication system is used for sensing and transmitting data generated by every movement of the body part to recognize a physical activity in [20] Acceleration data of a smartphone is investigated in [21]. Twenty-nine users participated in data collection, and each of them carried an Android phone in their pocket. They were asked to perform six activities: Walking, Standing, Sitting, Jogging, Stairs-Up and Stairs-Down. They used Logistic Regression, J48, and Multilayer Perceptron for the model evaluation. The accuracy was above 90%. They found it a little hard to differentiate between Stairs-Up versus Stairs-Down. For activity prediction purposes, the most popular approaches are to use Recurrent Neural Networks (LSTM) and Hidden Markov Model (HMM) [1]. This paper [22] shows the importance of prediction in intelligent environments. Most of the Prediction tasks are carried out as a sequence prediction.

Activity Prediction is the process of predicting an activity ahead of time that will be performed in the nearest future. It is a way to teach a machine to predict an activity by using machine learning models. Most of the prediction tasks carried out in the past are either in a Smart Home scenario to identify the next sensor that would generate the next event or from a video to infer what will happen next. Personalized activity prediction is still a new concept and is merely investigated as a research topic. An activity can be predicted for a specific user by learning from the pattern of activities performed previously by that user. So, the activity prediction problem can be formulated as a sequence prediction problem. Sequence prediction is a problem that includes using historical sequence information to predict the next value or values in the sequence. Various methods are available for sequence prediction, but Recurrent Neural Networks, especially LSTMs, have been the best in use.

Predicting future activity empowers different applications like personal assistants and context-aware systems to interact more efficiently with the user. The problem of next activity prediction is often addressed as sequence prediction, which can be adapted to predict the label of the activity that will occur next in the sequence. Du, Lim, and Tan [23] performed activity recognition on some ADLs to generate a series of activities and then implemented LSTM and Naive Bayes to find the accuracy of predicting the next activity. The active LeZi algorithm is implemented in this [24] work to identify the sensor in a home that would generate the next event. There have been works on predicting the next location [25] and user's location-based mobility [26]. Location-based human behavior is focused in these papers and is subject primarily to using the Markov models. Markov models lack the flexibility to explore past activities instead of making a prediction based on only the most recent previous state. This feature restricts Markovian models from getting high-level insight into the data. Another popular method is Sequence mining that can be used to address such problems [27]. A dataset consisting the name of activities was generated from a collection of human actions using mapping and word embedding using LSTM algorithms to predict the future activity was implemented in [28]. Some activity prediction works are also found to be vision-based [7], [29], [2]. Alfaifi and Artoli [30] evaluated recent improvements in activity prediction and proposed a 3D-convolutional neural network model that extracted features and classified them to predict the action by LSTM.

III. Architecture of Proposed Solution

In this paper, we intend to propose a conceptual model for activity recognition and next activity prediction. The model complements the existing wearable technology architecture [31]. As illustrated in Fig. 1, the current architecture has three main components: a wrist-worn device (i.e., fitness tracker/smartwatch), an intermediate medium (i.e., Smartphone, computer), and a server/cloud service. It follows

a Proprietary system. Wearable vendors use this system for data collection and analytics and send the analytical result to the user and the authorized third parties [31]. A wrist-worn device is used to collect data using the sensors integrated into it. Theoretically, the device should be capable of sending data directly to the server for permanent storage, but it is not in use [31].

It sends data to the server/cloud service via the intermediate platforms. The server performs analytical operations to generate insight from data and sends it back to the middle layer as an interface for the wearable device. Our work will enhance the analytical capability by adding the feature to recognize an activity with a machine learning model. The model will take a chunk of sensor data from the device as input and generate a label for that movement (i.e., activity). After successfully recognizing activities and storing them as an activity sequence for a certain period, another machine learning model will take the sequence of activities as input and predict the next possible activity.

The first task of our proposed work requires data for building an activity recognition model. A fitness tracker or smartwatch is the best solution for collecting such data, integrated with different sensors. Still, we have used a smartphone for data collection and storage simplicity, tying it on the participants' hands like a tracker/smartwatch. This approach has collected the desired data but with more straightforward storage options as we could save it directly as CSV files. We have used an android app named 'AndroSensor'[1] available on the Google Play Store to collect data. We have recorded accelerometer, gyroscope, and sound level data and also kept timestamps. The data recording rate has been set to: 0.125 s/per data (instance).

Table I shows the value of the day-of-the-week and corresponding value. One is a weekday, and another is the weekend. We have considered Sunday, Monday, Tuesday, Wednesday, Thursday as weekdays while Friday and Saturday as weekends according to local holidays. Table II illustrates time-of-the-day data. Furthermore, the datasets have used in this study can be categorized into two types: recognition dataset and prediction dataset. We have selected ten activities (Table III). Here, we have held a common assumption: A user will not perform multiple activities simultaneously. The recognition dataset consists of 330993 rows and ten columns. It has contained acceleration values of x, y, z-axis, orientation values of x, y, z-axis, sound level (in DB), day-of-the-week (Weekday/Weekend), time-of-the-day (Morning, Noon, Evening, Night). The last two features have been generated from a timestamp—the acceleration data of x, y, and z-axis have depicted hand movement through the corresponding axis. We have also considered the orientation data of the x, y, z-axis because sometimes there were activities that did not generate insightful acceleration data. Some activities have been performed in specific places, e.g., we have taken transport in noisy places rather than a closed room. So, the sound level has played an essential role in recognizing activities accurately.

In the data pre-processing task, we have converted timestamp data into day-of-the-week (Table I) and time-of-the-day (Table II). Sound level, day-of-the-week, and time-of-the-day are three novel features we have introduced in our research. A human annotator has labeled the collected data according to activity labels (Table III). There have been three participants; two of them were male and one female. Each of them has collected data for three consecutive days consisting of two weekdays and one weekend. This dataset has been used to detect activity.

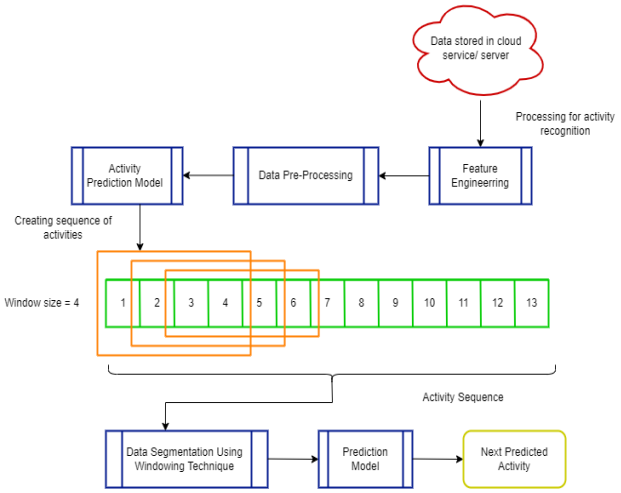

Fig. 2. System Workflow.

Fig. 2 depicts the workflow of our approach in this study. Our proposed model is initiated after data is collected by a wearable device and sent to the server. Feature engineering and data pre-processing are performed on the stored data for efficient modeling.

In our conceptual system architecture, data is then sent to the recognition model. In this study, we have investigated six machine learning algorithms: Artificial Neural Network (ANN), K-Nearest Neighbor (KNN), Naïve Bayes (NB), Random Forest (RF), Support Vector Machine (SVM), and Gradient Boosting (GB) to recognize activities. When the model has started identifying activities, the labels were sent to a pipeline to create a sequence of activities. We have implemented a windowing technique to extract data from the pipeline to prepare the dataset for the next activity prediction.

Activity prediction is a user-centric process. When the activity recognition algorithm is implemented in the wearable technology architecture, it starts detecting the user's activities. So, we propose that the sequence of activities will be stored in a log file and used as the dataset for prediction purposes. We have collected data for some consecutive days to make a sequence of activities for demonstrating the activity prediction problem.

The prediction dataset used in this paper has been prepared by recording activities for eight consecutive days and sixteen days to evaluate the model performance regarding time. As prediction of the next activity depends on a specific user's behavior, data has been collected from one participant. The prediction model has taken previous activities and the current activity into consideration for predicting the next activity. Table IV shows a glimpse of the sequence of activities performed by the participant. Hence, it has a various number of attributes depending on the window size we choose. Depending on different window sizes concerning 8 days and 16 days, the number of rows has differed in the prediction dataset.

TABLE IV. SEQUENCE ACTIVITIES

1	6	4	5	10	2	6	3	1	…..

TABLE V. TRANSFORMED DATA FOR NEXT ACTIVITY PREDICTION (WINDOW SIZE = 3)

	Prev_act2 (Feature 1)	**Prev_act1 (Feature 2)**	**Curr_act (Feature 3)**	**Next_act (Target)**
1	1	6	4	5
2	6	4	5	10
3	4	5	10	2
4	5	10	2	6
5	10	2	6	9

We have introduced a novel approach for the next activity prediction. We have transformed the sequence of activities into a feature and target-shaped data frame by implementing the windowing technique. It creates the opportunity to use the transformed sequential dataset in a supervised learning problem predicting human activities. Table V shows a sample of the dataset for the next activity prediction, where the window size is 3, which features were used as input and the target as output for the prediction model.

We propose another approach to predict the next activity, as shown in Fig. 3. An LSTM sequence prediction approach is adopted to predict the next value in the activity sequence.

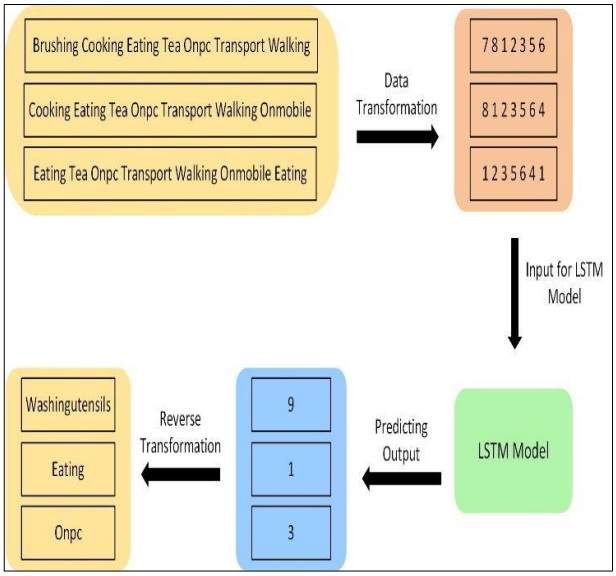

Fig. 3. LSTM Sequence Prediction Workflow.

IV. RESULT AND DISCUSSION

We have used python with scikit-learn ML packages for the Machine Learning algorithms implemented in our study [32]. Keras and Tensorflow are used to implement LSTM. Some modifications have been made in the default hyperparameters of the ML algorithms to achieve better accuracy. The codes run in the Anaconda Jupyter Notebook (Version3).

Fig. 4 illustrates the accuracy comparison of the six algorithms for activity recognition. For the Artificial Neural Network, the number of hidden layers has played an important role. The accuracy for the 3-layer network was 98.99% and for the 7-layer network was 99.01%. However, we have

considered the outcome of five hidden layer networks, as it performed the best for this dataset with an accuracy of 99.1%. On the other hand, the K-Nearest Neighbor yielded an accuracy of 99.2%. Where the accuracy of the Random Forest was 99.3%, for the Support Vector Machine, it was 98.7%. Though the Naïve Bayes performed poorly, having an accuracy of 61.9%, among all the six ML algorithms, the Gradient Boosting showed the highest accuracy of 99.7%.

As mentioned earlier, in this study, we have introduced three novel features: sound level, day-of-the-week, and time-of-the-day. These trio features help to detect the activity more accurately. As a comparison, we have run all six algorithms on the same dataset without these trio features.

Fig. 5 clearly describes that all six algorithms' accuracy had reduced compared to Fig. 4. Yet, Gradient Boosting had the best accuracy of 98.8%, and Naïve Bayes yielded the lowest accuracy of 54.4%. In comparison, the accuracy differed by around 2% for all the algorithms except for Naïve Bayes. Naïve Bayes accuracy difference was almost 7%.

After studying the accuracy score of the six implemented ML algorithms in the previous section for activity recognition, we can see that GB gave the best result [99.7%], where the nearest result was shown by KNN and the bagging algorithm Random Forest with an accuracy rate of 99.2% and 99.3% respectively. As we know, both bagging and boosting are ensemble methods and perform better compared to other ML algorithms. So, as expected, both of them have the highest accuracy among all six algorithms.

Fig. 6 explains the confusion matrix of our best model for detecting human activity, Gradient Boosting. Almost all the instances of the actual class have been predicted accurately by the model. Specifically, the activity 'Walking' is labeled as activity no. 4. Of all the instances of 'Walking,' data has been predicted correctly as 'Walking' with an accuracy of 99.9%. Also, the instances of other activities have been predicted correctly with varying accuracy from 98.8% to 99.8%.

For predicting the next activity, we have used two timeframes. The first one was a prediction on an 8 days activity sequence and the second one was on 16 days. We have used 3 ML algorithms to check the accuracy, e.g., ANN, KNN, GB. We have experimented with different window sizes to observe the effect on accuracy.

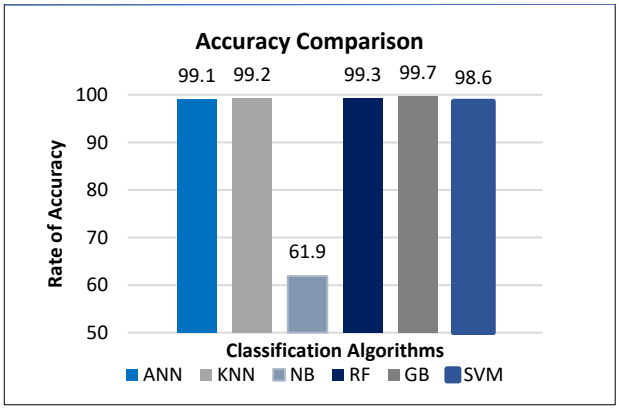

Fig. 4. Accuracy Comparison for Activity Recognition.

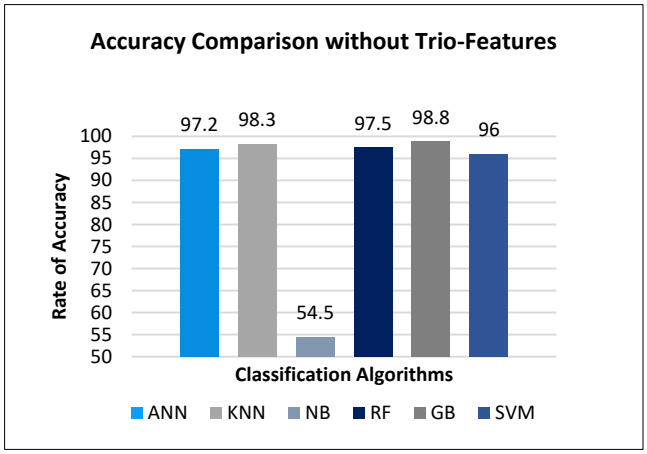

Fig. 5. Accuracy Comparison without Trio-Features.

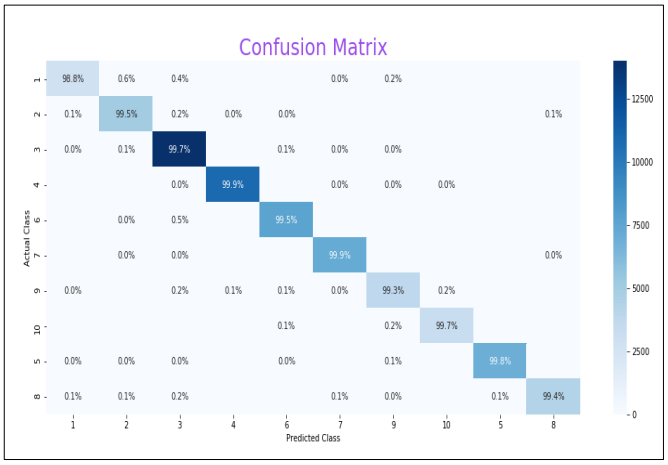

Fig. 6. Confusion Matrix of the Best Model (Gradient Boosting).

Here we have kept both training and test accuracy in determining if the models have overfitting or underfitting issues. For an 8-days timeframe, window size (W) was taken from 2 to 6 with an interval of 1 to explore the effect of window size on accuracy comparison. Fig. 7, Fig. 8, Fig. 9 show the accuracy comparison of training and test for 8 days on ANN, KNN, GB for predicting the next activity, respectively.

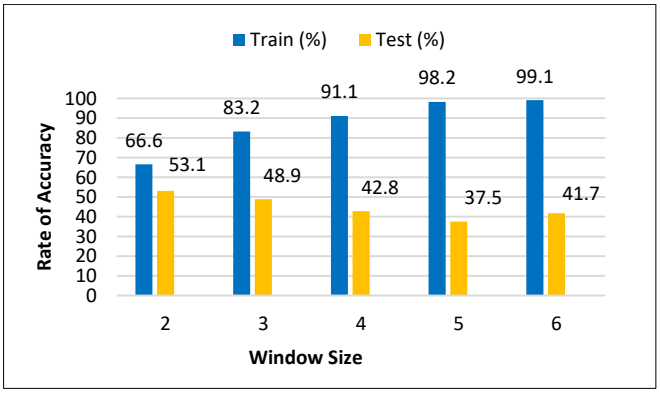

Fig. 7. Accuracy Comparison (8 Days) with varied Window Size for ANN.

Fig. 7 illustrates that an increase in window size increases training accuracy but decreases test accuracy. At W = 2, ANN yielded the highest test accuracy of 53.1% but kept lowering with the window size increase.

Similarly, in Fig. 8, training accuracy increases with the increase of window size, but there is a sudden drop at W = 6. However, the highest test accuracy for KNN was 46.9% at W = 2, 3. The test accuracy gradually kept decreasing with the change of window size. KNN showed similar behavior as ANN to predict the next activity from the activity sequence of 8 days.

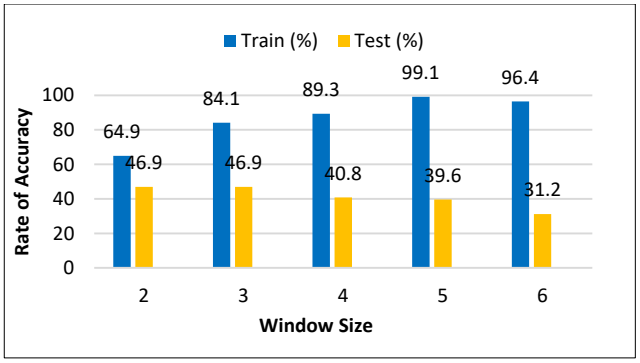

Fig. 8. Accuracy Comparison (8 Days) with varied Window Size for KNN.

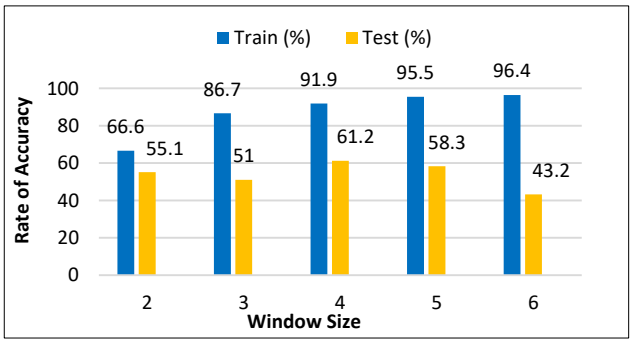

Fig. 9. Accuracy Comparison (8 Days) with varied Window Size for GB.

Fig. 9 displays that with the change of window size, training accuracy kept increasing. In the case of testing accuracy, there was some fluctuation of performance for varied window sizes. Notably, for W = 4, GB showed the best result of 61.2% accuracy.

We can sense a trend in training and test accuracy with varied window sizes. In most cases, for all the algorithms, an increase in window size increases training accuracy but results in a gradual decrease in test accuracy. So, there is a hint of slight overfitting of data here. Now we will be analyzing the same for a more extended timeframe of 16 days of activity sequence.

For a 16-days timeframe, the window size varied from 2 to 8. For predicting the next activity, the accuracy comparison of training and test for 16 days on ANN, KNN, and GB is illustrated in Fig. 10, Fig. 11, and Fig. 12, accordingly.

Analyzing Fig. 10, it can be said that, while training accuracy increases with the increase of window size, testing accuracy varies significantly. The highest test accuracy was yielded at W = 6, which was 81.6%.

Similarly, in Fig. 11, for KNN, training accuracy increased with the change of window size. KNN also varied for test accuracy, but like the previous one, it performed best at W = 6, 82.7%.

The accuracy comparison for GB on 16 days dataset is graphed in Fig. 12. With the increase of window size, training accuracy kept increasing. GB also yielded the highest accuracy of 87.8% at W = 6.

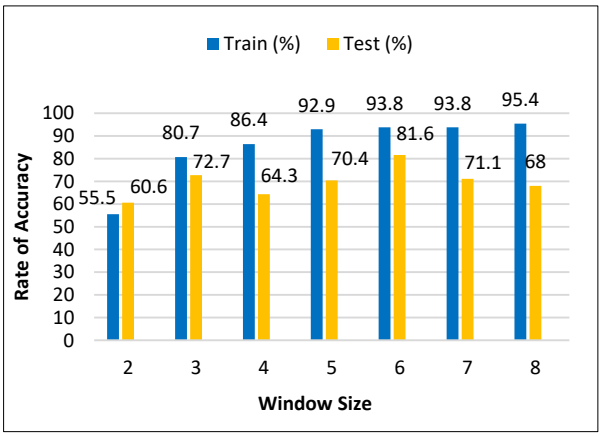

Fig. 10. Accuracy Comparison (16 Days) with varied Window Size for ANN.

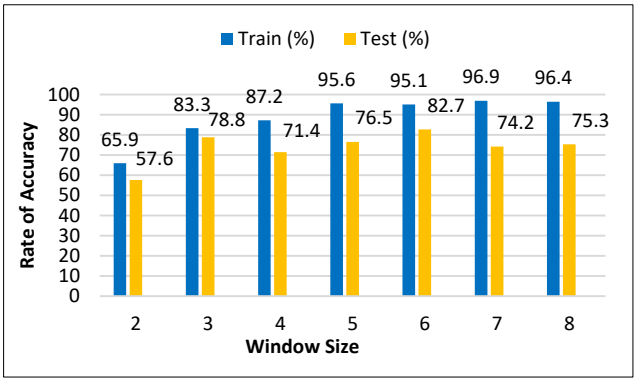

Fig. 11. Accuracy Comparison (16 Days) with varied Window Size for KNN.

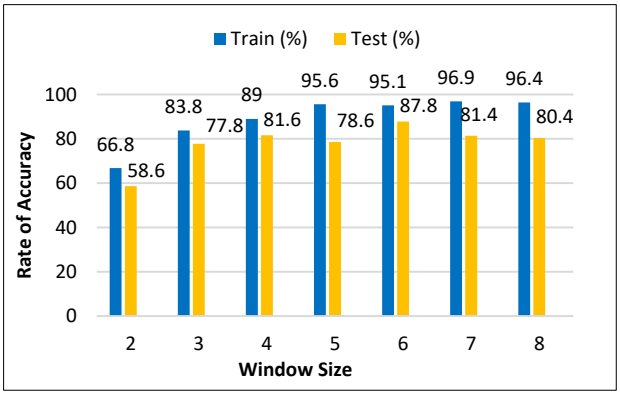

Fig. 12. Accuracy Comparison (16 Days) with varied Window Size for GB.

After vivid exploration of the above cases, a longer timeframe of activity sequence yields better performance for

predicting the next activity. Also, we can say that the algorithms are prone to overfitting with smaller timeframe datasets.

Observing Table VI, it can be said that increasing the window size gives a good test accuracy compared to the training accuracy for a specific limit. The training accuracy increases with the increase of window size. Just a small exception in the case of KNN when the window size was changed from 5 to 6, it decreased instead of increasing. But in the case of testing, while changing the window size from 4 to 5, the test accuracy started to decline and continued for all the algorithms. On the other hand, Table VII indicates the accuracy comparison between the training and testing dataset for 16 days. Unlike Table VI, after increasing the window size with an interval of 1, GB's testing accuracy was quite good, though the accuracy decreased for ANN and KNN on some points.

For training accuracy, we can say that the accuracy increased gradually with the change of the window size. Though after size 5, it decreased for some, at size 7, it rose again. It can be determined that for ANN and KNN the test accuracy varied while increasing the window size after analyzing Table VII. But for GB, the accuracy increased up to window size 6, and after that, it started to decrease even though the window size was increasing. This was the purpose of considering a higher range of window size for16 days compared to 8 days.

TABLE VI. TRAINING AND TESTING ACCURACY (8 DAYS) WITH VARIED WINDOW SIZE

Window Size	ANN		KNN		GB	
	Train (%)	Test (%)	Train (%)	Test (%)	Train (%)	Test (%)
2	66.6	53.1	64.9	46.9	66.6	55.1
3	83.2	48.9	84.1	46.9	86.7	51.0
4	91.1	42.8	89.3	40.8	91.9	61.2
5	98.2	37.5	99.1	39.6	95.5	58.3
6	99.1	41.7	96.4	31.2	96.4	43.2

TABLE VII. TRAINING AND TESTING ACCURACY (16 DAYS) WITH VARIED WINDOW SIZE

Window Size	ANN		KNN		GB	
	Train (%)	Test (%)	Train (%)	Test (%)	Train (%)	Test (%)
2	55.5	60.6	65.9	57.6	66.8	58.6
3	80.7	72.7	83.3	78.8	83.8	77.8
4	86.4	64.3	87.2	71.4	89.0	81.6
5	92.9	70.4	95.6	76.5	95.6	78.6
6	93.8	81.6	95.1	82.7	95.1	87.8
7	93.8	71.1	96.9	74.2	96.9	81.4
8	95.4	68.0	96.4	75.3	96.4	80.4

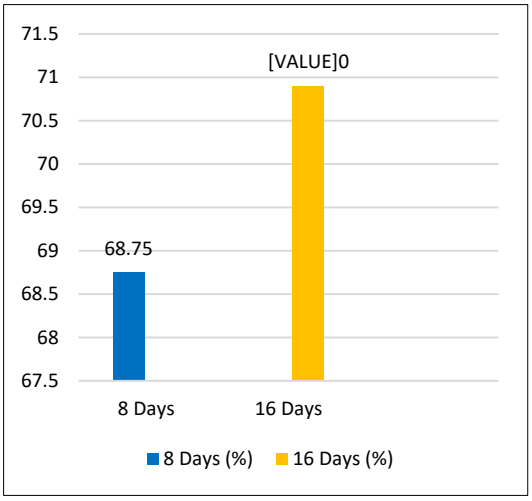

Fig. 13. Accuracy Comparison (8 Days vs. 16 Days) LSTM Activity Prediction.

Fig. 13 shows an accuracy comparison for the LSTM model used for predicting the next activity. Here we have assessed the performance of the model in a limited way. The model is assessed under timeframes of 8 and 16 days but considered a fixed window size for each timeframe, unlike the previous method that used varied window sizes. For the 8 days' timeframe, window size 6 was taken, and it was 8 for 16 days. It showed slightly better performance for a longer sequence of activities of 16 days than 8 days. For the 8 days' timeframe, the model yielded an accuracy of 68.75% and 70.90% for 16 days. We observe a similar behavior of the LSTM model performing with better accuracy for a longer timeframe, just like the previous method.

Both the supervised model and LSTM had performed well for predicting the next activity for an individual when there was a long activity sequence. Fig. 14 shows a performance comparison between LSTM and the supervised model used for predicting next activity. For 8 days timeframe and window size 6, LSTM outperforms our best-supervised model. But in the longer timeframe of 16 days and window size 8, the supervised model performs better than LSTM.

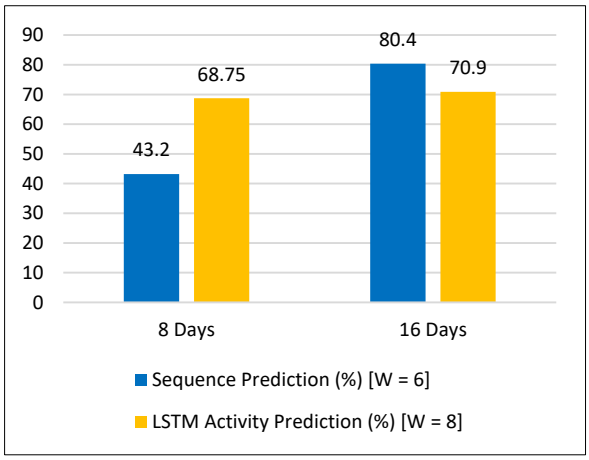

Fig. 14. Accuracy Comparison between Supervised Model and LSTM Activity Prediction (8 Days vs. 16 Days).

Hence, we can conclude that both the methods used for predicting the next activity perform better with an extended timeframe of activities.

Compared to the current work, our proposed model includes three new novel features: sound level, day-of-the-week, and time-of-the-day while collecting data. Moreover, the activities chosen to be recognized shows deviation quantitatively. Various machine learning algorithms have been applied, and their accuracy is as good as the current work. Furthermore, we have converted a sequential dataset into a supervised learning model, which was not conducted in previous work. The accuracy rate of the LSTM model for activity prediction performed better than the existing surveys.

To summarize, our proposed models show a significant outcome. The Gradient Boosting produced 99.7% accuracy out of all six algorithms for recognizing activity. In addition, a longer timeframe with a longer day count performs better than others for predicting next activity. Sequence and LSTM activity predictions provide 80.4% and 70.9% accuracy respectively for a 16-day timeframe with window size 8.

V. Conclusion

Due to resource constraints, we could not use a smartwatch or any wearable device to collect data; instead, we used a smartphone tying it on the wrist, which worked just like a wrist wearable. For data collection, we had to depend on only 3 participants. The work can be best understood and explained by deploying it in real-time. But we had to work with batch processing due to the lack of high-end machines and components.

This paper proposes a conceptual model for activity recognition and prediction, which can be extended with the existing wearable architecture. We have shown how sound level, day-of-the-week, and time-of-the-day can improve activity recognition model accuracy. We adopted a straightforward but effective approach to convert a sequence prediction problem into a supervised learning problem to predict the next activity. The accuracy was moderate, considering the dataset we have. We have also used a Long-Short-Term Memory (LSTM) model to explore the prediction process. The model we developed has shown good performance, yet the result is not always accurate.

Our models have shown promise for both activity recognition and prediction. Wearable technologies and home automation, security systems, and health monitoring systems can significantly leverage this concept. By integrating our model in a smartwatch or a wrist-worn wearable architecture, this unique technology can be readily available to common people. Predicting the next human activity can create a significant impact on existing and future technologies.

The next activity predictor model predicts the next activity based on previously detected activities. Prediction model accuracy depends mainly on the timeframe. The comparison between the 8 days dataset and 16 days dataset clearly shows the difference. If the dataset is sufficiently large and the hyperparameters are appropriately tuned, we expect a far better result. We have noticed that both prediction models yield better accuracy with a larger window size when the time frame increases from 8 days to 16 days. Though it is difficult to say which model can predict the next activity of a person more accurately, for different timeframes with different window sizes, both the supervised learning model and LSTM perform differently. We have a plan to extend our research with more participants.

Moreover, we want to determine if it is possible to predict which approach performs more precisely using even more timeframes with different window sizes. We will also investigate the fact that if there is any correlation between timeframe and window size. We intend to further mature this proposed model by implementing it in real-time with streaming data. In the future, we will try to make predictive modeling more efficient by incorporating timestamps in the model and the activity to create time series forecasting. We also intend to introduce some more valuable features and recognize more new activities. Furthermore, a recommendation system can be designed based on the predicted activity. The recommender system will use the next activity data indicated by the model to make corresponding recommendations.

***Abstract*—Object detection in general and pedestrians in particular in images and videos is a very popular research topic within the computer vision community; it is an issue that is currently at the heart of much research. The detection of people is a particularly difficult subject because of the great variability of appearances and the situations in which a person may find themselves (a person is not a rigid object; it is articulate and unpredictable; its shape changes during its movement). The situations in which a person may find themselves are very varied: They are alone, near a group of people or in a crowd, obscured by an object. In addition, the characteristics vary from one person to another (color of the skin, hair, clothes, etc.), the background simple, clear or complex, the lighting or weather conditions, the shadow caused by different light sources, etc. greatly complicate the problem. In this article, we will present a comparative study of the performance of the two detectors Haar-AdaBoost and HOG-AdaBoost in detecting people in the INRIA images database of persons. An evaluation of the experiments will be presented after making certain modifications to the detection parameters.**

***Keywords*—Pedestrian detection; learned-based methods; Haar-like features; HOG descriptor; AdaBoost; behavior analysis**

I. Introduction

The detecting of people in images is a very important subject in the field of computer vision. The pedestrians' detection is therefore a main concern of several researchers in the field of computer vision. These applications, ranging from surveillance, retail data mining and automatic pedestrian detection in the automotive industry, have fueled research over the past decade, leading to a growing number of approaches on the subject [1].

Many factors can influence the human figure, such as the constantly changing appearance, crowds, obscuration by objects, the type of environment and the unpredictability of pedestrians [2, 3].

In the literature, we find techniques that require segmentation or subtraction of the background and others directly detect the person without such preprocessing. These techniques use many characteristics to describe human appearance (shape, color, movement) in order to build shape models used on explicit or learning-based detection techniques.

Several systems have been developed in this context with dynamic methods such as Phantom [4] and Pfinder [5]. Other methods have been conducted [6, 7, 8, 9] for the detection of people with a measure of their activity in video sequences. Shooting with a fixed camera allows background subtraction to reduce search space. Finally, we find the system that performs fast and accurate human detection by integrating the cascade approach with histograms of gradient directions [10, 11].

Among these approaches, we find a so-called global one that has a principle of using the shape of the whole body as a source of information without taking into account local characteristics [10, 12, 13]. Viola and Jones [14, 15] [16] also proposed a detector based on Haar filters and the boosting algorithm. There are some aspects of this algorithm, based on infrared vision to detect a human in a room and provide a history of occupancy of the room.

Another so-called local approach uses local characteristics. Here we extract the characteristics from the image base and then we build the discriminating model, for example, Papageorgiou [17] that proposed a detector based on the Haar wavelet.

The latest so-called hybrid approach combines local and global characteristics to improve recognition performance [18].

The research work proposed in this article aims to contribute to the shapes (or objects) recognition modeling methods and more particularly of pedestrians by descriptors classification containing the most relevant information of an object and applying the models found to the human silhouette (people or pedestrians) detection in images or multimedia streams (video).

II. Learning Methods for Human Detection

The main approaches based on discriminate learning train different types of classifiers on a large number of samples of negative and positive images, where humans are well framed.

Each method must extract the appropriate characteristics and the main information captured from the training data is the spatial recurrence of local shape events. If the trained classifier does not detect an object (misses the object) or mistakenly detects the absent object (false detection), it is easy to make an adjustment by adding the corresponding positive or negative samples to the learning set.

However, due to the complexity of articulated human poses and variable visualization conditions, training data becomes very large (especially positive samples) therefore the generalization ability of the trained classifier may be compromised.

The Fig. 1 shows an illustration of the data formation process that is common basic in all detectors.

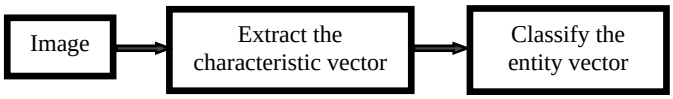

Fig. 1. Common Learning Process.

III. Study of Haar-AdaBoost and HOG-Adaboost Detectors for the People Detection

The study which we carried out in the paper [19] of 14 traditional techniques resulting from the literature and representing the state of the art allowed us to choose the two most popular methods in the detection of the objects Haar-AdaBoost (VJ, Viola and Jones) [14, 15] and HOG-AdaBoost (PoseInv, Pose-Invariant) [20] which constitutes a variant of HOG-SVM [12] (SVM design a Support Vector Machine classifier [21]) to study their feasibility for detecting people.

Note that the detectors Haar-AdaBoost and HOG-AdaBoost uses respectively the Haar-like features (or Haar wavelets) [14, 15, 17] and HOG (Histograms of Oriented Gradients) descriptor [12] to extract the characteristic vector from an image of person and they are based on the same classifier AdaBoost [21] to classify this vector. AdaBoost is one of the most powerful binary classification methods in supervised learning, its uses an iterative selection of weak classifiers based on a distribution of learning examples. Each example is weighted according to its difficulty with the current classifier. The main motivation for boosting was to form a procedure which combines the output of several weak binary classifiers to produce a powerful binary classifier [22].

In this approach we will present the experimental results carried out in the Computer Science and Systems Engineering Laboratory of the Faculty of Sciences of Tetouan for evaluing people detection in images using the two detectors Haar-AdaBoost and HOG-AdaBoost.

The performance analysis of these two detectors was carried out on the people images database from INRIA Person Dataset (http://pascal.inrialpes.fr/data/human/). This database provides 460 color bitmap (BMP) images of people at 640 × 480 resolution.

The study thus made is based on the plotting of the TP-IoU, FP-IoU, FN-IoU, IoU-Recall curves and the evaluation of the AR (Average Recall) metric. Plotting the Precision-Recall curve and evaluating the AP (Average Precision) metric cannot be performed in this study because the Haar-AdaBoost and HOG-AdaBoost detectors do not return a confidence score, but rather an indication whether an object detected belongs to the desired class or not.

Here is the meaning of the TP, FP, FN, Precision, Recall and IoU metrics:

- TP: True Positive, also called detection, is a correctly detected person (or object).
- FP: False Positive, also called false detection, occurs when the predicted box provided by the classifier does not contain any person to be detected.
- FN: False Negative, denotes a case where a person is missed.
- Recall: is the number of true positives divided by the sum of true positives and false negatives, this last sum is just the number of ground-truths boxes: $\text{Recall} = \frac{\text{TP}}{\text{TP+FN}}$. This metric measures the rate of true positives detected among all positives, so it is a measure of detector performance in finding positives.
- Precision: is the number of true positives divided by the sum of true positives and false positives: $\text{Precision} = \frac{\text{TP}}{\text{TP+FP}}$. This metric measures the rate that the detection is correct, so it is used to measure the accuracy of the detection.
- IoU: Intersection over Union, is the ratio of the area of the intersection between the predicted bounding box and the ground-truth bounding box on the area of their union.

The OpenCV library offers a list of classifiers in XML format already trained to respectively detect faces, eyes, profile heads, human bodies, etc. These classifiers are located in the opencv \data\haarcascades\folder.

Among the classifiers provided by OpenCV, we have chosen to study the performance of two of them which are already trained for detecting people in images, haarcascade_fullbody.xml and hogcascade_pedestrians.xml which provide two models for detecting people in the images obtained respectively by the implementations under OpenCV of the cascade classifier Haar-AdaBoost of Viola and Jones and HOG-AdaBoost of Lin and Davis (a variant of the Dalal and Triggs detector [12]).

IV. INRIA Person Dataset Image Database and Manual Images Labeling

Among the 460 images in the INRIA Person Dataset, we have manually annotated only 187 images from the first images of this dataset using the objectmarker annotation program, resulting in a total of 481 ground-truth bounding boxes. But, it was better to annotate all the images in the database, which requires more effort and time. Also note that during the annotation, we ignored some images containing a single person very close (or on a very large scale) that we did not consider interesting, the number of this last images was very little.

The Fig. 2 shows four images from the INRIA Person Dataset labeled using the objectmarker program. Each person presented in these images is manually framed using a rectangle, called a ground-truth bounding box. These boxes give precise positions of the people in the images; they are presented by the coordinates (x, y) of the upper left point of the rectangle, its width and its height.

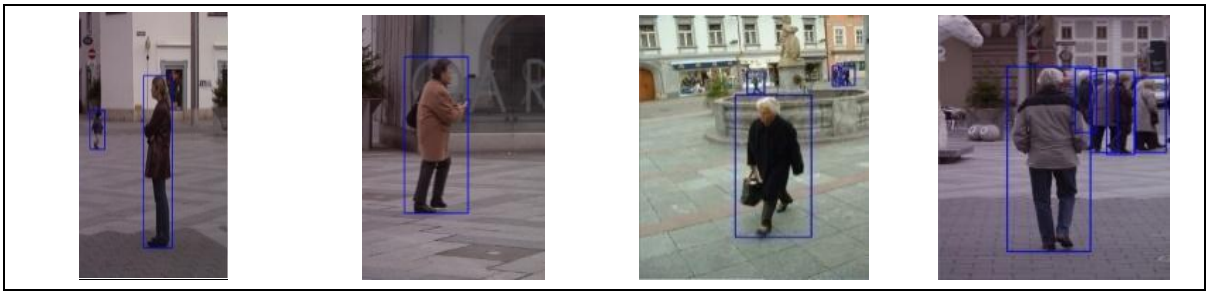

Fig. 2. People Labeled Manually in the INRIA Person Dataset Images using the Objectmarker Program and they are Framed with a Blue Ground Truth Bounding Box. The Four Images show Respectively the Labeling of One Person, Two Persons and Four Persons at different Scales and then One Person with a Crowd of People.

V. Comparison of the Two Detectors Haar-AdaBoost and HOG-AdaBoost using Examples of People Detection in the INRIA Person Dataset

In this paragraph, we will present a preliminary comparative study of the two detectors Haar-AdaBoost and HOG-AdaBoost. This comparison will be based on the application of these two detectors on the first 187 images that we were precedently annotated in the INRIA Person Dataset images. We will discuss the strengths of each of these two detectors as well as their failing.

Table I shows some examples of people detection obtained respectively by the application of the two detectors Haar-AdaBoost and HOG-AdaBoost on the 187 images tagged in the INRIA Person Dataset. The first column corresponds to the application of the Haar-AdaBoost detector, while the second column corresponds to the application of the HOG-AdaBoost detector.

To compare the two detectors and discuss their performance, we have chosen to show some of the most significant detection results obtained on a sample of well-selected INRIA Person Dataset images. In the images below, the blue frame corresponds to the ground truth bounding box produced by manual labeling using the objectmarker program. The boxes in green correspond to the boxes predicted respectively by the two detectors Haar-AdaBoost and HOG-AdaBoost.

Experimentation with Haar-AdaBoost and HOG-AdaBoost detectors on images from the INRIA Person Dataset allowed the following conclusions to be drawn:

- The two detectors generally fail to detect people on a small scale (or very far away).
- Likewise, on a very large scale or when people are very close and fill almost the entire image, the two detectors generally do not succeed in detecting them or sometimes generate, in particular by the HOG-AdaBoost detector, small predicted framing boxes whose IoU with their associated ground truth boxes is of small value.
- Sometimes the shape of the clothes (especially if a person is wearing a coat or a dust jacket) can also cause a person on a medium scale to not be detected by the Haar-AdaBoost and HOG-AdaBoost detectors.
- The HOG-AdaBoost detector is overall better than the Haar-AdaBoost detector for detecting people on a medium scale (i.e., people who are slightly close) and large scale (i.e., people who are close), but unfortunately it generates a lot of false detections (or false positives) than the Haar-AdaBoost detector.
- On a medium and large scale, the Haar-AdaBoostr detector sometimes sends two predicted bounding boxes corresponding to the detection of the same person. This does not happen with the HOG-AdaBoost detector which does a good job of eliminating duplicates and typically returns a single predicted box for each person detected.
- The choice of the IoU threshold is very important so as not to miss some correct detections. We have observed that with the IoU threshold set at 0.5, the Haar-AdaBoost detector sometimes returns detections which are correct, but which have an IoU lower than 0.5, this leads to an erroneous interpretation of the detections result obtained. This situation rarely happens with the HOG-AdaBoost detector where the IoU of detection is often greater than 0.5.

We have also found that the minimum value of the IoU threshold that must be set depends on how to label people, in fact, if the ground-truth bounding boxes are manually drawn too tight to the person that they frame, the detector can sometimes generate an IoU with the predicted bounding box less than 0.5.

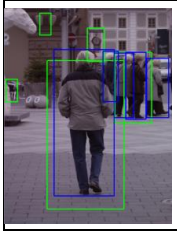
Based on the analysis of the detection results obtained by the Haar-AdaBoost and HOG-AdaBoost detectors, we found that for the minimum IoU threshold value set at 0.4, almost all detections that give rise to true positive are correctly determined. Therefore, to study the performance of the two detectors, it will be preferable to vary the minimum threshold of the IoU between 0.4 and 1 instead of 0.5 and 1, this is what we used in the plotting of the True Positive as a function of the IoU (TP-IoU), False Positive as a function of the IoU (FP-IoU), False Negative as a function of the IoU (FN-IoU) and Recall as a function of the IoU (Recall-IoU).

TABLE I. THIS TABLE SHOWS SOME PEOPLE DETECTION RESULTS OBTAINED RESPECTIVELY BY APPLYING THE TWO HAAR-ADABOOST AND HOG-ADABOOST DETECTORS TO THE IMAGES IN THE INRIA PERSON DATASET

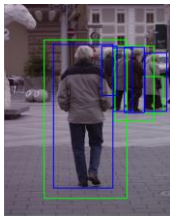
Haar-AdaBoost detector	**HOG-AdaBoost detector**
 The person on a large scale (or at a close distance) is not detected. This is therefore a false negative.	 Here, the same large-scale person is indeed detected with an IoU equal to 0.755259, this is a true positive. The image also shows a false detection that matches the green frame on the side of the display case, so this is a false positive.
 The medium-scale child is well detected (IoU equals 0.580247). The large-scale lady goes undetected. There is a true positive (the child) and a false negative (the lady) here.	 Here, the medium-scale child and the large-scale lady are well detected (the respective IoUs are 0.613888 and 0.482886). Despite the lady being detected, the IoU between the green and blue frame is 0.482886 which is less than 0.5. In this case, if the IoU threshold is set to 0.5, then the lady's blue and green frames will be considered as a false negative and a false positive respectively, which is incorrect. There are also two false detections (or false positives).
 The large-scale lady is well detected (IoU is 0.636414), but the small-scale people are not detected. There is therefore 1 true positive and 3 false negatives.	 The same thing here, the large-scale lady is detected (IoU equals 0.70401), but the small-scale people are not detected. There is therefore 1 true positive, 3 false negatives and 1 false positive (the statue).
 The same person is detected twice, the two predicted bounding boxes in green have respectively for IoU 0.622019 and 0.793165. Only the box with the maximum IoU, that is 0.793165 should be counted as a true positive, the other should be removed and it should not be counted. The small-scale person on a motorcycle is not detected, so in this example there is 1 true positive (one of the two predicted boxes is not counted) and one false negative (the person on the motorcycle).	 Both large scale and small-scale motorcycle people are not detected. There are 2 false negatives here. Apparently, here is the shape of the jacket worn by the person who trained it to go undetected by the HOG-AdaBoost detector.
 Same thing as the previous example, the same person at medium scale is detected twice with two predicted bounding boxes having respectively for IoU of 0.623512 and 0.181492. In this case the box having the IoU of 0, 623512 will be considered as a true positive, however the one with an IoU of 0.181492 will be considered as a false positive.	 The medium scale person is well detected with an IoU equal to 0.653686. There is 1 true positive and one false positive here.
 The medium-scale person is detected with a predicted bounding box having an IoU equal to 0.457869. If the IoU threshold is taken equal to 0.5, then the ground-truth bounding box in blue will be considered as a false negative and the predicted bounding box will be considered as a false positive, which is wrong.	 The medium scale person is well detected with an IoU equal to 0.580978. There is therefore 1 true positive here.
 A large-scale person is detected twice with the green boxes predicted having respectively IoU equal to 0.48906 and 0.0806955, the box with IoU 0.0806955 will be rejected and considered as a false positive. Likewise, the box with the IoU equal to 0.48906 will also be rejected if the IoU threshold is set to 0.5 and it will also be considered as a false positive.	 The large-scale person is detected twice with the predicted bounding boxes in green which have respectively for IoU 0.7074 and 0.153458.The box with the IoU of 0.153458 will be rejected and it will be considered as a false positive. On the other hand, the box with the IoU of 0.7074 will be accepted and considered as a true positive. The medium-scale lady is also detected with the predicted bounding box which has the IoU equal to 0.612489.

Both persons are detected, but they have respectively for IoU 0.437131 (person on the left) and 0.518307 (person on the right). If the IoU threshold is set to 0.5, then only the box predicted for the person on the right with the IoU of 0.518307 will be considered a true positive. On the other hand, the predicted box and the ground truth bounding box for the person on the left will be respectively considered as a false positive and a false negative. So, for the IoU threshold set at 0.5, there is 1 true positive, 1 false positive and 1 false negative, which is not correct.

Both persons are well detected with respectively IoU of 0.543696 (person on the left) and 0.5461 (person on the right). There are therefore 2 true positives here.



Two people are detected, the large-scale man and a lady in the medium-scale crowd. The IoUs obtained are 0.674091 and 0.522472 respectively. Note that the crowd side predicted bounding box overlaps with multiple ground truth framing boxes, but only the ground truth framing box having the highest IoU with predicted box will be taken, the others will be considered false negatives. In this example there are 2 true positives, 3 false negatives and 3 false positives.



Here, three people are detected, the large-scale man and two ladies in the medium-scale crowd, the obtained IoUs are 0.650545 and 0.449743 and 0.48198, respectively. If the IoU threshold is set to 0.5, the two detections in the crowd will be considered false positives and the corresponding ground truth framing boxes will be considered false negatives. With the IoU threshold set at 0.5, the detection in this example gives 1 true positive, 4 false negatives and 2 false positives.

VI. Simple Version of the TP, FN and FP Metrics Evaluation Algorithm

To evaluate the TP (True Positives), FN (False Negatives) and FP (False Positives) metrics, we will start by presenting a first simple version of an algorithm for calculating these values.

For simplicity's sake, let's assume that each person detected in an image is located only once with a predicted bounding box. In other words, there is a single predicted bounding box associated with the ground-truth bounding box framing a detected person.

Algorithm: *Evaluate the number of True Positives, False Negatives and False Positives.*

Input:

- *Database of labeled images.*
- *For each image in the database, we have the list of ground truth bounding boxes and the list of predicted bounding boxes.*
- *The minimum threshold of the IoU.*

Output: *TP, FN et FP.*

We initialize: TP = 0 and FP = 0.
For each image of the database:
    For each detection (or predicted frame box) in the current image:
        Choose from all the ground-truth bounding boxes labeled in the image, the one that has the highest IoU with the predicted bounding box.
        If all the ground-truth bounding boxes in the current image have an IoU below the minimum IoU threshold (typically 0.5), then :
            Detection is a false positive and increments FP : FP = FP + 1
        else:
            The detection is a true positive and we increment TP : TP = TP + 1
Since each predicted bounding box corresponds to one and only one ground-truth bounding box (or a person in the image), one can easily calculate FN by:
FN = Total number of ground-truth bounding boxes in the database – TP

This simple algorithm has the advantage of quickly calculating TP, FN, and FP metrics, but unfortunately it is only suitable if the detector effectively returns a single predicted bounding box for each object detected in an image. In our case, the considered object is a person labeled manually using a ground truth framing box.

This algorithm is therefore suitable for the HOG-AdaBoost detector, but not for the Haar-AdaBoost detector, since this last one sometimes returns two predicted bounding boxes for the same person and therefore this box will be counted twice as a true positive. Whereas normally only one predicted bounding box should be counted as a true positive and the other should be ignored.

Subsequently, we will propose a general algorithm making it possible to correctly calculate the TP, FN and FP metrics. This second version of the algorithm is unfortunately slower in computing time than the previous algorithm, but it has the advantage of working regardless of the number of predicted bounding boxes returned by a detector for the same object (or person) labeled in an image using a ground truth-bounding box.

VII. General Version of the TP, FN and FP Metrics Evaluation Algorithm

It is assumed that the same person can be detected more than once, that is, there are several predicted bounding boxes which may correspond to the ground-truth bounding box framing that person.

Here are two problems that can arise when it comes to associate predicted bounding boxes with ground-truth bounding boxes (or detected person):

- Several predicted bounding boxes can correspond to the same person if they have, together with the ground-truth bounding box framing this person, an IoU greater than a certain minimum threshold of the IoU (typically 0.5). In this case, only a one predicted bounding box should be counted as a true positive, others if not associated with other nearby people should be ignored.

- For people located side-by-side in an image, the ground-truth bounding boxes can usually overlap with each other. In this case, the predicted bounding boxes may also overlap with each other and with several ground-truth bounding boxes. These predicted bounding boxes can therefore have an IoU greater than the minimum threshold with several ground-truth bounding boxes (or several labeled people). We must therefore determine how to correctly associate each predicted bounding box with the ground-truth bounding box it represents (or the person detected).

To overcome these two difficulties and correctly evaluate the TP, FN and FP metrics, that is to say, to avoid repeatedly counting the same person detected with several predicted bounding boxes, which will distort the calculation of TP and FP, we propose a general algorithm whose idea is based on the principle of Non Maximum Suppression (NMS) [23]. We have used this late one to associate each ground-truth bounding box (or detected person) with the predicted bounding box that maximizes the IoU with it and eliminate other predicted bounding boxes that do not maximize the IoU provided that they do not match other people in the vicinity.

Typically on a sliding detection window, the exhaustive search for a person (or an object in general) in an image carried out by certain detectors such as Haar-AdaBoost and HOG-AdaBoost, for example, test all the possible detection windows at all scales and locations. For each of these detection windows, a decision on whether or not it belongs to the desired class is obtained by the detector.

For a person in the initial image, there is a window framing it in the most precise way. However, windows that are spatially close or in scale may also give a positive classification. We then obtain a constellation of positive detection windows around the same detected person, see Fig. 3.

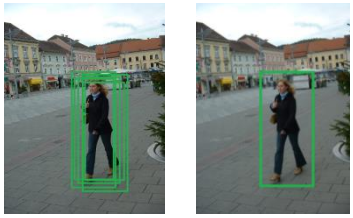


Fig. 3. For the Same Person in the Image, a Multitude of Windows are Detected (the Image on the Left). We must Determine which one Best Frames the Person (the Image on the Right). The Confidence Score is used by the non-maximum Elimination Technique to Find the Window that Maximizes it and to Eliminate the others that do not.

The Non Maximum Suppression technique is one of the methods used during the object detection phase to eliminate neighboring windows that do not maximize the confidence score for a detected object. The confidence score is a value between 0 and 1 generally predicted by a classifier, it represents the probability that a detection window contains an object. The confidence score is used as a comparison value between neighboring detection windows. The principle consists in keeping for a detected object only the detection window which maximizes the confidence score and to eliminate the others which do not maximize it.

In our case, we use the principle of No Maximum Suppression after the phase of the people detection, we based it on the comparison of the IoU between the predicted bounding boxes and those of ground-truth and not on the confidence score. This choice to use the NMS with the IoU was made for the following two reasons:

- The Haar-AdaBoost detector can sometimes generate for the same person detected two predicted bounding boxes that correspond to it.
- The Haar-AdaBoost and-HOG-AdaBoost detectors are respectively based on the binary classifier AdaBoost which do not return a confidence score, but rather the values -1 (or a negative value) for non-membership of the object class to be detected or 1 (or a positive value) to indicate membership of the object class.

The principle of the general evaluation algorithm for TP, FN and FP metrics that we have developed is as follows:

Algorithm: *Evaluate the number of True Positives, False Negatives, and False Positives.*
Input:

- *Database of labeled images.*
- *For each image in the database, we have the list of field truth bounding boxes and the list of predicted bounding boxes.*
- *The minimum threshold of the IoU.*

Output: *TP, FN and FP.*
We initialize TP = 0, FN = 0 and FP = 0.
For each image of the database perform the following processing:

- *Mark all bounding boxes predicted as not being assigned to a ground-truth bounding box.*
- *Associate with each ground-truth bounding box (or a labeled person) in the current image the list of predicted bounding boxes that have an IoU with it that exceeds a certain threshold (typically 0.5). The list of predicted bounding boxes is sorted in descending order of IoUs and all predicted bounding boxes in the list are marked as affected.*
  If the list of predicted bounding boxes is empty, that is, there is no predicted bounding box associated with the ground-truth bounding box, and then this last one is a false negative or a missed person. In this case, we increment the FN metric.
  The final goal of the algorithm is to determine for a ground-truth bounding box framing a person detected in the image one predicted bounding box that maximizes the IoU with it. In this case, only this predicted box will be counted as a true positive, the other predicted bounding boxes on the list if they are not associated with other people located side by side will be ignored.
- *Evaluate the FP metric: it corresponds to the number of predicted bounding boxes that are not marked as assigned to a ground-truth bounding box.*
- *If several detected bounding boxes correspond to the same ground-truth bounding box framing a person (or object in general), the Non Maximum Suppression principle is applied to keep only the detected bounding*

box having a maximum IoU with the ground-truth bounding box. This operation is necessary to properly calculate the TP number, as it avoids counting the predicted boxes for a detected person several times.
For each ground-truth bounding box b1 in the current image:
If the list of predicted bounding boxes associated with box b1 is not empty, then:
The predicted bounding box p1 at the beginning of the list has the maximum IoU. We then take this box p1.
For each ground-truth bounding box b2 in the current image:
If the box p2 at the beginning of the list of predicted bounding boxes associated with box b2 is the same as p1:
If the IoU of p2 with b2 is greater than that of p1 with b1 then it can be confirmed that the predicted bounding box p1 is not associated with the box b1.
Otherwise (the IoU of p2 is smaller than that of p1), we remove p2 from the beginning of the list of the predicted bounding boxes associated with the box b2.
If in the previous iteration it was determined that the predicted bounding box p1 was not associated with b1, then in this case p1 is removed from the beginning of the predicted bounding boxes list associated with box b1.

- *Evaluate the TP metric: it corresponds to the number of ground-truth bounding boxes with a list of predicted bounding boxes associated with them non-empty (these ground-truth bounding boxes therefore correspond to detected people).*

VIII. Analysis of the Two Detectors Haar-AdaBoost and HOG-AdaBoost Performance on the Images of the INRIA Person Dataset

After having implemented the general algorithm for evaluating TP, FN and FP metrics in C ++ language using the OpenCV library, we used it to evaluate the performance of the two detectors Haar-AdaBoost and HOG-AdaBoost.

The following two tables show the results of analyzes obtained by applying respectively the two detectors on 187 first images taken from the 460 bitmap color images of people in the INRIA Person Dataset. Manual labeling of the people in the 187 images resulted in a total of 481 ground-truth bounding boxes framing these people.

TABLE II. Result Obtained by Applying the Haar AdaBoost-Detector on 187 Images from INRIA Person Dataset Containing 481 People Labeled with Ground-Truth Bounding Boxes

Haar-AdaBoost					
IoU threshold	TP	FN	FP	Precision	Recall
0,4	179	302	90	0,665428	0,372141
0,5	144	337	127	0,531365	0,299376
0,6	73	408	203	0,264493	0,151767
0,7	18	463	261	0,064516	0,037422
0,8	2	479	277	0,007168	0,004158
0,9	0	481	279	0	0

TABLE III. Result Obtained by Applying the HOG-AdaBoost Detector on 187 Images from the INRIA Person Dataset Containing 481 People Labeled with the Ground-Truth Bounding Boxes

HOG-AdaBoost					
IoU threshold	TP	FN	FP	Precision	Recall
0,4	258	223	368	0,412141	0,536383
0,5	191	290	441	0,302215	0,397089
0,6	103	378	532	0,162205	0,214137
0,7	31	450	604	0,048819	0,064449
0,8	2	479	633	0,00315	0,004158
0,9	0	481	635	0	0

Since the two detectors are applied to the same images in the INRIA Person Dataset, we will start by making a simple comparison by plotting the curves of the True Positives as a function of the Intersection over Union (TP-IoU), False Positives as a function of the Intersection on the union (FP-IoU) and False Negatives as a function of the Intersection on the union (FN-IoU) (see these curves in Fig. 4).

It can be seen from the TP-IoU curve in Fig. 4 that the HOG-AdaBoost detector (curve in red) is more efficient than the Haar-AdaBoost detector (curve in blue), since it allows to detect more positives (or the persons labeled) than Haar-AdaBoost.

Likewise, the FP-IoU curve also shows that there are fewer false negatives or misses' people with HOG-AdaBoost than with Haar-AdaBoost.

On the other hand, the HOG-AdaBoost detector is less efficient than Haar-AdaBoost with regard to false detections, since in return for its efficiency in detecting positives, it has the disadvantage of generating a lot of false detections or false positives.

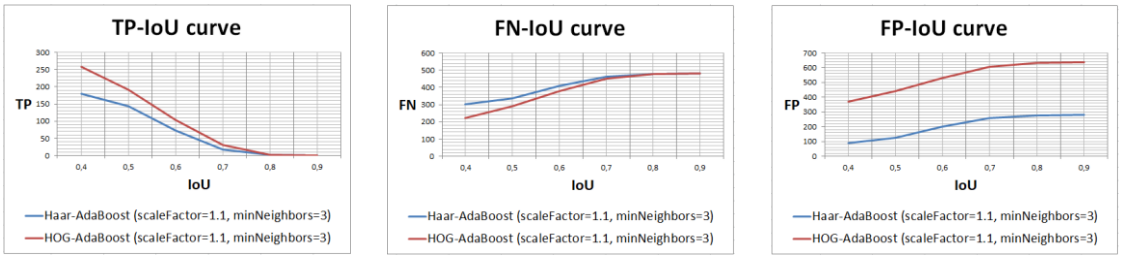

Fig. 4. These Curves show that the HOG-AdaBoost Detector (in Red) is more efficient to Detect People than Haar-AdaBoost (in Blue), but it Generates more False Detections than the Latter. These Results were Obtained for the Values of the Detection Parameters ScaleFactor and MinNeighbors respectively Equal to 1.1 and 3.

Since the two detectors are based respectively on the AdaBoost binary classifier which does not return a confidence score, but rather a response indicating whether the detected object is part of the required class or not, it will therefore not be possible to use the curve Precision-Recall that can be used to calculate the AP (Average Precision) metric. We will therefore use in its place the Recall-IoU curve which makes it possible to calculate the AR (Average Recall) metric.

Subsequently, we will complete the comparisons made by the curves in Fig. 4 by plotting the Recall-IoU curve (Fig. 5). This is more general than the previous curves, it is often used to study the efficiency in detecting true positives; in addition it allows evaluating the average recall metric AR (Average Recall) which is used to compare detectors even if they are applied to different image databases.

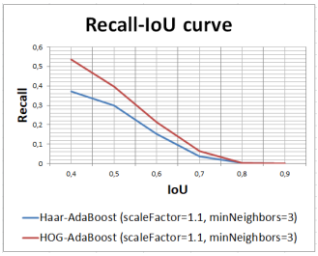

Fig. 5. This Curve shows that the HOG-AdaBoost Detector (in Red) is more Efficient at Detecting People than the Haar-AdaBoost Detector (in Blue).

Knowing that the AR metric corresponds to the area of the region below the Recall-IoU curve between the values of IoU 0.5 and 1 and, it is given by equation (1). To evaluate this metric, we will approximate the integral (1) using the rectangle method that is given by the equation (2):

$$AR = 2\int_{0,5}^{1} Recall(IoU) \quad (1)$$

$$AR = 2\sum_{i=1}^{n-1}(IoU_{i+1} - IoU_i)\, Recall(IoU_{i+1}) \quad (2)$$

Here, IoU_1 is equal to 0.5 and IoU_n is equal to 1. The interval [0.5, 1] is divided into n intervals of the same length equal to $IoU_{i+1} - IoU_i = \frac{1-0,5}{n} = \frac{0,5}{n}$, $1 \le i \le n - 1$.

Since in our case, we have taken n = 5 and the IoU variable between 0.5 and 1, we can deduce that the step of the variation will be fixed at $\frac{1-0,5}{n} = \frac{0,5}{5} = 0,1$, equation (2) will become:

$$AR = 2 \times 0,1 \times \sum_{i=1}^{n-1} sensibility(IoU_{i+1}) \quad (2)$$

With IoU1 = 0,5 and IoUi+1 = IoUi + 0,1, $1 \le i \le n - 1$.

Based on the detections results obtained by the Haar-AdaBoost and HOG-AdaBoost detectors and which are presented in Tables II and III, respectively, we evaluated the AR metric for each of the two detectors which made it possible to obtain the following result:

- Haar-AdaBoost : AR = 0,0985446.
- HOG-AdaBoost : AR = 0,1359666.

From the plot of the Recall-IoU curve and the evaluation of the AR metric for both detectors, the HOG-AdaBoost detector is more efficient to detect people than Haar-AdaBoost, because the HOG-AdaBoost AR is larger than the Haar-AdaBoost AR. But unfortunately, according to the FP-IoU curve in Fig. 4, the HOG-AdaBoost detector has the disadvantage of generating a lot of false detections than the Haar-AdaBoost detector.

IX. Experimenting by Changing Certain Detection Parameters

To perform the detection of people, we used the detectMultiScale method of the CascadeClassifier class. It admits seven parameters, the most important that can be varied to study the detection of people or objects in general are the following two parameters:

- scaleFactor : Allows to define how much the size of the detection window will be reduced with each iteration. The default value for this parameter is 1.1.
- minNeighbors : Defines the minimum number of neighboring detections that a candidate area must have to be retained. The default value for this parameter is 3.

The other parameters are: the image matrix, the flags (not used in detection), minSize (minimum size of the object, the default value is size 0×0) and maxSize (maximum size of the object, the value by default is the full size of the image) are not important for detection.

The results of the analyses presented in paragraph 8 above were obtained using the values of scaleFactor and minNeighbors parameters respectively equal to the default values 1.1 and 3.

We repeated these experiments by assigning to the scaleFactor parameter the fixed value 1.1 and by varying the value of the minNeighbors parameter by assigning it the successive values 2, 3, 4 and 5.

The results of the analyses obtained by the two detectors Haar-AdaBoost and HOG-AdaBoost are respectively shown in Fig. 6 and Fig. 7.

The TP-IoU, FN-IoU and Recall-IoU curves show that when the value of the minNeighbors parameter decrease from 5 to 2, the detection of people (or true positives) improves by both detectors, but, in return, the number of false detections (or false positives) increases (see the FP-IoU curve).

It can be seen that the lower the value of the minNeighbors parameter, the better the detection of people and the higher the number of false detections. A compromise between good detection and false detections can be achieved by the intermediate value of minNeighbors equal to 3 (values 4 and 5 also give a suitable result).

To complete this study, we also assigned other values to the parameters (scaleFactor,minNeighbors), such as (1.01, 5), (1.01, 4), (1.01, 3), (1.01, 2), (1.05, 5), (1.05, 4), (1.05, 3), (1.05, 2), (1.1, 5), (1.1, 4), (1.1, 3), (1.1, 2), (1,15,5),(1.15, 4),(1.15, 3), (1.15, 2), (1.2, 5), (1.2, 4), (1.2, 3),(1.2, 3).

The curves in Fig. 8 (Haar-AdaBoost) and Fig. 9 (HOG-AdaBoost) were obtained for the values of (scaleFactor,minNeighbors) equal to (1.01, 3), (1.05,3), (1.1,3), (1.15,3) and (1.2,3), they give an idea for comparing the

detections that we obtained by varying the values of the scaleFactor and minNeighbors parameters as shown above.

The analyses we performed for the scaleFactor parameter value varying from 1.01 to 1.2 and the minNeighbors parameter value fixed at 3 and which are illustrated by Fig. 8 and 9 allowed us to deduce the following conclusions:

- When the value of the scaleFactor parameter decreases, there is an overall improvement in the people detection due to an increase in the number of true positives (see the TP-IoU, FN-IoU and Sensitivity-IoU curves).

Unfortunately, this improvement is achieved in detriment of an increase in false detections (or the number of false positives, see the FP-IoU curve) and also in the time of detections calculation.

Tables IV and V also confirm the previous results, they give an overview of the detection rates obtained by the two detectors when the IoU value is set at 0.5, that of the minNeighbors parameter is set at 3 and by varying the scaleFactor parameter value which successively takes the values 1.01, 1.05, 1.1, 1, 15 and 1.2.

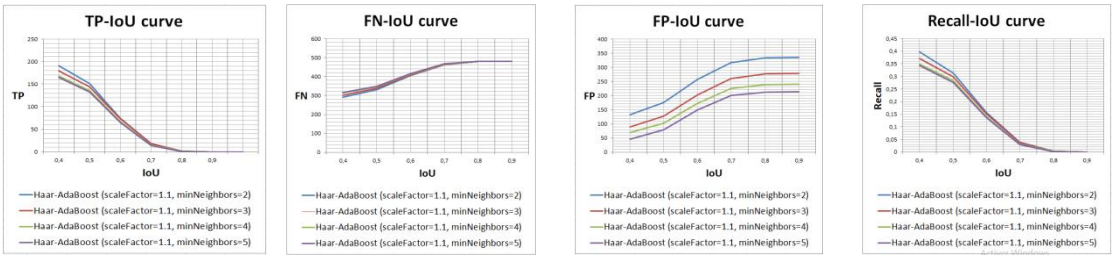

Fig. 6. Haar-AdaBoost Detector.These Curves show the Results of the Detections Analysis Obtained by the Haar-AdaBoost Detector by Setting the Value of the ScaleFactor Parameter to 1.1 and Varying the Value of the minNeighborsen Parameter Successively Assigning it the Values 2, 3, 4 and 5.

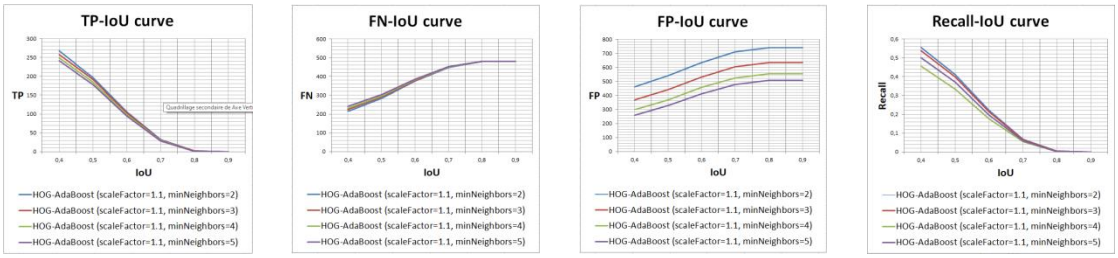

Fig. 7. HOG-AdaBoost Detector. These Curves show the Results of the Detection Analysis Obtained by the HOG-AdaBoost Detector by Setting the Value of the ScaleFactor Parameter to 1.1 and Varying the Value of the minNeighbors Parameter by Successively Assigning it the Values 2, 3, 4 and 5.

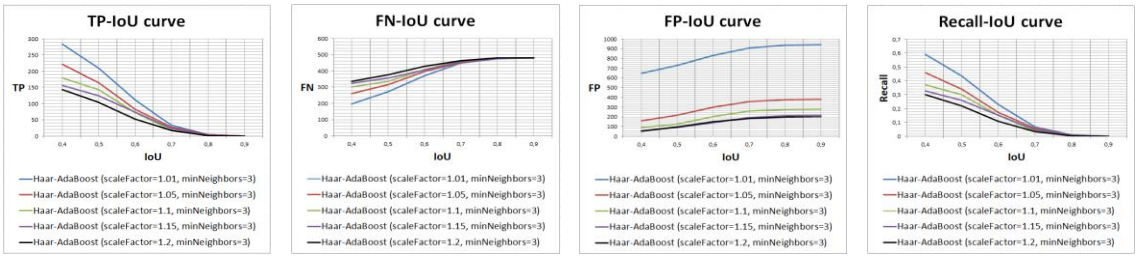

Fig. 8. Haar-AdaBoost Detector. These Curves show the Results of Detections Analysis Obtained by the Haar-AdaBoost Detector by Varying the Value of the ScaleFactor Parameter Assigning it the Successive Values 1.01, 1.05, 1.1, 1.15 and 1.2 and Setting the Value of the minNeighbors Parameter to 3.

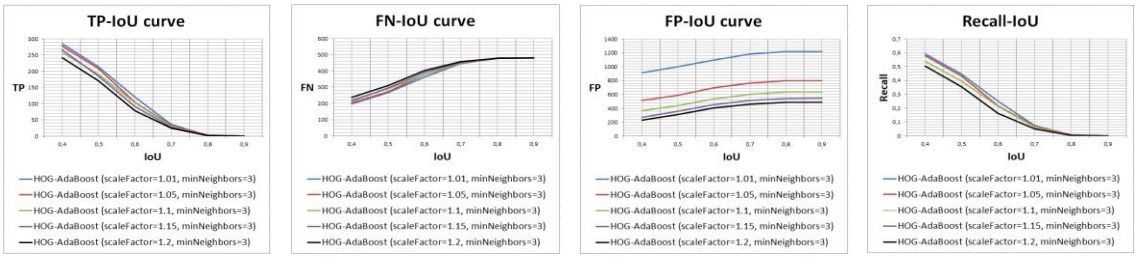

Fig. 9. HOG-AdaBoost Detector. These Curves show the Results of Detections Analysis Obtained by the HOG-AdaBoost Detector by Varying the Value of the ScaleFactor Parameter Assigning it the Successive Values 1.01, 1.05, 1.1, 1.15 and 1.2 and Setting the Value of the minNeighbors Parameter to 3.

Knowing that in the first 187 images of the INRIA Person Dataset, we have labeled 481 people by ground-truth bounding boxes, in this case, the detection rate (equal to the recall metric) will therefore be equal to the number of true positives detected in all 187 images divided by 481, that is, equal to $\text{Recall} = \frac{\text{TP}}{481}$.

It can be seen from Tables IV and V that the detection rate obtained by the two detectors is overall less than 50%, it increases when the scaleFactor parameter decreases from 1.2 to 1.01.

TABLE IV. DETECTION RATES OBTAINED BY THE HAAR-ADABOOST DETECTOR BY SETTING THE VALUE OF THE IOU TO 0.5, THAT OF THE MINNEIGHBORS PARAMETER TO 3 AND BY VARYING THE VALUE OF THE SCALEFACTOR PARAMETER

Haar-AdaBoost detector					
scaleFactor	1.01	1.05	1.1	1.15	1.2
TP	210	165	144	125	105
Detection rate in %	43,66	34,30	29,94	25,99	21,83

TABLE V. DETECTION RATES OBTAINED BY THE HOG-ADABOOST DETECTOR BY SETTING THE IOU VALUE TO 0.5, THAT OF THE MINNEIGHBORS PARAMETER TO 3 AND VARYING THE VALUE OF THE SCALEFACTOR PARAMETER

HOG-AdaBoost detector					
scaleFactor	1.01	1.05	1.1	1.15	1.2
TP	215	208	191	186	171
Detction rate in %	44,70	43,24	39,71	38,67	35,55

- The respective default values 1.1 and 3 of the two parameters scaleFactor and minNeighbors are central; they allow obtaining a suitable detection result that provides a compromise between true detections and false detections and a reasonable calculation time.
- The parameters (scaleFactor,minNeighbors) pairs of values (1.15,3) and (1.2,3) also provide a suitable detection result, since the TP-IoU, FN-IoU and FP-IoU and Recall-IoU curves obtained for these two pairs of values are very close to those obtained for the pair value (1.1,3). In addition, these two pairs of values make it possible to carry out detections with a lower calculation time than that obtained for (1.1, 3).

X. TRAINING THE HAAR-ADABOOST DETECTOR BY SUPERVISED LEARNING ON THE INRIA PERSON DATASET IMAGES

Training a classifier is a long step. It requires gathering and annotating a large number of images containing the object to be detected (positive images) and images not containing the object to be detected (negative images).

In our case, we used the first 187 images taken from 460 images in the INRIA Person Dataset. The manual people labeling in these 187 images resulted in 481 ground-truth bounding boxes that we will use to train the Haar-AdaBoost detector by supervised learning.

The training database therefore consists of 187 positive images and 273 negative images (also called background images). All these images are taken from the INRIA Person Dataset. The positive images are labeled in 481 people who will be used jointly with the negative images during the learning process as training examples of the Haar-AdaBoost detector.

The aim of this experiment is to test whether we can improve the detection of people on a medium and large scale by injecting into the learning database examples of people images on medium and large scales. During the learning phase, the training of the detector with the opencv_traincascade program takes a lot of time depending on the number of positive and negative images and the size w×h. In our case, the number of positive and negative images was set at 481 and 273 respectively. The training time of the Haar-AdaBoost detector increases according to the used size w×h.

For example, this time takes 1 hour and 50 minutes for the size 24×24, 3 days and 21 hours for the size of 32×32 and more than 5 days for the sizes 64×64, 24×60 and 32×80 on the Intel (R) Core (TM) microprocessor having the frequency of 1.8 GHz and a RAM memory of 4 GB.

After training the detectors for sizes 24×24, 32×32, 64×64, 24×60 and 32×80, we applied them to the INRIA images for analyzing the results obtained.

Fig. 10 shows some images of people detections obtained by Haar-AdaBoost detectors formed with sizes 64×64, 24×60 and 32×80. The frames in blue are the ground-truth bounding boxes, while the green frames correspond to the predicted bounding boxes.

These detections were obtained with the values 1.1 and 3 assigned respectively to the scaleFactor and minNeighbors parameters of the detectMultiScale method defined in CascadeClassifier class provided by OpenCV.

The detection results obtained by Haar-AdaBoost detectors formed with sizes 24×24, 32×32 are very bad, there is practically no detection of people and generate a very high number of false detections (see the curves in blue and red that are often confused in Fig. 11).

On the other hand, the results obtained by the detectors formed with sizes 64×64, 24×60 and 32×80 are suitable, they resemble practically to the detection results obtained with the detector provided by OpenCV.

In addition, since the learning examples of these detectors contained many people on a large scale, they thus made it possible to slightly exceed the OpenCV detector in terms of detecting people on a large and medium scale (see Fig. 10 and 11).

In addition, the TP-IoU, FN-IoU and Recall-IoU curves in Fig. 11 also show that detectors trained for sizes 24×60 and 32×80 provide a better detection result with regard to the number of true positives that is larger and the number of false detections that are smaller than those provided by the detector formed for size 64×64. This result comes from the fact that the aspect ratio, that is, the ratio of width to height, chosen for the

detectors 24×60 and 32×80 is equal to 0.4 ($\frac{24}{60} = \frac{32}{80} = 0.4$) which generally corresponds to the aspect ratio of people standing.

Unfortunately, the disadvantage of these detectors thus formed is that they generate a very high number of false detections compared to those generated by the OpenCV detector (see Fig. 10 and 11), this is most likely due to the number of negative (273 images) and positive (481 positive images of persons) examples of learning which is very low.

Normally, to train correctly a detector, it actually takes thousands of positive and negative examples, which requires gathering a very large number of positive images containing people to be labeled and negative images not containing people. In this case, the training of the detector will require a very high learning time.

XI. CONCLUSION

In this article, we first studied the two detectors Haar-AdaBoost (VJ) and HOG-AdaBoost (PoseInv) following the study that we did before in the paper [19].

After having studied the two methods we made a comparison of two approaches Haar-AdaBoost and HOG-Adaboost which constitutes a variant of HOG-SVM [12]. Secondly and after modifying certain detection parameters, we carried out an evaluation of the experiments found to have more performance.

The application of these two detectors on the images taken from the INRIA Person Dataset enabled us to draw the following conclusions:

- The HOG-AdaBoost detector is more efficient at detecting people on a medium scale (or nearby) than the Haar-AdaBoost detector, but on the other hand, it generates much more false detection than the latter.
- Generally, the two detectors studied do not correctly detect people on a small scale (or distant) and on a very large scale (or very close). This is most likely due to the training examples that were used to train these two detectors which contained very few examples of people on a small and on a very large scale.
- Sometimes the shape of the clothing, people close together, crowds, etc. can prevent these detectors from properly detecting people in images.
- The detection rate of people obtained by the two detectors Haar-AdaBoost and HOG-AdaBoost is less than 50%.

In an attempt to improve the detection of people at medium and large scale, five Haar-AdaBoost detectors were formed for the respective image sizes 24×24, 32×32, 64×64, 24×60 and 32×80 on an image database containing many examples of medium and large scale people.

There are practically no detection results provided by 24×24 and 32×32 detectors. In contrast, 64×64, 24×60 and 32×80 detectors have improved the performance of detecting people at medium and large scale compared to the detector provided by OpenCV, but on the other hand, they generate a very high number of false detections. This disadvantage is probably due to the reduced number of positive and negative images that we used to train these detectors.

Unfortunately, it is not possible to apply the finetuning operation to the Haar-AdaBoost and HOG-AdaBoost detectors. This operation consists of re-training a detector already trained on new examples in order to readjust it so that they can adapt to the recognition of these new examples, such as for example in our case, the detection of small, medium and large scale people.

In practice, the fine-tuning operation is preferable to training a new detector on a new sample database which is a very computationally expensive operation. The fact that this operation is not supported by Haar-AdaBoost and HOG-AdaBoost, this is a disadvantage of these detectors, as it will be difficult to expand the capacity of these detectors to new examples.

Another disadvantage of the Haar and HOG descriptors is that they only allow to process grayscale images and only take into account the shape of the objects.

An alternative to the Haar-AdaBoost and HOG-AdaBoost detectors is to use deep convolutional neural network models. Indeed, the latter have made it possible to obtain great performances by their training for the detection of objects [24, 25, 26] and in particular of people [27, 28, 29, 30, 31, 32].

In addition, it is very easy to expand the capacity of an already trained deep convolutional neural network to new learning examples through the fine-tuning operation.

Deep convolutional neural networks also have the advantage of being applied to color images, which gives them the ability to take into account not only the shape of objects, but their texture and color as well.

***Abstract*—Now-a-days, digital documents have become the primary source of information. Therefore, natural language processing is widely utilized in information retrieval, topic modeling, document classification, and document clustering. Preprocessing plays a significant role in all of these applications. One of the critical steps in preprocessing is removing stopwords. Many languages have defined their list of stopwords. However, a publicly available stopwords list isn't available for the Tamil language since it is under-resourced. This study identified 93 general and some domain-specific stopwords for sports, entertainment, local and foreign news by analyzing more than 1.7 million Tamil documents with more than 21 million words. Also, this study shows that removing stopwords improves the accuracy of a Tamil document clustering system. It showed an improvement of 2.4%, 0.95% in the F-score for TF-IDF with one pass algorithm and FastText with the one-pass algorithm, respectively.**

Keywords*—Stopwords; Tamil; pre-processing; TF-IDF; clustering

I. Introduction

Usage of digital text information is growing exponentially in today's world, not only in English but also in other regional languages. Managing this data and extracting the relevant information has become a challenge. Henceforth, Natural Language Processing (NLP) has emerged as a new research field. Yet, the text is more challenging to manipulate and process than numerical data since it is unstructured, ambiguous, and difficult to manipulate. Information retrieval, document clustering, question and answering, document classification, sentiment analysis, and text summarization are some trivial applications of NLP. In every such application, the very first step is data preprocessing. Typically, data preprocessing includes tokenization, stemming, lemmatization, and stopwords removal [1]. Preprocessing eliminates the noise in the data. Further, preprocessing improves the performance of applications. More than 70% of the total text classification process comprises of preprocessing of text alone [2].

Stopwords are the frequently occurring words in a language containing very little or no meaning when used alone. They influence the syntax of a language rather than the semantics of a language [3]. "Are, is, be, a, the, an, of" are some examples of stopwords in English [3]. Therefore, removing stopwords shrinks the size of the text corpus by nearly 35-45% [4] by leaving only the semantically significant words. Also, this aids in improving the accuracy and efficiency of application as the emphasis is given to the semantic of the text. For instance, in document classification, the corpus size reduction reduced the time needed to train a model [5].

In the literature, there are several studies conducted for stopwords identification for many languages such as English, Hindi, Arabic, Chines [4], [6]. Yet, there is no publicly available list of stopwords for Tamil as less research has been done. This paper focuses on identifying stopwords for the Tamil language. Tamil is one of the highly agglutinative languages. The language is used in Sri Lanka, India, Canada, Malaysia, and many other parts of the world. Also, its use in the online platform has shown a hike in the recent past. Therefore, there is a notable need for NLP applications to make use of these available online resources. Therefore, developing and defining stopword lists will benefit the preprocessing step for Tamil language NLP applications. In this research, the authors identify 93 general stopwords for Tamil. Apart from that, the authors identify some domain-specific stopwords for the domain of sports, entertainment, international and local news. Further, by incorporating the preprocessing step of stopwords removal in Tamil text clustering, an improvement of 2.4 and 0.95 in F-score were noted for TF-IDF with one pass algorithm and FastText with one pass algorithm accordingly.

The remaining part of the paper is laid out as follows. Section II elaborates on the related work. Section III details the methodology of stopwords generation for the Tamil language. Section IV reports on the evaluation conducted. Section V analyzes the result and discusses the findings. Section VI conveys the conclusion of the research.

II. Related Work

Fox[4] created a stopword list for English using Brown Corpus of 1,014,000 words. Here the author manually added the words that appeared more than 300 times in the corpus in a list and finalized it by manually analyzing. The stopword list contained 421 words. This approach is domain-independent and is widely used in retrieval systems. Hao et al. [6] generated a stopword list using the weighted Chi-squared statistic technique for the Chinese language. Researchers observed that the suggested methodology effectively improved the F1 classification score by nearly 7%.

Raulji et al. [7] proposed a dictionary-based approach to remove the stopwords for the Sanskrit Language. They used a predefined word list, compared it with the targeted text, and removed the stopwords. The researchers stated that from

87,000 words corpus, 11,200 words were removed as stopwords. This reduced the corpus size by 13% and reduced the feature space and CPU cycle.

Saif et al. [8] generated stopwords for the twitter sentimental analysis using a semantic approach. The researchers concentrated on word semantics and contextual semantics of the words. For this study, six different datasets were used. It was noticed that using semantically found out stopwords improved the accuracy by 0.42% and F-score by 0.94% than using a classic stopword list. Further stopwords removal reduced the classification features by 48.34% and size by 1.17% compared to traditional approaches. Miretie and Khedkar[9] generated a stopword list for the Amharic language by applying aggregated term frequency, entropy and inverse document frequency. El-Khair [10] conducted a comparative study to determine the effect of stopwords removal for the Arabic language. The notion of this study is to combine statistical and linguistic approaches. This study used three stopword lists: general list, corpus-based list, and combined list. Also, they used inverse document frequency, probability weight, and statistical modeling approaches. It was concluded that the general stopword list performed better than the latter two.

Bouzoubaa et al. [11] standardized the Arabic stopword list. They [12] used a statistical approach to find stopwords in the Arabic language. They concluded that this approach increased the performance of the Artificial Neural Network (ANN) classifier than when the general stopword list was used.

Ghag and Shah [5] studied the consequences of stopwords elimination in sentiment analysis and reported that the traditional classifier accuracy improved from 50% to 58.6% when stopwords were removed. However, when applying for "Average Relative Term Frequency Sentiment Classifier," "Senti-Term Frequency Inverse Document Frequency," and "Relative Term Frequency Sentiment Classifier," the improvement was insignificant.

Gunasekara and Haddela [13] created a domain-specific stopword list for the Sinhala language. Reported improved precision, recall, F-score, and accuracy when removed the stopwords in Naïve Bayes and Maximum Entropy-based classifier to classify the Sinhala news articles.

Ladani and Desai [3] surveyed the available stopwords removal techniques for Indian and Non-Indian Languages. They classified stopwords into two main categories as general and domain-specific. They were reported that removing stopwords reduces the size and improves the accuracy of text classification.

Jha et al. [14] proposed a Deterministic Finite Automata (DFA) based stopwords elimination algorithm for the Hindi language. Used JSON objects to implement DFA. For this study total of 200 Hindi documents were used as input, including a movie review dataset gathered from the internet. Here the accuracy and efficiency improved for text preprocessing.

Jayaweera et al. [15] proposed a dynamic approach to find Sinhala stopwords. In this study, they argued the cutoff point is subjective to the dataset. This study used 90,000 documents.

Wijeratne and de Silva [16] collected the data from patent documents between 2010-2020 and created a corpus with 540,276 words of Sinhala text and listed the stopwords using term frequency. Sarica and Luo [17] identified the stopwords in technical language.

Rakholia et al. [18] proposed a rule-based approach to detect stopwords for the Gujarati language dynamically. They developed 11 static rules and used them to generate a stopword list at runtime. They attained 98.10% accuracy for generic stopwords detection and 94.08% for domain-specific stopwords detection.

Multiple approaches have been tried in different languages in the literature to identify the stopwords. Those are mainly: a manual, dictionary-based, rule-based, statistical approach, term frequency, weighted term frequency, inverse document frequency. Most of them are static approaches and data-dependent. Further, these approaches require an intense amount of resources to gain better accuracy. Tamil is a low-resourced and highly inflected language. Therefore, applying these techniques directly to the Tamil language will not be feasible. Hence this study presents a dynamic approach for Tamil stopwords identification.

III. Stopwords Identification for the Tamil Language

A. Data Collection and Preprocessing

The data collected by Fayaza and Ranatunga [19] is utilized in this study. Datasets contain more than 1.7 Tamil documents with more than 21 million words. The datasets contain two types of data. Namely.

1) Online news data: The online news data was collected from nine news providers and covered the local, international, sport, business, and entertainment news. Each news consisted of title, body, URL, and date published. Every news domain is identified using a URL, and domain-specific groups were created as the first step. Using this data following datasets were created.

Dataset 1: International news.

Dataset 2: Sports news.

Dataset 3: Local news.

Dataset 4: Entertainment news.

The following procedures were carried out as preprocessing for all the datasets created above. Using <TITLE> and <BODY> tags, the news title and body were identified. Then the data was tokenized into distinct terms using the white space characters like space, tab, newline/carriage return, and punctuation marks. This was followed by the removal of non-Tamil characters and punctuation marks.

2) General data: It contains randomly collected data from multiple sources. The same preprocessing steps carried out on the previous data set were carried out.

B. Stopword Identification

Several approaches were implemented to identify the stopwords in different languages in the literature. However, most of these approaches are based on the term frequency of the text. In this study, term frequency (TF), inverse document frequency (IDF), and term-frequency-inverse-document-frequency (TF-IDF) are calculated for every term in the dataset. Authors select this approach since it is independent of the dataset size and domain, and it has been used in many other low-resource languages [15]. Further authors conducted multiple executions with different values to define the threshold. From that, the generated threshold value is selected by analyzing the stopword lists.

This automatic identification process consists of the following set of procedures:

- Calculate term frequency (TF) for each term in the document ($TF_{t,d}$).
- Calculate the document frequency (DF) for each term.
- Calculate the Inverse document frequency (IDF_t) : log10(N/dft) (N: total number of documents in the dataset).
- Calculate the TF*IDF for each term.
- Calculate the average TF*IDF for each term.
- List the TF*IDF in order.
- If TF*IDF is lower than threshold value term, added to stopword list.
- Identify intersect words in the lists and create a general stopword list.

It was identified that some stopwords are common among all the domain-specific stopword lists. Therefore, this study categorizes those words under general stopwords for the Tamil language.

IV. Evaluation

To date, there is no published work or publicly available stopword list for Tamil. This study created two types of stopwords lists (One general and four domain-specific). Three individuals manually evaluated these generated lists. Fleiss' Kappa statistic [20] was used to assess the agreement between the evaluators, which was 93.0.

Stopwords removal is one of the basic preprocessing steps in NLP. To evaluate the impact of stopwords removal on system performance of the NLP system, the generated lists were utilized for stopword removal in clustering for Tamil news, using ten datasets as of [19]. The incorporation was done over the same two approaches used in [19]. Those are:

1) TF-IDF with one pass algorithm [19].
2) FastText with one pass algorithm [19].

The system without removing stopwords was used as the baseline for this experiment. Then the stopwords removed datasets were tested. Generated results are compared against the manual clusters created in [19], and Pairwise F-scores [19] were calculated.

V. Result and Discussion

This study paved the way to create two types of stopwords lists, a general one and a domain-specific one. The general stopword list contains 93 words. Fig. 1 depicts the effectiveness of the clustering system with and without stopwords. Fig. 2 list downs the general stopwords. Domain-specific stopwords are listed in Fig. 3, Fig. 4, Fig. 5 and Fig. 6. Fig. 3 is the list of stopwords for the domain of International news. Fig. 4 is the same for the domain of Local news. Fig. 5 is for the Sports news, and Fig. 6 is for the Entertainment news.

Four experiments were conducted under this study. They are:

1) TF-IDF with one pass algorithm (TFIDF-OPA) clustering using the dataset with stopwords.
2) FastText with one pass algorithm (FT-OPA) clustering using the dataset with stopwords.
3) TF-IDF with one pass algorithm (TFIDF-OPA) clustering using the dataset without stopwords (stopwords removed).
4) FastText with one pass algorithm (FT-OPA) clustering with the datasets without stopwords (stopword removed.).

Table I describes the results obtained for the above 4 experiment setups. There is a significant improvement in the F-score when the dataset is used after removing stopwords with regard to that of the data set with the stopwords TFIDF-OPA increased by 2.4% and FT-OPA increased by 0.95%. This shows the impact of stopwords removal is higher in TF-IDF than that of FastText.

Tamil is a grammar-rich and highly inflected language. Even though some words are in stopwords, inflections of them are not included in the list. For example, அணி (Team – ani) is a stopword in the sports domain. It has the following inflected term: அணிகளுக்கு (for teams – Aṇikaḷukku), அணிக்கு (To the team - Aṇikku), அணியின் (Of the team- Aṇiyiṉ), அணிக்கும் (for the Team- Aṇikkum). TF-IDF fails to identify all these forms as stopwords in the clustering process. But Fasttext was able to handle this in the clustering process. Because Fasttext include representing sentences with bag-of-words and bag-of-n–grams, as well as using subword information, and sharing information across classes through a hidden representation. Further, TF-IDF considers inflected terms as different words.

Also, another challenge is some terms are written in different styles by different news providers. For example: கிரிக்கட் (Cricket -Kirikkat), கிரிக்கெட் (Cricket -Kirikket). TF-IDF considers these as two different terms.

All the following news samples reports on different arrests instances. All these news get grouped into one cluster without the stopwords removed if the clustering is performed. However, when the stopwords were removed, the system could cluster them into three different clusters based on the reason for the arrest. The first, second, and sixth reference the same instance about an arrest associated with drugs. The fourth and fifth are about an arrest related to an accident; they are

clustered together. The third news is in another cluster, which is about an arrest related to smuggling. Since the word கைது (arrested – kaitu) was in the stopword list, the stopword removal process removes it from the dataset. Therefore, it was possible to distinguish these news articles, increasing the clustering accuracy.

- 12 இலட்சம் ரூபா பெறுமதியான போதை மாத்திரைகளுடன் மூவர் கைது (12 Ilaṭcam rūpā peṟumatiyāṉa pōtai māttiraikaḷuṭaṉ mūvar kaitu) –Three arrested with drugs worth 12 lakh rupees.
- 12 லட்சம் பெறுமதியான போதை மாத்திரைகளுடன் மூவர் கைது (12 Laṭcam peṟumatiyāṉa pōtai māttiraikaḷuṭaṉ mūvar kaitu) - Three arrested with Rs 12 lakh worth of drugs.
- ஒருதொகை தங்காபரணங்களுடன் சிங்கப்பூர் பிரஜை கைது (Oru tokai taṅkāparaṇaṅkaḷuṭaṉ ciṅkappūr pirajai kaitu) - Singaporean national arrested with gold jewelry.
- மூவர் கைது (Mūvar kaitu) - Three arrested.
- 3 பேர் கைது (3 Pēr kaitu) - 3 people arrested.
- ஹெரோயின் வியாபாரத்தில் ஈடுபட்ட நபர் கைது (Herōyiṉ viyāpārattil īṭupaṭṭa napar kaitu)- The person involved in the heroin trade was arrested.

Further, the following is a set of news related to the same day. The first and the third related to a discussion on bus fare reduction, while the second is regarding a meeting between the president and the TNA parliamentarians. When they are clustered without the stopwords removal, all three are placed into one cluster. However, when classified after the stopword removal, the first and the third are allocated to the same cluster while the second is set onto another separate cluster. Since the word இன்று (today – inru) that was in the stopword list was removed in the stopword removal process, the documents similarly between first and third increased while for the second one reduced..

- பஸ் கட்டணம் குறைக்கப்படுமா ? இன்று கலந்துரையாடல் (Pas kaṭṭaṇam kuṟaikkappaṭumā? Iṉṟu kalanturaiyāṭal) - Will bus fares be reduced? Discussion today.
- தமிழ் தேசிய கூட்டமைப்பின் பாராளுமன்ற உறுப்பினர்களுக்கும் ஜனாதிபதி மைத்திரிபால சிறிசேனவுக்கும் இடையில் இன்று சந்திப்பு ஒன்று (Tamiḻ tēciya kūṭṭamaippiṉ pārāḷumaṉṟa uṟuppiṉarkaḷukkum jaṉātipati maittiripāla ciṟicēṉavukkum iṭaiyil iṉṟu cantippu oṉṟu) - Today a meeting between TNA parliamentarians and President Maithripala Sirisena.
- பஸ் கட்டணத்தைக் குறைப்பது குறித்த இறுதித்தீர்மானம் தொடர்பிலான கலந்துரையாடல் (Pas kaṭṭaṇattaik kuṟaippatu kuṟitta iṟutittīrmāṉam toṭarpilāṉa kalanturaiyāṭal)- Discussion on the final decision on reducing bus fares.

VI. CONCLUSION

This paper presents an approach to list out the stopwords in Tamil, which is a low-resource language. So far, there is no predefined published stopword list for Tamil. The widely used technique for stopwords identification is based on term frequency. In this study, TF*IDF with threshold value is used to identify the stopwords for Tamil. The research resulted in the generation of stopword lists for general domain and domain-specific ones for local, international, sport, and entertainment domains. To evaluate its impact on Tamil NLP, it was used in document clustering using TF-IDF with one pass algorithm and FastText with the one-pass algorithm. The results revealed that the removal of stopwords at the preprocessing stage improved F-score, mean, median, and standard deviation in both the approaches.

Improving Chi-Square Feature Selection using a Bernoulli Model for Multi-label Classification of Indonesian-Translated Hadith

Fahmi Salman Nurfikri, Adiwijaya
School of Computing
Telkom University
Bandung, Indonesia

***Abstract*—Hadith is the foundational knowledge in Islam that must be studied and practiced by Muslims. In the Hadith, several types of teachings are beneficial to Muslims and all of mankind. Some Hadith serve as advice, while others contain prohibitions that Muslims should adhere to. There are yet others that do not belong to these categories and serve only as information. This study focuses on increasing the performance of Chi-Square feature selection to obtain relevant features for multilabel classification of Indonesian-translated Bukhari Hadith data. This study proposes a Chi-Square-based Bernoulli model to improve Chi-Square feature selection which is appropriate for short-text data such as Hadith. The findings of this study show that the proposed method can select relevant features based on data classes; thereby improving Hadith classification performance with an error value of 9.38% compared to that (9.91%) obtained using the basic Chi-Square feature selection.**

Keywords*—Bernoulli model; Chi-Square; feature selection; hadith classification

I. Introduction

Hadith is an important textual source of law, tradition, and teachings in the Islamic world [1]. Following the advancement in technology, several research studies have been conducted on Hadith including the application of natural language processing to classify Hadith based on its content. Hadith classification is a method of categorizing Hadith based on its content [2]; the structure of an Hadith is different from other textual representations. A Hadith comprises three components: Matn, Isnad, and Taraf [1]. Matn is the central text, Isnad is the chain of narrators, and Taraf is the beginning phrase(s) of the Hadith. In addition, some Hadith, for example, the Hadith provided in the book of Sahih Al-Bukhari, belong to more than one label (i.e., the data is multilabel) [1], and therefore, a multi-label classification approach is required.

Multilabel classification is a type of supervised learning where a classification algorithm needs to learn from datasets and classify data into multiple classes; in single-label classification, data can only be classified into one class. For example, a movie is multilabel data as it can simultaneously be categorized as action, crime, and/or thriller [3]. However, the generality of multilabel data makes it more difficult to classify it compared to other data.

In text classification, the features are terms or words contained in the text. A document or textual data contain a considerable number of words that can cause high computational complexity and decrease accuracy as irrelevant features may be considered during the classification [4]. To overcome this limitaion, feature reduction must be applied. One method of feature reduction is feature selection [5] wherein only relevant features to be used for classification are selected. An example of a feature selection method that has been proved to produce good results is the Chi-square [6]. However, one of the limitations of the Chi-Square is that all measured participants must be independent, i.e., one individual cannot fit into more than one class or a single label. Further, its other disadvantage is that the data must have multinomial data frequency. This is a limitation in our case because the text in the Hadith is short. The Bernoulli model has been proved to work effectively with few features [7] and therefore, it is worth exploring.

II. Related Work

A. Hadith Classification

A considerable amount of research has been conducted on Indonesian-translated Hadith, with Faraby et al. [8] being a notable work in this area. Their study categorized Sahih Al-Bukhari Hadith data into three classes: advice, prohibition, and information. The study compared the classification results using artificial neural networks (ANNs) and support vector machine (SVM), and they applied term frequency-inverse document frequency. The results of the study showed that the SVM method performed better than the ANN method, with an F1-Score of 88% to 85%.

Furthermore, Afianto et al. [9] used a dataset similar to Faraby et al. [8]; however, they used random forest as the classification method. The study obtained an F1-Score of 90%, which is better than that of previous study [8]. The most significant process in this research study was the determination of the bootstrap method used where the bootstrap sample was set to 100.

Bakar et al. [10] conducted multi- and single-label Hadith classification using 1064 data points. The multilabel classification comprised three classes (advice, prohibition, and information), while the single-label classification comprised five (faith, knowledge, ablution, prayer, and prayer times). The

study used information gain (IG) as the selection feature technique and the backpropagation neural network (BNN) as the classifier. The study obtained an F1-score of 65.275% for single-label classification, while the Hamming Loss value for multilabel classification was 0.1158. Hence, using IG as the selection feature technique significantly improved the classification performance of the model.

B. Multi-Label Classification

Classification of multilabel data can be problem as such data can be categorized into two or more classes. Research on multilabel classification is motivated by medical diagnosis and text categorization problems. Two approaches can be used for multilabel classification: problem transformation and algorithm adaptation [3].

The problem transformation approach solves multilabel problems by transforming multilabel data into single-label data, while the algorithm adaptation approach classifies multilabel data using algorithms designed for multilabel classification. Multilabel classification using the problem transformation approach achieved better performance than that using the algorithm adaptation approach [3].

Several studies on multilabel classification have been conducted; however, only a few such as those of Bakar et al. [10], Mediamer et al. [11], and Kabi et al. [12] focused on the multilabel classification of Hadith data. Liu et al. [13] conducted multilabel classification using a correlation function; this was effective for overfitted and noisy data. However, such methods are not designed to obtain optimal parameters, and therefore, this can affect classification performance. Soleimani et al. [14] used semi-supervised learning methods and latent Dirichlet allocation for learning topic classes, and used a small number of labeled training data for multilabel classification. However, this method also had a limitation; it had a high time complexity given the large amount of data used in the study. Huang et al. [15] combined a feature selection technique and a classifier for multilabel classification thereby providing an advantage for selecting relevant features of each label and training the classifier to increase the effectiveness of the model. However, the drawback of this method was that it requied a high computational time to obtain optimal parameters.

C. Feature Selection

A problem with text classification is that textual data contain a considerable number of words that can cause high computational complexity and decrease the accuracy of classification results [16], [6], [17]. One approach to tackle this problem is applying feature selection to the data. Yang et al. [6] investigated document frequency (DF), IG, Chi-Square, mutual information (MI), and term strength as feature selection methods for the Reuters corpus. The experiment found that IG and Chi-Square were the most effective feature selection methods as they could remove 98% of irrelevant features without compromising classification performance. However, Chi-Square and IG showed a limitation in that they incurred high computational cost, whereas DF had the lowest computational cost but strong correlation with Chi-Square and IG.

Forman [18] presented an extensive comparative study of feature selection metrics for text classification of high-dimensional data focusing on SVM for the two-class problems. Forman found that the new feature selection metric—Bi-normal separation—achieved better performance compared to other feature selection methods. Xu et al. [19] compared DF, IG, MI, and pointwise MI and found that MI and IG achieved the same performance. Another study used a Bernoulli model as the feature selection method [7] and found that it worked best for documents with short texts, while a multinomial model was better for handling documents with long texts.

III. Design Process

The steps followed by the proposed method (Fig. 1) are described in this section.

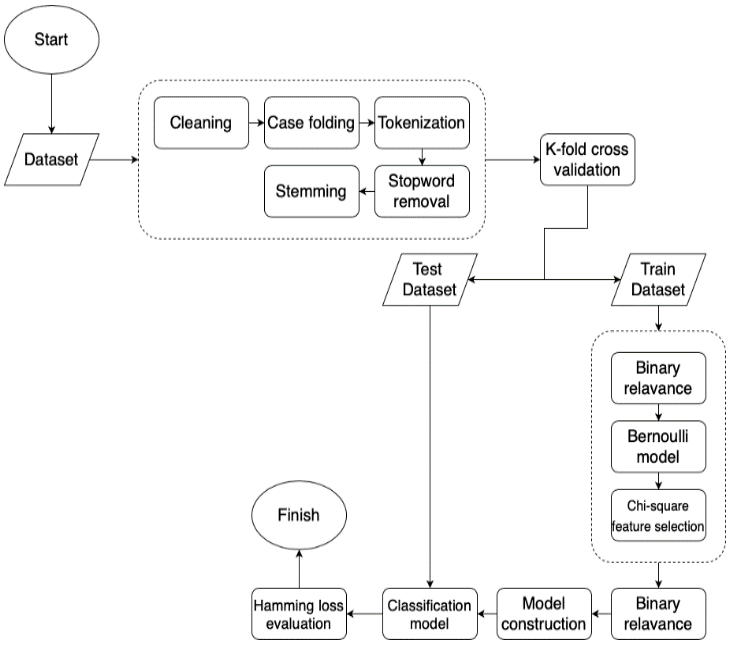

Fig. 1. System Design.

The initial stage involves collecting text-based data from the Hadith in Bahasa Indonesia from the book of Hadith Sahih Al-Bukhari; the book consists of 1066 data points and is divided into three class labels (Advice, Prohibition, and Information). An example of the data representation is listed in Table I.

TABLE I. Multi-Label Data Representation of Indonesia-Translated Hadith

Data	Class
'*Janganlah kalian berdusta terhadapku (atas namaku), karena barangsiapa berdusta atas namaku dia akan masuk neraka*.'	Prohibition Information
'*Kami pernah shalat Maghrib bersama Nabi ketika matahari sudah tenggelam tidak terlihat*.'	Information

TABLE II. COMBINATION OF CLASSES IN THE DATASET

No.	Advice	Prohibition	Information	Count
1	0	0	0	0
2	0	0	1	777
3	0	1	0	6
4	0	1	1	53
5	1	0	0	10
6	1	0	1	181
7	1	1	0	5

The class combination in the dataset is listed in Table II.

The dataset consisted of 230 Advice, 98 Prohibition, and 1045 Information data points. Based on these data points, it can be seen that the number of data points in the Advice and Prohibited classes is very small compared to that in the Information class; hence, the data is unbalanced. This can be a problem because unbalanced data can lead to less optimum classification results.

The first step to handle unbalanced data is preprocessing. This study used cleaning, case folding, tokenization, stopword removal, and stemming as the preprocessing steps to eliminate some sentences that are not used in the classification process. An Indonesian stopword list from a study conducted by Tala [20] was used and modified to match the Hadith dataset in this study. In addition, the Nazief–Andriani stemming algorithm [21] was also used. Next, the dataset was split into training data and test data using 5-fold cross-validation to make all observations in the dataset are nicely distributed in a way that the data are not biased.

Feature extraction was performed using the bag-of-words representation. In this study, a term frequency method was used to extract the feature. This method counts each word in the vocabulary list obtained from the training dataset for each data point.

Two general approaches for multi-label classification are problem transformation and algorithm adaptation. Problem transformation converts multi-labeled data into single-labeled data, while the algorithm adaptation uses algorithms specifically adapted to handle multilabel classification. Based on the research conducted by Irsan et al. [3], the problem transformation approach achieved better performance results compared to algorithm adaptation.

Binary relevance uses problem transformation approach [22] [23]. Binary relevance creates a number of k datasets (k = |L|, the total number of classes). Each dataset has the same instance as the original data; however, each dataset contains only one class. Using this method, class data representation must first be changed into one-hot encoding.

The next step involved duplicating the dataset of q, where q is the number of classes in the training data so that each dataset only has 2 classes, namely. 0 and 1.

Next, the extracted features are selected using Chi square. In this study, a Bernoulli model was used for Chi square feature selection. This model checks for the presence or absence of a word, and therefore, it only has two possible outcomes: yes or no. The Bernoulli model was used because every Hadith contains an average of 20 words, and hence, a small number of features is the type of data that the Bernoulli model can process effectively [7]. The algorithm of the Chi square Bernoulli model is presented in Algorithm 1 below.

Algorithm 1. Chi-Square Bernoulli model algorithm

```
function Bernoulli-Chi-Square-FS()
    Input: Array of attribute and its class C
    Output: Array of Chi value for each class
Initialize
arrayofchivalue (array)
arrayofclasschivalue (array)
Begin
Change class data representation into one-hot encoding
Break the class into k classes
for each c in class do
  for each a in attributes do
    for each row in a do
      if row >= 1 then
        row ← 1
      else
        row ← 0
      end if
    end for
    Calculate ChiSquare(a, c_i) and append it to arrayofchivalue
  end for
  Sort descending arrayofchivalue
  Get top-n attributes and append it to arrayofclasschivalue
end for
return arrayofclasschivalue
```

Based on Algorithm 1, each feature row is transformed into 0 and 1. In this model, words with three occurrences are the same as words with only one occurrence.

Then, feature selection is performed for each class. Feature selection is the process of selecting a subset of relevant features for training a classification model; it is used to select relevant features that will be included in the classification process, thereby efficiently and effectively improving the process [16]. Chi square feature selection is used in this study [6]; it is expressed by

$$X^2(t,c) = \frac{N*(AD-CB)^2}{(A+C)*(B+D)*(A+B)*(C+D)} \quad (1)$$

A Chi square statistic measures the lack of independence between term t and class c, and it can be compared to Chi square distributions with one degree of freedom to evaluate extremeness [6], where A is the number of times t and c occur; B is the number of times t occurs without c; C is the number of times c occurs without t; D is the number of times neither t nor c occurs; and N is the total number of documents.

The output of Chi square is the Chi value, which is between a feature and a class; the greater the Chi value, the greater is the relationship between the feature and the class. Each feature is calculated for each class. Once the Chi values are obtained, they are sorted in the descending order for each class, where greater the Chi value, the greater is the effect of a feature on a class [8]. Finally, the top-n features are obtained and used as inputs for the classifier.

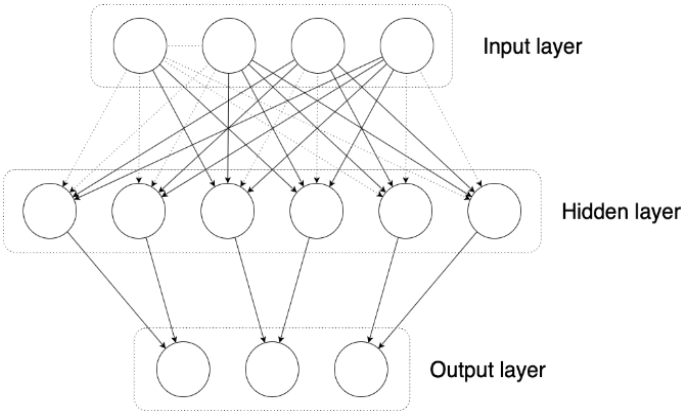

Fig. 2. Structure of the Neural Network.

The classifier is trained using the BNN. This algorithm was selected because it can process a wide variety of features to obtain a high classification performance [24], [4], [1], [10]. The classifier was trained using a modified BNN with the binary relevance approach, and therefore, the training process was conducted three times, which is equal to the number of classes. The selected features were used to train the classifier. Each class had different input data because of the different selected features. Therefore, in this the BNN was modified to tackle this problem, as shown in Fig. 2.

Fig. 2 shows that two main lines connect the input layer and the hidden layer, i.e., the bold and dotted lines. The bold line indicates that input and hidden neurons are connected, while the dotted line indicates that the input does not pass the feature selection for the class; however, it can pass the feature selection for other classes. Finally, the evaluation results of the classifier are expressed in terms of Hamming Loss. The Hamming loss is used because this method is appropriate for multilabel classification and assigns equal weight to each label [25].

IV. Results and Discussion

A. Effect of the Bernoulli Model on Chi-Square Feature Selection

The performance of the Bernoulli model was compared by varying the number of dimensions from 10% to 100%. This allows determining if the use of feature selection can help improve the performance of the classifier and to obtain the best dimensionality for optimal classification performance. The BNN input nodes are equal to the dimension of the document vector.

The results of the proposed model are compared with those of the typical BNN and Chi-square-based BNN feature selection models. The results are listed in Tables III and IV.

Based on the results listed in Tables III and IV, the proposed method achieves the best average result of 0.0938, while the CSBNN produced the best average result of 0.0991. A comparison chart of the three methods is shown in Fig. 3.

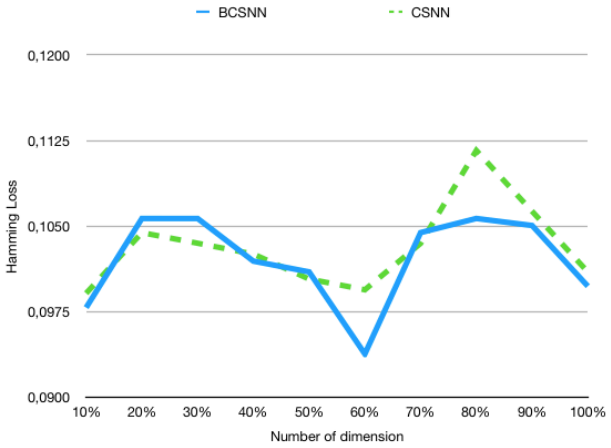

Fig. 3. Categorization Performance of BCSBNN and CSBNN according to the Number of Dimensions

As shown in Fig. 3, the performance of BCSBNN and CSBNN are not considerably different; however, on average, BCSBNN outperformed CSBNN. This is because Bernoulli distribution can select relevant features as inputs for the BNN and the Bernoulli distribution only has two possibilities (yes or no). For example, consider the word "hendak;" in the Bernoulli distribution, one word is enough to represent the word in the class to produce the probability p (hendak = 'yes' | class) and p (hendak = 'no' | class). Meanwhile, by using multinomials, the number of occurrences of each word has its respective probabilities such as p (want = 0 | class) and p (want = 1 | class). Therefore, this decreases the occurrence probability of each word.

Further, Fig. 3 shows that when using 60% of the data dimensions, the smallest Hamming Loss value is obtained. This is because the features used as inputs for the classification models match the test data. However, this can change depending on the data used. In addition, using feature selection produced better results than when the whole data (using 100% dimension) was used. This is because the feature selection technique removed irrelevant words/features from the dataset used in training and testing the classification model. However, it is necessary to determine the best parameters for choosing the number of feature dimensions to use.

B. Comparison of the Modified Backpropagation Neural Network and the Typical Backpropagation Neural Network Classification Performance

Table V lists the classification performance of the modified BNN using the binary relevance approach compared to that of the typical BNN. The performance of the networks was first compared using the Chi-Square Bernoulli Model (BCS) and then using the Chi-Square (CS) test.

TABLE V. PERFORMANCE COMPARISON BETWEEN THE MODIFIED BACKPROPAGATION NEURAL NETWORK (BINARY RELEVANCE) AND THE TYPICAL BACKPROPAGATION NEURAL NETWORK

Number of dimensions	Modified Neural Network		Original Neural Network	
	BCS	**CS**	**BCS**	**CS**
10%	**0.0979**	0.0991	0.1126	0.1129
20%	0.1057	**0.1044**	0.1135	0.1253
30%	0.1057	**0.1035**	0.1123	0.1263
40%	**0.1019**	0.1025	0.1110	0.1151
50%	0.1010	**0.1004**	0.1094	0.1119
60%	**0.0938**	0.0994	0.1094	0.1135
70%	0.1044	**0.1035**	0.1204	0.1126
80%	**0.1057**	0.1116	0.1088	0.1132
90%	**0.1051**	0.1063	0.1132	0.1163
100%	**0.0997**	0.1010	0.1094	0.1132

As shown in Table V, the modified BNN outperformed the typical BNN. This is because, in the typical BNN, the classifier must remember more patterns in the class, whereas, in the binary relevance, one classifier is focused on only remembering one pattern. For example, for the typical BNN, the classifier must remember eight different class patterns and a combination of unbalanced data, as listed in Table II. Meanwhile, the binary relevance method only focuses on each class, i.e., Advice, Prohibition, or Information.

Further, the BNN following the binary relevance approach requires less computational complexity than the typical BNN because the number of neurons connected in the former were reduced, thereby reducing the matrix computation. However, using binary relevance slightly increased time complexity because the classifier had to learn as many class patterns as possible. This can be a problem if the number of classes to be trained becomes very large.

C. Model Prediction

Samples of the classification results are listed in Table VI.

The conducted experiments and results listed in Table VI indicate that there are three types of predictions: correct prediction, partially correct prediction, and wrong prediction. Further, in the "correct prediction" row, the predictions and targets achieved the same results because the words that appear in the Hadith were relevant, and thus, only correct results were obtained.

In the "partially correct prediction" row, the system predicted only the information class, while the target classes were Advice and Information. This is because the number of Advice data points was so small that the probability of the system in retrieving the Advice class was trivial compared to that in retrieving the Information class, which has a very large number of data points. In the future, further processing of unbalanced data must be performed.

TABLE VI. SAMPLE PREDICTION

	Data	**Predicted**	**Target**
Correct prediction	*'Jika salah seorang dari kalian meludah maka janganlah ia membuangnya kearah depan atau sebelah kanannya, tetapi hendaklah ia lakukan kearah kirinya atau di bawah kaki (kirinya).'*	Advice Prohibition Information	Advice Prohibition Information
Partially correct prediction	*'Jika salah seorang dari kalian mengantuk saat salat, hendaklah tidur (dahulu) hingga ia mengetahui apa yang ia baca.'*	Information	Advice Information
Wrong prediction	*'Janganlah salah seorang dari kalian sengaja salat ketika matahari sedang terbit atau ketika saat terbenam..*	Advice Information	Prohibition

TABLE VII. SAMPLE OF ZERO PREDICTION

Data	Predicted	Target
'Luruskanlah shaf, sesungguhnya aku dapat melihat kalian dari balik punggungku.'	-	Advice Information

In the "wrong prediction" row in Table VI, which shows a sample of data that has been manually labeled before, many of the datasets used are still ambiguous when viewed in a meaningful way per word. For example, the data can be categorized into the Advice class as well. Hence, further validation of the dataset needs to be performed to achieve better performance.

A limitation of the binary relevance approach is the occurrence of zero predictions or data that cannot be categorized into any category. This happens because by following the binary relevance approach, each model is independent and so are the classes. Examples of these phenomena are summarized in Table VII.

In this research, 16 datasets could not be classified when adopting the binary relevance approach, while only 7 datasets from the overall 214 test dataset could not be classified when adopting the algorithm adaptation approach. This is attributed to unbalanced data. For example, in this study, there are only 98 data points for the Prohibition class with a total of 1066 data points, where the ratio of the Prohibition class and non-Prohibition class is 1:10, thereby making the classifier classify data as non-Prohibition class and so on for the other classes. By adopting the algorithm adaptation approach, a combination of classes connects the classes to reduce the possibility of zero predictions. Further, the use of feature selection may have an effect on the occurrence of zero predictions, as irrelevant words in documents are not selected, which causes a lack of features to sufficiently represent data. This is because the binary relevance approach entails that each model be independent and that no dependence exists among classes.

V. CONCLUSION

This research proposed a Chi-Square Bernoulli Model and a BNN model to classify Hadith into specific categories. The Bernoulli model was used as the feature selection method and was found to improve the classification performance, achieving the best average Hamming Loss result of 9.38%. This is because, in the Bernoulli distribution, one word is sufficient to represent the total number of occurrences of the word in a class, and therefore, the Bernoulli distribution can choose the relevant features as inputs for the BNN.

Furthermore, the binary relevance approach outperformed the algorithm adaptation approach. This is because when using algorithm adaptation, the classifier must remember most of the patterns in a class, whereas, in problem transformation (binary relevance), the classifier is only focused on remembering one pattern in a class.

For further research in this regard, more attention should be given to processing unbalanced data. Further, the future work should explore other methods such as the recurrent neural network, which works with data sequences or similar methods and determines their effectiveness in classifying Hadith data.

Transfer Learning-based One Versus Rest Classifier for Multiclass Multi-Label Ophthalmological Disease Prediction

Akanksha Bali, Vibhakar Mansotra
Department of Computer Science and IT
University of Jammu
Jammu, India

***Abstract*—The main objective of this paper is to propose transfer learning technique for multiclass multilabel opthalmological diseases prediction in fundus images by using the one versus rest strategy. The proposed transfer learning-based techniques to detect eight categories (seven diseases and one normal class) are Normal, Diabetic retinopathy, Cataract, Glaucoma, Age-related macular degeneration, Myopia, Hypertension and Other abnormalities in fundus images collected and augmented from Ocular Disease Intelligent Recognition (ODIR) dataset. To increase the data set, no differentiation between left and right eye images has been done and these images were used on VGG-16 CNN network to binary classify each disease separately and trained 8 separate models using one versus rest strategy to identify these 7 diseases plus normal eyes. In this paper, various results has been showcased such as accuracy of each organ and accuracy of the overall model compared to benchmark papers. Base line accuracy have increased from 89% to almost 91% and also proposed model has improved the performance of identifying disease drastically prediction of glaucoma has increased from 54% to 91%, normal images prediction has increased from 40% to 85.28% and other diseases prediction has increased from 44% to 88%. Out of 8 categories prediction, proposed model prediction rate has improved in 6 diseases by using proposed transfer learning technique vgg16 and eight different one versus classifier classification algorithms.**

***Keywords*—Fundus images; one versus rest strategy; transfer learning; VGG-16; augmentation**

I. Introduction

The motivation of this article comes from the fact that According to WHO at present, there are 2.2 billion people around the globe suffering with visual disability out of 2.2 billion at least a billion people could have been treated from visual impairment [1]. In the 21st century, eye blindness became normal because of high exposure towards electronic gadgets such as television, laptops etc. from early ages, though most of the eye diseases could be cured if detected in starting stages of the disease. Eyes are organs of the visual system, they capture light rays and regulate intensity using diaphragm and form an image using a lens. Eyes forward the captured image to the brain via optic nerve by converting them to electro-chemical impulses, any disturbances in the above process creates visual impairment or eye disorder. The study of eye diseases and disorders to diagnose is called Ophthalmology.

The primary sources for the cause of eye blindness are 1.exposure towards electronic gadgets 2.Lack of accessibility for medical facilities especially in developing and undeveloped countries 3. People in rural areas have a higher rate compared to their counterparts living in city 4. Aging people [2] and Indigenous people (tribes) 5. Accidents like facial fractures [3] e.t.c. The most common eye diseases occurring in day to day life are due to Diabetic Retinopathy, Glaucoma, Cataract, AMD, Hypertension, and Myopia. Some of these won't result in vision impairment but cannot be neglected from detection and treatment.

Diabetic retinopathy, a common disease for blindness in the age group of 20 to 70, initial days of this disease, diabetes patients of type -1 and 60 percent of type-2 diabetes suffered from retinopathy [4]. Glaucoma is a type of eye diseases having a common feature in cupping and atrophy of optic nerve head, visual field loss; often increase in intraocular pressure [5]. In 1990, 37 million people were estimated to be blind and 40 percent of them suffered from cataract [6] and it can be corrected with surgery but lack of facilities for treating cataract is a rising concern in developing countries and undeveloped countries.

Age related macular and degeneration (AMD) [7] is a natural thing but the numbers of these cases are increasing day by day due to the sharp rise in mortality rate because of development of medical facilities [8] and stable governments. Hypertension affects the retina significantly and the study of retaining provides valuable information to treat hypertension [9]. Myopia (short sightedness) considered as disorder, it can be corrected with glasses, contact lens and surgery (Lasik treatment), though it is less threatening but number of people suffering with this disorder has taken a step curve especially in children [10].

The state of the art solutions for retinopathy based on the classifications of these diseases are tedious tasks with the advancement of computers and computing techniques; various methods are proposed for the classification of objects. The most common types of classification are 1. Single labelled classification generates yes or no situations [11], such as person is suffering from eye disease enough to understand the

person is suffering but not to understand the reasons for suffering. 2. Multi labelled classification though it is computationally expensive, but it provides better intuitions and further depth analysis and it identifies more objects.

Machine learning algorithms have significantly done well in the field of image classifications, segmentation and enhancement techniques. Machine learning algorithms have generated better results initially but failed to learn more features with the increase of the dataset. Neural networks, a part of machine learning algorithms, have done significantly well with the data and deep learning algorithms that came into picture generated more features with increase of data. Deep learning algorithms became a common norm for any image classification, segmentation tasks.

The two common ways to represent eyes in the form of images are Fundus Photography, capturing images at the fundus. The main areas covered at fundus photography are the central and peripheral retina, optic disc and macula. The second way is Optical Coherence tomography (OCT), a technique to capture 2d, 3d and micrometer resolution images with low coherence light.

The paper findings as discussed in the upcoming section:

1) This paper focuses on Fundus images to classifyNormal, Diabetic Retinopathy, Glaucoma, Cataract, AMD, Hypertension, Myopia and other diseases using multi labelled dataset ODIR 2019 consisting of 5000 fundus images of patients of both eyes.

2) The primary reason to work on these datasets is its multi-disease data sets as most of the datasets encountered are mainly focused on one ophthalmic disease.

3) The paper carefully analyzes the machine learning, data variance and generative n probabilistic aspects of retinopathy and tries to devise a cross entropy modelling system for multi label classification.

4) It also formulates the utility of transfer learning, into the diverse and difficult field of retinopathy.

The rest of the paper, structured as: section 2, literature review briefly describes various research proposed in eye organ segmentation using both machine learning and deep learning algorithms, section 3 explains the methodology part which comprises subsection 1) data collection. 2) preprocessing and augmentation 3) Training, Section 4 explains the results and analysis which comprise subsection 1) performance metrics, section 5 describes the discussion and section 6 concludes the paper.

II. Literature Review

Deep learning and Machine Learning became solutions for computer vision problems such as image enhancement, segmentation and classification, especially in biomedical imaging. Many researchers have proposed various approaches for the classification of ophthalmological diseases.

J. Liu et al. [12], proposed an SVM based classification approach to classify myopia with an accuracy of 87% on test data from the Singapore Eye Research Institute. T.V. Phan et al. [13], proposed an SVM and random forest based method to classify AMD. V. Gulshan et al. [14], uses a deep convolutional neural network to identify diabetic retinopathy and DME in fundus images. H. Pratt et al. [15], proposed a CNN and data augmentation technique for the classification of micro-aneurysms, exudate and haemorrhages on the retina. The proposed architecture achieves sensitivity and accuracy around 95% and 75% on 5000 validation images.

J. Y. Choi et al. [16], used matConvNet for automatic detection of multiple retinal diseases on the STARE database, consisting of nine eye diseases. Optimal results were obtained by random forest transfer learning based VGG19. P. M. Burlina et al. [17], proposed a DCNN for the classification of AMD, this model compared with a pre trained DCNN by performing transfer learning. Y. Chai et al. [18], proposed a method to combine deep learning models with domain knowledge for automatic glaucoma detection on fundus images. The proposed model outperformed AlexNet, VGG16, InceptionV3 in accuracy, sensitivity and specificity. F. Grassmann et al. [19], utilized various convolutional neural networks to classify nine types of eye disease due to age, three types of AMD and one ungradable image, to classify these thirteen classes, ensembling has been done over six different neural network architectures.

M. N. Bajwa et al. [25], proposed a framework containing two stages, the first stage uses a CNN to localize and extract the optical disc from the retinal fundus image and the other one uses deep convolutional neural network for classifying disc extracted in the first stage. Due to the lack of original ground truth images, they proposed rules for generation of semi automatic ground truth images. They achieved a 2.7% improvement to the previously produced results on the ORIGA dataset. S. Keel et al. [26],proposed Inception V3 architecture for classification and severity possibility threshold on neovascular age-related macular degeneration. V. Das et al. [27], proposed CNN based classification detection techniques for DME and AMD up to two stages. The evaluation of the proposed method is performed on the OCT dataset and achieves a decent score of sensitivity, specificity and accuracy around 99.6%, 99.87% and 99.6% on test data. T. Li et al. [28], provided a new dataset of 13673 fundus images from 9598 patients for diabetic retinopathy and these images were classified into 6 types based on quality and DR level.

Y. Peng et al. [29], proposed DeepSeeNet architecture to measure the score of severity in the range 0 to 5 for the age related eye diseases study. T. Pratap et al. [30], used a pre trained CNN architecture for transfer learning to extract features for classifying levels of cataract and these features were classified using SVM. In this paper [31], M. S. Alabshihy et al. used direct technique such as problem transformation, multilabel cad system, segmentation, MSVM on dataset named as DiaretDB having two classes named as DR and hypertension and achieved an overall accuracy of 96.1%. Md. T. Islam et al. [32], proposed a classification model for eight ocular diseases using contrast limited adoptive histogram equalization as a pre-procesing step and CNN has used for feature extraction.

T. Nazir et al. [33], proposed a deep learning approach for segmentation of diabetic retinopathy, diabetic macular edema

(DME) and glaucoma using a fast region based convolutional neural network to localize and fuzzy k means to segment. A multi task loss was used as a loss for CNN. Intersection over union, mean average precision and dice coefficient as evaluation metrics and achieved mean average precision of 0.94. X. Pan et al. [34], compared DenseNet, Resnet50 and VGG16 to automatic classification and detection the four kinds of lesions of diabetic retinopathy such as non-perfusion regions, microaneurysms, leakages, and laser scars in fundus fluorescein angiography images. Sensitivity, specificity and region of curve were used as evaluation metrics. M. Aamir et al. [35], proposed a two phased CNN based architecture for classification, one for glaucoma detection and other for rating glaucoma in different scales like advanced, moderate, early, on fundus images, and adaptive thresholding was done before applying CNN. Sensitivity, specificity, accuracy and precision were used as metrics for evaluation. C. G. Gonzalo et al. [36], proposed a CNN ensembling methods to identify AMD and diabetic retinopathy in color fundus images. Inputs for CNN are contrast enhanced image and RGB image derived from original color fundus images.

R. Sarki et al. [37], proposed CNN based architecture for multi classification of diabetic eye disease in two ways, a low level multi class diabetic eye disease and another one is a high level multi class eye diabetic disease. Maximum accuracy for mild multi-classification and multi-classification are 88.3% and 85.95% using VGG16. K. Shankar et al. [38], proposed a synergic deep learning model for classifying the levels of diabetic retinopathy. The proposed method outperforms AlexNet, ResNet, GoogleNet and VggNet-19 with respect to accuracy, sensitivity and specificity. A. Ram et al. [39], used a CNN for feature extraction for classifying normal, cataract, myopia and AMD. The objective of this paper is to correlate the relationship between the number of classes and number of fully connected layers.

J. Wang et al. [40] used feature extraction based efficientnet in the first part and custom neural network in the second part for multilabel classification of fundus images. N. Gour et al. [41], used transfer learning for classification on fundus images by two approaches. In the first approach, images of both eyes were individually given as input for CNN and the results were concatenated and in the second method, images of both eyes were concatenated and given as input to CNN. Various state level architectures have used instead of CNN to generate better results and VGG16 pretrained architecture performed significantly. N. Li et al. [42], created a database of 10,000 fundus images of both eyes from 5000 patients to classify 8 diseases and multi level classification of images has improved significantly with the increase of complexity in state of art deep neural networks like AlexNet, ResNet, GoogleNet. J. He et al. [43], proposed a dense correlation network (DCN) for classifying multi labelled diseases. DCN consists of three modules for features extraction, features correlation and calculating classification score; a multi label soft margin loss was used as a loss function and produced way better results than benchmark deep neural networks.

In this paper [45], D. Muller et al. suggested ensemble heterogenous DL models for multi eye disease prediction. They also used fivefold cross validation on RFMID multilabel data containing 3200 images (1920 training data, 640 testing data and validation data each). This dataset contains twenty nine multilabel classes. The techniques used are data augmentation, bagging and stacking, transfer learning and stacked logistic regression. They achieved 0.95 AUROC for multilabel disease risk prediction by using ensemble DL models. In this paper [46], A. C. Garcia et al. used Resnet, Resnest, EfficientNet, ViT, Deit, NasNet, HRnet, CycleGAN on RFMID-2021 mainly focussed on the ERM category and achieved f1score of 86.82. In this paper [47], L. P. Cen et al. used DCNN on 249,620 images and 275,543 labels collected from different sources and achieved f1score, sensitivity, specificity, AUC of 0.923, 0.978, 0.996, 0.9984 resp. for multi-label classification dataset (Table I).

TABLE I. LITERATURE SURVEY OF RECENT STUDIES WITH SHORTCOMINGS

Reference No.	Author and year	Techniques used	Results	Limitations
[20]	M. Mateen et al., 2018	Gaussian mixture model (GMM), visual geometry group network (VGGNet), singular value decomposition (SVD) and principle component analysis (PCA)	Accuracy = 98.34	Does not consider the overfitting problem.
[21]	Q. Meng et al., 2019	Deep CNN with attention map mechanism	Accuracy = 94.5	Accurate classification accuracy can be checked on more data.
[22]	H. Chen et al., 2019	Deep hierarchical multi-label classification	AUC = 88.7	Results need to be evaluated using other performance parameters also.
[23]	L. Faes et al., 2019	Automated deep learning model	Sensitivity = 73·3–97·0 Specificity = 67–100% AUPRC = 0·87–1·00	Study should compare several state-of-art models with proposed one.
[24]	C. C. Jordi et al., 2019	VGG16 and InceptionV3	AUC = 88.71 F1-score = 88.76	Results can be improved with additional pre-processing steps.
[32]	Md. T. Islam et al., 2019	Shallow CNN architecture	F1-score = 85 Kappa score = 31 AUC = 80.5	Recent neural models can be implemented to evaluate results.
[44]	E. S. Kumar et al., 2021	Multi-Disease Classification Framework (MDCF) using stacking	AUC = 97.42 F1-score = 94.32	Different ensemble methods can be used.

A. Limitation in existing Architectures

The current state of the art methodologies has primarily 5 main limitations to highlight, as is discussed in the literature review section.

- Lack of a complete autonomous system to provide multi label classification at a medical acceptable rate. Majority of the research is done using one or multiclass eye disease. Applicability and deployment of deep learning techniques in classifying multilabel data is still in infancy stage.
- Absence of transfer running bio fueled ventures in retinopathy.
- The absence of high-volume dataset, diminishing the choice of deep learning.
- Use of traditional Machine learning techniques to measure the correlation of dimensional simulation, although feature extraction is difficult and eluding.
- Multiclass labelling pertains to quasi dimensional binary loss problem, general in multiclass labelling but deadly for retinopathy. To overcome this the paper hypotheses the use of cross-entropy modelling strategies.

III. Proposed Methodology

In this section, a pipelined architecture has been proposed based on deep learning using transfer learning techniques from Imagenet dataset to multi labelled classification of eye diseases. ODIR Dataset contains supervised data of 8 eye categories. They are Normal (N), Glaucoma (G), Diabetic Retinopathy (D), AMD (A), Hypertension (H), Cataract(C), Myopia (M) and other abnormalities (O) on fundus images as shown in Fig. 1. In this section, proposed architecture and database used has been explained.

A. Data Collection

The paper used Ocular Disease Intelligent Recognition (ODIR) dataset consisting 5000 images of ophthalmic patients of left and right eye, age and diagnostic key words of Doctor collected by Shanggong Medical Technology Co., Ltd. from different hospitals in China to classify diabetic retinopathy, glaucoma, cataract, age-related macular degeneration, hypertension, pathological myopia and other abnormalities. These multi labelled fundus images are captured by various cameras to create different resolutions. The Table II describes the count of each disease in the dataset and the augmentation details.

B. Pre-Processing and Augmentation

Images are cropped towards the centre to avoid the area which does not generate much information and various augmentation techniques were applied on the data sets labelled as Hypertension (H), Glaucoma (G), Cataract (C), AMD (A), Myopia (M) to create the balance among the datasets as these 5 diseases are largely outnumbered by other diseases. The augmented data set has increased from 7473 images to 14072 images as shown in Table II.

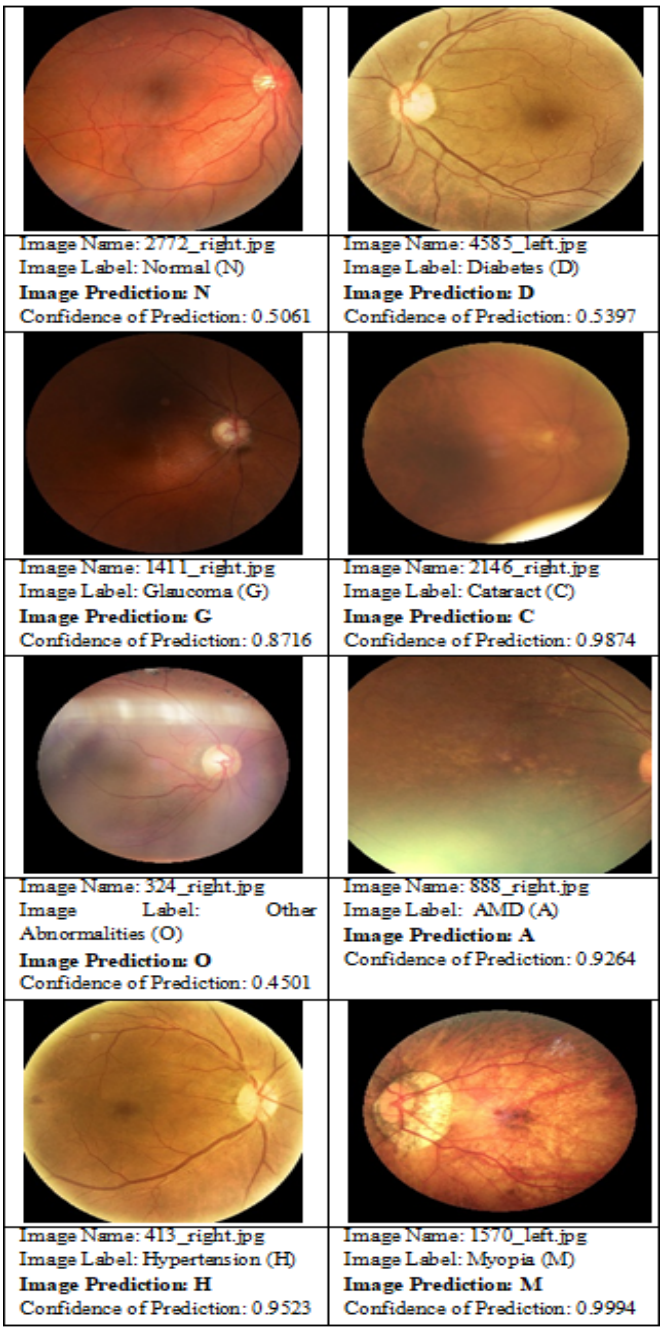

Fig. 1. Sample Images of 8 Eye Categories and their Confidence Levels of Prediction.

Each image of these 5 diseases were used to generate 8 more images using these 8 augmentation techniques, they are 1) Vertical flip, 2) Horizontal flip, 3) Both horizontal and vertical flip, 4) Clipped center of image and zoom of the original image, 5) Clipped center of image and zoom of the vertical flipped image, 6) Image rotation plus brightness enhancement, 7) Image rotation of the original image and 8) Image rotation of the vertical flipped image. Since it is a multi labelled dataset, augmentation of image containing two diseases creates 16 images in this augmentation approach, though no diabetic retinopathy images are augmented, its images are augmented due to multi labelled dataset.

TABLE II. TABULAR DESCRIPTION OF DATA SAMPLES AND AUGMENTATION DETAILS OF EACH DISEASE

Class	Total Samp-les	Training Split (70%)	Testing Split (30%)	Augmented	Augmented Sample (on training dataset)	Total Sampl-es (used for training)
N	3098	2169	929	No	0	2169
D	1801	1261	540	No	792	2053
G	326	229	97	Yes	1832	2061
C	313	218	95	Yes	1744	1962
A	277	193	84	Yes	1544	1737
H	193	135	58	Yes	1080	1215
M	268	188	80	Yes	1504	1692
O	1197	847	350	No	336	1183
Total	7473	5240	2233	Yes	8832	14072

C. Training

In proposed method, one versus rest strategy has used to classify each disease against all other 8 possibilities. The workflow of proposed methodology is shown in Fig. 2 and Fig. 3. Fig. 2 and Fig. 3 represent the flowchart and algorithm of our proposed methodology respectively. Eight different one versus rest classifier classification algorithms based on vgg16 were trained to detect N, D, G, C, A, H, M, O categories. Each eye image was taken separately (didn't consider left and right images of eyes as the same image) to double the size of the data set and implemented preprocessing and various augmentation methods to increase the data size to avoid over-fitting and to add versatility among the data. Images were cropped to the centre of fundus images and reshaped the size of image to 224×224 to avoid computational problems and these reshaped images are suitable to use VGG16 transferred weights.

1) Transfer learning: LeCun et al [48], proposed a convolutional neural network for extracting features in images, speeches and time series data. The basic layers in any convolutional neural network include convolution, pooling, batch normalization, fully connected layers as shown in Fig. 4. Various architectures are proposed by tweaking these layers by repeating more layers of one type or by changing the order of layers using different activation functions. The CNN's are great at localization and extracting features. CNNS are utilized in various fields like object detection, CNN's generated state of art results in segmentation, classification and enhancement on biomedical images and it requires a lot of data and computational power to perform matrix operations.

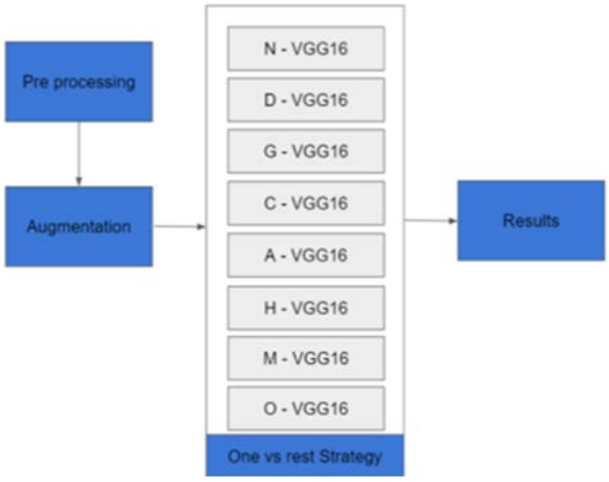

Fig. 2. Flowchart of Proposed Methodology.

For each batch on Train data do:

1. Resize image to 224 *224 Pixel.
2. Crop image to center.
3. If Image Labeled as G, C, H, A, M do:
   i. Vertical Flip.
   ii. Horizontal Flip.
   iii. Both Horizontal and Vertical Flip.
   iv. Clipped Center of image and zoom the original image.
   v. Clipped Center of image and zoom the vertical flipped image.
   vi. Image rotation plus Brightness enhancement.
   vii. Image rotation of original image.
   viii. Image rotation of vertical flipped image.
4. Else: No Augmentation.
5. For each label in data do:
   i. Train the VGG16 Model.
6. END

END

Fig. 3. Algorithm of Proposed Methodology.

TABLE III. FILTERS IN CNN LAYERS

BLOCK ID	Number of layers	Number of CNN layers	Filters dimension	Number of Pooling layers
1	3	2	(3× 3 × 64)	1
2	3	2	(3× 3 × 128)	1
3	4	3	(3× 3 × 256)	1
4 & 5	4	3	(3× 3 × 512)	1

CNNs model weights are stored in open domains which are trained on large databases like ImageNet. Various CNN architectures have done well on ImageNet databases to detect and classify objects, the recent architectures are AlexNet[49], GoogleNet[50], VGGNet[51], MobileNet[52] and ResNet[53]. Collecting a large volume of multi labelled data in the medical field is a tedious task and very time consuming. Recently researchers moved to transfer learning where they use pre trained models on standard datasets and they use these pre-trained models on their datasets. There are various benefits in transfer learning like 1) it saves a lot of time for training the model and flexible enough to adjust trainable layers and non trainable layers. 2) It was trained on large dataset and has more parameters that are useful for learning, on a low sized datasets if we apply these standard models they mostly end up overfitting the data.

Proposed model uses VGG16 where its first 10 layers are not trainable and the rest are fine tuned and the last layer was adjusted to binary classification. The VGG16 contains 5 blocks, details about filters, number of convolutional layers and max pooling layers were given in Table III. In pooling layers kernel size is of 2×2 with a stride movement of 2 and in CNN layers ReLU used as activation function. Final parameters after block5 is 102764544 and these are flattened and forwarded to three sequentially fully connected neural networks. The last one uses softmax as activation for classification that outputs a vector of probability R as shown in equation (1) and the rest uses ReLU as activation function P that introduces nonlinearity to the network as shown in equation (2).

The softmax equation is defined by:

$$R = \begin{pmatrix} R1 \\ R2 \end{pmatrix} \text{ Where } R_i = \frac{e^{x_i}}{\sum_{k=1}^{n} e^{x_k}} \quad (1)$$

The Relu equation is defined by:

$$P(z) = \max(0, z) \quad (2)$$

Detailed implementation of these architectures is shown in Fig. 4, and these architectures were trained 8 times, as shown in Fig. 2 and Fig. 3 i.e. one versus rest strategy to classify 8 diseases individually and their results are amalgamated for multi diseases classification. The model in Fig. 4 was trained for 16 epochs and utilized a batch size of 32 to train this model with a validation split of 0.2. Stochastic gradient descent [54] as shown in equation (3) was used as an optimization algorithm and hyper parameters such as learning rate, momentum, decay are adjusted as 0.0001, 0.9, 0.000006 and Nesterov Accelerated gradient as shown in equation (4) uses parameters θ calculated from momentum term γw_{t-1} gives approximation term for next parameter value through $\theta - \gamma w_{t-1}$ that improves the generalisation performance has applied with stochastic gradient to increase the speed of convergence. Binary cross entropy as shown in equation (5) was used for loss function and accuracy used as the measure of metrics. To train this model, hardware specifications of cpu with 4 crores of ram size 32 gb and 11 gb GPU of Tesla K80 Architecture have utilized.

The SGD equation for each training example $t^{(i)}$ and label $u^{(i)}$

$$\theta = \theta - \eta . \nabla_\theta \boldsymbol{J}(\theta; t^{(i)}; u^{(i)}) \quad (3)$$

The nesterov accelerated gradient equation is

$$w_t = \gamma w_{t-1} + \eta \nabla_\theta \mathbf{J}(\theta - \gamma w_{t-1})$$
$$\theta = \theta - w_t \quad (4)$$

The Binary cross entropy function is given by

$$BCE = -\frac{1}{N} \sum_{i=0}^{N} y_i . \log(\acute{y}) + (1 - y_i) . \log(1 - \acute{y}) \quad (5)$$

IV. RESULT

A comparison table was provided on various techniques used on ODIR dataset along with proposed method to classify these diseases in Table IV. These proposed models were evaluated on 2233 testing images of ODIR database as mentioned in section III (Table II) and results have been compared on the basis of accuracy of each disease with proposed method and with the base paper proposed by N. Gour et al. [41] and these results were shown in Fig. 5, contains details of training loss, validation loss of each disease and overall accuracy and individual disease accuracy. Proposed model detected myopia with more accuracy as its false positive rate and false negative rate are very less compared to other diseases as a result it showed significant improvement in accuracy, f1-score, and precision and recall whereas classification error became quite negligible. Identifying normal images became a quite tricky and its results are mediocre compared to identifying other diseases.

A. Performance Metrics

Various metrics such as Accuracy, Specificity, Precision, Sensitivity, and Classification error, F1-score, False Positive Rate, Negative Predictive Value and False Negative Rate of each disease on testing data have been shown in Table V and the barcharts for each disease and for the overall model shown in Fig. 6 and Fig. 7. The equations for performance metrics is shown in the equations 6 to 14.

1) Accuracy: It is defined as the ratio of sum of true positives and true negatives to the total number of samples.

$$Accuracy = (\text{True Positives} + \text{True Negatives}) \div \text{Total Number of Samples} \quad (6)$$

TABLE IV. COMPARISON OF EXPERIMENTS CONDUCTED ON ODIR DATASETS AND THEIR RESULTS

Reference No.	Method used	Eyes merging	Results
[32]	Proposed cnn architecture	No fusion techniques were used	F1-score: 0.85, kappa score: 0.31, AUC value :0.85
[39]	Model based on two cases 1)featured based efficient net and 2) custom based neural network for multilabel classification	No fusion techniques were used	Overall Validation Accuracy: 0.90, F1-score: 0.85 (for image size 299*299) Overall Validation Accuracy:0.92,F1-score: 0.89 (for image size 448*448)
[40]	Transfer learning applied on two cases 1) transfer learning on concatenated left and right eye images 2) transfer learning individually on left images and right images and they were merged before classification	Uses concatenation as fusion technique	Overall Validation Accuracy 0.89
[41]	Transfer learning	Both left and right eyes are merged using sum, product and concatenation	The mean of kappa, AUC and F1 score. Better results achieved for inception -v4 (0.7516) for product as fusion technique
[42]	Transfer learning with spatial correlation module	Uses concatenation as fusion technique	Uses average of kappa, AUC and F1-score. Resnet -101 produces better results around 0.827
proposed method	**Transfer learning using VGG-16**	**No fusion (considered left and right images as separate images)**	**Validation Accuracy :90.85 F1-score :0.91**

2) Specificity: Measures the accurate identification of true negative values, it is also called Selectivity and True Negativity.

$$Specificty = (\text{True Negatives}) \div (\text{False Positives} + \text{True Negatives}) \quad (7)$$

3) Precision: Measures the number of true positive values obtained over the total number of positive values, it is also called as positive Predictive value.

$$Precision = (\text{True Positives})\_ \div \_(\text{False Positives} + \text{True Positives}) \quad (8)$$

4) Sensitivity: The ratio of true positives to true positives and false negatives is called sensitivity; it is alsoreferred as True Positive Rate and Recall.

$$Sensitivity = (\text{True Positives}) \div (\text{True Positives} + \text{False Negatives}) \quad (9)$$

5) Classification error (C.E): It is defined as the ratio of sum of false positives and false negatives to the total number of samples.

$$C.E = (\text{True Positives} + \text{True Negatives}) \div \text{Total Number of Samples} \quad (10)$$

6) F1- score: It is defined as harmonic mean between precision and recall.

$$F1 - Score = 2 * (\text{Precision} \times \text{Recall}) \div (\text{Precision} + \text{Recall}) \quad (11)$$

7) False positive rate (FPR): It is measured as the ratio between false positive to false positive and true negative.

$$FPR = \text{False Positive} \div (\text{False Positive} + \text{True Negative}) \quad (12)$$

8) Negative predictive value (NPV): It is measured as the ratio between true negative to true negative and false negative.

$$NPV = \text{True Negative} \div (\text{True Negative} + \text{False Negative}) \quad (13)$$

9) False negative rate (FNR): It is measured as the ratio between false negative to false negative and true positive.

$$FNR = \text{False Negative} \div (\text{False Negative} + \text{True Positive}) \quad (14)$$

		Baseline (VGG16 - Multiclass)	Proposed Approach (VGG16 - One vs Rest, Binary model for each disease class)						
Eye Disorder	Disease Label	Baseline (Validation Accuracy)	Total Training Samples	Total Validation Samples	Training Time (per Epoch)	Training Loss	Training Accuracy	Validation Loss	Validation Accuracy
Normal	N	40.00%	9887	2472	282s - 29ms/step	0.2735	87.09%	0.3135	85.28%
Diabetic Retinopathy	D	89.00%	9887	2472	271s - 27ms/step	0.3302	85.16%	0.4536	82.56%
Glaucome	G	54.00%	9887	2472	270s - 27ms/step	0.0696	97.60%	0.2891	91.34%
Cataract	C	97.00%	9887	2472	272s - 27ms/step	0.0409	98.60%	0.1111	97.05%

V. DISCUSSION

The paper demonstrates the lack of embedded machine learning techniques to solve the multi-class classification of retinopathy images. An important aspect of understanding the problem of the binary loss function is that because of the persistent 8 different classes, the exponential loss function is not able to provide substantially valid results as per the medical requirement. Because of which most of the retinopathy algorithms tend to create only theoretical steps to the earthquake in an autonomous system for multiclass classification in this field. The paper also takes into account various transfer learning accomplishments in the depth of image classification and computer vision. Furthermore, the paper can showcase the genesis idea of combining transfer learning into multiclass labelling techniques by using cross-entropy loss modelling ideas. A holistic discussion on various heuristics used is provided in the previous section and would be concluded in section 6. In the final analysis as per the literature review, we tend to understand the significance of machine learning ideas that have only been bubbled up and not implemented thoroughly. The paper ideation and implementation successfully answered where the research question is posted. While analyzing the results, it can be observed that transfer learning (Vgg16) with one verses rest classifier technique have produced exceptionally better results than baseline paper [41].

From the literature review, it is observed that no prediction is done on odir-19 testing dataset and most of the research is mainly focused on multiclass or one eye disease prediction. From the results, it is analyzed that training has produced reasonably better results (sensitivity, Accuracy, positive predictive value, F1-score) on overall testing data. Normal class shows average performance in all cases due to similarity in the features.

VI. CONCLUSION

The paper proposed a pipeline to identify multiple diseases on ODIR datasets where the aim was to increase baseline accuracy from 89% to almost 91% and also proposed model

has improved the performance of identifying disease drastically prediction of glaucoma has increased from 54% to 91%, Normal images prediction has increased from 40% to 85.28% and Other diseases prediction has increased from 44% to 88%. Out of 8 categories (seven diseases plus normal class) prediction proposed model prediction rate has improved in 6 categories, except in diabetic retinopathy and hypertension where proposed model accuracy has decreased by 6.44% and 2% respectively. The reason for achieving high accuracy in other categories is due to augmentation techniques where more balanced data is created as possible. That has clearly shown in less annotated diseases like glaucoma. The further research will be on working to create more data using other augmentation techniques like generating artificial images and working various transfer learning algorithms to improve the accuracy of each disease in multi-labeled classification problems. As for future work, other DL algorithms need to be explored for training the model and a study regarding hyperparameter optimization should be done to find the optimal model configuration. Moreover, other multi-label datasets with the latest eye diseases should be explored and predicted.

***Abstract*—Object detection and retrieval is an active area of research. This paper proposes a collaborative approach that is based on multi-resolution maximally stable extreme regions (MRMSER) and faster region-based convolutional neural network (FRCNN) suitable for efficient object detection and retrieval of poor resolution images. The proposed method focuses on improving the retrieval accuracy of object detection and retrieval. The proposed collaborative model overcomes the problems in a faster RCNN model by making use of multi-resolution MSER. Two different datasets were used on the proposed system. A vehicle dataset contains three classes of vehicles and the Oxford building dataset with 11 different landmarks. The proposed MRMSER-FRCNN method gives a retrieval accuracy 84.48% on Oxford 5k building dataset and 92.66% on vehicle dataset. Experimental results show that the proposed collaborative approach outperform the faster RCNN model for poor-resolution conditioned query images.**

Keywords*—Faster RCNN; feature representation; multi-resolution MSER; object detection; object retrieval

I. INTRODUCTION

Object detection and recovery is one of the emerging areas of computer vision. In our daily routine, almost everything is related to object-based and its retrieval. Object retrieval can be applied as a solution to various real-time problems. Retrieving objects present in a given image scene are far more difficult than content-based image retrieval [1]. In content-based image retrieval, the image is recovered as a whole, but in object retrieval, the region of interest (ROI) only retrieved from a database. Various research studies are being conducted in this area through traditional and deep learning-based approaches. On the object retrieval task, the retrieval is mainly based on object-level features. To identify an object location in an image, it is pre-marked with a box called the object's bounding or anchor box. In the initial stage the bounding boxes are drawn for the areas of the essential object [2].

Object recovery is the process of searching for an object in an image from a large image collection or video configuration. Object recovery occurs in two important steps: first, it searches for an image in a large database, and then observes an object with an anchor box. Initially, there were content-based image recovery structures, which were later improved to recover a specific object from a scene utilizing some formal techniques. The fundamental reason for object recognition is to distinguish and find at least one efficient target from a given image or video database. It meticulously incorporates a variety of key technologies, specifically pattern recognition and digital image processing. It has wide application possibilities in different areas such as protection of brand name or logo, detection of defective parts in printed circuit boards (PCB), accident prevention in road traffics [3], alerts about hazardous products in manufacturing plants and military confined region checking [4],[5].

The object recovery process is conventionally settled by physically extricating feature representations, where the normal feature-elements are addressed by histogram-of-oriented gradients (HoG), scale invariant feature transforms (SIFT), Haar-like feature representations and other calculations that depend on grayscale [6]. In addition to the above-mentioned feature extraction procedures, specific object recovery can be performed using support vector machines (SVMs) or AdaBoost algorithms. These conventional feature extraction models are simply ready to recover low level feature components of an image data, such as colour, shape, texture, blobs and edges, and have restrictions in recognizing numerous objects under complex scenes because of their deprived generalization performances. Newer object detection models are mainly depending on deep convolutional neural network (DCNN / Deep conv-net) features. Their results are promising when compared with traditional models [7]. Some of the models based on DCNN are region-based convolutional neural network and its variants, you only look once (YOLO) and single shot multi-box detector (SSD) models. DCNN models are not just concentrating on the detailed surface features from the previous level convolution layer, but on the other hand, can get more significant level data from the next-level convolution layer [8],[9],[10],[11].

In addition to the conventional CNN process, the RCNN variants utilize a counter strategy to assume the target object regions in the feature maps, steadily adjusting the location info and optimize the object's location for categorization and retrieval. Conversely, other object discovery models will concurrently foresee the anchor boxes and categorize straightforwardly in the feature maps by applying diverse convolutional phases. The RCNN model has two activity stages that consider higher location precision, while SSD and YOLO can straightforwardly recognize the arrangement and the position data, which speeds up detection [12]. A faster RCNN model offers better object retrieval accuracy than its

predecessors. The limitation of faster RCNN is that it cannot efficiently recover objects from bad resolution images.

To overcome the limitations of detecting poor / bad resolution images in faster RCNN, the proposed system uses an existing algorithm called multi-resolution MRMSER to formulate a new collaborative MRMSER-FRCNN model that offers better retrieval accuracy, compared to individual faster RCNN or multi-resolution MSER. With this integrated approach, it can achieve better retrieval accuracy on images with poor resolution conditions. The proposed collaborative MRMSER-FRCNN model offers better retrieval accuracy, compared to individual faster RCNN or multi-resolution MSER.

The rest of this paper is arranged as follows. Section 2 gives a detailed study report on various object retrieval techniques, their feasibility and the problems in the existing models. The identification and implementation of collaborative model based on MRMSER and faster RCNN explained in Section 3. Section 4 gives a detailed discussion about the datasets used and the results obtained in the simulation experiment. Finally, Section 5 concludes the proposed model.

II. Related Work

This section provides a detailed review on the object detection and retrieval from images and also explores accessible strategies to summarize in-depth features nearby for creating conservative descriptions for image recovery. Krizhevsky A. et al. [13] achieved better categorization of images in IMAGENET by DCNN. Their study categorizes a large number of high-resolution images. They have designed a neural network consisting of MaxPooling layers and five convolution layers that are fully integrated with SoftMax functionality. An object identification strategy was proposed based on the calculation of a regional proposal by Ren S. et al. in [14]. A region based network (RPN) that expects object boundaries and object simultaneously in each pixel area proposed by Long J. et al. in [15] illustrates a complete CNN, which is remarkably capable of classifying set of images semantically. The primary goal of their study is to create a “fully convolutional network” that receives the variable-sized image inputs and produces equally-sized outcome with viable deductions and information. Here, they configured some recent taxonomic networks, for example, Alex-Net, VGGNet and GoogLeNet for taxonomic purposes. Their fully CNN completes the excellent classification of images. Recovered feature is used as a standard image representation to handle different image object classifications in [16] by Sharif Razavian A.

Hossaine D. et al. suggest a deeper belief NN strategy for object identification. Once the object identification task is done, a live-path is created. The arrangement holds the object and keeps it in a pre-defined place. This deep learning method extracts adequate feature to detect the objects utilizing a computer vision framework [17]. Experimental inferences exhibits that, their proposed model performs better than other strategies. Babenko A and Lempitsky V [18] discussed about different enhancements demonstrated by the image descriptors offered by deep CNN, which greatly enhances image classification and recovery. The convolution layer could be clarified as nearby feature sets that describe image bounds explicitly. Amitha I C and N K Narayanan discuss the state of art about the conventional approaches and their inadequacies for object retrieval in [19]. Amitha I C and N K Narayanan suggested a proficient object recovery method in images utilizing SIFT-RCNN in [20].

Li H. et al. [21] have suggested new recovery method of image objects from an image database. The suggested model utilizes the power of CNNs, they utilized the further developed variant of the faster RCNN. They have tried their technique with various freely accessible databases. Oh I. et al. [22] recommended a strategy for segmenting multi-scale image dependent on maximally stable extremal regions (MSERs). They extended the essential MSERs usefulness (blobs recognition in image) to regular image segmentations [23].

Wang R. et al. [24] have proposed an upgraded, faster RCNN situated on the MSER inference standard for SAR image transport discovery in the harbors. The test result represents excellent recognition, and it distinguishes between their prospective technique and faster RCNN approach. This faster RCNN is utilized for recovering similar objects in various scenes. Faster RCNN is presented to conquer the issues in the fast RCNN model, the previous variant of CNN. Dubey A. K et al. [25] have introduced an efficient way to deal with deformity detecting in a rail route track surfaces utilizing MSERs stamping. Through this strategy the imperfections in the railway track can be assessed without much computation. All the above activities were performed within CNN family to further develop a recovery cycle or MRMSER based calculation to work on bad resolution or improve the lower surface regions in an image. The specific collective method utilizes the remarkable components of faster RCNN and MRMSER computations to recover the queried object with better accuracy from the specified image database.

In this combined model, it inspects the use of the multi-resolution maximally stable extremal regions (MRMSER) estimation to perceive the whole space of an image, regardless of the surface details. Locating blobs in images can be performed effectively through MSER and multi-resolution MSER systems. MSER is generally utilized during edge discovery, which gives better results with the mix of faster RCNN [26],[27],[28],[29],[30]. A layer connection strategy is utilized to perceive objects in low-resolution regions. The suggested method fuses a strategy for layer connection, to distinguish object in lower surface areas.

The main focus of the proposed MRMSER-FRCNN model is to retrieve objects efficiently, even if, the query image is affected due to poor resolution conditions or lower surface areas. Here, improve the poor resolution of the query image by applying specific multi-resolution MSER, and then apply the enhanced image input to the faster RCNN phase, for further object detection and retrieval.

III. Collaborative MRMSER-FRCNN Model

Recovery of objects in images can be done by conventional methods or by deep learning based methods.

With pre-trained CNNs, a large scope image database of high-resolution images can be organized into certain categories [13],[15],[16],[31],[32]. A common problem of not being able to distinguish areas beyond a specific region, were found in both region based CNN (RCNN) [33] and fast region based CNN. As a solution for this issue, the regions proposals networks (RPNs) were presented and joined with the final layer of fast RCNN [34], and the new organization is called as faster RCNN. Faster RCNN model recovery accuracy is lower when the image has lower resolution conditions due to varied features in the image texture [21]. The maximally stable extremal regions (MSERs) method is used to increase the feature extraction capability of faster RCNNs in poor resolution conditions in [35].

Particular object recovery in images is truly challenging in lower resolution conditions. In faster RCNN, the RoI pooling layers uses only the feature-maps of the top (best) convoluted layers, which leads to incorrect movement of feature extractions at lower resolution. Because of this problem, faster RCNN cannot retain the local attributes of an object. The MRMSER algorithm is integrated to solve the problem found in the faster RCNN model for efficient object recovery of the bad resolution state of the query image. The working of this novel collaborative approach is shown in the Fig. 1.

The proposed collaborative model works on the combination of two procedures, a faster RCNN followed by MSER/multi-resolution MSER. The query image is directly applied to the MRMSER or MSER phase. During this phase the MSER algorithm produces such an output image which will help faster RCNN phase detect and retrieve image objects even if, it is from a poor resolution condition or various textured regions. MSER calculations are done through a series of tasks such as grayscale conversion, detecting the MSERs and edge recognition, filtering based on region properties, determination of bounding box region and then produce a segmented image output. The image output from our previous phase is applied as the input to faster RCNN module. The faster RCNN model used in this work consists of 7 convolutional layers marked as conv1, conv2, up to conv7. The first five convolutional layers extract the features from the input image. The last two convolutional layers, conv6 and conv7 are fixed as fully connected layers. The input image is convolved with different filter sizes with varying strides.

The stride is the number of pixels shifts over the input matrix. Apply these convolutional feature map values to region proposal network (RPN) after conv5 layer. After the generation of region proposals, perform RoI pooling and then pass it through the fully connected layer. The output layer contains the bounding box information and the class score values.

Finally, to retrieve the queried objects, perform a ranking by class score generated in the previous stage. The detailed computation of MRMSER and faster RCNN are explained in the following subsections.

A. Multi-Rsolution Maximally Stable Extremal Region (MRMSER) Calculation

MSERs maintain a well-established framework for finding blobs in images. It is utilized to measure the intelligence between image parts of two images with alternate perspectives, providing broader benchmark adjustments. MSER will be utilized for better edge-detection in the proposed object detection framework. The in-depth edge detection ability of MSER overcomes the problems due to poor resolution conditions.

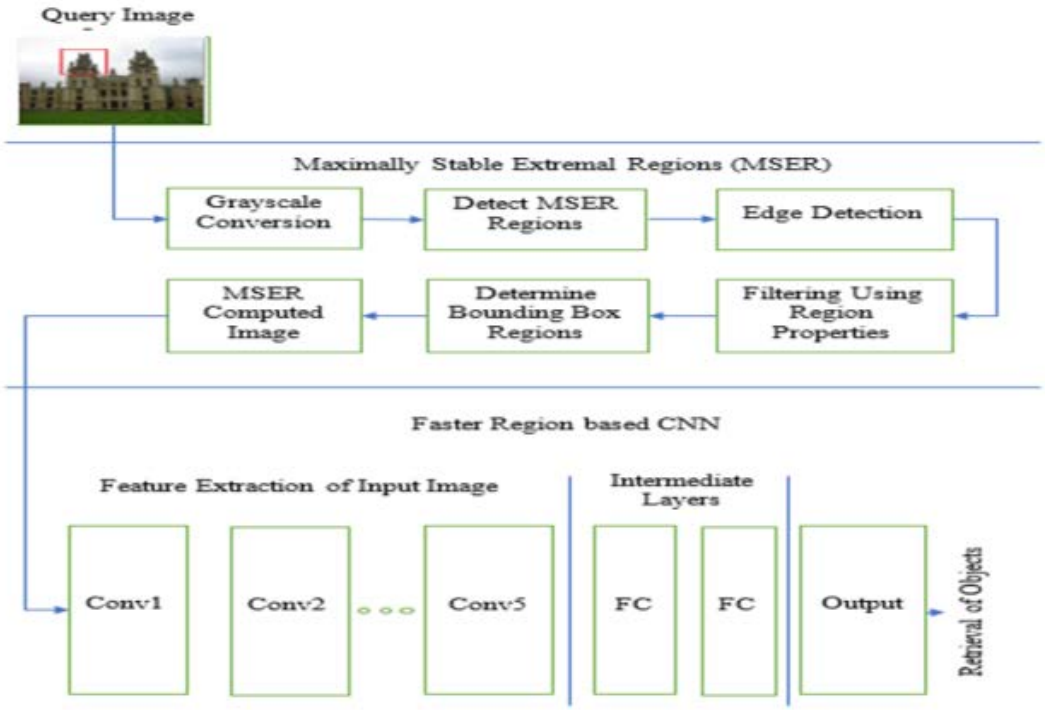

Fig. 1. Collaborative MRMSER-FRCNN Model.

MSER gives fundamental elements of an input image like all other feature detectors. MSER is reliably related fragment of two position sets of input images. This separates the image into several co-variant categories known as MSERs. MSER categories are related with regions describing uniform intensities surrounded by conflicting surroundings. The MSER procedure is described in the subsequent sections. In the initial step perform a grayscale conversion. Two options are there to perform the gray scale transformation in MSER - the average technique and the weighted technique or the luminosity technique. Each technique has its own advantages and disadvantages. Our system uses the weighted technique or the luminosity technique, which can be calculated as in Eq. (1) [24],[36].

$$I_G=0.3R+0.59G+0.11B \quad (1)$$

where I_G is the grayscale transformation and Red, Green and Blue channels are represented by R, G and B.

To guarantee the regions are maximally stable, ought to follow the requirements [35], which shown in Algorithm 1.

Algorithm 1: Algorithm for identification of areas utilizing MSER

Input:

Image I

Delta Parameters: To compute the similarities.

Step 1: For every pixel abbreviated by intensity values.

a. Spot a pixel in an image, when its turn arises.
b. Modify the pattern of the associated parts.
c. Update the region for affected related areas.

Step 2: For every single associated part.

a. Recognize areas with nearby minima concerning the speed of progress of the associated part region with an edge; characterize each such locale as MSE.

Output:

List of nested extremal areas.

Regardless, whether or not an extremely area is maximally consistent, it may be excused if:

- It is excessively large
- It is nearly nothing
- It is extremely shaky.
- It is exorbitantly similar to their parent.

Steps for the execution of MSER extractions are explained in Algorithm 2. Algorithm 3 gives the mathematical formulation of MSERs.

Algorithm 2: MSER extraction steps.

1. Perform the basic brightness of the image and change the intensity range from black to white.
2. Acquire related regions (“Extremal Regions”).
3. Identify a limit when an extremal region is “Maximally Stable”.
4. Estimate the region by an oval (optional).
5. Save those region descriptors as elements.

Algorithm 3: Mathematical Formulation of MSERs

Input:

Image I

I: D⊂Z2 →S

Extremal areas are well defined on image if:

S is completely arranged

A ⊂ D x D

p, q Є D are adjacent(pAq)

iff, $\sum_{i=1}^{d} |p_i - q_i| \leq 1$

∂Q= {q Є D\ Q:]p Є Q}

∂Q is the (Outer) Region Bounds

Extremal Region Q ⊂ D

I (p) > I (q) : Maximum

I (p) < I (q) : Minimum

Q1,….,Qi-1,….,Qi,….be the set of extremal areas/regions.

$Q_i \subset Q_{i+1}$

Q_{i*} is maximally stable

iff $q(i)=|Q_{i+\Delta} \setminus Q_{i-\Delta}| / |Q_i|$

| |: represents the cardinality

Δ Є S is a parameter of the process

To further develop the recovery exactness of the proposed procedure, a variation of MSER calculation is utilized named multi-resolution MSER (MRMSER). An MRMSER can be determined through the accompanying steps, which is shown in Algorithm 4.

Algorithm 4: Algorithm for MRMSER

Step1: Rather finding feature just from the image, generate a scale pyramid with an octave among scales.
Step 2: Identify MSERs exclusively at every resolution.
Step 3: Removes copy MSERs by erasing the best scale MSERs with comparative areas and sizes as MSERs found on the following rough scale.

Scale pyramid can be constructed through obscure and resample by a Gaussian filter.

After computing the MRMSERs of a given query image, generate the output and apply this image as an input to the faster RCNN phase.

B. Faster Region based CNN (FRCNN)

The second phase of the proposed system is based on faster RCNN. A common problem of not being able to distinguish areas beyond a specific region, were found in both region based CNN (RCNN) [33] and fast region based CNN. Faster RCNN model recovery accuracy is low when the image has lower resolution conditions.

FRCNN provides improved detection of analogous objects with the help of MRMSER. The proposed FRCNN consists of seven convolutional layers. The overall implementation task of FRCNN is performed across various convolutional layers. Initially, it receives an input image and pass it to a region proposal network (RPN), which initiates the RPN's task using the anchor boxes. Anchor boxes of different sizes were used depending on the size of the objects. After the generation of anchor boxes, compute intersection over union (IoU) on these bounding blocks / boxes. If IoU$\geq$ 0.5, accept it as the object bounding box and label it as foreground, else reject that box and recognize it as background. At the same time, the first five convolutional layers computes the feature maps and transfer it to RoI Pooling layer, which reduces the size of the feature maps created on the previous layers. A regressor refines the bounding box and classifier categorizes the object.

The real object recovery task is done in the FRCNN stage. The processed and modified image from MRMSER phase is applied as the input to FRCNN phase. The requested query image with poor-resolution condition was corrected by the MSER or MRMSER computation. The different steps associated with the FRCNN stage is described in Algorithm 5.

Algorithm 5: Algorithm for object detection using faster RCNN

1. A queried image is applied as input from MRMSER.
2. Concatenate conv3 and conv5 layers of the prospective system.
3. Finely tune the model.
4. Perform L-2 normalizations, which combines different scales and Norms in conv3 and conv5.
5. Compare the similarity of regional proposals.

a. Confidence score selections is done by setting up a threshold value.

b. According to the similarity score, rank the objects.

IV. Results and Discussion

To evaluate the efficiency of the proposed MRMSER-FRCNN method, the system is being simulated and tested on freely available Oxford buildings and vehicles database.

- Vehicle Dataset: The total number of images in this database is 150, which includes three different types of vehicles: bus, car and motorbike. Each individual vehicle class contains 50 pictures. Out of 150 images, 80% are utilized for training and the remaining 20% for testing.
- Oxford Building Dataset [37]: The total number of images in this dataset is 5062. This dataset provides 11 different landmarks for buildings. Each landmark was given five query images, so they affixed 55 query images to the entire dataset. All query images are marked with bounding boxes of required objects. Here also 80% images are utilized for training and the remaining 20% for testing.

Experimental results shows better object retrieval accuracy than faster RCNN or MSER-FRCNN. To check the retrieval accuracy of poor resolution, such images are tested and results are tabulated. The retrieval accuracy of the proposed method is compared with other similar methods also.

The object retrieval accuracy is calculated as the ratio of correctly retrieved objects and number of total objects in the reference dataset. The proposed MRMSER-FRCNN method gives a retrieval accuracy of 84.48 % in Oxford building dataset and 92.66 % in vehicle dataset. The previous method [35] gives 71.4 % in Oxford buildings dataset and 86 % in vehicle dataset. Faster RCNN shows 63.2 % in Oxford building dataset and 79 % in vehicle dataset. The sample object retrieval from Oxford building dataset is shown in the Fig. 2. The left most image surrounded by red colour box is the query image object and all other pictures surrounded by green colour box are the correctly retrieved image objects.

The detailed result analyses of MRMSER-FRCNN in Oxford building and vehicle dataset are shown in Tables I and II. The result comparison with various methods and proposed method is shown in Table III. Fig. 3 gives the bar chart comparison representation of the newly proposed MRMSER-FRCNN with other methods.

The object retrieval overall accuracy in Oxford building dataset with different methods are listed in Table IV. The proposed model retrieval accuracy is shown in bold values. Their performance comparison is shown in Fig. 4.

V. CONCLUSION

In this paper, a new collaborative approach to recovering objects from poor resolution images was proposed. The proposed MRMSER-FRCCN method can overcome the issue with the collaboration of MRMSER strategy. This will take care of smaller objects presented in the image with poor lighting conditions or poor resolution. Experimental results are obtained for collaborative method on two different publicly available datasets. The retrieval accuracies were compared with other individual as well as combined methods. The proposed MRMSER-FRCNN method gives a retrieval accuracy of 84.48% in Oxford building dataset and 92.66% in vehicle dataset. The previous works reported only a maximum

of 71.4% in Oxford building dataset and 86% in vehicle dataset. Hence it is found that the proposed MRMSER-FRCCN method outperforms conventional methods reported in literature.

A Framework for Weak Signal Detection in Competitive Intelligence using Semantic Clustering Algorithms

Bouktaib Adil, Fennan Abdelhadi
LIST Department of Computer Science
Abdelmalek Essaadi University
Tangier, Morocco

***Abstract*—Companies nowadays are sharing a lot of data on the web in structured and unstructured format, the data holds many signals from which we can analyze and detect innovation using weak signal detection approaches. To gain a competitive advantage over competitors, the velocity and volume of data available online must be exploited and processed to extract and monitor any type of strategic challenge or surprise whether it is in form of opportunities or threats. To capture early signs of a change in the environment in a big data context where data is voluminous and unstructured, we present in this paper a framework for weak signal detection relying on the crawling of a variety of web sources and big data based implementation of text mining techniques for the automatic detection and monitoring of weak signals using an aggregation approach of semantic clustering algorithms. The novelty of this paper resides in the capability of the framework to extend to an unlimited amount of unstructured data, that needs novel approaches to analyze, and the aggregation of semantic clustering algorithms for better automation and higher accuracy of weak signal detection. A corpus of scientific articles and patents is collected in order to validate the framework and provide a use case for future interested researchers in identifying weak signals in a corpus of data of a specific technological domain.**

Keywords*—Competitive intelligence; apache spark; big data; weak signal detection; web mining; semantic clustering

I. Introduction

In the era of big data, information flows from different sources and in huge volumes. Companies and organizations are under many threats coming from different opponents and competitors. Strategic decisions must be made in order to survive the market changes and cultural, technological, or political shifts that may occur in their environment. Economists rely on the most popular models for strategies to conduct a thorough competitive intelligence activity [1][2] for example : SWOT analysis's main purpose is to analyze threats and opportunities and develop plans to react strategically to those events, this model can be supported by using weak signal detection and early warning signs techniques [3].While PETS model analyzes the data concerning the environment of the company by monitoring political, economic, technological and social factors in order to prepare strategic responses to any change so it can maintain a dominant position in the market. Many organizations invest heavily in developing systems to automate the process of competitive intelligence [4] [5] and implement their adopted strategies. One of the main goals and features of those systems is the detection of weak signals in the environment surrounding an organization. Environmental scanning is gaining the attention of many stakeholders due to the benefits and advantages [6] it brings to the well-being and the contribution to the sustainability of their companies. The aim of most environmental analysts is to detect pieces of valuable information that will give them the strategic advantage of anticipation and early response planning, this can be done through weak signal detection. A weak signal is defined as a temporal change that occurs in a domain or a topic or in the environment in general [7], and it may have an impact on the future and become a trend. Therefore, the early detection and identification of this strategic information is crucial to the evolution of an organization. Many definitions are given to this concept, and different techniques and approaches are applied to detect this kind of information automatically, which is the subject of the next sections.

Companies must be able to understand and explore their environment to extract implicit knowledge that cannot be identified by experts. But it should also be able to predict the future evolution of a specific domain. The emergence of web data and the availability of information online pushes the companies nowadays to exploit these data to extract meaningful strategic information that allows them to make optimal and strategic decisions based on a scientific accurate analysis of the data, and an intelligent approach of web mining [8] to extract high-quality data.

Competitive intelligence systems are software that groups together a set of tools and technologies that companies have to implement in order to keep track of their evolving environment [9]. Many of these solutions neglect the anticipative information model that helps predict and monitor trends that unfold threats and opportunities that must be harnessed and used to gain a competitive advantage.

Weak signals are pieces of information that will help companies to identify threats and opportunities in their environment, which in turn will allow the implementation of an anticipative strategy rather than a reactive one that responds to the events as they happen.

With the rapid stream of data available online and the vast number of documents available on the web every second,

companies must use the latest big data technologies and advanced algorithms in order to process and analyze this data efficiently to identify weak signals [10]. In this paper we propose a framework for weak signal detection in collected data from the web, using big data technologies and aggregation of semantic clustering algorithms based on Apache Spark to detect weak signals and emerging trends and monitor opportunities and threats.

This paper is structured as follows: in section 1, we present the definition of the main concepts of this work: competitive intelligence, SWOT analysis strategy, weak signals detection, competitive intelligence systems, big data analytics, semantic clustering algorithms. Section 2 will present some of the related works that try to handle and propose novel tools and methods of weak signal detection and we will highlight some of their limitations. Section 3 presents the proposed framework and our approach to detect weak signals. Section 4 presents the results of a case study in collected articles about "big data", and we show the results of our approach, then we finish by a discussion and conclusion.

II. Problematic

In order to monitor competitors and identify early warning signs that help decision makers identify companies' key intelligence needs [11], we need a framework for weak signal detection that will allow us to listen to and anticipate the changes in the market [12] by providing an unsupervised manner of analyzing data and capturing potential weak signals that evolve through time.

We define the problem and the importance of our contribution as follows: The main problem is how to process and analyze large amount of unstructured big data automatically from various sources to detect weak signals and unveil some of the strategic information hidden in a large corpus of textual documents.

We use semantic clustering algorithms with an aggregation approach to automate the detection of weak signals that share some characteristics that we defined earlier in the framework and we propose them to the final user domain expert who will then judge their usefulness in a strategic decision or action.

Most solutions do not process a variety of sources and big data, so we will try to propose a framework that is capable of analyzing data coming from multiple sources, and architecture to support the evolution of volume and velocity of data while relying on Apache Spark capabilities and semantic clustering algorithms like LDA (Latent Dirichlet Allocation), LSA (Latent Semantic Analysis) and K-Means[13] to give accurate results and high semantically related clusters of terms that may represent a weak signal.

III. Main Concepts

A. Competitive Intelligence

Competitive intelligence is defined as a process, activity, service[14] that starts from the definition of a strategic need problem, passing by the collection of multiple data from different sources, and through the analysis of this data, analysts process the data using their set of tools and techniques to extract strategic information from the data and interpret it to transform it into a usable and a valuable knowledge to be disseminated to the stakeholders, every organization has a different model and strategy to conduct competitive intelligence, which varies depending on the size, the environment or the need of an organization, in order to enhance the decision making process.

The goal of conducting competitive intelligence is to define the position of an organization in the market and to help it be aware of the changes and competitive forces around its environment [15], by providing an organizational tool capable of generating valuable knowledge from raw data to guarantee better business performance by taking strategic actions at the right time [16].

B. SWOT Analyisis and PEST Model

Many models exist to implement competitive intelligence monitoring strategies. Economists proposed models to establish an environment scanning tools to prepare for any change in the market and give an objective perspective of the position of an organization. SWOT analysis [17] focuses on analyzing the strengths and weaknesses of a company through processing internal data, and opportunities and threats coming from external data. When talking about weak signals, we are more interested in analyzing the opportunities and threats coming from the market. The PEST model [18] stands for political, economic, social, and technological factors of an environment that could influence the existence of an organization and its evolution in the market. That external information can be collected and analyzed easily from external web data and exploited in technological intelligence to be able to detect innovation [19], which is present in both structured and unstructured form. The aim of this paper is to analyze big unstructured data using big data analytics technologies and efficient algorithms while respecting and following the main ideas and concepts of those two models, as in Fig. 1.

C. Weak Signals

According to Igor Ansoff [20], weak signals are defined as small changes and imprecise early indications that occur over a period of time on a specific topic that may have an ongoing impact on the future. Weak signals are temporal changes that hold important and strategic information that companies and organizations must detect and collect to stay ahead in the market [21]. This helps them implement an anticipative approach of handling the opportunities and threats present in the market in the form of unstructured data harvested from the web.

The identification of weak signals relies on some characteristics and key points. According to Ansoff weak signals are weakly mentioned in their first appearance, they are less frequent than the main concepts in the context where they exist, but they are new and novel and hold a sign of innovation or a surprise in the market. The interpretation of weak signals requires domain experts in order to contextualize the findings and transform data into knowledge, and classify them as opportunities or threats and disseminate them to stakeholders to make an appropriate strategic decision.

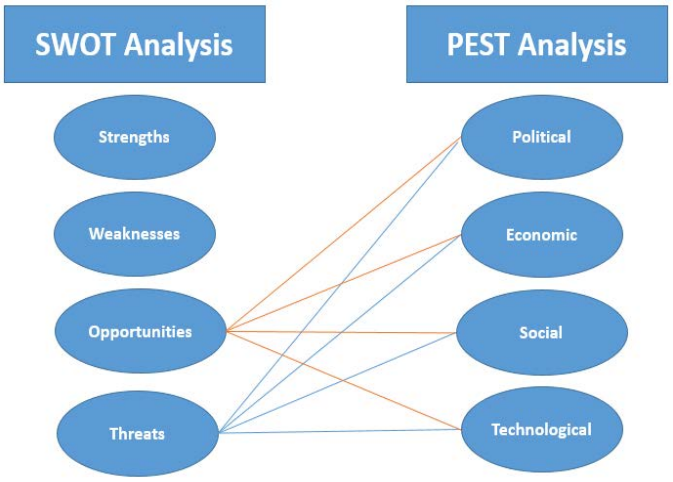

Fig. 1. SWOT Analysis vs PETS Model.

D. Apache Spark

Due to the volume of data available online, data must be collected from different sources in different formats. A homogenization step is mandatory to unify the structure of the data to be collected. Once the data is collected, we end up with huge volumes of data that cannot be processed by a normal computing approach, thus the need for big data analytics technologies that support huge volumes and fast streams of data. Few weak signal detection researchers have proposed a technological framework that addresses the issue of big data. Therefore, we propose in this paper a big data framework for weak signal detection with the implementation of semantic clustering algorithms in Apache Spark.

Apache spark [22] is one of the main big data analytics technologies, and the most well-known platforms for massive distributed computing, that are popular nowadays. This framework is gaining a lot of attention in the big data community and its use in a variety of applications [23] proved to give efficient results when dealing with large datasets. Hence we chose this framework in our attempt to develop a competitive intelligence system [24] to analyze and extract strategic information from the increasing amounts of data available in the environment of companies and organizations.

Apache spark has been used in a lot of applications [25] and it has been used to implement a variety of big data platforms and solutions. Apache Spark is a part of the Hadoop ecosystem introduced in 2009. While Hadoop processing is based on the MapReduce computing paradigm, Spark relies on the DAG (Directed Acyclic Graph) paradigm, which imposes sequential processing of RDDs, a distributed unit of data nodes in the cluster, that optimizes the consumption of resources by avoiding costly data copies used in iterative algorithms that we are going to be using in the weak signal detection framework.

IV. Related Work

Many researchers tried to apply variable methods to detect efficiently weak signals in large volumes of documents [26]. Those methods vary from supervised to unsupervised machine learning methods, automatic and semi-automatic methods, or manual methods relying on experts input, quantitative and qualitative methods, and many data sources were used to prove the approaches and detect weak signals.

One of the early approaches and attempts to discover weak signals in data, Yoon [27] used a keyword-based text mining method to identify opportunities in web news data. He used a quantitative method in which he performed a time-weighted analysis by calculating the occurrence and frequency of keywords during a period of time. But this attempt was limited to only one source of data, and it lacks an automatic crawling of data from multiple sources, and fails when it comes to dealing with large datasets. The result may not be easily interpreted when visualizing a large space of keywords.

El Hadadai.Anass et al [28] proposed a sequence data mining based method for extracting emerging trends and highlighting the evolution of domains through crossing terms with dates and other fields. With the application of correspondence analysis and multiple correspondence analysis and a visualization tool, this approach was able to extract clusters of weak signals from sorting and extracting clusters from the obtained matrix. The method was evaluated using a dataset from scientific articles and patents collected from scientific databases in order to identify technological weak signals, but this method lacks the possibility to be extended to support large datasets and its need for an expert to manipulate the tool to perform the analysis.

D. Thorleuchter et al [29], proposed a methodology based on idea mining and Latent Semantic Analysis to identify weak signals, by constructing a matrix based on the vectors and patterns discovered from the idea mining approach, by applying a dimensionality reduction on the matrix using SVD decomposition, which produces a set of semantically related clusters that may be a weak signal. The method is limited, as stated by the authors. They observed that the method lacked the possibility to discover implicitly cited weak signals and proposed an enhancement using Latent Dirichlet Allocation to get more accurate results.

Antonio.L.et.al [30] proposed a method to conduct an anticipative intelligence by analyzing text and identifying weak signals, using clustering k-medoids and a Jaccard function as a similarity function between obtained clusters in order to analyze similar clusters of weak signals, the method claims to be automatic but the dataset is collected from experts at the beginning of the process.

Julien Maitre et.al [31], the work that is closely related to what we are proposing is inspired by this paper, which presents a novel approach for weak signal detection in weakly structured data or unstructured data, by combining Latent Dirichlet Allocation and Word2Vec algorithm to perform clustering on a corpus of documents collected from the web, the article proposes also a method to identify the number of clusters k to be extracted from a corpus using LDA, which in most cases is hard to define and is crucial to the quality and robustness of the obtained results especially when it comes to weak signals, where the use of a small k may eliminate the identification of important weak signals.

In our approach, we try to group the three algorithms in order to reduce the mistakes and weakness of those approaches

by using a clustering aggregation [32] approach supported by the computational power of Apache Spark and the flexible nature of RDDs and their reusability in iterative algorithms in order to perform multiple tasks, and with using the ML pipeline feature of Apache Spark to facilitate and automate the process of weak signal identification with a minimum interaction of experts.

V. Proposed Framework

In light of the findings of the literature review conducted by C. Muhlroth et.al [26] and other reviewed approaches [33] [34] [35] [36], we found a need to propose a big data analytics framework for automatic weak signal detection. Thus we propose in this paper a framework that uses Apache Spark to implement the data analysis from data collection to weak signal identification using semantic clustering algorithms. The feature of Apache Spark that allows us to achieve this is the ML pipeline that aims at automating steps to be applied on a dataset, in order to extract implicit hidden information that may present key strategic indications to be processed and analyzed.

Fig. 2 presents the architecture of the proposed framework. It outlines the steps to be followed in the pipeline implemented using Apache Spark, starting from data collection to the identification of weak signals contained in the corpus of collected documents. In the following section, we provide a brief explanation of Apache Spark ML pipeline, and we explain the steps of the pipeline in detail.

A. Apache Spark DAG and ML Pipeline

Apache Spark provides an API to manipulate RDDs, resilient distributed datasets, which is a good structure for dealing with big unstructured data. The power of this data structure remains in the possibility to expand to huge volumes of data, thus the adoption of this technique in our work. RDDs will hold the corpus data to perform analysis using ML pipeline API that represents a set of processes to perform on a dataset to get the desired results. This makes it easier to aggregate multiple algorithms into a single pipeline. We will be using this technique in our work to implement an efficient big data analytics framework for weak signal detection, by combining the semantic clustering algorithms presented in Fig. 2.

The technology that allows Apache Spark to execute such processing is DAGs which is a new enhanced strategy to perform map-reduce tasks, as shown in Fig. 3, by organizing the planning of execution in stages and steps that form a directed acyclic graph of transformations to apply on the dataset.

All the algorithms used in this framework will be implemented using the Apache Spark MLlib library that contains a variety of tools and machine learning algorithms and clustering to be applied on the data. We combine LDA and implement LSI and K-means by using ML Pipeline to perform semantic clustering on the corpus of collected data. At the end, we communicate the findings to the stakeholders and experts to identify the clusters that hold potential weak signals.

B. Data Collection

The framework starts with data collection. We collect data from multiple scientific articles databases and patents and store them in the Hadoop file system. When we start the execution of the ML pipeline we load the data from Hadoop onto the Apache spark cluster in order to execute the outlined pipeline process depicted in Fig. 2. Scientific databases from IEEExplorer, ACM Digital, and patents from USPTO, contains many articles and documents having a lot of fields like text, date, abstract, publication date, etc. We are interested in the text and publication date of the document in order to conduct a temporal analysis of weak signals and the evolution of the topic in time to perform technological surveillance on a specific field of interest.

Many scrappers and crawlers are developed to collect data from those websites using web mining methods and Scrapy python framework [37], which gives the possibility to create scraping agents to crawl as many web pages as possible with the elimination of repeated documents. Our approach helps decision-makers and analysts to collect data automatically and conduct environmental scanning with no need for manual intervention, which could be a hard task for companies in this era of big data.

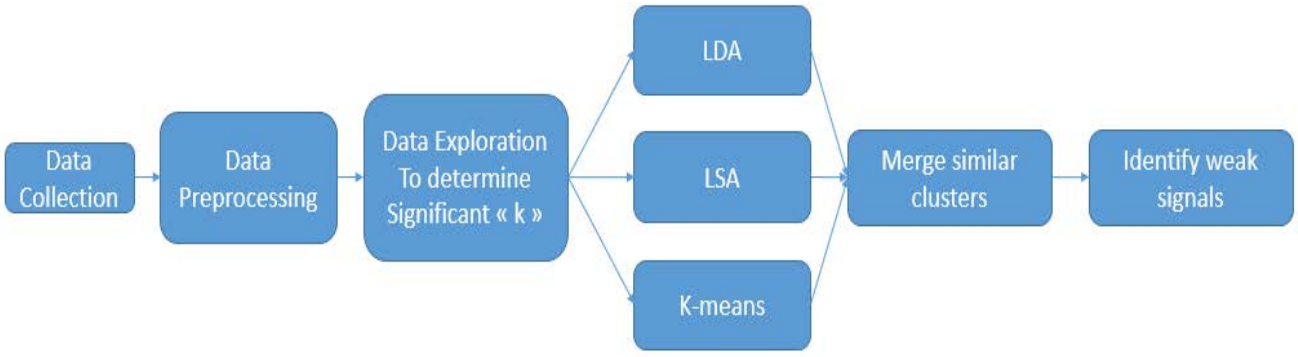

Fig. 2. Proposed Framework Architecture.

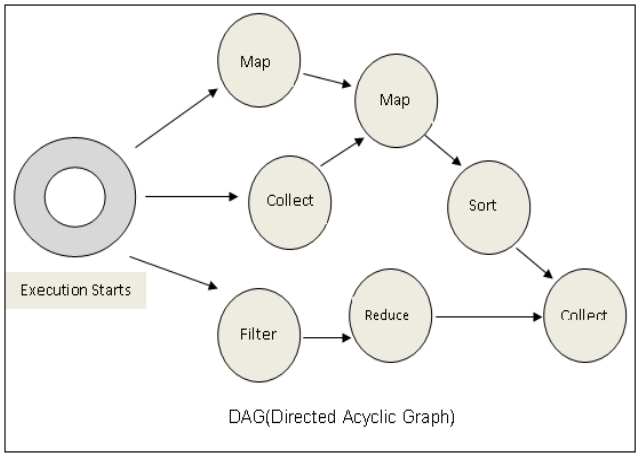

Fig. 3. DAG Excution Method in Spark.

C. Data Preprocessing

Preprocessing is an important step to clean data and format it to our needs. After choosing the text field we will use in analysis and the date field that will help us to filter emerging trends, we clean the text from ambiguous characters, then by removing StopWords, stemming and lemmatization, which will help us to get more accurate results and easily interpretable information from raw data. We create n-grams from the corpus to add them to the vocabulary of the corpus. This step is important to enable the clustering algorithms to identify multi-terms that may hold an important part of a weak signal, especially in the scientific field. Due to the nature of weak signals, which is low frequency and occurrence of words, we eliminate terms where the count is above a threshold, for example 200 occurrences, as we are not interested in highly frequently mentioned words that, in most cases, represent strong signals or trends, which are not the purpose of our analysis.

D. Data Exploration

The number of topics to be extracted cannot be determined previously as the algorithms used are unsupervised algorithms and the analyst does not have an idea about the number of clusters to be obtained. Therefore, we choose a rule of thumb and we define the number of clusters to be extracted as in eq.1 after the extraction of the vocabulary from the corpus:

$$k = \sqrt{n/2} \quad (1)$$

where n is the number of words in the vocabulary of the corpus.

The determination of an approximate k is an important step in the process of this pipeline. We can specify k based on many techniques of data exploration or using many methods from the literature [38], which is outside the scope of our research, or we can try different values of k and analyze the different clusters obtained. A small number of k though must be avoided in order to avoid the elimination of important potential weak signals that are not heavily cited.

E. LDA

Latent Dirichlet Allocation [39] is a generative probabilistic model for text classification and a topic modeling algorithm that aims at representing the documents as a set of topics, with the objective of assigning each term to a semantically related topic. When applying LDA in Fig. 4 to a corpus of documents, the algorithm tries to cluster the topics and their related terms according to their semantic relationships. It identifies k topics, k is a number specified by the analyst, many methods exist to choose the best k that gives accurate clusters.

LDA algorithm steps are defined as follows, for each document w in a corpus D:

1. Choose N ~ Poisson(ξ).
2. Choose θ ~ Dir(α).
3. For each of the N words wn:
   (a)Choose a topic zn ~ Multinomial(θ).
   (b)Choose a word wn from p(wn |zn,β), a multinomial probability conditioned on the topic

Those steps are the standard for the LDA model, in order to cluster a distribution of semantically related words to a set of specific topics, in our case those topics may represent innovations, opportunities or threats.

So we will use this algorithm to detect underlying topics in a corpus of documents. Those topics may include weak signals that are not easily identified and are not in the scope of the knowledge of experts, especially in the case of new innovations in a domain. After removing the most frequent terms from the documents, we aim at identifying sets of words that are less frequent and semantically related and belong to the same topic. That's why a maximal number of k is essential to the extraction of latent topics that represent a small proportion of the document, which is the nature of weak signals defined by Ansoff.

F. LSA

Latent semantic analysis [40] is a text mining technique that aims to create a semantic space to identify relationships between words in a corpus of documents. Those relationships are semantically detected using a linear algebra technique called SVD decomposition. Its goal is to decompose a document-term matrix created from the corpus into a lower-dimensional space in order to detect close words and extract coherent topics and similarities between documents.

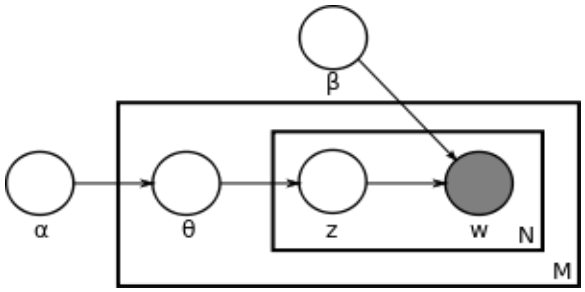

Fig. 4. Plate Notation Visualizing the LDA Model Parameters, Plate M Represent The Total Number of Documents, N Represent the Numbers of Terms in a Document, α the Per-Document Topic Distributions, β the Per-Topic Word Distribution, θ the Topic Distribution For Document m, z the Topic for the n-th Word, w is a Specific Word.

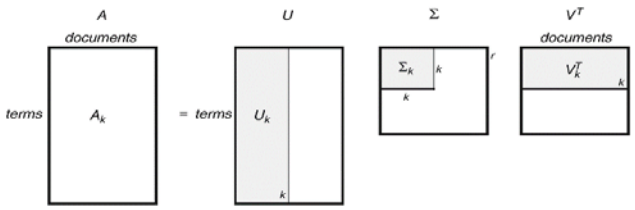

Fig. 5. LSA Algorithm Matrix Decomposition Process.

By applying this technique in weak signal detection we want to detect weak clusters that are appearing in the corpus, those highly coherent and newly emerging clusters may hold important strategic information, they may represent an opportunity for investment and collaboration, or a threat that a company has to plan a strategic response to face it and overcome its consequences.

After the creation of the matrix from the collected corpus by crossing the terms with their corresponding documents, we create an m*n matrix where m is the number of terms and n is the number of documents, then we apply SVD which will decompose the matrix into 3 new matrices as depicted in Fig. 5.

$$M = U\sum V^* \quad (2)$$

Where U is an m*k matrix that holds the word assignment to topics, Σ an k*k matrix which contains singular values that represent the importance of the topic, V* is an k*n matrix that contains the topic distribution across documents. In our case, we are interested in the first two matrices. By crossing the pairs of vectors of the two matrices, we obtain the clusters of topics and their corresponding terms. The clusters obtained in this step will be merged with the previous results to enhance the semantic understanding of the corpus.

G. K-MEANS

K-means is one the most important algorithms for clustering data, the power of this approach resides in its ability to perform unsupervised learning and clustering of data with no prior knowledge, hence the choice of this algorithm in our process to enhance the results of our approach and the quality of the obtained clusters.

As in the previous algorithms, we perform data preprocessing depicted in the previous section before applying k-means. To apply k-means we follow those steps in order to find semantically related terms, relying on the Word2Vec [41] model, and group them in cluster as depicted in Fig. 6:

- Cleaning and Preprocessing of text.
- Determination of number k.
- Feature extraction using Word2vec to represent each word semantically as a vector.
- Applying k-means.
- Getting clusters.

In the next step, we will merge the most similar clusters to unify and expand the clusters that are candidates to be weak signal clusters, containing information about potential opportunities or threats that must be noticed.

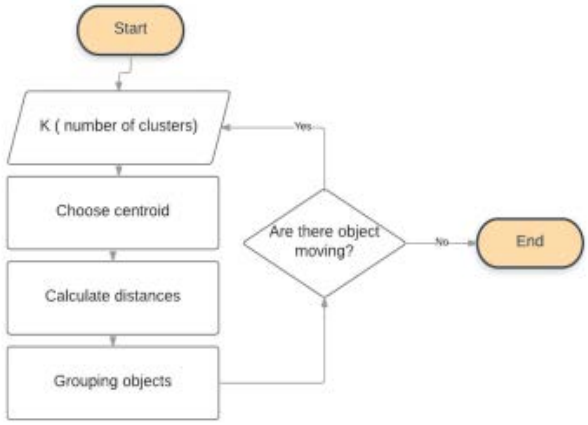

Fig. 6. K-Means Algorithm Steps.

H. Cluster Aggregation

Cluster aggregation [32] is a method that aims to apply different clustering algorithms on the dataset and find a consensus about the optimum cluster groups in order to eliminate duplicates, and eliminate the noise of each algorithm if it was applied individually, in order to improve the quality and robustness of the clustering.

After extracting the clusters from the previous steps, denoted C1, C2 and C3 from applying LDA, LSA and K-means respectively, we move to the merge step which consists of performing a similarity calculation between all pairs to identify similar clusters and merge them in order to eliminate redundancy and enhance the quality of the weak signals detection process by minimizing the disagreements between clusters according to Equation 4.

$$D(C) = \sum_{i=1}^{m} d_V(C_i, C) \quad (3)$$

where v is a set of words or multi-terms and m is the number of all clusters from the applied algorithms.

The implementation of Approximate Similarity Join of Apache Spark MLLib is used, which is based on the Jaccard similarity function eq (4). We calculate it for each pair of all clusters from all algorithms, and if it passes a threshold, we merge the clusters into one, in order to get the cluster that minimizes the number of disagreements.

$$J(A,B) = \frac{|A \cap B|}{|A \cup B|} \quad (4)$$

The resulted clusters from Algorithm 1 are shared with experts and stakeholders to identify potential weak signals from the corpus.

I. Weak Signal Identification

Extracted clusters will pass by the last step, which aims at calculating a score that represents the weighted term evolution inspired by Yoon et.al [27], the evolution rate “er*” of each term during a period t of the cluster “Ci” is calculated and the sum “eri” of all terms represent the score of a cluster, based on that score we can identify the clusters that may hold weak signals represented by semantically related terms from the corpus.

We order the clusters by their score, and based on that score and the interpretation of an expert in a domain, we can spot the clusters that are holding information about the weak signal, which, by interpretation, may be a threat, an opportunity of investment, or an innovation that needs further investigation or collaboration.

In the next section we present the results of applying this flow to the collected corpus, and we discuss the obtained results, advantages and limitations of our framework and we conclude with ideas for future researchers.

```

VI. Result and Disccusion

In order to evaluate the proposed method, we will conduct an analysis on a dataset of scientific articles about "big data" topic, we collected a corpus of 5800 documents and scientific articles about « Big Data » containing multiple fields, from the fields we are interested in are abstract field and publication date. We will perform text mining on the text field and perform growth analysis using the publication date.

The purpose of our analysis is to perform the clustering aggregation of three algorithms, K-means, LDA, and LSA in order to combine the results of each algorithm and select from the obtained clusters the ones that are potential weak signals and may hold information about opportunities or threats.

A. Data Collection

We collect data from IEEExplorer, ACM Digital Library, SpringerLink and Sciendirect to show a case study and illustrate the processes of our approach. We use the search query "big data" and choose a publication date range from 2000 to 2020, then we collect the documents and articles published in this range of time. We are interested in the abstract, title and publication year of a document as in Fig. 7, the scraper agents extract those fields using the CSS styling of each database website in order to ease the step of homogenization of those fields in the next step.

We create a data frame from the documents containing the three fields we are interested in, and process them in the remaining steps of the framework. Fig. 8 shows an extract of the collected data.

B. LDA Obtained Clusters

After the preprocessing and cleaning step of the articles obtained about big data, we perform the first clustering algorithm, LDA, to obtain k clusters from the corpus. The topics obtained are semantically related and clustered in one group.

A sample of clusters obtained from the corpus is presented (Table I):

TABLE I. List of Obtained Clusters from LDA

Cluster	terms	
Topic1	new concept secure communication collection data imbalanced data method consists probability distribution time big	experiments carried nir fmt proposed algorithms location data error rmse minimize total intermediate pointers
Topic2	low power performance overhead set data model predict clustering method method paper features paper	non uniform information big learning architectures cold start tasks cloud signal quality address challenge

Topic4	important information processing techniques video analysis word embeddings enhance performance deep hashing physical systems	linear programming existing work data intensive iot networks control mechanism stream processing cover problem

C. LSA Obtained Clusters

The application of latent semantic analysis is done. After applying LSA we obtain a different set of k clusters using the matrix decomposition of singular values (SVD). For each cluster, we select a set of terms that represent this concept and that are closely related to it using the singular values in the sigma matrix.

By applying the LSA on our corpus of data we obtain the following clusters (Table II):

TABLE II. LIST OF OBTAINED CLUSTERS FROM LSA

Cluster	terms	
Topic1	defect detection data fusion sar image detection method power supply tree boosting digital twin	high performance smart manufacturing data digital key management parking lot fabric defects address problem
Topic2	trajectory data lane changing social networks data driven data processing deep neural reinforcement learning	changing model spatial temporal uav bss onset date modis derived brain health health quality

Topic4	point cloud ant colony time delay electric power neutrosophic cubic point clouds dense point	security threats power data uwan security power systems algorithm based cloud generation healthcare insurance

D. K-Means Obtained Clusters

The application of k-means results in a set of k clusters after the calculation of word2vec of the text to create a feature of semantically related words. This was used as the measure of similarity between words or terms to perform semantic clustering. The following clusters were obtained from applying this algorithm:

In the next step, we will try to merge similar clusters into one cluster and build a cluster group that collects the power of all the algorithms and solves the problems and weaknesses of the other approaches (Table III).

TABLE III. LIST OF OBTAINED CLUSTERS FROM LSA

Cluster	terms	
Topic1	big personal personal data hidden transition process model industrial internet open data redundant tight	data big results indicate data processing attack path subgraph matching smart cue value data

E. Aggregation Algorithm Obtained Clusters

By applying the approximate join similarity, we get the pairs of similar clusters, by merging similar clusters we get p clusters $p < k*3$, which gives an idea about overall clustering and solve the mistakes that could have been made by using one individual algorithm, the obtained clusters represent all the small topics and semantically related terms that may hold an opportunity or a threat (Table IV).

TABLE IV. IDENTIFIED SIMILAR CLUSTERS

Cluster id	Cluster id	Similarity distance
33	30	0.307
36	33	0.307
23	36	0.428
25	6	0.428
23	1	0.428
6	25	0.444
36	23	0.444
23	24	0.461
24	23	0.461
1	23	0.473

We merge similar clusters into one in order to eliminate redundant clusters and improve the quality of visualization.

In order to visualize the results of the approach, we create a graph from the adjacency matrix term-topic and plot the graph using Gephi to see the clusters and the relationships between them. The graph obtained contains 670 nodes and 12 006 edges. We show an extract of the graph in Fig. 10, and an identified weak signal in Fig. 9 containing semantically related words about the application of big data in health.

F. Interpretation and Discussion

From the interpretation of the results, we can spot the weak signals and hidden information that are not visible to the experts, and by combining their expertise with results obtained, we can identify clusters that are potential strategic information holders and we should cross the data back to the original document for further analysis and understanding of the context of appearance and the identification of the importance of the discovered piece of information.

In our approach we filtered weakly cited words in a specific time, year of publication, from the corpus and applied three semantic clustering algorithms in hope of finding the most accurate clusters by using an aggregation method. Those obtained clusters may contain pieces of information that is crucial to the implementation of an anticipative strategy of an organization. A weak signal is characterized by the evolution of its presence or its number of occurrences through time, which makes it a strong signal in the future, though not all weak signals are destined to be strong.

In Fig. 9 we present the graph representation of filtered words from the corpus, those words are related by their co-existence in the same document and their appurtenance to the same cluster. In Fig. 10, we singled out a cluster so we can study the semantics of this potential weak signal with the help of a domain expert.

We see in Fig. 10 that the semantic cluster of topic 32 is weakly cited and highly rated in the last period of research, which means that this low visibility cluster may be a trend in the future, though we can comment on the choice of number k, which must be chosen wisely and we must experiment with different values of k, or we have to use a different algorithm to determine the optimal value of k that will give promising and accurate results.

Extracted Potential Weak signals must be harnessed to identify threats and opportunities in the market. Our method extracts the most promising clusters of weak signal topics. Using our approach and with expert intervention, we can spot the key information that will generate value for organizations. Though the advantage of this method is not to predict which weak signal will become strong, but to enhance the quality of extracted clusters from the corpus, so we can keep and analyze only the semantic clusters holding potential weak signals through the aggregation of three algorithms: LDA, LSA, and k-means, this approach will not eventually predict which one will become strong in the future. In order to predict whether a weak signal will become strong, we require labeled data, and with the application of supervised machine learning [42], we can extract the features of weak signals that are candidates to be strong and trend in the future.

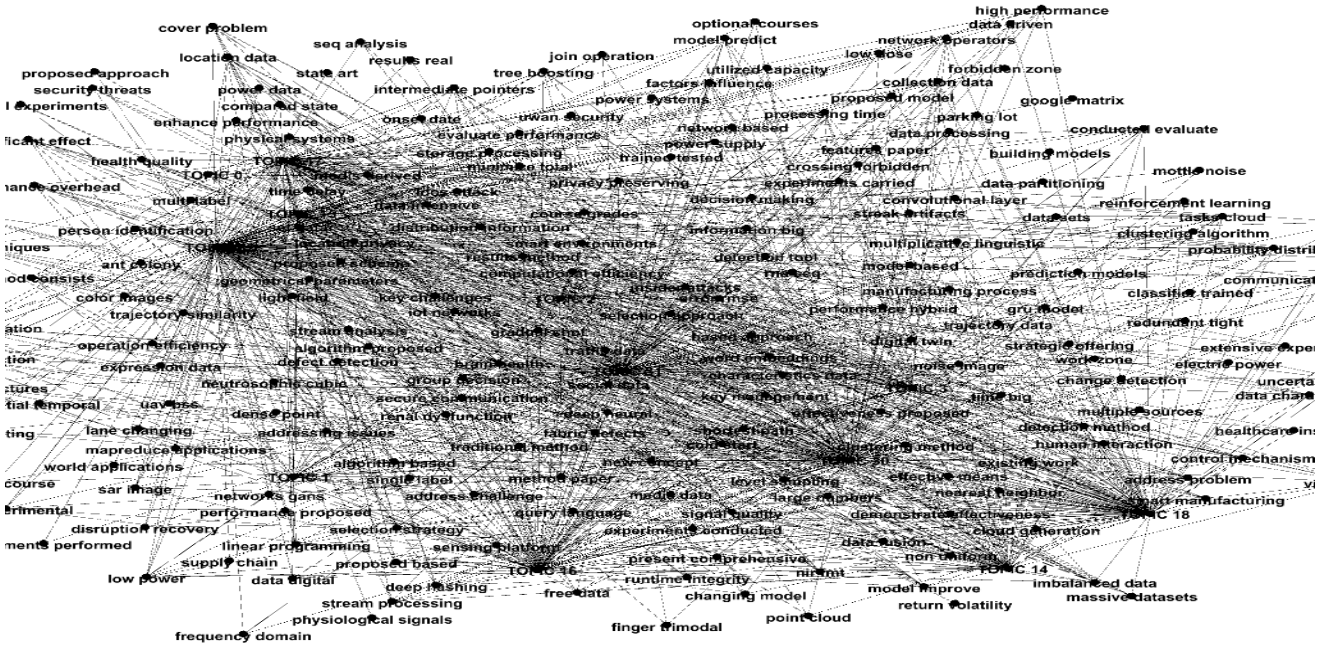

Fig. 9. Network of Collected Data from the Scrapping Agents of the Framework.

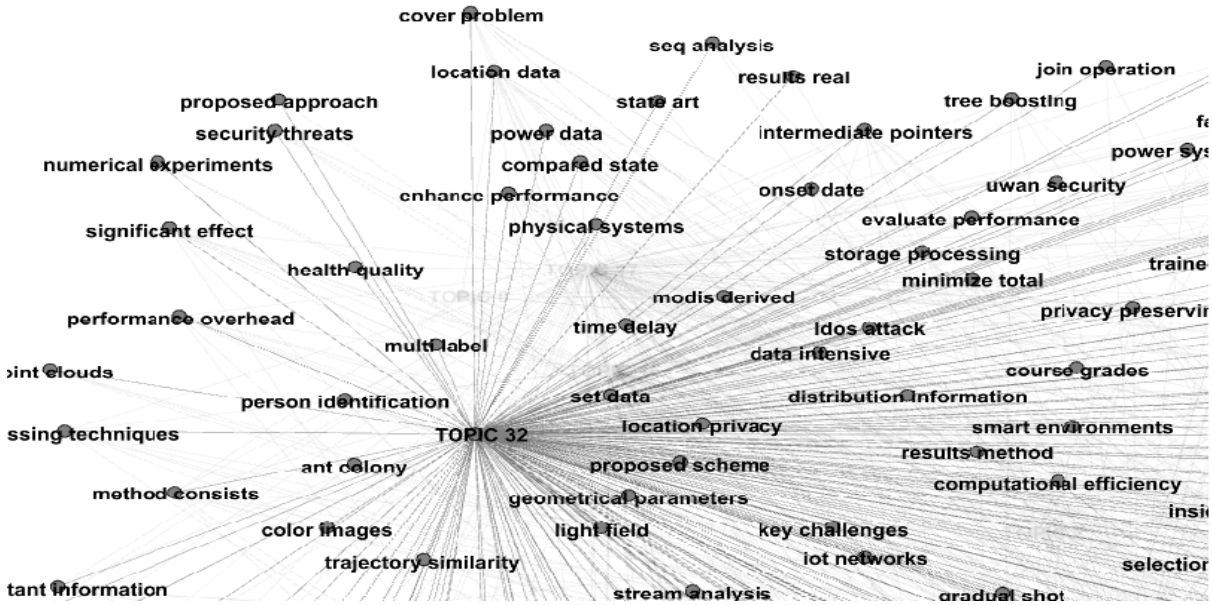

Fig. 10. Illustration of an Extracted Weak Signal Topic to be Analyzed (Topic 32).

VII. Conclusion

In this paper, we proposed a novel framework that uses semantic clustering aggregation models, made possible with the use of the computation power of Apache Spark, through the use of ML pipeline which gives the possibility of automating the process of weak signal detection in large volumes of data. The aim of aggregating clustering methods is to combine the features extracted from each method and hide its weaknesses. The use of such a tool in business will allow businesses and stakeholders to remain active and alert in the market. Semantic clustering methods have proven to be very efficient when it comes to topic modeling and extraction of variable topics semantically related from a large corpus of documents. Hence, we judge this approach to be very pragmatic in nature and it does contribute to the domain of weak signal detection.

Our framework will help stakeholders identify and prepare scenarios of intelligence needs. For each potential weak signal, there must be a strategic response ready to tackle it, which will help stakeholders implement an anticipative approach to conduct strategic competitive intelligence in a big data context, where manual extraction and analyzation of documents is impossible in this era where new data is available every millisecond.

Despite our framework contribution in the field we still think that there is more work to be done for future researchers in weak signal detection literature, for example the nature of data to be analyzed in weak signal detection research is unstructured, thus the need for more advanced clustering methods to perform unsupervised machine learning to label data as weak signals from the past data, and apply Text mining Deep Learning models [43] in order to be able to extract and identify weak signals in future data once available online, which will give a competitive advantage for organizations. In our future work we will apply Graph embedding technique [44] [45] as a technology that will allow us to reduce the dimensionality of the corpus and facilitate the semantic representation of weak signals, through the study of dynamic graph embedding to monitor the evolution of a domain terminology through time, in hope of detecting innovation, opportunity or a threat as early as possible.

In conclusion, we must mention the limitation of methods and approaches to validate the extracted weak signals in most of the literature [46]. As a future research project, we can propose a new direction of research in this field through adopting novel semantic clustering algorithms that rely on deep learning like Word2Vec and Glove word embedding [47] for a more precise semantic analysis of the corpus, and proposing novel approaches that relies on labeled data.

***Abstract*—The occurrence of COVID-19 pandemic has changed people's life in every aspect, such as applying social distancing, the transition from offline to online activity are applied in order to decrease and stop the spread of the virus. This sudden change causes a fairly high level of anxiety and stress in society, especially for children because of activity restrictions. Various innovations, especially technology have been carried out to overcome the problems in distance restrictions that have arisen due to the COVID-19 pandemic. Virtual reality believes becoming one of the innovations that can be used to reduced anxiety levels and boredom during activity rectrictions, because it creates an artificial environment for humans to socialize. In this research, combine the Unity3D and blender software to build a virtual reality simulation with the help of virtual glassed to give a real impression of the virtual room that has been created. This VR application consists of three environments that children can use it to explore the virtual room without need being in crowded atmosphere. Based on the result of pretest and posttest questionnaire in 30 participants with the range age from seven to ten, it concludes that this VR applications can decrease the level of stress and anxiety in children by one to two levels. Besides that, this application located in acceptable area based on SUS score system.**

***Keywords*—Blender; COVID-19; Unity3D; virtual reality**

I. Introduction

In the last decade, it can be seen that the development of information technology has grown rapidly, and has contributed to advancing world civilization, including the creation of borderless world especially for the access of information. One of the hot topic in tehcnological development field is Virtual Reality (VR), which is the creation of a technological simulation resulting from a three-dimensional (3D) environment [1][2]. Along with the development of increasingly advanced technology, there are many changes that occur in the world, one of the remarkable changes is the transfer from all offline activities to online due to the coronavirus disesase 2019 (COVID-19) pandemic.

The COVID-19 pandemic began to emerge at the end of 2019 in the city of Wuhan, Hubei Province, China and began to attract a lot of world attention [3]. Recently, COVID-19 has infected more than 89 million people in 218 countries [4], due to massive transmission cause many countries implementing new regulations to stop the spread of COVID-19. One of the effective way to minimalize the spread of COVID-19 to implement a lockdown which has an impact on restrictions and the closure of public access that has the potential to cause crowds, including : school closures, restrictions on shopping places and tourist attractions. This has a fairly serious impact in all aspects of life [5].

Based on research [6],[7] there are many psychological impacts that have arisen due to the COVID-19 pandemic, including increased levels of anxiety and stress and even more severe effects if people have to undergo self-quarantine. In this era of social restrictions, technological advances are considered to be able to help reduce the negative effects caused by COVID-19, as well as become a solution in the current massive social restrictions. This argument also pointed out in [21] which highligted that digital approaches, such as AR and VR should be optimised in order to help children mental and behaviour during this pandemic era. In line with research [5] that utilizes technological advances to conduct distance learning, or the use of augmented reality (AR) applications as tutorials related to effective hand washing in order to prevent COVID-19 infection [8]. Another research on AR [20] has a conclusion that the use of AR application improve the effectivenes of training while conduct on stressful environment.

In addition, one of the technological advances that can be utilized in overcoming the COVID-19 crisis is the use of VR technology that can help overcome current health problems [9]. In the study [10] discussed the relationship between the use of VR technology that can help reduce pain in children during burn replacement. Several research [19][22] has been conducted, and gain conclusion that VR, and AR have a significant effect to reduce or prevent stress during COVID-19 Pandemic. It is happen because using the virtual tour can generate sense of belonging and affective emotion which lead people able to reduce their stress level. Furthermore, in [12] conclude that VR have a possibility to becoming one of the tools that used in stress-related treatment especially during this pandemic era. However in those research papers which has been published there are very few area which explore to implement VR to reducing strees during Covid-19 for children from seven to ten years.

Based on this background, to fill the missing link on this research area, author create a VR simulation that focuses on helping children minimize stress and boredom levels during social movement restrictions, which offers four different outdor area. This research is deemed necessary so that children can stay at home and feel comfortable doing activities at home using this application in order to prevent the transmission of COVID-19, whose movement is still very massive and fast. This research is also a form of contribution in technology field which help childrens psychological issues especially during COVID-19.

II. Related Work

One of the literatures in this research is related to making learning applications regarding proper hand washing during a pandemic [8]. In this study, the use of AR uses hand movements as a marker and divides the learning process into three stages. The results of this study were 69% of respondents felt they better understand how to wash their hands properly after seeing this AR application. Another study [11] is a study that focuses on research on the use of VR for children with special needs (ABK) when they have to do rehabilitation at home during the COVID-19 pandemic. This study found that VR technology can be used in children with special needs to maintain and improve their motor function levels during home care. Another study [13] measured the accuracy and effectiveness of using VR as a companion tool for physical exercise in the elderly during the COVID-19 pandemic. The results of this study state that by using VR during the implementation of social restrictions, the elderly can improve motor skills, and can reduce the level of obesity in their body.

Research related to literature studies [14], conducting a review of the role of AR in handling the post-COVID-19 tourism sector, concluded that the role of ICT (Information and communication technology) such as AR, or VR is an innovative application that can be utilized by the tourism sector because it minimizes contact directly and can ensure tourist satisfaction and safety during the COVID-19 pandemic or after the pandemic is over. Another research related to the use of VR was carried out by [12] regarding the development of a VR-based project called MIND-VR which focuses on developing virtual psychoeducational experiences that provide basic information about stress and anxiety disorders in health workers. The results of related studies state that the therapeutic process using VR is more effective than using video. This study also states that further studies related to the implementation of VR to deal with stress and psychological trauma due to the impact of COVID-19 are needed, especially in the use of VR at home, or in the hospitals.

The study in [19] build a VR called “the secret garden” which provide refreshing scenery and calm voice to help people overcome their stress issue related to COVID-19. It took 7 days measurement to reach the conclusion. This research has an objective to reducing stress by improve people’s positive emotions using VR application. The result of the research already published in [23] which stated that, even in prelliminary stages, it shows positive impact that VR application can reduces participant stress during COVID-19 especially after two months lockdown. Another study regarding reduce stress during COVID-19 has been implemented in [22] that utilise 360° virtual tour. The study use VR application to allow participant explore place in 360° view. This research involves 235 participants and reach conclusion that using virtual tour have a high degree of satisfaction which lead to decreasing their stress level. This research also stated that VR have a contribution to improve people psychological well-being. Beside that, VR also becoming one of the technologies that becoming recommendation to use for people who want to reduce their stress level especially during or after this pandemic era.

Based on several studies that have been discusses, it can be concluded that technology, especially VR have many positive contributions for people live especially during lockdown era. One of the benefits that appeared by using VR can be used to reducing stress level, because sudden change in people daily life. However, there are very few studies about stress levels during this pandemic era which involves children. In fact, children becoming one of the most affected subjects this time, because they cannot play outside and study freely anymore. Based on several studies that have been discussed, to complement previous studies, and complete the missing link, this research has objective to builds a VR application that focuses on reducing and preventing stress in children during the COVID-19 pandemic. In addition to building VR applications, this study also measures the effectiveness of using VR, as well as the usefullnes of this application.

III. The Proposed Method

In this research, agile methodology has been choosed to develop the application. Even though according to [24] waterfall model still become the most commonly used in software development. It has lack of flexibility when major changes are happened [25]. Therefore, this research decides to use agile methodology which offer much flexibility of design changes in the future and offers faster release compare to the traditional one [25]. In addition, based on Fig. 1 before implementation process done, the whitebox and blackbox testing are carried out to make sure that VR application already meet the requirement.

The whole process of build a VR application can be seen in Fig. 1 and 2. In Fig. 1 showed the flow of VR application development, while Fig. 2 shows the overall research flow.

In Fig. 1, the research begins by analyzing the needs needed in the software and hardware sections including Unity3D, Oculus, and VR glasses. The application design stage consists of making storyboards, interface designs as well as terrain and environment assets that are created using blender and unity3D software. The programming process for building this VR application uses the default language of the Unity 3D software, namely C# which is assisted by visual programming on Playmaker assets. After the coding process is complete, it will be combined with various assets and 3D designs that have been built, then the rendering process is carried out. This process using the target API level 30 on the android system, and it is necessary to install the VR Google SDK for unity, as well as the VR headset that will be used. Before implementing the application, a testing process is

carried out using blackbox and whitebox tests [16] to ensure the application runs well. The next process is to do a demo to participants using the help of goggle glass to run VR applications. The overall research flow in the implementation process can be seen in Fig. 2.

In this study, as shown in Fig. 2, prior to do VR app implementations, participants were pretested first to determine the level of depression experienced using a "nine-symptom checklist" questionnaire [15] which divided the severity into 5 parts, namely:

- Minimal : scor 1 – 4
- Mild : scor 5 – 9
- Moderate : scor 10 – 14
- Moderately Severe : scor 15 – 19
- Severe : Scor 20 - 27

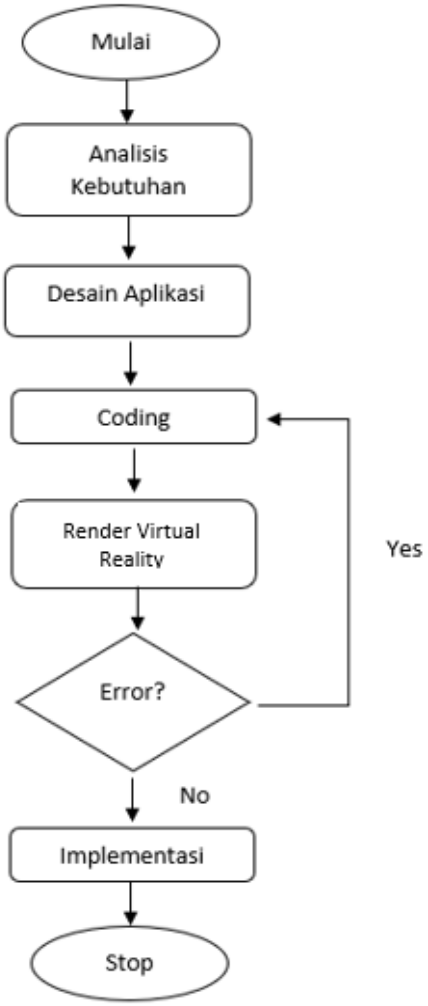

Fig. 1. VR Application Development Flow.

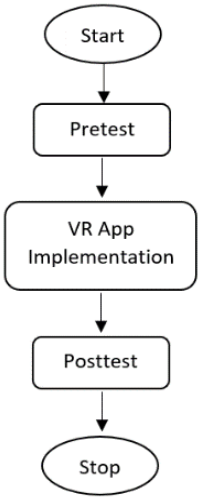

Fig. 2. VR Research Flow.

TABLE I. NINE SYMPTOM CHECKLISTS

No	Over the last 2 weeks, how often have you been bothered by any of the following problems?	Not all	Several Days	More than half the days	Nearly every day
1	Little interest or pleasure in doing things?	0	1	2	3
2	Feeling down, depressed, or hopeless?	0	1	2	3
3	Trouble falling or staying asleep, or sleeping too much?	0	1	2	3
4	Feeling tired or having little energy?	0	1	2	3
5	Poor appetite or overeating?	0	1	2	3
6	Feeling bad about yourself - or that you are a failure or have let yourself or your family down?	0	1	2	3
7	Trouble concentrating on things, such as reading the newspaper or watching television?	0	1	2	3
8	Moving or speaking so slowly that other people could have noticed? Or the opposite - being so fidgety or restless that you have been moving around a lot more than usual?	0	1	2	3
9	Thoughts that you would be better off dead, or of hurting yourself in some way?	0	1	2	3

The details of the "nine symptom checklists" questionnaire can be seen in Table I. This patient health questionnaire-9 (PHQ-9) is a recommendation to use as a self-measurement test to detect the rate of depression that consists from 0 to 3 level [26]. The primary reason this screening questionnaire has been chosed because it offers the ease of use the nine set of question. The ease of use the tools become the primary concern in this research because the subject that will be tested are children with has range of age from seven to ten. Beside the easiness, previous study which already used this PHQ-9 showed the accuracy screening using the nine set questions and the test also falled in acceptable area which obtain sensitifity around 0.84 and specifity about 0.77 [27]. Another reasearch that conducted in [28] showed a good sensitivy and specificity which fall below 0.83, and 0.72 respectively, using this PHQ-9 questionnaire does not necessary to divide the participants based on their gender. According to several reaseraches that already done which showed acceptable examination, it makes author believe that using this tools lead to the accurate results.

During the posttest stage, the same questionnaire table was used as already done in the pretest conditions, which aims to measure whether there is a positive impact obtained by respondents after using the VR application.

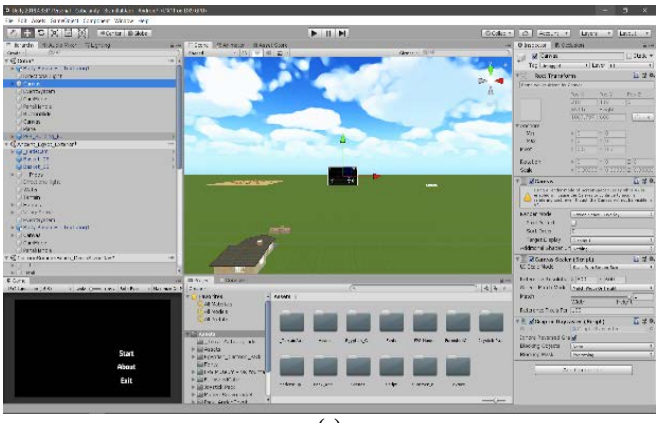
TABLE II. SUS LIST OF QUESTIONS

No	Questions	Strongly Disagree				Strongly Agree
		1	2	3	4	5
1	I think that I would like to use this system frequently.					
2	I found the system unnecessarily complex.					
3	I thought the system was easy to use.					
4	I think that I would need the support of a technical person to be able to use this system.					
5	I found the various functions in this system were well integrated.					
6	I thought there was too much inconsistency in this system					
7	I would imagine that most people would learn to use this system very quickly.					
8	I found the system very cumbersome to use					
9	I felt very confident using the system					
10	I needed to learn a lot of things before I could get going with this system					

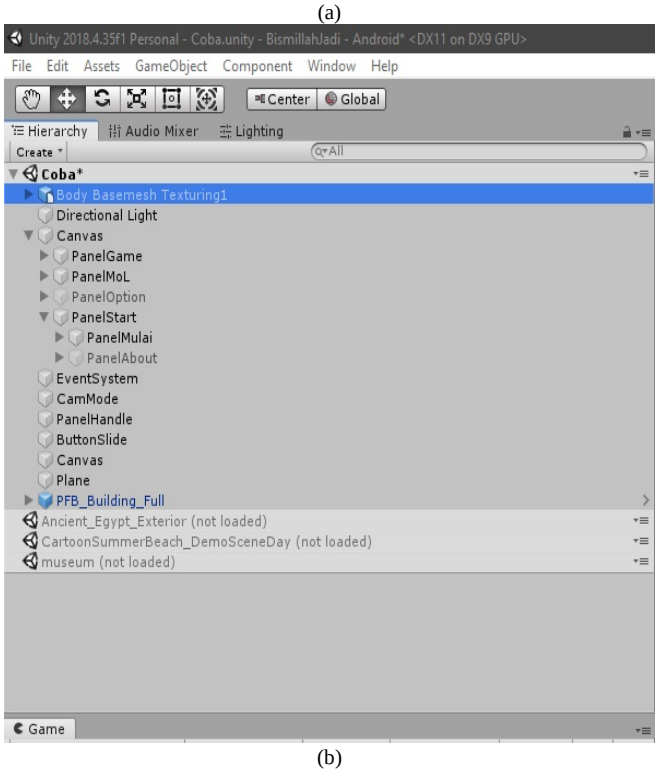
In addition, another test called System Usablitiy Scale (SUS) also carried out in order to measure the usefullnes of the application [17]. According to [29] SUS is one of the most tests that used to measure the perceive ussability and still remain relevant in the future. Based on those two researchers explain in the beginning, this SUS test is necessary to be done to meet the objectives in this research as written in Section 2. The details questioned of SUS can be seen in Table II, which have five scale, from the highest point (strongly agree) to the lowest point (strongly disagree).

IV. RESULT AND DISCUSSION

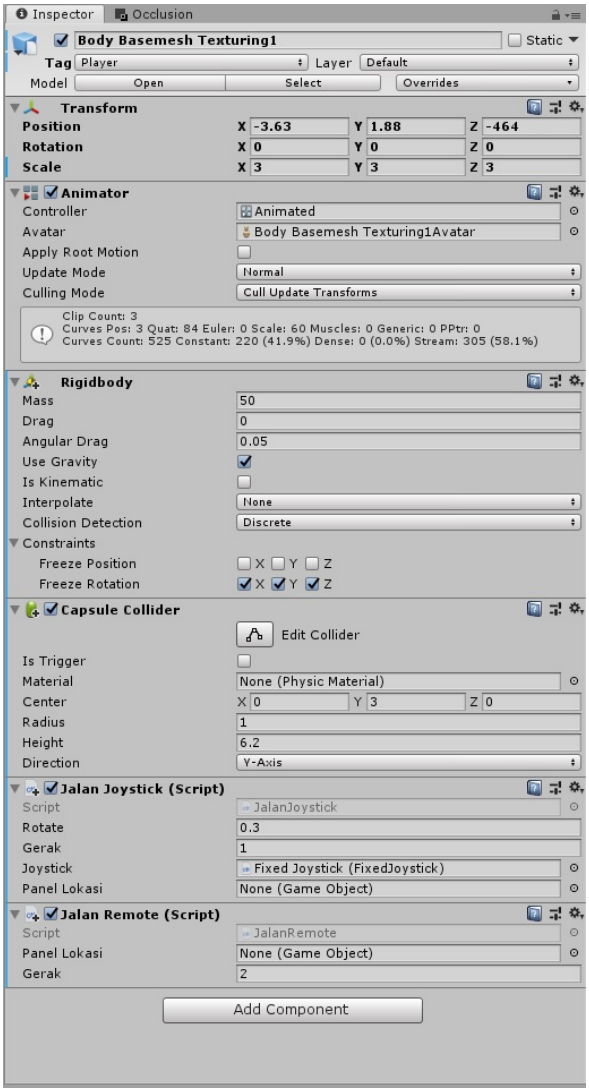
Based on the research flow in Section 3, the VR simulation application was built by adding the required assets, including Google Cardboard, Asset Image and Google VR SDK in Unity. One of the processes of making VR in unity3D can be seen in set collection of workspaces in Fig. 3a, 3b, 3c, and 3d.



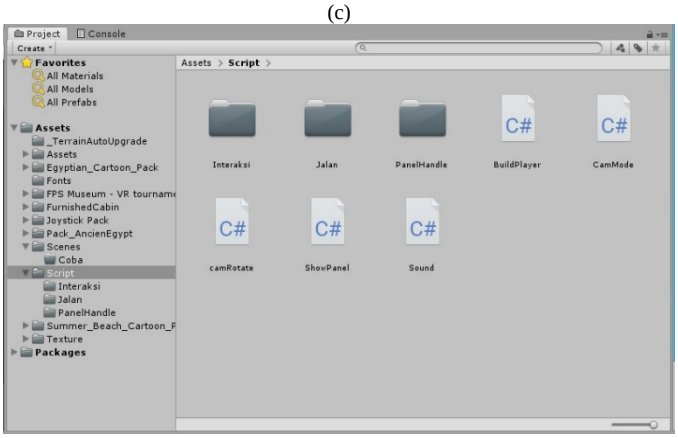
(a)



(b)



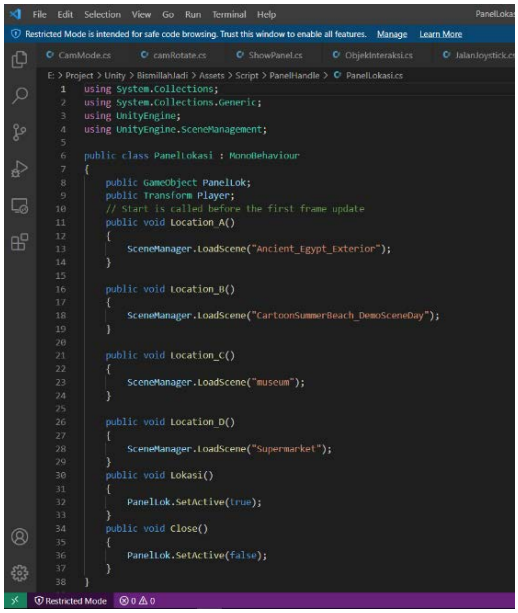
(c)



(d)

Fig. 3. (a) Whole Sample Image Process VR Development in Unity3D, (b) Hierarchy Page in Unity3D, (c) Inspector Page in Unity3D, (d) Project Struct.Ure in Unity3D.

In this VR application consists of four different scenes, namely: houses, beaches, Egypt and museums. The scene switching process is made using C# code, the snipped code of it process can be seen in Fig. 4.



```
using System.Collections;
using System.Collections.Generic;
using UnityEngine;
using UnityEngine.SceneManagement;

public class PanelLokasi : MonoBehaviour
{
    public GameObject PanelLok;
    public Transform Player;
    // Start is called before the first frame update
    public void Location_A()
    {
        SceneManager.LoadScene("Ancient_Egypt_Exterior");
    }

    public void Location_B()
    {
        SceneManager.LoadScene("CartoonSummerBeach_DemoSceneDay");
    }

    public void Location_C()
    {
        SceneManager.LoadScene("museum");
    }

    public void Location_D()
    {
        SceneManager.LoadScene("Supermarket");
    }
    public void Lokasi()
    {
        PanelLok.SetActive(true);
    }
    public void Close()
    {
        PanelLok.SetActive(false);
    }
}
```

Fig. 4. Snipped Code C# for Switching Each Scene.

The final results of the VR application in this study are presented in Fig. 5, and 6 which are images based on the participants point of view when viewed using VR glasses.

Fig. 5. Sample Application VR Views 1.

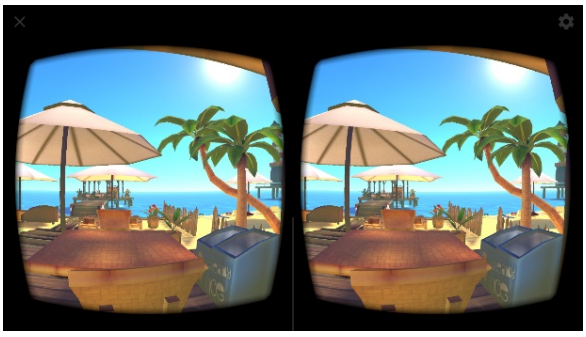


Fig. 6. Sample Application VR Views 2.

Before the application is used, as described in Section 3, blackbox and whitebox tests are carried out. The whitebox test is done by testing the program code of this application to make sure that no flaws appeared and the code written clearly. Afterwards, the blackbox testing perform to make sure all of the functionalities perform well. The overall results of blackbox testing can be seen in Table III.

TABLE III. RESULT OF BLACKBOX TEST

No	Test Class	Scenario Testing	Expected	Results
1	Start Menu	Pressing the Star Button	Displays a selection of VR mode and Mobile Mode	Valid
2	About Menu	Pressing about button	Displays about page	Valid
3	Exit Menu	Pressing the exit button	Exit the VR application	Valid
4	Mobile Mode Menu	Pointing the joystick right and left	Displays the appropriate direction with the joystick	Valid
		Pressing the Settings button	Displays the setting page	Valid
		Pressing Map button	Display various maps option	Valid
5	Map Menu	Pressing Egypt choice	Display Egypt Environment	Valid
		Pressing Beach choice	Display Beach Environment	Valid
		Pressing museum choice	Display Museum Environment	Valid
6	Egypt, Beach, and Museum Menu	Pressing the Back Button	Displays two choices menus are VR and mobile mode	Valid
		Pressing setting button	Display setting page	Valid
		Pressing Map btton	Display various map choices	Valid
		Pointing the joystick right and left	Displays the appropriate direction with the joystick	Valid

After passing the two functionality tests, the application was tested on 30 child respondents with an age range of 7-10 years which held with parental assistance using strict covid-19 protocol. In the process of testing the level of anxiety and SUS, parental assistance is necessary to obtain valid test results. The results of the comparison of pretest and posttest can be seen in Fig. 7. It can be seen that most of the children has obtain lower level of stress after used VR application.

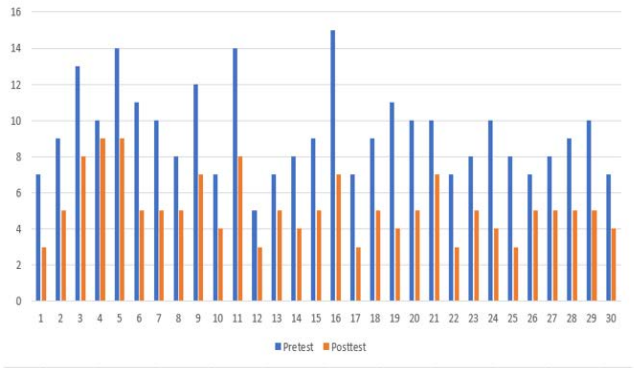

Fig. 7. Pretest and Posttest Results after Application Testing.

TABLE IV. RESULT OF SUS QUESTIONNAIRE

Respondent	Result of SUS Score										Total	Final Score
	1	2	3	4	5	6	7	8	9	10		
1	3	3	3	2	3	3	3	3	3	2	28	70
2	4	4	4	4	4	4	3	3	4	2	36	90
3	4	4	3	3	4	3	2	4	4	2	33	82.5
4	4	2	3	2	4	3	3	2	4	2	29	72.5
5	4	3	4	3	4	4	2	3	4	4	35	87.5
6	4	4	3	3	4	3	4	4	4	2	35	87.5
7	4	3	3	4	3	2	2	2	4	2	29	72.5
8	3	3	3	3	3	3	3	2	4	2	29	72.5
9	4	3	3	4	4	3	3	4	3	2	33	82.5
10	4	3	3	3	4	2	3	3	4	3	32	80
11	3	3	4	3	3	2	4	3	3	2	30	75
12	4	3	3	2	4	3	3	2	3	3	30	75
13	4	4	3	3	3	2	3	3	4	4	33	82.5
14	4	3	3	3	4	4	3	2	4	2	32	80
15	4	3	3	4	2	4	3	3	3	2	31	77.5
16	3	3	3	3	4	4	4	4	4	3	35	87.5
17	4	3	3	4	3	4	4	4	3	3	35	87.5
18	4	3	3	2	4	3	3	2	4	3	31	77.5
19	4	3	3	3	3	2	3	2	4	2	29	72.5
20	3	3	3	3	3	2	3	3	3	2	28	70
21	4	4	3	2	3	3	3	2	4	4	32	80
22	4	4	3	3	3	3	4	3	4	2	33	82.5
23	4	4	4	4	4	4	4	3	3	3	37	92.5
24	3	3	3	2	4	3	3	2	4	3	30	75
25	4	4	3	3	3	3	2	4	4	3	33	82.5
26	3	3	4	4	4	3	3	2	4	2	32	80
27	4	4	3	3	2	3	2	3	4	4	32	80
28	3	4	4	3	4	4	3	2	4	3	34	85
29	4	4	3	2	4	4	3	2	4	3	33	82.5
30	3	3	3	2	4	3	3	2	4	3	30	75
average												79.91

Based on the results of the pretest and posttest, it can be seen that before implementing VR application, most of respondents experienced depression in the mild and moderate ranges, there was only one respondent who was in moderately severe condition. However, after the respondent was given a VR application to get a new atmosphere of exploring several virtual places, it can be seen that there was a significant decrease in stress and anxiety levels, which can be seen in the survey results listed in Fig. 7. Based on Fig. 7, it can be seen that most of the respondents experienced decrease in anxiety level, about one level lower compare to pretest result. According on the results of the posttest respondents

experienced anxiety at a minimal and mild level. In order to measure the usability of the application, SUS questionaire in Table II already performed which use 30 respondents as subjects. The result of SUS testing can be seen in Table IV.

Based on the result shown in Table IV, it can be concluded that the average SUS score obtainend in this VR application around 79.91. It is located in acceptable area, between good and excellent adjective rating in SUS scoring system [18] and can be conclude that this application considered to be useful enough in order to show VR application.

V. Conclusion and Future Work

Based on the results obtained in Section 4, it can be concluded that this VR application has a contribution in reducing the level of anxiety and stress in children during the Covid-19 pandemic as evidenced by the results of the pretest and posttest presented in Fig. 7. Beside that, this VR application has a good adjective ratings SUS based on Table IV. Those two results that achieved in Section four already answer the objective which already discussed in Section two in this research, are to build VR application which allow reduce stress for children and measure the usefulness and effectiveness this application using SUS measurement.

However, many future works are needed to do in order to increase the usefullnes of this applicaion in society. One of challenges that need to tackle in this application are the addition of features to interacts in every scene so children can explore many things while enjoying the virtual environment. Beside that, the education about Covid-19 knowledge also relevant to be added in the future.

Acknowledgment

***Abstract*—The Arabic Sign Language has endorsed outstanding research achievements for identifying gestures and hand signs using the deep learning methodology. The term "forms of communication" refers to the actions used by hearing-impaired people to communicate. These actions are difficult for ordinary people to comprehend. The recognition of Arabic Sign Language (ArSL) has become a difficult study subject due to variations in Arabic Sign Language (ArSL) from one territory to another and then within states. The Convolution Neural Network has been encapsulated in the proposed system which is based on the machine learning technique. For the recognition of the Arabic Sign Language, the wearable sensor is utilized. This approach has been used a different system that could suit all Arabic gestures. This could be used by the impaired people of the local Arabic community. The research method has been used with reasonable and moderate accuracy. A deep Convolutional network is initially developed for feature extraction from the data gathered by the sensing devices. These sensors can reliably recognize the Arabic sign language's 30 hand sign letters. The hand movements in the dataset were captured using DG5-V hand gloves with wearable sensors. For categorization purposes, the CNN technique is used. The suggested system takes Arabic sign language hand gestures as input and outputs vocalized speech as output. The results were recognized by 90% of the people.**

***Keywords*—Arabic sign language; convolution neural network; hand movements; sensing device**

I. INTRODUCTION

Around 60 million people use body language around the world, and an automated tool for interpreting it might have a big effect on communication between those who use it and those who don't. Sign language is a means of wordless communication that includes the use of body parts. In sign speaking and listening, face features, as well as eye, hand, and lip gestures, are used to transmit information. People who are deaf or hard of hearing rely heavily on sign language as a form of communication in their daily lives [1]. Nevertheless, the lack of consistency in shape, size, and posture of the hands or fingers in an image made computer interpretation of hand signals exceedingly difficult. SLR can be approached in two aspects: image-based and sensor-based. The main advantage of expression frameworks is that users do not need to use complicated gadgets. In any scenario, extensive operations are required during the pre-processing stage. The importance of language in growth cannot be overstated. It facilitates the internalization of social norms and the development of communication control in addition to serving as a channel for interpersonal communication. Even though they can hear the language spoken across them, deaf children do not learn a language to express themselves in the same way that hearing impairment children do.

SLR research has recently been divided into two categories: vision and contact-based approaches. This between sensing users and devices is part of the interaction technique. It usually employs an interferometric glove that collects finger motion, bending, movement, and angle information of the produced sign via EMG signals, inertial estimate, or electromagnetism. As the platform's input, the vision-based technique uses data obtained from video streams or photos captured with the camera. It's also divided into two categories: presence and 3D model-based techniques [2]. The majority of 3D model-based strategies begin to gather the position of the hand and joint angle of the hand in 3D spatial into a 2D image. Whereas demeanor identification relies on features extracted from the image's PowerPoint display, recognition is completed by matching the characteristics [3]. Although many hearing-impaired people have mastered sign language, few "regular" people understand or can use it. This has an impact on impaired people's communication and creates a sense of separation among them and the "regular" society. This chasm can be bridged by deploying a technology that constantly converts sign language to textual and vice versa. Numerous paradigm advancements in many scientific and technological fields have now aided academics in proposing and implementing systems that recognize sign languages.

Disabilities people interact through hand signals, which is a gesture-based communication strategy rather than written or spoken language. Arabic is the official language of 25 different countries. In certain nations, Arabic is spoken by only a small percentage of the population [4]. According to some accounts, the total number of countries is between 22 and 26. Although the Arabic language is deontological, the Arabic gesture is not. Arabic is spoken by Jordanians, Libyans, Moroccans, Egyptians, Palestinians, and Iraqis, to name a few. Each country, though, has its unique dialect. To put it another way, there seem to be two forms of Arabic: standard and colloquial. As they all employ the same alphabets, the Arabic sign language (ArSL) is also the same. This function is quite beneficial to research studies. The Arab

deaf communities are a close-knit group. Interaction between the deaf and hearing communities is low, focusing primarily on communities with deaf people, relations of the deaf, and occasionally play companions and professionals.

The recognition of Arabic Sign Language includes a continuous identification program based on the K-nearest neighbor classifier and a feature extraction method for the Arabic sign language. However, the fundamental flaw with Tubaiz's method would be that patients must wear interferometric hand gloves to gather information on specific gestures, which can be extremely distressing again for users [5]. For the construction of an Arabic sign language recognition, an interferometric glove was created. Using hidden Markov model (HMM) and temporal characteristics, continual identification of Arabic sign language is possible [6]. A study was performed on the translation of Arabic sign language to text for usage on portable devices. While the above papers cover a wide range of sign languages, Arabic Sign Language was also the subject of research in a few instances. Using a Hidden Markov Model (HMM) quantifier, the researchers achieve 93% accuracy for a sample of 300 words. In comparison to HMM, they use KNN and Bayesian classifications [7], which produce equivalent results. This presents a network matching method for continual detection of Arabic Sign Language sentences. Decision trees and the breakdown of motions into stationary poses are used in the model. Using a polynomial runtime technique, they attain at least 63% accuracy when interpreting multi-word phrases.

This paper deals with the Gesture Based Arabic Sign Language Recognition for Impaired People and this uses the Convolution Neural Network process as the research system. There is different section that deals with the process of Arab Sign Language and the Convolution Neural Network. Section 1 organizes the Introduction of the gesture sign Arab language and the Machine Learning system. Different methods and research involved in Arab language recognition were expressed in detail in Section 2; the proposed methodology is presented in Section 3. The result and Discussion are investigated in Section 4 and finally, the paper gets concluded.

II. Literature Review

The most comfortable and creative way for the hard of hearing to communicate is through hand signals. With improvements in multimedia tools and networks, academics have long been drawn to innovation. Sign language communications systems as a way to increase network technology for the hearing and speech impaired, offering increased social possibilities and integration. This study introduces a framework for leveraging the Microsoft Kinect device to communicate in Arabic sign language. The proposed method is based on the gesture recognition architecture for Arabic signs proposed by [8] for language communication systems. The suggested Language for Arab sign technique has a sign identification rate of 96 %, according to experimental data. In addition, the typical mission completion time for an Arabic sign was roughly 2.2 seconds. As a result, the suggested technology can be used to develop a real-time Arabic sign languages communications network. Finally, survey respondents stated that the projected procedure is consumer and simple to use and that it may be utilized to recognize and show Arabic signs at a minimal cost.

Researchers attempt to be using ICT to improve the Deaf community at large life quality by building solutions that can help them improve communication with the rest of the world and among themselves. Designers describe work on the construction of an Avatar-based translation for Deaf individuals from Arabic Speech to Arabic Sign Language in this paper. The study begins with an overview of the Deaf community's situation in the Arabic-speaking population, as well as a brief assessment related to particular research. [9] a translation system based on the avatar of Arabic speech and Arabic sign language for deaf people is recognized. The study begins with an overview of the Deaf community's situation in the Arabic-speaking population, as well as a short assessment of various related research. The next section describes the research system's design considerations. The technology will be built around a dataset of captured 3D Arabic sign language movements. Data gloves will be used to capture the gesture recognition motion.

The use of an automatic speech recognition method for Arab sign language (ArSL) has significant societal and humanitarian implications. With the growing deaf culture, such technology will aid in integrating such individuals and allowing them to live a regular life. Arab sign language, like other languages, has many subtleties and distinct qualities that necessitate the use of a useful weapon to treat it. The author in [10] propose a novel system based on deep learning that will automatically recognize words and numbers in Arab sign language when fed with a genuine dataset. Research conducted comparison research to demonstrate the effectiveness and robustness of suggested method vs established approaches based on k-nearest neighbors (KNN) and Support Vector Machines (SVM). Hearing is essential for normal language and speech development, and hearing impairment occurs whenever the acuity to normally heard noises is reduced [11]. Many studies show that one out of once each three to four educated citizens with any degree of hearing loss faces educational, social, and impede learning. The goal of this study was to assess the hearing impairment in hearing-impaired child's psychological traits (communication, social, emotional, and cognitive), and then connect this pattern to a linguistic scale.

The author in [12] proposed the Arab sign Language recognition and for those with hearing impairments, sign language entails the movement of the arms and hands as a channel of understanding. The identification of certain characteristics and the classification of specific input data are the two key steps in an automatic sign identification system. Many methods for categorizing and identifying sign languages have been proposed in the past to improve reliability. However, recent advances in the field of machine learning have prompted us to pursue more research into the identification of hand signs and gestures using deep neural networks. The Arabic gesture has seen significant research on hand gestures and gesture recognition. This research proposes a vision-based system that uses CNN to recognize Arabic hand sign-based letters and translate them into Arabic speech. With a deep learning model, the suggested system

automatically recognizes hand sign symbols and shouts out another output in Arabic. This system recognizes Arabic hand sign-based letters with 90% accuracy, indicating that it is a very reliable technology. Using more powerful hand gesture recognition technologies like Motion Sensors or Xbox Kinect can enhance accuracy even more. The result will be given to the text into the voice engine, which will create the sounds of the Arabic hand sign-based characters.

Hearing-impaired people can be found throughout the world, so developing good local level sign language recognition (SLR) systems is critical. This did a thorough assessment of computerized sign language identification based on supervised learning strategies and processes published between 2014 and 2021 and found that existing systems require theoretical categorization to accurately interpret all available data. As a result, focus on aspects that are included in practically all basic sign detection methods. The author in [13] present a comprehensive framework for investigators that analyzes their advantages and weaknesses. This study also demonstrates the importance of types of sensors in this sector; it appears that acknowledgment based on the integration of datasets, such as vision-based and webcam channels, outclasses unimodal analysis. Furthermore, recent advances in research facilities have enabled them to advance from the official press of sign language protagonists and turns of phrases to the capacity to change ongoing gesture conversations with minimal latency. Many of the models available are adequate for a range of tasks, but neither of them currently has the requisite generalization potential.

III. Methodology

A. Arabic Sign Language Architecture

The Architecture for Arabic Sign Language Communication System is a proposed solution that serves as a low-cost multiple languages translation. A sign language-based communications network, all while retaining high precision and economical usability [7]. The following Fig. 1 Architecture of Arabic Sign Language is shown. Hardware, software, and the network are the three elements that make up the system architecture. A gesture authentication method and a video representation are included in the hardware device [14]. The Gesture recognition digital storage repository, the Sign recognition center, and the Sign media center are all part of a software component. The network device is responsible for sending and receiving Arabic sign language data across a network connection.

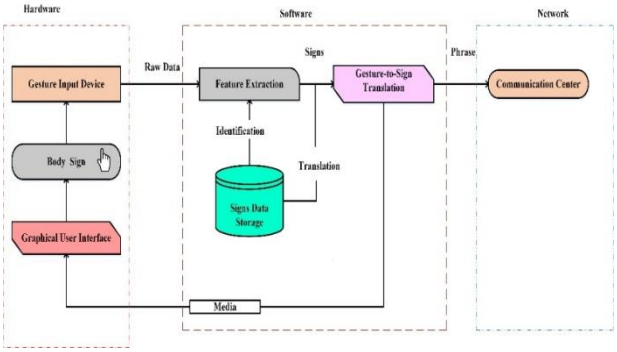

Fig. 1. Architecture of Arabic Sign Language.

1) Hardware: The transmitter and receiver channels via which the user controls the system are provided by the hardware components of the system. The Gesture input unit is a Microsoft Kinect from the first generations, which collects data and delivers it to the Sign recognition center [15]. The output data from the Sign media center is shown via the Display devices (audio system and digital display). In its current state, the stability supports visual data.

2) Software: The program's software is in charge of extracting features and movement translation, as well as offering a simple Graphical User Interface (GUI). Based on the existing and established lexicon, the Sign Identification Center turns the raw input into a collection of predefined signs [16]. The Sign language datastore is being used to obtain information about signs. The Sign media center translates the signs obtained from the Sign recognition center into the desired medium and speech, which it then sends to the Display technologies or engaging in dialogue.

The gesture recognition data store includes both gesture dictionaries and translating dictionaries from one vernacular to another. The size of something like the information storage is limited due to the project's concept stage.

Source: ArSLAT: Arab Sign Language Alphabets Translator [17].

3) Network: The Signs media player sends media to the Communication center, which then transmits this through the system to its intended destination [18]. This section is presently unimplemented because it is unrelated to usability testing. The above Fig. 2 shows the Arab Sign Language Alphabets and this image could be used for the further processing system.

Fig. 2. Arab Hand Sign.

B. Preprocessing of Data

The first stage in creating a working deep learning model is data preprocessing. This is used to convert raw data into a format that is both usable and efficient. The flowchart of data preprocessing is shown in Fig. 3.

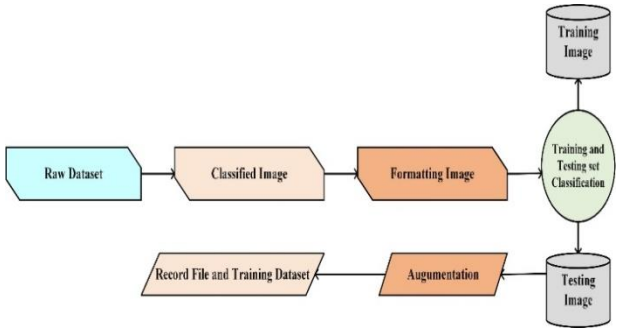

Fig. 3. Data Preprocessing.

1) Raw data: The image captured using the camera is termed the raw data in this section the raw image suits the hand sign image of the Arabic language and this is implemented in the proposed method [19]. The following environment is considered for image representation:

- Different angles.
- Lighting condition changing.
- Focus and good quality.
- Object size and distance adjustment.

The purpose of making raw photographs is to create a dataset that can be used for training and testing. the Arabic Alphabet from the dataset of the suggested program.

2) Classified image: The presented method categorizes the Arabic Alphabet's pictures. To understand the system, one subfolder is utilized to store photographs from one classification. In the developed framework, all subfolders that describe categories are maintained together in one primary special folder "dataset."

3) Number of epochs: The number of epochs represents how many times the complete dataset is processed into the neural network during training. There is no perfect number for it though, and it is determined by the facts.

4) Formatting image: The graphics of hand signs are usually uneven and have a varied background. To obtain the hand component, it is important to remove the unneeded elements from the photos. Images are referred to as digital data that has been rasterized for usage on a display device or printing in some of those types [20]. The extract was subjected is the process of converting visual data into a set of pixels.

5) Classification of training and testing dataset: The image taken for the formatting could be classified based on the training or testing image. A controlled learning method for classification examines the training data set to find, or learn, the best relationships between two variables that will produce a strong forecasting model. The goal is to create a trained (fitted) model that does a good job of generalizing to new, unknown data.

6) Augmentation: Real-time data is always incomplete and unusual due to several modifications (rotating, moving, and so on). Image augmentation is a technique used to improve the achievement of deep neural networks. It purposefully tries to manipulate images with methods such as shear, shifts, flips, and rotation. Using this image enhance raw images [21], the suggested system's images are rotated dynamically from 0 to 360 degrees. A small number of photographs were also ripped at random with a 0.2-degree range, and a small number of images were inverted horizontally.

C. Frame Work

The design of the Arabic sign language recognition utilizing CNN is shown in Fig. 4, Convolution Layer. CNN is a machine learning (ML) system that uses perceptron algorithms in the implementation of its operations for data gathering. These systems are categorized as artificial neural networks (ANN). The discipline of machine learning is where CNN is most useful. It mostly aids in the recognition and classification of images [22]. CNN is made up of two parts: feature extraction and classification. Each element has its own set of features that must be investigated. These elements will be explained in detail in the following sections. A convolutional neural network (CNN, or ConvNet) is a type of neural network that is used to analyze visual information [23]. One of the main reasons that researchers have realized the efficacy of deep learning is the vitality of convolution layers nets in image processing. They are in charge of significant advancements in computer vision (CV), which has significant application in self-driving cars, mechatronics, unmanned aerial vehicles, safety, medical advances, and treatment options for the visual impairments.

Convolutional neural networks employ an architecture that lends itself especially well to image classification. These systems allow neural nets to learn quickly. This enables us to approach enhanced deep multi-layer systems for image classification. CNN continues to learn from data using the Backpropagation algorithm and its derived products. Modern implementations make use of specialized GPUs to improve results even further.

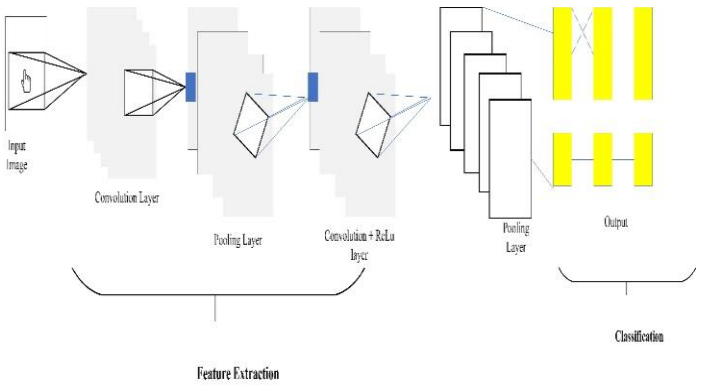

Fig. 4. Convolution Layer.

1) Input blocks: Squeeze Net requires an input block that would be at least 224 X 224 (With 3 channels for RGB). CNN is made up of numerous components. The Convolution operation, on the other hand, is CNN's most important component. The statistical combining of two roles to create a third function is referred to as a convolution layer. To create a feature map, the combination of the inputs using filtering or kernel is necessary. Convolution is performed by dragging each filtering over a specific input [24]. A matrix combination is performed at each location, and the outcome is added to a different feature map. Every image is turned into a 3D matrix with a defined width, height, and depth. Because the image (RGB) has color channels, the thickness is shown as a measurement.

Various convolutions can be conducted on raw data with various filters [25], resulting in various feature extraction. The output of the convolution layer is created by combining the multiple feature images. The output is then passed via an input layer, resulting in complex output. The length of a given step that the Fourier filter performs each time is referred to as the stride. The size of a step is typically 1; this indicates that the convolution filter is moving image pixel. When increasing the size of a step, the filters will slide across the input with a larger frequency, resulting in less overlap between the cells. Researchers should do something to stop extracted features from decreasing because it is always less than the input size. These are going to apply to cushion here.

$$Output_{size} = \frac{input_{size} - Filter_{size} + 2 * padding_{size}}{Stride_{\ size}}$$

2) Max pooling layer: In between Convolution layers, a pooling layer is naturally added. However, its primary goal is to reduce dimensionality and reduce calculation time by using fewer parameters. It also prevents overtraining and cuts down on training time. Pooling can take numerous forms, the most frequent of which is max pooling. It employs the maximum value in all windows, resulting in a smaller feature map with the same amount of information. To estimate the size of the pooling layer's output produced, the panel sizes must be specified ahead of time; the following equations can be used.

$$Output_{size} = \frac{input_{size} - Filter_{size}}{Stride_{\ size}} + 1$$

The pooling layer provides some high accuracy in all cases, indicating that a certain component will be recognizable regardless of where it appears on the panel.

The categorization component of CNN is the second most critical component. The objects are classified up of a few tiers that are all interconnected (FC). An FC layer's neurons have a strong relationship between the two to every one of the preceding layer's activations. The FC layer aids in the mapping of representations between inputs and outputs. The layer's functions are carried out using the same concepts as a conventional Neural Network [4]. One Dimensional data, on the other hand, can only be accepted by an FC layer. The flatten function of Python is utilized to create the new method for converting three-dimensional data to just one data.

3) Dropout regularization techniques: Overfitting is a significant and serious issue in deep neural networks. Dropout is a method of dealing with this difficult challenge. It is accomplished by randomly discarding some neural units in the neural network with an artificially designed ratio throughout training. The degree of co-adaptation between neuronal units has been greatly reduced. Using dropout on a neural network is equivalent to extracting a thinned network from the original entire network. During the training process, a series of thinning networks are collected using dropout at a specific dropout ratio. During the testing phase, it is not possible to directly help determine by combining the forecasts from exponentially thinning models. This should employ a whole untinned network with fewer weights to forecast outcomes by implicitly aggregating the results of all those thinned systems. Dropout greatly lowers overfitting and outperforms other regularization methods. The convolutional neural network using dropout would be discussed.

4) Activation function: The activation function is a node placed at the end of or between Neural Networks. This has various sorts of activation functions, but this discussion will concentrate on Rectified Linear Units (ReLU). The ReLU function is the most often used objective function in neural networks. ReLU has a significant benefit over other training algorithms in that it does not stimulate all neurons at the same time. The picture for the ReLU algorithm above shows that it turns all negative input to zero but does not stimulate the neuron. Because just a few neurons are stimulated at a time, it is incredibly computationally efficient. It does not reach saturation in the positive area. In reality, the ReLU activation function converges six times quicker than the $tanh$ and sigmoid activation functions.

5) Features extraction: The Convolutional Neural Network is made up of several basic parts. The convolution layer is a critical component of the CNN network. This layer denotes the mathematical description of functions that result in a third function. To generate a feature map, convolution must be performed within the input using a kernel or a filter. The convolution implementation consists of sliding each filter with sufficient input. At each location, matrix multiplying is conducted, and the outcome is placed on a feature map. Each image is converted to a 3D matrix with depth, height, and width. Because the image is made up of color channels, the depth has been deemed a dimension. Multiple convolutions are performed on the input dataset using appropriate criteria, resulting in distinct feature maps. The result of the convolution layer is obtained by combining the multiple feature maps. The kernel is a two-dimensional (2D) array of elements that would be used as weights generally. As demonstrated in Fig. 5, the convolution procedure is conducted by dragging the kernel across the picture. The result of the convolution layer is a feature mapping. Every section

that is subjected to the dragging and convolution processes is referred to as an interesting region (IR). The accompanying equation is used to carry out the convolutional procedure.

$$Z_{ij} = (I * K)_{ij} = \sum_m \sum_n I_{i-m,j-n} K_{mn} - 1$$

Where K is the kernel and I is the input image. Every layer's output in Convolution Neural Network can be stated as follows:

$$y_i^l = f(z_i^l)$$

Then, $z_i^l = \sum_{j=1}^{l-1} w_i^j x_j^{l-1} - 2$

Where y represents the outputs of the layer, z represents the activation function, i represents a layer l neuron, w represents the weight, and x represents the input information.

$$w = \{w_{ij}^l : l = 1,3, \dots L-1; i = 0,1, \dots I; j = 0,1, \dots J\} - 3$$

$$x = \{x_j^l : l = 1,3, \dots L-1;\ j = 0,1, \dots J\} - 4$$

The pooling layer is the CCN's second layer. The primary goal of this layer is to make the feature mapping from the convolution layer easier to understand. It emphasizes the characteristic by using the maximum, summation, or averaging operations. The fully connected layer is the third layer. This layer's primary function is to transform a two-dimensional (2D) feature map into a one-dimensional (1D) one. This style is appropriate for deciding on feature categorization based on pre-defined features.

This employed an Arabic sign languages dictionary in this research. In the training phase of hand symbol identification, employed certain motions from a lexicon as a ground truth. The lexicon is distributed in the form of graphic groups of motions. Every set of images symbolizes a different type of social setting. This chooses over 40 motions performed with one hand and over 10 motions performed with both hands. This database is used to train Convolutional Neural networks. The technology was put to the test with real-life motions performed by coworkers.

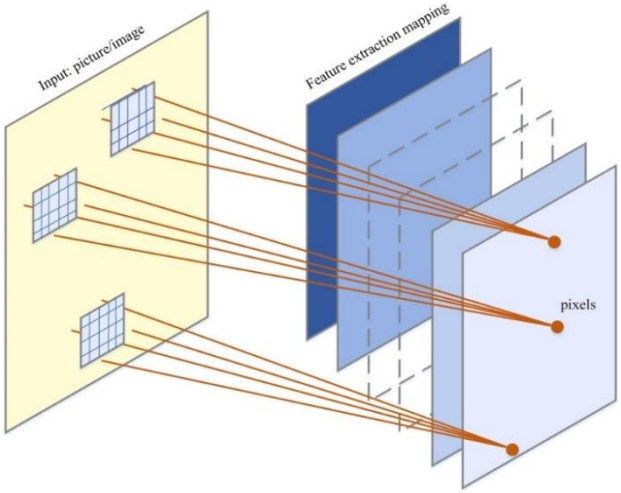

Fig. 5. Feature Extraction.

To recognize fingers and hands, computer vision architecture was created. Within its area of view, it separates and monitors them. The architecture collects movement monitoring data in the form of a series of pixels. The measured positions, sign orientations, and other information about every object recognized in the current frames are stored in the monitored data frames. A unique pixel is used to illustrate the identified fingers and hands. The flow chart for CNN proposed model is shown in Fig. 6. On still photos, summarize a technique using the methods below.

- Gesture frames are captured.
- Image denoising is a technique for improving the appearance of images.
- Employing Convolution Neural Network (CNN) to separate the face of a signer.
- Using Convolutional Neural Network to segment hand and finger gestures.
- Utilizing Convolution Neural Network to detect motions.
- By evaluating motions to elements in a pre-built database, motions can be recognized.
- Getting the translations for the motion that was recorded.

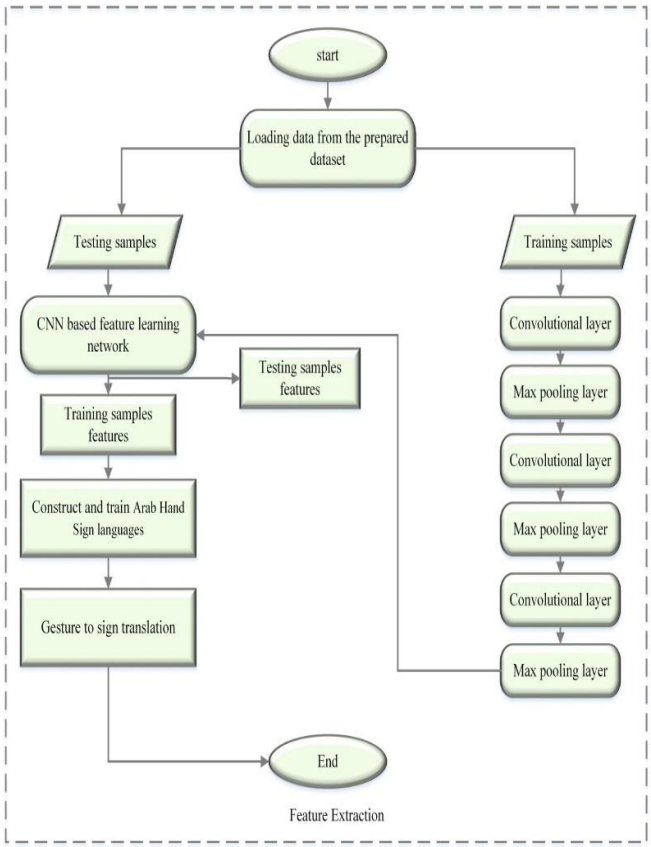

Fig. 6. Flow Chart for CNN Proposed Model.

IV. Result and Discussion

Two convolution layers are used to test the suggested system. After that, each fully connected layer is followed by two max-pooling layers. The first layer of the convolution operation has a different pattern; there are 30 kernels in the first layer, while the second level has 64 kernels; nonetheless, the kernel size in both layers is 3×3 layer. Each pair of convolution and max-pooling was examined using two alternative dropout regularization values of 25% and 50%, respectively. As a result, this option allows for the elimination of one input out of every four inputs (25%) and two inputs out of every four inputs (50%) from each combination of convolutional and pooling layers.

The various sizes of training sets, as can be seen in Fig. 7, when training the network using 80 % of the images from the dataset, the accuracy reaches its highest point of 90.03%. Table I shows the Percentage Training Set.

Researchers compared the suggested system's outcomes with KNN (k-nearest neighbor) with Euclidean distance and SVM (support vector machines) with various kernels processors typically shown in this field to demonstrate its effectiveness.

Other factors that influence identification, including such facial movements, have been explored in prior studies. Various input detectors, like the jump action controllers, are also employed, as well as integrating multiple input detectors to handle the various characteristics described above. In addition, a novel learning approach was applied in this study, which yielded encouraging outcomes.

TABLE I. Percentage Training Set

Training Image	Detection Rate
60%	85.65%
50%	83.28%
80%	90.03%
70%	88.45%

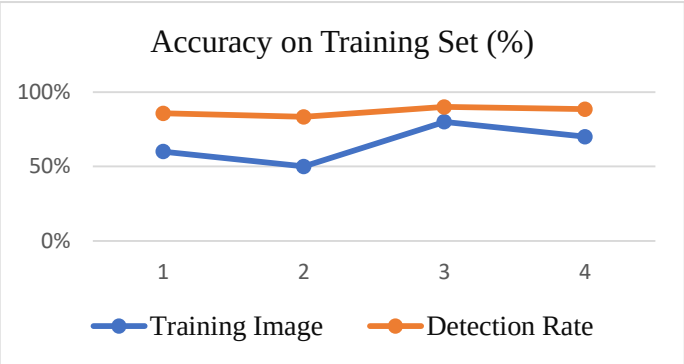

Fig. 7. Accuracy on Training Set.

TABLE II. The CNN Configuration's Categorization Results

Input depth	CNN layer	Accuracy	
Configuration 1	Kernel	$5 \times 5 \times 8$	91.5%
	Subsampling	2×2	
Configuration 2	Kernel	$5 \times 5 \times 8$	90.6%
	Subsampling	2×2	
Configuration 3	Kernel	$5 \times 5 \times 8$	94%
	Subsampling	2×2	
Configuration 4	Kernel	$5 \times 5 \times 8$	92%
	Subsampling	2×2	
Configuration 5	Kernel	$5 \times 5 \times 8$	89%
	Subsampling	2×2	
Configuration 6	Kernel	$5 \times 5 \times 8$	89.8%
	Subsampling	2×2	
Configuration 7	Kernel	$5 \times 5 \times 8$	86%
	Subsampling	2×2	

The scheme then exhibits an optimistic accuracy rate with reduced loss rates in the following phase (testing phase). The accuracy rate was reduced even further when augmented graphics were used while maintaining nearly the same precision. Each digital image in the testing stage was processed before being used in this model. The proposed system generates a vector of 10 values, with 1/10 of these values being 1 and all other values being 0 to represent the predicted class value of the given data. The system is then linked with its signature step, in which a hand sign is converted to Arabic speech, Table II.

The Fig. 8 Detection Rate Comparison is shown based on Table III Comparison of Detection Rate. In this, the comparison is done between the proposed system and the other method such as SVM with RBF kernel and linear kernel and KNN. Among those methods, a higher rate of accuracy is found in the proposed method. So, by implying this method the impaired people could easily recognize the sign.

TABLE III. Comparison of Detection Rate

Classifier	Detection Rate
Support Vector Machine with linear Kernel	86%
Support Vector Machine with RBF kernel	85%
KNN	68%
Proposed system	90.03%

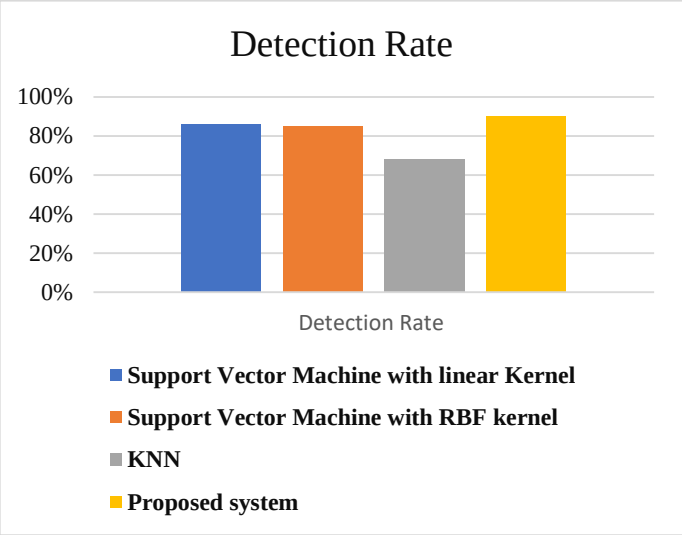

Fig. 8. Detection Rate Comparison.

ACKNOWLEDGMENT

The authors would like to thank the Deanship of Scientific Research at Jouf University for supporting this work by Grant Code: (DSR-2021-04-0317).

Funding Statement: This work was funded by the Deanship of Scientific Research at Jouf University under grant No (DSR-2021-04-0317).

Conflicts of Interest: The authors declare that they have no conflicts of interest to report regarding the present study.

V. CONCLUSION

The Identification of sign languages and Arabic Sign Language (ArSL), as well as several types of classifications and their outputs, were studied using various symbols and signs and ArSL. This suggested survey is carried out to take the best classifier for hand gesture recognition systems that depend on several sign languages. Some of the developed models were shown to be quite efficient, however only on limited applications. The studies originate from all across the world and include a wide range of sign language variances, which is critical for assuring worldwide coverage. The entire operation and performance of sign language recognition are represented using neural networks, machine learning, and deep learning classifiers, among others. In terms of accuracy, the Deep learning-based classifier CNN produced the results in research. Thus, the gesture Based Arabic Sign Language Recognition for Impaired People is based on Convolution Neural Network System. In addition, the size of the data collection could be enhanced further in future study projects. The suggested system's result is Arabic-language speech obtained through the detection of Arabic sign language. Furthermore, the solution presented here would be excellent for impaired people.

Micro Expression Recognition: Multi-scale Approach to Automatic Emotion Recognition by using Spatial Pyramid Pooling Module

Lim Jun Sian, Marzuraikah Mohd Stofa, Koo Sie Min, Mohd Asyraf Zulkifley
Department of Electrical, Electronic and Systems Engineering, Universiti Kebangsaan Malaysia, Bangi, Malaysia

***Abstract*—Facial expression is one of the obvious cues that humans used to express their emotions. It is a necessary aspect of social communication between humans in their daily lives. However, humans do hide their real emotions in certain circumstances. Therefore, facial micro-expression has been observed and analyzed to reveal the true human emotions. However, micro-expression is a complicated type of signal that manifests only briefly. Hence, machine learning techniques have been used to perform micro-expression recognition. This paper introduces a compact deep learning architecture to classify and recognize human emotions of three categories, which are positive, negative, and surprise. This study utilizes the deep learning approach so that optimal features of interest can be extracted even with a limited number of training samples. To further improve the recognition performance, a multi-scale module through the spatial pyramid pooling network is embedded into the compact network to capture facial expressions of various sizes. The base model is derived from the VGG-M model, which is then validated by using combined datasets of CASMEII, SMIC, and SAMM. Moreover, various configurations of the spatial pyramid pooling layer were analyzed to find out the most optimal network setting for the micro-expression recognition task. The experimental results show that the addition of a multi-scale module has managed to increase the recognition performance. The best network configuration from the experiment is composed of five parallel network branches that are placed after the second layer of the base model with pooling kernel sizes of two, three, four, five, and six.**

Keywords*—Micro expression recognition; facial expression; spatial pyramid pooling module; multi-scale approach; deep learning

I. Introduction

According to the research from [1], [2], faces are the main human "tools" to express information in terms of emotion. Facial expression is an important means that enable humans to undergo social interaction with each other. This is because 55% of human feelings are manifested by their facial expression. For example, an observer can deduce that someone is feeling disgusting if his/her upper lip is rising upward.

Facial expression can be broken down into two categories, which are macro-expression and micro-expression. A macro-expression is an intentional facial expression, while a micro-expression is an unintentional facial expression. Benjamin et al. [3] investigated that the major differences between them are the intensity and time taken to manifest the expression. Deng et al. [4] reported both expressions are widely used as an input to various applications and the most obvious application is to estimate the hidden emotions.

On the other hand, Micro-expression (ME) is an unintentional, quick facial movement that is primarily used to express the emotions of happiness, sadness, and surprise [5]. A ME happened in a short time, usually happened in the range of 0.04s until 0.2s. Hence, it is a hard task for a human to use their bare eyes to detect the occurrence of ME. Even if a human is undergoing training to detect an ME, their average performance is only slightly better than other people who do not undergo the training process. Hence, Zhao and Li [6] showed that machine learning is proposed to aid humans in analyzing the ME to understand human's true emotions.

Machine learning (ML) can be broadly classified into traditional machine learning and deep learning. Researchers in pattern recognition tasks have frequently applied both techniques to the applications of facial expression recognition [7], human activity recognition [8], recycling system [9], and image recognition [10]. Traditional machine learning relies on a set of handcrafted features, which is then passed to a decision-making module algorithm such as decision tree, neural network, and Support Vector Machine (SVM) [11], [12]. However, it is a time-consuming task for a computer vision engineer to judge which features are the best to describe the emotions.

The deep learning methodology is different compared to the traditional machine learning approach, whereby the features of interest are obtained through iterative optimal training such as through the convolution process [10], [13]. Usually, after the feature maps have passed through a convolution process, they will undergo a pooling process. Fig. 1 shows the generalized framework of traditional machine learning and deep learning algorithms for human emotion recognition tasks.

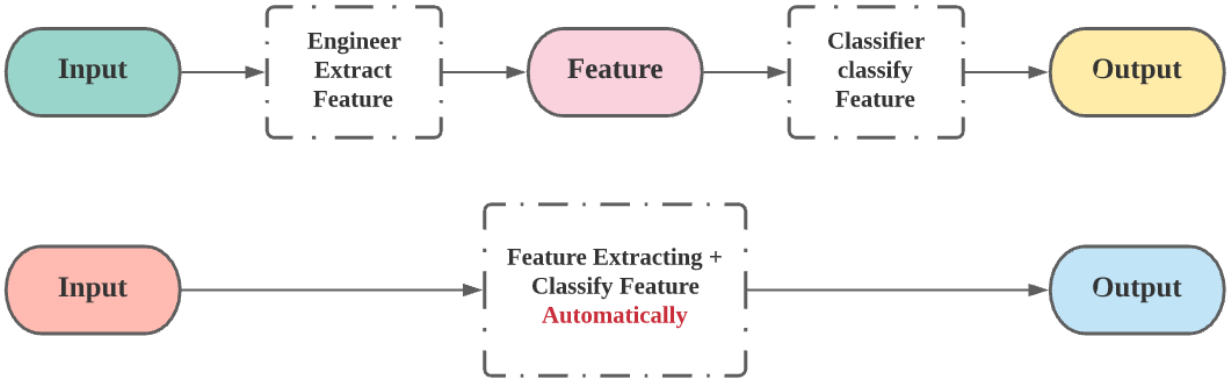

Fig. 1. Generalized Framework of Traditional Machine Learning (above) and Deep Learning (below).

Spatial Pyramid Pooling (SPP) originates from spatial pyramid matching that utilizes spatial statistical properties to represent global information for recognition purposes. Ke et al. [14] discussed the main benefit of the SPP module is it can produce constantly desired outputs without considering the input size requirement to the deep learning model. The training process of a deep learning model with multiple sizes of the image can also prevent over-fitting problems [15]. In this work, several configurations of SPP have been explored that include different numbers of layers and kernel sizes, as well as placement of the module. Besides that, the base model that has been used in this work is also compact in nature, whereby it is commonly used in tracking application, which requires fast computational model [16]. In Oh et al. [17] have surveyed different algorithms from different researchers, and their respective accuracy is summarized in Table I.

By referring to Table I, the previous works' accuracy using CASME II dataset is within the range of 40% to 60%, while for the SMIC dataset, the accuracy range is between 50% and 70%. In general, these accuracies are not satisfactory enough for real-life application. By referring to Table I, the previous works' accuracy using CASME II dataset is within the range of 40% to 60%, while for the SMIC dataset, the accuracy range is between 50% and 70%. In general, these accuracies are not satisfactory enough for real-life application. Micro-expression is a crucial set of facial cues that are extensively employed in all parts of human society. However, simple facial macro expression cues are not enough to effectively relay the real emotions. In order to resolve the issues, this study presents several variants of SPP to improve the recognition accuracy of the automated micro-expression recognition applications.

Continuing from this introduction section will be Section II that presents a comprehensive overview of the basic architecture, hyperparameter function, and related layers used in modeling the CNN model. In Section III, the new improved CNN model is introduced by embedding spatial pyramid pooling into the basic model. Then, the experimental results were discussed in Section IV. Finally, the last section concludes the paper with some suggestions for future works.

II. Related Work

A. Basic Architecture of CNN

The structure of a neural network is very much similar to a human being's brain neuron. When the neuron is excited, it will deliver a chemical substance to its neighboring neuron, which will alter the state potential. If the next neuron's potential is higher than the threshold, the state will be activated and vice versa [28]. A compact deep learning structure of a convolutional neural network (CNN) mainly comprises three convolutional layers, pooling layers, and full-connected layers. The convolution process happened in convolutional layers to extract features from the input image through a sliding window operation. Then, the resultant feature maps will be passed to the pooling layers to reduce the map dimension. Fully-connected layers will be used to segregate the data into different classes [29], [30]. Fig. 2 shows the basic architecture of a CNN.

B. Convolutional Layer

A convolution operator performs a linear operation to a spatial map through a sliding window process. The process starts by applying a small number array (kernel) on the input data (tensor) to compute the product of each element of kernel and tensor for all tensor data. After that, each of the computed outputs will be summed up to form a new value in the respective position of the tensor (feature map). The whole steps will be repeated by applying multiple kernels into the tensor [31]. Based on Ma et al. [32], one kernel can extract one pattern characteristic of the input image. Fig. 3 shows the summary of a convolution process.

C. Padding

According to Rikiya et al. [31], the overlapping between the center element of the kernel with the outermost element of the input tensor should be avoided. Hence, a padding operator was introduced to enlarge the feature map dimension. There are two popular types of padding operations which are zero padding (or called the same padding) and valid padding. The process of zero padding is to make the convolution image larger by adding the zeros to its borders. The size of the output from the zero padding will be the same as the size before undergoing the convolution process [33], [34]. Fig. 4 shows the summary of a zero-padding process.

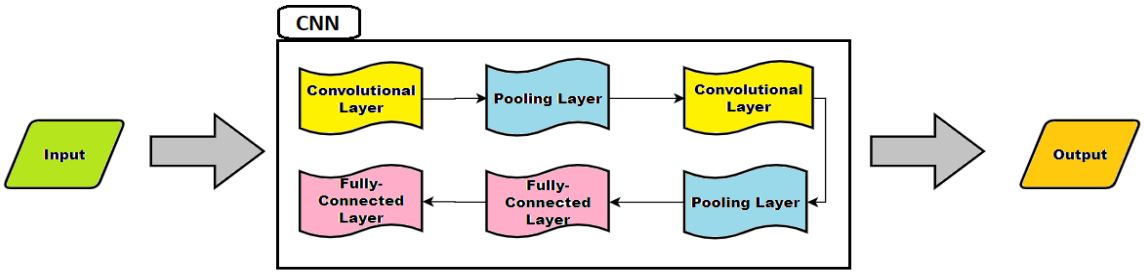

Fig. 2. Basic Architecture of CNN.

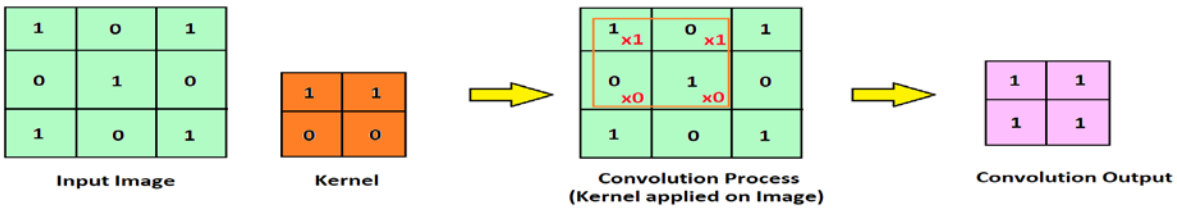

Fig. 3. Summary of Convolution Process.

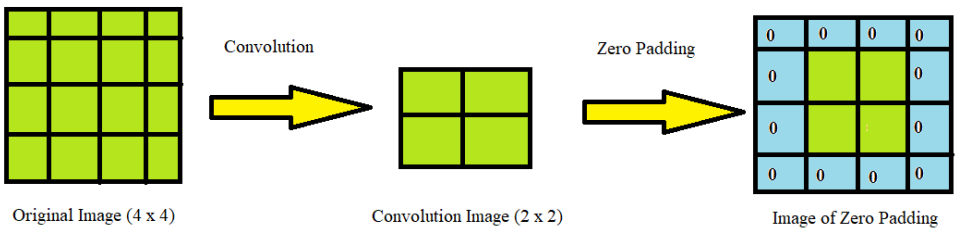

Fig. 4. Summary of Zero Padding Process.

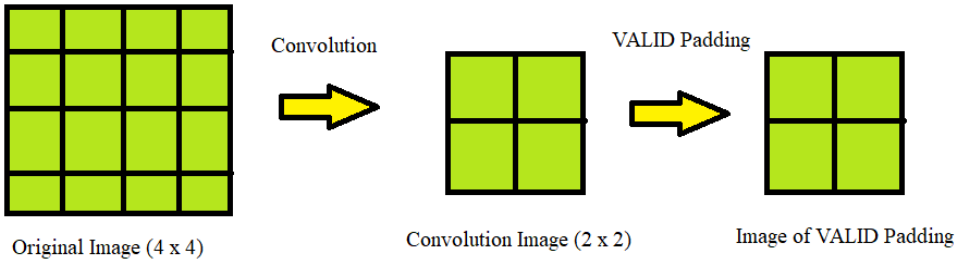

Fig. 5. Summary of VALID Padding Process.

If a Keras-Tensorflow library is used, a valid padding option means that no padding will be applied. The size of the image going through a valid padding option will be the same as the size of the convolution image as shown in Fig. 5.

D. Pooling Layer

There are two advantages of applying a pooling layer to the deep network. Firstly, it helps to decrease the size of the feature map and hence reduces the complexity of the network. Secondly, Guo et al. [35] shows it also helps to extract the important feature optimally. Based on Victor and Isabel [36], there are three types of pooling operators, which are maximum pooling, average pooling, and attentive pooling. For the maximum pooling operator, the maximum element in each overlapping area between the kernel and the feature map will be chosen as the resultant output. Shallu and Rajesh [37] identify the only disadvantage of maximum pooling operation is if most of the values on the feature map are high values, the significant features may be discarded. Fig. 6 shows the operational flow of the maximum pooling process with a 4 x 4 feature map, 2 x 2 kernel size with a step size of two pixels.

According to Sharma et al. [37], the average pooling operation process differs from the maximum pooling process. The new value in the respective position of the feature map is obtained by calculating the average pixels of each overlapping area between the kernel and the feature map. Fig. 7 shows the summary of an average pooling process with a 4 x 4 feature map, 2 x 2 kernel size with a step size of two pixels.

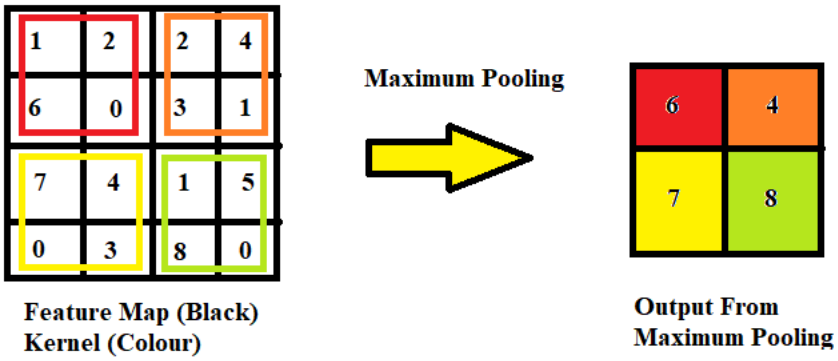

Fig. 6. Operational Flow of a Maximum Pooling Process (4 x 4 Feature Map, 2 x 2 Kernel Size with Step Size of Two Pixels).

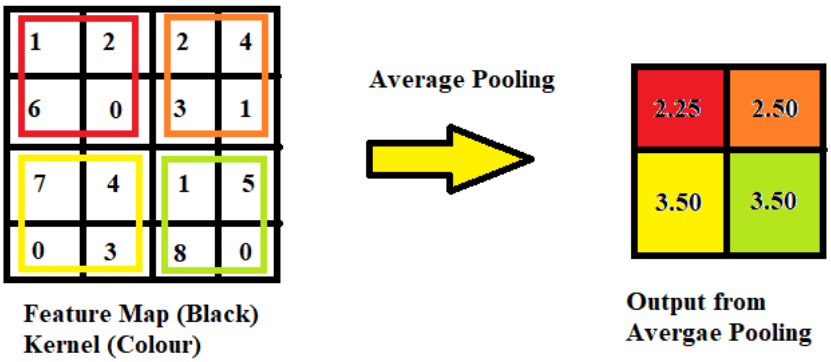

Fig. 7. Operational Flow of an Average Pooling Process (4 x 4 Feature Map, 2 x 2 Kernel Size with Step Size of Two Pixels).

E. Activation Function

The activation function, which is also known as the transfer function, is used to determine the neurons that will be excited and passed as the high state to the next neurons. According to Chigozie et al. [38] and Feng et al. [39], an ordinary neural network without an activation function, the output of each layer of the network will consist of a linear combination of its last layer, which is shown in (1). Let y = output, x = input, n = number of nth layers, b = bias.

$$y = w_1x_1 + w_2x_2 + ... + w_nx_n + b \quad (1)$$

According to the formula above, the range of the output will start from the negative infinity until positive infinity. This shows that the neurons in the network are not limited to a certain finite range. Conversely, with the presence of an activation function, the linear output will be converted to a non-linear result and the output range will fall within a finite value. According to Chigozie et al. [38] and Feng et al. [39], the non-linear result is shown in (2).

$$y = a(w_1x_1 + w_2x_2 + ... + w_nx_n + b) \quad (2)$$

In this study, two types of activation functions, which are ReLu and Softmax function will be utilized. Wang et al. [40] stated that ReLu is an activation function that is based on a piece-wise function. ReLu function is known to be good in handling gradient-vanishing problems. This is the main advantage of a ReLu function compared to other activation functions such as Sigmoid and Tanh functions [41]. Another advantage of a ReLu function is it can be computed at a faster speed compared to the other functions. A positive gradient with a value equal to one will be produced for positive input, while a negative gradient is produced when the input is negative. Fig. 8 shows the graphical representation of the ReLu function.

According to Martin et al. [42], the Softmax function is a useful function that converts the weight vector to the probability distribution. Such a function will make sure that the output is in the range between zero until one and the sum of the outputs will be unity [43]. The softmax function is commonly used in models with multiple classes. Chigozie et al. [38] showed that the probability of each class will be provided and the class with the highest probability is considered as the target class. The only disadvantage of the Softmax function is the output value of zero cannot be produced and hence, a sparse probability distribution cannot be produced through this function. This is because any small output value in the sparse probability distribution will be treated as a negligible value which is zero.

F. Fully Connected Layer

A fully connected layer means each neuron is connected to every neuron to its next layer. The major function of the fully connected layer is to classify the input image into a variety of classes. The Softmax function is used in its output layer [44].

G. Local Response Normalisation

Local Response Normalisation (LNR) is a non-trainable layer based on the lateral inhibition process. It decreases the neighboring pixels activation state, which deems to be too huge in order to form a big contrast in a feature map. This normalization process involves a decreasing operator by squaring and normalizing the pixel values of the feature map in a local neighborhood [45]. From Alex et al. [46], the (3) representation for LNR operation is shown as below, where $b^i_{x,y}$ = output neuron, $a^i_{x,y}$ = input neuron, N = total kernel in the layer, x, y = position of it kernel, others = constant value.

$$b^i_{x,y} = a^i_{x,y} / \left(k + a \sum_{j=\max(0,i-\frac{n}{2})}^{\min(N-1,i+\frac{n}{2})} (a^j_{x,y})^2\right)^B \quad (3)$$

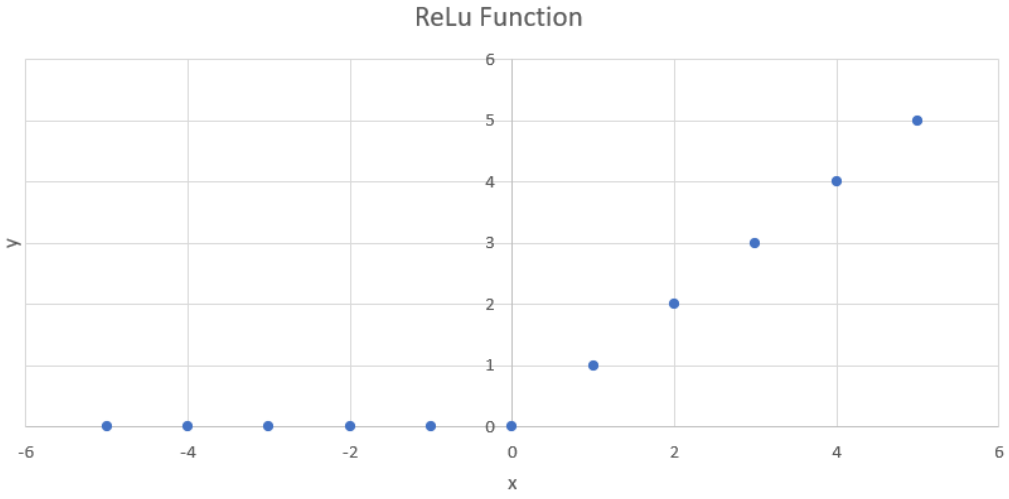

Fig. 8. Graphical Representation of ReLu Function.

III. METHODOLOGY

A. CNN Model

In this study, a compact CNN model [47] derived from the VGG-M model, which was introduced by Chatfield et al. [48]. A compact model is utilized because of the small number of available training data will lead to the problem of over-fitting according to the study by Nicholas et al. [49]. By having a compact property, a deep learning model can be optimized well even with a small number of data. In this study, the combined datasets have only 441 micro-expression videos, which is considered as a small training set. This is the primary reason deeper and newer models, such as Resnet [50] and DenseNet-SPP [51] are not used as the base model.

VGG-M has a good balance between computational speed and accuracy. Hence, it has excellent average performance and has been widely used in tasks involving the fields of vision such as multi-biometric recognition. The original VGG-M consists of nine layers network with five convolutional layers, three fully-connected layers and one flatten layer. The five convolutional layers have the kernel number of 96 for the first convolutional layer, 256 for the second convolutional layer, and 512 for the third, fourth, and fifth convolutional layer. Jiang et al. [52] proposed the fully-connected layers have a kernel size of 128 for the first and second layers, while three nodes for the third fully-connected layer to reduce the complexity of the training process. Each convolutional and full-connected layer is coupled with the ReLu activation function except for the last fully-connected layer, which is coupled with the Softmax activation function. In [53], LNR is applied after the first and second convolutional layers only. A maximum pooling layer is applied after each LNR layer and also after the fifth convolutional layer to make the model more robust and have a better generalization capability [54]. Table II shows the summary of the modified VGG-M architecture used in this study.

According to Table II, the primacy change that can be observed is the reduction in stride size for the first and second maximum pooling (Pool1 and Pool2) from two to one. This is because a larger feature map size is needed to insert the Spatial Pyramid Pooling (SPP) layer. Note that the size of the input image used in this study is 75 x 75. If the original stride size of the first and second maximum pooling layer is used, the feature map size after going through the second layer will become 3 x 3 only, which is not enough to embed the multiple average pooling processes in the SPP layers. Conversely, if the stride size is changed to one, the feature map size will be 13 x 13, which is enough to implement the multi-scale average pooling in the SPP layer.

TABLE II. SUMMARY OF THE MODIFIED VGG-M ARCHITECTURE

Table Head	Type of Layer	Kernel Number	Kernel Size	Stride	Padding	Activation Function
Conv1	Convolution	96	7 x 7	2 x 2	Valid	ReLu
Norm1	LRN	-	-	-	-	-
Pool1	Maximum Pooling	-	3 x 3	1 x 1	-	-
Conv2	Convolution	256	5 x 5	2 x 2	Valid	ReLu
Norm2	LRN	-	-	-	-	-
Pool2	Maximum Pooling	-	3 x 3	1 x 1	-	-
Conv3	Convolution	512	3 x 3	1 x 1	Same	ReLu
Conv4	Convolution	512	3 x 3	1 x 1	Same	ReLu
Conv5	Maximum Pooling	512	3 x 3	1 x 1	Same	ReLu
Pool5	Flatten Layer		3 x 3	2 x 2	-	-
Flat1	Full-connected Layer		-	-	-	-
FC1	Full-connected Layer	128	-	-	-	ReLu
FC2	Full-connected Layer	128	-	-	-	ReLu
FC3	Convolution	3	-	-	-	Softmax

B. Spatial Pyramid Pooling

For general SPP, the input will undergo three down-sampling operations separately which are average pooling, batch normalization, and rectified linear unit activation function (ReLu). The kernel sizes of average pooling are different between the parallel layers. After that, the size of the down-sampling output will be adjusted (resized process) according to the skip-connection layer size. Then, these outputs are combined using a concatenation operator [55] as shown in Fig. 9.

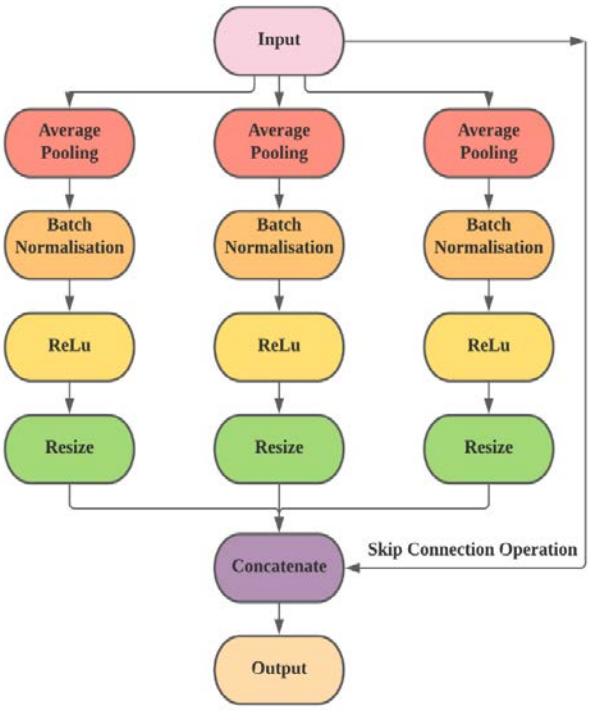

Fig. 9. General SPP Layer.

IV. Result and Discussion

A. Basic Settings

Google Colaboratory (Colab) was used as the platform to conduct the training and training process of the CNN model for micro-expression recognition for detecting a human's true emotion. Colab is a free cloud service developed by Google Research that enables the researcher to write and run Python code through the internet browser. It is a platform that is well suited for machine learning-based research. Another advantage of using Colab is it provides free GPU for the user that can be used for deep learning training. In this study, the programming language used is Python with Tensorflow library 2.4.1 through "Python three Google compute Engine Backend (GPU)" with Ram size of 12.72 GB and disk size of 68.40 GB. The virtual GPU used is Tesla P100-PCIE-16GB.

B. Hyperparameter

According to Lisha et al. [56] and Kandel et al. [57], hyperparameters can be considered as an input to a CNN algorithm which determines the performance of the deep learning algorithm towards the new and unseen data. Several hyperparameters that will be optimized in this work are learning rate, batch size, epochs, and type of optimizer. The type of optimizer determines how the weights are renewed by decreasing the loss or error [58]. In this study, Adamax optimizer is used as the sole optimization algorithm. This is because according to the research from [59], [60], Adamax produces a stable calculation method to renew the weights that ensure the stability of the CNN model.

Batch size is the number of data used for training of CNN model before the weights are updated. Smaller batch size can lead to slower convergence, while a larger batch size enables the CNN model to reach optimum minima. After performing several tests, a batch size of 64 is used throughout the experiment which achieves better stability and convergence compared to other batch sizes. Learning rate determines the rate of updating the weights. We are using 0.0001 as our learning rate for the CNN model. Jaya et al. [61] stated that the learning rate is not very high because a high value will cause the CNN architecture to become very unstable.

Epoch is defined as the number of iterations for a CNN model being trained by the whole datasets. Colab has a limitation that requires the user to interact with the system without idling by more than 90 minutes, after which it will stop the session automatically. Therefore, in [62] states that the number of epoch and learning rate need to be selected carefully so that the number of epoch can be minimized. This study has set the maximum number of epoch to be 120 iterations. Table III shows the summary of the other hyper-parameters that have been set in this study.

C. Dataset

Three ME datasets have been selected for this study, which are CASMEII [63], SMIC [64], and SAMM [65]. The first dataset, CASME II consists of 247 ME video clips from 26 subjects. The resolution of all videos is initially set to 640 x 480 pixels while the cropped image resolution is 340 x 280 pixels. Only five types of emotions are being considered, which are happiness, surprise, disgust, regression, and others [66]. The second dataset, SAMM involving 159 ME video clips from 29 subjects. The initial resolution of the videos is 2040 x 1080 pixels, while the cropped video resolution is 400 x 400 pixels. Rather than five emotion categories, SAMM consists of eight emotion classes, which are angry, contempt, disgust, fear, happiness, sadness, surprise, and others [67],[68]. The last dataset, SMIC comprises of 164 ME video clips from 16 subjects. The size of every image is 640 x 480 pixels. This dataset has three categories of emotion only that include positive, negative, and surprise [64], [66].

TABLE III. Hyperparameter Setting

Hyperparameter	**Value**
Learning Rate	0.0001
Batch Size	64
Epochs	120
Optimizer	ADAMAX

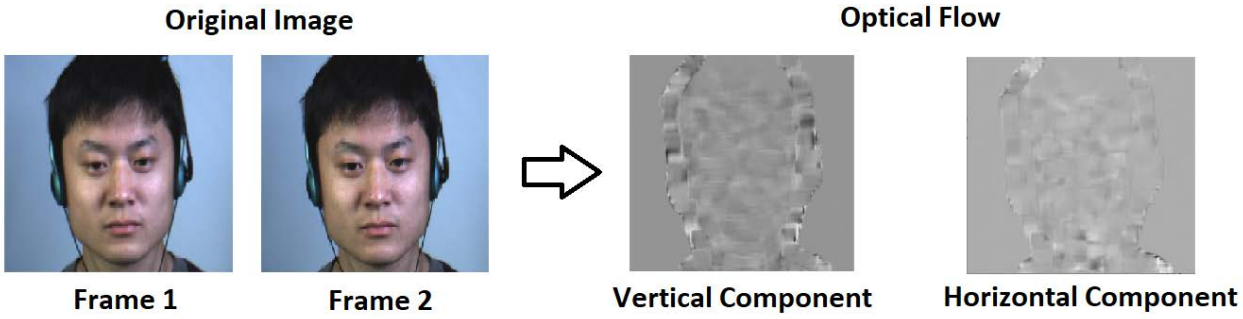

Fig. 10. Samples of Optical Flow between Two Consecutive Frames.

In this study, all images from all three datasets will be resized to 300 x 300 pixels, which will result in the same resolution for the respective vertical and horizontal components of the optical flow image. After that, the optical images will be down-scale again to the CNN input requirement, which is 75 x 75 pixels. According to Song and Zengfu [69], optical flow is the apparent motion between the video frame or image frame. It has a high-level feature in analyzing the visual motion information compared to the original image sequences, which allows it to have a better and more efficient data representation for ME [70]. Fig. 10 shows some examples of the calculated optical flow images, whereby the black and white color shows the presence of motion between the frames, while the grey color indicates that there is no motion for that respective pixels

The proposed system performance was verified by using 570 videos from 71 subjects that comprise of CASME II, SAMM, and SMIC datasets. There is no validation dataset used during the training phase. For the training and testing process, the dataset is divided according to leave-one-subject-out for testing, while the rest subjects will be used as training. This means that the model is trained using 70 subjects and 1 subject is used for testing. The output of this study will be labeled and classified into three classes: positive, negative, and surprise emotions. Positive emotion involves happy micro-expression which is considered as a "good" human emotion, while negative emotion is considered as a "bad" human emotion that can be further broken down into disgust, sadness, and fear. The third class of emotion, surprise is the emotion that a human expresses when he senses any difference between the expectation and the reality. Fig. 11, Fig. 12, and Fig. 13 portray an example of each type of emotion from different datasets.

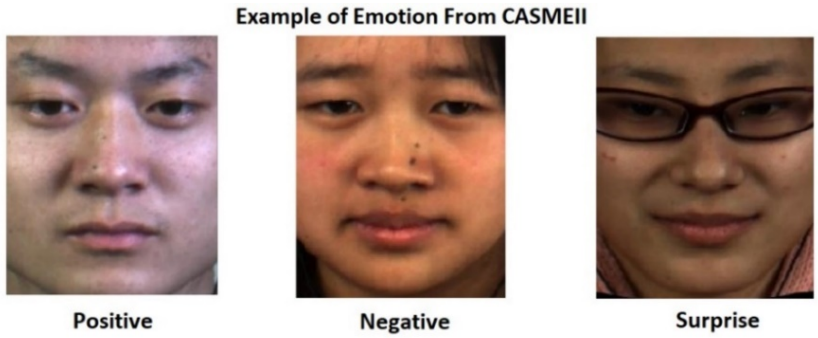

Fig. 11. Example of each Emotion from CASMEII.

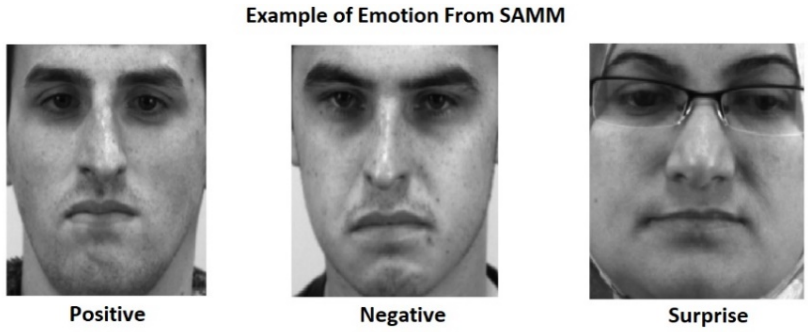

Fig. 12. Example of each Emotion from SAMM.

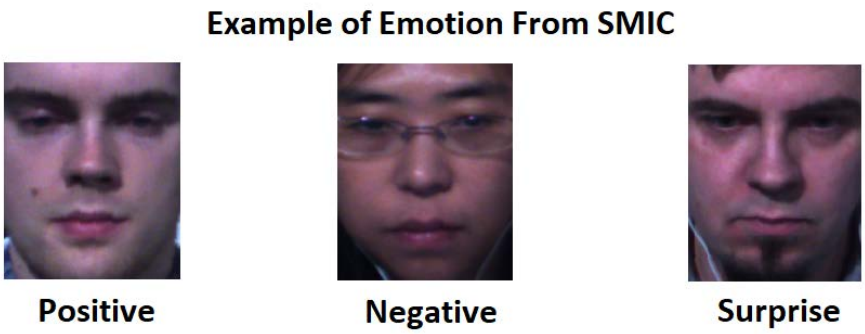

Fig. 13. Example of each Emotion from SMIC.

D. Evaluation Metric

The evaluation metric used in this study is the accuracy of micro-expression recognition for detecting a human's true emotion. According to Duygu [71], accuracy is defined as the ratio of true classification to total classification (true and false classification), which is formulated as in (4), whereby TP is defined as true positive, TN is true negative, FP is false positive, and FN is false negative.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (4)$$

E. Experimental Setting

Several training processes were performed based on the modified VGG-M architecture for micro-expression recognition to detect human's authentic emotions. For every experiment, the values of other hyperparameters are set to constant to make sure that the experiments are conducted in fair conditions. After that, the Spatial Pyramid Pooling (SPP) layer of various configurations (in terms of the number of layers, kernel size of average pooling, and position where SPP layers are added) will be embedded into the modified VGG-M architecture. The performances for each configuration will be compared and evaluated by computing their recognition accuracy by using combined datasets of CASMEII, SMIC, and SAMM. Fig. 14 shows the summary of the major procedures that were performed to extract the performance accuracy.

There will be eight variants of SPP architectures that will be tested as detailed out below:

- First Variant = two parallel layers, Kernel size: two, four, Position: After first Layer of VGG-M.
- Second Variant = two parallel layers, Kernel size: two, four, Position: After second Layer of VGG-M.
- Third Variant = three parallel layers, Kernel size: two, four, six, Position: After first Layer of VGG-M.
- Fourth Variant = three parallel layers, Kernel size: two, four, six, Position: After second Layer of VGG-M.
- Fifth Variant = four parallel layers, Kernel size: two, four, six, Position: After first Layer of VGG-M.
- Sixth Variant = four parallel layers, Kernel size: two, four, six, eight, Position: After second Layer of VGG-M.
- Seventh Variant = five parallel layers, Kernel size: two, four six, eight, ten, Position: After first Layer of VGG-M.
- Eighth Variant = five parallel layers, Kernel size: two, four, six, eight, ten, Position: After second Layer of VGG-M.

The SPP layers with the different number of SPP layers and kernel size of average pooling will be added in two ways, one of the ways is added after the first layer and another way is inserted after the second layer of the VGG-M module as shown in Fig. 15.

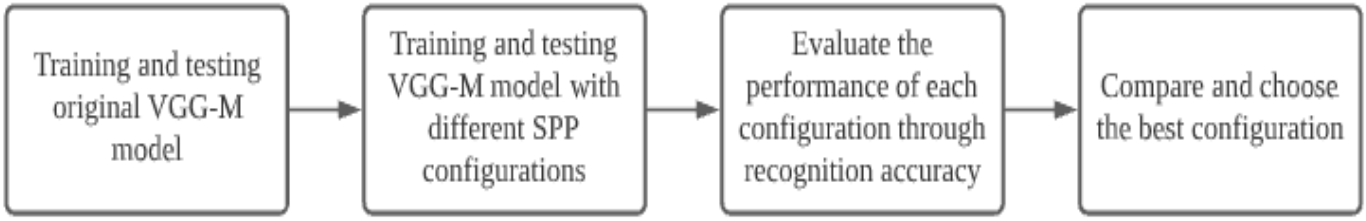

Fig. 14. Summary of the Experimental Procedures.

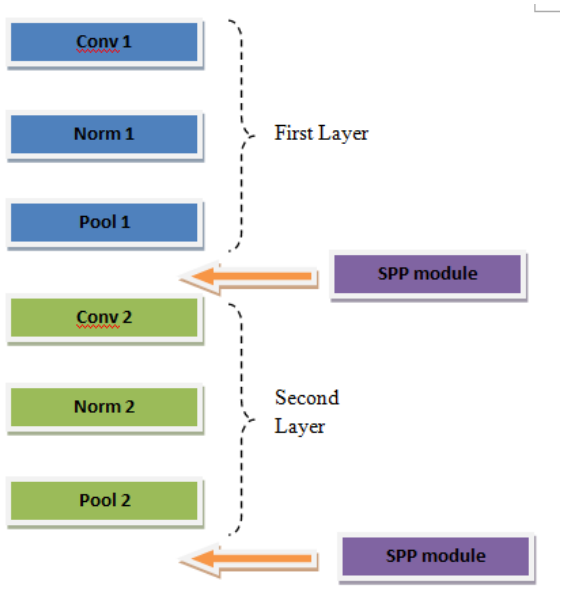

Fig. 15. Placement of the SPP Module.

F. Dataset Analysis

Table IV shows the results of modified VGG-M with several settings of parallel branches and placement of the SPP modules. Besides that, the results of combining both hyper-parameters are also reported in the same table. Fig. 16 shows the graph for training process of the original VGG-M and Fig. 17 shows the graph of the training results of VGG-M with SPP inserted after the second CNN layer.

TABLE IV. PERFORMANCE RESULTS OF VARIOUS SPP CONFIGURATIONS

Types of datasets	**Accuracy (%)**								
	Original (without SPP)	***After first layer***				***After second layer***			
		2 SPP	3 SPP	4 SPP	5 SPP	2 SPP	3 SPP	4 SPP	5 SPP
Combined	75.96	74.75	75.21	75.96	75.06	76.42	75.36	76.87	76.27
CASME II	86.21	84.37	86.67	83.45	86.67	88.05	83.91	86.67	86.67
SAMM	71.21	70.2	68.18	69.19	69.7	70.02	71.21	69.7	69.7
SMIC	70.73	69.92	70.73	74.8	69.11	71.14	71.14	73.98	72.36

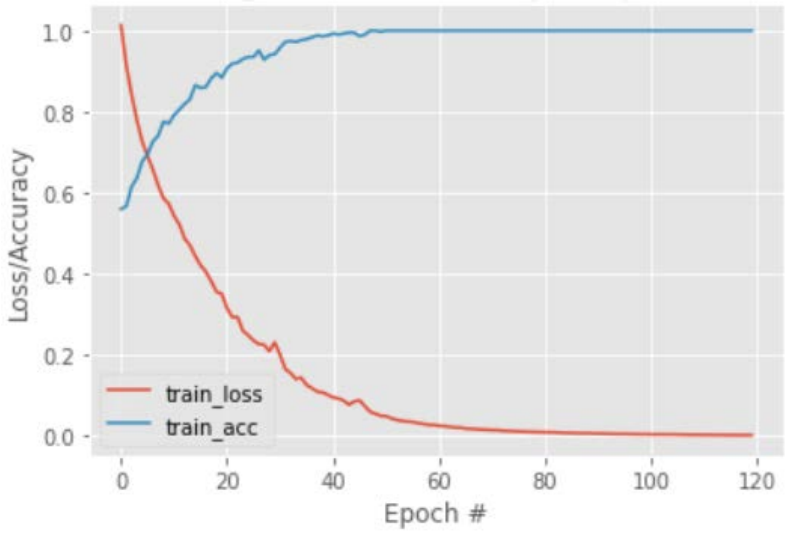

Fig. 16. The Original VGG-M Training Process.

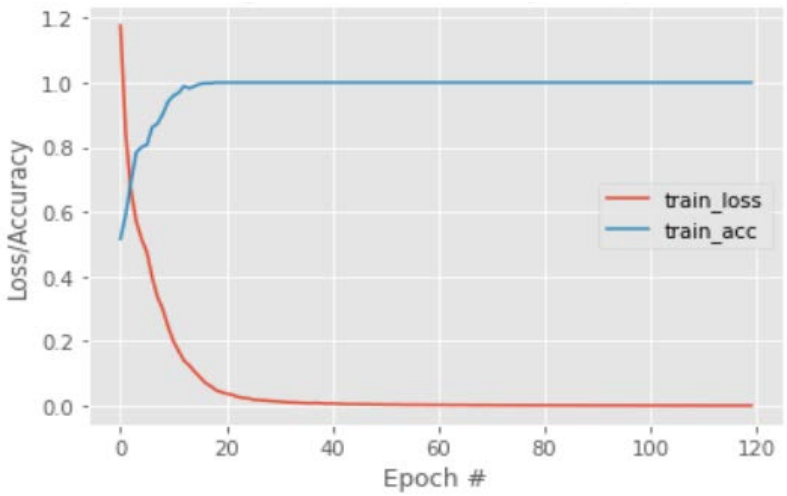

Fig. 17. VGG-M Training Process using SPP after the Second VGG-M Layer.

By optimizing the network configurations (different SPP parallel branches and module placement), the recognition accuracy of the proposed deep model has improved the recognition performance by four percent to seven percent when compared to the original network for the SAMM dataset. Meanwhile, for the SMIC dataset, the recognition accuracy of the model using the combined dataset has improved from 1% to 5%.

G. SPP Configuration and Placement

From Table IV, the results show that the recognition accuracy of the model using the combined dataset, CASME II and SMIC after the addition of the SPP module has improved the performance, except for the case of the SAMM dataset, in which the performance has become worst. Firstly, based on the combined dataset results, the best recognition accuracy is obtained with four SPP parallel layers, added after the second layer with an accuracy of 76.87%, which is an improvement of 0.91% compared to the base model.

For the CASME II dataset analysis, the best recognition accuracy is obtained by using two SPP parallel layers inserted after the second layer with 88.05% accuracies, which is an improvement of 1.84% compared to the base model. Among many datasets and configurations, this is the highest recognition accuracy obtained. While, for the case of the SAMM dataset, the addition of more SPP parallel layers into the base model does not increase the recognition accuracy, whereby the best number of SPP layers is three that is added after the second layer with a recognition accuracy of 71.21%.

On the other hand, for the SMIC dataset, four SPP parallel layers that are embedded after the first layer produced the highest recognition accuracy of 74.80% with an improvement of 4.07% compared to the base model. This is the greatest improvement in terms of recognition accuracy among many configurations that have been tested. Hence, the best setup for each dataset and the combined datasets are shown in Table V.

However, among all the configurations, SPP with four parallel branches produces the best general performance where it produces the best recognition accuracies for the combined datasets and SMIC dataset. Besides that, the best overall placement of the SPP module is if it is added after the second layer of the base model. On average, it produces results with higher recognition accuracy. In addition, most of the highest recognition accuracy is obtained after adding the SPP right after the second layer to the base model.

H. Improvement of the SPP Configuration

To further improve the base model performance, a few new variants of the SPP is introduced as follow:

- Ninth Variant = five parallel layers, Kernel size: two, three, four, five, six, Position: After first Layer of VGG-M
- Tenth Variant = five parallel layers, Kernel size: two, three, four, five, six, Position: After second Layer of VGG-M

TABLE V. SUMMARY OF THE BEST SETUP IN TERMS OF SPP CONFIGURATION AND PLACEMENT

Types of datasets	**Best configuration of SPP**	
	SPP number	***Position***
combined	Four	After second layer
CASME II	Two	After second layer
SMIC	Three	After second layer
SAMM	Four	After first layer

TABLE VI. PERFORMANCE BETWEEN DIFFERENT SETS OF KERNEL SIZE

Types of datasets	Accuracy (%)			
	After first layer		*After second layer*	
	first set Kernel	second set Kernel	first set Kernel	second set Kernel
Combined	75.06	74.91	76.27	76.42
CASME II	86.67	84.37	86.67	86.21
SAMM	69.70	71.21	69.70	70.20
SMIC	69.11	69.51	72.36	72.76

TABLE VII. SUMMARY OF THE BEST CONFIGURATION IN TERMS OF THE AVERAGE POOLING KERNEL SIZE FOR DIFFERENT DATASET SETUP

Table Head	**Table Column Head**
Combined	two, three, four, five and six
CASME II	two, four, six, eight and ten
SMIC	two, three, four, five and six
SAMM	two, three, four, five and six

The performance difference between the new variants of SPP with the earlier variants is due to the kernel sizes of average pooling, where the sizes are smaller for the latter variants. In short, the ninth and the tenth variants have bigger kernel sizes compared to the seventh and the eighth variants. Table VI shows the recognition accuracy of the modified model with different kernel sizes.

According to Table V, when adding the SPP layer after the first layer to the base model, the first set of kernel sizes produce better recognition accuracy compared to the second set for the combined datasets and CASME II dataset. On the other hand, it is the opposite trend for the SAMM and SMIC datasets. Besides that, if the SPP is added after the second layer, the second set of kernel sizes produces better accuracy compared to the first set for the combined, SAMM and SMIC datasets, except for the CASMEII dataset.

By comparing the overall results, the second set of kernel sizes result in higher average recognition accuracy for the test done on the combined, SAMM and SMIC dataset (76.42%, 71.21%, and 72.76% respectively). However, the first set of kernel sizes return the best recognition accuracy for the test done on the CASME II dataset (86.67 % accuracy). Hence, it can be concluded that the second set of average pooling kernel sizes is the better alternative compared to the first set as shown in Table VII.

V. CONCLUSION

This study has managed to improve the recognition accuracy of the CNN-based deep learning model by embedding SPP to the base model. Various configurations have been tested to find the optimal setup. For the combined dataset, the best SPP configuration is obtained by adding four parallel branches of the SPP after the second layer of the base model. This configuration has produced a recognition accuracy of 76.87%, which is an improvement of 0.91% over the base model. For the CASME II dataset, two parallel branches of the SPP layers added after the second layer of the base model have produced 88.05% recognition accuracy, which is an improvement of 1.84%. Meanwhile, the best SPP configuration for the SMIC dataset is four parallel branches added after the first layer with an improvement of 4.07%. There is not much performance improvement that can be observed with the addition of the SPP module when the test is done on the SAMM dataset. Generally, the overall best SPP configuration is by embedding four parallel branches of SPP with average pooling kernel sizes of two, three, four, five, and six, added after the second layer of the base model. For future works, more datasets can be combined to produce a more robust micro-expression-based automated emotion recognition system. Other than that, the dataset will be resampled using data augmentation methods to balance the class distribution between the emotion class. Besides that, synthetic data augmentation through the generative adversarial method can be employed to further increase the training samples.

***Abstract*—Machine printed or handwritten character recognition becomes a major research topic in several real time applications. The recent advancements of deep learning and image processing techniques can be employed for printed and handwritten character recognition. Telugu character Recognition (TCR) remains a difficult task in optical character recognition (OCR), which transforms the printed and handwritten characters into respective text formats. In this aspect, this study introduces an effective deep learning based TCR model for printed and handwritten characters (DLTCR-PHWC). The proposed DLTCR-PHWC technique aims to detect and recognize the printed as well as handwritten characters that exist in the same image. Primarily, image pre-processing is performed using the adaptive fuzzy filtering technique. Next, line and character segmentation processes are performed to derive useful regions. In addition, the fusion of EfficientNet and CapsuleNet models is used for feature extraction. Finally, the Aquila optimizer (AO) with bi-directional long short-term memory (BiLSTM) model is utilized for recognition process. A detailed experimentation of the proposed DLTCR-PHWC technique is investigated using Telugu character dataset and the simulation outcome portrayed the supremacy of the proposed DLTCR-PHWC technique over the recent state of art approaches.**

Keywords*—Optical character recognition; Telugu; deep learning; Aquila optimizer; BiLSTM; handwritten characters; printed characters

I. INTRODUCTION

Recognition of hand printed or machine printed documents plays a significant role in applications such as text-speech converter, automated language-language translator, and intelligent scanning machines [1]. The aim of document image analyses is to identify the graphics and text modules in the paper documents and for extracting the proposed data, as human beings do. The two modules of document image analyses are textual and graphical processing. The former textual processing handles the text element of the document images and the graphical processing handles symbol and non-textual line elements which form line diagrams, delimit straight lines among company logos and text sections, and so on [2]. The image processing method is utilized for recognizing the handwritten Telugu character. Telugu is widely speaking in Telangana and Andhra Pradesh in India.

Optical character recognition (OCR) is a procedure which transforms the handwritten or printed files to their equivalent text format [3]. The OCR can be separated into two classes: online and offline character identification. Offline character identification is additionally separated into two components i.e., machine and handwritten printed character identification. In hand-written character recognition, there is a large number of problems in comparison with machine printed documents [4]. It is a challenging and fascinating field of pattern detection using many real-time applications. Many commercial OCR systems are accessible for printed Arabic characters however they have a lot of technological issues, particularly in the segmentation phase the result isn't enviable [5]. During the past years, OCR has become increasingly important since the need for translating the scanned image into computer identifiable forms like text documents has improved application. The OCR challenging problems such as distortion, lighting variations, variance in font size, and blurring of the printed character images, have improved the demands for OCR in the study work. The significant disadvantage witnessed in OCR is that the infra-class variation is larger because of the huge amount of images accessibility for the processing [6]. The OCR system is currently under development for most of the common languages and Telugu is no exemption for it. The OCR process has become really hard for Telugu and possess its individual challenges to the developer of Telugu character recognition (TCR) system. In recent times, significant studies have been made toward the development of an effective TCR scheme [7].

This study focuses on the design of effective deep learning based TCR technique for printed and handwritten characters (DLTCR-PHWC) in the same image. The DLTCR-PHWC involves adaptive fuzzy filtering (AFF) technique for image pre-processing. Besides, line and character segmentation processes are performed to derive useful regions. Moreover, the fusion of EfficientNet and CapsuleNet models is used for feature extraction. Furthermore, the Aquila optimizer (AO). With bidirectional long short-term memory (BiLSTM) model is applied for recognition process. A comprehensive experimental analysis takes place using Telugu character dataset a detailed comparative analysis is carried out in terms of different evaluation parameters.

The rest of the paper in Section 2 discusses literature review, Section 3 briefs proposed model and Section 4 discusses results and discussion and Section 5 ends up with conclusion.

II. Literature Review

Prameela et al. [8] proposed an OCR method for Telugu documents that consists of 2 steps, i.e. classification, preprocessing, and feature extraction. In preprocessing phase, they used median filtering on the input character and employed skeletonization and normalization methods over character for extracting boundary edge pixel points. In feature extraction phase, first, all the characters are separated into 3×3 grids and the equivalent centroid for every 9 regions is calculated. Cheekati and Rajeti [9] deal in emerging a reliable, fast Telugu hand-written ResNet for offline and online character identification and improve classification accuracy. The method is estimated by IIITS-Telugu Handwriting Dataset; HP Lab databases (Telugu) India and attained a remarkable result. The presented residual net (ResNet-50) attains 2.37% error on ResNet-18 & 34 test set.

Lakshmi and Babu [10] perform a new Telugu script identification and retrieval method named HCH model. Hash coding would be utilized as a feature extractor and the hamming distance would be used as a replacement for traditional Euclidean distance for measuring the similarity among database and query images. Experimental analyses exhibit that the presented model has outstanding performances to the traditional methods proposed in the survey. Burra et al. [11] proposed 2 methods for improving the glyph/symbol segmentations in a Telugu OCR scheme. The main features having an effect on the entire performance of a Telugu OCR scheme can be able to divide/segment scanned document images into identifiable units. In Telugu, this unit is generally interconnected component and is known as glyphs. Once a document is removed, interconnected components-based algorithm for segmentation fails. They provide malformed glyphs (a) partial and results of break in the character because of uneven dispersal of ink on the noise /page, and (b) are an integration of more than two glyphs due to smudging in noise/print. The previous one is labeled broken and the last one is merged character. Hebbi et al. [12] introduce a cross language environment for recognizing the words and characters of lower resources script that is script which doesn't have typical database and the dataset isn't accessible for public access. Indic script comes from a popular origin and few scripts have a standard 3 regional structures. Identification of this script could be performed using another script having same structures. In order to identify this character, the models are trained using source language Kannada with zone wise testing and training is made by Kannada and the targeting language Telugu.

Rani et al. [13] proposed a method for feature classification and extraction of Telugu hand-written script based personalized template matching method through caching method for achieving better results. The method of caching is executed by main databases with a cache database maintain the frequently employed character template for a set of each character template. The XML databases are utilized in the class for different character templates and the class representation is given by new class structures depending on XML tags. In Sarika and Sirisala [14], OCR methods like preprocessing, digitization, feature extraction, recognition, and segmentation were discussed. HWCR with distinct ML methods like Bayesian decision theory, SVM, and Bayesian classifier was discussed. The current technique of HWCR is examined for native language and related their features and functionality.

Madhavi et al. [15] proposed an effective model named TR for correcting and detecting slant angles of MTW. Telugu language is India's common language speaking around 80 million people. The difficult character is attached with further marks called "vatthus" and "maatras" it is stimulating for detecting a slant angle. The presented TR model performs pre-processing and identifies interconnected components within the provided MTW. Later, estimate the slant angle of every interconnected component by acquiring interconnected slant lines on the boundary of every interconnected component. BJ et al. [16] handle classification and recognition of confusing Kannada characters. The RF and SVM as classifiers to categorize the confusing character. The presented method attained 78% of classifiers accuracy. Lastly, this method identifies the confusing characters with template matching and feature value outcomes-based classifier.

III. The Proposed TCR Model

In this study, a new DLTCR-PHWC technique is derived to detect and recognize the printed as well as handwritten characters that exist in the same image. The DLTCR-PHWC technique encompasses different operations such as AFF based pre-processing, line/paragraph segmentation, fusion-based feature extraction, BiLSTM based recognition, and AO based hyperparameter optimization. Fig. 1 showcases the overall block diagram of proposed DLTCR-PHWC model. The detailed working of every module is offered in the following subsections.

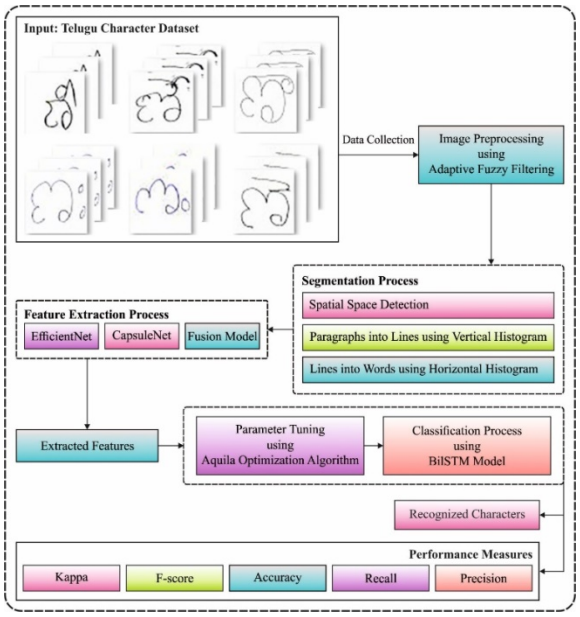

Fig. 1. Overall Process of DLTCR-PHWC Model.

A. Pre-Processing

In this model, the input receives image as input for removing the presence of noise. Once the image is reduced by high noise and the whole pixels in filter window are similar to the maximum values, it increases the window size up to a predefined maximal size $W_{\max}$, it changes $I(x,y)$ by the median values i.e., estimated from filter window. In the process of finding a median value, each pixel value is similar to the maximum values in filter window, through evaluated pixel value in filter window except the maximum values to obtain median values.

B. Segmentation Process

Segmentation is a major phase in detection method since it extracts significant fields for additional analyses. Typically, it is employed for verifying the boundary and objects such as lines, curves, and so on, in an image. The scanned images are segmented to the paragraph via spatial space recognition method, paragraph to lines through vertical histogram, lines to words through horizontal histogram [17]. Accurateness of character identification is based largely on segmentation performance. Mainly, this procedure has the subsequent steps:

- Recognize the text line on the page.
- Recognize single character in all the words.

The widely employed technique for line segment of the grayscale images is the projection profile model. By adding it to the horizontal course of the documents, gaps among the text line could be recognized through detecting the projection value. They employ horizontal projection profiles analyses since the text in most document images is arranged with the horizontal line. This method determines horizontal projection histogram, the amount of black pixel for every column of the raster images. Once these profiles are employed on M × N images, a column vector of M × 1 sizes were attained. Element of these column vectors is the amount of pixel value in every row of the document images. Afterward, the line segmentation the resulting outputs are fed into the character segments. Finally, the extracted line is segmented to the character. In order to detect the boundaries among the characters, they employ threshold values on the length of the space amongst the characters. Afterward detecting the position of the space among the characters they remove the part of the line segmentation. As per the abovementioned procedure, the character and lines are segmented from the pre-processed documents. Afterward the segmentation procedure the resulting outputs are fed into the feature extraction.

C. Fusion based Feature Extraction Technique

At this stage, the segmented images undergo feature extraction process using CapsNet and EfficientNet models. The underlying framework of the CapsNet, adapted in this study, is made up of 1 fully connected layer and two convolution layers. The 1st convolution layer is generated with 256 9 × 9 kernels using a stride of one and ReLU activation, deliver feature map which is additionally fed into the initial set of capsules in the abovementioned layers. The 2nd layers represent the initial capsule and accommodate thirty-two channels, therefore eight-dimensional convolution capsules of 9 × 9 kernels and a stride of two, in which every capsule captures each unit in the 1st convolution layer that receptive field overlaps with the center of capsules. Therefore, the set of initial capsules output an overall of 32 × 6 × 6 eight dimensional vectors, and the capsule of the similar grid share their weight with one another. The final layer of the CapsNet is an FC layer of 2 sixteen dimensional units which is interconnected to each capsule in the prior layer [18]. As the output of 1st convolution layer is 1D, it doesn't transfer the similar quality of data as capsule in the abovementioned layers (viz., the output of 1st layer doesn't offer orientation attribute to agree on), no routing is proposed with the initial capsule. It is notable that each logit Bij are initiated as zero that indicates the primary capsule output is transmitted to each possible parent capsule with equivalent probabilities Cij. In another word, previous to knowledge optimization, the initial capsule assumes an equivalent agreement with parent capsule (for example each entity tied with initial capsule is related to the entity tied to above parent capsule). Fig. 2 illustrates the framework of CapsNet model.

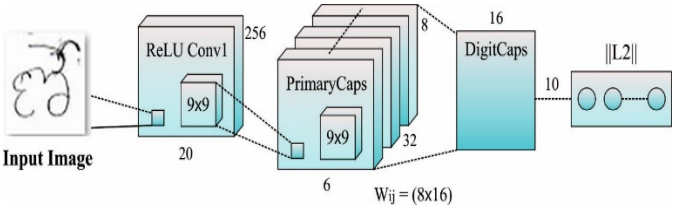

Fig. 2. Structure of CapsNet.

With respect to the loss function for the networks to learn, it consists in extending the length of instantiation vectors V_k for an entity class (car and solar panel in these cases) given that certain entity is witnessed in an image. This could be expanded for several entities through a single margin loss L_k for all entities k capsule :

$$L_k = T_k \max(0, m^+ - \|V_k\|)^2 + \lambda(1 - T_k) \max(0, \|V_k\| - m^-)^2 \quad (1)$$

Whereas T_k is fixed to 1 when the entity is existing.

In recent years, the rapid growth of DL method has spawned many excellent CNN models. From the initial simple network to the current complex network, the performance of the model is getting better and better in every aspect. EfficientNet combines the advantage of previous network, which summarize the development of network performances into 3D: (1) Deepen the network, i.e., use the skip connection to increase the depth of the neural networks, and attain feature extraction via deeper layer; (2) Widen the network, i.e., increase the amount of convolution layers to attain more functions and features; (3) By increasing the input image resolution, the network could express and learn more things, which is beneficial to improve accuracy. Then, use a compound coefficient ϕ to uniformly balance and scale the resolution, depth, and width of the networks, as well maximize the network performance on limited resources. Estimation of the compound coefficient is given in Eq. (1):

$$depth: d = \alpha^{\phi} \quad width: w = \beta^{\phi} \quad resolution: r = \gamma^{\phi}$$
$$s.t. \alpha \cdot \beta^2 \cdot \gamma^2 \approx 2 \quad (2)$$

$\alpha \geq 1, \beta \geq 1, \gamma \geq 1$

Whereas d, w, and r represent the coefficient used to scale the resolution, depth, and width of the networks [19]. The α, β, & γ denotes resource allocation for network depth, width, and resolution. EfficientNet largely consists of Stem, 16 Blocks, Conv2D, GlobalAveragePooling2D, and Dense layer. The design of Block is based mainly on the attention mechanism and residual structure, also other structures are similar to traditional CNN model.

The extracted features from both DL models are fused together. During the fusion process, it is needed to decide the value of λ, which calls the R feature fusion. The fusion of features can be defined as follows.

$$NF = \lambda \cdot LF + (1 - \lambda) \cdot HF, \quad (3)$$

where NF is the fusion feature, and LF and HF indicate the features derived by the CapsNet and EfficientNet models.

D. Design of AO based BiLSTM Model for Recognition Process

Finally, the BiLSTM model receives the feature vectors as input and carried out the recognition process. The LSTM refers to a special RNN model that resolves the problems of gradient vanishing of the RNN by presenting a threshold mechanism and memory unit [20]. But x represent the network input at distinct times, y indicates the network output, h represents the hidden layer, u signifies the weight from input to the hidden layers, w denote the weights of prior node hidden layer to the present node hidden layer, and v represents the weight from hidden to the output layers.

In the actual execution of the LSTM, the LSTM units are upgraded at time t as follows:

$$i_t = \sigma(w_i h_{t-1} + U_i x_t + b_t) \quad (4)$$

$$f_t = \sigma\left(w_j h_{t-1} + U_f x_t + b_f\right) \quad (5)$$

$$\tilde{c} = tanh(W_c h_{t-1} + U_c x_t + b_c) \quad (6)$$

$$c_t = f_t \odot c_{t-1} + i_t \odot \tilde{c}_t \quad (7)$$

$$o_t = \sigma(w_o h_{t-1} + U_o x_t + b_o) \quad (8)$$

$$h_t = o_{t-1} \odot tanh(c_t) \quad (9)$$

Now, σ represents the sigmoid function and $\odot$ indicates the equivalent product of the element. x_t denotes the input vector at time t. h_t signifies the hidden state vector, that is called output vector, and store each data at time t and the preceding time. U_i, U_f, U_c, U_o represent the weight of input vector xt for the input, forgotten, unit, and output gates, correspondingly. W_i, W_f, W_c, W_o denote the weight of dissimilar gates to the hidden state vector h_t. b_t, b_f, b_c, b_o denotes the off-set vector. Using the 3 gates structure, the LSTM allows the recurrent network to maintain the beneficial data for the task in the memory unit at the time of the training model, thus evading the problems of the RNN disappearing while obtaining long range data.

While processing sequence data, the BLSTM introduces further backward estimation processes, i.e., unlike normal LSTM case. This procedure could employ the succeeding data of the sequence. Finally, the reverse and forward evaluations were implemented. The value is output to the output layer concurrently; as a result, each data of a sequence is attained by two directions that is used for multiplying type of natural language processing task.

Followed by, the hyperparameter tuning of the BiLSTM model take place using AO technique. The Aquila is most famous bird of prey. Young Aquila generally attains entire assurance during the fall, subsequent that it can be moved extremely for building territory to themselves. Because of their hunting bravery, Aquila is a most considered bird globally. The Male Aquila become considerably further prey if the solo-hunting. An essential stimulus to the presented AO technique has been resultant in the techniques stated above. The subsequent subsections that define these procedures are modeled in AO. In AO, it can be population-oriented technique, the optimized rules start with population of candidate solution (X) as projected in Eq. (9) that has been created stochastically amongst the upper boundary (UB) and lower boundary (LB) of the provided issues. An optimum solution obtained during all iterations can be defined as follows.

$$x = \begin{bmatrix} x_{1,1} & \cdots & x_{1,j} & x_{1,Dim-1} & x_{1,Dim} \\ x_{2,1} & \cdots & x_{2,j} & \cdots & x_{2,Dim} \\ \cdots & \cdots & x_{i,j} & \cdots & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ x_{N-1,1} & \cdots & x_{N-1,j} & \cdots & x_{N-1,Dim} \\ x_{N,1} & \cdots & x_{N,j} & x_{N,Dim-1} & x_{N,Dim} \end{bmatrix} \quad (10)$$

where X refers the group of present candidate solutions that are created arbitrarily with utilizing Eq. (10), X_i indicates the decision values (places) of i^{th} solutions, N represents the entire amount of candidate solution (population), and Dim signifies the dimensional of the issue.

$$X_{ij} = rand \times \left(UB_j - LB_j\right) + LB_j, i = 1,2, \ldots\ldots, Nj = 1,2, \ldots, Dim \quad (11)$$

where $rand$ denotes the arbitrary number, LB_j demonstrates the j^{th} lower bound, and UB_j implies the j^{th} upper bound of provided issue [21]. The AO technique is transmission in exploration to exploitation stages utilizing distinct performance dependent upon this form if $t \leq \left(\frac{2}{3}\right) * T$ the exploration stages were excited; else, the exploitation stages are implemented. The mathematical process of the AO has been presented. During the primary technique (X_1), the Aquila distinguishes the prey region and elects an optimum hunting region by great soar with vertical stoop. At this point, the AO extremely explorers in great soar for determining the region of search space in which the prey is. This performance has been mathematically projected as in Eq. (12)

$$X_1(t+1) = X_{best}(t) \times \left(1 - \frac{t}{T}\right) + (X_M(t) - X_{best}(t) * rand), \quad (12)$$

where, $X_1(t+1)$ refers the solution of subsequent round of t that is created by initial searching technique (X_1). $X_{best}(t)$ signifies the optimum attained solution until t^{th}

iteration, this reproduces the estimated prey's position. The formula $\left(\frac{1-t}{T}\right)$ has been utilized for controlling the extended search (exploration) with the amount of iterations. $X_M(t)$ defines the places mean value of present solutions associated at t^{th} iteration that is computed utilizing in Eq. (12). $rand$ indicates the arbitrary value amongst [0, 1]. r and T demonstrate the present round and the maximal rounds, correspondingly.

$$X_M(t) = \frac{1}{N}\sum_{i=1}^{N} X_j\,(t), \forall j = 1,2,\dots,Dim \quad (13)$$

where Dim implies the dimensional size of issue and N represents the population size.

During the second technique (X_2), if the prey area has been initiated in a great soar, the Aquila circle on the target, arranges the land, and next attack. This performance was mathematically processed as in Eq. (14).

$$X_2(t+1) = X_{best}(t) \times Levy(D) + X_R(t) + (y-x)^{*} rand, \quad (14)$$

where $X_2(t+1)$ signifies the solution of next iteration of r that has been created by the next searching technique (X_2). D implies the dimensional space, and $Levy(D)$ demonstrates the levy flight distribution function that was computed utilizing in Eq. (15). $X_R(t)$ represents the arbitrary solution obtained from the range of $[1N]$ at i^{th} iteration.

$$Levy(D) = s \times \frac{u \times \sigma}{|v|^{\frac{1}{\beta}}} \quad (15)$$

where s indicates the constant values set to 0.01, u and v denotes the arbitrary numbers amongst [0, 1]. σ signifies the computed utilizing in Eq. (16).

$$\sigma = \left(\frac{\Gamma(1+\beta) \times sine\left(\frac{\pi\beta}{2}\right)}{\Gamma\left(\frac{1+\beta}{2}\right) \times \beta \times 2\left(\frac{\beta-1}{2}\right)}\right) \quad (16)$$

In Eq. (14), y and x are utilized for presenting the spiral shape during the searching process that is computed below:

$$y = r \times cos(\theta) \quad (17)$$

$$x = r \times sin(\theta) \quad (18)$$

where,

$$r = r_1 + U \times D_1 \quad (19)$$

$$\theta = -\omega \times D_1 + \theta_1 \quad (20)$$

$$\theta 1 = \frac{3 \times \pi}{2} \quad (21)$$

r_1 gets the value amongst [1, 20] to set the amount of search cycles, and U refers the lesser value set to 0.00565. D_1 defines the integer number in 1 to the length of search spaces (Dim), and ω indicates the lesser value set to 0.005. During the third approach (X_3), if the prey area has been identified perfectly, and the Aquila has been prepared to land and attacks, the Aquila inclines vertically with initial attack for discovering the prey reaction. This technique is named minimum flight. At this point, the AO utilizes the chosen region of the target for getting nearby prey as well as attack. This performance has been mathematically processed in Eq. (22).

$$X_3(t+1) = \left(X_{best}(t) - X_M(t)\right) \times \alpha - rand + \left((UB - LB) \times rand + LB\right) \times \delta, \quad (22)$$

where $X_3(r+1)$ implies the solution of succeeding round of r that is created by 3rd searching manner (X_3). $X_{best}(t)$ signifies the estimated place of prey till i^{th} iteration (the optimum attained solution), and $X_M(t)$ represents the mean value of present solution at r^{th} iteration that has been computed utilizing in Eq. (12). $rand$ stands for the arbitrary value amongst [0, 1]. During the fourth technique (X_4), if the Aquila became nearby the prey, the Aquila attack the prey on the land based on its stochastic movement. This process was mathematically projected as in Eq. (23).

$$X_4(t+1) = QF \times X_{best}(t) - (G_1 \times X(t) \times rand) - G_2 \times Levy(D) + rand \times G_1, \quad (22)$$

where $X_4(t+1)$ implies the solution of next iteration of t that has been created by the fourth search technique (X_4). QF demonstrates the quality function utilized for equilibrium the search approaches that are computed.

IV. Performance Validation

The performance validation of the DLTCR-PHWC technique is tested using benchmark Telugu character dataset. The results are investigated under different folds and a comprehensive comparative analysis is also performed. Fig. 1 shows the sample segmented output of the image comprising handwritten and printed characters. The figure stated that the DLTCR-PHWC technique has offered effective identification of characters exist in the applied image shown in Fig. 3.

Table I and Fig. 4 offers the detailed recognition performance of the DLTCR-PHWC technique under ten folds. The results stated that the DLTCR-PHWC technique has gained effectual outcomes on all the applied folds. For example, with F_1, the DLTCR-PHWC approach has obtained a precision of 98.53%, recall of 98.37%, accuracy of 98.24%, F1-measure of 98.43%, and kappa of 97%. Also, with F_2, the DLTCR-PHWC approach has gained a precision of 99.14%, recall of 97.81%, accuracy of 99.30%, F1-measure of 99.24%, and kappa of 96.10%. Moreover, with F_4, the DLTCR-PHWC approach has attained a precision of 98.48%, recall of 98.68%, accuracy of 99.14%, F1-measure of 97.54%, and kappa of 97.29%. Furthermore, with F_6, the DLTCR-PHWC approach has achieved a precision of 99.05%, recall of 99.42%, accuracy of 98.91%, F1-measure of 98.70%, and kappa of 97.89%. Concurrently, with F_8, the DLTCR-PHWC approach has gained a precision of 99.31%, recall of 98.16%, accuracy of 99.57%, F1-measure of 97.97%, and kappa of 98.30%. Lastly, with F_1, the DLTCR-PHWC algorithm has provided a precision of 99.58%, recall of 99.82%, accuracy of 99.78%, F1-measure of 98.03%, and kappa of 99.34%.

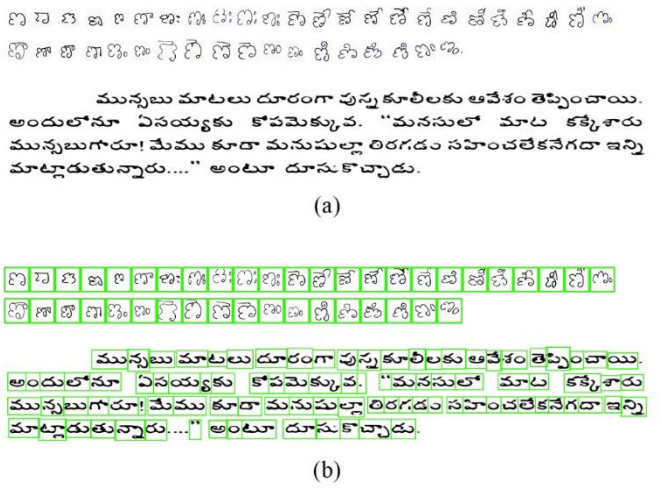

Fig. 3. Sample Segmentation Results (a) Original Handwritten & Printed Characters, (b) Segmented Handwritten & Printed Characters.

Finally, a detailed comparative results analysis of the DLTCR-PHWC technique takes place in Table II [22-26]. Fig. 5 provides a brief precision analysis of the DLTCR-PHWC technique with existing techniques. The figure reported that the MLP-HMM and DNN techniques have obtained worse outcomes with the least precision of 0.8467 and 0.9089 respectively. In addition, the CNN, KNN, MLP, and NN techniques have obtained moderately closer precision of 0.9567, 0.9415, 0.9572, and 0.9634 respectively. However, the DLTCR-PHWC technique has resulted in a higher precision of 0.9889.

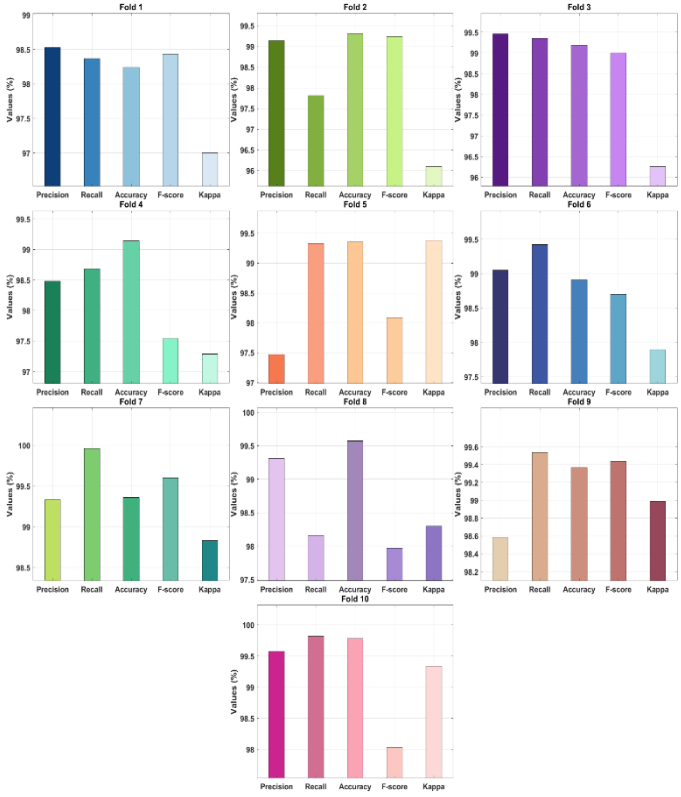

Fig. 4. Result Analysis of DLTCR-PHWC Model under Different Folds.

TABLE I. RESULT ANALYSIS OF PROPOSED MODEL IN TERMS OF DIFFERENT MEASURES

No. of Folds	Precision	Recall	Accuracy	F-score	Kappa
Fold 1	98.53	98.37	98.24	98.43	97.00
Fold 2	99.14	97.81	99.30	99.24	96.10
Fold 3	99.46	99.35	99.19	99.00	96.26
Fold 4	98.48	98.68	99.14	97.54	97.29
Fold 5	97.47	99.33	99.35	98.09	99.38
Fold 6	99.05	99.42	98.91	98.70	97.89
Fold 7	99.33	99.96	99.36	99.60	98.83
Fold 8	99.31	98.16	99.57	97.97	98.30
Fold 9	98.59	99.54	99.37	99.44	98.99
Fold 10	99.58	99.82	99.78	98.03	99.34
Average	98.89	99.04	99.22	98.60	97.94

TABLE II. RESULT ANALYSIS OF EXISTING WITH PROPOSED METHOD IN TERMS OF DIFFERENT MEASURES

Methods	Precision	Recall	F-score	Accuracy
DLTCR-PHWC	0.9889	0.9904	0.9860	0.9922
MLP-HMM	0.8467	0.8689	0.8512	0.8500
CNN	0.9567	0.9582	0.9572	0.9632
KNN	0.9415	0.9543	0.9512	0.9585
MLP	0.9572	0.9590	0.9578	0.9645
NN	0.9634	0.9685	0.9680	0.9750
DNN	0.9089	0.9144	0.9132	0.9210
CNN-RF	-	-	-	0.7140
CNN-MLP	-	-	-	0.7750
CNN-KNN	-	-	-	0.8160

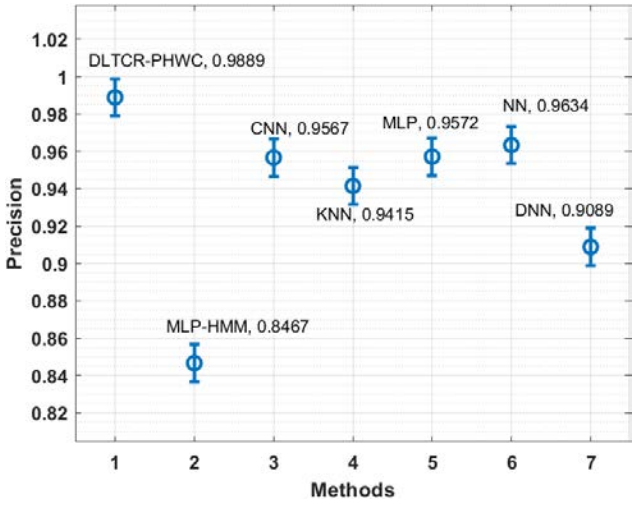

Fig. 5. Comparative Analysis of DLTCR-PHWC Model with respect to Precision.

Fig. 6 offers a detailed recall analysis of the DLTCR-PHWC algorithm with recent algorithms. The figure outperformed that the MLP-HMM and DNN manners have attained least outcome with the minimum recall of 0.8689 and 0.9144 correspondingly. Besides, the CNN, KNN, MLP, and NN approaches have gained moderately closer recall of 0.9582, 0.9543, 0.9590, and 0.9685 correspondingly. Finally, the DLTCR-PHWC methodology has resulted in an increased recall of 0.9904.

Fig. 7 showcases a brief F-score analysis of the DLTCR-PHWC manner with existing algorithms. The figure described that the MLP-HMM and DNN methods have reached minimum results with the reduced F-score of 0.8512 and 0.9132 correspondingly. Followed by, the CNN, KNN, MLP, and NN manners have achieved moderately closer F-score of 0.9572, 0.9512, 0.9578, and 0.9680 correspondingly. Eventually, the DLTCR-PHWC method has resulted in a superior F-score of 0.9860.

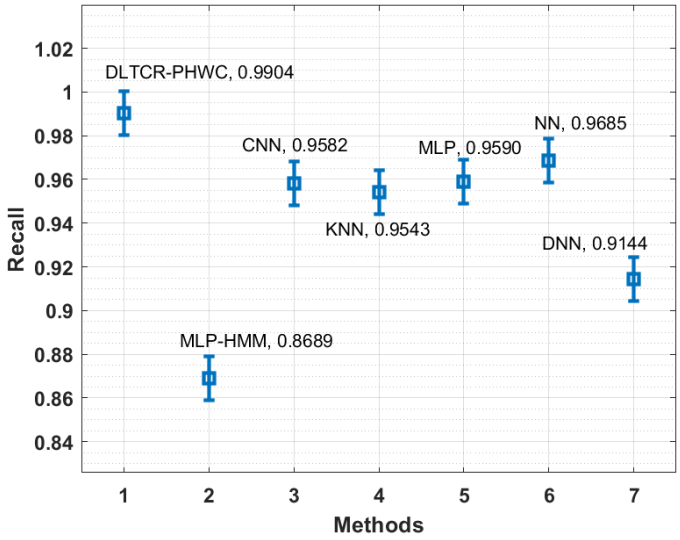

Fig. 6. Comparative Analysis of DLTCR-PHWC Model with respect to Recall.

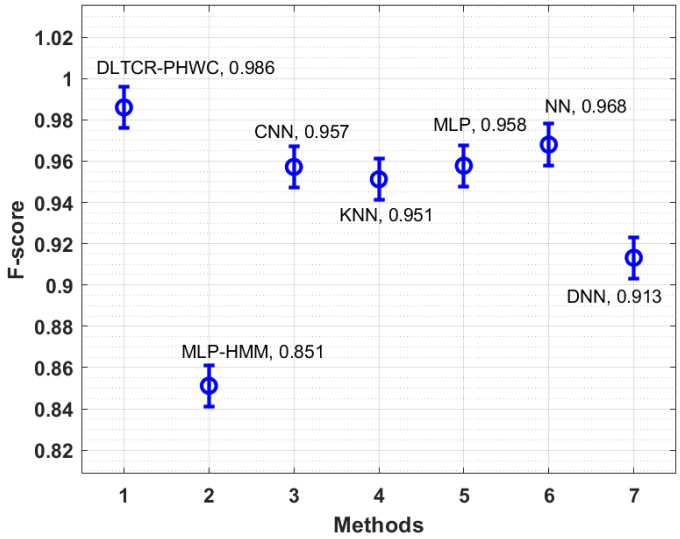

Fig. 7. Comparative Analysis of DLTCR-PHWC Model with respect to F-Score.

Fig. 8 demonstrates a brief accuracy analysis of the DLTCR-PHWC method with existing approaches. The figure stated that the CNN-RF, CNN-MLP, and CNN-KNN algorithms have gained worst outcome with the minimum accuracy of 0.7140, 0.7750, and 0.8160 respectively. At the same time, MLP-HMM and DNN techniques demonstrated a somewhat higher accuracy of 0.8500 and 0.9210 correspondingly. Along with that, the CNN, KNN, MLP, and NN techniques have obtained moderately closer accuracy of 0.9632, 0.9585, 0.9645, and 0.9750 respectively. At last, the DLTCR-PHWC methodology has resulted in a maximal accuracy of 0.9922.

After examining the above results and discussion, it is apparent that the DLTCR-PHWC technique has been found to be a proficient tool for effective TCR.

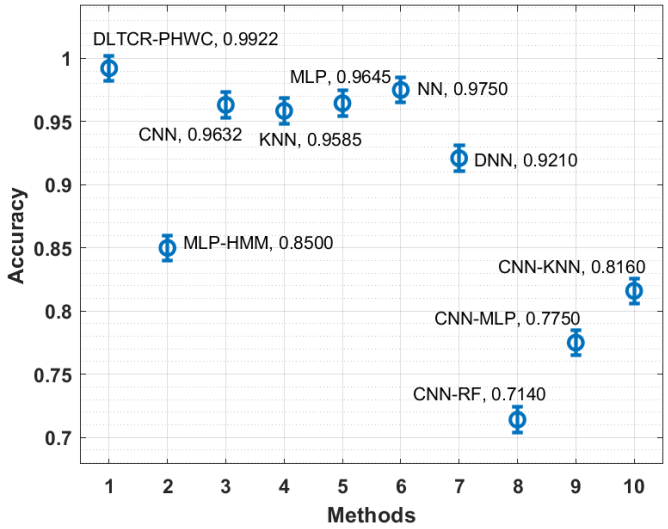

Fig. 8. Comparative Analysis of DLTCR-PHWC Model with respect to Accuracy.

V. Conclusion

In this study, a new DLTCR-PHWC technique is derived to detect and recognize the printed as well as handwritten characters that exist in the same image. The DLTCR-PHWC technique encompasses different operations such as AFF based preprocessing, line/paragraph segmentation, fusion based feature extraction, BiLSTM based recognition, and AO based hyperparameter optimization. The design of AO technique to fine tune the hyperparameters involved in the BiSLTM model helps to accomplish enhanced TCR outcomes. In order to showcase the supremacy of the DLTCR-PHWC technique, a wide range of simulations were performed against Telugu character dataset and the results have ensured the betterment of the DLTCR-PHWC technique. Therefore, the DLTCR-PHWC technique finds it useful to recognize both the handwritten and Telugu characters present in same image. In future, advanced DL models can be utilized for recognition process with hybrid metaheuristic-based parameter tuning process.

Industrial Revolution 5.0 and the Role of Cutting Edge Technologies

Mamoona Humayun
Department of Information Systems
College of Computer and Information Sciences, Jouf University
Al-Jouf, Saudi Arabia

***Abstract*—IR 4.0 emphasizes the interconnection of machines and systems to achieve optimal performance and productivity gains. IR 5.0 is said to take it a step further by fine-tuning the human-machine connection. IR 5.0 is more collaboration between the two: automated technology's ultra-fast accuracy combines with a human's intelligence and creativity. The driving force behind IR 5.0 is customer demand for customization and personalization, necessitating a greater human involvement in the production process. As IR 5.0 evolves, we may expect to see a slew of breakthroughs across various industries. However, just automating jobs or digitizing processes will not be enough; the finest and most successful businesses will be those that can combine the dual powers of technology and human ingenuity. IR 5.0 focuses on the use of modern cutting-edge technologies, namely, AI, IoT, big data, cloud computing, Blockchain, Digital twins, edge computing, collaborative robots, and 6G along with leveraging human creativity and intelligence. Wherever possible, IR 5.0 will change industrial processes worldwide by removing mundane, filthy, and repetitive activities from human workers. Intelligent robotics and systems will have unparalleled access to industrial supply networks and production floors. However, to understand and leverage the benefits of IR 5.0 better, there is a need to understand the role of modern CET in industrial revolution 5.0. To fill this gap, this article will examine IR 5.0 prospective, uses, supporting technologies, opportunities, and issues involved that need to be understood for leveraging the potentials of IR 5.0.**

Keywords*—*Industry 5.0; cutting-edge technologies; Internet of Things; Aartificial intelligence; big data

I. Introduction

From the industrial revolution to the digital transformation and beyond [1-3], the history of the IR traces the progress of the manufacturing industry. Each stage indicates a shift in the production process that has altered how we think about and operate in the business. When the major method of manufacturing shifted from people to machine power, the first IR began. The second IR, known as the Technological Revolution or IR 2.0, continued where the first left off, with improved electrical technology allowing for even more manufacturing and more complex machinery. The third IR, known as the digital revolution or IR 3.0, began with the invention of the first computers, which created the foundation for a society that is difficult to envision today without computer technology. We are currently in IR 4.0, which is defined by the amount of automation that has been accomplished. Machines can frequently govern themselves in many ways utilizing internet technology or the IoT. IR 4.0 also emphasizes the utilization of cloud technologies and the relevance of BGD. Although IR 4.0 has greatly improved the manufacturing industry by enabling security, scalability, control and visibility, customer happiness, and customization, the human drive for creativity still exists, and researchers are already predicting the next revolution that is IR 5.0 [4-6]. In short, if the current revolution focuses on converting factories into IoT-enabled smart facilities, IR 5.0 is expected to place a greater emphasis on the return of human skills and intelligence to the industrial framework. Fig. 1 illustrates all the IRs so far diagrammatically.

According to [7-9]; in IR 5.0, man and machine work together to optimize manufacturing process performance. Surprisingly, the fifth IR may already be underway among firms that are only starting to use IR 4.0 concepts. The reason for this is that when businesses adopt contemporary technology, they do not suddenly eliminate huge segments of their employees and shift to a fully automated operation. Thus, by delegating repetitive and boring activities to robots/machines and critical thinking tasks to people, IR 5.0 improves manufacturing quality. IR 5.0 supports more skilled occupations than IR 4.0 because experts handle the machines. Further, it focuses on improving consumer happiness by forming a collaborative relationship between humans and robots. Another advantage of IR 5.0 as mentioned by [10, 11] is that it provides greener solutions than traditional industrial transformations, which do not prioritize environmental protection.

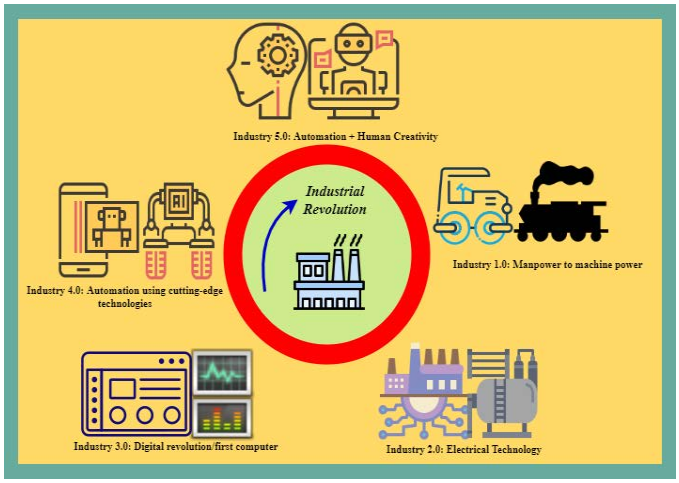

Fig. 1. Industrial Revolution.

Several current studies examine the enabling technologies (ETs), applications, and problems of prior industrial standards and supporting industrial technologies such as articles [10-15]. The authors of [14], for example, investigate the ETs of the IR 4.0 standard as well as the rationale for their inclusion in the standard. Simultaneously, [15] examines the ETs in the Web of Science database for IR 4.0, as well as the contributions of several forerunners in the development of this database. The authors of [16] have published a comprehensive review of the ETs and uses of virtual reality in IoT systems.

Industries can play an important role in addressing societal challenges such as resource preservation, climate change, and social stability. Businesses, employees, and society all benefit from IR 5.0. In addition to giving workers more control, it meets the ever-changing needs of employees in terms of skills and training. Competitiveness is boosted, and top talent can be attracted more easily. It is beneficial to our world since it encourages circular production models and supports technologies that increase the efficiency of natural resource utilization. Even though IR 5.0 is becoming more popular, we are unaware of any study that analyzes the role of modern CET in the revolution of IR 5.0. As a result of this observation, we intend to present the role of modern CET in the IR in the context of IR 5.0. In a nutshell, our work's contributions may be stated as follows:

1) Define IR 5.0 to have a comprehensive knowledge of the concept from several angles.
2) Comparing and contrasting IR 5.0 to earlier IR.
3) Discuss the most promising IR 5.0 applications
4) Discuss the role of modern CET in IR 5.0
5) Issues and challenges involved in IR 5.0

TABLE I. LIST OF ABBREVIATIONS USED

Abbreviations	**Used for**
CET	Cutting Edge Technologies
IoT	Internet of Things
AI	Artificial intelligence
BGD	Big Data
DT	Digital Twins
IR	Industrial Revolution
SCM	Supply Chain Management
BCT	Blockchain Technology
CPPS	Cyber Physical Production Systems
CAGR	Compound Annual Growth Rate
ITU	International Telecommunication Union
ZB	Zettabytes
CC	Cloud Computing
COBOTS	Collaboration Robots
ETs	Enabling Technologies
EC	Edge Computing
SME	Small and Medium size Organizations

The remaining paper is structured as: Section 2 will define IR 5.0 from various perspectives. Section 3 will summarize existing knowledge to compare and contrast IR 5.0 to the earlier IR. Section 4 will discuss the key applications of IR 5.0. Section 5 will highlight the role of modern CET in the fifth IR. Section 6 will discuss the associated issues and challenges. Section 7 will discuss the findings of the study. Finally, Section 7 will wrap up the paper by providing the conclusion of the paper and insights into future work.

Table I shows the list of abbreviations used in this research for better understanding.

II. LITERATURE REVIEW

This section will provide a general overview of IR 5.0 to provide a better understanding of the phenomenon. Further, it will also discuss the key pillars of IR 5.0.

A. IR 5.0 and State-of-the-Art

Since IR 5.0 is still evolving, several researchers and practitioners have presented varied definitions. Here are some of the definitions that are considered.

Definition1: By integrating work processes and intelligent systems, IR 5.0 brings the human workforce back to the factory, where humans and machines are partnered to boost process efficiency by harnessing human intelligence and creativity [4].

Definition2: IR 5.0 blends the inherent strengths of human intelligence and CPPS to build synergetic factories. In addition, authorities are searching for creative, ethical, and human-centered design to overcome the personnel shortages caused by IR 4.0 [17].

Definition3: IR 5.0 is a paradigm for the next phase of industrialization, which incorporates the return of labor to factories, distributed production, intelligent SCM, and hyper customization, all of which work together to create a tailored customer experience over time [18].

B. Pillars of IR 5.0

IR 5.0 focuses on stakeholder value rather than shareholder value, reinforcing the industry's role and contribution to society. Below are the key pillars of IR 5.0 (as shown in Fig. 2).

1) Human-centric: Human ingenuity and craftsmanship are combined with the speed, efficiency, and consistency of robots in IR 5.0. Thus it promotes human empowerment, talent, and diversity [4].

2) Sustainability: Additive manufacturing, often known as 3D printing, is one of the most notable elements of IR 5.0, and it is used to make manufacturing items more sustainable. In IR 5.0, additive manufacturing aimed to improve customer happiness by incorporating benefits into goods and services [19].

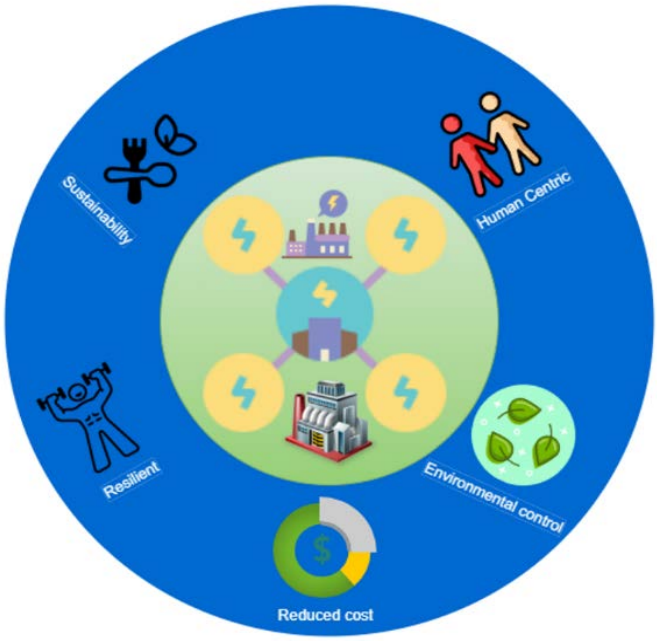

Fig. 2. Pillars of IR 5.0.

3) Resilient: The term "resilience" refers to the necessity to improve industrial production's robustness, equipping it better against interruptions and ensuring that it can offer and sustain key infrastructure during the crisis. High resilience can be attained when humans and robots operate together [20, 21].

4) Reduced cost and environmental control: Climate, humidity, temperature, and energy usage are all monitored in real-time and predicted using smart, networked sensors and specialized algorithms. This is especially beneficial in farms that are highly dependent on the weather. Knowing what to expect and where to act might help to avoid costly mistakes and boost the output [22].

C. Opportunities of IR 5.0

The prospects presented by IR 5.0 are as follows, these opportunities are discussed in the articles [8,23-26].

1) Better employment: Through the implementation of next-generation technologies, greater automation will have a favorable influence on employment in several areas.

2) Customization: Customers have more customization options with highly automated production methods.

3) Improved human efficiency: IR 5.0 opens up more options for creative individuals to come and work, allowing for improved human efficiency.

4) Employee safety: Employee safety on the work floor has improved since COBOTs can do hazardous tasks.

5) Customer satisfaction: More personalized products and services boost consumer happiness, loyalty, and attract new customers, resulting in higher profits and market share for businesses.

6) Better opportunities: It gives start-ups and entrepreneurs in creative and inventive fields, enormous opportunities to develop new goods and services related to IR 5.0, as long as enough money and infrastructure are available.

7) Human-machine interaction: IR 5.0 places a greater emphasis on human-machine interaction and gives a bigger platform for research and development in this industry.

8) Quality Service: With the support of IR 5.0, quality services may be offered in faraway regions, particularly in the healthcare business, such as surgical procedures performed by robots in rural areas.

9) Frequent follow-up: IR 5.0 will assist the customer digitally in handling frequent follow-up assignments by making machines adaptable according to employee demands.

10) Higher-value job: Because individuals are given the freedom to be responsible for building again, IR 5.0 provides higher-value jobs than before.

11) Better planning: In IR 5.0, the production cell operator is more involved in the planning approach than the more or less automated manufacturing method.

12) Creative freedom: It enables more custom-made and personalized items, as well as creative freedom.

13) Automation: With IR 5.0, it is easier to automate production processes.

In comparison to IR 4.0, the preceding discussion demonstrates that IR 5.0 is the next industrial revolution, in which human specialists and efficient, intelligent, and precise machines will work together to develop efficient and user-friendly manufacturing solutions. It will enhance the sector by bringing in human talents and competencies, as well as opening up new opportunities. We will further explore the strengths of IR 5.0 and the role of modern CET in IR 5.0 in the upcoming sections.

III. Comparison of IR 4.0 and 5.0

To better understand and visualize the benefits of IR 5.0, it's important to comprehend and see the differences between IR 4.0 and 5.0. This section will compare both of these IRs.

Today, we live in IR 4.0, which is rapidly evolving towards IR 5.0. The fourth IR, often known as IR 4.0, was constructed on top of the third to allow improved technology. Everything became "Smarter" during this period. IoT, CC, CPPS, and cognitive computing were among the most essential technologies discussed. IR 4.0 connects systems, components, and humans over a network as discussed in [27-30], making the production process more efficient and automated. Humans collaborating with these technologies to improve efficiency is the goal of the fifth Revolution, often known as IR 5.0. For optimal advantages, it is vital to strategize techniques of human-robot integration since it will seek to match the rising demand for individuals with unique customization and modifications. Improved human engagement with intelligent machines will lead to increased efficiency. Not to mention that, as a result of this shift, more high-paying positions will be created. Table II summarizes the comparison between IR 4.0 and 5.0 so that organizations could leverage the benefits of IR 5.0.

TABLE II. COMPARISON BETWEEN IR 4.0 AND 5.0

Industry 4.0	**Industry 5.0**
The goal is to automate processes.	The goal is to strike a balance between machine and human engagement.
The most crucial factor was technology	The most crucial collaboration is between people and robots.
The entire environment is virtual.	The shift back to the real world.
As new smart technologies were adopted, the number of personnel was reduced.	An increase in the number of people who come into contact with machines.
Machines that are smarter and more linked to the workplace.	Cognitive computers and human intelligence are being combined.
There is no way to personalize or customize the product.	Personalization and customization are available, allowing each product to be improved and tailored to the needs of the person.
It's still tossing back and forth between renewable and nonrenewable energy sources.	It is more environmentally friendly since renewable energy sources will be used more often.

IV. IR 5.0 APPLICATIONS

IR 5.0 is already in use in various areas, including healthcare, manufacturing, CPPS, SCM, education, disaster management, and so on, as mentioned in studies [23, 26, 31]. In addition to merging many CET with machines, such as AI, edge computing (EC), IoT, DT, COBOTS, 6G and beyond, BGD analytics, and so on, the intellect of people is also utilized when making judgments in IR 5.0. As a result, the personal human touch is added to the IR 4.0 pillars of efficiency and automation. Below we provide some core applications of IR 5.0.

A. IR 5.0 in Healthcare

IR 5.0 has the potential to revolutionize the healthcare industry [33], allowing for the production of individualized gadgets, implants, and other medical products. Routine occupations, such as routine checkups conducted by doctors, can be handled by COBOTS under IR 5.0. Similarly, human-robot collaboration can enhance the diagnosis and treatment process. Intelligent wearable gadgets, such as smartwatches and intelligent sensors, can, for example, continuously capture a patient's healthcare data in real-time and store it in the cloud [32]. The patients' medical condition may then be diagnosed using machine learning methods. These intelligent gadgets can interact with one another, and if a doctor's attention is necessary, these devices can feed the present state of the patient to the physicians and notify them to treat the patient. Doctors can use COBOTS to get assistance from robots that can interact with one another to perform surgery on patients.

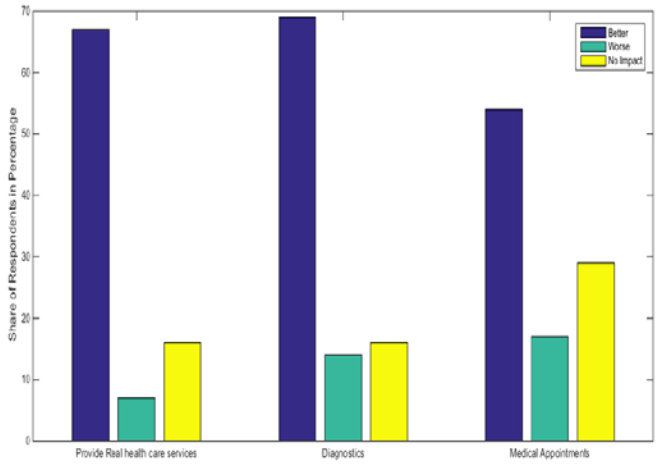

Fig. 3. Canadians' Predictions on the Influence of AI in Healthcare over the Next Ten Years, as of 2019[34].

In a poll conducted in Canada to assess the role of AI and robots in healthcare, approximately 70% of respondents said that AI programs or robots delivering genuine health care services, such as robot-aided surgery, early diagnosis, and so on, will make life better. As of August 2019, the data in Fig. 3 depicts Canadians' projections for AI-related health developments in the next ten years and their influence on life. Statista was used to compile the data for this research.

B. IR 5.0 in Manufacturing/Production

According to the co-founder of universal robots chief technology [35], IR 5.0 will transform the factory into a place where creative individuals can come and work, resulting in a more customized and human experience for both workers and consumers. The fifth IR will see substantially more complicated collaborative interactions between intellectuals, machinery, processes, and overall system for optimal performance optimization.

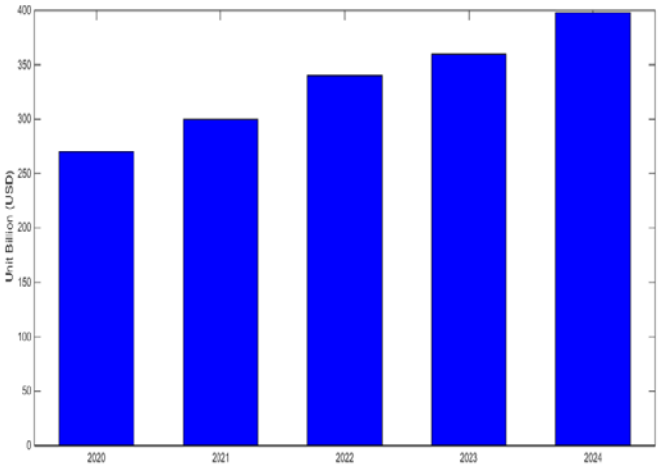

Fig. 4. Revenue of Global Manufacturing Industry.

According to the TrendForce investigation [36], as shown in Fig. 4, the manufacturing industry's income is predicted to improve in the near future owing to human and robot collaboration. This shows that the fifth IR might lead to paradigm shifts and profound changes in how we think about industry and production.

C. IR 5.0 and Supply Chain Management

IR 5.0 is expected to optimize the SCM by combining smart, linked digital environments with the human intelligence required to maximize their value. According to KBV research statistics [37], as shown in Fig. 5, the global SCM software market is estimated to reach $22.7 billion by 2024, growing at a 12.1 percent CAGR. SCM Software is a real-time analytical tool for managing the movement of products and other types of data throughout the SCM network. The software improves an organization's supply chain operations.

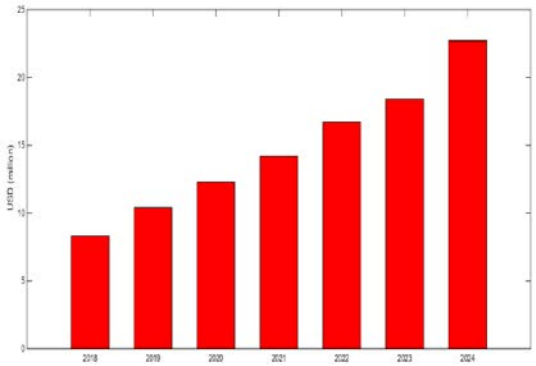

Fig. 5. Global SCM Software Market.

IR 5.0 will improve SCM in the following way [38]

- Increasing supply chain customization improves not just customer happiness but also efficiency and profits.
- Using more up-to-date data, reducing supply chain risks and waste.
- allowing supply chain and logistics units to spend more time on strategic innovation rather than putting out fires or dealing with fundamental execution issues.
- Improving supply chain integration to form more strategic alliances.
- Increasing the value of an organization's human capital by assisting in retaining and transferring knowledge about the features of a certain supply chain.

D. IR 5.0 and Education

IR 5.0 will also transform education [39, 40], the current education is fueled by information, and if it can be trained and equipped with digitally smart machines, or COBOTS, that are further supplemented with the human touch, it will take society along the path of personalized education. As a result, COBOTS will help to develop a human-centric society, which will be strengthened by human wisdom, enabling education 5.0, tailored education for everybody. Humans will be aided by many functioning COBOTS to assist them with day-to-day tasks and support their personal and professional development.

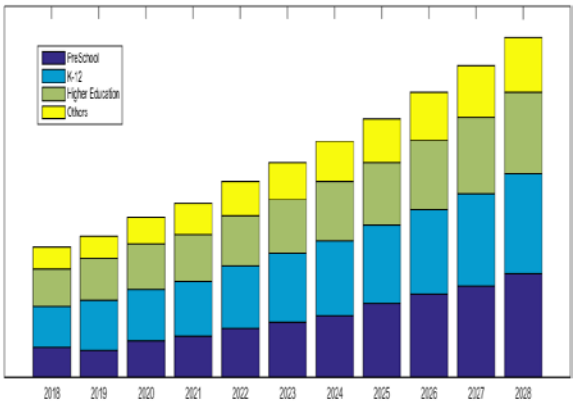

Fig. 6. Education Technology Market (Asia Pacific).

The worldwide education technology industry is expected to be worth USD 89.49 billion in 2020 [41], with a CAGR of 19.9% predicted between 2021 and 2028 as shown in Fig. 6. This shows that a blend of digital technology and human intelligence has the potential to expand educational opportunities.

V. Role of CET in the Revolution of IR 5.0

Edge computing, IoT, DT, Blockchain, BGD analytics, COBOTS, and 6G are just a few of the CET that, when combined with cognitive abilities and creativity, may help enterprises enhance output and offer customized goods more rapidly. IR 5.0 is an improved manufacturing model that focuses on the collaboration between humans and robots, and this collaboration makes human talents more productive and easier to automate for individuals and enterprises than they have ever been. According to the statistics provided by Statista in [42], as of 2020, new CET are projected to have the largest influence on businesses all around the world as shown in Fig. 7. The data of Fig. 7 shows that IoT is widely considered as one of the most crucial areas of current and future technology, the second CET that highly impacted organizations worldwide is AI robots, nearly used in every field to increase efficiency and complement our human skills [22]. Fig. 7 depicts the other CET that have had a significant influence on the global organization. Now we'll talk about how contemporary CET will play a part in the fifth IR.

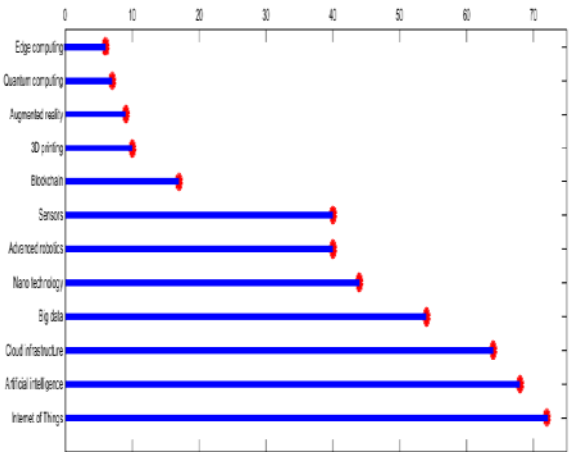

Fig. 7. CET Impact on Organizations Globally as of 2020.

A. IoT and IR 5.0

Humans define the strategy, give supervision, and contribute creative input in IR 5.0, while technology does the dull, repetitive, and error-prone activities. Businesses will benefit from this new division of labor not only in terms of cost savings but also in terms of tapping into new value streams provided by the human touch. The IoT is defined by two characteristics: automation and connection [43]. Given these characteristics, the IoT will need to leverage a variety of technologies to guarantee that data is sent, analyzed, and responded automatically across different devices. The IoT has changed the modern world and is a primary driver of the fifth IR [44]. The following are some of the most important advantages of IoT in terms of industrial advancement [45].

- Increased employee productivity and decreased human labor
- Effective management of operations
- Optimum utilization of resources and assets
- Cost-effective operation
- Workplace safety has improved.
- Marketing and business growth that is thorough
- Customer retention and service have improved.
- Better business prospects
- The company's image will be more trustworthy.

Because of IoT's widespread use and benefits, the number of IoT-connected devices is fast growing and is projected to continue to grow in the near future, as shown in Fig. 8. The data of Fig. 8 is taken from [46].

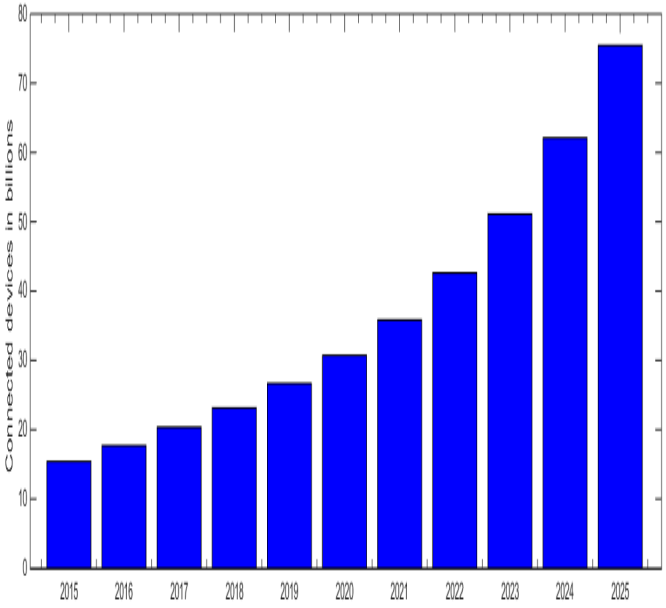

Fig. 8. Expected IoT Connected Devices Worldwide.

B. Cloud Computing and IR 5.0

CC is a concept that allows for the instantaneous leasing of computer resources with little or no communication with the provider. Cloud simplifies operations in this sense since it eliminates the need for rigorous resource dimensioning and planning, allowing for flexible usage without the user's previous commitment [47, 48]. Cloud users benefit from almost all the resources they need, and they may either utilize or supply everything as a service.

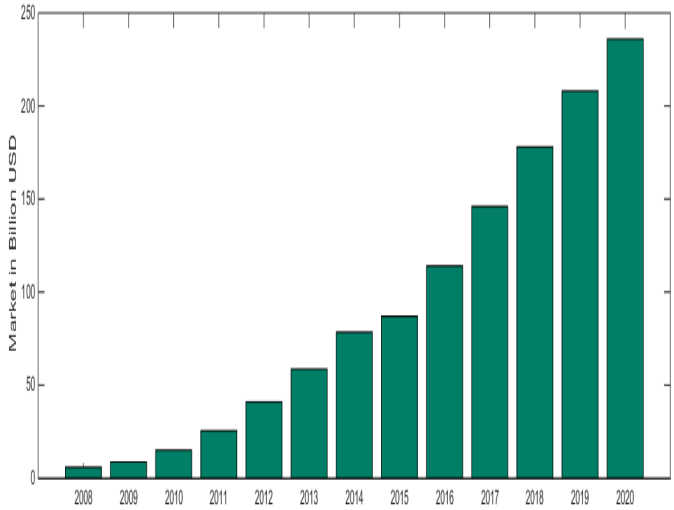

Fig. 9. Global Public Cloud Market Size Worldwide.

Cloud, in particular, is required to reap the benefits of IR 5.0 since it provides user mobility, distributed data analytics, resources' heterogeneity, and meets the needs of diverse applications with low latency. It also makes managing and developing computation, storage, and networking services easier between data centers and end devices. It's also a strong tool for processing BGD generated through IoT sensors, allowing IR 5.0 to realize its full potential [20, 47, 49]. Due to these potential benefits, the cloud market has grown at a tremendous pace as shown in Fig. 9. The statistics of Fig. 9 are taken from [50].

C. BGD and IR 5.0

In the realm of IR 5.0, BGD Analytics is expected to play a significant role. Some firms in IR 5.0 can utilize BGD Analytics to better understand customer behavior to optimize product pricing, improve manufacturing efficiency, and lower overhead expenses [51]. IR 5.0 apps can leverage BGD Analytics to make real-time choices to improve their competitive edge, with an emphasis on offering suggestions on predictive findings for significant events and customization [52]. Manufacturers can create and handle large amounts of data with the support of real-time analytical data. Another important problem in IR 5.0 is continuous process improvement, which frequently necessitates the collection of extensive data on the whole production cycle. To enhance predictability and explore new possibilities, BGD analytics approaches are utilized to identify and eliminate non-essentials. According to [53], the revenue from the BGD industry is growing and is likely to continue to grow in the future as shown in Fig. 10.

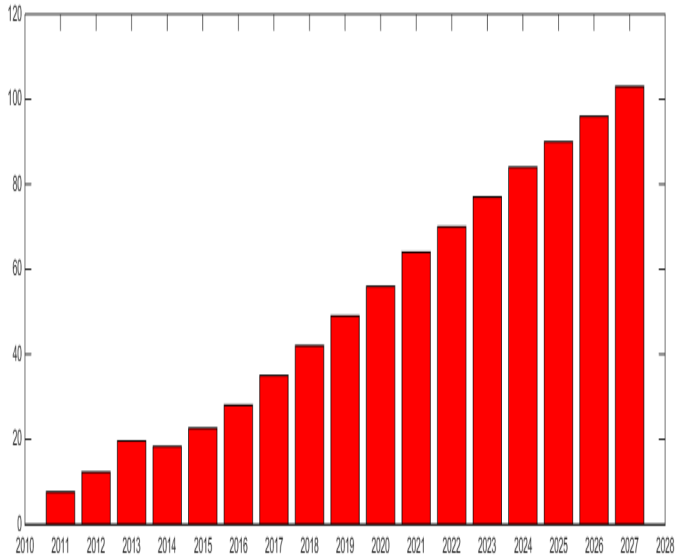

Fig. 10. Revenue Prediction for the Global BGD Market from 2011 to 2027.

D. Digital Twins and IR 5.0

DT can provide significant value to the creation of customized items on the market, improve business operations, fewer faults, and fast increase creative business models to make profits in IR 5.0. The DT may help IR 5.0 address technical challenges by finding them earlier, identifying configurable components, generating more accurate projections, forecasting future failures, and preventing enormous financial losses [54]. This form of smart architectural design enables businesses to get economic benefits more rapidly and sequentially than ever before. DT can be used for the access of real-time data and creating simulation models in IR 5.0, allowing organizations to edit and update physical things remotely. DT is also used in IR 5.0 for customization that allows clients to build virtual environments to realize the findings [55].

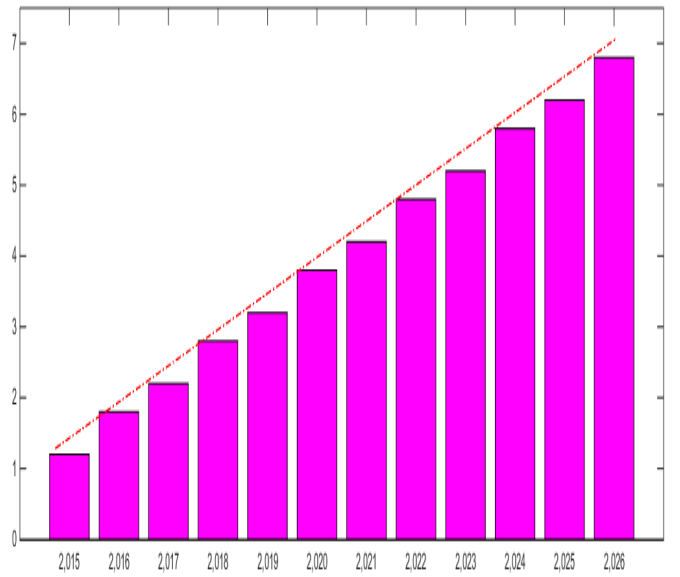

Fig. 11. DT Market 2015-2026.

As illustrated in Fig. 11 based on the statistics collected from [56], the global DT market is expected to reach USD 36.6 billion by 2025, rising at a CAGR of 38.5 percent from 2020 to 2026. Increased acceptance of new technologies such as IoT and cloud, increased demand for connected devices in the automotive and transportation industries, and expanding predictive maintenance usage are all driving market expansion.

E. COBOTS and IR 5.0

Robots are far superior to humans in the creation of high-volume items and are far more compatible. Robots are inefficient in critical thinking when compared to humans. When robots need to be guided, customizing or personalizing things may be a huge difficulty. As a result, managing human connections within manufacturing processes is critical. COBOTS have a lot of potential in IR 5.0. Robots can achieve their intended aim by collaborating with humans, allowing for the rapid and accurate delivery of mass customized and personalized items to clients [57]. Throughout IR 5.0, personalizing COBOTS may take various forms, including medical treatments. COBOTS aid with the improvement of safety and performance in IR 5.0 applications, while also providing more engaging tasks for human workers and enhancing product development. In highly competitive marketplaces, industries must recognize that COBOTS have the potential to increase corporate performance and minimize rising labor expenses [58]. According to the interact analysis report, material handling, assembly, and pick-and-place are expected to be the three most common uses of collaborative robots in the future [59]. In 2024, these three tasks will account for 62.7 percent of collaborative robot revenues, up from 71.9 percent in 2019 as depicted in Fig. 12. Pick and place is expected to remain the third most popular use for collaborative robots by 2024, according to Interact Analysis, but note the bar on the far right of each graph that denotes "other applications." Innovative COBOTS technologies are positioned to enter a variety of new products and non-manufacturing contexts settings for which industrial robots are unsuitable.

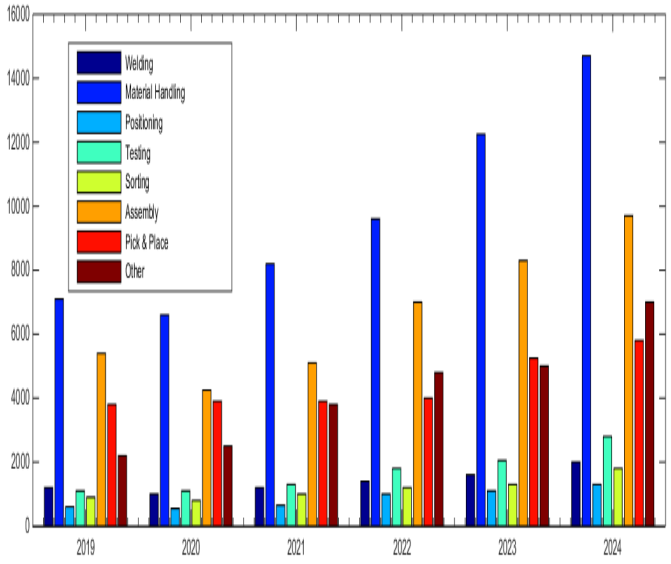

Fig. 12. Prediction of COBOTS Shipment by Application.

F. 6G & Beyond and IR 5.0

Due to the rapid rise of smart infrastructure and prospective applications, it will be impossible to quickly expand bandwidth requirements with present networks. The usage of 6G and beyond in the IR 5.0 revolution allows for lower latency, high-quality services, and vast IoT infrastructure, as well as integrated AI capabilities. 6G networks aid in the efficient and successful execution of IR 5.0 applications by enabling smart spectrum management and smart mobility. 6G networks are intended to satisfy the needs of future society by interconnecting the overall society [60]. IR 5.0 apps have a major challenge in terms of energy management due to a large number of connected smart devices and the significant quantity of energy they use. The employment of advanced energy efficiency algorithms and energy harvesting technology will make 6G networks more energy-efficient [61]. According to the ITU, the exponential growth trend will continue, and global mobile data traffic will reach a staggering 5ZB per month by 2030 [60], as seen in Fig. 13.

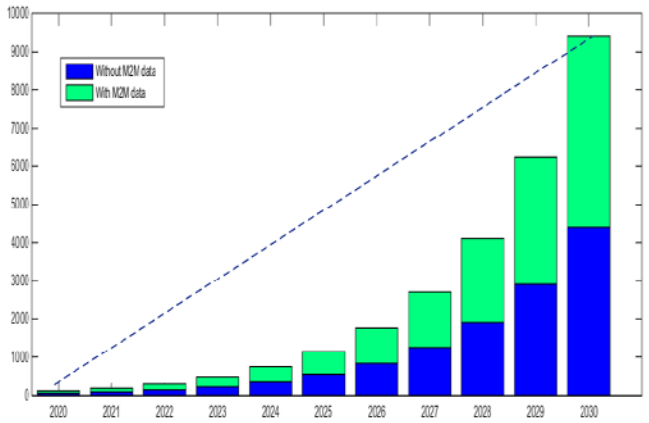

Fig. 13. Global Mobile Data Traffic Forecasting by ITU.

G. Blockchain Technology (BCT) and IR 5.0

BCT has the potential to provide significant value to IR 5.0 in the future. In IR 5.0, centralized administration of a high number of heterogeneous linked devices is a major difficulty. By enabling distributed trust, BCT may be utilized to construct decentralized and distributed management solutions. For effective subscriber management in IR 5.0, BCT may be utilized to generate digital identities for various persons and businesses. It's required for access management and authentication of stakeholders in any industrial activity that takes place via the internet [62].

Additionally, these digital identities may be used to manage properties, belongings, items, and services. BCT may also be used to catalog and save original work and register IP rights. By automating the agreement procedures between diverse parties, BCT can also assist to automate the contractual process [63]. According to [60], by 2028, the worldwide BCT industry is anticipated to be worth USD 394.60 billion. At the same time, financial institutions' increased interest in BCT is propelling industry expansion. According to [64], the market size of Blockchain is increasing with time as shown in Fig. 14, it shows that BCT is a widely used technology of the current time.

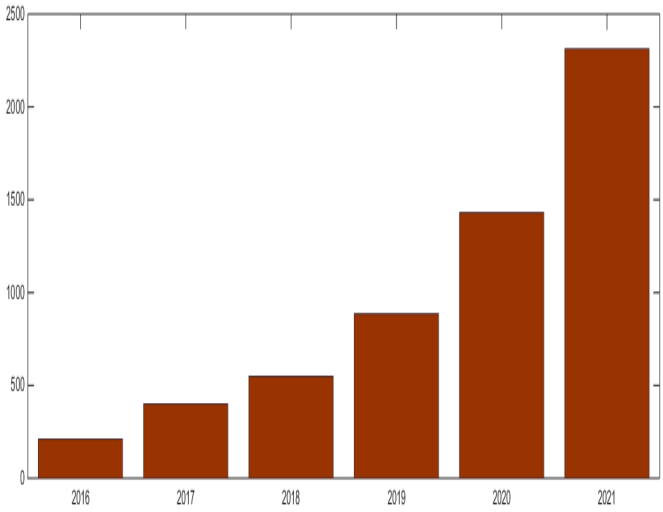

Fig. 14. Blockchain Market Size Worldwide.

H. Other Enabling Technologies

In addition to the above-discussed technologies, other CET such as EC, network slicing, augmented reality, and 3D printing also plays a vital role in IR 5.0. EC reduces communication costs and ensures that programs run smoothly even at faraway locations. Additionally, EC can process data without sending it to the public cloud, reducing security concerns for IR 5.0's major events [65]. Because IR 5.0 supports a broad collection of applications, a single physical infrastructure will be unable to meet the needs of heterogeneous networks. In this situation, network slicing can provide several virtualized networks at a low cost [66]. The way information is accessed, used, and transferred is changing because of augmented reality. In truth, augmented reality is data that broadens people's perceptions. This technology enhances our sensory perception by allowing us to engage with data. Because augmented reality can actively contribute to the success and transformation of industrial production processes, it will be useful as IR 5.0 focuses on human-machine collaboration [67]. The usage of 3D technology is increasing in a variety of industries, from food printing to the construction of Mars settlements. Innovations in the healthcare, automotive, construction, and manufacturing sectors are among the more practical applications for 3D printing. The 3D printer is being dubbed the forerunner of the 5th IR by scholars and practitioners for these reasons [68].

VI. Challenges of IR 5.0

Despite the benefits offered by IR 5.0, it also faces several challenges. Some of the most significant challenges of IR 5.0, as taken from available research [23-26, 69], are as follows:

1) Initial cost: IR 5.0 necessitates a significant amount of expenditure to completely execute all of its pillars, which is challenging for the industry, particularly SMEs, to accomplish.

2) Lack of precision and accuracy: For example, IR 5.0 has a lot of potential in the healthcare business, but it requires a lot of precision and accuracy. The research in this area is still in its infancy, and it necessitates a significant amount of investment and infrastructure.

3) Technology requirements: This presents a challenge for startups and entrepreneurs, as IR 5.0 necessitates a significant amount of investment and infrastructure, as well as CET requirements.

4) Skill-gap: This tendency exacerbates job polarization, as middle-skill employment declines and the workforce is divided into two groups: highly trained and qualified personnel and low-paid and unqualified workers. This may help to bridge the gap between the skilled and unskilled in society.

5) Need training: Due to highly automated manufacturing systems, skill development is a massive task that includes training employees to adopt advanced CET as well as inducing behavioral changes to interact with them.

6) Risk: Collaborative robotics is a type of technology that, along with human coworkers, poses a significant risk on the factory floor.

7) Data integration: It is difficult to obtain high quality and integrity data from industrial systems, and it is also challenging to accommodate several data sources.

8) Regulatory system: Due to the high level of automation in IR 5.0, it is difficult to develop regulatory systems. For example, who should be held accountable and to what extent in the event of a failure.

9) Process tailoring: The old company strategy and business models must be adjusted and tailored to match the requirements of IR 5.0 due to a greater degree of automation in the industries.

10)Mass personalization: As a result of mass personalization, company strategy will become more customer-centric. Customer subjectivity shifts throughout time, making it tough to adapt corporate strategies and models regularly.

VII. Discussion

Humans have recognized the possibility of using technology as a tool of advancement since the first IR. Steam machines, assembly lines, and computers are just a few of the technological developments that have occurred over the previous several centuries, all with the goal of producing more powerful technology and enhancing productivity and effectiveness. IR 5.0 shifts the paradigm and ushers in a revolution by putting less emphasis on technology and assuming that the ultimate potential for advancement resides in human-machine cooperation. IR 5.0 is not a passing trend, but rather it's a manufacturing paradigm change with ramifications for productivity, economics, and commerce. Due to the competitive benefits that the IR 5.0 model offers, organizations that do not adapt their production to this model will quickly become outdated.

IR 5.0 acknowledges that industry can fulfill social objectives beyond employment and development, such as becoming a dependable source of wealth, by making sure that production takes into account the limitations of our planet and places a premium on the well-being of industry employees. Keeping in view the benefits of IR 5.0, this study provides a full description of IR 5.0, as well as the functions of CET, so that scholars and practitioners may appreciate the significance of this revolution and recommend ways for maximizing its benefits.

VIII. Conclusion

IR 5.0 expands on the established IR 4.0 paradigm by placing a premium on research and innovation as critical drivers of the transition to a better industry. It refocuses attention on stakeholder value, which helps everyone. It places a premium on worker well-being throughout the manufacturing process and leverages new technologies to create wealth beyond employment and development, all while keeping conscious of the planet's production restrictions. In the upcoming days, the industries which will not follow IR 5.0 will obsolete from the market. Keeping in view the importance of IR 5.0, this conceptual paper provides a detailed overview of IR 5.0. The key topics covered in this research article include: providing a comprehensive knowledge of the IR 5.0 concept from several angles, promising applications of IR 5.0, the role of modern CET in the fifth IR, and opportunities and challenges faced by IR 5.0. This paper will help researchers and industry practitioners to better understand the role of IR 5.0 in the upcoming era.

CET's involvement in real-time IR 5.0 settings will be further examined in the future. Additionally, we'll combine human expertise with CET to study the real-world effects of IR 5.0.

Detecting Distributed Denial of Service Attacks using Machine Learning Models

Ebtihal Sameer Alghoson, Onytra Abbass
Department of Information Technology
University of Tabuk, KSA

***Abstract*—The Software Defined Networking (SDN) is a vital technology which includes decoupling the control and data planes in the network. The advantages of the separation of the control and data planes including: a dynamic, manageable, flexible, and powerful platform. In addition, a centralized network platform offers situations that challenge security, for instance the Distributed Denial of Service (DDoS) attack on the centralized controller. DDoS attack is a well-known malicious attack attempts to disrupt the normal traffic of targeted server, network, or service, by overwhelming the target's infrastructure with a flood of Internet traffic. This paper involves investigating several machine learning models and employ them with the DDoS detection system. This paper investigates the issue of enhancing the DDoS attacks detection accuracy using a well-known DDoS named as CICDDoS2019 dataset. In addition, the DDoS dataset has been preprocessed using two main approaches to obtain the most relevant features. Four different machine learning models have been selected to work with the DDoS dataset. According to the results obtained from real experiments, the Random Forest machine learning model offered the best detection accuracy with (99.9974%), with an enhancement over the recent developed DDoS detection systems.**

Keywords*—Cybersecurity; distributed denial of service (DDoS); machine learning (ML); Canadian institute cybersecurity - distributed denial of service (CICDDoS2019) dataset

I. Introduction

SDN stands for Software Defined Network Technology, a new technology in the network world, in which the network management and control function is separated from the data routing function, through which engineers attempt to rearrange the parts and roles of all network infrastructure components that have not been modified since the 1980s. It is the transition from NCP to TCP / IP and since then no change has occurred. A change in the level of the network infrastructure to keep pace with the great development that takes place in the field of information technology, especially in virtual computing, which made virtualization of all layers, and the infrastructure is still intractable to this technology, so SDN technology is a successful attempt to separate the data layer from the control layer [1].

Denial of Service (DOS) It is one of the types of electronic attacks, and it is a very powerful technology that has been launched to attack network devices and services, and this type can separate different services from the Internet. Distributed Denial of Service (DDOS) is a more powerful type of DOS and uses multiple distributed attack points [2].

DoS was originally appeared by Gligor in an operating system context [3, 4], where DoS became widely employed. In general, DoS attack tries to reach more than one computer to reach a victim in a coordinated manner is called a DDoS attack.

Software Defined Network (SDN) infrastructure is vulnerable to several security threats. Among the DDoS attacks are the most dominant one. The DDoS attacks are considered as one of the most destructive attacks in the Internet. In general, most website hacking are probably a DDoS attack. The DDoS attack aims to disrupting the normal operation of the system through making services and resources unavailable to legitimate users by overloading the system with unnecessary superfluous traffic from distributed source. In addition, DDoS attack aims to increase in strength and frequency day-by-day. Therefore, the new systems which have been developed should be able to enhance the performance requirements and improve scalability of modern data centers, and provide maximum protection against the DDoS attacks.

This paper aims to mitigate denial of service attacks in software-defined networks through developing an efficient DDoS detection system based on machine learning models. The main contributions of this paper includes the following:

1) Research and analyze the recent developed DDoS detection systems.

2) Adopt several feature selection methods before processing the training stage.

3) Employ various machine learning models in the training process in order to enhance the efficiency of the DDoS detection system.

4) Test the developed machine learning model using real datasets, and real experiments, in order to assess the efficiency of the DDoS detection system.

II. Related Work

This section discusses the recent developed DDoS detection systems employed using the CICDDoS2019 dataset. Authors of [5] proposed a hybrid machine learning-based system to detect DDoS attacks. The proposed system involves combining the Extreme Learning Machine (ELM) algorithm and the black-hole optimization algorithm. Authors conducted several experiments through adopting various datasets to assess the performance of the proposed hybrid machine learning system. The proposed hybrid system has been employed in

detecting the DDoS attacks in cloud computing, and achieves 99.80% detection accuracy using the CICDDoS2019 dataset.

On the other hand, authors of [6] proposed an Intrusion Detection System against DDoS attacks (DDoSNet) in SDN environments. The proposed system is based on the Deep Learning (DL) technique, integrating the Recurrent Neural Network (RNN) with autoencoders. The developed system has been evaluated using the CICDDoS2019 dataset. Authors obtained a significant enhancement in attack detection compared to the existing methods. Therefore, the proposed system offers great confidence in securing SDN environments.

The work presented in [7] includes examining the impact of data balancing algorithm in the network traffic classification problem on several types of DDoS attacks using the CICDDoS2019 dataset, which consists of various information about the reflection-based and exploitation-based attacks. The obtained results showed that the effectiveness of data balancing algorithms such as synthetic minority sampling, naïve random, and adaptive synthetic sampling in classifying network attacks.

Authors of [8] proposed a detection system which was able to detect the different types of DDoS attacks based on several classification algorithms using the CICDDoS 2019 dataset. In addition, authors captured packets from SDK environment, apply preprocessing function for the dataset, and then apply classification algorithm to detect the DDoS attacks. Authors revealed that the decision tree offers the better performance compared to SVM and Naïve Bayes machine learning models.

The work presented in [9] involves analyzing the success rate in the intrusion detection system through adopting several machine learning methods. The CICDDoS2019 dataset was employed, where several machine learning models were investigated, including: the ANN, Support Vector Machine (SVM), Gaussian Naïve Bayes, Multinomial Naïve Bayes, Bernouli aïve Bayes, Logistic Regression, K-nearest neighbor (KNN), Decision Tree, and Random Forest algorithms. Authors showed that the K-nearest neighbor, logistic regression, and Naïve Bayes offers the best prediction accuracy.

Authors of [10] employed the Deep Neural Network (DNN) as a deep learning method to detect the DDoS attacks on the sample of packets captured from network traffic. The DNN model can work rapidly and with high detection accuracy even with small samples, since it contains feature extraction and classification methods. Authors preformed their experiments using the CICDDoS2019 dataset which contains several DDoS attack types created in 2019. The proposed system achieves 94.57% accuracy rate using the deep learning model.

The work presented in [11] surveys the recent developed DDoS detection approaches using the machine learning models. Authors of [12, 13, 14] proposed a DDoS detection system using Naïve Bayes model. On the other hand, the support vector machine model has been adopted in this works [15, 16, 17] to detect the present of DDoS attacks. In addition, Decision Tree algorithm has also been adopted to detect the DDoS attacks, as presented in [18, 19].

TABLE I. A COMPARISION BETWEEN THE EXISTING SYSTEMS THAT EMPLOYED THE CICDDOS2019 DATASET

Research work	Algorithm	Detection Accuracy
[5]	Extreme Learning Machine & blackhole algorithms	99.80%
[6]	Recurrent Neural Network with autoencoders	92.54%
[7]	SMOTE	93.51%
[8]	Decision Tree	92.15%
[9]	Artificial Neural Network, Support Vector Machine, Guassian Naïve Bayes, Random Forest Algorithm & K-Nearest Neighbor	Naïve Bayes offers the best detection accuracy
[10]	Deep Neural Network	94.57%

As presented above, several DDoS detection systems have been developed recently based on the employment of the CICDDoS2019 dataset. Table I presents a comparison between the existing developed systems based on the algorithm used and the detection accuracy.

III. SYSTEM DESIGN

The Distributed Denial of Service (DDoS) attacks include transmitting multiple requests to the attacked web resource, with the goal of exceeding the website's capacity to handle multiple requests, and hence prevent the website from functioning correctly. Several researchers have discussed the DDoS attacks and analyzed the major security threats and the corresponding solutions. This section discusses the main methods which have been employed in order to develop the DDoS system. In addition, this section presents the experimental setup including: the development environment, the selected DoS datasets, and the experimental setup.

A. System Methodology

Fig. 1 shows the development process of the DDoS detection system. As presented below, the first stage includes searching an efficient DDoS dataset, that are being developed recently by several research works. The second stage involves cleaning up the dataset and apply feature extracting methods, in order to pick the most significant features. Next, several machine learning models will be implemented to test the performance of the developed machine learning system, and then obtain the model's accuracy after conducting the training and testing processes.

B. DDoS Dataset

For each single machine learning model, a training and testing processes are needed to be implemented in order to assess the performance of the developed machine learning model. An extensive research has been carried out in order to identify the best DDoS datasets, which will be employed later in the training and testing process. Several datasets are available online such as the CIC-DDoS2019 dataset, where it contains benign and the most up-to-date common DDoS attacks, which resembles the true real-world data.

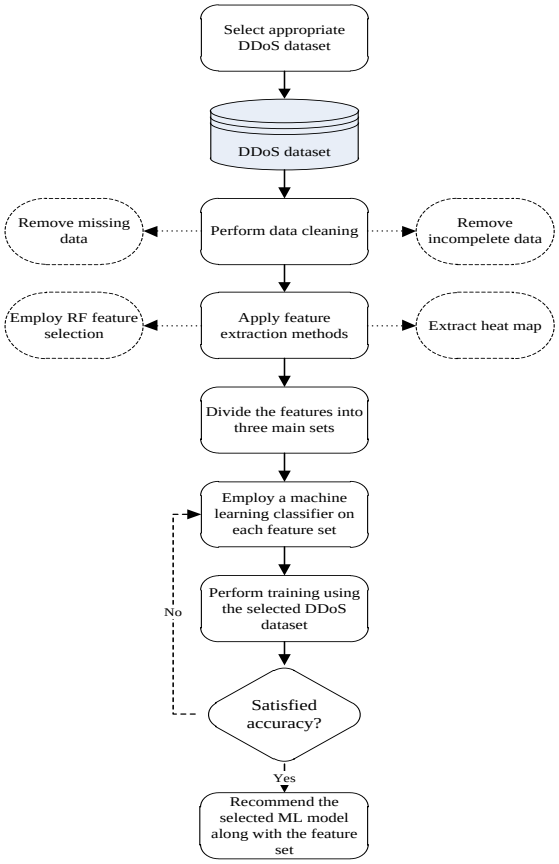

Fig. 1. The Development Process for the DDoS System.

Authors of [20] generated the CICDDoS2019 dataset that remedies several shortcomings and limitation which are presented in the existing datasets. CICDDoS2019 is labeled with 80 network traffic features that were extracted and calculated for all benign and denial of service flows. CIC-DDoS2019 dataset contains the results of the network traffic analysis with labeled flows based on the time stamp, source and destination IPs, source and destination ports, protocols and attack.

Therefore, the CICDDoS2019 dataset will be divided into two subsets: the training subset, and the testing subset. The training subset contains samples of data used to fit the machine learning models, whereas the testing subset is a gold standard employed to assess the performance of the trained machine learning model.

TABLE II. CICDDOS2019 DATASET GENERAL STATISTICS

Parameter name	**Total #**
Total number of records	12,794,627
Total number of features	82
Total number of labels	1
Total number of normal records	6,398,925
Total number of attack records	6,395,702
% of normal records	50.02%
% of attack records	49.98%

Table II shows the general statistics for the CICDDoS2019 dataset. CICDDoS2019 dataset is a large dataset in size and records, it consists of (12,794,627) records with a total memory size (6.3 gigabyte). The CICDDoS2019 is a balanced dataset, where the total number of normal records is (6,398,925) with the percentage of (50.02%), and the total number of fraud records is (6,395,702) with the percentage of (49.89%).

C. Data Preparation

In general, data preparation is considered as the most difficult stage in machine learning, and includes: data cleaning, data pre-processing, data wrangling, and feature engineering. Data preparation involves transforming raw data into a format where the machine learning algorithms can deal with, in order to uncover insights or make predictions. The data preparation process may consist of several steps, however, the most significant one involves processing the missing or incomplete data in the CICDDoS2019 dataset.

Data cleaning includes identifying and correcting errors or mistakes in the CICDDoS2019 dataset. Dropping columns that include missing or incomplete data, since missing and incomplete data affect the efficiency of the machine learning model. Therefore, it is important to process the missing and incomplete data in the dataset. For the CICDDoS2019 dataset, we noticed several attributes (columns) that contain zero values, and this will affect the machine learning model in negative way. For instance, *Fwd Byts/b Avg, Fwd Pkts/b Avg, Fwd Blk Rate Avg, Bwd Byts/b Avg, Bwd Pkts/b Avg, and Bwd Blk Rate Avg* attributes contain zero values in most of the records. Therefore, an important stage is required to remove these attributes from the CICDDoS2019 dataset.

The CICDDoS2019 dataset consists of several categorical data which are unsuitable for machine learning model. Therefore, there is a significant demand to remove these attributes from the CICDDoS2019 dataset in order to be able to train the machine learning model in a proper way. Moreover, the columns (attributes) that contain missing values more than 50% will be dropped from the CICDDoS2019 dataset. In addition, the rows where their columns contain more than 5% missing values are dropped. And finally, the faulty data in the CICDDoS2019 dataset are required to be considered. For instance, all records that contain negative values will be removed from the dataset.

The new shape for the dataset is presented in Fig. 2 after considering several data preparation methods. As noticed, the 19 attributes (columns) have been removed from the dataset, and 48,187 records have been removed from the CICDDoS2019 dataset.

On the other hand, the feature selection methods are considered next. According to [21], there are more than 2.5 quintillion bytes of data is produced every day. However, most of the generated data is required first to be pre-processed before starting any statistically analysis with the selected data, moreover, the produced data needs to be analysed using machine learning techniques in order to provide insights and to create predictions.

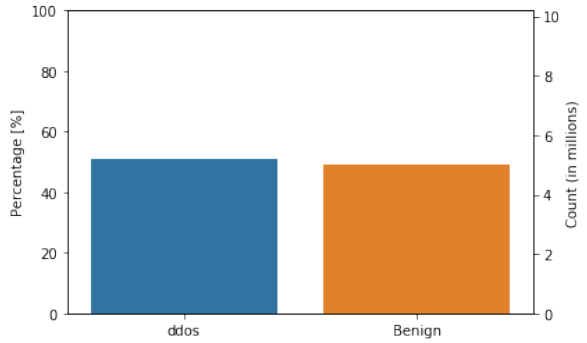

Fig. 2. Distribution of Records in the CICDDoS2019 Dataset.

As presented earlier in Table II, there are 82 features in the CICDDoS2019 dataset, and this makes the training and prediction tasks are very difficult. Therefore, it is important to minimize the number of features in CICDDoS2019 dataset through adopting several feature extraction models. This section discusses several methods which are used in order to extract the most significant features in the CICDDoS2019 dataset.

Minimizing the number of features may lead to several benefits, including: accuracy improvement, speed up in the training process, reducing the overfitting, and improve data visualization. Therefore, there are several different feature selection methods which can be applied to select the most significant feature in a given dataset, some of the most significant methods are: Filter method, and embedded method.

The first feature selection method is the filter method. Filter method involves filtering the dataset and take only a subset containing the most relevant features. This can be done using correlation matrix using Pearson Correlation. In general, the heat map (correlation matrix) is a graphical representation where individual values of matrix are represented as colours in order to display the correlation between attributes in a certain dataset and hence perform better prediction. The heat map for several features are shown below. For instance, Fig. 3 presents the heat map for 16 features, in order to show the relation among them. As seen in below, there is a high correlation between BWD IAT Std feature and FWD IAT Tot feature, and Bwd IAT Tot and FwdIAT Tot.

An embedded method is adopted next in order to enhance the prediction results. Embedded method includes examining the different training iterations of the machine learning model and then ranks the importance of the input features on how much each of the features contributed to the machine learning model through the training process.

For this stage, the Decision Tree model has been selected to rank the importance of CICDDoS2019's features. The Decision Trees models that are based on ensembles, can be used to rank the significance of the input features in the dataset. Since, extruding the most significant features offer vital importance on training the machine learning model, and hence obtaining efficient prediction accuracy. In addition, the features which will not offer any benefits to the machine learning model will be removed from the selected dataset.

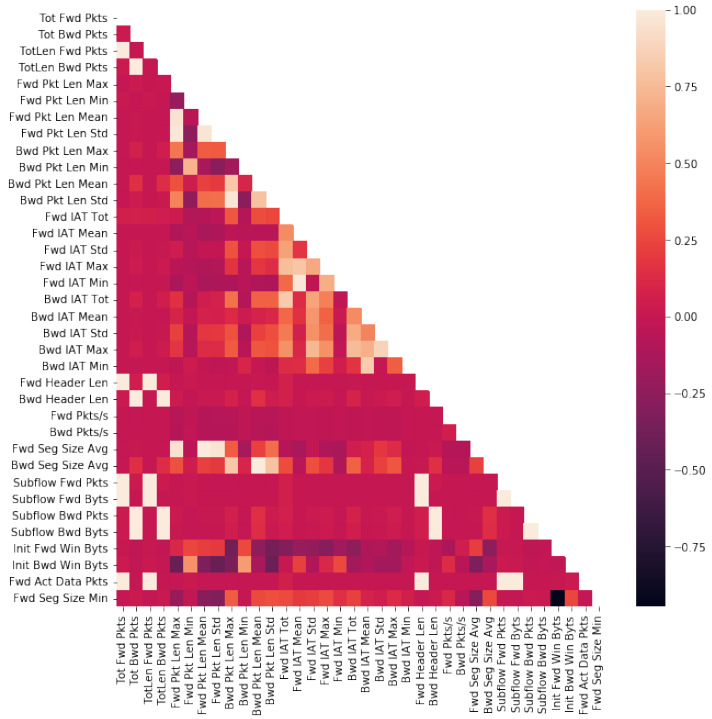

Fig. 3. The Heat Map for 36 Features.

In the Decision Tree, the CICDDoS2019 dataset was divided into two subsets: training subset, and testing subset, with 80% for training and 20% for testing. After completing the training process of the Random Forest Classifier, a set of feature importance plot is established according to the results obtained from the training stage. Fig. 4 shows the most 30 significant features in the CICDDoS2019 dataset.

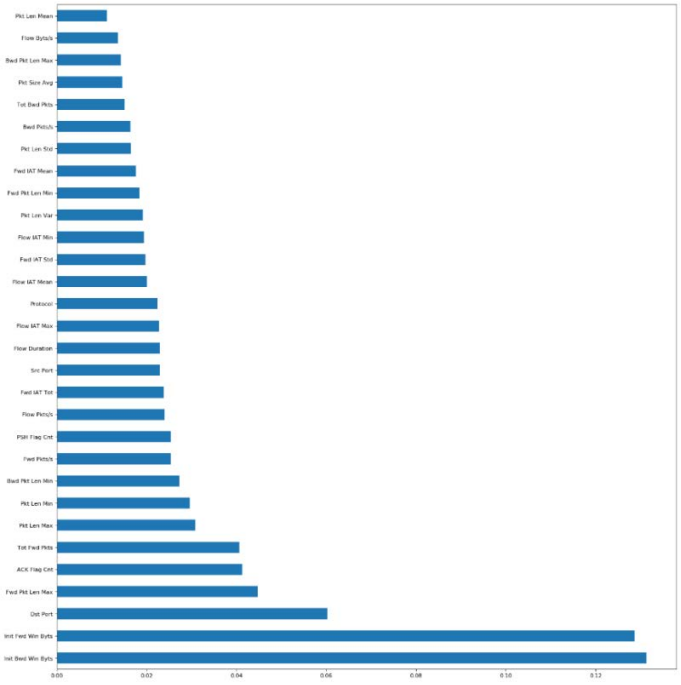

Fig. 4. The Feature Importance Plot for the 30 Most Significant Features.

In this paper, we investigate the efficiency of different features sets (10, 20, and 30), where each set is employed with every machine learning model and then assess and analyze the system's performance. The next section discusses the machine learning models which will be employed for the detection purposes.

D. DDoS Detection Models

In this project, several supervised machine learning models will be investigated, implemented, and tested, including: random forest, Light Gradient Boosting, CatBoost, and Convolutional Neural Networks.

- Random Forest (RF): it is also known as random decision forests that are ensemble learning method for classification and regression. RF operates through constructing multitude of decision trees at the training time, and producing the class which is the mode of the classes (classification) or average prediction (regression) of the individual trees.
- Light Gradient Boosting: is a light, fast, distributed, and high-performance gradient boosting framework, which is based on the decision tree algorithm, used for classification, ranking, and several machine learning tasks. It works by splitting up the tree leaf wise with the best fit, however, other boosting algorithms split the tree depth wise rather than the leaf-wise.
- CatBoost: CatBoost is an algorithm for gradient boosting on decision trees. CatBoost can be easily integrated with deep learning architectures. In addition, it can work with several data types to help solving a wide range of problem. CatBoost provides the best-in-class accuracy.
- Convolutional Neural Network (CNN): CNN is a deep neural networks, and is multilayer perceptron, which means that the CNN network is a fully connected. In any layer, each neuron is connected to all neurons in the next layer. CNN employs a mathematical operation named as convolution, where convolution is a specialized kind of linear operation.

IV. Expreimental Results

This section discusses the results obtained from several experiments conducted to assess the efficiency of different machine learning models. Several experiments have been conducted using the developed environment discussed earlier, in order to assess the DDoS systems' efficiency. Moreover, this section includes analyzing the obtained results and compares the system's efficiency with the recent developed systems.

A. Perforamcne Analysis

Several parameters are considered in order to assess the performance of the implemented DoS detection system; the parameters include:

- Average Training Time: this refers to the total time required to train the machine learning model.
- Accuracy: is the total of transactions that were correctly predicted over the total number of transactions.
- Precision: this indicates the total number of cases that were correctly classified among that class. Precision is the percentage of correctly predicted cases over the total predicted.
- Recall: is the ability of the classifier to correctly find all the positive instances. Recall is the ratio of true positives to the sum (total) of true positives and false negatives.
- Misclassification rate (error rate): this refers to how often the classifier is wrong.

B. Results of Average Training Time

The average training time is estimated for each machine learning model. As shown in Fig. 5, the RF model requires the largest training time (19,078 seconds), this is because the RF builds multiple decision trees and combines them together to obtain more accurate and stable prediction, and this makes the RF is a slow algorithm compares to others. Next, the average training time for the CNN model is (13,785 seconds), since the CNN training time depends on the training subset, batch size, and number of epochs.

On the other hand, the Light GB offers the minimum training time (150 seconds), since the Light GB is considered as a fast machine learning model for three main reasons: First, it splits the data based on their histogram, Second, it is gradient-based one-side sampling, and Third, the Light GB is used to deal with sparse features. Therefore, the Light GB machine learning model is best in terms of training time.

C. Evaluation of Essential ML Metrics

According to [22], there are three main metrics used to assess the machine learning classification model which are: accuracy, precision, and recall. As discussed earlier in the previous section, four different machine learning models were evaluated, where each machine learning model was evaluated through employing three sets of features. The best RF model was with 20-features set which offers (99.99740%) accuracy. On the other hand, the best LGB machine learning model was with the 20-features set which offers (99.99146%). The best accuracy result for the CatBoost model was with the 30-features set with accuracy (99.98592%). And finally, the best accuracy results for the CNN model was with 20-features set. Table III shows the detection accuracy for the best 4 machine learning models.

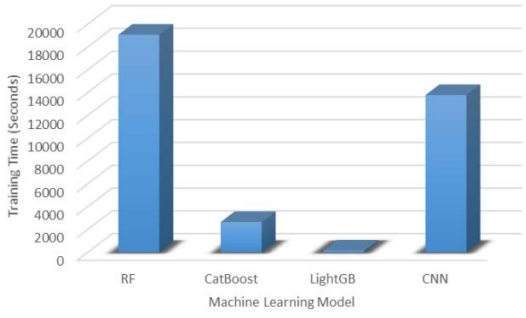

Fig. 5. Average Training Time (in Seconds) for 4 Machine Learning Models.

TABLE III. EVALUATION OF ACCURACY METRIC FOR 4 MACHINE LEARNING MODELS

	Accuracy
RF 20-features set	99.99740%
Light GB 20-features set	99.99146%
CatBoost 30-featues set	99.98592%
CNN 30-features set	98.29388%

TABLE IV. EVALUATION OF PRECISION METRIC FOR 4 MACHINE LEARNING MODELS

	Precision
RF 20-features set	99.99681%
Light GB 20-features set	99.98889%
CatBoost 30-featues set	99.97837%
CNN 20-features set	98.38997%

TABLE V. EVALUATION OF RRECALL METRIC FOR 4 MACHINE LEARNING MODELS

	Recall
RF 30-features set	99.99816%
Light GB 20-features set	99.99430%
CatBoost 30-featues set	99.99391%
CNN 20-features set	99.52368%

TABLE VI. EVALUATION THE FALSE NEGATIVE RATE FOR 4 MACHINE LEARNING MODELS

	False Negative Rate
RF 30-features set	19
Light GB 20-features set	59
CatBoost 30-featues set	63
CNN 30-features set	4,932

The Precision metric is discussed next, where the precision metric was assessed for every machine learning model. Precision refers to how often the machine learning model is able to predict the correct answer. The RF model with 20-feature set offers the best precision result (99.99681%). However, the best precision result using the Light GB model was through adopting 20-feature set with (99.9889%) result, whereas the CatBoost model achieves the best precision result with 30-feature set (99.97837%), and finally, the CNN model offers the best precision result with 20-feature set with (98.3899%) result. Consequently, as presented in Table IV, the machine learning model with best precision result was the Random Forest with 20-feature set.

Finally, the Recall metric is studied in this section. As discussed earlier in the previous section, the RF model with 30-feature set offers the best recall accuracy (99.99816%) among all the RF models (the three trained RF models using different number of features), whereas the Light GB model with 20-features set achieves the best recall accuracy (99.99430%) between all the LGB models. The CatBoost 30-features set offers the best recall result (99.99391%) amongst all the CatBoost models. And finally, the CNN 20-features set offers the best recall results among all the trained models with various number of features. Table V shows the recall results for 4 different machine learning models, and presents that the RF model with 30-features set offers the best recall results (99.99816%).

D. Results of False Negative Rates

This section evaluates the False Negative Rate (FNR) for each machine learning model employed above. FNR is a significant factor and refers to incorrectly predict the absence of DDoS attack when it is actually present, and this is the most significant metric in DDoS attack detection systems. Therefore, it is important to deal with machine learning model with the minimum FNR.

In this section, 14-different experiments were conducted to assess the efficiency of various machine learning models using 3 different DDoS subsets. Table VI presents the best FNR for 4 machine learning models. As presented in the Table below, the Random Forest classifier with 30-features set offers the best FNR with only 19 DDoS records which were misclassified and predicted as normal DDoS packets, whereas a large difference arises when adopting the CNN model. Fig. 4 depicts the false negative records for each machine learning model.

V. DISCUSSION

This section discusses the results obtained in this report with the results obtained from the previous research works, considering the CICDDoS2019 dataset. Most of the existing works evaluated the efficiency of the DDoS prediction model using the accuracy metric. Therefore, this section compares the accuracy metric obtained in this paper, with the existing works developed recently.

In this work, the detection accuracy that was achieved equal to 99.99740% using the random forest machine learning model with 20-features set. The high detection accuracy refers to the pre-processing methods which have been employed on the CICDDoS2019 dataset before applying the machine learning model. Two different feature selection methods were employed in this paper: filter method and feature extraction methods, in order to extract the most important feature which affect the machine learning model.

Therefore, in this paper, as shown in the previous section, the obtained detection accuracy results are greater than the results obtained from the recent developed works. Table VII presents the overall detection accuracy for various machine learning models used to detect the DDoS attacks. Fig. 6 shows the detection accuracy for several machine learning models, with different classification accuracy.

TABLE VII. DETECTION ACCURACY FOR SEVERAL MACHINE LEARNING MODELS

	Detection Accuracy
[5]	99.80
[6]	92.54
[7]	93.51
[8]	92.15
[10]	94.57
This system	99.99

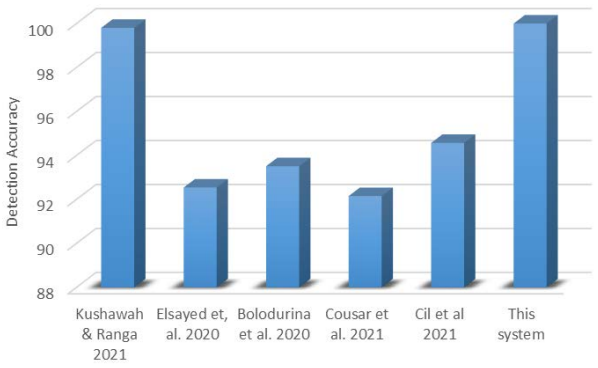

Fig. 6. The Detection Accuracy for Several Machine Learning Models.

VI. Conclusion and Future Work

Recently, the DDoS attack is considered as one of the most significant attack, which is a very powerful technology that has been launched to attack network devices and services. Therefore, in this paper, we consider the DDoS attack to be studied, analysed, and develop a machine learning model to detect such attacks. In this paper, we employed several feature selection methods in order to select the most significant features that can be used to predict the DDoS attacks in an efficient way. Three sets of features have been chosen from the selected dataset, and employed with four machine learning models. According to the obtained results, the RF-machine learning model with 20-features set offers the best precision, accuracy, recall, and false negative rate. For future work, we aim to work with real-time DDoS detection systems which will be able to detect the DDoS attack in real-time situations. Therefore, in this paper, we offered significant improvement in the detection of DDoS attacks using the CICDDoS2019 dataset.

A Patient Care Predictive Model using Logistic Regression

Harkesh J. Patel, Jatinderkumar R. Saini*
Symbiosis Institute of Computer Studies and Research
Symbiosis International (Deemed University), Pune, India

***Abstract*—Medical treatments and operations in hospitals are divided into in-patient and out-patient procedures. It is critical for patients to know and understand the differentiation between these two forms of treatment since it will affect the time of a patient's stay in a hospital or a medical institution as well as the cost of a treatment. In today's era of information, a person's talents and expertise may be put to good use by automating activities wherever possible. A medical service will be termed inpatient care if a doctor issues an order and the patient is admitted to the hospital on that order whereas a patient seeking outpatient care do not need to spend the night in a hospital. Choosing between in-patient and out-patient care is usually a matter of how involved the doctor wants to be with the patient's treatment. With the aid of numerous data points regarding the patients, their illnesses, and lab tests, our main objective is to develop a system as part of the hospital automation system that predicts and estimates whether the patient should be given an in-patient care or an out-patient care. The main idea of the paper is to understand and develop a logistic regression model to predict whether a patient needs to be treated as an in-patient or an out-patient depending on the results of laboratory tests. Furthermore, this study also focuses on how logistic regression performs for this dataset. In addition, research on how logistic regression performs for this dataset was also not done. From the study, the results show that logistic regression gives an accuracy of 75%, F1-score of 73%, precision of 74% and recall of 74%.**

***Keywords*—Health-care; inpatient care; logistic regression; machine learning model; outpatient care; stacking classifier**

I. Introduction

Inpatient and outpatient procedures can be used to classify medical treatments and operations. A patient should be aware of this distinction since it affects how long he or she stays in a hospital and how much the operation costs. The difference between an in-patient and an out-patient treatment is the duration of time a patient must spend time in a medical institution where the operation or treatment is performed. In-patient treatment compulsorily requires an overnight stay in the hospital or the medical institution.

Patients must spend time or stay at least for one night in the medical facility that is provided to them where their operation or treatment was performed, typically a hospital. During this period, kids are normally under the care of a nurse or a doctor.

Patients seeking out-patient care need not have to spend the night in a hospital. These patients are allowed to depart the hospital once their treatment is completed. In certain situations, they must wait while the anesthetic wears off or to ensure that there are no problems. Patients are not required to spend the night under supervision if there are no significant problems. In addition, the out-patient treatment is much more cost-effective in comparison to in-patient treatment [12].

To categorise patients' medical requirements into an in-patient or an out-patient treatment, doctors rely heavily on the results of lab tests. This time-consuming approach requires doctors to exert considerable effort in order to determine if the patient is required to be in the hospital and closely watched or not. Also, the patient's life may be in risk if the wrong decision is made [1]. Clinical machine learning research is largely restricted to proof-of-concept studies. Machine learning applications in clinical medicine are currently hindered by a number of obstacles. A major shift in medical practise may result from overcoming obstacles to potential deployment, with the use of specialised technologies helping the healthcare team provide better, more customised patient care [2].

Machine learning algorithms, it is widely accepted, find and extract information based on the data available. Yet a vast quantity of information is available in machine-readable format, ready to be incorporated into machine learning algorithms and models [4]. For this study, Logistic Regression, a supervised machine learning algorithm, is used. The main objective of this paper is to see how logistic regression works on such a problem. Furthermore, we will check the performance metrics, precision, recall and accuracy to get an idea of how useful logistic regression is for such problems.

II. Literature Review

Melhem et al. [1] built four models depending on the patient's circumstances and lab test results: support vector machine model, decision tree model, random forest model and k-nearest neighbours model. The major aim of their study was to make use of ML algorithms to categorize the patient treatment as an in-patient or out-patient, in order to lessen the time and effort expended by the healthcare experts, which reflects the kind of services provided to the patient. Furthermore, this research assists in the reduction of human errors, which can result in hazards to the patient's life as well as an increase in the overall bill amount. The best model out of four was picked based on its accuracy, sensitivity, specificity, and precision scores, as well as its low false-negative & false-positive rates. To construct and evaluate these models, the EHR dataset was utilised, which comprises of patients' laboratory test results from a private hospital that is in Indonesia. The outcomes of their study say that random forest algorithm had the best accuracy (77 %), precision-rate (72%) & sensitivity (65%) as well as the model had the lowest false-

*Corresponding Author

negative rate (35%) and almost the lowest false-positive rate (16%).

Ben-Israel et al. [2] conducted a review in keeping with the prisma criteria and concentrating on human studies which utilised machine learning to directly treat a hard-headed scenario. The studies were performed between 1st Jan, 2000 & 1st May, 2018 and offered data on the performance of the used machine learning technique. Reviewers looked over 1909 distinct publications and found 378 retrospective papers and 8 prospective ones that met eligibility requirements. 61% of papers published in the past four years were retrospective. Few articles met our inclusion criteria, with just 2% of them being prospection articles. When it comes to clinical medicine, a majority of the literature is retrospective and focuses on proof-of-concept ways to improving patient care. A major transformation in medical practise will be enabled by recognizing the key translational hurdles, including instantaneous access to hard-headed data, data reliability, medical practitioner approval of "black box" generated findings and performance evaluation.

Beaulieu-Jones et al. [3] have talked about the applications of ML in health-care which is increasing quickly and might have a major effect on the profession. Using ML for health-care research, the study was aimed to provide quantitative and qualitative assessments of the current status. In order to assess the present status of research in ML for health-care, including areas of methodological and medical focus and limits, as well as areas that are underexplored, they analysed contributions. Results showed that the clinical collaborators were involved in 58 (34.9%) of the 166 accepted entries, and in 83 (50.0%) of the submissions that focused on clinical practise. On average, (97 datasets) 58% of the data sets utilised were publicly available or needed registration. (70 articles (42.2%)) of them were in clinical practise, with brain & mental health (25(15.1%)), cancer (21 (12.7%)) and cardiovascular (19 (11.4%)) being the most prevalent specialities. Data that is well-annotated and freely accessible is critical to the development of translational implementations in ML for health-care research, according to current trends.

Radovanović et al. [4] proposed an approach to logistic regression that incorporates domain information in the form of ontologies/hierarchies via layered generalisation. Because ontology/hierarchy relations are stacked, they may be combined to create higher, abstract ideas. In this case, they were able to tackle the problem of unexpected 30-day hospital readmissions. The proposed framework outperforms ridge, lasso and tree lasso logistic regression in terms of accuracy. This framework increases AUC by up to 9.5% for children and up to 4% for severely over-weight patients. Also, it increases the AUPRC up to 5.7% for children and up to 2.6% for ghastly over-weight patients, the researchers found.

Mu-Yen Chen [5], when using Decision Tree (DT) classification, the accuracy decreased the more PCA was applied, according to this paper's findings. According to his findings in the study of financial hardship, the accuracy of their DT classification technique increased as time passed, with an accuracy rate of 97.01% for two seasons previous to financial difficulty. They found that PCA increases the error while attempting to identify firms in a financial crisis as "normal" enterprises, and that DT classification has a higher short-term prediction accuracy than the Logistic Regression (LR) classification technique (less one year). Instead, the LR method improves long-term prediction accuracy (above one and half year). A short-term financial distress prediction model using AI, rather than standard statistical methods, is proposed in this study as a possible alternative to traditional statistical methods.

El-Rashidy et al. [6] have come up with a new way to forecast ICU patient death using stacking ensemble. Compared to the literature study, their method is more accurate and intuitive from a medical point of view in collaboration with an ICU domain specialist, data were produced and features selected. On the basis of the expert's judgments, six categories of data were created. When it came to the prediction procedure, each modality was assigned a distinct classifier depending on its performance. Our classifiers included linear discriminant analysis, decision tree algorithm, multilayer perceptron, k-nearest neighbour (knn) and logistic regression, among others. A stacking ensemble classifier was then created and tuned using the five classifier decisions. The system was validated with the help of a benchmark dataset of over ten thousand patients from MIMIC III. Patients' time series data of varied durations was used to undertake extensive studies in order to predict death. The first six, twelve, and twenty-four hours of a patient's initial stay were tested. On the basis of the results, their model surpassed the current techniques in terms of accuracy i.e. 94.4%, f1-score i.e. 93.7%, precision i.e. 96.4%, recall i.e. 91.1% & ROC curve i.e. 93.3%. As a result of these findings, it's clear that their technique of predicting ICU mortality works.

Polikar [7] studied situations where ensemble-based systems are superior to single-classifier systems, techniques for producing separate parts of ensemble systems and methods for combining separate classifiers. Many ensemble-based algorithms like bagging and boosting have been discussed as well as generalisation and hierarchical mixtures of experts. They have also discussed typically used combination rules such as algebraic blend of outputs, voting-based approaches and behaviour knowledge space as well as decision templates. A last look at future exploration prospects for ensemble systems was conducted. In addition, ensemble systems have showed significant promise in a variety of other fields like as feature selection and learning with lost features, confidence estimation and fault-correcting output codes. It has been demonstrated that ensemble-based systems generate better outcomes than expert systems for a broad range of implementations and circumstances. In their paper, they have talked about how to design, build, and use such systems.

Saini et al. [8] in their study seek to present the importance of artificial intelligence in magnetic learning algorithm and examines their function in different sectors of health, such as bioinformatics, cancer gene identification, epileptic seizure, brain computer interface. It also examines the medical imaging of illnesses, including diabetic retinopathy, gastro-intestinal disease, and tumour via extensive learning. Finally, this essay highlights the real barriers to AI approaches which need to be addressed. They examined the reason why ML was used in healthcare in this work. The main category of ML, is also

discussed. They concentrated on deep learning, its architecture and explore various health data analysing and examining deep learning. However, ML technologies draw considerable attention in the field of medical research. There are still difficulties with real-time implementation. Regulations are one such difficulty. Recent rules lack safety, evaluation and efficiency criteria for the ML system. The US FDA provides advice for the evaluation of ML systems to preserve security and efficiency in order to solve this challenge. The existing health care environment does not encourage the exchange of information on the system. It is also a limitation. The ML training was therefore compromised before implementation. In many nations, the Health Care Revolution encourages data exchange.

Kirasich et al. [13] addresses the challenge of model selection by assessing the overall classification performance for datasets with diverse underlying structures between the random forest and logistic regression by increasing the variance in the explanatory as well as the noise variables, number of explanatory variables, noise variables and observations. They created a model evaluation tool which can simulate classification models for such data and performance indicators as real positive rates, false positives and accuracy in certain circumstances. They observed that logistic regression has continuously exercised a better overall precision than random forests by increasing the variance not only in the explanatory but also the noise factors. The true positive-rate for random forest algorithm was, however, greater than the logistic regression algorithm & the data set with rising noise factors showed higher false-positive rates. Each and every case study included thousand simulations and the model executions in it consistently demonstrated that the false positive-rate for random forest with hundred trees was scientifically different from logistic regression. Under varied simulated dataset circumstances, logistic regression algorithm & random forest algorithm produced variable corresponding classification scores in all four situations.

Maroof [14] says that based on the continuous predictor, logistic regression seeks to classify or predict a discrete, categorical variable from among continuous or discrete predictors. Clinical neuropsychology's preference for using this paradigm in research is connected to the discipline's fundamental structure, which includes the use of scientific terminology to explain cognition and behaviour, as well as the compartmentalization of syndromes into diagnostic entities.

Goldarag et al. [15] developed, tested and compared forest fire risk prediction models based on logistic regression and neural networks. The findings show that the neural network model is more accurate at categorising fire points than logistic regression, which is sensitive to fire point samples. The percentage of fire and non-fire samples must be matched to obtain high accuracy in logistic regression. A neural network with two hidden layers, twenty-eight neurons, and a logarithmic-sigmoid transfer function in both hidden layers was also tested and the best architecture was found to be a neural network with two hidden layers, 28 neurons, and a logarithmic-sigmoid transfer function in both hidden layers.

Pepe & Thompson [16] developed strategies for maximising the accuracy of routinely used diagnostic measures by discovering linear combinations of markers. The approaches were non-distributional, appeared to have strong statistical features, and could account for heterogeneity defined by variables.

Sadikin and Mujiono [17] created an electronic health record predicting dataset obtained from a private hospital in Indonesia. It comprises the findings of the patient's laboratory tests, which are used to determine the next patient treatment, whether the patient is in or out of the hospital.

In order to determine the allocation of staff care in community-acquired pneumonia, España et al. [18] created a new prediction algorithm based on the 5 risk classifications described by the Pneumonia Severity Index. There was no question about the decision to hospitalise low risk (I-III) classes, when one or more of the following was evident, namely: tension in arterial oxygen < 8.0 kPa (60 mm Hg), shock, coexisting decompensating diseases, plural effusion, unable to maintain oral intake, a social problem and a lack of reaction to prior empirical antibiotic therapy. The findings are presented in a number of 616 patients after 18 months following application of this new prediction criteria. In 221 patients treated as ambulatory patients, the death rate was 0.5% vs 8.9% in 395 patients treated as hospitals. Of the 178 low risk individuals treated as hospital patients, 106 were given the specific extra requirements for hospitalisation, while the other 72 evidently did not justify the decision to admit hospitalisation under the predictive criterion. These 72 patients had better results than high-risk patient and low-risk patient who fulfilled the extra particular criteria for admitting to hospital (substantially shorter admission, antibiotic days, death and complex course) their results were better. Therefore, rigorous adherence to the new prediction criteria might have prevented admission in these low-risk individuals. Another significant finding was that not all patients admitted to the hospital had been identified in the Pneumonia Severity Index alone.

Blais et al. [19], in their study identified factors related with length of stay (LOS) and included measurement of these variables into their normal preadmission evaluation. A retrospective research of 80 discharged patients looked at the relationship between LOS and 25 factors representing a combination of patient/demographic characteristics, disease variables, and therapy variables. According to multivariate analysis, ten factors independently accounted for 62% of the variance in LOS. The information utilised was largely gathered during the pre-admission screening. In the prospective research, the factors' predictive ability decreased. However, fewer individual factors were substantially related to LOS; the total of the variables' scores predicted 17% of the LOS variation. The findings showed that significant criteria for predicting LOS are accessible at the time of admission, and these variables may be systematically examined and incorporated into clinical decision making.

Cuffel et al. [20] examined the correctness of different models for projecting a rehospitalization in a maintained mental health organisation, as well as the efficacy of various

care or treatment management methods for improving out-patient treatment follow-up. In a randomised controlled trial, patients that had in-patient mental health or substance use admissions were assigned to one out of 3 types of treatment supervision based on the level of involvement of treatment executives in the release planning & post-release outreach i.e. usual (N=31), enhanced (N=94) or intensive (N=74). Here, the classes that were formed were compared to each other and to a cohort hospitalised the year before the research and given usual treatment (N=192) to see if there were any changes in time to out-patient check out, quantity of post-release care and rehospitalization at 30, 60 & 180 days. There weren't any differences between the classes found. The larger part of number of patients i.e. 69% got out-patient treatment within 30 days of being released. The number of hard-headed and socio-demographic risk variables reported by care executives was associated to the probability of rehospitalization at 60 and 180 days, according to logistic regression prediction models. Patients who were approved to receive intermediate treatment i.e. partial hospitalisation and those who did not attend the intermediate treatment, if it was authorised were more suitable to be re-hospitalized at 30, 60 & 180 days than other patients. With increasingly extensive release planning and outreach, outpatient follow-up following mental hospitalisation did not improve. Improved prediction of re-hospitalization risk may improve possibilities to deliver intensive treatments to difficult-to-engage patients.

III. Methodology

Most of the data science implementations depend heavily on ML models. Other expert knowledge exists outside of the given data, which may theoretically assist the ML algorithms better recognize the conditions and circumstances of the data that is provided [4].

Machine Learning employs three types of learning: supervised, unsupervised and semi-supervised learning.

Supervised learning is a type of training in which we educate or train the machine using well-labelled data, i.e. data that already has the correct answer. Following that, the machine is given a fresh collection of instances, i.e. the test data, so that the supervised learning algorithm may analyse the training data and generate a proper result from labelled data. Further, supervised learning approaches include regression and classification, which are further classified. Regression is a helpful statistical prediction approach that aims to establish a meaningful link between dependent and independent variables by attempting to find correlations between them. To forecast a continuous output, the regression technique is employed in machine learning (ML). The predicted result is a real number. The output of classification is discrete, but the output of categorization is continuous [8].

Unsupervised learning, on the other hand, is the training of a computer utilising input that has not been categorised or labelled and enabling the algorithm to operate on that information without supervision. Clustering and principal component analysis (PCA) are two of the most important techniques in unsupervised learning. PCA is typically used to reduce the size of an object. With numerous dimensions, PCA reduces the data to a few principle component directions without losing much of the data. PCA is often used before clustering to minimise the number of dimensions of the data before it is clustered. Instead of using output information, the clustering approach is used to create a collection of variables that exhibit similarities or commonalities. As a result of these algorithms, the cluster labels for the variable with the highest degree of similarity within and between the clusters are generated and displayed on a graph [8].

Semi-supervised learning, on the other hand, includes function estimation on both labelled and unlabelled data. This method is driven by the fact that labelled data is frequently expensive to create, but unlabelled data is cheap.

Here, we have used Logistic Regression as it a binary classification task i.e. 0 or 1. A discrete, categorical variable is classified or predicted using logistic regression using continuous or discrete predictor, such as yes/no depending on the continuous predictor [14]. In order to achieve high accuracy in logistic regression, the percentage of in-patient and out-patient care samples must be balanced [15]. It produces a linear score that clearly distinguishes between two outcomes [16]. Moreover, the research on how logistic regression model performs on such scenario was also not done. General approaches such as ensemble learning can be used to improve the accuracy of prediction or classification models such as decision trees and artificial neural networks [11]. Hence, Stacking Classifier is used for improving the accuracy of prediction.

A. Dataset and Experimental Discussion

The dataset comprises predictions from an Electronic Health Record gathered from a private hospital which in Indonesia. It comprises the laboratory test results of different patients, which are used to decide the next patient's treatment, whether in or out of the hospital. The dataset contains 4412 rows and 11 columns. The total number of features are 10, where number of numerical features are 9 and number of categorical feature is 1 [17].

B. Attribute Information

- HAEMATOCRIT: It is the patient's laboratory test result of haematocrit.
- HAEMOGLOBINS: It is the patient's laboratory test result of haemoglobins.
- ERYTHROCYTE: It is the patient's laboratory test result of erythrocyte.
- LEUCOCYTE: It is the patient's laboratory test result of leucocyte.
- THROMBOCYTE: It is the patient's laboratory test result of thrombocyte.
- MCH: It is the patient's laboratory test result of MCH.
- MCHC: It is the patient's laboratory test result of MCHC.
- MCV: It is the patient's laboratory test result of MCV.
- AGE: It is the patient's age.

- SEX: It is the patient's gender.
- SOURCE: Target i.e. Binary: in-patient/out-patient – 0/1.

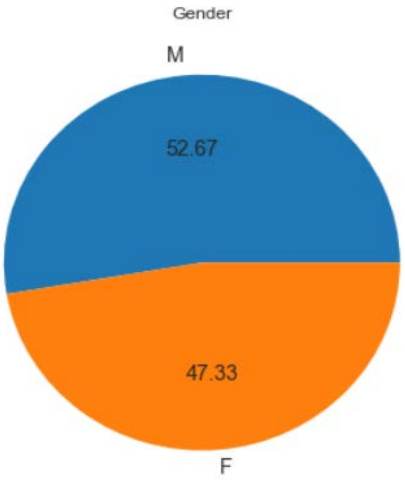

Fig. 1. Percentage of Males (M) and Females (F) in the Dataset.

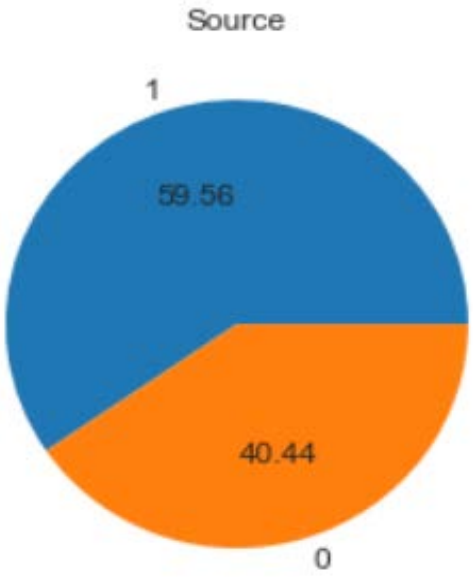

Fig. 2. Percentage of Inpatient (0) and Outpatient (1) in the Dataset.

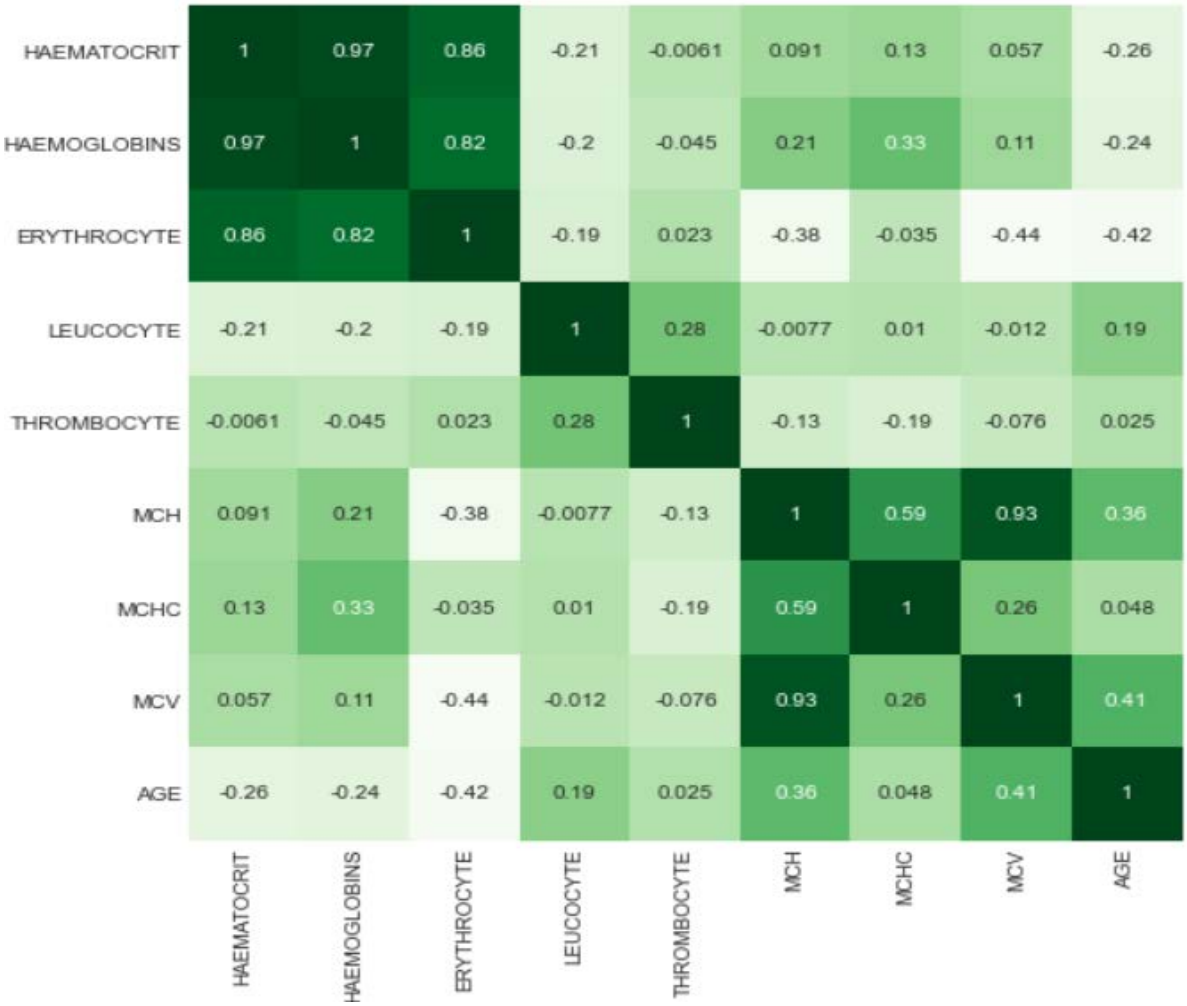

Fig. 3. Pearson's Correlation of Features with respect to each other.

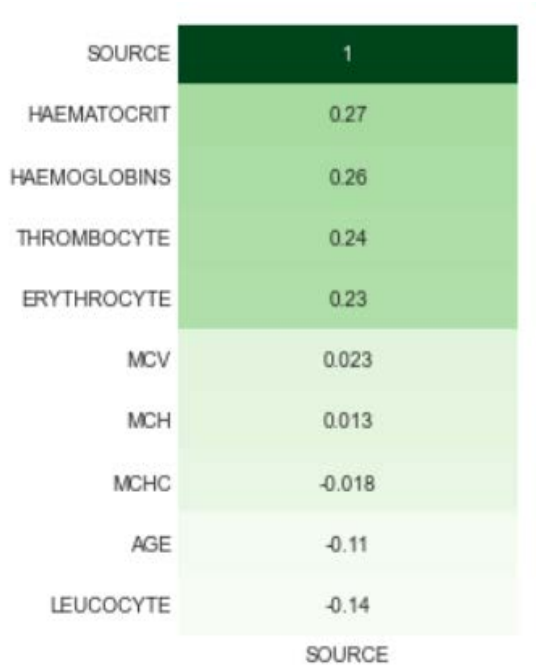

Fig. 4. Pearson's Correlation of Features with respect to Target.

TABLE I. FIRST FEW RECORDS OF THE DATASET

HAEMATOCRIT	HAEMOGLOBINS	ERYTHROCYTE	LEUCOCYTE	THROMBOCYTE	MCH	MCHC	MCV	AGE	SEX	SOURCE
35.1	11.8	4.65	6.3	310	25.4	33.6	75.5	1	F	1
43.5	14.8	5.39	12.7	334	27.5	34.0	80.7	1	F	1
33.5	11.3	4.74	13.2	305	23.8	33.7	70.7	1	F	1

TABLE II. PERCENTAGE OF MISSING VALUES IN EACH FEATURE

Attribute	Missing %
HAEMATOCRIT	0.0
HAEMOGLOBINS	0.0
ERYTHROCYTE	0.0
LEUCOCYTE	0.0
THROMBOCYTE	0.0
MCH	0.0
MCHC	0.0
MCV	0.0
AGE	0.0
SEX	0.0
SOURCE	0.0

The pie chart in Fig. 1 shows that there are 52.67% Males (M) and 47.33% Females (F) in the dataset. While the pie chart in Fig. 2 shows that 40.44% people were treated as inpatient (0) and 59.56% people were treated as outpatient (1) in the dataset. Fig. 3 shows the Pearson's Correlation of features with respect to each other whereas Fig. 4 shows the Pearson's Correlation of features with respect to the target i.e. SOURCE.

In the dataset, the 80% data was taken as training data and 20% data was taken as test data. The Tables I, II and III show the first few records of the dataset, percentage of missing values in each column and number of unique values in each column respectively. During the feature engineering part, we replaced the labels of sex column with binary numbers i.e. F = 0 and M = 1. Thereafter, MinMaxScaler was used to scale the features to a range of [0, 1]. At the end, we removed the least correlated features i.e. [MCH, MCHC, MCV] from the dataset. After performing feature engineering, my dataset was ready for the next step i.e. training the model. The exploratory data analysis and feature engineering was performed in order to increase the accuracy and precision of the model. Efficient and effective feature selection techniques allow better generalization of predictive models and improved interpretability, which is a very important property for applications in health care [10]. Furthermore, Hyperparameter tuning was performed for obtaining best case scenario.

Solving issues with a decision boundary which extends outside of the space of the function that is implemented by the specified classifier model is exceedingly difficult for a single classifier to do it successfully. This non-linear boundary may be learned by combining ensemble classifiers in the right way. To avoid bad selection of a single classifier that cannot generalise performance, combine many classifiers and average their output to lower the chance of poor performance of the single classifier that is picked. As a result, the chance of making a bad choice is reduced as well [6]. Thus, we have used Stacking Classifier in order to combine the skills of the models on the regression problem to produce predictions that outperform any single model in the ensemble.

It has been demonstrated that ensemble-based systems generate better outcomes than single-expert systems for a wide range of applications and circumstances [7].

TABLE III. NUMBER OF UNIQUE VALUES IN EACH FEATURE

Attribute	Number of unique values

HAEMOGLOBINS	128
ERYTHROCYTE	433
LEUCOCYTE	276
THROMBOCYTE	554
MCH	189
MCHC	105
MCV	406
AGE	95
SEX	2
SOURCE	2

IV. Result Analysis

After using Logistic Regression, we got the train accuracy as 70.9% and test accuracy as 71.5%. For increasing the accuracy, we performed hyperparameter tuning using RandomizedSearchCV and got best parameters for logistic regression i.e. {'penalty': 'none', 'max_iter': 300, 'fit_intercept': True, 'class_weight': {0: 1, 1: 1}, 'C': 0.01}.

After retraining the model, we got the train accuracy as 71.6% and test accuracy as 73%. The Table IV shows the classification report of the model.

Stacking is one of the most efficient methods for solving classification and regression issues. The concept of stacking is using the predictions of machine learning models from the previous level as the input variables in the following level's machine learning models [9].

And hence, we have used Stacking classifier. We got the train accuracy as 72% and test accuracy as 75%. It could be seen that there was a minor increase in the accuracy. Furthermore, I have used cross-validation but stacking classifier gave a better accuracy and so, we went for stacking classifier. The Table V shows the classification report of the model.

TABLE IV. Classification Report of the Logistic Regression Model

	Precision	**Recall**	**F1-score**	**Support**
0 (In-patient Care)	0.75	0.52	0.61	357
1 (Out-patient Care)	0.73	0.88	0.80	526
Accuracy			0.73	883
Macro Average	0.74	0.70	0.70	883
Weighted Average	0.74	0.73	0.72	883

TABLE V. Classification Report of Logistic Regression using Stacking Classifier

	Precision	**Recall**	**F1-score**	**Support**
0 (In-patient Care)	0.74	0.53	0.62	357
1 (Out-patient Care)	0.73	0.88	0.80	526
Accuracy			0.75	883
Macro Average	0.74	0.70	0.72	883
Weighted Average	0.74	0.73	0.73	883

The findings of Melhem et al. [1] reveal that out of four models i.e. Support Vector Machine (SVM) model, Decision Tree model, Random Forest model and K-Nearest Neighbors (KNN) model, Random Forest model had the best accuracy (77%), precision (72%) and sensitivity (65%). So comparing with that model, our model gave nearly a similar accuracy (75%) but gave better precision (74%). Moreover, Kirasich et al. [13] observed that logistic regression has continuously exercised a better overall precision than random forest model by increasing the variance in the explanatory factors as well as noise factors. Under varied simulated dataset circumstances, logistic regression model and random forest model had produced variable relative classification scores in all the four situations they observed.

V. Conclusion and Future Work

The results show that the logistic regression gives nearly 75% accuracy, 73% recall, 73% f1-score on the test data. It gives a decent result on the dataset. Furthermore, the main objective and idea behind the research was fulfilled.

Moreover, for logistic regression model, independent characteristics may be used to predict accurate probabilistic outcomes based on statistical analysis. The model may over-fit on the training set if the dataset has a high number of dimensions, and hence may not be able to predict correct outcomes on the test set if the dataset has a large number of dimensions. Sometimes this happens if a little amount of data is used to train the model, but the data has a large number of features. Regularization strategies should be explored for high-dimensional datasets in order to avoid over-fitting but this makes the model complex.

Using Stacking classifier, there was a slight increase in the accuracy. Moreover, using multiple machine learning algorithms with stacking classifier or using regularization techniques on logistic regression with stacking classifier on a huge dataset could be thought of.

***Abstract*—3D gesture recognition and tracking based augmented reality and virtual reality have become a big interest of research because of advanced technology in smartphones. By interacting with 3D objects in augmented reality and virtual reality, users get better understanding of the subject matter where there have been requirements of customized hardware support and overall experimental performance needs to be satisfactory. This research investigates currently various vision based 3D gestural architectures for augmented reality and virtual reality. The core goal of this research is to present analysis on methods, frameworks followed by experimental performance on recognition and tracking of hand gestures and interaction with virtual objects in smartphones. This research categorized experimental evaluation for existing methods in three categories, i.e. hardware requirement, documentation before actual experiment and datasets. These categories are expected to ensure robust validation for practical usage of 3D gesture tracking based on augmented reality and virtual reality. Hardware set up includes types of gloves, fingerprint and types of sensors. Documentation includes classroom setup manuals, questionaries, recordings for improvement and stress test application. Last part of experimental section includes usage of various datasets by existing research. The overall comprehensive illustration of various methods, frameworks and experimental aspects can significantly contribute to 3D gesture recognition and tracking based augmented reality and virtual reality.**

Keywords*—Augmented reality; virtual reality; 3D gesture tracking

I. Introduction

Dexterity is one of the most important driving forces of human intelligence. Our hands have enabled us to create arts and crafts as well as build massive constructions alike. In this age of technology, human use their hands to interact with electronic devices everyday. Touch and gesture input have become part of common life. Nowadays, people interact with digital devices by using touch screen displays or trackpads. Two dimensional (2D) touch screens are basically offered by the latest technology. However, mobile phone touch screens constrain us within a small space of the device. In this context, virtual reality refers convincing visual rendering of the simulated objects in lieu with manipulating them in a fast, precise, and natural way [1], augmented reality indicates machine generated image on user's view of the real world to enable composite view [56] and hand gesture refers movement of the hand to enable meaningful interpretation [60]. To extend the interaction space from 2D surface to real 3-dimensional (3D) space, this research investigates currently existing vision based 3D gestural architectures for augmented reality and virtual reality. The core goal of this research is to present comprehensive investigation on tracking and predicting hand gestures from RGB camera images and interact with virtual objects in mobile phones. Huge investments of the big technology companies on augmented reality and virtual reality has broadened the applications of this case where a relatively new branch has been introduced towards the direction of gesture tracking and recognition in the domain of computer vision and pattern recognition.

Tracking the hands of an user makes it a difficult task when the tracking camera is also moving, which is the case for augmented reality and virtual reality. While there have been numerous previous research works for tracking hands, the problem still remains as a research interest. Because of the progress in the area of computer vision and machine learning, computers are now capable of tracking hand gestures and pose through various techniques. This research analyzed those previous works to track hand gestures and interact with objects with hands in augmented reality and virtual reality. In the early days of this field, there were numerous approaches made with traditional image processing techniques to detect and track hands. But in the recent days, most of the research has been performed with respect to machine learning approaches. This research presents the benefits and shortcomings of these approaches in lieu with presenting existing experimental analysis with different approaches.

II. Core Background Study

Augmented reality and virtual reality have been a research interest for a long time. Researchers have been trying to do camera tracking based augmented reality and virtual reality for a long time. Recently these two domains have become a big interest of research because of advanced technology in mobile phones and smartphones. In recent years, there have been a lot of progress in the processing capability of smart phones. Because of this, handheld mobile phones can compute the necessary amount of data to perform camera tracking as well as rendering on corresponding display. In recent years, there has been a lot of progress in recognition and tracking of the

human face and we have seen a rise in user interest in such kinds of applications.

This research also relies on the research that has been done to track plane surfaces as well as wall or vertical objects and render digital objects on them to deliver the experience of augmented reality and virtual reality. There has been enormous research on this area and there have been massive breakthroughs in the area [56][60]. There have been games based on augmented reality and virtual reality where a planar surface such as floor or road is tracked and on the tracked surface a game object is drawn and players use their camera feed to see the object augmented on the video feed of that planar surface. There have also been a lot of applications to visualize shopping products in augmented reality and virtual reality. Big technology companies like Google and Apple have their own libraries to implement augmented reality and virtual reality. Furniture vendors such as IKEA has launched their app in which users are able to place a virtual 3d object in their living room and judge which product will look good in their room as well as the environment. These usages and demands of such applications have turned lots of active research interest in the area of augmented reality and virtual reality.

In the past, there has been research on recognizing human hands and tracking them. In the early days of the research, recognizing the hand and tracking the hand in an image was done by offline image processing as this was a computationally heavy task. After some successful research, it has also been possible to track human hands in real time using a web camera and a desktop pc as technology progressed. Now with the advancement in neural networks, feature tracking and modeling the network has been done by neural networks, and because of the easiness of modeling a human hand as an object for tracking has been easier. Now, there has been active ongoing research for tracking human hands via mobile phone camera as well as recognizing the pose of the hands in a camera frame. Research interest of this proposed investigation relies within the research of tracking and recognizing human hand pose and tracking it in continuous frames.

III. Qualitative Analysis on Methods

Early researchers used augmented reality and interaction with personal interaction panels which includes creating menu system and 3D interface [17] [39]. The Positive side of these researches were that there was instant feedback from users. However, in accuracy and unreliability were the main area of concern in these researches. Collaborative geometry learning based object constructions shown in Fig. 1 is an active area for the researchers which includes augmented reality by hybrid hardware and software setup [18][47]. However, requirement of comprehensive evaluation of the practical value such as development of substantial educational content demands for further investigation for real use in the classroom for teachers or students. Hand gesture recognition and AR marker recognition were designed previously for geometry learning [19][46]. However, applications for learning 3D geometry by these researches could also be expanded for multi-device environments. Observation on classes and assignments for the students by letting them work with augmented reality is an interesting broad domain which mostly depends on educational design research [20] [43] [44] [46] [48]. However, existing curriculums in the schools at junior level, more passiveness, less constructive contents in the context of teaching media used by researchers, limited understanding of the roles by teachers, lack of ability to create interesting teaching contents demand of extensive investigation in this area of research. Marker based positional tracking as well as picture based positional tracking is another common method among previous researchers due to easiness of implementation for these systems [21][22]. However, due to the limited validation inside classroom environments instead of real world scenarios, these researches could not provide expected satisfactory results. Some augmented reality researchers took gamification a step further in the gaming industry [23]. However, gamification hugely depends on users and participants feedback due to new technology.

For virtual reality based education systems are more reliable to design and construct geometries [24]. Unity3D engine and Vuforia plugin made the tasks easier using camera tracking [25] although previously tested to a small group of students demands further investigation. QR code based tracking method was an old method in this context still attracts researchers since these are quick and easy to implement [26]. However, with the aspects of language, contents, and design QR based tracking requires further validation. Surface tracking, geometry modification and structure from motion pipeline (SFM) has been considered as another potential subsets of augmented reality and virtual reality [27] [28] [29] [30]. Among these methods, structure from motion has been holding higher research interest among researchers. However, due to recent advanced computing systems and user friendly process to construct and visualize point clouds make these research challenging for practical usage although there have been significant improvements in visual quality which still needs deep focus in terms with reducing computational complexity [28]. Perspective geometry [29] is another option by the researchers which has been suffering significantly from complexity and dependency on external hardware. In addition, there are significant errors observed in these kinds of systems and video rendering through augmentation takes a lot of computational cost [29]. Planar surface tracking with the inclusion of background and foreground subtraction is one of the successful method in the area of surface tracking [30]. However, planar surface tracking method did not attain good frame rate although later occlusion management has been improved significantly by the recent advancement in machine learning technology. In the design industry, AR and VR has the most usage observed in the previous research. Some degree of success were found for spatial skill learning where specialized applications were designed and developed in order to put them into training purposes [31]. Existing technology as in research by [32] and [41] were used to build 3D models for visualizing augmented reality which was developed for improving students understanding capability. However, users for these applications requires some degree of geometry and 3D modeling skills. User experience on the existing applications is also another area for improvement observed by the researchers during implementation of gesture control [33].

In this context, hand pose estimation and shape recognition from single hand image or video stream were focused most by the researchers of such gestures and has many applications in augmented reality and virtual reality. Convolutional neural network and 3D hand meshing using LBS were used to recognize hand shape and pose estimation from depth images [34] and initially from RGB images. As part of hybrid approach, hand pose estimation was done from RGB images by adopting multiview RGB images and depth data [49]. However, reliable size of the dataset in lieu multidimensionality, hand to objects and hand to hand interactions were not considered in these researches in order to make the hand shape and pose estimation more robust. Deep learning [40] and monocular RGB cameras advances estimation of hand shape from RGB images [34]. In terms with datasets, researchers put effort to make hand gesture datasets for acceptable validation, however, models trained on one dataset did not perform well on other datasets due to lack of generalization in the training data [35] because researchers found significantly improved results in indoor and outdoor by exploring validation in generalized datasets. In this context, vision based Deep Convolutional Neural Networks (CNNs) attributes the success for hand pose estimation [36] [54] using depth cameras, depth map data with the analysis of effectiveness based on detection based method versus regression based methods. From different viewpoint perspectives, neural network was deployed to model human hands and pose in virtual reality, i.e. MEgATrack: Monochrome Egocentric Articulated Hand-Tracking [38]. In MEgATrack, depth based approaches was used and generated training data from model based tracking system. Research by [38] used DetNet to track hands KeyNet to predict 21 key-points in hand from the cropped image based on the bounding box provided by DetNet in the previous step. However, hand scale and distance recognition were their main challenge to achieve accuracy. MediaPipe pipeline shows prominent progress for handheld mobile phone based hand tracking and hand gestures recognition [37]. Research by [37] used single RGB camera consists of palm detector to provide bounding box of the hand and hand landmark model to predict hand skeleton. However, for multidimensional data, performance of MediaPipe is still not resolved.

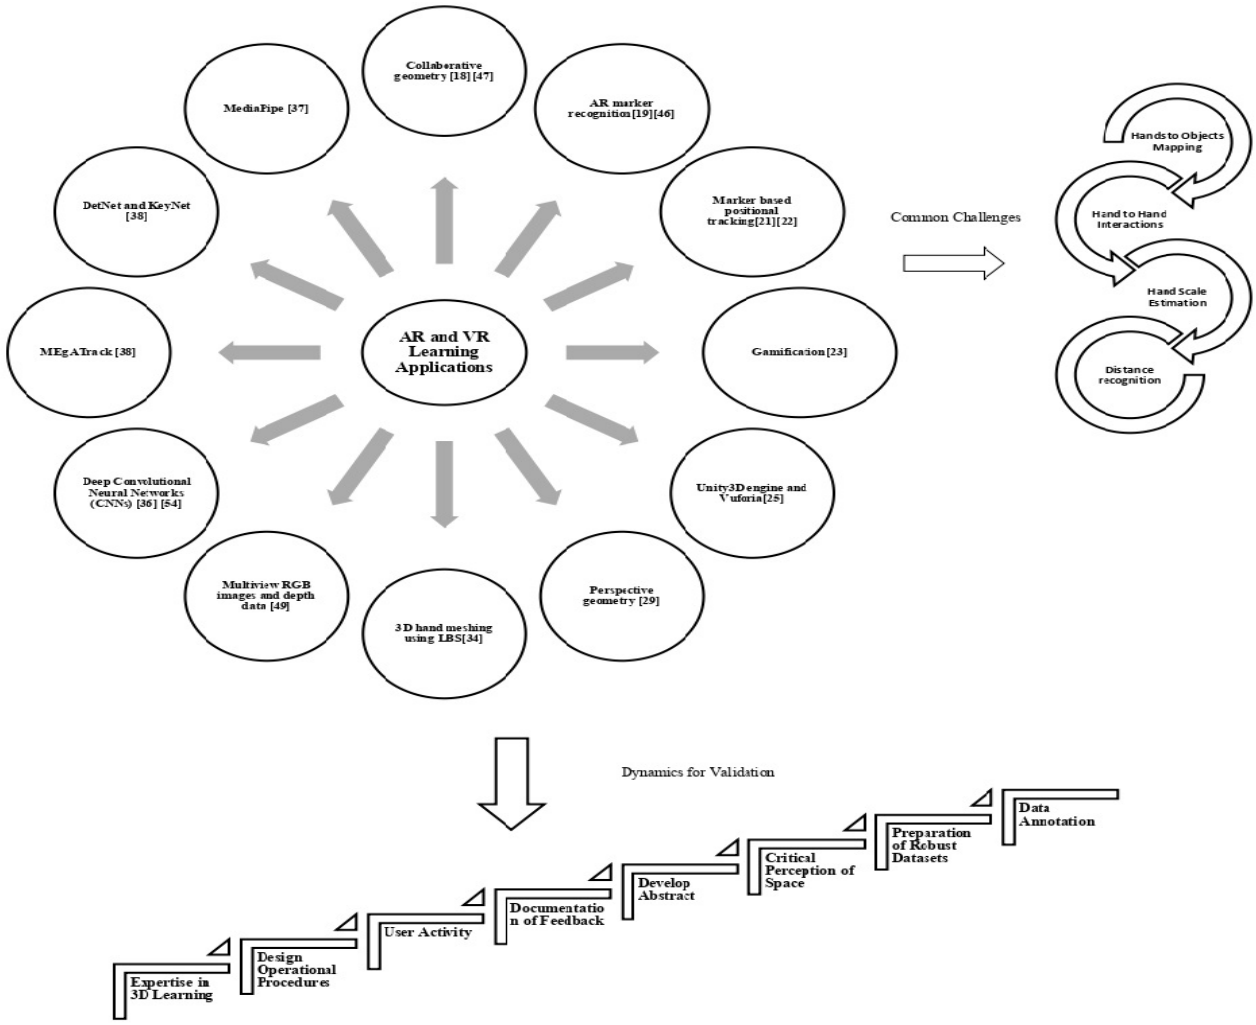

Fig. 1. Methods and Challenges for Augmented and Virtual Reality based Learning Applications.

IV. Step Wise Frameworks Analysis

Majority of the research done in the earlier days of augmented reality and virtual reality consisted of using specialized hardware. Frameworks using Construct3D involves creating user interface and then tracking user hand movement and giving input using pen-like tools [17]. Other similar methods also consist of similar frameworks. Researcher's implemented 3D layer based interaction systems [18]. These methods also require extensive hardware setups and screen projection. For Marker based augmented reality tracking, initial step is to acquire the markers and recognize them and track them in the scene. When combined with software design methodologies, applications become easier to develop and get feedback from users and participants. In these cases, first step is to choose the target participants, users or students, then making prototypes and improving it further [20] [21] [23] [25] [45]. Testing into small groups first and then to a broader range of participants also brings out better results for research [26].

Tracking surfaces for augmented reality was adopted for similar approaches by the second group of researchers. For 3D reconstruction, steps are to acquire a large number of images of the target object and then reconstruct it using different structures-from-motion pipelines [27] followed by rending these objects in 3D and shown on top of video camera feed [28]. In this context, most of the pipelines use offline processing step followed by real time camera tracking and rendering. In the same focus, foreground and background separation techniques provide better results for occlusion management [30]. Applying virtual reality and augmented reality for practical purposes have seen significant increase in recent times. By interacting with 3D objects in virtual reality, users get a better understanding of the subject matter. The primary requirement for these projects is expertise in 3D geometry modeling and then designing operational procedures for users or participants and observing user activity and documentation of feedback [32] [33] [47]. Investigating students understanding of the topic before going into development of the project is suggested by researchers, since that allows researchers to get to know their participants perspective better. Then allowing students to learn and practice by themselves is another good way to get feedback [31]. Researchers have also tried developing abstract and critical perception of space before putting students to use the applications [32].

Preparation of robust datasets and annotation for hand tracking were core research focus for one subset of researchers which not an easy tasks where most researchers prefer training models on synthesized hand gesture data. Straightforward solutions like human pose tracking and applying them to track hand and estimate pose were preferred by some researchers [34] where usage of multiview geometry was a popular approach to attain hand images [35] [41] required heavy hardware set up and accurate annotation manually [50]. Single shot detection is a preferred for image based tracking [58] whereas multicamera tracking in virtual reality is another favorable approach where computational complexity was a big concern.

V. Experimental Analysis

Several works were done in the past for 3D gesture tracking and recognition. A robust gesture detection system by using a single camera is a challenging issue in the area of computer vision [58]. The camera quality is also a challenging part in this context. Most of the researchers that are based on augmented reality uses marked gloves shown for accurate and reliable fingertip tracking [1] [2]. Few methods depend on the object segmentation for the shape or temperature [3] [4] [5]. In most devices, thermal based approaches and expensive infrared cameras are needed but not given in the previous research work. Most of the gesture tracking devices like Kinect are based on depth sensors. These gesture tracking devices are only available for stationary systems because of size and power limitations [6]. In few of the systems, color-based techniques were used but color-based techniques are sensitive for the lights and degrade the quality of gesture recognition and tracking process. Template matching and contour-based techniques suits well for these types of specific hand gesture recognition and tracking [7]. Few systems were designed based on the syntactic analysis of hand gestures by using syntactic pattern recognition paradigm [8]. Few approaches that were designed for smartphones and tablets use accelerometer-based methods with the device's acceleration sensor [9] [10]. For detecting the fingertips, in some gesture based interaction, visual color markers are used [11]. Several researches were proposed for recognition and tracking system of hand gesture which was based on low level edge orientation features and can be implemented by using the hierarchical scoring of the similarity between the query and database images. In these researches, fingertips and all the hand joints that consist of the finger joints are marked from the database. Then, overall system saves the exact position of the marked points with the help of the image coordinates and finds out the relation between the joints in the form [12]. Some researches were conducted to track 3D photos of the human body by using sensor-fusion algorithms [13] [14]. A sensor-fusion method that can track the articulation of the hand in the presence of excessive motion blur was proposed using HPF framework [15]. Gyroscopes are very popularly used when it comes to human body pose estimation but the investigation for the use of gyroscope for hand pose estimation is not completed yet. IMU sensor was used to assist model-based tracking to get more robust performance [16].

Research that was performed in the education domain requires multiple accounts of user questionnaire and feedback. Researchers let their participants use the application and later ask questions to acquire feedback from participants [17] [18] [19]. Researchers made attempts by giving primary knowledge about the subject before exposing them to the real application and later tested again their knowledge level to measure the improvement after using their applications [20] [43]. Extensive data documentation was required for these experiments. In classroom setups, researchers observed students using their application and later asking questions to get feedback. Making a prototype before the final application testing was used by some researchers [23] [45]. In every case, user questionnaires and recording student improvement in learning is the mandatory step for these researches.

Researches also included expert assessment to validate their research [26].

Surface tracking was experimented by researchers for a long time. Researchers experimented with different methods and choose suitable approaches for their research where it is common to experiment with multiple methods [27] [29]. In addition, it is also emphasized to stress test the application under different kinds of motions [39]. A subset of researchers utilizes a preprocessing stage for achieving better performance [30].

In recent years, augmented and virtual reality have been a subject of major experimentation to explore possibilities of different use cases. Researchers investigated students understanding before and after using the applications. Also, letting the participants find how to use the application is one more approach that returns good results [31]. One more investigation was done that lets users acquire little knowledge about a topic beforehand and then let them, use the application and quiz on how much they have improved [32]. Putting augmented reality as well as virtual reality into practical training purposes have brought out better results among technicians. Researchers verified their research by evaluating the participants knowledge and skill after each subsequent phase [33].

Usage of multiple datasets is common for researchers using different parameters and including or excluding different levels of details while annotating the data [34,51-53,59-63]. or FreiHAND, researchers performed cross-dataset generalization to achieve improved results [35]. Evaluating different levels of details and annotation was performed to optimize research effort. Numerous datasets are currently available for hand gesture recognition training [36, 55-57, 64-68] mentioned in Fig. 2. Availability of datasets is a major reason for the increase of research interest for augmented reality and virtual reality domain. For Google MediaPipe, researchers created their own annotated dataset of hand images in the wild, in-house hand images and synthetic hand gesture dataset [37]. By utilizing different datasets for their specific purposes, MediaPipe achieves greater efficiency in terms of performance.

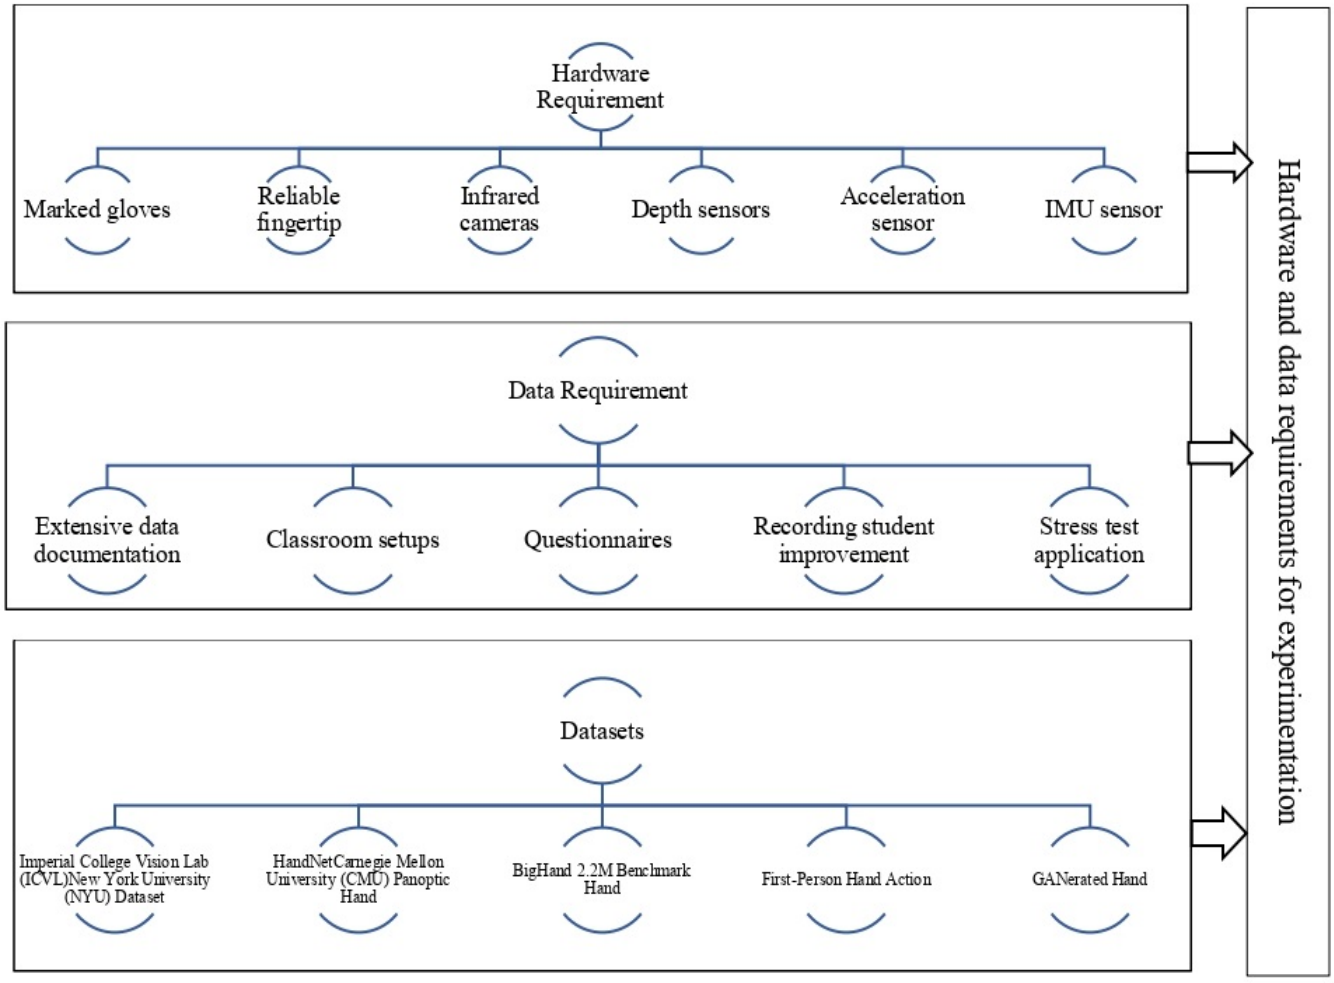

Fig. 2. Experimental Requirements.

VI. Observation and Discussion

This research observes that in recent years there has been a significant amount of research was done in computer vision in the context of 3D gesture tracking based on augmented reality and virtual reality. With the advancement of computer processing power, it is possible to compute and find solution quickly and more accurately. In the earlier days of research on augmented reality and virtual reality there have been requirements of customized hardware support and even so the performance and quality was not satisfactory. At a later stage there has been significant research on tracking planar surfaces as well as tracking objects. By tracking a surface camera position, efficient detection was proposed. On top of those technology, occlusion handling was performed. With greater computer processing power tracking have been more stable in recent times. While there were requirements for heavy hardwares and sensors, after a decade, now it can be performed on a handheld mobile device.

By introducing augmented reality and virtual reality into media, their popularity and research interest have been increased. Comprehensive investigation by this research has observed significant amounts of research as well as practical usage of augmented reality and virtual reality. In the early stage of research for these domains, there was requirement for specialized input pens as well as specialized input panels for interacting with the system. Naturally humans are used to use hands for performing day to day tasks, for this reason tracking hands has been a great interest in recent times. While the technology is not perfect, yet there has been a significant amount of improvement and technological advancement in the past few years.

This research also observed that big technology companies like Microsoft have been working with HoloLens technology which is a high-end mixed reality platform [42]. Google and Apple have their own augmented reality platforms named ARCore and ARKit respectively and there has been a rise in augmented reality applications ever since. Facebook has shown interest in Virtual Reality and with Oculus Virtual Reality systems they have been outperforming themselves every year.

While there have been significant hardware improvements, there has not been improvement in user experience as per with time. Human computer interaction research domain has been working on improving user experience for a few decades now a days and result is improving day by day. There have been touch input display for mobile phones and gesture tracked hand controller for gaming console systems. However, it is high time to investigate more on making the interactions more meaningful for human beings by making interaction between humans and computer more natural.

VII. Conclusion

Hand gesture detection based on augmented reality and virtual reality is an active and ongoing research field which are attracting a lot of research towards the topic. The vastness of both topics makes it interesting to pursue research problems further. In this research, investigation of different usages and implementations of augmented reality and virtual reality based systems was elaborated and discussed in detail. Besides, possibility of neural network based hand palm tracking and hand gesture tracking was illustrated comprehensively. This research found that hand interaction in augmented reality and virtual reality can be achieved with acceptable accuracy based on improved user experience. In addition, this research also emphasizes to focus on usages of augmented reality and virtual reality, tracking surfaces as well as tracking and 3D reconstruction of real life objects in the context of hand palm detection, hand tracking and detecting symbolic gestures from finger shapes. With the keypoint from hand landmark points, 3D mesh can be rendered and that 3D mesh can also be used to interact with augmented and virtual objects in future.

***Abstract*—In the current era of smart cities and smart homes, the patient's data like name, personal details and disease description are highly insecure and violated most often. These details are stored digitally in a network called Electronic Health Record (EHR). The EHR can be useful for future medical researches to enhance patients' healthcare and the performance of clinical practices. These data cannot be accessible for the patients and their caretakers, but they are readily available for unauthorized external agencies and are easily breached by hackers. This creates an imbalance in data accessibility and security. This can be resolved by using blockchain technology. The blockchain creates an immutable ledger and makes the transaction to be decentralized. The blockchain has three key features namely Security, Transparency, and Decentralization. These key features make the system to be highly secured, prevent data manipulation, and can only be accessible by authorized persons. In this paper, a blockchain-based security framework has been proposed to secure the EHR and provide a safe way of accessing the clinical data of the patients for the patients and their caretakers, doctors, and insurance agents using cryptography and decentralization. The proposed system also maintains the balance between data accessibility and security. This paper also establishes how the proposed framework helps doctors, patients, caretakers, and external authorities to securely store and access patients' medical data in EHR.**

Keywords*—Blockchain; electronic health record (EHR); storage; security; accessibility; cryptography; decentralization*

I. Introduction

In the modern world, medical data sharing leads to the discovery of new techniques and treatments for curing several diseases. This can be done by storing the medical data digitally and by facilitating remote accessibility. The data stored in the electronic record is from the patients after visiting the hospital and making them the only owner of such records. The number of data stored in the electronic records is going on the increase and forms big data which can be used for several purposes in the healthcare domain. The vitality of data storage and sharing gives rise to several business entities for collecting, processing, analyzing, and storing the data to share them with other authorized sectors. This process increases several business organizations to focus on cloud storage and processing, data analytics, and provenance that renders existing organizations depending on the availability of data to operate and for their existence. To achieve the high demand in big data storage, several stakeholders invested in cloud computing and storage. This storage attracted the interests of several users including the patients, healthcare sectors, and research sectors for data storage in cloud repositories and provides controlled, cross-domain and flexible sharing of data to the beneficiaries. The major challenge in cloud data storage and sharing is the risk of the data being exposed to unauthorized third parties [1].

With the fundamental development of information and telecommunication technology, health-related services have been brought to the patient's doorstep with the help of the Telecare Medicine Information System (TMIS). The TMIS can help doctors to provide medical support from any remote location by discussing with patients about their illness and also by sharing critical information with other medical experts. In this way, the TMIS can reduce the treatment cost drastically. This system facilitates accurate decision-making in disease diagnosis by accessing up-to-date medical history. But the limitation here is the decision-making for new patients whose medical history and other related data are not available in health records. This can be overcome by using the EHR which holds all the data such as patient's details, scan reports, clinical notes, sensor data, billing details, medications, medical history, insurance details, and other related information. This type of record would suffer privacy and security issues in data-sharing [2]. Recently, wearable device technologies and the Internet of Things (IoT) have been evolving in the healthcare sector. Data from each wearable device were stored in the cloud which can provide big health data and valuable visions. This data is linked with the EHR to improve monitoring the heath, diagnosing the disease, and in the treatment of diseases [3].

The Electronic Medical Record (EMR) is a systematized digital record that holds the healthcare details of patients and populations. The initial perspective of EMR is to replace the traditional paper-based medical records and to enhance hospital data management in healthcare sectors. After that, the increase in the self-health concern, the general population also needed to access health records of their own. Hence, a novel personalized data management of healthcare information has been introduced, which is named Electronic Health Record (EHR) [4].

The EHR and EMR are offering improved security and user experience along with other healthcare-related aspects. Still, some security concerns have been believed to be resolved using Blockchain technology. The blockchain in the healthcare sector provides a secure and temper-proof system for recording medical data. This technology can also prevent inefficiency, insecurity, non-temper-proof, unorganized nature, duplication, and redundancy of data that occurs from the paper-based medical record [5]. State of transactions must not be easily detectable back to the relevant patient populations, according to advocates for transaction privacy on the

blockchain. To do so suggests using tokenization, which is a method of making only a representation to the sensitive material public while keeping the raw, confidential data private. Furthermore, it designates the need for health records to be securely stored off the blockchain. Since this blockchain is frequently used to store references to records stored in an access database, the database should be protected in and of itself. Our architecture protects the information both on blockchain as well as in the database by encoding information in the database.

An EHR is an electronic version of the patient's medical history which includes the patient's clinical data obtained from demographics, progress reports, problems, symptoms, immunization reports, medications, radiology reports, laboratory reports, and immunization reports. Recording the patient details in a paper-based report leads to an extensive paper trail in many healthcare organizations and hence, they are moved to EHR. The EHR should satisfy the requirements like accomplishing whole data, flexibility to failure, being available at any time, and beinging reliable to security guidelines [6]. In the current decade, various technologies have been used to secure patients' private data from healthcare sectors. The healthcare data of a patient includes the patient's details, their height, weight, symptoms of disease-affected, and previous medical history. This medical data grows with time. The data recorded in electronic health records are simple data points but difficult to manage. This record has been generated, stored, and manipulated by several stakeholders for proper patient care and the effective use of such medical records. These stakeholders get authorization whenever they need the data. The EHR is made of the parameters as shown in Fig. 1 [7].

Blockchain consists of a continuous sequence of blocks that stores all the records like a conventional public ledger. A block consists of only one parent block with a block header that holds the previous block hash value. The Ethereum blockchain also stores the uncle block hash values. The first block is called the genesis block. The genesis block has no parent blocks. The block header is given in Fig. 2.

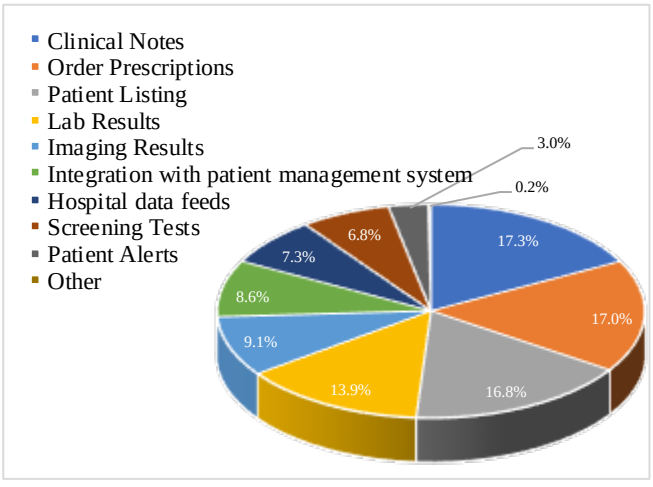

Fig. 1. Parameters of HER.

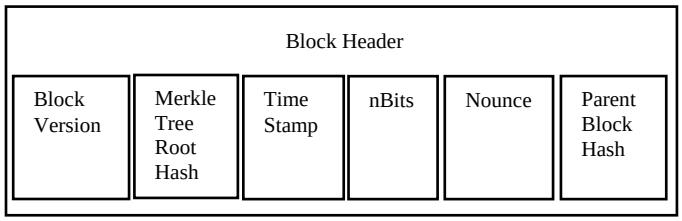

Fig. 2. Structure of Block Header.

Block version - Set of rules for block validation.

Merkle tree root hash - hash value of all records in a block.

Timestamp - Current time in seconds. Universal time since 1-Jan. 1970.

nBits - Target threshold value.

Nonce - 4-byte field starting from 0 and incremented while calculating each hash.

Parent block hash - Hash value with 256-bit pointing to the previous block.

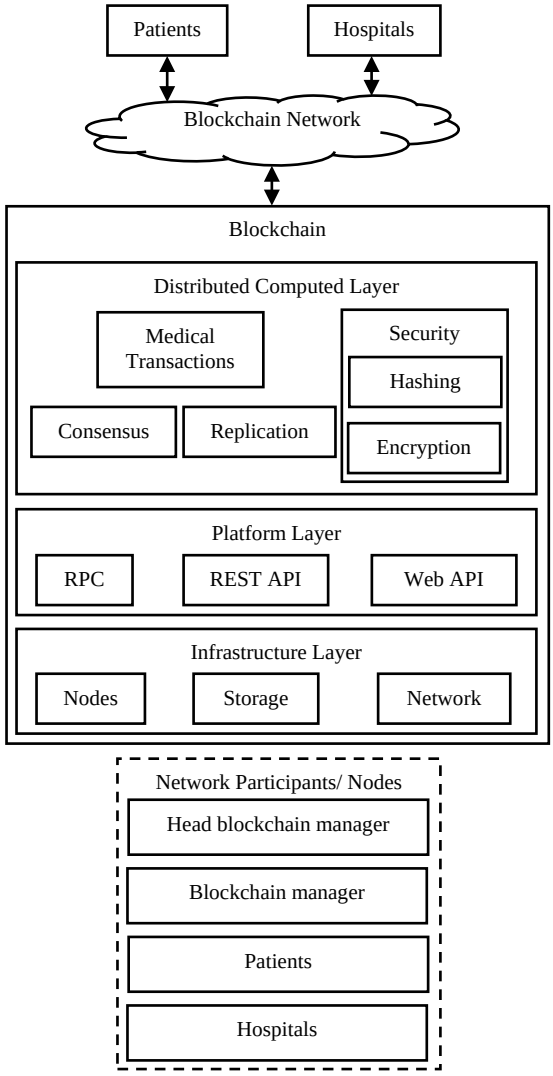

Fig. 3. Architecture of Blockchain Network in Healthcare Data Management.

While blockchain technology has many benefits for an EHR management system, it also has some drawbacks. The primary limitation of blockchain technology is that if % of the system's processing elements collide, the chain structure could be rewritten. To realize the benefits of a decentralized system, group members would have some confidence that at least mining nodes would not like to compromise the blockchain's immutability. Second, while using a permissioned blockchain undermines the incentive of external forces to connect PHI, it cannot hide transaction records. This gives nodes the ability to perform unfavorable network analysis. An adversary may indeed be able to identify the frequency through which a particular node attends a physician or the providers or third parties with whom a focus of previous associates by analyzing blocks of transactions. Finally, because cryptographic algorithms are distributed systems, their operation has a high memory usage. As a result, large amounts of data cannot be retained efficiently on the blockchain. As a result, while blockchains could be used for access management and data integrity, the information itself will be stored somewhere else and may be open to attack unrelated to the blockchain.

In a trustless environment, an asymmetric cryptography-based digital signature has been used throughout the network. Each user has a pair of private and public keys. The digital signature includes the signing and verification phase. The signing phase involves sharing the encrypted data with the private key and the original data. The verification phase involves validation of the data with a public key, whether it has been tampered with or not. The key characteristics of the blockchain are decentralization, persistency, anonymity, and suitability [8]. Fig. 3 shows the architecture of a blockchain network in healthcare data management.

Here, API – Application Programming Interface

RPC – Remote Procedure Calls

REST – REpresentational State Transfer

The traditional method is a Client-Server architecture or Singleton approach. The client is the end-user. The server gets the requests from the client which are then processed and the result will be forwarded to the client. A single authority (Server) will control the whole process. Whenever there is an attack on the server, the whole system will be collapsed. The modern Blockchain technology consists of data split over several systems. Each system is called a node. All the data are stored in a block that is connected via links formed by hash values. To calculate the hash value, the transaction in a block and the hash value of the previous block have been used [9].

The currently using healthcare data management involves centralized servers which seek permission to access multiple entities of medical data in a network which leads to delayed services and can be suspected to leakage of such information. Most of the patients are unaware of which entity stores and uses their medical data in such healthcare systems. The major challenge in this system is the security while accessing the data with various entities within the network. In such cases, Blockchain technology can be used to secure the accessibility and integrity of healthcare-related information [10].

The remaining sections in this paper cover the Related Works which describes the existing approaches that use blockchain in the management of healthcare data in Section 2, followed by the Proposed Methodology in Section 3, then Result and Discussion part in Section 4, and finally, the paper concludes in Section 5.

II. Related Work

A secure cloud-based EHR system has been implemented to accomplish confidentiality, authenticity, and integrity of healthcare data and to facilitate data sharing with the help of the C-AB/IB-ES scheme and blockchain. This system uses 5 entities namely key generation center, hospital, patient, cloud, and users who access the data. At first, the patients sign the health-related data and authorize the hospitals to access their data. This authorization letter will be submitted to the blockchain data pool and wait for consensus node processing. The hospital then encrypts the data and submits it to the data pool with the hospital's signature. The consensus node monitors the data pool and captures the matched authorization letter and the encrypted data. The signature is verified to make sure that the data is completed and with the patient's authorization. Then a consensus protocol would be performed to select a bookkeeping node that submits the encrypted data to the cloud along and the data description and its address were also written to the blockchain [11]. A prototype has been developed and implemented in a mobile platform for data sharing using Amazon cloud computing. This application uses the combination of blockchain and the decentralized Interplanetary File System (IPFS). The Ethereum blockchain has been used to demonstrate the performance of the developed Android mobile application. An Ethereum blockchain has been employed to build the e-healthcare system. Ethereum is a new distributed blockchain network like Bitcoin. The most significant merit of Ethereum is its adaptability and flexible nature which can be used to build an application using blockchain [12].

A permission blockchain network has been implemented for healthcare data management to overcome the issues associated with the permission-less blockchain network. This is because the permissioned blockchain network can overcome the problems like unauthorized network participation which causes impersonation of members, clear transaction data which includes the sensitive and confidential data of the patients that can be accessed by all the members in that network, network throughput is slow which hinders the treatment for patients, limited usability due to the payment for transaction and mining rewards. Also, the permissioned network prevents the demerits of permission-less networks such as high energy consumption, limited scalability, and low transaction throughput [13]. A survey on the investigation of the privacy and security issues while using wearable devices in the healthcare domain is given in [14]. For this survey, wearable healthcare devices have been designed and developed to collect the health-related data of the patients. By analyzing this data, the health status of a patient can be retrieved. The approach followed in this survey is the cross-sectional approach. This survey collected data from 106 respondents. Among them, 50% of respondents don't know the privacy concern in the healthcare data. The respondents

are also unaware of the security issues in the data collected using wearable devices. This survey finally suggests that the patients who are using the wearable devices should be educated about the privacy and security concerns in using them.

A new personal healthcare record sharing system with blockchain-based data integrity verifiable has been implemented in [15]. This scheme aims in resolving the issues that persisted in sharing the healthcare records like privacy disclosure, ability to search using limited keywords, loss in access control rights to share the personal health record. These issues have been overcome by using the techniques like searchable symmetric encryption and encryption based on attributes. This scheme varies from the existing methods in the way, that it uses an attribute private key to be distributed by the patients which avoids several problems that cause security issues in the existing systems. Also, this scheme uses blockchain to manage the keys which prevent the single-point failure issue in the management of centralized key. The efficiency of the data integrity verification has been improved by storing the hash value of the encrypted health data in the blockchain and storing the index set in the smart contract.

A blockchain-based access control manager for managing healthcare-related data has been described in [16]. This system is believed to overcome the challenges faced in interoperability by the industries stated by National Coordinator for Health Information Technology's (ONC) Shared Nationwide Interoperability Roadmap. Interoperability is one of the vital constituents for any structures that support Precision Medicine Initiative (PMI) and Patient-Centered Outcomes Research (PCOR). For access control management, this system uses a public blockchain for the data stored off-blockchain. Published research from the Massachusetts Institute of Technology has been borrowed to analyze the management and access control of personal data in a public blockchain. An implementation of a framework called Decentralized Application (DApp) in a private blockchain network platform using backend Distributed File System (DFS) has been given in [17]. The DApp is now using Proof-of-Work (PoW) consensus algorithm and is later suggested to use Delegated Proof-of-Stack (DPoS) consensus algorithm or Practical Byzantine Fault Tolerance (PBFT) consensus algorithm. This system uses Ethereum for implementing the smart contract-based healthcare blockchain. This application can easily detect anomalies, missing data, and the insertion of unauthorized data. The major elements used in the smart contracts are the events, functions, modifiers, and state variables which were inscribed via a high-level programming language called Solidity. To deploy the smart contract in test-net and test-net ethers, Remix and Kovan test network was applied to pay the fee for the transaction. There are three stages in creating a smart contract using Solidity, namely the writing, compiling, and then announcing. The real-time solidity compiler generates the bytecode and Ethereum Wallet is used in announcing the smart contracts to the blockchain.

The framework proposes prioritizes secure communication and contains several contributions aimed at improving privacy and interoperability. To begin, unlike other blockchain EHR systems that have been proposed, the blockchain stores hashing algorithms of data references while sending the real request network information in a private exchange over the framework. Our framework uses proxy re-encryption to simplify the secure transmission of EHRs, but it lacks techniques like private transactions for privacy. Furthermore, we can store keys and small encoded records straight on the blockchain using proxy re-encryption, making it easier to transfer records like prescribing to dispensaries or even other third parties. This eliminates the need for users to store keys locally, allowing patients to eliminate access permissions if preferred.

A review of Healthcare Information Management Systems (HIMS) based socio-technical issues has been performed and found the problems such as low privacy and security, lack of data transparency, data integrity and accessibility, errors in the prescription of medication and supply chain, and lack of knowledge interpretation. This review also provides the possible solutions in identity and risk management, auditing functions, and solutions for privacy and security issues using blockchain technology. Also, it provides some recommendations for future research and development of HIMS [18]. Model Chain, a healthcare predictive modeling framework for decentralized privacy-preserving in private blockchain network has been demonstrated which uses privacy-preserving online machine learning algorithm adopting blockchain technology, in which the transaction metadata has been applied for distributing the partial model and also designed a proof-of-information system for finding the order of online learning process. This approach aims to improve the interoperability among the organizations to support Nationwide Interoperability Roadmap and national healthcare delivery priorities such as Patient-Centered Outcomes Research (PCOR) and to find the solution for privacy-preserving healthcare predictive modeling by using a peer-to-peer network like blockchain [19].

The health information that is monitored and transmitted by the remote health monitoring devices through IoT has been protected by applying the smart contract mechanism based on blockchain technology to enable secure managing and analyzing the data obtained from medical sensors. Ethereum protocol is applied to a private blockchain network to make the medical sensors communicate with smart devices which call the smart contract and record the events completely into the blockchain network. The use of such a smart contract system facilitates real-time monitoring of patients and their medical data by transmitting them as notifications to the hospitals and patients in a highly secured platform. This approach can solve several security issues occurring in remote health monitoring of patients and automatically notifies the parties involved in the process in a HIPAA-compliant manner [20].

III. Proposed Methodology

The EHR has been managed by the healthcare institutions instead of the respective patients. This leads to difficulty for other health centers to access the patient details to provide perfect medical advice to the patients. Hence, the patients need to retain their health information for future access. The blockchain allows to store the healthcare data and provides

free access to the EHR via corresponding data providers and websites [21]. The proposed system develops a security framework for EHR which provides access to multiple authorities in a shared system using blockchain. Fig. 4 demonstrates the process flow of the proposed framework for healthcare data storage and access.

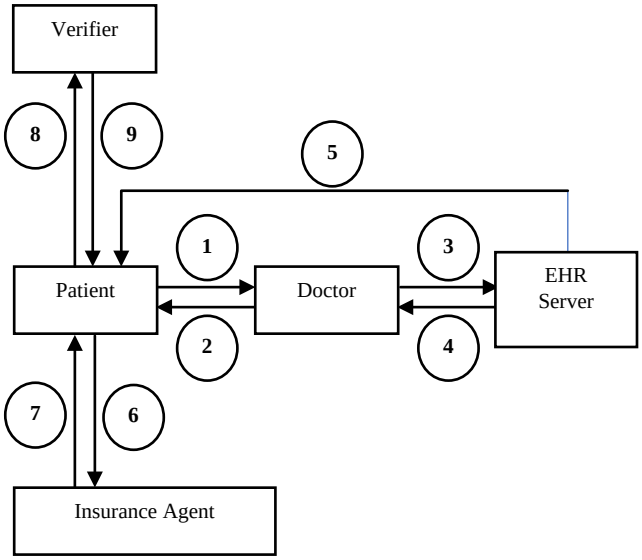

Fig. 4. Proposed Blockchain Framework for Healthcare Data Storage and Access.

The proposed blockchain framework enables the patients to directly access their data from EHR and can able to download and share them. There are 5 parties involved in the multi-user system. They are the Patient, Doctor, EHR Server, Insurance Agent, and the Verifier. The steps involved in the storage and sharing of patient's medical and personal data are given as follows:

1) The patient consults the doctor.

2) Treatment has been given to the patient by the doctor.

3) The EHR Server is a node present in the blockchain network which serves as a miner who collect the transaction data and store them as blocks. After creating the EHR, they are verified by all the nodes in the blockchain network whether it is a valid one or not. These transactions are stored in a memory pool which acts as a waiting area for all the transactions performed on each node and maintains those details within their node. The miner node collects this transaction information and forms it into blocks. The verification of such data can be done by using the hash, which is a 256-bit number that represents unique data. Once the verification got completed, the miner picks it from the memory pool and inserts them into a new block which will then be submitted to the blockchain.

4) Once the block is created, it will be distributed by the miner to all the nodes available in that blockchain network.

5) Access control has been provided to each of the nodes within the network. The proposed framework works in a way that the information of each patient will be secured by them. It means, the patient's details can be accessed by patients and also the doctor who gives treatment to them. This can be done only with the permission of that patient.

6) This data when claimed for insurance purposes, then it will be shared by the doctor who treated that patient to the insurance agent.

7) The insurance agent can refer the EHR of the patients, only who claimed from them and can approve the insurance payment to the patient.

8) The patient then sends the request for the verification of their data to the data verifier.

9) The verifier finally verifies and approves whether the data provided are safe and secured or not and delivers a verification result to the patients.

This framework allows only the patients to view their data in EHR. When a patient permits the doctor who treats them, then that doctor can also view the data. Likewise, the insurance agent can view only the data of the patient who claims insurance amount from them.

Algorithm-1: Formation and addition of Patient Blockchain

Input: Details of Patient for EHR

Output: Forming Patient blockchain and adding blocks to it

- Provide the medical data of the patient to the EHR
- Generate private and public keys using RSA cryptography technique
- The public key is used by the patients for encryption and the private key is for decrypting the encrypted data, by the doctor and insurance agent
- Generate the Hash for Encrypted EHR based on HMAC-SHA1 Algorithm
- With the help of the patient's ID, generate a Bilinear Map for the Encrypted EHR
- With the help of the Patient's name, ID and password, create a genesis block for the Patient
- Add the Encrypted EHR and Hash with Bilinear Map to the Block
- Add this block to the patient blockchain.

Algorithm-1 gives the formation and addition of Patient Blockchain. A Bilinear Map is used to enhance the security of the proposed framework. A function that combines 2 vectors to get a new vector is called the bilinear map which can be mathematically represented as:

$\overrightarrow{v_1} \times \overrightarrow{v_2} \rightarrow y$

Here, $\overrightarrow{v_1}$ = Encrypted EHR

$\overrightarrow{v_2}$ = Patient ID

y = Bilinear Map

This bilinear map is generated using the concept of identity-based encryption. Fig. 5 shows the Patient blockchain which consists of a genesis block with the patient's name, ID, and Password. The treatment taken by the patients has been added as a new block one by one. Only the patient can view the data stored in the patient blockchain, other than that no one can view it.

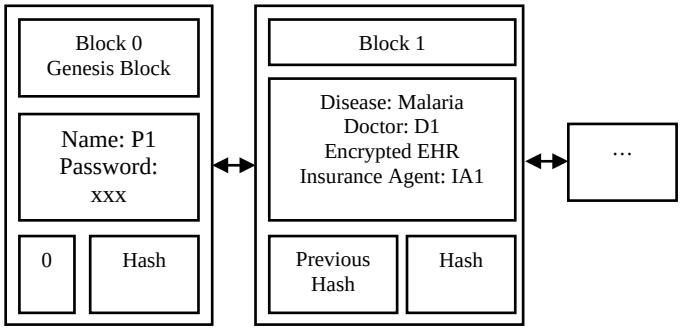

Fig. 5. Patient Blockchain.

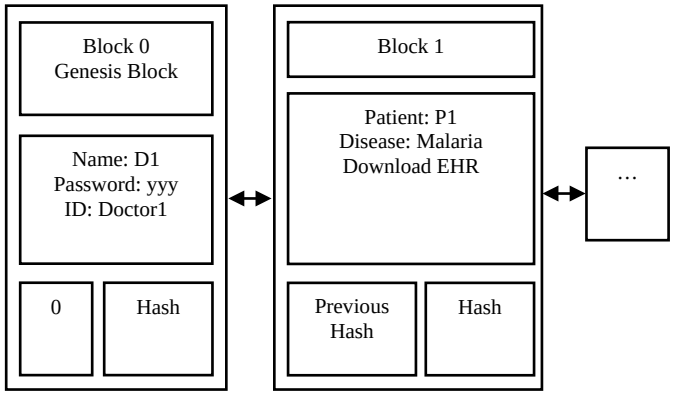

Fig. 6. Doctor Blockchain.

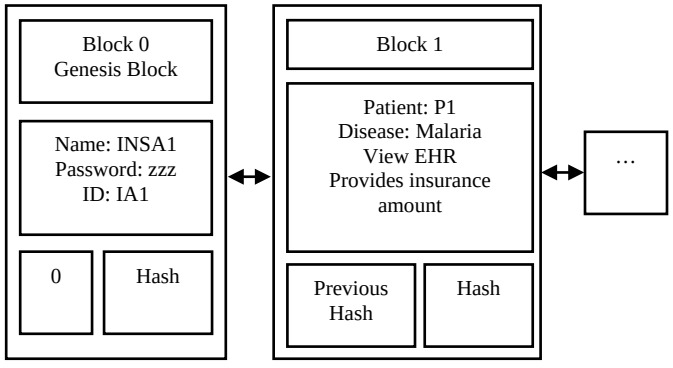

Fig. 7. Insurance Agent Blockchain.

Algorithm-2: Formation and addition of Doctor and Insurance Agent Blockchain

Input: Patient block which is referred from the patient blockchain. Forming Doctor blockchain and adding blocks to it

Output: Forming Insurance Agent blockchain and adding blocks to it

- The doctor and the Insurance Agent downloads the data of the referred patient block to their block with the help of a private key
- Encrypted EHR and Hash with Bilinear Map is retrieved from the block
- Using a private key, decrypt the Encrypted EHR
- The EHR is accessed by the Doctor and the Insurance Agent
- With the help of the Doctor's name, ID and password, create a genesis block for the Doctor similarly create for the Insurance Agent also
- Add the Encrypted EHR and Hash with Bilinear Map to the block
- Add this block to the Doctor blockchain and Insurance Agent blockchain
- The insurance amount for the treatment is transferred to the Patient block.

Algorithm-2 gives the formation and addition of Doctor and Insurance Agent Blockchain. Fig. 6 shows the Doctor Blockchain which consists of a genesis block with the Doctor's name, ID, and password. The information related to the treatment of the diseases was added as a new block one by one. Only the blocks with the patient's permission can be viewed by the doctors. Fig. 7 shows the Insurance Agent Blockchain which consists of a genesis block with the Insurance Agent's name, ID, and password. The information related to the treatment of the diseases was added as a new block one by one. Only the blocks with the patient's permission can be viewed by the insurance agents.

Algorithm-3: Blockchain Validation

Input: Patient Blockchain

Output: Validation Result (Safe or Not Safe)

- Download Patient blockchain
- Status is Safe
- **for** each Block from Blockchain
  - From Block, Encrypted EHR and Hash with Bilinear Map were retrieved
  - Generate new Hash for Encrypted EHR based on HMAC-SHA1 Algorithm
  - Generate new Bilinear Map for Encrypted EHR
- **if** ((Hash == new Hash) & (Bilinear Map == new Bilinear Map)
  - Block = Safe
- **else**
  - Block = Not safe
- **break**
- **end for**

All the data in the EHR were encrypted within the blockchain and cannot be accessed by anyone. The Data Verifier finally verifies the Patient Blockchain, whether it is safe or not. Algorithm 3 gives the steps involved in Blockchain Validation. The block which has to be verified by the data verifier will be searched in the blockchain. Then the Encrypted EHR and the Hash with Bilinear Map will be retrieved based on the HMAC-SHA1 Algorithm, a new Hash for the Encrypted EHR will be generated. Then, if the Hash value is equal to the new Hash value along with the Bilinear Map equal to the new Bilinear Map, the corresponding Block will be considered as Safe Block and if not, then the corresponding Block will be considered as not Safe Block.

IV. Result and Discussion

The access control of the proposed system has been designed in such a way, that the parties like insurance agents and doctors, who were granted permission from the patient can only have the access to the EHR of the patient blockchain so that preventing the access of unauthorized parties to the EHR.

The time consumed for the access of EHR in a blockchain using the proposed approach is compared with existing centralized storage systems and the result has been graphically represented in Fig. 8. Data has been requested to the EHR for accessing and the time is taken to receive the requested data has been noted.

In centralized storage, the EHR will be stored in a centralized server. The patient who needs access to those records should raise an EHR request to the centralized server and this time is noted as T_1. The centralized server, after receiving the EHR request, search for the availability of the particular data and then transmit them to the patient and this time will be noted as T_2. Hence, the time consumed for data retrieval will be calculated using the following formula:

$$Time\ consumtion\ (in\ secs) = T_2 - T_1$$

Moreover, the time consumed for searching and accessing the data would be directly dependent on the size of the EHR. It means the time consumption varies with the size of the EHR, i.e. if the EHR size is small, the time consumed will be less and if the EHR size is large, the time consumed will also be high. The comparison result proves that in centralized storage, the time consumption is higher than that of the proposed blockchain method which has been shown in Fig. 8.

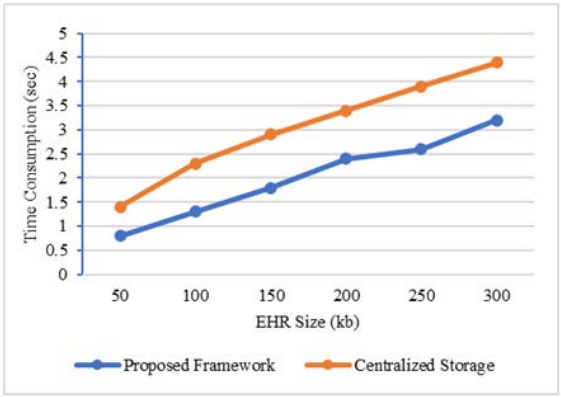

Fig. 8. Comparison of Time Consumption between Centralized Storage and Proposed Framework.

Table I gives the comparison of the features associated with the proposed approach with some existing approaches. The result of the comparison clearly shows that the proposed framework outperforms the existing works and can provide a safe and secure storing and sharing of patient details in EHR using blockchain technology.

TABLE I. Comparison of Proposed Framework with Some Existing Approaches

Feature	[3]	[8]	[9]	[10]	Proposed
Authentication	✓		✓	✓	✓
Identity Management	✓			✓	✓
Decentralized Access		✓	✓	✓	✓
Privacy	✓	✓	✓	✓	✓
Integrity	✓	✓	✓	✓	✓
Availability		✓		✓	✓
Flexibility		✓			✓

V. Conclusion

The proposed framework described the various features of blockchain in the field of healthcare for data storage in EHR and sharing them between the users. This framework overcame the limitations of current data models and supply chains. The access control, time consumption for requesting and searching data in EHR in a blockchain, and the feature comparison were also discussed in this paper and the results show that the proposed system outperforms the existing approaches in all possible ways. From the proposed approach, it is clear that the use of blockchain in healthcare data management prevents data breaches and fraudulent billing and enhances privacy, security, and transparency. Also, data sharing via blockchain facilitates safe and secure sharing among authorized third parties. This approach guarantees secure healthcare management among all the levels which include patients, doctors, hospitals, insurance companies, Pharmaceuticals, etc.

Usability Evaluation of Web Search User Interfaces from the Elderly Perspective

Khalid Krayz Allah, Nor Azman Ismail, Layla Hasan, Wong Yee Leng
School of Computing, Faculty of Engineering
Universiti Teknologi Malaysia Johor, Malaysia

***Abstract*—The elderly population is increasing in many countries, often with health and incapacity challenges, largely disengaged them from the world of digital tools like Internet usage. They browse the Internet daily for obtaining needed information through various search engines through the search UI. Earlier technologies were fabricated for improving daily life, but the specific needs of the elderly are neglected often. Currently, available online search UIs are well-developed, but they did not consider usability in their design specifically for the elderly. This research aims to evaluate web search UIs based on the elderly perspectives to identify existing search UIs usability issues and recommend improvements to web search UI designs. The observation technique evaluated two web search UIs (Google interface and Bing interface) with fifteen participants aged 60 years and above. System Usability Scale (SUS) questionnaire was applied to measure the user satisfaction of the current two interfaces. The data collected from the observations were analyzed using content analysis, while the data acquired from the questionnaires were analyzed using the t-test. The results revealed a statistically significant difference in SUS ratings, with Google scoring 73.5 and Bing scoring 66.5, indicating that users prefer the Google interface over the Bing interface. Besides that, the usability issues were identified, and recommendations to improve the design of the search UI were suggested. These findings contribute to a better understanding of the issues that prevent elderly users from using web search UI and valuable feedback to designers on improving the UI to suit the elderly better.**

***Keywords*—Usability; Google interface; Bing interface; SUS questionnaire; web search user interfaces; observation method**

I. Introduction

The number of elderly people is increasing rapidly in most of the countries in the world as well as their use of the Internet is also increasing [1, 2]. They use the Internet daily for searching various information, mostly via search engines. Due to the growth and impact of information technology in our day-to-day life, one should need to gather more information from the websites. So, searching on the Internet is an important cognitive process to find out the needs of different kinds of resources to achieve their aim [3]. The search UI is the way to communicate and interact the users with search engines to acquire the desired information [4]. Although research on estimation models based on web search logs aims to improve our daily lives, the needs of the elderly are frequently overlooked [5]. Those designs may be challenging to learn and use for elderly people. Researchers are looking at the web search activity for the usage of elders in professional and business domains as a result of this trend.

Furthermore, the user interface (UI) is considered to be an important component of any interactive software system from the users' perspective because it is the most visible front-end component through which the users could see and work with and perform primary evaluation while utilizing the system [6, 7]. As a result, the needs of users in system development would lead to effective user interfaces and useable collaborative systems. Alternatively, the bad user interface design would cause a greater challenge for the users. Yet, there is no clear evidence that poor user interface design is very much challenging.

The exposure to web search for the elderly user is less because of the cognitive functions that reduce due to age [8]. Both elderly and younger ones have some search strategies to use their knowledge and skills. The elderly person searches very little but attains more appropriate information and performs well by acquiring better results [8, 9]. However, elderly users cannot adapt to a newer searching strategy and change their search pattern or style even for highly challenging search tasks [9, 10]. Also, elderly users have physical problems like visual impairment, colour identification etc., cognitive impairment, knowledge about computers and technologies [10].

Usability is an essential key factor for the software developers or users, as it ensures the successiveness of the system and its further development by focusing on the needs and requirements of the users [11, 12]. Usability, according to ISO 9241 [13], is defined as the absence of usability difficulties or the measuring of efficiency, effectiveness and satisfaction. Usability is contingent on the absence of usability issues. The main concern of users is the usability of the software and the consequences of utilizing it without the knowledge of the systems core components, it is working, or its production [14]. While developing software, the needs of the users must be considered and given careful consideration.

Various usability evaluation methods were developed, which comprises a set of techniques for evaluating the usability of the systems user interface and identifying specific issues [15, 12]. In general, usability evaluation methods can be categorized into expert-based and user-based [8, 9].

Expert-based techniques, often called inspection methods, involve experts evaluating the user interface and identifying potential issues that users might encounter while interacting [16]. Such studies can result in a formal report highlighting problems or making suggestions for improvements [17]. The heuristic evaluation method and cognitive walkthrough

method are the two most commonly utilized expert-based usability approaches in the area of human interaction [18].

User-based techniques, as well known as test methods, are useful evaluation methods for obtaining information about real users' behaviours as well as finding and identifying usability issues by noticing people that represent users be using on the system interface [9, 10]. User-based techniques are used to see how well a system assists the end-user with their tasks [8]. Empirical or experimental techniques, methods used in this study, query methods, and physiological monitoring methods, such as gaze and heart rate and skin conductance measurements, are all extensively used in the field of human-computer interaction among the various approaches that are based on the users [18].

Several earlier studies evaluated the usability of search UIs based on user-based methods for elderly people [19, 20, 21, 22]. Furthermore, there seems to be a scarcity of research that assesses the usability of search engine UIs and offers particular changes to their design to make them easier to use by the elderly.

This research aims to evaluate the usability of web search UIs from elderly users' perspectives to uncover the usability issues on these UIs, and based on the results to suggest specific recommendations for usable web search UIs for elderly people.

The specific objectives of this research are:

1) To use observational techniques to identify usability issues on two common web search user interfaces; Google and Bing.

2) To use the System Usability Scale (SUS) questionnaire to measure the user satisfaction of the two web search user interfaces (Google interface and Bing interface).

3) To identify additional user requirements that could aid in creating a proposed design for the newly designed UI for the elderly group.

4) To recommend specific improvements to design usable web search user interfaces for elderly users.

The results of this research will uncover challenges on the search UIs from the perspectives of elderly users and would reflect the requirements to conduct the improvements process to meet users' needs and requirements. This will enhance the ease of use of web searching by the elderly community and provide information to web search interface designers about possible improvements for designing a user-friendly search user interface for elderly users.

This research is divided into six sections. Section II presents earlier studies that evaluated the usability of web search user interfaces for elderly users. The methodology is presented in Section III. Section IV presents the results, while Section V presents the discussion. Finally, in Section VI, the conclusion is outlined.

II. Usability Evaluation for the Elderly

The literature showed that research had been done to evaluate the usability of desktop or laptop user interfaces for elderly people. Many studies have been published that employed usability testing to evaluate the usability of websites and smartphone user interfaces for elderly users using representative user groups [19 - 23]. Specifically, Patsoule and Koutsabasis conducted a comparative usability evaluation of two websites where the participants with 12 older adults aged 65 years and over [24]. Controlled usability testing, as well as post hoc interviews and questionnaires, were employed to assess their performance on six standardized activities. The rebuilt website was far more functional and acceptable than the previous version [24].

In addition, Haesner et al. (2018) conducted a usability test with older users to analyze the usability and acceptance of Google Glass [25]. The participants were 30 elders aged 65 and up who were requested to complete a set of standardized tasks and evaluate usability using a system usability scale questionnaire in order to acquire valuable information into specific usability difficulties. The final findings revealed that usability should be considered while developing mobile applications for elderly people by using Google Glass [25].

Alternatively, there have been a number of user evaluation studies of web search UIs based on user-based methods [19, 20.21,22]. Sanchiz et al. (2019) used eye-tracking metrics to test 9 search issues using standard web browsers and/or empirical search interfaces. The final empirical findings showed that older adults spend significantly more time on search engines than younger adults [4].

More specifically, Aula et al. [19, 26] have conducted two usability tests to compare the usability of Etsin, a friendly search engine for the elderly, and Google by giving search tasks to elderly users. The observation method was used to monitor the elderly's interacting behavior during the search tasks, followed by an interview to find all usability problems of web user interface engines. The results identified age-related issues in the search UIs that should be taken into account, which are beneficial to elderly users. For example, the search engine interface should be a simple one that is easy to use and understand.

III. Research Methodology

This study is conducted in three phases: usability testing, evaluation, and analyzing and interpreting data, as shown in Fig. 1. To achieve the objectives of this research, two usability testing methods were employed: observation and System Usability Scale (SUS) questionnaire. This section consists of five sub-sections which describes: the methods employed in this research, participants, apparatus, the procedure of the testing, and the analysis of the collected data.

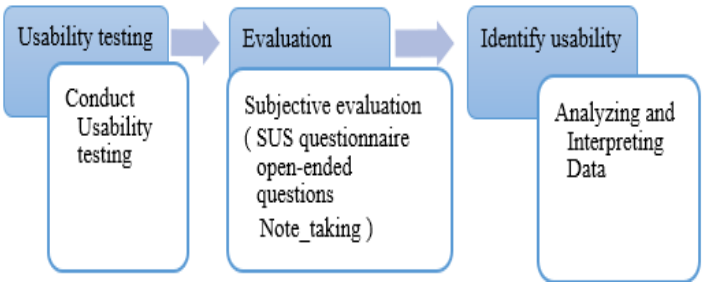

Fig. 1. Three Main Phases of the Methodology.

A. Methods

1) Observation and note-taking: Observing how users interact with a system is a common technique to learn more about its use. This technique tries to monitor participants while they utilize the web search user interface to conduct their searches. Taking notes during the usability test, these participants' reactions to the challenges they encounter while engaging with the system are also recorded [19, 22, 26]. Conducting a usability test is the most effective way to obtain high-quality qualitative data by observing the interface and users' reactions to the task, which allows the practitioner to quickly identify system design flaws [27, 28]. As a result, the practitioner observed the participants throughout the sessions and took notes. As a result, users are encouraged to "think aloud" about their actions [29].

In this research, observers were employed to take notes and observe the participation behaviors while interacting with the interfaces during the usability test.

2) System usability scale (SUS): The system usability scale (SUS) is a popular tool among HCI researchers for assessing perceived usability in both usability and survey research [30, 31, 32]. According to reports, the SUS was used in 43% of usability studies [33, 34]. Furthermore, a study that evaluated SUS discovered a valid and reliable tool for evaluating usability [34, 35]. The SUS is a ten items questionnaire with alternating positive and negative statements and a five-point Likert scale spanning from strongly disagree to strongly agree in ascending order designed to avoid answer biases. These ten items will be assessed, and a final score (0–100) will be determined by grading them from A to F or using adjective ratings. Bangor Different SUS grade rankings are presented by Kortum and Miller [36]. Before 2009, the SUS study was only focused on perceived usability (unidimensional). However, Lewis and Sauro [34, 37] suggested that the SUS is a bi-dimensional measure (usability and learnability sub-scales) in 2017. If the research situation is convenient and the participants are experienced, the SUS was advised in employing bi-dimensional analyses [37, 38]. Furthermore, according to Tullis and Stetson [34, 39], SUS allows researchers to test perceived usability with a small sample size of 8–12.

In this study, bi-dimensional and unidimensional analyses of the SUS scale were undertaken due to the diverse backgrounds of the participants.

B. Participates

The participants were recruited from elderly homes and through personal contacts. The participants in the study were given a feedback form with demographic information and questions regarding their computer and Internet search experience.

C. Apparatus

Windows operating system ten was utilized by all of the participants in the search sessions. Only nine users used Chrome to access the Google interface, while six used Mozilla Firefox to access the Bing interface. The monitors were identical in size and resolution (1024 x 768 on a 15-inch panel).

D. Procedure

At the start of the usability evaluation, all of the participants were told that the study was all about finding facts on the Internet and gathering data on how useful the interface is. They were also told that throughout the test session, they might run into some difficulties with a specific test task in which they don't have to worry, and if they feel difficult to finish it, then they can just say that it is difficult to continue and would like to stop, and can move on to the next task. They were also promised that if they typed text into the text field, the search engine would return any publications that contained the text or all the text they had entered. Before the test began, the participants signed a document indicating their consent to participate in the testing as well as the recording and reporting of their responses for the study.

All of the participants were given a sequence of seven search tasks containing a variety of interests. They were also instructed to conduct relevant searches on those topics using the Google and Bing search engines. They were then invited to ask the first question for the job of their choice and then proceed with the activity normally. The participants utilized the computer on their own during the search phase. They were, however, able to ask questions and receive assistance if needed during the search.

The search session was for 20-30 minutes. During the session, observers were present to take note of the participants' reactions while using the search engine. After the participants searched in the search engine, all the participants were given a questionnaire having a set of questions about the interface they have worked on to detect usability issues and additional users' requirements. The questions were intended in such a way that it uses the SUS questionnaire for UI satisfaction [18, 40]. The satisfaction of the participants is measured on a scale of 5-points. The questions include the overall reaction to the web search interface. Two open-ended questions allowed the participants to write down the positive and the negative feedback about the interface in their point of view. These questions provide valuable information about the interface design in addition to the statistical data. Finally, to make it easier to relate the interfaces, they were shown both of them simultaneously with the different questions with the same meaning.

E. Analyzing and Interpreting Data

Following the sessions, the observers went through their notes and the questionnaires to flesh out the usability issues, mostly experienced by more than eight of the fifteen participants for each search UI. During the search, the participants' verbalizations and behaviours were recorded. Following that, a list of usability issues for each interface was developed. Finally, the common usability issues and participant behaviour observations found in both the Google engine interface and the Bing engine interface were assembled.

IV. Results

A. Participants' Characteristics

A total of 15 people volunteered in this study, eight male (53%) and seven female (47%). All of the participants were above 60 years old, with an average age of 62.5 years for males and 61.5 years for females. The age ranges from 60 to 67 years for males and from 60 to 65 years for females. The demographic information of the participants is summarized in Table I. All of the participants used computers in their daily lives when it came to searching the Internet, with an average experience of 9 years (3 to 10 years). The majority of male participants utilized the Internet to search on a regular basis, while female participants had an average experience of 4 years (2 to 7 years). Most of the participants had previous experience with search engines like Bing, Google, and MSN Search, where the others are rookie searchers who are mostly directed to facts from well-known URLs, if at all.

TABLE I. The Participants' Information

Participates sample characterization		
Gender	Male, 8 (53%)	Female, 7 (47%)
Mean Age	62.5	61.57
Mean Experience	6 years	4 years

B. Qualitative Results

This sub-section presents the qualitative results obtained from the content analysis of the observation and note-taking methods and the questionnaire's open-ended questions. It shows the major problems that the elderly users faced while interacting with both interfaces, which provide important information about their perspectives and experiences. The collected data were transcribed as clear data, as shown in Table II.

TABLE II. Usability Problems Identified from the Qualitative Results

Usability Problems	**Google Interface**	**Bing Interface**
The default font size is small. Also, the font size varies from one browser to another.	✓	✓
The voice search button, the image search button and the text search button are small and close to each other.	✓	✓
Difficult to go back to bookmark and history in different browsers	✓	✓
A large number of results		✓
Misunderstanding suggested results such as People Also Search For and Related Searches	✓	✓
The home page is long		✓
Scrolling a page is a difficult task	✓	✓
Unclear to go back to the home page	✓	✓
Lots of different colours in the default page background		✓
The main and result page view is slightly unstructured	✓	✓
The setting menu is complex.	✓	✓

Despite some participants being less experienced Internet users, all participants could successfully complete at least five out of seven search tasks during the search sessions. Also, it was noticed that the number of tasks performed by the more experienced participants differed significantly from those done by less experienced in this field.

The majority of issues stemmed from a lack of understanding of the basic web structure (using the back button to go to the main page) and using standard interaction styles (typing a query into the search box without concentrating and expecting the request to be completed without clicking on the search button). These issues appeared to perplex new users; they were more annoying. The expectation that these issues will arise due to a lack of practice with standard interaction elements and the expectation that the problems will be less with the experience. These issues can also be alleviated by interface design solutions, which will be discussed later.

The results of the usability tests were analyzed to create a list of the issues discovered through the observational technique and open-ended questions. Then, a new solution for the prototype was proposed. The following go over the problems that were discovered:

1) Button size: For a user-friendly interface, bigger button sizes have greater significance. The button size of the main navigation links and the home page is intended to be an important standard because the on-screen button size has a greater effect on interacting speed and communication accuracy. The clicking accuracy with a target diameter of 64-pixels was significantly better than on 32-pixel targets for elders.

2) Font size: Also, font size is another major problem needed to be considered. Fancy font types with font sizes below 14 cause loss of clarity for the elderly people in accessing, and these findings are in line with previous research [41]. Therefore, the utility will be more effective if the font size chosen is at the size of 18 pts.

3) Searching ways: There are common ways of searching in use: searching by text, searching by voice, and searching by image. There is a misunderstanding between searching by voice, text, and image by elderly users. They should be separated from each other with enough space and recognized with the button. Also, the button should be having a recognized name or logo to show the differences between them.

4) Home page length: Page scrolling is a complex task for aged people as they require using drag-and-drop or mouse scrolling. Also, they have reduced memory capability than the younger. So, while scrolling the lengthy home page, the contents on the first screen couldn't be recalled, and they got confused. Hence, for older people, if the page length is within one screen, it would be better than having 2 to 3 screens. For aged ones, it would be easier if the average quantity of associated results exposed on the screen was around 5 to 7.

5) Backtracking support: The use of the back button to return to the home page or previous results page after seeing

the result document generates a lot of confusion among elderly users since they don't grasp the web's structure and can't tell the difference between the back and forward and home buttons. Elderly users frequently misunderstand the back button on a browser or a webpage, resulting in returning to the same page. These conditions cause elderly users to be unable to distinguish between the functions of each button. Every time an elderly user clicked on the forward, back, or home buttons, they needed some assistance from their moderators to confidently click on them and avoid being lost. These findings are consistent with Cioara et al.'s study [42]. For elderly users, it would be preferable if the search result were displayed in a separate tab or window, allowing them to go to the webpage they desired quickly. It is also quite beneficial if the pop-up window is smaller than the existing window since it allows them to return to the original window by simply clicking on it.

6) Colour contrast of foreground and background objects: Because of aging, elderly users cannot precisely distinguish colour variations like pink, magenta, and purple. Suppose the scenario rises for clicking the particular colour button to move on to the next. In that case, the aged people could not perform well, as their retina could not clearly support the vision to differentiate the color variations. This may lead to mistakes and errors while browsing, and this reduces the search accuracy. Also, the color contrasting of the foreground and the background objects is a major problem, i.e., if the texts in the light background are dim, then it would be hard for the older user to read and proceed further because their vision would not support with age. The web page layout with an off-white background and a high contrast text over a pale background is easy for the older to read.

7) Menu: The observation results found that elderly users are confused by the Hamburger menu and Dropdown menu. Pull-right menus are also challenging for elderly people to navigate, and they frequently have to make multiple attempts before even being able to choose their preferred option. Thus, simpler menus are healthier choices, such as the Classic navigation menu and Sidebar menu.

8) Search results: Search results refer to the list created by search engines in response to a query. Today's search results also include sponsored search results. In addition, the search results also show Related Searches, People Also Search For, People Also Ask, and Top Stories etc. Because of that, elderly people misunderstand these suggested results. For the elders, the view of less is more, so natural search results returned by the search engine's internal evaluation algorithm based on relevancy are better suited and do not include any other results.

9) Result page view: Because users do not often process search results in a logical order, today's search-results pages could have a wide range of layouts. They use the pin-ball pattern to distribute their attention more evenly across the page than in the past. Images, video, embedded text content, and even interactive features are frequently included in today's search engine results pages. Any given search can yield a wide variety of visual elements. The variety of information and presentation is crucial in shifting user attention throughout the SERP [43]. To make it easier for the elderly to find the information, they need a simple list of less than ten blue links, each neatly packaged with a URL, blue link, and text snippet.

C. Results of System Usability Scale (SUS)

In a test between two web search interfaces, randomly 15 users worked with two web search user interfaces (Google and Bing). They conducted seven different tasks on both interfaces before completing the ten-item SUS questionnaire [44], with the findings provided in Table III. (The difference score is calculated by subtracting the Bing interfaces score from the Google interfaces score) [45].

TABLE III. PAIRS OF SYSTEM USABILITY SCALE SCORES AND THEIR DIFFERENCES

Participant	Google interface	Bing Interface	Differences
1	77.5	72.5	5
2	67.5	65	2.5
3	70	65	5
4	65	57.5	7.5
5	65	32.5	32.5
6	80	72.5	7.5
7	70	67.5	2.5
8	77.5	65	12.5
9	70	70	0
10	77.5	67.5	10
11	80	70	10
12	77.5	75	2.5
13	75	75	0
14	70	67.5	2.5
15	80	75	5
Mean	73.5	66.5	7

To measure aspects related to interface usability, by using the SUS questionnaire [46], created by John Brooke in 1996 [47] with the minor modifications by Finstad [46] in 2006. It is a versatile and quick method that is extensively used to assess the system's usability.

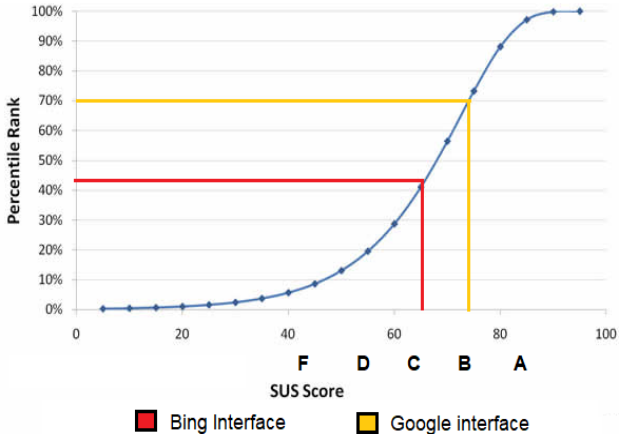

Fig. 2. Percentile Rankings of SUS Scores from between Bing Interface and Google Interface.

The SUS mark in Google Interface was estimated as 73.5, which is more than the average of 68, and the SUS mark in Bing Interface was 66.5, which is less than the average of 68. The results of the SUS are presented in Table III. In addition, the percentile rank recommended by Sauro in 2012 [40] was mapped to the measured SUS score, and the percentage was determined, as shown in Fig. 2. The SUS score of Bing is equivalent to 45% or grade C+, and the SUS score of Google Interface is equivalent to 69% or grade B+.

Following the score analysis recommended by Bangor et al. in 2009 [48], the usability of the Google Interface is valued as "Good", and the usability of the Bing Interface is valued as "Ok" (see Fig. 3). As a result, the usability level of the UI is considered to be difficult. However, it may not be said that the usability of the interface is poor.

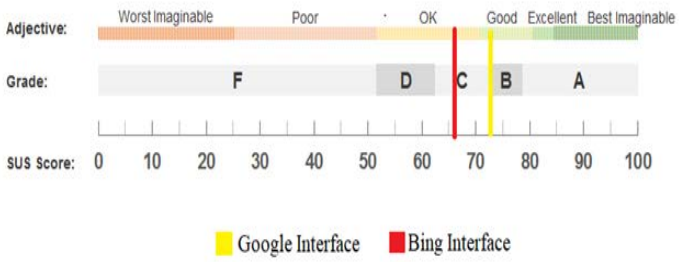

Fig. 3. Mapping the SUS Score on the Bangor & AL (2009) Interpretation Diagram.

According to Lewis and Sauro in 2009 [49], the learnability score of a system can be calculated individually from usability as the second aspect of SUS, as presented in Fig. 4.

Learnability = (item 10 + item 4) * 12.5

Usability = sum of Item (1,2,3,5,6,7,8,9) *3.125

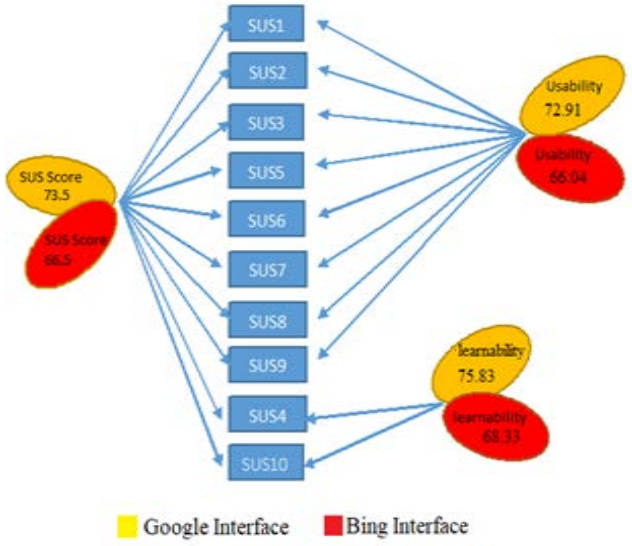

Fig. 4. Illustrate Usability, SUS Score and Learnability.

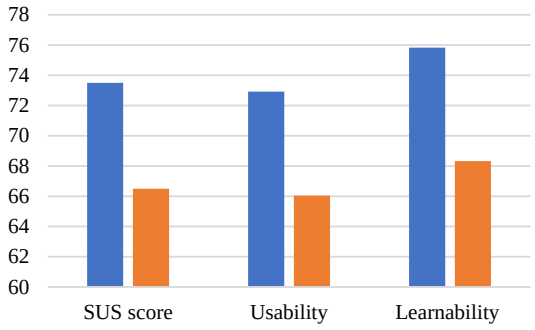

Fig. 5. Google Interface and Bing Interface and their Usability and Learnability Differences.

According to the collected data, the Google UI has a learnability score of 75.83, whereas the Bing UI has 68.33. They are remarkably low than the usability score in both interfaces, which was 72.91 and 66.04, as shown in Fig. 4. As a result, the usability level for the Bing interface is lower than the learnability level. It is rated as OK, whereas the usability level for the Google interface is virtually Good. Clearly, greater thought should be given to the factors that influence usability during the design process.

From Fig. 5, it is observed that the usability score of the Google interface is greater than that of the Bing interface, with the mean value of 72.91 and 66.04, respectively. This shows that the Google interface is more user friendly for elderly people compared with the Bing interface.

The paired t-test (often called the paired-samples t-test) compares the average of two related groups to see if they differ statistically significantly [45]. The results of the paired-samples t-test obtained using SPSS software are shown in Tables IV, Table V, and Table VI.

TABLE IV. GOOGLE AND BING SUS PAIRED SAMPLES STATISTIC

Pair 1	**Mean**	**N**	**Std. Deviation**	**Std. Error Mean**
Google_SUS	73.5000	15	5.49350	1.41842
Bing_SUS	66.5000	15	10.55597	2.72554

TABLE V. GOOGLE AND BING SUS PAIRED SAMPLES CORRELATION

Pair 1	**N**	**Correlation**	**Sig.**
Google_SUS & Bing_SUS	15	.696	.004

TABLE VI. GOOGLE AND BING SUS PAIRED SAMPLES TEST

Pair 1	***Mean***	**Paired Differences**				**t**	***df***	***Sig. (2-tailed)***
		Std. Deviation	***Std. Error Mean***	**95% Confidence Interval of the Difference**				
				Lower	***Upper***			
SUS of Google & Bing	7.0	7.80339	2.01483	2.67863	11.32137	3.474	14	.004

A test statistic (t) is equal to 3.474. The p-value is used to determine whether this is significant or not. Because this is a two-sided test, the result is significant at $p < .05$.

In this study, the p-value is = 0.004 and the p-value is <0 .05. This value is too small, which mean that there is less than one in a billion chances that the means SUS scores are equal to each other. We can also conclude that it can be over 99.6% sure that the Google and Bing interfaces have different SUS scores. Google interface's SUS score of 73.5 is statistically higher than Bing interfaces of 66.50. Also, the Google interface shows a reduced standard mean error rate of 1.41842 compared to the Bing interface (2.72554). So, it can be concluded that elderly users perceived the Google interface as easier to use than the Bing interface.

V. Discussion

In both Google and Bing, the least experienced users had significantly more usability issues when using the search engines. This shows that practice with search engines is advantageous, if not essential, for efficient search (the same is true for young; see Pollock and Hockley) [50].

In Google, the most frequent ease of use issue was with the usage of smaller fonts for buttons and explanation as the participants were not able to focus and understand the text written to bring the mouse over and click them properly. The user can change the size of the text on well-designed websites on their own. However, without resizing the entire page, which can be done using the browser's zoom, the text boxes and the font used inside the boxes cannot be resized well. As a result, to make searching easier for people with low vision, text boxes and fonts should be larger or, at the very least, resized as the text size is increased. It would be easier for elderly users to modify their queries if the font was larger and the gaps between letters were wider.

Another reason for the smaller font size concerns in Google and Bing is unquestionably the participants' lack of knowledge with the keyboard (e.g., both the Backspace button and Delete button confused participants) and the mouse (e.g., keeping the mouse still while clicking). Nonetheless, age-related psychomotor issues additionally added to this issue by making it harder to perform fine motor movements, particularly when the target text or button is small (e.g., when attempting to situate the cursor between two letters). Bigger textual style, bigger letter spacing and "clear content-box" buttons may help the elderly participants better as these would help focus them on the target with the cursor easily. Besides that, adding a clear button to clear the text box query with one click may help them to reduce using Backspace and Delete buttons.

Similar to Aula and kaki, many participants often had problems due to a lack of knowledge of the web's structure [19, 26]. Even though the participants understood the basic working of the back button, they could not get back to the first search page after following the result pages one after another. This outcome demonstrates that the Internet browser interfaces may not be as natural as Kubeck et al. [51] introduced. Some pre-planning may be necessary to make the initial browsing experience less perplexing. Opening the results in a new web browser or in browsers that allow tabbed browsers to open in new tabs might remedy the issues stated above. This technique keeps the main results page of the web search, allowing users to view back the results from there.

Apart from this, the many advanced functionalities of Google and Bing, like advanced search, search tools, language setting etc., confused the participants. Thus, aiming to provide older adults with a simple, easy–to–use interface would be more beneficial. Advanced searching can be thought of as an option for experienced users. Some participants accidentally clicked it and were confused with its working and couldn't get back to the basic search page without assistance. Thus, it's better to altogether avoid the advanced search option. However, the language option seems more important for those users who are not well acquainted with English, and so it's recommended to have the language option.

Participants in both Google and Bing frequently neglect to focus and click into the search text box before typing in the search text box, which is a widespread problem. The only visible difference between having the cursor on top of the search text box and really having the focus on the text box is whether or not the cursor blinks. You can type text into the search text box if it blinks. This indication is clearly insufficient for people with reduced vision as the elderly are more concentrated on the keyboard while typing than on the screen. To alleviate this problem when the search text box is off–focus, Aula et al. made the focused feedback increasingly via greying the search text box and the text and provided a thick border and black highlighted text whenever the focus was in the search text box [26]. When the user types without focusing on the search text box, an attention sound is recommended. Furthermore, some volunteers placed the mouse cursor on top of the search text box before attempting to edit the search query but then failed to press the click to move the focus to the search text box. Thus, the suggestion is similar to Aula et al. [26], which to grey the search text box and the button when the cursor is not in the text box and also to have a tooltip with the text "Click the mouse button to insert text" when the mouse pointer is above the text box.

In many cases, it was seen that the users started searching their queries within the resultant websites without even realizing that they had left the search engine. As an outcome, they came up with better new queries inside the site search but received no results. After being indicated to attempt the inquiry again utilizing a search engine, they could find the results. Thus, with better training regarding the web search engine, the participants would probably be more at ease in using the search engine.

In Google and Bing, information related to the previously visited search results is saved at the history menu and also bookmarked results are saved in the browser. Thus, participants faced difficulties going back to previously visited results and bookmarked results in different browsers. Because each browser has its way to bookmark results and save the history browsing, it would be better to design Bookmark and History menus in the main page interface as part of interface elements to solve this confusion. So whatever browser was used, all UI elements is still the same, and the bookmark and history menus will be loaded with when opened by any browser.

Occasionally, information from a previous search was mixed with information from a recent Google and Bing engine search. Thus, after typing in a new query and noticing a wrong result list, participants wanted to get back to the original search page, but they did not know how to. It would be better to provide users with a clear starting point for new searches to alleviate this confusion. Thus, a separate "Begin new search" button is recommended to clear all the information about the previous searches [19, 26] and provide a natural starting point for new search tasks.

VI. Suggested Solution

This study discovered that a simple design tends to make the search experience for elderly people less troublesome and more manageable. Many participants also expressed that search interfaces with all their different colours seemed messy and complex. It's recommended that the improved search engine for elders use colours sparingly.

The goal of the improved search engine interface is not to displace more complicated systems, but to provide elderly people with the option of using a basic search engine, personalized and adaptable interface and easy–to–use interface for using the web for their daily Internet searching to overcoming their weak intellectual and physical abilities, as well as their cognitive abilities.

Table VII presents suggested improvements to design a usable web search user interface for elderly users based on the elderly users' major problems during interacting with both interfaces.

The suggested elderly web search interface for the elderly community is based on the finding from the experimental results of Both Google and Being interface from the elderly perspective and previous studies. In addition to the original features of existing search interfaces, the new web search user interface for elderly users allows customization towards the users' wishes. According to Peter Brusilovsky and Maybury [52, 53], the adaptation of user interface for web applications could be in the areas given below:

Content selection: The presentation of contents in the user interface to users.

1) Information presentation: Visual presentation of every piece of information is in the interface.

2) Concepts of navigation: Navigation through the user interface by the users for gathering their desired information given in the webpage.

In order to achieve a coherent design between different variations, we suggest fixing the positions of different SUI parts. Fig. 6 depicts the general structure of the suggested search UI for the elderly. It consists of eight groups of elements: a setting section, a help section, login and logout, profile image, a menu for saved bookmarked results with different categories, a history section menu, a theme mode button, the main search results section. The search input consists of elements: text, voice, image with a larger button size and label. Besides adding a clear button to clean text search "query" and begin a new search. A bookmarked menu and history menu provide direct links for the elderly to access certain saved results for ease of use and navigation. A menus support the elderly to save time and effort instead of researching again for the same results and reduce the memory load of the elderly.

TABLE VII. Suggested Design Solutions based on the Identified Usability Problems

Usability Problems	**Design Solutions**
The default font size is still small.	The default font size is large, and it is constant in the interface without any change, even if using a different browser with ease of modification.
The voice search button, the image search button and the text search button are small and close to each other.	They should be separated from each other with enough space and recognized with a button. Also, the button should be having a recognized name or logo to show the differences between them.
The home page is long	Reduce the length of the home page
Scrolling a page is a difficult task	Reduce the length of the home page at most one screen and half
Unclear to go back to the home page	Make the results open in a new window and that can be clear to go back to the main home page.
Lots of different colours are on the page background.	The background is unchangeable and to be white or with clear color with font dark.
The main and result page view is slightly unstructured	Restructure it to show all UI elements on the main page
The setting menu is complex.	Reduce the elements of the setting that do not affect the main job of the interface. Thus, the simpler menus are healthier choices, such as the Classic navigation menu and Sidebar menu.
Difficult to go back to previous open results and bookmarked results in different browsers. That is because each browser has its way to bookmark results and save the history browsing.	Bookmark and result History should be put in the main home interface. So whatever browser was used, all UI elements is still the same, and the bookmark and history will be loaded with when opened by any browser.
A large number of results	Reduce the view search results on the screen to be 5 to 7 on each screen.
Misunderstanding suggested results such as People Also Search For and Related Searches.	Remove it

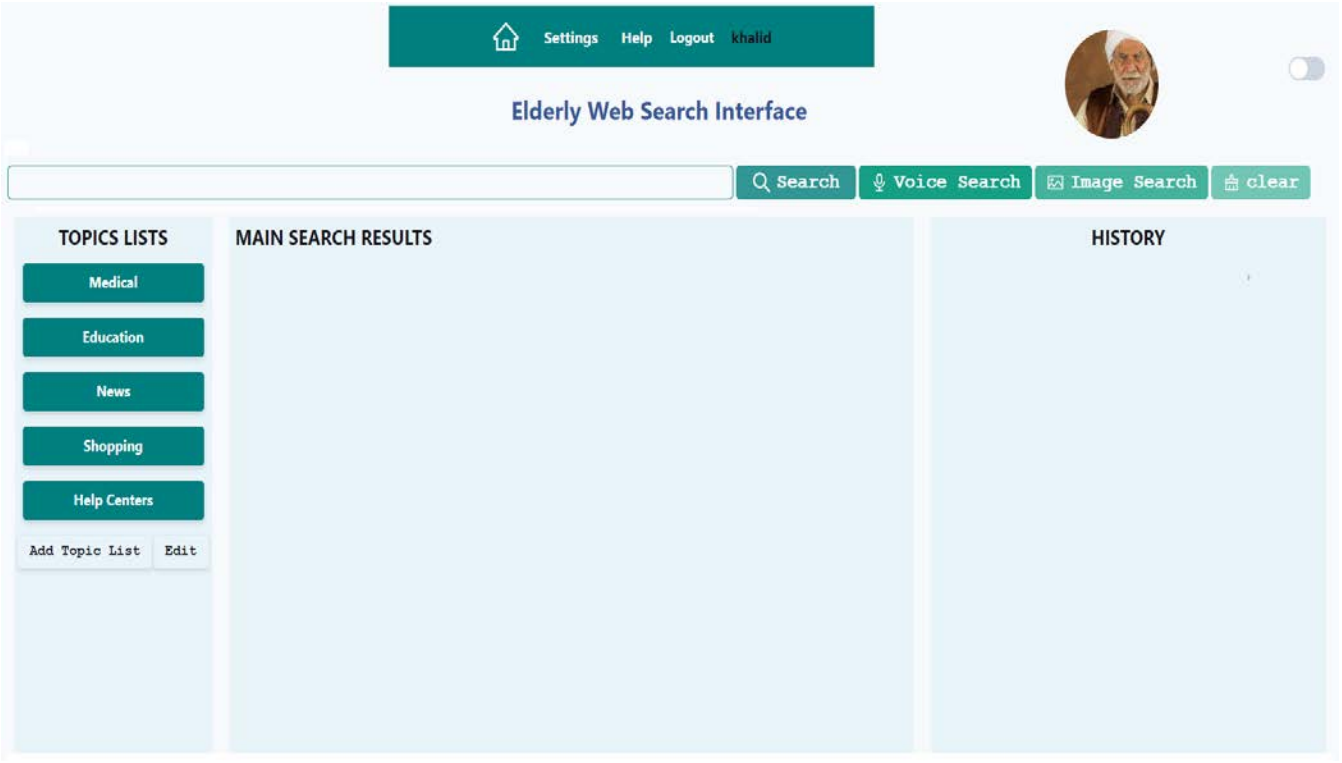

Fig. 6. The General Structure of the Suggested Search user Interface for Elderly.

VII. Conclusion

This research conducted usability evaluations of Google and Bing interfaces from the perspectives of elderly users and suggested how developers can better improve search engine interfaces to make them more usable to elderly users. Applying an observational evaluation technique and SUS questionnaire in this research was shown to be effective in identifying a large proportion of usability problems elderly users faced while interacting with web search UIs. The results show that the Google interface is much better than the Bing interface because it is more user-friendly and simplified to use. It has a larger button size and font size, reduced home page length, larger letter spacing, and visible content-box buttons that would assist the elderly better since it helps them easily focus on the target through the cursor. Also, the Google interface is more suitable for the intellectual ability of the elderly that includes their memory and learning capacity, technical knowledge and experience in using the computers. Moreover, it shows good usability and learnability with a higher SUS score than the Bing user interface. Therefore, the usability level is lower than the learnability level for the Google Interface and the Bing interface, and it is obvious that it should be paid more attention to the elements influencing usability during the design process.

Simple interfaces and simple result pages benefit elderly users by reducing issues produced by not understanding what is happening, reducing the total number of features to be learned, and, most importantly, making the users feel in control of the situation. Aside from that, it is recommended that a "clear text box query" button be added to avoid misunderstandings in using the Backspace and Delete buttons. Furthermore, the needs of senior users varied. Therefore interfaces should be adaptive and personalized for each user to match their individual requirements.

In light of the findings of this study, specifically the design solutions, a prototype of a web search user interface will be designed as future work. The prototype will be put through its paces with elderly volunteers. The elderly volunteers' interactions with the prototype while executing various tasks and their feedback from a think-aloud helped develop the prototype. The improved prototype can then be used to create a commercially viable web search user interfaces launcher.

Acknowledgment

Malaysia's Ministry of Higher Education (MOHE), Libya's Ministry of Higher Education, and the University of Gharyan all contributed to this work. We would like to thank the Universiti Teknologi Malaysia (MOHE) and the UTM VicubeLab research group.

A Novel Framework for Cloud based Virtual Machine Security by Change Management using Machine

S.Radharani, V.B.Narasimha
Department of CSE, UCE, Osmania University
Hyderabad, India

***Abstract*—The increased growth in the cloud-based application development and hosting, the demand for higher application and data security is also increasing. The cloud-based applications are hosted on virtual machines and the data generated or used by these applications are also hosted inside the virtual machines. Hence, the security of the applications and the data can be achieved only by securing the virtual machines. There are number of challenges to achieve the security of the virtual machines. Firstly, the size of the virtual machines is large, and the generic cryptographic methods are primarily designed to handle smaller size of the data. Thus, the applicability of these methods for virtual machine are subjected to analysis. Secondly, the additional time required for applying the cryptographic algorithms on the virtual machines impact the response time of the applications, which again impacts the service level agreements. Finally, the virtual machines during the migration are highly vulnerable as the virtual machines are migrated inside the data center networks as simple text data. A good number of research attempts have tried to solve these challenges. Nonetheless, most of the parallel research works have either compromised on the strength of the security protocols or have compromised on the time taken to apply the cryptographic methods. However, the need of the research is to identify the attacks based on the characteristics of connection requests and reduce the time for the encryption and decryption of the virtual machines. This work proposes a novel framework for detection of the attacks based on a machine learning driven algorithm by analyzing the connection properties and prevent the attacks by selective encryption of the virtual machines using another machine learning driven algorithm. This work demonstrates nearly 98% accuracy in detection of the newer and existing attack types.**

I. Introduction

The security for the cloud infrastructure has always been a persistent issue as most of the consumers and practitioners do not have clear understanding about the security factors and implementation details. To some extent, the service providers have made a closed loop about the knowledge of cloud security inside the organizations and sometimes only to the selective groups. This makes the deployment of the cloud-based security protocols even harder for the researchers. Nonetheless, the recent research outcomes by various research attempts are opening the closed loops of the knowledge and exploring the possibilities of the deployment of novel and higher performing security protocols. One such work presented by P. Mishra et al. [1]. Nevertheless, the challenges of cloud securities are not only restricted to the data stored on the cloud. Rather, the security challenges can be observed in all the layers of cloud implementations as on the infrastructure layer, platform layer and the services layer. Another work by P. Mishra et al. [2] have confirms this claim. Thus, deploying the security protocol for all the layers of cloud implementation is highly complex due to various aspects such as model complexity or compatibility or interoperability between the layers.

Henceforth, the implementation of the cloud security protocols can be best implemented using the virtual machine architectures. As the virtual machines holds the applications core and the data, generated or consumed by these applications, hence protecting the virtual machines must be the primary concern, which is implemented in this work. This work identifies the challenges of cloud security, internally which is virtual machine security and proposes a machine learning driven framework to protect the VMs.

II. Parallel Research Outcomes

The security of the cloud-based applications is critical as mentioned earlier. The applications and the data on the cloud are visible to authenticated and unauthenticated parties at the same time. Though, the access and identity management aspects of the online access can restrict the privileges on the applications and the data. Nonetheless, the visibility of data cannot be restricted. Hence, the possibilities of the attacks also increase on such data. The work by M. R. Watson et al. [3] have clearly listed the vulnerabilities on the cloud systems and also produced a clear guideline for managing the security. Considering the similar directions, to produce a framework for detection of the attacks based on characteristics, yet another work by V. Varadharajan et al. [4] can be highlighted. These parallel research outcomes are primarily focused on an old framework called Rekall [5] and the produced recent outcomes are the attempts to reduce the complexity and at the same time increasing the responsiveness of the same outlined characteristics. These outcomes have mainly concentrated on the prevention of the attacks.

In the other hand, the domains for attack detections are also very popular among researchers. The work by T. K. Lengyel et al. [6] have clearly listed the possibilities of the attack analysis frameworks to detect the attacks. Nonetheless, these detection processes can be highly complex for the distributed architectures such as cloud or fog or edge-based computing. The application, the data and the userbases are always distributed and most of the times, the execution is parallel. Hence, the protective framework must also comply with the

distributed nature of the architecture. The work by S. Gupta et al. [7] have confirmed to this believe.

The attacks are not only restricted to platform and the service layers. Multiple attacks are also reported on the physical hardware devices. The immediate but costly solution is to provide the hardware security modules or the HSM devices. Nonetheless, as mentioned these solutions are costly and for a cloud-based architecture, the applicability of the HSMs is very limited due to the limited physical access to the infrastructure. The work by D. Kirat et al. [8] have spoken in favor of this statement and confirms the claim. Although, the analysis of the intrusion or attack detections must take place at all the layers of cloud computing and infrastructure layer is not an exception. The work by C. Spensky et al. [9] have elaborated on the possibilities and feasibilities of monitoring for the attack detections on the physical infrastructure layer. This work has been criticized for not considering the possibilities for remote monitoring, which can be achieved using the access to the virtual machines. In the recent times, a good number of virtual machine managers have incorporated the monitoring layers in the VMM structure.

Reciting back to the monitoring of the virtual machines for attack detection and prevention methods have improved a lot using the virtual machine monitoring possibilities. The survey done by F. Cai et al. [10] confirms few claims directly and indirectly as firstly, the deployment of the security features can be best adopted on the virtual machines. Secondly, the existing cryptographic methods can easily be outperformed in the recent higher demand for best response times and finally, the newer types of the attacks are increasing day by day and a method for detecting the attacks based on the behavior must be adopted. Thus, the demand for the automated framework with these features is the demand of the current research as also demonstrated in the work by A. Almtrf et al. [11].

The primary features of the expected framework must comply with few additional characteristics. The first characteristics is the close association with the software and the hardware modules to track the flow of the application processing characteristics as rightly stated in the work by A. Khurshid et al. [12]. The second characteristics of the proposed framework is to track the changing nature of the data as mentioned in the work by N. E. Moussaid et al. [13]. The final characteristics must comply with the deployed virtual machine-based applications hosted on the cloud platforms as suggested by X. Lu et al. [14]. Thus, this work considers all the recommendations from the parallel research outcomes and further produces the proposed framework for detection and prevention of the attacks on the cloud application, in tern the virtual machine security.

Further, this work realizes the characteristic based detection of the attacks. This not only identifies the known attack types, but also identifies the newer attack types. The work by B. Sudhakar et al. [15] has clearly listed the attack types and the mapping to the connection properties. The conclusive mapping from this work is furnished here [Table I].

TABLE I. ATTACK TYPES AND CONNECTION PROPERTIES MAPPING [15]

Attack Type	**Connection Properties**
Browser Based Attacks	1. Count of the connection requests 2. Access Type Requests
Brute Force Based Attacks	1. Count of the connection requests 2. Ratio between the request and responses
DoS Based Attacks	1. Access Type Requests 2. Service Request Types 3. The rate of change in the service request types
SSL Based Attacks	1. Service Request Types 2. The rate of change in the service request types
Scan Based Attacks	1. Ratio between the request and responses
DNS Based Attacks	1. Service Request Types

It is worth the mention, that these all characteristics or connection properties are available in the KDD dataset [16].

Thus, in the next section of this work, the problem identified in this section in the parallel research outcomes is formulated using mathematical models.

III. PROBLEM FORMULATION & PROPOSED SOLUTIONS

After the fundamental understanding of the research problems in the previous section of this work, this section focuses and elaborates the core problems and proposes solutions to these problems using the mathematical modeling techniques.

The first problem elaborates on the responsiveness of the cloud-based applications due to the adaptation of the attack detection methods. The parallel research outcomes, as seen in the previous sections, shows higher time complexity. The increased time complexity is due to the nature of analysis deployed by these algorithms, which primarily focus on large number of characteristics or the connection properties. Hence, this must be resolved.

Lemma – 1: The reduction of the connection characteristics using the correlation method can reduce the time complexity of the detection method.

Proof: The connections characteristics or the properties extracted from the connection requests can be a very large dataset because of multiple monitoring system. Many of the times, these large datasets provide limited and redundant information, which is again at the cost of higher time complexity. Thus, a machine learning driven process to reduce the number of characteristics can certainly reduce the time complexity.

Assuming that, the set of connection properties, C[], is a collection of multiple characteristics and each characteristics can be identified as C_i. Thus, for n number of total characteristics, the relationship can be formulated as:

$$C[] = \langle C_1, C_2, C_3 ...., C_n \rangle \quad (1)$$

Also, assuming that, C_X is the class variable, which defines the nature of the connection in terms of attacks or normal from the historical information sets.

Hence, the characteristics analysis for detection of the attacks using the standard algorithms can be formulated as,

$$TH_i = \Phi(\exists C_i) : \prod_{RowID=C_i} C[] \tag{2}$$

Here, Φ is the function for extracting the threshold and further, the threshold for attribute C_i is stored in TH_i. Clearly, the threshold must be calculated relatively as with the consideration of the other parameters.

Further, the combined information from the thresholds from all the characteristics can decide the nature of the connection in terms of the class variable as,

$$C_X = \sum_{i=1}^{n} TH_i \tag{3}$$

It is natural to realize that due to Eq. 2 and Eq. 3, the time complexity, T_1, can be formulated as,

$$T_1 = n(n-1) \tag{4}$$

Or,

$$T_1 = n * n = O(n^2) \tag{5}$$

For a large dataset with 100s of parameters or characteristics, this time complexity for detection of the attacks can be very high. Thus, this problem must be solved using parameter reduction process.

Thus, based on the Eq. 1, the correlation formulation can be formulated as,

$$\rho(C_x, C_i) = \frac{(\eta(C[x]) - C_x).(\eta(C[i]) - C_i)}{\sigma C_x . \sigma C_i} \tag{6}$$

Here, ρ defines the correlation value or correlation coefficient, η defines the mean value and σ defines the standard deviation.

The standard deviation calculation can be formulated as,

$$\sigma C_i = \sqrt{\frac{\sum \{C_i - \eta(C[i])\}^2}{n}} \tag{7}$$

Further, the total correlation sets can be stored in Corr[] and the highest values can be taken to identify m number of characteristics for final analysis as,

$$Corr[] =< \exists \rho(C_x, C_i) > \tag{8}$$

And,

$$m :\rightarrow Corr[] \tag{9}$$

Thus, in the light of Eq. 4, the new time complexity, T_2, can be formulated as,

$$T_2 = m(m-1) \tag{10}$$

Or,

$$T_2 = m * m = O(m^2) \tag{11}$$

As, $m << n$, thus it is conclusive to state that

$$T_2 << T_1 \tag{12}$$

Thus, reduction of the time complexity using the attribute reduction method is highly feasible.

The second problem elaborates on the detection of the attack types. The attack types can be identified using a cluster analysis on the connection characteristics or the properties. As seen in the previous section of the work, the parallel research outcomes mostly fail to detect the newer attacks, though the types of the attacks are not very new and have a strong similarity with the existing and known types of attacks.

This problem can be solved using deep cluster technique. The clustering method for identification of the attacks is significant as the identification of attacks direct towards anomalies in the connection, which is easily identifiable as outliers using the clustering method.

Lemma – 2: The deep clustering method can identify the newer types of attacks using the outlier identification method.

Proof: The outliers as a result of clustering process identifies the anomalies using various characteristics and similarities of the characteristics domain values. Based on the nature of the data used in the clustering process, the outliers can define various meanings. As in this research the data used are the connection characteristics, hence the outliers will denote the abnormal connections or the attacks.

Continuing and revising the Eq. 1, for all the characteristics, there must be domains for each characteristic as,

$$C[][] = \langle C_1[], C_2[], C_3[]...., C_n[] \rangle \tag{13}$$

Further, the clustering process must be performed initially for each and every characteristic or attribute domains as

$$CL_i[] \leftarrow \Phi(\exists C_i[]) \tag{14}$$

Here, the set of clusters for the i^{th} attribute will be stored in $CL_i[]$ and Φ denotes the clustering process.

Henceforth, the number of members in each cluster must be validated and the cluster with the lowest number of members are the potential clusters, inside which the outliers will reside.

Thus, the iterative clustering must be performed until the outliers, in this case the attacks, is not identified as,

$$\omega \leftarrow \Phi(\exists \left| CL_i[] \right|_{low}) \quad (15)$$

The terminating condition for Eq. 15 iteration is $\omega \to 1$.

Henceforth, it can be stated conclusively, the minute deviations can be identified using this proposed method and further any new attack can also be detected, which has very little similarity to the existing attack types.

The final problem, which this research aims to solve is the reduction of the cryptographic algorithm implementation time. As seen in the previous section of this work, the cryptographic algorithms are not designed to handle the large data, which is case of virtual machine files are very large in volume. Also, due to the higher adaptability of the DevOps processes across all organizations for application development, the changes made to the application and indirectly to the virtual machines are very high. This makes the process of applying cryptographic algorithms further difficult.

Henceforth, the solution is to track the changes made to the virtual machines in terms of application code and data and apply incremental encryption process to reduce the time.

The proposed solutions are converted to algorithms, which are furnished in the next section of this work.

IV. Proposed Algorithms and Framework

After the formulation of the concepts of solutions in the previous section, in this section of the work, the proposed algorithms and the proposed frameworks are furnished.

Firstly, the Connection Characteristics Reduction using Correlation Analysis algorithm is furnished.

Algorithm - I: Connection Characteristics Reduction using Correlation Analysis (**CCR-CA**) Algorithm

Input:
Connection Characteristics set as CS[]

Output:
Reduced Characteristics set as RCS[]

Process:
Step - 1. Load the CS[] set
Step - 2. Mark the class characteristics as CX from CS[x]
Step - 3. For each attrbiute in CS[] as CS[i]
- a. Calculate the standard deviation, as SD[] using Eq. 7
- b. Calculate the correlation of CS[i] with CX as Corr[i] using Eq. 6

Step - 4. For each element in Corr[] as Corr[j]
- a. If Corr[j] Not Equal Corr[j+1] & Corr[j] is Max
  - i. Store RCS[j] = CS[i]
- b. Else,
  - i. Continue
- c. Corr[j] = Null
- d. Stop if Count(RCS[]) >= Count(CS[])/2

Step - 5. Return RCS[]

The above algorithm is framed to solve the first problem discussed and based on the proposed Lemma – 1.

Secondly, the Deep Clustering Based Attack Detection algorithm is furnished.

Algorithm - II: Deep Clustering Based Attack Detection (**DC-AD**) Algorithm

Input:
Reduced Characteristics set as RCS[][]
Output:
Detected Attacks as DS[]

Process:
Step - 1. Load the RCS[][] set
Step - 2. For each element in RCS[][] as RCS[i][]
- a. Apply K-Means Clustering on RCS[i][] and store the result in CL[i][] using Eq. 14

Step - 3. For each element in CL[][] as CL[j][]
- a. If count(CL[j][]) -> min(count(CL[][])
  - i. Apply K-Means Clustering on CL[j][] and store the result in CL1[i][] using Eq. 15
  - ii. Repeat the process untill Count(CL1[i][]) -> 1
  - iii. Identify the attack characteristics as DS[k] = RCS[i]
- b. Else,
  - i. Continue

Step - 4. Return DS[]

The above algorithm is framed to solve the second problem discussed and based on the proposed Lemma – 2.

Thirdly, the Random Crypto Key Generation algorithm is furnished.

Algorithm - III: Random Crypto Key Generation (**RCKG**) Algorithm

Input:
Large Random numbers as P & Q

Output:
I. Public Key as PK
II. Private Key as PKK

Process:
Step - 1. Calculate the modulus, M as M = P * Q
Step - 2. Select the derived encryption factor, DE as DE>1 and DE<(P-1).(Q-1)
Step - 3. Generate public key, PK as PK = (M,DE)
Step - 4. Generate private key, PKK as PKK = {1 MOD (P-1).(Q-1)}/DE
Step - 5. Return PK and PKK

Fourthly, the Progressive Virtual Machine Encryption using Change Detection algorithm is furnished.

Algorithm - IV: Progressive Virtual Machine Encryption using Change Detection (**PVME-CD**) Algorithm

Input:

I. Version Management of VM as VMS[]
II. Public Key as PK (M, DE)

Output:

Encrypted Virtual Machine as VME

Process:

Step - 1. Load the virtual machine versions as VMS[]
Step - 2. For each element in VMS[] as VMS[i]
  a. Configuration Management:
    i. Identify the import and include statements
    ii. Store the configuration management as CM[i]
  b. Data Management:
    i. Identify the variable in the code
    ii. Store the data management as DM[i]
  c. Life Cycle Management:
    i. Identify the loops and conditional statements
    ii. Store the life cycle management as LCM[i]
Step - 3. For each element in VMS[] as VMS[i]
  a. If CM[i] Not Equals to CM[i+1]
  b. Then, Store the changes CMC[j] = CM[i]-CM[i+1]
  c. If DM[i] Not Equals to DM[i+1]
  d. Then, Store the changes DMC[j] = DM[i]-DM[i+1]
  e. If LCM[i] Not Equals to LCM[i+1]
  f. Then, Store the changes LCMC[j] = LCM[i]-LCM[i+1]
  g. Merge the changed components as CC[i] = CMC[j] U DMC[j] U LCMC[j]
  h. Build the encrypted VMS[i] as VME = pow(CC[i],DE) mod M
Step - 4. Return VME

Fifthly & finally, the Progressive Virtual Machine Decryption using Change Detection algorithm is furnished.

Algorithm - V: Progressive Virtual Machine Decryption using Change Detection (**PVMD-CD**) Algorithm

Input:

I. Encrypted Virtual Machine as VME
II. Private Key as PKK (DE, M)

Output:

Decrypted Virtual Machine as VM

Process:

Step - 1. Load the encrypted virtual machine as VME
Step - 2. Build the decrypted virtual machine, VM as VM = pow(VME,DE) mod M
Step - 3. Return VM

The above algorithms are framed to solve the third problem discussed in the previous section of this work.

Further, the final framework is furnished here [Fig. 1]:

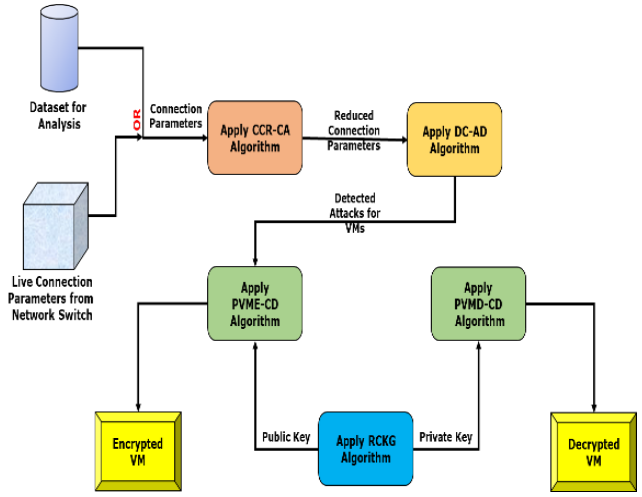

Fig. 1. A Framework for Cloud based Virtual Machine Security by Change Management using Machine Learning.

Further, in the next section of this work, the obtained results from these proposed algorithms are discussed.

V. Result and Discussion

After the detailed understanding on the proposed algorithms, here the obtained results are furnished.

Firstly, the used dataset [16] is analyzed here [Table II].

Further, the data is visualized graphically here [Fig. 2].

Here this is important to observe that, the many attributes have higher unique distributions and further demonstrates unique characteristics to detect large number of attacks.

Secondly, the impact or the correlation analysis results are furnished here [Table III].

The obtained results are again visualized graphically [Fig. 3].

Here it is natural to realize that the many of the attributes have demonstrated higher correlation than the other attributes. As per the proposed algorithm, the threshold of the correlation is calculated as 0.223 and based on the correlation theory, the positive impacted and meaning full attributes correlation must be above 0.50. Thus, again based on the proposed algorithm, the median value of the correlation is considered as 0.135.

Henceforth, based on the new correlation threshold, the following attributes are identified in the reduced set [Table IV].

Further, the reduced set is also analyzed graphically here [Fig. 4].

Here, it is worth noting that, due to this process the information loss is minimum as the diversified nature of the dataset with high distribution is kept intact.

Further, the results from the deep clustering process to detect the attacks are furnished here [Table V].

TABLE V. ATTACK DETECTION ACCURACY ANALYSIS

Analysis Metric	Number of Values	Percentage (%)
"Correctly Classified Instances"	84248	98.2335
"Incorrectly Classified Instances"	1515	1.7665
"Kappa statistic"	0.9638	-
"Mean absolute error"	0.032	-
"Root mean squared error"	0.12	-
"Relative absolute error"	-	6.5494
"Root relative squared error"	-	24.2856
"Total Number of Instances"	85763	-

The results are observed visually here [Fig. 5].

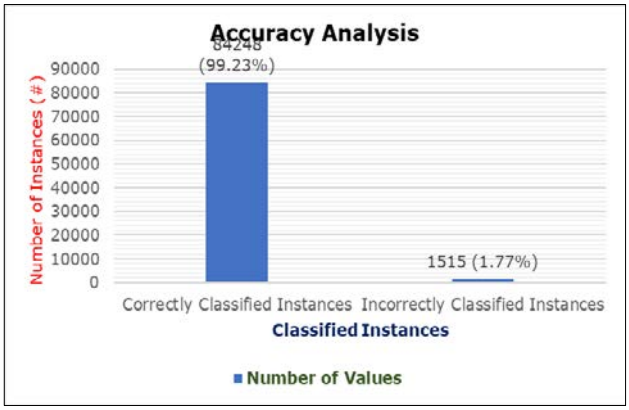

Fig. 5. Detection Accuracy Analysis.

Clearly from the results it is worth noting that the accuracy of the proposed deep clustering algorithm for attack detection is 99.23% with the newer types of attacks.

Further, the change detection algorithm for the virtual machines produces a log of tracked changes. The analysis is performed over 1000 virtual machines, however, for the visualization on 10 virtual machine logs are presented here.

Sample Change Detection Log File
Change Tracking for VM #1 Tracking for version #1 VM Size reduced by 126 GB
Change Tracking for VM #2 Tracking for version #1 VM Size reduced by 95 GB
Change Tracking for VM #3 Tracking for version #1 VM Size reduced by 94 GB Tracking for version #2 VM Size reduced by 42 GB
Change Tracking for VM #4 Tracking for version #1 VM Size increased by 138 GB
Change Tracking for VM #5 Tracking for version #1 VM Size reduced by 183 GB Tracking for version #2 VM Size increased by 28 GB
Change Tracking for VM #6 Tracking for version #1 VM Size increased by 236 GB Tracking for version #2 VM Size reduced by 28 GB
Change Tracking for VM #7 Tracking for version #1 VM Size increased by 208 GB
Change Tracking for VM #8 Tracking for version #1 VM Size increased by 275 GB
Change Tracking for VM #9 Tracking for version #1 VM Size reduced by 32 GB Tracking for version #2 VM Size reduced by 42 GB Tracking for version #3 VM Size increased by 79 GB
Change Tracking for VM #10 No Changes Detected

From the above sample log file, the following aspects are conclusive regarding the virtual machine change detection algorithm:

1) The changes for any virtual machine can be detected over multiple versions of the same VM.

2) The changes are reflected in terms of size; however, the actual change management is tracked based on characteristics of the virtual machines.

3) The detection algorithm also ensures no changes if the version of the same virtual machine is not updated.

Henceforth, it is conclusive that, the change management algorithm is perfectly justifying the claims made is this work.

Further, the key generation algorithm outputs are analysed here [Table VI]. During the testing phase, the algorithm is tested for more than 1000 instances. However, for representation purposes only 10 examples from the total outcomes are furnished.

TABLE VI. KEY GENERATION TIME ANALYSIS

Test Sequence #	**Key Generation time (ns)**
Seq #1	7
Seq #2	9
Seq #3	14
Seq #4	7
Seq #5	10
Seq #6	20
Seq #7	15
Seq #8	25
Seq #9	10
Seq #10	14

The results are visualized graphically here [Fig. 6].

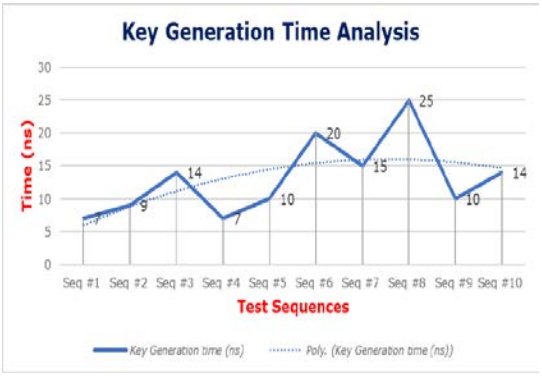

Fig. 6. Key Generation Time Analysis.

It is evident from the above results, that the time taken for the key generation demonstrates fairly liner characteristics, which is always expected for any best key generation algorithms.

TABLE VII. CRYPTOGRAPHIC ALGORITHMS TIME ANALYSIS

Test Sequence #	**Encryption Time (ns)**	**Decryption Time (ns)**
Seq #1	19	22
Seq #2	6	16
Seq #3	4	19
Seq #4	10	7
Seq #5	17	1
Seq #6	11	20
Seq #7	18	14
Seq #8	14	20
Seq #9	8	15
Seq #10	12	16

Further, the encryption and decryption time analysis is furnished here [Table VII]. During the testing phase, the algorithm is tested for more than 1000 instances. However, for representation purposes only 10 examples from the total outcomes are furnished.

The results are also visualized graphically here [Fig. 7].

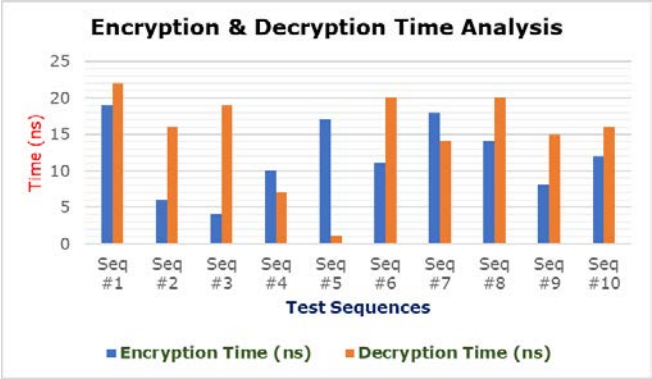

Fig. 7. Encryption and Decryption Time Analysis.

The results obtained in terms of time taken to perform the encryption and decryption operations on the detected changes on the virtual machines clearly showcase a trend of reduced time. This reduction is achieved due to the change management algorithm deployed for the virtual machine versions.

Further, in the next section of this work, the obtained results are compared with the other parallel research outcomes.

VI. Comparative Analysis

The obtained result from the proposed framework is highly satisfactory. Nonetheless, without a comparative analysis, no work can be concluded as benchmarked outcome. Thus, in this section of the work, the proposed framework using various parameters is compared with the parallel popular research outcomes [Table VIII].

Henceforth, it is conclusive to state that, the proposed framework has outperformed the parallel popular research works in terms of capabilities and as well as in terms of model complexity.

Finally, in the next section of the work, the research conclusion is presented.

TABLE VIII. Comparative Analysis

Author, Year	Methodology	Capabilities	Model Complexity
X. Lu et al. [14], 2020	Machine Learning	Reactive Security	$O(n^2)$
N. E. Moussaid et al. [13], 2020	Machine Learning	Reactive Security	$O(n^2)$
F. Cai et al. [10], 2019	Machine Learning	Reactive Security	$O(n^2)$
B. Sudhakar et al. [15], 2019	Machine Learning	Reactive Security	O(n*m)
Proposed Framework	Machine Learning	Reactive & Proactive Security	O(n)

VII. Conclusion

This research establishes benchmark in many aspects. In any of the parallel research outcomes, the reduction of time for applying the cryptographic aspects is ignored, which as per this work is most evident to increase the responsiveness of the cloud security. Also, this work elaborates the possibilities of detection of the attacks with the simplest model with least complexity. The proposed mathematical models and algorithms are strong evidence of the claim that, this framework is not only capable of detection of existing or known attacks, rather, this framework can also detect newer or unknown types of attacks based on the connection characteristics analysis. The detection rate on the benchmarked dataset is over 98%, which is again a benchmark for these types of framework.

***Abstract*—In 2020 World Health Organization (WHO) has declared that the Coronaviruses (COVID-19) pandemic is causing a worldwide health disaster. One of the most effective protections for reducing the spread of COVID-19 is by wearing a face mask in densely and close populated areas. In various countries, it has become mandatory to wear a face mask in public areas. The process of monitoring large numbers of individuals to comply with the new rule can be a challenging task. A cost-effective method to monitor a large number of individuals to comply with this new law is through computer vision and Convolution Neural Network (CNN). This paper demonstrates the application of transfer learning on pre-trained CNN architectures namely; AlexNet, GoogleNet ResNet-18, ResNet-50, ResNet-101, to classify whether or not a person in the image is wearing a facemask. The number of training images are varied in order to compare the performance of these networks. It is found that AlexNet performed the worst and requires 400 training images to achieve Specificity, Accuracy, Precision, and F-score of more than 95%. Whereas, GoogleNet and Resnet can achieve the same level of performance with 10 times fewer number of training images.**

***Keywords*—Convolution neural network; deep learning; transfer learning; computer vision; facemask detection; COVID-19**

I. Introduction

Wearing face masks in public area is becoming more common due to the prevalence of COVID-19 outbreak all over the world [1]. Before the pandemic, small minority of the population especially in east Asian countries have been wearing face masks as a prevention against common flu. COVID-19 is the most recent pandemic virus to make a huge impact on human health in the past century. The exponential rate of COVID-19 transmission has forced the World Health Organization (WHO) to declare COVID-19 a worldwide pandemic in 2020. 150,047,341 have been infected by COVID-19 as of April 2021 across 188 countries. The virus is spreading through close contact, as well as in overcrowded publica areas. In multiple countries, individuals are constrained by the law to wear face mask in public areas. The rule was implemented as a reaction to a sudden spike in cases and fatalities in a various country. To enforce the public to comply with this rules, governmental agencies such police and health agency have to allocate significant number of their workforce to continuously public areas.

This paper demonstrates the application of Convolution Neural Network CNN to automate the classification of images of an individual wearing facemask and those without facemask. The ability to automate facemask detection can significantly reduce man power requirement and governmental expenditure. This paper also presents the performance comparison of popular CNN architectures for images classifications namely AlexNet, GoogleNet, ResNet-18, ResNet-50, and ResNet-101. The results presented in this research can be used by other researchers and machine learning engineers to identify suitable CNN architectures given the number of training data set, hardware capabilities and required accuracy to automate the images classification of a person wearing face mask.

This paper is organized as follows. Section II, provides discussion on the findings by other researchers on facemask detection and classification. Section III, describes the methodology on how the five different CNN architectures; AlexNet, GoogleNet, ResNet-18, ResNet-50 and ResNet-101 are being trained. Section IV, discussed the performance evaluation metrics that were used to compare the 5 different CNN architectures. The results of the study are presented and discussed in Section V. Finally, conclusions are drawn.

A. Deep Learning

Deep Learning is a subset of Machine Learning, which in turn is a subset of Artificial Intelligence. The term "Artificial Intelligence" (AI) refers to techniques that enable computers to mimic human behavior. Machine Learning is an algorithm that has been trained using data to emulate human like decision making. Deep Learning and Artificial Neural Network are a subset of Machine Learning that are inspired by human brain structure. [2] Deep learning methods take the opportunity to achieve the same findings as humans by consistently assessing data using a specified structured methodology. Deep learning does this through the use of a multi-layered structure of algorithms known as neural networks.

As shown in Fig. 1, the design of the Artificial Neural Network is based on the anatomy of the human brain. Artificial Neural Network can be trained to detect objects and categorize various sorts of data in the same way that humans do. Singular layers of neural organizations might be considered as a type of filter that capacities from coarse to fine, expanding the likelihood of recognizing and creating the right outcome. The human brain works in a similar way. While going up against with new data, the brain endeavors to contrast it with recently known objects. Deep neural networks employ the same principle. It may be use neural networks to accomplish a variety of tasks such as grouping, classification, and regression. Can be use neural networks to categorize or classify unlabeled data based on similarities between samples. In the classification process, it might prepare the network on a labeled dataset to characterize the examples in the dataset into discrete classifications.

B. Convolution Neural Networks (CNN)

As illustrated in Fig. 2 and Fig. 3, a CNN contains three layers as a convolutional layer, a pooling layer, and a fully connected layer [3]. The 'input layer' of each CNN utilized receives pictures and recompress them before passing data on to following layers for extracting features. The next layers are referred to as 'Convolution layers,' and they serve as image filters, extracting features from pictures and generating match local features during testing. Activation function 'Rectified Linear Unit' (ReLU) is employed to replace every negative integer in the pooling layer with zero. ReLU also helps the CNN maintain mathematical stability by avoiding learnt values from being stuck at zero or blowing up toward infinity. Then the data is transferred to the 'pooling layer' [4]. This layer decreases the size of large pictures yet retaining the most important information. It maintains the most value from each frame by retaining the best fits of every feature within the frame. Flatten is the way toward changing over information into a one-dimensional cluster for contribution to the next layer. The yield of the convolutional layers is flattened to make a solitary extensive component vector. It is also connected to the final classification algorithm, forming a fully connected layer. The next-to-last layer is a fully connected layer that turns the greater filtered pictures into labeled with probability for every class of every picture being categorized. To give classification output, the last layer of the CNN architecture employs a classification layer such as softmax [5].

C. AlexNet

AlexNet was created by Alex Krizhevsky and is a convolutional neural network model that has made huge contributions to Artificial Intelligence (AI), particularly the use of deep learning to machine vision [6]. The CNN model won the ImageNet Large Scale Visual Detection (ILSVRC) competition in 2012, which evaluates methods for huge object recognizing and picture classifications. AlexNet consists of 60 million parameters, three fully connected layers, 650,000 neurons and five convolutional layers [7]. Convolutions of 11x11, 5x5, and 3x3 dimensions were used, as well as max pooling, dropout, data augmentation, ReLU activations, and SGD with momentum. The initial two convolutional layers are normalization and a maximum pooling layer. Plus, the third and fourth are directly connected while the fifth is joined by a maximum pooling layer. [6] The input is given it into softmax classifier, the second of which feeds into a softmax classifier. The authors used a regularisation approach termed "dropout" with a ratio of 0.5 to avoid overfitting in the fully-connected layers. The use of Rectified Linear Unit (ReLU) on each of the first seven layers is another AlexNet model feature.

D. GoogleNet

Szegedy proposed GoogleNet, which was the champion of the ImageNet Large Scale Visual Recognition Challenge (ILSVRC) in 2014 [6]. For the major auxiliary classifiers in the network, GoogleNet features four convolutional layers, three softmax layers, seven million parameters, five fully connected layers, nine inception modules, three average pooling layers and four max-pooling layers. In the fully connected layer, dropout regularization is used, and ReLU activation is used in all of the convolutional layers. GoogleNet has 22 total layers and is significantly deeper and wider than AlexNet, but it has a much smaller number of network parameters. The DistBelief distributed machine learning system was used to train GoogLeNet architecture with a small amount of model and data parallelism. In the RGB color space, the size of the receptive field in this network is 224x224 with a zero mean. GoogleNet was developed with the intent of being able to function on a variety of devices, including those with limited computational resources, such as those with a low memory footprint [6]. GoogleNet is 22 layers deep if just layers with parameters are counted, or 27 levels if pooling is counted, and has 7 million parameters. This network has a 27MB file size and a 224-by-224 image input size. The GoogLeNet was intended to be a computational force and reckoned with higher computational proficiency than a portion of its archetypes or equivalent organizations created at that point. The main convolution layer utilizes a filter patch that is altogether huge in contrast with other patch sizes in the network. The significant objective of this layer is to quickly limit the input image while holding spatial data by utilizing enormous filter sizes. The size of the input image is diminished by a factor of four at the subsequent convolution layer and another factor of eight preceding arriving at the primary initiation module, however a more noteworthy number of highlight maps are produced. The GoogLeNet architecture is comprised of nine inception modules. Furthermore, some inception modules include two max-pooling layers.

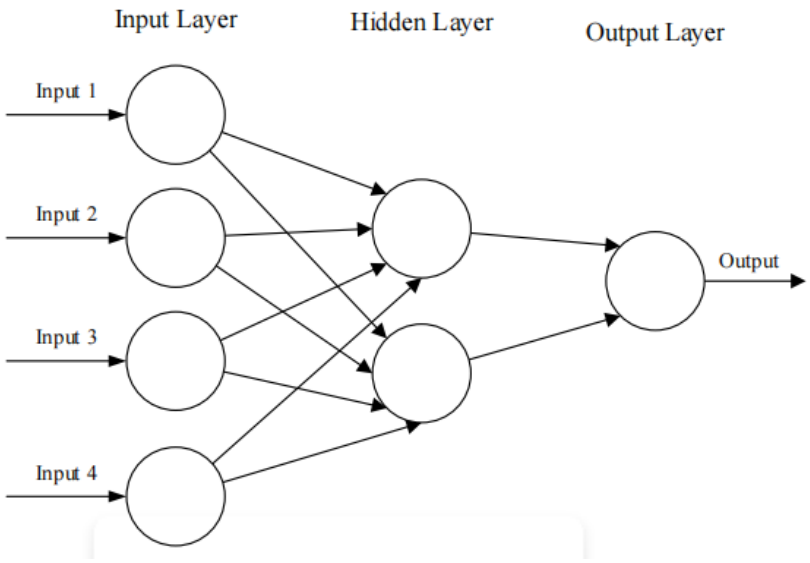

Fig. 1. Artificial Neural Network Connection [8].

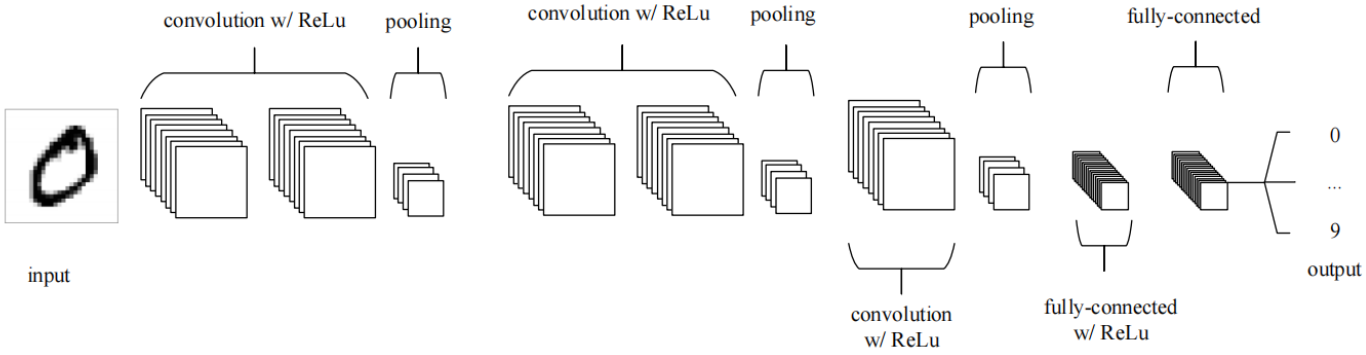

Fig. 2. Convolutional Neural Networks [8].

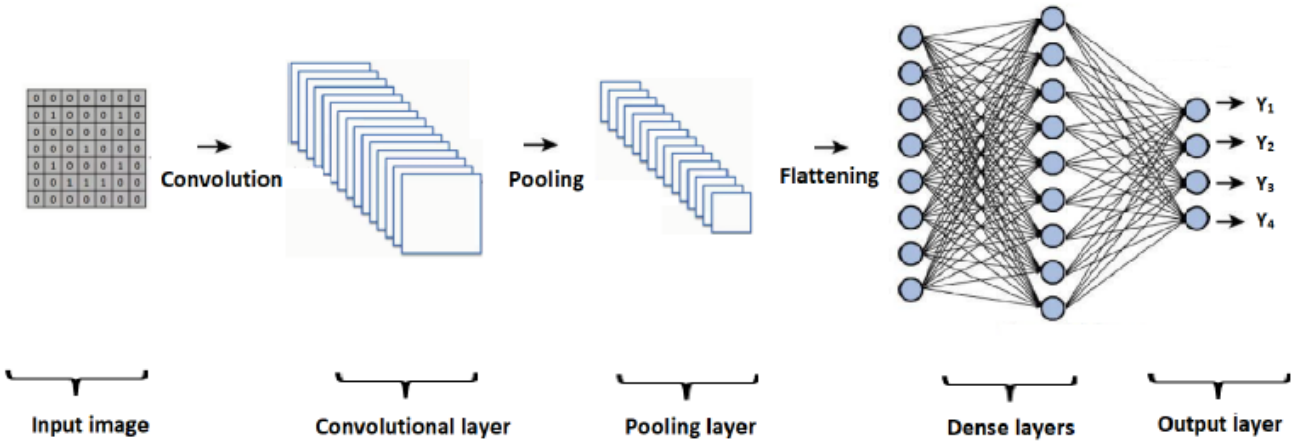

Fig. 3. Representation of a Convolutional Neural Network's Architecture [6].

Just before the linear layer, a dropout layer is being utilized. The dropout layer is a regularization procedure utilized during preparing to keep the network from overfitting. The linear layer is comprised of 1000 hidden units that compare to the 1000 classes in the Imagenet dataset. The last layer is the softmax layer, which utilizes the softmax function, an actuation function used to assess the likelihood circulation of an assortment of the number contained inside an information vector. A softmax actuation function is a vector wherein the assortment of qualities addresses the likelihood of a class or occasion event. The vector's qualities all amount to one.

E. ResNet (Residual Network)

The ResNet feature is based on deep architectures that have demonstrated good convergence and accuracy, were created by He et al. [6] They won the ImageNet Large Scale Visual Recognition Challenge classification competitions in 2015. A residual neural network (ResNet) is a form of Artificial Neural Network (ANN) that is based on pyramidal cell frameworks in the cerebral cortex. Skip connections, or shortcuts, are used by residual neural networks to skip over some layers. ResNet was created using numerous stacked residual units and a variety of layer counts such as 18, 34, 50, 101, 152, and 1202. The number of operations, on the other hand, might vary depending on the architecture. The residual units for all of the preceding are made up of convolutional, pooling, and layering operations. The ResNet 18 network provides an excellent balance of depth and performance, and it is made up of a fully connected layer with a softmax, five convolutional layers, and one average pooling layer. ResNet-18 comprises 11.7 million parameters and an 18 depth layer with a size of 44MB.

Resnet-50 has 49 convolutional layers, 25.6 million parameters, 50 depth layer with a size of 96MB and a fully connected layer at the end of the network. [9] ResNet-101 is a deep convolutional neural network with 101 layers. This architecture has 44.6 million parameters and 101 depth layers, and it is 167MB in size. It will load a pre-trained rendition of the network that has been trained on over 1,000,000 images from the ImageNet information base. The network was pre-trained to recognize images into 1000 distinctive item classes. ResNet is a reliable architecture for identifying a wide range of classes, having won the 2016 ImageNet competition.

A deep residual network (ResNet) is made up of modules, which are entities with identical loops layered on top of each other. Each module is made up of multiple convolutional layers that are used to become familiar with the features of the input space. After the second convolutional layer, a dropout layer was added. Each module delivers more generalized output with greater regularization with the inclusion of the Dropout layer. Many architectures in the literature use dropout, and it is often used on layers with a large number of parameters to minimize feature adaptation and overfitting. Dropouts outperform in generalization. As a default, Softmax is utilized after fully connected layers.

II. Related Work

This section discusses similar research that has been conducted relating to face mask detection.

A. Facial Mask Detection using Semantic Segmentation

The objective of the paper presented by Meenpal et al., 2019 [10] was to develop a binary face classifier that can identify each face in the frame regardless of alignments, including a strategy for generating accurate face segmentation masks of any arbitrary size input image. The approach begins with an RGB image of any size and utilizes Predefined Training Weights of VGG – 16 Architecture for feature extraction. For segmented face masks, experiments on the Multi Parsing Human Dataset revealed a mean pixel-level efficiency of 93.884%.

B. Real-Time Face Mask Identification using Facemasknet Deep Learning Network

Inamdar & Mehendale, 2020 develop a deep learning architecture called Facemasknet [11] COVID-19 face mask classification. The proposed architecture provides three characterizations which are people wearing a mask, erroneously worn masks, and no mask detected. Utilizing a deep learning technique called Facemasknet, they got a precision of 98.6%.

C. Covid-19 Facemask Detection with Deep Learning and Computer Vision

Vinitha & Velantina, 2020 developed a real-time face detection from a live feed via their webcam [12]. The research was conducted using OpenCV framework and A.I framework such as Python, Tensor Flow and Keras. Their aim is to employ deep learning and computer vision to determine if the person in the picture or video feed is wearing a mask.

D. Deep Learning based Safe Social Distancing and Face Mask Detection in Public Areas for COVID-19 Safety Guidelines Adherence

Yadav, 2020 presents a technique for forestalling the transmission of the virus by observing individuals progressively to check whether they are utilizing safe social distance and wearing face mask in public area [13]. The method used for this research includes Raspberry pi4, OpenCV framework, MobileNetV2 and TensorFlow. The detection of face mask wearing achieves an accuracy of 91.2%.

E. A Hybrid Deep Transfer Learning Model with Machine Learning Methods for Face Mask Detection in the Era of the COVID-19 Pandemic

Loey et al., 2021 presents a hybrid model for face mask identification based on deep and conventional machine learning. There are two elements to the technique that follows [1]. The first element will use Resnet-50 to extract features. The ensemble method, decision trees, and Support Vector Machine (SVM) are used in the second element to categorise face masks.

F. Validating the Correct Wearing of Protection Mask by Taking a Selfie: Design of a Mobile Application 'CheckYourMask' to Limit the Spread of COVID-19

The COVID-19 contagiousness is considered to be high in comparison to the flu. Hammoudi et al., 2020 presents a mobile application design that allows anybody with a smartphone the ability to snap a picture to verify that his or her protective mask is properly positioned on his or her face [14]. The technique used in this research included Android, OpenCV, and Haar-like. True Detection (TD) accuracy for the face is 99.92% and the nose is 100%.

G. Identifying Facemask-Wearing Condition using Image Super-Resolution with Classification Network to Prevent COVID-19

Qin & Li, 2020 proposed another facemask wearing condition identification technique as a cooperation with picture super-resolution with classification algorithm (SRCNet) to quantify three different classification issues using

unconstrained 2D facial image photos [15]. The suggested technique included four major steps which are pictures pre-processing, image recognition and cropping, picture super-resolution and recognition of wearing a face mask circumstances. The proposed technique reported a 98.7% accuracy rate.

H. An Application of Mask Detector for Prevent Covid-19 in Public Services Area

Henderi et al., 2020 created systems for real-time monitoring of those who do not wear a face masks in public areas [16]. The authors utilize images and video input from a camera and connects it to a Speed Maix Bit CPU to process data and show it onto the LCD display. The materials used to develop the system are MicroPython, Sipeed Maix Bit, MaixPy and Python 3.

I. An Automated System to Limit COVID-19 using Facial Mask Detection in Smart City Network

Rahman et al., 2020 propose a framework that limits COVID-19 spread in an active city network where all open spots are monitored by Closed-Circuit Television (CCTV) cameras by recognizing people who are not wearing any facial masks [4]. When an individual without a face mask is detected, the city network alerts the necessary authorities. The materials used for this system is CCTV and GPS. The system achieved an accuracy rate of 98.7% of facemask detection.

J. Retinamask: A Face Mask Detector

Jiang & Fan, 2020 presented RetinaFaceMask, a high-accuracy and effective face mask detector [17]. The presented RetinaFaceMask detector is a one-stage detector comprised of a feature pyramid network that combines high-level semantic information with numerous feature vectors and a novel context attentive modules focused on identifying face masks. Furthermore, they provide a cross-class object removal approach for rejecting predictions with low confidence and a high intersection of a union. The framework used in this research were MobileNet, ResNet, and PyTorch.

K. Performance Evaluation of Intelligent Face Mask Detection System with Various Deep Learning Classifiers Keywords

The research by [18] focuses on the use of deep learning algorithms to identify persons who do and do not wear a face mask. The framework has been trained to decide if an individual is wearing a face mask or not. At the point when the algorithm perceives an individual without a mask, an alarm will be set off to caution the people around or the relevant authorities, so that appropriate action may be taken against such offenders. Like most establishments, associations, businesses, shopping centers, and hospital must resume normal operations before the epidemic is removed, to incorporate a face mask recognition strategy with the current information system at the passage and leave entryways is emphatically encouraged.

III. Methodology

The main objectives of this research are to demonstrates the application of using existing CNN architectures; ResNet-101, ResNet-50, ResNet-18, GoogleNet and AlexNet in classifying images of an individual wearing and not wearing facemask. The first stage is to conduct transfer learning on the networks using image datasets. The most essential criterion for evaluating the performance is to see if the prediction accuracy varies among all CNN architectures used in this research. This study is divided into two phases which are training and testing of the face mask detector.

In the training phase, the dataset is loaded for the model to be trained, and the model is serialized. The training datasets consist of images of faces with and without facemask. Fig. 4, 5, 6, 7 and 8 shows example of training images of faces at various angles without facemask. To gauge and compare the performance of ResNet-101, ResNet-50, ResNet-18, GoogleNet and AlexNet, the dataset were varied as follows:

- 20 datasets (10 images with facemask, 10 without facemask)
- 40 datasets (20 images with facemask, 20 without facemask)
- 60 datasets (30 images with facemask, 30 without facemask)
- 80 datasets (40 images with facemask, 40 without facemask)
- 100 datasets (50 images with facemask, 50 without facemask)
- 200 datasets (100 images with facemask, 100 without facemask)
- 300 datasets (150 images with facemask, 150 without facemask)
- 400 datasets (200 images with facemask, 200 without facemask)

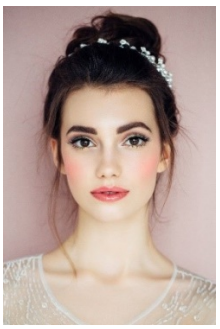

Fig. 4. Example on Front Facing Image [19].

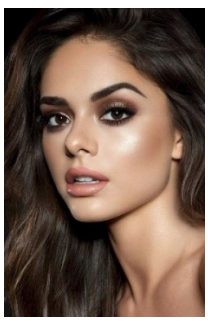

Fig. 5. Example on Left Facing Image [19].

Fig. 6. Example on Right Facing Image [19].

Fig. 7. Example on Bottom Facing Image [19].

Fig. 8. Example on Top Facing Image [19].

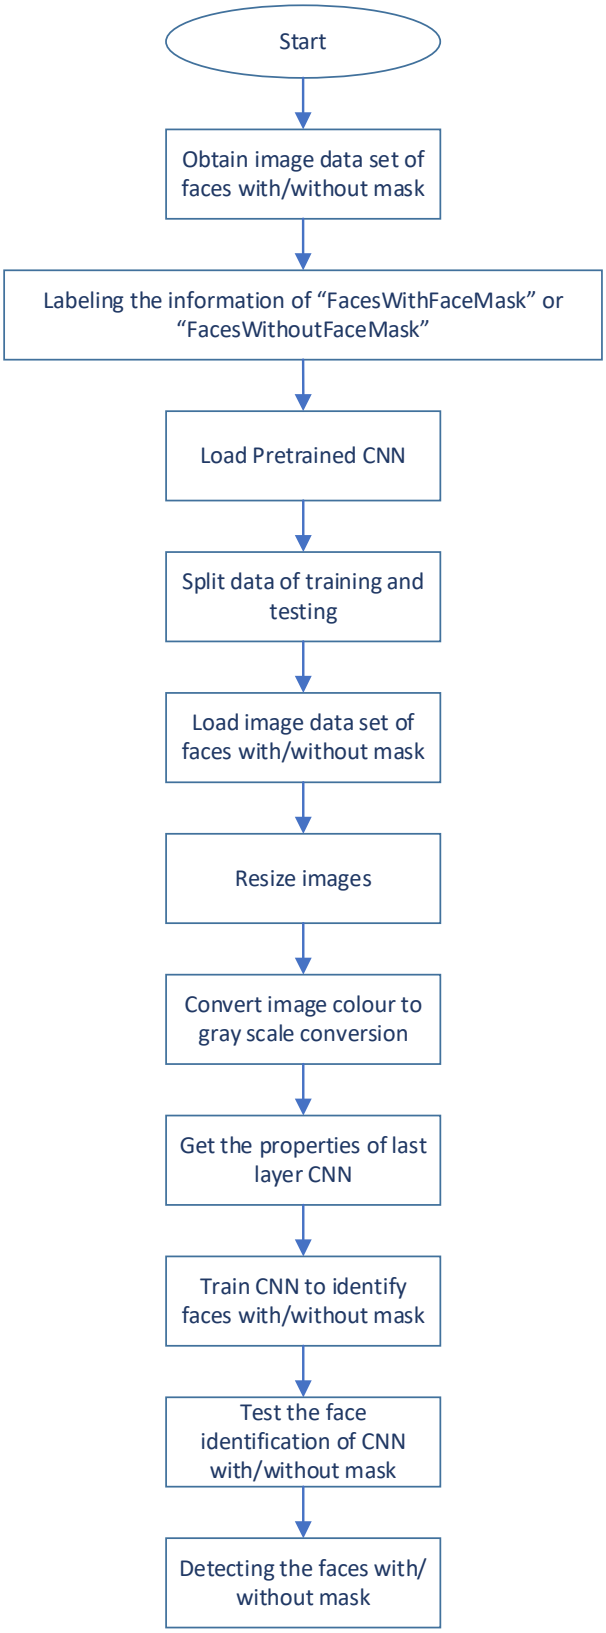

Fig. 9. Process Flow for the Transfer Learning.

The limitation of this research each of the training images used consists of only one face and Matlab programming was used to perform the transfer learning. For Alexnet, all the training images were resized to 227 x 227 x 3 pixels. Whilst for the ResNet-18, ResNet-50, ResNet-101 and GoogleNet the training images were resized to 224x224x3 pixels. After the model was trained, the images were stacked as input to recognize whether an individual was wearing a face mask or not.

In the testing phase, the dataset consists of a total of 200 images which were not part of the training data set, 100 images of faces without face masks and 100 images of faces with face masks. The testing datasets consist of faces at various angles and were fed into a trained CNN architectures to classify if the face detected in the image is wearing a face mask or not. After that detection of face mask takes place, the result will state either the face on the images uploaded wearing a face mask or not wearing a face mask and appeared on the screen display. The screen will mention 'FacesWithFaceMask' for the result of images of people wearing a face mask and 'FacesWithoutFaceMask' for the images of people not wearing a face mask.

Fig. 9 summarizes the flowchart for the transfer learning of CNN for face mask classification. First, the data set of human faces wearing and not wearing a face mask were compiled. The data sets were labelled with their respective categories, "FacesWithFaceMask" and "FacesWithoutFaceMask." A specific CNN architecture is then loaded. The training datasets are then randomly divided into training and testing with a ratio of 70:30. All the images are resized according to the requirements of specific CNN architectures and converted into a grayscale. The features of the final layer CNN are obtained as every CNN network has a different final layer. The CNN network is then train to recognize faces with and without a face mask using the training dataset. Using an image which are not part of the training dataset, the performance of the various trained CNN networks in classifying face with and without facemask are evaluated.

IV. Performance Metrics

Several performance measures are used in this research to compare the performance of the various CNN networks in classifying images of a person with and without facemask.

The sensitivity performance, also known as recall, refers to the accuracy of true positives and how many positive class samples were appropriately labelled [20]. Sensitivity can be calculated using (1), where True Positive (TP) is the number of events that are both positive and accurately identified, which means the number of images with a person are wearing a face mask and are correctly identified as such. While, False Negative FN is defined as the number of positive events that are incorrectly classified as negative. In this research FN, is the number of images of a person wearing facemask but has been incorrectly classified by CNN as not wearing a facemask.

$$\text{Sensitivity} = \frac{TP}{TP + FN} \tag{1}$$

Specificity is defined as the probability distribution of true negatives with a secondary class, which generally corresponds to the possibility that the negative label was correct, and is presented in (2). True Negatives (TN), also known as negative cases that are classified as negative, showing that individuals are not wearing a face mask but are labeled as wearing a face mask. False Positive (FP) is the individuals who are not wearing a face mask but are erroneously categorized as wearing a face mask.

$$\text{Specificity} = \frac{TN}{TN + FP} \tag{2}$$

Accuracy is the most often used parameter for assessing classification performance. This measure computes the proportion of properly identified samples and is represented by (3) [20].

$$\text{Accuracy} = \frac{TP + TN}{T\,P + TN + FP + FN} \tag{3}$$

Precision is calculated by using (4), which divides the total number of true positives plus false positives by the number of true positives. This statistic evaluates the algorithm's predicting capabilities and is concerned with accuracy. Precision refers to the model's "accuracy" in terms of both the number of positive predictions and the number of positive predictions that occur. [20].

$$\text{Precision} = \frac{TP}{T\,P + FP} \tag{4}$$

The harmonic mean accuracy and recall are used to generate the F-score, as shown in (5). It is related with the examination of positive classes. A perfect score for this parameter means that the model leads the positive class [20].

$$\text{F-score} = 2 * \frac{\text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}} \tag{5}$$

V. Result and Discussion

Fig. 10 and 11 illustrates the correct classification of trained CNN networks in identifying 'FacesWithFaceMask' and 'FacesWithoutFaceMask'. Results shown to Fig. 12, 13, 14, 15 and 16, all of the networks performed differently in terms of its statistical significance.

The performance results of AlexNet shows that the Sensitivity is highest at 20 and 40 training images, as shown in Fig. 12. However, for Specificity, Accuracy, Precision, and F-score, the results are its lowest at 20 training images. The performance of AlexNet to classify images of a person wearing facemask can be improved by providing it with more training data set. AlexNet has the lowest accuracy and performed the worst when compare to other CNN architectures. Similar findings was also reported by Neha Sharma et al. [21]. To achieve an acceptable level of performances, AlexNet requires 200 training images to achieve average performance (sensitivity, accuracy, specificity, precession and F-score) of more than 95%. More training data can result in longer training processing time which can undesirable for low powered machines. AlexNet has relatively poorest performance compared to other CNN architectures is because the network has far fewer layers (AlexNet consists of only 8 layers).

Fig. 10. Result will show "FacesWithoutFaceMask' for the Image of People Not Wearing a Face Mask.

Fig. 11. Result will Show "FacesWithFaceMask' for the Image of People Wearing a Face Mask.

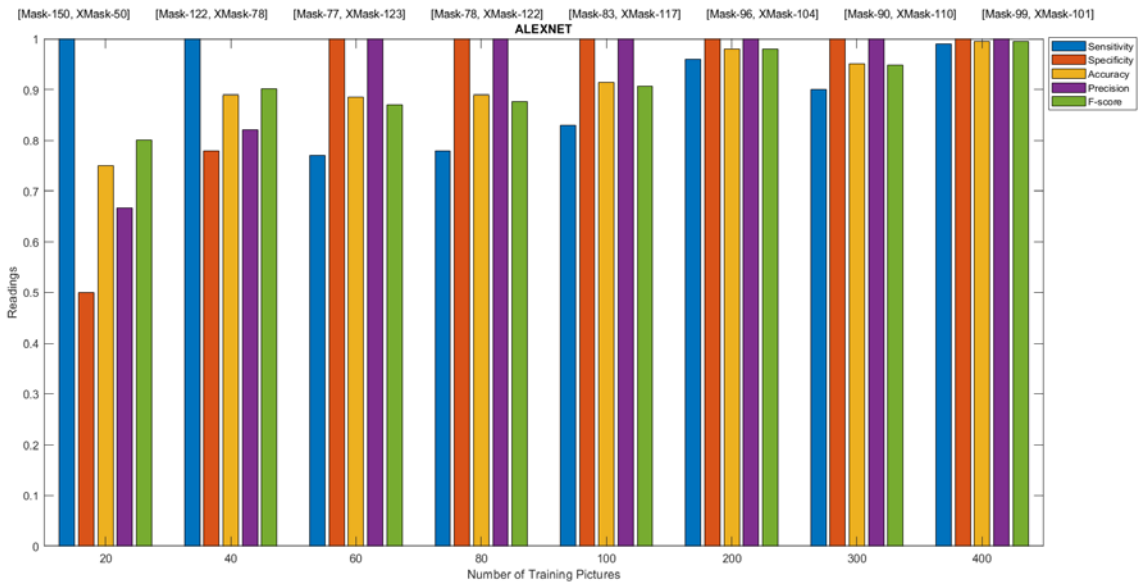

Fig. 12. Performance Results (%) for AlexNet.

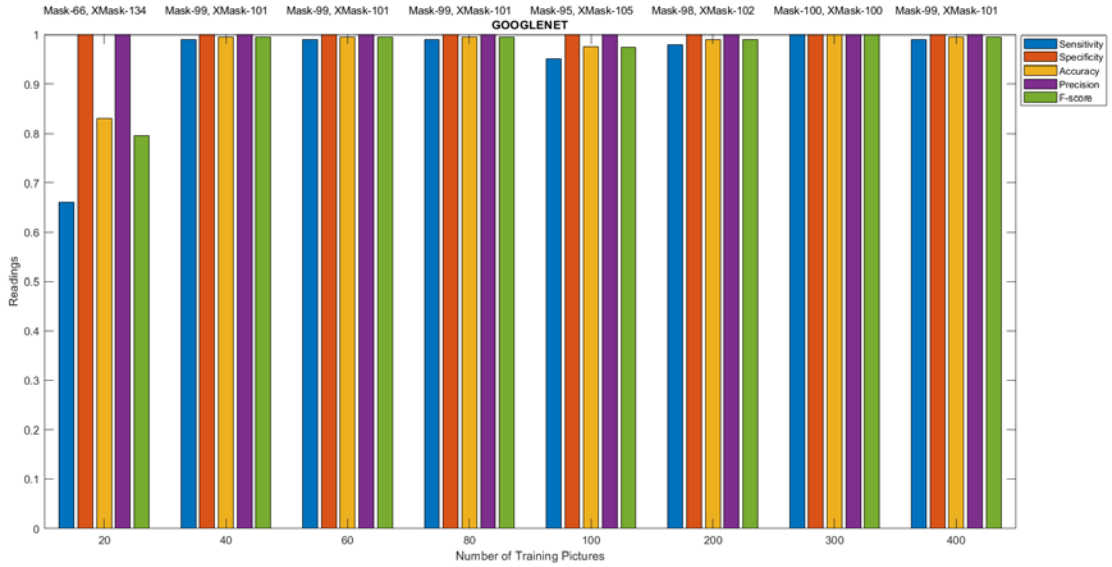

Fig. 13. Performance Results (%) for GoogleNet.

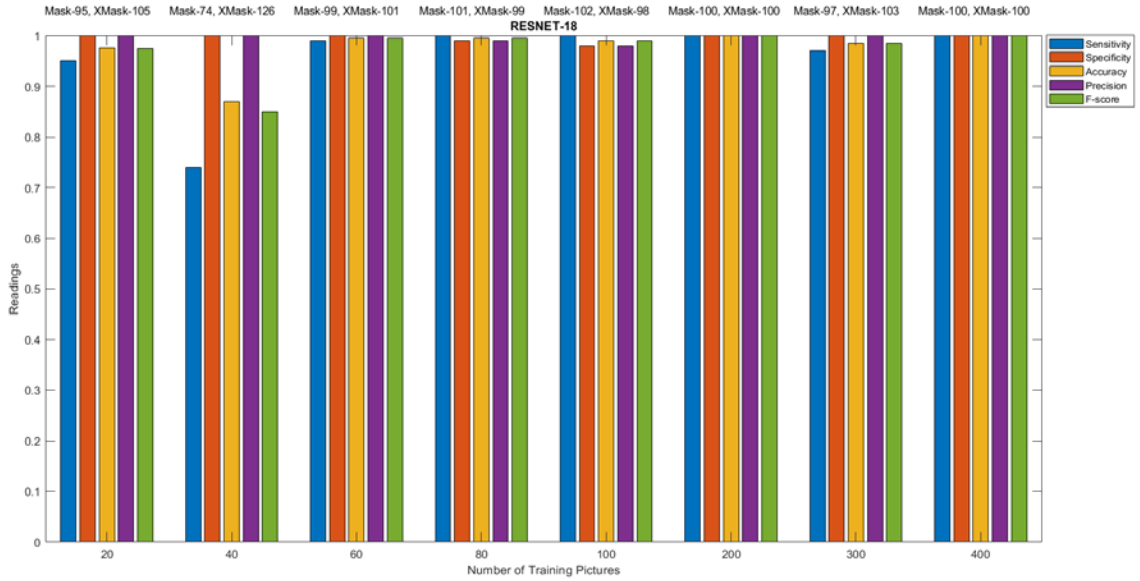

Fig. 14. Performance Results (%) for ResNet-18.

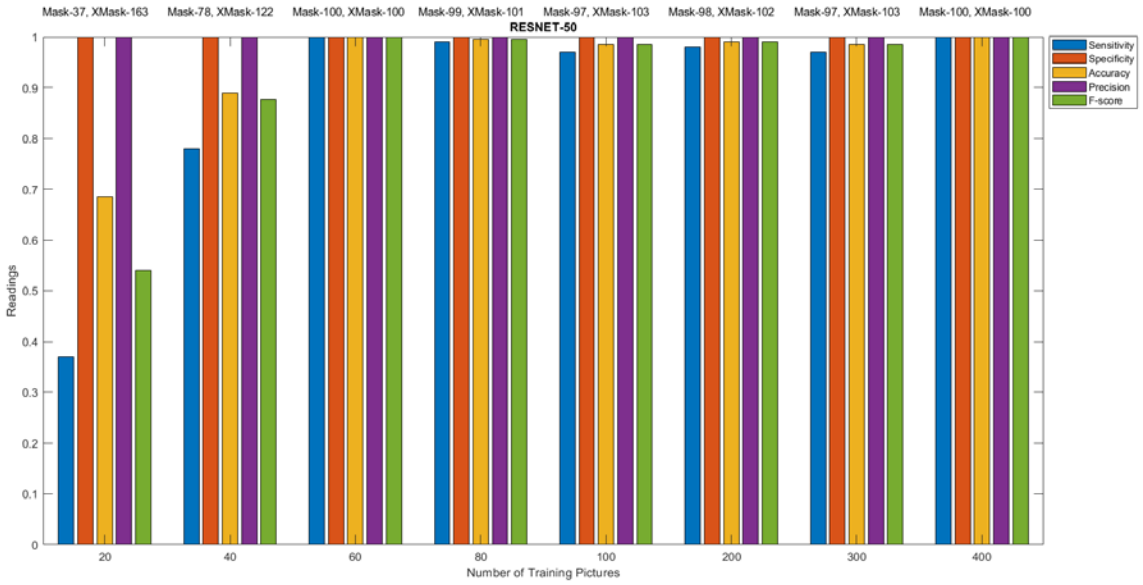

Fig. 15. Performance Results (%) for ResNet-50.

In comparison, GoogleNet which consists of 22 layers only needs 40 images of training data to achieve Accuracy, Sensitivity, Specificity, Precision and F-score of more than 95%.

Fig. 14 and 15 shows that the percentage of performance results for ResNet-18 and ResNet-50 for Sensitivity, Specificity, Accuracy, Precision, and F-score are unstable at 20 to 40 training images. However, as the number of training images increases to 60, the results stabilize with an average performance evaluation of 97%. According to Fig. 16, the best performed network based on the performance evaluation metrics is ResNet-101. ResNet-101 only needs 40 images of training data to achieve Accuracy, Sensitivity, Specificity, Precision and F-score of more than 98%. ResNet-101 achieved the highest average performance as the network has far more layers compared to the CNN architectures presented in this paper. As the name implies, ResNet-101 consists of 101 layers. However, the complexity of the network means it requires more processing power.

The Specificity and Precision performance of GoogleNet, ResNet-50, and ResNet-101 are consistently more than 98% from the start. However this is not the case for AlexNet and ResNet-18 which indicates that these architectures struggle to classify faces without facemask with low number of training data. Low Precision value means that the networks made several incorrectly classification on faces without facemask as wearing facemask. Overall, as the number of training images increases for AlexNet, GoogleNet, ResNet-18, ResNet-50 and ResNet-101, the performance in terms Specificity, Accuracy, Precision, and F-score also improve.

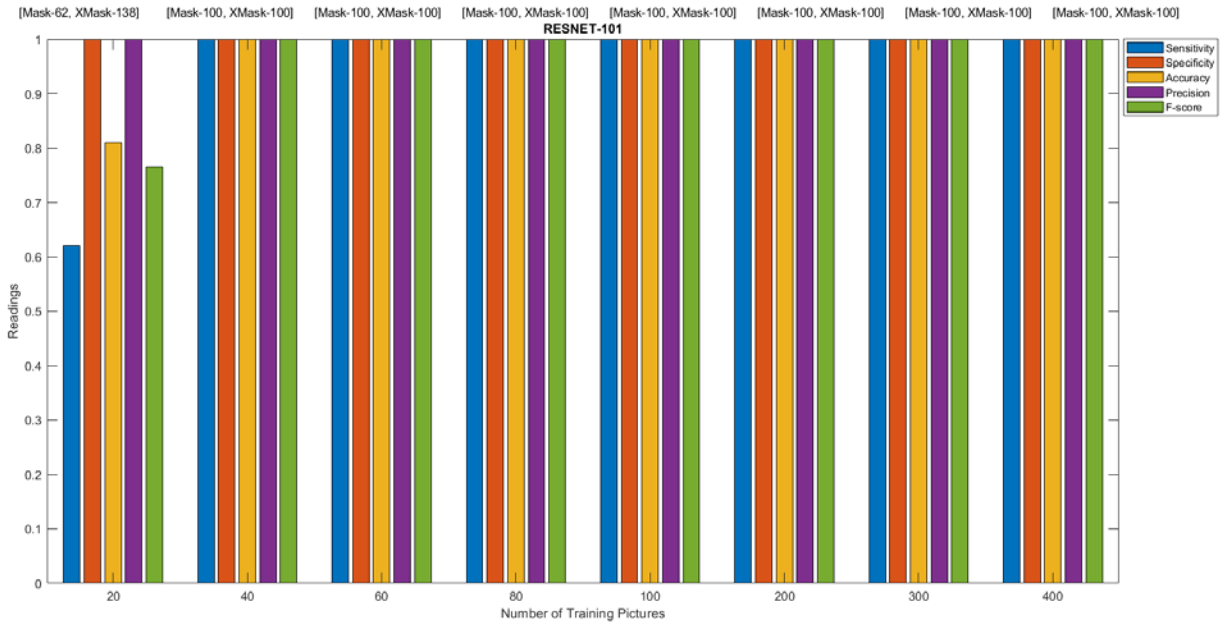

Fig. 16. Performance Results (%) for ResNet-101.

VI. Conclusion

This papers successfully demonstrates application of transfer learning in popular CNN architectures to classify images of a person wearing or not wearing a facemask. In this study, five network architectures were compared using performance metrics; AlexNet, ResNet-18, ResNet-50, GoogleNet, and ResNet-101. It is found that on average AlexNet performed the worst and requires far greater training data to achieve accuracy of more than 95%. ResNet-101 achieved the highest accuracy and requires smallest number of training data to far more 95% accuracy. However the complexity of ResNet-101 means that it requires far greater processing power. GoogleNet strikes the balance of not being overly complex whilst achieving an acceptable level of performance with relatively small number of training data images. Further research can be conducted to gauge the performance and computational resources requirement of various CNN architectures to determine whether a person is wearing a face mask correctly or incorrectly.

Research Center for Physics, National Research and Innovation Agency, Banten, Indonesia[1,3, 5, 6]
Department of Computer Engineering, School of Electrical Engineering, Telkom University, Bandung, Indonesia[1,2,4]

***Abstract*—In this paper a new approach of unique markers to detect and track moving objects with the encoding LED marker is presented. In addition, an LED spotlight system that can shoot light in the direction of the target is also proposed. The encoding process is done by making a unique blinking pattern on the LED, and thus the camera and a servomotor as an object recognition system would only recognize a unique marker given by an LED. In this work the camera with OpenCV could capture a unique marker in all variant of blinking patterns. A unique marker is important on object recognition system so the camera could identify the object marked by our unique marker and ignore all other markers that might captured by the camera. In addition, analysis of the PWM signal from an LED is carried out here to determine the characteristics of the LEDs in each color, determine the accuracy of the duty cycle, and the use of the bright-dim method on the LEDs. The results show that the highest accuracy is obtained when a 50% duty cycle is used with the on and off time are set to be 1 second for all LED colors. The benefit of the proposed system is confirmed by implementing an integrated control system as a unique marker. The effectiveness of the blinking LED against other laser interferences is also discussed.**

***Keywords*—Encoding LED; PWM signal; target markers; object recognition system**

I. Introduction

The optics and optoelectronics have made significant progress over the years, particularly towards more powerful and efficient laser devices [1]. Much of these advances are responsible for making them indispensable in modern warfare. There has been a large-scale growth of electro-optics devices and systems for various applications, such as target tracking and designating, range finding, and target acquisition [2][3]. Moreover, [4] and [5] suggested that the use of lasers for military purposes continues to grow every year. There are numerous benefits associated with electro-optics technology, for example, detecting markers by using a light-emitting diode (LED) [6][7].

LED has some benefits, such as low power consumption and more brightness compared to the others [8]. LED technology also presents an option for information display on a flat screen, offering a wide viewing angle and a bright and clear image suitable for outdoor applications. LEDs have become the necessary option in lighting environmental renovation. LEDs have many advantages, including high fidelity, high rendering, and supporting green technology [9][10]. In [11] it is reported that LED pulse response behavior, taking into account the junction capacitance and the spreading resistance distributed over the entire junction area, this research makes possible to be able to control LED in the future. LED has recently become a new light source in many areas due to its efficiency and durability. It has the merits of being environmentally friendly and low power consumption. Furthermore, LEDs are used in various sensors and other technological developments, such as LED markers [12][13].

Recently, LEDs cannot only emit continuously, but also dim and blinking. The author in [14] reported the dimming is accomplished by adjusting the average current in the LEDs through pulse width modulation of a switch in series with the load. Meanwhile, [15] suggested that a camera with image processing software is used to recognize the target. The color, size, and variant of blinking of the LED markers detected by the camera is the main limiting factor of this method.

In [16] it is reported that the object recognition system by using single camera. The quality of the camera greatly influences the object detection limits. Meanwhile, the increase of interest and need for the camera generates increasingly complex object tracking algorithms. The object tracking system is often used for security, surveillance, traffic monitoring, navigation, and human-computer interactions [17][18]. Moreover, LED marker is a marker of a particular light. This marker is usually used just before the bullet is fired.

LED needs the electric current to emit the light. The higher the current flowing in the LED, the brighter the light produced. However, it should be noted that the amount of current allowed is 10mA - 20mA and at a voltage of 1.6V-3.5V according to the character of the wavelength. If the current is higher than 20mA, the LED will burn. Changing the electric current on LED according to a certain pattern at a certain time can produce LED blinking [19][20]. In this work, the aim to develop an object recognition system and unique marker by using a variety of LED blinking. The LED spotlight and object recognition based on computer vision were studied, resulting in the fact that the correlation was small.

II. Method

A. Scheme of LED Blinking

The diode forward current can control the LED luminance. The most convenient method for LED dimming without altering the current is the pulse-width-modulation (PWM). PWM regulates the output voltage on the LED to get different average voltages. Meanwhile, PWM adjusts the output voltage

signal on the led to get different average voltages. Two factors limiting the shortest PWM pulse duration are driver response time and LED response time. Typically, driver response time is clearly stated by a manufacturer. LED manufacturers are not aware of the need for faster LED response times. Usually, the manufacturer considers it to be fast enough to satisfy dimming requirements. However, the LED manufacturers do not specify the response time. Therefore, the investigation was needed to evaluate the current state of the response time of visible light LEDs.

In this work, LED is controlled by a microcontroller, which can show the continuous or blinking light, as shown in Fig. 1. Here, the LED is controlled by an Arduino Uno and will generate a PWM. In addition, the Arduino Uno can adjust the blinking signal with a variety of frequencies and duty cycles. For the optimum condition, the maximum speed of the duty cycle on LED depends on the speed rate of spectrometer capture led light.

The spectrometer used in this work has a limitation of speed rate in 10 µs. Therefore, the speed of the duty cycle was set at over 10 µs. The spectrometer has captured the spectrum of LED and converted it to the PWM signal. The comparison between the PWM signal in the input and the output was analyzed to generate the precision and resolution numbers.

B. Object Recognition System

The detection of objects using markers is one of the easiest methods of detection. Markers are artificial objects that are designed to be easily recognized and identified. The marker usually is at a known position or size, serving as a reference point or a measure for other objects. In this work, a camera with image processing software called OpenCV is used to recognize the target. The motor servo is used to steer the laser beam. An external camera is used to recognize the target. This camera can capture pictures with a resolution of 1920 × 1080 pixels for 30 fps and a 76° angle of view. However, the camera also needs a particular program to recognize the object intended as the target. There are several methods of OpenCV that can be used for target recognition. Since the target is dynamic (moving objects), the shape and size of the target, which is recognized by the camera, might slightly change when it moves.

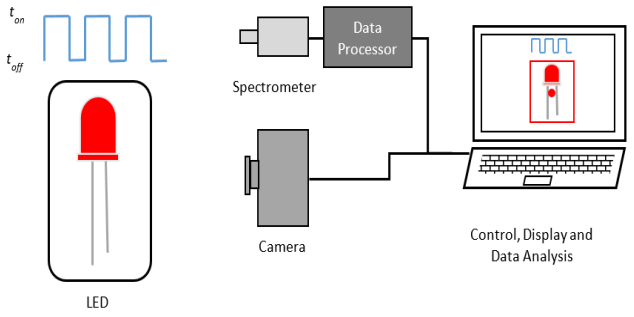

Fig. 1. Encoding LED Blinking Mechanism. A Camera Captured the Display of LED, and a Spectrometer Captured the PWM Signal.

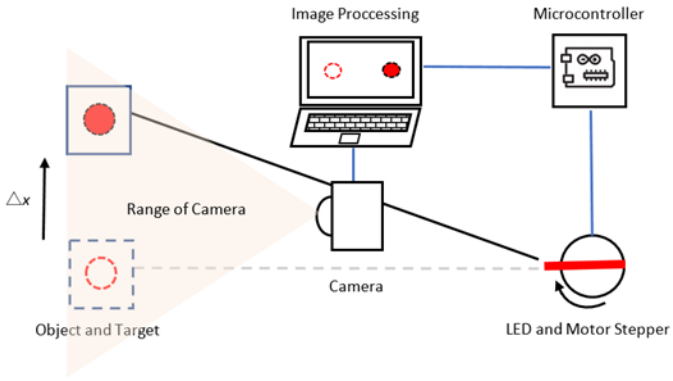

Fig. 2. Object Recognition System consists of the Camera, Image Processing, LED as a Marker Embedded to the Servo Motor and Microcontroller.

The object recognition system consists of multi-colored LED that can emit continuous light, external cameras for capturing an object, and a spectrometer for capturing a PWM signal. When the LED was on, the camera captured the visualization of the colored LED, and the spectrometer captured the PWM signal simultaneously as shown in Fig. 2. Visually, the light looks on and off with the particular period. The PWM signal goes up (t_{on}) and down (t_{off}) on a particular blinking type, and the duty cycle follows the rules as shown in (1). When the light is on, t_{on} is always straight without breaking up, and there is no signal at the t_{off}, vice versa. The blinking system is the combination of both t_{on} and t_{off} that can produce the PWM signal. Typically, the camera will capture the visual object when the light is on (t_{on}) and will be lost when the light is off (t_{off}).

III. Result and Discussion

A. Characteristics of LED Blinking

In this work, LEDs of various colors have been characterized and analyzed for their resolution and precision values. The colors used in this experiment are red, yellow, green, and blue. The duty cycle is the fraction of one period when a signal is active, and its calculation follows (1). Moreover, the PWM duty cycle's accuracy is related to the duty cycle's correction. The precision analysis of Duty Cycle (DC) follows (2).

$$DC = \frac{t_{on}}{t_{on}+t_{off}} x\ 100\% \quad (1)$$

$$Accuracy\ of\ PWM\ DC = \left[1 - \left(\frac{DC_{inp} - DC_{out}}{DC_{inp}}\right)\right] \times 100\% \quad (2)$$

Here, the duty cycle is the ratio of time a load, and the t_{on} and t_{off} are the conditions when the light is on and off. The duty cycle correction for the color LED can be calculated by comparing the input duty cycle and the output duty cycle. The four colors have different wavelengths, resulting in different accuracies. It can be seen on the t_{on} and t_{off}, where the time variations are carried out to see the maximum speed captured by the photo detector and spectrum processing software. The concept of t_{dim} was proposed to capture all the time on Computer Vision as shown in Fig. 3.

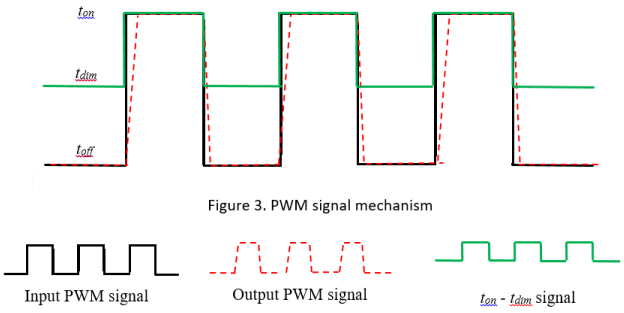

Fig. 3. The Mechanism of PWM Signal, separately by the Various Color.

Initially, the LED has a 50% duty cycle. It means that in the blinking system, the length of time when it turns on is the same as the length of time it turns off. Following this, the PWM signal was analyzed. In this work, the duty cycle is calculated by t_{on} = 1s and t_{off} = 1s. Furthermore, the variety of duty cycles and range of time were analyzed as well.

When the duty cycle is gradually decreased, the accuracy of the duty cycle decreases, as shown in Fig. 4a. The smaller the duty cycle, the t_{off} is higher than a $t_{on,}$ the duty cycle's accuracy drops significantly. Due to the photo detector's response, these phenomena are also affected by the speed ratio (t_{on} and t_{off}). Meanwhile, the duty cycle data after 50% show no significant accuracy shift, as shown in Fig. 4b. Therefore, 50% duty cycle is a simpler form of PWM signal and gives the higher accuracy of the duty cycle. The result indicates that when the LED switched from on to off, the spectrometer still receives the LED beam signal in a short time. The increasing value of the duty cycle correlates with the decrease's correction value. The result shows that at a longer t_{on}, the photo detector will capture the object better. The combination of t_{on} and t_{off}, correction values, and accuracy of duty cycle describes the encoding system for object recognition systems.

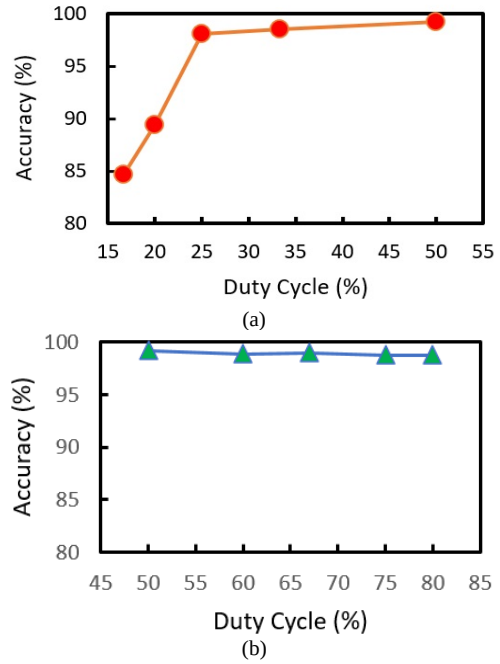

Fig. 4. Duty Cycle Dependency of Accuracy on the Red LED.

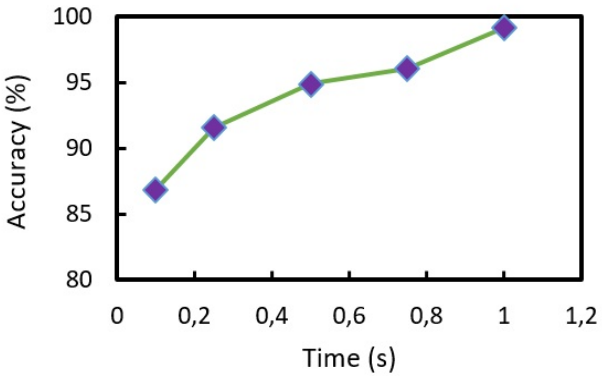

Fig. 5. The t_{on} and t_{off} Dependency of Accuracy on the Red LED under 1 s.

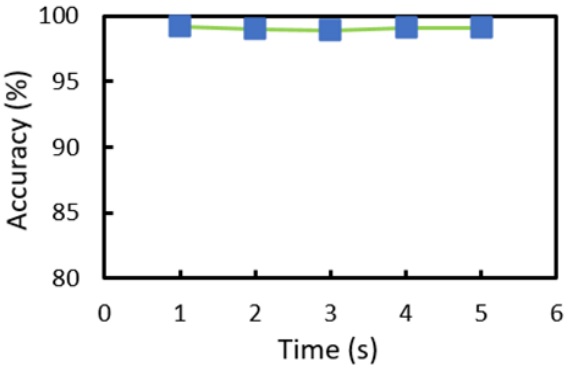

Fig. 6. The t_{on} and t_{off} Dependency of Accuracy on the Red LED after 1 s.

On the data of the 50% duty cycle, the time dependencies of accuracy were analyzed. When the t_{on} and t_{off} are getting smaller, the blinking speed increases, and the accuracy of the duty cycle drops significantly, as shown in Fig. 5. Meanwhile, the variant t_{on} and t_{off} data after one second with the periodic time indicates no significant accuracy shift, as shown in Fig. 6.

Therefore, one second of t_{on} and t_{off} is the cut-off point of time signal and gives the higher accuracy of the duty cycle. Here, all the measurement is on the operating range of the spectrometer. The transformation of the accuracy of the duty cycle due to the variant of t_{on} and t_{off} describes the blinking system. Due to the photo detector's response, these phenomena are also affected by the speed ratio (t_{on} and t_{off}).

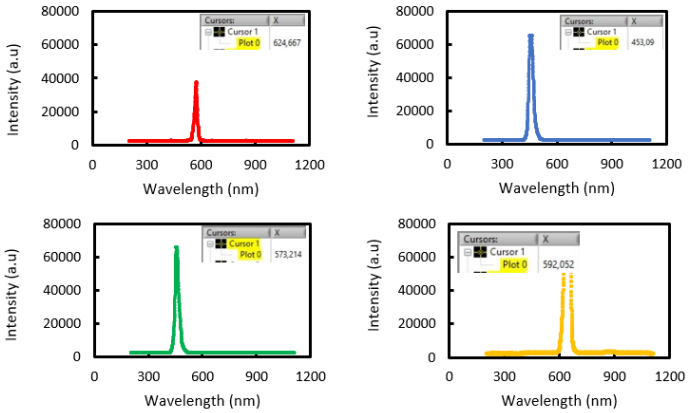

Fig. 7. The Various Wavelength on the Red, Blue, Green and Yellow LED.

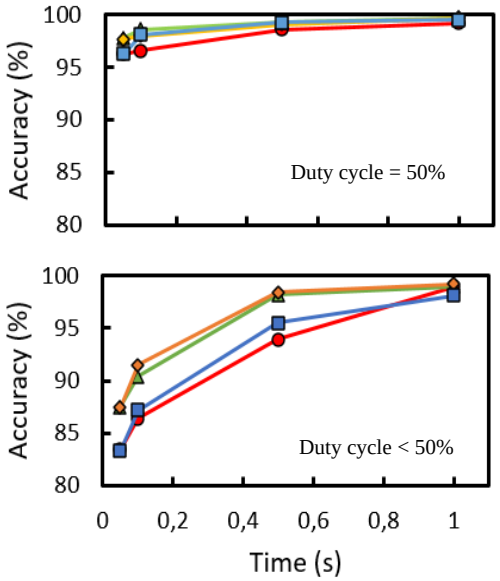

Fig. 8. Time Dependency of Precision Value on the Several Wavelengths LED.

The enhanced measurement was also analyzed with the same method based on the experimental result of duty cycle and variant of t_{on} and t_{off}. Fig. 7 shows that the red LED has 624.67 nm in wavelength. Meanwhile, blue, green, and yellow have 453.09 nm, 573.21, and 592.05, respectively.

On the 50% duty cycle data, the time dependencies of accuracy were analyzed on the various color of the LED, as shown in Fig. 8 (upper side). When the t_{on} and t_{off} are getting shorter, almost the color of LED has lower accuracy, especially at the $t_{on} = t_{off} = 0.05$ s and 0.1 s. When the variant of t_{on} and t_{off} is higher, all the colors of LED get closer to similar accuracy. This result shows LEDs with the various wavelengths has similar accuracy at the highest duty cycle. Moreover, the shortest time range produces the smallest accuracy when the duty cycle is lower than 50%, as shown in Fig. 8 (lower side). Meanwhile, the duty cycle after 50% shows the similar accuracy of duty cycle. The time dependencies accuracy increases significantly when the time range increases periodically. On the t_{on} and t_{off} equal 1 s, almost the variant of LED has a similar accuracy. Note that the red and blue LED has the lowest accuracy in almost all conditions.

B. Object Recognition of LED Blinking

LED with continuous light always keeps and locks on the computer vision as shown in Fig. 8. However, when the LED blinking is on, the LED is on t_{off}, and the camera cannot recognize the object as shown in Fig. 9. In this work, the report evidence that the combination of t_{on} and t_{off} and the value of the duty cycle can lead computer vision always to capture objects and lock them in the visual display.

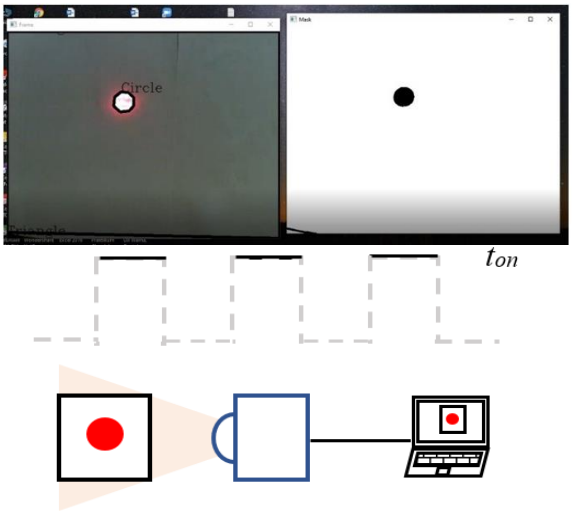

Fig. 9. The t_{on} Condition, the Marker Captured Well by the Camera.

The display in Fig. 9 consists of the original frame and masking the frame. The original frame shows the object and the bounding of object contour for the object recognition system. Then the masking frame display is the original frame with the reducer noise filter. The masking frame is presented in the black and white mode. The object is represented in the white color, and all the background will show in black color area. In this condition, the PWM signal is always in upper position (t_{on}). However, t_{on} condition of LED in range of camera was captured continuously as sown in Fig. 9.

Meanwhile, Fig. 10 shows the original and the masking frame cannot recognize the object contour for t_{off} condition. In this case, the PWM signal is always in under position (t_{on}). However, t_{off} condition of LED in range of camera was not captured continuously. Here, the dotted circle is the representative of the LED position.

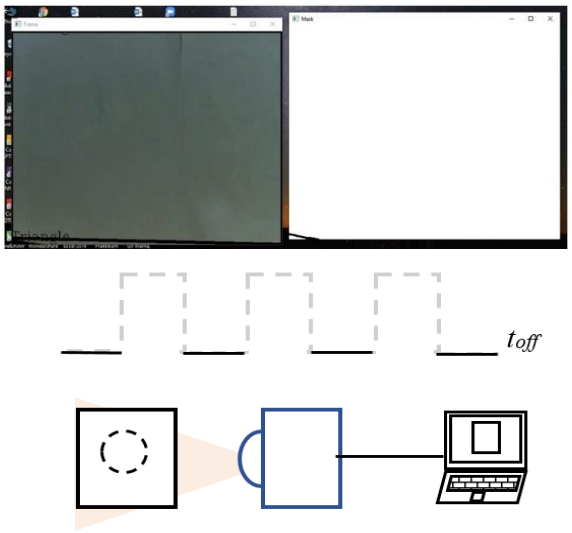

Fig. 10. In the t_{off} Condition, the Marker is not Captured All the Time by the Camera.

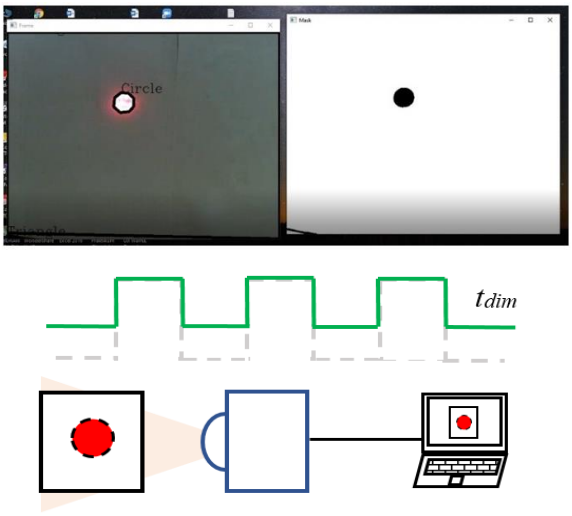

Fig. 11. The Combination between t_{on} and t_{dim}, the Marker Captured Well by the Camera.

The unique blinking of encoding LED as a marker is captured perfectly on the camera as well as shown in Fig. 11. As long as the unique blinking consists of the bright-dim method, a camera always locks the *x*-axis and *y*-axis. However, the bright-dim condition was proposed to solve the t_{off} condition as shown in Fig. 10. In bright-dim condition, the PWM signal is always in upper and middle position. However, t_{bright} - t_{dim} condition of LED in range of camera was captured continuously. LED with bright-dim condition always keeps and locks on the computer vision as shown in Fig. 11.

Fig. 12 shows the unique blinking concept and the evident of it sent in other files. This unique marker will be recognized, and the distractor markers will not be recognized by camera.

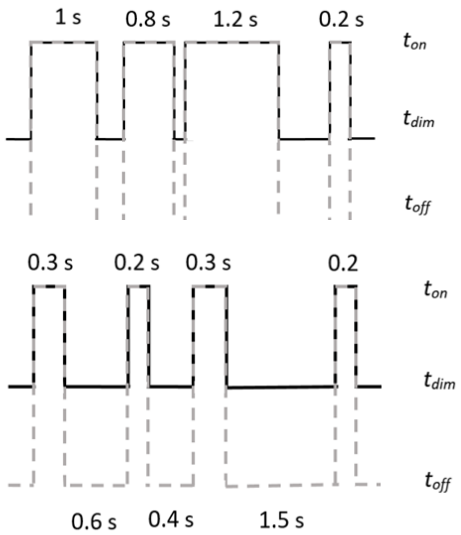

Fig. 12. The Variant of PWM Signals that can be produced to Unique Markers. A Combination of Bright-Dim Captures the Markers All the Time on a Camera.

IV. Conclusion

A new object recognition approach with the unique LED marker is studied rapidly to propose an encoding marker. Camera and image processing would only recognize the unique marker. Characterization LED blinking has been successfully analyzed by controlling the PWM signal with a variety of duty cycles. The accuracy of the duty cycle is one of the parameters to describe the characteristics of LED blinking. The experiment results show that the highest accuracy is obtained on a 50% duty cycle with the range of time 1 s on any LED color. The object recognition system captured all variant LED blinking with the bright-dim method.

This method potentially applied for the future work to the smart weapon in the military system, especially the movement of three-dimensional objects that can applied to air-ground smart missiles.

Inherent Feature Extraction and Soft Margin Decision Boundary Optimization Technique for Hyperspectral Crop Classification

Mr. M.C.Girish Babu, Dr. Padma M.C
Department of Computer Science and Engineering
PES College of Engineering
Mandya, India

***Abstract*—Crop productivity and disaster management can be enhanced by employing hyperspectral images. Hyperspectral imaging is widely utilized in identifying and classifying objects on the ground surface for various agriculture application uses such as crop mapping, flood management, identifying crops damaged due to flood/drought, etc. Hyperspectral imaging-based crop classification is a very challenging task because of spectral dimensions and poor spatial feature representation. Designing efficient feature extraction and dimension reduction techniques can address high dimensionality problems. Nonetheless, achieving good classification accuracies with minimal computation overhead is a challenging task in Hyperspectral imaging-based crop classification. In meeting research challenges, this work presents Hyperspectral imaging-based crop classification using soft-margin decision boundary optimization (SMDBO) based Support Vector Machine (SVM) along with Image Fusion-Recursive Filter (IFRF) and Inherent Feature Extraction (IFE). In this work, IFRF is used for reducing spectral features with meaningful representation. Then, IFE is used for differentiating physical properties and shading elements of different objects spatially. Both spectral and spatial features extracted are trained using SMDBO-SVM for performing hyperspectral object classification. Using SMDBO-SVM for Hyperspectral object classification aid in addressing class imbalance issues; thus, the proposed IFE-SMDBO-SVM model achieves better accuracies and with minimal misclassification in comparison with state-of-art statistical and Deep Learning (DL) based Hyperspectral object classification model using standard dataset Indian Pines and Pavia University.**

I. Introduction

Agriculture plays a very important role in improving major developing country economy. High productivity of food yield will aid in meeting food security. However, with global warming, it is hard to achieve a very high yield. A significant amount of crops is lost worldwide due to natural disasters such as drought, cyclones, and floods; leading to loss of life of farmers/people. A farmer requires timely relief of funds for disaster management. Allocating the right kind of funds is challenging, as farmer grows multiple crops within the same region. Thus, efficient crop identification methodologies are needed. Hyperspectral Imaging (HSI) is an efficient method used for crop identification. Extensive work has been done in recent times for crop recognition in agriculture environment such as Locally Adaptive Dictionary (LAD) through Multiscale Joint Collaborative Feature (MJCF) [1], spatial-spectral feature extraction through end-to-end deep learning framework [2], neural network learning framework for extracting adaptive Spatial-Spectral Features [3], Improved CNN framework combining Markov random fields for extracting spatial-spectral feature [4], Conditional Random Field and Deep Metric Learning for HSI classification [5]. However, following challenges such as high dimension size, presence of noise, and high similarity among spectral features, shapes, textures of different crops must be addressed in building an effective hyperspectral imaging-based crop classification method. Hyperspectral imaging consists of hundreds of Narrow Bands that are continuous with high spectral correlation. Thus, results in Hughes phenomenon, space, and computation complexity as shown in following work such as band selection through End-to-End deep learning architecture [7], hierarchical spatial-spectral feature maps through CNN [8], spectral-spatial feature extraction using CNN and information measure [9], and Active learning-based CNN model [10], a hybrid model combining Inception and Deep Residual Network [11] for HSI crop classification.

The crop classification accuracies can be improved by the utilization of feature extraction and feature selection methods. Existing methodologies predominantly used Principal Component Analysis (PCA) and Independent Component Analysis (ICA) for reducing the feature size of hyperspectral images [12]. The ICA-based hyperspectral crop classification methodologies assure the extracted feature is independent; nonetheless, ICA induces high computation overhead and doesn't guarantee to retain spatial information. On the other side, PCA-based hyperspectral crop classification methodologies realize good classification accuracy when compared with ICA- based methodologies. The PCA- based methodologies aid in assuring stabilizing features with a limited size of high meaningful representation. Nonetheless, PCA-based HSI crop classification methodologies are not efficient in retaining useful spectral features. Thus, for retaining spectral features more efficiently Image fusion (IF) methodologies are used in recent work. However, IF-based methodologies achieve poor classification performance; this is because they are affected due to the presence of noise and

mixed pixel due to different illumination and climatic conditions [13], [14].

Recently, Deep Learning (DL) methodologies [15], [16] have been adopted for HSI crop classification [17], [18] with good accuracies [19], [20] which is studied in literature survey section. However, these DL-based methodologies induce high computation overhead and require a higher number of training parameters [21]. Further, induces high misclassification when data is imbalanced. For overcoming research problems it is important to extract meaningful features both spectrally as well as spatially; further, it is important to eliminate shading features from crop inherent features to classification accuracies. Here we used image fusion and recursive filter (IFRF) [22], [23] for obtaining semantic features across different bands i.e., spectrally. The usage of IFRF aided in reducing feature size with meaningful representation. Then we present an inherent feature extraction (IFE) method for distinguishing physical properties and shading elements of different crops. Existing models are trained using a Support vector machine (SVM) [18] for performing crop classification; the classification accuracies using SVM are affected due to misclassification [19]; especially when data is imbalanced and two objects exhibit similar physical features [20]. Thus, to address data imbalance issues and reduce misclassification in this we introduced a soft-margin decision boundary optimization model for SVM. The SMDBO-SVM based crop classification model aided in achieving high classification with less misclassification in comparison with the deep learning-based classification model.

The significance of using IFE-SMDBO-SVM is described below:

- Presented effective spatial-spectral feature extraction mechanism namely IFE. The IFE model can extract semantic features even under different illumination and climatic conditions.
- Presented soft-margin decision boundary optimization model for performing classification when HSI data exhibit data imbalance and also under mixed pixel environment.
- SMDBO-SVM based HSI achieves high classification accuracies with less misclassification (i.e., Kappa coefficient) in comparison with recent deep-learning-based HSI classification models.
- The SMDBO-SVM based HSI classification model reduces computation overhead in comparison with deep-learning-based HSI classification models.

The rest of the paper is organized as follows. Section II discusses various existing hyperspectral crop classification models and establishes the benefits and limitations, and hypotheses of the proposed method. Section III presents Inherent feature extraction and soft margin decision boundary optimization for Hyperspectral image-based crop classification methodology. In section IV, the performance efficiency of IFE-SMDBO in comparison with the existing HSI classification methodology is discussed. In the last section, the benefit of IFE-SMDBO is discussed and the future direction of work is discussed.

II. Literature Survey

This section presents some of the recent methodologies presented for performing crop classification using the hyperspectral image. In [2] presented HS-CNN (Hybrid Spectral Convolutional Neural Network) based HSI classification model. They first employed 3D-CNN for extracting spectral-spatial information followed by 2D-CNN. The classification performance of the HSCNN model heavily relies on both spectral and spatial information of HSI. The HS-CNN model can joint retain spatial-spectral feature sets from different brands. The hybrid CNN model aids in learning more abstract level spatial features with minimal overhead in comparison with the 3D-CNN model. In [6], presented recurrent neural network (RNN)-based HSI classification. Here the spectral information is considered as a sequence; however, they showed standard RNN models are difficult to train and are not efficient as spatial features are not used. Thus, they presented Shorten Spatial-spectral RNN Parallel-GRU (St-SS-pGRU) by combining convolution layers to achieve better HSI classification performance. In [16] showed that the 2D CNN just focused on extracting spatial features; however, neglects to extract spectral features. Similar, to [2], [21] presented a 3D CNN model that jointly considers extracting both spatial and spectral features; however, with reduced computational overhead by distributing spatial and spectral features extraction across different layers. In [15] showed CNN is widely used for HSI classification; However, they significantly because of high misclassification at the pixel level. In particular at the edges of neighboring crops; this is because the impact of adjacent pixels crops is different from target pixels. To address this, here they presented a center attention network (CAN) for HSI classification. The CAN-HSI can extract spatial and spectral features of both target pixel and adjacent pixels together in a simultaneous manner for performing HSI classification. In CAN major importance is given to highly correlated features concerning target pixels; thus aiding HSI classification performance. Further, CAM reduces parameters through a weighted sum of spatial and spectral features to reduce computation overhead without compromising on HSI classification accuracies.

In [14] showed DL-based method generally use patch-wise learning architecture for HSI classification. In recent times fast patch-free global learning (FPGA) frameworks have been modeled for HSI classification considering global spatial contextual information. Nonetheless, when HSI data is imbalanced the FPGA-based HSI classification finds it difficult in extracting discriminative features. To address they presented "spectral-spatial dependent global learning (SSDGL) architecture employing global joint attention (GJA) technique and global convolution LSTM (GCLSTM). In SSDGL for addressing data imbalance issues employed hierarchical tradeoffs sampling solution and weighted softmax loss function are modeled. The GCLSTM model is used for extracting LSTM dependencies of spectral features and later these dependencies are used for distinguishing spectral features for crop types. The GJA model is used for extracting attention areas for identifying the most discriminating features. In [17],

for improving the robustness of standard machine learning models, recent work has emphasized integrating traditional ML models into DL methodologies. Here they studied modeling Deep SVM (DSVM) for HSI classification. The DSVM is modeled by implementing four kernel functions as polynomial, neural, Gaussian radial basis function, and exponential radial basis function. The standard SVM model is used for interconnecting weights of the entire network; the interconnecting weights act as a regularization parameter.

The research hypothesis the problems that existing SVM-based Hyperspectral object classification [18] are modeled using hard margin decision boundary [19], [20]; thus, high induce misclassification for smaller classes. Thus, are not efficient when data is imbalanced and induce high computational overheads. Further, the classification outcome is improved through better representation of spatial and spectral information; the proposed research work addresses the aforementioned problems in designing a better hyperspectral object classification model in the next section.

III. Inherent Feature Extraction and Soft Margin Decision Boundary Optimization for Hyperspectral Image-based Crop Classification

This work presents the inherent feature extraction (IFE) and Soft Margin Decision Boundary Optimization (SMDBO) Technique for Hyperspectral Crop Classification. Here first the working model of IFE-SMDBO based hyperspectral crop classification is presented. Second, present an inherent feature extraction model to reduce spectral features and exploit inherent features spatially to distinguish between actual crop and shadowing elements. Then, it discusses the standard SVM model used for HSI classification and highlights its limitation. Finally, present an improved decision boundary mechanism namely soft-margin decision boundary optimization (SMDBO) for addressing data imbalance and mixed pixel problems in HSI classification.

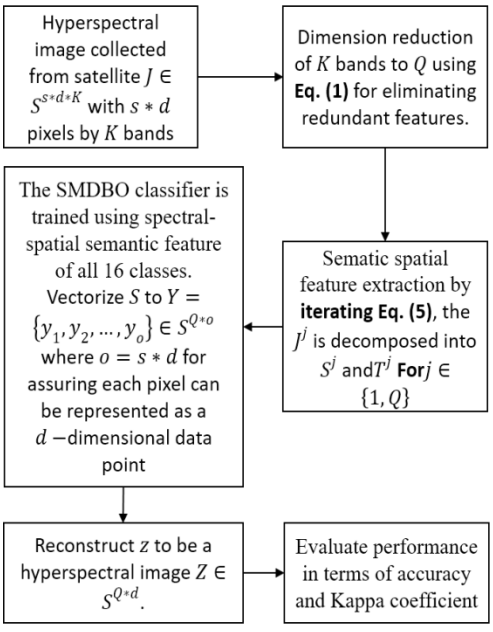

Fig. 1. Block Diagram of IFE-SMDBO based Hyperspectral Crop Classification Technique.

A. Working Model of IFE-SMDBO based Hyperspectral Crop Classification

The step involved in the proposed hyperspectral crop classification using the IFE-SMDBO model is shown in Fig. 1. The first step loads the HSI and reads the entire band information. Second, the HSI size is reduced spectrally using Eq. (1). Third, semantic features are extracted in an iterative manner using Eq. (5). Then, the sematic spatial-spectral feature bare trained using modified SMDBO and performs classification. Finally, the image is reconstructed for validating the accuracy of HSI classification models. The algorithm of the proposed IFE-SMDBO model is shown in Algorithm 1.

Algorithm 1. IFE-SMDBO based hyperspectral crop classification technique.

Input. Hyperspectral image collected from satellite $J \in S^{s*d*K}$ with $s*d$ pixels by K bands.

Output. A classified outcome (i.e., labeled Hyperspectral image Z).

Step 1. Start.

Step 2. Dimension reduction of K bands to Q using **Eq. (1).**

Step 3. For$j \in \{1, Q\}$ do

Step 4. By **iterating Eq. (5)**, the J^j is decomposed into S^j andT^j.

Step 5. End for.

Step 6. Vectorise S to $Y = \{y_1, y_2, \dots, y_o\} \in S^{Q*o}$ where $o = s*d$ for assuring each pixel can be represented as a $d-$dimensional data point.

Step 7. For obtaining labels $z \in S^o$**soft-margin decision boundary optimization-based support vector machine learning (SMDBO-SVM) algorithm** is used.

Step 8. Reconstruct z to be a hyperspectral image $Z \in S^{Q*d}$.

Step 9. Stop.

B. Band Selection and Feature Extraction

Effective selection of band plays a very important role in achieving high accuracies with minimal computation overhead for performing crop classifications. Existing HSI classification methodologies used PCA for reducing band size; however, PCA fails to provide a higher number of useful features. Let consider hyperspectral data with K bands which are reduced to Q bands. Here we employ IFRF [23] for reducing band size and assuring eliminating noisy and redundant pixels spectrally through the following equation.

$$J^l = \frac{\sum_{m=(l-1)n+1}^{ln} J^m}{n},\ l = \left\lfloor \frac{K}{Q} \right\rfloor, \quad (1)$$

where n defines the sub-group band size considered, l defines band indices of reduced spectral bands, m defines band indices of actual spectral bands, and $\lfloor \cdot \rfloor$ a value closer to $-\infty$.

Next, the inherent properties of different crops are extracted by eliminating shading elements in obtaining high-quality features spatially using the following equation.

$$J_q = S_q T_p, \tag{2}$$

where q defines pixel index, $T \in \mathcal{S}^{s*d}$ describes inherent features shading component, $S \in \mathcal{S}^{s*d}$ defining inherent feature component, and $J \in \mathcal{S}^{s*d}$ defines intensity feature. The variable S_q and T_p in the above equation are unknown; however, J_q is a known variable. Generally, the reflectance value changes rapidly in edges and remains constant otherwise; similarly, the pixel with the same value will have the same reflectance value. Keeping the aforementioned context in consideration the S_q is computed as follows

$$S_q = \sum_{r \in \mathcal{O}(q)} b_{qr} S_r, \tag{3}$$

where r defines pixel index and b_{qr} affinity matrix features for measuring similarities between J_q and J_r. the adjacent pixel obtained through Gaussian window as follows

$$GW = \exp\left(-\frac{\|q-r\|_2^2}{2\sigma^2}\right) \tag{4}$$

and σ defines the size considered. Further, defining affinity graph (AG) plays a very essential part in semantically extracting inherent characteristics. Using Eq. (2) and Eq. (4), the meaningful feature is extracted through linear properties as follows

$$\begin{cases} S_r = \sum_{r \in \mathcal{O}(q)} b_{qr} S_r, \\ \tilde{T}_q = \frac{1}{J_q} S_r, \end{cases} \tag{5}$$

where $\mathcal{O}(q)$ defines neighbor pixel q, $\tilde{T}_q = \frac{1}{J_q}$ after obtaining the estimated value of S_r and T_q. Thus each pixel physical properties of different crops are retained, where shading properties are not related to semantic feature sets properties and using inherent features the spatially useless feature can be eliminated.

C. SVM Classification

The feature space is represented as $Y \in S^e$, the index of different crops are represented as $Z = \{-1 + 1\}$, and respective crop distribution over $Y * Z$ is repressed as E. Let us consider that there are o feature points in respective hyperspectral data and n training features as described below

$$T = \{(y_1, z_1), (y_2, z_2), \dots, (y_n, z_n)\}, \tag{6}$$

Here training features selected are identical based on the distribution of E. For predicting the sample considered the following function is defined

$$f(y) = x^U \alpha(y), \tag{7}$$

where x represent the forecaster, $\alpha(y)$ represent corresponding feature mapping of y to kernel L as described below

$$L_{jk} = \alpha(y_j)^U \alpha(y_k). \tag{8}$$

In precise Y represent the matrix where its j^{th} column is $\alpha(y_k)$ which is defined as follows

$$Y = [\alpha(y_1), \alpha(y_2), \dots, \alpha(y_n)], \tag{9}$$

And z is its column vector which is defined as follows

$$y = (z_1, z_2, \dots, z_n)^U \tag{10}$$

The classification margin for describing a crop feature is computed using the following equation

$$\beta_j = z_j x^U \alpha(y_j), \;\; j = 1,2,3, \dots, n. \tag{11}$$

The state-of-art SVM based classification model generally considers that crop features are separable and the hyperplane has the capability in distinguishing the training crop features T with no errors; thus, the SVM classification margin is obtained using the following equation

$$\min_x \tfrac{1}{2}\|x\|^2 \;\; such\ that\ z_j x^U \alpha(y_j) \geq 1, \;\; j = 1,2,3, \dots, n, \tag{12}$$

That maximizes its minimum margin.

D. Soft Margin Decision Boundary Optimization Model

Using above Eq. (12) will lead to high misclassification when used for classifying crops under a mixed cropping environment, when crops exhibit similar features, and when data is imbalanced. Further, there exist scenarios where a very limited feature is available for some crops and the high number of features for other crops; leading to concept drift and data imbalance issues. Using a hard-margin-based SVM classification model defined in the above equation gives a very poor result. Thus, for addressing this paper introduce soft margin decision boundary optimization SVM (SMDBO-SVM) for classifying crops considering concept drift and data imbalance issues. The SMDBO-SVM model optimizes the margin/boundary by minimizing the margin difference and simultaneously maximizing the margin average. Using Eq. (11), the margin difference is computed as follows

$$\hat{\beta} = \frac{1}{n^2} \sum_{j=1}^{n} \sum_{k=1}^{n} \left[z_j x^U \alpha(y_j) - z_j x^U \alpha(y_j) \right]^2$$

$$= \tfrac{2}{n^2} (n x^U Y Y^U x - x^U Y x x^U Y^U x). \tag{13}$$

similarly, the margin means is obtained as follows

$$\bar{\beta} = \tfrac{1}{n} \textstyle\sum_{j=1}^{n} z_j x^U \alpha(y_j) = \tfrac{1}{n} (Yz)^U x, \tag{14}$$

The Eq. (2) decision boundary can be optimized using the following equation

$$\min_x \tfrac{1}{2}\|x\|^2 + \delta_1 \hat{\beta} - \delta_2 \bar{\beta} \text{such that } \alpha(y_j) \geq 1, \;\; j = 1,2,3, \dots, n \tag{15}$$

where δ_1 and δ_2 are parameters used for bringing good tradeoffs.

In non-distinguishable scenarios, the training crop features T can't be distinguished with zero error and ideal hyperplane can't be obtained by minimizing objective function (tradeoffs model of error minimization and margin maximization). For addressing in SMDBO-SVM the error minimization are an

additional parameter used for penalizing misclassified crop features, which is described below

$$\min_{x,\mu} \frac{1}{2}\|x\|^2\, \delta_1\hat{\beta} - \delta_2\bar{\beta} + D\sum_{j=1}^{n}\mu_j \text{ such that} z_j x^U\, \alpha(y_j) \geq 1-\mu_j,\ \mu_j \geq 0,\ \ j = 1,2,3,\dots,n, \quad (16)$$

where μ represent the slack parameter for quantitating feature loss and is computed defined as follows

$$\mu = [\mu_1, \mu_2, \dots, \mu_n]^U \quad (17)$$

D represent the regularization variable that is used for controlling the penalty given to misclassifications. The higher the error, the higher penalty is given to it.

Using Eq. (13) and Eq. (14) into Eq. (16) will result in quadratic programming problem as follows

$$\min_{x,\mu} \frac{1}{2}x^U x + \frac{2\delta_1}{n^2}(nx^U YY^U x - x^U Yzz^U Y^U x) - \delta_2\frac{1}{n}(Yz)^U x + D\sum_{j=1}^{n}\mu_j \text{ such that } z_j x^U \alpha(y_j) \geq 1-\mu_j,\ \mu_j \geq 0,\ \ j = 1,2,3,\dots,n. \quad (18)$$

The ideal forecasting/prediction model x^* for the optimization problem of Eq. (18) is defined using the following equation

$$W^* = \sum_{j=1}^{n}\varphi_j\alpha(y_j) = Y\varphi, \quad (19)$$

where φ described its coefficient which is described as follows

$$\varphi = [\varphi_1, \varphi_2, \varphi_3, \dots \varphi_n]. \quad (20)$$

Using Eq. (19) into Eq. (18), Eq. (18) is updated as follows

$$\min_{\varphi,\mu} \frac{1}{2}\varphi^U R\varphi + q^U + D\sum_{j=1}^{n}\mu_j \text{ such that } z_j\varphi^U L_j \geq 1-\mu_j,\ \mu_j \geq 0,\ \ j = 1,2,3,\dots,n, \quad (21)$$

where the parameter R is computed as follows

$$R = 4\delta_1\frac{[nL^U L - (Lz)(Lz)^U]}{n^2+L}, \quad (22)$$

Then, q is computed as follows

$$p = \frac{-\delta_1 Lz}{n}, \quad (23)$$

The kernel matrix L is computed as follows

$$L = Y^U Y, \quad (24)$$

and L_j represents the j^{th} column of kernel matrix L.

In general, the state-of-art SVM model are used for binary classification purpose; however, in this, we propose SMDBO-SVM as a multiclass classifier. Let consider $Z = \{1,2,3,\dots,m\}$ as a set of crop classes in hyperspectral data; then, $m(m-1/2)$ hyperplane is built all probable pairwise classifier using SMDBO-SVM. Here the SMDBO-SVM model first performs binary classification among two classes j and k through discriminant function $f_{jk}(y) \in \{-1,1\}$ where $j \neq k$ and belongs to Z. Further, it is important for computing weighted function $T_j(y_q)$ for respective individual class $j \in Z$, before making any decision of predicted value y_q. Thus, a weighted strategy is modeled for distinguishing different crops from one another is described as follows

$$T_j(y_q) = \sum_{\substack{k=1 \\ k\neq j}}^{m}\text{sign}\{g_{jk}(y_q)\}, \quad (25)$$

where sign(·) represents the sign function used for binary representation of value. The decision of classified crop y_q is done based on the highest weighted crops as described below

$$j^* = \arg\max_{j\in Z}\{T_j(y_q)\}. \quad (26)$$

The semantic feature extracted from HSI data is trained using the SMDBO-SVM model to aid in attaining better crop classification performance in comparison with the state-of-art crop classification model which is experimentally proven below.

IV. Simulation Analysis and Results

This section evaluated the effectiveness of IFE-SMDBO-SVM based hyperspectral crop classification over various recent state-of-art hyperspectral classification model [1], [4], [6], [10], [14], [15], and [17]. Total two publically available benchmarks HSI datasets such as Indian pines and Pavia University are used for analyzing HSI classification models. The performance of different classification models is measured using the most widely used metric in many existing HSI classification models such as average accuracy, overall accuracy, Kappa coefficient, and computation time. Attaining a higher accuracy value of accuracy and higher value of Kappa coefficient indicated good performance. Alongside, reducing time indicates the model is suitable for real-time deployment.

A. Dataset Description

The Indian Pines dataset is collected through an AVIRIS sensor deployed over the northern-west side of Indiana. The hyperspectral data is collected by setting a wavelength of $0{:}4-2{:}5\times10^{-6}$ meters with 224 bands and 145×145 pixels. The reason for using IP is because the majority of the area covered is the agriculture environment i.e., $2/3^{rd}$ and the remaining $1/3^{rd}$ measured areas are forest and other vegetation that is grown naturally. Further, IP data encompasses small roads, houses, low-lying buildings, and two-lane highways. Alongside, there are crops with early stages of growth which is less than 5% of overall data collected in IP. The ground truth data is composed of a total of 16 crops (i.e., labels) as shown in Table I. Similar, to [14]-[17], the water absorption bands are eliminated and spectral bands size are reduced to 200.

The Pavia University hyperspectral data is collected through the ROSIS sensor. The PU dataset is measured with a spatial resolution of $1{:}3$ meters, with total 103 spectral bands, and composed of 610×610 pixels. Before analysis some data are eliminated they don't provide any information similar to [14]-[17]. The ground truth data is composed of total 9 classes as shown in Table II.

B. Comparative Analysis for IndianPines Dataset

Here experiment is conducted using Indian Pines Dataset for validating the performance achieved using IFE-SMDBO-SVM and other state-of-art HSI crop classification methods such as CNN-AL-MRF, CAM, FPGA, SSDGL, and DSVM. The accuracies achieved for different classes of an object by the individual model are shown in Table III. From the experiment, it can be seen the proposed IFE-SMDBO-SVM achieves much better results than other HSI crop classification methods such as CNN-AL-MRF, CAM, FPGA, SSDGL, and DSVM in terms of accuracies and Kappa coefficient. Further, the IFE-SMDBO-SVM induces very little computation overhead in comparison with CNN-AL-MNF.

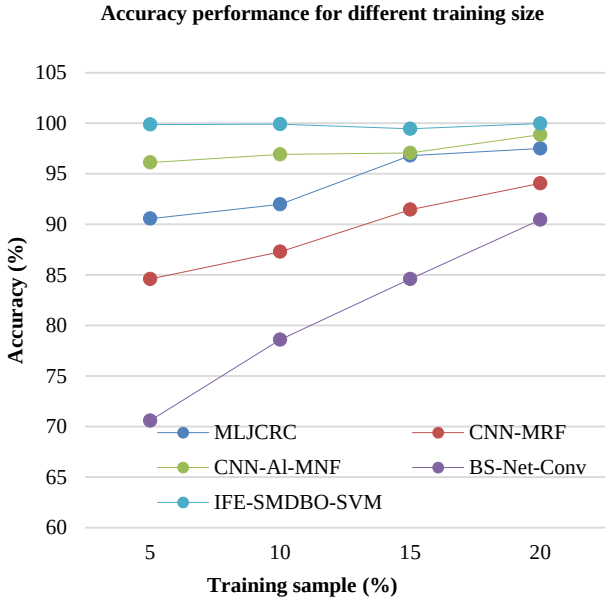

Fig. 2. The Classification Outcome was attained using IFE-SMDBO-SVM and Various Existing Classification Methods.

D. Effect of Varying Training Sample size

This section presents a comparative analysis of the proposed IFE-SMDBO-SVM classification over state-of-art HSI classification methodologies considering the effect training sample size. Here the training sample size is varied from 5 to 20% and the experiment is conducted as shown in Fig. 2. The existing HSI classification methods are MLJRC (Yang et al., 2018) [1], BS-Net-Conv (Cai et al., 2020) [7], and CNN-MBF (Cao et al., 2018) [4], and CNN-Al-MNF (Cao et al., 2020) [10]. From the result achieved it can be seen that among deep learning methodologies CNN-Al-MNF achieves very good performance with accuracies of 96.12% and 99.41% considering the training sample size of 5% and 20%, respectively. On the other, BS-Net-Conv achieves very poor performance with accuracies of 70.58% and 90.45% considering the training sample size of 5% and 20%, respectively. The IFE-SMDBO-SVM achieves very good performance accuracies with accuracies of 98.7% and 99.97% considering the training sample size of 5% and 20%, respectively when compared with other state-of-art HSI classification algorithms such as MLJRC, BS-Net-FC, BS-Net-Conv, and CNN-MBF. From the result, the SFR-HSI is very efficient when there is a very limited training sample available.

E. Effect of Inherent Feature Extraction Method

This section evaluates the effect of using IFE in a classification task. The classification accuracies obtained by IFE-HSI and other existing HSI crop classification methodologies are graphically shown in Fig. 3. The effect of using and not using IFE is shown in Fig. 4. From Figure, it can be seen how IFE aids the classification accuracies enhancement. Thus, it can be stated the IFE-SMDBO-SVM model can learn crop inherent features more efficiently by eliminating the shadow component.

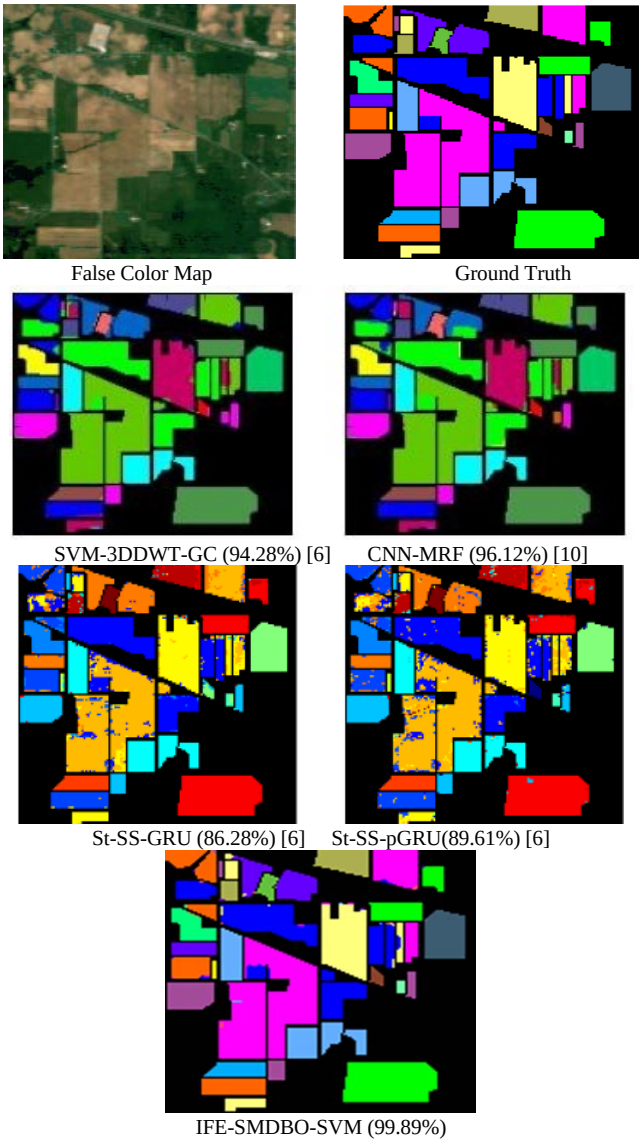

Fig. 3. Classification Maps were Obtained by All Methods on the Indian Pines Dataset (Overall Accuracies are reported in Parentheses).

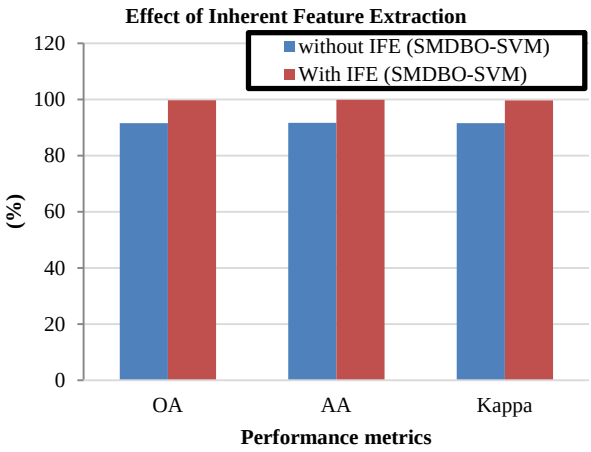

Fig. 4. Effect of IFE on Hyperspectral Object Classification Performance.

V. Conclusion

Designing hyperspectral crop classification with high accuracies with minimal computation time is challenging. In achieving high accuracies existing methodologies used machine and deep learning models; however, induces high training and computation overhead. In addressing computation overhead, dimension reduction technique has been emphasized; however, these model does not attain good accuracies due to poor spatial-spectral feature representation. This paper presented a hybrid design namely IFE-SMDBO-SVM using dimension reduction and machine learning model together for bringing tradeoffs among achieving higher accuracies with minimal time. The IFE-SMDBO-SVM works significantly well even with a fewer number of training samples; further, modeling of soft margin decision boundary aid in addressing feature imbalance issues during classification. The IFE-SMDBO-SVM much better result accuracies, Kappa coefficient, and computation time in comparison with recent HSI classification models such as SS-pGRU, CNN-Al-MNF, CAM, FPGA, SSDGL, and DSVM. The proposed model attains a much superior OA performance of 98.89% which is better than and slightly better than CNN-Al-MNF 2020. However, the accuracies of existing HSI methodologies are highly dependent on a higher number of samples and induce high computation overhead. However, IFE-SMDBO-SVM can work efficiently even with a small number of training samples with high speed. Thus, the proposed IFE-SMDBO-SVM model is much efficient when compared with existing hyperspectral image classification. In the future would consider introducing artificial noise into the hyperspectral image to meet the real-time requirement of the agriculture environment and see how the proposed HSI classification model can perform.

***Abstract*—Social media networks facilitated the availability and accessibility of a wide range of information and data. It allows the users to share and express their opinions. In addition, it presents the appraisals of the top news and the evaluation of movies, products, and services. This headway has been controlled by a well-known field called Sentiment Analysis (SA). Compared to the research studies conducted in English Sentiment Analysis (ESA), little effort is exerted in Arabic Sentiment Analysis (ASA). The Arabic language is a morphologically rich language that poses significant challenges to Natural Language Processing (NLP) systems. The purpose of the paper is to enrich the Arabic Sentiment Analysis via proposing a sentiment analysis model for analyzing an Arabic multi-dialect text using machine learning algorithms. The proposed model is applied to two datasets: ASTD Egyptian-Dialect tweets and RES Multi-Dialect restaurant reviews. Different evaluation measures were used to evaluate the proposed model to identify the best performing classifiers. The findings of this research revealed that the developed model outperformed the other two research works in terms of accuracy, precision, and recall. In addition, the Bernoulli Naive Bayes (B-NB) classifier achieved the best results with 82% for the ASTD Egyptian-Dialect tweets dataset, while the SVM classifier scored the best accuracy result for the RES Multi-Dialect reviews dataset with 87.7%.**

Keywords*—Arabic sentiment analysis (ASA); arabic tweets; sentiment analysis (SA); natural language processing (NLP); machine learning (ML)

I. Introduction

Most Internet users tend to shift from traditional communication tools (e.g., traditional blogs or mailing lists) to Micro-blogging services. It has a free format of messages and is easy to use. Micro-blogging today has become a top-rated communication tool between Internet users, reflecting users' opinions [1]. These opinions represent any kind of information (political, sport, technology, etc.) that comes from different sources. Sentiment analysis (SA) aims to extract or predict the polarity of users' opinions in a specific area which is a challenging task [2], [3]. SA is considered an important area in Natural Language Processing and Artificial Intelligence to identify emotions and trends about a specific topic. Two main approaches are adopted for SA: machine-learning and Lexicon-based approaches [3]–[5]. The machine learning approach uses a supervised learning approach where a classifier is trained on a human-annotated dataset [6], [7]. Many sentiment analysis researches have been done, especially in the English language. However, there are a huge number of Arabic users on social media posting and sharing their opinions in the Arabic language, expressing feelings and opinions, which can affect many businesses and domains.

Simultaneously, there are many Arabic dialectal variants such as classical Arabic, the language of the Quran, and modern standard Arabic (MSA). The standardized official language is written in the news and taught in schools. In addition, dialectal Arabic (DA) is used in daily life and communications. The Arabic dialects are divided into (1) Egyptian-Dialect Arabic for Egypt and Sudan (EA), (2) Levantine Arabic for Lebanon, Syria, Palestine, and Jordan (LA), (3) Gulf Arabic for Gulf area (GA), and (4) Maghrebi Arabic for Morocco, Algeria, Tunisia, Mauritania, and Libya (MA). Furthermore, Arabic used in social media is usually a mixture of MSA and one or more Arabic dialects [8]–[10].

Arabic sentiment analysis has challenging issues based on two main vectors: Arabic-specific and general linguistic problems. Arabic morphological complexity, limited resources cause the Arabic-specific, and dialects, while the general linguistic issues include polarity fuzziness and strength, implicit sentiment, sarcasm, spam, reviews quality, and domain dependence [9], [11], [12].

The importance of this research is that a sentiment analysis model for analyzing and extracting Arabic text multi-dialect opinions is proposed based on machine learning algorithms and gets high accuracy results. The proposed model experimented using two different datasets (Egyptian and Multi-Dialects datasets). First, the Arabic text is preprocessed to enhance the classifier's performance, such as de-nosing, removing stop words, and applying the lemmatization technique. Then, feature weight and feature selection methods are used. Finally, several machine learning classifiers are applied to extract the text polarity.

The rest of the paper is organized as follows: Section 2 reviews the previous studies and related work, while Section 3 introduces the proposed model. The experimental results are presented in Section 4.

II. Related Literature

Numerous investigations on sentiment analysis approaches have been conducted. The English language has the largest number of research works, while the research efforts exerted for the other languages, including Arabic, are more restricted. This section examines the research work conducted in the field of Arabic Sentiment Analysis (ASA).

Most of the research efforts on ASA studies focused on text processing in a public domain or in news articles, while few efforts were developed in specific domains such as [1], [2], [13]–[18].

Some of the research studies achieved low accuracy results with ML classifiers, as in [1]. On the other hand, some of the research studies used two balanced classes to avoid bias and to achieve better results, such as [15] and [19].

Nabil, Aly, and Atiya [13] used an automatic approach to construct their sentiment dataset in a public domain. They collected 84000 Arabic tweets, and then they determined the most active Egyptian twitters to get the list of the top 30 users. Finally, they filtered the top recent Hashtags to get a list of 2500, and they called it ASTD; it consists of 10,006 Arabic Hashtags classified into machine learning algorithms "SVM, LR, M-NB, B-NB, KNN, SGD, Passive Aggressive, and Linear perceptron" into Subjective "positive 793, negative 1684, neutral 832" and Objective 6691 which has no opinion. Moreover, the objective class doesn't have any effect on sentiment, and its size is too big compared to subjective, positive, and negative classes. The used TF-IDF and CBOW as Text feature and accuracy results showed the best value with B-NB classifier with accuracy 74, 9%.

Abdellaoui, and Zrigui [14] used an automatic approach to construct their sentiment dataset. They collected 5,615,943 Arabic tweets, and then they determined the top 20 most used emojis on Twitter. After that, a list of the ten most used Emojis on Twitter is selected. They dealt with four different dialects, "Egyptian, Levan, Maghrebi, and Gulf," they also used various lexicons to translate dialects to modern standard Arabic MSA. After filtering, they called it TEAD; classifying it with machine learning algorithms "SVM, LR, M-NB, B-NB, DT and RF" into three classes "positive 3,122,615, negative 2,115,325, neutral 378,003 by using TF-IDF and CBOW as text feature and accuracy results showed the best value with SVM classifier with accuracy 84,8%. In this study, they translated dialects to MSA before preprocessing to facilitate the classification process. Further, the number of neutral classes is too small compared to others.

ElSahar and El-Beltagy [20] used an automatic approach to the annotated dataset. They collected four domains as follows "Hotel Reviews, Restaurant Reviews, Movie Reviews, and Product Reviews (PROD)." The dataset was divided into "15K, 8.6K, 1.5K and 15K Arabic reviews for each domain". They dealt with different dialects, "Egyptian, Gulf, and MSA." After filtering, they called each one as (HTL, RES, MOV, and PROD); it classified into two classes "positive, negative," using different machine learning algorithms as "Linear SVM, B- NB, LREG, SGD and KNN" and SVM showed the best accuracy as 82.4%. In this study, they tested the model for each domain separately, so they achieved good results.

Al Mukhaiti, Siddiqui, and Shaalany [1] utilized a new dataset by gathering data from different resources, such as Twitter, Facebook, and Instagram. Thus, overall, 58% of the reviews collected are from YouTube, 37% from Facebook, and 5% from Instagram. They manually annotated the filtered data as negative and positive and segregated them. The best result was 77.7% for accuracy. The study was in the general domain; also, the accuracy results are low despite using two classes.

El-Masri, Altrabsheh, Mansour, and Ramsay [2] utilized a new tool that applies sentiment analysis to Arabic text tweets using a combination of parameters. They tested their work in 8000 tweets with lexicon and machine learning results, and accuracy showed 66.5% with dictionary-based and 34% for SVM.

Oussous, Benjelloun, Lahcen, and Belfkih [15] decided to extract 2000 Moroccan reviews: 1000 positive and 1000 negative, and manually annotated them. They tested their system with machine learning and deep learning techniques. The best experimental results showed 80% with SVM and 95.5% for CNN.

Refaee and Rieser [8] made an Arabic dataset for conclusion investigation, which contains 2000 tweets; categorized into positive, the main half, and negative, the subsequent half. Two techniques were applied to the dataset: corpus-based "Administered Learning" and dictionary-based "Unaided Learning." Four regulated AI calculations were used, i.e., SVM, NB, D-Tree, and K-Nearest Neighbor. The SVM and NB got better outcomes, around 80%. Then again, the vocabulary-based methodology demonstrates that with a huge dictionary, the exactness results were improving. There El-Beltagy, Kalamawy, and Soliman [16] also developed an Arabic sentiment analysis task. The authors were ranked first in the SemEval 2017 task for Arabic SA. They used a set of hand-engineered and lexicon-based features, the classifier of choice was a complement NB classifier, and the accuracy result showed 77%.

Gamal, Alfonse, El-Horbaty, and Salem [17] used a dataset that included more than 151,000 different opinions in variant Arabic dialects, which are labeled into two balanced classes, namely, positive and negative. Various machine learning algorithms are applied to this dataset, including the ridge regression, which gives the highest accuracy of 99.90% with ridge Regression (RR) classifier and 98.95% with SVM. The study showed good results as they used two balanced classes.".

III. Proposed Model

The proposed model aims to extract the people's opinions in Arabic text. The opinions can be classified into three classes: positive, negative, and neutral. The proposed model is based on machine learning algorithms, where six different machine learning algorithms are exploited: Naïve Bayes (NB), Support Vector Machines (SVMs), Decision Tree (DT), Stochastic Gradient Descent (SGD), Logistic Regression (LR), and Random Forest (RF) [21], [22].

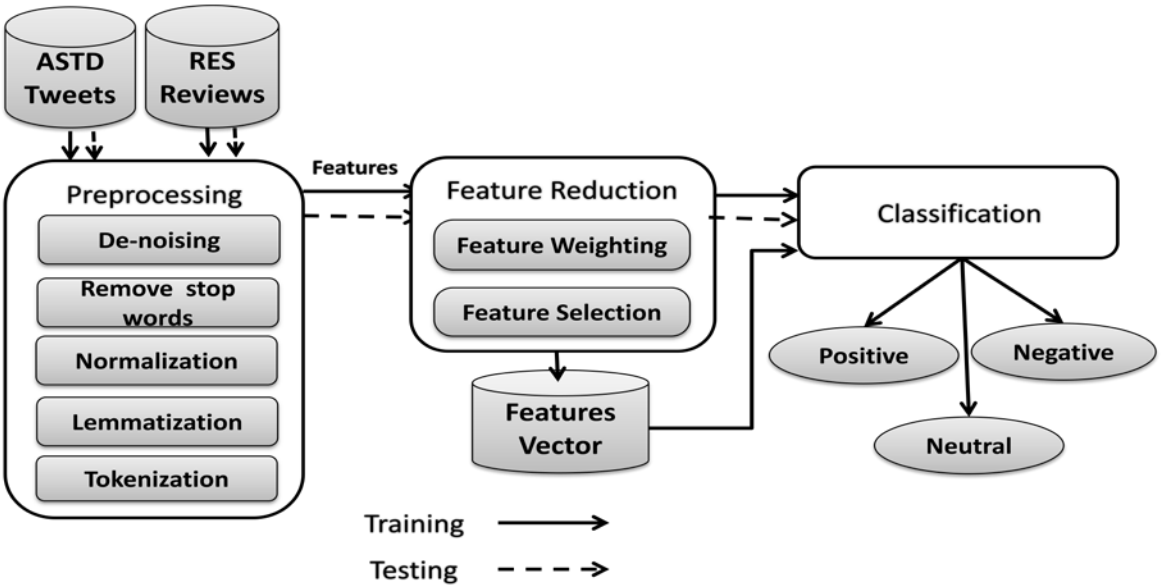

Fig. 1. The Proposed Model.

As shown in Fig. 1, the model consists of three modules, namely the preprocessing, feature reduction, and classification modules. In the preprocessing module, the data should be cleaned and transformed into a format that could be fit into the feature reduction phase. It consists of de-noising, stop-words removal, normalization, lemmatization, and tokenization steps. The feature reduction module is divided into feature weighting and feature selection, which are responsible for scoring each feature and for selecting the most effective features to build the features vector, respectively. Both Sections 3.1 and 3.2 describe the preprocessing and the feature reduction modules in detail, respectively.

Finally, the classification module is applied by using six different machine learning algorithms to classify tweets into three classes (positive, negative, and neutral), as will be explained in detail in Section 3.3. As shown in Fig. 1, the classification process is achieved in two phases: the training and the testing phases, which are represented as solid and dashed arrows, respectively.

A. The Preproccessing Module

The preprocessing process is typically conducted to convert the text into textual features that fit into the SA methods. The preprocessing was applied in a set of sequential steps on two different datasets: Egyptian-Dialect tweets and social media reviews datasets. These steps are tokenization, de-noising, normalization, stop-words removal, and lemmatization.

The preprocessing algorithm is illustrated in Algorithm (1), where the tokenization is the task of chopping a sequence of characters in a document up into pieces, called tokens, perhaps at the same time throwing away certain characters, such as punctuation, space, and punctuation marks [19], [23]. Then, it applies the de-noising step that simply involves using a neural sequence transaction model to back translate the noised text to the original clean text [24]. The de-noising text includes removing URLs, which began by (http ://) until the following space, hash-labels subjects, mentions, punctuations, and special characters. In addition, the symbols for emotions are removed [25].

Algorithm 1 Pre-processing

```
//Tokenization
Input:          tweets_table
Output:         token_table
While (more tweets exit in tweet table) do
        { T=next tweet; P=1;
        While not end of T
                { I= next_space (T);    // determine the position of next
space in T
                  Token = tirm_substring (T,P,I,string);
                   Insert into token_table (tweet number,     token);
                  T=rest_string;}
//De-noising and normalization
Input:          tokens_table

Output:         Updated tokens_table
Arabic_punctuations = {'"', `, ÷, ×, <,>, _, (,), *, &, ^,], [, ,+ ,¦ ,~ ,{,} ,‘ ,“ ,/ ,-
,؛,؛,؛,‘,‘,-,–,“,…,”,!,|}
Emotions = {⌨, ↪, •,          ,.,.,.#...}
S=a set of Arabic vowels
While (more token exist in tokens_table) do
{T=next token;
F= the first letter of T;
While (F in Emotions or Arabic_punctuations or Emotions or S) do // remove
symbols from the beginnig of token
                                {trimleft (T.F.T):
                                 F= the first letter in T:}
                        E= the last letter of T;
While (E in symbols) do //remove symbols from the end of token
                                {trimright (T.F.T):
                                 E= the last letter of T;}
                               Concatenation (T, E, T);
 If (T starts with # or @ or the length of T<=2) then
                        Delete T from tokens_table}
//Stop word removing
While (more token exist in tokens_table) do
{T=next token;
If (T in stop_words_table then
 Delete the entry of T from token_table}
//Lematization
While (more token exist in tokens_table) do
{T=next token;
          If (T=3) then
                        Lemma=T
                        Root=T
                If (T>t) then
                        Remove suffixes from T
                        Lemma=T}

                }
```

While the normalization is responsible for transforming text into a single canonical form [19], for example:

- Removing Arabic short vowels (diacritics) [26] such as " ً، ٍ، َ".
- Removing the duplicate characters that doesn't influence the significance of the word such as "جمييييييييل" is converted to "جميل" "Beautiful" [26].
- Replacing the letter "ة" to the letter "ه ", replacing the letters "أ ، إ ، آ" to the letter "ا".
- Normalizing the words that can be written in different forms to one form. For example, the "emergency" word can be written in Arabic language as "الطوارى" or "الطوارئ". It should be mapped into "الطوارئ".
- Normalizing compound words by going along with them by the character "_ "; for example, "في عالم موازي", which will be standardized to "فى_عالم_موازى" ""in_aparallel_world".
- Furthermore, in removing stop words, there are some words which don't have any effect on sentiment analysis, such as "من ، في ، عن""from, in, about". These stop words are removed using a pre-defined list of stop words [15]. Here an example for removing stop words form a tweet " موقعه مناسب ممكن الوصول اليه بسهولة عن طريق التاكسي" "Convenient location, easily accessible by a taxi" comes to " موقعه مناسب ممكن الوصول بسهولة طريق التاكسي", which minimized data size.

The last step is lemmatization, which converts inflected words to their root form; It helps to minimize the dataset size, which improved the accuracy and performance. For example, "معاك لو تعيدها الف مره" "With you if you repeat it a thousand of times" begins to "مع لو أعاد ألف مر".

After the tweets/reviews data are preprocessed, a list of features is generated and can be represented as ([f1], [f2] … [fn]).

B. The Feature Reduction Module

The Feature reduction module aims to reduce the extracted features. It consists of two processes, which are feature weighting and feature selection. In feature weighting, the extracted features are weighted using the Term Frequency-Inverse Document Frequency (TF-IDF).

Finally, feature selection is applied to select the most candidate features. Then, the selected features will be used as an input for the classification modules.

1) Feature selection: Term frequency-inverse document frequency (TF–IDF) [27] was applied to find strongly affected words for sentiment by evaluating the weight of the feature, where each term 't' is weighted by a weight 'w' using TF-IDF [28]. The Term frequency computes the number of instances of "t" term that appears in the tweets/reviews document, as shown in Eq. (1).

$$Tf(t,d) = (fd(t))/(max[fd(t)]) \quad (1)$$

Where fd (t) is the frequency of the term "t" in tweet/review "d".

The Inverse Document Frequency (IDF) is used to estimate the importance of a given term. It measures how rare a given term in the whole tweet/ review document, using Eq (2):

$$IDF(t) = log(N/dft) \quad (2)$$

Where dft is the number of tweets /reviews with the term "t", and "N" is the total number of tweets / reviews per document.

Finally, the TF-IDF is calculated as the result of the multiplication of TF and IDF as shown in Eq(3):

$$TF\text{-}IDF = tf(t,d)\ IDF(t) \quad (3)$$

2) Feature weighting: After feature weighting, the feature selection process is applied to select the most important and relevant features. The used techniques are classified into two categories are supervised and unsupervised techniques. The supervised technique is used for labeled data to identify the relevant features for increasing the efficiency of supervised models like classification and regression. In unsupervised technique, it can be used for unlabeled data.

In addition, threshold-based approach is applied to identify the least number of features as shown in Table I.

TABLE I. TWEETS-BASED EXPERIMENT ACCURACY RESULTS USING DIFFERENT NUMBER OF FEATURES

NUMBER OF FEATURES		SGD	DT	M-NB	B-NB	SVM	LR	RF
2000	ACCURACY	68	50	60	68	45	62	62
5000		71	57	65	75	50	70	64
10000		78	74	78	82	78	78	77.8
15000		78	74	78	82	78	78	77.8

Cross-validation is used to tune the soft margin parameter C ($\lambda = 1/2C$). Higher values of C add a higher penalty for the misclassified points rather than maximizing the separation margin. Therefore, the optimization problem will lead to a larger number of selected features to reduce the misclassified errors then the threshold value is determined for each experiment to get the results for accuracy.

C. The Classification Module

The most important advantage of ML algorithms is that they deal with a complex problem and gets closer results than humans. In Arabic text processing, complex problems exist and need efficient solutions to solve these problems [6], [29], [30].

In the proposed model, six supervised machine-learning (ML) classifiers were exploited: NB, LR, SVM, DT, SGD, and RF. The used NB algorithms are Multinomial Naive Bayes (M-NB) and Bernoulli Naive Bayes (B-NB). These classifiers have been chosen since they are the most commonly used in the literature of SA [7], [31], [32]. These algorithms are applied to the training set to build the classification model.

SVM is one of the most robust prediction methods based on statistical learning frameworks [33]–[35]. While the NB assumption of attribute independence works well for text categorization at the word feature level [35], [36]. On the other hand, DT is a decision support tool that uses a tree-like model of decisions and their possible consequences, including chance event outcomes, resource costs, and utility [37], [38].

Furthermore, the SGD is an iterative method for optimizing an objective function with suitable smoothness properties. RF is an ensemble learning method for classification, regression, andother tasks. It is operated by constructing many decision trees at training time and outputting the class that is the mode of the classes (classification) or mean/average prediction (regression) of the individual trees [37]–[39].

IV. Experimental

This section presents the experiments conducted in this research and a discussion of the results. The Two experiments have been conducted using two different data sets: Arabic Sentiment Tweets Dataset (ASTD) [13] and Restaurant Reviews dataset (RES) [20].

A. Tweets-based Experiment

In this experiment, the ASTD [13] dataset is used, which contains 10,006 Egyptian-Dialect tweets that are divided as follows: 793 positive sentiment, 1684 negative sentiment, 832 neutral sentiments, and 6691 objective tweets. An example for a positive labeled tweet statement is "محبين البرنامج بيزيدوا", which is equivalent in English to "fans of El-Bernameg are increasing". Further, ASTD data were used in different ASA research because it is completely available. In the first experiment, as the objective class isnot effective in SA, only three classes were considered: positive, negative, and neutral with a total data size of 3,316 Egyptian-Dialect tweets.

Six different classifiers were applied in the tweets-based experiment: DT, SVM, RF, LR, M-NB, B-NB, and SGD. It has been applied to the ASTD Egyptian-Dialect tweets dataset with all the preprocessed steps described above, and hence a feature vector, which consists of 10000 top selected features has been created.

Table II illustrates the evaluation measures of the proposed model using the precision, recall, and accuracy measures. Since tweets in our model are divided into three classes, we have three precisions and recalls value for each class to be calculated [40], [41]by the following Eq. (4):

$$Precision_i Or\ Recall_i = \frac{Tweets\ correctly\ assigned\ to\ class_i}{Tweets\ attributed\ to\ class_i} \quad (4)$$

The B-NB scored the best accuracy with 82 %, followed by SVM, LR, M-NB, and SGD with 78% accuracy, as shown in Fig. 2.

Further, the tweets-based experiment results are compared with the related works that used the ASTD Egyptian-Dialect tweets dataset, as shown in Table III. The results show the different machine learning algorithms used by the proposed model and the related work with their evaluation measures.

TABLE II. Tweets-based Experiment Classifiers Results using ASTD Egyptian-Dialect Tweets Dataset

	SGD	DT	M-NB	B-NB	SVM	LR	RF
ACCURACY	78	74	78	82	78	78	77.8
PRECISION	77	72	80	82	78	77	70
RECALL	78	74	79	82	78	78	86

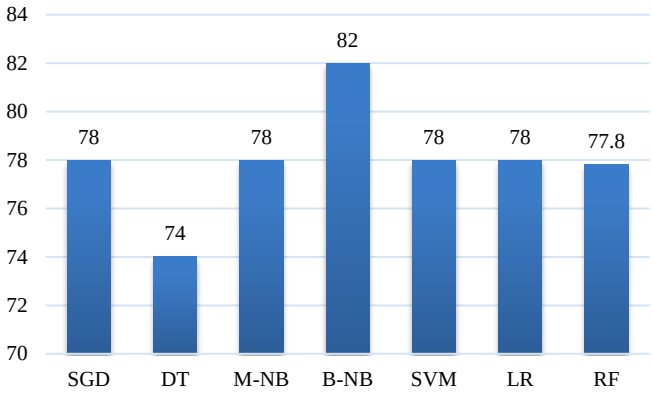

Fig. 2. Proposed Model Accuracy Results for Tweets-based Experiment.

TABLE III. Tweets-based Evaluation Results: the Proposed Model Versus the Related Work using ASTD Egyptian-Dialect Tweets

		SGD	DT	M-NB	B-NB	SVM	LR	RF
Abdellaoui&Zrigui[14]	accuracy	--	68.7	74.4	74.9	75.5	74.9	68.7
	precision	--	78	72	81	75	76	84
	Recall	--	73	72	74	76	74	73
Kaseb and Ahmed [42]	accuracy	--	--	--	--	64	--	--
	precision	--	--	--	--	58.3	--	--
	Recall	--	--	--	--	63.9	--	--
Nabil and Atiya[13]	accuracy	67.1	--	67	66.9	68.9	67.6	--
The proposed model	accuracy	78	74	78	82	78	78	77.8
	precision	77	72	80	82	78	77	70
	Recall	78	74	79	82	78	78	86

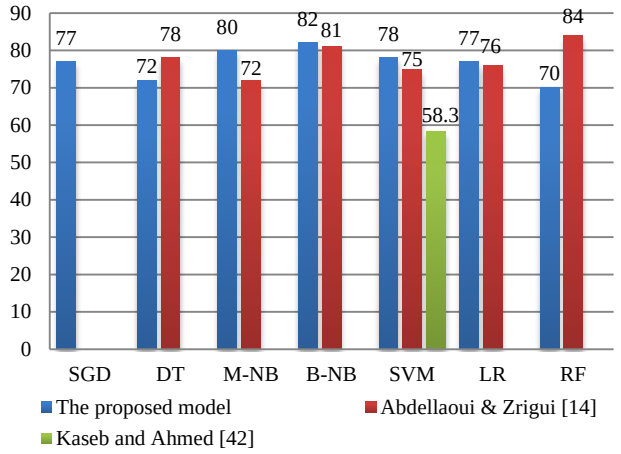

Fig. 3. Precision Value Results for Proposed Model Compared with Related Works for the Tweets-based Experiment.

It is noticed that the proposed model has better values with all classifiers compared with Nabil and Atiya [13] who classified the ASTD Egyptian-Dialect tweets dataset into four classes (positive, negative, neutral, and objective); while the proposed model classified the ASTD Egyptian-Dialect tweets dataset into three classes (positive, negative, and neutral), which are the most popular classes. Further, Nabil and Atiya didn't apply DT and RF classifiers; on the other hand, they are applied by the proposed model.

Both Fig. 3 and Fig. 4 show the precision and the recall for the proposed classifiers model versus two related works.

In Abdellaoui and Zrigui [14] research, SGD is not applied to the ASTD Egyptian-Dialect Tweets dataset, but the proposed model applies it. Moreover, the proposed model achieved better values with all classifiers compared with the above study.

On the other hand, Kaseb, and Ahmed [42] filtered and cleaned ASTD Egyptian-Dialect tweets to 1652 records. Unfortunately, they applied only one SVM classifier and achieved a lower accuracy of 64% compared with the proposed model with 78%.

As shown in Fig. 5, the proposed model with B-NB, SVM, LR, M-NB, and SGD achieved a better accuracy compared to the related work. B-NB achieved 82% versus 66.9% and 74.9% for the related works [13]&[14]. While SVM achieved 78 % versus 68.9%, 75.5%, and 64 % for the related works. Further, LR has higher accuracy with 78% compared to related works with 67.6% and 74.9%. M-NB achieved 78% with higher accuracy than the related works.

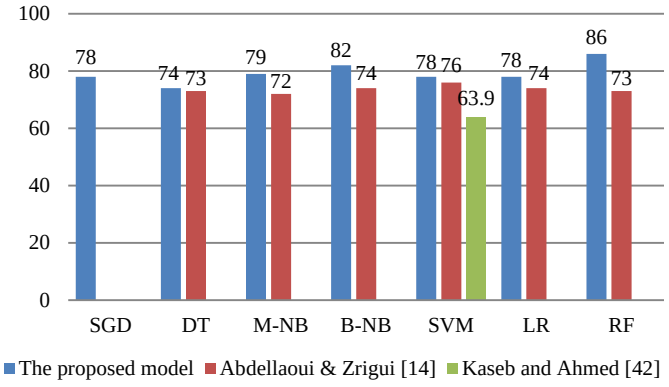

Fig. 4. Recall Value Results for Proposed Model Compared with Related Works for the Tweets-based Experiment.

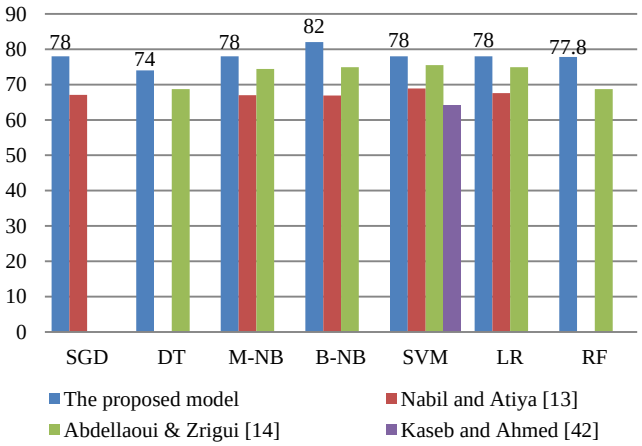

Fig. 5. Accuracy Value Results for Proposed Model Compared with Related Works for the Tweets-based Experiment.

In DT classifier, our module has higher accuracy rating than [14], but without knowing its recall, we cannot comfortably trust the results. Interestingly, recall and accuracy are often at odds with each other, as attempts to boost recall often negatively impact accuracy and vice versa.

B. Review-based Experiment

The Restaurant Review dataset RES [20] is used in the review-based experiment, which was collected from the trip advisor site with a total number of 10,871 reviews. The RES is divided as follows 8021 positive sentiments, 2625 negative sentiment, and 225 neutral reviews. An example of a positive sentiment tweet is "مطعم ممتاز و خدمة حلوى أوى و مكان متميز و معاملة راقية" which is equivalent in English to "Excellent restaurant, great service, excellent place and classy treatment" [20].

TABLE IV. COMPARING REVIEWS-BASED EVALUATION RESULTS AND THE RELATED WORK USING RES DATASET

		SGD	**DT**	**M-NB**	**B-NB**	**SVM**	**LR**	**RF**	**KNN**
ElSahar and El-Beltagy[20]	accuracy	78.4	--	--	82.1	81.4	70.4	--	49.5
The proposed model	accuracy	85.6	76.9	82	79.8	87.2	85.9	83.8	--
	precision	84	74	83	80	85	82	84	--
	Recall	86	77	82	80	87	84	86	--

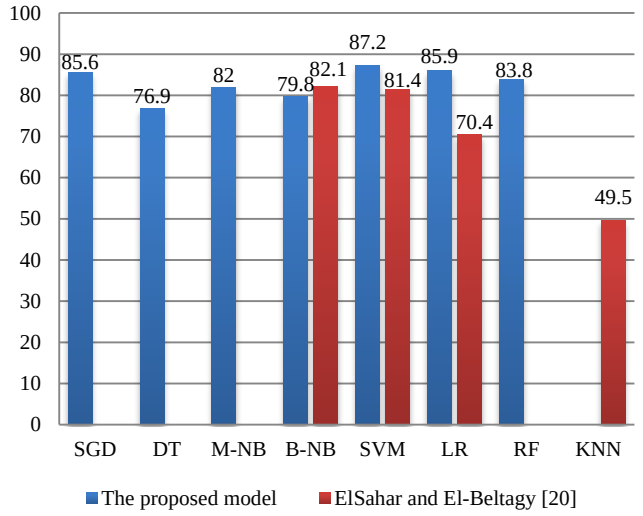

Fig. 6. Accuracy Value Results for Proposed Model Compared with Related Works for the Review-based Experiment.

The review-based experiment is applied using different classifiers DT, SVM, RF, LR, M-NB, B- NB, and SGD with a feature vector that consists of 15000 top selected features. The review-based experiment evaluation results are shown in Table III. It has been revealed that SVM scored the best accuracy with 87.2%, followed by LR with 85.9%, and SGD with 85.6% accuracy. On the other hand, the tweets-based experiment results are compared with the related works that use the RES dataset, as shown in Table IV. The table presents the different machine learning algorithms used by the proposed model and the related work with their evaluation measures. It is noticed that the proposed model has better values with most classifiers compared with ElSahar and El-Beltagy[20]. Also, ElSahar and El-Beltagy did not apply DT and M-NB classifiers, while the proposed model applies them.

Moreover, Fig. 6 Shows the accuracy of the proposed classifier model versus the previous works. The proposed model with SVM, LR, and SGD achieves better accuracy than the previous works. SVM achieved 87.2% versus 81.4% for the previous work while LR achieved 85.9 % versus 70.4% for the related work.

V. Conclusion

The paper has introduced a new model for Arabic sentiment analysis and the effect of different text preprocessing techniques on classification accuracy. The proposed model was evaluated using recall, precision, and accuracy measures. Two different types of Arabic datasets are used: (1) ASTD is an Egyptian-Dialect tweets, and (2) RES, which is Multi-Dialect reviews. Two main experiments have been conducted using machine learning algorithms (DT, SVM, RF, LR, M-NB, and B-NB). The first experiment was applied to the ASTD dataset with 3,316 Egyptian-Dialect tweets. It is noticed that B-NB scored the best accuracy with 82%, followed by SVM, LR, M-NB, and SGD with 78% accuracy. The second experiment was applied to the RES dataset with 10K Multi-Dialect Arabic reviews. In addition, SVM achieved accuracy with 87.2%, followed by LR with 85.9%, and SGD with 85.6%. These results revealed that the proposed model outperformed the related works in the two conducted experiments.

Further, the experiments showed that de-noising, stop words removal, lemmatization, and normalization slightly improved the classification's performance. The proposed model will use different techniques in future work, such as deep learning or lexicon-based approaches.

***Abstract*—The electronic devices that are targeted to the end users have become day to day essential parts. Traditional methodologies have changed drastically resulting in efficient mode of communication and fast information retrieval. As the demand and the production are exponentially growing, patterns of sales, storage and their destruction and then again, their collection have also been changed. This paper analyses many such behaviors of (electronic) waste management and recommends solutions like recycling management, different directives and policies required to be followed. Authors have emphasized on providing substantial information that can be useful to the regulating authorities responsible for waste management or the manufacturers of various electronic products and then the policy makers. With an extensive review of electronic wastages, authors have emphasized three variables (sales, stock and lifespan) for replacing/upgrading the older products with advanced versions. The root causes of electronic wastages are found in industrializing countries like India, China, Vietnam, Pakistan, the Philippines, Ghana and Nigeria whereas industrialized countries also play equally important role for its generation. This paper signifies the importance of e-waste management practice to reduce the emerging electronic waste hazards. Authors focus on today's demand of electronic devices, importance of e-waste management and management practices. The paper recommends key findings based on surveying data regarding the lack of regulation to manage the e-waste. The review concludes that the lack of regulation and improper awareness are the basic factors responsible for e-wastage and requires major focus to manage the e-waste.**

I. Introduction

E-wastage or E-waste is a phrase, widely used to cover items of all types of electrical and electronic equipment (EEE) and its parts that have been discarded by the owner as waste without the intention of reuse. In addition, used electronics which are meant for refurbishment, reuse, recycling through material recovery, or disposal are also considered e-waste. E-waste includes almost any household or business item containing circuitry or electrical components with either power or battery supply. To name a few, Microwaves, Fans, Refrigerators, washing machines, dryers, home entertainment devices, computers, laptops, tablets, mobile phones, Medical equipments like Dialysis Machines, Imaging Equipment, Autoclave, Defibrillator, Office and Information technology equipments like Copiers/Printers, IT Servers, Cords and Cables, WiFi dongles, switches, hubs, routers, Uninterrupted Power Supplies (UPS Systems) and other electronic utilities like Heating Pads, Remote Controls, Electrical Cords, Smart Lights, Treadmills, Smart Watches and many more. [www.ewaste1.com/what-is-e-waste/]

Few decades from now, the major proportion of e-waste was generated from the equipments that were discarded as they were no longer workable but it has been found in recent years that the current advancements in innovations in electronics and electrical technology has resulted into increasing demand for upgraded/faster/new electronic products for replacing/upgrading the older products with advanced versions. Although the exponential growth in electronics and electrical industry has benefited consumers to a great extent with massive technological advancements by making routine tasks easier and time-efficient but has also highly contributed in 'declaring' many workable electronic devices to be considered as obsolete. Thus, contributing to a great extent in generation of global electronic wastage. For instance, Video Cassette Recorder (VCR) players got replaced with Digital Versatile Disc (DVD) players and recently DVDs are being replaced by Blu-ray players. Although DVD players are working fine for normal videos but cannot showcase High-Definition (HD) videos with high quality like Blu-ray players. So, DVDs are now becoming a part of e-waste.

As there has been a sky-rocketing surge in the amount of e-waste due to dumping of electronic products by owners just because new models arrive every day especially for computers, laptops, smart phones and other electronic devices, the e-waste management has become a daunting task for both industrialized and industrializing countries. The Global E-waste Monitor 2020 report has presented statistics related to e-waste generation from 2014 onwards. In 2014, 44.4 MT of e-waste was reported to be generated globally which has risen to 53.6 MT in 2019. The report has predicted e-waste generation to gain manifold increase by the year 2030 and estimated a shocking figure of 74.7 MT.

A. Sources of e-Wastage

Generally, the sources of e-waste comprises of almost all types of electronics and electrical equipments. But due to advancements in technology, new electronic and electrical devices are being introduced that are added up accordingly to the list of sources. So, from time to time authors have given

*Corresponding Author

different categories of devices to be considered for as sources for e-waste.

B. e-Waste Management: A Global Challenge

E-waste management refers to the disposal of electrical and electronic devices in a secured and environment friendly way. Unlike, municipal waste, e-waste requires more sophisticated techniques to be followed for management and disposal due to crucial nature of components being used in electronic and electrical devices.

Most of the electrical and electronic devices especially IT hardware contain toxic, non-biodegradable and hazardous materials including mercury, lead, cadmium, beryllium, chromium, and chemical flame retardants, or or polychlorinated biphenyls (PCBs) which have the potential to leach into soil and water as well as could be hazardous if exposed to air.

C. Impact of E-Waste

The outrageous increase in the amount of e-waste being generated every year across the world has put forth many challenges for industrialized and industrializing countries and has created intense pressure for the execution of sustainable practices to redesign and recycle the products.

In developed countries, several conventions, directives and laws to regulate the e-waste disposal have been formulated for efficient e-waste management which includes Basel Convention, StEP initiative, 3Rs(Reduce, Reuse and Recycle) etc. Product manufacturing industries are taking back items which are collected by retailers and local governments for safe destruction, redesign, recycle and recovery of materials. Undoubtedly, industrialized countries have gone to great lengths to formulate efficient high-cost systems to handle e-waste which includes elaborated collection systems, deployment of clean recovery technologies, carefully engineered disassembly stations, plasma furnaces to prevent release of dioxins. But, despite following various conventions, directives to protect environment from the hazardous implications of e-waste, the majority of e-waste across Europe and North America still remains unrecycled (Barba-Gutierrez et al., 2008). Therefore, to ensure proper disposal of e-waste, developed countries are shipping e-waste to developing countries like China, India, Pakistan, and Nigeria due to availability of cheap labour for recycling.

II. Literature Survey and Background Study

In order to develop a conceptual framework, a systematic review of e-waste management research reported by various authors has been presented in this section. An extensive review is conducted comprising of research papers published between 2005 to 2021. A comparative analysis has been presented in the tabular form.

Both valuable metals and extraordinary materials, like Pb, Hg, As, Cd, Se, Cr, etc. are major factors in creating electronic wastages [1]. These non-ferrous and uncommon metals can be recuperated for additionally reuse and reuse, while the strengthened sap and epoxy sap (with generally bring down financial esteems) can be recouped for their warmth esteems through burning or reused as coatings, clearing and building materials subsequent to being powdered[2,3]. The yearly total entirety of overall EW age ranges from 20 to 50 million tons in created nations [4]. On the off chance that we allude to paper referenced at [5], the total residential electronic and electric waste is required to ascend to around 400 million units by 2015.

In 2010 Yu et.al [6] studied the existing framework for EW management in China counting regulatory policies and pilot projects. In 2012, Chibunna et. al [7], identified and talked about EW management challenges among establishments through a case study at UniversitiKebangsaan Malaysia (UKM).In 2012 Sthiannopkao and Wong [8] provided deeper knowledge about the different directives and policies needed to be followed while handling with EW. In 2013 Wang et. al [9], tried to address how to enhance EW estimates by giving techniques to increase information quality and proposed an advanced IOA method including each of the three variables (sales, stock and lifespan) and best available information focuses to prepare better datasets for modeling. In 2015 Reddy [10], concentrated upon informal EW recyclers who subsidize the environmental costs of Bangalore's IT blast. In 2016 Tansel [11], reviewed the challenges associated with increasing EWquantities. In 2016 Awasthi et. al. [12], explored the environmental contamination from EW recycling at numerous little formal and informal workshops in India. In 2017 Resmi and Fasila [13], proposed a novel calculation for establishing a standard methodology to manage and refurbish EW called EW Management and Refurbishment Prediction (EMARP), which can be adapted by refurbishing industries in order to improve their performance. Here Table I indicated the comparative analysis with advantage and disadvantages of different authors.

Both valuable metals and extraordinary materials, like Pb, Hg, As, Cd, Se, Cr etc. are major factors in creating electronic wastages [14]. These non-ferrous and uncommon metals can be recuperated for additionally reuse and reuse, while the strengthened sap and epoxy sap (with generally bring down financial esteems) can be recouped for their warmth esteems through burning or reused as coatings, clearing and building materials subsequent to being powdered. The yearly total entirety of overall EW age ranges from 20 to 50 million tons in created nations [15]. On the off chance that the total residential electronic and electric waste is required to ascend to around 400 million units by 2015.

TABLE I. COMPARATIVE ANALYSIS

SN	Year	Authors	Advantages	Limitations
1	2021	Tetiana Shevchenko et. al [16]	Proposed a smart reverse system for e-waste management based on intelligent information technology (IT) tools with an aim to minimize collection costs and ultimately, carbon dioxide emissions.	- The proposed smart e-waste reverse system has not been tested in real life scenario. - Lacks real life cost – benefit analysis.
2	2020	Yigit Kazancoglu et.al [17]	Proposed a collection and classification framework for efficient electronic wastage management by incorporating data-driven technologies that would certainly ensure social, environmental and economical sustainability in industrializing and less industrialized nations.	- The initial cost of investment is high. - Absence of adequate knowledge related to data-driven technologies for formulating sustainable solutions.
3	2020	Piotr Nowakowski and Teresa Pamuła [18]	Deep learning techniques have been used for categorizing and measuring the size of e-waste that would aid e-waste collection companies to prepare an effective collection plan.	- The research is confined to Large home appliances. - Small appliances and other categories of e-waste are not considered.
4	2020	Sudan Jha et. al [19]	Almost all aspects of smart cities have been implemented with IT enabled services.	- Despite inclusion of smart technologies in smart cities still they lack in efficient e-waste management.
5	2019	Charu Gangwara et.al [20]	The significant spread of cardiovascular morbidity, namely hypertension, among local residents and on site workers engaged in e-waste processing is explored. The significant correlations between the inhabitants' heavy metal concentration in the blood and corresponding metal concentrations in atmosphere are identified.	- No specific guidelines and safeguard plans have been suggested.
6	2018	Abhishek Kumar et.al [21]	Detailed analysis of e-waste management status, legislation formulated, and technology being used for e-waste recycling in India.	- No specific guidelines and safeguard plans have been suggested.
7	2018	Ashwani Kumar and Gaurav Dixit[22]	Identified '10 barriers' that restrict efficient e-waste management and used interpretive structural modeling (ISM) and Decision Making Trail and Evaluation Laboratory (DEMATEL) for understanding the hierarchal and contextual relationship among the barriers of e-waste management to aid in policy and decision making.	- The proposed model is highly susceptible to judgment and expertise of experts involved for framing the barriers. - Even more barriers could be explored and validated according using different statistical techniques.
8	2017	Stefan Salhofer [23]	Discussed different challenges being faced in e-waste management regarding collection and treatment of e-waste with an overview of technologies applied for the removal of hazardous materials for the recovery of valuable materials. The study focuses on three global areas, namely; Europe, China and Vietnam.	- Deals with hypothetical proposal which are yet to be implemented.
9	2016	Borthakur and Govind[24]	Studied on consumers' EW transfer behavior and awareness with respect to the case of India. Provides a detailed view on the current worldwide EW scenarios.	- Research is primary - Adequate detail.
10	2017	Rahman[25]	Investigated into the responsibilities of peoples played in the EW management in Bangladesh and also examined the existing policy gap and environmental management issues in terms of EW.	- Many issues have been highlighted which is not enough but need to provide solution for the issues.
11	2016	Debnath et. al. [26]	Tried to establish EW management as a parameter for green computing.	Various questions have been raised but did not provide any solution.
12	2013	Dwivedy and Mittal[27]	Attempted to understand the critical elements related with EW	Recycling program in the context of India
13	2013	Pariatamby and Victor[28]	Examined the strategically trends of EW management in Asia	Various questions have been raised but did not provide any solution.
14	2015	Jaiswal et. al. [29]	Individual awareness is addressedregarding EW handling.	Proposes a green framework for EW.

15	2015	Kumar and Rawat[30]	Analytical presentation for managing information for efficient management of EW.	It gives theoretical reasoning only. No realization on the theries proposed.
16	2015	Davis and Garb[31]	Endeavored to give broad field employments and optional written works to offer a logical order of administration positions towards casual EW hones.	The proposed method tackles a noteworthy however not overwhelming portion of the puzzle No other critical issues were addressed
17	2015	Dwivedy et. al. [32]	- Discusses on the "takeback" policies - The paper was based on reasonableness for the Indian conditions.	- Focused on copper links in the EW stream - Discusses upstream and downstream changes - limits and business components of a formalizing division
18	2016	Garlapati[33]	Presented an idea of worldwide EW details, health concerns of EW components alongside the waste management, recycling.	Various regulatory, regulatory bodies and their problems, and corresponding suggestions, recommendations related to EW are not addressed
19	2016	Singh et. al. [34]	Given a review of world's present CRTs squander situation, to be specific extent of the request and preparing, current exchange and reusing operations.	Various questions have been raised but did not provide any solution.
20	2017	Ikhlayel[35]	Attempted to evaluate the environmental effects and	Given a review of world's present CRTs squander situation, to be specific greatness of the request and preparing, current exchange and reusing operations.

Fig. 1. Comparative Analysis of Electronic Wastages w.r.t. the Electronic Product.

TABLE II. POLLUTANTS AND THEIR RESPECTIVE COMMON SOURCES

Pollutants	**Sources of pollutants**
As	Electric diodes, Light Emitting Diodes, Semiconductors, μ-waves, Solar panels
Cu	Printed circuit boards, conductors, etc.
Ba	Filters, insulators
Cd	Cathode Ray Tubes, Cell-batteries, soldering alloys
Pb	Almost all kind of transistors and batteries
Cr	Hubs, Routing devices, switches, etc.
As – Arsenic, Ba – Barium, Cd – Cadmium, Cr – Chromium, Co – Cobalt, Cu – Cuprum/Copper, Pb - Lead	

In an existing framework for EW management in China counting regulatory policies are discussed along with the pilot projects. It also identified EW management challenges in Malaysia (UKM) and provided deeper knowledge about the different directives and policies needed to be followed while handling with EW and addressed how to enhance EW estimates by giving techniques to increase information quality and proposed an advanced IOA method including each of the three variables (sales, stock and lifespan) and best available information focuses to prepare better datasets for modeling. The Global E-waste Monitor 2020 concentrated upon informal EW recyclers who subsidize the environmental costs of Bangalore's IT blast. The challenges associated with increasing EW quantities were of big concern that explored the environmental contamination from EW recycling at numerous little formal and informal workshops in India. It proposed a novel calculation for establishing a standard methodology to manage and refurbish EW called EW Management and Refurbishment Prediction (EMARP), which can be adapted by refurbishing industries in order to improve their performance.

Table I indicates the comparative analysis with advantage and disadvantages of different authors. Fig. 1 shows

Comparative analysis of electronic wastages w.r.t. the electronic products.

The toxic substances contained in Waste Electric and Electronic Equipment (WEEE) are mostly non-degradable plastics [36]. The sources are as shown in Table II.

Apart from these, casings, PCBs, cables etc. are inevitably the most common toxics among assembled electronic devices. Firing, igniting the electronic waste materials are most commonly used today. In developing nations, these practices are done around human inhabitants or residential areas of cities. This lead to the formation of unsafe gasses which seriously damage the respiratory systems of each and every surrounding living being.

In some cases, we observe dumping these materials and landfilling which is less harmful than the preceding one. However, these may sometime become poisonous due to cyanide, lead, arsenic and mercury composition that contaminates at the out scale. Table II features the significant contaminations that cause serious health dangers when recycled improperly [37]. Separated of the few mentioned here, numerous elements pose as health risks.

III. Challenges and Open Issues

In this section, different challenges and issues related to e-waste management have been highlighted to seek attention of stakeholders and general public. Different initiatives and agreements have been established between post industrialized, industrialized, less industrialized and industrializing countries to save our environment and human health from the dangerous effects of e-waste. Various eco-friendly tools and techniques are being formulated for efficient disposal of e-waste with minimal environmental consequences. Moreover, various governmental and non-governmental organizations around the globe have joined hands to spread awareness among communities about e-waste management and related consequences to make them understand its need and criticality.

Despite the active participation of Governmental organizations, non-governmental organizations, industries, other stakeholders, the e-waste management is an 'open challenge' for both developed and developing countries. There are various issues that pose hindrance in the execution of systematic e-waste management strategies. Furthermore, the alarming increase in the amount of e-waste being generated around the years which is expected to reach a limit of 55 million tons in the year 2030 is really 'jaw-dropping'.

It has been observed by author in that with advancement in technologies paved way for change in composition of electronic and electric devices. So, the traditional recycling and disposal e-waste techniques are no longer applicable for the extraction of constituent elements. In Fig. 2 below, change in composition of Personal computers (PCs) over the time has been depicted. In earlier PCs, mainly three constituent elements were present like glass, plastic and metals but in recent PCs, we could varied elements like Zinc, Lead, Iron, Aluminium, Copper, etc.

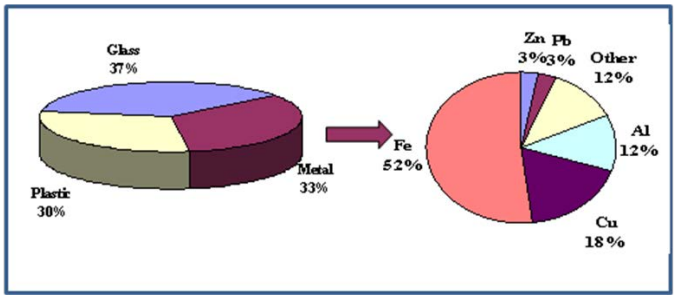

Fig. 2. Change in Composition of Personal Computers.

Therefore, it is evident that e-waste recycling and disposal methodologies need to revised and reformulated for the inclusion of changing composition of e-waste.

A. Switching to Transboundary Shipment

The management of e-waste in developing and transition countries is getting worse day by day. The major factors responsible for this are.

1) Illegal trafficking of waste materials
2) Unauthorized recycling of e-waste
3) Lack of skilled man power
4) No regulatory rules and regulations / protocols flourished for stakeholders and institutions that are involved in e-waste management.

It has become a normal trend that (a) the large amount of e-waste generated from developed countries are exported to developing countries or (b) those discarded by developing countries, are rapidly taken up by transition countries; and this has resulted into a very high impact on emerging economies of these countries.

B. International Treaties

One such example is Basel Convention in which it has been reported that.

- Only 20% of the global electronic wastage are recycled every year; i.e. 40 Mt electronic wastages are burned or destroyed or illegally traded. Further, 50% of these wastages consist of handheld devices and TVs along with household appliances.
- The rate of e-waste generated in emerging economies like India and China is increasing from 5% to 10% annually. These data do not include the imported electronic wastages whether they are legal or illegal.
- The first country in the world where e-waste management system was formally established is Switzerland where 11 kg/capita of e-waste are recycled. Their policy targets 4 kg/capita as regulated by the European Union (EU).

IV. Interoperability of Electronic Wastages

In this section, we characterize e-waste by investigating its criticality. The reuse of EW, state enactment, and the issue of the worldwide shipment of risky e-wastages are also adhered. Various hazardous development in the hardware business has prompted a quick raising issue of end-of-life (EOL) gadgets or

e-squander. Squandering of electronic is growing thus resulting in a high surge for the requirement of powerful hardware reusing programs.

It is assessed that 75% of electronic things are secured in view of defenselessness of how to supervise it. These electronic hurls out lie unattended in houses, work environments, dissemination focuses et cetera and regularly mixed with family wastes, which are at last orchestrated off at landfills. This requires implementable organization measures. In wanders organization of EW should begin at the explanation behind age. This should be possible by waste minimization methodologies and by supportable thing design. Waste minimization in endeavors incorporates getting a handle on:

1) Inventory organization.
2) Changing the production-process.
3) Volume reduction.
4) Recovery and reuse.

Challenges of EW Recycling: The toxic substances contained in Waste Electric and Electronic Equipment (WEEE) are mostly non-degradable plastics. The sources are as shown in Table III. Apart from these, casings, PCBs, cables etc. are inevitably the most common toxics among assembled electronic devices.

Firing, igniting the electronic waste materials are most commonly used today. In developing nations, these practices are done around human inhabitants or residential areas of cities. This lead to the formation of unsafe gasses which seriously damage the respiratory systems of each and every surrounding living being.

TABLE III. POLLUTANTS AND THEIR RESPECTIVE COMMON SOURCES

Pollutants	**Sources of pollutants**
As	Electric diodes, Light Emitting Diodes, Semiconductors, μ-waves, Solar panels
Cu	Printed circuit boards, conductors, etc.
Ba	Filters, insulators
Cd	Cathode Ray Tubes, Cell-batteries, soldering alloys
Pb	Almost all kind of transistors and batteries
Cr	Hubs, Routing devices, switches, etc.

As – Arsenic, Ba – Barium, Cd – Cadmium, Cr – Chromium, Co – Cobalt, Cu – Cuprum/Copper, Pb - Lead

TABLE IV. MAJOR POLLUTANTS AND THEIR EFFECTS OF HEALTH

Pollutants	**Major organic attack**
Lead	- Psychological degradation
Plastics	- Respiratory organs damage
Cadmium	Affecting - bones and joints - digestive systems
Acid Leachates	- Respiratory issues - Eye infection - Skin erosion

In some cases, we observe dumping these materials and landfilling which is less harmful than the preceding one. However, these may sometime become poisonous due to cyanide, lead, arsenic and mercury composition that contaminates at the out scale. Table IV features the significant contaminations that cause serious health dangers when recycled improperly. Separated of the few mentioned here, numerous elements pose as health risks.

Waste Electric and Electronic Equipment (WEEE) or EW joins a wide and growing collection of electronic devices going from tremendous family unit contraptions, for example, coolers, ventilation systems, PDAs, singular stereos, and buyer equipment to PCs disposed by the customers. These equipment needs to be well treated, mostly mercury, chromium, arsenic, lead, cadmium, and plastics responsible for various toxics.

V. SCHEMATIC FRAMEWORKS FOR E-WASTAGES PRACTICED TILL DATE

The electronic wastage has been practiced in a smaller note in most of the countries. Table III justifies this statement. The countries adhering to their policies also aren't able to implement the same as per the expectation. Fig. 3 is a schematic (conceptual) framework carried out based on the rigorous survey and relevant literature done by the authors. This clearly indicates that there are some of the unorganized sectors seem to be active in many regions. Due to the lack of proper policy, the authorities are not in a position to give the proper regulatory actions to be taken in care of these wastages. Even it is very disappointing to note that there is no reliable source available that can state about (a) the total number of organizations involved in such activities and (b) amount of e-waste that is recycled by the concerned dominants.

Descriptive analysis of our review work includes central tendency, mean and variation of variables of the study (See Fig. 1). Each of the variables are segregated into 24 aptitude questions.

A. Political or Regulating Factors (PRF)

The PRFs are analyzed based on four measuring questionnaires.

PRF1 – The degree of governments' initiation in managing EW

PRF2 – Properness of policy for EW Management.

PRF3 – Consciousness among of international community in EW management, and

PRF4 – Degree of following the international practices to handle the E-Waste

Fig. 4 depicts the bar diagrammatic view of PRF1, PRF2, PRF3 and PRF4. This clearly indicates the lack of significant policies for EW management. Proper policy helps to manage the e-waste in effective ways that is generating every year.

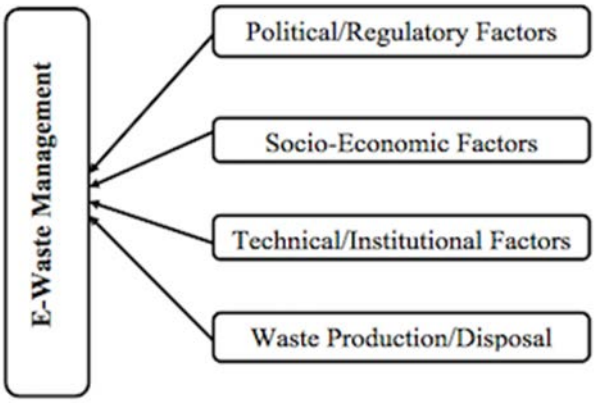

Fig. 3. Theoretical Framework of E-Waste.

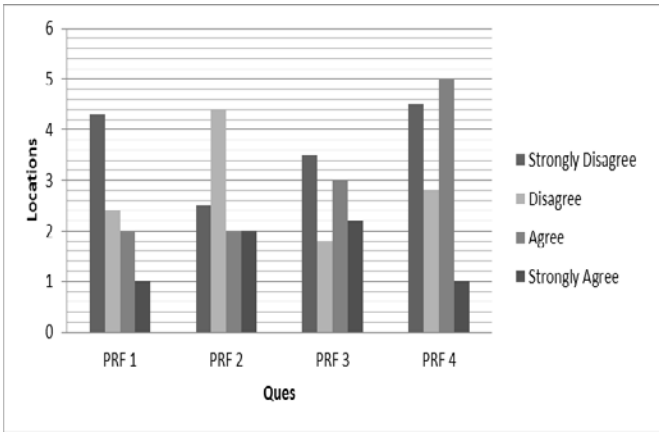

Fig. 4. Political/Regular Factor.

B. Waste Production/Disposal (WPD)

Four different questionnaires were been floored to analyze the effect of waste Production and Disposal.

WPD1 – referred to the scale at which the EW are generated on daily basis,

WPD2 – referred to the rate at which the electric or electronic equipment were discarded or donated per person,

WPD3 - referred to the status of discarded electric or electronic equipment – whether they are thrown away cumulating other waste, and

WPD4 - if those discarded or disposed electric and electronic equipment had any hazardous parts and that if any special method for safety disposal were applied.

Fig. 5 can be concluded with respondents' response that a special procedure is required utmost for disposal of electronic wastages. Due to the advanced technology, every year many electronics items are being produced and side by side every year electronics items are getting damaged and e-waste are produced. In developing countries, there is no advanced technology to manage this e-waste; i.e. damaged items are not disposed properly.

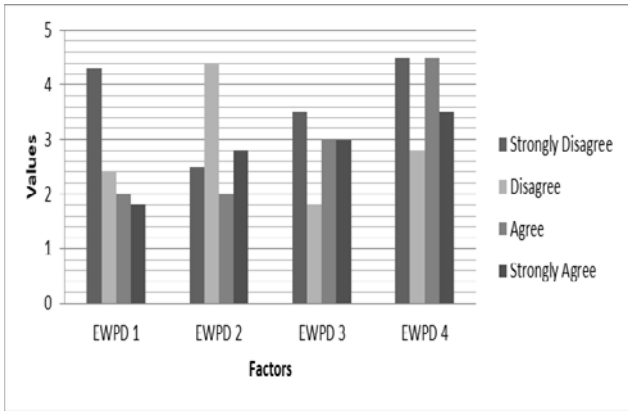

Fig. 5. Waste Production/Disposal.

C. E-Waste Management (EWM)

The four different questionnaires polled for EW management were as below:

EWM1 - awareness about EW management,

EWM2 – necessity of EW collector

EWM3 – convenience of the existing method for EW, and

EWM4 – accessibility of information regarding EW management.

Based on above queries, Fig. 5 is schematized. Fig. 5 depicts electronic wastage collector is the need of the hour which will ease the process of disposal. It will also reduce / resolve the confusion regarding purpose of e-waste.

VI. Findings and Recommendations

We have performed a rigorous review on electronic wastages. The reviews were based on five main factors. They are (a) Political / Regulating, (b) Social-Economic, (c) Technical / Institutional, (d) Waste Production / Disposal and (e) EW Management factors were examined. Based on analysis and various literature survey, the findings are listed as below:

1) Lack of regulatory body in tracing and handling EW
2) Lack of Solid governmental policies to tackle EW
3) Managing electronic wastes

a) from house hold, and
b) work-places

4) Reusability and finding out the possibility of reusable of these components or EW for future use without affecting any of the other factors

5) Regular updates regarding the current (and past) status of EW of various EEE

6) Finding out the correct sources that are responsible for EW

7) Assessing the barriers of EW management.

The survey was conducted among 151 individuals who were "understood as aware of EW" and data were collected in physical form. These individuals were categorized as individual working in technology related companies; electrical

or electronic (or both) shops; the individual working in handling the e-waste management. Out of 151 individuals, 61 females and 90 males comprising the percentage of 40.4% and 59.6%, respectively.

In addition to age, there are 37.7% of respondents who fall under the age group below 25 years, 56.3% respondents are aged 26-35 years, 2.6% respondents are of age group 36-45 years and 3.4% of respondents are of age group of 46 and 55 above year. 23.1% of respondent are student, 42% of respondents are Service holders, 11.9% of respondent are self-employed (Business) and, 22 % of respondent are engaged in other professions.

Based on the survey, data and findings indicated above, authors propose the recommendations as below:

1) Awareness / consciousness regarding managing EW is mandatory. There is a very less human resource working for EW, their efforts and activities need to be maximized one of which may be done through promotional activity.

2) It is well understood that the growth of generation of EW is exponential. Advanced technology as perturbed by UN (2014) should be availed specially to developing countries.

3) EW collector needs to avail to each sector for the E-Waste Management.

4) Technical manpower to be produced by the authorized body by providing related technical knowledge and thus generating skilled manpower in EW management.

5) The rapid advancement in ICT has result in improve capacity in computing devices but simultaneously decreases in the product lifetime as a result the generation of EEE components are growing rapidly. A concrete policy and budget in e-waste management should be allotted.

VII. Conclusion

Electric and electronic wastages can result into an environmental disaster. An analytical study was done regarding EW and it was found that despite of consciousness, and awareness about these kind of wastages, appropriate measures are still not initiated for proper monitoring, mitigating and managing the EW scientifically. Sources responsible for creating electric and electronic wastages were also discussed. No authorized sectors have been officially designated for the same in most of the developing countries which is the need of the hour. Therefore, this paper focuses on the importance of e-waste management and its management practice and identifies some key findings along with recommendations based on various socio-tech factors. Based on surveying data, the paper concludes that lack of regulation regarding e-waste is the major concern to manage the e-waste.

VIII. Future Work

To measure the reliability of this study, Cronbach's alpha will be used after the collection of data from wide sectors and a significant procedural conceptual model will be proposed.

Lima-Perú

***Abstract*—The objective of this article is to show the application of a supervision, control and acquisition system of an industrial network of chemical products, for which the design of the control logic and the architecture of the industrial network on Profibus-DP protocols is described and Ethernet, with a peripheral terminal station ET-200, through the Siemens CP433 programmable logic controller and level sensor sensors, coupled to radar-type transmitters with an accuracy of ± 0.5 mm. As findings of the implementation of the control system, it was possible to demonstrate the optimal regulation of the filling system of the 3-compartment trucks with a capacity of 300 Kilos each, generating the elimination of spills of the chemical product, as well as the reduction of polluting particles in the work environment. Finally, as a direct consequence, the productivity of the company was improved, which is a relevant aspect at the level of planning, management and direction.**

Keywords*—Distributed control; supervision; acquisition; chemical products; dispatch of chemical supplies

I. Introduction

Organizations dedicated to the distribution and dispatch of chemical products are susceptible to generating negative environmental impacts due to the lack of technological strategies that minimize risks of spillage [1], [2]. And it is necessary to be aware of and highlight the risks and consequences of not supervising or monitoring the correct process of transporting or transferring the chemical input for its storage and dispatch [3]. When these processes lack or are not linked to technological tools, but on the contrary respond to strictly manual processes, in which the personnel or operator is exposed to these chemical inputs, effects are totally adverse to health, since they are less likely intrinsic generates toxicity and pollutes the environment [4]. The maneuvers in the dispatch processes of chemical inputs when they are manual or executed by some personnel, increase the risk of spills, which, as already stated, affects the human being and the environment, but also affects production, due to actions corrective measures that must be generated at that moment [5]. It is clear that these organizations must get involved with technologies that reduce all types of spill risk, since the negative consequences are derived from there [6].

Industrial automation is currently used as a tool that contributes to improving various stages immersed in production processes, thus improving aspects related to precision in component dosing, accuracy in the sequencing of events, self-regulation and improvement of the location of the final product [7]. Automating a process guarantees the logical control relationship between sensors and actuators of a process, however through communication protocols it is necessary to seek to implement supervision, control and data acquisition systems [8]. These communications protocols guarantee the adequate interface in the sensors and actuators of a process, interrelating it through an industrial network, which allows the supervision and monitoring in real time of the variability of the indicators during the execution of the production process [9, 10].

Distributed control systems (DCS) allow an industrial plant to integrate its different production processes, linking the various programmable logic controllers (PLC), which are associated from a logical point of view to sensors and actuators, thus guaranteeing a fluid communication of data, which allows making decisions from the generation and processing of information [11, 12]. Referring to a distributed control system implies the generation of relevant data, which goes beyond operational aspects, becoming linked to very useful and important information systems at a strategic level in an organization [13]. With the purpose of supervising, monitoring and acquiring data for decision-making on aspects related to the operation or operation of an industrial process, SCADA systems (Supervisory Control and Data Acquisition) are used [14-17]. The application of SCADA systems is diverse, however among the processes that use it the most are electricity generation, natural gas, mining deposits, thermal systems, oil pipelines and chemical products dispatch [18-20]. One aspect to highlight in SCADA systems is that they allow in a friendly way to show the behavior of the critical variables in a process, becoming a strategic element at the industrial level, integrally linking geographically dispersed subsystems arranged in a plant [21-23].

It is then justifiable from the point of view of the monitoring, supervision and control capacity, the integration of DCS systems and SCADA systems [24-26]. As its application is diverse and by using different communication protocols as interface elements, its contribution is relevant, even more it is linked to the improvement of the operating and working conditions of the operators and their environment with the environment [27-29].

Under the above, the purpose of this article is to contribute through the description of the application of distributed control systems (DCS) under their integration to the SCADA system in a chemical products distribution company; seeking to reduce the remnants or spills of these inputs during their dispatch or filling in distribution trucks; guaranteeing the reduction of pollutants in the work environment and consequently eliminating any adverse effect on the personnel working in the plant.

II. Literature Review

In relation to relevant studies on this topic, we have in [30], which highlights the importance of the use of the SCADA system and its integration in the architecture of industrial processes, in which the performance and safety of processes related to oil industry or chemical inputs. In the same line of research in [31], a proposed solution is described for a process related to oil as a chemical input in which the SCADA system guarantees safety from the detection of abnormal events or events, thus avoiding any effect adverse on staff and work environment.

It should also be noted that this scientific article is supported by two studies already published in [32–34] which detail the composition of the industrial network that allows automating the chemical products dispatch process, as a solution to the reduction of pollutants due to spillage of the input due to a bad maneuver by the operators; These studies also highlight that as an effect of supervising, controlling and monitoring the dispatch system, from the perspective of improving the filling precision of the transport truck tanks, another positive effect, quite apart from the reduction of pollutants, is productivity improvement, a very relevant contribution to the organization, and which gives sustainability to a large-scale solution proposal such as the implementation of a distributed control system integrated into a SCADA system.

The implementation of intelligent systems through hardware and software, allow to guarantee the control of the operating parameters and variables of the industrial processes [35, 36].

III. Control Philosophy and Architecture of the Distributed Control Network

In order to understand the control logic that allows automating the chemical products dispatch process, in a simplified way the control philosophy represented in the flow diagram is shown in Fig. 1.

In the flow chart, two sensors are established that will determine the correct location of the containers for the filling process; if his position is not adequate, he will not proceed to execution; furthermore, only if the filling level of the container is adequate, a sensor will establish that the valves should be closed and proceed to fill the next container; It is necessary to indicate that the number of compartments to fill in a truck storing the chemical product is three.

In Fig. 2, the location and disposition of the three sources that contain the chemical product (Acetic acid) are schematized, and that from displacement pumps, valves controlled by electric actuator, overfill sensors, the same ones that were mentioned in the flow chart above; and making use of Siemens CP443 programmable logic controllers, I will proceed with the programming logic that establishes the link between the input and output elements of the process.

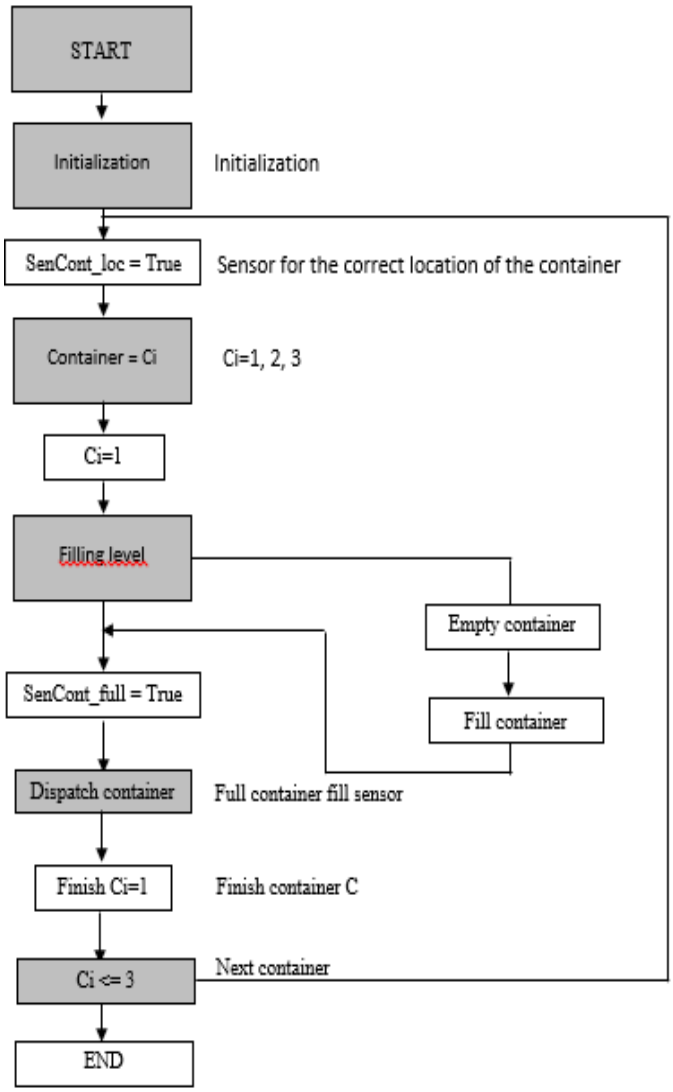

Fig. 1. Control Philosophy of the Chemical Product Dispatch Process.

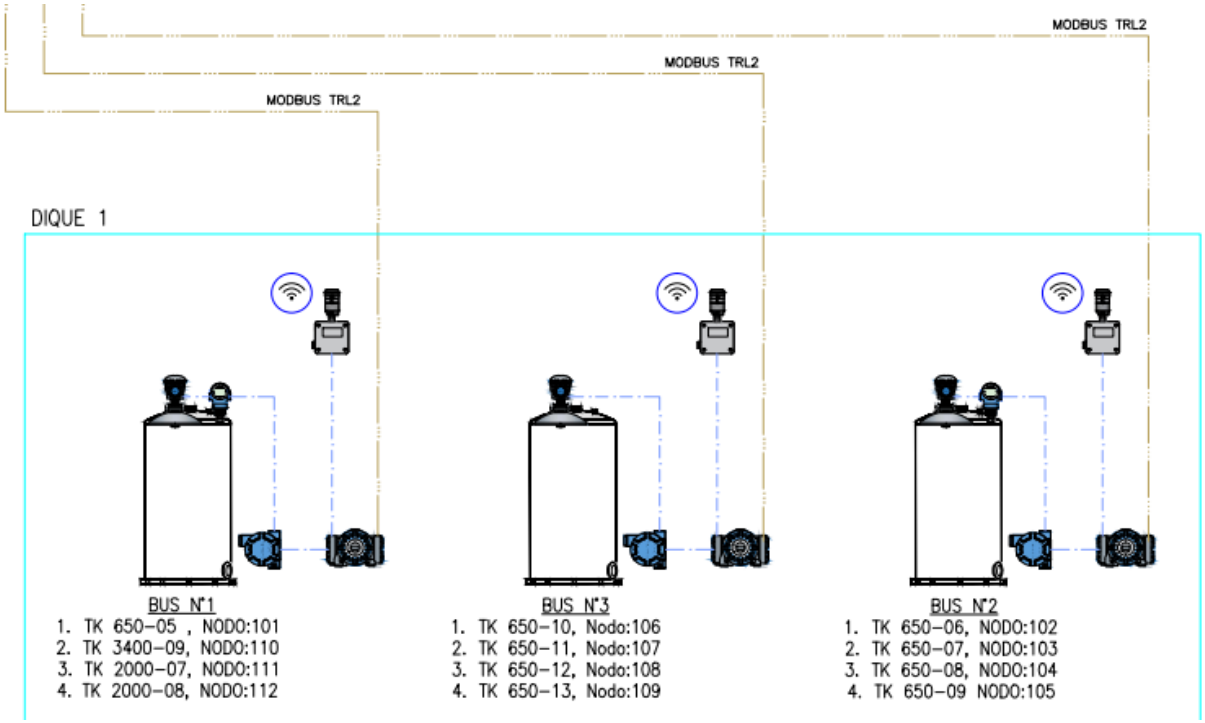

Fig. 2. Layout of Chemical Storage Tanks.

In Fig. 3, the connection between the sensors, actuators, scale zone and displacement pumps for filling with respect to the chemical product packaging trucks is shown; It should be noted that the pumps in operation operate in remote mode and in automatic sequence; in such a way that the valves also respond to a similar operating logic, that is, in remote mode and automatic sequence, which indicates that it is open; The displacement pump as well as the valves will always be monitored through the supervision and data acquisition system, the same as from the WinCC runtime Project system will allow the activation and shutdown of the mentioned elements and start the dispatch process. It should be noted that the valve is a 3" butterfly type that is located on the second level of the truck station between the 45 ° elbow and the start of the stainless steel hose. This system developed through the WinCC Runtime Project system will trigger an alarm 300 kilos before reaching the indicated weight for that compartment.

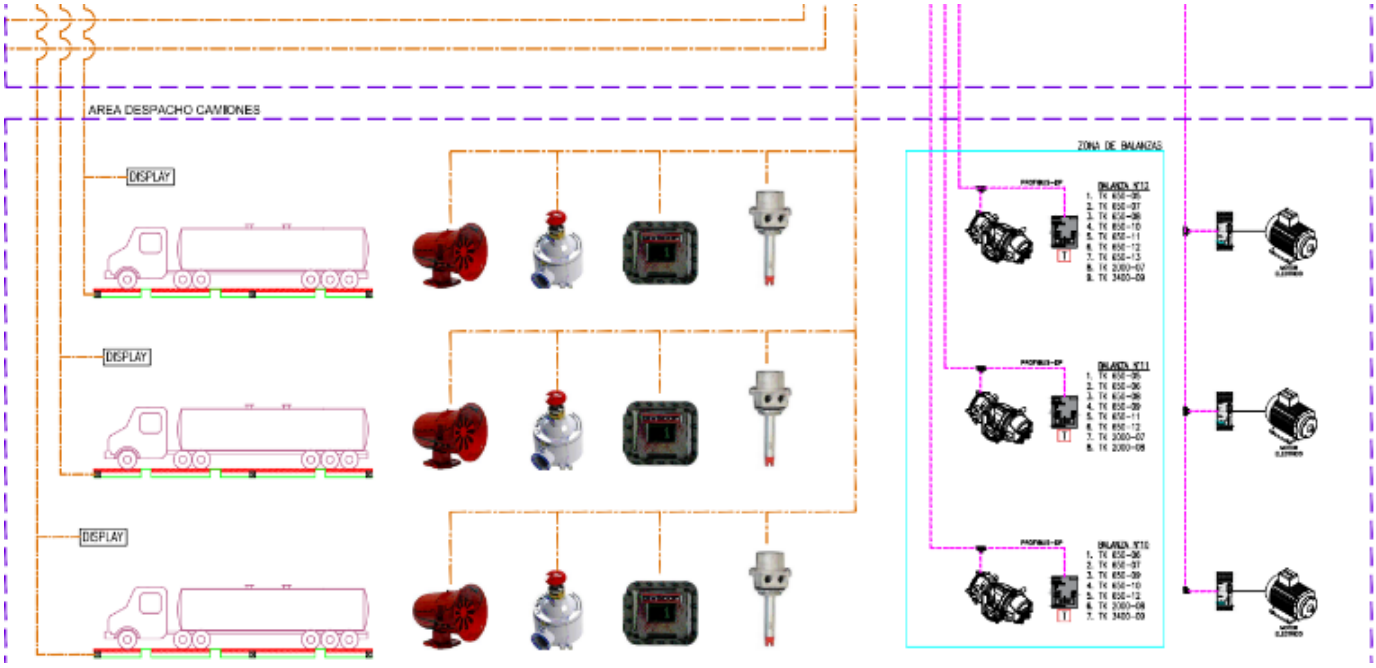

Fig. 3. Connection between Sensors, Actuators, Scale Zone and Displacement Pumps with respect to Packaging Trucks.

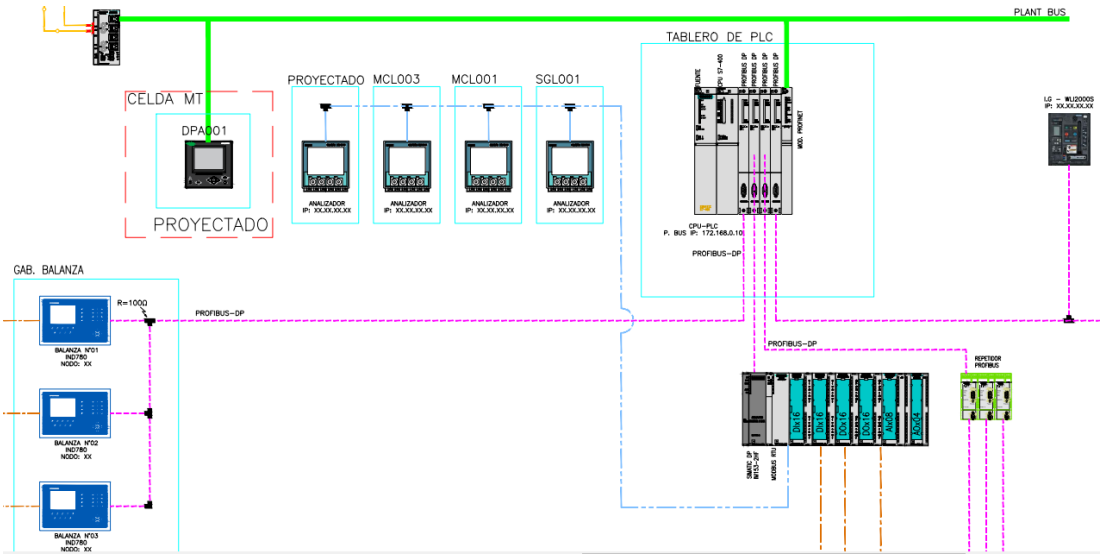

Fig. 4. Connection of Automated Industrial Network System Components.

The data server of the industrial network will be located in the server room and will be interconnected through a fiber optic network with the instrumentation equipment and located in the industrial instrumentation cabinets. The communication switch of the control system will allow the interconnection and exchange of information between the programmable logic controller and the data server, for this reason they must be installed in the same cabinet mentioned above, in accordance with the Control architecture, shown in the Fig. 4. For the monitoring of electrical variables, it is considered that all the data received from the multifunction meters will be sent to the data server for its proper use; in such a way that the displacement pumps must be composed of local control pushbuttons (located in the field, for starting and stopping the engine), selectors and status indicators. All remote start and stop signals coming from each programmable logic controller will be using the control logic and sent to the control center through Profibus DP communication.

IV. Control Board and Development of the SCADA System Configuration

A. Control Panel

In Fig. 5, the electrical control cubicle is shown in which the main switch that energizes the entire control system of the previously selected transfer pump is enabled.

Fig. 5. Control Cube where the Central Switch is Located.

In Fig. 6, it is shown that to confirm that there is no blockage enabled in the field, this due to the incorrect location of the chemical product packaging trucks, it is necessary that the state of the switches that do not have the insurance be verified in the field placed. When the safety lock is in stop mode, it will prevent the transfer pump from being controlled from the control room in automatic mode.

Fig. 6. Safety Switch Status.

Fig. 7. Automatic Remote Actuation Switch and Scale Platform.

In Fig. 7, the scale platform is shown, in which it will be verified that the selector is in the remote mode position, as shown in the figure. It should be noted that remote and automatic operation is achieved in the control mode shown.

B. SCADA System Configuration

A first relevant aspect for the configuration of the SCADA system is related to access security, the criteria of which has been considered at the time of making the configuration, for which the operation of the equipment has been restricted only to authorized users; in such a way as to avoid that personnel outside the operation of the plant can mainly start up equipment without prior permission; that is, only by entering the username and password can they be enabled. Fig. 8 shows the configuration window in which the enabling of the key is highlighted.

Once your user has been entered, the system will enable the access screens or menus, which are located in the upper part of the supervision system, it is available throughout the project. Through these menus we can enter any screen according to the user's requirement. These menus display a collection of screens classified by function; as evidence of the above, Fig. 9 is shown.

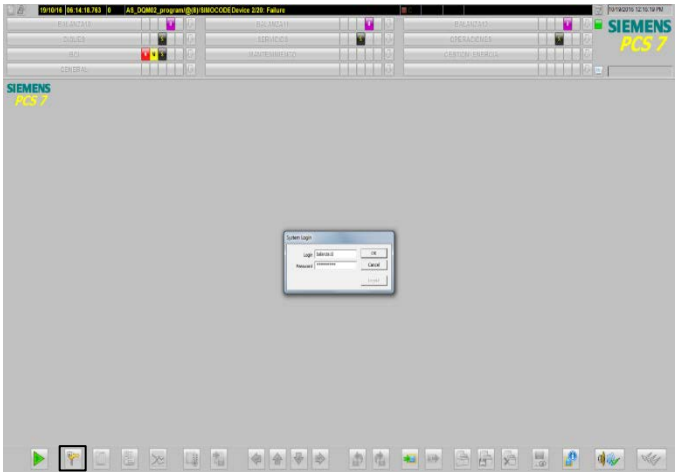

Fig. 8. Configuration of Restricted Access to the SCADA System.

Fig. 9. SCADA System Supervision Menus Configuration.

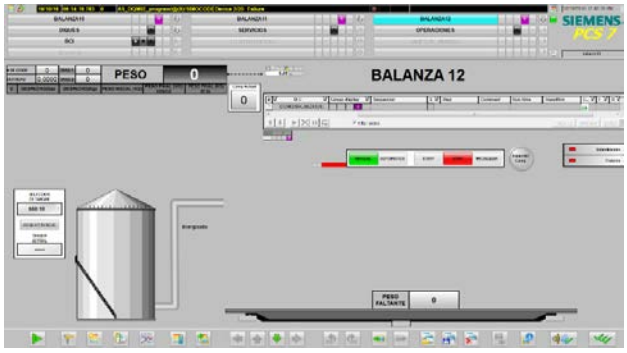

Fig. 10. Setting the Balance Selection in the SCADA System.

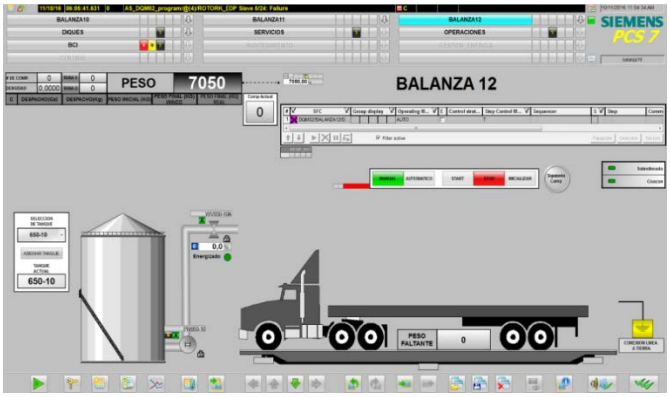

Fig. 11. Configuration of the Tank Selection and Start of the Dispatch Process, in the SCADA System.

Once the scale is entered from where the chemical product will be dispensed, the selected scale will be indicated by the background color of the selected tab. Once located on the balance, the following distribution will be available as shown in Fig. 10.

This is also configured to make the selection of the tank, which must be correctly located to start the dispatch process. Immediately, the actuator and the displacement pump will be enabled in automatic operating mode, with which the tanker truck or also called container truck will enter the scale platform recording the initial weight, so that next the sensor will be connected overfill and sensor ground, as shown in Fig. 11.

V. Result and Discussion

A. Results

As a result of the integration of the distributed control system and the SCADA system of the chemical product filling process in Fig. 12, the monitoring and supervision obtained in real time from the SCADA system is already shown, in which the valve is located at a 50% opening restricting the access of the chemical product, for when the missing weight is less than 300 kg. The displacement pump motor will keep its nominal speed, while in the field the beacon and siren will be active for 3 seconds, with the objective to notify the scale operator of the completion of the chemical product dispatch.

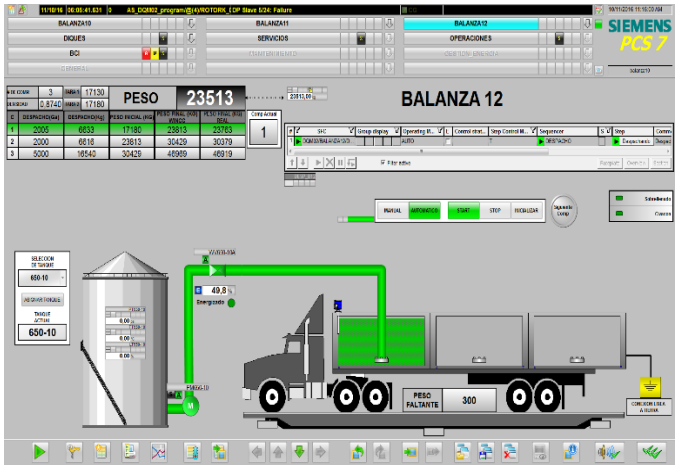

Fig. 12. SCADA System Commissioning: Filling System Control, Valve Restriction to 50%.

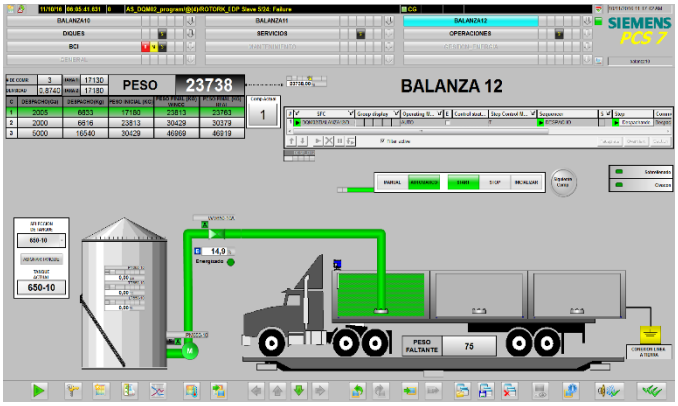

Fig. 13. SCADA System Commissioning: Filling System Control, Valve Restriction to 75%.

In Fig. 13, it is shown that when the missing weight is less than 150kg, the electric actuator will proceed to close to 75%.

In Fig. 14, it is shown that when the missing weight is less than 75kg, the electric actuator will proceed to close to 85%.

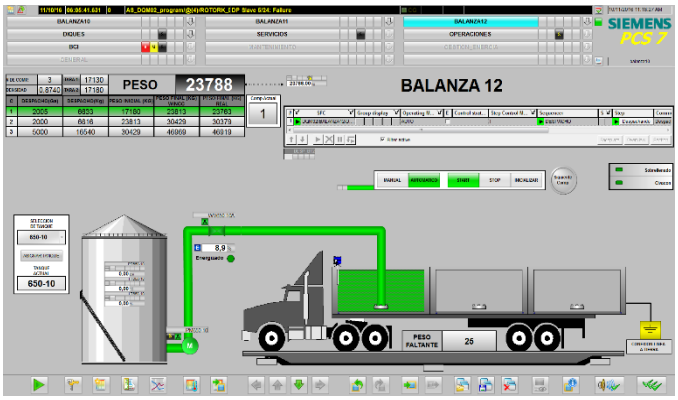

Fig. 14. SCADA System Start-Up: Filling System Control, Valve Restriction to 85%.

Upon reaching the missing weight, the electric actuator will fully close and the displacement pump will stop. The "SenCont_full" button will flash, showing that the dispatch in container 1 has ended, moving on to the next container. As evidence of the above, it is evidenced in Fig. 15.

Fig. 15. Commissioning of the SCADA System: Complete Filling of Container 1.

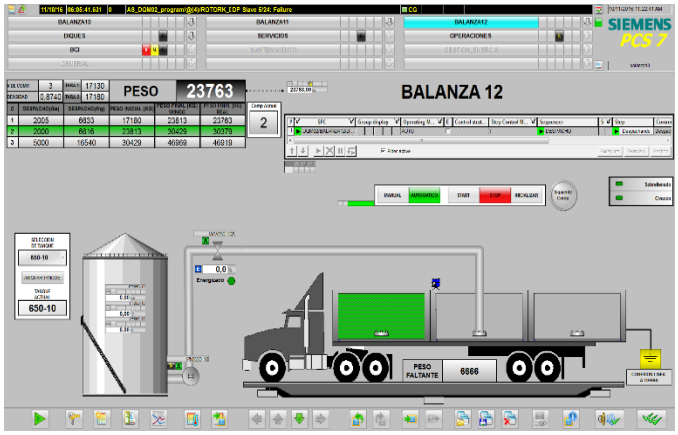

Fig. 16. Commissioning of the SCADA System: Filling Process of Container 2 of the Tank Truck.

In Fig. 16, it is shown that the tank truck tank 2 is automatically filled; for which precision and total elimination of spillage of the chemical product is guaranteed.

B. Discussion

According to the results evidenced in the screenshots of the SCADA system, it shows correct operability and optimal performance in the chemical product dispatch process, from the integration with the distributed control system developed under the Siemens CP443 controller and structured under an industrial network with Profibus DP protocol and remote station simenes ET 200, in this regard in [8] the author also obtains as a finding an optimal functioning in the integration of the distributed control system of a plant in which the flow of energy is monitored and regulated. raw material; highlighting that his proposed solution is developed using the Profibus DP and Ethernet protocol; however, he used as part of his solution a CP-343 controller also from Siemens and an ET200 peripheral junction terminal. The difference between the controllers used is due to the fact that in my solution proposal, I control a greater number of actuators, sensors and that I seek that the industrial rd has scaling capacity due to terminals projected to be implemented in the future.

Another aspect to highlight is the improvement in filling precision and eliminated any possibility of loss of the chemical product due to spillage, it has significant relevance at the management level because it generates an impact on productivity. In this regard, in [10] the author applies a SCADA system for dosing the entry of basic reagents to three tanks, for which he used, as in the proposed solution, a Siemens 400 controller, in which he evidenced in his research that the Automated system will contribute to the improvement of productivity in the organization. Also in [23] it is highlighted that from the implementation of a SCADA system to a process linked to the improvement of the dosage of components in the stage of crushing and pulverization of inputs, it contributed to the improvement of results in the productivity of the company.

A third point to highlight as part of the development of this article is the contribution to reducing environmental pollution in the work environment; The fact is that when the process of dispatch of inputs or chemical products is automated, there will

no longer be any spillage, so its impact is on the generation of polluting particles in the environment; In this regard, in [30] the author points out that in his study the distributed control system and the SCADA system showed an optimal functioning of the supervision and control process in liquid petroleum plants, guaranteeing the safety of the work environment and minimizing the conditions abnormal operation of the process.

VI. Conclusion

It is concluded that the distributed control system (DCS), implemented from a Siemens CP443 unit, the same that was structured under the philosophy of an industrial network with Profibus DP protocol, remote station Siemens ET-200, and integrated into a SCADA (developed through the WinCC Runtime Project system) in a chemical product dispatch plant (acetic acid), showed to work optimally and efficiently, guaranteeing a regulation of the container filling or dispatch system composed of 3 compartments of 300 Kilos, the same that regulates from the gradual opening of valves the filling level of acetic acid. The most significant contributions that are generated as an effect of this control are the elimination of the spillage of chemical product as well as the reduction of polluting particles in the work environment and finally improvement of productivity, a relevant aspect at the level of planning, management and direction of the company.

Acknowledgment

The recognition to J. Yataco-Yataco for his contribution in the information and contributions from his experience obtained in the company.

***Abstract*—In this competitive scenario of the educational system, higher education institutions use intelligent learning tools and techniques to predict the factors of student academic performance. Given this, the article aims to determine the supervised learning model for the predictive system of personal and social attitudes of university students of professional engineering careers. For this, the Machine Learning Classification Learner technique is used by means of the Matlab R2021a software. The results reflect a predictive system capable of classifying the four satisfaction classes (1: dissatisfied, 2: not very satisfied, 3: satisfied and 4: very satisfied) with an accuracy of 91.96%, a precision of 79.09%, a Sensitivity of 75.66% and a Specificity of 92.09%, regarding the students' perception of their personal and social attitudes. As a result, the higher institution will be able to take measures to monitor and correct the strengths and weaknesses of each variable related to satisfaction with the quality of the educational service.**

Keywords*—Supervised learning; classification learner; predictive system; personal and social attitudes; engineering students

I. Introduction

At present, the permanent search for educational quality is one of the main objectives of this sector [1], which is why strategies and methodologies designed to optimize student satisfaction factors [2], [3] have been implemented. Specifically, in the field of university higher education, the need to comply with quality standards in the educational service offered is evident [4].

Therefore, continuous self-evaluation of the dimensions related to student satisfaction is necessary, in order for this to improve institutional processes by identifying their strengths and weaknesses [5]-[8]. Taking into account the various influencing factors, it is complex to determine the strategic actions and decisions that correctly optimize these factors [9].

One of the factors that are related to student satisfaction is the self-perception of personal and social attitudes of university students. As indicated in [10] there is a need to evaluate the self-perception of personal and social attitudes in students, since this will generate the obligation to reflect on how the university community is contributing to social development. The importance of identifying the self-perception of the university's personal and social attitude lies in identifying what aspects need to be improved, in such a way that this leads to a significant contribution to higher education in the social context, allowing the student to meet their professional goals and personal [11], [12].

As indicated in [13], the higher educational level, has the duty to instill in university students the sense of social responsibility proper to the performance of professional activity. In this sense, the consequence of the acquisition of personal and social attitudes is a process that encompasses a significant portion in the lives of students in their passage through different organizations. Now if we develop this analysis in the context of educational virtualization, it leads us all to wonder to what extent this scenario has altered aspects related to personal and social attitudes of university students [14], [15] taking into account. As indicated in [16] that engineering students have perceived a greater change in the teaching process, due to the theoretical and practical nature of the subjects of the curriculum.

Given this, over time, information technology systems have been designed for different organizational sectors, from transactional to decision-making [17]. Within these information technology systems is the data mining tool. Data mining is conducive to the treatment of large amounts of information, and its purpose is to generate knowledge [18], [19]. Data mining uses databases, from which information is extracted in an automated way and through mathematical and statistical analysis deduces patterns and trends [20]. Data

mining makes data analysis easier, compared to traditional exploration, which, due to the large amount of data, makes this process much more complex [21].

Regarding the education sector, Educational Data Mining (EDM) is an emerging discipline that seeks to develop methods to explore data generated in the education sector, in order to achieve a better understanding of the characteristics of students and the way they learn [22]. Its development uses statistical techniques and artificial intelligence to detect patterns and anomalies in large amounts of data [23].

Within the field of artificial intelligence is Machine Learning, this learning is an automated process that extracts patterns from the data for the construction of models that allow prediction using supervised algorithms [24], [25]. One of the learning modalities that Machine Learning has is supervised learning, whose function is based on training the algorithm by granting it the questions, called characteristics, and the answers, called classes, in order that the algorithm combines them and can make predictions [26].

Within the two supervised learning techniques, is the classification, the classification algorithms look for patterns that will then allow them to classify the elements and determine which groups or classes they belong to. It should be mentioned that the values for these algorithms must be discrete values [27]. Among the classification algorithms is Kernel, which extends the regular logistic regression, used for binary classification, to deal with data that are not linearly separable [28].

Given what has been described, the need arises to design a predictive model of the personal and social attitudes of university students, which allow optimizing the services offered by the higher institution. Taking into account even more that the personal and social factors of the students are related to their academic performance [29], [30]. The research takes on even more relevance, due to the fact that, as indicated in [31], most predictive analysis research is related to primary and secondary education, so there is a small number of applications in higher education that serve the institutions as a base source for the improvement of educational quality.

In this sense, the main objective of this article is to determine the supervised learning model using the Classification Learner technique for the predictive system of personal and social attitudes of university students of professional engineering careers. To do this, it will analyze the performance metrics such as Accuracy (A), Precision (P), Sensitivity (S) and Specificity (R), to determine the most appropriate algorithm for the predictive model, also, the confusion matrix and the curve will be identified receiver operating characteristic (ROC) of the model.

The purpose of the research is to generate a significant contribution, for the taking of preventive and corrective actions that allow to comply with the quality standards of the educational service, whose improvement will be reflected in the satisfaction of the students and the academic performance.

The structure of the research development is divided into the methodology where the level of research is detailed, the participants, the data collection techniques, the validation of the collected data and the design of the supervised learning methodology through the technique classification. Next, the results and the discussion of them are presented, to finally make the conclusions of the investigation.

II. Research Methodology

A. Research Level

The research is descriptive in nature, since it focuses on determining the most optimal model of supervised learning using the Classification Learner technique for the predictive system of personal and social attitudes of university students of professional engineering careers, through the analysis of the performance metrics of the obtained algorithm (Accuracy (A), Precision (P), Sensitivity (S) and Specificity (R)).

The research starts from the identification of a problem, related to the improvement of the quality of the educational service, which is reflected in the satisfaction of the university students. Student satisfaction encompasses different dimensions, this study focuses on the self-perception of engineering students from a public university in Peru with personal and social attitudes. To do this, use of methods or tools already defined such as predictive systems through the modality of supervised learning.

This research also seeks to design a predictive multidimensional model that can be used to create and store new data for the higher institution. Based on this technological tool, it determines patterns and calculates association rules, providing support and reliability to the results obtained.

B. Participants

The participants in this research are made up of students from the sixth to the tenth cycle of professional engineering schools, with a total of 715 students. This selection criterion is part of a regulation established and approved by the public university of Peru. Due to the mandatory nature of the survey, it was possible to collect data from all participants.

TABLE I. Indicators that Measure the Self-Perception of Personal and Social Attitudes

Item	Indicators
1	Take on your studies with responsibility, seriousness and dedication
2	With the pride of belonging to the university
3	With the commitment of raising the name of the university
4	With the respect you show for the authorities, teachers and administrative staff
5	With the respect that you treat your colleagues
6	With the treatment you receive from your colleagues
7	With your interest to be better every day
8	With your commitment to the surrounding society

C. Data Collection Technique and Instrument

The data collection technique is the survey, and the instrument used to collect data regarding the self-perception of engineering students about personal and social attitudes is the questionnaire, which was carried out online, at through the university's virtual platform, due to the implementation of the online teaching-learning process in the context of the health emergency. In addition, access to the online questionnaire was given through the student code of each participant.

It is necessary to indicate that the questionnaire was made up of 8 indicators (characteristics), which are detailed in Table I. Likewise, the responses to the questionnaire for the present study were transformed into a 4-level Likert scale (1: dissatisfied, 2: not very satisfied, 3: satisfied and 4: very satisfied), these levels of satisfaction, in the present analysis represent the classes of the supervised learning predictive model.

D. Reliability of the Collected Data

The validation of the collected data is carried out by means of the Cronbach's alpha coefficient through the SPSS statistical software. Table II shows the reliability result, whose value is 0.962.

E. Data Processing Design

The methodology of the research process begins with the collection of data through the online questionnaire of the self-perception of engineering students about personal and social attitudes. The responses are stored in a database, the information of which is processed by the Open Data Base Connectivity (OBDC) driver and the Matlab R2021a software. In this way, the supervised learning process begins, through the Classification Learner technique, the best Machine Learning algorithm is identified, through the evaluation of performance metrics, after which the prediction is made, which will allow the analysis of the results. In Fig. 1, the scheme of the supervisory learning methodology used is shown.

TABLE II. CRONBACH'S ALPHA TEST

Reliability statistics	
Cronbach's alpha	***No. of elements***
0.962	8

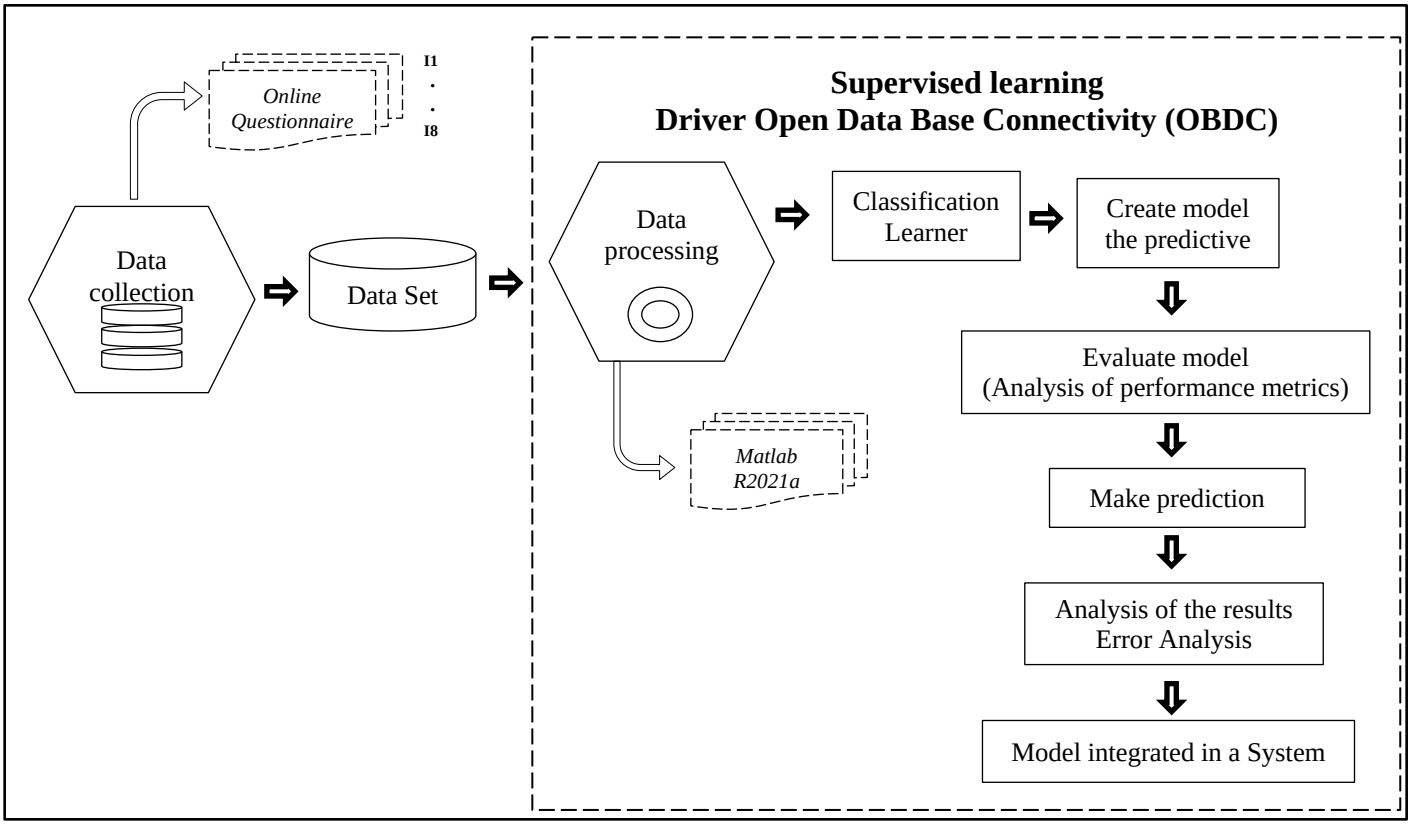

Fig. 1. Supervised Learning Methodology.

III. Result and Discussion

A. Determination of the Predictive Model

By means of the Matlab R2021a software, and through the Classification Learner technique of Machine Learning Toolbox 12.1, the best predictive model determined by the validation of the accuracy is identified, in statistical terms it is related to the bias of an estimate and is represented as the proportion of true results (true positives and true negatives) divided by the total number of cases examined (true positives, false positives, true negatives, false negatives).

In Fig. 2, the generated results are shown, which show that the Kernel algorithm: Logistic Regression Kernel, is the one that presents a better accuracy of 86.9% for the predictive system of the personal and social attitudes of engineering students This is followed by the algorithms Tree: Coarse Tree with an accuracy of 86.6%, SVM: Coarse Gaussian SVM with an accuracy of 86.4% and SVM: Linear SVM with an accuracy of 86.2%.

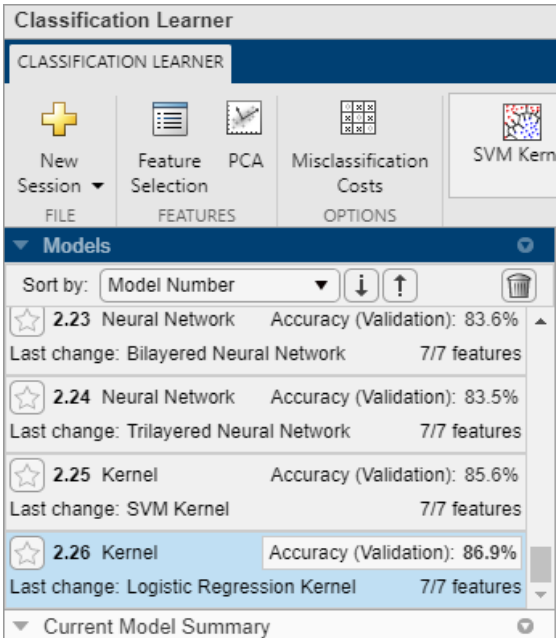

Fig. 2. Determination of the Classification Algorithm.

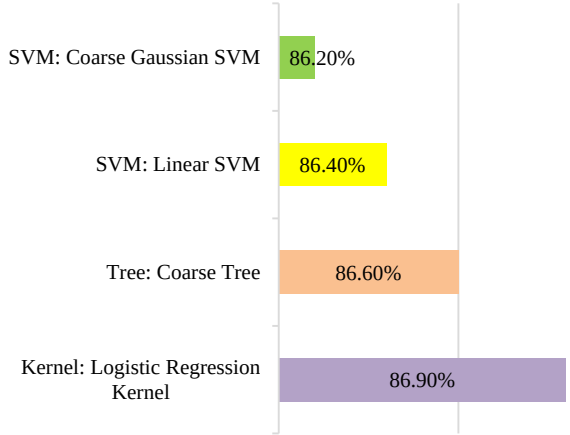

Fig. 3. Comparative Analysis of Accuracy Results.

Likewise, Fig. 3 shows the four algorithms with the highest accuracy, which identified the classification technique, where the Logistic Regression Kernel algorithm is observed as the best.

Being precision, the parameter that measures the percentage of cases that the model has hit, according to Fig. 3, it can be said that the predictive model through the Logistic Regression Kernel algorithm offers a total of 86.9% of the number of positive predictions which will be correct, that is, the value refers to how close the result of a measurement is to the true value.

B. Results of the Predictive Model Metrics

As part of the analysis of the performance metrics, we will visualize the confusion matrix of the Logistic Regression Kernel algorithm, the confusion matrix allows us to visualize the performance of a supervised learning algorithm and each column of the matrix will represent the number of predictions of each class (1: dissatisfied, 2: not very satisfied, 3: satisfied and 4: very satisfied), while each row represents the instances in the real class, in other words this analysis allows us to see what types of successes and errors our predictive system has .

In Fig. 4, the confusion matrix is shown, where the percentage of false negatives test (FNR) is displayed, also called the error rate, it is the probability that a true positive will miss it, the rate is also displayed of true positives (TPR), which measures the sensitivity metric, this metric comes to make the probability that a real positive result will be positive.

As can be seen in Fig. 4, of the 4 classes on which the predictive model acts, class 3 (satisfied) shows 89.9% sensitivity and 10.2% false negatives, this means that the predictive model has the ability to discriminate between a true positive (TP) from a false negative (FN), that is to say, there is an 89.9% capacity to be able to correctly detect satisfied students among dissatisfied students. On the other hand, class 2 (not very satisfied) shows a lower percentage of sensitivity equal to 64.4% with a percentage of false negatives of 35.6%, that is, it has the ability to detect only 35.6% of satisfied students among dissatisfied students.

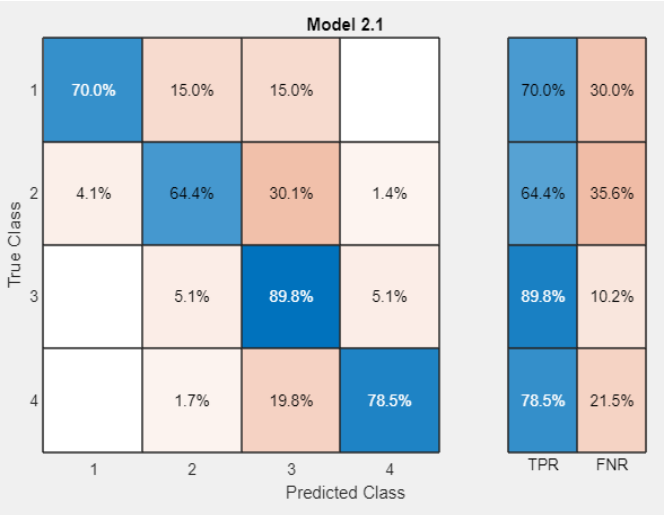

Fig. 4. Confusion Matrix based on TPR and FNR Rates.

In Fig. 5, the confusion matrix is shown, where the positive predictive value (PPV) and the false discovery rate (FDR) are displayed. It should be noted that the precision metric measures the quality of the machine learning model in classification tasks, it should be taken into account that the lower the dispersion value, the higher the precision of the model.

As can be seen in Fig. 5, the predictive model for class 3 (satisfied) shows the highest precision value, in this case it is 87.3% and a FDR percentage of 12.7%, that is, only 87.3% of students will be really satisfied with perceived personal and social attitudes, while 12.7% of examples will be wrong in the prediction.

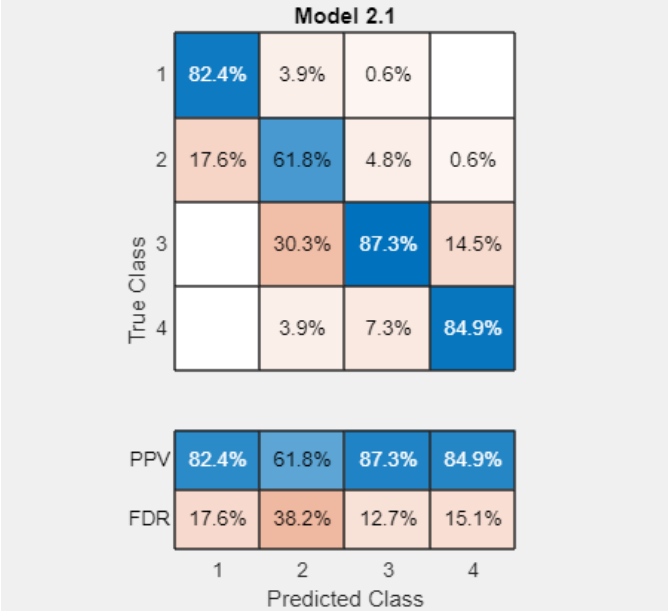

Fig. 5. Confusion Matrix based on PPV and FDR Rates.

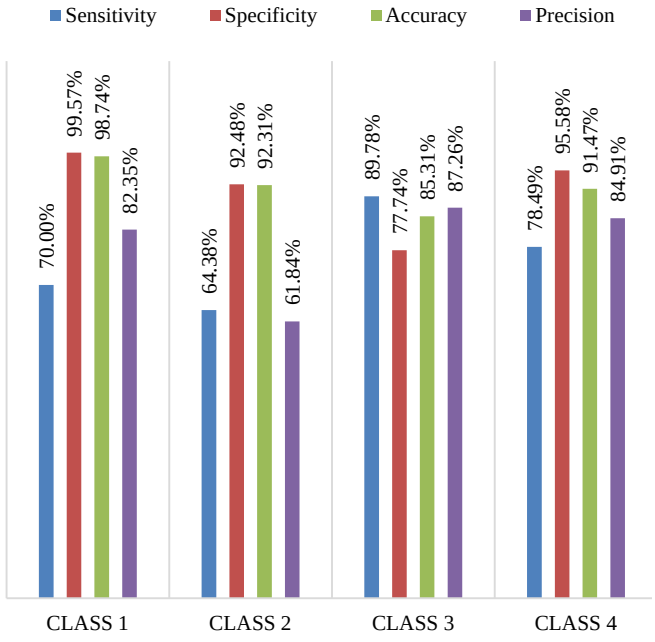

Fig. 6. Metrics of the Four Classes of the Predictive System.

In Fig. 6, the metrics of the predictive model of the four classes (1: dissatisfied, 2: not very satisfied, 3: satisfied and 4: very satisfied) are shown through the Logistic Regression Kernel algorithm, with this it can be said, in general, the Precision is 79.09%, the Sensitivity is 75.66%, the Specificity is 92.09% and the Accuracy is 91.96%.

Next, the analysis of the Receiver operating characteristic (ROC) curves of the Logistic Regression Kernel algorithm will be carried out, which constitutes a statistical method to determine the accuracy of the model, this test is carried out for three purposes, to determine the cut-off point of a continuous scale in the that the highest sensitivity and specificity is reached, evaluate the ability to differentiate satisfied and dissatisfied students, and compare the discriminative ability of two or more diagnoses that express their results as continuous scales. It is necessary to specify the more the value of the area on the curve (AUC), approaches 1, and the model will have a better performance and greater precision.

In that sense, in Fig. 7, the ROC graph for class 1 (dissatisfied) is shown.

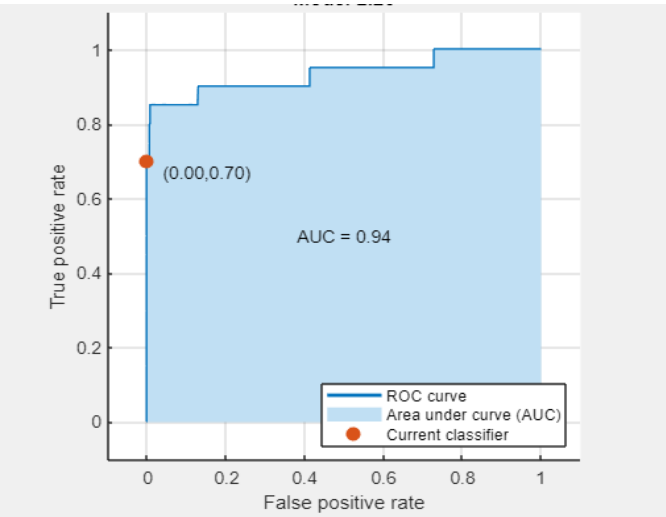

Fig. 7. ROC Charts for Class 1.

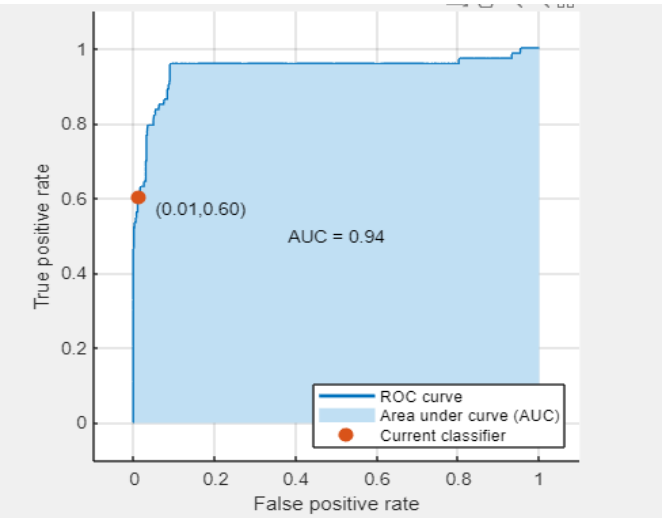

Fig. 8. ROC Charts for Class 2.

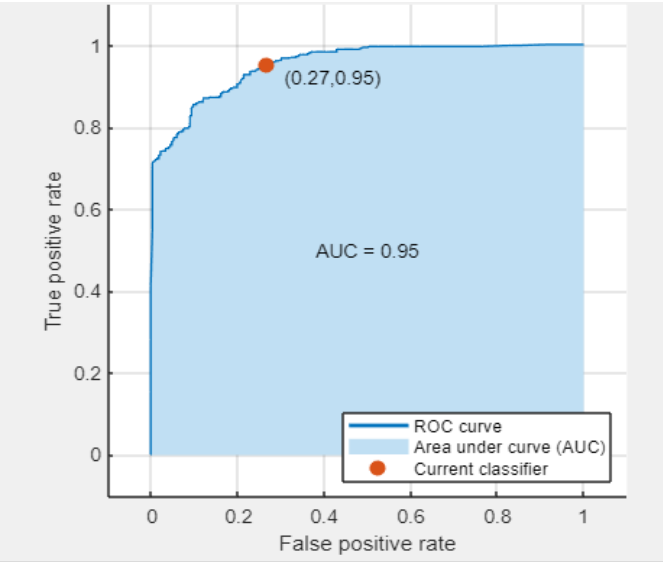

Fig. 9. ROC Charts for Class 3.

In Fig. 7, it is evident that for class 1, there is a sensitivity of 94%. In addition, the discrimination threshold is 0.70 for the true positive rate and 0.00 for the false positive rate, showing an optimal area value on the curve (AUC) of 0.93.

In Fig. 8, the ROC chart for class 2 (not very satisfied) is shown.

In Fig. 7, it is evident that for class 1, there is a sensitivity of 94%. In addition, the discrimination threshold is 0.70 for the true positive rate and 0.00 for the false positive rate, showing an optimal area value on the curve (AUC) of 0.93.

In Fig. 8, the ROC chart for class 2 (not very satisfied) is shown.

In Fig. 9, it is evident that for class 3, there is a sensitivity of 95%. In addition, the discrimination threshold is 0.95 for the true positive rate and 0.27 for the false positive rate, showing an optimal area value on the curve (AUC) of 0.95.

In that sense, in Fig. 10, the ROC graph for class 4 (very satisfied) is shown. For class 4, a sensitivity of 97% is evidenced. In addition, the discrimination threshold is 0.78 for the true positive rate and 0.03 for the false positive rate, showing an optimal area value on the curve (AUC) of 0.97.

Finally, it is shown in Fig. 11, the graph of parallel coordinates, used to plot multivariate data, this graph shows the relationship between the indicators of self-perception of engineering students on personal and social attitudes among the four classes of the predictive model (1: dissatisfied, 2: not very satisfied, 3: satisfied and 4: very satisfied).

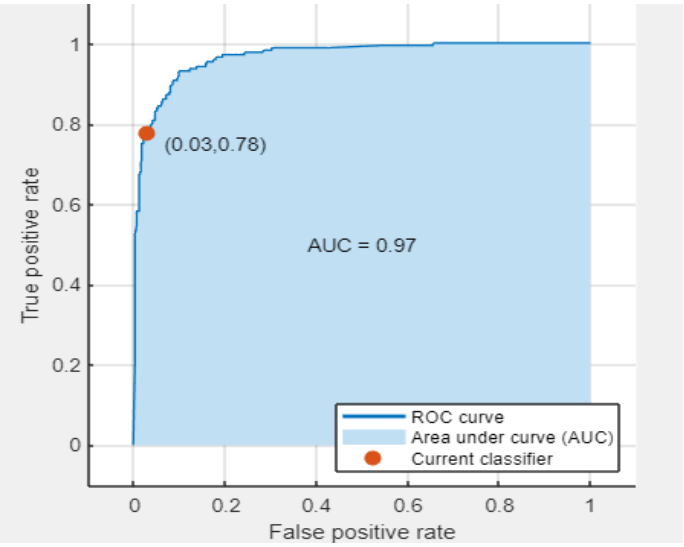

Fig. 10. ROC Charts for Class 4.

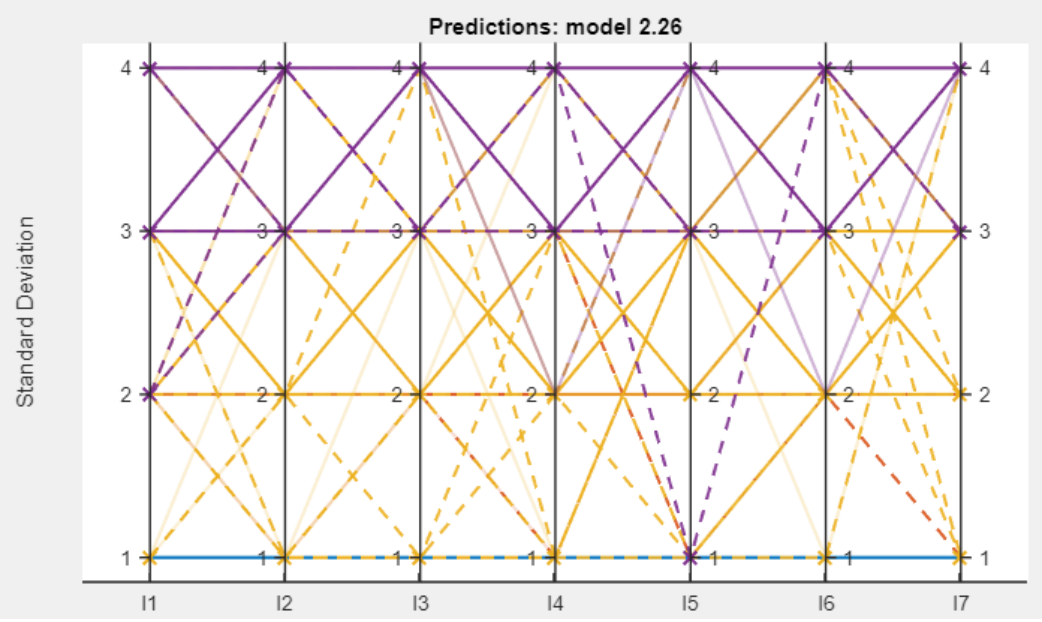

Fig. 11. Parallel Coordinates Graph.

It should be noted that the data are linked to 8 descriptors related to the levels of satisfaction of the self-perception of engineering students about personal and social attitudes, during the virtual teaching-learning process, said data are ordinal qualitative types, thus defining the four classes, likewise, as part of the determination of the predictive model using the Matlab R2021a software, the data collected was used based on the first 7 indicators, which are called predictors, and the indicator of the variable under analysis (which represents the satisfaction of the self-perception of engineering students on personal and social attitudes), is defined by the final indicator (I8), because it is the one that generally encompasses the variable under analysis, for this reason in Fig. 11 only displayed from indicator I1 to indicator I7.

C. Discussion

The results of the prediction model metrics through the Logistic Regression Kernel algorithm, in relation to satisfaction with personal and social attitudes, generally present, in its 4 classes, a precision of 79.09%, a Sensitivity of 75.66%, a Specificity of 92.09% and an Accuracy of 91.96%.

Also the ROC chart for class 4 (very satisfied) shows a sensitivity of 97%, a discrimination threshold is 0.78 for the rate of true positives and 0.03 for the rate of false positives, showing an optimal area value on the curve (AUC) of 0.97.

Regarding the optimal value of the performance metrics, it is sustained that they are optimal values, based on the research of [18] where it is stated that a model is made to predict the academic performance of incoming students through machine learning, the Results showed that it is feasible to predict performance, since the model has 69% accuracy. Similarly, in [26] it is indicated that the results show a precision of 82%, therefore, it can be pointed out that the predictive model will have optimal performance when implemented.

Regarding the ROC obtained of 97% in the present investigation, in [20], the author points out that his predictive model was good since its general precision was 75.42% and an area under the ROC curve of 0.805. This is based on the established theory that the closer this value is to 1, the better the model will perform and the more accurate it is. In the same way in [23], the author points out that an AUC of 60% of 91% or 99%, represents a better performance of the classifier algorithm, these results being favorable for the investigation.

In [29] it is pointed out that in relation to the accuracy of the model for the academic performance class, the value obtained was 62.45% lower than the value obtained in the research carried out by [24] who, in their prediction model, obtained the value 73%, very close to the result obtained by [25] which was 69%.

Comparing the results with the research carried out by [31] where a lower accuracy value of 80% was obtained in the predictive system for the training data and 76% for the validity data, this study presents higher performance results. In turn, in the investigation of [27], 82.87% accuracy was obtained using the decision tree algorithm, representing a lower value than the result of our investigation.

In the study carried out by [19] a data from 914 students was used to predict their final classification (passed or failed), with a predictive model of supervised learning and the Classification Learner technique and thus obtain a model to predict the results of the students, showing that with the network algorithm (Naive de Bayes) which showed optimal precision with 71.0%, compared to four analyzed techniques (neural networks, logistic regression, decision tree and Bayesian network) with a higher percentage for the class passed and minor for failed.

IV. Conclusion

With the results obtained, it is evident that it is possible to apply the supervised learning methodology uses Classification Learner techniques for the predictive system of the personal and social attitudes of the students, through the graph of parallel coordinates the association and / or relationship of the indicators of the variable under analysis with the four classes of the predictive model through the Logistic Regression Kernel algorithm. The results of the prediction model metrics in relation to satisfaction with personal and social attitudes are concluded, it generally presents an optimal performance of its validation metrics in its 4 classes, with a precision of 79.09%, a Sensitivity of 75.66%, a Specificity of 92.09% and an Accuracy of 91.96%.

It is recommended to extend the line of research to others with other indicators related to student satisfaction with the educational service, because not only does it allow the higher institution to have a database or reference through a rapid and reliable classification technique for take preventive and corrective actions, to improve the quality of education, but also the predictive system influences the reduction of dropout rates and improve the academic performance of students.

Workflow Scheduling and Offloading for Service-based Applications in Hybrid Fog-Cloud Computing

Saleh M. Altowaijri
Department of Information Systems, Faculty of Computing and Information Technology
Northern Border University, Rafha 91911, Kingdom of Saudi Arabia

***Abstract*—Fog and edge computing has emerged as an important paradigm to address many challenges related to time-sensitive and real-time applications, high network loads, user privacy, security, and others. While these developments offer huge potential, many efforts are needed to study and design applications and systems for these emerging computing paradigms. This paper provides a detailed study of workflow scheduling and offloading of service-based applications. We develop different models of cloud, fog and edge systems and study the scheduling of workflows (such as scientific and machine learning workflows) using a range of system sizes and application intensities. Firstly, we develop several Markov models of cloud, fog, and edge systems and compute the steady-state probabilities for system utilization and stability. Secondly, using steady-state probabilities, we define a range of system metrics to study the performance of workflow scheduling and offloading including, network load, response delay, energy consumption, and energy costs. An extensive investigation of application intensities and cloud, fog, and edge system sizes reveals that significant benefits can be accrued from the use of fog and edge computing in terms of low network loads, response times, energy consumption and costs.**

Keywords*—Workflow scheduling; workflow offloading; cloud computing; fog computing; edge computing; scientific workflows

I. Introduction

In recent years, new computing paradigms, named fog computing [1]–[5] and edge computing [6]–[11] have emerged as an extension of cloud architecture to the edge of the network to support the computational demands of real-time, latency-sensitive, and location-aware service-based applications (SBA) of largely distributed Internet-of-Things (IoT) devices/sensors. Fog and edge computing are considered among the most important archetypes in the current world. While some communities differ in the precise definitions of and differences between fog and edge computing or nodes, we prefer the following definitions. Edge computing refers to the computing at the edge of the networks, near the device and IoT layers. Fog computing refers to the computing at the intermediate layers between cloud data centers and IoT devices (many works have considered such definitions, see [3], for example). Edge and Fog layers have been proposed to bridge the gap between the cloud and IoT devices by enabling data management, computing, networking, storage, and application services at the intermediate layers and edge of the network while offering the possibility to interact with the cloud. Many applications have been proposed to benefit from fog and edge computing such as smart districts [9], SMS (Short Message Service) spam detection [12], networked healthcare [3], smart societies [2], QoS management in networks [8], Smart airport [9], Distributed Artificial Intelligence (AI) as-a-service (DAIaaS) [9], and many others applications [13]–[18]. However, the development and management of fog-based and edge-based systems for SBA face many challenges that need to be tackled. These include investigating and designing applications and systems for these emerging computing paradigms. One of the core challenging issues is workflow scheduling and offloading in such a dynamic, geo-distributed, heterogeneous environment where the set of computing nodes contains edge nodes, fog nodes, and cloud datacenters such as discussed in many works in the literature [19]–[23].

Further research is needed, for instance, for investigating dynamic scheduling of multiple workflows executions, i.e., invocations of multiple sets of linked elementary IT-enabled services, in hybrid edge-fog-cloud computing environments while ensuring the individual Quality-of-Service (QoS) requirements of all the workflows and their services and reducing services latency, energy consumption, and costs.

This paper provides a detailed study of workflow scheduling and offloading of service-based applications. We abstracted high-level challenges and requirements of cloud, fog and edge systems and developed different models of cloud, fog and edge systems, and study the scheduling of workflows (such as scientific and machine learning workflows) using a range of system sizes and applications intensities. Firstly, we develop several Markov models of cloud, fog, and edge systems and compute the steady-state probabilities for system utilization and stability. Secondly, using steady-state probabilities, we define a range of system metrics to study the performance of workflow scheduling and offloading including, network load, response delay, energy consumption, and energy costs. An extensive investigation of application intensities and cloud, fog, and edge system sizes reveals that significant benefits can be accrued from the use of fog and edge computing in terms of low network loads, response times, energy consumption, and costs.

The proposed workflow scheduling and offloading models can be utilized in practice to study a range of applications and derive several benefits. Firstly, different well-known standardized workflow can be plugged in our proposed workflow scheduling models to study their various performance behaviors including network load, average response delay, energy consumption, and energy cost, and this can be done for a range of cloud-only, cloud-fog, and cloud-

fog-edge systems. Some examples of standardized workflows include Montage workflow, SIPHIT workflow, epigenomics workflow, LIGO workflow, Cyber-Shake workflow, and more; see [23], for explanations and use cases of these workflows, and [19]–[22] for additional examples for practical utilization of our work. We elaborate this further in the methodology, results, and the discussion sections.

The rest of the paper is organized as follows. Section II reviews related work. Section III details the methodology and design. Section IV provides an analysis of the results. Section V discusses the practical utilization of the proposed models and concludes the paper. Section VI provides future research directions.

II. Literature Review

The focus of this paper is on combining the use of edge, fog and cloud computing for executing service-based applications. Fog computing has been attracting a lot of attentions in the last few years from researchers all over the world to bring out its potential. It has been seen as a complement of cloud computing to allow satisfying the increasingly sophisticated applications demanded by users that combine the use of time-sensitive services and intensive-processing services, such as big data analysis which can be performed only in the cloud. The coupling of fog and cloud computing requires providing scheduling and offloading mechanisms that allows to manage the execution of multiple workflows of interconnected services in fog and cloud resources.

The problem of scheduling and offloading in fog computing environments has been an active research topic for the last few years. Many researchers have been extensively focusing on providing solutions to this problem [24]–[32]. However, the research on fog computing, in general, and on workflow/task scheduling and offloading, in particular, is still in its early stages and the problem is not completely solved and there is still a lot of challenges that need to be addressed [33].

In [34], Zeng et al. tackled the problem of minimizing the maximum task completion time in Fog computing supported software-defined embedded system (FC-SDES) by jointly considering task scheduling and task image placement. The authors considered a scenario where tasks (requests) can be processed either on the client node or a fog (edge) node and task images can be saved on storage servers. Based on that scenario, they formulated their optimization problem as a mixed-integer non-linear programming (MINLP) problem. Then, in order to tackle its computational complexity, the authors proposed a heuristic algorithm for task completion time minimization based on the concept of “partition and join”. The main consideration in the proposed algorithm is that, by balancing the load between client nodes and fog nodes, the overall computation and transmission latency of all requests, therefore, their completion time, can be significantly minimized.

Similarly, Chen et al. [35], formulated the task offloading problem in ultra-dense network as a mixed-integer non-linear programming problem. Their aim, in this work, was to minimize the delay while saving the battery lifetime of user’s device. To do so, the optimization problem has been divided into two sub-problems, i.e., task placement and resource allocation sub-problems. Based on the solution of the two sub-problems, the authors proposed an offloading scheme which considers the battery lifetime of user’s device while reducing the task duration.

In [36], Huang et al. focused on providing a solution to the problem of computational offloading for multimedia workflows in mobile cloud computing. They proposed an energy-efficient offloading method using Differential Evolution (DE) algorithm to optimize the energy consumption of the mobile devices with time constraints.

Targeting the problem of task scheduling in smart factory, Wan et al. [37], introduced a method for energy-aware load balancing and scheduling (ELBS) based on Fog computing. They first formulated a load balancing optimization function by taking into account the energy consumption of the equipment in the smart factory. Then, they introduced a multi-agent system for achieve the dynamic scheduling of equipment workload with the task scheduling mechanism.

Considering a scenario where both edge/fog and cloud computing are used to serve mobile users, Zhao et al. [31], proposed to maximize the probability of tasks satisfying the delay requirement by jointly scheduling them either to the edge/fog network or to the cloud and allocating computational resources in the edge/fog network. So, they proposed to offload tasks with stringent delay bounds to resources in the edge level while the ones with loose delay bounds to resources in the cloud level. The proposed solution has been introduced to allow users with different delay requirement to be simultaneously served.

In [38], the authors presented a ranking-based method for task scheduling in fog-cloud computing networks. The aim of the proposal is to schedule user’s requests based on their different preferences and fog nodes’ constraints. To do so, the authors proposed to use linguistic quantifiers and fuzzy quantified propositions to rank fog nodes from the most to the least satisfactory one based on their requirements, then, the one that satisfies more user task preferences will be selected as a destination fog node.

Another work for task scheduling in hybrid fog-cloud computing has been proposed in [39]. In their work, Aburukba et al. modeled the problem of scheduling IoT service requests as an optimization problem using integer linear programming to minimize latency. They proposed a heuristic optimization approach in order to find feasible solutions with a good quality in a reasonable computational time. The genetic algorithm (GA) has been chosen and customized to schedule the IoT service requests to achieve the objective of minimizing the overall latency.

Even though there is many research works for scheduling and offloading in fog computing and hybrid fog-cloud computing, most of them fail to meet the scalability and mobility of nodes criterion. Also, they consider the scheduling of a single task which is not applicable for workflows composed of a set of linked tasks. The dependency between

tasks in workflows adds more challenge to the scheduling and offloading problem. More importantly, many efforts are needed to develop high-level understanding of cloud-fog-edge systems.

III. Methodology and Design

A. Workflow Scheduling Cloud-Fog-Edge Model

Consider a workflow scheduling system that is programmed to manage its capacity periodically -- such as monthly, weekly, daily, or hourly -- by scrutinizing the quantitative variations in the workload. A possible method that can be used for planning is building Markov models and solving these models for their steady-state probabilities.

Let us represent the demand of a workflow scheduling system in terms of the aggregate computational nodes by λ_A, where the subscript 'A' represents the 'aggregate' demand per hour. The demand λ represents the inter-arrival times that are exponentially distributed. The aggregate demand includes the demand for cloud, fog, and edge servers that are represented by λ_C, λ_F, and λ_E, respectively. We can write the aggregate demand in a mathematical form as in the following equation.

$$\lambda_A = \lambda_C + \lambda_F + \lambda_E. \quad (1)$$

Now consider that the aggregate hourly capacity of the collective cloud, fog, and edge system is μ_A, where, as for the arrival rate λ, the subscript 'A' represents the 'aggregate' hourly capacity in terms of the number of nodes. These nodes can be the physical nodes in the system or virtual machines. Similar to Equation (1), the following equation gives the breakdown of the aggregate capacity, which is the sum of the cloud, fog, and edge capacities, respectively.

$$\mu_A = \mu_C + \mu_F + \mu_E. \quad (2)$$

The total number of physical or virtual nodes in the system are represented by N_A, which is the sum of the total number of cloud, fog, and edge nodes, represented by N_C, N_F, and N_E, as formulated in Equation (3) below. Note that the capacities defined in Equation (2) are the hourly service capacities of the system while Equation (3) defines the number of cloud, fog, and edge nodes in the system.

$$N_A = N_C + N_F + N_E. \quad (3)$$

Note that "capacity" in this paper implies to be the server capacity in terms of the physical nodes or virtual machines the cloud, fog, and edge are able to provide in terms of their hourly rates. Note also that the three arrival rates or demands and capacities in the two equations given above can assume any reasonable values and their quantities do not affect our model. Indeed, not only that the model is independent of the values λ and μ can assume, the number of sub-arrival rates and capacities can also be extended to any number of clouds, fogs and edges. That is, using the model described above, we can model any number of clouds, fogs and edges by embedding in Equations (1) and (2) their individual arrival rates and server node capacities.

Fig. 1 depicts the CTMC (Continuous Time Markov Chain) transition diagram of our proposed cloud-fog-edge workflow scheduling model. There are three parts of the transition diagram, one part each for cloud, fog, and edge. The symbols used in the figure have already been defined in the earlier paragraphs and equations. The cloud layer model is depicted in the top row, as is evident by the use of "C" subscript in all the variables and parameters (arrival and departure rates, and node capacities), followed by the fog layer (use of the subscript "F") and edge layer (use of the subscript "E") in the second and third rows, respectively.

Inside the cloud layer, we have the system moving from the zero or idle state with no task in the system to be executed to one task, two tasks, until "c" tasks, where "c" could be any state between zero and N_C. Once the maximum number of tasks allocated to the cloud(s) have reached, the fog can start receiving tasks, moving from state one, to two, to "f" where "f" could be any state between one and N_F. Once the maximum number of tasks allocated to the fog(s) have reached, the edge can start receiving tasks, moving from state one, to two, to "e" where "e" could be any state between one and N_E. Note that any reasonable values can be assigned to the quantities in Equations (1), (2), and (3), with the exception that arrival rate cannot exceed the capacity otherwise the system will not be stable. Note also that the system can be equally modelled as first receiving the tasks in the edge layer followed by the fog and cloud. Similarly, we can conveniently place another set of parameters -- let us call them n_C, n_f, and n_e, to replace N_C, N_F, N_E, respectively – such that they can be any number between zero and N_x ($x \in \{C, F, E\}$. This would enable the model to allocate any maximum number of nodes in cloud, fog, and edge layers up to the maximum capacities of the three layers. That is, we can model such that any or all of the three layers do not have to work to their full capacities to avoid instability and provide higher reliability. Finally, note that the arrival and departure rates are dependent on the specific state the system is in but in the figure (Fig. 1) these are shown the same for simplicity (e.g., λ_C and μ_C).

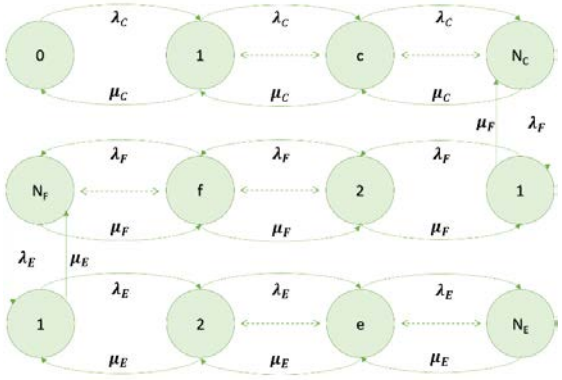

Fig. 1. The Cloud-Fog-Edge Workflow Scheduling Model – CTMC Transition Diagram.

$$\begin{pmatrix} -\lambda_C & \lambda_C & 0 & \cdots & \cdots & \cdots & \cdots & \cdots \\ \mu & -(\mu_C+\lambda_C) & \lambda_C & 0 & \cdots & \cdots & \cdots & \cdots \\ 0 & 2\mu_C & -(2\mu_C+\lambda_C) & \lambda_C & 0 & \cdots & \cdots & \cdots \\ 0 & 0 & 3\mu_C & -(3\mu_C+\lambda_C) & \lambda_C & 0 & \cdots & \cdots \\ \vdots & \vdots & \cdots & \ddots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & N_C\mu_C & -(N_C\mu_C+\lambda_F) & \lambda_F & \cdots & \cdots \\ \vdots & \vdots & \cdots & \cdots & \ddots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & 0 & N_F\mu_F & -(N_F\mu_F+\lambda_E) & \lambda_E & \cdots \\ \vdots & \vdots & \vdots & \vdots & \cdots & \cdots & \ddots & \cdots \\ 0 & 0 & \cdots & \cdots & \cdots & 0 & N_E\mu_E & -(N_E\mu_E) \end{pmatrix}$$

Fig. 2. The Cloud-Fog-Edge Workflow Scheduling Model: CTMC Generator Matrix Q.

Fig. 2 depicts the CTMC generator matrix of our proposed cloud-fog-edge workflow scheduling model. The model itself is depicted in Fig. 1 and has been explained. This generator matrix, represented by A, can be used to calculate the steady-state probabilities vector, x, using the following equation.

$$Ax = 0. \tag{4}$$

The vector x is a probability vector and therefore the sum of the vector is normalised to the value of 1. The details about the numerical solution of Markov chains can be found in the nominal book [40], or our earlier works such as [41], and other works such as [42].

We define a range of cloud, fog and edge system sizes in terms of the computational nodes and task arrival and departure rates and solve them for the steady-state probabilities. We use these steady-state probabilities to compute the system utilization and stability as formulated in Equations (5) and (6). The system utilisation (U) is defined as the maximum relative state that has the highest probability for the system to be in, in terms of the number of computational nodes.

$$U = \frac{i}{N} \mid x[i] = \max(x). \tag{5}$$

The relative state in the equation above is computed by dividing the state number that has the highest probability in the vector (indicating that the system will be in this state with the highest probability) by the total capacity of the system (the hourly capacity in terms of the number of nodes); higher this number, higher will be the utilisation of the system in terms of the number of busy computational nodes. A higher utilisation is desired to make the best use of the available computational resources. However, a higher utilisation could reduce the stability of the system.

The system stability defines inverse of the maximum relative state that has the highest probability and can be computed by dividing 1 by the system utilization.

$$S = \frac{1}{U} \tag{6}$$

The average network workload in bytes per second is represented by NWL and its computation is formulated by the following equation.

$$\text{NWL} = \frac{\psi * \sum_{i=1}^{\kappa} (\eta_i * t_i)}{\kappa}, \qquad \eta_i \, \epsilon \, \eta, t_i \epsilon \, \{\kappa\}. \tag{7}$$

In the equation above, η_i is the network load of the task number i, given in bytes, t_i is the time the task number i takes to be transferred over the network, and η is the set of all tasks in a given state. There are κ tasks in a given state, and $\{\kappa\}$ is the set of all κ time durations required to complete all tasks. In our experiments, we have used a fixed size of 5MB for the network load for all tasks. The times for each task are also fixed according to the latency of different networks (cloud-fog latency is 100ms, fog-edge latency is 2ms, and edge latency is 0.1ms). Not that this is not a limitation of our approach; a distribution of task sizes and task network transfer time can easily be used in these equations. Finally, ψ is a factor that depends on the state the system is in and this is computed using the following equation.

$$\psi = 1 + \omega * U^{\sigma}, \quad \forall \psi, \psi \leq 1 + \omega. \tag{8}$$

The equation stats that ψ can be computed using system utilization U, ω, and σ, but its value cannot exceed $1 + \omega$, means that the value of U^{σ} cannot exceed 1. The parameter ω is a regulation weight given to the network workload calculation that regulates the factor ψ. We set it to 1.0. A lower value for this parameter will have a lower effect on the network load computation and vice versa. This can be set by the user based on their knowledge of the system or focus of the study. The parameter σ is set to 5 in our calculations. It is a dampening factor over utilization so that the effect of utilization is balanced over the various operational states of the workflow scheduling system. A higher value of the dampening fact σ will create higher dampening implying that the values of ψ will increase slowly for the earlier states towards the higher-numbered states (see Fig. 1 and Fig. 2).

The average response delay (RD) of the system can be computed by the following equation. The parameter ψ is the same factor that depends on the state the system is in and this was computed using Equation (8). The variable d_i is the delay of job "i" (the time it takes to complete the job) and there are τ jobs in the system, each with its own delay.

$$\text{RD} = \frac{\psi * \sum_{i=1}^{\tau} d_i}{\tau}, \qquad d_i \epsilon \, \{\tau\}. \tag{9}$$

The network energy consumption per hour (NE) is calculated by the following equation. The network energy consumption depends on the network load, NWL, and the estimated energy ζ. Several studies have reported the network energy consumption. We use the values reported in [9], [43], which is 0.54 kWh/GB. NWL has already been computed earlier. Since it was computed in MBps, we have added in the equation a denominator of 1000 to convert the network load into GBps. The value is multiplied by Ƭ which is the time factor, in this case it is 3600 (the number of seconds in an hour).

$$\text{NE} = \frac{Ƭ * \zeta * NWL}{1000}. \tag{10}$$

Finally, we compute the network energy cost (EC) per hour as given in the following equation. The cost depends on the network energy consumption, NE, calculated earlier, and the unit price of energy (γ), which we have taken from [44] as GBP 0.174 per kilowatt-hour (kWh).

$$\text{EC} = \gamma * NE. \tag{11}$$

IV. Results and Analysis

A. Workflow Scheduling System (Cloud)

We use the CTMC model described in Fig. 1 and Fig. 2 and model a cloud-only workflow scheduling system. We set the number of cloud nodes to 16,000, and the number of fog and edge nodes to zero each. This gives according to Equation (3), $\boldsymbol{N_A} = 16{,}000 + 0 + 0 = 16{,}000$. We study different CTMC system with varying aggregate arrival rates, λ_A, beginning from one task per hour ($\lambda_A = 1$) to 500 tasks per hour ($\lambda_A = 500$), up to 16,000 tasks per hour ($\lambda_A = 16{,}000$). The service rate or departure rate or hourly capacity of this system is kept at constant, which is 16,000 tasks per hour

($\mu_A = 16{,}000$). These settings result in 33 different CTMC models that we solve using iterative methods and compute the steady-state probabilities for each model. These are plotted in Fig. 3. The figures shows that the x-axis that plots the number of states varies between 0 and 16,000, and the y-axis provides probability values ranging from 1E-19 to 1.0 on a logarithmic base 10 scale. The system is idle in the zeroth state. Initially, with lower arrival rates, the probabilities of the lower-numbered states are higher compared to the higher-numbered states, and in these cases the maximum probabilities fall to a certain low, near-zero values (manifested in the vertically dropping lines before the state number 16,000). As we move towards higher arrival rates, the probabilities for the lower-numbered states start decreasing and the probabilities for the higher-numbered states start increasing. This trend continues until the probabilities rise towards the high-numbered states and do not fall vertically even after reaching the states nearer the state number 16,000. This shows that these cloud scheduling systems will be operating with high computational node utilization but with low stability and the risk for the system to drop the tasks off the system or its waiting queues.

Fig. 4 plots the utilization and stability of the 33 cloud workflow systems that we have described in the previous paragraph. Note that the utilization (y-axis, blue line) rises with the increasing arrival rates (x-axis), while the stability of the system (orange line) decreases with the increasing arrival rates. This is an expected behaviour from such systems.

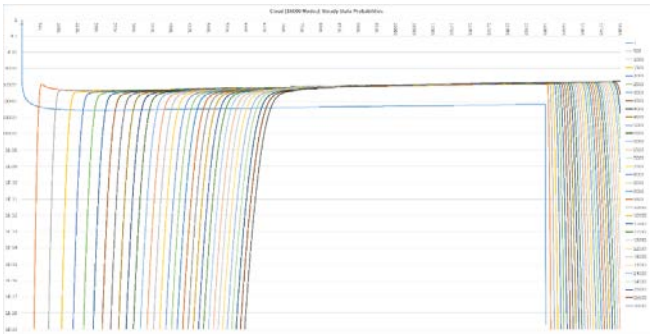

Fig. 3. Steady State Probabilities: Cloud Only System (16000 Nodes).

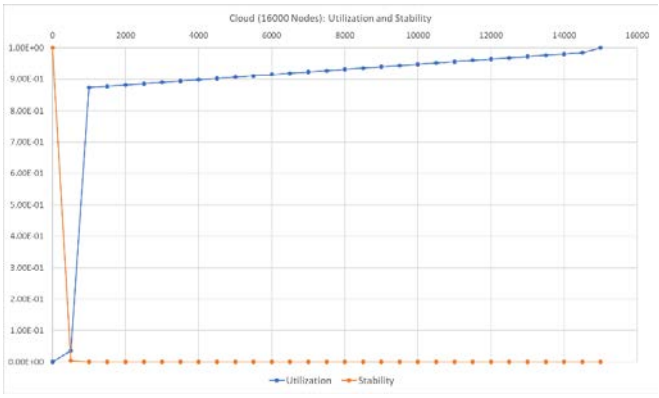

Fig. 4. Cloud (16000 Nodes): Utilization and Stability.

B. Workflow Scheduling System (Cloud-Fog-Edge)

We now model cloud-fog-edge systems where the workflows are scheduled to all three layers. Fig. 5 plots the steady-state probabilities of 23 workflow scheduling systems with different configurations. Some execute on cloud only (the top nine systems represented by Cloud-1, Cloud-1000, … Cloud-8000). While others run on fog (Fog-333 to Fog-333) and edge (Edge-166 to Edg-3166) layers. The numbers alongside Cloud-, Fog-, and Edge- represent the arrival rates for those nodes types. The strange numbering is used to avoid lines coming on top of each other and causing difficulty in reading and differentiating the plots. Note that since the fog and edge layers add to the capacity of the cloud, the probabilities for the higher-numbered states near the state number 16,000 are zero, indicating that those systems will not be unstable.

C. Network Load

The network workload (NWL) computations were explained earlier in Section III along with its Equation (7). In this section, we will study the network workload related performance of various cloud, cloud-fog, and cloud-fog-edge systems.

Fig. 6 depicts the network workload in GBps for a cloud-only workflow scheduling system containing 16,000 nodes. There are a total of 31 different systems that have been modelled and their network load has been computed. These 31 systems relate to different workloads on the systems in terms of the tasks being received by the system, beginning from 1 task, to 500 tasks, up to 15000 tasks per hour. The capacity in all of these 31 systems has been kept constant. The minimum network load is for the system with one task; it is actually 0.51 GBps but is rounded off to 1GBps in the figure. Note that the network load consistently rises to reach 15,315 GBps for the busiest workflow scheduling system. Note that the increase in the network load is due to the equal load of each job as have been explained in Section III. However, this increase can be varied by using a distribution of network loads related to different tasks, and these network loads and tasks can even be varied based on different system states. Moreover, note that the increase in the network load is not linear. This is due to the factor ψ, which is dependent on the steady-state probabilities and system utilisation.

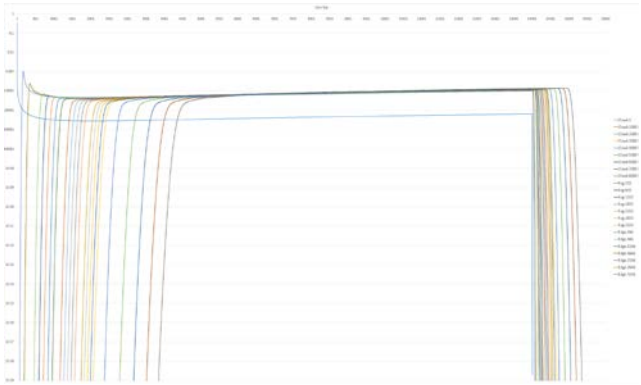

Fig. 5. Steady-State Probabilities: Cloud-Fog-Edge System (8000-4000-4000 Nodes).

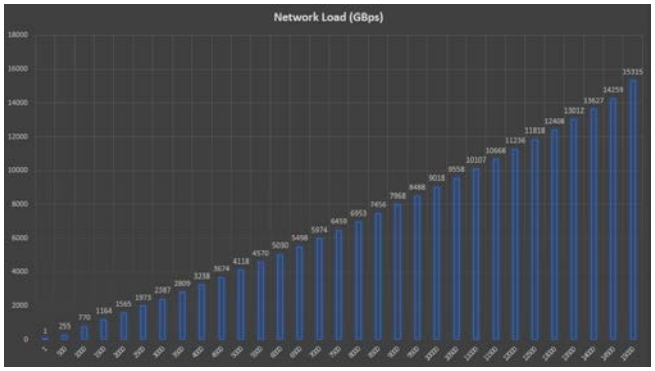

Fig. 6. Network Load in GBps (Cloud with 15,000 Nodes).

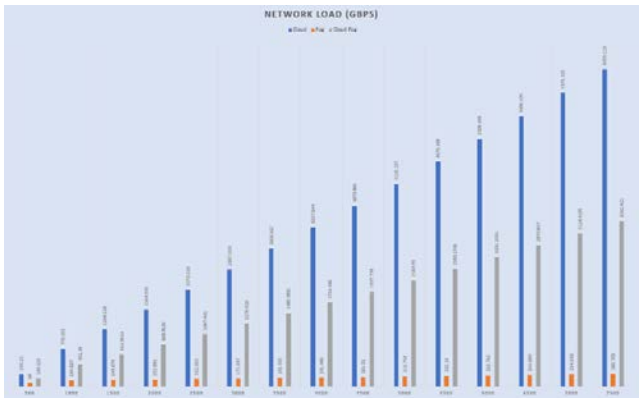

Fig. 7. Network Load in GBps (Cloud-Fog System with 7,500 Nodes Each).

Fig. 7 shows the network workload in GBps for a cloud-fog workflow scheduling system containing 7,500 nodes each in the cloud and fog. As mentioned earlier, an equal number of nodes are used for simplicity of explanation and it does not pose any limitations on the design of the systems. There are a total of 15 different systems for cloud and fog each that have been modelled and their network loads have been computed. These 15 x 2 systems relate to different workloads on the systems in terms of the tasks being received by the system, beginning from 500 tasks, up to 7,500 tasks. The capacity in all of these 30 systems has been kept constant. The cloud network load is depicted using blue bars and the fog network load is depicted using orange bars. The third set of bars in the grey colour represents the aggregate network load of the cloud-fog systems. The minimum network load is for the system with 500 tasks; it is 255 GBps for cloud and 84 GBps for the fog system, with ~170 GBps the aggregate network load. The network load consistently rises to reach 6,459 GBps (cloud), ~266 (fog), and 3362 GBps (aggregate) for the busiest workflow scheduling system. Note that the consistent increase in the network load is due to the equal load of each job as has been explained earlier. The relatively smaller values for fog systems is due to the smaller network latencies, implying a much lower time period for the fog tasks to travel over the fog-edge networks compared to the fog-cloud networks.

Fig. 8 plots the network workload in GBps for a cloud-fog-edge workflow scheduling system containing 5000 nodes each in the cloud, fog, and edge layers. An equal number of nodes are used for simplicity of explanation and it does not pose any limitations on the design of the systems. There are a total of 10 different systems for cloud and fog each, which have been modelled. These 10 x 3 systems relate to the different workloads on the systems in terms of the tasks being received by the system, beginning from 500 tasks, up to 5000 tasks per hour while the capacity all the systems is constant. The network load is depicted using blue, orange, and grey bars for cloud, fog and edge respectively. The edge values are relatively small and therefore their bars are not visible but the labels can be seen on the right of the orange bars. The fourth set of bars in the yellow colour represents the aggregate network load of the cloud-fog-edge systems. The minimum network load is for the system with 500 tasks; 255 GBps (cloud), 58 GBps (fog), 5 GBps (edge), and 106 (aggregate). Note that the network load for the fog system with 500 nodes was 84 in the cloud-fog system depicted in Fig. 7; the higher value in that case is due to the cloud system that had 7500 maximum nodes. Since we modelled systems with cloud scheduling first, the fog is scheduled after the 7500 cloud nodes and this increase the overall load of system and in turn the factor ψ, which is dependent on the steady-state probabilities and system utilisation. The network load consistently rises to a maximum of 4,118 GBps (cloud) and 1433 GBps (aggregate) for the busiest workflow scheduling system with 5000 nodes each in the cloud, fog, and edge. The reason for relatively smaller values for fog (and edge) systems has been explained in the previous paragraph.

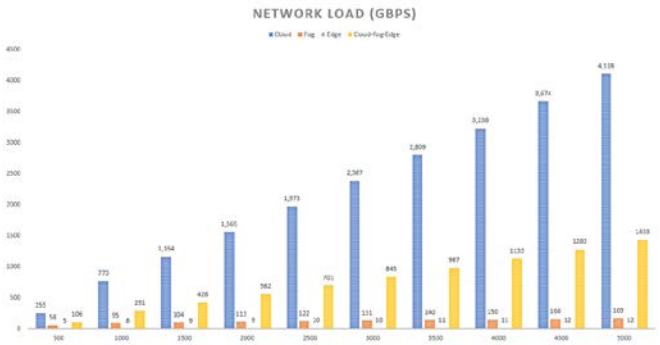

Fig. 8. Network Load in GBps (Cloud-Fog-Edge System with 5,000 Nodes Each).

D. Average Response Delay

The calculations of average Response Delay (RD) were explained earlier in Section III and Equation (9). We now in this section will analyse the system performance related to response delay of various cloud-fog, and cloud-fog-edge systems. We have modelled cloud-only and several other different configuration systems but we will limit our analysis to the cloud-fog and cloud-fog-edge systems for the sake of brevity.

Fig. 9 depicts the average response delay in milliseconds (ms) for a cloud-fog workflow scheduling system containing 7,500 nodes each in the cloud and fog. This system is similar to the one depicted in Fig. 7. There are a total of 15 different systems for cloud and fog each that have been modelled and their average response delays have been computed according to Equation (9). The cloud response delay is depicted using blue bars and the fog delay is depicted using orange bars. The third set of bars in the grey colour represents the aggregate

response delay of the cloud-fog systems. The minimum delay is for the system with 500 tasks; 404ms, 102ms, and 253ms for cloud, fog, and aggregate delays, respectively. The increase in the delay is consistent and non-linear, however, minimal. The minimal increase is because the system serves the jobs in parallel. Also, this minimal value and consistent increase is due to the equal load of each job as has been explained earlier. This increase in the delay depends on the system and task characteristics that can be tuned using the factor ψ and using tasks with some low or high-variance distributions.

Fig. 10 depicts the average response delay in milliseconds (ms) for a cloud-fog-edge workflow scheduling system containing 5000 nodes each in the cloud, fog, and edge. This system is similar to the one depicted in Fig. 8. There are a total of 10 different systems for cloud, fog, and edge, each, which have been modelled and their average response delays have been computed according to Equation (9). The cloud, fog, edge, and aggregate response delays are depicted using blue, orange, grey, and yellow bars. The minimum delay is for the system with 500 tasks; 404ms, 102ms, 100ms, and 202ms for cloud, fog, edge, and aggregate delays, respectively. The increase in the delay is consistent and non-linear, however, minimal. We have explained the reasons for this while explaining Fig. 9. Note that using a cloud-fog-edge system as opposed to cloud-only or cloud-fog system significantly decreases the aggregate delay bringing to half of it (from 652 to 326 ms). Obviously, increasing the relative number of edge nodes compared to cloud and fog can significantly bring down the aggregate delays.

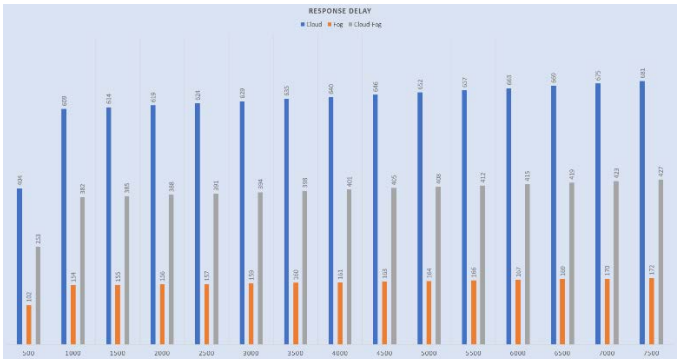

Fig. 9. Response Delay -- Milliseconds -- Cloud-Fog System with 7,500 Nodes Each.

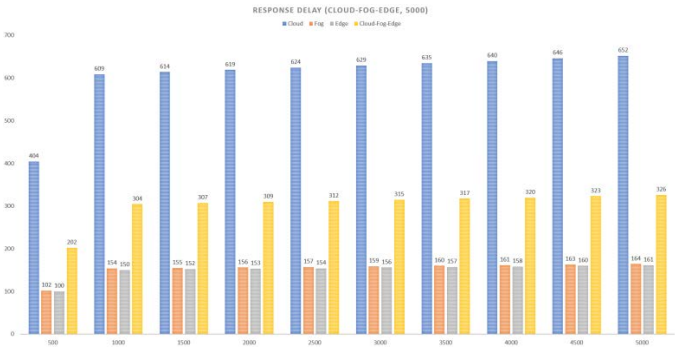

Fig. 10. Response Delay -- Milliseconds -- Cloud-Fog-Edge System with 5000 Nodes Each.

E. Energy Consumption

The network energy consumption per hour (NE) was defined and explained in Section III and calculated using Equation (10). We, in this section, analyse the system performance related to network energy consumption of various cloud-fog-edge systems. We have modelled cloud-only and cloud-fog, and several other different configuration systems, however, for the sake of brevity, we will limit our analysis in this section to the cloud-fog-edge systems.

Fig. 11 depicts the network energy consumption in MWh for a cloud-fog-edge workflow scheduling system containing 5000 nodes each in the cloud, fog, and edge. This system is similar to the one depicted in Fig. 10, however, it provides network energy consumption data. There are a total of 10 different systems for cloud, fog, and edge, each, which have been modelled and their energy consumption have been computed according to Equation (10). The cloud, fog, edge, and aggregate network energy consumption are depicted using blue, orange, grey, and yellow bars. The minimum energy consumption is for the system with 500 tasks; 496, 112, 10, and 206 MWh for cloud, fog, edge, and aggregate energy consumption, respectively. The increase in the consumption is consistent, non-linear, and reaches roughly 16 times (496 to 8006) as opposed to the 10 times increase in the number of nodes (500 to 5000). We have explained the reasons for this while explaining Fig. 9. Note that using a cloud-fog-edge system as opposed to cloud-only or cloud-fog system significantly decreases the aggregate energy consumption (from 8006 to 2786 MWh).

F. Energy Cost

The energy cost (EC) per hour was defined and explained in Section III and calculated using Equation (11). We here analyze the system performance related to network energy cost of various cloud-fog-edge systems. We have modelled cloud-only and cloud-fog, and several other different configuration systems; however, for the sake of brevity, we will limit our analysis in this section to the cloud-fog-edge systems.

Fig. 12 depicts the energy cost in GBP (x million) for a cloud-fog-edge workflow scheduling system containing 5000 nodes each in the cloud, fog, and edge. There are a total of 10 different systems for cloud, fog, and edge, each, which have been modelled and their energy cost have been computed according to Equation (11). The cloud, fog, edge, and aggregate monthly network energy consumption are depicted using blue, orange, grey, and yellow bars. The minimum monthly energy cost is for the system with 500 tasks; 62, 14, 1, and 26 million GBP for cloud, fog, edge, and aggregate monthly cost respectively. The increase in the cost is consistent, non-linear, and reaches roughly 16 times (62 to 1003) as opposed to the 10 times increase in the number of nodes (500 to 5000). Note that using a cloud-fog-edge system as opposed to cloud-only or cloud-fog system significantly decreases the aggregate energy consumption (from 1003 to 349 million GBP).

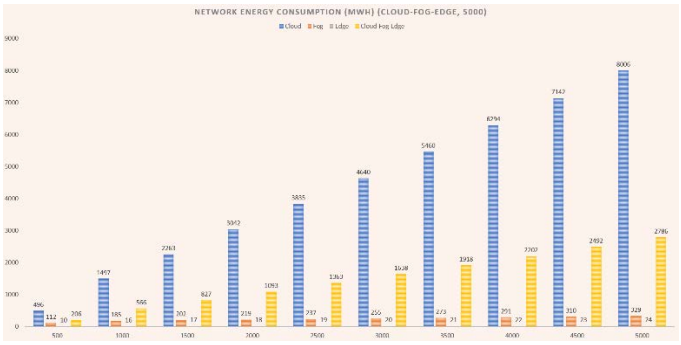

Fig. 11. Network Energy Consumption -- MWh -- Cloud-Fog-Edge System with 5000 Nodes Each.

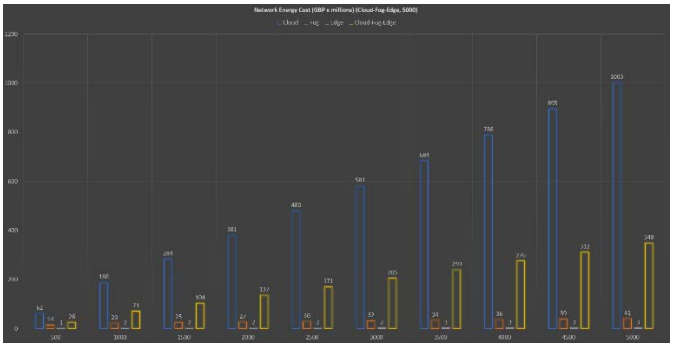

Fig. 12. Monthly Energy Cost – GBP x million -- Cloud-Fog-Edge System with 5000 Nodes Each.

V. Discussion, Utilization and Conclusion

Fog and edge computing has emerged as an important paradigm to address many challenges related to time-sensitive and real-time applications, high network loads, user privacy, security, and others. These developments offer huge potential; however, many efforts are needed to study and design applications and systems for these emerging computing paradigms.

This paper provided a detailed study of workflow scheduling and offloading of service-based applications. We developed different models of cloud, fog and edge systems and studied the scheduling of workflows using a range of system sizes and application intensities. Firstly, we developed several Markov models of cloud, fog, and edge systems and computed the steady-state probabilities for system utilization and stability. Secondly, using steady-state probabilities, we defined a range of system metrics to study the performance of workflow scheduling and offloading including, network load, response delay, energy consumption, and energy costs. An extensive investigation of application intensities and cloud, fog, and edge system sizes revealed that significant benefits can be accrued from the use of fog and edge computing in terms of low network loads, response times, energy consumption and costs.

The proposed workflow scheduling and offloading models can be utilized in practice to study a range of applications and derive several benefits. Firstly, different well-known standardized workflow can be plugged in our proposed workflow scheduling models to study their various performance behaviors including network load, average response delay, energy consumption, and energy cost, and this can be done for a range of cloud only, cloud-fog, and cloud-fog-edge systems. Some examples of standardized workflows include Montage workflow, SIPHIT workflow, epigenomics workflow, LIGO workflow, Cyber-Shake workflow, and more; see [23], for explanations and use cases of these workflows, and [19]–[22] for additional examples for practical utilization of our work. Let us take the epigenomics workflow as an example that captures the execution workflows related to the operations involved in genome sequences. Such a workflow can be embedded in our proposed Markov model by defining the execution workflows within the Markov chain and thereby we can study how that workflow will behave for cloud-only, cloud-fog, and cloud-fog-edge systems in terms of the network load, average response delay, energy consumption, and energy cost of the system.

The computational loads used by the different tasks modeled in this paper are the same. Similarly, the network loads in terms of the bytes sent around the network are also the same. However, this is not the limitation of the model. The equations developed in the models do use different computational and network loads and other parameters. The proposed models can capture the additional network load due to the task offloading or the different execution times of tasks in nodes due to the differences in their computational performance such as device speed and power that may also lead to higher energy consumption by the devices and networks. This is because the models define separately each of the tasks' computational and network loads, as well as computational and network characteristics of the devices and networks in the cloud, fog and edge layers. These could be easily changed based on various workflows to study their performance. However, the developed system is a Markov chain and therefore it does use exponential distribution to capture the arrival and departure rates.

VI. Future Work

The future work will focus on investigating variations in the cloud, fog, and edge system configurations, variations in application intensities, and variations in task sizes. Moreover, we plan to investigate system utilization and stability models and their effects on the computations of system characteristics including energy consumption and costs, response times, and network throughput.

***Abstract*—House price is affected significantly by several factors and determining a reasonable house price involves a calculative process. This paper proposes advanced machine learning (ML) approaches for house price prediction. Two recent advanced ML algorithms, namely LightGBM and XGBoost were compared with two traditional approaches: multiple regression analysis and ridge regression. This study utilizes a secondary dataset called 'Property Listing in Kuala Lumpur', gathered from Kaggle and Google Map, containing 21984 observations with 11 variables, including a target variable. The performance of the ML models was evaluated using mean absolute error (MAE), root mean square error (RMSE), and adjusted r-squared value. The findings revealed that the house price prediction model based on XGBoost showed the highest performance by generating the lowest MAE and RMSE, and the closest adjusted r-squared value to one, consistently outperformed other ML models. A new dataset which consists of 1300 samples was deployed at the model deployment stage. It was found that the percentage of the variance between the actual and predicted price was relatively small, which indicated that this model is reliable and acceptable. This study can greatly assist in predicting future house prices and the establishment of real estate policies.**

***Keywords*—House price; house price prediction; machine learning; property; regression analysis**

I. Introduction

House is one of the most essential basic needs in human life, along with other basic needs such as food and water. Demand for houses has rapidly increased through the years as people's standard of living has improved. Even though there are people who make their house as an investment and asset, yet most people around the world buy a house to live in. Undoubtedly, the housing sector has a positive impact on a country's currency, which is an important scale for the national economy [1]. Homeowners will buy goods such as furniture and house appliances for their house and home builders or contractors will buy raw material to make houses to fulfil the demand for houses, which is an example of the economic wave effect created from new house supply. Meanwhile, consumers have the capital to make a large investment, and the construction industry is vibrant or otherwise can be seen through the high level of house supply or demand in a country. Nevertheless, house has become unaffordable as there is a significant price expansion in the housing market sector in many countries [2].

In Malaysia, buying a house is never an easy experience because this decision can cost a lot of money. According to the Department of Statistics Malaysia, the average price of a house in the 2nd quarter of 2018 was RM 408,774 compared to ten years ago which was RM 199,431 [3]. The average house price in Malaysia was obviously two times higher in 2018 compared to 2009. A wide variety of factors may affect house prices such as the facilities provided, type of houses, number of bedrooms and size of a house. These factors also vary depending on the location of the house, for example, there will be an obvious difference in house prices, in Singapore compared to Malaysia. Yet, we cannot simply say that the price of each house is similar throughout Malaysia as the prices of houses in Kuala Lumpur (urban area) is not the same as the price of houses in Perlis (rural area). Yop [3] in his report mentioned that the average house price in Kuala Lumpur in 2018 was RM 772,398, while the average house price in Perlis for the same year was just RM 177,945. It is suggested that the prediction of house prices could be more accurate if the prediction is considered based primarily on a specific region.

House prices can be predicted using machine (ML) algorithms including support vector regression, artificial neural network, and linear regression. The ML model that provides the best prediction results will be beneficial for researchers, home buyers, property investors, and house builders in terms of gaining a lot of knowledge and information of the house price values in the present sector. Additionally, this model can facilitate potential buyers to determine the characteristics of a house they prefer that adhere to their budget [4]. Prediction of house prices in Kuala Lumpur would be a significant research as Kuala Lumpur is the capital city of Malaysia that offers a range of facilities

including efficient public transportation, shopping malls, and many more compared to states in a rural area such as Perlis has yet to provide. All the facilities provided can encourage many home buyers, investors, and house builders to supply more houses in this area, at the same time the demand for houses in this specific region would increase. Nonetheless, the suitable model in predicting house prices in Kuala Lumpur remains unclear as there is limited study conducted in this region.

Research showed that ML algorithms have proven extremely useful for addressing many predictions and classification problems with broad application scope, including customer classification and segmentation [5], market analysis [6], [7], and education [8]. Unfortunately, ML is relatively limited and very far from being used in real estate applications mainly in the Malaysian sense. Evaluation of property prices and values is extremely critical for the real estate sector, the stock market, the economics and tax sector, as well as the scale of buyers' and sellers' wallets [9]. Although researchers are relatively aware of the existing current prediction model, consideration should be given to the current methodologies constrained by the scope of data of the current system in the real estate industry. Therefore, it is important to examine the correlation between house prices and housing attributes and identify significant variables that are essential to the use of the ML techniques in the real estate industry, involving pre-processing and exploration of the datasets obtained.

As various factors such as location and property demand could affect house prices, most parties involved including buyers and investors, housebuilders, and real estate market may want to know the exact attributes or the main factors affecting house prices to assist investors in making decision and to facilitate house builders in setting house prices [2], [10], [11]. Nevertheless, other characteristics including distance from local facilities and the physicality of a house might be overlooked. This may contribute to the creation of a house price model that does not reflect the actual condition of the housing sector. In comparison, houses with identical attributes may be priced at varying rates, while houses with different type of attributes can be priced at the same amount. Besides that, real-estate industry in Malaysia is far behind compared to that in the United States and United Kingdom in valuation [2], [12] as Malaysia is still using the traditional method to valuate a house. Developers or real-estate agencies will send valuers to each house, to appraise the house price resulting in wastage of time and cost, also the fluctuation of house prices. However, this issue and many other pressing industrial problems can be effectively addressed using big-data technologies that includes ML in this age of Industry 4.0.

This paper presents an exploration of ML algorithms for house price prediction by focusing on Kuala Lumpur housing data. The study aims to propose an advanced ML algorithm that can generate a promising model for house price prediction. To achieve this aim, four models namely multiple regression analysis, ridge regression, light gradient boosting machine (LightGBM), and XGBoost are used to learn about the relationship between the house attributes and house prices as well as to predict the house price. The remainder of this paper is organized as follows: Section II describes related works on prediction of house price in Malaysia and followed by housing price prediction models. Subsequently, in Section III and Section IV, the experimental designs and the data modeling are presented consecutively. Section V presents the model deployment while Section VI discusses the results and findings of the study. Finally in Section VII, the study is concluded.

II. Related Work

A. Prediction of House Price in Malaysia

Prior to 2019, there were several studies regarding the prediction of house prices in Malaysia. In 2018, a study has been conducted by Yap and Ng [13] to determine house affordability in Malaysia. This study found out that key factors affecting affordability of houses were income, price of a property, land cost, policy of supply and demand, and changes in the economy. Their study [13] offered detailed insights into exploring housing market in Malaysia; however, they only provided a descriptive analysis, which lacked in the predictive analysis towards the housing market in Malaysia. The study by [2] found out that there were several attributes that play a significant role in determining house prices in Petaling District. Another significant finding from this study was Puchong and Petaling Jaya was classified as less volatile housing markets compared to Sungai Buloh. A similar study conducted by Abdullahi et al. [14] using Multiple Regression Analysis and Hedonic Regression Analysis in explaining price variations in Malaysia found that one of the most influential attributes was the location of a house.

Apart from that, building area and building age were significant in variations of prices of houses in Malaysia. The locations mentioned in the study were based on states in Malaysia; hence location is the most dominant attribute compared to others (attributes). Meanwhile, this study focused on the location of a small region of Kuala Lumpur to predict the house price. Thus, location cannot be generalized as the main significant attribute in predicting house prices. Another similar study conducted examined the prediction of house prices in Petaling District Malaysia. The study by Chang et al. [9] used a different method called the Functional Relationship Model. The model was used to identify the impact of residential property attributes on house price in Petaling District. Several attributes were identified such as building size and bedroom numbers which had a significant effect in predicting the house prices. The study successfully developed a new predictive model and then applied on the Petaling District terrace-houses only, even though, there existed various types of houses in the area such as bungalows, condominiums, or apartments. Taking everything into account, the model was unable to reflect the whole housing market in Petaling District.

B. Housing Price Prediction Models

ML algorithms to develop house price prediction models have been actively researched and models are constructed by using algorithms such as random forest, decision tree, lasso, and linear regression [12], [15]. A study by Wu et al. [12] categorized models in analyzing the real-estate market into the

conventional valuation system and the advanced valuation system. The traditional valuation system includes the multiple regression method and stepwise regression method, while the advanced valuation is the hedonic pricing method, artificial neural network (ANN), and spatial analysis method. The choice of a model that needs to be used to predict house prices is quite critical as there is a variety of models available. One of the most widely used models in the real-estate field is the regression analysis namely the multiple linear regression, support vector regression, and hedonic regression analysis, which is used by several researchers including [9], [16]–[20]. In addition, several other machine learning models such as the gradient boosting model including Catboost, XGBoost and LightGBM, random forest, decision and artificial neural network have been used frequently in the study of real- estate [10], [11], [21]–[23]. In this study, four models namely multiple regression analysis, ridge regression, LightGBM, and XGBoost are used to learn about the relationship between house attributes and house prices as well as to predict house prices. The next subsections explain further these four models.

- Multiple Regression Analysis

Multiple Regression analysis is an extension of simple linear regression to predict the value of a variable based on the value of two or more other variables. It can determine the strength of the relationship between an outcome (the dependent variable) and several predictor variables as well as the importance of each of the predictors to the relationship [24] [25]. Four basic assumptions need to be fulfilled to use the multiple regression analysis model [26] as cited in [27]. The first assumption is the variable used in the model must be normally distributed. Multivariate data cleaning is also an important consideration in multiple regression.

The second assumption that needs to be met is the relationship between the dependent and independent variables which must be linear to estimate the variables accurately. Next, the assumption to use this model is no perfect multicollinearity between variables. The last assumption to be fulfilled is little or no auto correlation. There are various other assumptions for this model; however, these assumptions are among the easiest to deal with if needed. The prediction of house prices using multiple regression model is conducted by assigning the price of a house as a target variable or dependent variable, while other attributes are set as independent variables to determine the most significant variables by identifying the correlation coefficient of each attribute.

- Ridge Regression

Ridge regression is a technique used to assess the presence of collinearity in multiple regression data [28]. As multicollinearity happens, the estimates of the least-squares are unbiased, but their variances are large enough such that they can be far from the real value. Ridge regression provides a more credible performance by reducing the standard errors. There were several industries that have deployed ridge regression model as their solution. For example, in medical industry, this model was deployed in healthcare analysis system and blood-base tissue gene expression as well as in wind speed forecasting [29]–[31]. According to Manasa et al. [10], the ridge regression model is a regularization model that incorporates and optimizes an additional variable (tuning parameter) to resolve the effect of multiple variables in linear regression, typically referred to as ‘noise’ in a statistical sense. This model has been used by a lot of researchers in the real-estate previous studies including [10], [32]–[34]. In their study, [33] found that ridge regression is able to provide the lowest MSE value for the house prediction model compared to other models in that study including lasso and gradient boosting.

- Light Gradient Boosting Machine (LightGBM)

Initially launched in late 2017, the Light Gradient Boosting Machine or LightGBM has a stable release in November 2020. This model has been used by many researchers in their fields such as medical fields [35], and biochemistry [36], [37]. This model, however, is still rarely used in the real estate market, since there is only one academic study that has utilized this model [22]. In their research related to prediction of house prices, [22] combined this model with another prediction model, which were CatBoost and XGBoost model to forecast house rentals in China. This joint model managed to provide the smallest RMSE value of the house price prediction model.

- Extreme Gradient Boosting (XGBoost)

XGBoost is the most powerful algorithm for any regression or classification problem which stands for ‘extreme gradient booster’. The developers [38] of this model in their article describe XGBoost as a scalable tree boosting machine learning system. The framework of this model can be seen as an open-source kit. In a range of machine learning and data mining problems, the influence of this model has been widely recognized. In fact, many successful machine learning competitions utilize these styles of model. Besides, this model is often used in real-world development networks, including internet ads. According to [34], XGBoost algorithm addresses issues of the linear regression model. The XGBoost model can handle numerical as well as categorical variables very well. This model can automate different loss functions and offers many tuning choices for machine learning engineers to modify the model. This model had been used in many fields including the real estate and housing market sector [10], [32], [34], [39]. Most studies in the real estate industry that use the XGBoost model found out that this model is able to provide the lowest RMSE value for the prediction of house prices compared to other models [23], [34]. Table I summarizes past studies that work on similar domains from 2011 until 2020. As can be seen, the first four ML models appear to be the most commonly used by past researchers. The list of variables that associate with this domain can be referred in our paper [40]. As stated in the paper, the factors influencing house prices can be classified into three categories: location, structural and neighborhood condition.

III. EXPERIMENTAL SETUP

A. Data Preparation

This study is based on a secondary dataset and retrieved from the Kaggle website (https://www.kaggle.com/dragonduck/property-listings-in-kuala-lumpur) and Google Maps. The dataset has originally scrapped from property listings in Kuala Lumpur, Malaysia in 2019. The original dataset contains only 8 variables including location, price, rooms, bathrooms, property type, size, and furnishing. Other than that, there were other four variables that also showed a significant impact to house price prediction derived from Geocoder and Googleplaces Python package used to retrieve locations through Google Maps. The variables were distance to shopping mall, distance to hospital, access of public transport, and distance to nearest school. Thus, the final dataset contains 53883 observations with 12 variables including one target variable. In this study, the target variable was the price (which is a continuous variable) in Ringgit Malaysia (MYR). Meanwhile, the independent variables were location (location of a house), bedroom (number of bedrooms available), bathroom (number of bathrooms available), car park, size (house lot size), furnishing status, property type, shopping mall (the nearest shopping mall to the house in KM), school (the nearest school to the house in KM), hospital (the nearest hospital to the house in KM) and public transport (the nearest LRT and MRT station to the house in KM). Table II shows the description of these variables.

TABLE II. DESCRIPTION OF VARIABLES

No.	Variable Name	Role	VariableType	Description
1.	Price	Target	Continuous	Price of house sold in the market
2.	Location	Input	Nominal	The location of a house for example: 1. Mont Kiara 2. City Centre 3. Bangsar 4. Desa Park City 5. Bukit Tunku (KennyHills)
3.	Room	Input	Discrete	Number of rooms in a house
4.	Bathroom	Input	Discrete	Number of bathrooms in a house
5.	Car Park	Input	Discrete	Number of car parks provided for a house
6.	Size	Input	Continuous	The built-up area of a house or the land area of a house
7.	Furnishing	Input	Nominal	Furnishing status of a house: 1. Fully furnished 2. Semi-furnished 3. Unfurnished
8.	Property Type	Input	Nominal	The type of condominium: 1. Corner 2. Duplex 3. End Lot 4. Intermediate 5. Penthouse 6. SOHO 7. Studio 8. Triplex
9.	Shopping Mall	Input	Continuous	The nearest shopping mall to the house in kilometer (KM)
10.	School	Input	Continuous	The nearest school to the house in kilometer (KM)
11.	Hospital	Input	Continuous	The nearest hospital to the house in kilometer (KM)
12.	LRT/MRT	Input	Continuous	The nearest LRT or MRT station to the house in kilometer (KM)

The data preparation stage included several tasks to create the final dataset. Tasks for data preparation were likely performed several times, and not in any specified order. Tasks included selection of table, record, and attribute, data cleaning, new attribute building, and data transformation for modeling tools were performed at this stage. For this study, the original dataset of a property listing was reduced through the data cleaning process stages and data transformation. Data cleaning can be referred to as a process of identifying and correcting errors in a dataset, for example removing missing values, and data transformation refers to a process of transforming a data to be more valuable towards a study. The invalid data including missing values and inconsistent data observed in this stage. A total of 21,995 rows containing missing values in which the majority of the missing values existed in more than two columns (good if we know the variables). All 21,955 rows with missing values were removed using Python. There were 31,899 rows left after removing missing values from the dataset.

B. Data Transformation

To examine whether the dataset is normally distributed or not, the study used three graphical methods such as histograms, QQ-plot, and boxplot. On the other hand, skewness and kurtosis were also used to assess normality of each variable. According to [45], a standard normal dataset has a kurtosis value between -3 to 3. If the kurtosis value is higher or lower than this value, it will be considered as a thin bell shape. Meanwhile, [46], [47] suggested that if the skewness value is between -2 to 2, the dataset can be roughly considered as normal. Based on Fig. 1, the skewness value is 5.03 and the kurtosis value is 62.75. It means that the dataset is not normally distributed. Hence, data transformation needs to be done to make the dataset conform to normality. The transformation of the dataset was executed by using log-transformation to normalize the dataset. The transformed data showed better value of skewness and kurtosis which were 0.7699 and 0.3670, respectively. These two values are depicted in Fig. 1 and Fig. 2. The skewness value (0.77) between -2 and 2 can be considered as normally distributed.

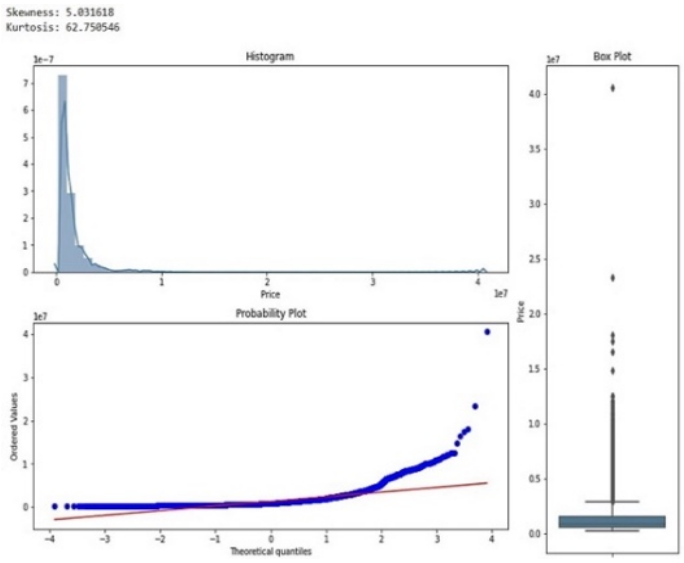

Fig. 1. Distribution of Price before Transformation.

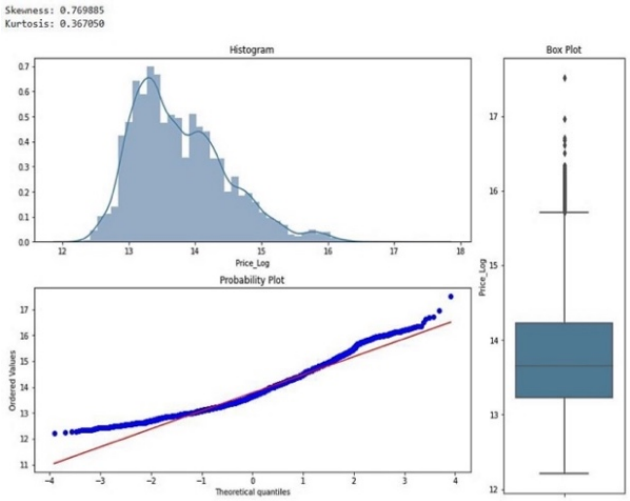

Fig. 2. Distribution of Price after Transformation.

C. Identification of Importance Features using Correlation Score

Pearson correlation matrix was utilized to check for the correlation value between independent and dependent variable. This test helped this study determine which attributes played an important role in valuating house prices. On the other hand, the correlation value was also used to detect whether there is multicollinearity in this dataset. According to Ratner (2009), multicollinearity values between 0 and 0.3 (0 and-0.3) imply a weak positive (negative) linear relationship via a shaky linear law, while values between 0.3 and 0.7 (0.3 and−0.7) via a fuzzy-firm linear rule suggest a moderate positive (negative) linear relationship and the values between 0.7 and 1.0 (-0.7 and -1) suggest a strong positive (negative) linear relationship. Fig. 3 illustrates the heatmap of the Pearson correlation coefficient matrix based on each variable. As depicted in Fig. 3, variable hospital which is the distance to the nearest hospital has a weak negative correlation which is -0.19. Meanwhile, other attributes show a moderate and strong correlation value. However, there are no attributes being dropped from this study, as this study utilizes machine learning model that can detect itself which attributes is good or not.

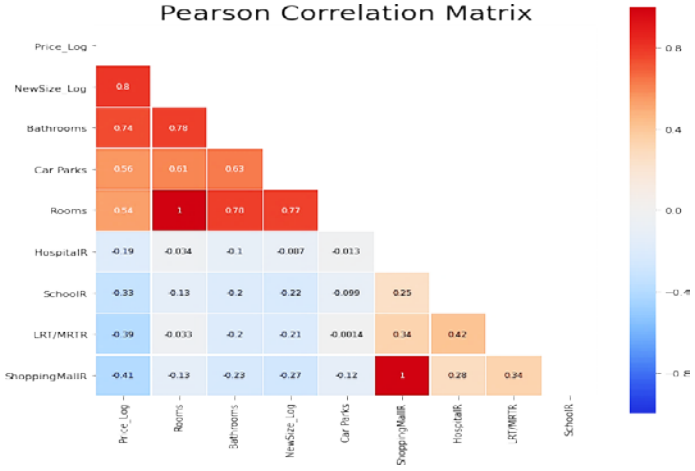

Fig. 3. Heatmap of Pearson Correlation Coefficient Matrix.

D. Data Representation using One Hot Encoding

One hot encoding is a technique used to express categorical features as numerical variables with more interpretable outcome values that will be easier to be understood by a machine learning model. For instance, the furnishing status is conveyed by a name that characterizes how furnished the space is (fully furnished, semi-furnished, and unfurnished). This technique transformed the input into 3 columns. Each column denotes a condition or status of furnishing. The column of a specific status of furnishing is 1, and those in the same row are set to 0.

IV. Data Modeling

In this study, predictive modeling was carried out using multiple regression analysis, ridge regression, LightGBM, and XGBoost. The dataset then was partitioned into two groups, training and testing sample. The training sample partition which consists of 70% of the dataset and 30% of the dataset was used in the testing sample. These four models were then compared in order to select the best model. This study utilized the hyper-parameter automated search module-GridSearchCV to search for the optimal parameter values to enhance the efficiency of each model [48]. Without losing generality, the RMSE value with optimal parameters can be generated in this module.

A. Implementation of Multiple Regression Analysis

The assumption of linear regression such as linear relationship, normal distribution of all variables, no perfect multicollinearity and little or no autocorrelation was checked before the model was used. Supposed that y represents the dependent variable, which is the prediction of house price, βk is the coefficient value of the linear function, and xk denotes each of the attributes used in this model such as the size of house and furnishing status. According to Manasa et al. [10], this model can be represented in a mathematical model as in equation (1):

$$y = \sum_{k=0}^{k} \beta_k x_k \quad (1)$$

where;

x_k, k = 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 and 11 denote eleven attributes for each house, y = the predicted price of a house in Kuala Lumpur. Several assumptions regarding linear regression were checked prior to the usage of this model. The first assumption of linear regression model is linearity. This model assumes that there is a linear relationship between the independent and dependent variables. Fig. 4 shows the graph of newsize_log against price_log. As can be seen, the graph shows a non-perfect linear relationship. However, it can still be said that the independent variables have a linear relationship towards dependent variable (price of house). The second assumption of linear regression is regarding the distribution of variables. This model assumes that all variables are normally distributed. This assumption has been checked by using the Q-Q plot as illustrated in Fig. 5.

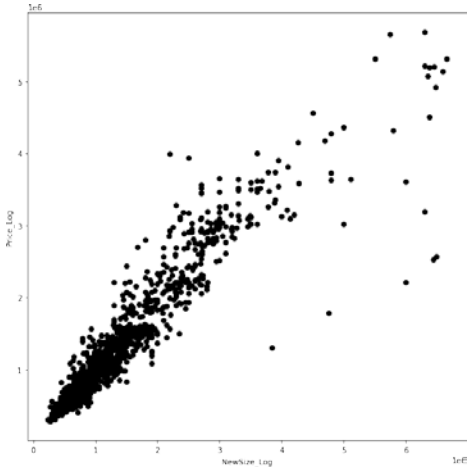

Fig. 4. Graph of Actual Price against Predicted Price.

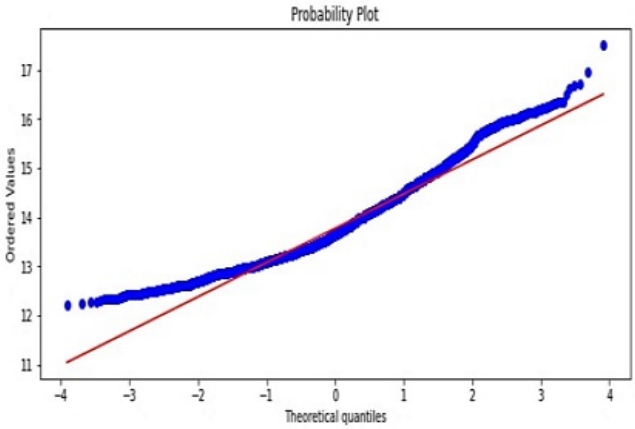

Fig. 5. The Q-Q Plot of All Variables.

Fig. 5 shows that not all the points lie perfectly on the red line which indicates that, all variables used in this study are not perfectly normal distributed. The third assumption for linear regression model is that there is no perfect multicollinearity from the variables. The multicollinearity can be examined by using the Pearson correlation score, as shown in Fig. 6.

As can be seen in Fig. 6, that there is no perfectly multicollinearity between each variable. Thus, all variables were used in this study. The last assumption for linear regression model is that there is little or no autocorrelation.

Fig. 6. The Correlation Score of Each Continuous Variable.

This last assumption was tested by using Durbin-Watson test. According to [49], there is no autocorrelation in the dataset if the Durbin-Watson test is in the range of 1.5 to 2.5. This indicates that there is no autocorrelation in this dataset. The multiple regression analysis model is being used as all the assumptions of the model have been fulfilled. The most important predictor variable analyzed by multiple regression analysis model was NewSize_Log followed by Rooms and Bathrooms which indicated the size of a house, the number of bedrooms and bathrooms. Analysis of the feature importance with Multiple Linear Regression model shows the rank of features (in sequence, highest to lowest): size of the house, number of rooms, number of bedrooms, public transport, shopping mall, carparks, school, and hospital.

B. Implementation of Ridge Regression

Equation (2) presents the equation of simple linear regression.

$$y = xb + e \quad (2)$$

where y represents the dependent variable, which is the prediction of house price, while x is the features of the matrix (number of bedrooms, location, etc.), b is the regression coefficients, and e is the residual errors. Ridge regression is a model tuning method that is used to analyse any data that suffers from multicollinearity that performs L2 regularization. On this basis, the variables were standardized by subtracting and dividing the respective factors by their standard deviations [10]. The rank of these five features is similar to the earlier model (i.e., Multiple Linear Regression). The first three features are NewSize_Log which is the size of a house followed by the number of bathrooms and the number of rooms. Next in the list are the nearest distance to public transport, the nearest distance to shopping mall, number of car parks, the nearest school to the house and the hospital.

C. Implementation of LightGBM

LightGBM is a Microsoft GBDT open-source algorithm. The histogram-based algorithm is used to accelerate the training process, reduces memory usage, and incorporates advanced network communication to optimize parallel learning known as the algorithm for the parallel voting tree. The leaf-wise method is used by LightGBM to find a leaf with the greatest gain in splitters. For the LightGBM algorithm, the Python LightGBM module was used to evaluate the house price dataset. The house price dataset, containing 12 attributes, was allocated randomly for 70% training and 30% testing.

D. Implementation of XGBoost

Extreme Gradient Boosting (XGBoost) is an enhanced gradient boosting machine using the tree ensemble boosting process. This process ends in the sum of the outputs from all the trees. The XGBoost algorithm used the XGBoost package in Python to evaluate house prices. The sample data allocation scheme used in this model is the same as the previous model which is LightGBM algorithm. Analysis of the feature importance with XGBoost model shows the rank of features (in sequence, highest to lowest): size of the house, the number of parking lots provided for a house, and the nearest distance to the public transport feature. The selection of the features is quite different compared to the previous two models (Multiple Linear Regression and Ridge Regression).

V. Model Deployment

Based on the analysis results, it was recommended to deploy the XGBoost model for the prediction of Kuala Lumpur house prices using new data. This model was being executed by removing the actual house price to generate the predicted house price. To perform this task, a new dataset consists of 1300 samples of Kuala Lumpur house price was collected and our data audit results show that there are no missing values in the sample. The predicted house price was then compared with the actual house price, and the percentage difference between these two values was calculated. Fig. 7 shows the sample of the dataset which had been executed using this model. As illustrated in Fig. 7, the percentage difference for actual and predicted log price is relatively small, which indicated that this model could provide very accurate results. The percentage difference is a bit high when the log price is being inversed to get the real price.

Fig. 8 shows a few rows that contain very high values in percentage difference between predicted and actual house prices. Based on these figures, a high value in percentage difference, which is above 60%, is coming from high-end locations, for example, KLCC and KL City. It can be concluded that a house in a high-end location is difficult to be priced as it might be below or above market value. A group of highest percentage difference value which is above 80% is usually because the price of a house is under market value and is located at KLCC which is a high-end location.

Location	Price	NewSize	SalePrice_PredXGB2	Difference	Percentage	SalePrice_PredXGB3	Difference	Percentage

Fig. 10. Sample of Dataset with High Value of Positive Percentage Difference.

Fig. 9 and 10 illustrate that the highest negative and positive difference in predicted and actual price is also coming from a high-end location in Kuala Lumpur, which is KLCC. A group of high positive difference which is colored in darker green and a group of high negative difference which is colored in darker red is also coming from similar locations which are KLCC, Bangsar, Ampang Hilir, and Bukit Tunku. These locations are considered as high-end locations in Kuala Lumpur, thus the process of pricing a house might be difficult, resulting in the pricing of below or above market value.

VI. Result and Discussion

A comparison of all four models was conducted to determine which model delivers the most accurate results. The performance metrics used were mean absolute error (MAE), root mean squared error (RMSE) value, and adjusted R squared. The model that recorded the smallest MAE, RMSE value and adjusted R squared value closest to 1 was chosen and then used in the model deployment phase. Model comparison and evaluation results are shown in Table III. The model evaluation results comparing four models which are multiple linear regression, ridge regression, LightGBM, and XGBoost show that the XGBoost model has slightly better performance with the lowest MAE and RMSE values and has adjusted R-squared closest to one which indicated a good fit model compared to multiple linear regression, ridge regression, and LightGBM model. The XGBoost model was chosen as the best predictive model.

The aim of this study is to provide an accurate machine learning model for forecasting condominium house prices in Kuala Lumpur. A machine learning model has been proposed to evaluate the relationship between a dependent variable (housing price) and a series of independent variables (attributes). Multiple linear regression, ridge regression, LightGBM, and XGBoost were used and measured against each other. To evaluate the performance of the model, statistical measures such as mean absolute error and root mean square error was also established. The coefficient of determination (R-squared) was also derived to determine how accurately the model predicted the outcome. The XGBoost model was used in the deployment phase as this model was able to accurately predict house prices in Kuala Lumpur, with the highest coefficient of determination (R-squared), which means this model is best-fitted to the dataset. Even though this model was able to predict house prices with the best coefficient of determination value, however, there were still a high percentage difference in predicted house prices and actual house prices in several rows which is less than 5% of entire dataset. Based on these findings, it can be concluded that several locations which can be categorized as high-end locations such as Mont Kiara and KLCC were difficult to be priced. The price of the house might be below or above market value.

The proposed XGBoost model is the first application of XGBoost to the study of the Kuala Lumpur housing market. The model used in this analysis was able to tackle the problems of the housing market in Kuala Lumpur as the XGBoost model has a better fitting and predictive abilities. The XGBoost model was able to generate results that were more consistent and justifiable than other models used for housing market data. The XGBoost model achieved better predictive ability, with the lowest mean absolute error (MAE) and root mean squared error (RMSE), and adjusted R-squared value closest to 1, which indicates the most accurate model. In addition, consistent model performance was found in the XGBoost model as XGBoost outperformed other models in the training and testing R-squared value. The proposed XGBoost model is, therefore, effective in predicting housing prices, which favor not only future house buyers but also investors and policymakers in the real estate industry. In other words, the proposed model will be used to estimate the selling price of the house and then equate it with the currently offered price to know the actual market conditions.

TABLE III. Model Comparison and Evaluation Result

Model	MAE	MSE	RMSE	R-Sq*	R-Sq**	AdjR*
XGBoost*	0.148	0.039	0.197	0.921	0.912	0.911
LightGBM	0.161	0.044	0.210	0.902	0.899	0.898
MLR	0.181	0.057	0.238	0.872	0.871	0.869
RR	0.195	0.064	0.252	0.855	0.855	0.853

R-Sq* for Training Data; R-Sq** for Testing Data;

VII. Conclusion

This paper demonstrated the use of the advanced ML models on house price prediction based on the Kuala Lumpur housing data. The two most recent ML models, namely LightGBM and XGBoost were implemented and compared with the traditional models, namely Multiple Linear Regression and Ridge Regression. The results showed that the XGBoost model was the most promising with 0.0387 for the MSE and was used in the deployment phase. This model accurately predicts house prices in Kuala Lumpur, with the highest coefficient of determination (R-squared). Future works can include more attributes such as the size of the house and proximity to amenities, which can significantly affect the accuracy of the predicted outputs. In addition, future research might consider other locations in their study as this study is only focused on locations in the Kuala Lumpur region. Future research might expand the area of this research, whether to conduct and include the whole nation in Malaysia. This study can significantly assist in predicting of future house prices and the establishment of real estate policies.

***Abstract*—Tourism is among the significant source of income to Malaysia and Taman Negara Pahang is one of the Malaysia's tourism spots and the heritage of Malaysia in achieving the Sustainable Development Goals (SDG). It has attracted many international and local tourists for its richness in flora and fauna. Currently, the information of tourists' visits is not properly analyzed. This study integrates the internal and public information to analyze the visits. The regression models used are multiple linear regression, support vector regression, and decision tree regression to predict the tourism demand for Taman Negara, Malaysia and the best model was deployed. Predictive analytics can support the decision-making process for tourism destinations management. When the management gets a head-up of the demand in the future, they can choose a strategic planning and be more aware about the factors influencing tourism demand, such as the tourists' web search engine behaviors for accommodation, facilities, and attractions. The factors affecting the tourism demand are determined as the first objective. The role of independent variable was set to the total number of visitors, subsequently being set as the target variable in the modeling process. A total of 30 models were generated by tuning the cross-validation parameters. This study concluded that the best model is the multiple linear regression due to lower root mean square error (RSME) value.**

Keywords*—Regression models; SDG; Taman Negara Pahang; tourist analytics

I. Introduction

Attractions of tourism destinations produce economic values as it impacts the number of tourist arrivals in Malaysia. As a result, tourism has become one of the highest revenue industries after automobiles and oil (REF). Today, one of the largest service sectors is the tourism industry where the industry became one of the highest in terms of revenue after automobiles and oil. This significant growth is a result of the efforts undertaken by the Ministry of Tourism where the planning and execution policy underlined by the government spearhead the success of the tourism industry. It is the long-term aim of the government to make Malaysia as one of the most popular tourism destinations. The success of the tourism industry is defined by the demand and supply which can be measured by tourists arrivals and receipts [1].

One of the famous tourism destinations is Taman Negara Malaysia, also known as Taman Negara National Park. This natural park protects a diverse flora and fauna, renowned for its nature trails, and adventure activities hence making it a valuable tourism source [2]. Encompassing an area of 4,343 km2, Taman Negara National Park straddles three states of Malaysia; Taman Negara Pahang, Taman Negara Kelantan, and Taman Negara Terengganu; in which Taman Negara Pahang takes up around 57% of the total national park area [3]. There are two different main entrances for Taman Negara Pahang namely, Kuala Tahan and Sungai Relau. There are many activities to do in Taman Negara such as jungle trekking, hiking, and fishing. Panoramic scene and captivating places such as waterfall cascades and canopy walkway attract many people to visit the Taman Negara National Park. Therefore, the service industry needs to be concerned about visitors' management of the tourism destination. In 2013, a research study was made about Ecotourism in Taman Negara National Park: the issues and challenges [4]. One of the issues that they found is the lack of visitor management especially on overcrowding problem and excess visitors during certain period of time. Moreover, based on the news [5], it was pointed out early on those statistics shows of slightly higher number of visitors to Taman Negara in January to February. The lack of proper service management on popular places at the park lead to overcrowding problem, mainly due to the inability to optimize staff's workload/working hours. In addition, overcrowding of tourists lead to the loss of authenticity and implies a significant risk to the destination's future attractiveness, especially towards vulnerable destinations such as the Taman Negara National Park.

The attractiveness of Taman Negara Malaysia as a tourism destination has been studied by Universiti Putra Malaysia [6]. The study evaluated that there are total of thirteen attractions in Taman Negara, namely oral history, local culture and lifestyle, flora, fauna, building architecture, nature trails, shopping opportunity, canopy walkway, caves, stream, fishing, mountain, and adventure activities [6]. The attractions of tourism destinations produce economic values as it also gives an impact to the number of tourist arrivals in Malaysia. These attractions have been characterized as demand structures. Thus, demand studies are needed for decision making support of tourism destination management.

Therefore, tourism demand forecasting is vital and will benefit the nation's tourism industry greatly. The study of regression techniques helps to forecast future and seasonal demands for tourism growth, management, and planning purposes. Regression analysis is a collection of statistical methods for estimating relationships between a dependent variable and one or more independent variables which can be used to determine the strength of a relationship between

*Corresponding Author.

variables and to predict how they will interact in the future [7]. This study was made to determine the factors affecting the tourism demand, to make a comparison study of regression techniques, and develop an analytical dashboard based on the best regression model that helps in forecasting tourism demands components, incorporating the applicable criteria in the following sub-sections.

A. Factors Affecting Tourism Visit

In demand studies, factors affecting tourism demand was determined as the independent variables that might affect the target variable, where the target variable is the total number of visitors. The comparison study was made to find the best model in predicting the target variable. Tourism industry has been a huge contribution factor to the economy, even though there exist many factors affecting tourism demand in Malaysia. Several studies have shown that the economic variables play an important role as the key economic factors. Based on [8] and [9], the key economic factors are exchange rate, income, consumer price index (CPI), and population of the country. The studies found a strong relationship between these key economic factors and the volume of tourists. However, the study also showed that there is a negative correlation between the exchange rate and the number of tourists, the higher the exchange rate, the lower the volume of tourists' arrivals. The exchange rate is related to the depreciation of Ringgit Malaysia (RM) that affects the cost of living in Malaysia.

As many researchers used economic factors as the contribution to the demands, some researchers [10-12] observed the tourist's web search behavior by using Google Trends data. Specific keywords were identified for web scraping related to tourism activities, such as "skiing", "skiing in sweden" or "sweden skiing" or "ski sweden" [10]. Meanwhile, [12] made use of these keywords: "destination", "destination + guide", "destination + travel guides", "destination + tickets", "destination + weather", depending on the tourism destination, strategy, ticket price, scenic spots, weather, and accommodation, among many other factors. At the end, 50 initial keywords related to the decision-making process were selected [11]. Due to the time gaps between web search activity and tourist arrivals, this new approach is truly relevant. Web-based data sources, such as search engine traffic, often have a natural relationship with tourism demand. Because of strong interest in certain tourism destinations, potential tourists for instance, browse websites extensively before visiting these destinations.

In other study, climate change is an additional factor to know the relationship with tourism demand. Research by [13] was conducted regarding the dimension of climate change in Malaysia based on tourists' perception. Generally, Malaysia has an equatorial climate. Extreme weather and seasonality are commonly related with climate change in Malaysia. Temperature, rainfall, and, to a smaller extent, wind are all examples of extreme weather factors. Seasonality, on the other hand, is always linked to the dry and wet (monsoon) seasons. The main variables for this factor are the average temperature and the average precipitation. The weather in Malaysia is hot and humid all year with Malaysia's average daily temperature ranges from 21°C to 32°C. Precipitation is the measure of the falling water from the sky which is the rainfall. The findings of the study revealed that tourists had sufficient knowledge of climate change, which influence their travel decisions [13].

B. Prediction in Tourist Domain

Many past research studies have been conducted in order to predict the tourism demand. A comparative study made by [14] to forecast the tourism demand in Turkey using data mining techniques based on regression modelling. The techniques used include multiple linear regression (MLR), multilayer perceptron (MLP) regression, and support vector regression (SVR). The author in [14] used monthly data points for their study, unlike previous studies which usually uses yearly or quarterly data. The author in [14] decided to choose these regression models because of the nonlinear mapping capabilities. In addition, the conventional methods like these models are more efficient to use for data that are likely to pattern the trends, seasonality, and cyclicality. SVR originated from a machine learning model hence a support-vector machine (SVM) can work for regression tasks and is suggested in order to forecast tourism demand. Unlike most conventional neural network model, SVR applies the theory of structural risk minimization which based on the idea of empirical risk minimization, to minimize the upper limit of the generalization error, instead of minimizing the error in training [15-17].

A research on tourists visit in the province of West Sumatra was done using MLR and Artificial Neural Network (ANN) [25] with inflation rates and Rupiah exchange rates. The results show an impressive accuracy within 96 to 99 percent. Other researchers from Indonesia made use of seven independent variables including the characteristics of foreign tourists (sex, age, occupation/profession, length of stay, nationality, purpose of visit, and accommodation) to identify the effect on total expenditure [26]. They also found that American and European tourists contributed to the largest average of the total expenditure for vacation purpose. Regression tree was used by [27] to segment the tourist length of stay in Barbados, with socio-demographic profile of the tourist, trip-related characteristics, distance, and economic conditions in the source country. Another study on tourism to model the revenue from international tourism using the foreign trade balance of the country shows the positive correlation in Azerbaijan example [28]. The result also showed that tourism will increase the country's foreign trade turnover. More advanced methods were explored in tourism domain in China [29] with social evaluation index as the attributes and hybrid methods of back propagation and fuzzy as the model.

Another angle on predicting tourism trend is by looking at the flow of tourists' movement in a specified area, as studied by [30-31]. Usage of user-generated content assisted in narrowing down specific criteria to forecast tourism demand apart from projecting possible point-of-interest for tourists [30]. By creating trajectory graphs on past data, the study by [30] yield a better result than traditional machine-learning based algorithms for forecasting the next tourist movement, which is useful for predicting tourism demand in certain areas. While the study by [31] focuses more on statistical-based techniques, they applied statistical method with BPNN model (SMBPNN) on variously collected data such as historical tourism flow, weather, and temperature. Their hybrid model which combines statistical technique with neural network

suggested an improvement of forecast as compared to stand-alone neural network models [31].

The methodology used by other researcher suggested using various techniques and at the same time, incorporating a multi-dimensional dataset. Hence for this study, an integrated dataset were created from various sources that will be described later in this paper. The suitability of the techniques with the available real-world dataset was also considered; hence this study will be focusing on application of regression techniques.

In the rest of the paper, we first provide some necessary background of proposed modelling methods in Section II, and the data source and evaluation are discussed in Section III. The experimental results are demonstrated and discussed in Section IV. Finally, the conclusion and future works are explained in Section V.

II. Modelling Methods for Regression

Regression analysis is used for predicting real values, for instance, to forecast the daily sales of the business which makes the number of sales as the target or dependent variable. To determine the relationship between the variables of interest, the data collected will be trained using a regression model. In order to determine the optimal model, Goodness-of-fit measurements, such as the square of the correlation coefficient (r^2 or squared correlation), was used to examine the scatter of data points around the fitted value. The number denoted the percentage of variance in one variable that can be explained by the other. The higher the r^2 score, the more precise the prediction. However, the number does not tell how precise the forecasts were in the dependent variable's units.

A. Multiple Linear Regression

Multiple Linear Regression (MLR) aims to model the linear relationship between the independent (explanatory) variables and dependent (response) variables, whereas simple linear regression only has a single input to estimate the value of the coefficients used in data representation. MLR model helps to predict an outcome based on multiple explanatory variables provided with details [18]. The representation of multiple linear regression will be like the following:

$$Y = a_0 + a_1x_1 + \ldots + a_nx_n \quad (1)$$

In which Y refers to the dependent variables, x_1, …, x_n represent independent variables, a_1, …, a_n as regression coefficients, and a_0 is y-intercept (a constant term).

By measuring slope and regression coefficients, it can be represented in the form of mathematical equations in multiple linear regression. Using the regression coefficient formula, the intensity and direction of the relationship between the two variables can be calculated [19]. Hence when comparing with simple linear regression, MLR perform better with less error rate. Moreover, multiple regression can be implemented in linear and non-linear modelling. Multiple regression is based on the statement that there is a linear relationship between both dependent and independent variables, where no assumption was made for major correlation between the independent variables [18-20].

B. Support Vector Regression

Support-vector regression (SVR) comes from a machine learning model namely the support-vector machine (SVM). SVM can work for regression tasks and is suggested in order to forecast tourism demand. SVM is a class of linear algorithms that can be used for classification, regression, density estimation, novelty detection, and other applications. SVM uses classification techniques to build a predictive model where its algorithm's main purpose is to find a hyperplane in an N-dimensional space that distinctly classify the data points. Separating two classes of data points may lead to many possible hyperplanes. The hyperplane equation is reflected in (2) and in Fig. 1:

$$\vec{w} \cdot \vec{x} + b = 0 \quad (2)$$

where w is a weight vector, x is input vector and b is bias. SVM searches for the hyperplane with the largest margin in separating the circle objects and square objects with minimum classification error.

An optimal network structure can be achieved by SVR on the basis of the theory of structural risk minimization which the margin of the hyperplane will be maximized [15, 21]. The main differences between Least Square Support Vector Machine (LSSVM) and SVM is that LSSVM includes the equality of constraints instead of the inequalities, and it is based on the least squares cost function [22]. SVR has been successfully implemented to solve forecasting problems in many fields, such as financial time series (stock index and exchange rate) forecasting, engineering and software (production values and reliability) forecasting, atmospheric science forecasting, electric load forecasting and commodity demand forecasting [16].

The SVR model has been successfully applied to forecast tourist arrivals too. Empirical research has shown that the choice of the parameters in an SVR model significantly influences the accuracy of forecasting. SVR solves the problems of estimation, classification, and nonlinearity via its loss function [17]. Tourism data often exhibit nonlinear characteristics, with SVR widely used in the tourism demand forecast. Low speed, however, is the key drawback of SVR in the training process [23], due to various hyperparameters setting in the model. Some inappropriate SVR parameters allow for the occurrences of overfitting or underfitting problem.

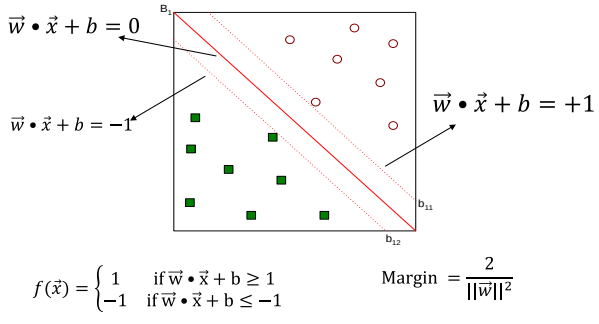

Fig. 1. The Hyperplanes for Two Classes of Objects [21].

C. Decision Tree Regression

Decision tree algorithm that has been used for classification or regression predictive modelling problems is called Classification and Regression Trees (CART). Decision Tree is one of the classifiers in supervised learning algorithm with a tree-like structure. It consists of root, interior, and leaf nodes in which the outcomes are represented at leaf node. CART is relatively straight-forward for prediction making. The algorithm works through multiple iterations until the tree is able to predict a proper value for the data point. Among the benefits of using CART algorithm is that it is easy to understand, less data cleaning process, non-linearity does not affect the output of the model, and the number of hyper-parameters to be tuned is almost null [21, 24]. The drawback is that it may have an overfitting problem, but which can be solved using the Random Forest algorithm.

The split attribute in the tree is chosen based on the standard deviation for the independent variable and dependent variable (outcome), and the formula for the standard deviation based on an attribute *x* as shown in equation (3):

$$S(x) = \sqrt{\frac{\sum(x_i - \overline{x})^2}{n}} \quad (3)$$

where, S is standard deviation, x_i is the value of the attribute, $\overline{x}$ is the mean value of x and n is the record of x.

The standard deviation reduction is based on the decrease in standard deviation after a dataset is split on an attribute. Construction of a decision tree is basically finding an attribute that have the highest standard deviation reduction (SDR), where according to the calculation in equation (3) as the most homogeneous branch. In other words, the standard deviation of the target will be compared to different standard deviation of each independent variables in the dataset.

III. Data Source And Model Evaluation

A. Data Preparation

The data collection is obtained from different sources which are opened to both public and private use. This research study used monthly data points with observation period from year 2012 until 2018. The first dataset collected was from Google Trends, which is a search trends feature that displays the frequency with which a certain search term is entered into Google's search engine in relation to the site's total search volume over time. There are six keywords or search term used for this study: 1) "Taman Negara", 2) "taman negara accommodation", 3) "taman negara resort", 4) "taman negara canopy walkway", 5) "Cuti Cuti Malaysia", and 6) "visit Malaysia".

The second dataset was retrieved from the Federal Reserve Bank of St. Louis (FRED) where the dataset recorded monthly currency exchange rate with units of Malaysian Ringgit to One U.S. Dollar. The third dataset was extracted from Visual Crossing website that provides historical weather public data. To generate the worldwide weather observation database, the website processes millions of hourly weather observations from thousands of observation stations. However, the dataset extracted from the website is in weekly frequency. Hence, the need to calculate the monthly frequency of average attributes were done using the formula of average in Microsoft Excel. The attributes extracted from the source are Location, Date and Time, Maximum Temperature (degC), Minimum Temperature (degC), Temperature (degC), Heat Index (degC), Chance Precipitation (%), Precipitation (mm), Wind Speed (kph), Wind Direction, Wind Gust (kph), Visibility (km), Cloud Cover, Relative Humidity, and Conditions. However, for this research process, only two attributes were selected: 1) Temperature (degC); 2) Precipitation (mm).

The last and most important dataset is the total visitors' arrival to Taman Negara Pahang, Malaysia. This public dataset was found in a Malaysia Open Data Portal at data.gov.my. However, the data is in a yearly term basis and only covers data from the year 2012 until 2018. Thus, an additional data obtained from Jabatan Perlindungan Hidupan Liar dan Taman Negara (PERHILITAN) Pahang was used to identify the monthly number of visitors to Taman Negara Pahang. Since the data collected for this research were huge and obtained from different sources hence making it unstructured, data transformation process needed to be done. Data preprocessing is the process of changing the variety of raw dataset into one dataset suitable to be used in software such as RapidMiner. For this study, the regression modelling was done with the help of data analytics software tool, RapidMiner. Fig. 2 shows the conceptual framework for the regression modelling that illustrated the source of data, independent variables, and dependent variables. The variables for the observation period (year 2012-2018) were Date, Currency Exchange, Visit Malaysia, Cuti Cuti Malaysia, Taman Negara, Taman Negara accommodation, Taman Negara Resort, Taman Negara canopy walkway, Average Temperature, Average Precipitation and Total of visitors.

B. Model Evaluation

For this study, a comparison was made between three predictive models, namely Multiple Linear Regression (MLR), Support-Vector Regression (SVR), and Decision Tree Regression (DTR), as shown in Fig. 3. Among the important tasks conducted were data preparation from four data sources: data preprocessing, training and testing data split, modeling with three algorithms, and finally evaluation and deployment. The model development in this research study used RapidMiner's default values. The comparison was measured based on the models' performances by manipulating the sampling type and number of folds in cross validation.

The RMSE (Root Mean Squared Error) is the square root of the variance of the residuals. It indicates the absolute fit of the model to the data–how close the observed data points are to the model's predicted values. While squared_correlation is a relative measure of fit, RMSE is an absolute measure of fit. Thus, the lower the values of RMSE, the better it is. The formula for Root Mean Square Error (RSME) is as in (4),

$$\sqrt{\sum_{i=b}^{n}(X_{actual} - X_{model})^2} \quad (4)$$

where, x_{actual} is an observed value and x_{model} is the predicted value.

Fig. 2. Conceptual Framework of Tourist Visit Regression Model.

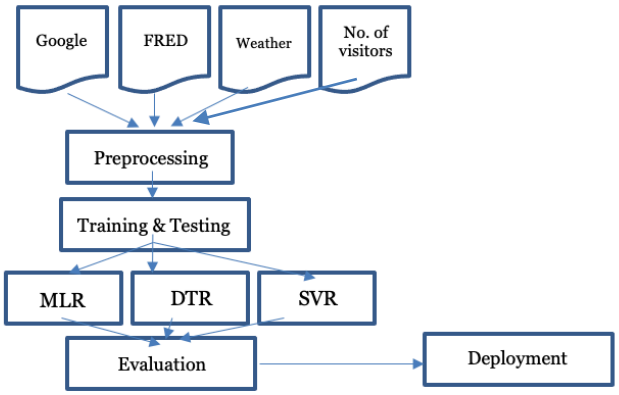

Fig. 3. The Overview of Processes Involved in the Study.

Another useful measure to determine the optimal model is goodness-of-fit measurements, such as the square of the correlation coefficient (r^2 or squared_correlation). This measure is used to examine the scattered-locations of data points around the fitted value. The number denotes the percentage of variance in one variable that can be explained by the other. The higher the r^2 score, the more precise the prediction. It does not, however, tell how precise the forecasts are in the dependent variable's units.

IV. Result and Discussion

This section presents the results and provides a discussion based on the outlined framework given in Fig. 2 and Fig. 3.

A. Data Description

The final dataset was constructed based on the following data sources:

- The Google Trends dataset, in Fig. 4 recorded 504 data which were generated from monthly frequency of year 2012 until year 2018 for six related keywords, as mentioned in section 3 (12 months/year × 7 years × 6 keywords = 504 data).

- Third dataset, extracted from Visual Crossing website which provides historical weather public data. To generate the worldwide weather observation database, the website processes millions of hourly weather observations from thousands of observation stations. However, the dataset extracted from the website is in weekly frequency.

- Fourth dataset consists of the number of visitors in Taman Negara National Park, including nearby places and Gunung Tahan from Malaysia Open Data Portal by yearly and PERHILITAN Pahang, by monthly, starting from January till December, as in Table I. The highest number of visitors found was in March.

Based on the gathered information, the final dataset consists of 11 variables or attributes with 84 rows of monthly data points for the observation period (year 2012-2018). The variables/columns are observation date (month), Currency exchange, the six keywords: Visit Malaysia, Cuti Cuti Malaysia, Taman Negara, Taman Negara accommodation, Taman Negara Resort and Taman Negara canopy walkway, Average Temperature, Average Precipitation and Total Visitors. The Fig. 6 shows the snippets of 10 rows from 2012 as the sample of the real dataset used in the study.

Fig. 6. Sample of Merged Dataset.

Meanwhile Fig. 7 to 10 show statistical measures of selected attribute. In Fig. 6, the currency exchange is represented in real value, while for the six keywords (Visit Malaysia, Cuti Cuti Malaysia, Taman Negara, Taman Negara accommodation, Taman Negara Resort and Taman Negara canopy walkway) are represented as the count of the words mentioned every month. The count of word "Taman Negara accommodation" being mentioned were found to be more as compared to other words. The total number of word count in the dataset is as shown in Fig. 10, with "Visit Malaysia" being the highest count and "Taman Negara canopy walkway" as the lowest count.

Name	Type	Missing	Statistics			Filter (11 / 11 attributes):
Currency exhange	Real	0	Min 3.019	Max 4.457	Average 3.697	
visit malaysia: (Worldwide)	Integer	0	Min 25	Max 85	Average 44.202	
Cuti Cuti Malaysia (Worldwide)	Integer	0	Min 16	Max 57	Average 30.048	
Taman Negara: (Malaysia)	Integer	0	Min 29	Max 67	Average 44.083	
taman negara accommodation: ...	Integer	0	Min 0	Max 100	Average 11.464	
taman negara resort: (Malaysia)	Integer	0	Min 5	Max 75	Average 24.024	
taman negara canopy walkway: ...	Integer	0	Min 0	Max 75	Average 6.786	

Fig. 7. Statistical Measures for Currency Exchange Rate and Count of the Keywords Searched in Google.

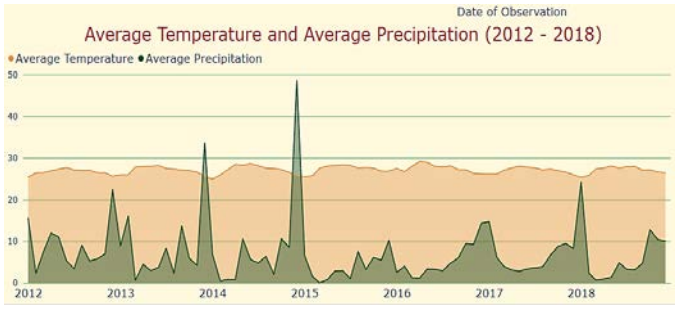

Fig. 8. The Graph for Average Temperature and Average Precipitation from 2012 Till 2018.

In Fig. 8, the average temperature and average precipitation are presented from 2012 till 2018, with gathered information from Visual Crossing. The average temperature is between 25 and 30 degrees Celsius. Here, the precipitation shows the highest value in 2015 and the lowest are shown to be present in every year, due to the dry season that occurs in the respective years.

Fig. 9 illustrates the graph of total visitors in every month to the Taman Negara from 2012 till 2018. The total number of visitors continuously changed over time.

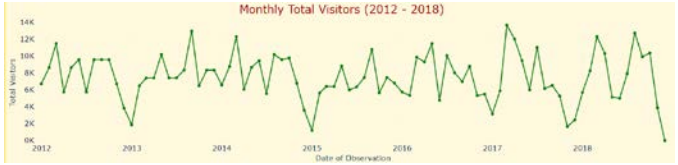

Fig. 9. The Graph for Monthly Total Visitors from 2012 Till 2018.

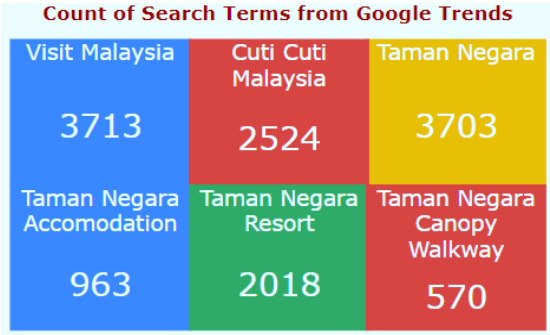

Fig. 10. Count of Words related to Taman Negara.

A total of 30 experiments were performed by tuning five different numbers of folds with two types of sampling in three predictive models (5×2×3 = 30). The comparison table shows the overall performance recorded during the experiment for the modelling.

B. Multiple Linear Regression Results

The best model, multiple linear regression, resulted with the RMSE values of 2545.977 and the values of r^2 is 0.276 which is the highest value with linear sampling among four models, as shown in Table II. Thus, linear regression equation for the best model is as the following:

*Predicted (Total Visitors) = - 631.866 * Currency exchange*
*+ 7.229 * visit malaysia: (Worldwide)*
*- 9.240 * Cuti Cuti Malaysia (Worldwide)*
*+ 113.991 * Taman Negara: (Malaysia)*
*- 7.465 * taman negara accommodation: (Malaysia)*
*- 2.319 * taman negara resort: (Malaysia)*
*+ 5.474 * taman negara canopy walkway: (Malaysia)*
*+ 1062.211 * Average Temperature*
*- 20.455 * Average Precipitation*

TABLE II. LINEAR REGRESSION MODELLING

Sampling method	**RMSE**	r^2
Linear Sampling (k = 10)	2624.972	0.301
Linear Sampling (k = 8)	2545.977	0.276
Shuffled Sampling (k = 10)	2570.164	0.227
Shuffled Sampling (k = 4)	2591.315	0.162

C. Decision Tree Regression Results and Rules

Modeling of decision tree resulted in a set of rules represented in a tree-like structure. Each node corresponds to a splitting rule for a single attribute. Fig. 11 shows the extracted tree and the conditions of each predicted total of tourist visit. Table III shows the result of RMSE and r^2 for the decision tree regression, in which the RMSE is higher as compared to multiple linear regression. As can be seen, average temperature and the count of the keywords appeared to be among the important variables.

```
Average Temperature > 26.984
|   Currency exhange > 4.371: 12859.000 (count=2)
|   Currency exhange ≤ 4.371
|   |   Taman Negara: (Malaysia) > 49.500
|   |   |   taman negara accommodation: (Malaysia) > 38: 6295.000 (count=2)
|   |   |   taman negara accommodation: (Malaysia) ≤ 38
|   |   |   |   visit malaysia: (Worldwide) > 40
|   |   |   |   |   Average Temperature > 27.417
|   |   |   |   |   |   Currency exhange > 4.070: 11782.500 (count=2)
|   |   |   |   |   |   Currency exhange ≤ 4.070
|   |   |   |   |   |   |   Currency exhange > 3.408: 8386.500 (count=2)
|   |   |   |   |   |   |   Currency exhange ≤ 3.408: 9907.000 (count=2)
|   |   |   |   |   Average Temperature ≤ 27.417
|   |   |   |   |   |   taman negara canopy walkway: (Malaysia) > 16: 12665.500 (count=2)
|   |   |   |   |   |   taman negara canopy walkway: (Malaysia) ≤ 16: 11138.000 (count=2)
|   |   |   |   visit malaysia: (Worldwide) ≤ 40
|   |   |   |   |   visit malaysia: (Worldwide) > 35: 6377.000 (count=2)
|   |   |   |   |   visit malaysia: (Worldwide) ≤ 35: 9122.000 (count=2)
|   |   Taman Negara: (Malaysia) ≤ 49.500
|   |   |   visit malaysia: (Worldwide) > 49.500
|   |   |   |   taman negara resort: (Malaysia) > 32.500: 9070.500 (count=2)
|   |   |   |   taman negara resort: (Malaysia) ≤ 32.500
|   |   |   |   |   Taman Negara: (Malaysia) > 44.500: 6309.500 (count=2)

```

Fig. 11. Rules Extracted from the Decision Tree Regression.

TABLE III. DECISION TREE REGRESSION MODELLING RESULTS

Sampling Method	**RMSE**	r^2
Linear Sampling (k = 4)	3278.578	0.07
Linear Sampling (k = 9)	3474.772	0.104
Shuffled Sampling (k = 4)	3424.049	0.096
Shuffled Sampling (k = 9)	3570.849	0.058

Based on the lowest RSME, the best SVR is when linear sampling done with k = 4, at 3278.578, though the r^2 is the lowest among the other experiments.

D. Support Vector Regression Results

The Support Vector Regression produces an average result between Multiple Linear Regression and Decision Tree Regression. Table IV displays the best result for linear sampling and shuffled sampling. Based on the lowest RSME, the best SVR is at linear sampling with k = 9, at 2727.532 and the r^2 is the second best among the experiments conducted.

TABLE IV. SUPPORT VECTOR REGRESSION MODELLING RESULTS

Sampling Method	**RMSE**	r^2
Linear Sampling (k = 9)	2727.532	0.286
Linear Sampling (k = 10)	2749.607	0.306
Shuffled Sampling (k = 9)	2741.599	0.234
Shuffled Sampling (k = 10)	2741.599	0.234

E. Best Model Deployment

Selection of best model is measured by the lowest RMSE value and the highest value of the squared correlation between the predicted and the actual values. The experiment proved that the decision tree model displayed a weak performance for this research study as it produced a greater error as compared to other model at any parameters tuning. Between MLR and SVR, the error produced in MLR is almost the lowest, but the squared correlation value is lesser than the SVR model. Additionally, the cross-validation with number of folds, k = 8 for the linear sampling type indicated the best model is MLR which outperforms SVR and Decision Tree. The assumption is made that the number of folds is depending on the number of instances in the dataset and the sampling type is based on the problem model, which in this study the input is the linear problem to find the relationship between these variables.

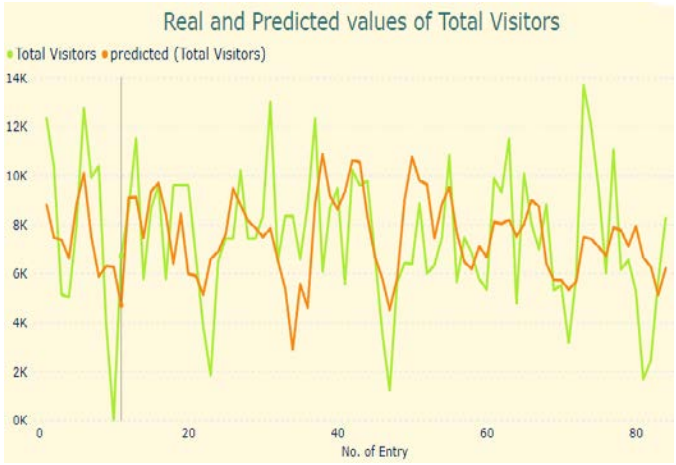

Fig. 12. The Graph of Real (Actual) Value and Predicted Value of Total Visitors.

Fig. 13. The Graph of Prediction until 2030.

Fig. 12 represents the real (actual) value of visitors and the predicted value of visitors by using multiple linear regression. The advantage of using multiple linear regressions is that when given values in decimal point, the results can be easily interpreted by the decision maker. The graph also visualizes clearly the gap between actual and predicted value of the visitors. Subsequently, Fig. 13 shows the predicted total number of visitors until 2030 with some simulated values for each variable in the best MLR model. In future, this research can be extended by providing the estimated values for each relevant variable, and the predicted total number of visitors can then be stipulated to the tourist management.

V. Conclusion

This paper presented the implementation of regression models, namely Multiple Linear Regression (MLR), Support Vector Regression (SVR) and Decision Tree Regression (DTR). A set of variables were constructed based on the selected keywords, the currency exchange and the weather variables for predicting the number of total visitors. The experiments conducted had indicated that these regression algorithms were able to predict the total number of visitors to Taman Negara National Park. The results for the experiments after tuning of parameters demonstrated an improved accuracy of the models since it can control the complexity, which indirectly prevented from overfitting of the model. In this study, the linear problem (input) discovered was to find the relationship between the factors affecting the demand for the total number of visitors to Taman Negara National Park.

Multiple Linear Regression model with linear sampling type and 8-fold cross validation approach appeared to be the best model. The experiments showed that the best parameters setting was based on the instances of the dataset itself. Consequently, some suggestions for future works to improve the quality of the research study were identified. Firstly, the use of advanced visualization tools to work with real-time data to the dashboard can be applied. Next, more data ought to be collected to produce a better performance of predictive models, such as different keywords and any other related campaigns. Lastly, the use of hybrid machine learning and optimization algorithms can be considered to optimize the parameter tuning for better accuracy. The developed model is useful to the tourism management, for predicting the number of visitors to Taman Negara National Park, Malaysia. The tourism management as the user can improve their operations by making a strategic decision making based on the predicted outcomes. If the tourism destination can operate more smoothly, the visitors can reap the benefits from the meaningful experience they received when visiting the national park. Other study can also be performed such as the length of stay and recommended activities based on the tourists' profiles.

***Abstract*—The researches show that software quality depends on Functional Requirements (FR) and Non-Functional Requirements (NFR). The developers identify NFR attributes by interviewing stakeholders. The difficulty in identifying NFR attributes makes quality requirements often ignored. The basic concept of software quality measurements is the quality measuring of the software product. During product-based quality measurement, the potential of software development process repetition will occur. Factors measuring software product quality are not suitable for NFR identification. These differences result in the software development process repeating itself and additional costs. This research proposes easy NFR attributes identification using FR characters. The NFR and FR tightly relations are obtained by extending the NFR measurement at ISO/IEC25023 to programming coding level, then generalizing to get the FR character. The generalization uses the Grounded Theory method. The result is the NFR attributes identification method using FR character based on ISO/IEC 25023. The analyst or programmer can identify the NFR attributes from the FR using the FR character in the requirements stage. This research produces an NFR Identification Method that has been validated by experimenting with several programmers and experts. Tests on programmers identify NFR using the FR character method. The test is to see the level of similarity of the resulting NFR. The result of the test shows level similarity upper 75%.**

***Keywords*—Non functional requirements; FR character; ISO/IEC 25023; NFR identification**

I. Introduction

Software development success requires quality measurement results of the software product. The Software quality measurements base ISO/IEC 25023 is a complete software product quality measurements [1]. The quality classification of the software in ISO/IEC 9126 [2] updated ISO/IEC 25023 [1] is the NFR attributes classification. NFR attributes identification awareness determines the quality of software products. NFR Identification affects the resulting software product [3], [4]. Failure of NFR attributes identification may be repeatable in the software development process [5], [6]. The results of the NFR attributes identification determine the success of the software product [7], [8]. This paper shows that awareness for the NFR attributes identification is essential. The problem of improper NFR identification causes dissatisfaction with product quality, resulting in repetition of the software development process and increasing costs.

The broad meaning of quality towards software products has prompted several studies to classify NFR. Several researchers have solved the problem of NFR identification using the NFR Classification [5] [9]. Problems arise again in determining an unambiguous NFR classification [10]. Developers based on the Agile method need NFR identification quickly and precisely. The problem software developments are NFR attributes identification suitable with software quality measurements. This research uses ISO/IEC 25023 as a basis so that the process of quality identification and measurement has the same reference. How to NFR attributes identification use ISO/IEC 25023?.

This research aims to develop ISO/IEC 25023 for NFR attributes identification. This Research in ISO/IEC 25023 extended the measurement function to the programming coding level. The generalization programming code to get FR character use grounded theory. The research is NFR attributes and FR character tightly relations. The result of this research is the NFR attributes identification method using FR character. This research on the NFR identification process uses FR characters based on ISO/IEC 25023. NFR attributes identification testing uses the FR character on several programmers. The result of the test is to determine the level of similarity of the NFR attributes obtained above 75%. This research method is open coding stage, axial data stage, selective coding stage, forming theory stage, and memoing. Writing systematic of this paper is abstract, introduction, related works, research method (the generalization use grounded theory), discuss, conclusion, acknowledgments, and reference. The grounded theory method consists of stages open coding, axial coding, selective coding, and forming theory. Forming of theory determines NFR attributes identification formulation method and NFR attributes method testing.

detection uses NFR attributes categorization and classification based on semantic patterns [6]. Singh use ISO/IEC 9126 standard for NFR attributes categorization dan classification [12]. Li uses the quality specification of domain and subdomain for NFR attributes classification [13]. Chung classifies NFR attributes from several studies literature such as RADC (Rome Air Development Center), Sommerville, Mac Calls, Matsumoto, Grady, and others. Some studies classify NFR based on software products [5]. Kaur develops integration of the NFR attributes and formal reference model for the NFR classification [14]. NFR attributes classification uses quantitative NFR with questioners for minimizing ambiguity [15].

Chung presents a goal-object pattern framework. That framework uses a model-driven by way of UML metamodel extension. The framework is capturing and reusing FR and NFR knowledge of the small-scale application [16]. Singh identifies NFR attributes using NFR attributes classification with different thematic roles based on ISO 9126 quality factors [12]. Kassab makes metamodel by tracing NFR attributes and FR relation based on strong interdependencies [17]. Farid identifies NFR attributes, its using risk-driven algorithms to the prioritization scheme [18]. Liu develops automatization to detect conflict of the NFR attributes evaluation. NFR classification approach uses ontology realizing with metamodel based on cause-effect and inferences knowledge [19].

The determination of the NFR classification so as not to be confused needs to be standardized. ISO/IEC issued standards for the quality classification and measurement of product quality in ISO/IEC9126 [2]. ISO/IEC9126 updated by ISO/IEC 25023 [1]. The NFR classification according to ISO / IEC 25023 is functionality suitability, performance efficiency, compatibility, usability, reliability, security, maintenance, and portability [1].

Several researchers made improvements to the method stages of the Agile Method to be able to identify NFR. Lawrence Chung uses approaches of modeling and techniques to explain software requirements.[20]. Farid, Agile processes use a risk priority approach with the Non-functional Requirements Planning (NORPLAN) method [18]. Domah uses the NERV methodology to obtain NFR artifacts on the User Story Card, the NAI (NERV Agility Index) score, and so on [21].

III. Research Method

This research generalization process of NFR attributes classification uses the Delon-style Grounded Theory method (Fig. 1) [22]. The first stage is open coding. The open coding stage is collecting and identifying data. The data is from the results of the SLR [23], updating papers, and ISO/IEC 25023 files. The results in this stage are NFR attributes measurement identification and classification (Table I) based on ISO / IEC 25023 standards. The Second stage is axial data. This stage is marking or tagging the measurement functions with programming codes. The result axial coding stage is the classification of NFR attribute measurements and the extension of the measurement function to code programming characteristics (Table II). The third stage is selective coding. The stage is the selecting and comparing of data programming code characteristics, it is the generalization process. The process of generalization results NFR attributes and FR characters relationship (Table III). The fourth is forming theory. This stage is the formation theory to NFR attributes and FR characters relation. The forming theory stage is formulation to NFR identification method (Fig. 2) and testing result (Fig. 3). The Fifth stage is memoing. The memoing stage record of this research to a paper journal.

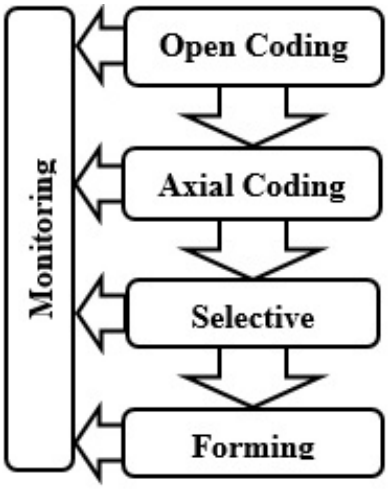

Fig. 1. Delon-style Grounded Theory [22].

IV. Results

A. Open Coding

Referring to SLA takes the condition of the established attributes NFR. That refers standard of software quality. This research uses ISO/IEC 25023 as an international standard product quality software. The measuring factors for software product quality in ISO/IEC 25023 are NFR attributes [24].

ISO/IEC 25023 is a software product quality standard. The elements of quality measures determine measurement functions. Software quality measurement in this way can determine the quantification, characteristics, and sub-characteristics of quality. System and software product quality programs explain that quality measures follow quality characteristics in evaluating internally or externally.

The result of quality measurement identification has eight NFR attributes. The eight NFR attributes in ISO/IEC 25023 are functional suitability, performance efficiency, compatibility, usability, reliability, security, maintainability, portability. Each attribute is classified and specified into several measurement functions. The ISO/IEC 25023 file on page 10 is an example of measuring performance on Time behavior with specifications for measuring mean response time, response time adequacy, mean turnaround time, and turnaround time. The measurement function has measures the quality of the software product and characteristics of quality. The result of quality measurement identification is the example in Table I.

TABLE I. NFR ATTRIBUTE MEASUREMENT FUNCTION BASED ON ISO/IEC25023 (EXAMPLE: FUNCTIONAL SUITABILITY AND PART OF PERFORMANCE EFFICIENCY)

Specifications	Sub-specifications	Measurement Function	
		Measurements	**Measurement Characteristics**
NFR1. Functional Suitability			
NFR1.1. F. Completeness	NFR1.1.1. F. Completeness	What proportion of the specified functions has been implemented?	1) All FR has boolean value (yes/no=1/0) 2) The Unit of Number FR 3) Number of FR codes that have been made 4) Number of FR encodings that work 5) The number of FR accordance with the function of the actor 6) The number of FR has conformity to the system (average for point (5))
NFR1.2. F. Correctness	NFR1.2.1. F. Correctness	What proportion of functions provides the correct results?	
NFR1.3. F. Appropriateness (FA)	NFR1.3.1. FA of usage objective	What proportion of the functions required by the user provides appropriate outcomes to achieve a specific usage objective?	
	NFR1.3.2. FA of system	What proportion of the functions required by the user to achieve their objectives provides appropriate outcomes?	
NFR2. Performance Efficiency			
NFR2.1. Time Behaviour	NFR2.1.1. Mean response time	How long is the mean time taken by the system to respond to a user task or system task?	1) Unit of time is ms (millisecond) 2) Response time is the time of the page to page 3) Average of response time
	NFR2.1.2. Response Time Adequate	How well does the system response time meet the specified target?	
	NFR2.1.3. Mean turnaround time	What is the meantime taken for the completion of a job or an asynchronous process?	1)Unit of Time is ms (millisecond) 2) Turnaround time is the time of process to one task or process to asynchronous until the finish 3) Average of turnaround time
	NFR2.1.4. Turnaround Time	How well does the turnaround time meet the specified targets?	
	NFR2.1.5. Mean Throughput Time	What is the mean number of jobs completed per unit time?	1) This unit is the number of data transfers per time (number of data every ms) 2) Throughput time is the time needed to start transferring some data to completion to the destination 3) Average throughput time
NFR2.2. Resource Utilization	NFR2.2.1. Mean processor utilization	How much processor time is used to execute a given set of tasks compared to the operation time?	1) The unit of time, ms (millisecond) 2) Processor time is time used to execute a given set of tasks 3) Operation time to perform the tasks 4) Time required for 1 task to perform arithmetic OR logic functions 5) Mean processor time
	NFR2.2.2. Mean memory utilization	How much memory is used to execute a given set of tasks compared to the available memory?	1) Unit size of memory (byte) 2) Size of memory used to perform series of task 3) Average for point (2) 4) Size of memory available
	NFR2.2.3. Mean I/O device utilization	How much of the I/O device's busy time is used to perform a given set of tasks compared to the I/O operation time?	1) Unit of time (ms) 2) The time of I/O device used to perform a series of task 3) Time of I/O operation
	NFR2.2.4. Bandwidth utilization	What proportion of the available bandwidth is utilized to perform a given set of tasks?	1) Unit of bandwidth (bps/bits per second) 2) Size of data (byte) carried to perform a series of tasks per time (second)
NFR2.3. Capacity	NFR2.3.1. Transaction processing capacity	How many transactions can be processed per unit time?	1) Unit number of transaction processes for per time (second) 2) Average of point (1) 3) Transactions related to record in the database (Create, Read, Update, Delete)
	NFR2.3.2. User access capacity	How many users can access the system simultaneously at a certain time?	1) Maximum number of users at the same time 2) Unit number of user
	NFR2.3.3. User access increase adequacy	How many users can be added successfully per unit time?	1) Unit number of users per time 2) Acceleration of user growth

TABLE II. EXTENDING FROM MEASUREMENT FUNCTION TO PROGRAMMING CODE (EXAMPLE: PERFORMANCE EFFICIENCY OF THE TIME BEHAVIOR SPECIFICATION)

ID_NFR	Measurement Function		
	Measurements	**Measurement Characteristics**	**Programming Code**
NFR2. Performance Efficiency			
NFR2.1.1.	How long the meantime took by the system to respond to a user task or system task is?	1) Unit of time is ms (millisecond) 2) Response time is the time of the page to page 3) Average of response time	Link, submit, download, upload, back, next
NFR2.1.2.	How well does the system response time meet the specified target?		
NFR2.1.3.	What is the meantime taken for the completion of a job or an asynchronous process?	1)Unit of Time is ms (millisecond) 2) Turnaround time is a time of process to one task or process to asynchronous until the finish 3) Average of turnaround time	Proses CRUD in the database (Create, Read, Update, Delete)
NFR2.1.4.	How well does the turnaround time meet the specified targets?		
NFR2.1.5.	What is the mean number of jobs completed per unit time?	1) This unit is the number of data transfers per time (number of data every ms) 2) Throughput time is the time needed to start transferring some data to completion to the destination 3) Average throughput time	Sum of data per unit time for the transfer process to or from the database (CRUD)
NFR2.2.1.	How much processor time is used to execute a given set of tasks compared to the operation time?	1) The unit of time, ms (millisecond) 2) Processor time is time used to execute a given set of tasks 3) Operation time to perform the tasks 4) Time required for 1 task to perform arithmetic OR logic functions 5) Mean processor time	1) Process of logic and arithmetic functions 2) Process of mathematics operation (+, -, /, *) 3) Process of logic (<, >, = =, <=, >=) 4) Process of condition functions (IF, FOR, While, Switch - Case, Do – While)
NFR2.2.2.	How much memory is used to execute a given set of tasks compared to the available memory?	1) Unit size of memory (byte) 2) Size of memory used to perform series of task 3) Average for point (2) 4) Size of memory available	Functions of variable OR declaration
NFR2.2.3.	How much of the I/O device's busy time is used to perform a given set of tasks compared to the I/O operation time?	1) Unit of time (ms) 2) The time of I/O device used to perform a series of task 3) Time of I/O operation	Time used to I/O operation (example, process to print, download(curl_setopt), upload(fungsi; input type="file") and scan functional view to report, tranfering data network)
NFR2.2.4.	What proportion of the available bandwidth is utilized to perform a given set of tasks?	1) Unit of bandwidth (bps/bits per second) 2) Size of data (byte) carried to perform a series of tasks per time (second)	Transmission (variable array)
NFR2.3.1.	How many transactions can be processed per unit time?	1) Unit number of transaction processes for per time (second) 2) Average of point (1) 3) Transactions related to record in the database (Create, Read, Update, Delete)	The Number of CRUD function process in the database
NFR2.3.2.	How many users can access the system simultaneously at a certain time?	1) Maximum number of users at the same time 2) Unit number of user	The active user name function
NFR2.3.3.	How many users can be added successfully per unit time?	1) Unit number of users per time 2) Acceleration of user growth	

B. Axial Coding

This stage performs the preparation of NFR measurements and decreases from measurement function to programming coding. The composition of the software quality measurement is the arrangement of the NFR attributes in Table I. This research extends from measurement functions to programming code. This measurement results in a more precise measurement. That NFR measurement determines FR and NFR relations. The fragment of an ISO / IEC 25023 file of Time Behavior Measures in the Measurement Function column contains the measurement algorithm for that quality. For example, the measurement algorithm for response time adequacy on the performance efficiency attribute says Ai = the time it takes the system to respond. The time needed by the system to respond has the meaning of time when the user clicks on a function until the function appears. Simplifies, it is the span of the time from one page to the next page. The time has a unit of time in ms (millisecond). The time-span from one page to another on the measurement translates in the code programming, namely link, submit, download, upload, back, next in the code programming column with the id number NFR2.1.1 in Table II. The result of this stage extends from the measurement function to the programming code, as shown in Table II.

TABLE III. FUNCTION CHARACTER OF NFR ATTRIBUTE BASED ON ISO/IEC 25023

No	NFR Attributes	Function Characters
1	**Functional Suitability**	The function runs according to the actor
2	**Performance Efficiency**	CRUD (Create, Read, Update, Delete)/ database Process
3	**Compatibility**	Files Transfer
4	**Usability**	Make it easier for users and reduce human error
5	**Reliability Measures**	Failure/error detection in the system
6	**Security**	Security at the time of transfer, data, access rights, and control
7	**Maintainability**	Module-related functions (reusability, log, analysis, modification, testability)
8	**Portability**	Configuring apps; Functions to adapt to other environments/applications/software (installations, products)

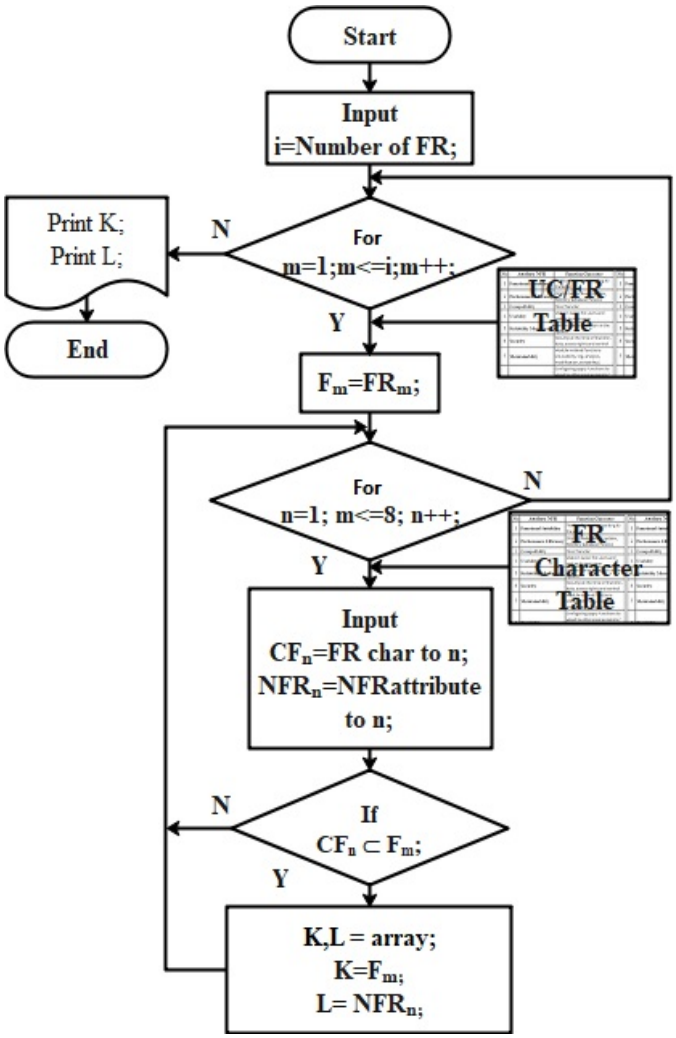

Fig. 2. Pseudo Code NFR Identification use FR Character Method.

C. Selecting Coding

The research takes as an example the NFR attributes of performance efficiency (Table II) with the behavior of time, resource utilization, and capacity specifications. The table contains the ID_NFR, measurements, measurement characteristics, and programming code columns.

Comparison of 2 is the process of CRUD with the process of arithmetic and logic in line 4 on ID_NFR 2.1.4. The CRUD process follows some arithmetic and logical process more than others. The arithmetic and logic processes for measuring processor speed followed by the CRUD process significantly affect processes that are not followed by the CRUD process because there is a process for bringing extensive data from the database. The arithmetic and logic processes that need to be measured are those that the CRUD process follows.

Comparison of 3 is the process of CRUD with rows 5,6,7 and 9, on ID_NFR 2.2.1, ID_NFR 2.2.2, ID_NFR 2.2.3, ID_NFR 2.2.5. These rows have a profound effect on the process the CRUD process follows. That it can ignore another process because the process represents that the CRUD process follows. Performance efficiency measurement for FR concludes that all FRs have a function for the CRUD process. The data comparison results show in Table III, namely that FR's characters have NFR attributes.

D. Forming Theory

The generalization results in Table III show that each FR character has an NFR attribute. NFR is highly dependent on the FR. The determination of the NFR attribute is from the character content in the FR. NFR has a relationship with FR. Research shows that NFR has tightly coupled with FR. FR has more than one character means it has more than one NFR attribute. Each NFR attribute can be on multiple FRs. The relationship between FR and NFR has cardinality, many to many, meaning that FR has more than one NFR, and conversely, NFR has more than one FR. Identification of quality can be known early based on the FR obtained.

The FR character is the result of the generalization from the measurement function, as shown in Table III. NFR attributes can be detected quickly and accurately against FR by an analyst at the requirements stage. Early identification of NFR attributes can monitor the quality of functions during the development process.

1) NFR attributes identification method formulation: The requirements stage is the identification process of FR and NFR. The determination of the NFR attribute at that stage is after the FR determination. Determination of NFR attributes using the FR character (Table III) against the FR. Each FR will derive NFR attributes based on the characters it contains. Further research formulates a method for the identification of NFR attributes using the FR character. The FR from Use Case Specification (UC Spec) or the FR table is the input. Each FR determines the content of FR characters in Table III to obtain NFR attributes. The result is that FR is related to NFR attributes. Fig. 2 is the NFR identification method algorithm using the FR character.

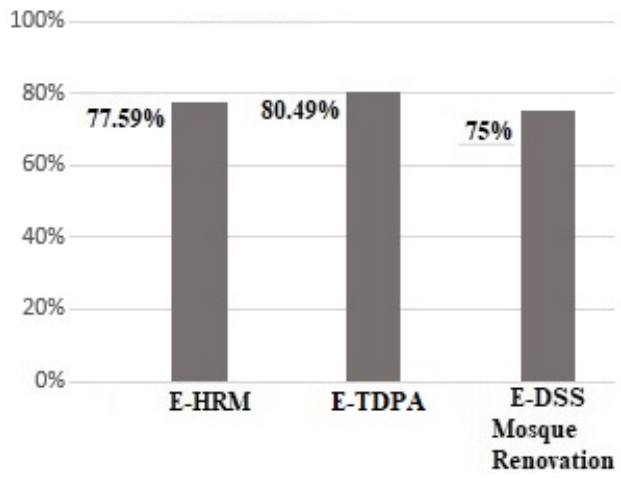

Fig. 3. The Result of the Similarity Level of NFR Attributes Identification.

2) NFR attributes identification method testing: Testing the NFR attribute identification method to determine the level of similarity of the programmers to determine the NFR attributes to their FR. The testing used the samples of 3 web applications based on PHP and MySQL, namely e-HRM, electronic Tax Dispute Power of Attorney (e_TDPA), Electronic DSS Renovation of Indonesian Mosques (e-DSS Mosques Renovation). The study identified FR in all three applications according to its SRS. The research identified the FR of the SRS documents in each application, then arranged them in the FR table. The programmer uses the FR character table guide to fill in the NFR attributes contained in each FR. The research uses the samples of 5 programmers. The test results show the similarity level of NFR attributes above 75% (Fig. 3). These results indicate that the programmers have a high common perception of NFR attributes.

V. Discussion

Pratama determined software quality using ISO/IEC 25010. He assessed software quality of 8 attributes using Black-Box testing, stress testing, and questioner of the 100 respondents. And then leveling of the 8 attributes used AHP [25]. This research for software quality using ISO/IEC 25023 standard of software quality product. That standard measure to suitable between software product quality with requirements. ISO/IEC 25010 is the family of 250n standards. ISO/IEC 25010 is measurements to software quality model and ISO/IEC 25023 is measurements to software product quality. Yusop classified NFR attributes based on qualitative research results [11]. Sharma classified NFR attributes only performance, availability, and security is not using an international standard, Li used quality specifications into domain and subdomain [13], and Singh used ISO/IEC 9126 [6], [26]. Kaur classified NFR attributes with NFR attributes and formal reference relations. The Formal References are domain knowledge, customer requirements, specification, programming platform, and machine [14]. This research NFR attributes categorization and classification use ISO/IEC 25023 that is updating from ISO/IEC 9126. Then, the research develops NFR attributes categorization and classification to get NFR attributes and FR characters integration.

Chung identified the requirements to use the objective-object pattern of FR and NFR relations. The knowledge patterns have format from the experience of several applications samples [16]. Farid used a risk-driven algorithm for NFR attributes identification [18]. Liu detected NFR attribute conflict using ontology realization. This research NFR attributes identification used the FR characters approach. Kassab used an understanding of NFR attributes and FR relationships for the detection of NFR attributes [17]. This research uses NFR attributes and FR relation with FR characters approach. Research identifies NFR attributes based on the character from FR. Each FR has characters. FR character comes from NFR attributes categorization and classification based on ISO/IEC 25023 extend. NFR attribute identification and software quality measurements have the same based on ISO/IEC 25023. The result of software quality measurements suite requirements.

VI. Conclusion

ISO/IEC 25023 is a standard for measuring software product quality. This research succeeded in constructing the FR character from ISO/IEC25023 for the NFR Identification Method. The FR character to identify the NFR attribute of each FR that has the characters. FR character and measurement of quality software products have the same basis, namely ISO/IEC 25023. Identification of NFR attributes using FR character will produce NFR attributes following the desired quality software product.

FR character is a bridge that connects FR with NFR quality or attributes. NFR and FR are relations that both have tightly coupled. Stakeholders are very helpful in determining NFR attributes without having to interpret the type of software quality. Programmers can control the quality of built-in functions while coding these functions. Product software quality is in line with the same NFR attributes based on ISO/IEC 25023. Quality control of software before it becomes a product avoids repeating the software development process and adding costs. Identifying the right NFR attributes determines a quality software product. The future research monitors software quality using FR characters in the Scrum software development method.

Blockchain-oriented Inter-organizational Collaboration between Healthcare Providers to Handle the COVID-19 Process

Ilyass El Kassmi, Zahi Jarir
Computer Science Engineering Laboratory
Faculty of Sciences, Cadi Ayyad University
Marrakech, Morocco

***Abstract*—Collaborative business activities have aroused great interest from organizations because of the benefits they offer. However, sharing data, services, and resources and exposing them to external use can prevent organizations involved in collaboration from being engaged. Therefore, the need for advanced mechanisms to ensure trust between the different parties involved is paramount. In this context, blockchain and smart contracts are promising solutions for performing choreography processes. However, the seamless integration of these technologies as non-functional requirements in the design and implementation phases of inter-organizational collaborative activities is a challenging task, as reported in the literature. Consequently, we aim in the proposed approach to extend the modeling and implementation of the choreography lifecycle based on service-oriented processes. This is fulfilled by integrating blockchain transactions and smart contract calls, to allow collaboration and interoperability between different entities while guaranteeing trust and auditability. Moreover, to conduct this extension efficiently we use a BPMN choreography diagram combined with Finite State Automata to ensure a meticulous modeling which targets the processes' internal interactions. Hyperledger Fabric is used as a permissioned blockchain for proof-of-concept implementation. A use case of COVID-19 collaborative processes is used to experiment our approach, which aims to guarantee a fluid collaboration between healthcare providers and epidemiological entities at a national scale in Morocco.**

Keywords*—*Blockchain; inter-organizational collaboration; choreography; permissioned blockchain; business process management; COVID-19

I. Introduction

Collaborative business activities have aroused great interest from organizations because of the benefits they offer. This success is due to the technological advances that the interconnected digital world has known. However, sharing data, services, and resources, and exposing them for external use can prevent organizations involved in the collaboration from being engaged. Therefore, the need for advanced mechanisms to ensure trust between the different parties involved is paramount. In this context, blockchain and smart contracts are promising solutions for performing choreography processes. They aim to create effective and secure infrastructures to ease coordination between interacting organizations, ensuring greater achievement of common goals, and avoiding data redundancy caused by the multitude of exchanged messages in conventional schemes.

However, the seamless integration of these technologies as non-functional requirements (NFRs) [1] in the design and implementation phases of inter-organizational collaborative activities is a challenging task, as reported in the literature. This is the case for the inter-organizational healthcare domain, as an example, which is characterized by its complexity both in terms of the management of sensitive data and the heterogeneity of the activities involved in the collaboration process. Blockchain can be introduced to overcome the problem of lack of secure links connecting healthcare organizations including and not limited to public healthcare centers, private clinical centers, ministry regulation entities, specialized centers (dental, laboratory, imagery) and insurance organisms. Moreover, the privacy property characterizing the blockchain provides protection either for exchanged data through security policies or for healthcare professionals' identities as participants in the network.

Blockchain technology has gained attention over the last few years. It has extended its foundation to cover, in addition to the commonly known implementations of digital currencies, the integration of decentralized applications (DApps) [2] in a broad range of industries. This technology aims to overcome the reliance on a centralized authority to certify information's integrity and ownership, and provides a platform for decentralized business logic ensuring transparency and immutability of exchanged data between the distributed interacting parties. Advances in this technology have encouraged organizations to gain confidence in sharing information with other entities without requiring an intermediate trust third party [3]. In order to support the control and exchange of digital assets in the distributed ledger, for common blockchain infrastructures, smart contracts [4] are introduced for this purpose. These contracts are defined as executable programs that allow manipulation of data and functions within the blockchain. They aim to facilitate, verify, or negotiate a contract agreement under a set of conditions to which users agree. When these conditions are met, the agreement terms are automatically carried out.

In collaborative business processes [5][6], the integration of smart contracts aims to create an effective and secure infrastructure dedicated to facilitate collaboration between

interacting organizations and achieve common goals. Furthermore, the tamper-proof property and the exhaustivity provided by the logging characteristic of the blockchain allow the interacting organizations to track who, what, and when transactions are performed and shared to the ledger, according to the agreed security policies. This property guarantees auditability and thus, develops trust between participants without the need for an intermediate trust authority.

In previous contributions, we proposed approaches to tackle the modeling of both functional requirements (FRs) and NFRs [7] and their integration as part of composite services in order to produce an optimal composition, while guaranteeing a prior validation of user properties using model checking verification. Currently, we aim to enhance this approach by providing the ability to handle collaborative processes, ensuring that each process can be executed independently unlike one-time execution in the context of orchestrated service composition. The second important contribution of the proposed approach is the integration of blockchain transactions and smart contract execution as a potential implementation to support the collaboration of business processes based on a service-oriented architecture (SOA). The proposed solution is supported by a proof-of-concept applied to the healthcare domain to meet the emerging collaboration requirements raised by the coronavirus disease 2019 (COVID-19) pandemic.

Our current contribution aims to propose an approach that has the advantages of extending the modeling and implementation phases of the choreography lifecycle by integrating blockchain transactions and smart contract executions, to allow collaboration and interoperability between different entities while guaranteeing trust and auditability. As a case study, this approach was applied to COVID-19 collaborative processes integrating healthcare providers and epidemiological entities at a national scale in Morocco. The proposed solution has the following advantages:

- Proposing a modeling process based on two phases: first using the Business Process Modeling Notation (BPMN) choreography diagram to design the interactions between collaborative business processes, then using Finite State Automata (FSA) to design the internal interactions of the corresponding service compositions.
- Integrating the blockchain technology to tackle common challenges of collaborative business processes such as trust and auditing.
- Providing a support for transactions and smart contract executions, adapted to the context of collaborative business process as service compositions.
- Taking advantage of the security properties and policies granted by the integrated blockchain solution in order to enhance inter-organizational collaboration.
- Proposing a proof-of-concept based on a real-world problematic of inter-organizational collaboration among healthcare entities during the COVID-19 pandemic.

As stated, the proposed approach is based on SOA, consequently, it supports a service-based integration that can be adapted to different blockchain platforms. In this contribution, we implemented a proof-of-concept based on the Hyperledger Fabric architecture [8]. This technology improves the security measures by integrating identity management, access control over assets and resources, and offering the ability to create and use special sub-networks restricted to users with granted permissions. Although we highlight some security improvements offered by the selected technology, our research scope does not focus on vulnerabilities and blockchain-related security threats. The focus is preliminarily oriented to the aspects of modeling and integrating the blockchain as a NFR, to tackle the challenges of inter-organizational business process collaboration.

The remainder of this paper is organized as follows. Section 2 presents a brief overview of the blockchain technology concepts. In Section 3 we expose some interesting contributions tackling business process collaboration challenges using blockchain and SOA. In Section 4, we present a novel approach for handling the integration of permissioned blockchain technology to manage decentralized business processes. Section 5 presents a COVID-19 related case study to demonstrate the behavior of this approach. Finally, in Section 6, we summarize the suggested approach and highlight future works and upcoming perspectives.

II. A Brief Blockchain Overview

Blockchain is a decentralized ledger that records the provenance of digital assets, using a set of protocols and cryptography technologies to securely store data on the network [9]. It can be defined as a sequence of blocks that store all exchanged transactions in a peer-to-peer network [10]. Each block contains, in addition to the stored data, the hash of the previous block and the timestamp of its production. Thus, all the peers store a complete and exact copy of the database, ensuring immutability, decentralization, anonymity and auditability, which promotes trust between participants without the need for a central authority. These cited characteristics, among other remarkable features, have opened the opportunity for diverse research fields around the blockchain, and provided the foundations for a number of application domains, beyond cryptocurrency, such as non-fungible tokens (NFTs) [11], Internet-of-Things (IoT) implementations [12-14], decentralized finance platforms (DeFi) [15], blockchain gaming, and DApps [2].

According to the literature and recent advances in blockchain-oriented technologies, different architectures have been proposed that vary according to the implementation purpose. The most popular architecture is the public blockchain, also known as permissionless blockchain [16], it is a publicly accessible network that does not require special roles for connecting or sending transactions. Thus, any person can access the ledger and interact with it (i.e., read and write data). A public blockchain ensures full transparency of the ledger while maintaining user anonymity. Additionally, no particular participant has total control over the data, as block validation is achieved through consensus mechanisms implying all mining nodes. In contrast, private blockchains are restrictive blockchain architectures that operate in closed networks [17]. They are mostly adopted in enterprises, organizations, and applications that require handling sensitive data, with the aim of using this

technology for internal usage. Moreover, private blockchain is often considered a more centralized architecture than public blockchain because the maintainability of the network is commonly ensured by a single authority. Hyperledger Fabric [18], Sawtooth [19], and Corda [20] are examples of private blockchains. Finally, the permissioned blockchain constitutes a mixed architecture that combines both public and private blockchains. They support numerous customization options, such as identity management, allowing only certain activities to be performed on the network.

Each blockchain platform uses a specific consensus mechanism to achieve the necessary agreement for storing data on a distributed ledger. A consensus mechanism is a procedure through which all the peers of the blockchain network reach a common agreement about the present state of the distributed ledger [21]. A large variety of consensus protocols have been described in the survey [22], such as Proof-of-Work (PoW) [23], Proof-of-Stake (PoS) [24], Proof-of-Authority (PoA) [25], and practical Byzantine fault tolerance (PBFT) [26]. PoW is the most popular consensus mechanism allowing miners to compete to solve the puzzle in order to validate a block and append it to the ledger. Bitcoin [27] and Ethereum [28] are the most popular implementations of public blockchains that use PoW consensus.

Provided that the robustness of the consensus protocols is guaranteed, smart contracts are deployed on the distributed ledger to manipulate data and functions using an analogy similar to classes/objects in object-oriented programming (OOP). Smart contracts can then be composed of attributes and methods, allowing better code structuration and business-oriented modeling of assets and their relationships. This allows the design and development of DApps in a fine-grained manner [4]. They can be used to automate the execution of an agreement so that all participants can be certain of the outcome, without involving any third party. They are also used to automate a workflow or trigger an action when specific conditions are met.

To support business process management (BPM) using blockchain technology, Mendling et al. proposed an interesting survey describing the main challenges and opportunities for this emerging technology [29]. They concluded by presenting seven future research directions based on the conducted research. Among these research directions, two are linked to our proposed approach: (1) the investigation of methods for analyzing and engineering business processes based on blockchain technology, and (2) the definition of appropriate methods for blockchain evolution and adaptation. Another interesting systematic literature review was presented by Garcia-Garcia et al., which aimed to identify opportunities and gaps in the area of collaborative business processes using blockchain technology [30]. They provided different comparative tables to illustrate the contribution scope of each research study. Among the 34 research papers studied, most of the contributions are oriented to public blockchain architecture using Ethereum, while only 15% use Hyperledger blockchain solutions. On the other hand, only 37% integrated process modeling and 45% used or extended BPMN, against 3% using languages based on state machines. The authors concluded that there is a rapid and growing interest in scientific communities and software industries to explore opportunities provided by blockchain technology to improve the management of collaborative business processes in a decentralized manner. Similarly, Xu et al. conducted a comparative analysis of consensus mechanisms [31], and presented an approach incorporating smart contracts and PBFT consensus to address challenges regarding time, prejudice, and trust of process executions in the context of collaborative business processes and IoT. They concluded by highlighting the advantages of the voting mechanism designed to decrease the delay caused by prominence consensuses such as PoW.

III. Related Work

We previously stated that our current approach consists of modeling collaborative processes, building appropriate service-oriented systems, and integrating the blockchain as a service to guarantee decentralization for desired interactions through transactions or smart contract executions. Therefore, in this section, we present some interesting approaches and implementations that address the modeling and integration of blockchain technology for collaborative business processes.

Modeling blockchain-oriented collaborative processes constitutes an open challenge because of the variety of blockchain platforms offering multiple possibilities and usages according to the desired blockchain architectures and consensus mechanisms. Most of the proposed approaches tackling the process choreography using blockchain technology are implementing permissionless blockchains, particularly Ethereum, which represents the first Bitcoin's alternative for public blockchains. Weber et. al proposed one of the first approaches to address the lack-of-trust problem in collaborative business processes based on the blockchain [X]. They aim to map the business processes, designed using BPMN choreography modeling, onto a peer-to-peer execution infrastructure that stores transactions in the blockchain. Smart contracts can then be used as a direct implementation of the mediator process control logic. Authors presented the built modules such as the translator allowing to parse and convert BPMN choreography diagrams files to Solidity scripts, and the Triggers that connect the participants' internal processes with the blockchain. The authors highlighted some of the limitation of their approach based on the presented permissionless platform, which consists on the lack of privacy once the organizations public keys are known, which constitutes opportunities for competitors to inspect and track the data on the ledger. Another approach presented by Garcia-Bañuelos et al. consists on presenting another aspect surrounding the use of blockchain in business process executions, which is the optimization [Y]. They introduced a two-phase modeling based on BPMN processes translated into Petri Net models, then reduced to be converted into Solidity smart contracts. The purpose consists on optimizing costs by reducing gas consumption for overall collaborative business processes. On the other hand, a model-driven methodology for choreography-based systems adapted to the Ethereum blockchain was proposed by Corradini et al. [34]. They implemented all process phases from modeling to execution using a framework that takes BPMN choreography models as input and provides the appropriate Solidity smart contracts [35] adapted to Ethereum. To provide more specifications and capabilities associated with blockchain technologies while dealing with choreography

processes, the authors in [36] assessed the capabilities and limitations of current choreography modeling approaches, and then proposed new language concepts adapted to BPMN choreography processes with their appropriate operational semantics. Di Ciccio et al. proposed another interesting study [37] that presented a comparison between two model-driven approaches, 'Lorikeet' [38] and 'Caterpillar' [39], to deal with the design and implementation of blockchain-based collaborative process execution. Both approaches are focused on BPMN-style process models and implement the Ethereum blockchain.

On the other hand, Pourheidari et al. proposed a study investigating the applicability of the execution of a real-world untrusted business process on a permissioned blockchain [40]. They highlighted the advantages of using the permissioned blockchain for collaborative business processes, and then proposed an order processing model based on the BPMN standard, considering the particularities of Hyperledger Fabric as a blockchain platform and Hyperledger Composer as a framework. This study focused on implementing blockchain to support an existing business process, taking advantage of the modeling capabilities offered by Hyperledger Fabric in addition to the use of identity management to handle permissions. According to the cited contribution, each process is executed independently and cannot be automated. In contrast, our proposed approach is based on a service-oriented architecture that automates the execution of interacting services through a service composition, by integrating blockchain transactions as services. Authors Autili et al. presented an approach to address the problem of trust in service choreography [41]. They proposed blockchain technologies to support decentralized and peer-to-peer collaboration in a trustworthy manner. A model using a BPMN2 choreography diagram is presented to illustrate the peer-to-peer communication between interacting parties. The proposed solution allows trust-based coordination between participants and the verification of the correctness of exchanged messages by providing the ability to validate transactions and manage permissions. The interactions with the blockchain are however weakly expressed during the modeling phase. In comparison, we use in our approach a second phase of modeling based on automata to define, in a fine-grained manner, each interaction with the blockchain to fulfill decentralization requirements.

The following contributions highlight approaches of tackling the interactions with blockchain technology based on SOAs. An interesting contribution [42] proposed a taxonomy based on an analysis of the Blockchain-as-a-Service (BaaS) market, according to service characteristics, the support of different distributed ledger technology (DLT) protocols and consensus mechanisms, and related pricing models for service provisioning. This study highlights the predominance of large IT service providers in the BaaS market, offering a variety of services to match the requirements of corporate customers, who prefer permissioned distributed ledger solutions, and prioritize quality characteristics such as performance, ease of use, and availability. In the same context, Daming et al. proposed a systematic review of recent research studies covering BaaS models [43]. They aimed to categorize the applied scenarios, trends, evaluated quality of service (QoS) factors, new challenges, and open directions on BaaS models in IoT management. According to the conducted study, the BaaS models are mainly applied to the network layer to manage the IoT environment more than other layers. In addition, security and privacy are two important factors for evaluating existing BaaS models in cloud-edge IoT environments. In accordance with these results, Zheng et al. proposed a platform for BaaS called NutBaaS [44]. This platform is based on a four-layer model and provides blockchain services over cloud computing environments, such as network deployment and system monitoring, smart contract analysis, and testing. It also provides some key built-in features, such as identity-chain profile management and smart contracts' security-related vulnerability detection. The proposed solution is technically complementary and based on Hyperledger Fabric. Comparably, our proposed approach uses specific services to interact with the ledger through simple transactions or smart contract execution. However, prior to this integration, we provide a fine-grained modeling process to describe the overall interactions of these blockchain-oriented services, to meet the existing service composition scheme and accomplish the associated business process. Another contribution presents a unified blockchain as a service platform (uBaaS) [45] to support both the design and deployment of blockchain-based applications. This solution combines a deployment as a service, aiming to avoid lock-in to specific cloud platforms, with a design pattern-as-a-service that aims to apply design patterns for data management and smart contract design to address the common scalability and security issues.

Finally, Table I presents a summary of the common aspects of the cited contributions. The covered compared characteristics are as follows: (1) the modeling used, (2) the type of blockchain architecture, (3) the platform used, (4) the implemented consensus mechanism, (5) the adaptation ability to more complex use cases, (6) the approach evolution to cover other blockchain architectures and platforms, and (7) the security attributes and additional behavioral NFRs covered when applicable.

TABLE I. A COMPARATIVE TABLE DESCRIBING CHARACTERISTICS OF CITED CONTRIBUTIONS

	[32]	[33]	[34]	[40]	[41]	[43]	[45]	Our proposed approach
Modeling	BPMN2 Choreography Diagram	BPMN Process Petri Net	BPMN2 Choreography Diagram	BPMN	BPMN2 Choreography Diagram	N/A	BPMN	- BPMN2 Choreography Diagram - Finite State Automata
Architecture	Public Permissionless	Public Permissionless	Public Permissionless	Permissioned	Permissioned	Permissioned	Public Permissionless	Permissioned
Platform	Ethereum	Ethereum	Ethereum	Hyperledger	Hyperledger	Hyperledger	Ethereum	Hyperledger
Consensus	Proof-of-Work	Proof-of-Work	Proof-of-Work	N/A	N/A	Kafka	Proof-of-Work	RAFT
Adaptation	Yes	Yes	Yes	N/A	Yes	Yes	Yes	Yes
Evolution	Yes	No	N/A	N/A	N/A	Yes	N/A	Yes
Security & Behavioral NFRs	N/A	N/A	- Role Management	- Privacy - Access Control	- Transaction Validation - Permission Management	- Profile Management - Smart Contract vulnerability detection	- Permission Management	- Identity & Role Management - Permission Management - Privacy - Custom Security NFRs

We notice in the comparative table that most of the presented works used either BPMN process diagram or BPMN2 choreography diagram to model the case study workflow. However, the designed modeling lacks expressiveness regarding the interaction between the current system and the blockchain. In contrast, we introduce automata-based modeling to describe in a fine-grained manner each interaction between the existing services fulfilling the business requirements and the desired blockchain transactions. Additionally, most of the presented contributions are oriented into a unique blockchain platform, which constitutes a strength when considering the advanced features characterizing the platform, but also a limitation when dealing with the implementation of heterogeneous blockchain architectures that might be implied in the collaborative inter-organizational business processes. Our proposed approach tackles this challenge by adopting a service-oriented architecture in which blockchain interactions are considered as services executed to fulfill predefined behavioral NFRs. Another concern that most cited papers has pointed to is security. Privacy and identity management are key security attributes that are integrated differently, depending on the adopted blockchain platform. For instance, Hyperledger Fabric integrates a built-in permission management system that aims to manage participant roles in accordance to business requirements. However, in Ethereum-based implementations, the permission module can be developed and integrated separately to control access permissions through smart contracts. In our approach, we have a limitless choice of security attributes to integrate. We can either use the built-in security policies provided by the chosen blockchain platform, such as access control lists and channels, and on the other hand, our service-based approach also allows us to define any desired security process as a behavioral NFR during the modeling phase, which, consequently, calls appropriate concrete services and inject them into the generated service composition.

According to the parameters listed in Table I, our contribution covers the overall phases allowing the production of a reliable business process collaboration with the integration of blockchain interactions. The proposed approach combines the benefits of two powerful technologies: SOA and blockchain, and provides an advanced modeling process that combines them with an exhaustive definition of their interactions.

IV. PROPOSED APPROACH

Inter-organizational collaboration implies interactions between heterogeneous components to achieve external processes controlled by foreign entities. This raises numerous challenges depending on (1) the number of interacting organizations, (2) the complexity of published processes, and (3) the agreed policies to secure access and manage permissions. To overcome these challenges, model-driven methods can be helpful to rigorously describe the overall interactions using modeling languages, propose a fine-grained overview abstracted from any technical implementation, and allow reliable interoperability with the ability to customize code execution according to the runtime environment.

In this study, we propose an approach for designing and implementing collaborative business processes based on SOA. Additionally, we aim to introduce the ability to integrate blockchain transactions as a way to guarantee a higher level of decentralization while ensuring reliable collaboration. The proposed approach is supported by a proof-of-concept proposed to fulfill the emerging need raised by the COVID-19 pandemic, which consists of ensuring a wide collaboration between healthcare organizations. The proposed solution will allow healthcare actors to interact and exchange key medical information in accordance with the Moroccan governmental information systems and policies.

In previous contributions, we focused our research on modeling and generating business-oriented service compositions capable of fulfilling both FRs and NFRs [46]. The proposed solution integrates a modeling module that allows the design of interactions between desired services with the ability

to inject behavioral and quality-oriented NFRs, and then generates the optimal appropriate service composition. In the current approach, we aim to extend the scope of handling orchestrated composite services to allow their interactions with external business processes and, therefore, promote inter-organizational collaboration. Thus, we describe a business process as a complex business workflow that can be achieved by executing a service composition to fulfill certain predefined functional and non-functional requirements. A comprehensive modeling of these complex business processes is performed using the FSA. BPMN choreography diagram modeling is used from a wider perspective to define the interactions between multiple inter-organizational business processes. Moreover, we enhance our approach by introducing the ability to inject specific services, allowing interactions with the blockchain through transactions or smart contract executions. These blockchain interactions are covered from the modeling to the execution phases.

A. Modeling Collaborative Business Processes based on Automata

We previously stated that, in our preceding contributions [7, 46], we proposed approaches tackling the service composition challenges and integrating a modeling module based on FSA, allowing a graphical description of the desired FRs and NFRs. The generated composition is an orchestration of concrete services that fulfill the requirements of abstract services designed in the modeling phase. The context of collaborative business processes is slightly different, as it consists of a choreography of different processes achieved on the need, discontinued over time, and not reliant on an orchestrator. For instance, a patient can perform the investigation operation on day *d*, and two days after he completes the PCR laboratory test on *d+2*. In the service composition context, the process is completely executed on the fly to fulfill all the desired requirements at once. In this contribution, we combine both concepts, allowing an initial modeling of the desired collaborative system using the BPMN choreography diagram. Subsequently, we design each process in a fine-grained manner using FSA modeling. Fig. 1 illustrates the proposed modeling approach with a graphical description of each phase.

The first phase, surrounded by orange color, illustrates a BPMN choreography diagram, which defines the interactions between different organizations' processes to fulfill inter-organizational collaboration. As the choreography diagram lacks modeling expressiveness adapted to a more fine-grained level to address internal interactions, we complement it using the automata-based modeling. The automata formalization used was introduced in our previous contributions [7, 46]. It allows a service-oriented modeling of all business processes, and then offers the ability to integrate behavioral NFRs, when needed, to concisely express complex requirements. We used this modeling formalization to design (1) the desired FRs and (2) both measurable and behavioral NFRs. We take advantage of the automata expressiveness to implement complex security NFRs into the desired service composition. An example of implementing complex security attributes into automata modeling is the integration of the Shamir multi-cloud sharing algorithm in a previous study [47]. In our current approach, we adopt this modeling method to address the challenges of designing blockchain interactions. Thus, a blockchain interaction is integrated as a service injected into an automatically orchestrated service composition. The Abstract Functional Automaton (AFA) is introduced to design the desired FRs of a specific business process, in order to allow its translation to a ready-to-use service composition that fulfills these requirements. These FRs are designed in the form of abstract services that constitute automata states, while transitions define the desired interactions between these abstract services. The formalization is inherited from the inputs/outputs/pre-conditions/results scheme (IOPR), allowing fine-grained modeling capabilities to describe complex case studies. From our perspective, the NFRs integrated into the service composition can either be measurable, such as quality-of-service attributes, or behavioral (e.g., security attributes). In this study, we aim to integrate blockchain transactions as behavioral NFRs. This integration can be introduced into AFAs to grant decentralization and immutability properties to any business process. The formalization used provides the ability to use behavioral scopes to graphically design the desired blockchain interactions. Behavioral scopes are graphical automata scopes that specify the subset of states associated with the integrated behavioral NFR. These are illustrated using dashed lines surrounding the target abstract service states. The arrow direction in the scope defines whether the concrete services fulfilling the behavioral NFRs should be implemented before or after scoped abstract services. In the illustrated example, we use a post-execution scope associated with the abstract service (AS_2), aiming to integrate a blockchain transaction as a service. The concrete representation of this integration is illustrated in the third phase, which defines the interactions between the concrete services and the integrated blockchain service.

B. The Proposed Blockchain based Service-Oriented Architecture

In our contribution, we aim to implement a service-oriented architecture that allows fluid interaction with the blockchain to ensure process collaboration using smart contracts. For the implementation, we opted for a permissioned blockchain because of the specificities of the introduced case study. It allows us to restrict interactions to only authorized participants due to the criticality of exchanged information in the context of healthcare business process collaboration. In this perception, despite the heterogeneity of the internal information systems used by collaborating organizations, we are able to provide on-the-fly invocation of blockchain transactions or smart contract execution to meet the requirements described in the initial modeling.

On a large scale, the diversity of providers' roles and the variety of functionally similar services published make business process collaboration a challenging task. The integration of API gateways allows the unification of service calls by using common URI suffixes for functionally similar services. This facilitates service lookup and consumption, especially when the number of organizations is important.

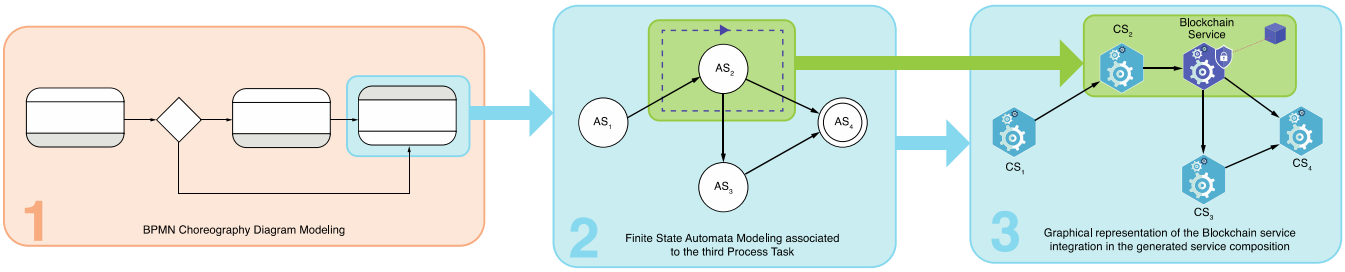

Fig. 1. Graphical Illustration of the Two Phases Modeling Process based on Choreography Diagram and Finite State Automata.

In our opinion, in addition to fulfillment of the primary requirements for a reliable business process collaboration, the privacy, identity management, and consensus mechanisms are crucial factors to consider when choosing a blockchain platform. In the proposed contribution, and to align with the context of the introduced case study, we integrate the Hyperledger blockchain as part of the proposed SOA, aspiring to improve collaboration between healthcare organizations, especially during the pandemic and post-pandemic periods. Hyperledger Fabric is a pillar platform for distributed ledger solutions that aims for democratization and standardization of blockchain for the business landscape, by allowing organizations to build custom blockchain apps to address their business requirements in a secure decentralized way [48]. It ensures a high level of confidentiality, resiliency, flexibility, and scalability. Hyperledger Fabric gained popularity through its plug-and-play approach, using the container technology to run its components to meet the desired business requirements and level of complexity. One of the essential components is the chaincode, which constitutes Hyperledger's native smart contract, defining the rules and operations for specific business processes. Additionally, Hyperledger comes with the ability to choose a consensus or even use a custom consensus implementation to define relations between members of the chain. Another significant improvement provided by Hyperledger Fabric is the support for channel creation [49]. This feature constitutes an additional security layer that allows a group of participants to create separate ledgers of transactions, especially for networks where some participants might be competitors and not want every transaction they make to be known to every participant. These previously cited features constitute the basis of our choice, which makes Hyperledger Fabric the most appropriate for the proposed blockchain proof-of-concept, especially when applied to a healthcare project.

The main components defining business logic in a blockchain solution are assets and transactions. The assets provide the ability to model business network logic in an object-oriented similar way. This feature allows designers to define business logic exhaustively using abstraction, inheritance, dependencies, and relationships. On the other hand, transactions constitute a structured and behavioral business-related description that allows the manipulation of assets through functions. These two components are explored to describe the business logic behind the implementation of collaborative processes.

The illustrated example presented in Fig. 2 describes a workflow showing the benefits of combining SOAs with blockchain technology. The blockchain is integrated as a service to constitute a complementary ledger while maintaining the organization's internal information system functioning and updated continuously. The API gateway intercepts the user requests and executes the appropriate services. The first service endpoint called allows updating the internal database to keep the local information system up-to-date. The second endpoint executes the appropriate blockchain transaction. The ledger is then updated, and events are triggered when applicable. The end-user receives a response describing whether all the steps were successfully performed. On the other hand, Fig. 3 illustrates the interactions of the integrated blockchain service with the modeled service composition. We graphically describe a simplified workflow that represents the interactions with the adopted Hyperledger platform. It shows the usage of the provided software development kit (SDK) to automatically launch the endorsement process, and then to validate the transactions by the orderer once the consensus is reached. Hyperledger Fabric achieves consensus through its ordering service. This service establishes the total order of transactions submitted to the network. In previous versions, Hyperledger Fabric used Kafka to achieve consensus while guaranteeing crash fault tolerance (CFT). As Kafka is commonly used to manage messaging queues, it is known to not provide a Byzantine fault-tolerant (BFT) consensus. Thus, the system cannot be prevented from reaching an agreement in the case of malicious or faulty nodes. In the latest versions, Hyperledger Fabric relies on RAFT [50], which is a distributed consensus algorithm for managing replicated logs, following a "leader and follower" model, where a leader node is elected for each channel. Leaders' decisions are then replicated by followers. This allows different organizations to provide nodes that contribute to the formation of a distributed ordering service.

In the proposed approach, we provide a model based on a choreography diagram with FSA to design the desired business processes, including the ability to perform blockchain transactions. The automata-based modeling of each process is translated into a composite service handled by the orchestrator to fulfill the business process requirements. A blockchain transaction is wrapped into an atomic service that is injected into the generated composition according to the NFR scope defined in the abstract automaton. As presented in our previous study [7], the orchestrator performs a lookup into the NFR registry to select the matching service fulfilling the behavioral NFR defined in the scope. In the current contribution, the behavioral NFR consists of a smart contract execution, which constitutes a blockchain transaction in the Hyperledger context.

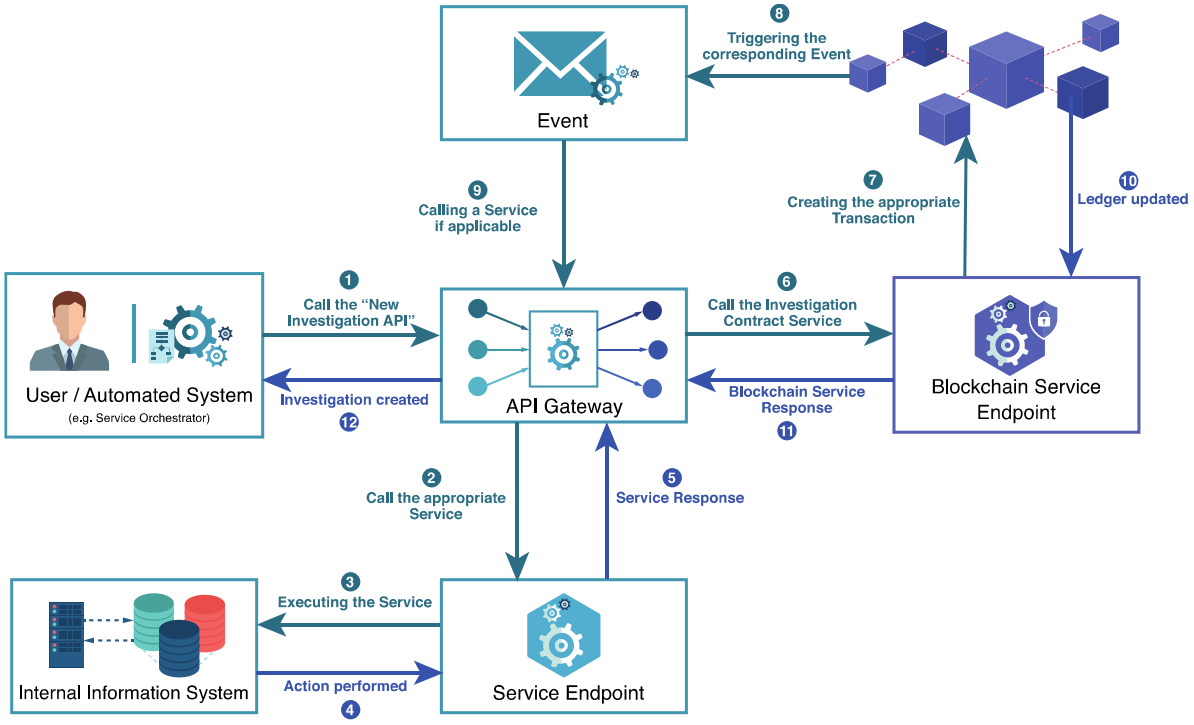

Fig. 2. The Workflow of a Blockchain as a Service Integration into the Service Composition.

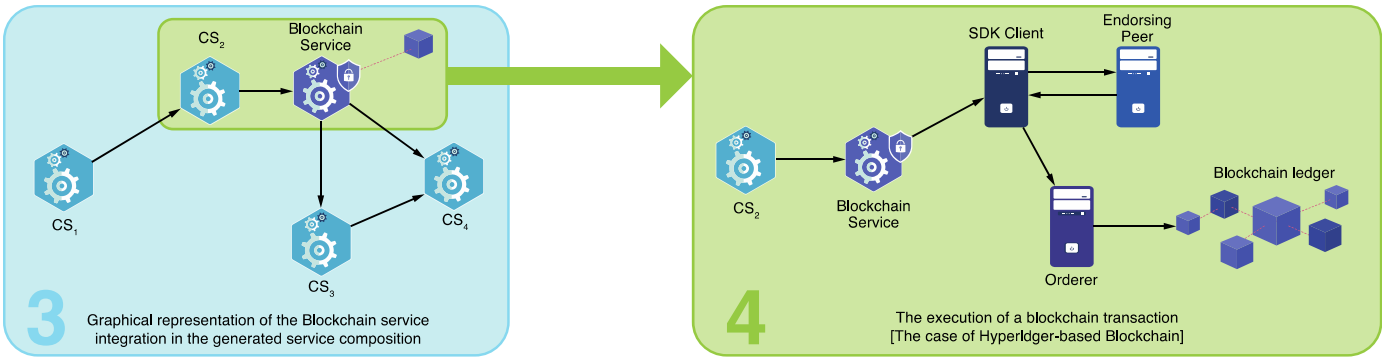

Fig. 3. The Blockchain Service Interactions with the Service Composition and the Ledger according on the Integrated Behavioral NFR Scope.

Finally, the advantage of using a service-oriented architecture is that it provides interoperability with the used blockchain platforms. The provided blockchain-as-a-service concept is not limited to Hyperledger technology, which is used in our proof-of-concept to meet the requirements of the considered case study. Subsequently, the approach is viable as long as the implemented blockchain platforms allow the automation of executed transactions using services, such as the Solidity-based smart contracts implemented by Ethereum blockchain.

V. The Proposed Implementation

In this contribution, we aim to introduce a prototype to overcome the collaboration issues between healthcare entities during the hospitalization process for affected patients, with the ability to extend the current model to cover vaccination processes in an upcoming phase of the project. Our proposed proof-of-concept is based on previously highlighted technologies by combining the composition of services with the blockchain. To fulfill this implementation, we opt for Hyperledger Composer, which is an open-source development toolset based on Hyperledger Fabric. Hyperledger Composer provides advanced abilities for modeling business networks and ensures the easy integration of blockchain applications with existing systems [51]. The main components of blockchain-related business network applications are the chaincode, assets, transactions, participants, events, and access-control rules. Chaincode is a program installed and instantiated onto a blockchain network to enable interactions with the ledger. It runs in a separate process from peers and is responsible for the initialization and management of the ledger state through transactions submitted by applications [52]. It provides also the ability of creating real-world decentralized applications, modeling business processes using assets and relationships, updating and exchanging information in the ledger through transactions, managing participants and their associated roles, and triggering specific business functions or services through events. The next subsections briefly define each of these

components with real-world examples inspired by the COVID-19 case study.

A. Case Study Overview

The world has experienced a remarkable health crisis, which has damaged the economy and negatively impacted healthcare systems. Most healthcare organizations are not logistically and structurally ready to deal with unpredictable large-scale healthcare-related challenges, which require urgent mobilization of resources to prevent additional losses. In the context of the Moroccan government, the healthcare ministry was very vigilant by publishing a new web-based platform allowing epidemiological centers to follow-up the cases of suspected and affected COVID-19 patients. In addition, they deployed a new mobile application allowing to notify users of any suspected physical interaction with affected patients using a geolocation tracking history. For both cited platforms, we noticed a lack of collaboration between healthcare providers, constituting the first and main destination for suspected and affected patients during the pandemic. These providers are required to maintain a continuous coordination with their respective regional epidemiological centers in order to process and investigate daily collected data, and then forward them to the national epidemiological organization within the healthcare ministry.

The collaboration between healthcare organizations in the cited context implies a good understanding of their interactions and their common processes. Briefly, the central epidemiological organization within the healthcare ministry collaborates closely with the regional epidemiological centers in each of the 12 regions of the kingdom. Similarly, each of these regional centers collaborates with all healthcare providers in their respective regions. Thus, in order to support the heterogeneity of methods and optimize interactions guaranteeing an exhaustive exchange of information, we introduce a complete process that allows the modeling and integration of collaborative business processes, with the extended ability to integrate the blockchain on demand. To present a realistic prototype, we aim to cover the overall healthcare processes and dependencies related to COVID-19, such as investigation, laboratory tests, and hospitalization, etc. Additionally, to allow an exhaustive collaboration and enhance inter-organizational interactions, we involve specialized healthcare entities, such as medical imagery centers and medical analysis laboratories. Each entity might contribute to one or multiple phases of the overall COVID-19 process, depending on the policies defined through our modeling process.

Among many interesting contributions integrating blockchain solutions to tackle collaborative challenges in the healthcare domain, especially during the COVID-19 pandemic, J. Xu et al. proposed a privacy-preserving scheme for fine-grained access control adapted to large-scale health data based on blockchain [53]. This platform, named Healthchain, is based on two blockchains to allow the users to upload IoT data and read doctors' diagnoses; on the other hand, it allows doctors to read users' uploaded data and upload appropriate diagnoses. The proposed blockchain-based platform prevents data from being tampered or denied; however, at any time, users can revoke doctors to preserve data privacy when needed. In contrast to the cited solution, and in the first phase of the project, our contribution focuses on business-oriented inter-organizational collaboration, and thus does not integrate patient interactions with the ledger. We are currently exploring the combination of heterogeneous blockchain architectures in order to connect a permissionless ledger for patients' interactions with the permissioned architecture presented in our current approach. Another solution was proposed by Alsamhi et al., aiming to integrate blockchain and multi-robot collaboration to combat the COVID-19 pandemic [54]. The proposed conceptual framework can increase the intelligence, decentralization, and autonomous operations of connected multi-robot collaboration in a blockchain network. The proposed architecture integrates Ethereum as a permissionless blockchain platform. The proposed solution presents the scope of use of each consensus algorithm in addition to shard techniques to maintain connectivity between collaborating robots, avoid collisions, and thus improve real-time. In the same direction, the authors in [55] proposed a blockchain-based system using Ethereum smart contracts to generate statistical information based on reported data related to the number of new cases, deaths, and recovered cases obtained from trusted sources. They presented a comparative analysis of the security and cost incurred by the stakeholders to prove the feasibility of integrating the proposed solution to ensure data integrity, security, transparency, and data traceability among stakeholders. Finally, the authors in [56] conducted a scoping review to identify relevant studies by searching 11 bibliographic databases. They conducted backward and forward reference list checking of the included studies and relevant reviews. According to their study based on 10 use cases of blockchain to tackle COVID-19 challenges, the most prominent use cases were contact tracing and immunity passports. Public blockchain technology was the most commonly used type in the included studies. Out of these 10 studies that identified the platform used, nine studies used Ethereum to run the blockchain, and Solidity was the most prominent programming language used to develop smart contracts. Although Ethereum continues to be the most popular and used blockchain platform in various industries and research fields, it is still susceptible to privacy leakage as public keys are made transparent to members of the network. This constitutes a key factor impacting the choice of blockchain solution and migration to permissioned blockchains, especially for addressing business process collaboration.

In the proposed implementation, we aim to tackle the business process collaboration challenge by implementing comprehensive well-designed composite services, fulfilling all business process requirements, and providing the ability to perform transactions over the blockchain. As illustrated in Fig. 4, we allow healthcare organizations to collaborate through well-defined processes, described using exhaustive modeling. The validated automata models are translated into composite services, integrating blockchain interactions and further behavioral NFRs when necessary. The concrete business services in blue color describe the services executed to perform a specific business need, whereas the concrete blockchain services in purple specify the services executed to perform an action on the blockchain, such as obtaining data from the ledger, or executing transactions to update the ledger's world state.

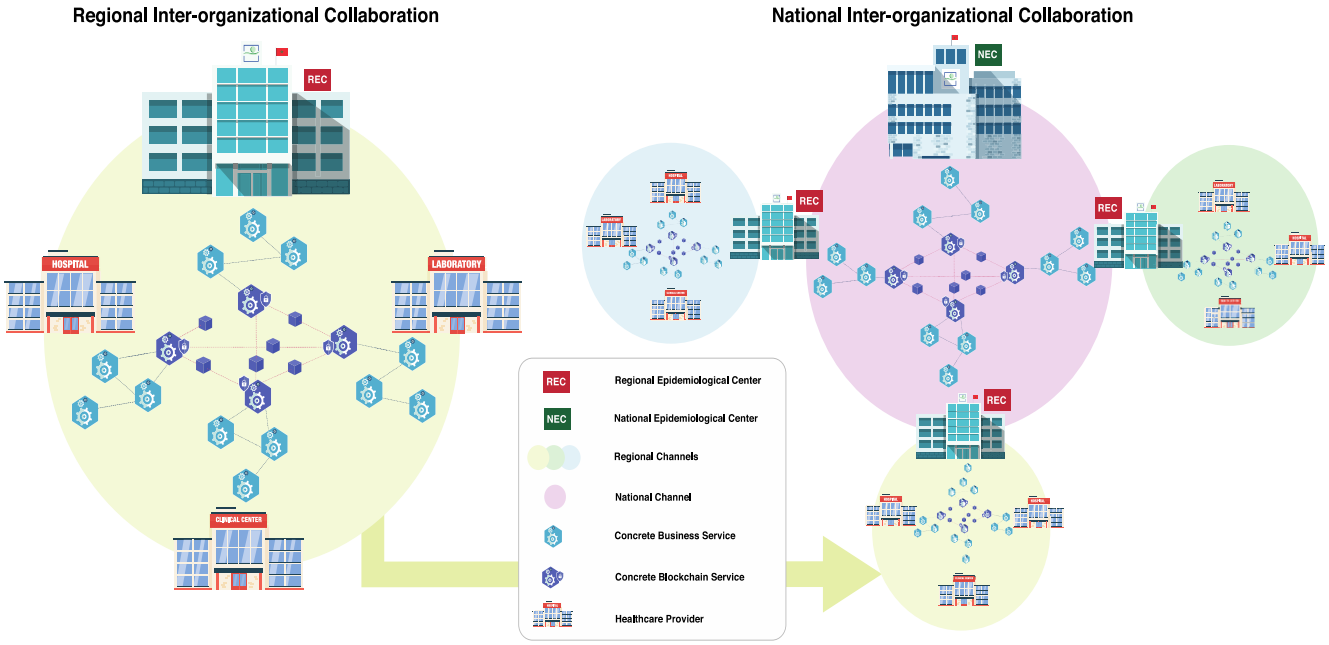

Fig. 4. The Proposed Implementation of Regional and National Inter-Organizational Collaborations based on the Blockchain.

To align the proposed architecture with the policies and hierarchical specificities of the healthcare case study, we integrate the channel feature, allowing the creation of sub-networks to ensure data privacy in accordance with each regional perimeter. This segmentation allows each regional epidemiological center (REC) to play a key role in federating and managing all organizations and participants falling under its regional administrative perimeter. Thus, coordinators of RECs will be in charge of managing the roles and permissions, and supervising the continuous conformance to healthcare ministry policies. Consequently, each REC coordinator interacts with two different ledgers: (1) the main ledger through the national channel, and (2) the regional ledger associated with the regional channel he manages. Examples of regional channels are depicted using blue, yellow, and green circles, whereas the pink circle defines the national channel.

B. COVID-19 Workflow Modeling

The initial phase in the proposed modeling process consists of defining the collaboration workflow through a choreography diagram. In Fig. 5, we present an illustrative model covering the main processes related to the COVID-19 workflow. The participant roles in this example continuously collaborate with RECs. These centers constitute, for each region in the kingdom, the main entities responsible for processing and analyzing collected data, before forwarding the daily COVID-19 key performance indicators (KPIs) to the national epidemiological center (NEC). Additionally, these RECs constitute the decentralized representatives of the healthcare ministry in the region, forwarding all epidemiological-related decisions to healthcare providers, and supervising their execution. The illustrated modeling depicts all phases of a COVID-19 patient, taking into account all cases, depending on the PCR results for both diagnosis and control laboratory tests. The main phases in the choreographic scheme can be shared by different actors; for example, a hospitalization can either be processed by a healthcare public provider or private provider. Similarly, laboratory tests can be performed by either a healthcare provider or a private laboratory center. These processes are examples reproducing real scenarios, summarized and abstracted into one choreography diagram. This diagram is shared by the 12 regions, all replicating the same unified process with the same common roles. The organization's roles participating in the process example are briefly described below, and defined more in deep in the following subsections.

- The regional epidemiological center, which is the focal organizational authority in the region, is responsible for collecting, processing and analyzing epidemiological data from all healthcare providers within its region.
- The healthcare provider, which can be any healthcare entity among of the previously cited organizations. Its main role is to provide healthcare services to patients.
- The medical analysis laboratories, which are the medical laboratories authorized by the RECs to issue PCR tests to patients.

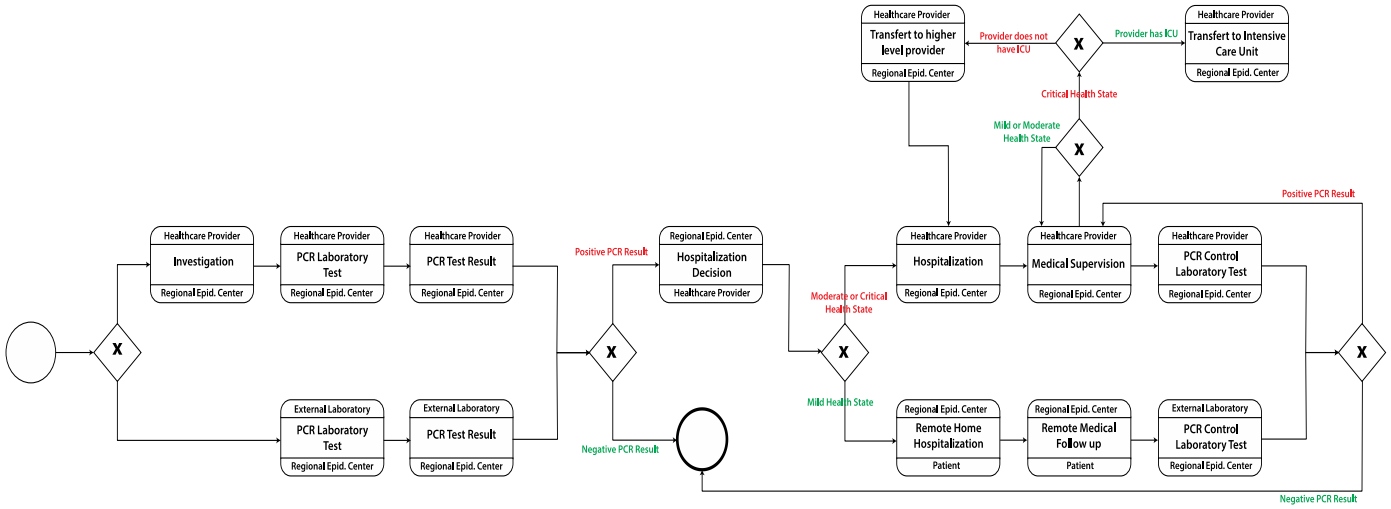

Fig. 5. A Proposed Choreography Diagram for the Adopted COVID-19 Business Processes.

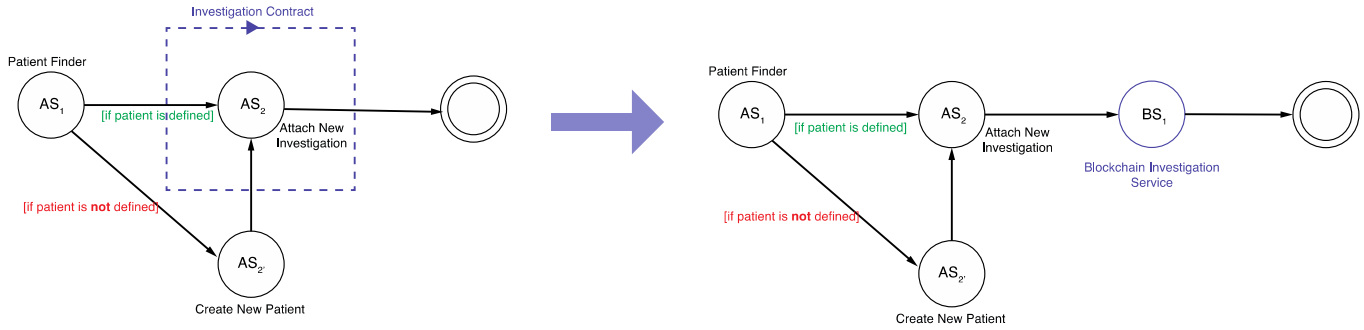

Fig. 6. A Proposed Modeling for the Investigation Process using the AFA.

In the same modeling perspective, we illustrate in Fig. 6 a simple modeling example of interacting services that describes the investigation process. The service composition described in the automaton allows the creation of a new investigation for a patient. In this AFA modeling, we design the desired FRs using state interactions, in addition to the new scope defining the blockchain-oriented behavioral NFR. Thus, the concrete service composition integrates a service invocation that sends a transaction to the blockchain. Consequently, in addition to the usual persistence of the investigation data in the provider's internal information system, a new transaction will be executed in the blockchain, and propagated to local copies of all contributing participants.

The provided automata formalization uses descriptive names or regular expressions to index behavioral NFR [7]. In the context of blockchain, we integrate the possibility of performing the NFR-lookup operation taking as a parameter the label used to index the transaction or the smart contract to execute. In the provided example, a forward-direction arrow is used in the *InvestigationContract*, which means that the transaction service fulfilling the behavioral NFR should be executed after the scoped service. This integration implies a lookup operation performed in the behavioral registry, returning the concrete service metadata that matches the specified query.

C. The Asset Modeling

Recall that assets constitute the main resources in Hyperledger technology; they can range from tangible to intangible entities. Hyperledger Fabric provides the ability to modify assets using chaincode transactions. They are represented in Hyperledger Fabric as a collection of key-value pairs and can be represented in binary and/or JSON forms. In Composer, assets are defined in .cto files using a structure similar to the class structuration in object-oriented programming. In our case study, we used assets to model all phases of the COVID-19 healthcare processes.

Our case study modeling based on the presented choreography diagram can be defined in a fine-grained manner using appropriate assets. This allows us to design the desired information system exhaustively, and consequently, improve inter-organizational collaboration. Fig. 7 presents some asset definitions extracted from the modeling file *ma.gov.ehealthcare.assets.cto*. In the same figure we also provide the class diagram illustrating the relationships between the presented assets. In the current phase of implementation, the patient is integrated as an asset, which constitutes a subject and not an interacting participant.

Fig. 7. A Proposed Example of Asset Definitions of COVID-19 Processes and their Appropriate Class Diagram Modeling.

The main assets constituting the COVID-19 healthcare processes are the following:

1) The investigation asset usually constitutes the first point of contact between the patient and the healthcare provider, allowing a doctor to investigate the patient's health state, symptoms and medical history for the recent period before his/her admission by the healthcare organization.

2) The PCR test asset gathers all PCR-related information and constitutes the key element in defining the consequent phases according to the test results. In other words, in addition to other factors, a positive result may imply a patient hospitalization, whereas a negative result implies a non-affection for diagnosis tests or a patient recovery for control tests.

3) The hospitalization asset describes the process of taking care of a patient in a healthcare organization during a period of time according to medical instructions related to his/her health state.

4) The home hospitalization asset defines the newly introduced process of taking care of a patient remotely in his/her home through continuous supervision based on telecommunication and regularly filled reports.

5) The ICU admission asset defines the process of transferring a patient internally to the intensive care unit (ICU). This transfer depends on the health status of the patient and the availability of the ICU room.

6) The medical supervision asset describes the operation of performing regular medical checks in order to follow up and update the patient's health state.

On the other hand, in order to keep track of all participating organizations in each phase of the workflow, we adopt a model that considers collaborating organizations as assets. This allows us to identify the healthcare providers responsible for any performed action, thereby improving supervision and auditability. In each region, these healthcare organizations communicate with the REC, which constitutes their higher focal authority. In their turn, RECs are continuously reporting to the NEC. The collaborating organizations defined using assets in the studied scenario are the following:

1) The healthcare organization asset is the parent of the overall organizational assets, containing common attributes such as the identifier, name, address, and region.

2) The healthcare provider asset inherits from the healthcare organization asset and gathers all key information regarding the provider's capacities in terms of hospitalization, laboratory tests, and imaging examinations.

3) The public healthcare center asset inherits from the healthcare provider and unites both university healthcare centers and regional healthcare centers.

4) The private clinical center asset inherits from the healthcare provider asset, and defines the external private healthcare entities collaborating with the public healthcare organizations during the pandemic.

5) The private imaging center asset inherits from the healthcare organization and defines the key capacity information for the main imaging examinations related to COVID19 affections.

6) The private laboratory asset inherits from the healthcare organization and defines the laboratory daily PCR exam capacity supported during the pandemic.

7) The regional epidemiological center asset inherits from the healthcare organization and defines the administrative entity responsible for collecting, processing, analyzing and reporting all epidemiological-related information through the built collaborative system.

8) The national epidemiological center asset inherits from the healthcare organization and defines the head entity responsible for collecting, processing, analyzing and reporting all epidemiological-related information gathered from RECs through the built collaborative system.

D. The Participants

Participants are the members of a business network. They constitute the main actors of the blockchain, managing assets and submitting transactions. For each participant, one or more identities can be assigned, allowing him/her, depending on the attributed rules, to perform actions and interact with the ledger. In the first phase of this project, we omit adding the patient as a participant, as in this initial phase of the project, we consider only inter-organizational collaborative processes, which excludes patient interactions. In other words, all patient data are updated by coordinators of healthcare organizations that they interact with, such as doctors, healthcare provider coordinators, etc.

We introduce different role definitions, which all inherit from the healthcare participant role. They are listed below:

1) The healthcare provider coordinator role defines the main actor representing his/her *healthcare organization*. It allows to manage internal data and also to update the ledger. We link this role to *the healthcare provider's asset* to easily identify the organization of each coordinator.

2) The regional epidemiological center coordinator plays a key role in our case study. On the one hand, this participant is responsible for managing and supervising all blockchain information related to his/her attributed region. On the other hand, it allows interaction with the NEC through the main national channel.

3) The national epidemiological center coordinator role allows users of the healthcare ministry to investigate and follow the daily summaries received through the national channel. It has higher administrative privileges allowing to manage participants, organizations, and entities on a national scale.

4) The laboratory coordinator role allows interaction with the ledger as a coordinator of a private laboratory, in order to update the patients' COVID-19 processes by integrating information related to PCR tests and their respective results.

5) The imaging center coordinator defines the role assigned to the participants responsible for coordinating the private imaging centers. Their main contribution consists of

integrating all affected patients' imaging data in the blockchain, such as chest X-ray, CT scan, or MRI results.

In Fig. 8, we present some examples of collaborating organizations and their associated participants supported by the appropriate class diagram.

E. The Transactions

Transactions are the mechanisms by which participants interact with assets. They define the core business logic of the process. Once executed, the state of the associated assets changes. Consequently, the world state can be recreated by replaying all transactions with respect to their accurate order, which constitutes one of the strengths of blockchain technology.

Fig. 8. A Proposed Example of Organizations and Participants Assets and their Appropriate Class Diagram Modeling.

We use transactions to populate blockchain assets using organizational and healthcare data. First, we use our proposed automata-based approach to illustrate the modeling of each business process to produce a valid abstract service composition. Then, we integrate the appropriate blockchain transactions using behavioral scopes associated to the abstract services. In Fig. 9, we present a model of the patient investigation phase, which consists of collecting patient data, such as health state, symptoms, and comorbidities, etc. According to patient collected data, the investigating doctor estimates if there is a risk that patient might be affected, and consequently redirects him to the appropriate service for a PCR test or for an imaging examination. On the other hand, the *healthcare provider coordinator* performs a lookup to verify whether the patient already has an EHR, and creates a new patient profile otherwise. The second step consists of creating a specific *COVID-19 process* blockchain asset to assign to the patient if he/she interacts for the first time with the *healthcare organization*. All these scenarios are modeled as part of the investigation process, where states identify the abstract services described as follows: The states outlined with a black color define the abstract services denoted AS. Each of these abstract services will be associated with a pool of concrete services fulfilling the desired FRs defined in the AFA. The states outlined in blue are abstract services fulfilling behavioral blockchain NFRs of requesting data from the ledger on a read-only basis. Thus, their associated concrete services will interact with the blockchain, but will not impact the world state of the ledger. Finally, the states outlined in green constitute the abstract services defining blockchain transactions, and whose concrete services have the ability to update the world state of the ledger.

We provide below a brief description of the provided Automata modeling example:

- The concrete service CS1 associated with the first abstract service AS1 (Patient Finder) allows to return, from the internal information system, the unique electronic health record (EHR) for a given patient, using a set of personal information as input parameters.
- The concrete services CS2/CS2' associated with the abstract services AS2 and AS2' respectively, are conditioned by the result of execution of the first concrete service CS1 during the runtime. Thus, if CS1 returns a valid patient, the concrete service CS2 will be executed to fulfill the query "Covid Process Finder". In this case, CS2 will only interact with the blockchain on a read-only basis to obtain the requested data. However, in the second case, the concrete service CS2' will be executed to fulfill the query "New Covid Process and Patient Assignment". In this case, CS2' will call a blockchain transaction to create a Covid Process asset with a nested patient asset filled with the patient information.
- The concrete service CS3 fulfills the requirements of the AS3 associated with the query "Investigation Assignment". This service will perform a blockchain transaction to create a new investigation asset and assign it to the previously returned Covid Process asset.

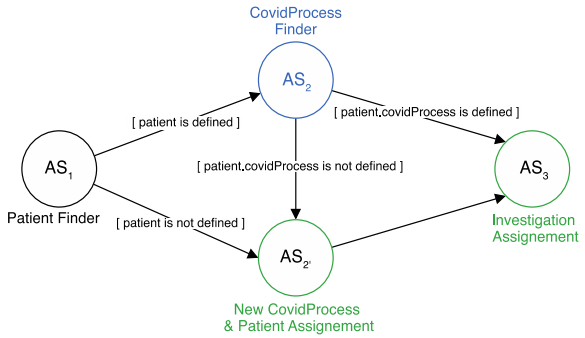

Fig. 9. The Proposed Automata Modeling of the Investigation Process Including Blockchain-Oriented Abstract Services.

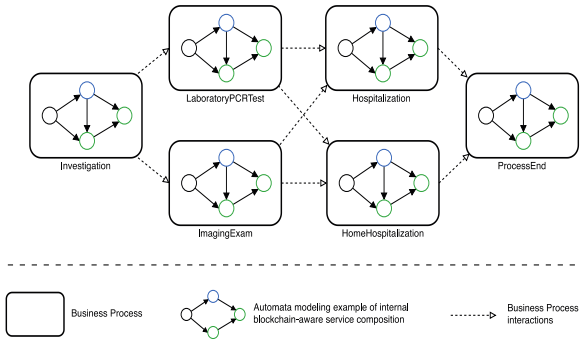

Fig. 10. Simplified Representation of the Process Choreography and Associated Internal Service-Oriented Automata.

Similarly, we extend the same modeling to design the remaining processes. In Fig. 10, we describe a simplified example representing how collaborating business processes can be seen from a wider and closer perspective, combining both FSA modeling and choreography diagrams.

Thus, in practice once a busines process is required, the system executes the appropriate service composition, which includes regular business-oriented services and blockchain-oriented services injected as behavioral NFRs in the designed AFA.

Finally, in the context of our proposed case study, we present in Table II a comparative table describing the implementation and collaboration aspects of some of the main COVID-19 operations. It specifies how these operations are implemented, and whether (1) they allow an automatic collaboration with external organizations or (2) are limited to the internal information systems and are shared manually with external organizations through messaging or data transfers. Most public healthcare providers are using local web applications, handling common operations regarding hospitalizations, medical consultations and exams. This application is exhaustive for handling medical data, however, does not cover the specificities of some important COVID-19 operations, such as investigation which comes with a long questionary storing meticulous information about patient's heath state, laboratory and imaging exams data which are handled using complementary applications connected to automates, etc. Accordingly, the healthcare ministry deployed urgently a new COVID19-oriented web application to gather investigation information and daily statistics. These applications

are not connected to each other, and do not provide web services or APIs to allow their interoperability. Thus, an automatic collaboration is only available using the web application that can be accessed by multiple participants and roles to handle investigation, patient health state, recovery/death and statistic data. For other daily operations not covered by any of implemented applications, manual registration is used then to ensure follow-ups and data transfers to higher organizations. The proposed contribution based on service-oriented collaboration and using decentralized ledgers to parallelly store and update information overcomes all these collaboration limitations, and provides accessible operations through blockchain transactions, with respect to the implemented access-control policies and regional channel configuration.

F. The Events

Events in Hyperledger Fabric, as for their common use in software engineering, provide a way to interact with external components or systems. In Hyperledger Composer, they are defined in the same way as assets or participants, and can be emitted by transactions to indicate to external systems that something of importance has happened to the ledger. Applications can then subscribe to events through the composer-client API [57]. In our context, events are mainly associated with the blockchain services updating the ledger, outlined in green in the described automata model. In the present case study, events allow the notification of the higher authority of updates regarding the overall healthcare status related to COVID-19. For instance, transactions launched by healthcare organizations trigger events to update statistics and notify the REC. Similarly, at a higher level, transactions launched by the RECs trigger events notifying the NEC of updates regarding the epidemiological status in their respective regions.

TABLE II. A RECAPITULATIVE TABLE CLASSIFYING COLLABORATION LIMITATIONS FOR SOME OF COVID-19 PROCESS ACTIONS

Action	**Organization**	**Initial Collaborative Environment**					**Current Implementation**	
		Local Application	Complementary Documents/Apps	COVID-19 Web Application	On demand Collaboration (Messaging, Data Transfers)	Automatic Collaboration	Decentralized Service-oriented Solution	Automatic Collaboration
COVID19 Investigation	Healthcare Provider	X	✓	✓	X	✓	✓	✓
Laboratory PCR Data	Healthcare Provider	Partial	✓	X	✓	X	✓	✓
	Private Laboratory	✓	X	X	✓	X	✓	✓
Laboratory PCR Results	Healthcare Provider	X	✓	✓	X	✓	✓	✓
	Private Laboratory	✓	X	On approval	X	On approval	✓	✓
Hospitalization	Healthcare Provider	✓	X	X	✓	X	✓	✓
Medical Supervision History	Healthcare Provider	X	✓	X	✓	X	✓	✓
Imaging Exam	Private Imaging Center	✓	X	✓	X	✓	✓	✓
Health Status History	Healthcare Provider	X	✓	X	✓	X	✓	✓
Home Hospitalization	REC	X	✓	X	✓	X	✓	✓
ICU Admission	Healthcare Provider	✓	X	X	✓	X	✓	✓
External Transfer	Healthcare Provider	Partial	✓	X	✓	X	✓	✓
Process End (Recovery)	Healthcare Provider	✓	X	✓	X	✓	✓	✓
Process End (Death)	Healthcare Provider	Partial	✓	✓	X	✓	✓	✓
Data Anonymization Process		X		X			✓	
Access Control – Application Level		✓		✓			✓	
Access Control – Module Level		✓		✓			✓	
Access Control – Action Level		Partial		-			✓	
Access Control – Resource/Data Level		X		-			✓	
Channel Restrictions		X		-			✓	

To make our proposed implementation more exhaustive, we implement some statistic-oriented assets allowing the COVID-19 statistics to be updated daily for each region. These assets are automatically updated when appropriate events are triggered. In our case study, we use events to notify REC coordinators about updates regarding COVID-19 daily status in their respective regions. Another concrete example consists of using events to notify a target healthcare provider about a transfer request for a patient in a critical health state, where the requesting participant receives an acknowledgement as soon as the target provider validates the transfer.

Finally, in a service-oriented approach ensuring a choreography between different organizations, events constitute an essential pillar allowing an efficient collaboration, and facilitating the implementation of real-time notification systems to increase reactivity towards critical scenarios. In Fig. 11, we provide a definition of the investigation transaction associated with an event emission to subscribed components.

G. Access Control and Security Implementation

Hyperledger proposes a high-end permissioned system that allows to manage and control participants' permissions for each action. This constitutes the backbone and main purpose behind using an identity-based permissioned blockchain. Hyperledger provides an access control language based on declarative permissions over each element of the domain model. Access control rules are defined in specific files and are described using two different methods. The first definition type, which is the simplest, allows to control the access to a namespace, an asset, or an asset's property for a participant type or participant instance. The second type is a more advanced conditional rules system, based on JavaScript Boolean expressions. These expressions are evaluated in runtime to allow or deny access to a resource for a participant. Participants can have their access to transactions restricted based on their role's permissions defined in the access control files. In our perception, collaborating organizations and their attributed participants are dynamically managed. Identities and business network cards can be managed under administrative privileges through the Hyperledger API. The roles of coordinators for both regional and national epidemiological centers are given the ability to manage participants, identities and network cards, for their regional and national organizations, respectively.

In the present case study, we notice that none of the essential assets constituting the main COVID-19 process contain or point to the patient's assets. The aim behind omitting this relationship is to enhance confidentiality and ensure data anonymization, which constitutes an essential feature implemented in our contribution, as highlighted in Table II. Accordingly, participants with restricted permissions can only access and handle the data of assets associated to their scope. For example, they can handle COVID-19 hospitalization information, PCR results information or statistics information without accessing the corresponding patients' data (e.g., personal information). This modeling-based separation of assets, combined with the fine-grained layers of access-control management provided by the Hyperledger Fabric blockchain, constitute the backbone of security attributes implemented in this contribution, in order to provide a meticulous management of roles and permissions for overall participants, according to their administrative attributions.

On the other hand, and in order to meet the ambitions and efforts of the Moroccan government to deploy the advanced regional decentralization, we aimed in the proposed case study to use an exclusive channel for each individual region to promote data privacy. From our perspective, these channels allow to concentrate the efforts of regional epidemiological centers coordinators to securely manage the permissions of collaborating organizations falling under their administrative perimeters. Similarly, a national channel is implemented, allowing communication between all RECs with the ministry entities (e.g., National Epidemiological Center, Ministry Secretary). The aim of this channel is to ensure continuous data forwarding and reporting based on the daily statistics generated for each region.

        event.investigationId = investigationId;
        emit(event);

        return
investigationRegistry.addAll([investigation]);
    });
}
```

Fig. 11. A Definition Example of the Investigation Transaction and the Associated Emitted Event.

VI. Conclusion and Future Work

In this study, we aimed to provide a complete solution for the design and implementation of inter-organizational collaborative processes based on a two-phase modeling using BPMN's choreography diagram and FSA. We provided the ability to integrate blockchain transactions as services to promote decentralization, immutability, integrity, and trustless interactions between collaborating organizations. To illustrate our approach, we presented a proof-of-concept implementation adapted to the healthcare domain, and handling COVID19-related collaborative processes. Although we opted for Hyperledger Fabric as a permissioned blockchain platform to meet the collaboration requirements of the studied scenario, the introduced blockchain as a service concept can be adapted to any blockchain platform as long as it supports the automation of transaction calls. Our proposed proof-of-concept modeling is based on real business processes aiming to promote collaboration between healthcare organizations in Morocco.

Using an architecture based on a specific blockchain topology will always rely on its limitations in term of performance, scalability, security, and other key aspects characterizing the chosen blockchain platforms. On the other hand, the misuse of permissioned blockchains can cause colossal damage, especially in the context of inter-organizational collaboration, as the reliability of the ledger relies on the integrity of its members. Thus, identity and role management are key features implemented to ensure healthy collaborations. In this contribution, the proposed service-oriented approach does not rely on any specific blockchain topology and can integrate both permissioned and permissionless blockchain platforms, since the execution of a transaction or a smart contract is wrapped into a concrete service.

In future work, we will focus on two principal aspects: (1) Covering intra-organizational collaboration by encouraging progressive migration of internal information systems toward the blockchain, requiring the deployment of new blockchain transactions as concrete services and an exhaustive definition of interacting assets using the proposed modeling process. (2) Integrating end-users (e.g., patients) as participants in the collaborative ledger by experimenting the integration of a hybrid topology, pairing permissionless and permissioned blockchains. To achieve this objective, numerous challenges arise and are associated, for example, to the correlation of performance with the scalability, shared identity management, and the implementation of unified security requirements while merging the heterogeneous platforms.

A Language Tutoring Tool based on AI and Paraphrase Detection

Anas Basalamah
Computer Engineering Department
Umm Al-Qura University

***Abstract*—A language tutoring tool (LTT) helps learning a language through casual human-like conversations. Natural language understanding (NLU) and natural language generation (NLG) are two key components of an LTT. In this paper, we propose a paraphrase detection algorithm that is used as the building block of the NLU. Our proposed tree-LSTM with a self-attention method for paraphrase detection shows accuracy of 87% with a lower parameter of 6.5m, which is much robust and lighter than the other existing paraphrase detection algorithms. Furthermore, we discuss an LTT prototype using the proposed algorithm with having some featured components like- message analysis, grammar detection, dialogue management, and response generation component. Each component is discussed in detail in the methodology section of this paper.**

***Keywords*—LTT; NLG; NLU; paraphrase detection; LSTM**

I. Introduction

The conversation is an effective technique for learning a second language [1]. When people try to learn a new language, they learn it through verbal and written communication, including reading, writing, listening, and speaking skills. The former includes listening and speaking, and the latter includes reading and writing. A partner is mandatory for whatever conversation a learner wants to make. It is easy these days to make friends from different countries, cultures, and tribes with the rise of the internet and social media. People can easily share their cultures and values and can teach their languages to others. However, learning a second language requires regular practice for a long time. It isn't easy to find someone available for live conversation every day for a long time because of different time-zone, work schedules, and many other reasons. Although movies, prerecorded videos, or online courses that provide video lessons can be useful equipment to some extent for understanding a language but not adequate for making conversations.

In recent times, smartphones and computers with internet connection are available to everyone from developed to emerging countries. What if someone develops an LTT that can act as a language expert and help the learner with grammar errors, spelling or syntax errors, dictionary and sentence corrections. People can speak and chat with it at their convenient time to learn a new language. For example, if a traveler visits a country without knowing its languages, it becomes difficult to communicate with the local people. This LTT can help the traveler in such a case. Many researchers have already researched on various conversation applications for both pedagogical and industrial purpose [2], [3], [4] but the idea of language specific LTTs (language other than English) is relatively new in this domain.

The concept of an LTT comes from the $chatbots$ providing 24-hours customer support or technical support on online platforms [2]. $Chatbots$ are widely used to serve as a customer service agent in many web-platforms. However, an AI-based LTT is different in functionality comparing to a $chatbot$. A $chatbot$ is only capable of conversation related to customer service management whether an AI-based LTT performs conversation related to language tutoring. The LTT consistently learns through conversations with the user. It is a game changer as a language tutor and impacts significantly in learning a second language effectively.

Generally, human agents provide service to the customers in online platforms, but recently they are getting replaced by $chatbots$. Because a $chatbot$ saves time, money, energy, and physical costs for the company. Besides, it generates responses with fewer grammatical errors and typos. Since the text-based conversation part is also a feature of the conversation agent, it is important to adapt the mechanism of a $chatbot$ in the development of a conversation agent. However, it is never easy to develop such a $chatbot$ system to continue a meaningful conversation with customers and solve their problems. The critical issue here is to detect different sentences with the same meaning, i.e., paraphrase detection. Naturally, people use different expressions and structures of sentences to express the same thing when they make conversation in different circumstances. For example-

Sentence-1: "I have to learn this language very quickly."

Sentence-2: "I need to pick up this language as soon as possible."
Clearly, 'Sentence-1' and 'Sentence-2' have two distinct structures but express the same meaning. Paraphrase detection and its natural language understanding (NLU) component play an essential role in detecting these sentences. Therefore, paraphrase detection is considered a vital element of a conversation agent or a dialogue system. The next important step is natural language generation (NLG), as the system has to respond to customers after understanding their problems. This paper follows these NLU and NLG steps for making a conversation agent that acts as a language learning tool to the user.

We develop an AI-based human-like interactive system that can understand the context of natural language sentences and help learn a new language. When the system is trained on a massive dataset of semantic relatedness, it retains the relative behavior of words and vocabulary in the sentence.

The developed application is efficient for people learning or exploring a second language. A novel tree-LSTM with self-attention is proposed that is implemented as the system core of the developed application. The proposed tree-LSTM with self-attention shows moderate accuracy than the existing models but offers the best efficacy as a lightweight and robust model. Performance comparison of the proposed and existing methods are demonstrated in Section III.

The remaining part of the paper is structured as follows. The methodology of our proposed LTT with its demonstration, components, architecture, and workflow is discussed in Section II. The performance of the proposed method is analyzed and compared in section III. Previous research works on language learning agent and paraphrase detection are studied in Section IV, and finally, the paper is concluded in Section V.

II. Methodology

This section describes the components, architecture, and workflow of the LTT. In learning, tourism, visiting, hosteling, and exposing to new places, LTTs are very efficient as the way of interaction is human-like. Additionally, the mapping of sentences to intent makes it more flexible for users to interact by using any phrases. Contextual conversation makes the user or learner feel more active and realistic. A user-LTT sample communication is depicted in Fig. 1. Fig. 1 illustrates how the grammar detection component of an LTT corrects grammatical errors and helps with dictionary.

The primary goal is to create a task-oriented AI-based contextually aware LTT which can interact with humans naturally. This research proposes and trains the system to learn a second language through chat or voice LTT.

Instead of traditional language learning platforms or apps, the LTT will communicate with the learner. It is inspired by the natural phenomenon that humans can learn a new language better when he visits a new place and communicates with natives. In this situation, the primary concern of the visitor is to convey his intention through a message. This case study motivates to create a contextually aware platform that can talk, understand and reply to the user more personally and intelligently. Unlike Google assistant or Alexa, the system does not need to be a knowledge-based assistant; it will be solely trained for language practicing. User will share his feeling: e.g., "how was the day, what he took in the lunch, what he observed today" in second language, and the bot would extract the context, understand the user and reply appropriately. The proposed system can recognize the same sentence in multiple ways as it is trained to paraphrase detection. The language learning contextual system would teach the language to the learner by analyzing the input sentence and informing the user about sentence accuracy.

Fig. 2 represents the machine learning-based architecture of the LTT. The message analysis component (as NLU) extracts entities and classifies intents. This module recognizes the intention of the user and the semantic of the sentence. The grammar detection component checks grammar and punctuation errors, correct sentences, and acts as a dictionary. The dialogue management module tracks the text, implements relevant policy, and triggers the appropriate action based on the database. Finally, the Response generation component provides the corresponding response of the query based on the context. This system communicates with user training on the proposed architecture based on tree-LSTM and attention.

RvNNs are efficient for natural language tasks but require structural input, which is hard for data preparation and implementation. This paper proposes a natural language task-specific model that can compose a tree structure of a plain text. The architecture of the system consists of Tree Long-Short term memory and Attention mechanism. Tree-LSTM is a refined version of RvNN and LSTM that manages the information flow from child to parent more structurally than LSTM. In tree-LSTM, the cell state computes parent representation by utilizing cell dependencies at a vertical distance.

Tree-LSTM extracts information from unstructured sentences by creating a structure of input dynamically. The information about the structure of the input is not provided to the Tree-LSTM model. Therefore, an extra process is required to compose task-specific tree structures of the input sentence. In the equation, $q.h$ express the score of representation validity $r = [h; c]$.

The trainable composition query vector is required to measure the representation validity for building the tree structure from the unstructured sentence. At the first layer, the candidacy for the parent representation is computed using equations 1 to 3. Query vector calculates the validity score for each candidate. Then, the validity of each candidate is prioritized based on their score. During training, the softmax estimator samples the parent node among candidates weighted by the query vectors, and for the testing, the model itself selects the candidate with the highest validity.

$$\begin{bmatrix} i \\ f_l \\ f_r \\ o \\ g \end{bmatrix} = \begin{bmatrix} \sigma \\ \sigma \\ \sigma \\ \sigma \\ tanh \end{bmatrix} \left(w_{comp} \begin{bmatrix} h_l \\ h_r \end{bmatrix} + b_{comp} \right) \tag{1}$$

$$c_p = f_l \odot c_l + f_r \odot c_r + i \odot g \tag{2}$$

$$h_p = \mathbf{o} \odot tanh(c_p) \tag{3}$$

$$v_i = \frac{exp(q.\tilde{h}_i^{t+1})}{\sum_{j=1}^{M_{t+1}} exp(q.\tilde{h}_j^{t+1})} \tag{4}$$

Additional components are also added to encode the input sentences into vectors dynamically using the bottom-up tree structure technique. We focused on a type-specific attention mechanism that aims to encourage the model to focus on salient latent information of the composition or constituency tree relevant to the classification decision. We denoted the output of the intermediate nodes and leaf nodes in the layers of the tree-LSTM as $\underset{h1}{\rightarrow}, \underset{h2}{\rightarrow}, ..., \underset{h_{2n-1}}{\rightarrow}$ where 'n' is the sentence length. The information of the architecture is as follows:

$$\tilde{a_i} = exp(W_a \times h_i) \tag{5}$$

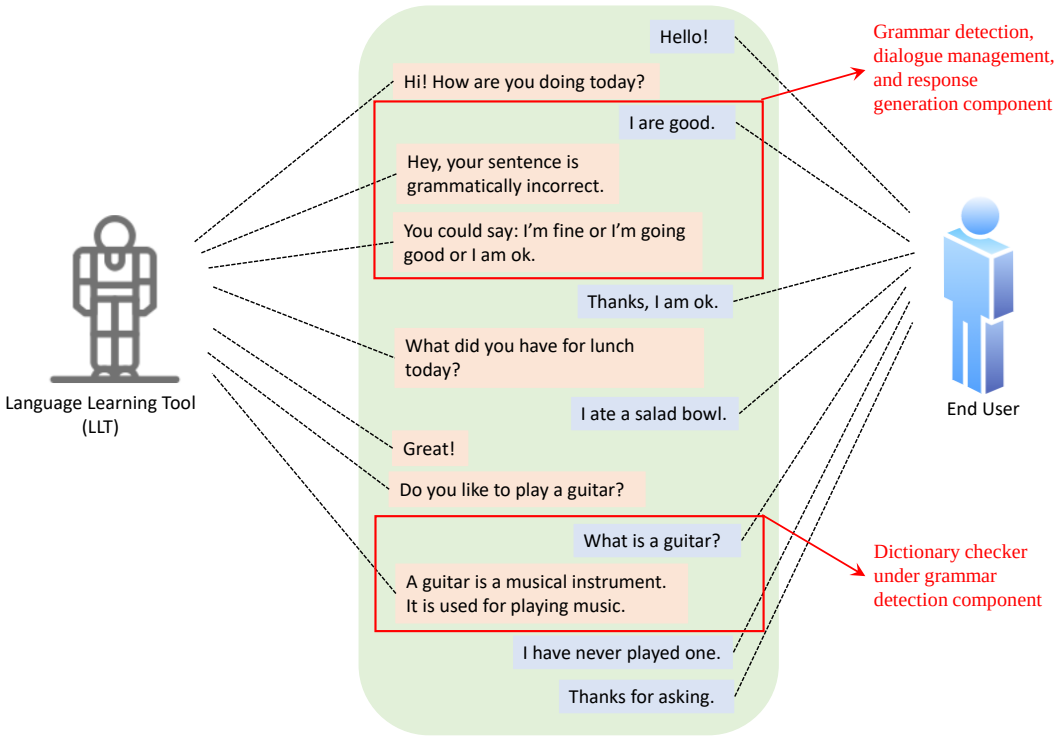

Fig. 1. A Sample Chat Window of End user with the LTT.

$$a_i = \frac{\tilde{a}}{\sum_{i=1}^{2n-1}(\tilde{a})} \tag{6}$$

$$\vec{H_c} = \sum_{i=1}^{2n-1}(a_i \vec{h_i}) \tag{7}$$

In our architecture, the context vector H_c is learned using attention-weighted contextual representation by passing Node vectors to the fully connected layer with Da hidden units in a hidden layer. For each such hidden state vector e_i, a scalar unit a_i is learnt with the weight matrix $W_a \epsilon R^{1Da}$. These scalar units are then normalized to 1, and the whole formulation of the context word vector is defined in equation 7. The process is visually summarized in the diagram of the architecture in Fig. 3.

III. Experimental Results

The section describes a complete experimental setup, hyperparameters, and dataset to analyze and evaluate the proposed model for paraphrasing and contextual similarity in conversation agents. The natural language inference (NLI) task is conducted to investigate the semantic relationship between two sentences. The proposed model is trained on the standard SNLI dataset that contains 570K pairs of English sentences.

The SNLI dataset* and Glove embedding* are available at resources. The model is trained on a large dataset containing sentences and learns from vector representation considering grammar and language constraints. The GPU Geforce RTX 2080 ti with 11GB memory and Cuda version 10.1 was used to train the model. Experimental results are evaluated in the table. The accuracy matrix in the table is employed to assess the model's efficiency and compare the results. The proposed model is reached based on pre-trained vectors' dimensions and several parameters used in training.

The presented table shows that Bi-LSTM with inner Attention is one of the stable models that use fewer parameters, 2.8m trained on 600D word vectors. The model achieved 84.2% testing accuracy, which is reasonably comparable with other models. The DiSAN uses 300D word vectors and achieves 85.6% accuracy with 2.4m parameters. This model is time efficient and consumes fewer parameters, but the proposed approach would only work for context-aware representations with temporal information encoded. Gumble tree-LSTM consists of tree-LSTM based on 600D word vectors and attains 86% inadequacy, but the deficiency is that it utilizes 10M parameters. BERT base model is proficient at reaching 90% testing accuracy. However, it stands among the list of large models as it utilizes 335m parameters.

TABLE I. Different Model Results

Model	Emb Dim	Params	Testing Accuracy
Bi-LSTM with inner Attention	600D	2.8m	84.20%
DiSAN	300D	2.4m	85.6%
Gumbel Tree-LSTM	600D	10m	86%
Tree-LSTM with attention	300D	6.5m	87%
BERT BASE		335m	90.7%

The above discussed models can be utilized for the same task, but they are not entirely appropriate in terms of task,

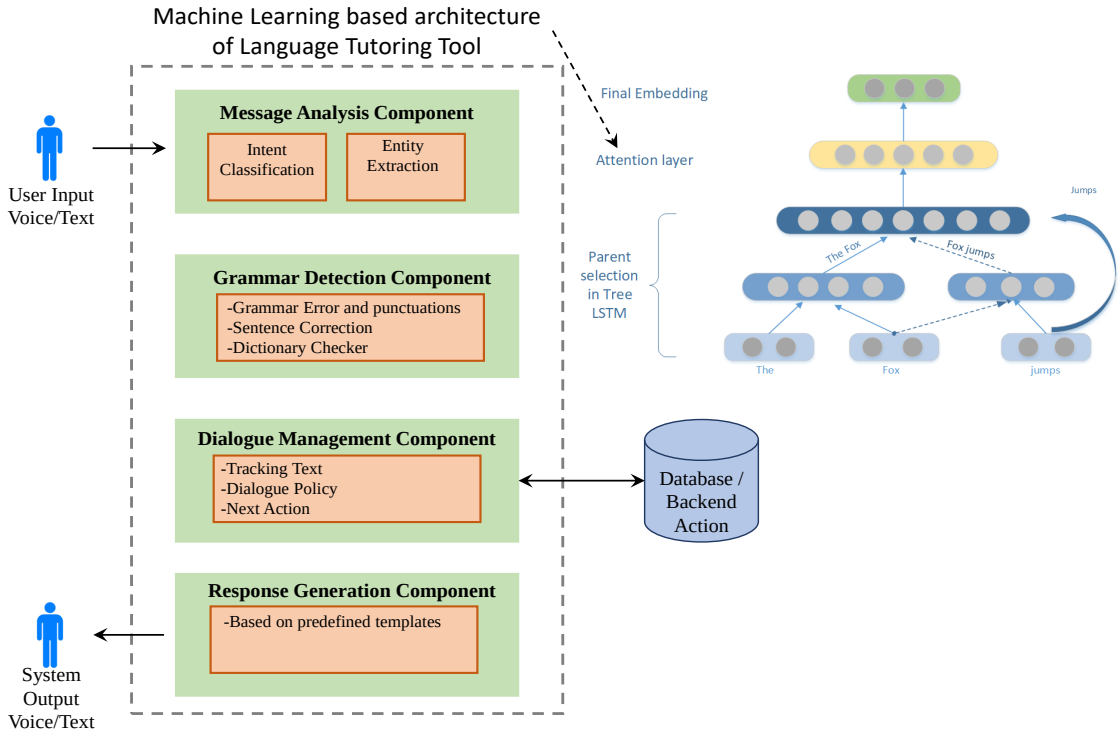

Fig. 2. Primary Components of the LTT based on the Proposed Architecture.

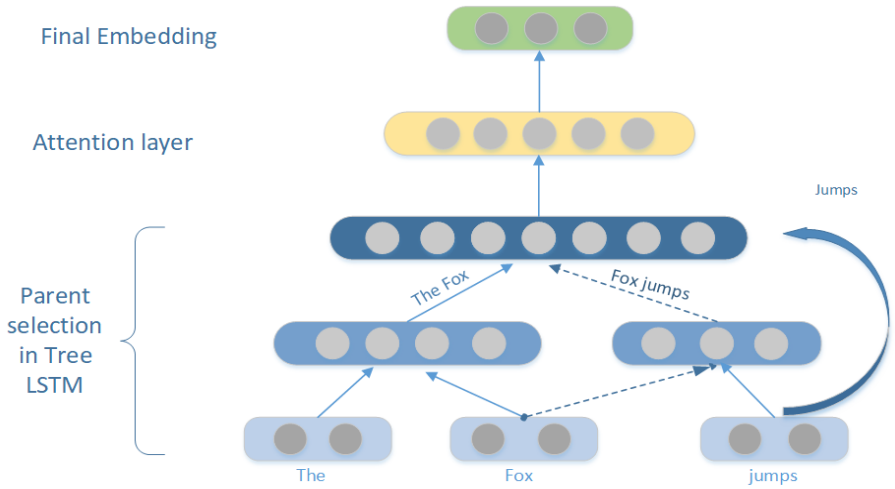

Fig. 3. Proposed Architecture for the LTT.

resources, and parameters. The proposed model is more robust, lightweight, and remembers the hidden states that help it in the question answering system. Therefore, our proposed model is efficient to be used in an LTT.

IV. Related Work

AI-based LTTs have the potential for human-like conversation. They work well for companies that have a lot of data. Despite the fact they need colossal time to train, they do save many in the long run. Based on previous information, they gather the information that learns new patterns from the input and improves the system after iterative training. Assistants understand patterns and behavior, and have a broader range of decision-making than any person, and over time they get to be very sophisticated. Many researchers investigated foreign language learning using a *chatbot*, where the *chatbot* mainly helps to learn english as a foriegn language [5], [6], [7], [8], [9], [10]. Our proposed model is generic and can be used for learning any language if the model is trained with respective languages' data set.

Our proposed platform comes under the task-oriented dialogue system in which end users will learn second language

through conversation. The proposed platform is initially trained on English language which will be extended further using datasets of other languages. However, the NLU and NLG are two must-have components that we needed to develop in the LTT. In the past decades, these modules are implemented individually and optimized using statistical models[11], [12]. Due to rapid and growing advancements in technology and algorithms, deep learning and reinforcement learning have reached the stage of producing human-like conversation agents. The trend to talk with a machine is not as new as more than 50 years ago; an agent is released that tries to maintain a conversation as mentioned in [13]. In recent years, messaging platforms offer developers to custom their chats and develop AI-based LTTs. The integration of AI modules to task oriented $chatbot$ can be complicated.

After the vector representation to evaluate the semantics of natural language text, sentence representation came into the ground to perform NLP tasks. The LSTM and its variants (RNN) sequentially process sentences to extract sentence meaning where the output depends on all previous hidden states. Recursive NN is the generalized version of RNN based on the structured input for sentence encoding as it extracts semantics through a hierarchical structure. The number of rvNNs were proposed in Socher et al. [14] which consider phrases instead of the complete sentence.

Matrix-Vector RvNN was reported as the best model that represents the word as vector and matrix at the same time. After that, Tai et al. [15] proposed two variants of standard LSTM (Child sum and N-ary tree-LSTM) that perform better for hierarchical and structural data. Additionally, hidden and cell states do not depend on the entire previous sequences in these variants as only the children's hidden and cell conditions contribute to the parent's states.

The Tree RNNs were extended by Zhou et al. [16] into attention-based tree RNN for semantic relatedness. In this model, semantic similarity is extracted by encoding attention in the tree structure of one sentence with vector representation of other sentences. Attention is used in machine translation by aligning the source or target sentence. It can focus on the most concerning sentences. The pioneers of the machine translation [4], [17] developed a model based on RNN variants that use attention for source words to generate target words.

A task-specific conversational agent is a kind of $chatbot$ that tries to imitate a human-like response bypassing the Turing test. Unlike pattern matching and simple algorithm-based $chatbot$, AI-based conversation agents contain complex algorithms and structures. Whether, we present a system in which an AI-based voice bot as a tutor provides services to learn a second language. A person or a student or a learner can speak a sentence multiple-way regardless of the vocabulary's dimension, as the system would efficiently detect the paraphrased sentences. At the beginning stage, when a person is learning the second language, it demands freedom to speak sentences and require hint to improve himself. This system considers the language constraints, grammar knowledge, and contextually aware algorithms trained on paraphrase detection.

V. Conclusion

This paper proposed an AI-based system that can perform casual conversation with a user in the second language for teaching and training purposes. The system based on the tree-LSTM with self-attention efficiently extracts contextual information from unstructured sentences and long conversations. The system is trained on a standard SNLI dataset that has been used widely for contextual understanding and paraphrasing detection systems. The experimental results expressed that the proposed model has achieved efficient results compared with state-of-the-art models.

***Abstract*—Today, the traditional username and password systems are becoming less popular on the internet due to their vulnerabilities. These systems are prone to replay attacks and eavesdropping. During the Coronavirus pandemic, most of the important transactions take place online. Hence we require a more secure method like one-time password generation to avoid any online frauds. one-time password generation has multiple techniques. With one-time password generation it has become possible to overcome the drawbacks posed by the traditional username and password systems. The one-time password is a two-way authentication technique and hence secure one-time password generation is very important. The current method of one-time password generation is time-consuming and consumes a lot of memory on backend servers. The 4-digit one-time password system limits its uses to 9999 users and with advance deep learning approaches and faster computing it is possible to break through the existing one-time password generation method. Hence we need a system that is not vulnerable to predictive learning algorithms. We propose a 6-digit one-time password generation technique based on a B-exponential chaotic map. The proposed 24-bit (6-digit) long one-time password system offers 120 times higher security as compared traditional 4-digit systems, with a faster backend computing system that selects 24-bits out of 10^8 bits in 89 seconds at 1.09 Kilo-bits per milliseconds. The proposed method can be used for online transactions, online banking, and even automated teller machines.**

Keywords*—*One-time password generation; B-exponential chaotic map; 6-digit one-time password; online transactions; security

I. Introduction

Our manuscript introduces a 6-digit OTP generation system using the B-exponential chaotic map. The methods that are currently used to generate OTPs such as time-based OTP and hash-based OTP are prone to brute force attacks, forging attacks, etc. This leads to the research question, "Whether there was another method that could be used to generate a highly secure OTP system that was less prone to such threats?". Chaotic maps that are widely used for their highly random behavior were chosen to check whether they can be used to produce highly random OTPs. Also, instead of 4-digit OTPs, our objective is to make a system that generates 6-digit OTPs with a limited validity time makes it extremely difficult for a general computer to crack the OTP with brute force.

To prevent unauthorized access, access restriction methodologies are used [1]. The unauthorized attacker should be prohibited from making any changes to the system, at the same time the authorized user should not face any difficulties in accessing or updating the system [2]. Traditional identification control used badges and passwords to control the access authentication and provided a security safeguard [3]. Money transfers, mobile merchanting, account checks, and payment of different types of expenses (school fees, medical bills, and residential maintenance) are some of the examples of rapidly expanding mobile banking operations. Because an attacker can perceive some part of the key, conventional passwords are vulnerable to replay attacks and type scheme assaults [4]. Although ID/password methods are vulnerable to eavesdropping and replay attacks they are still better than only password systems because of the added unknown factor of the user name [5]. Most of the users tend to forget their passwords and hence they write them down or store them on a PC. This poses a greater threat to the traditional security system. To overcome the weaknesses of the traditional method, the One-Time Password (OTP) solution has been proposed [6]. OTP is an additive system that requires a new key to be entered by the user every time along with the user name and password. OTP was initially called a One Time Authorization Code (OTAC) [7]. It is a dynamic password that remains valid for a certain amount of time or till the successful login within a session. In earlier days, the OTPs were sent to a keyring fobe device or pager. The OTP generation algorithm is typically a pseudo-random algorithm that is difficult to be guessed by the attacker. The additive cryptographic hash functions make it very difficult to derive or guess the OTP. Some of the recent literature [8] has shown time-dependent OTPs, thus making it hard for the attacker to guess them.

An OTP is suitable for signing in to sessions or financial deals on any digital device like a computer, mobile. OTPs avoid several flaws associated with traditional (static) password-based authentication; some implementations also include two-factor authentication by ensuring that the one-time password requires access to both something a person has (such as a device with the OTP calculator built-in, or a smartcard or specific cell phone) and something (such as a PIN).

This manuscript proposes a mechanism for generating an OTP using a bit file generated by a pseudo-random sequence generator. This pseudo-random sequence generator uses the B-exponential chaotic map. Each session generates a 6-digit random OTP that will provide more security than the 4-digit OTP systems.

Fig. 1 shows the conceptual diagram for 6-digit (24-bit) OTP generation using B-exponential chaotic map. As per this concept, after inserting an ATM card into the machine, the user enters the correct user name and password. After validating the username and password, the bank server generates a 6-digit

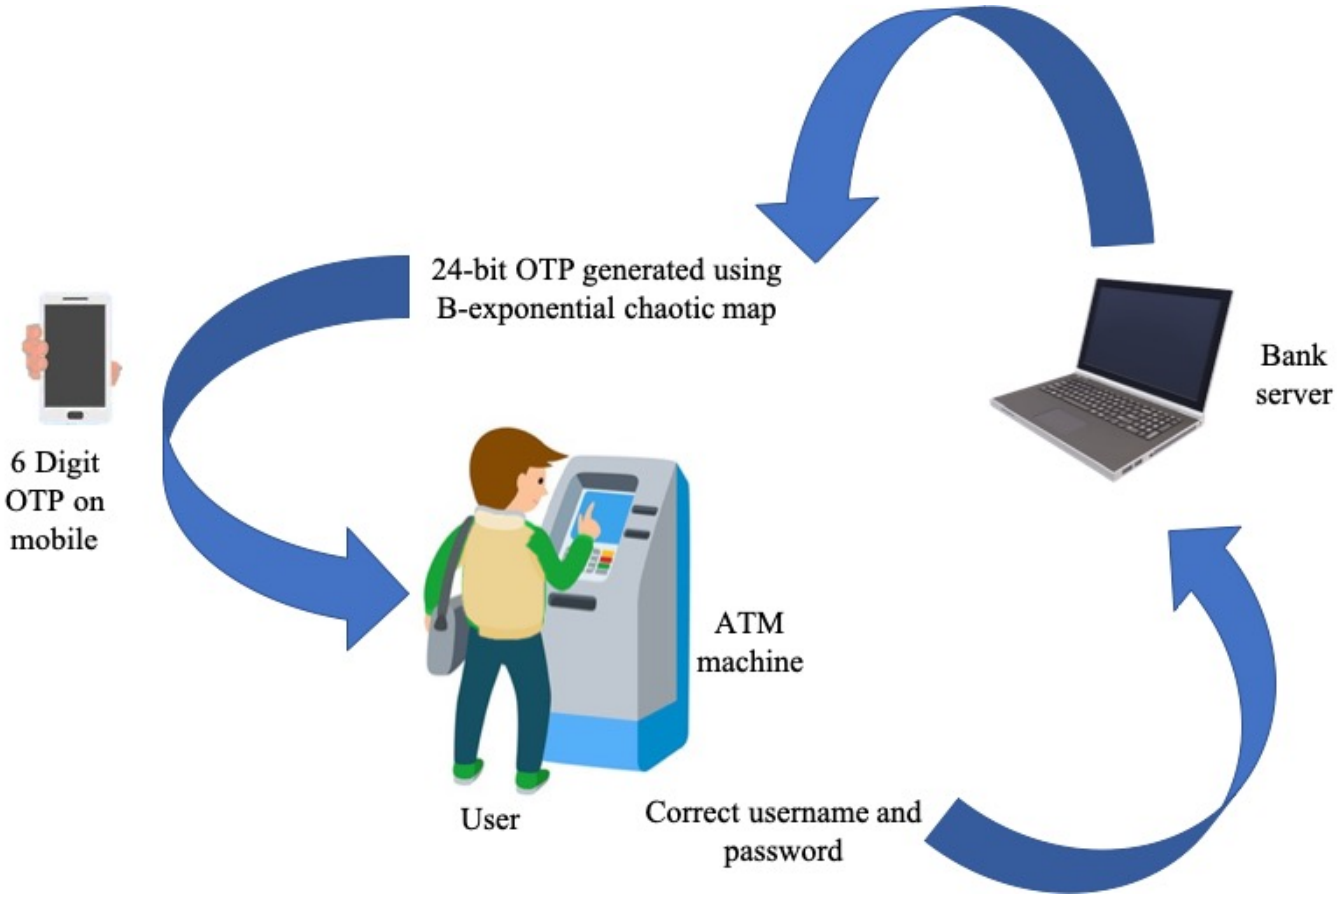

Fig. 1. Concept Diagram of 6-digit (24 bit) OTP Generation using B-exponential Chaotic Map. A user Enters the Correct User Name and Password after Inserting an ATM Card into the Machine. Upon Validation of Correct User Name and Password, Bank Server Generates 24-bit OTP using B-exponential Chaotic Map. This 6-digit OTP is sent on a Registered Mobile Number where the User will Enter the same in the ATM Machine.

(24-bit) OTP using a B-exponential chaotic map. This 6-digit OTP is sent to the user's registered mobile number, which the user enters into the ATM machine. This ensures a transfer to be secured on four levels. The first level is the user must have an ATM card. The second level is the user should know his or her personal username and password. Third, the mobile on which the OTP is sent should be in the network and in the same cell as the ATM machine. Finally, the B-exponential chaotic map is used to generate the time dependant OTP that makes the system more secured.

In this proposed methodology, we have shown how a 6-digit OTP can be generated using a novel B-exponential chaotic map method. Although this method was reported earlier in 2006, no one has ever used it generates a 6-digit OTP and validated using the NIST SP800-22.

We have proposed this system as with the increasing demand for online transactions, there is a need to develop a system that offered higher accuracy and security. The existing systems are more susceptible to brute force attacks. Also, as compared to 4-digit OTP systems 6-digit OTPs provide higher security. There are many ways that OTPs can be created but by using chaotic maps we provide a fast and simple method for OTP generation. Chaotic maps are simple to implement and also produce thousands of bits in a few milliseconds providing more security. They also have a special feature where they create a unique key that allows us to decode the OTP.

The manuscript has been organized into five distinct sections. The first section is the 'Introduction' section. It introduces the need to develop secure OTP systems and also highlights how chaotic maps can be used in them. The 'Literature review' section summarizes the most recent literature available on OTP generation systems. The 'Methodology' section explains in detail the steps we followed to implement our proposed OTP generation system. The 'Results and discussions' section mentions all the results that were obtained while implementing the system and also discusses these results and the future scope of the system. The final 'Conclusion' section briefly summarizes the entire manuscript.

II. Literature Review

Many efforts have been taken by different research groups in order to develop robust OTPs.

Most of the OTP generation techniques suggest time-based OTP [9], [8] and others have used Hash-based Message Authentication Code (HMAC) [10]. Recently, a captcha based OTP [11], real-time eye-tracking based OTP [12] where also proposed. Some of the researchers have also tried a combination of hashed and time-based OTP [9], [13]. RSA SecureID time-bas generates a safe OTP after specific seconds based on

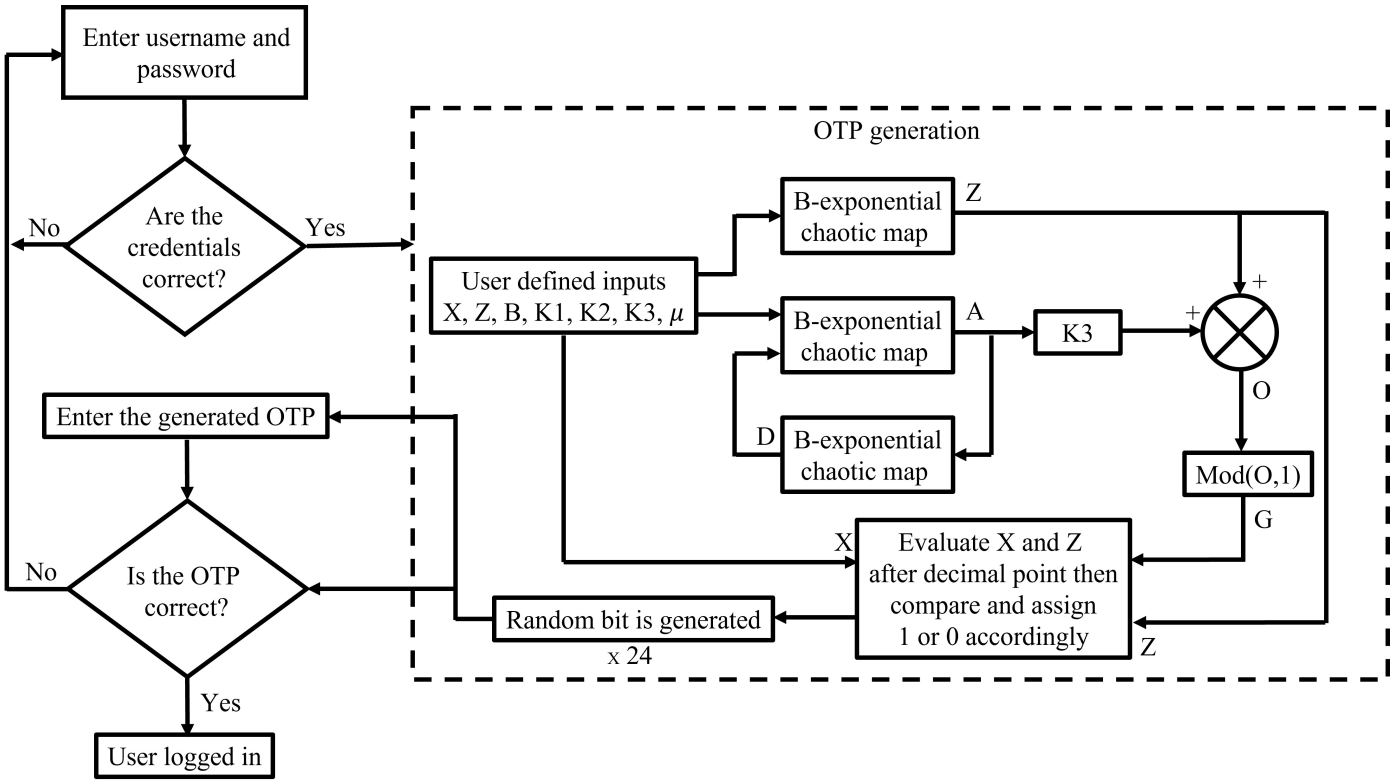

Fig. 2. Flow Diagram of OTP Generation using B-exponential Chaotic Map. The User Enters the User Name and Passwords and its Credentials are Checked. If the Credentials are False then the user is asked to Enter User Name and Password again. If the Credentials are Correct then the OTP Generation Algorithm is called on the Server-side. Once the OTP is Generated, User is asked to Enter that OTP and its Validation is Done. If the User Enters a Valid OTP then the OTP System allows him to Log in, else User Name if prompted for User Name and Password again. During the OTP Generation, User-defined Inputs are Passed through Three B-exponential Chaotic Maps. A Closed-loop Output of the B-exponential Chaotic Map Loop is Weighted and then Added to the Non-loop Output. This Summation is Modulo Operated and then Generated Bit is Evaluated against User Input and B-exponential Chaotic Map Output. The Final Evaluation is One Random Bit and this Process is Repeated 24 Times to Get the Final OTP.

arithmetic functions using the internal clock and stored seed. Each token carries its own initial value or conditions. However, these codes can be hacked because there is no reciprocal authentication. Time-based OTPs suffer from man-in-the-middle attacks. There were some attempts made to generate soft-token systems having unrivaled tamper resistance. Hardware tokens or keyring fobe devices or USB-based tokens with embedded chips were also implemented.

Lamport's technique [14] is the most common algorithm to generate hash chain-based OTPs (HOTP). These techniques are either OTP mechanism based on time to produce the OTP, like the algorithms suggested by El *et al.* [15] and Nugroho *et al.* [16], or hardware-based HOTP algorithm, like Lamport's [14] or S/Key [17].

Despite the widespread use of HOTPs in protocols like Secure Socket Layer (SSL), IPsec, and others. Algorithms used in HOTPs are typically vulnerable to attacks like collision, forging, and birthday attacks [18]. In comparison to time dependant OTPs, HOTP systems have additional flaws like more hashing steps and complicated computations, thus increasing resource utilization. Nontraditional bilinear map-based OTP developed by Lee *et al.* [19] was found to be vulnerable to insider attacks.

Chaotic maps can also be used for implementing other applications. There are many chaotic maps that are available. Akgul *et al.* [20] have proposed a random number generator using chaotic order systems.They test the algorithm with NIST 800-22, Federal Information Processing Standards (FIPS) 140-1, and ENT. Flores *et al.* [21] implemented a chaotic cryptosystem using a multi-precision algorithm. They had used four chaotic maps Rossler, TinkerBell, logistic, and Henon. Saber *et al.* [22] have developed a PRNG using a Lemniscate Chaotic Map (LCM). Deng *et al.* [23] have used chaotic maps to encrypt digital images using a scrambling algorithm.

Chaotic maps are not the only mechanisms for OTP generation. There are many recently reported works that generate OTP in a novel manner. Kumar *et al.* [24] have built an OTP generation system that uses the Vigenère cipher algorithm. They use this algorithm as it is not complex and still provides very high randomness which is required for OTP generation. Goel *et al.* [25] have proposed a system that uses cryptography and cloud computing to create a secured connection for Internet of Things (IoT) systems. They implemented the algorithm on MATLAB software and compared it with other methods. Kadum *et al.* [26] developed a novel OTP generation algorithm by generating an unsystematic key. They have created a random number and then ciphered plaintext. The random key created can make different ciphering texts.

The OTP generation is not only useful for secure banking and transactions but can also be used in encryption as a key.

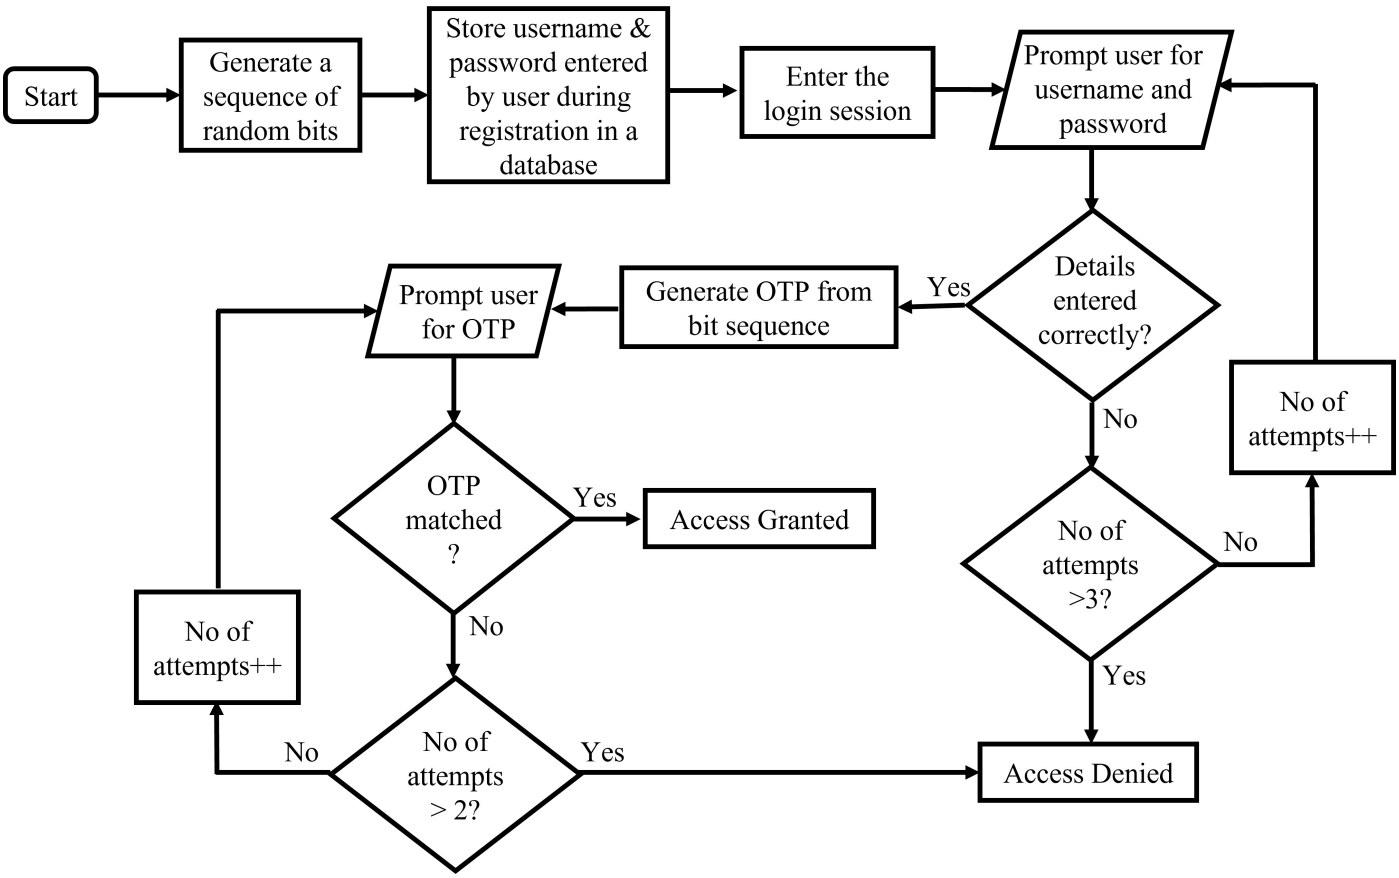

Fig. 3. Flowchart of the Proposed Methodology. A Random Bit Sequence is Generated Anticipatorily to Save Time during the Real-time Execution of the Proposed Method. A Database is Created to Store all the User Names and Passwords. All the Valid User Names and Passwords were Entered into the Database during Registration. A Login Session is Created for the User. The User is Prompted for the User Name and Password. If the Details are Entered Correctly then a 24-bit OTP is Generated else three more Attempts are given to the User before the Access is Denied. Once the OTP Generation is Completed, the User is Prompted for the OTP. If the OTP is Matched, the Access is Granted else two more Attempts are given to the User before the Access is Denied.

Thus a secure OTP generation algorithm will help in other applications as well. Recently, Shakir *et al.* [27] have developed an image encryption system. Using the Haar transform, One-Time Pad, and Playfair algorithms they have created an image encryption algorithm and then applied the Inverse Fourier Transform to get a ciphered image. The decryption is done by reversing the encryption method.

A. Challenges and Limitations of Existing Systems

A hash-based OTP suffers from an attacker who can position himself in front of hash and can access clear private information. A time-based OTP system relies on seed sequence and right counter. Such systems can be vulnerable if an attacker knows the right time and seed sequence. Although, it is very difficult to predict the time in advance as well as seed-sequence determination is still a challenge. physical token have concerns like being stolen, destroyed, running out of batteries, and clock drifting that takes hours to correct. There have been attacks reported using malware and sheet-based phishing.

From the survey done it was seen that the existing methods suffer from various attacks that can put private information at risk. Man-in-the-middle attacks and seed determination attacks are some of the major flaws of these OTP generation systems. Even tokens generated for OTP creation can be hacked into. To work on these drawbacks we have proposed a B-exponential chaotic map-based 6-digit OTP generation technique.

III. Methodology

Fig. 2 shows the flow diagram for OTP generation using a B-exponential chaotic map. According to the concept, when a user enters the username and password, the credentials are checked; if the credentials are incorrect, the user is prompted to enter the username and password again. If the credentials are correct, the server-side OTP generation algorithm is invoked. Once the OTP is generated, the user is prompted to enter it, and the OTP is validated. The OTP system allows the user to log in if he enters a valid OTP. If the OTP entered is incorrect then the user is prompted to enter the username and password again. User-defined inputs are passed through three B-exponential chaotic maps during the OTP generation process. The B-exponential chaotic map loop's closed-loop output is weighted and then added to the non-loop output. This summation is modulo-operated, and the generated bit is compared to the user input and the output of the B-exponential chaotic map. The final evaluation is one random bit, and the process is repeated 24 times to produce the final OTP.

Fig. 4. Different Output Cases. Case (a): In the First Attempt, the User Enters the Wrong Password after which the User is Prompted to Enter the Login Details again. In the Second Attempt, the User Enters the Correct Credentials and is then Prompted to Enter the Generated OTP. Once the Correct OTP is Entered by the User in the First Attempt, they are Granted Access. Case (b): The User Enters the Wrong Credentials in the First Attempt. The User is then Prompted to Enter the Login Details for the Second Time. The Details Entered by the User are Invalid in this Attempt as Well and the User is then Offered a Third Chance. Since the Details Entered in the Third Attempt are also Incorrect, the User is Denied Access. Case (c): Initially the User Enters the Correct Credentials. The User is then Prompted to Enter the Generated OTP. The OTP Entered by the User is Wrong in the First and Second Attempts. Hence, the User is Diverted Back to the Login Page. This Time the User Enters the Correct Login Credentials and OTP and is given Access. Case (d): The User Enters the Incorrect Credentials in the First Two Attempts and is given a Third Chance to Enter the Right Details. Once the User Enters the Right Login Details in the Third Attempt they are Prompted to Enter the OTP. As the OTP Entered by, the OTP Matches the Randomly Generated OTP, the User is Granted Access.

A. OTP Generation using B-exponential Chaotic Map

During the OTP generation, user-defined inputs (X, Z, B, K1, K2, K3, μ) are passed through three B-exponential chaotic maps. The B-exponential chaotic map closed-loop output (A) is weighted (multiplied by K3) and then added to the non-loop output (Z). This summation (O) is modulo-operated by 1, and the generated bit (G) is compared to the user input (X) and the output of the B-exponential chaotic map (Z). The final evaluation is one random bit, and the process is repeated 24 times to produce the final OTP.

B. OTP Generation Process Flow

Fig. 3 shows the flowchart of the proposed methodology. As per this concept, to save time during the proposed method's real-time execution, a random bit sequence is generated ahead of time. A database is created to store all of the usernames and passwords. During registration, all valid usernames and passwords were entered into this database. For the user, a login session is created. The user is prompted to enter his or her username and password. If the details are entered correctly, a 24-bit OTP is generated; otherwise, the user is given three more attempts before access is denied. When the OTP generation is finished, the user is prompted to enter the OTP. If the OTP is matched, access is granted; otherwise, the user is given two more attempts before access is denied.

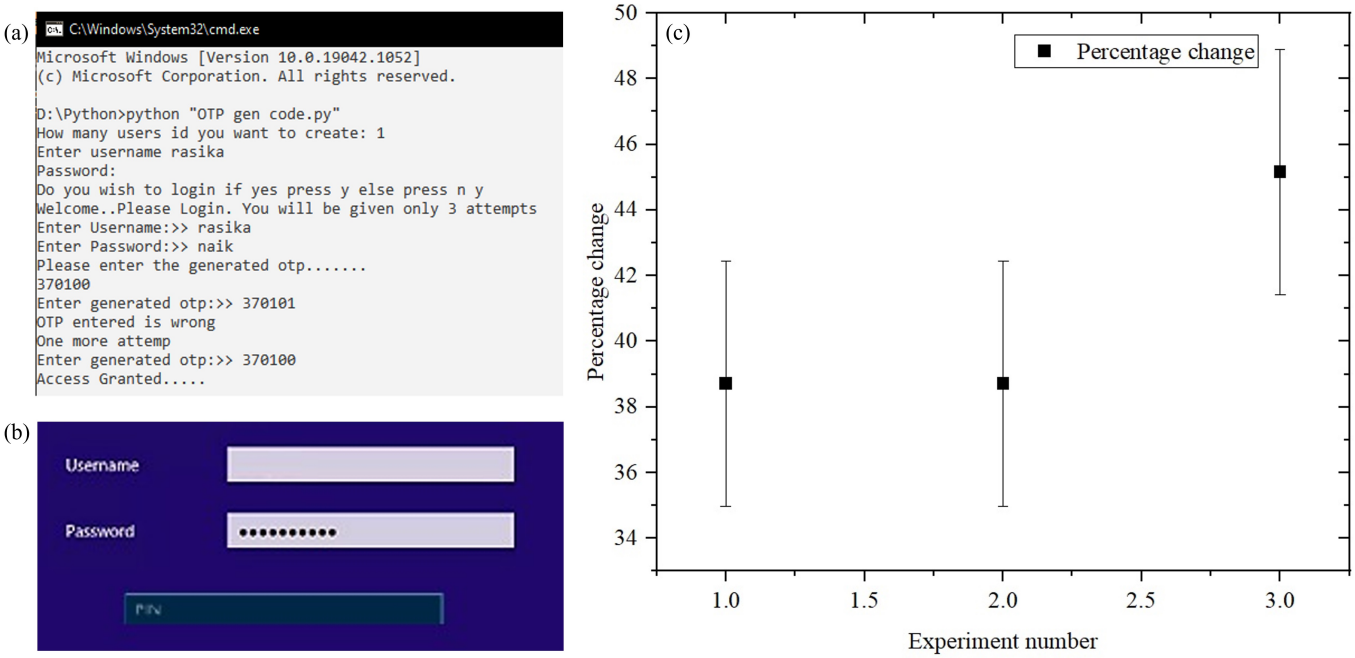

Fig. 5. (a) Console Output shows User has Entered the Right Password, one Wrong OTP and still gets Access Granted since the User has Entered Correct OTP on the Second Attempt. (b) Final Front-end UI showing User Name, Password and Pin. The Password is Masked and the Pin is Deactivated. (c) Different Experiments Carried with User Input Versus Percentage Change in Bits. In the First and Second Attempts, almost 40 % bits were Changed and in the Third Attempt, almost 46 % Bits Changed showing the Time Dependency on the OTP Generation for the same Set of Inputs.

IV. RESULT AND DISCUSSION

Fig. 4 shows the various output scenarios obtained. Initially, the users are given the option to enter the number of login IDs they want to create. They are then asked to enter the login ID and password. This information is stored in a database. Fig. 4(a) shows the first case where the user enters the incorrect password on the first attempt. The user is now left with two more attempts to enter the right credentials. In the second attempt, the user enters the correct credentials. After this, he/she is prompted to enter the OTP generated by the proposed B-exponential chaotic map. The duration of the OTP generation process is 00:01:29 and the entire process takes 00:1:53. Once the OTP is generated by the system and received by the user, he/she is then prompted to enter the OTP. Since the OTP entered by the user matches the generated OTP, the user is granted access. Fig. 4(b) shows the second case where the user enters the incorrect credentials on the first try and is then left with two more attempts to enter the right credentials. On the second attempt, the user enters incorrect details again and is left with only one more try. Here on the third attempt, the user enters the wrong details again and is denied access. Fig. 4(c) shows the third case where the user initially enters the correct credentials. After that, the user is prompted to enter the OTP generated by the proposed B-exponential chaotic map. In the first attempt, the user's OTP is incorrect. This leaves the user with one more attempt to enter the OTP. As the OTP entered by the user does not match the generated OTP, he/she is redirected to the login page. The user is then prompted to enter the login credentials once again. Upon entering the correct credentials in the first attempt the user is prompted to enter the generated OTP. Once the OTP entered by the user matches the generated

TABLE II. COMPARISON BETWEEN THE EXISTING STUDIES REPORTED IN LITERATURE AND THE PROPOSED METHOD. THE ACCURACY IS OBTAINED FROM THE NIST TEST SUITE. OUR PROPOSED METHOD DEMONSTRATED BETTER CORRELATION COEFFICIENT AND ENTROPY THAN THE ONES REPORTED

Method	Accuracy (%)	Correlation coefficient	Entropy
De *et al.* [28]	99	-	-
Flores *et al.* [21]	98.39	-	-
Saber *et al.* [22]	-	0.0014	7.9980

Proposed method	98.45	0.00076	7.9999

OTP, he/she is granted access. This entire process takes a total time of 00:02:45 for completion. Here, the duration of the OTP generation process where the login details and OTP entered by the user are both entered correctly in the first attempt is 00:01:45. Fig. 4(d) shows the fourth case where the user enters the wrong credentials in the first attempt and is left with two more attempts to enter the correct details. As the details entered in the second try are incorrect the user is asked one last time to enter the right details. When the user enters the correct login information on the third try, they are prompted to enter the OTP. the entire process takes 00:1:53. Since the OTP entered by the user matches the OTP generated by the proposed B-exponential chaotic map the user is granted access.

Fig. 5 (a) shows the console output demonstrating the entries made by the user. The user entered the correct password, then entered one incorrect OTP but was still granted access because the correct OTP was entered on the second attempt. Fig. 5(b) shows the final front-end UI, displaying the username, password, and pin. The password has been masked, and the pin has been disabled. Fig. 5(c) shows the graph of user input versus percentage change in bits acquired from performing various experiments. In the first and second attempts, nearly 40 % of the bits were changed, and in the third attempt, nearly 46 % of the bits were changed, demonstrating the time dependency on OTP generation for the same set of inputs.

The proposed system was able to select 24-bits out of 10^8 bits in 89 seconds at 1.09 Kbits/ms. We have also checked the 4-digit password generation using the same B-exponential chaotic map and found that the probability of hacking 4-digital systems is 0.00012 using brute force attack. Whereas, the probability of hacking a 6-digit OTP generation system created using the B-exponential chaotic map was 0.000000991. This shows that the 6-digit OTP system provides 120 times higher security than a 4-digit OTP system. The maximum time-out period observed for the 6-digit OTP generation system was 15 minutes i.e. the OTP has to be reset within 15 minutes before it can become susceptible to brute force attack. The B-exponential chaotic map was also able to obtain a correlation coefficient of 0.00076 and an entropy of 7.9999. This proves that the chaotic map algorithm we have proposed is highly random and can produce secure output.

A. NIST Test Suite Result and Comparison

Table I shows the accuracy obtained for the bit-streams generated. The NIST SP800-22 testing parameters were used for validation purposes. The results obtained were, the system achieved a 98 % accuracy with a p-value of 0.43 and 196 successful attempts out of 200 for the approximate entropy statistical case. For the block frequency test, the system achieved a 99 % accuracy with 198 successful tests out of 200 with a p-value of 0.15. For the forward cumulative sums test, the system showed 97 % accuracy with 194 successful tests out of 200 with a p-value of 0.69. For the backward cumulative sums test, the system achieved a 98 % accuracy with 196 successful tests out of 200 with a p-value of 0.59. In the Fast Fourier Transform (FFT) test, the system successfully passed 196 attempts out of 200 with a 98 % accuracy and a p-value of 0.3. The system achieved 196 successful attempts out of 200 with a 98 % accuracy and p-value of 0.03 for the frequency test. For the linear complexity test, the system achieved a 98 % accuracy with 196 successful tests out of 200 with a p-value of 0.98. In the longest run test, the system successfully passed 196 attempts out of 200 with a 98 % accuracy and a p-value of 0.27. The system achieved 196 successful attempts out of 200 with a 98 % accuracy and p-value of 0.51 for the non-overlapping template test and also achieved 98 % accuracy for the overlapping template test with a p-value of 0.19. In the random excursions test, the system successfully passed 198 attempts out of 200 with a 99 % accuracy with a p-value of 0.43 and in the random excursions variant test it achieved a 99 % accuracy with a p-value of 0.64. The system also achieved a 99 % accuracy in rank parameter test with 198 successful attempts out of 200 and a p-value of 0.67. In the runs test the system was able to achieve a 98 % accuracy with 196 successful attempts out of 200 and a p-value of 0.4. The serial test showed an accuracy of 97.5 % with 195 successful attempts out of 200 with a p-value of 0.17 and the universal test achieved a p-value of 0.38 with a 97 % accuracy with 194 successful attempts out of 200. All the tests were passed with a successful result.

Table II provides a comparison between some of the works reported in the literature that use chaotic maps for different applications and our proposed method. The accuracy of 98.45 % which is obtained as a result of the NIST test suite indicates that our proposed system is one of the best. The correlation coefficient and entropy indicate the randomness of the proposed algorithm. It can be seen that with a 0.00076 correlation coefficient and 7.9999 entropy our system has outperformed the exiting works reported.

B. Data Science and OTP Generation

Chaotic maps are used in applications in which creating confusion in the initial data to encrypt it is required. They are dynamic systems. But due to their chaotic behavior, chaotic maps on their own are generators of huge amounts of random data. These maps lead to the generation of millions of unique

bits before repeating themselves due to their large periodicity. The huge amounts of data and random trajectory that the maps produce make it difficult for hackers to decipher them. Another application of chaotic maps relating to data science is that these maps are capable of encrypting the data available. A vast amount of data is available on the internet today and it is crucial to encrypt it to provide security and avoid hacking attacks. Chaotic maps are also valuable in encrypting images and audio files.

Due to the frequent usage of online websites and online transactions it has become important to secure data. OTP generation using chaotic maps plays a big role in this application. We have seen that OTP generated using chaotic maps is highly unpredictable and secure. This will allow users on the internet to continue secure browsing, protect their data and be safe from hackers.

V. Conclusion

Due to the vulnerabilities in traditional username and password systems, there was a need to develop a more secure system, especially due to the increased use of online transactions during the COVID-19 pandemic. We have developed a 6-digit OTP generation method over traditional 4-digit OTP using a novel B-exponential chaotic map. As the current methods of generating OTPs are time-consuming and uses a large amount of memory on backend servers, we developed a fast and less memory-consuming system. The 4-digit OTP system is limited to 9999 users, but with our 6-digit we could expand this database to 100 times more users which will be suitable for the upcoming 5G technology. The proposed 24-bit (6-digit) long OTP system was able to achieve 120 times more security than traditional 4-digit systems with a faster backend computing system that selected 24-bits out of 10^{8} bits in 89 seconds at 1.09 Kbits/ms. The proposed method is applicable to any online transactions or banking applications.

Mobile Application Aimed at Older Adults to Increase Cognitive Capacity

Ricardo Leon-Ayala, Gerald Gómez-Cortez, Laberiano Andrade-Arenas
Facultad de Ciencias e Ingeniería
Universidad de Ciencias y Humanidades
Lima, Perú

***Abstract*—The research work focuses on people with dementia of the Alzheimer's type, since, among the types of dementia, this is the most common worldwide. In Peru, more than 200 thousand adults over 60 years of age suffer from this disease and many others who still do not know it or are in its initial stage. Therefore, it was decided to create a prototype of a mobile application with memory games, riddles, reminders and different types of physical activities to perform during the day. The scrum methodology was implemented to promote good practices for team and collaborative work, in terms of us phases from inception to launch of the product which is the mobile application. In addition, balsamiq was used as a prototype design tool. And so the objective of creating the prototype for its development was achieved. The goal of creating the prototype for the application was achieved. Positive results were obtained in terms of user and customer satisfaction. This will allow the benefit of adults for the improvement of cognitive ability, being able to perform their daily activities in the best way and socializing with family and friends.**

***Keywords*—Alzheimer's; balsamiq; mobile; prototype; scrum**

I. Introduction

Dementia prevents us from performing the activities of daily living properly, as it is a syndrome that affects memory, understanding and behavior. Worldwide, dementia has become a major public health problem. Risk factors for dementia vary from country to country. It is estimated that the number of new cases of dementia each year worldwide is close to 7.7 million, with one new case every four seconds. Each year, there are 3.6 million new cases (46%) in Asia, 2.3 million (31%) in Europe, 1.2 million (16%) in the Americas and 500,000 (7%) in Africa [1].

Epidemiologists around the world have conducted research on the prevalence of dementia, with predicted estimates coming from a variety of sources, including epidemiological surveys, hospital records and electronic medical record databases. A meta-analysis included 157 epidemiological studies conducted worldwide between 1980 and 2009. The report showed that the prevalence of dementia among people over 60 years of age was 5.8% to 8.0%, showing an exponential increase with age, doubling every five years. A different global meta-analysis study reported similar results, with a prevalence rate of 4.8% for people over 60 and a period prevalence rate of 6.9%.

Although dementia affects the world, it represents a unique danger for Latin American and Caribbean countries compared to the lower, stable and declining prevalence rates in Europe and the United States, the prevalence of dementia in people over 65 years of age in this region of the continent is high, and increasing, between 7.1% and 11.5%. In addition, there are several related risk factors, including significant genetic heterogeneity and social determinants of health [2]. In Peru, according to the Ministry of Health (Minsa) indicated that in 2019 more than 200 thousand people over 60 years of age suffer from dementia. This report was presented by the psychiatrist Manuel Escalante.

Due to the COVID-19 pandemic, the government of Peru, through the former president Martín Alberto Vizcarra Cornejo, has been taking preventive measures since the first wave of this disease, such as the use of masks, face shields, social distancing, etc. One of these provisional measures was social isolation, a strict but necessary posture. In this situation, there was a statistically significant increase in the population in the levels of agitation, depression, appetite, eating disorders, nocturnal behavioral disturbances and aberrant motor activities [1]. It is not yet known what cognitive damage these measures may have caused in the population, according to experts the results of these new routines may be chaotic.

Among the types of dementia, Alzheimer's disease (AD) is the most common, accounting for 60-70% of dementia cases. In the initial stage of AD, cognitive impairment progresses progressively, showing orientation difficulties, language alterations and cognitive dysfunctions. During the course of the disease many psychological symptoms occur in behavior, affecting activities of daily living [3].

According to the author [4], there is an inverse relationship between sedentary time and cognitive ability, although studies on this topic are inconsistent. However, not all sedentary challenges are equal. Passive sedentary behaviors, such as watching television, appear to be harmful; whereas more cognitively stimulating activities, such as reading, using a computer or solving puzzles, are shown to be associated with improved cognitive ability and recognition.

By means of the analysis carried out research work is to develop a mobile application model using basic principles of mental health experts. Enabling the improvement of FE and delaying future Alzheimer's problems in older adults.

The article is made up of sections. In Section II for literature review, in Section III, the methodology was applied to, In Section IV a case study was conducted, in Section V result and discussion, and finally in Section VI the conclusion and future work.

II. Literature Review

The research topic of this article is cognitive ability in older adults, likewise, of the various applications created on the basis of cognitive enhancement, based on this I design an application to enhance the cognitive capacity of older adults through interactive games.

The author [5], reviewed the studies of the last decade in the field of cognitive training using communication and information technologies, also recorded those cognitive improvement strategies and thus evaluated the effectiveness of these programs, that is why I come to the following conclusion, entertainment applications, video games among others could be used in intervention studies for cognitive improvement of healthy or cognitively impaired individuals.

On the other hand, the author [6], It is recognized that there is limited understanding of how older adults use smartphones and how their use changes compared to younger users, in addition, mentions that based on data collected from the telephones of 84 healthy adults during the last three months, the most common characteristic is that they open fewer applications, take longer to perform daily tasks and send fewer text messages, then a cognitive analysis was performed on each respondent and it turns out that 79% had cognitive impairment, This is why their study suggests that researchers and developers should take cognitive impairment into account when developing any type of project.

On the other hand, according to the author [7], tells us that taking into account the illnesses of people due to their age, an application consisting of four modules was developed: news, reasoning games, reasoning questions and a calendar. The app was put to the test and the results show that there is an increased interest in memory games and entertaining brain games.

According to the author [8], modern cell phones have generated new interactive scenarios that require complex interfaces. The major operating system developers of these devices provide APIs for developers to implement their own apps, including different solutions for graphical interfaces, sensor control and voice interaction. While these resources are useful, there is no clear strategy to combine the multimodal interface with the possibilities offered by the device to identify and adapt to user needs, which is particularly important in areas such as environmentally assisted living.

In addition, the author [9], argues that digital apps for seniors should be evaluated to support senior independence and home care. Apps provide increasing opportunities for older adults and their family caregivers to educate, participate and share health information through digital platforms. Few applications have recorded evidence of availability for the elderly and their caregivers. By conducting a survey, the author concluded that technology use among older adults and caregivers was high. Usability and engagement of the mobile application was average. Additional training is needed for older adults and their caregivers, including that on specific behaviors for digital maintenance.

In conclusion, the good contributions of the authors mentioned for the development of this topic were analyzed, also, certain shortcomings were observed in the interactivity with the application, so a new contribution will be added by applying what was analyzed and incorporating new knowledge.

III. Methodology

In order to carry out the research, the agile Scrum methodology was used, is considered agile because it uses incremental and iterative process approaches. On the other hand, has proven to be more useful than the traditional waterfall model because it improves the productivity of the processes and helps to reduce the time consumed for their realization. In a traditional waterfall model, planning is performed prior to testing, in addition, the process is managed in phases and once it has been completed, it is not possible to return to the previous phase. On the other hand, Scrum at any stage changes can be made to improve the outcome. In Fig. 1, the Scrum flow is shown [10].

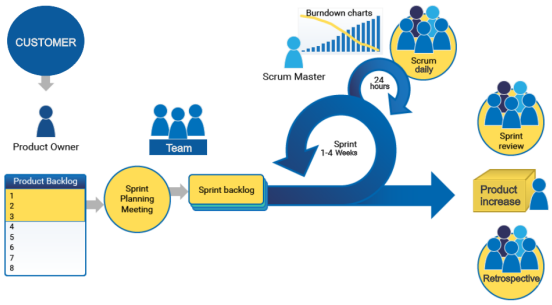

Fig. 1. Scrum Flow.

A. Scrum

The use of scrum involves integrating roles between work teams, an advantage of using scrum is that it allows teams to adapt quickly to manage and plan their work, since, each step of scrum allows you to plan, design, develop and test the code, all these activities are divided between roles [10], Fig. 2 shows the roles proposed by Scrum [11].

Scrum has three roles: Product Owner, Scrum Master and the Team:

1) The Product Owner: For this role, the manager is responsible for the definition and prioritization of the client's needs, in addition to communicating all the information of the client's requirements to the entire team and in this way maximize the value of the product.

2) The Scrum Master: Who assumes the role is the "Servant Leader" of the team, also known as moderator, is responsible for solving problems of the team, also motivates the same to develop its activities.

3) The Team: For this role, the person in charge is the entire team in charge of the development of the project, usually made up of 3 or 9 members. It is responsible for making the deliverables established in the Product Backlog, on the other hand, a characteristic of the team is its proactivity, ability to multitask and have the necessary knowledge to help in the activities of its colleagues [12].

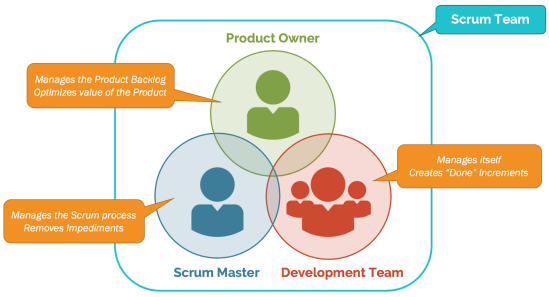

Fig. 2. Roles in Scrum.

B. Scrum Practices

Scrum has practices also called Scrum formalities: Daily Meeting, Sprint Review, Sprint Planning and Sprint Retrospective Meetings:

1) Daily Meeting: The meeting is held every day, the team discusses the problems and the process of the project.

2) Sprint Review: A meeting is held in which the team presents the results at the end of each Sprint to the owner.

3) Sprint Planning Meetings: A meeting is held to define the activities to be carried out during a Sprint.

4) Sprint Retrospective: The entire Scrum team meets with the objective of evaluating the team's performance during the Sprint and the practices to be carried out to improve team productivity [12].

C. Structure of Scrum Development

1) Requirements Stage: It is established to obtain the project planning requirements.

2) Definition of User Stories: It is the description of the functionality of the system, for which the requirements are analyzed in collaboration between the client and the team, the user stories will be improved throughout the life of the project.

3) User Stories Prioritization: The priority of each of the user stories is established and the order in which they will be developed is determined, taking into account which one is the most fundamental for the project and thus following a hierarchy [13].

4) Analogous Estimation: When the user stories are obtained, they go through an examination where the use of a tool or estimation method is required, this consists of a study of each of the user stories concerning the time that the scrum team believes it can develop it, this phase involves both time and the resources and expenses that may be required.

5) Definition of Sprint Speed: The speed and time of development of each Sprint is performed through an analysis that varies according to the experience of the Scrum team [14].

6) Creation of the Product Backlog: User stories, priorities and required tasks are included in a Product Backlog. t includes the features or short term requirements and long term functionalities that have been defined jointly by the development team and Product Owner, moreover, the points or level of effort for each task are established. During the Sprint process, assigned tasks are movable depending on the Product Owner's requirements [15].

7) Sprint Presentation: The Sprint is presented according to the requirements and the determined times, in this phase, the scrum team performs tests on what is presented and it is either accepted or rejected, this is repeated according to the number of sprints a project contains [16].

8) Feedback: At the end of the project or each sprint, the scrum team holds a feedback meeting where they analyze everything developed in order to know their successes and failures in all aspects, para poder mejorar en un próximo proyecto o Sprint.

D. Development Tools

1) Kotlin Programming Language: Kotlin is a programming language with 100% interoperability with Java that combines functionality and object oriented features so that developers can use it. Write a new file in an existing Java project or write a new file Use Kotlin applications from scratch. In addition, the official IDE is used for android development [17].

2) Android Studio: The Android operating system is a linux-based open source software, this means that it can be used by anyone for free and free of charge. It was developed primarily for portable devices, including tablets and smartphones. Its architecture allows compatibility with the Java language. Ever since the first version of Android 1.0 was released in 2008, have been developing it up to version 11. Android studio is being powered by IntelliJ IDEA, what is integrated development Environment (IDE) [18]. IntelliJ IDEA's contribution makes it even simpler to create Android applications.

3) FireBase: Firebase is a web application platform. Helping developers create quality applications. The data are stored as objects using the JSON format. Firebase does not depend on the most common queries, how to add, insert, delete or update. This tool is basically a backend for your system, used to store data used to store the data and use it according to your needs [19].

4) Balsamiq: It is software used to create diagrams of a web page, which is widely used by application designers [20]. Balsamiq encourages us to focus on the structure and content of a website, avoiding position and detail errors, at the same time it allows us to create prototypes quickly, recreating the experience of a computer board [21].

IV. Case Study

A. Start-up Stage

1) Requirements Identification: Table II lists the functional requirements of the system., based on the survey and results shown in Table I.

2) User Stories: Table II shows the list of User Stories created based on the functional requirements shown in Table II.

TABLE I. REQUIREMENTS LIST

N°	Requirements
R-1	The application must have a section that allows me to register or log in with an alternative account, Gmail, Facebook, etc.
R-2	The application should perform a test where I evaluate the phase in which I am in encounter, early stage, middle stage or final stage.
R-3	The application allows me to select the preferred activities depending on the phase I'm in.
R-4	The application must show my progress during its use, in order to be able to evaluate my improvement during the use of the application.
R-5	The application should show me recommendations, advice or information based on my results or the phase I am in.
R-6	The application must have activities that include logic and mathematics.
R-7	The application should have a game customization stage to improve my user experience.
R-8	The application must show my results at the end of each section or activity.

TABLE II. USER STORIES

N°	User Stories
H1	As a user, I want the application to allow me to login or register to have access to all functionalities..
H2	As a user, I want the application to have a test or entry game to know what stage I am in.
H3	As a user, I would like to have different sections where I can evaluate my knowledge according to the stage I am in to perform the activities your preferences.
H4	I as a user, I want the application to show my progress as I use the application to see my progress over time.
H5	As a user, I want the application to suggest activities, information and recommendations based on my results to improve my current state.
H6	I, as a user, want the application to include mental reasoning games to improve my cognitive memory.
H7	I as a user, I want the application to allow me to customize the games to enhance my user experience.
H8	As a user, I want the application to show me the results at the end of each section to observe my performance in each activity.

B. Planning Phase

1) Analog Estimation: At this stage, the complexity estimate is made with respect to the development of each story, for this purpose, the rating range is from 1 to 13, 1 is the lowest level of complexity and 13 is the highest. he estimation is based on H1, since this is where the "Login" is developed, then by way of example, H5 is located in column 5, which indicates that H5 is 5 times more complex to develop than H1, the same logic applies to the other stories. Thanks to the analog estimation, an idea of the functional development of each story for a future project was presented. To arrive at the following result, the work team held a discussion on the estimation of each story, were also classified according to personal criteria. As shown in Table III.

TABLE III. ANALOG ESTIMATION

	1	2	3	5	8	13
H1	1-Login					
H2						13-Login
H3						13-Login
H4		2-Login				
H5				5-Login		
H6					8-Login	
H7				5-Login		
H8			3-Login			

2) User Stories Prioritization: In order to arrive at the following result, the work team performed an analysis of each story to determine those that are most relevant to the operation of the mobile application, that is, is sorted according to priority, as shown in Table IV in the first column all the user stories are ordered, then the second column contains the information obtained in Table III, and each estimate is added according to the corresponding history and finally, in the last column, the prioritization is carried out, for this it is considered that user stories are important to develop first for the correct functioning of the application.

TABLE IV. USER STORIES PRIORITIZATION

User Stories	
H-U	Priority
H1	1
H2	2
H3	3
H4	4
H5	5
H6	6
H7	7
H8	8

3) Definition of Sprint Speed and History Points: In order to carry out the following chart it was decided together with the development team to divide the Sprint into three deliverables, also details which user stories belong to each Sprint, for example, H1 and H2 belong to Sprint 1. As shown in Fig. 3, Sprint 1 has 14 points, this result was obtained thanks to the information in Table IV, the effort points obtained by the stories were added up there, H1 only obtained 1 point and H2 13 points, Adding both values together gives the result. The sprint speed refers to the estimated time for the completion of a sprint, speed is determined by the development team, the equipment is new, is why at the beginning the speed is high, however, Sprint 3 the speed slows down as the team is already more consolidated.

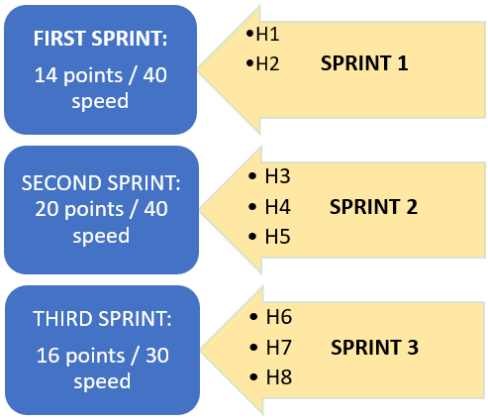

Fig. 3. History and Speed Points.

The Sprint Backlog table shows the three Sprint with their respective functionality to be developed, also, the estimated time for its development is defined. Estimated project development time is 3 months and 2 weeks. also, deliverables are completed in a shorter time. All this is shown in Table V:

4) Creation of the Product Backlog: For the creation of the complete backlog, ordered according to their history and priority, likewise, in the "Sprint" column, each story is sorted

TABLE V. SPRINT BACKLOG

Interface	Duration
Cognitive memory enhancement application	3 months and 2 weeks
Sprint 1: Login Interface	1 week
Sprint1: Registration Interface	1 week
Sprint 1: Home Interface	2 week
Sprint 1: Input evaluation	2 weeks
Sprint 2: Creation of activities	2 weeks
sprint 2: Creation of interactive games	2 weeks
Sprint 3: Activity customization functionalities	2 weeks
Sprint 3: Results reports	2 weeks

according to which Sprint it belongs to, is why it has been numbered from 1 to 4. Finally, the Estimate is listed from 1 to 13, and this information is obtained from the analog estimating Table. The Product Backlog is shown in Table VI.

TABLE VI. PRODUCT BACKLOG

User Stories	Priority	Sprint	Estimation
H1: As a user, I want the application to allow me to login or register to have access to all functionalities.	1	1	1
H2: As a user, I want the application to have a test or entry game to know what stage I am in.	2	1	5
H3: As a user, I would like to have different sections where I can evaluate my knowledge according to the stage I am in to perform the activities I prefer.	3	2	13
H4: As a user, I want the application to show my progress depending on how long I have been using the application to see how much progress I have made.	4	2	2
H5: As a user, I want the application to suggest activities, information and recommendations based on my results to improve my current state.	5	2	5
H6: As a user, I want the application to include mental reasoning games to improve my cognitive memory.	6	3	8
H7: As a user, I want the application to allow me to customize the games to improve my user experience.	7	3	5
H8: As a user, I want the application to show me the results at the end of each section to observe my performance in each activity.	8	3	3

V. RESULT AND DISCUSSION

A. Presentation of Prototypes by user Stories

This stage presents the design of the prototypes created based on the requirements and user stories, in order to graphically represent the functionalities of the application.

First Sprint: As shown in Fig. 3, the first sprint has a total of 14 story points, the estimated time is one month and two weeks.

H1: I as a user, I want the application to allow me to login or register to have access to all functionalities. As shown in Fig. 4, the option to log in via Facebook and Gmail has been implemented, also, in Fig. 5, in case you do not have any of the accounts you have the option to register to start using the application.

H2: I as a user, I want the application to have a test or entry game to know what stage I am in. After logging in, the application automatically directs you to a 10-activity entry test to assess your current status (see Fig. 6), the app presents you with several interactive games, among them the following stand out: 4 pictures one word, crossword puzzles, mathematical problems, sound recognition (sounds of animals, things, instruments, etc.). in addition, each test has a time limit for answering. These are shown in Fig. 4 and Fig. 5.

Fig. 4. Login Screen.

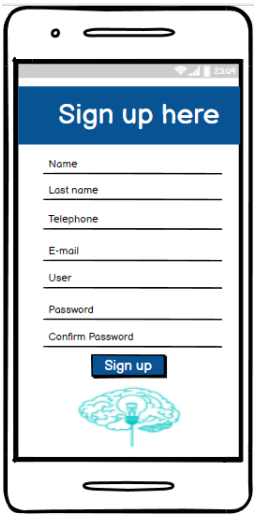

Fig. 5. Registration Screen.

At the end of the test, the results are shown, in the initial part it shows you where you are based on your results, Fig. 8 shows that at the end of the 10 activities, at the top shows you the result, in this case the status is ”Initial”, which indicates that the tests were performed in the estimated optimal time.

Second sprint:

H3: As a user, I would like to have different sections where I can evaluate my knowledge according to the phase I am in to perform the activities I prefer. As shown in Fig. 9, 6 interactive games have been developed for this story, which are intended to stimulate the mental agility of our users.

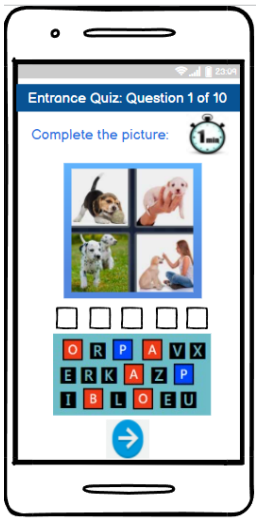

Fig. 6. Question 1 of the Test.

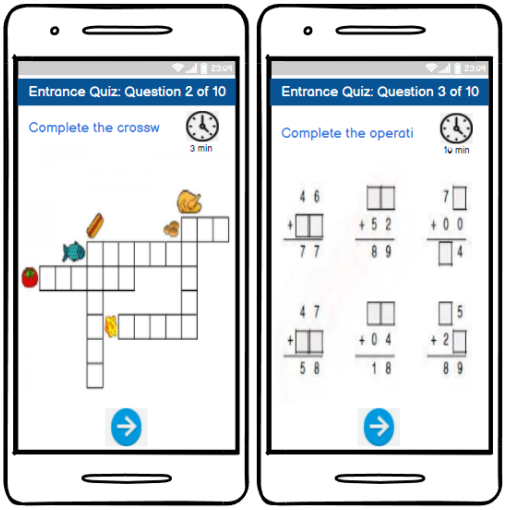

Fig. 7. Test Questions 2 and 3.

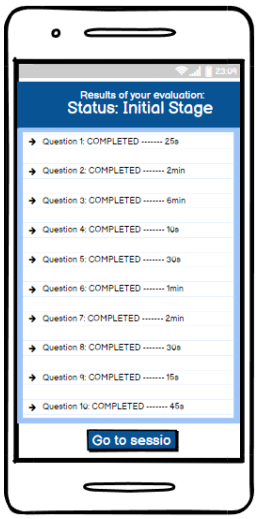

Fig. 8. Entry Test Results.

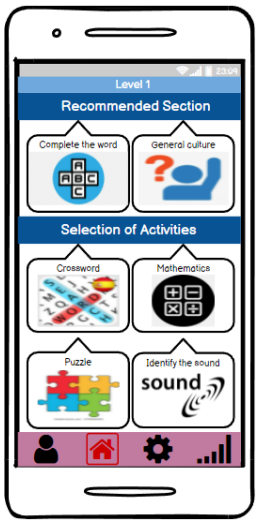

Fig. 9. Games Section.

H4: As a user, I want the application to show my progress depending on how long I have been using the application to see how much I have progressed, this functionality was implemented through general and game levels. When you select a game the app directs you to an interface where you find all the levels, this stage was designed for the user to progress over time, to pass to the next level you must necessarily finish the previous level. As you progress through the games your overall level will increase. this section is shown in Fig. 10.

H5: I, as a user, want the application to suggest activities, information and recommendations based on my results to improve my current state. As shown in Fig. 9, this can be seen in the initial part, where it is shown that "Complete the word" and "General culture" are the recommended games, this recommendation depends on your initial test result and your current condition.

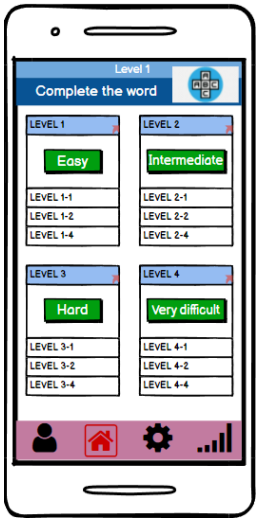

Fig. 10. Game Levels Section.

Third Sprint:

H6: I as a user, I want the application to include mental

reasoning games to improve my cognitive memory. As shown in Fig. 7, n this section, mathematical reasoning problems are developed, since the team considers that it is essential to maintain an active mind.

H7: I as a user, I want the application to allow me to customize the games to improve my user experience. As shown in Fig. 11, this section allows the user to customize all games, you can change the background of each image, this function was implemented in order to make the user more familiar with the app by including images of their choice, also, has the option to include custom music for each game, since music is an active stimulant of the mind and influences the mood generally in a positive way.

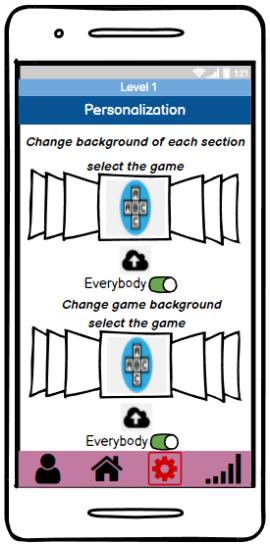

Fig. 11. Customize Games.

H8: I, as a user, want the application to show me the results at the end of each section to observe my performance in each activity. As shown in Fig. 12, this section shows the user's progress in each game, depending on the time of use, this information varies depending on the time of use. The information presented is updated daily and shows the results of the last month, order to allow users to graphically observe their progress and thus motivate them to continue making progress.

All the prototypes shown in the research were validated by testing the functionality.

B. Comparison between Methodologies

The following are a series of methodologies, which have different standards, covering all aspects of requirements, development, design and quality. Table VII shows a comparison of the requirements considered for each method studied. In this table, agile methodologies are compared, as well as with traditional methodology; This allows us to know the importance of the use of scrum in research.

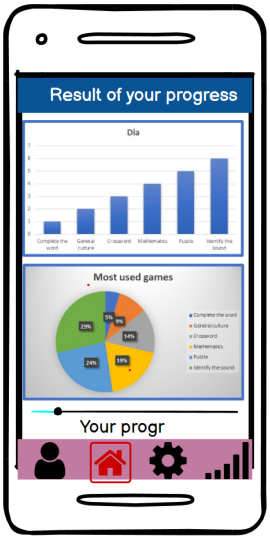

Fig. 12. Result of the use of the Games.

1) Assessment between Methodologies: Table VIII shows the evaluation of the methodologies studied and the scores obtained. The criteria are scored 1, 3, and 5, with 1 = low, 3 = medium, and 5 = high. The criteria have allowed a score to be made according to the methodology under study, where the scrum methodology obtained the highest score. In addition, Table IX shows the 11 questions asked in the survey; this allowed for an exhaustive analysis.

C. Analysis of the Survey Carried out for user Stories

For the creation of the requirements, a survey of 35 people between 35 and 60 years of age was conducted, using the GoogleForms tool, the survey was conducted directly from their cell phones. The following questions were created by the development team in order to know the user's preferences. Table I shows the questions asked to the 35 respondents.

In Fig. 13, the results and user presence can be seen, thanks to this information, the functional requirements of the application were created, the following are the most relevant results for the system.

Of the 35 people surveyed, 31 prefer that the application allows you to log in through an alternative account: Gmail or Facebook, this is why it is necessary to implement this functionality in the system.

Of the 35 people surveyed, 32 agree with the creation of an initial test, which should be developed in order to determine the user's level: "Beginner", "Intermediate" or "Moderate".

D. Analysis of Each Sprint using Burndown Chart

At this stage, each Sprint was analyzed with the help of a graph, the X-axis shows the time range, which has a duration of 1 month and 2 weeks (42 days). The Y-axis shows the score for Sprint 1, the analogous estimate seen in Table VI indicates that it has a total of 14 history points. The Blue line is the expected result and the Orange line is the actual result.

TABLE VII. COMPARISON OF METHODOLOGIES

	METHODOLOGIES		
CRITERIA	**SCRUM**	**RUP**	**XP**
Description	A model that is strengthened by the active participation of all project members.	Characterized by the iterative and incremental model.	Extreme programming model, allowing for the incorporation of new functionalities.
Type of Review	A daily review is needed, analyzing the following: 1. Work done the day before. 2. Work to be performed. 3. Tasks with impairments or that can be performed.	In this methodology, the phases are developed one after the other, thus perfecting the objectives. If a phase is not completed, the next phase is not continued.	It must be integrated at least once a day, and tests must be performed on the entire process.
Objectives	Suitable for projects in complex environments: Innovation and competitiveness. Get fast results. Changing requirements.	Object-oriented that establishes the basis, templates and examples for all aspects and phases of software development.	Defined by giving priority to work with direct results. Customer satisfaction. Group work. Acting on variables: Cost, time, quality and scope.
Stages	Planning. Mounting. Development. Release.	Home. Prepared by. Construction. Transition.	Define roles Estimate the effort Choosing what to build Program Repeat.
Characteristics of the model	Increased active customer collaboration.	Focuses on using use cases with an incremental model.	Emphasis on Programming.

TABLE VIII. EVALUATION BY PROCESSING CRITERIA

	METHODOLOGIES		
CRITERIA	**SCRUM**	**RUP**	**XP**
KNOWLEDGE	5	5	3
TIME	5	1	5
ADAPTABLE	5	5	5
APPLICABLE	5	3	5
TOTALS	20	14	18

This leads to the conclusion that the team at the time was not consistent in its work, since the actual line is not lines, has inconsistent variations, also, the Sprint was successfully completed, this is shown in Fig. 14.

For Sprint 2, has a total of 20 story points, with a duration of 1 month (28 days). As shown in Fig. 15, the development of the project was carried out with a higher consistency, the first two weeks progress was slow and from the second week onwards the activity intensified until the Sprint was finally completed.

Finally, in Sprint 3, has a total of 16 history points, in addition, has a duration of 1 month (28 days). At this stage of the project, the team is already consolidated, since, as can be seen the expected time and the actual time does not vary much compared to the first Sprint, which indicates a greater commitment of the team to the project, the activities were developed gradually until the end. As can be seen in Fig. 16.

TABLE IX. QUESTIONS ASKED OF RESPONDENTS

No	Survey Questions
1	Have you played games that are based on strategy to win?
2	Would you like the application to allow you to enter through your Gmail account?
3	Would you like the application to take an entrance test to know if you are in the ”initial”, ”medium” or ”moderate” stage?
4	Would you like the application to include basic math operations?
5	Have you solved solving puzzles and riddles? health?
6	Would you like an application that allows you to play your favorite songs? for the diagnosis?
7	Would you like to have several games within the application?
8	Would you like to see your progress after a certain time of use of the application
9	Would you like the application to show you the results of your progress in a graph?
10	Would you like to include levels of difficulty for each game?
11	Do you think an application can improve your cognitive memory?

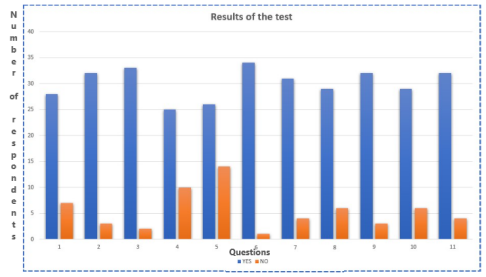

Fig. 13. Results of the Survey.

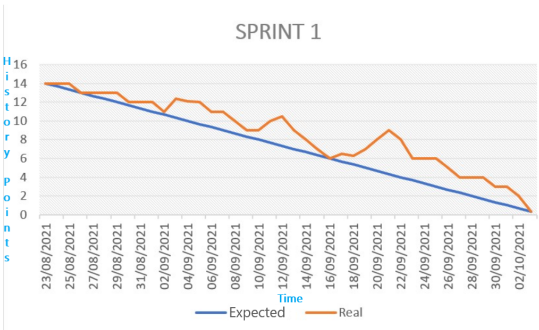

Fig. 14. Result of the First Sprint.

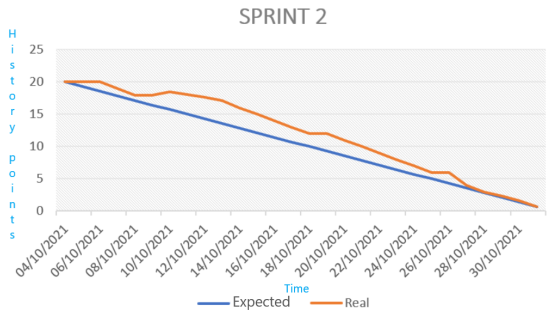

Fig. 15. Result of the Second Sprint.

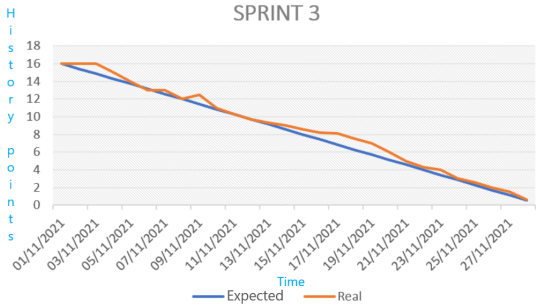

Fig. 16. Third Sprint Result.

E. Analysis of Electronic Glasses to Improve Vision

In the research, the design of glasses is presented whose objective is to improve the vision of the elderly, applying various technologies [22], including the use of augmented reality, real-time motion sensors and the use of GPS, among others, as seen in Fig. 17 and Fig. 18. The development of this research [23], will be of great help to those older adults who consume applications from their Smartphone, including our application, since it would be a pity if due to visual problems it is not possible to use our application, that is why the development of electronic glasses is a complement to take into account when thinking about the scope and comfort of the user.

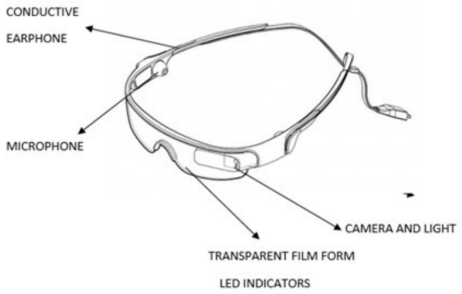

Fig. 17. Design of the Electronic Glasses [23].

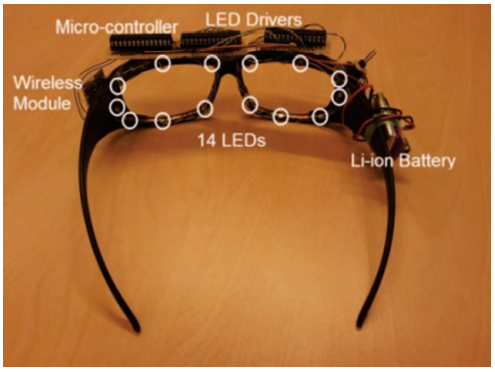

Fig. 18. LED Indicators Implanted in the Frame of the Glasses [23].

VI. Conclusion and Future Work

The research work concludes that a mobile application prototype has been developed to improve cognitive ability in older adults. The research contribution will allow the improvement of the health of these citizens. Using the Scrum methodology and applying the Balsamiq design tool, the functionalities required by the respondents were successfully represented.

In terms of methodology, the Scrum framework was of vital importance, since it allows a high-value sequential development, thus improving the quality of the application. In addition, the variety of tables and graphs provided by Scrum are the key to presenting information clearly and accurately.

In the future, it is expected that this research will be complemented with the development of a mobile application implementing the use of Artificial Intelligence to improve the initial diagnosis, also, it is suggested to apply all the steps presented above and in this way make the application a reality, as it will be very useful for people in the early stages of Alzheimer's disease, thus preventing the disease from progressing. It is expected that this mobile application will soon contribute to the health sector and be of great help to people.

Implementation of an Expert System for Automated Symptom Consultation in Perú

Gilson Vasquez Torres, Luis Lunarejo Aponte, Laberiano Andrade-Arenas
Facultad de Ciencias e Ingeniería
Universidad de Ciencias y Humanidades
Lima, Perú

***Abstract*—The human being has a fragile life, and is attacked by different diseases throughout his life, neglecting or ignoring some of them because it is considered minimal, can be fatal, but many do not want to attend a health center, so they seek your symptoms on the Internet and finding pages with false information, that is the problem that we will address in this investigation. The objective of the research is to implement an expert system, creating a web page that provides real information when a user enters their symptoms. This was achieved based on the logic of rules developed in Prolog, so when a user fills out the created questionnaire, the expert system will follow. the rules to conclude with the desired diagnosis; all these steps were carried out using the buchanan methodology. The result was an improvement in the accessibility of truthful information through the Internet, facilitating the management of appointments of users if they have a serious illness, or the treatment in case of a minor illness. The beneficiaries of the research were the population that required the use of the automated query application.**

***Keywords*—Automated query; buchanan; expert system; prolog; symptoms**

I. Introduction

Since the end of 2019, there is no person who has not been affected by the pandemic experienced, every area of life itself was changed in many ways, the general population is in a state of constant alarm and concern as to whether they are sick from COVID-19 or not [1].

Globally, there were waves of excessive contagions, which brought high peaks of death, in addition, very few people considered that the COVID-19 is not the only disease in recent years, even in the midst of the pandemic, people were struggling with other diseases, from the simplest [2] , such as the common flu, to the strongest and deadliest, such as cancer.

It is for all this that millions of individuals in Peru and the world resort to the use of the Internet to learn about their illness, by entering their symptoms in the search engine of their choice, in order to get immediate help, and in most cases, proceed to self-medication to avoid the cost of medical appointments or time spent in the hospital [3].

Many times when resorting to unreliable sites, people are exposed to receive information that can be harmful to them, since many of these diagnoses are written by bloggers or people who did not have a higher education and who do not have the appropriate knowledge to derive a clinical solution [4].

The main objective is the creation and implementation of a system through a web page with accurate information, this would be achieved by affiliating doctors as editors, in addition to having a relationship with a nearby medical center for prompt attention [5] [6]. The aim is to classify the patient's level of need for care, whether he/she can be treated using telemedicine or referred to a face-to-face appointment .

To achieve the best selection for the benefit of the user, at the time of putting their symptoms, is through an expert system, which is a branch of artificial intelligence [7], that allows decision making based on a set of rules, so when a patient indicates their ailment, the system will select the diagnosis with more matches [8].

The resulting benefits are the clearest, both for the person himself, because at last, he will have a place where he can have a solution to his health problem and that it is also reliable and, on the other hand, it is very beneficial for the network of hospitals and clinics affiliated to the website [9], because they will have a greater number of patients .

On the other hand, another of the great benefits that we obtain by applying directly on a web page, is the direct interaction with the user. Peru is a country with a large sector of poverty, not everyone can buy expensive devices for downloading mobile applications, but websites are more accessible to all Peruvian citizens [10]. At a general level, there is a need to modernize the prompt care of the population, especially in a health crisis, such as a pandemic.

The paper is structured as follows: in Section II, the literature review; in Section III, the methodology, where the steps to be carried out are indicated; in Section IV the results and discussions; finally in Section V the conclusion and future work.

II. Literature Review

The research principle allows the visualization in a global way, how expanded and well executed the digital format related to the health area is, speaking specifically about the search for symptoms and treatments for non-lethal situations, in the current context of the pandemic. The number of searches on websites has multiplied, to know for sure if the symptoms suffered by a person could be a serious illness, but when doing this search for symptoms on the Internet we are faced with a main problem, of finding a sea of pages with erroneous or unverified content.

With respect the subject of study, research shows the great growth of internet searches on health issues, being this way that [11] Jozsef in its research on Health Information on the

Internet, tells us that research has revealed that more and more Internet users are accessing health-related websites to search for health information and are relying on it to answer their health questions. Therefore, in the following study [12] it is confirmed that Internet searches can help people find not only the symptoms of the disease, but also various treatment options, this information is largely hosted in social media communities such as blogs, social networks, e-mails, among others [13].

Based on this, it is known that there is a need for the population to understand the medical situation they are going through, Macrohon in a study on real-time COVID-19 data visualization and information [3] reveals that studies have shown that people of all age groups search the Internet for information about their health, illnesses, care and treatment, in addition, a great variety of texts, images, graphics, files and audio and video applications that are uploaded on different websites, supported by the poor knowledge of people on health issues, affects people's search for information, since this information is of low quality and from not very credible sources.

Knowing that most of the health information found on the internet is not very reliable [12] Waltters in a study on virtual clinic care in these pandemic times, I affirm that the websites and health-related information on the internet show inconsistent quality with incorrect data and unreliable sources, the medical community has therefore begun to question the reliability of using websites to search for information.

For this reason [11] indicates that professionals who are in charge of developing websites to provide health services with respect to people's health, focusing on the needs of the users, this help is necessary to eliminate any health ignorance.

On the other hand, in the following study on the adaptation of an expert system for medical diagnosis [14] it was found that at present most websites are not properly prepared to provide health information. Many of the sites studied violated the basic guidelines for remote access, whether mobile or web, and non-governmental sites have proven to be in a better position to adapt to the new needs of patients. This is, a limitation of cyber resources for the population, so the state or government web pages related to health must adapt to the new changes quickly in order to meet the needs of the population.

To put the situation of the websites in order, author Muhammand in his research on web-based clinic management system compared by scores the level of information of the websites [15] These showed us that the level of help provided is directly referential to the type of search, which means that there are searches that will be helpful and useful, such as searching for beneficial help on websites, but a lower percentage of useful information and help on personal help sites [16].

Reviewing other research can see that in addition to being able to score the various health sites, they were also rated by percentage of truthfulness, as in the following study on user participation in health websites, [17] shows a worrying result, 87.2% of the pages that have been examined are not verified and do not have official code certificates, which could result in false information about the current health crisis in the world. Entities should improve their satellite education dissemination system as soon as possible, which would make more people literate in the area of health and personal care.

Finally, must be clear that the population is looking for a lot of information on health food care, [18] this recent study revealed that websites in Europe do not have good information quality despite having unique criteria patterns. It should be noted that only half of the websites had correct information.

In addition, the following research on the digital inclusion of health information websites [18] tells us that none of the websites found in this study had nutritional advice that met the quality criteria 100%. In conclusion, several works have been analyzed, including scientific articles and theses. Objective to implement an expert system for automatic symptom queries.

Applying an expert system in the healthcare area is an important step in obtaining reliable medical diagnoses. At this time, people are putting their physical and mental health at risk by consulting symptoms of any kind on the Internet. What intend with this research is to establish a reliable source for anyone who wants quick help. Any person would only have to go online, enter their symptoms and the system would automatically determine what these people suffer from, helping a lot to make decisions, to go to a medical center or buy basic medicines that do not require a prescription.

III. Methodology

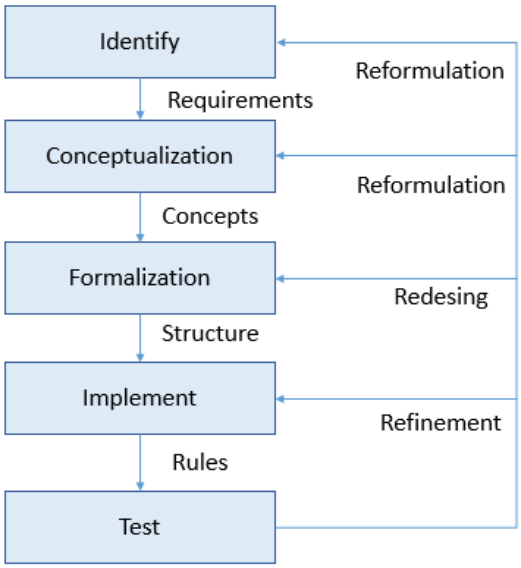

Fig. 1. Methodology Buchanan.

A. Stages of the Methodology

For the development of the expert system was used the BUCHANAN methodology shown in Fig.1. Which is a methodology based on the cascade life cycle that was used in the beginnings of software engineering, with this it is deduced that the process of construction or development of the expert

system will be carried out with a process of almost constant revision since this methodology follows the software (expert system) in its different phases [19] , which make a hierarchical life cycle; these are defined in 6 modules.

1) Identification: In this step the participants, roles, actors to build the system and their functions in the construction are identified. At this stage, the available resources and sources of knowledge are also identified, as well as the objectives or goals of the expert system.

2) Conceptualization: The knowledge of the field expert is described, knowledge obtained for the project, in order to delimit the system, this to identify and characterize the problem, the scope of the expert system is defined, this means that the specific problems to be solved by the expert system must be specified.

3) Formalization: The structure of the expert system is obtained, and with the problem well defined, was begin to identify what is required to be done in the different functions or tasks to be solved by the expert system, relevant and important concepts are identified, as well as the result of formalizing the conceptual information diagram the Bayesian network, which will be used to identify the rules of the expert system, at this stage of the methodology, the specifications are defined to first build the prototype of the knowledge base.

4) Implementation: This step begins with the development of the expert system, based on the data previously obtained, such as the identification of the study variables, the tasks of the expert system, the use cases, the Bayesian Network, the rules, among others, then the programming language will be chosen,the programming environment, which is the choice of the set of programs for the realization of the project and finally the general organization of the development, all this allows an adequate creation of the knowledge base of the expert system and of the prototype to be tested in the following step [20].

5) Test: Having the prototype, observe the behavior it has during its execution, and the key points that analyze are, the operation of the knowledge base, that is, how it reacts to the information it processes within the system and the second point is the structure of inferences, which is the response it has in the interaction.

B. Methodology Development

1) Identification:

- Problem:
  Currently, there is no website adequate to the needs of people who search for their symptoms on the Internet, and even less, an expert system that can provide a reliable basic diagnosis for the user to make health care decisions.
- Solution:
  Propose the creation of a rule-based expert system with the utility to provide basic diagnostics for a virtual triage process, thus streamlining existing medical consultations.
- Familiarization with the Domain:
  In order to carry out the familiarization and mastery, the face-to-face triage process was studied with all the corresponding procedures. Once the problems and domains have been identified, continue with the development of the expert system tasks.
- Expert System Tasks
  - Enable to register patients to the system, this module is shown in the Fig. 2.
  - Allows triage from home, a module shown on the Fig. 3.
  - To allow through a module the learning of the expert system, in order to continue expanding the knowledge base.
  - Allow the system to diagnose possible disease based on the patient's symptoms, diagnosis module.
  - Enable the system to display the results of the diagnostic, as shown in the Fig. 4.

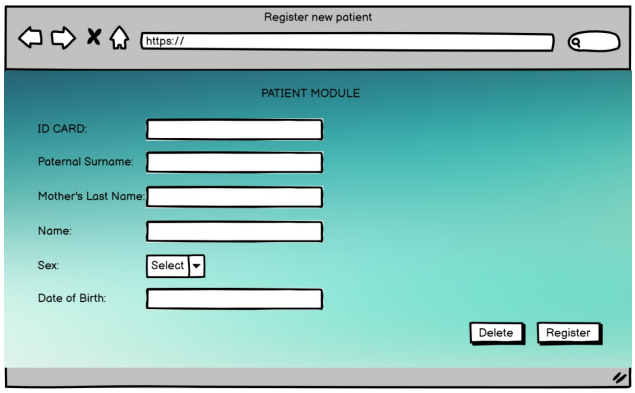

Fig. 2. Patient Registration Module.

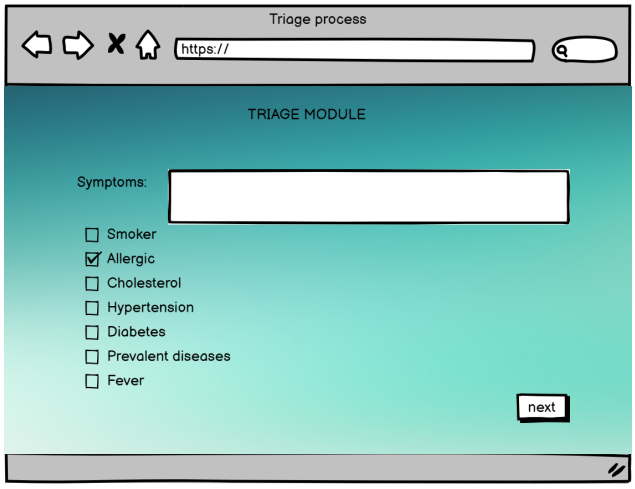

Fig. 3. Triage Module.

2) Conceptualization: In this stage of the methodology, proceeded to obtain the knowledge of the expert system, qualitative information was needed for the research, this to be able to apply it in the rule-based model to be used, from the different models that can be applied for decision-based structures, the Bayesian network was chosen, to be able to use this model and implement it in the expert system for the creation of the knowledge base, the target variable was

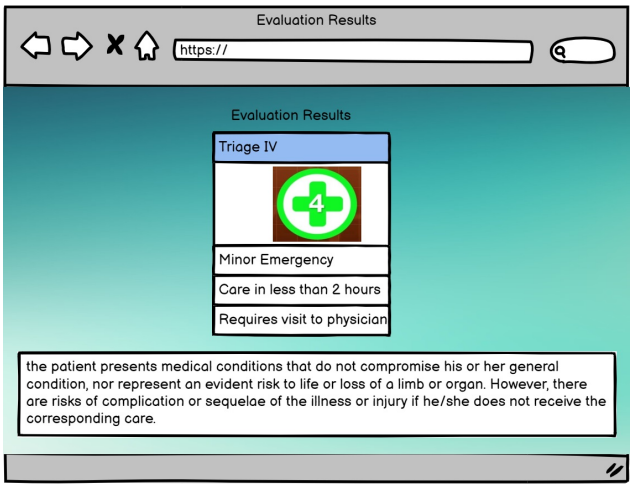

Fig. 4. Result Module.

identified as shown in Table I, as well as the observation variables that are specified in Table II, once these 2 variables were identified, the knowledge base will be created.

- Target Variable: As shown in Table I.

TABLE I. IDENTIFICATION OF THE TARGET VARIABLE

Description	Variable	Range
Symptom consultation	Triage Priority(PT)	Triage I, Triage II,Triage III, Triage IV, Triage V

- Observation Variables: As shown in Table II.

TABLE II. IDENTIFICATION OF OBSERVATION VARIABLES

Nro	Description	Variable	Range
1	Age	ED	Under Age, Adult
2	Can walk	CA	Yes, No
3	Over Weight	SP	Yes, No
4	Allergy	AL	Yes, No
5	Smoke Cigarettes	FU	Yes, No
6	Cholesterol	CO	Yes, No
7	Can Speak	HA	Yes, No
8	Fever	FI	Yes, No
9	Muscle pains	DM	Yes, No
10	Hypertension	HI	Yes, No
11	You can obey simple orders	OB	Yes, No
12	Diabetes	DI	Yes, No
13	Prevalent Diseases	EP	Yes, No
14	High pressure	PA	Yes, No
15	Can Breathe	RE	Yes, No
16	Dizziness	MA	Yes, No
17	Nausea	NA	Yes, No
18	Loss of Memory	PM	Yes, No
19	Blurred Vision	VB	Yes, No
20	Vital Signs	VB	Yes, No

3) Formalization: For this stage of the methodology, having already identified the target variable and the observation variable in the previous step, was proceed to build the chosen graphical model, which is the "Bayesian network" as shown in Fig. 5. this model is developed according to the symptoms identified in the previous section. At this stage, by using the Bayesian network graphical model, knowledge base presentation created, for this we identify the rules of inference that will be used for the construction of the knowledge base through logic programming, it should be noted that this stage of the methodology is important because it establishes the rules of inference that are used for the solution of the problem posed, the criteria for the development of the rules of inference is observed in Table III and to culminate in this stage is the one that establishes everything necessary for the implementation stage of the expert system in prolog.

Rules of inference

• Ruler 1 YES (Walk and YES SP1 and No AL and No FU and No CO) THEN TN-V
• Ruler 2 YES (Walk and YES SP1 and YES AL and No FU and No CO) THEN TN-V
• Ruler 3 YES (Walk and YES SP1 and No AL and YES FU and No CO) THEN TN-V
• Ruler 4 YES (Walk and YES SP1 and No AL and no FU and YES CO) THEN TN-V
• Ruler 5 YES (Walk and YES SP1 and YES AL and YES FU and No CO) THEN TN-V
• Ruler 6 YES (Walk and YES SP1 and YES AL and No FU and YES CO) THEN TN-V
• Ruler 7 YES (Walk and YES SP1 and No AL and YES FU and YES CO) THEN TN-V
• Ruler 8 YES (Walk and YES SP1 and YES AL and YES FU and YES CO) THEN TN-V
• Ruler 9 YES (Walk and No SP1 and No AL and No FU and No CO) THEN TN-V
• Ruler 10 YES (Walk and No SP1 and YES AL and No FU and No CO) THEN TN-V
• Ruler 11 YES (Walk and No SP1 and No AL and YES FU and No CO) THEN TN-V
• Ruler 12 YES (Walk and No SP1 and No AL and no FU and SI CO) THEN TN-V
• Ruler 13 YES (Walk and No SP1 and YES AL and YES FU and No CO) THEN TN-V
• Ruler 14 YES (Walk and No SP1 and YES AL and No FU and YES CO) THEN TN-V
• Ruler 15 YES (Walk and No SP1 and No AL and YES FU and YES CO) THEN TN-V
• Ruler 16 YES (Walk and No SP1 and YES AL and YES FU and YES CO) THEN TN-V
• Ruler 17 No (Walk and YES HA and YES SP1 and No FI and No DM and No HI) THEN TN-IV
• Ruler 18 No (Walk and YES HA and YES SP1 and YES FI and No DM and No HI) THEN TN-IV
• Ruler 19 No (Walk and YES HA and YES SP1 and No FI and YES DM and No HI) THEN TN-IV
• Ruler 20 No (Walk and YES HA and YES SP1 and No FI and No DM and YES HI) THEN TN-IV

IV. RESULT AND DISCUSSION

1) Implementation: In this step of the methodology chose to develop the Prolog expert system that gives us the tools for logic programming, this system was connected to a web environment interface that will be implemented in netbeans and will be supported by a SQL database. As step I the specifications of the use case of the system were defined.

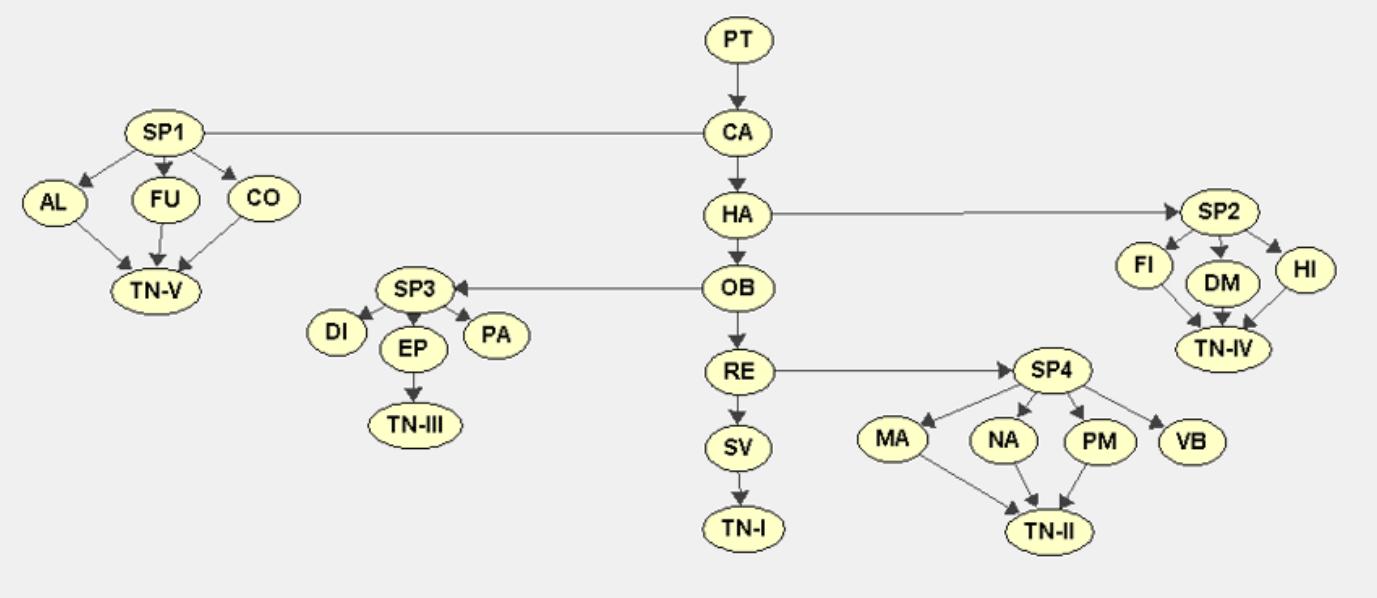

Fig. 5. Knowledge base: Graphical Model Bayesian Network.

TABLE III. RULES OF INFERENCE

Rule	Age	Weight	Commom diseases	Cholesterol	Hypertension	Memory loss	Diagnosis
Rule1	MA	Yes	Yes	Yes	No	Yes	TN-I

TABLE IV. USE CASE MODULE REGISTER PATIENT

Use Case	Register Patient	
Code	CU01	
Target	Allow to register new patients in the database, in order to obtain a better diagnosis from the expert system.	
Preconditions	The user must be logged in.The user must have permission to access this module.	
Post conditions	The patient's data is recorded.	
Actors	User	
Main Flow	1.	User logs in to the system.
	2.	The user accesses the patient module.
	3.	The user presses the add button of the patient module.
	4.	The system displays the form to register the patient.
	5.	The user enters the patient's DNI, surname and first name, sex, age, date of birth and then clicks on the add button.
	6.	The system stores the patient.
Performance	High.	
Frequency	Infrequent.	
Priority	High.	

- Patient registration use case: This use case is going to allow registering patients in the database, a procedure that was performed to obtain a better diagnosis from the expert system, this can be seen in Table IV.
- Search patient use case: This use case allows the user to be able to search for patients registered in the system, as shown in Table V.
- Add triage variable use case: Use case that allows the user to add new variables for the triage process, as shown in Table VI.
- Register symptom use case: Use case that allows the user to register new symptoms that are the knowledge base for the expert system, as shown in Table VII.
- Search symptom use case: Use case that allows the user to search and list the symptoms registered in the system, with their respective characteristics, as shown in Table VIII.
- Use case obtain diagnosis: Use case that allows the user to carry out the process of diagnosing the patient, this is done by selecting the symptoms presented by the patient, as shown in Table IX.
- Consult diagnosis use case: Use case that allows the user to consult the patient's diagnosis together with a possible treatment, as shown in Table X.

This database was created in order to store the data obtained from the patient's admission as well as the results obtained from each patient's consultation to the expert system, thus expanding the knowledge base, it contains the following tables with which the database diagram shown in Fig. 6 was generated.

- Patient Table.

TABLE V. USE CASE SEARCH FOR PATIENT

Use Case	Patient Search	
Code	CU02	
Target	Allow the user to search, consult patients registered in the system.	
Preconditions	The user must be logged in.The user must have permission to access this module.	
Post conditions	Patient data is displayed.	
Actors	User	
Main Flow	1.	User logs in to the system.
	2.	The user accesses the patient module.
	3.	The user clicks on the search button and enters the DNI of the patient to search for.
	4.	The system displays the form to register the patient.
Performance	High.	
Frequency	Infrequent.	
Priority	High.	

TABLE VI. USE CASE ADD TRIAGE VARIABLE

Use Case	Add triage variables	
Code	CU03	
Target	Allow user to add variables for the triage process.	
Preconditions	The user must be logged in.The user must have permission to access this module.	
Post conditions	Data was saved correctly.	
Actors	User	
Main Flow	1.	User logs in to the system.
	2.	The user accesses the triage module and presses the add button.
	3.	The system displays a form to add more triage variables.
	4.	The user fills in the data and clicks on save.
	5.	The system stores the information.
Performance	High.	
Frequency	Infrequent.	
Priority	High.	

TABLE VII. USE CASE REGISTER SYMPTOM

Use Case	Record symptom	
Code	CU04	
Target	Allow user to register new symptoms (knowledge base).	
Preconditions	The user must be logged in.The user must have permission to access this module.	
Post conditions	The symptom is recorded.	
Actors	User	
Main Flow	1.	The user accesses the symptoms module.
	2.	The user clicks on the add new symptom button.
	3.	The user enters the symptom code, name, description, then clicks the add button.
	4.	The symptom is saved in the system.
Performance	High.	
Frequency	Infrequent.	
Priority	High.	

TABLE VIII. USE CASE SEARCH FOR SYMPTOM

Use Case	Record symptom	
Code	CU05	
Target	Allow the user to search for the symptoms registered in the system.	
Preconditions	The user must be logged in.The user must have permission to access this module.	
Post conditions	The searched symptom is displayed in a table.	
Actors	User	
Main Flow	1.	The user accesses the symptoms module.
	2.	The user clicks on the search symptom button and enters the symptom to search for.
	3.	The system displays a table with the searched symptom and its respective characteristics.
Performance	High.	
Frequency	Infrequent.	
Priority	High.	

TABLE IX. USE CASE GET DIAGNOSTIC

Use Case	Obtain diagnosis	
Code	CU06	
Target	Allow the user to make the diagnosis to the patient, by means of the choices of the symptoms presented by the patient.	
Preconditions	The user must be logged in.The user must have permission to access this module.	
Post conditions	Not applicable.	
Actors	User, system.	
Main Flow	1.	The user enters the diagnostic module.
	2.	The user clicks on the test button.
	3.	The system redirects to a page where the patient triage process is performed first.
	4.	The system initiates the diagnostic process by means of a test.
	5.	The user enters the patient's symptoms.
	6.	The system displays the results of the diagnosis.
Performance	High.	
Frequency	Infrequent.	
Priority	High.	

TABLE X. USE CASE CONSULT DIAGNOSTICS

Use Case	Consult diagnosis	
Code	CU07	
Target	Allow the user to query the patient's diagnosis by displaying a treatment.	
Preconditions	Perform CU10.	
Post conditions	Not applicable.	
Actors	User	
Main Flow	1.	The user enters the diagnostic module.
	2.	The user clicks on the search button and enters the patient's ID number.
	3.	The system displays the results of the diagnosis performed, providing a possible treatment.
Performance	High.	
Frequency	Infrequent.	
Priority	High.

2) Test: In this stage of the methodology the expert system developed in prolog was tested based on the rules established in the Bayesian network, starting with the statement of facts as shown in Fig. 7 where the first step was to enter the possible symptoms that a patient may have for the triage process, as well as the symptoms that the expert system will handle for this stage of the development process, this part is very important because they are the statements regarding the knowledge base, then the rules were typed as shown in Fig. 8. The rules are the knowledge representation of the expert system that is expressed in natural language and through a conditional, in this case to determine a diagnosis the rules evaluate the symptoms of the knowledge base together with the symptoms that the patient is going to perform and compares them with a priority of attention, which allowed to obtain a good diagnosis. Subsequently, the web application interface was developed, which can be seen in Fig. 9. In order to make the system

Fig. 8. Expert System Rules.

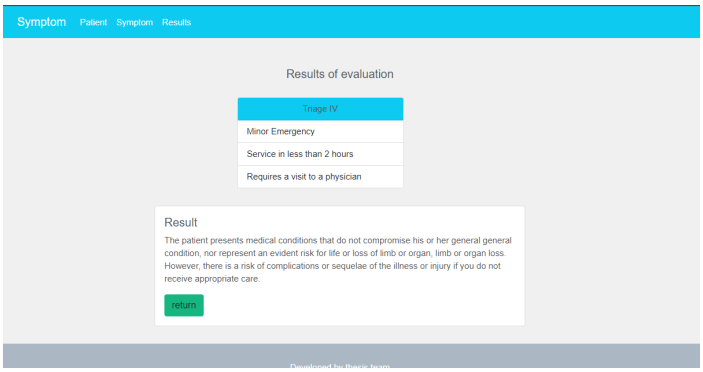

Fig. 9. Test Result.

usable, intuitive and generate a comfortable experience for the user, this interface displays the results obtained from the expert system.

3) Symptom Comparisons on the Web: The results in terms of internet search show interesting data such as for example that the words in terms of search for symptoms related to COVID-19, such as fever, dry cough, sore throat, are the most searched on the web to corporation of other diseases or symptoms such as could be allergy or any other, in Fig. 10. shows the trend of internet search with respect to some symptoms, in this graph you can see that among the symptoms or diseases shown, the term COVID-19 has been the most searched during the last 4 months from July to October 2021, it should be noted that these data are only from searches made in Peru, these data are important to know because they indicate that there is a high trend with respect to queries on the web related to health issues.

V. Conclusion and Future Work

As a final part of this research, it is concluded that there is a perpetual need for digital improvement in healthcare, people will only be able to change their way of thinking by obtaining truthful sources of diagnosis, when they are presented quickly.

The implemented system is a good short term solution that helps to put an end to the problem of the lack of information

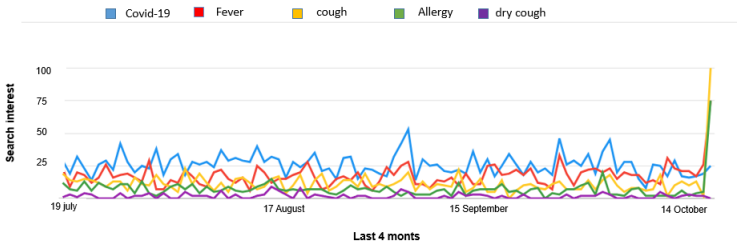

Fig. 10. Comparative Symptom Search.

sources and successfully benefits all types of users, both those who want to search for diagnoses and appointments on the web, as well as those who want to offer their health services, both hospitals and clinics.

For future work, we recommend analyzing well the sequence pattern that needs to be regulated, the logical aspect is one of the most representative parts of the expert system, the rules must comply with a specific and well-structured order. It is recommended to continue with the investigation applying other types of machine learning algorithms.

Implementation of a Web System to Detect Anemia in Children of Peru

Ricardo Leon Ayala, Noe Vicente Rosas, Laberiano Andrade-Arenas
Facultad de Ciencias e Ingeniería
Universidad de Ciencias y Humanidades
Lima, Perú

***Abstract*—Now-a-days, anemia is considered a worldwide problem that not only seriously affects our health, but also has economic and social consequences. Therefore, seeks to provide a solution to the problem to detect anemia with a non-invasive method quickly, simple and low-cost way. In this research work, a web system was designed applying the scrum methodology to detect anemia and simplify the detection process of anemia in Peruvian children. In addition, this study shows as a result a technological prototype that helped in the diagnosis of anemia ; at the same time it provides food recommendations to patients to combat anemia efficiently, with a variety of recipes and ingredients that are available in any home, helping in the recovery process. In addition, the analysis carried out on children with anemia in Peru is shown, where it is known that Puno is the most affected department. With respect to the capital Lima, the most affected district is Callao. However, this amount is expected to drop considerably in the coming years.**

***Keywords*—Anemia; diagnosis; health; scrum; web system**

I. Introduction

Anemia is considered today a global problem, which not only seriously affects health, but also has economic and social consequences. Anemia is characterized by a decrease in the level of red blood cells or by an abnormal reduction in hemoglobin of less than 11 g/dl for children under 6 years of age and 12 g/dl for children over 6 years of age [1]. Therefore, it is currently known that 2 billion people suffer from this disease worldwide [2].

A review of studies, conducted in 19 European countries, found that between 2 and 25 percent of children aged 6 to 12 months were iron deficient. In addition [3], preschool children in low- and middle-income countries are estimated to be anemia.

On the other hand, a diagnosis carried out on 112714 children, indicated that the low consumption of iron in food is one of the main causes of infant anemia in India. Since 80% of children between 12 and 23 months had anemia and 69.5% of children under 5 years of age were anemics [4].

Peru, is no exception [5], since anemia in the country is mostly found in the low-income Andean regions, since several studies affirm that the population of approximately 463 districts has this disease, which is a major problem that threatens public health.

The Ministry of Health [6], published a report, indicating that 6 out of 10 children between 6 and 12 months of age have anemia, a worrying situation that requires further follow-up.

As we know, children are more prone to anemia, and this is due to iron deficiency, the same happens with children under 12 months, in premature infants anemia occurs in the first months of life [7]. In addition, it was identified that Puno, Pasco, Cusco, Loreto, Ucayali and Madre de Dios are the places most affected by anemia [8]. For this reason, this research work offers a viable solution to the problem of anemia, using a web system, in order to contribute to the reduction of the high percentage of anemia in Peru.

The proposed research, seeks to provide a solution to the problem, to detect anemia with a non-invasive method, in a fast, simple and low-cost way. It allows us to reduce the process of blood analysis, leaving aside the conventional invasive methods to measure hemoglobin levels and identify anemia. Thanks to the use of technology, anemic children under 8 years of age are easily recognized in Peru, thus reducing the impact of that disease on society and treating it at the earliest possible stage.

The objective of the research, is to design and develop a web-based system, applying the scrum methodology, to non-invasively detect and simplify the process of detecting anemia in children in Peru.

This research work is conformed as follows: Section II presents the Literature Review. Section III defines the methodology to be applied to the project and defines each stage in a theoretical way. Section IV describes the case study, Section V describes and shows the result and discussion obtained. Finally, Section VI defines the conclusion and future work.

II. Literature Review

The problem of anemia in children is common today, both in Lima and in the province for different reasons. The different results, methodologies and limitations found in the different articles on anemia in children are analyzed below.

The application of expert systems is applied in different fields, such as the following article [9]. In it applied expert systems oriented to deep learning. Applying artificial intelligence and taking into account the best known models such as the neural network in the short and long term. They carried out the prediction by collecting information to perform the training of the model, in addition, this information helped them to discover more accurate patterns. To demonstrate the effectiveness of the predictive model, they applied this knowledge in the field of air pollution and power generation. In both cases the prediction had a high success rate when comparing the results with real data.

On the other hand, according to research [10], indicates that the development of a non-invasive mobile application based on the pulse oximetry method and the use of a sensor, based on oxygen saturation values and hemoglobin concentration, can detect anemia in children, facilitating and benefiting the low-income population, since parents who suspect that their children may have anemia, have to submit them to clinical examinations, which are usually expensive and require specialized equipment. Adding to this, the vast majority of children with this disease are in rural areas with few resources, which makes it a bit complicated to have enough money to carry out the corresponding tests.

In other words [11], the creation of a mobile application and the use of additional tools would help to simplify the process of diagnosing anemia in an easy, simple and non-invasive way, making it accessible to anyone with no prior medical knowledge and low resources. However, in another research, another method is described to detect anemia in a non-invasive way by incorporating an algorithm based on neural networks in the mobile application, to detect hemoglobin levels by simply taking pictures of the fingertips.

Similarly, in the following thesis [12], presented an app, that provides recommendations to reduce poor nutrition, in case of anemia, in children in the school "Apostle of Punchauca", the mobile application was developed in order to reduce cases of anemia, source of information for parents, in addition, to prevent future cases of anemia in children, which is why thanks to its application they were made aware of the risks of anemia, how to combat it and know how to identify it.

In the same way, another research, details that used a similar methodology as the previous author, highlighting that the development of the application, with an image analysis algorithm, that analyzes the color data and image metadata allows quantitative and non-invasive self-mea,surement of hemoglobin levels in the patient's blood with high accuracy without the need for any accessories or calibration equipment [13].

On the other hand, [14] also implements a server-side algorithm to process the collected data, employing machine learning algorithms, that are trained using deep learning concepts to enable it to publish accurate results by simply analyzing fingertip color. The author [2] considers that anemia is originated when the concentration of hemoglobin within the red blood cells it is below normal.

In conclusion, different research works have been studied with similar methods that have successfully achieved the proposed objectives. Thanks to this, can highlight that the use of algorithms allows a more accurate diagnosis to detect anemia with a non-invasive method, achieved with the help of technology allowing access to any person.

III. Methodology

The agile scrum methodology, was used for the elaboration of this research work. It is considered agile because it uses incremental and iterative process approaches. On the other hand, it has proven to be more useful than the traditional waterfall model, because it improves the productivity of the processes and helps to reduce the time consumed for its realization. In a traditional waterfall model, planning is done before testing, and the process is managed in phases and once it is done, it is not possible to go back to the previous phase. On the other hand, scrum can make changes at any stage to improve results [15]. The scrum flow is shown in Fig. 1.

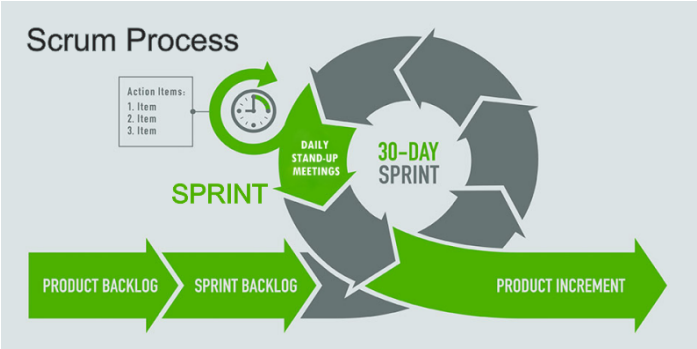

Fig. 1. Scrum Flow.

A. Scrum

The use of scrum involves integrating roles between teams, an advantage of using scrum is that it allows teams to adapt quickly to manage and plan their work, since each step of scrum allows you to plan, design, develop and test the code, all these activities are divided between the following roles [15]

B. Scrum Practices

Scrum has practices, also called Scrum formalities: Daily Meeting, Sprint Review, Sprint Planning Meetings and Sprint Retrospective [16]:

1) Daily Meeting: The meeting is held every day, where the team discusses the problems and the process of the project

2) Sprint Review: A meeting is held in which the team presents the results at the end of each Sprint to the owner.

3) Sprint Planning Meetings: A meeting is held to define the activities to be carried out during a Sprint.

4) Sprint Retrospective: A meeting is held to evaluate the team's unemployment during the Sprint and the practices to be carried out in order to improve team productivity.

C. Scrum Development Structure

1) Requirements Stage: It is established to obtain the planning requirements of the project.

2) Definition of User Stories: It is the description of the functionality of the system, for this the requirements are analyzed, in collaboration between the client and the team, the user stories will be improved throughout the life of the project.

3) User Stories Prioritization: The priority of each of the user stories [17], is established and the order in which they be developed is determined, taking into account which is the most fundamental for the project and thus following a hierarchy.

4) Analogous Estimation: When the user stories are obtained, they go through an examination, where the use of a tool or an estimation method is required [18], this consists of a study of each of the user stories, referring to the time that the scrum team believes can develop it, in this phase involves both the time and the resources and expenses that may be needed.

5) Creation of the Product Backlog: User stories, priorities and required tasks are included in a Product Backlog. It includes the features or short and long term requirements and functionalities, that have been defined jointly by the development team and Product Owner, and also establishes the points or level of effort for each task. During the sprint process [19], the assigned tasks are movable depending on the requirements of the Product Owner.

6) Definition of Sprint Speed and History Points: The speed and time of development of each Sprint, is analyzed through an analysis that varies according to the experience of the Scrum team [20].

7) Sprint Presentation: The established Sprint is presented according to the requirements and the determined times, in this phase tests are performed on what is presented by the scrum team, being accepted or denied, this is repeated according to the number of sprint that contains a project.

8) Feedback: At the end of the project or each sprint, the scrum team, holds a feedback meeting, where they analyze everything developed in order to know their successes and failures in all aspects, in order to improve in the next project or sprint.

D. Development Tools

1) C (Sharp) programming language: C is a modern programming language, based on the c++ language and taking functions from other languages such as Java. The programming is mainly used object oriented. Currently it is still a language that is eating in the computer world and is mainly used for web development, software development and mobile applications [21].

2) ASP.NET Technology: ASP.NET technology, is a program architecture created on the basis of several programming languages, developed by Microsoft Corporation. In comparison with other developed models [22], ASP.NET stands out for having tools that help the programmer. In addition, has a high-level interactive graphical interface, a large customization layer, easy operation and high efficiency, when executing development processes, such as: creation of dynamic web pages. In addition ASP.NET incorporates servers, request, responsive pages, etc. In this way, it facilitates the development of a web. That is why, in the present research work ASP.NET was used for the development of a web site.

3) Microsoft Visual Studio: It is a modern development environment, which can be used to create programs, applications and software components for Microsoft Windows. Using object-oriented promotion, the program text consists of a set of descriptions of components when certain events occur. It uses the principles of component inheritance, which allows the creation of properties, events and methods [23]. The concept of Visual programming is implemented in the Visual Studio environment with the help of Windows.

TABLE I. USER STORIES

N°	User Stories
H1	I as a user want the Web System to allow me to log in with my Gmail, Outlook or other alternatives to have a more convenient access.
H2	As a user, I want the Web System to allow me to register my personal data to have access to all the functionalities.
H3	As a user, I want the Web System to inform me how to perform the test in order to have an assertive diagnosis.
H4	I as a user want the Web System to allow me to perform a test to diagnose my status.
H5	As a user, I want the Web System to allow me to perform the diagnosis through my own photos in order to obtain a more efficient result.
H6	As a user I want the Web System to provide me with the statistics and results according to my diagnosis to know why the diagnosis has been positive or negative.
H7	As a user, I want the Web System to provide me with dietary recommendations, diets and information based on my diagnosis to improve my current condition.
H8	I as a user want the Web System to have a selective food section according to my preferences in order to get personalized recommendations.
H9	I as a user want the Web System to show a section of recipes with high nutritional level to strengthen my hemoglobin level.
H10	I as a user would like the Web System to allow me to provide feedback and comments on the recipes to inform the effectiveness of each recipe.

4) Balsamiq: Balsamiq mockup,is one of the software tools used for design or prototyping, also to develop the user interface of an application. Balsamiq Mockup [24],[25], makes it easy to create the user interface, by providing you with the necessary tools to facilitate the creation of the application design. That is why Balsamiq was used, for the creation of the research prototypes.

5) Development architecture: For the development of the application, both front-end and back-end tools are needed, that is why in Fig. 2, the development architecture is shown, in each section the tools to be used are listed.

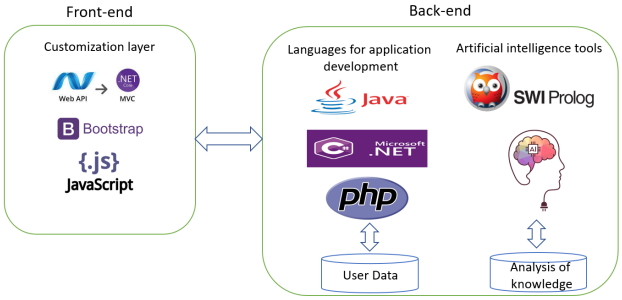

Fig. 2. Development Architecture Diagram.

IV. CASE STUDY

A. Start-up Stage

1) User Stories: After knowing the functional requirements, user stories were created, which were defined based on the requirements, as shown in Table I.

B. PLanning Stage

1) Analogous Estimation: In this stage, the complexity estimation was made with respect to the development of each

story, for this, the qualification range goes from 1 to 13, 1 is the lowest complexity level and 13 is the highest. To make the estimation, H1 and H2 are taken as a base, since this is where the "Login" is developed, so as an example, H3 is located in column 2, which indicates that H3 is 2 times more complex to develop than H1 and H2, the same logic applies to the other stories. Thanks to the Analogous Estimation, it is possible to present an idea about the functional development of each story for a future project. To arrive at the following result, the team discusses the estimation of each story and classifies them according to criteria. As shown in Table II.

TABLE II. ANALOGOUS ESTIMATE

	1	2	3	5	8	13
H1	Login					
H2	Login					
H3		2 Login				
H4					8 Login	
H5						13 Login
H6				5 Login		
H7			3 Login			
H8				5 Login		
H9				5 Login		
H10		2 Login				

2) Creation of the Product Backlog: For the creation of the complete backlog, it was ordered according to its history, priority and estimation. This information is obtained from the analog estimation table and the prioritization of the user stories. Table III, shows the Product Backlog.

3) Sprint Speed Definition and History Points: o carry out the following chart, it was decided together with the development team, to divide the sprint into four, in addition to detailing which user stories belong to each sprint. For example, H1, H2 and H3 belong to sprint 1. As shown in Fig. 3, sprint 1 has 4 points, this result was obtained thanks to the information of the analog estimation table, where the effort points obtained by the stories were added, H1 and H2 obtained 1 point each and H3 obtained 2 points, the sums of these stories belonging to the first sprint gives us as a result 4 points. sprint velocity refers to the estimated time for the completion of a sprint, the velocity is determined by the development team. In total, there are 45 points of history and an average of 30 points of speed.

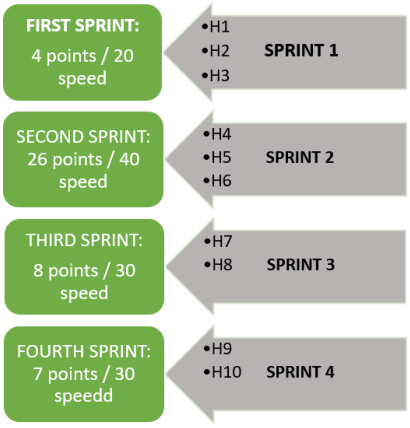

Fig. 3. History and Speed Points.

The estimated duration of the project is 4 months, Table IV shows the duration of each Sprint, as well as the estimated time to develop each functionality.

TABLE III. PRODUCT BACKLOG

User Stories	Priority	Estimation
H1: As a user, I want the Web System to allow me to log in with my Gmail, Outlook or other alternative accounts to have a more convenient access..	1	1
H2: As a user, I want the Web System to allow me to register my personal data to have access to all the functionalities.	2	1
H3: As a user, I want the Web System to inform me how to perform the test in order to have an assertive diagnosis.	3	2
H4: I, as a user, want the Web System to allow me to perform a test to diagnose my status.	4	8
H5: As a user, I want the Web System to allow me to perform the diagnosis through my own photos in order to obtain a more efficient result.	5	13
H6: As a user, I want the Web System to provide me with statistics and results according to my diagnosis to know why the diagnosis has been positive or negative.	6	5
H7: As a user, I want the Web System to provide me with dietary recommendations, diets and information based on my diagnosis to improve my current condition.	7	3
H8: I, as a user, want the Web System to have a selective food section according to my preferences in order to get personalized recommendations.	8	5
H9: I, as a user, want the Web System to show a section of recipes with high nutritional level to strengthen my hemoglobin level.	9	5
H10: I, as a user, want the Web System to allow me to provide feedback and comments on the recipes to inform the effectiveness of each recipe.	10	2

TABLE IV. SPRINT BACKLOG

Interface	Duration
Web system to detect anemia	4 months
Sprint 1: Login Interface	1 week
Sprint1: Registration Interface	1 week
Sprint 1: Home Interface	2 week
Sprint 2: Input evaluation	2 weeks
Sprint 2: Creation of activities	2 weeks
sprint 2: Creation of interactive games	2 weeks
Sprint 3: Activity customization features	2 weeks
Sprint 3: Interactive game customization features	2 weeks
Sprint 4: Results reports	2 weeks

V. RESULT AND DISCUSSION

A. Development of Prototypes by user Stories

1) Sprint Presentation: In this stage of development, the prototypes of the web page are shown, ordered according to the sprint and its estimation. Each image specifies which story it belongs to and the criteria they have had for the creation of the design.

- First Sprint: As shown in Fig. 3, the first sprint has a

total of 4 points, which include H1, H2 and H3, the design of each of them will be shown below.

H1: As a user, I want the Web System to allow me to log in with my Gmail account, Outlook or other alternatives to have a more convenient access.

For Story 1 we show the page where the user can log in, plus you have the option to register using your Gmail or Facebook account. It was decided to split the structure of the page in order to focus the user's attention to the form. this is shown in Fig. 4.

Fig. 4. Start of Session.

H2: As a user, I want the Web System to allow me to register my personal data to have access to all functionalities. Fig. 5 shows the user registration form in case you do not have a user name and password. The data requested are basic but necessary to access the system's functionalities.

Fig. 5. Registration.

Fig. 6 shows, the main page, in the menu there is a button that takes you to the diagnostic test. Continuing with the content of the page, it has a section where it includes the "Informative Guide", this button will take you to the previous guide to perform the diagnosis.
H3: As a user, I want the Web System to inform me how to take the test in order to have an assertive diagnosis. A guide is shown in Fig. 7, which was designed for the user to follow and take into account the recommendations before performing the test, in order to avoid errors during the test.

Second Sprint:

It consists of a total of 26 story points, which is a more complex indication for system development and prototyping. The design of each story is shown below.

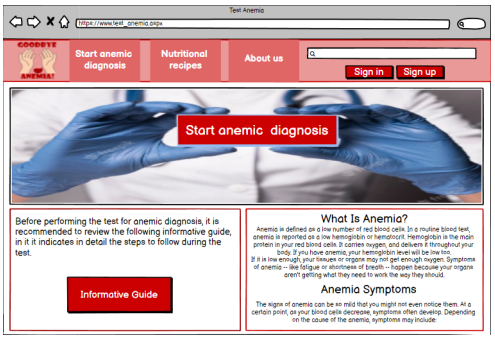

Fig. 6. Home Page.

Fig. 7. Informative Guide.

H4: I, as a user, want the Web System to allow me to perform a test to diagnose my status. The test design is shown in Fig. 8. The test is developed in two stages, the first stage consists of answering various questions necessary for the diagnosis.

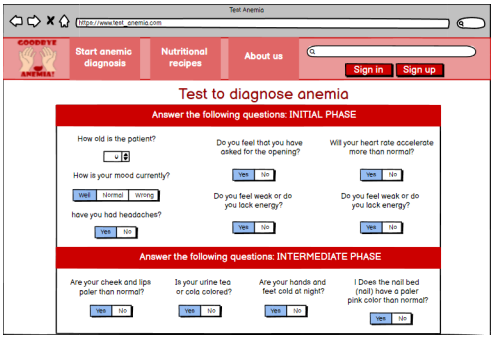

Fig. 8. Diagnostic Test.

H5: As a user, I want the Web System to allow me to perform the diagnosis through my own photos in order to obtain a more efficient result. After having carried out a previous questionnaire, the next section allows us to upload a photo of the patient's nails. upload a photo of the patient's nails, in this way with the help of artificial intelligence the application will detect, based on the color of the nails, whether anemia is present, this analysis directly influences the final diagnosis. All

this is shown in Fig. 9.

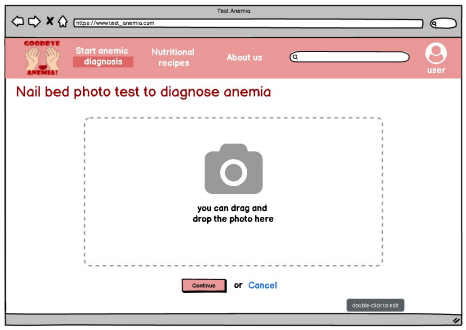

Fig. 9. Photo Diagnostic Test

H6: As a user, I want the Web System to provide me with statistics and results according to my diagnosis to know why the diagnosis has been positive or negative. As shown in Fig. 10, the results of the diagnosis are shown in the following bar graph: on the x-axis is the result of the questions and on the y-axis is the maximum score. It should be added that it shows the result "Negative" or "Positive", this result varies depending on the patient's diagnosis. The Recommendations section will be discussed later.

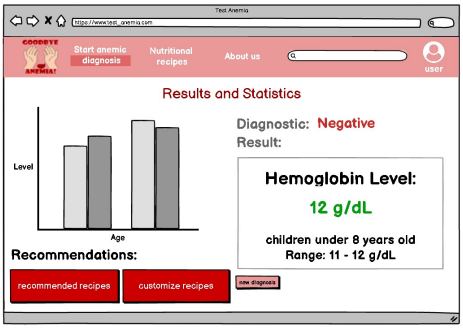

Fig. 10. Diagnostic Results Table.

Third Sprint:
H7: As a user, I want the Web System to provide me with dietary recommendations, diets and information based on my diagnosis to improve my current condition. The recommendations section is shown in Fig. 10, however this section is shown in Fig. 11.

H8: As a user, I want the Web System to have a selective food section according to my preferences to obtain personalized recommendations. As shown in Fig. 11, in the recommendations section, the patient has the possibility to select the foods of his or her preference, this information will later be displayed in a section of recipes, which include these previously selected foods in order to personalize the patient's food in a certain way.
Fourth Sprint:

H9: I, as a user, want the Web System to show a section of recipes with high nutritional level to strengthen my hemoglobin level. As shown in Fig.

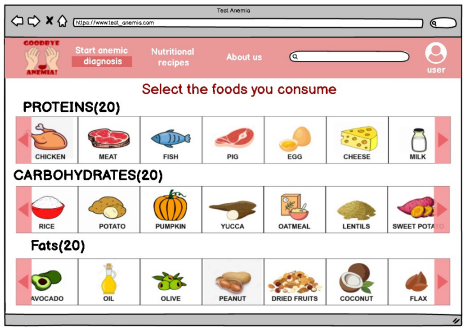

Fig. 11. Selective Food Section.

12, the web system has a recipe section, where the patient has the possibility of choosing the recipes of preference, and also where the recipes are displayed with the foods chosen in Fig. 11.

H10: I, as a user, want the Web System to allow me to give feedback and comments on the recipes to inform about the effectiveness of each recipe. Finally, in Fig. 12, the patient can rate the recipe using star points ranging from 1 to 5, as well as make a comment on the recipe in order to help or motivate future patients to try the recipes.

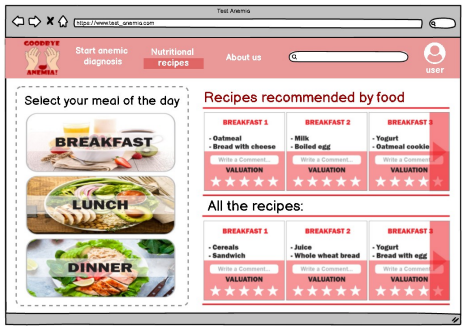

Fig. 12. List of Recipes to Combat Anemia.

B. Survey Conducted for the Creation of user Stories

For the development of the requirements, a survey was conducted among 40 people, including fathers and mothers in Lima-Peru. The survey was conducted with the help of the Google Forms tool. The questions were formulated with the purpose of knowing the user's preferences. Likewise, the answers were limited to the conditional "true" and "false". Table V, below shows the questions asked to the respondents.

1) Survey Analysis: According to the survey, it was obtained, the following results, which helped us to define the list of requirements, for the development of the web system, that will allow us to detect anemia and include some additional options that will help in the improvement of the patient as shown in Fig. 13.

- Of the 40 people surveyed, 32 opted to register before, accessing the website because it would give them a personalized profile and access to additional functions.

TABLE V. QUESTIONS ASKED TO RESPONDENTS

N°	Survey Questions
1	Have you suffered from anemia?
2	Have you ever used a website that detects anemia?
3	Would you like to enter directly to the website or do you want to register?
4	Would you like the page to allow login with your account from Gmail?
5	Would you like to carry out a previous survey related to your current state of health?
6	Do you consider the implementation of AI (Artificial Intelligence) necessary for the diagnosis?
7	Would you like to show the results with graphs and tables?
8	Would you like the website to give you advice and recommendation at the end of the diagnosis?
9	Do you know foods that avoid suffering from iron deficiency?
10	Do you know recipes to combat anemia?
11	Would you like recipes to fight anemia included?

- On the other, hand 36 people would like to log in quickly, using their Gmail account for immediate access.
- 30 of them want to carry out a previous survey regarding, their current health status in order to have a more assertive diagnosis.
- In addition, 28 respondents who were aware of artificial intelligence, considered it necessary to incorporate it for a better diagnosis, offering them greater reliability of the results.
- 35 of the participants would like to be able to graphically, display the results for better understanding.
- On the other hand, respondents were asked if they would like to see the incorporation of advice and recommendations after a diagnosis, with the result that all respondents were in favor of incorporating those functionalities. Likewise, 38 of them would like to include recipes to combat anemia according to the results obtained in their diagnosis.

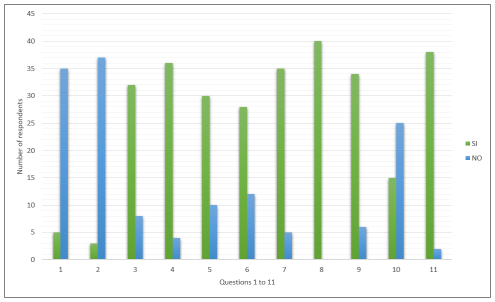

Fig. 13. Survey Results

C. Analysis of each Sprint by Burndown Chart

The use of Burndown chart, also called burndown diagram, represents graphically the effort and the follow-up of the tasks, during the established time of each sprint [26]. Generating the data graphically, the x-axis of the Burndown chart shows the time set per sprint and the y-axis shows the history points. Moreover, the blue line represents the expected values and the orange line reflects the progress of the history points, the further away from the blue line the less incremental value has been added. In other words, user stories are not completed or advanced.

1) First Sprint: According to the results obtained, the first sprint is made up of 4 story points with a set time of 4 weeks. As can be seen in Fig. 14, during the first few days, the points were successfully advanced, but between the end of August and the beginning of September, this changed, delaying the proposed advances.

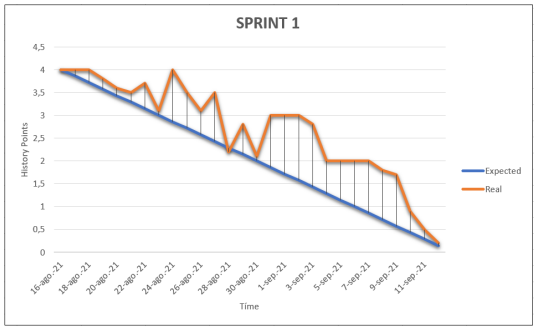

Fig. 14. Analysis of the First Sprint.

2) Second Sprint: It is made up of 26 story points, with a time frame of 6 weeks. During the development of the sprint we can observe that the advances in some days were completed on time and there were even early story deliverables as shown in Fig. 15.

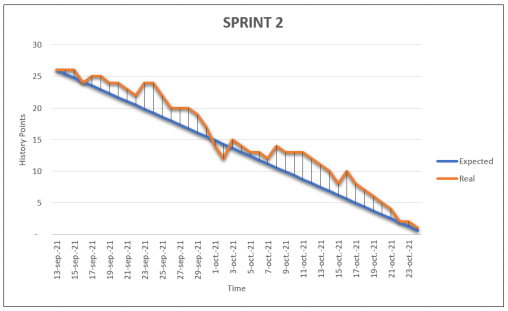

Fig. 15. Second Sprint Analysis.

3) Third Sprint: Composed of 8 story points, with a set time of 4 weeks, the development of the sprint was very good with all story points being completed starting with an early delivery and then with minimal delay with progress, but manageable as shown in Fig. 16.

4) Fourth Sprint: It has 7 story points, with a planned time of 2 weeks. Likewise, as in Sprint 3 the results were very parallel to the expected values demonstrating, a great development and performance of the sprint, culminating with the development of the web page for anemia diagnosis as shown in Fig. 17.

D. Analysis of Children with Anemia in Peru

1) Analysis in Peruvian Children: As shown in Fig. 18, the departments with the highest prevalence of anemia in children are the following: Puno, Loreto, Pasco, Huancavelica

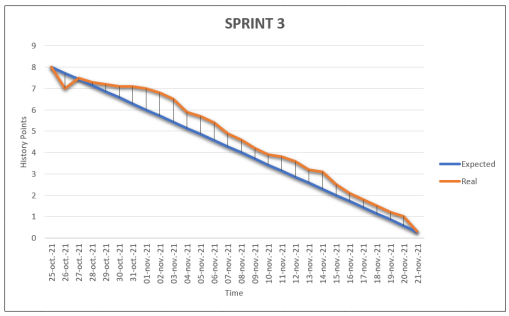

Fig. 16. Third Sprint Analysis.

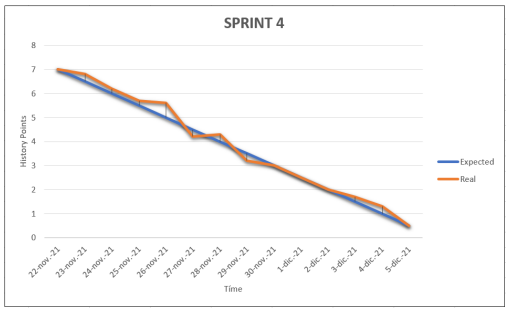

Fig. 17. Fourth Sprint Analysis.

and Ucayali. Thanks to this information, it was concluded that the first test carried out by the web system, be performed in these departments, since they are the most affected by this disease, and therefore, they should be attended as soon as possible. On the other hand, the departments with the lowest prevalence are: Lambayeque, Moquegua, La Libertad, Tacna, Lima and Cajamarca. Similarly, the Web System will be beneficial. However, it will not have the same impact as in the most affected departments. In Peru, practically 50% of the child population does not have a good control of their diet and this is reflected in the following graph. In short, our web system will present a solution to this problem and reduce these results to improve the quality of life of our Peruvian brothers and sisters.

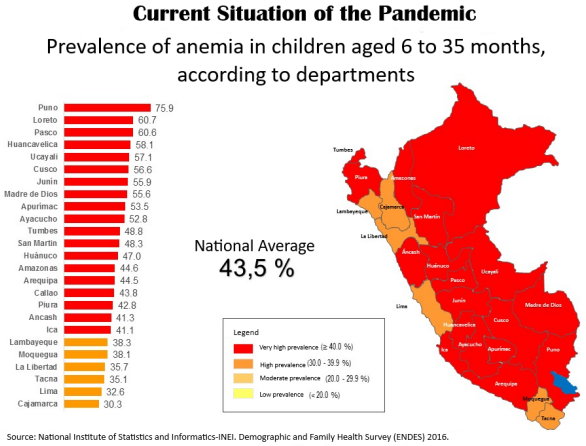

Fig. 18. Situation of Children with Anemia in Peru [27].

2) Analysis of Children in Callao: The district of Callao, has a high prevalence rate of anemia in children under 3 years of age. children under 3 years of age, which is why an in-depth analysis was carried out. As Fig. 19, the blue line represents the infection rate in Peru and the orange line represents Callao. and the orange line represents Callao. Thanks to the following analysis, it is known that, in 2021, only 2 out of every 10 children under 3 years of age will be affected by anemia, which is great news, given that years of This is great news, since years ago this result was alarmingly higher.

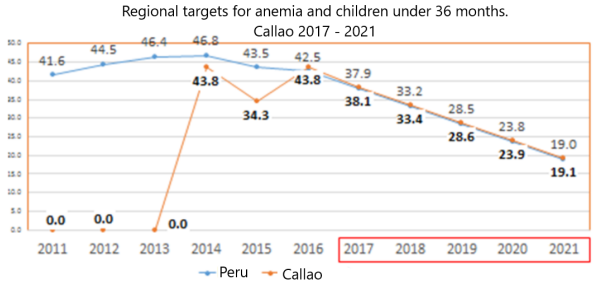

Fig. 19. Situation of Children with Anemia in Callao [27].

VI. Conclusion and Future Work

In conclusion, in this research work it was possible to design a web system to detect anemia in children, with the help of the design tool Balsamiq and applying the Scrum methodology. Thanks to Balsamiq it was possible to present the creative idea and the functionalities requested by the users through eye-catching and intuitive graphics.

With respect to the methodology, the Scrum framework was of vital importance, since it allowed a sequential development with high value, thus improving the quality of the product. In addition, the various charts and graphs that Scrum presents are key to presenting information clearly and accurately.

In the future, it is expected to complement this research by developing the web system, applying all the steps of this article to make this web system a reality. The development of the tool will be useful for people who do not have an adequate diet or feel they need an anemic diagnosis. This is why the implementation of the web system is expected as soon as possible, in order to contribute to the health sector and help people who require a diagnosis.

***Abstract*—This research work analyzes the relationship between stress and academic performance of engineering students at the University of Sciences and Humanities, in Peru, in the context of the pandemic. During this period, classes at the university were held virtually; and the difficulties that students present to carry out their classes were identified, such as lack of connectivity, family and financial problems and anxiety. The objective of the research is to analyze the relationship between stress and academic performance of engineering students. The work is part of a mixed approach, and data collection was carried out through interviews and surveys of engineering students based on the two variables identified: stress and academic performance. It began with a descriptive analysis, then moving on to inferential analysis to perform the hypothesis test. The SPSS was used for the reliability analysis using Cronbach's alpha with 0.84 as a result and validation by expert judgment with 84.5% acceptance. It was obtained as a result that between the Stress variable based on its three dimensions and academic performance there is not relationship since it was obtained that its P-value is greater than 0,05; it is concluded that stress is not only academic but also should consider others as labor, social. In addition, the positive stress that drives academic performance emerged. The beneficiaries with the research are students, and the university. It is concluded that there is no relationship between stress and academic performance.**

***Keywords*—Academic performance; anxiety; stress; teaching-learning; virtual mode**

I. Introduction

The health crisis that is being experienced around the world, due to the COVID-19 pandemic, has led various states to partially or totally close schools and universities to prevent the spread of the virus. In this context, the new educational challenge of virtual or distance education is imposed in almost all the countries of the world, bringing with it effects that not only represent a massive impact on productivity; but also, for social life and student learning [1]. Worldwide, it can be seen that the effects of social isolation and virtual education affect all students emotionally. According to the various studies carried out on this subject, it is evident that the majority of students have shown an increase in their levels of anxiety and stress, due to the drastic change around learning and future demands in the professional field [2]; to concern for their academic progress, performance, and their adaptation to distance learning. That is why the need for greater psychological counseling of students is emphasized [3].

In the new context of virtual education, the University of Sciences and Humanities (UCH) has implemented sundry measures that guarantee the achievement of the objectives proposed in the study plan. For this, it has implemented divers pedagogical resources available to teachers and students through the virtual platform that show good results; However, it has been shown that many of our students have expressed feelings of anxiety and stress that, in some cases, have led them to the determination to abandon their studies. This has been evidenced in the increase in the number of students who drop out; and although the university does not have reliable studies on this subject, teachers perceive this problem every day. The research work has as a unit of analysis, a student of the Faculty of Science and Engineering. In this Faculty, students manifest difficulties with connectivity, the internet, family problems due to the pandemic, as well as psychological problems. In this sense, it investigates the different manifestations of stress that may be affecting students in their academic performance.

Besides, the importance of the study is to be able to analyze the relationship between stress and academic performance, of our students from the Faculty of Sciences and Engineering, determining the levels of stress experienced by students and academic performance, in the virtual modality. For this, support mechanisms can be established for our students with comprehensive work with teachers and the educational community in general, based on the comprehensive training proposal. In this way, students will benefit, to improve their academic performance, and cope with stress through proposals that will come out of the research. Also, the university can avoid dropping out, which can be one of the causes of stress. Faced with the problem, formulate the following research question: What is the relationship between stress and academic performance of the students of the Faculty of Sciences and Engineering in times of pandemic?

The objective of the research is to analyze the relationship between stress and academic performance, of students of the Faculty of Sciences and Engineering of the UCH, in the virtual

modality, in times of pandemic. For this, the degree of stress of university students is described in the virtual mode in times of pandemic; in addition, academic performance and its effects related to stress are analyzed.

The investigation is made up of six sections. In Section II, In the literature review; in Section III, the methodology was carried out; also in Section IV are the results; in Section V, the discussion, ending in Section VI with the conclusions and future work.

II. Literature Review

A. Theoretical Basis

1) Stress: As for the definition of stress, it is quite diverse and, until now, it has focused on a psychological approach, conceiving it as a disease that is associated with certain alterations of the organism [4]. However, stress can also be positive to face certain difficulties. The author [5] distinguished between pleasant stress, which he called stress; and stress or distress, when it comes to unpleasant stress. When it comes to stress, in general, it refers to anguish, but not everyone can relate to pleasant situations or events that have caused us stress: weddings, births, promotions, receiving awards, meeting old friends and many more. In that sense, any change, positive or negative, requires a response from our bodies to adapt and bring us back to our relatively peaceful state.

Stress is also seen as a state of imbalance between demands, be they from within or from external sources, and our perceived capacities to meet those demands. This is most acutely experienced when the expectation of meeting demands is not met, which will have consequences for the person.

In the academic field, the study of stress focuses mainly on a positivist stance, which leaves aside a phenomenological and qualitative look; that is, a holistic pedagogical approach that provides a comprehensive view of the phenomenon is not assumed. In order [4] to conceive the definition of stress in the academic field, it is necessary to take into account: both the psychobiological and the psychosocial components. According to what was stated by [6], academic stress is the process of change in the components of the teaching and learning process, through a set of individual and institutional adaptive mechanisms, a product of the overwhelming and demanded demand in the teaching and learning experiences that are developed in higher education institutions, with the purpose of maintaining a steady state in the educational process.

2) Academic Performance: Academic performance is a value associated with the quality of higher education institutions; since, it allows to have a better panorama of the educational reality; however, there are various criteria when measuring it. The concept of academic performance [7], must consider the diverse and complex factors that are revealed in learning; in this sense, academic performance is considered when there is a contribution in the achievement of student results, through evaluation. Likewise, it is pointed out that it is a multicausal phenomenon, which makes its assessment complex. Among the factors that intervene, they point to the components of internal and external order to the individual, which can be of a social, cognitive and emotional order.

In the case of stress and its relationship with academic development, studies indicate stress rates in university students, which are observed with greater preponderance in the first years of the degree and in evaluation periods. In addition, it has been shown that university students can present various stressful situations that affect their performance [8]. Regarding the relationship between stress levels and academic performance, there are numerous studies, such as those of [9] who carried out a study with 162 university students from the University of Balarias Islands (UIB), for which They used the Systemic Cognitive Inventory (SISCO) of academic stress as a measurement instrument. Among the main findings, it was reported that teacher evaluations and the jobs that teachers ask for are the main cause of stress in students; however, no direct relationship was found between stress and academic performance.

B. Related Work

This research work seeks to establish the relationship between stress and academic performance. For this, a search of the works related to this topic has been carried out, based on divers methodologies and results, which allows a broader overview of the problem studied.

In recent years, numerous studies have been conducted with various methodologies. For example [10], they identified the causes of stress and its effects on the academic performance of Malaysian Higher Education students. In this study, it is determined that life and interactions on campus are related to stress and academic performance. It is for this reason that the researchers suggest that university authorities guarantee suitable environments for learning and advisory centers [11].

The study carried out by [12] on stress in Astana Medical University, satisfaction and academic performance and online learning during the pandemic, carried out in a nursing school, reveals that for students learning during this period, in virtual mode, was stressful; and the perception of satisfaction was low and moderate. Regarding the academic performance of the students, they indicate that they were affected by the pandemic. Likewise, a significant and inverse correlation is shown between academic performance and stress during online learning [13].

On the other hand, the study carried out with students from the University of Nairobi, revealed that stress was related to academic performance; therefore, the majority of students stated that they had moderate to high levels of stress [14]. In the study carried out on the relationship between stress and academic performance, a high percentage of stressed students was obtained: about 65%. Performance was statistically significant at ages ranging from 19 to 23 years. Besides, the linear regression was inverse; that is, the higher the stress, the lower the academic performance. To reduce this problem, it is recommended to carry out programs with academic workshops [15].

Although it has been proven in various studies, to establish the relationship between stress and academic achievement, there are other factors to take into account: physical and psychological aspects. In the study carried out by [16], on the effects of COVID-19 on the mental health of university students in the United States, an increase in stress and anxiety

levels was reported. This increase was associated with multiple factors, such as fear and concern for their health, difficulty concentrating, disorders with sleep patterns, decreased social interactions and greater concern about their grades.

In the study carried out at the University of Pakistan, it is observed that the body mass index, stress and academic performance in students had a negative correlation of stress. Likewise, in order to calculate the process, the global system for data analysis (SPSS) was used [17]. According to the study carried out with Albanian students, on the averages of the students and their relationship with stress, the direct relationship between optimal academic performance and student tranquility was evidenced. Also, they used already elaborated questionnaires based on the stress scale and on attachment. The authors suggest that more in-depth research should be carried out, since the study was exploratory in its first phase [11].

The effects of the pandemic may increase dropout rates in educational institutions. Distance education, although not new, has been introduced on a large scale by trial and error to alleviate these effects; however, it has evidenced problems in learning and levels of understanding of students. In this sense, the recovery of this sector is essential to avoid a major generational catastrophe [18]; that is why higher education institutions have been forced to implement alternative methods to guarantee the continuity of studies and minimize the gap in this new context. For this purpose, the use of virtual platforms has been arranged with the objective that the actors of the educational process interact with each other, mainly teachers and students, and achieve the established curricular learning outcomes. This has meant a challenge to become familiar with the new teaching-learning methods; unfortunately many students state that they are not satisfied with this type of learning, increasing the rate of anxiety and depression [3].

It should be noted that the stress experienced by students is generated by academic and non-academic aspects such as: environmental, sociocultural and psychological factors. This means that students feel the pressure to perform well in order to meet the expectations of their parents and thus obtain benefits at work level in the future [19]. Specialists point out that academic stress can be decreased over time, and only a small portion of students will develop chronic disorders, if they do not receive medical help on time; this implies that the severity of the initial reactions to stress can predict their continuity and treatment [20].

It cannot be denied that stress influences academic performance; however, this can be reduced. On the one hand, through the decisions made by teachers and institutions, to facilitate the transition to the virtual modality, influencing the reduction of class hours, qualification requirements and support in evaluations. On the other hand, students also put in place various mechanisms to deal with it. They can be adaptive behaviors: acceptance and adaptive coping, or maladaptive ones like denial and disengagement [21]. On the other hand, students also put in place various mechanisms to deal with it. They can be adaptive behaviors: acceptance and adaptive coping, or maladaptive ones like denial and disengagement [2].

Likewise, students in this period have been forced, in many cases, to work to pay for their studies, which means a higher level of concern that affects their academic performance. In recent years, stress has been increasing moderately every year. According to the research between stress and performance, can observe that those who are exposed to work and academic hours their stress level increases considerably. Likewise, it has been shown that students who do not work their stress level is moderate. In summary, the authors found in the research that stress has different forms of manifestations; as well as the presence of positive stress is evidenced; the relationship between stress and academic performance was also found; however, more innovation is lacking in the uses of instruments to measure stress. In addition, positive stress must be related to academic performance, with an in-depth study to know the consequences of it.

III. Methodology

A. Methodological Design

The research work has a qualitative-quantitative approach, that is, mixed. This approach is often presented as two paradigms that complement each other to carry out a deeper investigation, with the perception and interpretation of the research data [22]. The research design is non-experimental, which is characterized by not manipulating the variable in the research [23]. Likewise, the research is descriptive, correlational, causal and cross-sectional in scope.

B. Development of the Methodology

The following steps were performed:

1) Modeling: A hypothetical model was carried out, between the variable stress and academic performance. According to Fig. 1, the relationships between them are observed, as an assumption, where the positive sign means that there is a direct relationship between the variables; and the negative sign, that there is an inverse relationship. That allows to be able to contrast, if there really is a correlation and if there is, what type it is, inverse or direct.

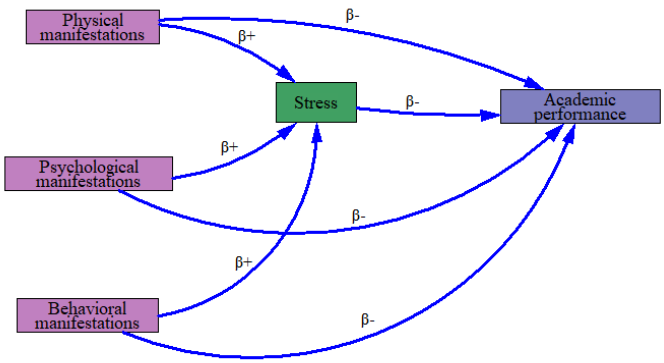

Fig. 1. Hypothetical Model.

2) Interview: 8 students from the 1st to 4th cycle of the Faculty of Engineering were interviewed. For this, the following steps were taken into account (see Fig. 2).

- Elaboration of the questions.

- Selection of students.
- Recording the interview.
- Analysis of the interview.

A semi-structured interview with 6 questions was conducted, as shown in Table I.

TABLE I. INTERVIEW QUESTIONS GUIDE

Questions	
1	During your academic preparation at the university, have you felt stress? If you have felt stress, how do you think it affects your studies?
2	When you are stressed for academic reasons, do you have health problems such as pain, insomnia, indigestion or others? If yes, can you specify which ones and how they are manifested?
3	In periods of stress, do you usually have problems on an emotional level, that is, in your mood, your feelings, lack of concentration or others? If yes, can you specify which ones and how they are manifested?
4	During the last semester, you were seized with feelings of depression and / or sadness In what newspapers specifically? How are you coping?
5	How do you perceive stress affects your participation in class?
6	Do you have problems of aggressiveness, conflicts and of social relationships with your colleagues? Why?

3) Survey: For this study, a survey has been prepared, based on the SISCO questionnaire on stress. In Peru, in recent years, several studies have been carried out on stress in students based on the SISCO SV-21 inventory. Among these works, have [24] who analyzed the psychometric evidence of the SISCO SV-21 inventory in 560 students from public and private universities in Metropolitan Lima; reaching the conclusion that said inventory gathers the evidence of validity and reliability for its use [25].

In the present work, the survey was applied using the Google form questionnaire as an instrument. The student population under study is 150 students from the first to the fourth cycle. Through a simple random sample, 109 students were obtained from the morning and night shift.

In addition, the academic performance variable was analyzed by placing intervals to the average grades from 0 to 20, considering the levels very low, low, regular, and high and very high. This information was obtained from academic records; This consists of their average grades from the first stage of the 2021-2 semester (see Table II).

TABLE II. AVERAGE NOTE RANGE

Scale	Academic performance	Average note range
1	Very low	[0;5[
2	Low	[5;11[
3	Regular	[11;15[
4	High	[15;18[
5	Very high	[18;20]

IV. RESULTS

A. Instrument Reliability and Validation

- Reliability with Cronbach's Alpha
  The instrument's reliability result must be greater than 0.70 for it to be approved (see Table III) [26]; since the value must range between 0 and 1 [27] [28]. The reliability of the instrument was determined with 10% of the population. For this, the data were collected and processed with the SPSS program. The result was 0.84. The analysis of questions 1 to 17 of Table IV shows that if a question is deleted from the survey, the Cronbach's alpha varies between 0.82 and 0.85. That is, it is within the mean of Cronbach's alpha, which is 0.84. From the penultimate column of Table IV, its values must be greater than 0.200. It is observed that questions 2 and 5 do not comply; for this the modification was made.

TABLE III. INTERVAL FOR RELIABILITY

Interval	Reliability assessment
[0 ; 0,5[	Unacceptable
[0,5 ; 0,6[	Poor
[0,6 ; 0,7[	Weak
[0,7 ; 0,8[	Acceptable
[0,8 ; 0,9[	Well
[0,9 ; 1]	Excellent

TABLE IV. ALFA DE CRONBACH

Questions	Mean scale if item has been suppressed	Scale variance if item has been suppressed	Total correlation of corrected elements	Cronbach's alpha if the item has been suppressed
1	32,00	57,78	0,31	0,83
2	33,40	61,52	0,09	0,84
3	31,75	56,30	0,45	0,83
4	32,15	53,61	0,50	0,83
5	33,15	61,61	0,04	0,85
6	32,25	51,67	0,75	0,81
7	33,35	56,13	0,54	0,83
8	32,75	57,57	0,30	0,84
9	32,50	53,32	0,60	0,82
10	32,15	53,50	0,73	0,82
11	32,65	55,82	0,48	0,83
12	32,65	55,29	0,33	0,84
13	33,30	57,38	0,42	0,83
14	33,55	58,37	0,62	0,83
15	32,80	53,75	0,61	0,82
16	33,60	58,67	0,63	0,83
17	32,80	52,91	0,48	0,83

- Validation by Expert Judgment
  Expert judgment was carried out to validate the contents of the instrument [29], (see Table V). The profile of the experts that was considered for the validation was: specialists in psychology and education who work at the university. The validation by expert judgment was taken as a reference for approval, greater than 75%. As a result, 84.7% acceptance was obtained as the average of all the questions evaluated. For this, the following criteria were taken into account: clarity, updating, coherence, consistency, objectivity, content and sufficiency.

B. Qualitative Analysis

According to the interviews carried out with the students from the first to the fourth cycle of the Faculty of Sciences and Engineering, the following categories could be constructed.

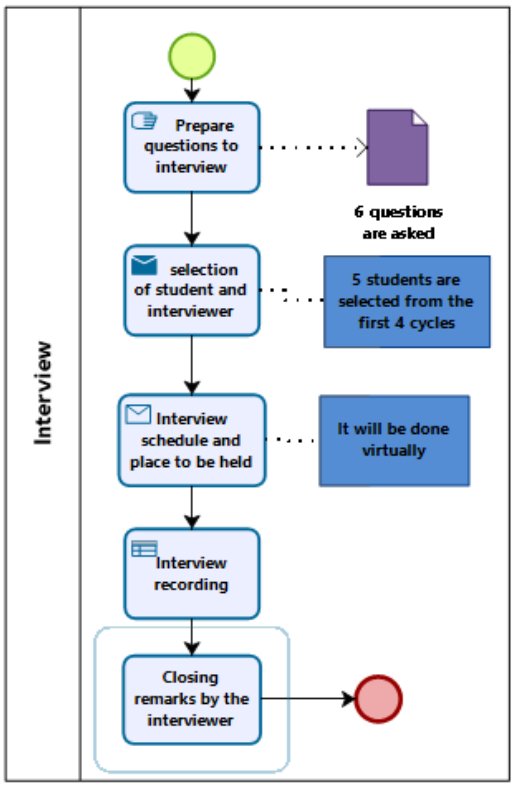

Fig. 2. Steps of an Interview.

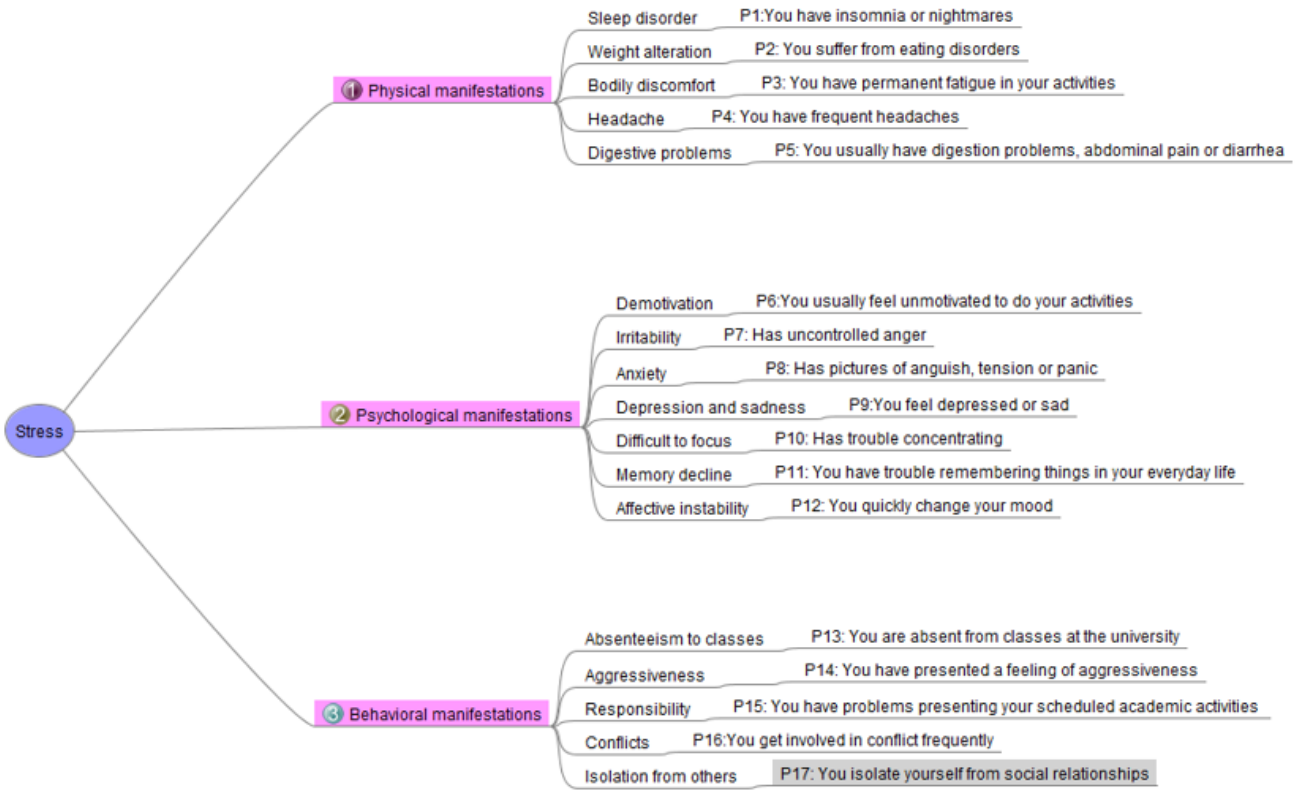

Fig. 3. Dimensions of the Stress Variable.

TABLE V. EXPERT JUDGMENT

Question	Expert1	Expert2	Expert3	Percent
1	80%	85%	90%	85%
2	75%	80%	85%	80%
3	70%	90%	80%	80%
4	90%	90%	90%	90%
5	80%	80%	80%	80%
6	90%	90%	90%	90%
7	70%	90%	80%	80%
8	90%	90%	90%	90%
9	80%	85%	90%	85%
10	75%	80%	85%	80%
11	70%	90%	80%	80%
12	90%	90%	90%	90%
13	80%	80%	80%	80%
14	90%	90%	90%	90%
15	70%	90%	80%	80%
16	90%	90%	90%	90%
17	90%	90%	90%	90%

1) Stress and Academic Performance Relation: All students report feeling stress during their academic preparation; but they point out that this occurs in specific periods when they approach the date of the evaluations; or in some courses they don't understand. At this point they coincide in cases of students who work and study, they more accurately recognize the symptoms of stress. Likewise, students recognize that stress affects their studies, as it causes them to lack concentration and lack of motivation. As stated by [30], academic stress can reduce academic performance, decrease motivation and increase the risk of dropping out of school.

E1: *Yes, definitely especially in these times of the pandemic was when I decided to study and the moments of greatest stress ehh I think are the evaluations and when jobs are put together ... duties that I have to perform at work sometimes I am short on the time ... I think that in part yes because ... I am very stressed or ... I am not sometimes like I lose motivation.*

2) Physical Manifestations: In the student's discourse, it stands out that most have presented physical symptoms due to stress. The main physical manifestations are headache, insomnia, palpitation of the eyes and digestive problems. These findings coincide with that reported by Silva et al. [31], where it was found that the physical manifestations of stress are headaches or migraines and an increase or decrease in food consumption. These symptoms occur in short intervals and can usually be managed without the need for medical treatment.

E3: *Yes, when I am under stress I have headaches, not always ... headaches or insomnia. The headache lasts for hours, not long, but regular. I mostly control it when I start to calm down*

3) Psychological Manifestations: All students present emotional manifestations as a consequence of stress. They usually present anxiety, reluctance, lack of motivation, sadness and anger [32]. These symptoms appear in short periods and may be associated with comprehension problems; or to the development of various activities at an economic and academic level. It should be noted that anxiety at the academic level may be due to the courses that they consider more difficult or the expectation of their grades, since they consider that they are assigned a low grade and that it is not related to the effort made.

E4: *Some anxiety. There comes the issue of anxiety sometimes there are days that I have to stay up late to be able to review or the same issue of knowing what I am going to do the next day as I am going to leave to be able to do the different activities generates stress, generates anxiety more than anything, well it is linked to stress ... and my mind is going elsewhere.*

4) Behavioral Manifestations : Most students participate in various classroom activities, depending on the courses. While some interviewees indicate that they prefer not to participate, as they consider that it is not necessary because they know the issues. Given this, can indicate that there is not direct relationship between stress and participation in activities developed in class. These results are complemented by those presented by Encina Meza et.al. [33] who points out that in stressful situations, the most frequent behavioral symptoms are lack of concentration, decay, isolation and the tendency to feel more conflictive and with a tendency to argue. In this sense, can point out that in terms of aggressiveness, conflict and social relationship problems between students, a direct relationship with stress is not observed. However, some students emphasize that group work can generate stress, due to the fact that not all participate actively and certain communication problems.

E4: *...perhaps that out there there are not all cases of a student who perhaps are the ones who want to do everything according to their interpretation and maybe out there they are a little susceptible to changes, but after I have crashed, I have felt rather like Many of them are also young, as they look for some support from people who are of age, I see that sometimes they lean on me in some things.*

C. Emerging Categories

1) Stressors: It was identified that the most frequent stimuli that generate stress are evaluations, overload of activities and work; added to this is the limited time to perform them. On the other hand, it is observed that students present greater stress in the periods close to the evaluations; since they feel pressured to pass the courses, and their expectations may be offset by their results. These results correspond to those presented by Cordova et al. [34]. Who point out that within the demands of the academic environment, the ones that generate the most stress for the student are overload of tasks, type of work and evaluations. Besides, several of the students indicate that they are not organized properly; therefore, they are joined by various jobs and evaluations that they feel they will not be able to fulfill.

E1: *but the previous cycle if from the midterm exam and until the final exam I had these symptoms.*

Likewise, we observe that the courses that generate the greatest stress are those related to formal sciences: mathematics, physics and those of the specialty of engineering.

E6: *mostly because of the area that was mathematics and that was systems. Then it got a bit complicated and I kind of left your mind blank.*

2) Coping Strategies: Within the interviews, it has been observed that students test various stress coping strategies. These strategies focus on direct actions after personal evaluation and analysis, before seeking support from external elements.

This coincides with the findings obtained by Boullosa [35], who points out that the techniques most used by students to overcome stress are to strive to achieve their academic goals by concentrating on solving the problem and looking for spaces for relaxation. Most of them indicate that they handle the situation personally, without resorting to external help, since they consider that they are prepared to cope with this situation. Some techniques they use are trying to calm down or think about positive aspects of their preparation, doing an activity that they like or resorting to a metacognitive strategy to evaluate their learning process.

E1: *First I try to calm down, I try to see the positive side of that of the situation and for another opportunity to do it much better.*

However, a small number of students indicate that they have resorted to interpersonal relationships as a coping strategy; that is, to family or some belief. These findings are related to the study conducted by Barraza [36], who points out that the strategies most used by students are the elaboration of a plan, execution of tasks or activities, and assuming these stressful situations with humor; while the least used are praising their progress or religiosity.

E3: *Not the other way around, they try to support me (my family) but at the moment I am with all the stress ... and I get defensive but it can be controlled.*

E7: *ehhh, I do it by myself; bone also raised a small prayer also as it is called, I say to God give me strength, please ...*

3) Positive Stress: According to Díaz & Fierro [37], positive stress or eustress is a positive physiological and emotional response to academic stressors, which are perceived by the student as a challenge or challenge and not as a threat. In this sense, it is pointed out that the resources available to the student allow them to respond to academic demands and strengthen their skills. Besides, some students point out that stress can be positive for the development of their academic activities, since it motivates them and provides them with that "pressure" necessary to achieve their academic goals.

E6: *no, because of ... with this pressure I feel that I have to study more and about going out so that next week I have good results.*

D. Descriptive Analysis

The survey is made up of two sections: in the first, the sociodemographic data, such as age, sex, cycle, shift; and in the second section, the questions of the stress variable that have 3 dimensions with 17 questions (see Fig. 3). These were built with the Lickert scale, where 1 is never; 2 hardly ever; 3 sometimes; 4 usually; y 5 always. It is observed in Fig. 4, the gender and age of the student with its frequency, being the male gender the one that predominates over the female; likewise, the most frequent age is 21 years and 1 student over 50 years of age. Regarding the female students surveyed, 9 are 20 years old more frequently and one student is 40 years old. An asymmetric bell with accumulation between 17 and 21 years old is evidenced in both graphs, both for male and female, with greater frequency and the others are scattered. Likewise, in Fig. 6 it is observed that the average of the male and female gender are close to 2,10. The one with the greatest amplitude of length of the stress average is in females, with a range of 1.90 to 2,28 and in the male gender, the length of their stress averages is 2 to 2,15.

In Fig. 5 the dimensions of the stress variable were analyzed, where the three obtained a median close to 2, with respect to the average stress score. Además en la Fig. 7, it is observed that 16,85% have high stress; analyzing the moderate percentage, it is wide with 57,30% where the majority of students remain neither very high nor very low. Relating to the percentage of academic performance, 45,96% is high and what is shown in Table VI the percentages of the stress dimensions is moderate, concluding that stress and performance in both is on the moderate average. Besides, the analysis of academic performance was carried out by means of the average grades of the students from the first to the fourth cycle of the students of the Faculty of Engineering. The mean of 3,90 indicates that it is above the average, it means that the students have a high average close to 46%, the low average is little significance, since it is approximately 5% (ver Fig. 8).

TABLE VI. PERCENTAGE OF STRESS

Dimensions	Low	Moderate	High
Physical manifestations	30,34%	50,56%	19,10%
Psychological manifestations	25,84%	55,06%	19,10%
Behavioral manifestations	25,84%	51,69%	22,47%

E. Comparison Analysis of Gender Means by Dimensions

Through statistical analysis, the Mann-Whitney U test was performed for sample variables, which corresponds to the male and female gender, with respect to the dimensions of the investigation, (see Table VII). It is observed that the P-value is 0,140 of the first dimension. By theory it is known that if the P-value is less than 0,05 there is a difference of the means in the comparison and if it is greater than 0,05 there is no difference between the averages.In this sense, in the 3 dimensions, the P-value is greater than 0,05; therefore, it is concluded that in the three dimensions the means are not different since their P-value for the 3 is greater than 0,05, with a margin of error above 5%.

F. Relationship between Variables

The relationship between all the variables of the Stress dimensions was made, using Spearman since it is non-parametric. From Table VIII it is observed ** means that the correlation is significant at the 0,01 level (bilateral); where is interpreted as 1% margin of error. In the Table IX, the scale of the correlation coefficient is observed; comparing with the results obtained, the dimension of psychological manifestations and with physical manifestations is 0,512 **; that is, moderate positive correlation. Likewise, the dimension behavioral manifestations with physical manifestations is obtained 0,647 ** which is in the range of correlation, moderate positive and finally the dimension behavioral manifestations with psychological manifestations is 0,816 **, being in the range of high positive correlation. It is observed in the Table IX highlighted in blue, the range where the results obtained are found. On the other hand, the relationship between the academic performance variable and the 3 dimensions of stress is observed where the result is very low. In Table VIII it is

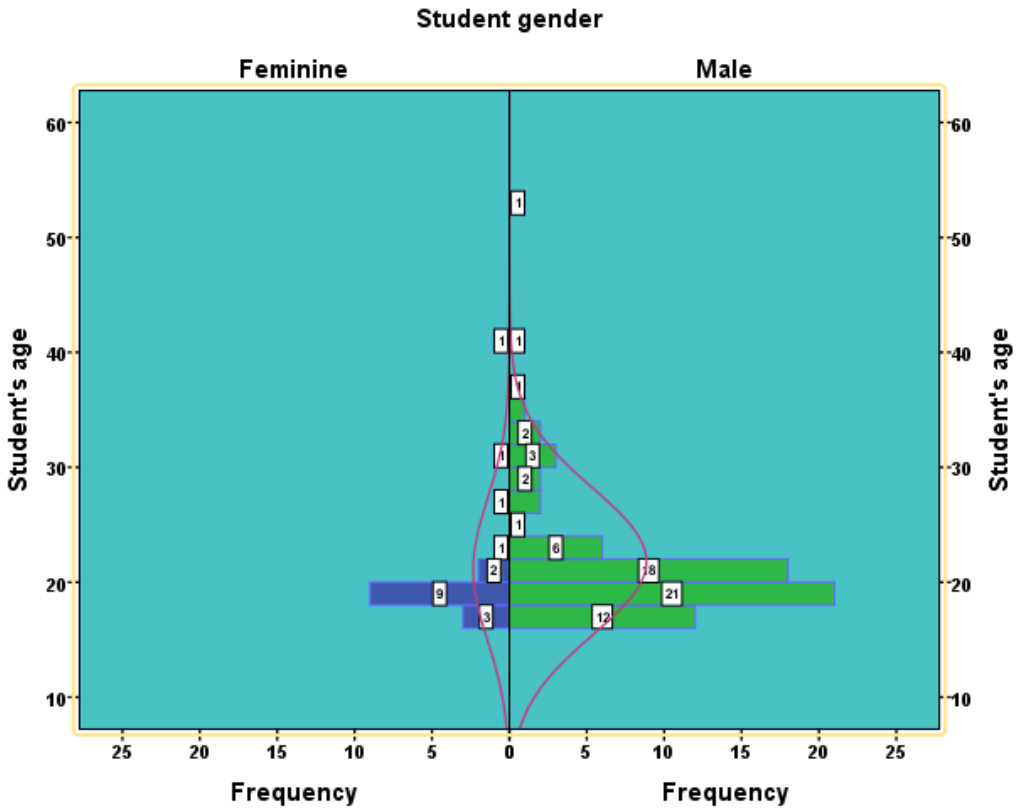

Fig. 4. Analysis of Gender and Age.

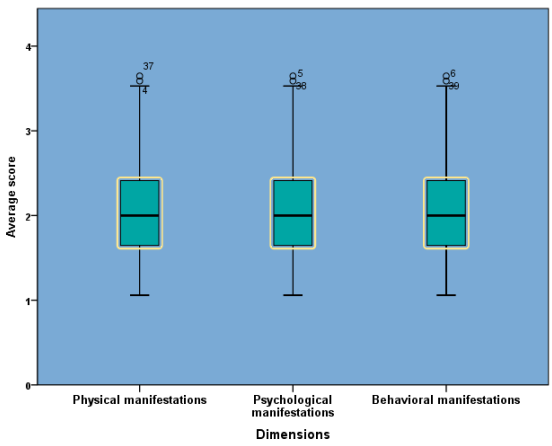

Fig. 5. Analysis by Dimensions.

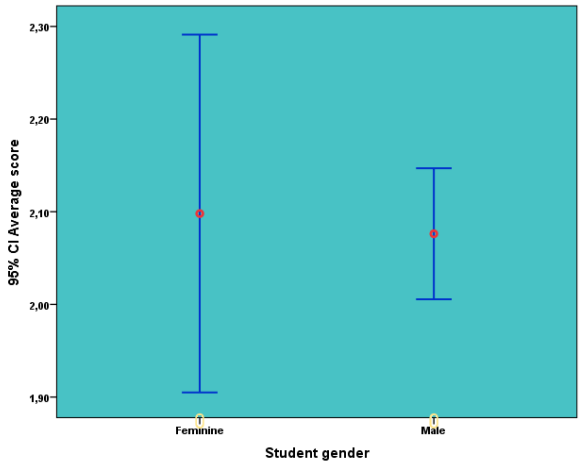

Fig. 6. Confidence Interval Analysis.

observed that the psychological and behavioral manifestations are inverse but very low, that is, the greater the stress, the less academic performance, but it is very low; this can be verified with Fig. 8 where 45,96 % academic performance is high and in Fig. 5 where the 3 dimensions of stress are not higher than the average.

TABLE VIII. RELATIONSHIP BETWEEN VARIABLES

Variables	1	2	3	4
1.Academic performance	1			
2. Physical manifestations	0,076	1		
3. Psychological manifestations	-0,106	0,512**	1	
4. Behavioral manifestations	-0,108	0,647**	0,816**	1

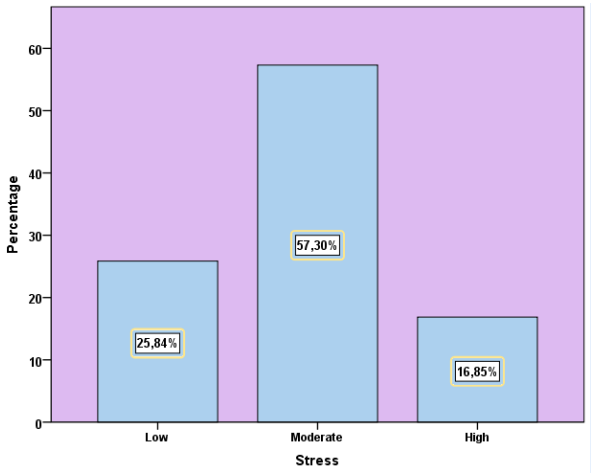

Fig. 7. Student Stress.

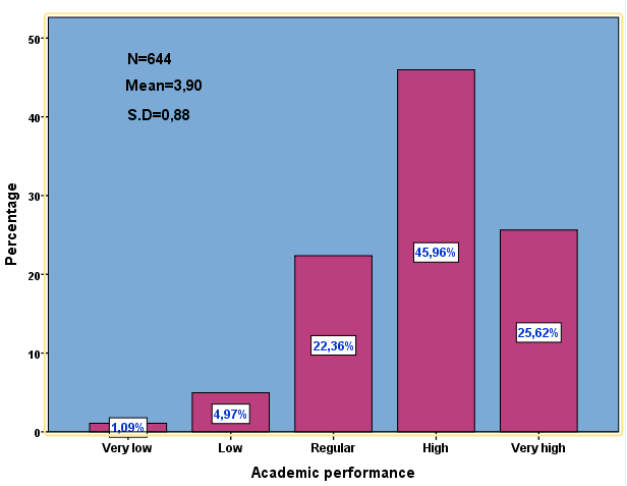

Fig. 8. Academic Performance of Students.

G. Multiple Linear Regression

It is observed in the Table X the predictor variables that are the dimensions of the stress variable and where academic performance is the dependent; it is observed that the significance is greater than 0.05 in the three dimensions of stress. It is stated then that none of the three dimensions of the stress variable is related to academic performance. Besides, $R^2 = 0,040$ indicates that 4% of the academic performance variable is explained by the variables of the Stress dimensions. Analyzing the value of Beta for the prediction of the variables under study, it was found that the beta of the physical and psychological manifestations are positive, that is, but very low, observing the significance greater than 0,05, concluding that there is not relationship; that of psychological manifestations is close to one its significance value, that is, there is not relationship in a determining way.

TABLE VII. COMPARISON OF MEANS OF 2 INDEPENDENT SAMPLES

Dimensions	Gender	Z	P
Physical manifestations	Male	-1,475	0,140
	Femenine		
Psychological manifestations	Male	-0,341	0,733
	Femenine		
Behavioral manifestations	Male	-0,906	0,365
	Femenine		

TABLE IX. SCALE OF VALUES OF THE CORRELATION COEFFICIENT

Value	Meaning
-1	Large and perfect negative correlation.
-0,9 a -0,99	Very high negative correlation.
-0,7 a -0,89	High negative correlation.
-0,4 a -0,69	Moderate negative correlation.
-0,2 a -0,39	Low negative correlation.
-0,01 a -0,19	Very low negative correlation.
0	Null correlation.
0,01 a 0.19	Very low positive correlation.
0,2 a 0,39	Low positive correlation.
0,4 a 0,69	**Moderate positive correlation.**
0,7 a 0,89	**High positive correlation.**
0,9 a 0,99	Very high positive correlation.
1	Large and perfect positive correlation.

TABLE X. MULTIPLE LINEAR REGRESSION

Predictor variable: The 3 dimensions of the stress variable	**Dependent variable: Academic perfomance** $R^2 = 0,040$		
	Beta	**t**	**Sig.**
Physical manifestations	0,235	1,686	0,095
Psychological manifestations	0,012	0,067	0,947
Behavioral manifestations	-0,249	-1,199	0,234

V. DISCUSSION

In the research it was obtained that the relationship between stress and academic performance is very low. This may have an explanation, that stress is not unique to academics; in other words, there are other forms of stress, such as work stress, psychosocial stress and others, product of the pandemic.The academic performance in times of pandemic, with distance classes, in the students of the Faculty of Engineering is high and very high with a percentage of 45,92% and the stress dimensioned in the physical, psychological and behavioral aspects has an average result regular. If compare with the study carried out by [38] on stress and academic performance, they found that if there is an inverse relationship between these 2 variables under study. However, his study was in another context, where there was no presence of the COVID-19 pandemic. They obtained a moderate stress, approximately 72% of students; on the other hand, the research carried out in the article is approximately 50%. In the research, students from the morning shift but also the night shift were surveyed where almost all students work, and may also have work stress, since they do it remotely. This last variable was not considered in the research.

VI. Conclusion and Future Work

According to the quantitative study, it is observed that there is not relationship between stress and academic performance; where the average of the students is high and very high with 45,96% and the stress of the 3 grouped dimensions is moderate with 57,30%. However, students report feeling stress in their academic preparation. Stress manifests itself on a physical level, mainly with headaches and insomnia, with 50,56% of the moderate form; psychologically, with anxiety, demotivation and sadness; but this does not directly affect their interpersonal relationships; obtaining a 55,06% in the moderate way and in the behavioral manifestations a 51,69%. The students indicate that the periods close to the evaluations generate more stress at the academic level; as well as the pressure to pass the subjects, mainly those of science that are considered the most complex. To cope with stress and anxiety, they resort to direct strategies, based on a personal analysis without resorting to external elements. On the other hand, it should be noted that stress is positive to the extent that it allows us to respond correctly to demands or difficulties. In addition, it is observed in students that stress is used as a kind of fuel to achieve their academic goals. There is a relationship between the three dimensions of the stress variable.

The methodology carried out with the techniques of surveys and interviews, allowed to have a holistic panorama of being able to analyze and cross information in the investigation. New studies are suggested in relation to positive stress and academic performance in university students. Also, delve into the situation generated in the teacher as part of teaching in the virtual mode. On the other hand, analyze the subject from a qualitative methodology that allows us to know the perception of those involved in this process.

Implementation of a Web System to Improve the Evaluation System of an Institute in Lima

Franco Manrique jaime, Laberiano Andrade-Arenas
Facultad de Ciencias e Ingeniería
Universidad de Ciencias y Humanidades
Lima, Perú

***Abstract*—In Peru and the world, millions of students saw their education interrupted caused by the problems brought by the COVID-19 virus, due to this many educational entities began to adopt learning platforms and web systems so that the teaching process is not affected, having to comply with all the guidelines and requirements of the institution to solve any academic difficulty. That is why in the present work the implementation of a web system was proposed for the improvement of the qualification and evaluation processes of an institution using the scrum methodology since it is an agile framework that is based on empiricism and offers adaptation and flexibility in the projects. For the software development, the open source language PHP was used since it is more adapted to these web systems, Mysql was also used, which is a database manager for relational databases. The results of this research was the correct implementation of this system to the educational institution, verifying the absence of errors and the improvement of the processes involved so that the institution can provide students with an adequate learning process.**

Keywords*—COVID-19; evaluation; learning platform; scrum; web system

I. Introduction

Today the percentage of educational institutions that adopt a virtual teaching platform is increasing, this due in large part to confinement due to pandemic, creating a change in the global teaching process, Currently, virtual teaching is defined as the development of the learning process through the use of digital and information tools, where the student and the teacher are not physically present in the same room. Nowadays, many students went from the face-to-face to the virtual, bringing with them new problems to solve. This new reality brought new methods and ways to have a better understanding of the educational process in universities and institutions [1]. The change in the way of teaching in institutions due to the COVID-19 pandemic forced many educational entities to adopt virtual teaching systems since, due to the circumstances, classes and online interaction are considered the best option that can be adapted to this new form of teaching and that complies with the confinement regulations issued by the governments of different parts of the planet. These web systems provide all kinds of tools so that students can learn from home without having to return to face-to-face classes or be in contact with other people [2]. Although most institutions have some type or form of software to process, retrieve, store information, today these systems need to be increasingly accurate with a minimum error percentage because these systems must provide students and teachers tools and resources quickly and safely [3]. Some platforms have certain limitations that prevent covering all the needs of the institutions, these institutions, by not having the required modules and by not satisfying all the needs of the different areas involved, are not able to provide the information necessary for decision-making in an academic setting. This affects students because the student, guided by the teacher, makes use of the different tools and resources offered by these web systems to access important information and develop activities that help the student consolidate knowledge and develop skills.

For all the aforementioned and with the purpose of solving these academic difficulties of the Institute of Sciences and Humanities (ICH), through technology, specifically in the design and development of a web system, the following question was asked: What measure will a web system of qualification and evaluation improve the process of monitoring and control of information in the Institution of Sciences and Humanities?

Due to the lack of adherence of some processes with the requirements of the institution, this can harm its decision-making, affecting the learning and teaching process. This work offers a proposal, solution to the problems of the educational institution through the web system that will optimize resources by improving the level of satisfaction of those involved as teachers and students, in addition, the web system will accelerate the evaluation and qualification processes of the institution making them more efficient and with fewer errors.

The objective of this project is to seek to improve through a web system the qualification process and results of mock admission exams managed by the directorate of systems and communications of the ICH.

In Section II, a review of the literature was carried out; in Section III the methodology; as well as in Section IV the case study; in Section V the result and discussion; and finally in Section VI Conclusion and future work.

II. Literature Review

The project consists of designing and implementing a web system for the improvement of the qualification process and results of the mock admission exam of an educational institution to provide a better experience for students in addition to processing and analyzing the grades of students to obtain information performance and progress. A large percentage of educational institutions in Peru use learning platforms for virtual teaching and with the presence of COVID-19 and

quarantine this percentage is increasing even more, so knowing these tools today is essential for institutions educational.

Regarding virtual education due to pandemic, there are different positions such as that of the author Eduardo Norman Acevedo [4] which says that due to the current situation referring to the health situation caused by COVID-19, educational institutions had to change the teaching processes to adapt to this new way of teaching and learning, being mainly evaluative, ethical, sociological, pedagogical changes. On the other hand, María Laura Picón [5] indicates that millions of students were affected by this problem, having to adapt to these new tools in order to receive online classes, however, how prepared were not only the institutions but also the students? This change in teaching brought with it new problems for students such as lack of technological resources, lack of internet in rural areas, students with disabilities, etc. This need to apply virtual teaching revealed the inequality of training for the use of these technologies and the lack of knowledge by both teachers and students. Based on the above, Javier Arturo Hall López [6] mentions that virtual teaching also brought problems on the physical health of students, due to sedentary lifestyle and lack of exercise make students more likely to suffer from weight problems, this is a challenge pedagogical in teaching and in the way of teaching classes, which has to propose better teaching methodologies so that the student can be guided in the development of their motor skills. At the same time, these education platforms are increasingly being adopted by more education centers, as explained by D. Benta [7] in his report, where he mentions that tools such as Moodle help motivate students and those involved in solving collaborative and individual tasks.

About traditional teaching, Jacinto Joaquín Vertíz Osores [8] indicates, that the traditional form of evaluation used in universities has been attributed almost entirely to the criteria of the professors, who guided the process towards the quantification of the indicators expressed in their links and that they are supposed to reflect the level of progress of the students. In retrospect, this traditional way of evaluating students to measure learning and level of knowledge has remained frozen in time and does not appear to have changed in the last 50 years [9]. However, at the current stage, where the educational scheme is not the same, with means of remote interaction, in this new scheme, teachers ask university authorities about evaluation methods, consult strategies and propose methods, being fully aware of the shortcomings of the new interaction scenario. On the other hand, Olga V. Bondarenko [10] points out that, in a virtual educational environment, the nature of the interaction of those involved in learning (a student, a group of students or a teacher) changes fundamentally. The term study is not used because it is interpreted as a cognitive activity of students who, under the guidance of a teacher, master skills, knowledge. The involvement of students in a virtual education environment means that the teacher must change his role from mentor and director to tutor, facilitator and moderator [11]. The teacher strives to help students find an individual educational path. Currently and due to the pandemic, there are more and more modern students living in a media environment where the use of computers, internet resources and the use of mobile devices is part of their day to day. It is for this point that virtual educational environments are now a reality that basically deals with an information space for the interaction of students in an educational process generated by communication and information.

The advantages of a virtual educational environment include: flexibility, economic efficiency, interactivity, mobility. In this context, M'Balia Thomas [12] indicates that the change to virtual classes due to the pandemic forced teacher educators to rethink them, they do not normally teach or design the content of online courses. Thus, as the global pandemic grows and accelerates a continued rise in e-learning, teacher educators must reexamine what it means to be equitable, responsive and inclusive to the individual needs of a diverse set of pre-service teachers and take into account consideration of collective professional needs. With regard to systems related to virtual education, there are various authors such as Cristian Enrique Mejía and Mariano Enrique Álava [13] who developed a grade registration system for a school with 60 years of service that lacked a virtual education environment, it is for this reason that there was a deficient management of the file with important content such as qualifications, enrollment, etc., and that they were solved by this software that optimized said processes. It also allows to reduce the response time of processes and improve the teaching process and thus increase the satisfaction of the students. It is clear that these web systems helped learning from home, institutions such as those mentioned had to adapt to these new platforms so that this training process is not interrupted and although not all have the means to take this type of non-face-to-face classes, a large percentage were able to continue with their training process.

In summary, the authors analyzed in their research show that there is still a need to carry out digital transformation in institutions to make the implementation of the evaluation system more effective and efficient. The investigation that will be carried out is to see how to optimize with the implementation of the web page in an effective way in its processes.

III. Methodology

A. Methodology SCRUM:

The Scrum methodology is a framework that addresses complex problems (ver Fig. 1), where a lot of ambiguity can be observed; in addition, it helps to promote creativity and productivity of teams because events tend to generate creative tension in the team [14]. In addition to this always tends to seek to deliver products of the highest value. both scrum and other methodologies allow the team to make the most of resources and time, however this does not mean that this framework does not have disadvantages. Scrum is based on empiricism, rather, learning as you go, it is for this reason that the incremental interactive life cycle is usually perfect for this framework [15]. In Scrum there are roles which are the Scrum Master, the Scrum team and the Product Owner [16]. This agile framework or framework created in the 90's by Schwaber and Sutherland. It follows an approach that is based on evidence, starting from the premise that problems can never be defined or understood in their entirety, which is why organizations and companies have to focus on getting trained teams to respond to change.

The characteristics that most identify this framework [17], are the following:

- Flexibility and adaptation.

- Return on investment.
- Risk mitigation.
- An always motivated team.
- An alignment between the client and the team Productivity and quality.
- This intensified work entails a high prediction of times since the speed and performance of the equipment is known.
- The method of work and continuous review produces a higher quality of the software.

B. Scrum Activities

1) Sprint Planning: This is a meeting that has to be held at the beginning of a sprint and it is necessary for the entire team to participate [15]. This task planning is divided into two main parts:

First part of the meeting. This has a Timebox of 4 hours.

- This is where the client shows the list of requirements to the manager, and specifies the priority requirements.
- Then the list is analyzed, doubts are resolved and it is agreed which requirements will be a priority in each iteration.

Second part of the meeting: As in the first part, here a timebox is made that can last a maximum of 4 hours. Here the iteration is analyzed and planned, and proceeds to create tactics that will help you meet the objective.

- Team members can assign themselves tasks to perform.
- The effort to perform each task will be calculated.

2) Sprint: In Scrum we have iterations, these iterations in Scrum are called sprint, each one of the sprint delivers value to the end users or to those who are solving a particular problem, this value grows with each iteration.

3) Scrum Daily Meeting: In these meetings, what is sought is the transfer of relevant value together with the collaboration of team members to improve productivity. Here each member reviews everyone's work to be able to make the necessary changes to finish and comply with the sprint.

4) Sprint Retrospective: This is the event where all members of the Team evaluate and inspect themselves, this in order to improve during the next Sprint. Here we analyze how they are working, why they achieve or not the objective in which they are failing.

5) Sprint Review: This event takes place at the end of each sprint. During this informal meeting the increase is reviewed, rather, what was done during the sprint and if there were changes, the Product Backlog is analyzed.

6) Team Roles: This methodology is made up of three main roles. Each of these roles has different responsibilities and must act differently [18].

- **Scrum Master:** He is an expert in scrum, he is a facilitator coach, he trains and removes the impediments that can be seen in daily meetings.
- **Product Owner:** It is the empowered person, who establishes the product backlog, is responsible for the return on investment, is represented by a single person and works on the product vision.
- **Development team:** All the members are called developments and they are full time in what they are doing, it is a multidisciplinary team that is self-managed and estimates its own time, it is a small team and it is recommended that it be from 3 to 9 people.

7) Product Backlog: This is a list with elements, these elements are called PBI (Product backlog item), this artifact is not only composed of user stories, in the scrum guide they mention that other values such as needs, requirements, cases of uses, defects etc. This stack is ordered, being the first in the stack the ones that generate the greatest value to the business or the highest value to the end users and therefore the last in the stack is what generates the least value or little value compared to the first pbi. Scrum, being iterative and agile, allows new PBIs to be entered into the backlog that may arise as we advance in the project, that is why it is said that the product backlog is emergent, which means that we can be adding new things according to the product or according to the project I need it.

8) Burndown Chart: This is a graph that shows over time the speed and the time in which the objectives and requirements are being completed. Provides a better overview of the team's pace of progress in order to predict whether the team will complete the work in the estimated times.

9) ScrumTaskboard: This is a board with the tasks to be done. And be organized in such a way that the objectives are assigned the necessary tasks to finish it, usually post-its are used, and they change position according to their status. To differentiate the tasks that each member is performing, smaller colored stickers are used.

10) Disadvantages of Scrum: Scrum is not perfect. Therefore, we can mention some of the most important disadvantages of Scrum:

At the time of starting with Scrum, the whole team must know very well its principles and theoretical framework, also that there be knowledge of the Scrum roles or this could alter the functions and tasks. To a large extent, much of the success of the project will depend on the level of knowledge of the scrum master (rather than on the innovation, creativity or quality of the inputs). If for some reason some task is not completed, other tasks may be compromised due to that sometimes these can be related, this can generate delays in the sprints or the delivery of an unsatisfactory value.

The following figure shows the stages of this methodology graphically, showing the order of the activities [14].

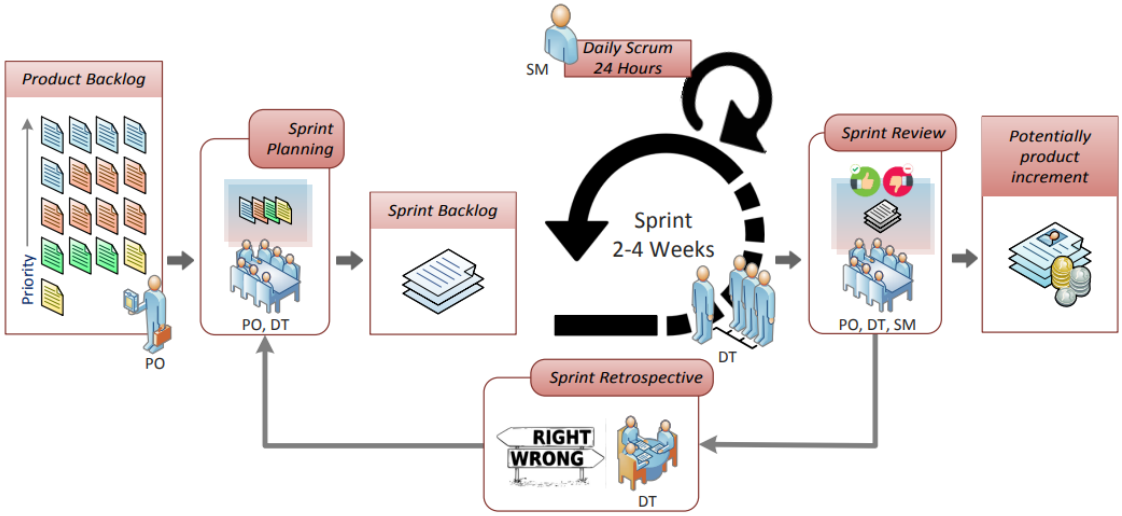

Fig. 1. The Phases of the Scrum Methodology.

IV. Case Study

A. Initiation Phase

1) User Story: In Table I, was create user stories, that are general and informal explanations of the characteristics of the software, these are from the point of view of the end user, in our case we identified 22.

2) Product Backlog: In the product backlog basically organize the list of tasks was carried out for the project. In Table II, we show the priority or rather the degree of importance and to which module it belongs, in this work we were able to identify 4 modules.

B. Planning and Estimation Phase

1) Sprint Backlog: In Table III, Table IV, Table V are the objectives, the elements chosen in the product backlog to be completed in each sprint, in our project we identify three sprints.

In Table VI, the weighting that was used is detailed in the following.

2) User Story Sprint 1:

a) Exam management module 1: In this module 7 user stories were created for the creation, deletion, modification and list of exams, likewise a time can be assigned for taking the test, also for greater convenience the exam can be copied.Table VII and Table VIII show the windows of this module.

b) Exam management module 2: In this module 4 user stories were created for the management of sections, questions and courses, this window can only be used by administrator type users.In the part of the questions because they are associated with an exam, the questions cannot be eliminated directly, what is done is a logical elimination. Table IX and Table X show the windows of this module.

TABLE I. User Story

ID	USER STORY
1	As an administrator I need to view the windows to configure the exams.
2	As Administrator I need to register an answer for each question.
3	As Administrator I need to register the sections to place the questions.
4	As Administrator I need to record the time for each area.
5	As Administrator I need to register the number of questions for each area.
6	As Administrator I need to record the total time for all sections.
7	As Administrator I need to register the total number of questions to set limits.
8	As Administrator I need to register the courses for each section.
9	As Administrator I need to have reports by dates to indicate the day the exam was taken.
10	As Administrator I need a merit report by specialty to see your information.
11	As Administrator I need a general merit report to see your information.
12	As an administrator I need to edit the number of questions per area to update the data.
13	As Administrator list the sections to view the existing information.
14	As Administrator I need to have a course report to see your information
15	As Administrator I need to view the exam model to see the changes made.
16	As a student, I need to take the exam for the evaluation.
17	As a Student I need to visualize the windows for taking exams.
18	As a Student I need a report card to see my results.
19	As a Student I need to finish the test to choose a new section.
20	As a Student I need to see the detailed result, showing which ones were incorrect, which ones were correct and which ones I did not answer.
21	As a Student I need to finish the exam even if time is not over yet.
22	As a Student I need to be able to enter an exam to view their schedules.

3) User Story Sprint 2: In this module the administrators will be able to observe the progress of the students in the courses as well as view the reports of the students by date, year, course and type of exam. These data can later be analyzed to obtain statistical tables as a result. Table XI and Table XII show the windows of this module.

TABLE II. PRODUCT BACKLOG

ID	USER STORY	Priority	Sprint	MODULE

5	As Administrator I need to manage the scores by section.	4	3

is modified, in addition the student's information is saved and processed for future reports Table XIII and Table XIV show the windows of this module.

5) Design Pattern MVC: The model view controller pattern (mvc) is a pattern that separates the data into three different modules, each fulfilling a function different. This software architecture pattern applies code reuse, facilitating software development and maintenance as shown in Fig. 2 [14]. In Fig. 3, we can see the order of the folders following this pattern. This model can be used to develop desktop applications or mobile applications in this way creating the mobile version of the system will be much easier.

6) Database Model: Fig. 4 shows the diagram of the database.The diagram has 15 tables; the main ones being the exam table where the exams with the corresponding questions are recorded and the configuration table which relates the students with the grades.
The DB was developed in MYSQL since it is a database manager that best adapts to web systems as well as being free and easy to use. This manager is compatible with Windows and Linux operating systems.
The database was developed using Navicat which is a tool for the development of BDs and that allows managing multiple databases.This tool was chosen for its compatibility with the manager and for its easy handling.

V. RESULT AND DISCUSSION

A. Sprint 1 Testing and Review

1) Exam: In Fig. 5, the exam window is shown where the exams will be shown, registered, deleted and modified, also it will be possible to create schedules and register questions. For the administrator's convenience, it will also be possible to duplicate the exam including the questions.

2) Section: Fig. 6 shows the section window where sections will be displayed, registered, deleted and modified. To register a section it is necessary to specify its name.

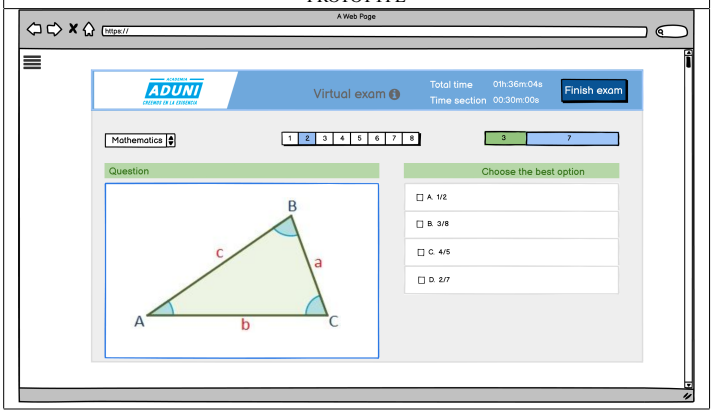
The system calculates the scores	
PROTOTYPE	



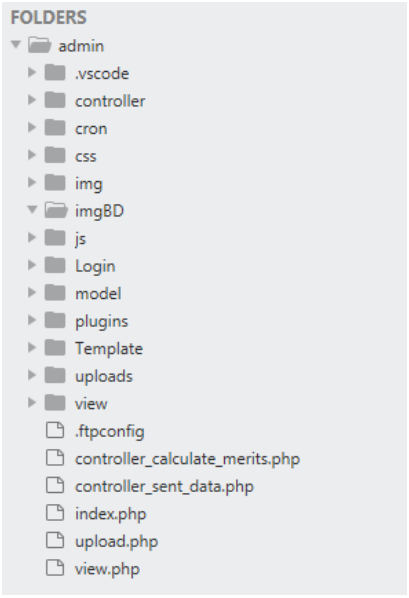


Fig. 3. MVC Order.

database handles a large number of records, a search engine was added to find the student quickly.

C. Sprint 3 Testing and Review

1) Exam: Fig. 13 shows the time list window where the student will view the available schedules, if the student has already completed the test, the buttons will be blocked preventing entry.

2) Test: Fig. 14 shows the exam window where the student will take the virtual practice, the practice has a general time limit and by section, if the student finishes before they can press the button finish exam to finish it, once finished a message will be displayed thanking you for your participation and will redirect you to the schedule list window.

3) Student results: Fig. 15 shows the results window where the student will view the scores obtained from the test in addition to the position by general merit and by specialty, he will also be able to view all the test questions along with the correct answer and the alternative marked by the student.If the student does not take the test, a new date is scheduled, however the merits will not be shown.

The notes are calculated from time to time through files called CRON which are responsible for executing the code every 40 minutes, modifying the time in which the CRON will be executed is done manually. It is due to this file that if a student takes the exam after the scheduled date, it will have no merit and only their score will be recorded.

According to the author [2], his studies were based on the use of web systems by students remotely, where the advantages of using the platform in times of pandemic stand out, which is consistent with our research since it was also carried out in the same pandemic context where the Authorities show support for the investigation as there is satisfaction on their part.

VI. CONCLUSION AND FUTURE WORK

According to the requirements and needs of the Institution of Sciences and Humanities, a web system was implemented for the improvement of evaluation and qualification processes, which consists of three modules which are the exam, results and student management module. The response time of the system was also reduced when displaying the exam and scoring the tests, in the same way it was possible to create a friendly interface for both students and administrative staff, thus improving the creation and taking of virtual evaluations.It is suggested that future work be implemented a mobile application that allows complementing the institute's evaluation system.

Design of an Anti-theft Alarm System for Vehicles using IoT

Jorge Arellano-Zubiate, Jheyson Izquierdo-Calongos, Laberiano Andrade-Arenas
Facultad de Ciencias e Ingeniería
Universidad de Ciencias y Humanidades
Lima, Perú

***Abstract*—Automobiles have become one of the most sought-after targets for criminals due to their worldwide popularity. Crime is reflected in the statistics, which show that over the years, the crime rate of vehicle theft has been on the rise. As part of the fight against this crime, the vehicles come with certain systems incorporated to avoid this type of situations; obtaining many outstanding results. In this research project, a system was developed that allows through the application of the Internet of Things (IoT), the management of software and hardware technologies that allow the user to have access to various actions, such as vehicle location through the global positioning system (GPS), and identification of the offender, through radio frequency identification (RFID), as well as the global system of mobile communications (GSM). The objective of the research is to design a mobile and IoT application to reduce robberies in the department of Lima-Peru, using the scrum methodology. The result obtained is the design of the mobile application, with its anti-theft system, vehicle blocking and notification of unauthorized ignition.**

***Keywords*—Global mobile communications system; global positioning system; internet of things; radio frequency identification; scrum**

I. Introduction

Since its inception, the automobile has played a very important role in the industrial field, which has been demonstrated by a steady increase in its production and sales. Thus, in India, it is observed that the number of vehicles purchased has reached 100 million units, and it is expected that this figure could reach 450 million by 2021. Likewise, in the United States (US) [1], the picture is not much different as the number of people with driver's licenses is much lower than the number of cars.

However, this boom in the production of motor vehicles has brought with it the appearance of people who seek to obtain them illegally, regardless of the fact that some of them have protection systems, which so far have not been sufficient to stop this type of behavior [2]. Now, this increase can be seen reflected in the country of Mexico, where the percentage of vehicle theft has increased by 27.5% during the first half of 2020 [3]. Similarly, in our country the situation does not vary [4], since in the department of Lima the increase in vehicle theft complaints has been increasing from 3% to 27% in the period of time between 2017 and 2019 according to figures provided by the National Institute of Statistics and Informatics (INEI).

Likewise, this type of activity has intensified in the search for ways to avoid the systems with which the vehicles are equipped, since most of them only have GPS location systems [5], so these criminal gangs have implemented a system whereby they block these signals in certain strategic locations, thus gaining an advantage in their actions.

Now, the systems that use IoT technologies provide us with a series of options such as being able to visualize the status of the peripherals that the vehicles have, in this sense,According to the author [6] can know when the headlights are turned on or that the vehicle's engine has been started; all this through notifications to mobile device. Likewise, it is possible to implement systems that, after the vehicle is started, initiate a monitoring process by means of GPS signals, which allow the owner to know the location of the vehicle in real time. Similarly [7], the IoT allows the owner to interact with this system by remotely turning off the engine.

Indeed, the IoT allows systems to provide many more options to suit the needs that users have, for example, the implementation of vehicle security systems that have the ability to monitor by silent video surveillance unauthorized persons inside the vehicle, which not only prevents the theft of the vehicle, but can also identify the person who did it [8]. On the other hand, there are vehicle security systems with complex identification methods that raise the cost of their development and acquisition. However, the IoT allows different devices, such as RFID tags that are low cost [9], can be used in the identification and operation of these systems with which it becomes a viable option for those who have the need to create such systems and have low economic resources.

This research has been developed taking into account the various factors that IoT technology has, in this sense, an anti-vehicle theft system that manages the different actions of identification and action within a vehicle by means of IoT was carried out.

The objective of the research is to design, through a mobile application, an innovative vehicle security system through which it is expected to reduce the percentage of cases of people who suffer the theft of their vehicles in the department of Lima-Peru.

Then, the following points was developed in the paper: in Section II the literature review where analyze those works that served as a basis for the development of the research, in Section III on the methodology used during the development of the project and the steps that were performed, followed by Section IV the results that have been obtained at the end of the development of the project, then in Section V we develop the

theme of discussions where we analyze the similarities with other projects, finally in Section VI the conclusions and future work.

II. Literature Review

In this research a vehicle anti-theft system has been developed by applying IoT technology to control the different actions of the system, in order to reduce the rate of vehicle theft in the area of the department of Lima - Peru. In this sense, it has been taken into account other research works that have implemented technologies, which have been used in this work.

Thus, we see how [6] implements light and sound sensors inside a vehicle in order to know the state in which it is; this information is centralized in an Arduino Mega 2560 device. Then, by means of a 3G-Shield, this information is transmitted to the user for its respective visualization. As a result, the user can remotely visualize the status of the headlights (on, off), the doors (open, closed), the saloon light (on, off) and the vehicle's engine (on, off). In short, the user can become aware of his habits with respect to the state in which he leaves his vehicle after use.

However, [7] addresses the problem of vehicle theft through the implementation of GSM and GPS technologies. Consequently, IoT is used to communicate with the user by notifying him that his vehicle has been forcibly started and also initiates a constant report of the vehicle's location. Then, the user can interact with the system allowing him to turn off the vehicle by sending a text message which will be received by the system and will trigger the vehicle to stop. In conclusion, the user can access this way to a low-cost anti-theft system that allows him to locate his vehicle in real time, without the need to have specialized knowledge in the field of smartphones.

In addition, the author [8] implements a vehicle security system with video surveillance of the driver. Consequently, IoT is applied together with a biometric driver identification system, which aims to prevent unauthorized persons from operating the vehicle. However, the system adds the functionality to identify the person who tries to perform such action by means of real-time video surveillance of the driver's cabin. In short, the vehicle owner can identify through silent video surveillance any person driving his vehicle, all this through a low-cost system.

However, in [9] the author's problem is that security systems are expensive and cannot be implemented in two-wheeled vehicles. For this reason, a low-cost system is developed that implements the recognition of the driver by means of an RFID tag, which allows the system to turn on the vehicle. A GPS location system is also used, which is visualized by means of an application installed in the owner's cell phone. As a result, the system performs the identification of the RFID tag which allows the ignition of the vehicle by means of the key, then the vehicle can be monitored by means of GPS signals sent by the GSM device connected to the system's Arduino. In summary, it is possible to protect two-wheeled vehicles (motorcycles) with a low-cost security system that gives the location and the ability to identify the driver through RFID tags.

On the other hand, [10] mentions that in recent years with the growth of the global and national economy, vehicles have become a necessity for people and at the same time a great loss of money because of theft, criminals use the method of hot wiring to disable the anti-theft system that comes as part of the vehicle, so they designed a system that turns off the engine when the thief starts the vehicle and can capture the image of the offender when starting the vehicle, so they had to use Arduino, relay, GPS and a camera, to develop the system. As part of the results, all the tests were 100% effective. Finally the results showed that the system worked correctly and efficiently.

Finally, the authors provided very interesting research, helping to complement the research conducted, however, in the research implemented a more innovative system, which is helping drivers of vehicles in Lima.

III. Methodology

For the development of this research project, made use of an agile methodology in conjunction with various tools both in the field of software and hardware. In this sense, the project was developed based on the Scrum methodology, which was detailed later, and also mention which are the technological tools that allowed to implement the system in conjunction with the various electronic devices.

A. Scrum

This is known as one of the best methodologies, but it is actually an agile project development framework [11], as shown in Fig. 1 presents each of the stages and the order they take during the application of the same in a project. In addition, it has principles which allow satisfying customer needs, being accessible to changes in requirements, having a collaborative environment between the development team and customers, regular delivery of progress, reflection on how to improve the errors that can be found [12]. The following is a brief description of each of the stages that make up this framework:

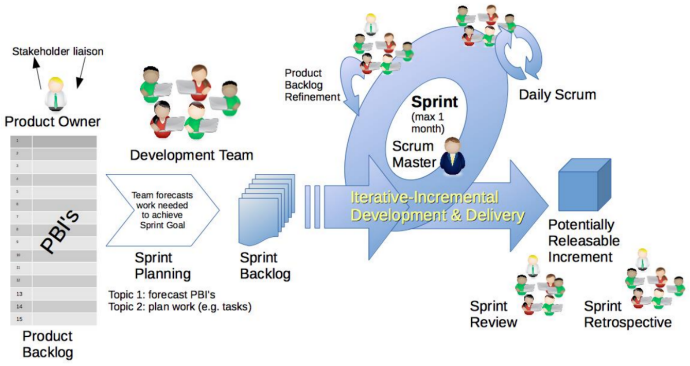

Fig. 1. Scrum Methodology Process [13].

1) Determination of Roles: This is the first stage in which the team as a whole must assign roles within the project development, such as the Product Owner, the Scrum Master and those who was part of the Development Team [14].

2) Planning: At this stage, the team must determine which are the tasks to be developed, in this sense, several meetings are held to discuss each one of them [15]. In this way, a list of the tasks to be performed is obtained, which allows to estimate

each one of them and therefore to have knowledge of the period of completion of the project [16]. At this stage, each of the sprints to be developed is determined, which are considered as mini-projects within the overall project [11].

3) Development: Also, known as the implementation stage, its purpose is to develop each of the Sprints established according to their order of prioritization [14]. It must be taken into account that each of these Sprints must be carried out within the time frame that has been previously established [15].

4) Review and Retrospective: Upon completion of each Sprint, the project development team conducts an analysis to determine whether the project meets the requirements for approval [14]. Then, the team should determine which were the highlights and also those in which difficulties or failures were found, in order to help the team to improve.

B. Software Tools

As part of the development of the research project, the software technologies necessary for its correct development were taken into account.

1) Kotlin: To perform the programming of the application we make use of this system that is compatible with Android, in addition [17], this technology since it was created by JetBrains and Kotlin in 2010 has been characterized by its compatibility, performance and its learning curve.

2) Firebase: It is a service provided by Google through the cloud through which you can perform instant messaging, user authentication, real-time database, and many other functions [18]. However, it must be taken into account that the initial configuration of this service must be carefully carried out, so that all its functions can be used normally [18]. Fig. 2 shows how this medium allows data to be centralized and then distributed to different devices, as well as allowing several actions to be performed simultaneously [16].

3) Moqups: In order to obtain high quality prototypes that are understandable to the naked eye, the Moqups tool is used, which uses some of the services provided by Firebase, which is extremely convenient for compatibility in the development of the project.

C. Hardware Tools

In this section we mention which devices and hardware technologies have been used in the development of this research project.

1) RFID Reader: Within the concept of communication that is established in RFID technology we find the tag reader which fulfills the functions of transmitter and receiver, in such a way [18], the transmitter radiates electromagnetic waves which allow to feed the tags at the time of wanting to detect them and emits the information that was required.

2) RFID Tag: It is one of the emblematic elements of RFID technology due to its production characteristics, which include low production cost, compatibility in manufacturing materials and electromagnetic resistance to the environment in which it is located. In addition [18], there are different types and sizes, which are chosen primarily for their detection capability, which can range from a few centimeters to 25 meters using microwave or UHF antennas.

3) Arduino: The Arduino is an electronic device in which various modules (GSM, GPS, RFID reader) and sensors (light, sound) can be connected to collect information and send on/off signals as needed [6].

4) GPS Module: This is a module whose main functionality is to provide the coordinates in which it is located, this can be sent to a system with Arduino device with which you can track it.

5) GSM Module: This GSM module has the characteristic of providing a means by which communication can be established with it, so, as this GSM technology has evolved, it has a greater coverage which allows a better availability in communication [1].

6) Camera Module: The camera module used for this project is the ESP-32 model, since it has features that fit the needs of the project such as: low acquisition cost, live video transmission, and ease of adaptation to the use of android applications for video transmission via the Internet.

D. Methodology Development

1) Determination of Roles: In this first meeting the roles were determined according to the capabilities of each of the members, Table I shows the different roles and the persons responsible for them.

TABLE I. DETERMINATION OF ROLES

Role	Responsibility
Scrum Master	Laberiano Andrade Arenas
Product Owner	Laberiano Andrade Arenas
Development Team	Jorge Arellano Zubiate Jheyson Izquierdo Calongos

2) Planning: Now, at this stage, the project development team determined which Sprints are required according to the project needs:

- Sprint 1: Implementation of the GSM system that allows the connection between the device and the mobile application. Table II shows the user stories that was developed in this Sprint.
- Sprint 2: Implementation of the RFID system that allows the detection and notification of forced starts in the mobile application. Table III shows the user stories that was developed in this Sprint.
- Sprint 3: Implementation of the GPS system that allows the location of the vehicle through the mobile application. Table IV shows the user stories that was developed in this Sprint.
- Sprint 4: Implementation of the camera system in the vehicle cabin for driver identification through the mobile application. Table V shows the user stories that was developed in this Sprint.

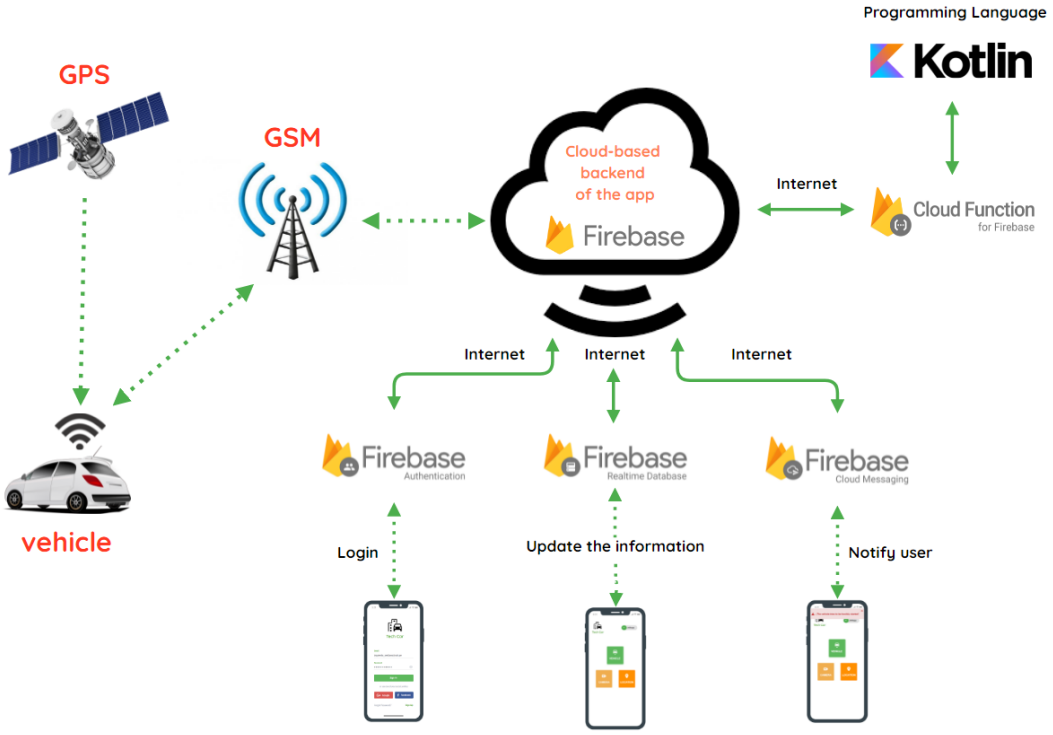

Fig. 2. Diagram of Firebase Operation.

TABLE II. SPRINT 1 USER STORIES

User Stories
I as an administrator want to integrate a GSM device to obtain remote vehicle information.
I as administrator want to implement a server for remote connection to the vehicle.
I as an administrator want a status notification in the app to know the status of the vehicle.
I as an administrator want a registration module for the user to register within the system.
I as an administrator want a login module for the user to validate his login to the system.
I as an administrator want a linking module for the user to get the vehicle information.

TABLE III. SPRINT 2 USER STORIES

User Stories
I as the administrator want to integrate an RFID tag reader to identify the tags.
I as an administrator want an electrical fluid blocking system to block the ignition of the vehicle.
I as the administrator want to register the owner's RFID tag to unlock the vehicle's ignition system.
I as the administrator want an RFID notification to let the user know when the vehicle was forced started.
I as an administrator want a main module for the user to have access to the main options.

TABLE IV. SPRINT 3 USER STORIES

User Stories
I as the administrator want to integrate a GPS device to detect the location of the vehicle.
I as the administrator want to implement Google Maps to facilitate the location of the vehicle.
I as an administrator want a record of the locations so that the user can know the last location of the vehicle.
I as an administrator want a location module in the application to display the vehicle location information.

TABLE V. SPRINT 4 USER STORIES

User Stories
I as an administrator want to implement a camera module to visualize the vehicle cabin.
I as the administrator want a video log so that the user can view who entered the vehicle.
I as an administrator want a usage acceptance module for the user to grant permission to use the vehicle.
I as an administrator want a video module in the application so that the user can view the video in real time.

3) Development:

- Sprint 1: As shown in Fig. 3, the different electronic devices that are part of the circuit of the research project were connected. Each of these devices fulfills

a function . as it allows the IoT concept to be applied. In addition, in this Sprint priority is given to obtaining information through the GSM module, which allowed us to make the remote connection between the Arduino and the mobile application. In this Sprint, the

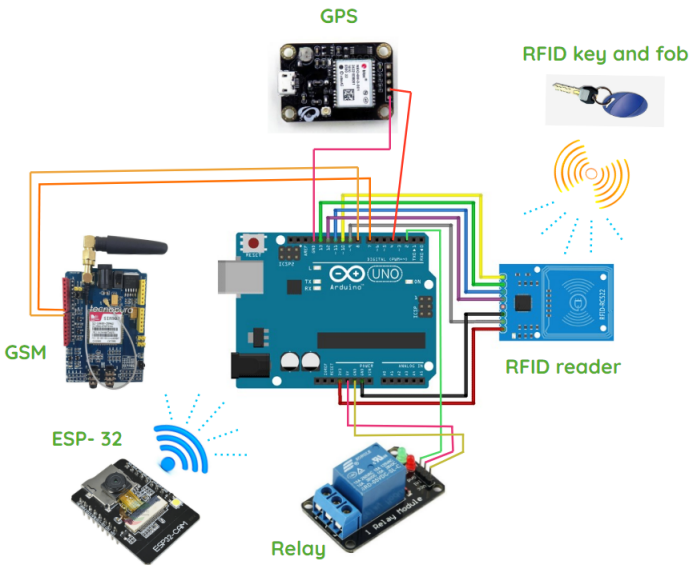

Fig. 3. Physical Diagram of the Anti-theft System.

remote connection between the Arduino circuit and the mobile application was implemented by means of a server that serves as an intermediary between the two. In this sense, the GSM implementation was carried out achieving the remote connection as shown in Fig. 4, where you can see the communication between both points through the server, which allowed us to obtain information on the status of the vehicle and perform the respective actions remotely through the cell phone.

In order for the user to communicate with the system, he/she must be previously registered with a user name and password. Fig. 5 shows the prototype of the form by which the user registers in the application. After registration, the user can use the login form, as shown in Fig. 6, which with the appropriate credentials allows the user to enter the system. Also, Fig. 7 shows the prototype of the main menu through which the user can access the different functions of the system.

- Sprint 2: In this Sprint, the implementation of the RFID tag reading module within the system was carried out. By means of this implementation, the RFID tags will be read and identified in order to unblock or block the electric fluid that allows the ignition and operation of the vehicle's engine. In Fig. 8 the system allows the user to appreciate which is the state (On - Off) in which the vehicle is.
- Sprint 3: In this Sprint, the implementation of the GPS module was carried out, which allows the location of the vehicle. In this sense, as shown in Fig. 9, this module provides the necessary information so that the system can graphically display the location of the

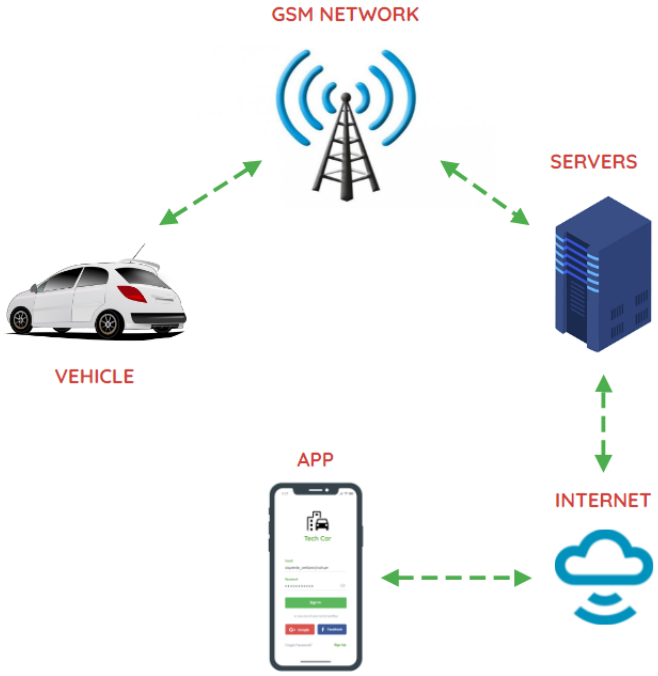

Fig. 4. Diagram of GSM Module Operation.

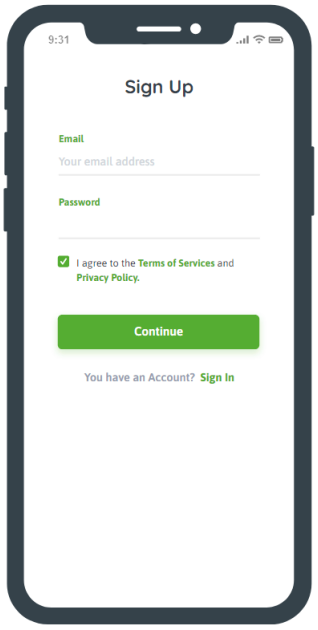

Fig. 5. Registration Prototype.

vehicle in real time, so that the user can know exactly where to locate the vehicle, since it has the coordinates of its location.

- Sprint 4: In this Sprint the implementation and connection of the video camera module is performed, as shown in Fig. 10 it allows the user to visualize the people inside the vehicle in real time. In addition, the options to allow and deny the use of the vehicle

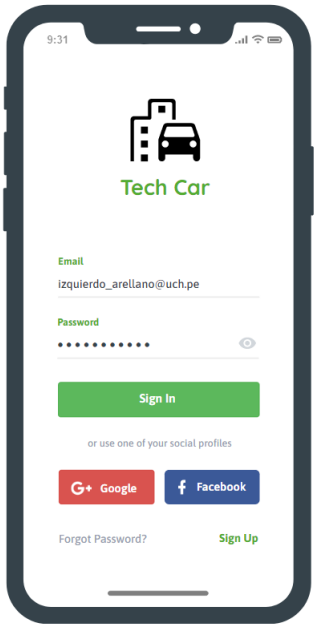

Fig. 6. Login Prototype.

Fig. 7. Prototype of the Main Menu.

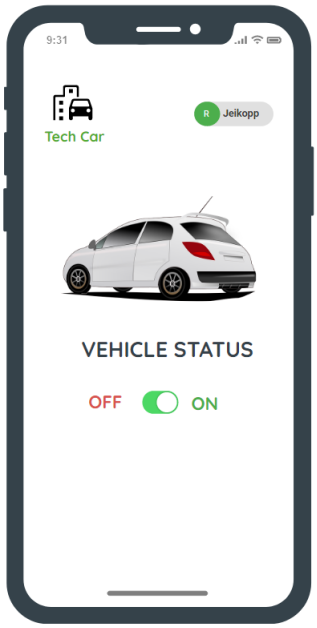

Fig. 8. Vehicle Condition Prototype.

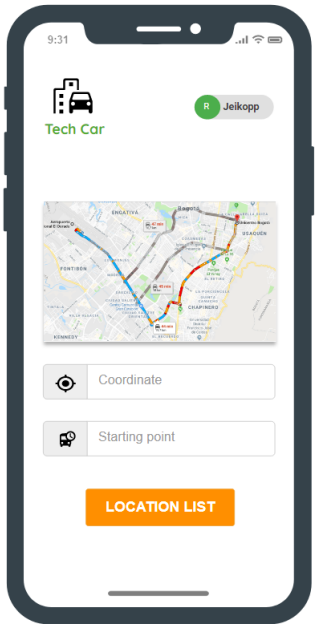

Fig. 9. Vehicle Location Prototype.

according to the user's criteria were implemented in this sprint.

IV. Results

In this section, the analysis of each of the results obtained after the development of each of the Sprints, which are part of the functional structure of this research project, was carried out.

A. System Analysis

Among the results obtained with the development of this research project, we find the flowchart, which is a guide that allows us to know which are the actions taken by the project in various situations.

In this sense, Fig. 11 shows that the system is activated after the vehicle ignition action is performed, then the identification of the RFID tag is performed, which when not identified launches a forced ignition alert. Then, the location of the vehicle is visualized through the use of the GPS device that has

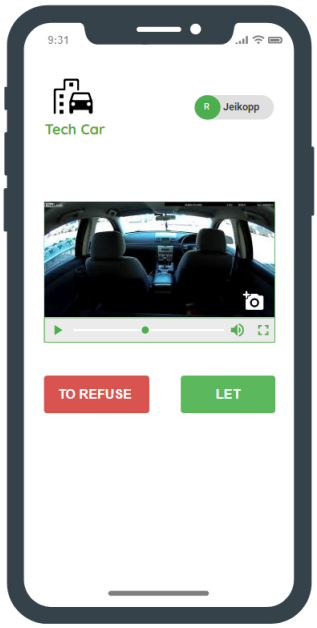

Fig. 10. Prototype of the Visualization of People Inside the Vehicle.

been implemented. In addition, it starts with the transmission of video images, which can be viewed by the user in the application. Finally, there is the option to authorize the user, in case the use of the vehicle is necessary. If the user is not authorized, the vehicle operation is blocked, which is confirmed with a notification.

B. Anti-theft System

1) Notification of Ignition Attempt: As part of the implemented system, RFID tags are used to detect when someone tries to start the vehicle in a forced way. Thus, when someone makes an attempt to start the vehicle without the RFID tag, the system immediately detects the non-existence of the RFID tag reading so it launches a notification which will be displayed on the vehicle owner's computer.

Therefore, after the non-existence of the tag has been detected at the time of the vehicle ignition attempt, an alert is launched in Fig. 12 shows the notification that is displayed by the user from the start menu of the application, which provides access to the functions of GPS location or access to the vehicle's camera module.

2) Notification of Unauthorized Ignition: Now, when the vehicle is started by force or unauthorized by a person who does not have the RFID tag, the system detects that the engine is running and sends an alert to the user in Fig.13 shows the respective notification from the start menu giving the user access to the GPS and Camera module options.

3) Vehicle Locking: When the vehicle has been forcibly started, the user can, as shown in Fig. 14, access the vehicle's camera module and view the real-time video feed from the vehicle's cabin. In addition, it is possible to visualize the person who started the vehicle, so the user has access to the options to allow the use of the vehicle in the case of an authorized person or to block the use of the vehicle.

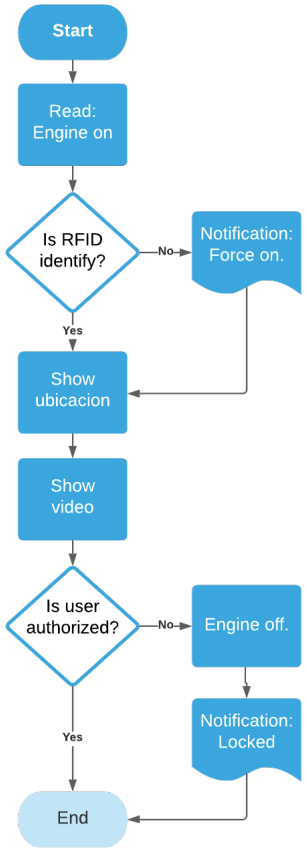

Fig. 11. System Flow Diagram.

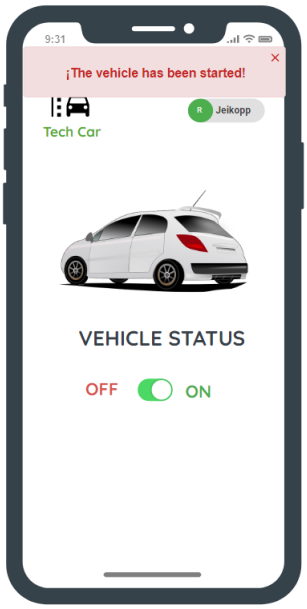

Fig. 13. Vehicle Status Alert.

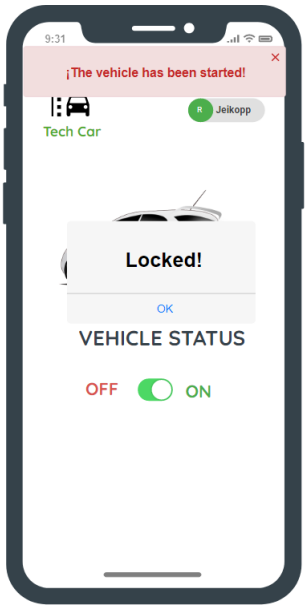

Fig. 15. Locking of the Vehicle.

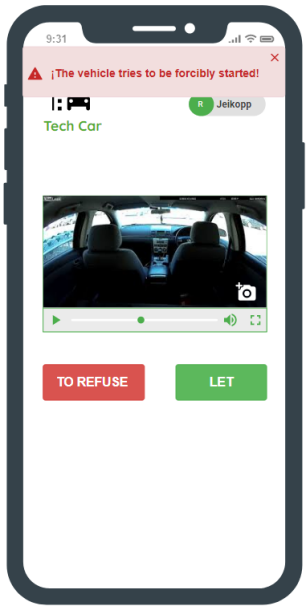

Fig. 14. Alert from the Camera Module.

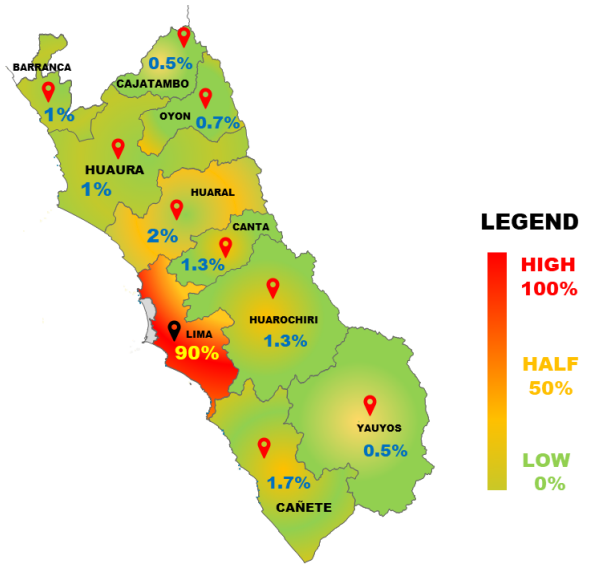

Fig. 16. Heat Map of the Crime Rate in the Department of Lima - Peru.

In fact, when the user determines that the person inside the vehicle is not authorized, he has an option in the system that allows him to block the vehicle. Thus, Fig. 15 shows that when the user blocks the vehicle correctly, he will be notified with a message on the device.

C. Analysis of Robberies in Lima

This research was developed in response to the problem of vehicle theft in the department of Lima, Peru. As shown in Fig. 16, the department of Lima has a vehicle theft rate of no more than 3% in its different provinces; however, the department of Metropolitan Lima has the highest rate, reaching 90%.

The purpose of this research project is to progressively reduce the rate of vehicle theft in the department of Metropolitan Lima. In Fig. 17 we can see that this rate is reduced over time because users have access to the location of their vehicle in real time, the means to visualize who is inside their vehicle, an RFID tag identification system, and the possibility of remotely blocking the vehicle through the IoT application.

This project, being implemented with IoT, allows the user to access the information of those devices with which it has, in addition, it offers the option of interacting with them by giving remote indications, which greatly facilitates the remote control of the vehicle.

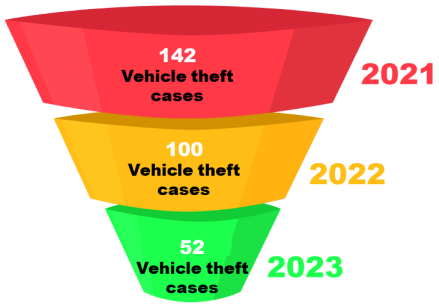

Fig. 17. Crime Projection in Lima - Peru.

V. Discussion

The present research has certain differences in comparison with other research papers dealing with the same technologies.

In fact, he took the trouble to [6] as a reference to the management of the information provided by the sensors to the Arduino device and then transmitted to a mobile application. On the other hand, in our research project the same principle was used to detect the information from the different devices that are connected to the Arduino and to be able to perform actions with them remotely.

In this regard, in comparison with the system developed by [7] which uses the vehicle's coordinates to be displayed by means of text messages on the owner's mobile device, in our system we use these coordinates through an API which allows the visualization by means of a map, allowing a better visualization of the vehicle's location by the user.

Likewise, in the work developed by [1] the system displays the location of the vehicle in the same way with the possibility of sending messages as a response and that these provoke an action in the system. However, in our system the same actions are shown with the difference that they are not a text message, but are commands that are executed after triggering them through the interface which is safer and easier for the user because it can not always have in mind the commands to send them by a text message. It is suggested to carry out research on the topic of RFID implant application such as [19] indicates that this technology can be used for the identification and subsequent operation of devices, thus avoiding the use of tags that can be easily stolen or lost by the user. It is also recommended to study the work of [20] which explains in detail how RFID implant technology works and the different applications that can be performed with it. Therefore, it is recommended to involve a Systems Engineer, an Electronic Engineer, an Automotive Technician and a General Practitioner, in order to carry out a multidisciplinary research.

VI. Conclusion and Future Work

In conclusion, this research allows, through the fusion of different technologies together with the IoT, the reduction of crime levels in vehicle theft, which favors all those who need an innovative system that offers various options in the management of this type of situations. The agile methodology with its scrum framework, allowed to have a more holistic outlook for the design of the prototypes. As a future stage to be developed within our system, it is suggested to develop a history of the locations where the vehicle has been the victim of attacks to obtain data from the places with the highest rate of vehicle theft attacks. There were certain limitations to the analysis that were beyond the scope of systems engineering. In this sense, it is suggested to carry out research in an interdisciplinary, multidisciplinary way, that is, with sociologists, electronic engineers, among others.

***Abstract*—Rapid urbanisation and infrastructure shortcomings leading to heavy traffic, heavy construction activities are major contributors to emission of particulate matter into the ambient atmosphere. This is especially true in developing countries, such as India and China. There have been numerous attempts from government authorities and civic agencies to curtail pollution, but these efforts have been in vain. Cities like Beijing, New Delhi suffer from extremely unhealthy air quality during multiple months of the year. Hence, the onus of keeping oneself safe from extreme affects of air pollution falls on the individual. The following study presents a method and framework to measure particulate matter (PM2.5) concentration using low cost sensors, and infer patterns from the data collected. The study uses a SDS011 high precision laser PM2.5 detector module combined with a raspberry pi, which communicates the measurements through *message queueing telemetry transport* (MQTT) protocol to a ponte server which inturn persists the data into a MongoDB, which can be consumed by algorithms for further analysis. For example, the data obtained from the sensors can be fused with data from measurement stations and geographical land use information to estimate dense spatio-temporal pollution maps which is the basis for computing individual exposure to pollutants.**

***Keywords*—Air pollution; low cost sensor; optical dust sensors; particulate matter; MQTT; ponte**

I. Introduction

Particulate matter is a major source of air pollution across the world. Exposure to particulate matter can cause a multitude of problems to individuals including higher risk of hypertension Prabhakaran et al. [1], lung cancer Ciabattini et al. [2], cardio-vascular disease Jaafari et al. [3]. The affects of pollution are more prominent in the most vulnerable subset of population such as pregnant women Tapia et al., Zhu et al. [4, 5], infants Zhou et al., Rivera et al. [6, 7], and the elderly Wang et al., Han et al. [8, 9].

Recently, there have been major strides in quantifying the exposure of individuals to pollutants. Government agencies report air quality in the form of *Air Quality Index* (AQI), which signifies short term effects of pollutants in the atmosphere. Additionally, there have been numerous studies exploring the use of low cost and mobile sensors to measure individual exposure in an efficient manner. Karagulian et al. [10] provides a comprehensive review of various studies for measurement of different pollutants using low cost sensors.

There have been a few studies where the sensors are mounted on a moving vehicle, and pollution mapping is done along the path of the vehicle. DeSouza et al. [11] mounted Alphasense OPC-N2 sensors on garbage trucks to map out air quality in Cambridge, MA. The study used the collected data to identify clusters signifying pollutant hotspots, and explored techniques to generalise the measurements across the entire traversed route.

Low cost sensors are an efficient way for measuring individual exposure to pollutants. Mahajan and Kumar [12] explored the usage of low cost sensors to quantify individual exposure. The study used a PMS5003 sensor which published data using an ESP8255 wifi module. Similar to this study, calibration of the PMS5003 sensor was performed by the colocation technique with a GRIMM EDM 107 dust monitor. Motlagh et al. [13] provide a vision for the use of low cost sensors for dense air quality monitoring and the study also documents an example implementation in the city of Helsinki, Finland.

Chen et al. [14] used a SDL-607 to measure school students' exposure to PM2.5. The sensor measures particulate matter concentration by means of laser scattering using the principle of nephelometry. The data was stored in internal memory and manually transferred to a computer. Candia et al. [15] propose a system and framework for using low cost sensor networks for air quality monitoring. The study used Nova SDS011, SDS021, and SHINYEI PPD42 sensors connected to an Arduino Mega, with an ESP8266 wifi module and a LoRaWAN module in the absence of a wifi network.

Most of these studies concentrate on the efficacy of the sensors, but there are not many studies which propose a comprehensive framework for acquisition and management of pollution data effectively. There are some platforms available which have been used, for example Schneider et al. [16] used *AQMesh* (AQMesh [17]) platform to map out urban pollution in Oslo, Norway. AQMesh provides a proprietary solution for data management which includes web, API and other modes of access. Lim et al. [18] used *AirCasting* (HabitatMap [19]), an opensource data visualisation platform, to map out pollution in Seoul, South Korea.

In the following sections, a detailed description of the proposed framework is provided. Firstly, the sensors utilized and their internal components are described. Section II-B describes the calibration process for the sensors to avoid drift

and inaccuracies in the reading. Finally, Section II-C describes the overall data acquisition process, including the edge devices, protocol and server infrastructure involved.

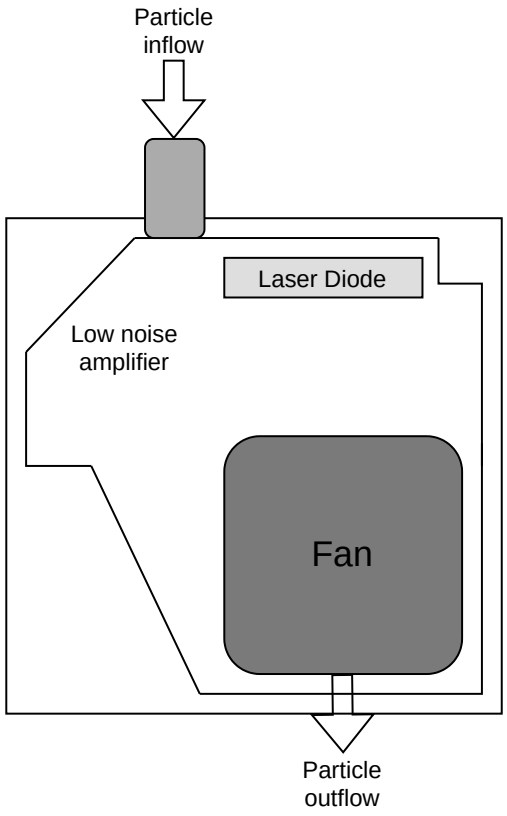
II. Measurement Framework

A. Sensors

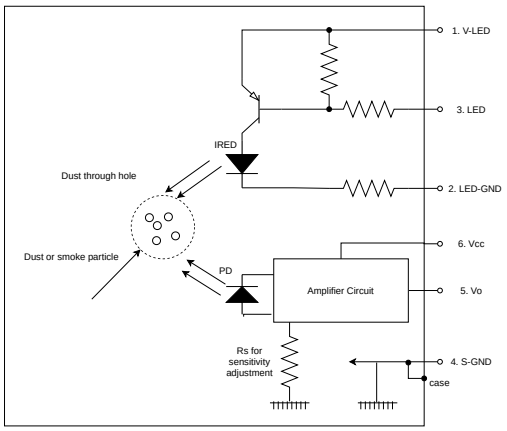
During the study, two sensors were evaluated viz., a Sharp GP2Y1010AU0F optical sensor and a SDS011 laser sensor. Both the GP2Y1010AU0F and the SDS011 sensors use light scattering principle to count the number of particles in the air sample. While the Sharp sensor uses infra-red light, the SDS011 sensor uses laser scattering. Fig. 4 shows the circuit diagram used to connect the sensor to an Arduino Uno in order to get the particulate matter concentration. The SDS011 sensor is easier to use. It has a UART connector that can be directly connected to raspberry Pi using a USB connection. Another advantage of the SDS011 sensor is that it has an inbuilt fan, in order to ensure uniform distribution of the particles in the measurement air sample.

SDS011 is a dust sensor developed by Nova fitness, which uses laser diffraction principle to measure the concentration of particulate matter in the air sample. 1a shows a schematic diagram of the internal components of the SDS011 sensor. It has a sensor output frequency of 1Hz, with a sensitivity range of $0 - 999.9 \mu g m^{-3}$. The sensor has an inbuilt fan and is the most accurate for the size with a relative error of 10%. The sensor has a working range in 0-70% humidity and $-20 - 50^0 C$.

The SHARP GP2Y1010AU0F is an optical dust sensor similar to the SDS011. b shows the inner circuit diagram of the sensor (Fig. 1). It uses an IR LED and phototransistor to measure the amount of dust in the air sample. One of the salient features of the sensor is that it can detect dust from a single pulse, hence works at much higher frequency of upto 100Hz. The sensor measurements are read as voltage which is proportional to the density of particulate matter in the air sample. The sensitivity of the sensor ranges from $0.35 - 0.65 V/(0.1 \mu g m^{-3})$. The main drawback of the sensor is that it does not have an inbuilt fan, hence it needs to be housed in a mixing chamber with a fan in order to get reliable readings. However, when mounted on a moving vehicle, proper placement can eliminate the need for a mixing chamber.



(a) SDS011 Sensor



(b) GP2Y1010AU0F Sensor

Fig. 1. The SDS011 and GP2Y1010AU0F Sensors.

B. Sensor Calibration

Low cost sensors are very capable of detecting pollutant concentrations effectively. With proper maintenance and calibration, they are suitable for long term usage too. Liu et al. [20] studied the performance of a Plantower PMS1003 sensor for PM2.5 measurement at two locations in Australia and China, over a period of 13 months. Zusman et al. [21] provide a comprehensive guide to calibrating low cost sensors using multiple techniques. In this study, sensor calibration was performed by co-location method.

The calibration for the SHARP GP2Y1010AU0F sensor was done by colocation technique. The sensor was colocated near Jayanagar air quality monitoring station maintained by Karnataka state pollution control board (KSPCB) located at 12.920984 LAT, 77.584908 LONG. Simultaneous readings were taken for a duration of two weeks. Fig. 2 shows the outputs of the two sensors. Pearson correlation between the SHARP sensor measurements vs reference sensor is 0.9121332.

C. Data Acquisition Infrastructure

The data measured from the sensors is published through MQTT to ponte server which provides a MQTT broker. The data is persisted in MongoDB, which is used for offline and realtime data analysis. Fig. 3 shows a Schematic representation

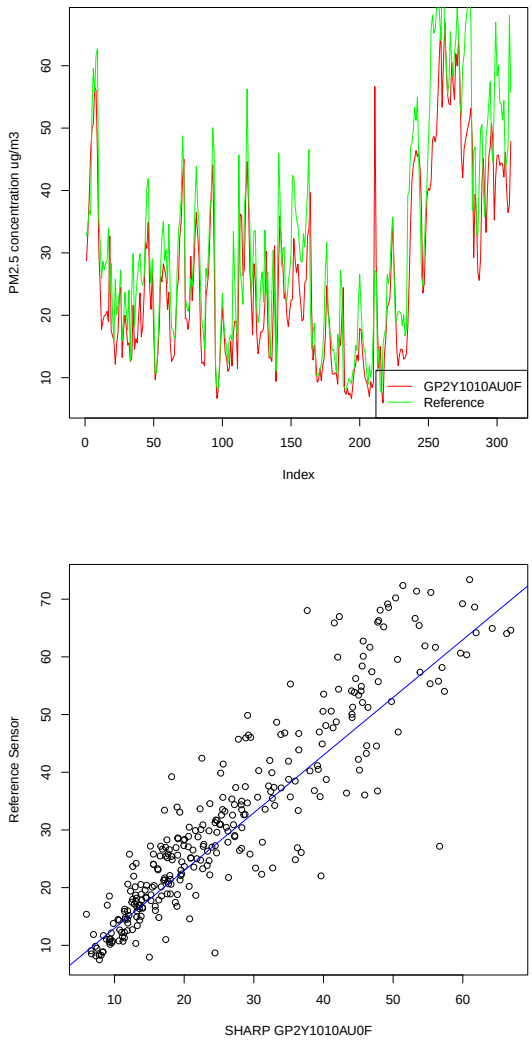


Fig. 2. SHARP Sensor Measurements VS Reference Sensor

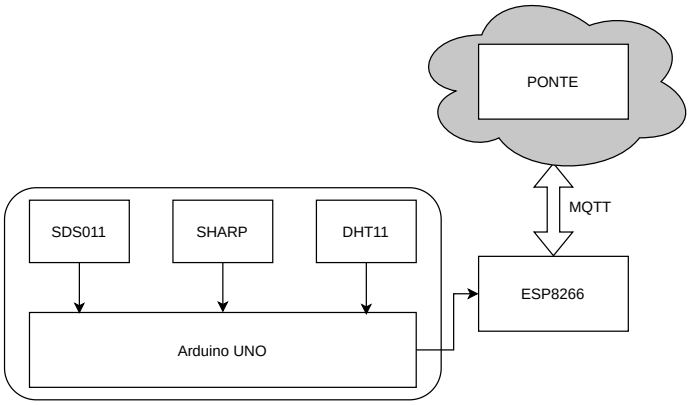

Fig. 3. Schematic Showing the Overall Data Acquisition and Persistence Framework.

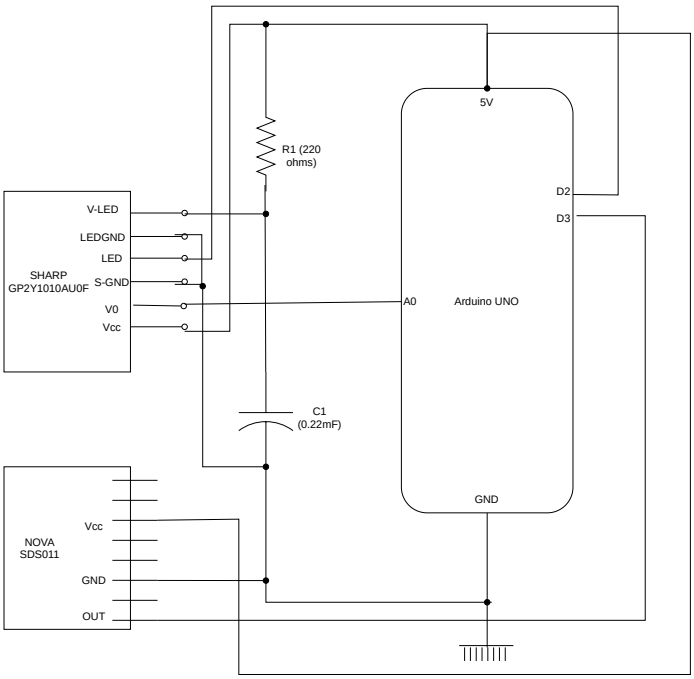

Fig. 4. Circuit Diagram to Connect the Sensors to an Arduino Uno.

of the overall data acquisition and persistence framework.

1) Message Queueing Telemetry Transport: MQTT is a publish-subscribe type messaging protocol which is widely used in IoT (Internet of Things) applications. One of the major advantages of MQTT is that the client applications are very light weight, making it ideal for deployment in small embedded systems such as low power micro-controllers. Additionally, the protocol is scalable, potentially capable of incorporating millions of devices.

Fig. 5 shows an example of an IoT system using MQTT. There are mainly three types of nodes in a MQTT network, viz., the publisher, the subscriber and the MQTT broker. A node can take the role of a subscriber or publisher or both simultaneously. The broker is part of the infrastructure and resides in a server machine. The publisher node publishes data using a specific *topic*, while subscriber nodes which have subscribed for the specific topic, will recieve the message with the data.

MQTT also provides an option for the broker to store messages when a subscriber is down, so that the messages are delivered when the client comes up. Another advantage of a publish/subscriber model over a traditional client servers is that the publisher does not need to be aware of the nature or number of subscribers. Although, the subscribers need to be aware of the message format and the topic of the publisher. MQTT and publish/subscribe model for communication is an efficient model for low power sensor networks such as the one used in the study. It also supports OAUTH based authentication, so that the data is protected from unauthorised access. It also provides for TLS/SSL data encryption.

In this study, each edge node containing an Arduino Uno is assigned a MD5 hash, which acts as an identifier string, and each node publishes the measured PM2.5 concentration, temperature and humidity using a topic which includes the

identifier. For example, 84474b87cafa5f22d8aa2a5b990bfe98 is the identifier for the node which was colocated with the Jayanagar 5th Block monitoring station, and the sensor measurements from the node is published using a topic strings 84474b87cafa5f22d8aa2a5b990bfe98_dht11, 84474b87cafa5f22d8aa2a5b990bfe98_gp2y, and, 84474b87cafa5f22d8aa2a5b990bfe98_sds011 for the temperature and humidity values from the DHT11 sensors, PM2.5 concentrations from the SHARP GP2Y1010AU0F and the Nova SDS011 sensors respectively in the form of a JSON object.

2) Server Infrastructure: The data published by the edge nodes need a MQTT broker to route the messages to the subscribers. Also, there is a need for a scalable database where the data can be persisted for future analysis. Additionally, a HTTP server interface is helpful for a web based dashboard with visualization and realtime data showcasing. In this study, eclipse ponte is used, to accomplish the above requirements. Ponte provides a seamless integration with MongoDB for persisting the data as well as sessions. Additionally, it provides HTTP and CoAP services with REST like APIs.

Fig. 6 shows the schematic architecture of Ponte, with interfaces for MQTT, HTTP and CoAP (Constrained Application Protocol) protocols. The figure also shows the persistence module which connects to MongoDB which not only stores the published data, but also the session information for facilitating seamless communication even in fickle networks.

On the server, different analysis and visualisation applications can provide good insights into the individuals exposure to pollutants. Additionally, a cumulative exposure index (C) can be calculated based on pollutant concentrations exposed to and the amount of time spent. It can be computed as an integral over time, or a simplified summation (C') for discrete readings as shown in equation 1 and 2.

$$C = \int_t d_t dt \tag{1}$$

$$C' = \sum_t d_t \tag{2}$$

where d_t is the pollutant concentration at time t. The measurements, d_t can be geographically distributed across the city.

III. Discussion

Low cost sensors and their efficacy in measuring pollutant concentrations is the subject of multiple studies, hence this study does not go into the details of these factors. However, there are only a few studies which elaborate on the framework and infrastructure involved in collecting the measurements in a database and the interfaces required for analysing the data. This study provides a comprehensive guide to the processes, system and framework necessary for measurement, persistence and analysis of pollution data.

Sensors used in the current study require periodic calibration. Chain calibration technique, where a correctly calibrated low cost sensor co-located with the deployed sensors can be used to avoid sensor drift and other errors in the measurements. Additionally, temperature and humidity play a major role in the accuracy of the measurements. Hojaiji et al. [23] provide a way to calibrate the SHARP sensor to compensate the effects of temperature and humidity. The SDS011 sensor is relatively robust to temperature and humidity variations. In the current study, we smooth the variations caused due to temperature and relative humidity for the SHARP sensor. The study also ignores readings from both sensors when the humidity level rises beyond 70%. Spatial and temporal regression techniques can be used to interpolate the measurements from the monitoring stations. In a future work, a combination of long short term memory (LSTM) networks and land use regression (LUR) in order to build a dense spatio-temporal pollution map is evaluated.

MQTT is a robust transmission protocol which supports the necessary data distribution, encryption and authentication features. Publish/subscribe model of communication is also a very efficient mode for medium scale networks which is necessary for pollutant modeling for a city. However, MQTT transmit cycles are not well equipped for large networks, CoAP could be a feasible alternative when designing a network larger than 250 measurement nodes. Ponte server, used in the study, supports publishing data through CoAP using a simple REST API. This would be the focus of a future study to augment the findings presented in this article.

The framework presented above, is capable of being extendible to different types of sensors, different and more efficient protocols, more stringent and effective security measures, and different persistence technologies. The framework presented above serves as an outline for a more complex and feature rich system implementation.

A. Conclusion and Future Scope

In this paper, a system and framework for measurement, persistence and analysis of pollution data using low cost sensors was proposed. A SHARP GP2Y1010AU0F and a SDS011 dust sensors were used to measure the PM2.5 concentration in ambient atmosphere and the data was sent to a server running ponte using MQTT. The data was persisted in MongoDB which is used for further analysis on the server. Additionally, in order to compensate for the effect of temperature and relative humidity, a DHT11 sensor provided the necessary readings.

The above work is the first step towards a comprehensive estimation and prediction of individual exposure to pollutants and it's deposition in the human lungs. In the future, as a progression of this work, the authors intend to estimate dense spatio-temporal pollution maps with the fusion of data measured using these low cost sensors, and from measurement stations and provide a predictive methodology to quantify lung deposition of these pollutants for an individual.

Sustainable Android Malware Detection Scheme using Deep Learning Algorithm

Abdulaziz Alzubaidi
Computer Science Department,
College Computing in Al-Qunfudhah
Umm Al-Qura University

***Abstract*—The immense popularity of smartphones has led to the constant use of these devices for productive and entertainment purposes in daily life. Among the different operating systems, the Android system plays a very important role in the development of mobile technology as it is the most popular operating system. This makes it a target for cyberattack, with severe negative effects in terms of monetary and privacy costs. Thus, this study implements a detection scheme using effective deep learning algorithms (LSTM and MLP). Also, it tests their ability to detect malware by employing private and public datasets, with accuracy of over than 99%.**

***Keywords*—Smartphone security; machine learning; mobile malware; classification; big data**

I. Introduction

The current century has witnessed various inventions such as smartphone devices. These devices are characterized by advanced features in terms of sophisticated operating systems and gigabytes of memory. They are equipped with advanced sensors such as accelerometer, magnetometer, global positioning system (GPS), and biometric sensors. Due to these developed features, the owner of smartphones can perform various activities, such as sending/ receiving electronic emails, performing financial transactions, contacting with others, taking photos and recording videos, etc. [1]. Statistics show the number of smartphone users surpassed 6.4 billion users globally in 2021, and it is expected to reach 7 billion in 2026 [2].

Mobile applications (apps) are implemented to perform one or more tasks. They are available in official markets and third parties. As of 2021, the popular mobile market apps are: Google Play (3,482,452 apps), Apple app store (2,226,823 apps), Windows store (669,000 apps), and Amazon App store (460619 apps) [2]. Smartphones and mobile market apps are targets for attackers in terms of privacy and security. According to [3], the instances of mobile cybercrime surpassed 14.4 million attacks in the second quarter of 2021, 95% of Android devices can be hacked using a simple text message, and 87% are exposed to serious vulnerability. In September of 2020, the Apple store has pulled 40 apps infected by the XcodeGhost botnet attack [4], which indicates that the malware apps might be found in official apps. Therefore, several approaches from academic and industrial fields have been proposed using machine learning algorithms.

Machine learning is an effective method for intelligent detection of malware on smartphones. Malware detection on smartphones is based on feature analysis by static, dynamic, and hybrid methods [2]. The detection and prediction effectiveness of any machine learning algorithm relies on selecting suitable data and understanding malware behavior.

Problems and Motivation

Previous studies have been proposed to detect known and unknown malware samples using public and private datasets. However, most of utilized public datasets are collected between 2010 and 2017, which raise an important question about how they can detect recent implemented malware while the behavior of mobile malware is changeable. Therefore, there is need to collect updated apps . Besides that , understanding the malware patterns and classifying them into families is an effective way to detect unknown malware.

This study proposed a sustainable and cost-effective malware detection scheme with respect to collecting an updated dataset, classifying malware families , and observing malware behavior .

Contributions

This work address the above-mentioned issues related to detecting Android malware. Its contributions are listed below.

1) A dataset is build with 30,000 samples at the present time, plan to expand to be larger and make it publicly available
2) An Android malware detection approach is proposed using machine and deep learning algorithms with respect to sustainability metrics.

The remaining part of this article is organized as follows: Section II summarizes recent studies in this field. Sections III and IV introduce the proposed methodology and describes the dataset used. Finally, the conclusion of this research work is presented in Section V.

II. Prior Research

Detecting Android malware has gained attention last two decades. There are several proposed approaches employed machine and deep learning. Alzubaidi [2] provides a comprehensive survey in terms of static, dynamic and hybrid feature analysis methods using machine learning algorithms, while Qiu et al. [5] review recent deep learning approaches and addressed challenges like the architecture of deep learning. This sections discusses sustainable Android malware detection approaches then summarizes common public datasets.

A. Sustainable Detection Malware Approaches

Onwuzurike et al. [6] introduced a static approach to detect Android malware, which is known as MaMaDroid. This approach is comprised of three phases. The authors first acquired a dataset with size of 43,940 apps (35,493 malware apps from Drebin and 8,447 normal apps from the Google Play store). Second, they extracted the API calls for each feature, then used principal component analysis (PCA) [7] to rank them. Third, they employed random forest (rf) [8], 1-Nearest Neighbor (1-NN), 3-Nearest Neighbor (3-NN) [9], and support vector machine (SVM) [10] to construct their approach. The authors performed two experiments on detecting unknown malware samples and examined the sustainability of their approach. For the first experiment, they achieved accuracy of 0.99. For the second experiment, they examined the sustainability of the samples in terms of one-year and two-year periods and obtained accuracies of 0.87 and 0.75, respectively.

Zhang et al. [11] developed a method to detect Android malware employing sustainability analysis, which they called APIGRAPH. To construct APIGRAPH, a private dataset was collected consisting of 322,594 samples (290,505 normal apps and 32,089 malware apps). The authors extracted API calls, exceptions, and permissions features and employed RF [8], Model Pool, SVM [10], and deep learning neural networks (DNNs) [12] classifiers. They evaluated their developed method using MamaDroid [13], DroidEvolver [14], Drebin-DL [15] and Drebin [16], based on sustainability, and found that the average enhancement for [13], [14], [15] and [16] was 19.2%, 19.6%, 15.6% and 8%, respectively.

Cai and Jenkins [17] investigated how Android app behavior might change over time. For this purpose, the authors used 155 predefined metrics from [18], which are based on general, ICC and security perspectives. They added the extent, frequency, and distribution for the source and sink invocations of sensitive API calls. A dataset was built including 6432 apps (3431 normal apps and 3001 malware apps). In order to evaluate their approach, they constructed two groups of datasets, based on the year, then performed a comparison using the predefined metrics to rank the most informative metrics and found 52 features to be most informative, which were used for further evaluations. They employed RF and obtained an accuracy of 93% while achieving an accuracy of 82% for their sustainability metric.

Cai et al. [19] implemented a scheme called Droidcat to detect Android malware in terms of systemic app-level profiling. The authors created a private dataset consisting of 34343 apps (17,365 normal apps, 16,978 malware apps). Then, they reduced the samples to 271 apps (136 normal apps, 135 malware apps) meeting their requirements. A total of 122 metrics were defined based on structure (method calls, declaring classes, callback), ICC (Intent, carrying data through URI only), and security (distributions of sources, sinks). The authors utilized RF to detect unknown malware samples, and obtained Precision, Recall and F1 of 97.96%, 97.91%, and 97.84%, respectively. Another experiment was carried out to evaluate the sustainability and obtained results with small standard deviations of 1.34-2.38% in terms of F1.

An approach was introduced by Cai [20] called DroidSpan based on behavioral profiling features. The author collected a total of 26382 samples (13,627 normal apps and 12,755 malware apps), then extracted 52 features based on the extent of sensitive access, categorization of sensitive data and operations accessed, and sensitive method-level control flows. Then, the approach employed RF [8], k-NN [9], SVM with both linear and radial basis function kernels [21] , decision trees [22], naïve Bayes [23] with three models (Gaussian, Multinomial, and Bernoulli), AdaBoost [24], Gradient Tree Boosting [25], Extra Trees, and the Bagging classifier, and evaluated DroidSpan in terms of F1-measure, recall and precision. Among all classifiers, RF obtained the best results. Then, another experiment was performed to examine the sustainability based on same-period detection and obtained 92.88%, 92.68% and 92.61% for precision, recall and F1-score.

B. Common Public Datasets

Current approaches rely on two types of data: private and public datasets. This section summarizes common public datasets.

1) Drebin: Arp et al. [16] built a dataset called Drebin between 2010 and 2012 and comprised of 123, 453 samples for normal applications and 5560 abnormal samples from 179 different families. It is available on https://www.sec.cs.tu-bs.de/~danarp/drebin/.

2) AndroZoo: Allix et al. [27] began building a public dataset in the latter part of 2011, called AndroZoo. The authors implemented a crawling tool to examine the application if it had not been downloaded previously. Then, they installed the application, calculated the s SHA256 checksum, and stored the sample. These samples were submitted to VirusTotal, a portal that allows users to analyze potential malware using various antivirus scanners, including several commercial products, such as McAfee, Symantec, and Avast. The total instances of AndroZoo is 10,774,100 samples and available on https://androzoo.uni.lu/.

3) Malgenome: Malgenome was introduced by Yajin and Xuxian [28] with total of 1260 malware samples covering 49 Android malware families between 2010 and 2011. Malgenome is available on http://malgenomeproject.org/.

4) Contagio Mobile Mini-dump: Contagio Mobile Mini-dump was developed by Mila [29]. Data collection involved a blog published in 2008 that allowed researchers to upload and download malware. As of April 2020, 370 malware samples had been collected. We tested this dataset and found some samples cannot be installed. Contagio can be found on http://contagiodump.blogspot.com/?m=1.

5) PRAGuard: PRAGuard is a publicly available dataset introduced by Maiorca et al. [30]. The dataset contains 10479 malware samples from on 50 malware families. PRAGuard is available on http://pralab.diee.unica.it/en/AndroidPRAGuardDataset.

6) Android Malware Dataset (AMD): The AMD was compiled by Wei et al. [31], and consisted of 24,650 samples collected between 2010 and 2016. The dataset includes various types of malware, such as Trojan, backdoor, and ransomware.

TABLE I. SUMMARY OF UTILIZED PUBLIC DATASET

Dataset	# of samples	Years of collection
Drebin [16]	5560	2011 - 2012
CICAndMal2017 [26]	10854	2015 - 20017
AndroZoo [27]	16,487,972	Late 2011- 2016

The authors employed antivirus scan results as well as automation methods to classify these samples based on behavioral semantics (135 varieties), and 71 malware families. It is available on http://amd.arguslab.org/ .

III. PROPOSED SCHEME

The proposed scheme categorizes into two parts: first part relies on examining how feature engineering might affect on obtained results. The machine learning classifier extracts static and dynamic features, finds most informative features and employs state of the art machine classifiers, while the deep learning scheme studies how deep learning might enhance the gained performance. We performed several scenarios to present the effectiveness of developed scheme.

A. Machine Learning Classifiers

The Machine Learning classifiers scheme consisted of four parts. First, we build a dataset comprised of public and private datasets. Then, two types of features are extracted: permission-based and network traffic features. Once the features are extracted, the most informative features are ranked for further analysis in the third phase. Finally, the developed scheme is evaluated among four scenarios: detecting malware in terms of binary classification, classifying the samples based on their packages and families, and finally considering sustainability metrics in our scheme. Fig. 1 depicts the structure of the proposed scheme.

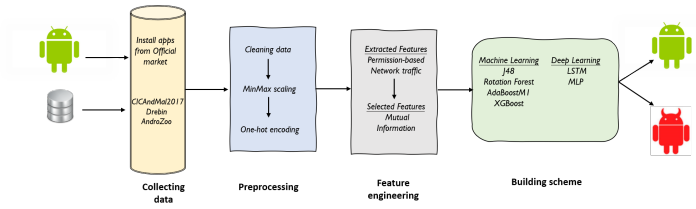

Fig. 1. Architecture of the Implemented Scheme.

1) Acquiring Data: Since the commonly used public datasets were collected between 2008 and 2017 [2], we started to construct a public dataset to be available in the near future for academic research purposes. For this purpose, we picked three public datasets: Drebin [16], CICAndMal2017 [26] and AndroZoo [27], which are summarized in Table I. We, then, targeted the official market for Android devices: the Google Play store to download up to 500 popular apps for 30 different categories using 15 different smartphone devices. Finally, we analyzed and stored downloaded apps in a local database. The process of collecting apps started November 2020 and we are continuing to build our dataset.

2) Pre-processing the Data: Once the data was collected, we performed a pre-processing step for the data which aims to observe any possible noise, remove duplicate apps and keep the updated version of the app, as well as to find missing, redundant and invalid data. For normalization, we used Min-Max scaling [32], and One Hot Encoding [33] to transform non-numeric data into numeric values. After performing this process, we had a total dataset of 15,000 malware apps, and 16500 normal apps. For balance, we constructed an updated dataset with a total of 30,000 samples (15,000 normal apps and 15,000 malware apps) and continued working to make the dataset larger.

3) Extracting Features: To extract the features from our dataset, we developed a tool called AndroAPKF Analyzer, installed it on our devices, ran each app, then extracted permission-based and network traffic features. We extracted two types of features: permission-based (280 extracted features) and network traffic (80 extracted features).

Once the features are extracted, they are stored temporarily in the phone, then sent to the local database for further process. The final stored data had a CSV file extension.

4) Selecting Features: Finding the most informative features is a subsequent phase during construction of the scheme. Using selected features will help to reduce evaluation time and over-fitting and improve the obtained results. There are several approaches that can be used to find most informative features such as mutual information (MI), which is a method to measure the mutual independence of the amount of information that a variable contains about the occurrence of another variable [34].

$$MI(X;Y) = \sum_{y \in Y} \sum_{x \in X} P(x,y) log_p \frac{x,y}{p(x)p(y)} \quad (1)$$

where X, Y are discrete or continuous random variables, $p(x)p(y)$ is the product of marginal distributions. For our approach, we adopted the implemented ranking scheme proposed by Alzubaidi et. al [35] to find the most informative features. We ranked permission features and network traffic individually in terms of the top 10, top 50, and all features. Tables II and III present highest informative extracted permission and network traffic features, respectively.

TABLE II. TOP 10 PERMISSION-BASED FEATURE RANKING USING [35]

Feature set	Rank
Android.permission.INTERNET	0.937
Android.permission.READ_PHONE_STATE	0.925
Android.permission.ACCESS_NETWORK_STATE	0.909
Android.permission.SEND_SMS	0.886
Android.permission.WRITE_EXTERNAL_STORAGE	0.881
Android.permission.RECEIVE_BOOT_COMPLETED	0.867
Android.permission.ACCESS_WIFI_STATE	0.852
com.Android.launcher.permission.INSTALL_SHORTCUT	0.834
Android.permission.INSTALL_PACKAGES	0.785
com.android.alarm.permission.SET_ALARM	0.748

B. Experimental Setup

We ran experiments using Microsoft Windows 10 on a 2.11 GHz Intel Core i7 178 processor with 16 GB RAM dGPU

TABLE III. TOP 10 NETWORK TRAFFIC FEATURE RANKING USING [35]

Feature set	Rank
Source IP address	0.913
Source Port	0.906
Destination IP address	0.883
Destination Port	0.876
Flow Duration	0.833
Total Foward Packets	0.795
Total Length of Forward Packets	0.792
Total Backward Packets	0.748
Total Length of Bakward Packets	0.741
Maximum Forward Packet	0.705

device. We also used a virtual machine p2.xlarge EC2 instances to perform further experiments and a local database for storing the data.

C. Performance Evaluation Metrices

Common evaluation metrics that can be used to examine the performance of the implemented methods for detecting malware such as true positive, false positive, accuracy, recall, precision and sustainability are summarized in Table IV. In our implemented scheme, the data are evaluated using accuracy, precision, recall and f1-score.

TABLE IV. COMMON EVALUATION METRICS

Metric	Definition
True positive	A sample is a true positive if the sample is labelled positive as well as prediction being positive
False positive	A sample is a false positive if the sample is labelled negative while it is predicted as a positive
False negative	A sample is called false negative when the sample is labelled positive and is predicted as a negative class
Precision	It is the proportion of correctly classified instances to the instances predicted as positive
Recall	It is the proportion of instances predicted to be positive to the total positive instances
Sustainability	Indicates how the model is adopted for new samples with retraining (re-usability) and without retraining (stability) over times

D. Experimental Evaluation

We initially utilized four machine learning classifiers to examine the effectiveness of the ranking features: J48 [36], rotation forest [37], AdaboostM1 [38], and XGBoost [39]. Table V outlines these classifiers with respect to their definition and platform.

We evaluated the machine learning classifiers using ranking features with the top 10, 50 and all features for the detection of unknown malware (binary classification) using permission and network traffic features.

Using Permission based Feature: We compare the utilized classifiers using top 10,50 and all features in terms of accuracy, precision, recall and f1-score. Among all three feature sets, rotation forest achieved better results with accuracies of 94.4%,98.6% and 96.5%. The rest results are illustrated in Tables VI, VII, and VIII.

TABLE V. CHARACTERISTICS OF THE CLASSIFIERS EMPLOYED

Classifier	Definition	Availability
J48 [36]	Implemented classifier of C4.5 decision tree	Weka 3.8.5
Rotation Forest [37]	Ensemble classifier, categorizes features into subsets, then run Principal Component Analysis on each subset	Weka 3.8.5
AdaBoostM1 [38]	An ensemble classifier used for boosting a nominal-class	Weka 3.8.5
XGBoost [39]	A boosted decision tree, which associates objective functions based on the gradient of the loss optimized function	R 4.0.0

TABLE VI. MALWARE DETECTION BASED ON PERMISSION FEATURE SET (TOP10 FEATURES)

Classifier	Accuracy	Precision	Recall	F1-score
J48	91.8	91.8	91.7	91.7
Rotation Forest	**94.4**	**94.5**	**94.3**	**94.5**
AdaBoostM1	89.6	88.6	89.7	89.5
XGBoost	93.7	93.6	93.5	93.7

1) Using Network Traffic Feature: We also evaluated the proposed approach using network traffic with respect to top 10,50 and all features. Among employed aforementioned classifiers,XGBoost is able to gain the best results with accuracies of 89.8%, 94.2% and 91.6%. The rest results are illustrated in Tables IX, X, and XI.

IV. DEEP LEARNING SCHEME

Deep learning algorithms are a subset of machine learning algorithms based on artificial neural networks, which can be applied to various fields such as computer vision, speech recognition, natural language processing, and lately malware detection. We employed two deep learning classifiers: long short-term memory (LSTM) [40] and multilayer perceptions (MLPs) [41] to enhance the obtained results.

A. Long-Short Term Memory

A brief definition Long short-term memory (LSTM) considers recurrent structures having the ability to learn a sequence of data. Generally, the sequence of features for the Android apps are $x = (x_1, x_2, x_3, ...x_t)$, which represent the input values to the LSTM. Then, the calculated output will be denoted as $ot = (o_{t1}, o_{t2}, o_{t3}, ...o_{tt})$ with respect to continuous calculation of the forget state vector, input/update gate activation vector, output vector, and cell state vector for time $T = 1, 2, 3, ...t$. The calculation of the hidden layer can be calculated as listed below.

$$f_t = \sigma_g(W_f x_t + U_f h_{t-1} b_f)$$

$$i_t = \sigma(W_i x_t + U_i h_{t-1} + b_i)$$

$$o_t = \sigma_g(W_o x_t + U_o h_{t-1} + b_o)$$

TABLE VII. MALWARE DETECTION BASED ON PERMISSION FEATURE SET (TOP50 FEATURES)

Classifier	Accuracy	Precision	Recall	F1-score
J48	97.3	97.2	97.3	97.3
Rotation Forest	**98.6**	**98.5**	**98.4**	**98.5**
AdaBoostM1	95.4	95.5	95.4	95.4
XGBoost	98.5	98.5	98.6	98.5

TABLE VIII. MALWARE DETECTION BASED ON PERMISSION FEATURE SET (ALL 280 FEATURES)

Classifier	Accuracy	Precision	Recall	F1-score
J48	95.4	95.3	95.2	95.4
Rotation Forest	**96.5**	**96.6**	**96.4**	**96.5**
AdaBoostM1	91.2	91.1	91.2	91.3
XGBoost	96.4	96.3	96.3	96.4

$$\tilde{c_t} = \sigma_c(W_c x_t + U_c h_{t-1} + b_c)$$

$$c_t = f_t o c_{t-1} + i_t o \tilde{c_t}$$

$$h_t = o_t o \sigma_h(c_t)$$

where ft, it, ot,ct, ht, and xt denote the forget state vector, input/update gate activation vector, output vector, cell state vector, hidden state vector, and input vector, respectively.

B. Experimental Result

We evaluated the deep learning scheme in three scenarios, as listed below.

1) Detecting unknown Malware using Binary Class Classification: We initially performed a comparison among: LSTM, MLP and XGBoost in terms of detecting unknown malware using accuracy, precision, recall and f1-score using permission-based features. The obtained results show the superiority of LSTM compared to MLP and XGBoost, which achieved accuracy, precision, recall and f1-score higher than 99%. Fig. 2 depicts the results.

2) Detecting Categories of Malware : Another comparison was performed to examine how these classifiers are able to detect malware based on malware categories. Our malware samples belong to four categories: Adware, Ransomware, Scareware and SMS Malware. We performed four multi-class classifications to examine to which malware family each malware belong to. Comparing LSTM, MLP and XGBoost, LSTM is achieved the better results with accuracy of 97.5%. Fig. 3 outlines the comparison among these classifiers in terms of accuracy, precision, recall and F1-score.

3) Detecting Malware Families: A third comparison was performed to detect which package the malware belongs to. In our evaluation, we defined 45 malware families; therefore, we performed 45 class- classification procedures to examine the samples. We compared LSTM, MLP, and XGBoost and found LSTM achieved best accuracy of 99.5%. Fig. 4 illustrates the obtained results.

TABLE IX. MALWARE DETECTION BASED ON NETWORK TRAFFIC FEATURE SET (TOP10 FEATURES)

Classifier	Accuracy	Precision	Recall	F1-score
J48	87.7	87.6	87.6	87.7
Rotation Forest	88.6	88.5	88.6	88.5
AdaBoostM1	83.3	83.2	83.2	83.3
XGBoost	**89.8**	**89.6**	**89.7**	**89.6**

TABLE X. MALWARE DETECTION BASED ON NETWORK TRAFFIC FEATURE SET (TOP50 FEATURES)

Classifier	Accuracy	Precision	Recall	F1-score
J48	90.4	90.4	90.3	90.3
Rotation Forest	92.6	92.5	92.4	92.5
AdaBoostM1	86.5	86.5	86.4	86.5
XGBoost	**94.2**	**94.1**	**94.2**	**94.1**

4) Examining the Sustainability Performance: Third evaluated of our scheme is examined how our scheme is sustained. We divided the datasets into normal and malware apps based on implemented year with a span of nine years (2010 to 2019) . Then, we trained and tested apps that developed in the same year. The average obtained accuracy is 92.21%. Table XII presents the obtained results in terms of accuracy, precision and recall metrics.

C. Discussion

Although previous studies have obtained promising results in terms of sustainable detecting malware, there are some limitations, which are:

1) Choosing an updated dataset and selecting informative features are vital methods to detect unknown malware and improve obtained results. For example, Onwuzurike et al. [6] utilized a dataset collected between 2010 and 2017, neglected feature selection during building their scheme, and obtained accuracy between 75- 87% .
2) Studying mobile malware in terms of detecting unknown malware families, and categories using multi-class classifications has not covered from Onwuzurike et al. [6], Zhang et al. [11], Cai and Jenkins [17], Cai et al. [19], and Cai [20]

Table XIII presents a comparison between the proposed approach and prior studies. The introduced approach achieved accuracies of 99.2%,99.5%, 97.5%, and 92.2% for detecting unknown malware, detecting malware families, detecting malware categories, and sustainable malware detection, respectively.

V. CONCLUSION

Since the amount of mobile malware increases annually, it is important to implement malware detection that is able to detect possible threats to smartphone devices. This study leveraged machine and deep learning to detect unknown malware apps with accuracy over 99%. We also employed multi-class classification to detect the packages and families of mobile malware, and finally we examined the sustainability of our implemented scheme.

TABLE XI. MALWARE DETECTION BASED ON NETWORK TRAFFIC FEATURE SET (ALL 80 FEATURES)

Classifier	Accuracy	Precision	Recall	F1-score

For future work, we aim to extend our dataset to download more apps, then make it available for academic use. We also plan to use various deep learning classifiers with different dynamic and static features to detect unknown malware, as well as assess datasets over a period of years for sustainability purposes.

ACKNOWLEDGMENT

The author would like to thank the Deanship of Scientific Research at Umm Al-Qura University for supporting this work by Grant Code: 18-COM-1-01-0007.

Solving the Steel Continuous Casting Problem using an Artificial Intelligence Model

Achraf BERRAJAA

Euromed University of Fes, Fes, Morocco

***Abstract*—Over the past decade, the steel continuous casting problem has revolutionized in important and remarkable ways. In this paper, we consider a multiple parallel device for the steel continuous casting problem (SCC) known as one of the hardest scheduling problem. The SCC problem is an important NP-hard combinatorial optimization problem and can be seen as three stages hybrid flowshop problem. We have proposed to solve it a recurrent neural network (RNN) with LSTM cells that we will executed in the cloud. For our problem, we consider several machines at each stage that are the converter stage, the refining stage and the continuous casting stage. We formulate the mathematical model and implemented a RNN with LSTM cells to approximately solve the problem. The proposed neural network has been trained on a big dataSet, which contains 10 000 real use cases and others generated randomly. The performances of the proposed model are very interesting such that the success rate is 93% and able to resolve large instances while the traditional approaches are limited and fail to resolve very large instances. We analyzed the results taking into account the quality of the solution and the prediction time to highlight the performance of the approach.**

***Keywords*—Artificial intelligence; SCC Program; RNN; LSTM; big data**

I. Introduction

Iron and steel industry is the cornerstone of an industrialized economy. Since it is capital and energy intensive, companies have constantly laid great emphasis on technological advances to be employed in the production process in order both to increase productivity and to save energy. Due to the complex production process and potential constraints, the latter faces difficult planning and scheduling problems. For example, in the scheduling problem, we usually define a set of n resources, a set of m tasks and a specific optimization goal, called makespan Sol_{max}. The classic flowshop (FS) considers scheduling a set of tasks on one machine at each stage, while the hybrid flowshop (HFS) aims to schedule a flow shop with multiple parallel machines at each stage [1]. In the steelmaking industry, we have three main stages principals for the production that are the converters (CV), the refining stands (RS) and the continuous castings (CC) stages. Each one can include one or more devices, and each product is processed on only one device in each stage. Fig. 1 summarized this configuration, the SCC problem can be seen as a hybrid flow shop. More generally, the goal of SCC is to determine the sequence, timing, and system of equipment involved in the entire production process. This problem is a NP-hard combinatorial optimization and it is considered to be one of the more difficult scheduling problems in the literature [30].

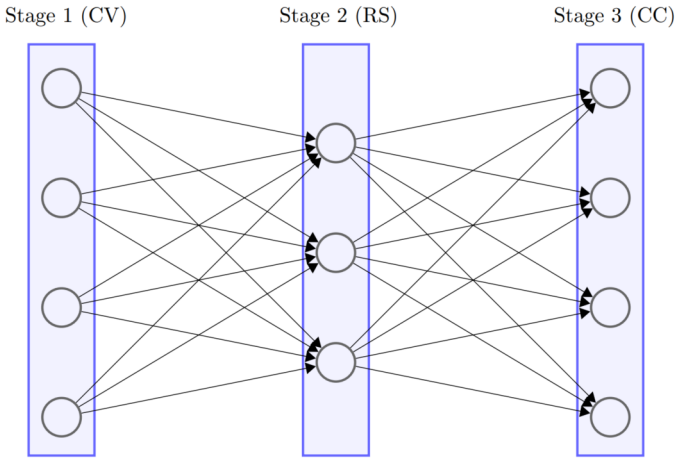

Fig. 1. The Principle Stage of the SCC.

The principal stages and constraints are as follows :

1) The length of stay is minimized,
2) The deadline must be met,
3) The continuity constraint must be satisfied.

We propose in this research, a system with three stage M_i machines at each stage $i(i = 1, \ldots, 3)$, such that M_1 identical parallel CV machines are available in the first stage (denoted as CV_{M_1}), M_2 unify the parallel RS machines at stage two (denoted as RS_{M_2}) and M_3 unrelated parallel CC machines at stage three (denoted as CC_{M_3}). In addition, we consider the inter-sequence correlation setting time between every two consecutive sequences λ to be processed on the same CC machine with non-preemptive scheduling. Similarly to the notation by [8], we write our system as a hybrid flowshop (HFS) : $CV_{M_1}, RS_{M_2}, CC_{M_3} \mid \lambda \parallel Sol_{max}$. The first modeling of the problem was considered as a special case of m-stages HFS, which has irrelevant machines and related setup time, which proved to be NP-Hard [14]. For example, [22] has proven the NP hardness of a single machine with a set time.

Some recent research work have been developed to study the steel making continuous casting problem. Most of the developed models deal with high complexity, so solving them as optimal is not always effective, especially for the large instances problems. The most of the methods proposed for the HFS problems are approximation methods, most of which are meta-heuristics. The SCC problem is a special set time scheduling problem, which is difficult to solve due to the high

computational complexity [22]. The SCC problem is based on a chronological step chain (the three stages: CV, RS, and CC), where CV, RS, and CC devices are considered to be single, and only one sequence of loads is processed on the machine M_i according to the rules. Among the key rules of the SCC problem, the charging will not start processing on the device until the previous charge is completed. This architecture can be represented by a neural network (forward propagation principle [11]) which allows the automation of the problem SCC. To the best of our knowledge, this is the first work that proposes a model of artificial intelligence to solve the problem of SCC, in particular a Recurrent Neural Network (RNN) with Long Short-Term Memory (LSTM) cells.

In the remainder, the article is organized as follows: Section 2, presents a literature review on the works related to the steelmaking industry in general and the continuous casting in particular. Sections 3 and 4 detail the structure, the sequences and charges, the constraints and formulate the objective function and the mathematical model for the SCC. Section 5 we present the construction of learning big data and we describe our recurrent neural network with LSTM cells for SCC. Section 6 is devoted to the numerical experiments. We also discuss and comment the obtained results and show the efficiency of the method. Finally, Section 7, presents a conclusion that summarizes the study and gives some potential perspectives for the developed approach to improve the current results for the SCC.

II. Related Work and Problem Statement

Continuous casting is one of the most commonly used processes in steel production and has received special attention in the past ten years [31]. Several research works have been developed, both exact and heuristic algorithms have been elaborated to solve several SCC problem variants. The authors in [28] reviewed several SCC models used in steelmaking production, and other works considered mathematical and non-mathematical techniques [3] to solve these variants. Optimization methods such as genetic algorithm (GA) [33], taboo search (TS) [14], mathematical model [32] or swarm intelligence optimization [10] have been developed to optimize production. The hybrid method [27] is also tailored for a continuous steel plant.

Also exact MILP methods are proposed to unravel the SCC. Usually, these methods can only solve small problem instances with commercial solvers, but the real challenge is to use smart and optimized methods to solve large instances. The author in [29] proposed a MILP model for the production order scheduling problem. This model describes a system with more than two machines in each stage, and also more than two sequences must be processed in the final stage, in addition there is an inter-sequence setting time. This model is solved by commercial solvers for relatively small instances. In [9] a mathematical model of the process and a state-of-the-art industrial control system are presented, and they mentioned the importance of using a real-time computational model. In [6], a method has been developed for a steelmaking plant with 2 converters, 2 refining stands, and 2 continuous casters. The authors in [12] develop a discrete-time mixed-integer linear programming (MILP) formulation for a new SCC scheduling problem where different processing routes are used to produce diversified and personalized slab products. The authors in [23] developed a method to minimize the total delay and waste of scheduling problems for different product types by minimizing batches.

Scheduling problems are mainly NP-Hard optimization problems ([5]). In order to overcome their complexity, heuristics and approximation methods may proposed a solution for this types of problems. In the literature approximation methods were developed for SCC. In [18], heuristic-based combinatorial auction technology is also used to solve the SCC containing 4 production orders and a 10-hour planning range. The authors in [16] have developed approximate techniques to solve some planning and scheduling problems of downstream production lines. In [13], the authors have developed a soft-decision based two-layered approach for strong uncertain scheduling. The paper [26] presents an Improved Artificial Bee Colony (IABC) algorithm for the SCC scheduling. Other uncertainty optimizations have been developed for SCC, such as a novel efficient solution algorithm using Augmented Lagrange multiplier method (e-ALM) through relaxation of the coupling constraints and incorporation of penalty components [12].

Several evolutionary algorithms have also been developed for SCC. In [20], we find the description several approaches for computerized scheduling solutions. They include application of techniques in operations research, artificial intelligence, and a hybrid of these two. Nature-inspired optimization methods have also been used in SCC. For example, in [7] the steel industry has been modeled through a combination of a steady-state heat transfer approach and a pareto-converging genetic algorithm (PCGA). In [2], the authors developed a algorithm, that is based on a combination of ant colony optimization and non-linear optimization methods. The authors in [17] have implemented a multi-objective GA to minimize penalties for completion and lateness. In [24], the authors developed a swarm heuristic method for SCC. In the paper of [25], the authors develop a discrete-time mixed-integer linear programming (MILP) formulation for a new SCC scheduling problem where different processing routes are used to produce diversified and personalized slab products. A multi-objective hybrid genetic algorithm combined with local search was presented in [32], in which the enhanced evolutionary mechanisms combined with the improved genetic operators and the local search were also designed. Regarding this work, our approach is based on an artificial neural network, where artificial neural network, is a system whose design is originally schematically inspired by the functioning of biological neurons. The idea has no relation to the way a human being reacts, but to the way of designing the data. It adapts and gives good results when there is a lot of sample information (Features). To the best of our knowledge, this is the first work that proposes a model of artificial intelligence to solve the problem of SCC, in particular a recurrent neural network with long short-term memory cells.

A. Problem Statement

The system processes the costs of different stages under the continuity constraint $(i = 1, \ldots, 3)$. These sequences are pre-ordered costs on the continuous castings machine, and their costs are allocated to any converter machine. Since handling and transportation operations occur in the entire process, the transfer time between stages $\tau_{i,i+1}$ (i = 1, 2) is considered.

We also believe that all converters devices have the earliest and latest start time for the first charge of a sequence with a usable date. The working principle of the system is as follows:

- A sequence represent a set of charges dedicated to one continuous casting machine, and has priority constraints on fees;
- The processing time is limited for any converter, who can be used in the first stage;
- There is a limited residence time (transmission) between the termination of charging in converter and the start of continuous casting to comply with the required temperature;
- Due to continuous constraints, there is no idle time for the charges on the continuous casting;
- The processing time of the continuous casting stage is a decision variable belonging to a given interval;
- The sequence start time at continuous casting is bounded, and the delay between two consecutive sequences is the setup time we define.

The sorted total batch represents the industrial order book so that the sequence can be assigned to the continuous casting.

1) Concept of Sequence and Continuity Constraints: The sequence Seq_{l_3} is defined as a set of $n_{Seq_{l_3}}$ charges to be used in the M_3 casters CC_{l_3} $(l_3 = 1, \ldots, M_3)$. The relevant constraints are summarized as follows:

1) The converter can be used in the first stage, there is no specification, and it has a constant processing time and availability date;
2) There is a transition time $\tau_{i,i+1}$ between all stages i (i = 1, 2);
3) The stay (transit) time of the charge j (the time between the termination of the first stage $i = 1$ and the start of the final stage) must not exceed a certain value $T_{l_3,j}$;
4) No idle time is allowed between two consecutive charges in the same sequence in the third stage (continuous constraint);
5) The setting time depends on the sequence time;

III. Continuous Casting of the Ordered Sequences

This section describes all the data (sets, indexes, etc.), parameters, and decision variables that describe the problem being studied. For a given CC_{l_3}, a pre-ordered dedicated sequence Seq_{l_3} $(Seq_{l_3} = 1, \ldots, S_{l_3})$ is a list of $n_{Seq_{l_3}}$ charges to continuously process on CC_{l_3} with setup times.

Collections, constants, and indexes :
i : the index of the stage, $i = 1, \ldots, 3$;
M_i : the number of the machines l_i at stage i $(l_i = 1, \ldots, M_i)$;
S_{l_3} : the number of the sequences Seq_{l_3} to be processed on the machine CC_{l_3};
Seq_{l_3} : a sequence to process on CC_{l_3} $(Seq_{l_3} = 1, \ldots, S_{l_3})$;
$n_{Seq_{l_3}} = |Seq_{l_3}|$: the number of charges (jobs) j of the sequence Seq_{l_3};
$n_{l_3} = \sum_{Seq_{l_3}=1}^{S_{l_3}} n_{Seq_{l_3}}$: the total number of the charges to process on CC_{l_3} $(l_3 = 1, \ldots, M_3)$;
$n = \sum_{l_3=1}^{M_3} n_{l_3}$: the total number of the charges;
j : the charge index dedicated to the sequence Seq_{l_3} of CC_{l_3}, $j = 1, \ldots, n_{l_3}$;
l_1 : the index of the first stage machine CV_{l_1}, with $(l_1 = 1, \ldots, M_1)$;

The consider assumptions :
ω_{l_1} : position of a charge on CV_{l_1}, $\omega_{l_1} = 1, \ldots, \Pi_{l_1}$;
$l_1 = 1, \ldots, M_1 - 1$
$\Pi_{l_1} = \frac{\sum_{l_3=1}^{M_3} n_{l_3}+1}{M_1}$;
ω_{M_1} : position of a charge on the last machine CV_{M_1},
$\omega_{M_1} = 1, \ldots, \Pi_{M_1}$;
$\Pi_{M_1} = \frac{\sum_{l_3=1}^{M_3} n_{l_3}}{M_1}$;

Settings and parameters
pro^1 : processing time (constant) for a charge j on any one of the CV_{l_1} at the 1^{st} stage;
$pro^2_{l_2}$: processing time for a charge j on the RS_{l_2};
$[P^{min}_{l_3,j}, P^{max}_{l_3,j}]$: the interval of $pro^3_{l_3,j}$ is dedicated to the processing time of the cost j of CC_{l_3};
$[\lambda^{min}_{Seq_{l_3}}, \lambda^{max}_{Seq_{l_3}}]$: the interval between sequences depends on the setup time $\lambda_{Seq_{l_3}}$.
$date_{l_1}$: available date of CV_{l_1};
$T_{l_3,j}$: maximum allowed sojourn time for a charge j between the termination of any processing in CV_{l_3} and the start of processing in CC_{l_3} $(j = 1, \ldots, n_{l_3}, l_i = 1, \ldots, M_i, i = 1, 3)$;
τ_{12} (resp. τ_{23}) : transfer time required between CV_{l_1} (stage 1) and RS_{l_2} (stage 2) (resp. RS_{l_2} (stage 2) and CC_{l_2} (stage 3)).

Decision variables
The model considers continuous and binary decision variables. For any $l_3 = 1, \ldots, M_3$:
$x^i_{l_3,j}$: start time of the charge j dedicated to CC_{l_3} at stage i $(i = 1, 2, 3)$ for $j = 1, \ldots, n_{l_3}$,
$pro^3_{l_3,j}$: processing time dedicated to the charge j of CC_{l_3} at the 3^{rd} stage for $j = 1, \ldots, n_{l_3}$,
$\lambda_{Seq_{l_3}}$: setup time between two consecutive sequences, $(Seq-1)_{l_3}$ and Seq_{l_3} to process at CC_{l_3}, that occurs between the charge $n_{(Seq-1)_{l_3}}$ and the charge $l_{Seq_{l_3}}$.

$$y^{l_3}_{j,\omega_{l_1}} = \begin{cases} 1 & \text{if charge j dedicated to } CC_{l_3} \\ & \text{is assigned to a position } \omega_{l_1} \text{ in } CV_{l_1} \\ 0 & \text{otherwise} \end{cases}$$

$j = 1, \ldots, n_{l_3}, \omega_{l_1} = 1, \ldots, \Pi_{l_1}, l_1 = 1, \ldots, M_1.$

IV. The Mathematical Model for the SCC

In the research problem, we intend to maximize productivity, that is, minimize the manufacturing span (Sol_{max}) and the sequence-dependent setup time, which represents the required duration between two consecutive sequences.

Our modeling method uses the position of the sequence charge and the priority defined by the processing start time of stage 1 (CV). We are also considering pre-orders for charging CC machines in the third stage.

A. The Constraints

We may remember that due to the high complexity of its structure and function, this problem is subject to several constraints that we detailed below:

$$\sum_{l_1=1}^{M_1}\sum_{\omega_{l_1}=1}^{\Pi_{l_1}} y_{j,\omega_{l_1}}^{l_3}=1;\quad j=1,\ldots,n_{l_3},\quad l_3=1,\ldots,M_3 \tag{1}$$

$$\sum_{l_3=1}^{M_3}\sum_{j=1}^{n_{l_3}} y_{j,\omega_{l_1}}^{l_3}=1;\quad \omega_{l_1}=1,\ldots,\Pi_{l_1},\quad l_3=1,\ldots,M_3 \tag{2}$$
$$\text{and}\ \sum_{l_3=1}^{M_3} y_{1,1}^{1}=1$$

$$y_{j+1,t_{(l_1=1)}+1}^{l_3}\le\sum_{l_1=1}^{M_1-1}\sum_{\omega_{l_1}=1}^{t_{l_1}} y_{j,\omega_{l_1}}^{l_3}; j=1,\ldots,n_{l_3},\quad t_{l_1}=1,\ldots,\Pi_{l_1}-1 \tag{3}$$

$$y_{j+1,t_{l_{M_1}}}^{l_3}\le\sum_{l_1=1}^{M_1}\sum_{\omega_{l_1}=1}^{t_{l_1}} y_{j,\omega_{l_1}}^{l_3}-y_{j,t_{l_{M_1}}}^{l_3};\ j=1,\ldots,n_{l_3}-1,\quad t_{l_1}=1,\ldots,\Pi_{l_1}; \tag{4}$$

$$z_{l_3,j}^{1}=\sum_{l_1=1}^{M_1}\sum_{\omega_{l_1}=1}^{\Pi_{l_1}}(date_{l_1}+pro^{1}(\omega_{l_1}-1))y_{j,\omega_{l_1}}^{l_3};\ j=1,\ldots,n_{l_3}; \tag{5}$$

$$z_{l_3,j}^{2}\ge z_{l_3,j}^{1}+pro^{1}+\tau_{12}; j=1,\ldots,n_{l_3}; \tag{6}$$

$$z_{l_3,j}^{3}\ge z_{l_3,j}^{2}+pro_{l_2}^{2}+\tau_{23}; j=1,\ldots,n_{l_3}; l_2=1,\ldots,M_2; \tag{7}$$

$$z_{l_3,j+1}^{2}\ge z_{l_3,j}^{2}+pro_{l_2}^{2}; j=1,\ldots,n_{l_3}-1; l_2=1,\ldots,M_2; \tag{8}$$

$$z_{l_3,j+1}^{3}=z_{l_3,j}^{3}+pro_{l_3,j}^{3};\quad \forall j\notin\{n_1,n_1+n_2,\ldots,\sum_{Seq_{l_3}=1}^{S_{l_3}} n_{Seq_{l_3}}\},\forall\ l_3=1,\ldots,M_3; \tag{9}$$

$$z_{l_3,j+1}^{3}\ge z_{l_3,j}^{3}+pro_{l_3,j}^{3}+\lambda_r;\quad \forall j=\sum_{Seq_{l_3}=1}^{r} n_{Seq_{l_3}}, r=1,\ldots,S_{l_3}-1; \tag{10}$$

$$P_{l_3,j}^{min}\le pro_{l_3,j}^{3}\le P_{l_3,j}^{max}; j=1,\ldots,n_{l_3} \tag{11}$$

$$z_{l_3,j}^{3}-(z_{l_3,j}^{1}+pro^{1})\le T_{l_3,j}; j=1,\ldots,n_{l_1} \tag{12}$$

$$\lambda_{Seq_{l_3}}^{min}\le\lambda_{Seq_{l_3}}\le\lambda_{Seq_{l_3}}^{max}; Seq_{l_3}=1,\ldots,S_{l_3}-1 \tag{13}$$

The constraint (1) represents that the charge j is allocated to only one converter machine and is located in only one position ω_{l_1}. The constraint (2) represents that the converter CV_{l_1} must process the charge j once and only once at a specific position ω_{l_1} ($l_1=1,..,M_1$). In addition, must assign the charge $j=1$ to the first position of the converter CV_1 ($l_1=1$). The constraint (3) demand that the charge (j+1) must be affected on the CV_1 converter where ($l_1=1$) at the position ($t_1=1$) only if the charge j is to process at any of the positions in $1,\ldots,t_{l_1}$, on one of the M_1-1 first converters CV_{l_1}. The same way, for two consecutive charges j and $j+1$, for the last converter CV_{M_1}, constraint (4) has the same meaning. The constraint (5) is set for the start time to process the charges in the converter stage (CV_{l_1}; $l_1=1,\ldots,M_1$). Constraints (6)-(7) represent the sequencing in the same charge, exactly for two consecutive operations. The last operation can be started after the first operation reaches its end time and the charge has been brought to the next stage. In addition, constraint (6) (resp. (7)) represents the priority rules between CV_{l_1} and RS_{l_2} (between RS_{l_2} and CC_{l_3} (respectively)). The constraint (8) means that for two consecutive charges to process on the same refining stand (RS_{l_2}), the second charge can only be processed when the first one has reached its end time. The constraint (9) represents the continuity constraints for all the sequences. The constraint (10) defines the inter-sequence correlation setting time between two consecutive sequences to be processed on the same continuous casting machine (CC_{l_3}). Constraint (11) defines the limit of the third stage charging processing time on the machine CC_{l_3}. The constraint (12) means that the stay time (transport) of the charge is finite, and (13) defines the boundary of the set time between the sequence of the third stage. They set the necessary preparation time before the first charging of the sequence after the last charging end time of the previous sequence on the same machine in the third stage.

B. The Objective Function

We define makespan (Sol_{max}) as a function representing the time required to completely process all sequence sets (from the start time of the first charge in the first stage to the termination time of the last charge at the third stage with their inter-sequence dependent setup times.

The objective function we consider for the problem has the following mathematical form:

$$Sol_{max}=\max_{1\le l_3\le M_3}\{\lambda_{S_{l_3}}+z_{l_3,S_{l_3}}^{3}+pro_{l_3,S_{l_3}}^{3}\}$$

In order to maximize productivity and the goal is to minimize completion time, we have defined the following goals:

$$Minimize\ Sol_{max}=min\max_{1\le l_3\le M_3}\{\lambda_{S_{l_3}}+z_{l_3,S_{l_3}}^{3}+pro_{l_3,S_{l_3}}^{3}\}$$

In this form, the problem is non-linear. Therefore, in order to avoid this situation, we define a new non-negative decision variable z so that we can obtain a new objective (linear) equal to minimizing z and add new constraints:

$$\lambda_{S_{l_3}}+z_{l_3,S_{l_3}}^{3}+pro_{l_3,S_{l_3}}^{3}\le z\quad\forall l_3=1,\ldots,M_3$$

V. The Proposed Contribution to Solve the SCC

Several evolutionary algorithms are developed to solve complex optimization problems, among them we cite [21]. But the real challenge for the SCC problem is to solve instances with an approach intelligent and optimal. Here we develop an adapted neural networks to the SCC with inter-sequence setup times at the last stage using LSTM cells. The adapted neural network trained on a large database of 10 000 use cases solved with CPLEX based on the mathematical model that we presented in the first part of this article.

In the following we detail the evolutionary strategy that we have adopted for this problem but before that we will explain what deep learning is and why exactly the use of the recurrent neural network (RNN) in particular LSTM.

A. Deep Learning

Machine learning is a field of study of artificial intelligence that gives computers the ability to learn from data, that is, to improve their performance at solving tasks without being explicitly programmed. In several areas of machine learning research, it is about creating neural networks.

Deep learning can be defined as special kind of neural networks composed of multiple layers. These networks are better than traditional neural network in persisting the information from previous event. Recurrent neural network is one such machine that has a combination of networks in loop. The networks in loop allow the information to persist. Each network in the loop takes input and information from previous network performs the specified operation and produces output along with passing the information to next network. Some applications require only recent information while others may ask for more from past, exactly the case of the SCC problem. The common recurrent neural networks lag in learning as the gap between required previous information and the point of requirement increases to a large extent. But fortunately Long Short Term Memory Networks [15], a special form of RNN are capable in learning such scenarios.

B. LSTM Neural Networks

Long-term memory (LSTM) is an alternative solution proposed in [15]: the traditional architecture of a Recurrent Neural Network (RNN) that is based on a simple activation function is modified in such a way that the vanishing gradient problem is explicitly avoided, while the learning method remains unchangeable. For more information on this architecture ([4]). But what are the strengths of LSTM ? why the LSTM will be effective to solve the steel continuous casting problem ?

A LSTM neuron network is made up of several cell that have not just one activation function but rather three that are represented as an input gate, a forget gate and an output gate. Each cell remembers the state of the problem treat in several time intervals, and the three gates regulate the flow of information in and out of the cell. The LSTM network is very suitable for classification, processing and prediction based on time series data, because there may be lags of unknown duration between important events in the time series. This is what is needed to schedule tasks between the three stages (CV, RS and CC) of the SCC problem. Also as we explained, LSTM was developed to deal with the explosion and disappearance of gradients that may be encountered when training traditional RNNs. Fig. 2 shows the internal architecture of a LSTM cell.

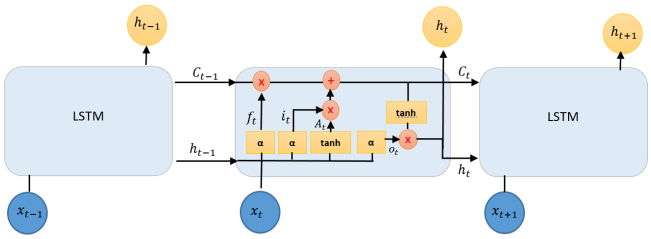

Fig. 2. The Internal Architecture of a LSTM Cell [4].

- **Forget gate:** It is the power of forgetting information. Unlike the classic neural network where it must to memorize all the information in a long sequence, a LSTM has the power to forget unnecessary information that will probably not be used in the prediction. In the LSTM the power to forget non-useful information is represented by the function $f_t = \alpha(W_f * [h_{t-1}, x_t] + b_f)$, where α is a sigmoid function, W_f is the weights and $[h_{t-1}, x_t]$ is the concatenation of the two vectors h_{t-1} and x_t.

- **Input gate:** is responsible for adding relevant information and providing new information. The function that allows this is $C_t = C_{t-1} * f_t + i_t * A_t$ where $i_t = \alpha(W_i * [h_{t-1}, x_t] + b_i$ and $A_t = tanh(W_c * [h_{t-1}, x_t] + b_c)$.

- **Output gate:** This last operation allows to define the current state of the unit. So far, we have forgotten informations, and we have added new informations to the memory. We still need to define the state of the current cell, which represents the output of this cell and which will be the input of the next cell. This is summarized by the following functions: $h_t = \alpha(W_o * [h_{t-1}, x_t] + b_o) * tanh(C_t)$.

C. The Evolutionary Strategy: Training Data, Network Architecture and Choice of Parameters

The proposed neural network will be used as a heuristic to solve the SCC with smart solutions. For this a LSTM is applied to approach the objective function. The proposal to solve the SCC problem is explained in Fig. 3. The system generates a data set in the domain of variables to train a neural network. The objective function of the optimization problem is redefined with the multilayer neural network that transforms the function, allowing to generate a polynomial equation to solve the optimization problem. To define a neural network, it is necessary to establish parameters, such as the training data, the type of neural network, connections, number of layers, activation functions, propagation rules, etc.

Various methods exist to train these networks to produce a specific output for a specific input. Among the current training methods, we have error propagation, which consists of adjusting the network by adapting the weights of each neuron. The use of the partial derivative makes it possible to know in which direction we must modify the weights of our neural network to have the requested output. Also a genetic algorithms are used to train a neural network [19]. By training

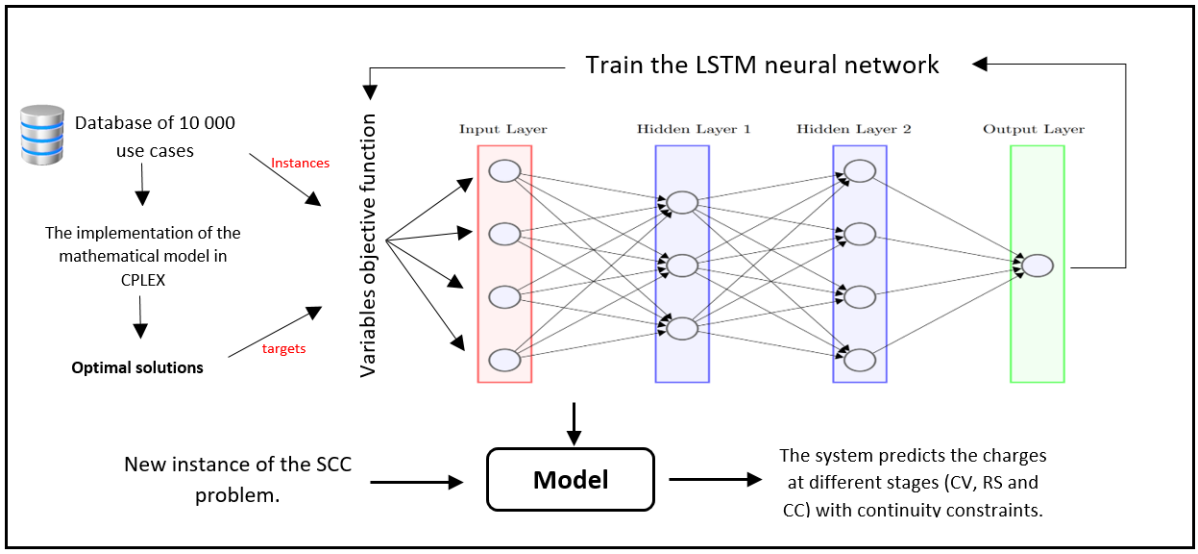

Fig. 3. The Evolutionary Strategy for the SCC.

these networks on a set of data for which the correct output is known, the network will return the appropriate results for similar data. We trained our LSTM on data from 10 000 use cases (instances), where the correct output was generated by the CPLEX based on the mathematical model that we proposed above.

Regarding the architecture, there are several architectures in the literature, but just some differences between them in the neural network language model. The architecture that we propose to solve the steel continuous casting problem was obtained after several tests and it is the one that which gave best results. It can be summarized as follows:

Input sequence represents the input of our LSTM, in our implementation it is encoded by an encoding from 1 to Sl_3 where Sl_3 is number of the sequences $Seql_3$ to process on the machine CC_{l_3}. Note that the sequenes are generated in 128 batches with 5% diversity, where the purpose of adding diversity in the learning stage is to give flexibility to the model and to avoid overfitting. The model predicts the assignment of sequence loads from different stages (CV, RS and CC) with continuity constraints.

The network topology, an architecture with three hidden layers has been applied, each with 256 LSTM units. Each cell LSTM use the "relu" activation function (to have faster convergence compared to other activation functions as tanh or sigmoid). However the output layer, the "softmax" activation function is used to generate the correct normalized probability value in order to select sequential charges in different stages (CV, RS and CC).

As a learning criterion, Adam optimizers is used with a precision of 0,001.

The following algorithm summarizes the main steps :

Algorithm 1 : The proposed LSTM model.

- According to the unified law on [0;1], the weights are initialized by random drawing.
- Codage : list all sequence charges, represent each one by a number from 1 to Sl_3.
- Creating a LSTM network : create four layers, where the three hidden layers have 256 LSTM units for each one. The output layer uses the "softmax" activation function to predict the sequence charges of different stages (CV, RS, and CC) with continuity constraints.

while counter $\leq$ iterMax **do**
1. Generate 128 batches with 5% noise.
2. Train the model.
3. The learning rate of the Adam optimizer is 0.001.
4. Update each weight

end while

VI. Experimental Tests

All experiments were performed on the Google colab under GPU, namely CPLEX 12.6 was used to determine the optimal solutions for the SCC instances in order to prepare the training data and also to compare with the results of the LSTM.

A. The Learning and Test Rate:

The learning rate gives an idea of the quality of the model. In Fig. 4, we present a graph that represents the learning rate (93%) and the test rate (91%) per epoch.

As can be seen from the convergence of the cost function (Fig. 5), our model performed well and the fact that there is not a large discrepancy between the loss of the training and the loss of the test allows us to conclude that we do not have an overfitting. We have also to mention that the learning rate is 93% and the test rate is 91%.

B. Test Instances

For the instances taken form the literature, we compare our LSTM with the CPLEX solutions, the proposed RNN with LSTM cells has improved the total makespan Sol_{max} and was

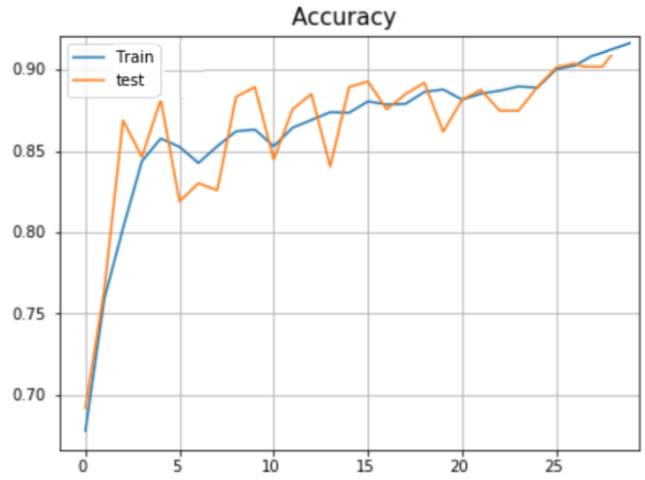

Fig. 4. The Learning and Test Rate per Epoch.

10	1256	10341.19	8.90

up to 1000 times faster than the CPLEX on CPU as shown in Table I.

Table II shows our tests on randomly generated large instances for which no solution is known. These instances span a large number of charges until 10 CC machines at the last stage. As an example, for the following batches size of a 4 CC system [30,25,20,25][25,30,15,25,15] [30,35,30,20,30 [40,20,55] (number of charges per each sequence) with different $[\lambda^{min}_{Seql_3}, \lambda^{max}_{Seql_3}]$ ranges of setup times, the CPLEX fails to solve it. However, the LSTM runs it on 1.42 seconds and gave a solution with Sol_{max} = 6330,13. This allows us to say that the obtained numerical results show the efficiency of the proposed recurrent neural network with LSTM cells with a total success of solving all the instances.

VII. CONCLUSION

In this paper, we have implemented a recurrent neural network with LSTM cells in order to solve the SCC with intersequence dependent setup times and dedicated machines at the last stage known as one of the harder problem in scheduling. Especially, we have shown that with RNN with LSTM cells, one can tackle very large instances arising in complex industrial systems where the number of sequences, of charges or of any devices type (CV, RS or CC) is bigger than 10. Better solutions are obtained with better quality and execution time. The performances of the proposed model are very interesting such that the success rate is 93% and able to resolve large instances while the traditional approaches are limited and fail to resolve very large instances.

One of the future works that we intend to develop is to generalize the approach on a cluster of GPUs in order to deal with more complex and robust cases and to enable solving very large size instances in order to improve the quality of the up to day known solutions. Also, we intend to generalize our approach to similar SCC problems in particular or to solve very complex hybrid flowshops in general. Another feature that could also be envisaged is the lagrangean relaxation for typical hard constraints that we could relax.

ACKNOWLEDGMENT

The author would like to thank the Editor-in-chief and anonymous reviewers for their comments and suggestions to improve the quality of the paper

***Abstract*—Deep learning has transformed many fields including computer vision, self-driving cars, product recommendations, behaviour analysis, natural language processing (NLP), and medicine, to name a few. The financial sector is no surprise where the use of deep learning has produced one of the most lucrative applications. This research proposes a novel fintech machine learning method that uses Transformer neural networks for stock price predictions. Transformers are relatively new and while have been applied for NLP and computer vision, they have not been explored much with time-series data. In our method, self-attention mechanisms are utilized to learn nonlinear patterns and dynamics from time-series data with high volatility and nonlinearity. The model makes predictions about closing prices for the next trading day by taking into account various stock price inputs. We used pricing data from the Saudi Stock Exchange (Tadawul) to develop this model. We validated our model using four error evaluation metrics. The applicability and usefulness of our model to fintech are demonstrated by its ability to predict closing prices with a probability above 90%. To the best of our knowledge, this is the first work where transformer networks are used for stock price prediction. Our work is expected to make significant advancements in fintech and other fields depending on time-series forecasting.**

***Keywords*—Stock price prediction; time-series forecasting; transformer deep neural networks; Saudi Stock Exchange (Tadawul); financial markets**

I. Introduction

We have come a long way in developing our societies, improving and optimising every task and thing we do, and artificial intelligence (AI) is at the heart of these endeavours [1], [2]. Machine and deep learning-based AI has revolutionised many aspects of our daily activities, be it healthcare [3], [4], transportations [5], [6], big data [7], distance learning [8], disaster management [9], risk prediction in aviation systems [10], DNA profiling [11], smart cities [12], [13], and more. The use of machine and deep learning in the financial sector is one of the most lucrative tasks. Forecasting time-series data is an important topic that plays a key role in analysis, decision-making, and resource management in many industrial sectors. For example, in the financial sector, forecasting based on historical data can be helpful for investors in maximizing return and reducing risk on investments [14], [15]. Many works have been reported on the use of AI for the financial sector, such as the use of multilayer perceptrons (MLP) for NSADA stock index [16], the use of stacked autoencoders for US stock forecasting [17], and the use of Long short-term memory network (LSTM) to predict the closing prices of iShares MSCI United Kingdom index [18] (for further motivation on the subject, see Section II).

A time-series forecast is a way of determining future values based on historical experience. Correlational data is used for this process, either time-based correlations (years, months, weeks, etc.) or sequential correlations, for gaining insights that inform decisions. A range of methods has been developed to predict, ranging from traditional to machine-learning approaches. Despite their wide usage, traditional time-series prediction methods such as auto-regression (AR), Seasonal Naïve, ETS, and integrated moving average ARIMA are designed to fit each time-series separately [19]. Moreover, practitioners should learn how to select specific trends, seasonal components, and other data components manually, especially for financial data series with highly nonlinear and fluctuating data. These drawbacks have limited their applications in advanced large-scale time-series prediction tasks.

The challenges mentioned above can be overcome by algorithms that can capture the patterns in the data and the dynamics underlying them. In deep neural networks, continuous developments have led to breakthroughs that are proposed as another alternative. An array of deep neural network architectures has been applied to time-series models to understand trends and patterns by learning from ground truth data. However, many challenges remain. For example, while a Recurrent Neural Network (RNN) can model and process sequential and time-series data, its gradient vanishing and exploding properties prevent them from detecting long-term dependencies (relationship between entities that are several steps apart). In real-world forecasting, there are long-term and short-term repeating patterns [20], which means that complex RNN models are required to analyze long-term time series and study long-term effects. Therefore, long short-term memory (LSTM) models have been proposed to improve the standard RNN model for time series analysis. Theoretically, they are explicitly geared towards minimizing long-term dependency problems. However, according to [21], LSTM has an adequate context size of 200 tokens on average, but they are only able to distinguish 50 tokens within a context, suggesting that even it is incapable of capturing long-term trends. Furthermore, RNNs and all their variants use mostly sequential operations, thus cannot benefit from the performance advantages offered by modern GPUs.

Rather than RNNs, the next big step was a completely new architecture – Transformer [22] utilizes attention mechanisms that leverage self-attention mechanisms to process the entire sequence of data. The transformer architecture is the most prevalent model for natural language modelling and has proven quite successful in several other applications. The complexity of the space corresponding to self-attention can grow quadratically as sequence length increases; for this reason, self-attention cannot be extended to extremely long sequences [20]. The quadratic complexity of computing poses a significant challenge when forecasting time series with long-term solid dependence and fine granularity. Researchers had the same challenges adapting transformers from language to computer vision applications due to pictures containing more significant amounts of information than sentences. However, they are able to replace this quadratic computational complexity with a linear computational complexity to image size.

In this work, we specifically delve into adapting the computer vision transformer model [23] to time series forecasting. We propose a novel fintech machine learning method that uses Transformer neural networks for stock price predictions. In our method, self-attention mechanisms are utilized to learn nonlinear patterns and dynamics from time-series data with high volatility and nonlinearity. Our Contributions follow.

- We propose a novel predictive Transformer based model with divided time series data into patches for predicating future value. Regardless of how complex a situation is, our proposed method can discover the broad conditional probability distribution of the future values.
- The model makes predictions about closing prices for the next trading day by taking into account various inputs, Open, High, Low, Volume, and Closing Prices. We used pricing data from the Saudi Stock Exchange (Tadawul) to develop this model. We validated our model using a range of metrics; Mean Absolute (MAE), Square (MSE), Root MSE (RMSE), and Percentage (MAPE) Error.
- The applicability and usefulness of our model to fintech are demonstrated by its ability to predict closing prices with a probability above 90%.

Novelty: As mentioned earlier, transformers are relatively new and while these have been applied for NLP and computer vision, they have not been explored much with time-series data. Our work is expected to make significant advancements in fintech and other fields depending on time-series forecasting. To the best of our knowledge, this is the first work where transformer networks are used for stock price prediction.

The structure of this paper is as follows. We discuss related research in Section II as well as past innovations using deep learning for stock forecasts. The methodology for this study, the dataset, and the transformer model with divided space are described in Section III. This section also provides details of data prepossessing, and hyperparameters selection. Section IV provides the results and analysis. Section V concludes and provides directions for the future work.

II. Related Work

In the not-so-distant past, Neural Networks (NN) were criticized by many forecasting practitioners as not suitable and not being competitive in forecasting fields [24]. Consequently, practitioners have usually selected statistical methods that were considered more straight forward to apply [19]. However, with the ever-increasing availability of data, neural networks (NNs) and deep learning have revolutionized and achieved remarkable success in many research fields and practical scenarios, including medical predictions, NLP, image recognition, etc. Because of their capabilities to identify complex nonlinear patterns and explore unstructured relationships without hypothesizing them a priori. These technological breakthroughs have attracted significant attention from the enthusiasts' researcher community presenting many complex novel NN architectures on time series forecasting. Over recent decades, plenty of works and research exist where deep learning is used for forecasting. There is a possibility to predict stock price changes and foreign exchange rates according to [14]. As a result, AI applications are becoming increasingly popular among investors to increase returns and reduce the risk [15].

Selvin et al. [25] illustrated how deep neural network architectures can capture hidden dynamics and can be used to forecast. Guresen, Kayakutlu, and Daim [16] predicts the NASDA stock index by using multilayer perceptrons (MLP), dynamic, and hybrid artificial neural networks. Using a stacked autoencoder and deep neural network, Takeuchi and Lee [17] obtains an accuracy of 53.36 % when predicting the US stock direction.

Since their inception in 2014 by Hochreiter and Schmidhuber [26], the Long short-term memory network (LSTM) introduced is a variation of the Recurrent neural network model (RNN), which is the most commonly used architecture for sequence prediction problems [8]. In contrast to RNN, LSTM networks are capable of detecting long-term dependency and can prevent gradient vanishing. It utilizes historical information via the input, forget and output gates. In their study, Nikou, Mansourfar, and Bagherzadeh [18] predict the closing prices of iShares MSCI United Kingdom index using an LSTM model. The model performed significantly better than the ANN, Support Vector Regression (SVR), and RF models. LSTMs are utilized in another study by [27] in order to forecast future stock returns. Also, an Autoregressive Integrated Moving Average (ARIMA) and an LSTM model were utilized to improve forecast accuracy [28]. According to Nelson, Pereira, and De Oliveira [29], the average accuracy for predicting the direction of some stocks traded on the Brazilian stock exchange could reach up to 55.9% with the LSTM model.

Because of its powerful pattern recognition ability, the convolutional neural network (CNN) is a variation of the multilayer perceptron (MLP). Its use has extended increasingly for time-series forecasting. The work by [30], [31], and [32] used CNN to predict stock trends. Ugur Gudelek, Arda Boluk, and Murat Ozbayoglu [32] have also experimented with 2D CNN for trend detection. The model performance evaluation has 72% accuracy values and looks promising.

A comparison study of differences between Multi-layer Perceptron (MLP), Convolutional Neural Network, and Long Short-Term Memory (LSTM) was performed by [33]. They

TABLE I. SUMMARY OF RELATED WORKS

adopted a sliding window approach, using 30 previous days to predict the value of the 31st day using historical data of the S&P500 index from 1950 to 2016. CNN's results are exceptional even without the use of additional features such as technical analysis.

Recently, the well-known self-attention-based Transformer [22] was proposed for sequence modeling is the most prevalent model for natural language modeling and has proven quite successful in several other applications such as as translation, speech, image generation, and music [22], [34], [35]. The extension of self-attention to extremely long sequences would, however, be computationally prohibitive since space complexity increases quadratically with the sequence length [20]. However, Vision Transformer (ViT) [23] and TimeSformer (Time-Space Transformer) [36] offer entirely new architectures for image classification, and video understanding based solely on Transformers eliminating the problems associated with long sequences. In particular, ViT divides an image into patches (also called tokens) with fixed length; then following the practice of using transformers to model language, ViT then uses transformer layers to model the relationship among tokens for classification. The TimeSformer, on the other hand, translates the input video into a sequence of image patches derived from the individual frames. The model then captures the semantic information about each patch through comparison with those of the other patches. This allows TimeSformer to capture the space-time dependency based on the whole video. Transformers' recent success in natural language processing (NLP) has motivated researchers to implement this model in computer vision applications and tasks.

Table I summarises the related works discussed in this section. It lists the various ML models that the researchers have used for stock price prediction along with the respective datasets used and the model accuracies reported in the respective works. The most commonly used architecture for problems involving stock price prediction is the LSTM. It can detect long-term dependency and prevent gradient vanishing to some extent. However, LSTM accuracy is much less than the convolutional neural network (CNN) because of CNN's powerful pattern recognition ability. The accuracy metrics are reported in the table if these are provided by the researchers, otherwise, we reported the numeric value from the article without the accuracy metric name. As shown in the table, the best result achieved is 72% accuracy. Our transformer model with its attention features has provided 90% or higher accuracy. We have kept the content in the table to the minimum due to the space issue, please refer to the listed works for details.

III. METHODOLOGY, DATASETS AND MODEL DESIGN

The objective of our study is to predict the subsequent and future closing of the trades in the Saudi Stock Exchange (Tadawul). We use a transformer-based temporal model architecture. In this section, we describe our methodology, Transformer neural network model design, datasets, preprocessing, and validation metrics.

We first present an overview of our methodology in Section III-A. The transformer-based temporal model architecture is described in Section III-B. The the Saudi Stock Exchange (Tadawul) datasets are explored in Section III-C. The data modelling methodology using transformer neural networks is summarised in Section III-D. In Section III-E, we describe the preparation of the dataset, including data splitting, normalization, and feature selection. We discuss the hyperparameter configuration for the model. Section III-F describes the concept of sliding window for framing the dataset. Section III discusses hyperparameter configuration of our model.

A. Methodology Overview

The overall methodology we have adopted is depicted in Fig. 1. It consists of seven main phases as highlighted in the figure. The first process involved extracting Saudi Stock Exchange (Tadawul) data, followed by data cleaning and normalization. As a result of this procedure, we only get data that is appropriate for machine learning algorithms. We then select the four features (open, low, high, previous closing) that the model will use. Thereafter, the data are sorted into non-overlapping batches, which are then fed into the model until performance measures are optimized. Ultimately, the optimized model is used to forecast future closing prices for unseen stock data.

B. Transformer Neural Network Architecture

A significant influence on our architecture is a vision transformer (ViT) [36] using divided space. The vision transformer (ViT) is among the first attempts to apply the outstanding performance of Transformers [22] to image classification tasks rather than natural language processing. The vision transformer (ViT) model, which comprises three main elements: a linear layer for patch embedding, a stack of transformer blocks with multi-head self-attention and feed-forward layers, and a linear layer classification score prediction.

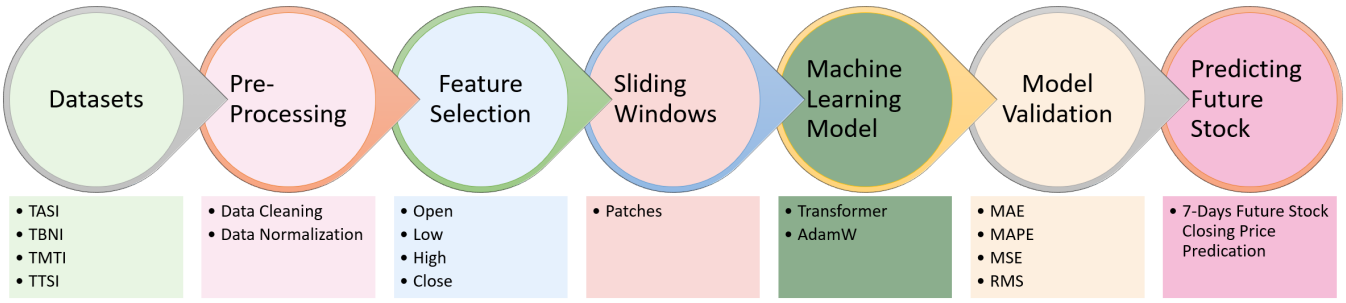

Fig. 1. An Overview of Our Methodology.

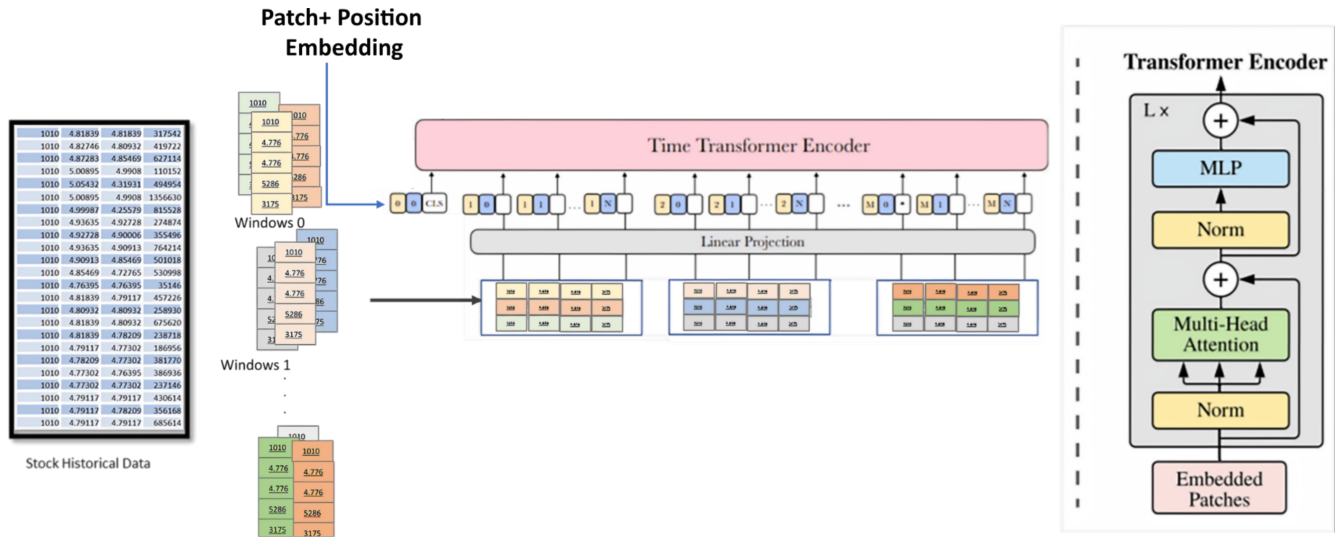

Fig. 2. Proposed Transformer Encoder Model Overview (Illustration Inspired by [22]).

An overview of our suggested model is depicted in Fig. 2. The Vision Transformer (ViT) model serves as the basis for our predictive model. Our suggested model added one more component to ViT architecture. Its primary purpose is to create sliding windows from historical data. Since daily trading volumes on the stock market are substantial, historical data on the market can be challenging to manipulate, and manipulating it can cause a computational burden. Furthermore, the effect of more recent data on a training model is greater than that of older data [37]. Braverman et al. [38] developed a sliding-window method that utilizes recent data while disregarding older observations to solve this problem.

The range of data of interest is selected using a window. The sliding window represents a period that stretches backward in time from the present to the past. The sliding window is held steady (the number of data stays constant), and only the window is moved. Resulting, the training data volume is reduced while maintaining the model's efficiency and general usability [37].

In summary, Fig. 2 depicts our proposed model as follows. The historical data is split into windows and then those windows are divided into fixed-size patches. Linear embeddings are then applied to the patches, followed by position embeddings. Then we feed the resulting sequence of vectors to the Transformer encoder. As a standard approach, we add an extra token to the sequence of learnable tokens to perform prediction. The Transformer encoder diagram in Fig. 2 was inspired by [22].

C. Datasets

The Saudi Stock Exchange (Tadawul) database contains stock trading information for more than 200 Saudi Arabian listed companies. The companies are grouped into sectors with different indices for each industry. The data we downloaded spans the period from 1993-01-02 through 2021-06-17 and consists of 772,189 trading days. Listed companies' and indices trading information includes their Open, High, Low, Volume, and Closing Price for each trading day. From the dataset, we extracted four indices to illustrate model capabilities and performance. These are Tadawul All Share Index (TASI), the Banks Index (TBNI), Materials Index (TMTI), and Telecommunication Services Index (TTSI).

Table II lists a small selection of the dataset. Specifically, it shows the trading information in the dataset for the TASI index for the period 1994-01-26 to 2021-07-01, which corresponds to 7311 trading days. The rows correspond to one trading day and contain the following features: the index column, the transaction date, the ticker code, High, Low, Volume, and Closing Price. Fig. 3 depicts the histograms of the closing price feature of the four datasets. There are four panels in the figure,

TABLE II. TASI SAMPLE DATA

	date	ticker	open	low	high	vol	close
0	1994-01-26	TASI	1751.71	1751.71	1751.71	312907	1751.71
1	1994-01-29	TASI	1751.71	1750.91	1751.71	204831	1750.91
...	...	...	...	...	...	...	...
7310	2021-06-30	TASI	11002.74	10940.44	11009.70	374658538	10984.15
7311	2021-07-01	TASI	10987.13	10968.11	11006.66	352200486	10979.05

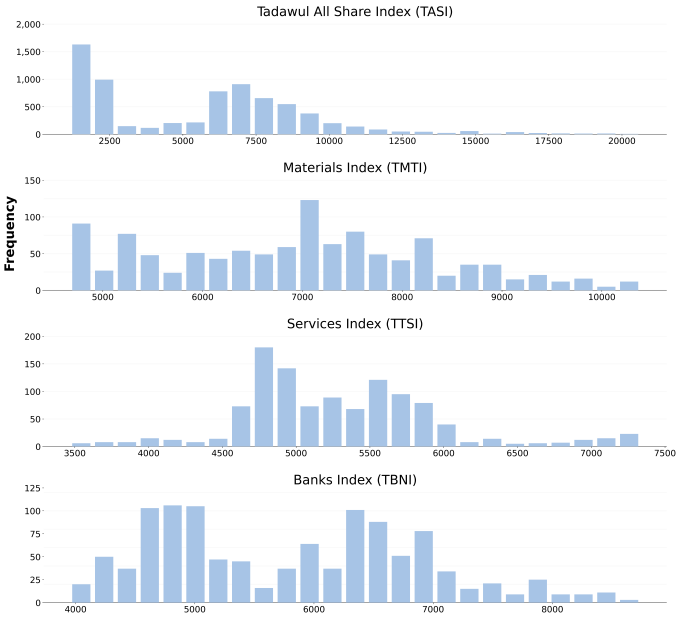

Fig. 3. The Histograms of the Closing Price for the Four Datasets.

each showing the histogram of its respective index. A display of the closing price is shown on the x-axis for each panel, grouped into 25 bins of equal width. Each bin is plotted as a bar whose height (the y-axis) indicates the number of closing prices (frequencies) occurrences in that bin.

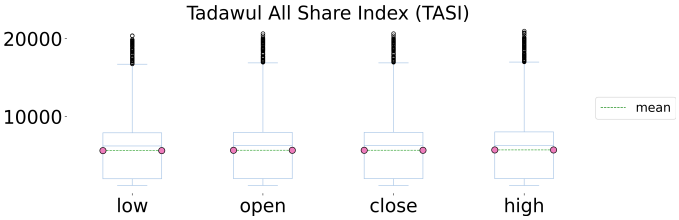

Fig. 4. TASI Boxplot.

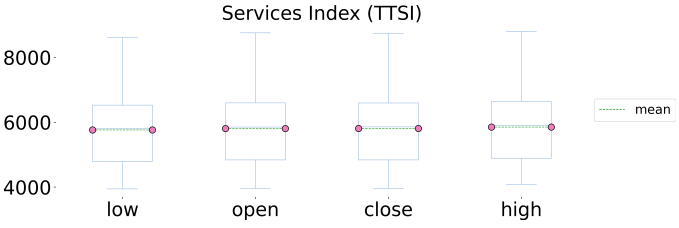

Fig. 5. TTSI Boxplot.

Fig. 4 to 7 depict the four features (open, low, high, close) of the four indices in our dataset as a boxplot. A boxplot is an in-depth statistical data analysis tool for gaining a broad perspective on the center and spread of the data distribution, which can assist with checking for errors and protecting other analyses. The median, interquartile range box, and whiskers are the primary elements of the boxplot to help understand the center and spread of the sample data. You'll see the green line representing the median in each box, which is the center of each feature. The interquartile range (the range between the third quartile and the first quartile) box, on the other hand, represents the middle 50% of the data and reflects how the data is distributed. The whiskers extend from both sides of the box (the bottom line is called lower whiskers, whereas the upper one is called higher whiskers). The whiskers denote the ranges for the bottom 25% and the top 25% of the data values, excluding outliers. Graphs that are skewed have the majority of data on the high or low side. Skewed graphs indicate that the data isn't normally distributed.

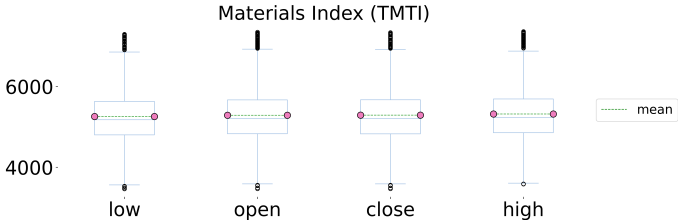

Fig. 6. TMTI Boxplot.

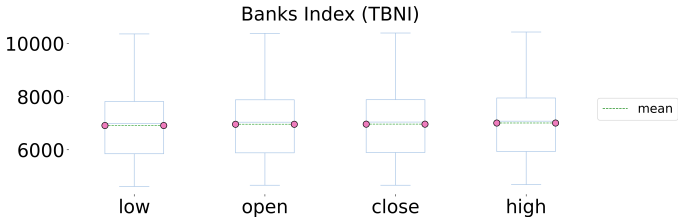

Fig. 7. TBNI Boxplot.

The data distribution for the TTSI, TMTI, and TBNI in the figures (Fig. 5 to 7) is almost normally distributed while it is positively skewed for the TASI index (Fig. 4). Moreover, any value greater than higher whiskers and less than lower whiskers values is an outlier and is represented in the figure as circles beyond the minimum and maximum values. Fig. 4, shows reasonable outliers points for TASI, which is expected as the closing of TASI is directly impacted by each and every listed company.

Fig. 8 highlights the correlation between the features (High, Low, Volume, and Closing Price), which is considered an essential step in the feature selection phase of data pre-

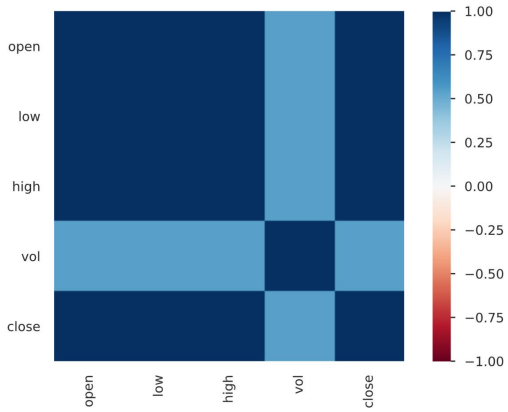

Fig. 8. TASI Correlation Matrix.

processing, especially if the data types of the features are continuous. As you can see in the figure, there is a high correlation between volume and the other features.

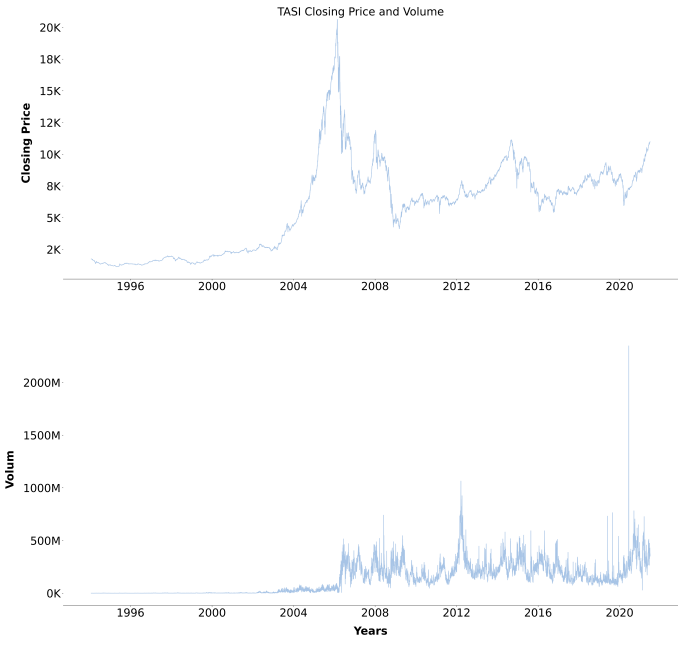

Fig. 9. TASI Closing Price and Volume.

Tadawul All Share Index (TASI) volume and closing figures are shown in Fig. 9.

D. Data Modelling Methodology

At first, the historical stock data of earlier days $X \in \mathbb{R}^{M \times F}$ consisting of M periods with F features (previous closing, opening, high ,low and volume) is split into a sequence of flattened 2D Windows $\mathbf{x}_w \in \mathbb{R}^{L \times F}$ of size $M-L$, where L is look back time interverls. Then the input window is divided into non-overlapping temporal patches of size $\mathbf{x}_p \in W \times (F \times 2)$.

Finally, following the protocol in ViT ,the patches $\mathbf{x}_p \in \mathbb{R}^{W \times (F \times 2)}$ are flattened forming a sequence of embeddings. Using learnable 1D position embeddings, we embed positional information into the patch embeddings so that all patches within a given window w are given the same temporal position. This allows the model to determine the temporal positions of patches.

E. Data Prepossessing

It is imperative to preprocess data in order to achieve good predictions. The indexes data were checked to determine whether the Tadawul Dataset contained inconsistencies. All the numerical data were normalized, and the missing values were removed. The open, high, low, volume and close prices were used to calculate the features, but information such as the stock code and stock name was omitted since they do not make sense. The following sections describe how the various preprocessing steps are implemented.

1) Splitting the Dataset: The training and test datasets are separated, similar to the ideas presented by [39]. We reserve apart from the end the training for validation from each time series. This approach is illustrated in the Fig. 10.

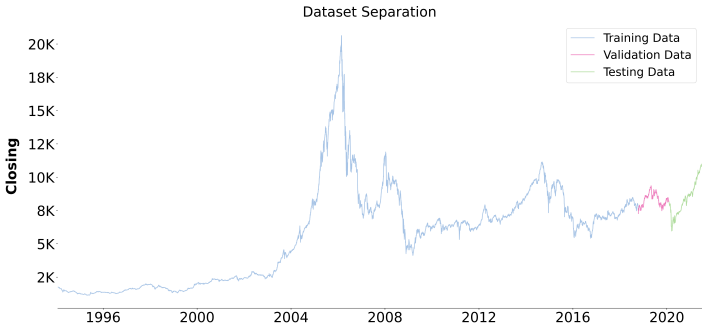

Fig. 10. Training, Validation and Testing Dataset Allocation.

2) Data Normalization: Normalization refers to the process of changing the range of values in a set of data. As we use prices and volume data, all the stock data must be within a typical value range. In general, machine learning algorithms converge faster or perform better when they are close to normally distributed and/or on a similar scale. Also, in a machine learning algorithm, the activation function, such as a sigmoid function, has a saturation point after which the outputs are constant [40]. As a result, when using model cells, the inputs should be normalized before being used. This process was done using MinMaxScaler methods of the scikit-learn library. When MinMaxScaler is applied to a feature, it subtracts the minimum value from each value in the feature and divides the range by the result. Thus, the range of a feature is the difference between the maximum and minimum values. In this way, MinMaxScaler preserves the shape of the original distribution. MinMaxScaler normalizes input values to be between [0,1].

3) Feature Selection: The downloaded data contains several features, including stock code, stock name, opening price, high price, low price, volume and closing price. Aside from some features that may not make any sense, these initial data have a lot of noise. For this reason, the data should be neglected when it is being trained. Based on [41] using open price, high price, low price, volume and close price, the input features will

yield a satisfactory result. Therefore, we have selected the first five features as our input and have neglected irrelevant data like stock names and stock codes.

F. Divided Space

At this stage, we apply the concept of the sliding window for framing the dataset. With a window size of 2, we use the data before two days to predict the subsequent day closing. The process is repeated until all data are segmented. Then, the framing dataset is further split into patches.

G. Hyperparameter Selection

A number of parameters, called hyperparameters, are usually included in all deep learning models (apart from Naïve Bayes) that need to be adjusted to optimize results [42]. The various hyperparameters used during training are summarized in Table III. The AdamW optimizer is used during training with a learning rate of 0.001 and a weight decay of 0.0001. We train the model for 500 epochs with early stopping and dropout to prevent overfitting using TensorFlow [43] library.

TABLE III. VARIOUS HYPERPARAMETERS USED IN THIS MODEL WITH THEIR VALUES

Hyperparameter	Value
Learning Rate	0.001
Optimizer	AdamW
Batch size	256
Epochs	500
Early stopping	Patience = 70 epochs Monitoring parameter = validation loss
Loss Function	MSE

H. Evaluation Metrics

Deep learning evaluation is categorized into accuracy index, financial index, and error-index [44]. Accuracy and financial index are widely used for prediction by classifying data (e.g., price direction prediction) and stock trading and portfolio management. On the other hand, error terms are frequently used in the evaluation for predicting numeric dependent variables (for instance, exchange rates or stock market predictions). The error terms evaluation rules compare the Real Data Y_{t+1} and the prediction data F_{t+1} using performance metrics: MAE, MSE, MAPE, and RMSE. Detailed information about the measures is provided below:

MSE is used to assess model performance based on the average error of forecasting. The formula of the MSE is given below:

$$\sum_{i=1}^{m} \frac{(Y_{t+i} - F_{t+i})^2}{m} \tag{1}$$

RMSE is one of the most commonly used error metrics in regression. It is equal to the square root of the MSE. RMSE is a measure of how spread out the residuals are. Based on the RMSE formula, it is possible to determine how well the data was focused around the optimal line. The optimal RMSE value is close to zero.

$$\sqrt{\sum_{i=1}^{m} \frac{(Y_{t+i} - F_{t+i})^2}{m}} \tag{2}$$

MAPE shows how much error was in the forecast. It measures how accurate the forecast is. A value of accuracy is calculated by subtracting the actual values from the average values of the previous period. The concept of MAPE is separated from the measurement level by data conversion. MAPE has minimal deviation in practice and cannot tell which direction the error is coming from. Ideally, MAPE should be close to zero. MAPE can be calculated using the following equation:

$$\frac{100}{m} \sum_{i=1}^{m} \frac{|Y_{t+i} - F_{t+i}|}{Y_{t+i}} \tag{3}$$

IV. RESULT AND DISCUSSION

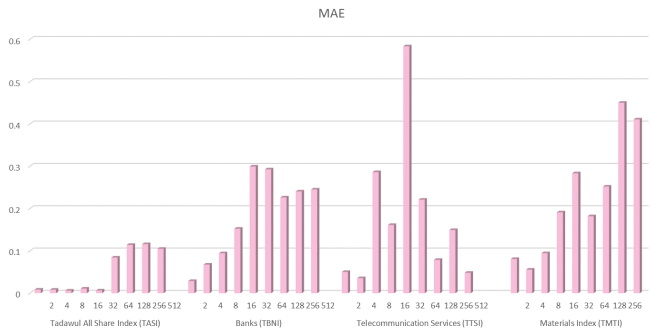
We now discuss the results beginning with results on model optimisation in Section IV-A, model validation in Section IV-B, and future stock closing price prediction in Section IV-C.

A. Model Optimisation

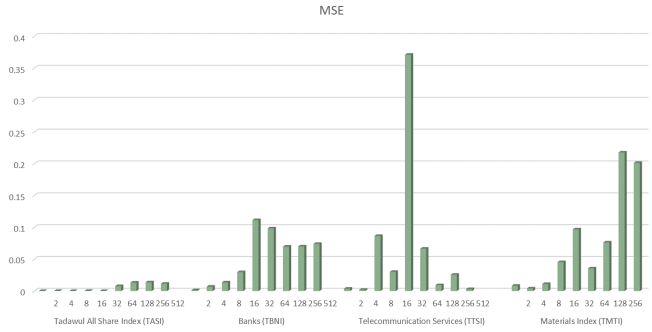
For this study, we experimented with different batch sizes and kept all the other hyper-parameters unchanged. Our predictive transformer model is implemented using TensorFlow written in Python. The study found that training smaller batches yielded better estimates but had a long training process. Our findings indicate that models perform better for all the four indices until the batch sizes reach around 4, with other batches not delivering significant performance improvements worth the time and effort devoted to estimating them. Fig. 11 depicts the four prediction performance measures MAE, MAPE, MSE, and RMSE results, respectively, for the Tadawul All Share Index (TASI), the Banks Index (TBNI), the Materials Index (TMTI), and the Telecommunication Services Index (TTSI).

Fig. 11a Mean Absolute Error (MAE) measure. It shows the batch size of the Tadawul All Share Index(TASI) is increased, and we find that forecast measures enhance until it reaches its best results at a batch size of 8 at a value of 0.0001, while it gets fluctuated for the other indices. Taking the MSE for Banks (TBNI) Index as an example, the optimal value for the TBNI index at batch size 2 is 0.0013, and it increases to 0.1114 at batch size 32. Thereafter, the index decreases with batch size. Similarly, when batch size over batch size exceeds eight, the Materials Index (TMTI) and Telecommunication Services Index (TTSI) also apply. Fig. 11b illustrates the mean square error (MSE) measure. It shows the batch size of the Tadawul All Share Index(TASI) is increased, and we find that forecast measures enhance until it reaches its best results at a batch size of 8 at a value of 0.0001, while it gets fluctuated for the other indices. Taking the MSE for Banks (TBNI) Index as an example, the optimal value for the TBNI index at batch size 2 is 0.0013, and it increases to 0.1114 at batch size 32. Thereafter, the index decreases with batch size. Similarly, when batch size over batch size exceeds eight, the Materials Index (TMTI) and Telecommunication Services Index (TTSI) also apply.

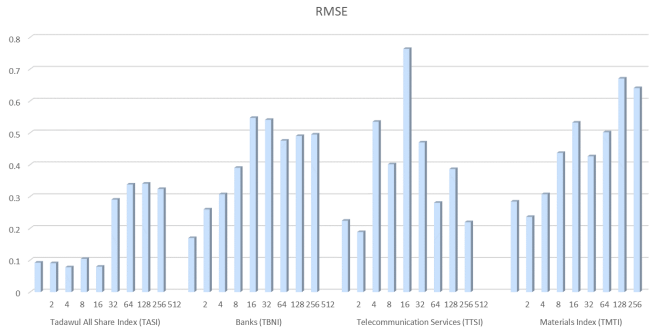
Fig. 11c, however, presents the root means square error (RMSE) of each batch size determined by the indices. For each batch size, each experiment was repeated 500 times(number of Epochs). As indicated in the figure, the RMSE is substantially higher for the Banks Index (TBNI), the Materials Index



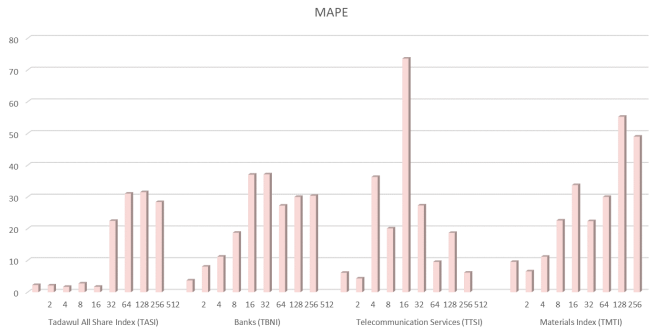
(a) MAE



(b) MSE



(c) RMSE



(d) MAPE

Fig. 11. Model Performance Versus Varying Batch Sizes.

(TMTI), and the Telecommunication Services Index (TTSI) mainly because of the number of trading days for these indices compared to the Tadawul All Share Index(TASI). Results show an evident dependence on the number of trading days. The RMSE ranges from 0.1697 to .5409 obtained for the Banks Index (TBNI), from 0.1885 to 0.7638 for Telecommunication Services (TTSI), from 0.2361 to 0.5323 for Materials Index (TMTI). Fig. 11d shows the Mean Absolute Percentage Error (MAPE) for each batch size for the four indices. Despite outperforming practically all other indices with a MAPE value of 1.681 for batch size 8, there is another batch size where TASI does just as well on this accuracy measure. Considering the effects of sampling (trading days) on results, it makes sense that the result would differ.

B. Model Validation

Fig. 12 to 15 depict the predicted versus actual closing price for the four datasets: Tadawul All Share Index (TASI), Banks (TBNI), Telecommunication Services (TTSI), and Materials Index (TMTI) indices. These graphs show the best results based on a comparison between the actual and forecasted stock prices (close prices). On each chart, orange and blue lines depict the actual values and predicted values, respectively. The plots provide the timelines of the whole dataset. Fig. 12 plots the closing prices for the TASI dataset for the period from early 1990s to 2021. Note in the figure that there is a relatively bigger difference between the actual and predicted values of the stock closing prices in the earlier period of the data. However, the differences get smaller for the later time periods. Overall, all the four figures show a reasonably small differences between the actual and predicted values, indicating a good model performance. The results of our study indicate that the proposed model is very effective in analyzing and capturing trends, as well as forecasting them accurately.

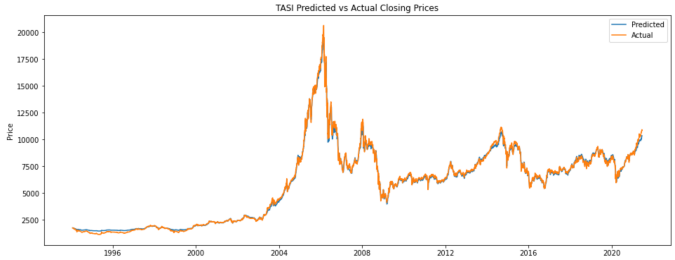


Fig. 12. TASI-Predicted vs Actual Closing Price for the whole dataset.

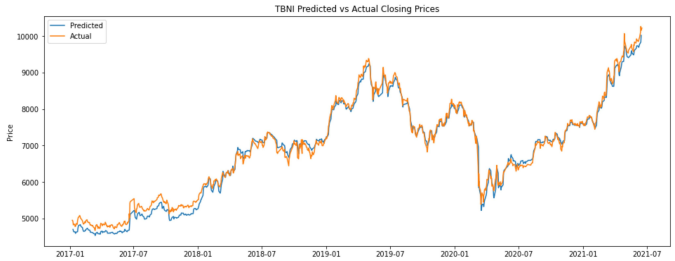

Fig. 13. TBNI-Predicted vs Actual Closing Price.

C. Predicting Future Stock Closing Prices

The next day's closing price of the selected stock is derived from the model prediction. Fig. 16 depicts the predicted and

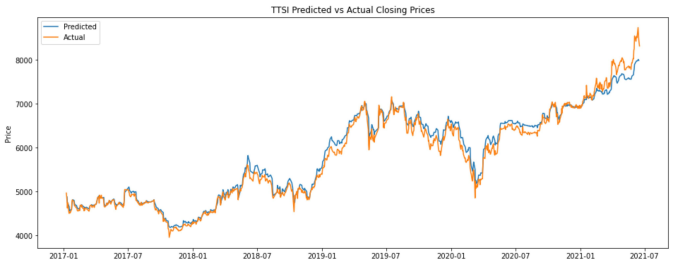

Fig. 14. TTSI-Predicted vs Actual Closing Price.

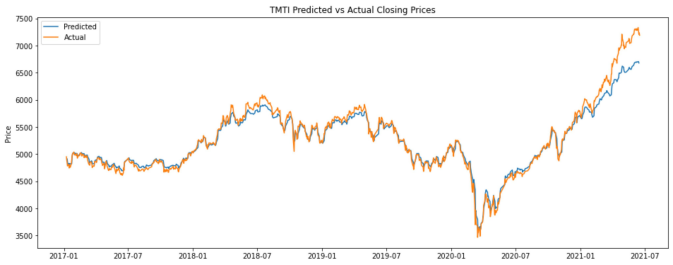

Fig. 15. TMTI-Predicted vs Actual Closing Price.

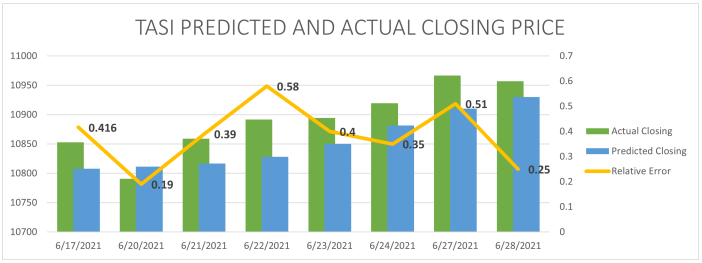
actual closing for eight trading days starting from 6/17/2021 till 6/28/2021 by using the model for the four indices TASI, TBNI, TTSI, and TMTI. The figure illustrates that the range of relative error fluctuation within the eight working days is between 0.19 and 0.58 for Tadawul All Share Index (TASI) and between 4.43 and 6.15 for the Banks index. As a result, the model accurately predicted the closing price of TASI and Bank with more than 99 and 94 percent, respectively. According to the model, TASI's closing price, for example, on 2021/06/17, will be 10807.94, while it was actually 10853.12 at the time. 45.18 points is a relatively small difference. In contrast, the relative error of Telecommunication Services (TTSI) fluctuated between 0.2, and 2.12, while Materials Index (TMTI) fluctuated between 5.25, and 7.33. Consequently, TMTI and TTSI closing prices were correctly predicted with more than 92, and 97 percent, respectively. The proposed model predicts the market closing price with a better than 90% accuracy, making it an exceptionally effective and practical model.

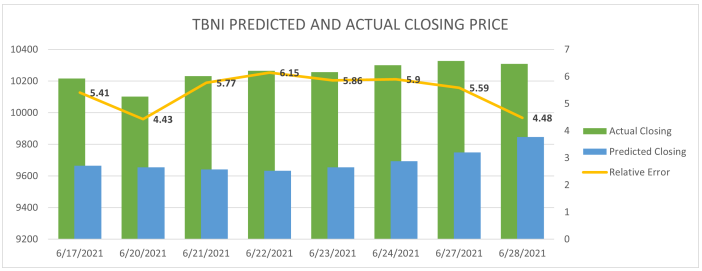
V. Conclusion and Future Work

We propose a transformer-based formalization model for stock price prediction. A significant influence on our architecture is a vision transformer (ViT) [36] using divided space. The vision transformer (ViT) is among the first attempts to apply the outstanding performance of Transformers. Using transformer network architectures with split time series into patches shows that hidden dynamics can be captured and predictions made reasonably. The model was trained using data from the Saudi Stock Exchange (Tadawul). As a result, we were able to predict the stock price of the TadawulAll Share Index (TASI), Telecommunication services Index (TTSI), Banks Index (TBNI), and Materials Index (TMTI) with accuracy that exceeds 90%.

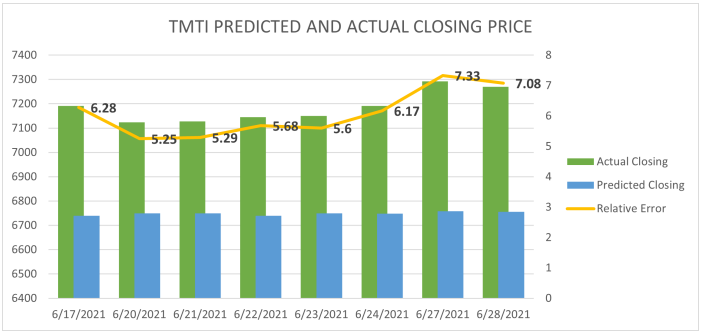
We evaluated the proposed transformer model using four accuracy metrics, MAE, MSE, MAPE, and RMSE. We described the experimental results related to model optimisation



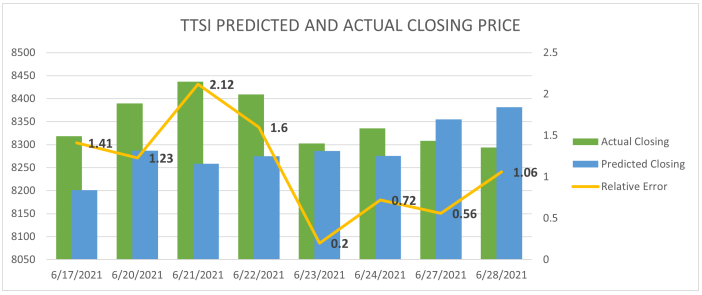
(a) TASI



(b) TBNI



(c) TMTI



(d) TTSI

Fig. 16. Prediction of Unseen Future Stock Closing Price.

and model validation for all the four datasets. Subsequently, we presented results for the prediction of future stock closing prices. We were able to achieve over 90% accuracy compared to the best 72% reported in the literature (see Table I). Furthermore, the experiments showed that the proposed model architectures that split time series into patches were able to identify the dynamics and complex patterns from irregularities in financial time series. Transformer architecture has also been shown to identify sudden changes in stock markets, as reflected in the results. However, the changes occurring may not always

appear regularly or follow the same cycles each time.

ACKNOWLEDGMENT

The experiments reported in this paper were performed on the Aziz supercomputer at King Abdulaziz University.

***Abstract*—Computer Vision has set a new trend in image resolution, object detection, object tracking, and more by incorporating advanced techniques from Artificial Intelligence (AI). Object detection and tracking have many use cases such as driverless cars, security systems, patient monitoring, and so on. Various methods have been proposed to overcome the challenges such as long-term occlusion, identity switching, and fragmentation in real-time multi-object detection and tracking. However, reducing the number of identity switches and fragmentation remains unclear in multi-object detection and tracking. Hence, in this paper, we proposed a multi-object detection and tracking technique that involves two stages. The first stage helps to detect the multiple objects with high uniqueness using Faster RCNN and the second stage, Improved Sqrt cosine similarity, helps to track the multiple objects by using appearance and motion features. Finally, we evaluated our proposed technique using the Multi-Object Tracking (MOT) benchmark dataset with current state-of-the-art methods. The proposed technique resulted in enhanced accuracy and reduces identity switching and fragmentation.**

***Keywords*—Multi-object detection; tracking; faster RCNN; convolution neural network; data association**

I. Introduction

MOT tracks moving objects with the regular time interval via camera as the input device. In 1998, Zenon Pylyshyn [1] was first developed multi-object tracking. Each detected object is assigned a unique identification number. This identity number retains its association with the object when changing the object's appearance or object moving and draw the motion trajectories of the object based on the unique identities. Fig. 1 shows the basic steps of object detection and tracking. Multi-object detection finds the objects under a unique frame and MOT is integrated with the detected objects in the sequence of frames.

Fig. 1. Basic Steps of Object Detection and Tracking.

A wide range of real-time applications is implemented using MOT, with which it is having extraordinary significance nowadays [2]. Some real-time applications are Human tracking, monitoring Alzheimer's activities, monitoring security, autonomous driving, robotic vision, traffic control, medical images, and others. Gulraiz *et al.* [3] say that tracking is useful because of a specific reason as follows. In the video frame, multiple objects are detected, then establish the identity of the targeted objects in the frame while tracking the objects. Suppose object detection fails, it may be possible to track the object using appearance features and stored location of the previous frame. Local search is initiated instead of global search during tracking. Whenever the movements of the targeted objects are high, the tracking algorithm loses track of the target objects. Hence, the proposed system integrates the detection and tracking methods. The proposed hybrid system has two stages. In the first stage, multi-object detection performs every n^{th} frame of the input. The second stage, multi-object tracking, will take the target objects of n^{th} to $(n+1)^{th}$ frame based on the appearance features and object position in the different frames. Some applications of the proposed work are Alzheimer's patient tracking, monitoring the activities like cooking, hand washing, dressing and others, as shown in Fig. 2.

Fig. 2. Applications of MOT.

In recent years MOT has had many scopes. By the incorporation of AI techniques, the present object detection and tracking techniques are giving better performance than the traditional methods. Most of the traditional methods track the objects from frame to frame. It gives good tracking performance. However, traditional methods are facing computational problems in complex scenarios. They also face difficulty in handling noise and occlusion problems.

Most of the traditional methods are not suitable to adopt in real-time applications. Batch-based movement tracking [4] and probability-based systems [5] must complete batch video processing to track the targeted object. These methods take more time to convert a batch to a performance tracking process. Hence, it is not suitable for real-time scenarios.

Currently, researchers are concentrating on tracking performance by reducing the missing detection rate with the combination of detection and tracking methods. However, we are facing some challenges in tracking moving objects. The

challenges are occlusion, identity switching, time efficiency, motion blurring, viewpoint variations, Background changing, low resolutions, etc. In this work we concentrate mainly occlusion in the long term, time efficiency, identity switching and fragmentation. The objective of this research work is given below.

1) Multiple object detection.
2) Develop a technique to reduce identity switching and fragmentation.
3) Compare the performance of the proposed technique with existing techniques.

The batch and probability-based tracking algorithms have some limitations in time efficiency to apply the real-time application. Much work has been done to overcome the above challenge.

Identity switch problem means detected object changing the identity number in the frame to frame. Identity switching problems mainly occur in two situations: failure of object detection and long-term occlusion occurs. To overcome the failure of object detection, we used the deep learning-based multi-object detection method to detect the person, Bread, Jam, Coffee Maker, Coffee cup and Spoon. To avoid the occlusion problem, we mainly focused on the localization features of the object's appearance. Every object has a different appearance and different locations of the frame. Hence we are implementing the tracking based on the appearance features.

Fragmentation of trajectories may fail when the identity switches have not occurred or object detection fails. With the help of motion and appearance features, a complete trajectory path of one fragmented frame to another fragmented frame can be obtained.

To overcome the above challenges, we proposed the novel multi-object detection and tracking technique. This work has two stages: the first stage detects multiple objects using Faster RCNN, and the second stage is tracking the multiple objects using unique appearance and motion features. The proposed method improves the tracking performance by making robustness in the occlusion.

Paper is organization is as followed: Related methodologies for object detection and object tracking are discussed under Section 2. Section 3 provides the architecture of the proposed system. Section 4 describes the evaluations and results. Finally, Section 5 gives the conclusions of the proposed work.

II. Literature Survey

Recent researchers have concentrated on tracking an individual object in various contexts with multi-object detection and tracking progress. The proposed multiple object tracking method is mainly focused on the association problem. The association problem is used to associate the detected object of one frame to another frame. Hence object detection is carried out before object tracking. The following section primarily focuses on the existing methods and methodologies for object detection and object tracking.

A. Object Detection Algorithms

In the 1990's Anil *et al.* [6] proposed object detection by object matching using deformable templates. These templates have prior knowledge of the object shape like edges and set of edge information. In the late 1990s, object detection was based on the associated geometric appearance feature [7]. The geometric appearance methods involve some geometric properties such as height, width, angle and so on.

Object recognition was moved to the low-level characteristics of the image in the 2000s, based on statistical classifiers. Ojala *et al.* [8] developed rotation invariant classification for grayscale images using the binary patterns locally. Dalal *et al.* [9] proposed Histogram oriented gradients method of object detection in static images. Lowe *et al.* [10] present a method to extract the invariant features of the images. The features are the uniform image scale and rotation, 3D viewpoint and addition of noise. Tuzel *et al.* [11] describe the covariance-based computation method on the internal images. Compared to other statistical methods, a covariance matrix is better to handle large rotations and illumination changes.

Handcrafted conventional features were adopted for object detection in the computer vision sector for many years. In 2012 the deep learning method gave terrific results for the image classification challenge [12]. After successful classification, the researcher concentrated on object detection using deep learning. A Convolution Neural Network (CNN) acts as a backbone network for object detection in deep learning. The CNN is used to extract the local and global feature maps of the input image. Researchers use different backbone networks such as VGG16, AlexaNet, MobileNet, ResNet, and others to achieve the best accuracy.

Now-a-days, research community has moved to region-based networks for object detection. Gulrciz *et al.* [13] proposed a video-based variety of object interaction and spatial relations of the objects. However, to solve a more complex object detection problem, we need to find the object's coordinates in the input image. Girshick *et al.* [14] developed a region Convolution neural network (RCNN) for object detection to overcome the above problem. Here instead of running the classification of many regions. Firstly, they use selective search to extract the region from the image. Then classification will run on the extracted regions. The RCNN has four steps as follows. The selective search algorithm passes on images to generate a region proposal network. Once the region of interest for each image is determined, then resize all proposed regions to match the predefined size of the classes. SVM classifier is used to classify the object and background of the image. Finally, train a linear regression model to generate the bounding boxes of the detected objects. The RCNN has some drawbacks that are as follows. RCNN consumes more time in the training process because the selective search generates the Region of interest. For classification purposes, they used a separate SVM classifier. It is expensive to extract the convolution feature maps for individual regions.

Spatial Pyramid Pooling (SPP-net) method [15] takes any size of the input image. In the SPP-net method, there is no need to compute the convolution feature maps of every region repeatedly. SPP-net generates the entire image features map at a time.

Girshick *et al.* [16] proposed the Fast RCNN to address the above problem. Fast RCNN is similar to RCNN, and Fast RCNN feeds full input images to CNN to generate the feature

map. Then identify the different region proposals from the convolution feature map. The region proposals are different in size. Hence they add these region proposals to the Region of Interest (ROI). Pooling Layer to generate the fixed-size feature maps of the individual regions. The ROI feature vector is further split into two divisions that are classification and regression. Using softmax layer the image is classified into a predicted object and background object and regression is used to generate the bounding boxes. Compared to RCNN, the Fast RCNN has better performance.

Ren *et al.* [17] proposed the Faster RCNN object detection algorithm similar to Fast RCNN. To predict the region proposal, they used a separate network instead of a selective search algorithm. Redom *et al.* [18] proposed the YOLO object detection method. YOLO does not use the region proposal step. It simultaneously detects all bounding boxes of all classes in the input image. Hence YOLO can be an optimized, end-to-end training model. YOLO describes the image into S*S grids. Each grid has probabilities of B (Bounding boxes), C (classes). Yolo can predict the object at 45fps while running the real-time images. However, missed detection raises to identity switch and fragmentation issues.

B. Object Tracking

Some Researchers have investigated spatial features for multiple object tracking [19] and appearance-based approach to capture the association between previous and currently detected frames [20]. Motion-based multiple object target tracking with similar appearance features was proposed in [19]. This method recovers missing data efficiently during the long-term occlusion and also reduces misidentification. However, this method fails to maintain the association between different frames. JuHog *et al.* [21] constructed a Relative Motion Network (RMN) method to track a relative movement between the camera and objects resulting in better data association between different frames and accurate tracking during the camera movement.

Donald *et al.* [22] developed an algorithm for multiple target tracking and Fortmann*et al.* [23] introduced the Joint Probabilistic Data Association (JPDA) algorithm. Rezatofighi *et al.* [4] revisited the JPDA method that has better performance. They utilized some current methods to discover the m-best solution for linear programming. However, there is a delay in decision making. Hence these methods are not suitable for real-time scenarios.

Gabin *et al.* [24] proposed a method to track the multiple football player trajectories from the multiple cameras using a distributed scene algorithm. Improve the performance of online tracking of multiple objects using existing trajectories. Some researchers are using the correlated association for online detection purposes. Yang *et al.* [25] prepared the multi-person online tracking of dynamic appearance features. The temporal dynamic approach incorporates the spatial structure appearance features. This method gives an accurate approach using the data association technique. It also improves the affinity management between the detection and trajectories of the frames. However, it faces the difficulty of online tracking for complex scenes. Xiang *et al.* [26] used the Markow Decision Process (MDP) method to track multiple online objects.

Recently researchers worked on deep learning-based online multi-object tracking of live videos. Alex *et al.* [27] proposed the Simple Online and Real-time Tracking (SORT) method. SORT mainly focused on the association of the objects from one frame to another in online tracking. Firstly, identify the quality of the object detection. Then the Kalman filter is used to estimate the different positions like center, height, aspect ratio and linear velocity of one frame to another. The Kalman filter eliminates the duplicate track of the frame using the Hungarian algorithm. Finally, detect and create the track identities of the object. But, SORT is unable to handle the object re-identification and long-term occlusion problem.

To avoid problems with the SORT method, Nicolai *et al.* [28] integrate the SORT with the in-depth appearance information. In a deep sort, they change the association matrix with the integration of motion and appearance information. Then apply CNN for the target appearance to a large-scale object re-identification dataset. It reduces the loss track of the long-term occlusion. However, this system misses the track during the poster changes in real-time and detects the large frames.

Gulraiz *et al.* [3] proposed multi-person detection and tracking using state-of-art methods. Faster RCNN is used for accurate detection and the deep SORT method is used for tracking. It gives better accuracy in real-time human detection. In tracking, it misses re-identification of objects from one frame to another.

In this paper we propose a system to reduce the number of objects being missed from detection in multiple objects using Faster RCNN. Improved sqrt Cosine similarity method is applied to overcome the object re-identification problem. It uses to find the association matric between two consecutive frames.

III. Proposed Method

The Deep learning methods are the better choice for multiple object tracking. Object detection is the foundation of multiple object tracking. To solve object detection problems with greater accuracy in real-time, deep learning algorithms are preferable for detection. We have solved the multiple object tracking problems using state-of-the-art techniques. The projected method gives critical components of multiple object position prediction in the future frames, and tracking the association of the different frames and managing the lifespan of the tracked multiple objects.

The CNN methods are commonly used in object detection, such as Region-Based Convolutional Neural networks (R-CNN), Fast CNN, Faster R-CNN, etc. The CNN method divides the image into various regions and then classifies every region into different objects, but it needs many regions to predict the object. R-CNN method selectively searches together with the region, but it requires high computation time and prediction is carried using three different models. Fast R-CNN involves a single model that takes features from regions, classifies them, and delivers the border boxes for each class simultaneously. However, it is a slow and time-consuming process to find the Region of Interest. So we conducted a survey to choose the best detection algorithm that is Faster R-CNN. We have divided the proposed work into three models

are shown in Fig. 3. The first one is object detection, the second one is tracking handling, and the third is an association.

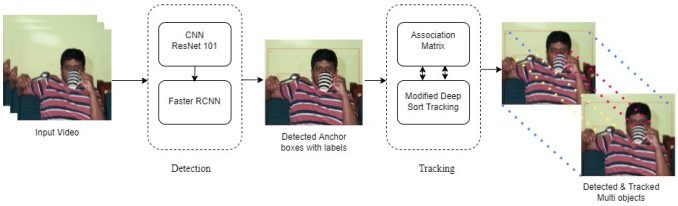

Fig. 3. Block Diagram of Proposed System.

A. Multi-Object Detection using Faster RCNN

The Faster R-CNN involves two stages: Region Proposed Network (RPN) and object detection network. The region proposed network is further divided into three steps. Initially, to extract features map by using a convolutional neural network. After it generates anchor Boxes for using the sliding window approach. Finally, generated anchor boxes are reanalyzed using a tiny network that computes the loss function to select the containing object. The CNN is the backbone of the RPN and object detection network. It requires a step for extracting the convolution feature map.

1) Residual Network-101: The Object detection problem mainly depends upon the feature extraction process. So, we used the ResNet-101 Network model in our method to produce a feature map. ResNet-101 is a convolutional neural network that contains 101 layers between the residential connections. The main advantage of the ResNet-101 is to train the module efficiently without increasing the training error. It also helps to solve the vanishing gradient problem by adding a shortcut connection technique. The shortcut connection is skipped one or more layers to perform the identity mapping. The shortcut connection takes the input x to the output after a few weighted layers. This x is added to the output of the sketch layer. The pictorial representation of the residential network shows in Fig. 4. In different scenarios, the two types of shortcut

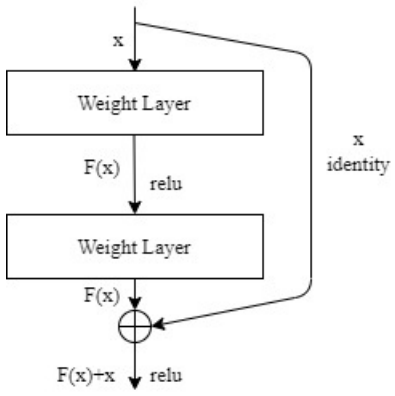

Fig. 4. Building Block of Residual Learning.

connections are used in ResNet. When the input and output are the same dimensions then shortcut(x) is used directly.

$$z = F(x, w_i) + x \tag{1}$$

When the input and output are different dimensions. Then identity mapping is preferred by padding extra 0 to make dimensions suitable.

$$z = F(x, w_i) + w_j x \tag{2}$$

In equations 1 and 2, where x is the feature map value of the previous layer, F is the convolution function and w is the weighted matrix.

2) Anchor Box Generation: The RPN takes the convolution feature map that the ResNet-101 generates as an input, and the output is anchor boxes generated by RPN using the Sliding window approach. This Sliding window approach adopts a 3 * 3 window size upon the future map. Sliding window traverse across the future map to generate the anchors. The sliding window generates a set of 9 anchors for each pixel, each pixel center point is (x,y). All 9 anchors are three different vertical scales such as 128 * 128, 256 * 256 and 512 * 512 and three different aspect ratios of 1:1, 1:2 and 2:1 as shown in Fig. 5. Then, determine the number of anchor boxes

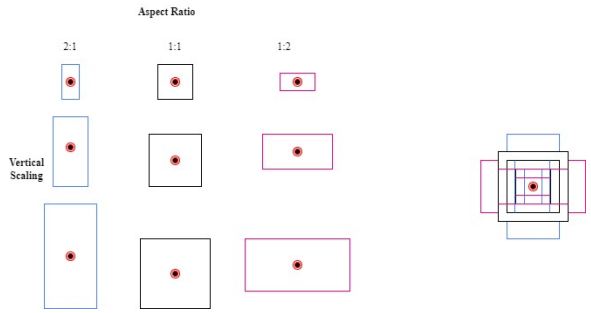

Fig. 5. Nine Anchor are Generted in Each Pixel.

that is overloaded with Background Classes (Bc) using the intersection of union approaches. We set the threshold value to the intersection of the union approach. If the threshold value is greater than 0.8 then consider the object is present in the region. Suppose the threshold value is less than 0.2 then no object is present in the region.

$$IOU = \frac{anchor \cap Bc > 0.8 = ObjectPresent}{anchor \cap Bc > 0.2 = NoObjectPresent} \tag{3}$$

3) Loss Function: The loss function is used to fine-tuning the selected anchor boxes. The loss function mainly contains two tasks: regression and classification. We use binary classification to predict whether the concerned anchor boxes contain the object or background. The regression determines the position of the predicted anchor box. The loss function calculates for both the classification and regression to fine-tuning the anchor box. The loss function is shown in equation 4.

$$L(p_i, t_i) = \frac{1}{N_{cls}(\sum_i L_{cls}(p_i, p_i^*))} + \frac{\lambda}{N_{reg}(\sum_i p_i^* * L_{reg}(t_i, t_i^*))} \tag{4}$$

In equation 4, Where p_i means the predicted probability of anchors containing objects, p_i^* means the ground-truth value of anchors contains an object, t_i coordinates of predicted anchors, t_i^* is ground truth coordinates associated with anchors,

L_{cls} classification loss, N_{reg} is normalization parameter of regression, L_{reg} regression loss and λ is a constant value.

4) Region of Interest (ROI): The output generated from the RPN is the input of the ROI Pool layer. The output of RPN anchor boxes are different sizes, so the task of the ROI is to reduce the different size anchor boxes to the same or fixed size anchor boxes. For this purpose, we use classification and regression methods. The classification method identifies the object or background class of the image. Then regression gives the bounding box values (dx,dy,dh,dw) to cover the complete object. Where (dx,dy) is the center point of the bounding box, dh is the height of the bounding box and dw is the bounding box width. The performance and accuracy of the Faster R-CNN is good enough than all of the available traditional object detection algorithms. The framework of the Faster R-CNN is shown in Fig. 6. We have trained Faster R-CNN and

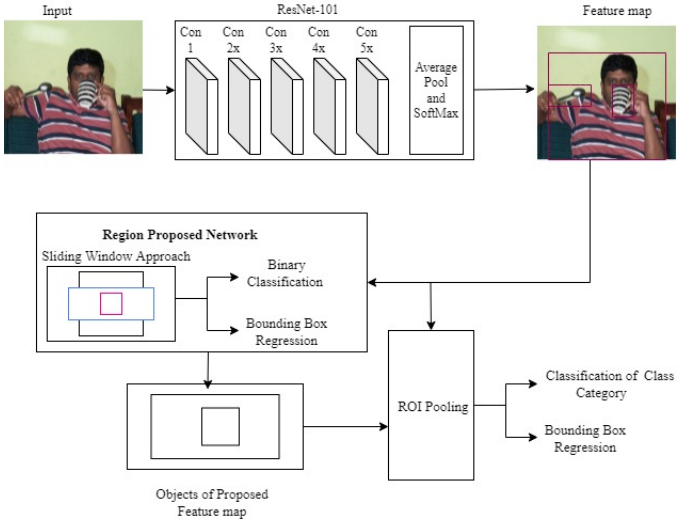

Fig. 6. Faster RCNN Complete Framework.

5000 annotated images like a person, coffee cup, coffee maker, bread, jam and spoon. The Faster R-CNN gives the improved detection accuracy effectively.

B. Multiple Object Track Handling of Feature Frames

We proposed a multi-object tracking method using the modified deep sort technique. The modified method takes the input as detected bounding boxes from Faster R-CNN. We are using the Kalman filter to extract the spatial and tracking information of the bounding boxes. The deep CNN model helps to extract the appearance feature of the frame. To find a track association between current and next frame of appearance feature using Mahabolish distance and improved sqrt-cosine similarity measures. If the track association's threshold value is equal to 1, the track is confirmed and updated; otherwise, delete the frame immediately. The modified deep sort is shown in Fig. 7. The frame-by-frame data association method and the Kalman filter are the essential components of the modified deep sort. The trackers scenario is based on the multidimensional state space(u,v,Y,h,a,b,c,d) that contains the center of bounding box is (u,v), expectation ratio is Y, height

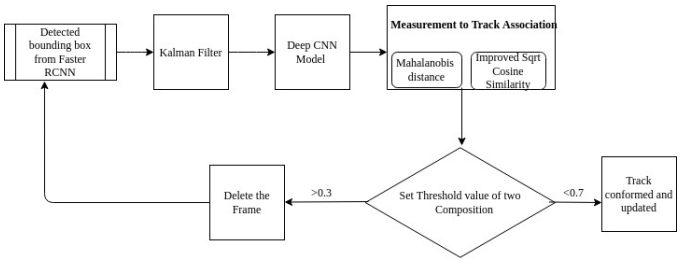

Fig. 7. Modified Deep Sort.

is h and the respective velocity coordinator are (a,b,c,d). The entire count of each track frame since the last successful measurement association of Tn is given by n for each track. The Kalman channel predictions occurred, the counter is incremented, or when the track has been assigned with the previous list, the counter is reset to 0. Suppose a new track prediction is started for each detection that cannot be assigned to any of the current lists. The first three frames of the new track are classified as tentative. These frames are kept for further processing when the association measurement is found at every timestamp, otherwise deleted.

1) Association of the Current Frame and Predicted Frame: The Hungarian algorithm solves the measurement to track the association between the predicted Kalman state and the next frame. By creating two relevant measures, we were able to combine motion and appearance data. We utilized Mahalanobis Distance between the predicted frame and the next frame to get motion information.

$$d^{(1)}(p,q) = (d_p - y_p)^T S_i^{-1}(d_q - y_p) \tag{5}$$

Equation 5 denotes the projection of the pth track distribution into measurement space (yp, Sp), and the detection of the qth bounding box by dq. The Mahalanobis Distance removes the state estimation uncertainty between the protected and newly arrived state mean track location. Further, it is possible to provide false Association by the threshold value at 95% confidence interval computed from the inverse distribution we denote

$$b^{(1)}_{(p,q)} = 1[d^{(1)}(p,q) \leq t^{(1)}] \tag{6}$$

Mahalanobis Distance is suitable only when motion uncertainty is less for the association metric. Our image space Kalman filtering framework provides the approximate value of the predicted object location. The Mahalanobis Distance is an uninformed metric for tracking in occlusion when the rapid displacement of the image plane. Therefore we integrated the second metric for tracking each bounding box. With the help of a protected CNN to extract the appearance feature of the bounding boxes, the architecture of the appearance feature network is shown in Fig. 8. To detect the space of the pth and qth track proposes most of the authors used cosine similarity. The cosine similarity is derived from the Euclidean distance. However, the Euclidean distance is not good for dealing with the probability-based approach. Zhu *et al.* [29] proposed the Sqrt cosine similarity. It is

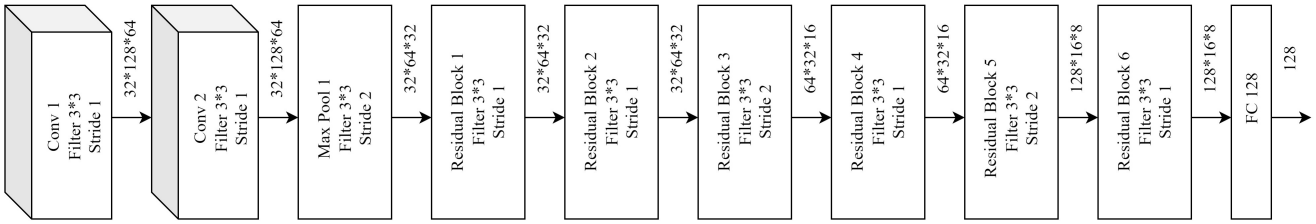

Fig. 8. Architecture of Appearance Feature Extractor Network.

derived from Hillinger distance, but there is conflict to define the similarity measures in some cases. Hence we adopted improved sqrt cosine similarity [30] to find the pth and qth track detection in appearance space.

$$d^{(2)}(p,q) = \frac{\sum_{i=1}^{T} \sqrt{p_i q_i}}{\sqrt{\sum_{i=1}^{T} p_i} \sqrt{\sum_{i=1}^{T} q_i}} \tag{7}$$

The binary variable is used to indicate if the association is good according to this metric.

$$b_{(p,q)}^{(2)} = 1[d^{(2)(p,q)} \leq t^{(2)}] \tag{8}$$

By addressing different aspects of the association method in a combination of both matrices. Mahalanobis Distance gives the information of the object position based on the motion for short-term prediction. The improved sqrt cosine distance is used to recover identities after long-term occlusion. Based on the Association problem, we combine what the metric is using a weighted sum.

$$C_{(p,q)} = \lambda d^{(1)}(p,q) + (1-\lambda) d^{(2)}(p,q) \tag{9}$$

Where we call the association appearance if it is within the range of both metrics.

$$b(p,q) = \prod_{i=1}^{2} b_{(p,q)}^{(i)} \tag{10}$$

In the equation 10, value is 1 it indicates both the metrics are equal, if zero metrics are not equal. It also indicates (p,q) is a true match between appearance and spatial Information. video sequence the next new frame detection is effectively associated with the present track OK then the track is continued as long as It is successfully associated and that track is confirmed and tracking update else deleted immediately.

IV. Evaluations and Results

The proposed system used a self-generated dataset to perform the multi-object detection and tracking. We use Google collaboratory for evaluation and python programming language and Detectron 2 for the experimental setup.

A. Dataset

To train the detection algorithm, we used a self-generated dataset containing 5000 pictures of people, jam, bread, spoons, coffee cups, and coffee makers. The dataset images are collected from different weather conditions, different viewpoints, different lighting of day and nights, blurring of images, crowded places and malls. Some images are collected from surveillance cameras and the internet. After collecting the images, we annotated images in different classes using the Labelimg tool. We classify images into 6 different classes: person, jam, bread, spoon, coffee cup, and coffee maker shown in Table I. The LabelImg tool after annotating it generates the XML files after we convert them into JSON format.

TABLE I. Proposed Dataset Classes

Classes	Number of Instances	Number of Images
Person	2100	1000
Bread	878	700
Jam	900	750
Spoon	1212	800
Coffee Maker	1278	900
Coffee Cup	1211	850

B. MOT Benchmark Dataset

We have evaluated our proposed system in the MOT benchmark dataset [35]. This dataset contains a combination of 21 different datasets. The dataset has contained 645 second video and it is the combination of 21 different sequences with proper annotation.

C. Results

The proposed system has two stages: stage 1, Multi-object detection and stage 2, Multi-object tracking. Multi-object detection purpose we compared different Deep learning based object detection methods based on the accuracy and loss. After evaluating, we discovered that ResNet-101 based Faster RCNN is giving better performance. The evaluating different detection algorithm results are shown in Fig. 9. In Fig. 9(a) shows the multiple object detection output. (b) Gives an accuracy comparison of the Faster RCNN, Mask RCNN and Retinanet detection methods. Compared to all Faster RCNN gives better accuracy. (c) Shows the False negative results of Faster RCNN, Mask RCNN and Retinanet detection methods. Mask RCNN gives less False negative but Faster RCNN also gives better Results. (d) Shows the regression time box loss of Retinanet and Faster RCNN, (e) Gives the class name loss and (f) Gives a comparison of the total loss of Retinanet and Faster RCNN. Faster RCNN gives less detection loss compared to Retinanet and Faster RCNN. Compared to different detection methods, Faster RCNN gives good Accuracy and less detection

TABLE II. EVALUATED TRACKING RESULTS OF MOT BEHCHMARK DATASET

		MOTA	MOTP	MT	ML	ID	FM	FP	FN	RunTime
Batch	KBNT [31]	68.2	79.4	41.00%	19.00%	933	1093	11479	45605	0.7Hz
	LMPp [2]	71	80.2	46.90%	21.90%	434	587	7880	44564	0.5Hz
	MCMOT HDM [32]	62.4	78.3	31.50%	24.20%	1394	1318	9855	57257	35Hz
	NOMTwSDP16 [33]	62.2	79.6	32.50%	31.10%	406	642	5119	63352	3Hz
Online	EAMITT [34]	52.5	78.8	19.00%	34.90%	910	1321	4407	81223	12Hz
	POI [31]	66.1	72.5	34.00%	20.80%	805	3093	5065	55914	10Hz
	SORT[27]	59.8	79.6	25.40%	22.70%	1423	1835	8698	63245	60Hz
	DEEP SORT[28]	61.4	79.1	32.80%	18.20%	781	2008	12853	56668	40Hz
	Proposed System	71.2	80.1	33.40%	17.90%	825	1225	4115	54724	41Hz

loss. Hence we used Faster RCNN for detection purposes. It has variable performance on different classes of Self-Generated Dataset.

We proposed a Multi-object tracking method based

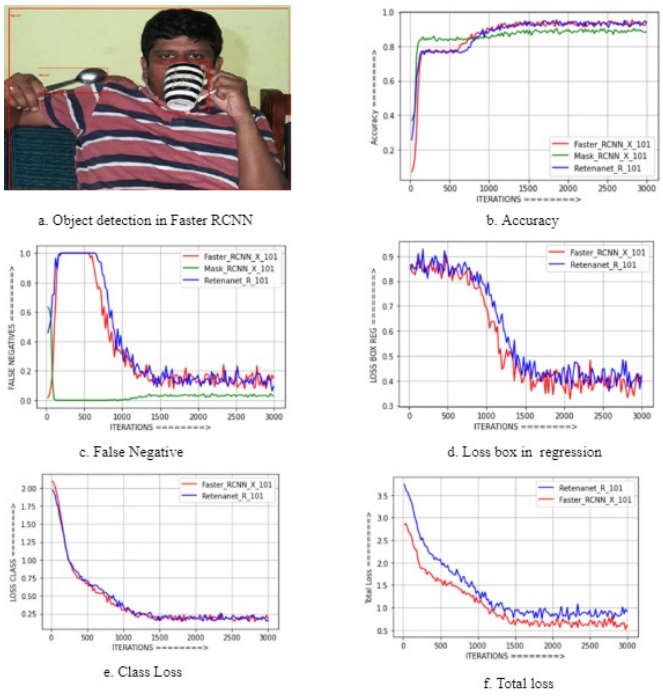

Fig. 9. Object Detection Output and Comparision Graphs of Different Deep Learning Detection Methods.

on the appearance and motion features. Firstly we trained the dataset using the Faster RCNN and then we run modified deep sort on the same evaluation dataset. Fig. 10 shows the tracking of the different frames with identity numbers.

In Table II shows the results of our proposed system's assessment on the MOT dataset. We used an object detection threshold of 0.8and further fine-tuned it with the different parameters to produce an efficient model. The following parameters are used for evaluation.

Multi-Object Tracking Accuracy (MOTA) - Summarizes the tracking accuracy terms of identity switches, false negative and false positive.

Fig. 10. Tracking with Unique Identity Number.

Multi-Object Tracking Precision (MOTP) - Provides the tracking precision for bounding boxes average dissimilarity between ground-truth value and predicted location.

Mostly Tracked (MT) - The percentage of ground-truth tracks has had the same label for at least 80% of their life span.

Mostly Lost (ML) - The proportion of ground-truth tracks that are tracked for at minimum 20% of their lifespan.

Identity Switches (ID) - It gives the number of times identity number changes the ground truth track.

Fragmentation (FM)- Identifies the number of times tracks have been interrupted due to missed detection.

Table II shows the results of our proposed work. It increases accuracy from 61.4 to 71.2 and also reduces the fragmentation problem. At the same time, identity switches increase slightly due to occlusion. We have seen a significant increase in the mostly tracked object. Hence our proposed model is suitable for online tracking.

Existing techniques were not efficient in reducing identity switching, fragmentation, and accuracy. However, using the modified deep sort technique it is possible to reduce identity switching and fragmentation reasonably better. Proposed research work contribute in reducing false identification due to

the presence of frequent identity switching and fragmentation. It helps to track the multi objects in real time environment with better accuracy.

V. Conclusion

In this paper, we presented an improved multi-object detection and tracking technique that will reduce identity switches and fragmentation in the presence of occlusions. The proposed technique employed the Faster RCNN method to detect multiple objects and to overcome occlusion challenges. We also presented a modified deep sorting technique for multi-object tracking to reduce identity switch and fragmentation issues. The technique is simulated on a series of experiments using real and synthetic datasets has yielded better accuracy, reduced identity switching, and fragmentation compared to existing techniques. The specified objectives are achieved in this work. Improvement of performance in dark environmental conditions is yet to be investigated.

OBEInsights: Visual Analytics Design for Predictive OBE Knowledge Generation

Leona Donna Lumius, Mohammad Fadhli Asli*
Faculty of Computing and Informatics
Universiti Malaysia Sabah, Malaysia

***Abstract*—Gaining traction in modern higher education, outcome-based education (OBE) focuses on strategizing pedagogical approaches to help the student achieve specified learning outcomes. In the context of Malaysia, OBE is oriented towards holistic development of graduates to ensure readiness towards the working sector. To empower OBE implementation, standardized measuring instrument iCGPA was introduced to higher education institutions nationwide. With lower dependency on provided curriculum, graduate abilities and values development are also attainable via extracurricular activities. However, analyzing the curriculum results in hand with extracurricular activities can be a daunting task, albeit the potential enriched performance assessment. In addition, the current iCGPA instrument employs radar map that restricts data exploration despite its capability in visualizing multivariate information. This study aims to enable predictive knowledge generation on understanding the relationship between learning activities and performance in OBE. Therefore, a predictive visual analytics system namely OBEInsights is proposed to facilitate education analysts in assessing OBE. The system development started with the identification of crucial design and analytic requirements via a domain expert case study. The system is then built with deliberate considerations of guiding factors of a design framework conceptualized from the case study. Subsequently, the system was then evaluated in usability testing with 10 domain experts that consist of usability rating and expert validation. The evaluation and expert validation results demonstrated the effectiveness and usability of OBEInsights in facilitating OBE predictive assessment. Several design insights on constructing visual analytics for OBE assessment were also discovered in terms of effective visualization, predictive modeling, and knowledge generation. Analytic designers and builders can leverage the reported design insights to enhance knowledge generation tools for OBE assessment.**

Keywords*—Visual analytics; visualization; learning analytics; outcome-based education (OBE)

I. Introduction

Outcome-based education (OBE) has become a prominent higher education strategy and pedagogical approach around the globe. OBE focuses on organizing teaching and assessment that help students achieve specified outcomes or goals [1]. Many countries have adopted the OBE approach in their higher education structures and initiatives along with additional unique goals. In Malaysia, OBE in higher education is oriented towards the development of holistic graduates and readiness towards the working sector. To achieve this goal, an initiative and instrument namely Integrated Cumulative Grade Point (iCGPA) were introduced to Malaysian higher education institutions [2]. iCGPA helps the institutions in determining the graduate's achievement based on the program learning outcomes (PLO) set by the faculty.

The instrument also eases the recording of graduates' ability and values attainment throughout the study program duration. The recorded data is then visualized in the form of a radar map, indicating the graduate's improvement in terms of abilities and acquisition of values. However, graduate abilities and values attainments are also attainable via extracurricular activities with less dependency to the provided curriculum. Analyzing the curriculum results with extracurricular activities could provide enriched understandings towards assessing the student performance.

Despite these potentials, merging curriculum results with extracurricular activities in an analysis can cause information overload. In addition, the current radar map representation of iCGPA restricts data exploration despite its capability in visualizing multivariate information. Visual analytics is a data exploration method supported by interactive visualization [3], allowing the analyst to pursue new inquiry throughout the exploration [4]. The main motivation of this study is to facilitate education analysts in performing predictive analysis on OBE learning activities and performance. Prior studies on educational visual analytics were observed to primarily focus on visualization tool creation and system features [5], [6]. Furthermore, this study found limited visualization work that discusses OBE-specific domain users, analysis tasks, and visualization design.

This paper reports our empirical investigation on the visualization design for supporting OBE knowledge generation with regard to design requirements, development, and evaluation. To address the gap, this study proposes a predictive visual analytic namely OBEInsights that enables education analysts and practitioners to perform predictive OBE assessment. This study firstly explores the design requirements and analytic practices by interviewing 5 domain experts in a domain characterization case study. A design framework is conceptualized based on the identified requirements and analysis tasks from the case study. Next, the visual analytic OBEInsights was designed and developed with design consideration guidance of the framework. Subsequently, this study evaluated and demonstrated the effectiveness of OBEInsights in usability testing with 10 domain experts. The major contributions of this paper are as follows:

1) A novel visual analytics design framework for supporting OBE knowledge generation.
2) A visualization system namely OBEInsights for facilitating OBE predictive learning analysis.
3) Empirical evaluation report to demonstrate the effectiveness of OBEInsights in supporting knowledge generation.

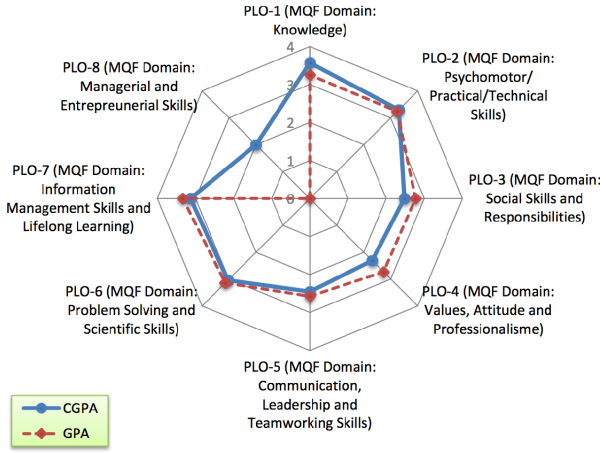

Fig. 1. iCGPA's Radar Map of Student's Achievement based on Specified LOD.

The remaining content of this paper is organized as follows. Section 2 introduces the fundamentals of OBE predictive analysis and visual analytics. Next, Section 3 describes the methodology in deriving the design framework, visualization system development, and design evaluation. Section 4 then presents and discusses the results of empirical design evaluation in a user case study. Finally, the conclusions and future work are presented in Section 5.

II. Background

This section introduces the background of this study by summarizing the underlying principles and fundamentals of outcome-based education (OBE), predictive analytics, and visual learning analytics. The adoption of OBE in modern higher education calls for efforts in developing new analytics to support OBE-oriented analysis.

A. Outcome-Based Education and Predictive Analytics

Outcome-based education (OBE) is an educational approach or pedagogical perspective that emphasizes curriculum choices based on student performance [7]. Apart from the core approach, OBE implementations in many countries can be different with additional goals or structures. OBE implementation in Malaysia's higher education is oriented towards producing graduates equipped with relevant expertise, morals, and social skills.

Malaysia practices top-down approach for organizational management and decision-making process [8], [9]. To standardize OBE in Malaysian higher education institutions, the Malaysian Qualifications Agency (MQA) has set 8 specific Learning Outcome Domains (LOD). In 2015, the Malaysian Ministry of Higher Education introduces the Integrated Cumulative Grade Point Average (iCGPA), an evaluation instrument for Malaysian OBE [2]. iCGPA records and reports on the students' holistic attainment throughout the study duration as per specifications of LOD set by the MQA. Currently, iCGPA report of students' holistic achievement throughout each semester is visualized as a radar map as shown in Fig. 1.

Education analysts can analyze the OBE datasets like iCGPA by using predictive modeling to identify future patterns and trends [10]. Parameters like the students' knowledge levels, performance, scores, or marks are commonly analyzed and assessed in higher education [11]. Predictive models are applied against the dataset to automatically learn and generate predictions based on recorded historical data. However, there are limited advances in OBE evaluation platforms and tools, particularly in integrating student learning performance with extracurricular activities. In addition, there is limited work that clearly describes the OBE analytic practices and users specifically in Malaysia.

B. Visual Learning Analytics

Visual analytics combines the prowess of automated analysis with interactive visualization, allowing the user to gain efficient understanding, reasoning, and decision-making on large and complex datasets [12]. Applied into the education domain, visual learning analytics is defined as the use of computational tools and methods for understanding educational phenomena via interactive visualization [6]. Educators leverage visual analytics to understand or measure students' progress for diagnostic pedagogical decision-making in real-time [13].

Literature indicates many advances of visual analytics approaches in the educational context especially in enhancing learning analytics and decision-support tools [6]. In addition, prior work also explores the educational analytic practices via design study to characterize analysis scenarios, target users, and viable visualization. Several design studies have investigated visualization design for different focus like online classroom [14], [15] and massive open online courses (MOOC) [16], [17], [18]. Prior work also reported that the visual form of graphs, maps, and dashboards have greater potential to generate effective visualization especially for performance assessment [19].

Despite many advances in visual learning analytics, there are limited discussions for facilitating knowledge generation of specific learning pedagogy like OBE. Therefore, this study was carried out to investigate and offer insights in constructing predictive visual analytics for OBE assessment. This study then designed and developed OBEInsights, a visual analytics system for supporting OBE assessment as described in the following section.

III. Visual Analytics System: OBEInsights

This section presents OBEInsights, a visual analytics system to support education analysts in performing OBE predictive analysis. Detailed descriptions of requirement analysis leading towards the conceptualization of its design framework are also presented. Furthermore, the specifications and features of OBEInsights including data sources, automated data analysis, and visualization are explained.

A. Domain Characterization and Design Framework

To identify the visualization design requirements for facilitating OBE analysis, this study adopted part of the design study methodology [20], specifically the problem characterization. Related to requirements analysis in software engineering [21], problem characterization serves as a discovery stage in understanding domain-specific analysis tasks. Understanding the domain analysis helps the designer to translate and fit it

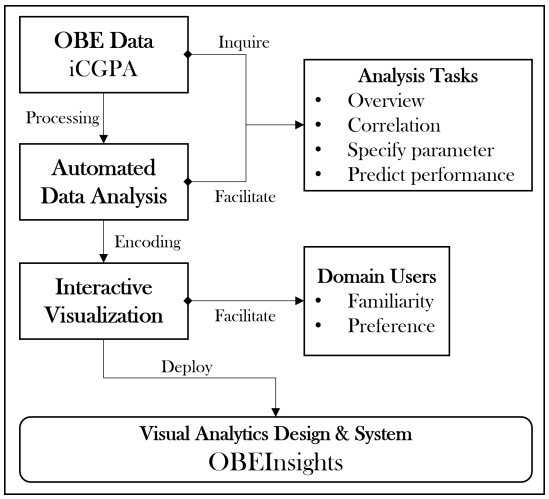

Fig. 2. Visual Analytics Design Framework for Supporting OBE Predictive Analysis.

TABLE I. BACKGROUND OF DOMAIN EXPERTS

Expert	Qualification	Teach Experience	Expertise Area
Exp1	PhD	30 years	Natural Science
Exp2	PhD	20 years	Tourism, Entrepreneurship
Exp3	PhD	30 years	Higher Education
Exp4	PhD	35 years	Engineering
Exp5	PhD	20 years	Accounting

into generic visualization language and create actionable visual metaphors. 5 domain experts from the higher education field with different expertise but have considerable proficiency and experience in OBE were interviewed as described in Table I. A semi-structured interview was carried out with the aim to learn and discover OBE-specific analysis tasks and nature from the experts. The interview helps the study to understand these major requirements: domain analytic practices, domain user's visualization knowledge, and domain user's analysis interests.

Based on the identified requirements, a visual analytics design framework was conceptualized for facilitating OBE predictive assessment as shown in Fig. 2. The purpose of this framework is to guide visualization designers in translating domain analysis tasks and considering appropriate visualization to facilitate OBE analysis. Referring to the visual analytics model [22], this study mapped the visual analytics components for the context of predictive OBE assessment. The interview results reveal interesting insights on OBE analytic practices in Malaysia, specifically in pedagogical decision-making and analysis interests. The experts explained the major factors that need to be considered in determining the faculty's program learning outcomes: curriculum revisit, external feedback, and standard compliance. Based on the interview, 3 major analysis tasks in OBE predictive analysis were identified:

1) Overview on student curriculum results and activities.
2) Correlation between student performance and extracurricular activities.
3) Prediction on student progression and achievement based on activities.

In terms of domain users, the experts stated that most education analysts and practitioners possess limited knowledge and familiarity with visualization. Therefore, the factors of familiarity and preference need to be considered in generating appropriate visualization. The presented framework is a refined iteration of prior work [23], added with additional focus on design development. Driven by the identified requirements and factors, a visual analytics system was designed and developed for facilitating OBE predictive analysis. The following subsection presents detailed descriptions of the visual analytics system including specifications and development process.

TABLE II. INTEGRATED RELEVANT ATTRIBUTES IN ICGPA DATASET

Attribute	Remarks
`student_id`	Identifier for student information
`sem`	Identifier for semester sessions
`igpa`	Grade point average
`icgpa`	Cumulative grade point average
`po_value`	Program learning outcomes (PLO)
`po_this_sem_course`	PLO per semester
`po_igpa`	Student PLO achievement per semester
`po_courses`	No. of courses contribute to PLO
`po_grade_pointer`	Grade point obtained per PLO
`po_achievement`	Achievement distribution

B. Visual Analytics Design and Development

Guided by the conceptualized framework, this study designed and built OBEInsights, a predictive visual analytic system for supporting OBE assessment. The system was built with specifications and considerations as follows.

Data Sources: In this study, two different OBE datasets generated by iCGPA consisting of the 'Accounting' program of our institution that contains students' PLO information were used. These datasets were selected after thorough consideration of easier access and its uniformity with many OBE datasets. The dataset consists of students' PLO results and extracurricular activities in each semester. The datasets were prepared for automated analysis by integrating key relevant attributes as shown in Table II.

Automated Data Analysis: Based on identified analysis requirements, this study designed the automated data analysis particularly for facilitating student achievement prediction. Literature recommends the following algorithms for modeling prediction due to model flexibility and customizable parameters: random forest, gradient boosting, neural network, and support vector machines [24], [25]. An experiment was conducted upon these algorithms in terms of lower and upper intervals to determine the most precise predictive modeling for OBE assessment. Before the experiment, the variable correlation within the dataset was firstly identified by using best subset classification. The classification result shows that `igpa`, `icpga`, `po_igpa`, `po_value`, and `sem` to be the impacting variables on the prediction modeling. Furthermore, the classification result indicates linear dependency towards `po_grade_pointer` that could lead to poor accuracy measures. Next, the prediction accuracy of the trained models was measured in an experiment with additional validation by using misclassification error. The results of the prediction models' performance are shown in Table III.

The experiment result shows that the random forest algorithm to be the best model for predicting student achievement.

TABLE III. LOWER AND UPPER INTERVALS OF PREDICTION ACCURACY

Algorithms	Accuracy (Low)	Accuracy (High)
Random Forest	91.0%	94.9%
Gradient Boosting	88.2%	93.0%
Neural Network	45.2%	53.2%
Support Vector Machines	46.4%	54.4%

This study infers that the lower performance by neural network and support vector machine is due to sharpened model flexibility that overfits prediction. Moreover, random forest and gradient boosting use sequential model training, simulating and refining decision tree based on prior accuracy. Therefore, the random forest prediction technique was incorporated into our automated data analysis design for OBE prediction assessment.

Interactive Visualization: With the constructed automated data analysis component, this study needs to assess the appropriate visualizations and interfaces to display it. Upon deliberate consideration of the critical factors of user familiarity and preference, simple visual metaphors and layouts are selected. The visual analytics is then deployed in a form of simple dashboard front-end integrated with predictive modeling back-end. The front-end was developed using HTML, CSS, and Javascript, while the back-end was developed using Phyton. OBEInsights incorporates the existing radar map iCGPA to ensure continuous familiarity towards further OBE prediction analysis. The interfaces of OBEInsights are as shown in Fig. 3.

The user can select students to observe from the student list on the left sidebar, and the main window updates the visualization as per students' information. The main window can be scrolled down to show more analysis items like student activities in Fig. 4 and the prediction panel in Fig. 5. The user can access 'Predict & Analyze' tab to open the prediction assessment panel for specific program outcomes (PO). User can customize the parameters like student achievements or extracurricular activities, and the predictive model generates results. The prediction result for the selected PO then can be interpreted based on achievement distribution categories.

IV. DESIGN EVALUATION WITH DOMAIN EXPERTS

This section presents and discusses the design evaluation of our OBEInsights visual analytics system. This study demonstrates and evaluates the effectiveness of OBEInsights

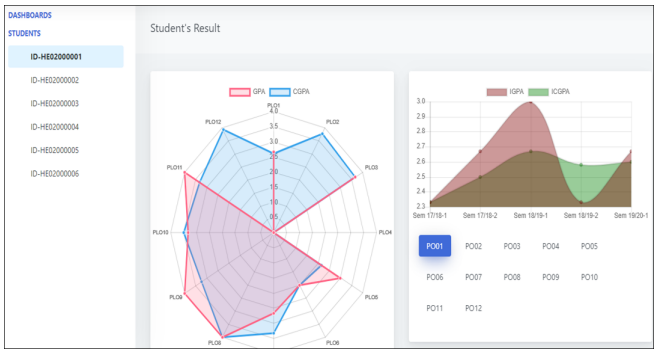

Fig. 3. Overview Layout of OBEInsights.

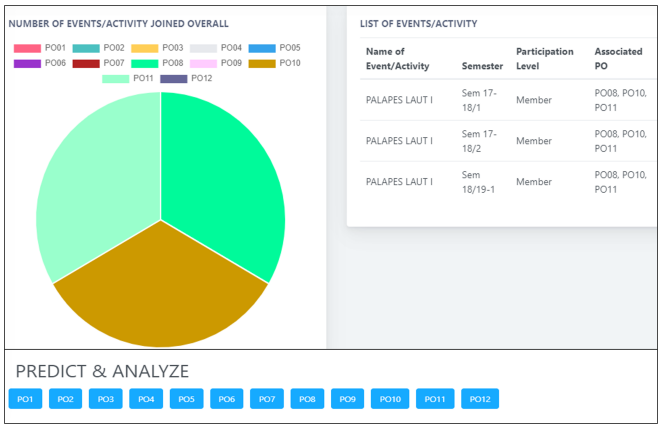

Fig. 4. Student Activities and Achievements from Extracurricular Activities.

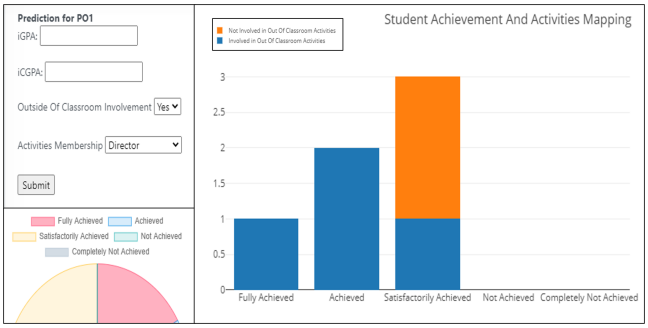

Fig. 5. Prediction Assessment Panel for Student Achievement and Activities.

in visualization system usability testing with domain experts. Subsequently, this section discusses the significant findings from usability testing in terms of effective visualization, modeling, and knowledge generation.

A. Case Study with Domain Experts

To evaluate and demonstrate the effectiveness of the system, this study conducted a usability testing with the domain experts. This test specifically measures OBEInsights' usability effectiveness in visualizing OBE predictive assessment. 10 domain experts from the higher education field with great proficiency and expertise in OBE participated in the test. The test was performed in an observation session with each expert for approximately 1 hour. The session starts with a brief introduction of the features of OBEInsights with an allocated 15 minutes for the experts to use the system.

After the introduction, the test began with inquiring the experts to perform several OBE analyses tasks as followings.

1) Display the overall performance of a student.

TABLE IV. SUS SCORE INTERPRETATION

SUS	Grade	Adjective
>80.3	A	Excellent
68 - 80.3	B	Good
68	C	Okay
51 - 68	D	Poor
<51	F	Awful

TABLE V. USABILITY SCALE RATING OF OBEINSIGHTS

Usability Scale	P1	P2	P3	P4	P5	P6	P7	P8	P9	P10
I will use this system frequently.	5	3	5	4	3	5	3	4	4	5
The system is unnecessarily complex.	2	2	1	2	2	3	1	1	1	2
The system is easy to use.	4	4	5	4	4	4	4	3	4	4
I will need technical support to use this system.	2	2	1	2	2	3	2	2	2	1
The system functions are well integrated.	4	3	4	4	4	3	4	3	4	3
The system has too many inconsistencies.	3	3	2	3	3	2	2	2	3	1
I can learn to use the system quickly.	4	4	5	4	3	4	4	5	3	4
The system is cumbersome to use.	2	1	1	2	2	1	2	1	3	2
I feel confident in using the system.	4	4	4	4	4	4	4	4	3	4
I need to learn many things to use the system.	2	2	1	2	5	3	4	2	1	1
Total Scale (x/50)	32	29	29	31	32	32	30	27	28	27
SUS Score (%)	**75**	**70**	**75**	**72.5**	**70**	**75**	**70**	**77.5**	**70**	**82.5**

TABLE VI. VISUALIZATION SCALE RATING OF OBEINSIGHTS

Visualization Scale	P1	P2	P3	P4	P5	P6	P7	P8	P9	P10
Featured visualizations offers different perspectives.	4	4	5	5	5	5	4	4	4	4

Visualizations displays OBE performance data effectively.	5	4	4	5	5	4	4	3	5	4
Featured visualizations allows me to discover new patterns.	4	4	5	4	5	3	4	5	4	5
Visualizations enables me to explore and discover insights.	4	5	4	3	5	4	4	5	3	5
Total Scale (x/25)	21	20	22	21	24	21	20	21	21	21
SUS Score (%)	**84**	**80**	**88**	**84**	**96**	**84**	**80**	**84**	**84**	**84**

2) Find the relationship between the student's PLO achievement and extracurricular activities.
3) Review a student's iCGPA progression for specific PLO over the study duration
4) Predict a student's future performance for specific PLO with customized parameters for extracurricular activities, position, iGPA and iCGPA.

The purpose of inquiring about these tasks is to allow the users to practically utilize the featured interactive visualization to perform major OBE analysis. Furthermore, the effectiveness and limitation of OBEInsights in facilitating the analysis from the direct perspective of the domain user can be observed. Upon completing the tasks, the experts were then asked to answer two sets of questionnaires that were designed based on the system usability scale (SUS) [26]. The resulting scores can be interpreted based on rating as shown in Table IV. The questionnaires inquire the experts' perception towards the usability and visualization of OBEInsights by scale rating. The results of the usability testing are shown in Table V and Table VI.

B. Discussion

Based on the presented results, this study further discusses and reflects on the significant findings from the conducted design evaluation. This study found several visualization design insights that can be explored in three spectrums: visualization, predictive modeling, and knowledge generation as discussed as follows.

1) Effective Visualization Design for Student's Holistic Development: Referring to earlier domain characterization, this study identified three major analyses in OBE assessment: (1) Overview of student results and activities, (2) Student's PLO results over the semesters, and (3) Relativity of student extracurricular activities with performance. The domain characterization helps specify the analysis interests and practices from OBE analyst and practitioners to identify crucial design requirements. The factors of visualization familiarity and preferences plays a role in enhancing the learnability of the system [27]. The evaluation result in Table V and Table VI indicates that the featured interaction and visualization encodings applied into OBEInsights are effective in facilitating OBE predictive analysis. With average SUS score of 84.8%, the experts' rating demonstrates and validates the effectiveness of the design in visualizing OBE predictive assessment. The inclusion of visualization literacy into the design consideration greatly affects the perceived effectiveness of presented visualization to the users [28]. Despite the positive results, the implemented design only employs basic visualization that can be limited when visualizing advanced or complex analysis scenario. This study are interested to explore the implementation of advanced visualization into OBEInsights to facilitate complex OBE analysis. Furthermore, we intend to reiterate and refine the current design especially on main interfaces and deployment by incorporating user experience design.

2) Modeling Accuracy on Predicting Student's Performance: Based on the earlier accuracy experiment, we learn that the 'Random Forest' algorithm yields the highest accuracy rate on low-prediction (91%) and high-prediction (94%) for OBE prediction assessment. The prediction results were also validated with misclassification errors. Our findings correlate with other studies that also found 'Random Forest' and 'Gradient Boosting' to produce accurate prediction results. However, the predictive algorithms that were investigated in this study were typical in handling structured datasets. Future research can investigate further on predictive machine learning algorithms with regards to flexibility in handling unstructured datasets. Despite the positive accuracy result, our study has not included human-user confidence in its design consideration and evaluation. Further investigation on human-user confidence towards the automated OBE analysis output helps curate the

prediction reliability. In addition, the datasets used in this study only pertain information limited to one study program and limited extracurricular activity variables. Analyzing many different OBE datasets from other institutions using the visual analytics system may yield different results or reveal interesting insights.

3) Framework Supports on Knowledge Generation: OBEInsights was built based on deliberate guided consideration towards many factors in the conceptualized design framework in Fig. 1. Inspired by the visualization mantra "Overview, zoom and filter, then details-on-demand" [29], the framework was designed to support analysis tasks in each step in the top-down decision-making process [30]. Starting from raw data, the domain user first overviews the entire OBE information from the dataset with no specific analysis subject. Next, the user specifies their analysis by selecting subjects and parameters for the automated data analysis to process. The automated analysis design needs to facilitate the user's potential OBE analysis interest throughout their data exploration. Finally, the generated output needs to be encoded into appropriate visualization and interaction features to be displayed to the user. Currently, OBEInsights facilitate knowledge generation in a linear way, having the user select or customize specific analysis subjects and parameters. We intend to reiterate the design framework to support multifaceted analysis that allows for the inclusion of multiple subjects and parameters. Enabling multifaceted analysis could enrich the knowledge generation on pedagogical consideration for attaining learning outcomes. The presented design framework and system only cover the OBE assessment scenario that involves standardized parameters and specific stylized pedagogical decision-making in Malaysia. Other researchers can pursue further investigation on designing visual analytics for many different OBE analyses with regards to unique geographical contexts or variants.

V. Conclusion and Future Work

This paper has presented the empirical investigation in designing visual analytics for supporting OBE predictive assessment on learning activities and performance. The findings from this study offer insight into visual analytics design development for OBE analysis particularly in automated prediction and interactive visualization. This paper also presented the predictive visual analytics system namely OBEInsights along with elaborate descriptions of its design conceptualization and development. The effectiveness of OBEInsights is demonstrated and validated via a design evaluation study with domain experts. Design evaluation results indicate the system's effectiveness in facilitating OBE predictive assessment with great usability rating. Moreover, this study also learns the impact of crucial factors like visualization familiarity and preference towards the system usability. For constructing automated analysis components, several recommended algorithms were experimented with to determine the best predictive modeling for OBE assessment. The experiment result reveals the Random Forest model as the highest performing technique for OBE predictive modeling. In terms of supporting knowledge generation, a visual analytics design framework was conceptualized to guide visualization development for OBE assessment. The design evaluation results also demonstrated the framework capability via the deployed OBEInsights in supporting major OBE analysis tasks. The scope of this study is limited to OBE predictive assessment with specific parameters and pedagogical decision-making. This study recommends further investigation on visualizing many advanced OBE analysis that handles different context, variables, or users. Future research can also explore the potential of incorporating human-confidence design and unstructured handling capabilities. In our future works, we intend to reiterate the design and explore its performance against many different datasets that possess different structures and complexity. Furthermore, this study intends to enable multifaceted analyses to augment the knowledge generation process for OBE predictive assessment.

Modelling and Simulating Exit Selection during Assisted Hospital Evacuation Process using Fuzzy Logic and Unity3D

Intiaz Mohammad Abir, Ali Ahmed Ali Moustafa Allam, Azhar Mohd Ibrahim*
Department of Mechatronics Engineering
International Islamic University Malaysia
Kuala Lumpur, Malaysia

***Abstract*—Evacuation procedures are an integral aspect of the emergency response strategy of a hospital. Evacuation simulation models help to properly evaluate and improve evacuation strategies. However, the issue of exit selection during evacuation is often overlooked and oversimplified in the evacuation simulation models. Moreover, most of the available evacuation simulation models lack integration of movement devices and assisted evacuation features. However, finding a solution of these limitations is a necessity to properly evaluate evacuation strategies. To tackle this problem, we propose an effective approach to model exit selection using a fuzzy logic controller (FLC) and simulate assisted hospital evacuation using Unity3D game engine. Our research demonstrates that selecting exits based on distance only is not sufficient for real life situation because it ignores the unpredictability of human behavior. On the contrary, the use of the proposed FLC for exit selection makes the simulation more realistic by addressing the uncertainty and randomness in an evacuee's decision-making process. This research can play a vital role in future developments of evacuation simulation models.**

Keywords*—*Evacuation simulation; exit selection; fuzzy logic; unity3D

I. Introduction

Hospitals are generally called a safe building and an emergency care centre for individuals. Planning for disasters is essential to reduce the number of disaster-related deaths and injuries. However, Planning a well-timed evacuation of complex buildings such as hospitals is difficult. Hospitals have many patients with fractures or injuries. Majority of them face evacuation difficulties as they must use wheelchairs or crutches and can't move normally.

It can be asserted that the behavioural reaction of the evacuees throughout the movement plays a vital role in the evacuation process. The modelling of the movement of the evacuees which is correlated with behavioural reaction has been given importance while designing evacuation models. For safe evacuation, the importance of designing evacuation models to predict the evacuation process is paramount [1] Some of these models are; SGEM [2], [3], [4], SIMULEX [5], [6] EXODUS[7] , EGRESS [8], [9]. Behavioural reaction plays a major impact in the evacuation process and choosing an exit is a comparatively complex factor while evacuating. The term exit not only refers to the final exit which leads outside the structure but also internal exits which lead the evacuees from one confined area to another. As there are several exit options available in a multi-exit structure, the evacuees face a major dilemma while choosing the right exit. In a situation where evacuation is necessary, everything occurring in the environment works as stimuli and shapes the reaction of the evacuees (e.g., the activity of other evacuees [1]).

Today's evacuation simulation software allows designers to easily evaluate evacuation performance for various conditions and designs of the building's internal structure. Over the years, a vast number of models have been developed for general building evacuation simulation. However, it could be impossible or inappropriate to use most of these models for simulating hospital evacuation as it is necessary for hospital environments to include movement devices (e.g., wheelchair and crutches) and assisted evacuation features (i.e., the ability to assist wheelchair users to evacuate). Moreover, proper modelling of exit selection is needed to make the simulation process smoother. Hence, we propose an effective approach to select a proper exit for each evacuee agent (doctors, nurses, patients, or visitors) using a fuzzy logic controller (FLC) and develop an assisted hospital evacuation simulation model using Unity3D game engine.This model can be used by the hospital authorities to calculate the total evacuation time of the evacuees. In this way, the efficiency of evacuation measures will also be quantified which will lead to a safer evacuation planning and designing.

The rest of the paper proceeds as follows: Section II explores previous research related to our work. Section III explains the methodology and implementation of this research. Section IV analyses and discusses the results. Finally, Section V provides the conclusion of the research.

II. Related Work

There are many evacuation models that can simulate the evacuation process of a general building. However, most of these models lack proper integration of movement devices and assisted evacuation features as these models were developed to simulate ambulant evacuees. Some of the current evacuation models which are not explicitly designed to simulate assisted evacuation but are sufficiently flexible to accomplish this purpose indirectly. Disabled people were included in certain models by reducing their speeds. For example, FDS+Evac [10] model simulates the evacuation of elderly agents at a lower speed than normal agents. The assisted evacuation of hospitals and wheelchairs was only investigated by a small range of studies. For example, Hunt et al. [11], Alonso et al. [12],

Ursetta et al. [13], and Rahouti et al. [14] simulated assisted evacuation procedures in a hospital environment. However, these models lack proper modelling of exit selection.

It is important to take exit selection on a serious note as the behavior of an individual has considerable impact in the evacuation process and also has the potential to cause another emergency [15]. Complications arise when there is an imbalance in the evacuee crowd. If the structure has uneven design of exits it will result in an imbalance in the number of evacuees in the exits [16]. Researchers demonstrated that some components have direct impact on the evacuees' decision making such as, exit distance, the decision of following other individuals, the exit being in the range of vision, availability of light in the surrounding, crowd distribution, human psychology, width of the doors, the capacity of a particular exit , obstacle position, the queue length in the exits, familiarity with the structure, density of the crowd in particular exits, exit familiarity, angle made by the exit in respect to current movement direction, movement direction of other evacuees and social influence [1], [17], [18], [19], [20], [21], [22], [23], [24] . A study by Lovreglio et al. [25] demonstrated that in certain circumstances evacuees crowd up to particular exits avoiding other available exits. Wang et al. [26] analyzed the behavior of evacuees during a panic situation by using a combination of automata and multi-agent based model and demonstrated that the selection of exit behavior varies based on the crowd around that exit. These findings were also validated by Xu et al. [27].

Many models have been developed by researchers in past decades in order to regulate exit selection during evacuation [28], [29], [30], [31], [32]. Dynamic background field [33], [34], bayesian game theory [35], simulated annealing (SA) and depth-first search (DFS) [36] are some of the proposed methods to solve this issue. The selection of exit is made by considering the reciprocity of the group of evacuees in a game theory based model proposed by Lo et al. [1] which can be considered as one of the most notable works done in this research field.

In recent years, researchers have adopted methods like fuzzy logic, least effort algorithm, game theory, random utility theory, modified multinomial logit model, reinforcement learning to model exit selection. For example, Yang et al. utilized fuzzy logic to model exit selection using two input parameters: Normalized distance and normalized density [37]. Liu et al. followed a similar approach like Yang et al. However, they combined the output of the fuzzy logic system with exit width and herding behavior to determine the target exit [38]. Wang et al. utilized game theory to model exit selection. He considered factors like distance, visual range and choice firmness [39]. Zhang et al. proposed a multi-exit selection model considering three factors: distance, density and exit width [40]. Fu et al. proposed Two multi-exit selection models based on the social force model to analyze the dynamic change in exit selection by considering the effect of the exit distance, exit width, crowd number and crowd distribution [41]. Xu et al. proposed deep reinforcement learning based exit selection model named MultiExit-DRL [42]. Cao et al. implemented exit selection model based on random utility theory [15]. Edrisi et al. proposed three different exit choice models which are: the shortest path exit choice, the multinomial logit model, and the modified multinomial logit model with revising decisions. Their research demonstrated that the modified multinomial logit model with revising decisions outperforms the other two models [43]. Ma et al. modified the social force model and proposed an integrated exit selection model where evacuees can observe nearby evacuees and choose the appropriate exit by calculating the shortest estimated evacuation time [44]. Fu et al. combined least effort algorithm with a cellular automaton model to model exit selection while considering the distance to exits and crowd density around exits [45].

The movement of the evacuees can be distributed in three levels and among them, exit choice belongs to the highest strategic level. Mostly it is presumed that the exit selection is done entirely based on shortest distance optimization [46], [47], [48]. However, considering only distance is not enough to properly model the exit selection problem as in real time situations evacuees consider other relevant factors as well. Moreover, from the above review we can conclude that most of the existing exit selection models considered environmental factors (e.g., exit width, crowd density) while ignoring psychological factors (e.g., exit familiarity). Previous works/experiments suggest that factors like familiarity [18], [24] and visibility [22], [23], [24] can play a vital role in exit selection as human behavior is unpredictable and does not depend on one single factor. Thus, a simpler method is necessary for helping the evacuee agents in quick decision making. This paper proposes a new approach which considers psychological factor (exit familiarity) and environmental factors (exit distance and exit visibility) of exit selection by using a Fuzzy Logic Controller (FLC). Hence, it will be able to address the unpredictability of human behavior to some extent. These three factors are taken from the available literature that were discussed previously. This method will be able to provide a more realistic evacuation simulation compared to other methods where exit selection is done solely based on distance or on random.

III. Methods

Evacuation simulation models are important for investigating various evacuation strategies suitable for different scenarios. Reviews of general evacuation simulation models indicate that these models were mainly developed for normal building environments where evacuees can usually move unaided. Only a few studies are available on assisted evacuation.

In this paper, we propose an assisted evacuation simulation model to simulate the evacuation process of a hospital where assistants transfer non-ambulant patients from a risky place to a safe place using hospital devices such as wheelchairs and other ambulant evacuees (e.g., Doctors, Nurses, patients, and visitors) evacuate on their own. The proposed model utilizes a FLC to regulate the exit selection behavior of the ambulant evacuees (e.g., Doctors, Nurses, patients, and visitors). This section describes the details of the proposed system design.

A. Software

The simulation was carried out using Unity3D which is a game development engine developed by Unity Technologies. This software is capable of building 3D, 2D, Virtual Reality games, simulations, and other interactions. Fuzzy logic

modelling was done using MATLAB and later implemented in Unity3D. Finally, 3DS Max, which is a professional 3D graphics computer tool designed to create 3D animations, models, and games was used to design the agents and the movement devices

B. Types of Agents

Occupants with different levels of dependence will be expected at health facilities. To better simulate the process of evacuation in this form of setting, it is important to introduce two types of agents: ambulant agents such as patients, employees or visitors who can move without help, and non-ambulant agents such as dependent and highly dependent patients. For the simulation, six types of agents were considered. These are: doctors, nurses, visitors, patients with crutches, dependent patients with wheelchairs, independent patients with wheelchairs. Fig. 1 illustrates the different agents.

C. Movement Devices

Explicit representation of movement devices is a necessary requirement to simulate the evacuation of health facilities. Two types of movement devices were considered for this simulation. These are wheelchairs and crutches. The wheelchairs can be operated in two ways. In the first case the patient is disabled but independent. Which means the patient can operate the wheelchair on its own. In the second case the patient is both disabled and dependent, so assistance is required from ambulant agents (e.g., staff, nurse) to move the wheelchair. On the other hand, crutch users can move on their own without requiring any assistance. The usage of movement devices is illustrated in Fig. 1.

D. Layout Design

In this paper, the simulated hospital area is a W x H hall with 40m x 60m dimension. The considered floor has twenty-one rooms for patients including beds, one room for nurses, cafe, one room for dentist, one room for X-ray, one room for general practitioner and reception. Fig. 2 shows the layout of the simulation area.

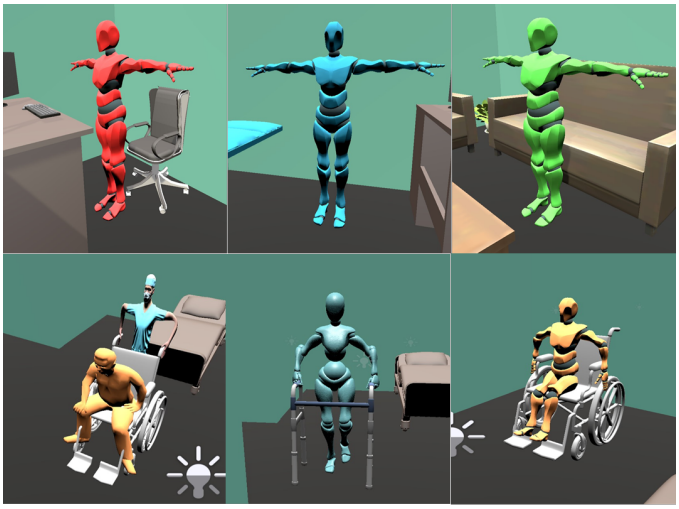

Fig. 1. Agents and Movement Devices used for Simulation. Doctors(red), Nurses(blue), Visitors(green), Patients with Crutches, Independent Patients with Wheelchair, Dependent Patients with Wheelchair.

E. Agent's Navigation System

For this research, we used Unity's built-in navigation system named NavMesh AI [49] which is divided into two main components. The first one is NavMesh (Navigation Mesh) area, which is used to define navigable areas in the environment. This component specifies areas where agents can walk, as well as the position of obstacles that the agent needs to avoid. This system is used for pathfinding and AI-controlled navigation. The second one is the NavMesh Agent component which is used to define an object as agent and also to set the agents' characteristics and features. This NavMesh AI helps agents to avoid each other, move around the environment towards a goal/target (e.g., exit). The agents can only move in the walkable surfaces while avoiding the obstacles and other agents. In Fig. 2 the blue area is the NavMesh area which is the agents' walkable surface. No agent can navigate in the remaining area. The walls and the furniture are obstacles for agents and the agents must avoid them while navigating.

F. Modelling Exit Selection

Most of the classical mapping or classification techniques, regardless of the number of classes or sets can be normalized down to two sets or classes namely 0 (false) and 1 (true). When an element belongs to a set, binary mapping evaluates it as 1 or true. If an element does not belong to a set, it is evaluated as 0 or false. Because of their objective nature traditional mapping methods only apply to exact correspondence. But in real life there are many relationships which are not so black and white. So, these relationships can't be described using the traditional binary mapping techniques. Fuzzy logic however can be utilized to solve this issue to some extent. It is a mathematical modelling method based on fuzzy sets and the related membership functions. In fuzzy logic "degrees of truth" is taken into consideration rather than exact true or false (1 and 0). Unlike crisp sets, a fuzzy set allows partial belonging to a set, that is defined by a degree of membership, denoted by μ, that can take any value from 0 (element does not belong at all in the set) to 1 (element belongs fully to the set).

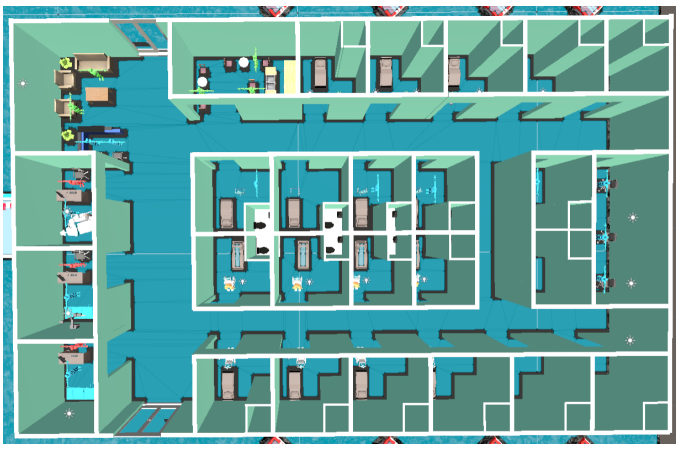

Fig. 2. Layout of the Simulation Environment.

Everything in between 0 and 1 denotes the extent to which the element belongs to one set or the other. A fuzzy system is a repository of the fuzzy expert knowledge that can interpret data in subjective terms instead of precise Boolean logic. The expert knowledge is a collection of fuzzy membership functions and a set of fuzzy rules, known as the rule-base, having the form: IF (conditions are fulfilled) THEN (consequences are inferred)

Fuzzy logic is proposed in this paper to deal with human behavior uncertainty while selecting the proper exit during evacuation. As these parameters are hard to quantify using crisp calculation. The integration of fuzzy logic into computer models produced positive results where perception, feelings and judgment play a significant role. Therefore, human thinking and environmental adjustments are integrated in the proposed model using fuzzy laws to model the evacuee agent's exit selection behavior during the evacuation.

There are four major parts of a typical Fuzzy Logic Controller, namely fuzzifier, rule-base, inference engine and defuzzifier.

The fuzzifier performs fuzzification which is the process of converting crisp input values into fuzzy data points. In this process fuzzifier obtains the membership degree of the fuzzy set from the specific input according to the membership function. For this research, we have utilized triangular membership functions for all the linguistic variables.

After attaining the degree of membership for each input value from the fuzzifier, a rule-base is needed which contains the if - then rules/conditions that are required to form the inference process of the output variable. Generally, the rules are expressed by the fuzzy natural language. The number of fuzzy rules needed can be determined by multiplying the number of linguistic variables of all the inputs, for example, our proposed FLC has 3 input variables: Distance (four linguistic variables), visibility (three linguistic variables) and familiarity (three linguistic variables) so a total of (4 x 3 x 3) = 36 if -then rules are required for the rule base. The rule-base of our proposed FLC is demonstrated in Table I.

The Inference Engine provides the decision-making logic of the controller. By applying the fuzzy rules of inference, it evaluates the fuzzy input values and the provided rules to deduce the fuzzy output values. For this research, we have adopted a typical Mamdani fuzzy inference engine [50], [51].

Finally, the defuzzifier converts the fuzzy output into quantifiable and objective crisp output. In this paper the output of the defuzzifier is the probability of choosing a certain exit. The centroid defuzzification method is used for the defuzzification process of our proposed FLC.

Our proposed FLC has three input variables and one output variable. These are described below:

1) Inputs:

Visibility: Visibility represents the visibility of the exits which may vary due to different smoke conditions or crowd density. The visibility of each exit is assigned randomly. The variable has three linguistic variables: Low Visibility (LV), Medium Visibility (MV), High Visibility (HV). The range of visibility is from 0-10.

Distance: This variable provides the distance between an agent and an exit. The variable has Four linguistic variables: Very Near (VN), Near (N), Far (F), Very Far (VF). The range of distance is from 0-45 meter.

Familiarity: Familiarity represents how familiar an agent is with a specific exit. Same as visibility, familiarity is also selected randomly. The range is from 0-10. The variable has three linguistic variables: Not Familiar (NF), Familiar (F), Very Familiar (VF). Figure 3 visualizes the input variables

2) Output:

Probability of Exit Selection : This variable determines the selection probability of an exit. The variable has 8 membership functions: Zero Probability (Z), Very Low (VL), Medium Low (ML), Low (L), Medium High (MH), High (H), Very High (VH), One (O). Fig. 4 visualizes the output variable.

IV. Results And Discussion

This section describes the result of the simulation and discusses the findings of this research. At the beginning, the agents were placed randomly in the simulation area. When the simulation begins, the unity NavMesh system allows the agents to move into the target point (e.g., exit). The FLC determines the exit for each agent. The simulation ends when all the agents evacuate from the floor. Fig. 5 shows the initial and the final position of the agents. The simulation was carried out by considering two cases.

In the first case the proposed FLC was not included. In the second case the process was again repeated with the inclusion of the FLC. A total of 44 agents were simulated in the environment (3 doctors, 15 nurses, 5 patients with crutches, 11 patients with nurses, 5 patients with wheelchairs and 5 visitors).

For simplicity and ease of visualization only the results of 10 randomly picked agents were included in the tables (1 doctor, 2 nurses, 2 patients with crutches, 2 patients with nurses, 2 patients with wheelchair, 1 visitor). The simulation was conducted 10 times for each case. The details of the simulations are provided below.

A. Results

1) Case 1 (Without using FLC): The simulation is conducted without the FLC for the first experiment. The speed of each agent was set to 1.4m/s. The agent will choose the nearest exit as we have only considered distance in this case. Table II provides the simulation results of 10 randomly picked agents for the first experiment. The table shows the evacuation time (in seconds) of each agent for each simulation run and the standard deviation of the evacuation time

2) Case 2 (Using FLC): For the second experiment, the appropriate exit selection was done by the proposed FLC instead of selecting the nearest exit. The FLC takes the distance, visibility, and familiarity of each of the exits from each agent to the exits and calculates the probability of selection for each exit. The exit with the highest probability of selection is chosen as the target for each agent. Similar to case 1 The speed of each agent was set to 1.4m/s. Table III provides the simulation results for the second experiment.

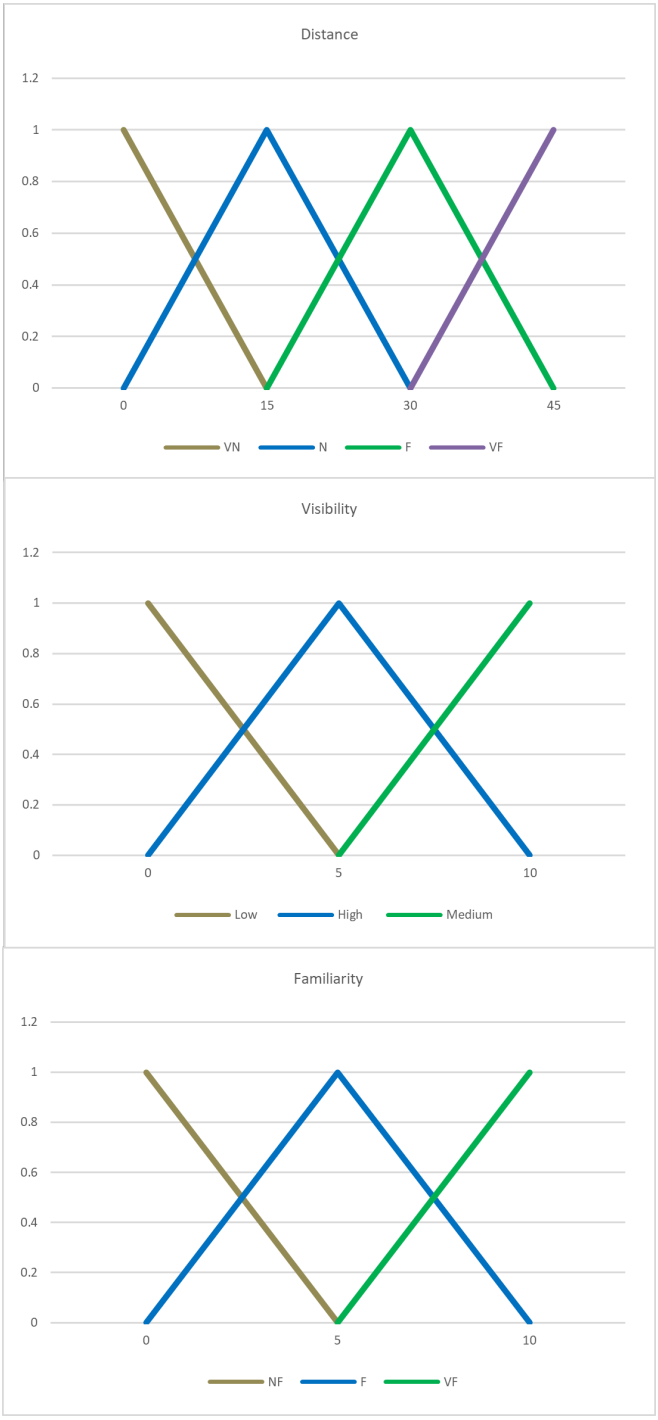

Fig. 3. Membership Function for Input Variables (Visibility, Distance, and Familiarity).

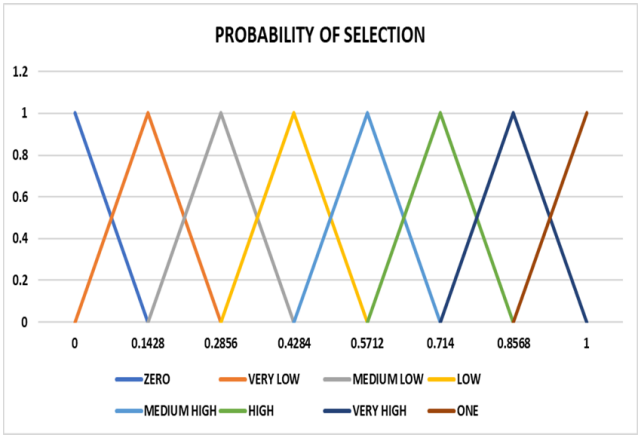

Fig. 4. Membership Function for Output Variable (Probability of Exit Selection).

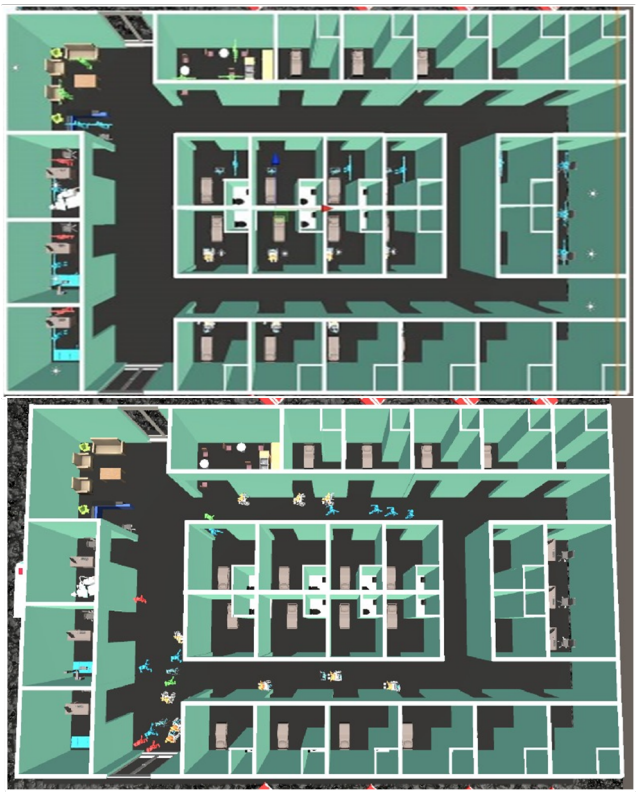

Fig. 5. The Initial Position of Agents (Top), The Final Position (Bottom) of the Agents During Simulation.

B. Discussion

When the exit is selected based on only distance the simulation fails to reflect human uncertainty and randomness. From Table II, it can be seen that the evacuation time of the agents remained almost the same for each test run and the standard deviation of the evacuation time is close to 0. On the contrary, when the FLC is utilized, the agents selected the exit based on distance, familiarity and visibility which impacted their evacuation time. From Table III it can be seen the standard deviation of the evacuation time of each agent is higher than experiment 1. This result provides an important finding. While simulating without using the FLC the exit is selected solely based on the distance. So, the agents always select the nearest exit without considering other factors which is not the case in real life evacuations. From the reviewed literature it can be seen that humans consider many factors (e.g., the exit being in the range of vision, availability of light in the surrounding, familiarity with the structure, exit familiarity) while choosing an exit for evacuation [1], [17]–[22]. This issue

is solved when the FLC is used as the FLC considers not only the distance but also the visibility and the familiarity of the exits. Our proposed method is able to reflect and demonstrate human uncertainty and randomness to some extent. Hence, this research demonstrates that considering only distance is just not enough to select the exit. Including other factors (e.g., visibility, familiarity) help to make the evacuation simulation more realistic and increase the evacuation performance.

V. Conclusion

The objective of this research is to model and simulate assisted hospital [15] evacuation by modelling exit selection for individual agents (doctors, nurses, patients, or visitors) using FLC. For this research, only three types of transport devices have been simulated. Our research findings demonstrate that the proposed FLC can reflect human randomness and uncertainty to some extent.

However, the research has some limitations. For example, the exit is selected only once for each agent. This approach is not very feasible as the visibility of the exits are constantly changing in a practical situation. A more dynamic solution is needed for the selection procedure to properly reflect the change in visibility and the effect it causes in exit selection. Another limitation of the proposed FLC is that it only reflects the effect of three factors. However, in reality humans consider many other factors while selecting the proper exit which are not included in the proposed FLC.

Other movement devices should be considered during simulation to imitate real life situations such as stretchers and rescue sheets. Moreover, multiple floors and intermediate exits should be added to the simulation to analyze its effect in evacuation performance. Finally, the effect of social distancing should also be considered in the simulation model as social distancing is a must in the time of pandemic.

***Abstract*—Swarm robotic systems control multiple robots in a coordinated manner for using this flexible coordination to solve complex tasks in various environments. Such systems can utilize the individual capabilities of robots scattered within the swarm as well as the collective capabilities of the assembled robots. By coordinating these capabilities, swarms can solve tasks with a range of purposes, including carrying out rough sweeps of the overall environment using scattered robots or detailed observation of a part of the environment using assembled robots. This study developed a self-organization method for constructing regular groups of robots from scattered robots to achieve coordination between individual and collective states. An approach that integrates elements of self-organization with different input information requires centralized control to manage them. To provide this self-organization without centralized control, we focus on using the phase-field method and cellular automata to facilitate crystal growth that produces ordered structures from scattered particles. We formulate a method for arranging robots in a self-organizing manner based on the geometrical regularities of tile-able lattices (honeycomb, square, and hexagonal lattices) on a two-dimensional plane, demonstrate the process undertaken in carrying out the proposed method, and quantitatively evaluate the effectiveness of the lattice-based geometrical regularity approach. The proposed method contributes to carrying out tasks with a range of purposes by organizing states with either individual or collective capabilities of robot groups.**

***Keywords*—Multi-robot systems; self-organization; distributed control; crystal growth**

I. Introduction

Swarm robotic systems, which apply swarm intelligence through the control of multiple homogeneous robots, have the features of scalability, flexibility, and robustness [1]. In recent years, researchers have assessed techniques for the practical application of such systems [2], [3]. Changing the manner in which the swarm is embodied can enable the robots to process multiple small tasks using parallel capabilities as well as medium- to large-scale tasks using collective capabilities. This gives the robot swarm advantages relative to single robots in carrying out large-scale/wide-area tasks such as surveillance and environment exploration and cooperative tasks such as multi-shape object transportation [4]. In this study, we examined a robot swarm-based-transporting application that manages individual and collective capabilities simultaneously to enable parallel transportation of small objects that depends on the performance of a single robot and cooperative transportation of heavy or large objects that exceeds their performances by robot groups.

When a swarm system performs multiple similar tasks, the swarm divides into multiple robot groups to carry out the tasks in parallel. However, only this simple group structure is not suitable for performing some tasks. Considering the transporting task as an example, groups with scales, shapes, and structures should be constructed such that they satisfy the size, shape, and weight of an transported object, and the system should self-organize its groups based on the given conditions.

The self-organization of a swarm robot system involves aggregation, pattern formation, and self-assembly [5]. Aggregation is a method for allocating robots to several groups from a set of scattered robots or dividing a robot swarm into several groups. Several methods have been proposed for the allocation of robots based on external factors such as task value and distance [6], [7] and the division of robot swarms based on internal factors such as the number of tasks given by the host system [8], [9]. Allocation approaches allow for the flocking of scattered robots after information relevant to the tasks has been gathered from the environment; division approaches enable robots to work in rough groups to explore an environment. Pattern formation is a method for arranging robots in pre-designed shapes. In this approach, the robot swarm will often construct designed formations from pre-aggregated arbitrary shapes. The robots to be added will then search for the edge of the target group or region and converge to positions suitable for enlarging the pattern designed on a 2D plane [10] or in 3D space [11], or the edge of a designed region [12]. Recently, a method focusing on reaction-diffusion systems for morphogenesis through growth was proposed as a pattern strategy [13], [14]. This approach is expected to facilitate large-scale distributed patterning because it can adapt to changing self-healing defects caused by the partial failure of the robot swarm or changes in the environmental geometry. Self-assembly is the third method for maintaining either physical or cyber positioning between organized robots. Physical connections using grippers [15], magnets [16], and welding [17] as well as virtual connections using networks and non-contact sensors [18], [19] have been proposed to facilitate self-assembly through the fabrication of rigid or elastic body-like swarms without physical constraints, respectively. In pattern formation and self-assembly, the environment-adaptive structure [14], [17] produces groups suitable for foundation shapes and structural loads that self-organize via flexible coupling by controlling the reinforcement around heavily loaded robots. By contrast, lattice-based structures [11], [18] produce groups with geometrical regularities among robots. Depending on the geometrical conditions, dense or sparse groups can be constructed,

allowing a lattice-based structure to adapt to changes in robot density, that is, the number of robots required to carry out tasks such as coordinative transportation or observation. Thus, the implementation of self-organization requires the integration of each elemental method. This complicates the configuration of robots and systems.

In robot groups for transporting—which is the objective of this study—ordered arrangement enables the robots to efficiently support heavy or light objects on agerage by changing their density. Self-organization through these elemental technologies can be used to produce such an arrangement from scattered robots. However, this approach requires centralized control management because the information that must be used differs by task. To solve this self-organization challenge without centralized control, we focus on crystal growth, a natural phenomenon that produces lattice-based structures such as snowflakes, salt, and ores from scattered particles. This paper proposes a self-organization method for constructing groups of crystalline (ordered) robot arrangements from scattered robots without the use of centralized control. To this end, we formulate an autonomous distributed control model for introducing crystal growth into swarm robotic systems to induce enlargement.

In the process of crystal growth, particles find the surfaces of existing crystals through solidification and deposition and then adhere to positions on those crystals determined by existing meteorological conditions and molecular properties, thereby continually increasing the number of crystal layers and enlarging the crystal structure [20]. In this manner, crystal growth constitutes a self-organizational process. There are two existing mathematical tools for predicting and reproducing crystal growth: the phase-field method and cellular automata. The phase-field method describes the changes in a crystal surface during growth by calculating the state transitions of particles using scalar values that denote the stochastic state between the solid and liquid phases instead of independent thermodynamic states. Cellular automata reproduce the complex systems underpinning phenomena such as crystal growth and the formation of traffic jams. In this approach, rulesets for updating the states of cells in terms of discrete neighboring states are applied over discrete space-time intervals to reproduce macroscopic phenomena. By combining the state transitions of particles under the phase-field method with the growth rules of cellular automata, we seek to apply crystal growth to swarm robotic systems. To this end, we propose a self-organization method (Fig. 1) for constructing groups with a crystalline structure from scattered robots based on local information obtained from contact between robots.

The remainder of this paper is structured as follows. Section II defines the configuration of robots and robot swarms and sets the problem of the self-organizing task. Sections III and IV describe, respectively, a behavioral model for robots based on state transition using the phase-field method and a layer-forming method based on cellular automata under several lattice conditions and with different coverages. In Section V, we describe the results of a robot swarm self-organization simulation based on the proposed method and quantitatively verify that the robot swarm can construct lattices with layers at arbitrary scales. Finally, Section VI concludes the paper.

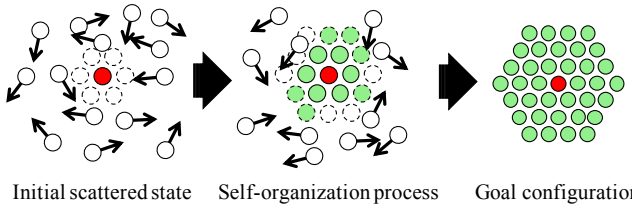

Fig. 1. Self-organizing a Regularly Arranged Group from Scattered Robots.

II. Problem Statement

In this study, we considered a swarm comprising N-unit homogeneous mobile robots. Each robot is equipped with a ranging sensor and local wireless communicator and can move in any direction on a two-dimensional plane within an upper velocity limit of v [m/s]. Each mounted sensor and communicator interfaces with the sensors and communicators on other robots and can be used to observe obstacles directly on lattices tiled on the two-dimensional plane, as shown in Fig. 2. To prevent errors in measuring the distances between robots, the robots cluster into groups with circular perimeters of diameter σ [m]. Under this condition, we define r_{ij} as the relative distance vector between the i-th robot and the j-th neighboring robot it observes. Each robot updates its velocity control value and communicable state based on the relative distance vectors and the exchanged state for a given interval using asynchronous timing. The robots move according to the calculated velocity control values.

For constructing a group of robots to navigate various lattices from randomly arranged states on a two-dimensional plane, a landmark robot is designated to collect other robots around an observed target. The other robots find the landmark robot through environment exploration and converge on positions that enlarge the group uniformly. The resulting organized group is a regular structure based on the geometrical regularities of honeycomb, square, or hexagonal lattices that can tile a two-dimensional plane at equally spaced intervals. In this process, if the robots are not oriented so that they face in the same direction, the group cannot construct the lattice recursively; therefore, the angular references of the robots are all assumed to be aligned along the same direction.

III. Behavioral Control of Robot

To carry out the proposed self-organization process, the robots must utilize the following functionalities: environmental exploration to move individually, surface exploration to find

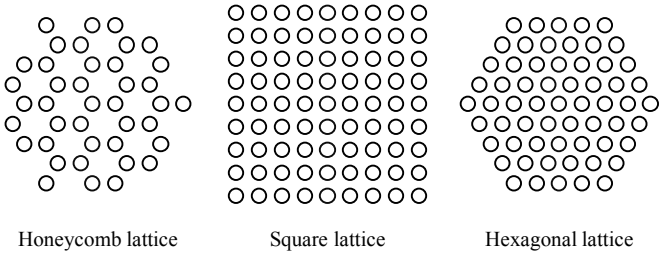

Fig. 2. Structures of Tile-able Lattices on a Two-dimensional Plane.

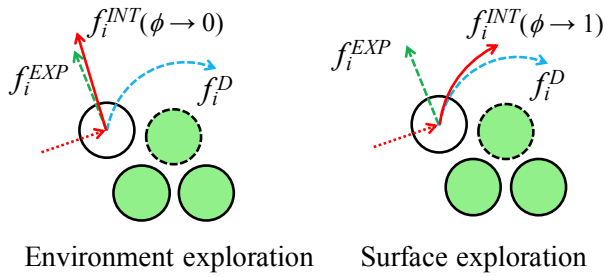

Fig. 3. Illustration of Output Behavioral Vector According to the Order Parameter Value when (left) ϕ is Close to Zero and (right) ϕ is Close to One.

adherable sites on the organized group, and maintenance of the lattice. In addition, the magnitudes of these controls must be altered according to the individual robot's progress. To achieve these behavioral transitions, we apply a phase-field method to represent the state probability between the solid and liquid phases.

The phase-field method involves the application of a reaction-diffusion equation that combines diffusion based on the state difference between a particle and its neighbors with a reaction based on the particle's state to formulate the path of surface movement in crystal growth. The following simple surface movement model is used:

$$\frac{d\phi}{dt} = \nabla^2\phi + 8\phi(1-\phi)(\phi - 0.5 + \beta) \tag{1}$$

where ϕ is an order parameter denoting the phase of the particle, which is a continuum value between zero (liquid phase) and one (solid phase), and β is the reaction rate, which is a constant parameter that solidifies under the condition $\beta > 0$.

When a robot exchanges order parameter information with other organized robots, it updates its internal state as reflected by this equation to proceed with its solidification and transition, depending on its order parameter value, from environment exploration via object-reflecting to surface exploration via edge-following, as shown in Fig. 3. Through this solidification process, the robots exploring an environment find sites of adherence on the organized group.

Each robot recognizes other robots that have been organized based on the construction state of the lattice, s_{j0}, which is obtained from the cellular automata produced by the j-th neighboring robot. If $s_{j0} > 0$, the neighboring robots are recognized as an organized group, with the set of recognized organized robots defined as CS_i, which is used to calculate the output of the phase-field method (in the next section, we will explain how the detailed cellular automata states are derived).

The order parameter that represents the state between the solid and liquid phases controls the i-th robot's behavior. When this parameter contacts the j-th organized robots, it is updated according to (1) as follows:

$$\phi_i \leftarrow \phi_i + \left(\frac{\sum \phi_j - \phi_i}{|CS_i|} + 8\phi_i(1-\phi_i)(\phi_i - 0.5 + \beta) \right) \Delta t \tag{2}$$

where Δt is the interval of the algorithm. According to this order parameter, the controller that decides the priority of environment and surface explorations is represented as follows:

$$f_i^{INT}(\phi_i) = \begin{cases} (1-\phi_i)\,\hat{f}_i^{EXP} + \phi_i f_i^D & ; CS_i \neq \emptyset \\ \hat{f}_i^{EXP} & ; otherwise \end{cases}. \tag{3}$$

The order parameter transitions from zero to one when the crystal growth produces a solidified state. This model prioritizes surface exploration, f_i^D, when close to the solidification state and environment exploration, f_i^{EXP}, otherwise. Note that a robot that does not yet neighbor an organized group uses only environment exploration to find a group. These environment and surface exploration behaviors must involve interactive reflection to avoid other robots and obstacles and edge-following drift of the outline of the organized group; these behaviors are described as follows.

The avoidance behavior used in environmental exploration is generated by constructing a reflection vector between the pre-behavioral vector and the point of collision with a target as follows:

$$f_i^{EXP} = \begin{cases} \sum\limits_{j \in TS_i} f_i^{INT} - 2\left(f_i^{INT} \cdot \hat{r}_{ij}\right)\hat{r}_{ij} & ; TS_i \neq \emptyset \\ f_i^{INT} & ; otherwise \end{cases} \tag{4}$$

where TS_i is the set of reflected objects, which contains obstacles that can be contacted by the robot and neighboring robots within a balanced potential distance, r_0. To compare the magnitudes of environment and surface exploration behavior, the calculated reflection vector is normalized and integrated into the behavioral vector.

The drift behavior for surface exploration used to search for a position of adherence to an organized group is described using a vector that rotates around the neighboring robot group while maintaining the potential, i.e., the distance needed to construct the lattice. It is calculated as follows:

$$f_i^D = f_i^P - \begin{cases} R\left(+\frac{\pi}{2}\right)\hat{r}_{id} & ; |f_i^{INT} \times r_{id}| \geq 0 \\ R\left(-\frac{\pi}{2}\right)\hat{r}_{id} & ; |f_i^{INT} \times r_{id}| < 0 \end{cases} \tag{5}$$

where the first and second terms on the right-hand side are the potential functions used to maintain a constant distance between robots as an surface and the rotation surrounding the neighbor closest to the pre-behavioral vector among organized robots, $d = \forall \arg\max\left(f_i^{INT} \cdot r_{ij} | j \in CS_i\right)$, respectively. The boundary conditions of the model determine the direction of this rotation along the pre-behavioral vector. By combining these, the robot can explore around an organized group at a certain distance.

The inter-robot potential works not only for drift but also for positioning. This potential generates attraction and repulsion forces that maintain the distance between robots needed to construct a group based on the lattice. As this approach focuses on a particle system, we incorporate the Lennard-Jones potential [21] as the distance potential and a simple sinusoidal potential as an angular potential, which is represented as follows:

$$f_i^P = \sum_{j \in CS_i} \frac{1+\cos(L(\theta_{ij}+l_i\pi))}{2|CS_i|} f^{LJ}(r_{ij}) + \sin(2L\theta_{ij}) R\left(\frac{\pi}{2}\right)\hat{r}_{ij} \quad (6)$$

where L is the number of neighboring robots depending on the target lattice. f^{LJ} is the Lennard-Jones potential adjusted for the attraction, as shown follows:

$$f^{LJ}(r) = \frac{169\sqrt[6]{\frac{13}{7}}}{63\cdot 2^{\frac{5}{6}}}\frac{1}{r}\left(12\left(\frac{\sigma}{r}\right)^{12} - 6\left(\frac{\sigma}{r}\right)^{6}\right). \quad (7)$$

This potential outputs a maximum attraction value of one to maintain a constant balanced distance r_0 (where $f^{LJ}(r_0)=0$) that depends on the diameter of the robot. In addition to this potential, the robot is attracted in a direction that satisfies the geometric regularity of the lattice according to the period of the angular potential. By these interactions, the robot moves to the position that places the the neighbors in the direction according to the regularity of the lattice. If the robot does not maintain the lattice-based structure, such as during drift, L is given zero to ensure that the angular potential does not work.

The i-th robot moves according to the movement vector, $v_i = vf_i^{INT}$, based on the behavioral vector calculated using these equations.

IV. Enlarging Algorithm

According to the behavioral model described in the previous section, a robot can find an adherence position suitable for further construction of the lattice that forms the group. We propose a ruleset of cellular automata to provide this position to the robot and a self-organizing potential function to maintain its tiled position. Fig. 4 shows the neighborhoods of these lattices, which can exchange information with neighboring robots in the same layer (unfilled layer), and the neighboring relations for constructing the lattice. The transition function of the cellular automata for these neighborhoods is represented as follows:

$$s_{i0} \leftarrow \begin{cases} \delta(s_{i0}, s_{i1}, s_{i2}, s_{i3}, s_{i4}, s_{i5}, s_{i6}, s_{i7}, s_{i8}, s_{i9}, s_{i10}, s_{i11}, s_{i12}) & ;\text{Honeycomb lattice} \\ \delta(s_{i0}, s_{i1}, s_{i2}, s_{i3}, s_{i4}) & ;\text{Square lattice} \\ \delta(s_{i0}, s_{i1}, s_{i2}, s_{i3}, s_{i4}, s_{i5}, s_{i6}) & ;\text{Hexagonal lattice} \end{cases} \quad (8)$$

where s_{i0} is the lattice construction state and s_{i1} to s_{iN} are the neighbor states, which depend on the number of neighbors in the lattice, with N = 12, 4, and 6 denoting a honeycomb, square, and hexagonal lattice, respectively. Because each lattice has rotational symmetry around its central robot, the surrounding states can be defined by any neighboring robot [22].

To build a group, a set of transition functions, called a ruleset, that repeatedly fills and enlarges the layers of the group by counting the number of filled corners in the outer layers is applied. The construction states s_{i0} to s_{iN} are therefore defined as continuous natural numbers from zero, indicating that the liquid phase searches for a position of adherence of to up to S_{max} and the solid phase fills the layers. S_{max} is at least eight, six, and eight for honeycomb, square, and hexagonal lattices, respectively, with adhered and layer-filled states included in the number of corners of the layer formed by each lattice.

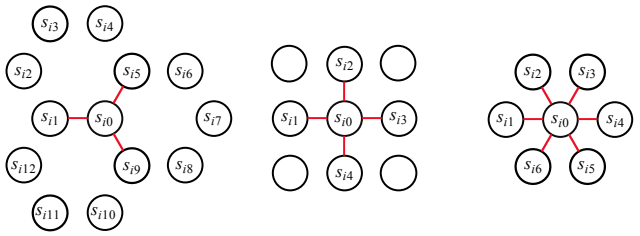

Fig. 4. Directly Observable Neighbors and Coupling Neighbors in Lattices.

Counting and sharing the values in the outer layers requires the neighbor values of the left and right neighbors, s_{il} and s_{ir}, respectively, in the layer inhabited by the i-th robot. The left and right reference directions of a robot can be toward either the inner or outer layers; therefore, to recognize its neighbors within its layer, the i-th robot calculates the layer l_i at the current position based on the layer l_j of the neighboring robots as $l_i = \min(l_j | j \in LS_i)+1$. For reference, the layer of the landmark robot is set to zero. LS_i, the set of neighboring robots within the range $\sqrt{2}r_0$, can be used to observe the robots in the inner layer from a constructible position in the outer layer. Consequently, the i-th robot obtains the neighbors from the layer adjacent to the inner layer as s_{il} and s_{ir}, respectively. The ruleset for synchronously enlarging the layers of a lattice based on these neighborhoods is then

$$s_{i0} \leftarrow \begin{cases} 1 & ;s_{i0}=0,\ \exists S_{max} \in s_{in} | 1 \le n \le N \\ 1 & ;s_{i0}=0,\ 0<s_{ir}<S_{max} \text{ or } 0<s_{il}<S_{max} \\ s_{ir}+1 & ;0<s_{i0}, s_{ir}, s_{il} < S_{max} \text{ and } \theta_{ril} < \frac{N-0.5}{2N}\pi \\ s_{ir} & ;0<s_{i0}, s_{ir}, s_{il} \end{cases} \quad (9)$$

This ruleset is constructed from the top two enlarging rules and the bottom two filling rules that produce the process shown in Fig. 5. By applying these enlarging rules, robots that are adjacent to either a filled inner layer or a neighborhood in the same layer will converge to that position and be organized into the group. The robots applied this rule complete the exploration by (3) to construct the group, and apply the potential model according to the number of neighbors of the organized lattice. The robots in the outer layer then count the number of corners in that layer based on the filling rules. If the angle between s_{il} and s_{ir} is less than π rad, the corresponding robot is in a corner and the adjacent robots are located on the sides. The robots identified as being in corners then transition to a state that adds one to s_{ir}, whereas the others continue sharing s_{ir}. By repeating this process, the robots in the outer layer reach their maximum state, S_{max}, allowing the robot swarm to synchronously enlarge the layers of the organized group.

V. Evaluation of Synchronistic Enlargement of Robot Aggregation

Using the proposed self-organization method, we confirmed that the self-organization process is integrated and that scattered robots can synchronously enlarge the layers of a lattice-based structure to self-organize a group. To this end,

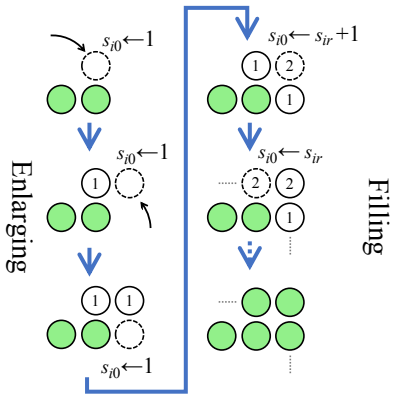

Fig. 5. Filling Process of the Robots in the Outer Layer by the Proposed Ruleset. The Robots Construct a New Layer on the Outside of the Green-colored Robots.

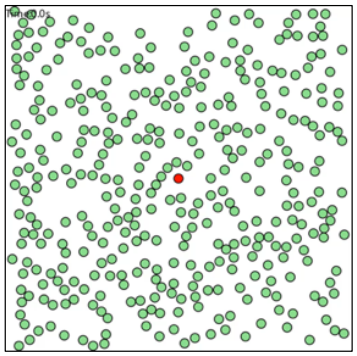

Fig. 6. Example of Field Generated by Simulation, with Green Robots Self-organizing Around a Red Landmark Robot.

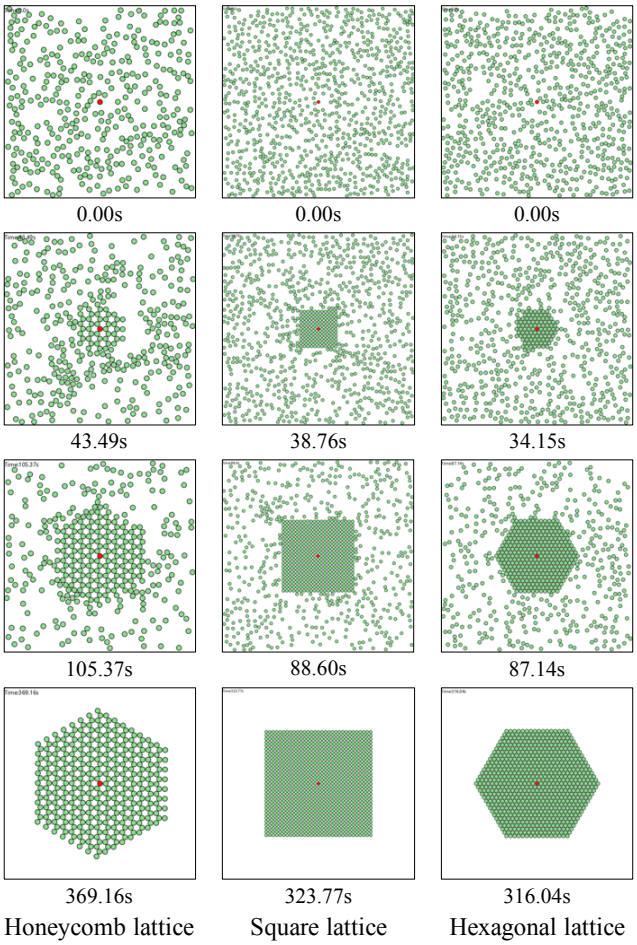

Fig. 7. Group Enlargements up to Self-organization of 15-layer Robot Groups on Different Lattice Types.

we simulated the process of building self-organizing lattice-based groups based on honeycomb, square, and hexagonal lattices. We also evaluated the geometrical regularities of the organized groups relative to their collective centers. Transportation requires a robot swarm comprising several tens to several hundred robots, depending on the size, weight, and shape of a transported object. In our simulation, we confirmed that the proposed method can be used to direct robots in the construction of a group to perform transporting tasks for large objects and that these groups can arrange the robots regularly to distribute the load for the weight of the transported objects.

We evaluated the dynamics of mobile robots under the following conditions: the robots were generated at random positions within a square region based on the average exploring range of an individual robot, with the landmark robot placed at the center of the region, as shown in Fig. 6. Note that this region size affects the search time of the robots. Each initialized robot had a diameter of 20 pixels, could move in all directions within an upper-velocity limit of 50 pixel/s, and was able to begin moving in a random direction. The robots also updated their behavioral vectors and communicable information computed using the proposed method with a reaction coefficient β of 0.1 at intervals of 10 ms. We simulated the movement of the robots for each lattice and layer condition.

A. Appearance of the Self-organization Process

To verify that a robot swarm could synchronously enlarge a layer based on the proposed cellular automata ruleset, we simulated self-organization of 15-layer groups on honeycomb, square, and hexagonal lattices using the required number of robots (361, 481, and 721, respectively) for each case and setting the average exploration area to 40×40 pixel2. The self-organization results obtained under these conditions are shown in Fig. 7.

From top to bottom, the rows in the figure show the groups constructed at 0 (initial state), 5, 10, and 15 (completed state) layers, respectively. In each case, the robots, which had been initialized with individual behaviors, converged to regular positions on the applied lattice and enlarged the organized group in all directions around the landmark robot. The shapes of the in-progress and completed organized groups were, in general, similar, and there were no defects in the filled layers or overgrowth in the outermost layers of the organized groups. These results indicate that the layer-filling process based on the proposed cellular automata ruleset worked as designed, with all robot swarms applying the proposed method achieving the construction of ordered arrangements from scattered robots.

The robot behavioral paths overlap and increase depending

on the random reflection vectors of the other robots, therefore, this paper cannot compare and discuss their time requirements. In the enlargement process, a robot exploring its environment will have to move in the path with little overlap to find an organized group. We expect to improve by incorporating behavioral models, such as random walk [23] and Lévy flight [24], that can effectively explore the overall environment into the proposed method.

B. Convergence Location of Scalable Self-organization

We then confirmed that the self-organization by a scalable robot swarm can satisfy the geometric regularity of a lattice. To evaluate this, we compared the differences between the simulated collective centers and the coordination of the landmark robots. Here, by "collective center" we mean the geometric condition-dependent coordination of the landmark robot as the organized robots converge to their ideal positions. Based on this difference, we could evaluate the geometrical regularity of the self-coordination process. The evaluation index for an individual robot is given by

$$O_c = \frac{1}{100}\sum_{try=1}^{100}\sqrt{\left(\sum_{i=1}^{N}\frac{x_i - x_c}{N}\right)^2 + \left(\sum_{i=1}^{N}\frac{y_i - y_c}{N}\right)^2} \tag{10}$$

where x_c and y_c are the coordinates at which the landmark robot is initially placed, x_i and y_i are the coordinates of the i-th robot when self-organization is complete, and N is the number of robots required under each experimental condition. To account for the randomness of the sequence of enlargement and the robot behavioral paths, the index was measured 100 times and the average value and standard deviation were calculated.

The index was measured for the first- to twentieth-layer group of each lattice with the average exploring area set to 60×60 pixel2. Fig. 8 shows the measurement results for each lattice. In each case, the obtained difference was shorter than the distance at which the potential model converged over time, indicating that the differences satisfied geometrical regularity. In addition, the indices for the series of honeycomb lattices were larger than those for the other lattices because, in the honeycomb lattice, the supported range of the proposed angular potential has wider than those of the others, and half of the robots in the outermost layer only construct with one robot. The indices also increased and scattered as the number of robots neighboring only one robot with weak convergence forces and wide support ranges increased with the number of layers.

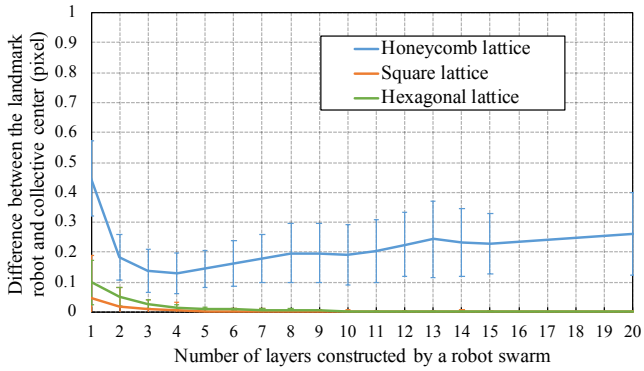

Fig. 8. Error in Measured Geometric Regularity as a Function of Number of Layers. The Solid Lines and Error Bars are the Average Values from 100 Trials and the Corresponding Standard Deviations, respectively.

VI. Conclusion

This paper proposed a self-organization method that integrates the self-organization process to utilize the cooperative capability of swarm robot systems. To achieve this, we focused on crystal growth and developed a distributed control/algorithm that combines a phase state transition based on the Phase-Field method and a group enlargement based on Cellular Automata. We demonstrated the self-organization process and evaluated the geometrical regularity of organized groups based on honeycomb, square, and hexagonal lattice-based arrangement conditions. From this result, we have achieved to produce a collective state from a parallel distributed state of a swarm robot system based on local robot positions and information exchange between the local robots.

Because the proposed method is a self-organizing approach based on the use of identical robots to fulfill a given lattice condition, it is limited by its inability to be used to construct flexible shapes (e.g., amorphous structures) based on long-range ordered coupling. Nevertheless, under the proposed method various group shapes can be represented by increasing the number of robots, i.e., the resolution. This will allow us to develop an approach for constructing designed group shapes by controlling the landmark robot and the layer growth speed. Furthermore, the proposed method has been shown to be effective at fixed-point observation; for the robots to engage in dynamic observation or the cooperative transportation of large objects, they will have to move in organized groups. Therefore, in the future, we will address the development of a dynamic approach in which the geometric conditions of the lattice are maintained.

***Abstract*—Data deduplication is an effective mechanism that reduces the required storage space of cloud storage servers by avoiding storing several copies of the same data. In contrast with server-side deduplication, client-side deduplication can not only save storage space but also reduce network bandwidth. Client-side deduplication schemes, however, might suffer from serious security threats. For instance, an adversary can spoof the server and gain access to a file he/she does not possess by claiming that she/he owns it. In order to thwart such a threat, the concept of proof-of-ownership (PoW) has been introduced. The security of the existing PoW scheme cannot be assured without affecting the computational complexity of the client-side deduplication. This paper proposes a secure and efficient PoW scheme for client-side deduplication in cloud environments with minimal computational overhead. The proposed scheme utilizes convergent encryption to encrypt a sufficiently large block specified by the server to challenge the client that claims possession of the file requested to be uploaded. To ensure that the client owns the entire file contents, and hence resist collusion attacks, the server challenges the client by requesting him to split the file he asks to upload into fixed-sized blocks and then encrypting a randomly chosen block using a key formed from extracting one bit at a specified location in all other blocks. This ensures a significant reduction in the communication overhead between the server and client. Computational complexity analysis and experimental results demonstrate that the proposed PoW scheme outperforms state-of-the-art PoW techniques.**

***Keywords*—Client-side deduplication; proof of ownership; convergent encryption; could storage services**

I. Introduction

Cloud computing is the provision of on-demand access to different computing services and resources, such as storage space, servers, networks, databases, and software, over the internet [1]. The different models of cloud computing can provide a wide range of capabilities, adapted with different business goals, to diverse clients and/or consumers [2, 3]. The rapid development and integration of cloud computing have led organizations, institutions, and individuals to increasingly turn to utilize services provided over the cloud [4]. Consequently, an increasing number of individuals and organizations tend to move their data on cloud storage services (e.g., Dropbox, SkyDrive, Google Drive, iCloud, Amazon S3). This resulted in rapid growth in the volume of data that is stored on the cloud storage servers [5, 6, 7].

To increase efficiency as well as reduce the storage space required on storage servers, cloud storage providers tend to avoid downloading and uploading duplicated data [5, 8]. Data deduplication is an effective mechanism that aims at reducing the required storage space of the cloud storage servers by avoiding storing several copies of the same data. There are two main types of deduplication [9, 10] namely, server-side deduplication and client-side deduplication. The server-side deduplication schemes [11, 12] remove duplicated copies of the same files after uploading them to the server. On the other hand, In client-side deduplication [10, 13], duplicated copies are identified on the client side and not uploaded to the server. Hence, in contrary to server-side deduplication, client-side deduplication can not only save storage space and uploading time but also reduce network bandwidth.

However, client-side deduplication schemes might suffer from serious security threats [13, 14, 15]. For instance, an adversary can spoof the server and gain access to a file that he/she does not possess by claiming that he/she owns it. To thwart such a threat, Halevi et al. [16] proposed a cryptographic primitive, referred to as "proof of ownership" (PoW), to allow the server to verify whether a client owns a file. They pointed out that a robust PoW scheme should alleviate potential security threats without introducing I/O and computational overhead at both client and server sides. Since the introduction of the proof-of-ownership concept, several PoW schemes have been proposed in the past few years [14, 16, 17, 18, 19, 20, 21, 22]. However, the security of such schemes cannot be assured without affecting the computational complexity of client-side deduplication.

An efficient PoW scheme should satisfy several requirements. First, the chances that an adversary successfully passes a PoW run should be negligible if the adversary does not possess the file in its entirety. Second, a small fixed amount of information should be loaded on the server-side regardless of the file size. Third, the amount of processed information on both the client and server sides should be minimal. In addition, the amount of transmitted data between the client and the server should be reduced to minimize the bandwidth. Unfortunately, the PoW schemes discussed above do not fulfill all of these requirements. Thus, new techniques that can resolve the security-efficiency trade-off and reduce communication and storage overhead should be proposed.

This paper proposes a secure and efficient proof-of-ownership scheme for client-side deduplication in cloud environments that fulfills the requirements mentioned above. The proposed technique utilizes convergent encryption to encrypt a sufficiently large block specified by the server to challenge the client that claims possession of the file requested to be uploaded. To ensure that the client owns the entire file contents, and hence resists collusion attacks [23, 24], The server challenges the client by requesting him to split the file he/she asks to upload into fixed-sized blocks and then encrypts

a randomly chosen block using a key formed from extracting one bit at a specified location in all other blocks. This ensures a significant reduction in the communication overhead between the server and client. Moreover, the proposed scheme resists attacks of honest-but-curious servers [25, 26, 27].

The rest of the paper is structured as follows. Section II provides a brief background on the concepts of data deduplication, convergent encryption, and proof-of-ownership. Section III describes the proposed PoW scheme in detail. Section IV presents a computational complexity analysis of the proposed scheme and provides a comparison with the state-of-the-art schemes. Section V describes the experimental results and discussion. Finally, Section VI concludes the paper.

II. Background

A. Data Deduplication

Data deduplication, also called single-instance storage, techniques aim to eliminate duplicate copies of the same data to improve storage utilization and reduce the unnecessary cost of storage capacity needs [13]. A prominent example of the usefulness of data deduplication is redundant file attachments in email systems. Consider a typical email system containing 50 copies of the same 20 megabyte (MB) file attachment. Saving or archiving this email platform requires 1000 MB of storage space. The storage demand can drop to only 20 MB if data deduplication is employed. The example shown in Fig. 1 demonstrates the main concept of data deduplication. There are two main types of data deduplication in cloud environments: server-side deduplication and client-side deduplication. Server-side deduplication techniques identify repeated data after uploading them to the server, whereas client-side deduplication techniques identify duplicate copies of data before they are uploaded to the server. Therefore, client-side deduplication techniques can reduce network data transfers in addition to storage capacity.

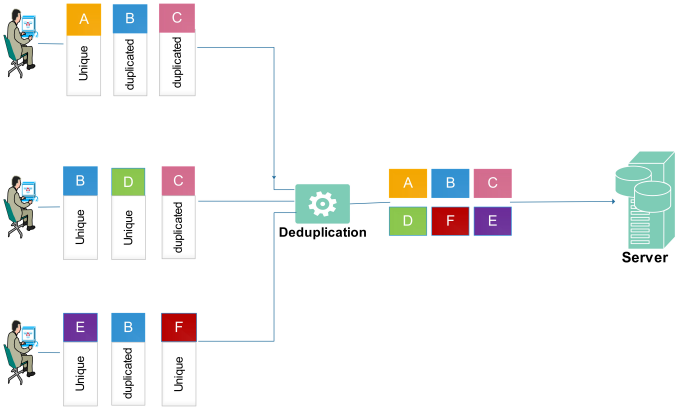

Fig. 1. Data Deduplication Technology.

B. Convergent Encryption

Data deduplication techniques can benefit from convergent encryption (CE) to achieve security smoothly and more easily [10, 15]. Convergent encryption is a cryptographic concept that ensures security in the cloud by achieving confidentiality and data privacy. The main idea behind CE is to create similar ciphertexts from similar plaintexts (see Fig. 2). Unlike traditional cryptography, in which data encryption and decryption are carried out using cryptographic keys that are independent of the data being encrypted, and hence different ciphertexts are obtained from the same plaintexts, CE ensures that the same key is used for the same plaintexts. In CE, the data digest or hash is used as a key to encrypt the data. Encrypting data in CE undergoes the following three steps: 1) the digest (hash value) of the plaintext in question is computed, 2) the plaintext is then encrypted using its digest as a key, and 3) finally, the hash is encrypted with a key chosen by the user and stored along with the obtained ciphertext. These steps ensure that identical data copies will generate the same key and the same ciphertext.

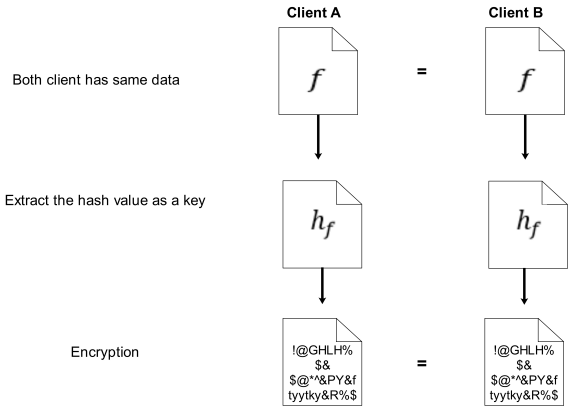

Fig. 2. Convergent Encryption Concept.

C. Proof of Ownership (PoW)

In client-side deduplication techniques, the hash value of the file requested to be uploaded by the client is firstly computed and sent to the server. If this hash value exists in the list of previously uploaded files to the server, the server will request the client not to upload the file again to avoid storing redundant data. However, in order to append the client to the list of owners of that file, the server has to verify that the client owns the entire file and not try to spoof it. Traditional proof of ownership protocols, Such as the one proposed by Halevy et al. [5] oud storage provider (CSP) has access to the original file. In other words, such protocols depend on trust between the cloud storage provider and the client. However, this trust might generate many potential security risks since cloud storage providers (CSPs) should not be fully trusted. The process of adapting PoW protocols so that they can work properly on encrypted data is an open problem so far [13].

Several PoW schemes have been proposed over the past few years. Gonzalez-Manzano et al. [14] proposed an attribute-based symmetric encryption proof of ownership scheme, referred to as ase-PoW, for hierarchical environments. The main goals of this scheme are to resist honest-but-curious servers and to provide flexible access control to ensure that users have access to sensitive files with the right and real privileges. The

idea behind this scheme is based on recursively encrypting parts of the file being uploaded to the server to assure its possession by the user. The ase-PoW scheme has the advantage of its ability to resist guessing attacks on the content and reduce the cloud workload. However, it does not take into account the issues of user revocation and key updating.

Dave et al. [17] proposed a secure proof of ownership scheme based on utilizing Merkle trees. The idea is based on calculating the responses of challenges in advance at the server-side to avoid computational overhead while uploading the file. The cloud server does not need to hold over the resources until the response is received, which is preferable to the utilization of stateless protocols. The user on the client-side is requested to encrypt the file to be uploaded to the server using its digest as a key (a.k.a. convergent encryption (CE)). Afterward, the user computes a file tag (usually a cipher-text hash) to check the file's existence on the server. The file uploading process consists of four stages (metadata generation, challenge generation, response generation, and response verification). If the file tag does not exist in the FileList kept by the server, the client will be requested to upload the file with the tag. In the case of subsequent uploads, the server sends an unused precomputed PoW challenge to the client. If the client owns the entire file, then the client will correctly respond to the server.

Islam et al. [18] proposed a secure and reliable storage scheme for cloud environments with client-side deduplication (SecReS). The authors combined convergent encryption and secret sharing techniques to achieve data confidentiality. They used the Reed-Solomon erasure code to achieve fault tolerance through distributing data to multiple storage servers. Moreover, Merkle trees are utilized to verify the ownership of data and to perform secure data deduplication. Mishra et al. [19] proposed a merged PoW scheme (MPoWS) for block-level deduplication in cloud storage. By employing a random test approach, MPoWS meets the requirements of client-side and server-side mutual verification. In MPoWS, large files are uploaded to the servers, and then their duplication is checked using various blocking flags. The authors used a random test approach to increase security and make it difficult to predict which block will be validated.

Fan et al. [20] proposed a secure deduplication scheme based on a trusted execution environment (TEE), which provides secure key management by using convergent encryption with cloud users' privileges. Trusted execution environments improve cryptographic systems' capability to resist chosen-plaintext and chosen-ciphertext attacks. The authors proposed assigning a set of privileges to every cloud user. Therefore, data deduplication can be performed if and only if the user of the cloud has the right and valid privileges. In [21], Ouda proposed a secure and effective proof of ownership scheme for client-side deduplication in the cloud. This scheme verifies if the client owns the entire file for which he/she claims possession. In other words, the proposed scheme does not allow an adversary to engage in a successful proof of ownership without fully owning the file's content. This can be achieved by requesting the client to encrypt the entire file using the file hash as the key before uploading the file to the server. This prevents the curious server from disclosing the file content.

Du et al. [22] proposed a proof of ownership and retrievability framework (PoOR) in which the cloud client can prove ownership of files to the server without uploading or downloading the files. The proposed framework consists of the pre-processing two phase, proof of ownership phase, and retrievability phase. The proof of ownership phase depends on the Merkle Tree protocol and comprises three steps: prove, challenge, and verify. Cui et al. [28] proposed a new attribute-based storage system that supports secure and efficient deduplication. The proposed system runs on a hybrid cloud environment where the private cloud is responsible for detecting identical copies for storage management. Ma et al. [29] demonstrated how attribute-based encryption can be used to minimize storage space and share data efficiently. In this technique, if the attributes of certain user is matched, then the user is given the right to decipher the encrypted data.

Blasco et al. [30] proposed a PoW scheme, called bf-PoW, that utilizes the Bloom filters to mitigate the server-side overhead. The main drawback of the bf-PoW scheme is that it does not consider data privacy. Di Pietro and Sorniotti [9] introduced another scheme, referred to as s-PoW in which the server requests clients to send bit-values of randomly selected bit positions of files requested to be uploaded by those clients. Although this scheme is computationally efficient at the client-side, it is not efficient on the server-side. Manzano and Orfila [31] proposed a PoW scheme, called ce-PoW, employing the concept of convergent encryption to encrypt file chunks before uploading them to the server. This scheme reduces issues related to key management. However, since the encryption is applied at the chunk level, the number of encryption keys increases linearly with the number of requested chunks. This can put a significant burden on both storage space and bandwidth as the security parameters increase.

Huang et al. [32] proposed a bidirectional and malleable proof-of-ownership scheme for large files in cloud storage (BM-PoW). The proposed BM-PoW protocol allows the server and user to interact to ensure ownership of the file to be uploaded even if the file is updated. Thus, secure and efficient deduplication for large files in static and dynamic archives is guaranteed. Miao et al. [33] proposed a novel PoW protocol that benefits from the distinguishable properties of chameleon hashing. Although this protocol is more efficient than existing PoWs based on Merkle hash tree, it is vulnerable to brute-force attack (BFA) due to its limited keyspace [34].

Although some solutions have been proposed to improve the efficiency at the server-side, other solutions tend to enhance the computational cost at the client-side. Besides, most of the existing schemes cannot satisfy all the security requirements in terms of resisting honest-but-curious servers and collusion attacks without affecting the efficiency and/or communication bandwidth requirements. Therefore, it is promising to study how to develop PoW schemes that can balance the trade-off between the security and efficiency requirements.

III. Proposed PoW Scheme

As we previously mentioned, the main goal of our proposed PoW scheme is to provide an efficient means to prove the ownership of files in client-side deduplication environments securely. Precisely, we aim at minimizing the exchanged

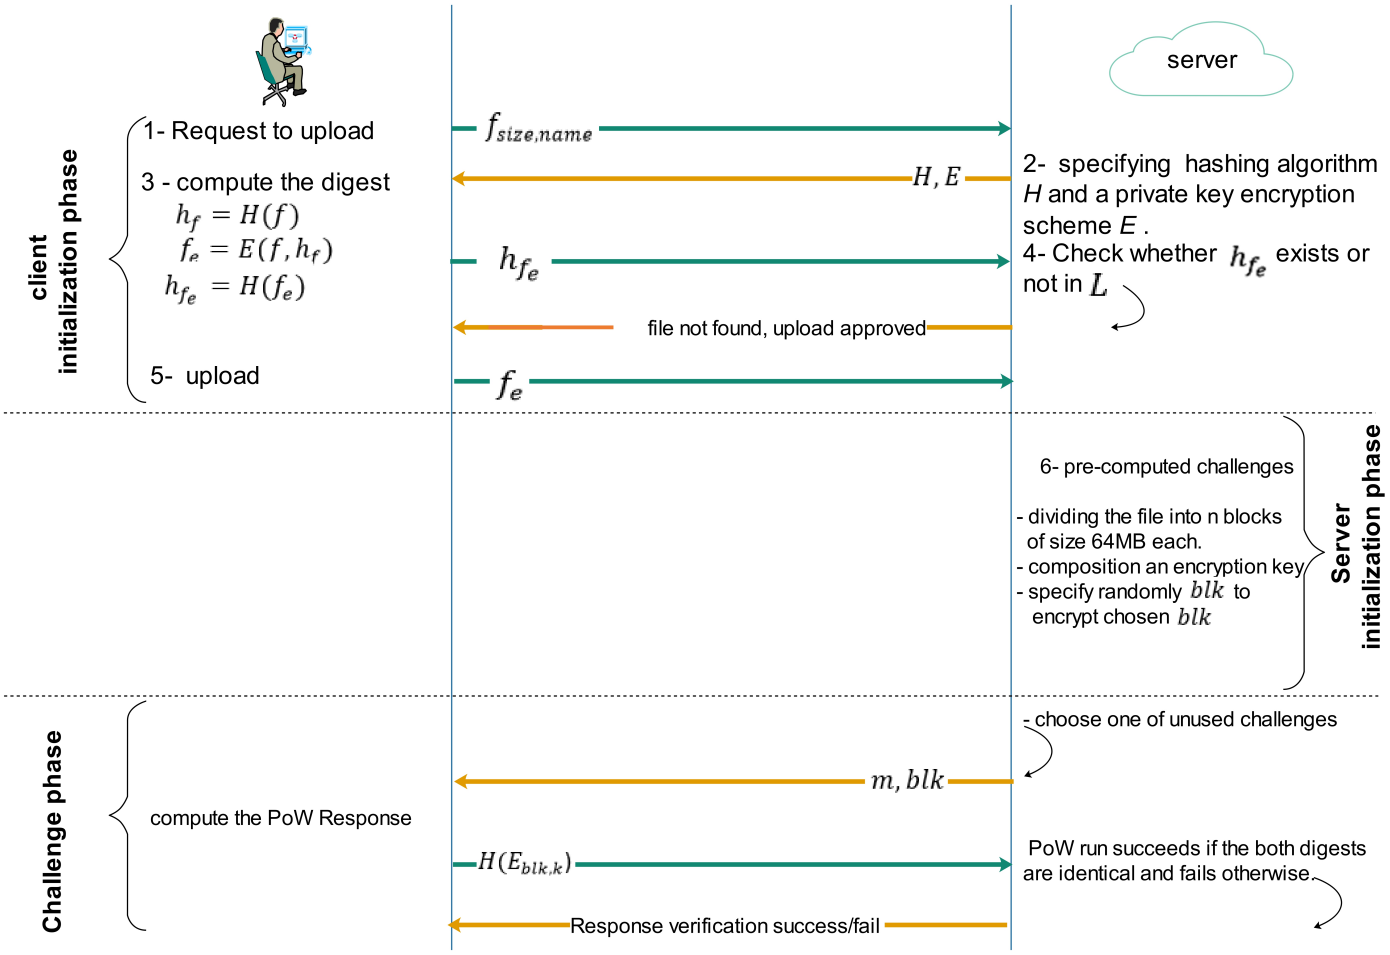

Fig. 3. Proposed PoW Scheme.

information between the client and server, reducing the data uploaded in memory during a PoW session, and decreasing the likelihood that a malicious client can successfully respond to the challenge sent to him/her by the server via increasing the amount of exchanged information between a malicious client and a legitimate owner of the file. Definition of abbreviations and symbols are given in Table I.

As illustrated in Fig. 3, the proposed PoW scheme consists of three phases: the client initialization phase, server initialization phase, and challenge phase. In the client initialization phase (see Algorithm 1), the client initiates a file (f) upload request to the server by simply sending general attributes of the file, such as its name and size. The server responds to the client by sending a message specifying a robust hashing algorithm $\mathcal{H}$ (e.g., MD5, SHA1, etc.) as well as a private key encryption scheme E (e.g., DES, AES, etc.). The client uses the specified hashing algorithm to compute the file digest, $h_f = \mathcal{H}(f)$, which is then used as a key to encrypt the file using the encryption algorithm specified by the server to obtain an encrypted file $f_e = E(f, h_f)$. The encrypted file f_e is then hashed using $\mathcal{H}$ to obtain its digest $h_{f_e} = \mathcal{H}(f_e)$. Finally, the client sends h_{f_e} to the server so that it can decide whether the file has been uploaded before by a different user.

TABLE I. DEFINITION OF ABBREVIATIONS AND SYMBOLS

Abbreviation	Definition
f	File to be uploaded to the server
f_e	Encrypted file
$\mathcal{H}(f)$	Hash of the file f
blk	A block of f
j	Block number
n	Number of non-overlapping blocks
κ	Encryption key
m	Bit position
$\mathcal{L}$	List of uploaded files
$\mathcal{C}$	The client
$\mathcal{S}$	The server

Assuming that the server stores the digest of each previously uploaded encrypted file, the server can decide whether f has been uploaded before by searching for h_{f_e} in the list $(\mathcal{L})$ of the stored digests. It is worth noting that our scheme

Algorithm 1 Client Initialization Phase

Input: File f
Output: $\mathcal{H}(f_e)$, f_e

Client $\mathcal{C}$ sends a request to server $\mathcal{S}$ to upload the file f
$\mathcal{S}$ sends to $\mathcal{C}$ the name of the hashing algorithm $\mathcal{H}$ and encryption algorithm E
$\mathcal{C}$ computes the digest $\mathcal{H}(f)$ of f using $\mathcal{H}$
$f_e \leftarrow E(f, \mathcal{H}(f))$
$\mathcal{C}$ computes $h_{f_e} = \mathcal{H}(f_e)$ and sends it to $\mathcal{S}$
$\mathcal{S}$ searches for h_{f_e} in the list ($\mathcal{L}$) of uploaded files
if $\mathcal{H}(f_e)$ is found in $\mathcal{L}$ **then**
    Go to the Challenge Phase
else
    Allow $\mathcal{C}$ to upload f_e to $\mathcal{S}$
    Go to the Server Initialization Phase
end if

Algorithm 2 Server Initialization Phase

Input: File f_e
Output: The entry $\mathcal{L}[h_{f_e}]$

Divide f_e into n blocks of size 64MB each
for $i \leftarrow 1$ to c **do** /* c = No. of challenges */
    Choose two integers m and $j < n$
    Extract the m-th bit of each block in f_e
    Generate a cryptographic key κ by concatenating the n extracted bits
    Encrypt the j-th block in f_e using κ to obtain $E(blk_j, \kappa)$
    Compute the digest of $E(blk_j, \kappa)$
    $Challange[i] =< m, j, \mathcal{H}(E(blk_j, \kappa)) >$
end for
Create a new entry for f_e consisting of all the generated challenges and append it to $\mathcal{L}$

assumes that files are encrypted before uploading them to the server to prevent honest-but-curious servers from disclosing the contents of the uploaded files. If h_{f_e} is not found in the list of the stored digests, the server sends a message to the client to start uploading f_e; otherwise, the server initiates the challenge phase.

After the file f_e is uploaded, the server initialization phase (see Algorithm 2) starts by creating a new entry for f_e. This entry consists of h_{f_e} and a pointer to a set of pre-computed challenges that will be used to prove the ownership of f_e by other clients who might request to upload the same file in the future. A challenge is created by dividing the file into n non-overlapping blocks sufficiently large to resist collusion attacks. It is assumed that sharing data $\geq$ 64MB among colluders would discourage them launch collusion attacks [30]. Thus, we recommend setting the block size at such levels. Then, the encryption key (κ) is composed by concatenating all bits at a specific position (m) across all blocks. For instance, if $m = 3$ and $n = 128$, then the third bit in each block is extracted, and the set of the 128 extracted bits are concatenated to create a 128-bit cryptographic key κ. An example that illustrates the key generation process, where $m = 3$ and the file and block sizes are 8 GB and 64 MB, respectively, is shown in Fig. 4. The generated key is then used to encrypt a randomly chosen block (blk_j) of the encrypted file f_e using the AES

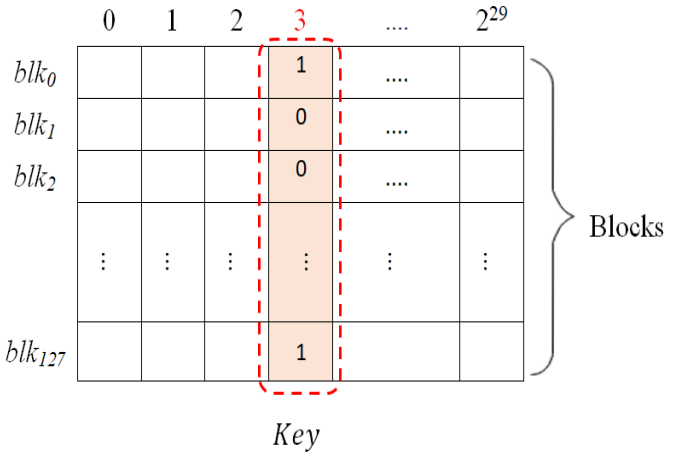

Fig. 4. An Example that Illustrates the Key Generation Process.

encryption algorithm to obtain $E(blk_j, \kappa)$. Finally, the digest of the encrypted block $\mathcal{H}(E(blk_j, \kappa))$ is obtained and stored along with m and j as one challenge for f_e. The previous challenge creation process is then repeated using different values of m and j to encrypt different blocks of f_e in order to generate as many challenges as needed.

The challenge phase is initiated when an entry is found for f_e in the list of uploaded files kept by the server. In this case, the server chooses one of the available challenges in $\mathcal{L}[h_{f_e}]$ to verify that the client possesses the file he/she requests to upload. The server challenges the client by sending m and j corresponding to the chosen challenge. Note that with just these two values, the amount of information sent from the server to the client is minimized. This satisfies an important design objective of the proposed PoW scheme. The client responds to the challenge by dividing the file, after encrypting it using the same procedure described in the client initialization phase, into n blocks, generating κ by extracting bits at position m of all blocks, encrypting the block blk_j specified by the server using κ, and finally calculating the digest of the encrypted block $\mathcal{H}(E(blk_j, \kappa))$ and sends it to the server as a response to the received challenge. The server matches the received block digest with the corresponding digest stored in $\mathcal{L}$. The PoW run succeeds if both digests are identical and fails otherwise.

It is important to note that all design goals of the proposed PoW scheme are satisfied. The data exchanged between the client and server are minimized. In the challenge phase, the server sends two small pieces of information; namely, the bit position index m used to generate the key κ and the index of the block to be encrypted. Similarly, the client is required to respond to the challenge received from the server by just sending the specified block digest. From the security perspective, the block size is set to 64MB because a PoW scheme is considered secure if the amount of exchanged information between a legitimate owner of f and a malicious client required to pass a PoW run is not smaller than 64MB [30]. Moreover, since one bit per block is used to generate the key (κ), a large number of challenges can be generated for each uploaded file. Precisely, more than 2^{29} different challenges can be generated if the block size is set to 64MB.

TABLE II. COMPARISON BETWEEN THE PROPOSED SCHEME AND FIVE RELATED POW SCHEMES CONCERNING SPACE AND COMPUTATIONAL COMPLEXITY. κ: SECURITY PARAMETER, n: NUMBER OF PRE-COMPUTED CHALLENGES, l: TOKEN LENGTH, F: FILE SIZE, B: BLOCK SIZE AND p_f: FALSE POSITIVE RATE (BF-POW SCHEME)

	ase-PoW	ouda-PoW	ce-PoW	bf-PoW	s-PoW	Proposed
Client computation	$O(B).Sym.n_r.hash$	$O(F).CE.hash$	$O(B).CE.hash.hash$	$O(F).hash$	$O(F).hash$	$O(B).CE.hash$
Server init computation	$O(B).hash$	$O(F).hash$	$O(B).hash.hash$	$O(F).hash$	$O(F)$	$O(B).hash$
Server init I/O	$O(F)$	$O(F)$	$O(F)$	$O(F)$	$O(F)$	$O(F)$

Algorithm 3 Challenge Phase

Input: m and j of an unused challenge
Output: PoW response

1: $\mathcal{S}$ sends m and j to $\mathcal{C}$
2: $\mathcal{C}$ divides f_e into n non-overlapping blocks of size 64MB each
3: $\mathcal{C}$ extract the m the bit of each block in f_e
4: $\mathcal{C}$ generate a cryptographic key κ by concatenating the n extracted bits
5: $\mathcal{C}$ encrypt the j the block in f_e using κ to obtain $E(blk_j, k)$
6: $\mathcal{C}$ send to the $\mathcal{S}$ the challenge $\mathcal{H}(E(blk, k))$
7: $\mathcal{S}$ reciving the challenge $\mathcal{H}(E(blk, k))$
8: **if** Clinet $\mathcal{H}(E(blk, k))$ = Server $\mathcal{H}(E(blk, k))$ **then**
9: PoW success
10: **else**
11: Fail to PoW
12: **end if**

IV. COMPLEXITY ANALYSIS

This section demonstrates how the proposed PoW scheme fulfills bandwidth and space efficiency requirements by comparing it to five well-known PoW schemes from the literature, as shown in Table II. Specifically, we compare the complexity of our proposed scheme by focusing on bandwidth, server memory usage, client/server computation, and I/O. It can be noticed from Table II that the complexity of the proposed scheme is similar to the complexity of the other schemes with respect to server initialization I/O as it primarily relies on the file size. For the regular server I/O, the complexity of the proposed scheme is also similar to the complexity of the other schemes except for s-PoW. Moreover, the complexity of the proposed scheme outperforms the complexity of the other schemes with respect to client computation and server initialization computation, mainly because the proposed scheme only encrypts a randomly chosen block in the file rather than encrypting the whole file. It is worth noting that this does not affect the security of the proposed scheme since the employed cryptographic key is extracted from all blocks of the file.

V. EXPERIMENTAL RESULTS

This section describes the experiments conducted to evaluate the performance of the proposed PoW scheme. All experiments were conducted on a personal computer with Intel Core i7-4770 CPU (2.4 GHz) and 8 GiB RAM. The performance of the proposed scheme was compared with the performance of the ce-PoW scheme proposed by Gonzalez-Manzano et al. [14], ase-PoW scheme proposed by Manzano and Orfila [31], Ouda-PoW scheme proposed by Ouda [21], bf-PoW scheme proposed by Blasco et al. [30], and s-PoW scheme proposed by Di Pietro and Sorniotti [9]. In all experiments, the schemes were evaluated using randomly generated test files of sizes ranging from 4MB to 2GB, doubling the size at each step. We used the C++ programming language for the implementation and utilized the OpenSSL cryptographic library [35] for the encryption and hashing operations, namely, AES (in counter mode) and SHA-256.

The clock cycles spent by the client to upload a file for the first time and to respond to the server challenge have been measured and compared with the corresponding clock cycles spent by the other tested PoW schemes. Fig. 5 shows the computational cost (clock cycles) spent in the client initialization phase for the four tested schemes. It can be noticed from the figures that the proposed PoW scheme outperforms all the other schemes. This is mainly because the s-PoW dealing with file level and the server requests from the clients to send bit-values of randomly selected bit positions of files requested to be uploaded. whereas in bf-PoW the clients compute a token for each segment index using the hash function, which in turn increments the executed operations. The ce-PoW scheme requires implementing multiple hashing and encryption operations separately for each file chunk. In ase-PoW, on the other hand, the client has to encrypt each part of the file chunks provided by the Attribute Certificate Service (ACS) symmetrically, whereas in the Ouda-PoW scheme, the entire file should be hashed twice and encrypted once. However, we can also notice that the performance of both the Ouda-PoW and ase-PoW schemes is close to the performance obtained by our proposed scheme with respect to the complexity of client

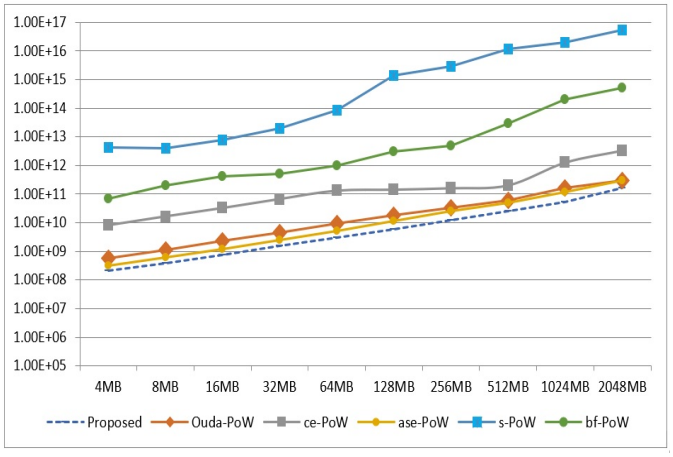

Fig. 5. Clock Cycles Required for the Client Initialization Phase.

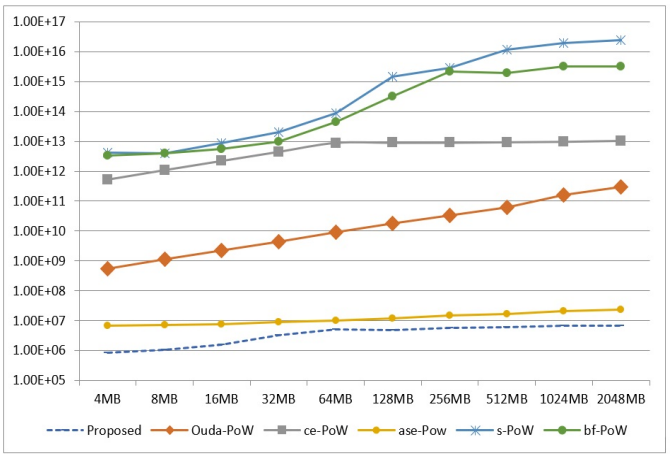

Fig. 6. Client Response Creation Clock Cycles.

initialization.

Fig. 6 shows the results obtained from comparing the proposed scheme with the other evaluated schemes regarding the time spent by the client responding to the server challenge. It is clear from the figure that the proposed scheme outperforms the other three schemes. This result is expected because the server in s-PoW uses a pseudorandom number generator to precompute the challenges that contain random file bits. In bf-PoW, the server initializes the bloom filter and divides the input files into chunks of fixed size, then creates the token chunks of each and inserts the function of each token into the bloom filters. In ce-PoW, the client encrypts all chunks specified by the server and then computes the hash over each encrypted chunk, increasing the computation time. The client in the ase-PoW scheme, on the other hand, performs several frequent encryptions of the designated chunks. In ouda-PoW, the client generates a random string of the same file size using the random seed received from the server, performs an XOR operation on the generated string with the CE file, and finally computes the hash of the resulting string. By contrast, in the proposed scheme, the client extracts the key from all blocks in the file and then encrypts only the block specified by the server.

VI. Conclusion

In this paper, we have proposed a secure and efficient proof-of-ownership scheme to thwart potential collusion attacks against client-side deduplication in cloud environments. The proposed PoW scheme's main idea is to divide the file to be uploaded into a number of fixed-sized blocks and then encrypt a randomly chosen block using a key formed by extracting one bit at a specified location in all other blocks. Unlike existing PoW schemes, the proposed scheme minimizes the exchanged information between the client and server and reduces the amount of data uploaded in memory during a PoW session. Moreover, it decreases the likelihood that a malicious client can successfully respond to the challenge sent to her by the server by increasing the amount of exchanged information between a malicious client and a legitimate file owner. The computational complexity of the proposed scheme was compared to five different PoW schemes, and experimental results showed that the proposed scheme outperforms the state-of-the-art PoW schemes concerning the time spent (clock cycles) for client initialization and response to the challenge received from the server.

A Secure Fog-cloud Architecture using Attribute-based Encryption for the Medical Internet of Things (MIoT)

Suhair Alshehri, Tahani Almehmadi
Department of Information Technology
Faculty of Computing and Information Technology
King Abdulaziz University
Jeddah 21589, Saudi Arabia

***Abstract*—The medical internet of things (MIoT) has affected radical transformations in people's lives by offering innovative solutions to health-related issues. It enables healthcare professionals to continually monitor various medical concerns in their patients, without requiring visits to hospitals or healthcare professionals' offices. The various MIoT systems and applications promote healthcare services that are more readily available, accessible, quality-controlled, and cost-effective. An essential requirement is to secure medical data when developing MIoT architectures, as MIoT devices produce considerable amounts of highly sensitive, diverse real-time data. The MIoT architectures discussed in previous works possessed numerous security issues. The integration of fog computing and MIoT is acknowledged as an encouraging and suitable solution for addressing the challenges within data security. In order to ensure data security and to prevent unauthorized access, medical information is kept in fog nodes, and safely transported to the cloud. This paper presents a secure fog-cloud architecture using attribute-based encryption for MIoT to protect medical data. It investigates the feasibility of the proposed architecture, and its ability to intercept security threats. The results demonstrate the feasibility of adopting the fog-based implementation to protect medical data, whilst conserving MIoT resources, and the capability to prevent various security attacks.**

I. Introduction

Technology has transformed the lives of both individuals and organizations. Electronic healthcare services are considered to be an essential factor in the digital transformation of healthcare, helping to expand both the field and the kinds of healthcare services available, to improve the quality of healthcare services' delivery, and to reduce the cost associated with it [1].

The medical internet of things (MIoT) now leads technological advancements in healthcare, with the emergence of wearable and implantable medical devices and other technologies that enable the capture of medical data contributing to the considerable growth in this field. The value of the MIoT in the healthcare business is expected to increase to $534.3 billion by 2025, concurrent with an upsurge in the number of individuals with chronic conditions. According to the Grand View Research, this rise supports the need for technologically advanced medical devices [2].

The cost of healthcare services has increased significantly in recent years, although the costs concerned can be minimized via the industry's rapid digital transformation by improving operational efficiency [1]. Organizational and patient-care operations are enhanced when healthcare institutions are given real-time access to data generated by medical devices and MIoT-based devices. However, these advancements cause many challenges, particularly those related to the security and privacy of medical information [3].

Medical information is extremely susceptible to security threats [18], and the challenges imposed by privacy and security concerns hamper the widespread implementation of MIoT-based services. Thus, maintaining the confidentiality and safekeeping of information collected by MIoT devices remains a major research topic and must be prioritized, whether the information concerned is sent over the internet or stored in the cloud. Although the advent of fog computing resolved several issues that were apparent in traditional cloud-based architectures, medical data security remains a concern [4].

The current MIoT architectures that are developed in the literature to protect MIoT data fail to consider the limited capabilities of devices, such as storage and energy capacity, which affects the lifespan of the devices and their effectiveness in capturing and transmitting signals [4], [5], [7], [8], [9]. Thus, in order to ensure the adequate protection of medical information for MIoT services, a secure fog-cloud architecture is needed.

This paper develops a secure fog-cloud based architecture for the MIoT to ensure the security of medical data, while preserving the resources of these devices. It utilizes fog nodes to perform the encryption of the medical data, instead of MIoT devices using ciphertext-policy attribute-based encryption (CP-ABE). This is considered to be an ideal solution for protecting the privacy of medical data, as the data is encrypted by fog nodes before being stored in the cloud. The paper also considers minimizing the energy consumption of the processing overhead, improving the availability, and reducing the latency. The main contributions of this paper are as follows:

Our main contributions of this paper are as follows:

1) The design and development of a secure fog-cloud system using attribute-based encryption (ABE) for MIoT environments;

2) The definition of a set of requirements for achieving secure fog-cloud systems for MIoT environments;
3) The evaluation of the proposed system, in terms of a performance analysis, including network use, energy consumption, and security analysis.

This paper is organized as follows: Section II presents the fundamental details of the attribute-based encryption (ABE) employed in this paper. Section III discusses the current state of the art, focusing on the techniques that integrate ABE with fog computing. Section V-C defines a set of requirements for achieving secure fog-cloud architectures for MIoT environments. Section IV presents the proposed model, and Section V provides the evaluation results of the proposed model. Finally, Section VI concludes the paper.

II. Background

In widely distributed environments, especially the cloud environment, the symmetric encryption technologies with the same key for encrypting and decrypting suffer from key distribution and management issues. However, asymmetric encryption methods that use public and private keys lack computational efficiency [13], because the data owner is required to specify the identity of each recipient and their public key in advance, in order to implement the encryption algorithm, and to send the encrypted data to each recipient separately. This means the encryption process is repeated, according to the number of recipients. Since this type of individual scheme cannot be used to encrypt data once and send it to several users, ABE has emerged as a suitable solution for reducing the significant computational overhead of traditional encryption operations, while preserving data confidentiality and access control.

ABE is a novel and secure method for data sharing. It performs encryption and decryption while it obtains flexible access control [19], and was first introduced by Sahai and Waters [6]. It is an encryption mechanism that allows individuals to encrypt and decrypt data according to their attributes, such as job function, department, and specialty. ABE is an asymmetric cryptographic technique for one-to-many encryption that changed the traditional understanding of public-key encryption [6]. In traditional public-key encryption, the message is encrypted for a specific recipient using the recipient's public-key. In contrast, in ABE, one public-key is used to control access to encrypted data, using access policies and attributes [10].

Meanwhile, CP-ABE is a type of ABE that addresses the open challenge to organize access control and maintain the security of sensitive data, especially for internet of things (IoT) applications [13]. In a CP-ABE scheme, attributes are associated with the individual's secret key, and the encrypted message is associated with an access policy. Thus, authorized individuals can decrypt the message only if their secret keys and the associated attributes satisfy the decrypted message's access policy. This allows the storage of confidential data encrypted using CP-ABE on untrusted servers, without implementing authentication controls for the data access [13].

According to the extant literature, there are additional advantages to CP-ABE, compared to traditional cryptographic techniques [13], [20], [21], [22]. These advantages are as follows:

- It provides a high level of data confidentiality.
- It enables encrypted access control mechanism for access control applications.
- It reduces communication overload, because the generation of a user's secret key occurs only once.
- It achieves collusion resistance, because each attribute is associated with a polynomial or a random number that prevents legitimate users from colluding with each other.
- It supports user scalability; as the number of authorized users increases, the system can work efficiently.

A CP-ABE scheme consists of four fundamental algorithms: setup, encrypt, key generation, and decrypt. A detailed description of these algorithms can be found in [6].

III. Related Work

The model of the MIoT is believed to be tremendously valuable for remote health monitoring systems. The critical nature of the functions that use these systems requires a great degree of precision and accessibility. The lack of accessibility and punctuality, as well as the reliability of cloud-based IoT is a much debated topic, particularly regarding instances when the internet connection becomes undependable, and/or slower than expected. Furthermore, due to the centralized resource management and policies set by service providers that are related to the nature of cloud computing, the systems are susceptible to infiltration. An electronic healthcare system cannot be sustained with this vulnerability, due to the necessity to protect medical data. This necessitates the adoption of fog-based MIoT systems to overcome the limitations of cloud-based MIoT systems.

Fog computing is a distributed platform that generates a new layer between the cloud and MIoT devices that decreases the amount of processing done in the cloud, thereby allowing more efficient and effective service delivery. However, fog computing involves a number of security issues that are inherited from the cloud itself, including the ability to verify identities, to authenticate user inputs, to enforce access control, and to preserve privacy. Several procedures exist that can be applied to resolve the issues faced by fog computing.

In their work, Alrawais et al. [4] proposed a key exchange protocol based on the CP-ABE that can be employed to facilitate authentic transmissions between the set of fog nodes and the cloud, while maintaining confidentiality. To accomplish this goal, the researchers integrated digital signature techniques with a CP-ABE protocol, within which they studied the effectiveness of the protocol, in terms of both performance and security. To demonstrate its practicality, the protocol was implemented and contrasted with the certificate-based scheme. The results indicated that the protocol proposed was more practicable, as well as more effective than the certificate-based schema. However, the study did not examine the security requirements between the fog nodes and the end users.

Meanwhile, Vohra and Dave [5] held a similar view to Alrawais et al. [4], and investigated the privacy problems in fog computing, and the efficiency of the ABE schema suggested in [6]. The outcomes of the investigation demonstrated that ABE successfully guarded sensitive information, but that this method alone was not adequate, due to several security problems, such as backward and forward issues. Thus, a number of methods, such as re-encryption, were suggested by previous researchers, and Vohra and Dave [5] recommended a system that used CP-ABE for encryption and re-encryption to provide access control for the communication between the cloud and the fog. According to the findings of this study, the schema suggested demonstrated improved operation and protection. However, there was a need to reduce the number of messages generated to enhance system efficiency.

In contrast, Zhang et al. [7] presented an access control mechanism using a CP-ABE approach for the secure sharing of data that supported the outsourcing of fog computing for complex encryption and decryption operation. In this approach, a number of operations were implemented locally by the data owner and end user, such as implementing the symmetric algorithm on the data, and additionally encrypting or decrypting the symmetric key, partly via the CP-ABE algorithm. However, the study neglected the limited resources of smartphones, as these operations drain their energy and resources.

Meanwhile, Porwal [8] modified the CP-ABE protocol to enhance the secure exchange of content keys between the IoT, fog devices, and the cloud by exploiting the hierarchy in the attribute set of access policy to obtain a single integrated access policy. In order to reduce the cost of storage, to distribute encrypted content, and to reduce the number of decryption operations, a fog device and cloud received solely entitled content keys using one decryption operation. Despite the limited resources within IoT devices, the study assumed that they were capable of implementing advanced encryption standard (AES) to protect data, and that they shared the content keys used for encryption with fog devices and the cloud that might be unreliable and untruthful.

Finally, Fan et al. [9] considered the problem that when the access policy is sent clearly with the ciphertext it may reveal confidential information, although the CP-ABE scheme provides a secure access policy within the ciphertext (10). Thus, they developed an efficient multi-authority access control mechanism for the fog that supported the IoT. The scheme outsourced partial decryption, and transformed user attributes to anonymous aspects to preserve users' privacy. However, the scheme used fog devices for decrypting only while the complex CP-ABE encryption operations were performed by the data owner on end devices, an approach that is not suitable for IoT devices, because of their limited resources.

A. Data System Requirements in MIoT Environments

The concerns regarding data security, such as data scams, theft, forgery, or destruction, take precedence over the numerous advantages of utilizing fog computing in MIoTs. The primary emphasis of the present research was (1) the safeguarding of information when transporting from sensor network to fog, (2) the safekeeping of data during the transfer from fog to cloud, and (3) the security of data buffering in the fog, and the final storage in the cloud. To achieve these goals, a set of requirements were defined that were based on the previous literature in the field, and then the related work that utilized ABE for the fog-cloud architecture was compared, in terms of these requirements. The comparison is presented in Table I, and the requirements were defined as follows:

- **Confidentiality:** Sensitive data available to authorized users only.
- **Access Control:** Only authorized users can access the functionality and data within the device.
- **Availability:** Medical information can be accessed from anywhere within reach of the cloud services when needed.
- **Integrity:** Unauthorized users cannot change or alter the data.
- **Low-latency:** Protect data near its source; the delay in data protection increases the possibility of attacks on the system, and discloses patients' sensitive medical data.
- **Forward Security:** The prevention of nodes/users who have exited the database from retrieving the information exchanged.
- **Energy-Efficiency:** Preserve energy by transferring the encryption/decryption processes from the end devices to the fog nodes.

TABLE I. DATA SYSTEM REQUIREMENTS IN MIOT ENVIRONMENTS FOR DIFFERENT STUDIES

Low-latency			✓	✓	✓
Forward Security		✓			✓
Energy-Efficiency					

The limited capabilities of MIoT devices, such as low power and dependence on limited-life batteries, impose restrictions on the kind of operations that can be utilized by these devices. As illustrated by the discussion of the previous studies in this field and Table I, authors of previous work relied on implementing cryptography operations in the IoT devices, which engendered the depletion of their limited resources. This was inconsistent with the energy efficiency requirement that this paper sought to attain, alongside the other security conditions.

IV. THE PROPOSED MODEL

Fog computing can offer a viable solution for handling various security issues in MIoT successfully [11], due to the existence of fog nodes on the network edge that gather confidential health-related data. This thereby provides data processing on the edge, decreasing the transfer of confidential information to the cloud, and supporting the protection of confidentiality by protecting the health-related information in

the fog nodes, and between the fog nodes and the cloud. A variety of procedures can be utilized between the fog nodes and the cloud to preserve data protection [12]. This paper proposes a secure fog-cloud architecture for MIoT to enhance the safety of user data, without affecting the efficient functioning of MIoT. Accordingly, it proposes that fog nodes are an appropriate platform for protecting medical data, due to their closeness to the end-user.

It was necessary to ensure the security requirements for the manipulation of medical data, including transmission and storage, that were identified and discussed in the previous section. Thus a scenario was examined in which the stream of data captured from MIoT devices was transmitted to cloud storage through fog nodes that implemented CP- ABE security. As an advanced type of encryption technology, and the most common type of ABE, CP-ABE addresses the open challenge for maintaining access control, and the security of sensitive data, especially for IoT applications [13]. In a CP-ABE scheme, the attributes are integrated with the user's secret key, and the encrypted text is integrated with an access policy. Therefore, only users with the correct attributes that meet the access policy can decipher the data. Hence, the main advantage of CP-ABE is that it enables the storage of confidential data on an untrusted server, with no need to implement authentication or access control mechanisms [13].

A. System Components

The proposed scheme contains five types of entities: data owner (DO), data user (DU), multiple fog nodes (FN) at the edge, cloud server (CS), and key authority (KA). The model is shown in Figure 1, and the description of the model entities is as follows:

- **Key Authority (KA)** This is responsible for generating cryptographic parameters, and creating the secret keys of all users, according to their attributes. Additionally, the KA has the duty of publishing a list of users (UL) to the FN, and updating the list when adding or revoking a user. This function is necessary to achieve forward security;
- **Data Owner (DO)** This is also referred to as a 'patient' in the proposed scheme. The DO uses MIoT sensors, which are miniature apparatuses with limited capabilities regarding storage, computing processing, and energy. Medical data is collected from the body of the patient and transferred to the fog node linked to the devices. To safeguard the transmissions between the medical devices and the fog, a secure sockets layer (SSL) is used to establish an encrypted channel between the MIoT and the fog node. In the case where the medical device and the FN fail to communicate, the MIoT devices seek the closest alternative FN to contact and transmit the medical data. Each MIoT device has a unique identifying attribute, called an internet protocol (IP) address. The MIoT device can transmit/collect information over the network using its IP address. The framework of the internet affords universal connectivity to medical devices in a heterogeneous network. In MIoT devices, the communication and data transmission is conducted via wireless technology. There are many aspects to consider when using wireless technology. Specifically, for MIoT devices, factors such as energy efficiency, cost-effectiveness, physical dimensions, and user-friendliness must be considered. Hence the suitable wireless specifications for MIoT include Bluetooth, RF4CE, IrDA, Wi-Fi, ZigBee, RFID, NFC, and ANT;
- **Fog Nodes (FN)** These are positioned at the edge of the network, and provide an array of amenities, such as minimal inactivity occasions and real-time functionality. They also control the performance of the encryption processes. Each FN has a unique identity that is connected to the cloud server by an IP network. It is important to note that the structural design of fog computing can facilitate MIoT devices in supplying efficient storage services, processing raw data near its source, and reducing network traffic to prevent congestion, all of which are critical characteristics of MIoT healthcare applications;
- **Cloud Server (CS)** This can store huge amounts of data, and has formidable computing power. It is responsible for storing encrypted data, as well as for processing requests for access to medical data from authorized healthcare providers.
- **Data Users (DU)** These are also referred to as 'healthcare providers', and are the parties who monitor a patient's condition, and request their data from the CS, in order to recommend the appropriate treatment.

B. Security Assumption

In order to simulate the security environment in this study's scheme, the following security assumptions were considered:

- It was assumed that MIoT sensors, FN, and the KA were within the same local network, and that the connection link between them was secure;
- The KA was trusted fully in the scheme, which meant that it would not leak data, or collude with any users;
- Each FN was trusted, but could be vulnerable to attack;
- The CS was a semi-trusted service provider. It was honest and ensured data security, but was curious, and therefore performed analysis to collect private information;
- The DU may collude to gain unauthorized data. It was assumed the revoked DU could not perform data decryption from the FN.

C. CP-ABE Functions

The CP-ABE functions adopted in the scheme were based on [10], where a full description of these algorithms can be found. The main functions included in the proposed solution were as follows:

- **Setup( )$\Longrightarrow$*MK,PK*:** The setup algorithm takes no input, and outputs the master-key (*MK*) and public-key (*PK*);

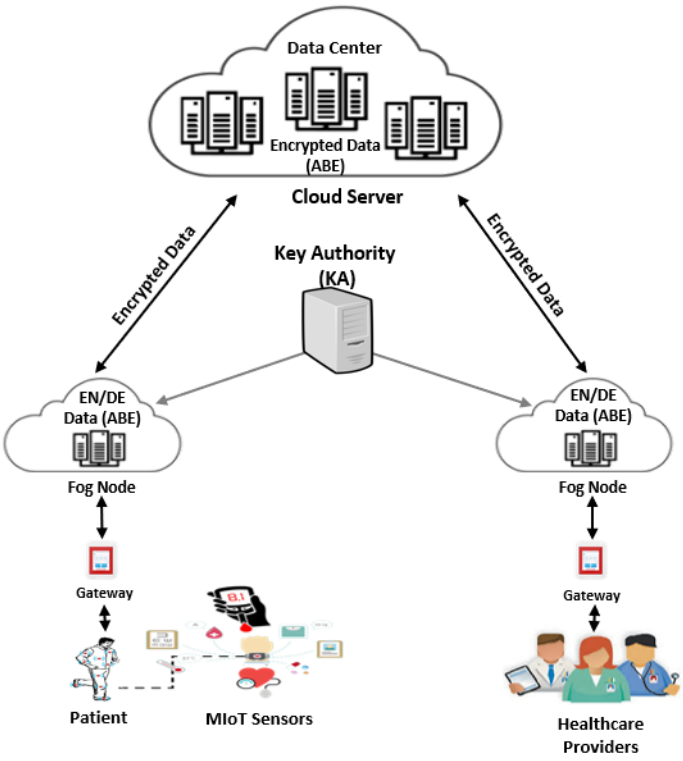

Fig. 1. The Proposed Architectural Design.

- **Encrypt(PK, $Data$, $\mathbb{A}$)$\Longrightarrow CT$:** The encrypt algorithm takes as input the PK, data, and the access-policy ($\mathbb{A}$) of the user. It enciphers the data and outputs a ciphertext (CT) in which only a user who owns a key with a set of attributes that fulfill the $\mathbb{A}$ can decipher the data;
- **KeyGen(MK, S)$\Longrightarrow SK$:** The key-generation algorithm takes as input the MK, and the set of attributes (S) of a user to produce the secret-key (SK) of this user;
- **Decrypt(PK, SK, CT) $\Longrightarrow Data$:** The decrypt algorithm takes as input the PK, SK, and the CT, which contains an $\mathbb{A}$. If the user attributes satisfy the $\mathbb{A}$, then the algorithm deciphers the CT and returns the original data ($Data$).

D. System Workflow

As shown in Fig. 2 the proposed system works in the following steps:

- **Step 1:** The system is initialized, with the KA executing the setup algorithm to generate the MK and the PK. The PK is broadcast to all FN that are connected to the local domain, while maintaining the MK. In addition, the UL is distributed to the FN, which carry the users' identities in the system, SK, S, and $\mathbb{A}$ that are used in the encryption/decryption operations;
- **Step 2:** When receiving the data from the MIoT sensors, the FN performs the encrypt algorithm, after authenticating the identity of the DO via checking the UL to ensure the presence of the user in the system, and to obtain the $\mathbb{A}$ that was used for the encryption. The CT is sent for storage in the CS;
- **Step 3:** If a DU requests data from the CS, the request passes through an FN that first verifies the user's identity from within the UL. This is to prevent users who have left the system from accessing the data, since the data request is sent only to the CS if the user is currently on the UL. Otherwise, the request is rejected;
- **Step 4:** The FN executes the Decrypt algorithm after receiving the CT based on the user's SK that was verified in the UL, then sends the original data to the data user.
- **Step 4:** The FN executes the decrypt algorithm after receiving the CT, based on the user's SK that was verified in the UL, then sends the original data to the DU.

V. Evaluation

In order to represent the proposed model, iFogSim [14], [15], [16] was used to create the physical components and to design the application model as a group of modules, namely the client module, security module, and storage module, that constituted the data processing elements. The client module received the raw ECG signals. It then performed the abstraction process on the signals, and ignored any inconsistent readings.

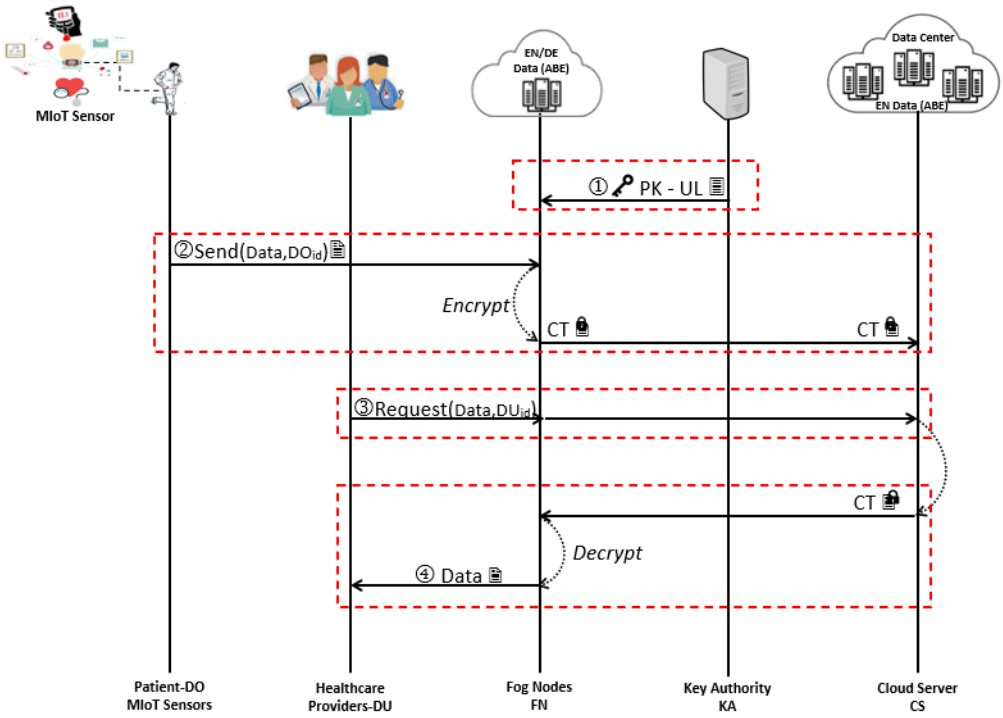

Fig. 2. System Workflow.

If the value of the signal sensed was consistent, it was sent to the security module. In the case of receiving information from the security module, it sent it to the DISPLAY actuator to display. The security module was responsible for protecting the medical data, performing encryption and decryption operations on the data received. The storage module represented the database in the cloud where the encrypted medical data was stored for patients, and recovered when needed.

In addition, this study used CP-ABE, an open-source Java implementation of the ABE scheme found in the paper by Bethencourt et al. [10], and developed by Wang et al. [17], to evaluate the efficacy of the model. Three different placement strategies were tested by implementing the security module, the main module of the present study, in the cloud, fog, or end device, as shown in Fig. 3. The feasibility of the proposed architecture was assessed, in terms of performance, network use, and energy consumption. Furthermore, the capability of the proposed system to deal with the related security vulnerabilities within the MIoT, the FN, and when information was transferred between the FN and the cloud, was examined.

The test was conducted on a local PC with a Windows 10 Home 64bit operating system, a 2.2 GHz Intel Core i7, and an 8GB Memory by Eclipse IDE for Java Developers. In order to test the performance on different sizes of topology, the number of FN was changed, and the number of end devices connected to each FN fixed was retained. Different sizes of network topology were simulated, starting with one FN with four connected end devices, and advancing to 20 FN with 80 connected end devices.

A. Performance Analysis

The various metrics that iFogSim showed were collected, and the results illustrated how different placement strategies for implementing a security module affected the system performance.

1) Time to Security Module:: The time it took to transfer the data from its source to the security module to implement the encryption was the most important factor in this research, as a delay in the transmission of data increased the possibility of the data being attacked. Fig. 4 shows the time taken to transfer the medical data to the security module, illustrating that it decreased significantly when applying the security module to fog devices or end devices. This was more apparent when the number of devices was increased.

The results of the implementation of a security module in the cloud were excluded from the study, which focused on performing a comparison between implementing the security module in the fog and in the end devices, as most of the previous research reviewed focused on implementing the security mechanism in the end devices, because such devices are close to the data source (end users), without considering the limited resources of these devices. In contrast, this study sought to move the security operations to the fog devices to preserve the end devices' resource consumption. As shown in Fig. 5, there was a very small difference in time of not more than six milliseconds between implementing the security module in the fog and in the end devices. This slight delay in data transfer would not affect the data security, especially since the

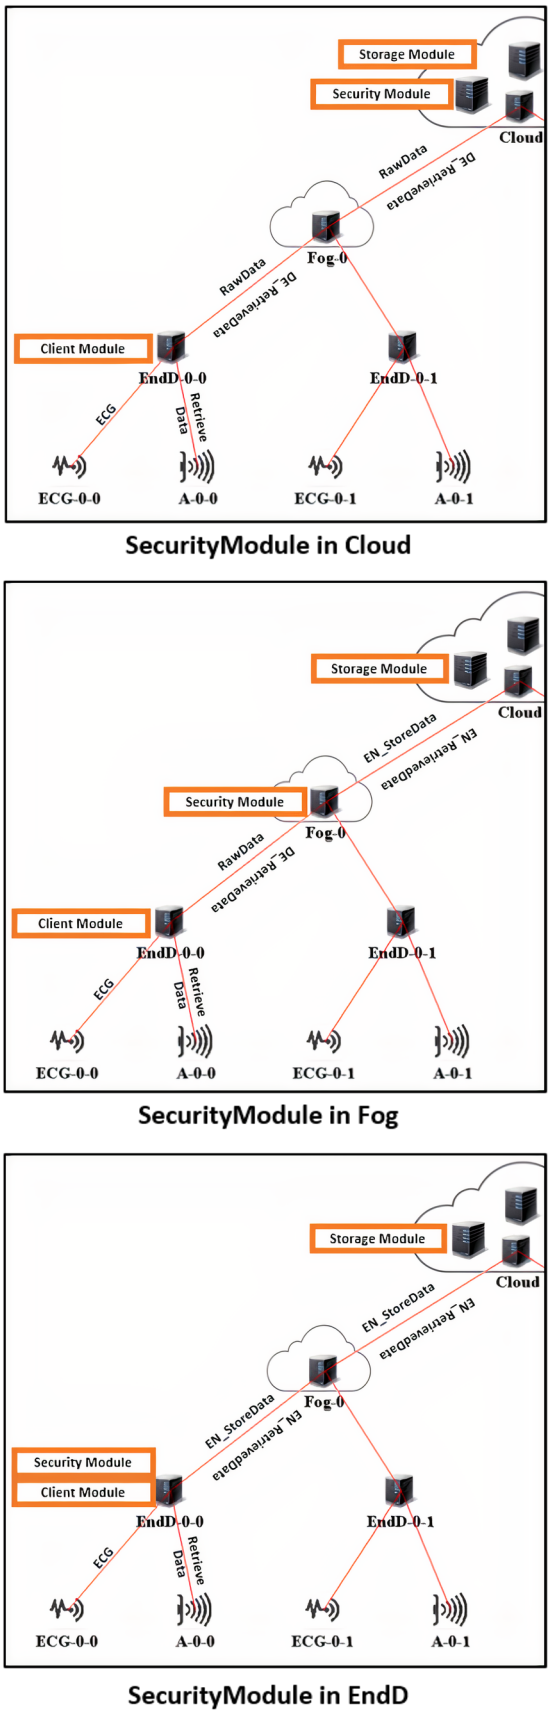

Fig. 3. The Different Placement Strategies.

FN and the end devices were in the same local network, and the connection between them was secure.

2) Network Use:: As shown in Fig. 6, the increase in the number of the connected devices greatly increased the load on the network, especially when implementing the security module in the cloud or end devices. When considering the security module's implementation strategy on the FN, the network use decreased significantly.

This result demonstrated that network congestion can be avoided when adopting a fog-based implementation, as the data is processed near the data source, thereby reducing the amount of information sent to data centers in the cloud significantly. Other placement strategies engender degradation and congestion in the network.

3) Energy Consumption:: MIoTs and end devices, or gateways, have limited processing capability, minimal storage space, and inadequate power, because they are often battery operated, and therefore lack sufficient power to secure medical data. This study sought to preserve the resource consumption, such as the energy resources of the MIoT layer, and consequently recorded various measurements of energy consumption in the end devices, according to different placement strategies for applying the security module.

Fig. 7 shows the average energy resource consumption in the end devices when implementing the security module in the cloud, end device, or FN. A significant reduction in energy consumption was observed in the case of the fog-based implementation that contributed to the preservation of the limited resources in the end devices.

B. Security Analysis

The security of the proposed model was analysed from the perspective of data confidentiality, fine-grained access control, collusion attack resistance, and forward secrecy.

1) Fine-grained Access Control:: This is a mechanism whereby legitimate users are given different access privileges to the data. Fine-grained access control was also attained in the model as it was a feature of the CP-ABE scheme that gave each legitimate user different access to the medical data concerned, according to the user's attributes and role.

2) Data Confidentiality and Privacy:: This is a basic and important requirement when using the cloud for data storage. In this model, it was accomplished using CP-ABE, whereby the medical data was encrypted near its source in the local network, before it was sent for storage in the remote data centers or the cloud. Therefore, no unauthorized user could access the content of the medical information stored there.

3) Collusion Attack Resistance:: In this type of attack, users combine their attributes to obtain unauthorized data illegally. These attacks can be conducted by system users seeking higher access rights, therefore, a system should prevent users from undertaking such attacks. To avoid this kind of attack, and to prevent users from combining their attributes in order to decipher the medical data, the proposed data protection scheme employed CP-ABE; since each attribute was associated with a polynomial or a random number, different users could not collude to obtain higher data access rights.

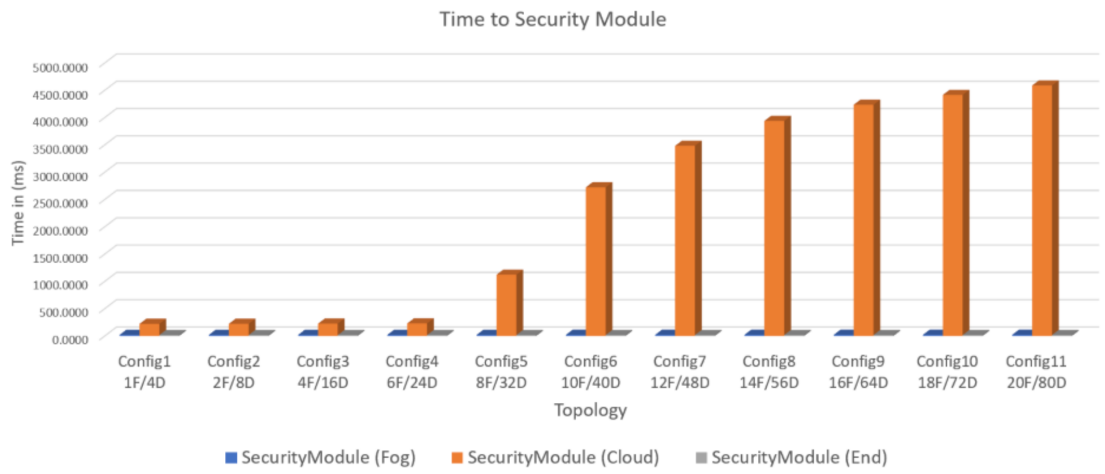

Fig. 4. Time to Security Module.

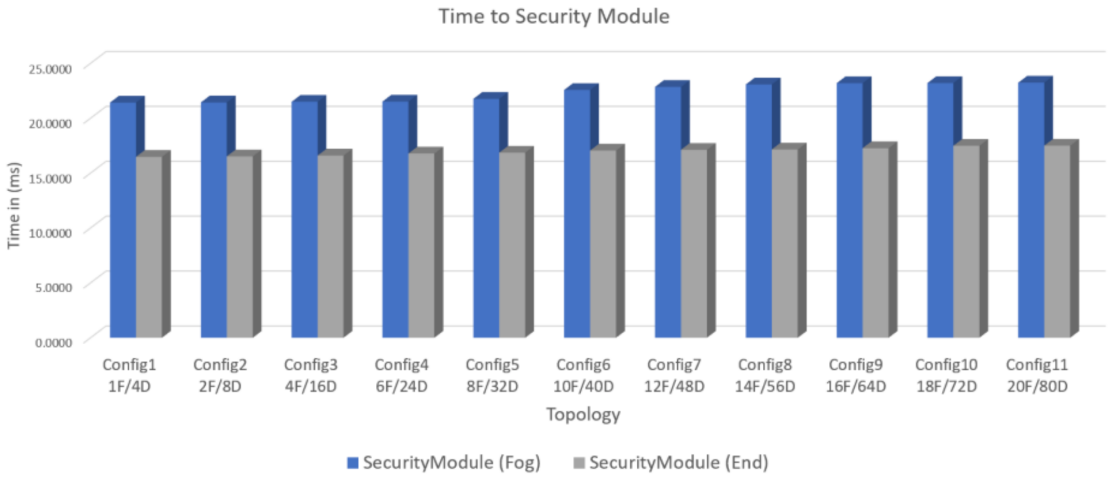

Fig. 5. Time to Security Module - The Comparison between Fog and End Device.

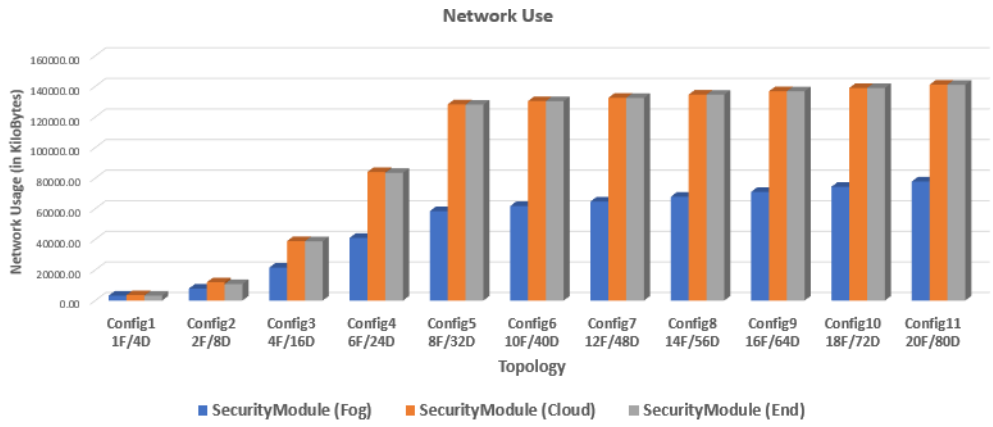

Fig. 6. Network Use.

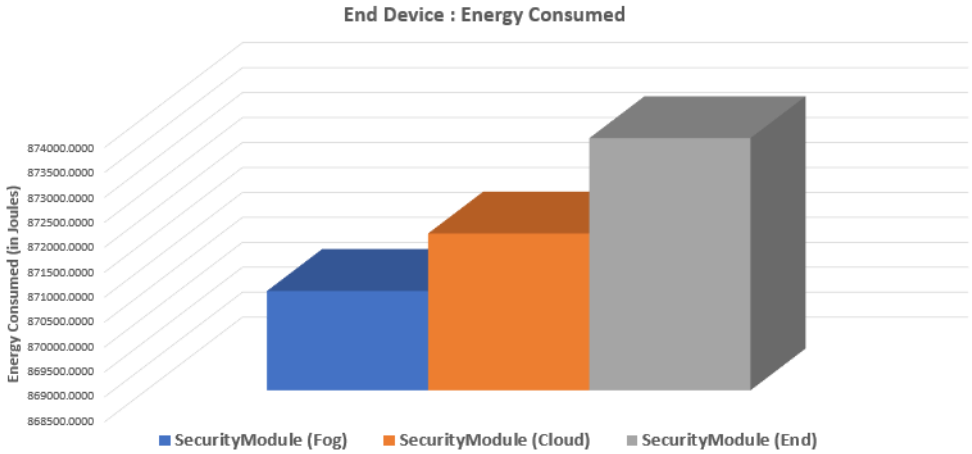

Fig. 7. Energy Consumption.

4) Forward Security:: This involves the prevention of any user who has been revoked from accessing and deciphering the medical data concerned. It was achieved in the proposed model by publishing the UL in the FN that contained the legitimate users with their set of attributes. Once a user left, the list was updated by the KA, thereby preventing the user who had left the system from accessing the medical data.

C. Comparison Analysis

The proposed model was compared with the previous works discussed in Section III in terms of the requirements presented in Section V-C. As previously mentioned in Section V-C, the related works as in [9] relied on MIoT devices to preserve data security and perform complex computations. This engenders the rapid depletion of the end device's energy and occupies it with other non-medical processes that may affect the efficiency of the sensors and the monitoring of vital parameters. In the proposed model, we employed FN to prevent costly computations, and thus, preserve the energy consumption of the MIoT devices. Concisely, the proposed model achieves all the predefined requirements including energy efficiency.

VI. Conclusion

This paper presented a fog-cloud system for the MIoT, in which the resource-limited end devices employed FN to prevent costly computations. It examined the feasibility of the proposed architecture, and the capability of the schema to manage security threats. The results demonstrated the benefits of adopting the fog-based implementation for protecting medical data and conserving MIoT resources, together with the ability to optimize network usage, and to avoid congestion, while reducing the amount of data sent to the data centers in the cloud significantly. It is hoped that the proposed model will encourage the adoption of MIoT devices and services, and thus encourage the healthcare industry to improve patient care services, and provide a better healthcare experience. For future work, we want to consider a technique with a wider range coverage to allow reducing the number of gateways. We also plan to conduct a real-time experiment to validate the proposed model.

Efficient Weighted Edit Distance and N-gram Language Models to Improve Spelling Correction of Segmentation Errors

Hicham GUEDDAH
Intelligent Processing and Security of Systems Team- F.S.R,
E.N.S, Mohammed V University in Rabat,
B.P:8007, Avenue des Nations Unies, Agdal, Rabat, Morocco.
https://www.researchgate.net/profile/Hicham-Gueddah

***Abstract*—In most research that has dealt with the correction of spelling errors, the errors are caused by the misuse of space (deletion or insertion of space) are not tackled. Forgetting to deal with this type of errors in the texts poses a problem of understanding and ambiguity of the meaning of the sentence containing these errors. In this article, we propose a new approach to correct errors due to the insertion of space in a word, and at the same time correct other types of editing errors. This approach is based on the edit distance and uses bi-grams language models to correct words in context. The test conducted on hundreds of erroneous words (by insertion of space and/or by simple editing errors) made it possible to assess the relevance and validity of the methods developed to correct this type of error. The approaches proposed in this article provide a very important clarification and reminder by comparing them to those of other existing approaches.**

***Keywords*—Spelling correction; error; natural language; insertion; space; distance; language models; probability**

I. Introduction

For several years now, the language industry and new information and communication technologies have been evolving. Alongside this progress, thousands of electronic documents such as newspapers, emails, blogs, dissertations and theses are produced on a daily basis. Therefore, the existence and need for spelling correction systems in NLP applications is of paramount importance to improve and help with sound and unambiguous writing.

Automatic spelling error correction is currently ubiquitous and integrated into all computer tools such as word processing, email, social media, search engines, which are frequented every day by millions of people around the world.

For a long time, by analyzing the strategy of correction systems integrated into large word processing software such as Microsoft's WinWord, OpenOffice Writer, or those embedded in web textures (email, search engine), we have pointed out that these remain ineffective for correcting certain types of spelling errors. They're committed when typing Arabic text, for example, which we cite as errors resulting from insertion and/or untimely deletion of the space character in a lexical form.

Their strategies consist only in proposing solutions separately to segments divided by the insertion of space.

Automatic correction of spelling errors has been the topic of much research since the 1960's [1]. Despite the monopolization of this axis by the major computer production industries,it remains a promising domain of research [2][3]. The principle is to propose the most similar solutions to a word detected out of vocabulary based on the lexical similarity inter words.

Among the work in the subject area of spelling correction, we mainly include:

Damerau's analysis of typographical errors [4]. He indicated that about 80-95% of mistakes in English texts are unique errors that are induced by poor insertion, deletion, permutation of a single character or the transposition of two adjacent character. This analysis has been the cornerstone of the concept of error as a simple or multiple combinations of operations, called elementary editing operations (insertion, deletion, transposition, and permutation).

Based on Damerau's work, Levenshtein [5] considered only three editing operations (insertion, deletion, permutation), and subsequently defined a metric that allows us to compare two words while calculating the number of editing operations undergone on one word to turn it into some other word. This distance is also called edit distance which remains, despite the technique, the most widely used in spelling correction and which has also been the themes of several adaptations and weighting [6]. Then a series of similar works were carried out. We can put them into different categories:

- Metric-based correction approaches such as Jaro distance [7], Jaro-Winkler distance [8], Jaccard distance [9], distance of Stoilos [10].
- Probabilistic correction approaches such as n-grams decomposition [11], the correction method based on the noisy channel model [12], Alpha-code methods [13], or those based on probabilistic automatons [14], [15]
- Since 2012 Gueddah, Yousfi and Nejja have carried out a series of work on spelling correction for the Arabic language, with the aim of improving the scheduling rate of solutions returned by the classical edit distance [16] [17] [18], or integrating the morphological analysis into the spelling correction phase [19] [20], or integrating context into spelling correction [21] [22].

II. Related Work

Based on our bibliographical research on spelling correction, we noticed that the bulk of this work did not adequately address the errors due to insertion or deletion of space in the seized texts. The number of works dealing with this category of error is very negligible compared to the number of works in the field of spelling correction.

The work that dealt with errors due to the insertion or deletion of space is of two types:

- Census-type studies: Mitton [3], and Kukich [1] noted that more than 14% of spelling mistakes in seized text are mainly related to the omission of the space between words. Conforming to a statistical study of errors made in Urdu typed text, Tahira [23] found out that space errors are a fairly significant percentage of errors, more than 75% of errors are neighborhood errors, 32% of which are linked to the insertion of space in words.
- Research work that provides hints for dealing with errors due to the insertion/deletion of space in words, either at the level of detection of this type of error or in the actual correction. This work includes, for example, the work that relies on the generation of all possible partitions of the erroneous word and testing whether or not the segments exist in the dictionary [24][25][26].
- The study presented by Alkanhal and al [27], according to the latter, the correction of space insertion errors uses two procedures, the initiative is to merge the different neighboring words from the wrong word. The outcome of this procedure is a list of the various possible combinations of this merger. This list may contain valid fragments and other erroneous fragments that will subsequently be handled on to the second correcting procedure.

In this article, we suggest a new metric approach that uses bi-gram language models to correct spelling errors due to the insertion of spaces (also called segmentation errors), into a correct or incorrect word taking into account the context in which this type of error was induced.

III. Errors Due to Space Insertion and Deletion

A. Defining Space Errors

Although the emergence of new generations of near-present correctors in most word processing editor, emails, blogs, social media, smartphones, these remain ineffective and unsuccessful [28] with regard to correcting errors due to the insertion or deletion of space in or between words. These forms of mistakes can be induced in several situations:

- Because one writes by accelerating without regard to who has been seized, the editor may unintentionally insert one or more spaces within a word in the belief that he inserted it to separate between two words. Therefore, this type of error leads to the appearance of two or more segments of words that may be lexicon or wrong words.
- Moreover, this kind of error can be due to poor optical text recognition (OCR), which can additionally insert the space character inside the word, or as a result of a file type conversion, such as converting Word documents to Pdf or vice versa.

However, the problem of actual word error is more complex. Generally, such an error disrupts the syntax and then rectify it.

Example:

Instead of typing the word "misspelled", you add a space in that word and you get both sequences "missp" and "elled". Instead of typing the two words "to get vaccinated", you remove the space between these two words, and you get the only word "toget vaccinated".

There are cases where this type of error is combined with other types of editing errors, i.e. in the same word w, we have errors due to editing operations more than a space insertion(after inserting the space we have both words w_1 and w_2).

In this case, there are four cases:

- Both segments w_1 and w_2 are not changed. In this case the solution of the correction is simply w_1-w_2-w, for example "vacci nating instead of vaccinating".
- The first segment w_1 has been modified, and w_2 not, for example: "vaxi nating instead of vaccinating".
- w_2 has been modified and w_1 not, example of "vacci nathing instead of vaccinating".
- Both segments w_1 and w_2 are modified, for example: "vaxin ating instead of vaccinating".

In the last three cases we must stick the two segments w_1 and w_2 (w_1-w_2) and then correct the new merged word.

In the recently published work Yousfi and al.[30], the authors used and adapted the Levenshtein's algorithm to detect and correct errors due to space deletion between words in the case of Arabic texts.

In this paper, we will propose a new approach to correct space insertion errors, and to integrate it with other approach that which corrects deletion errors and other editing errors, in a single one that corrects these three types of error at the same time.

B. Introducing the Approach to Correcting Deletion Space Errors

Either w_{err} a erroneous word of length n, and w_i a word of the lexicon of p_i length. Among the errors in the wrong word w_{err} perhaps the space that is removed between several words more other types of editing errors (insertion, deletion, and permutation).

The approach is done in two stages:

- The detection of the position in the word w_{err} where space will be inserted.
- The correction of the two sequences obtained after the insertion of the space.

We note by: $D_L(w_{err}, w_i) = D_L(n, p_i)$, Levenshtein's distance between two words w_{err} and w_i. For the detection of the position where space will be inserted (noted $pos.space_i$), the authors gave the following rule:

$$pos.space_i = \underset{j=1,\ldots,n}{\arg\min}\ DL(j, p_i) \tag{1}$$

After the insertion of space, we get the two words w_{1space_i}, w_{2space_i}, and we move on to the second phase.

The second phase verifies whether the two words exist in the lexicon or not, otherwise we move on to the correction. To correct errors due to the deletion of spaces between words and other types of editing errors at the same time, the authors defined a new distance (noted D_{LS} based on the Levenshtein distance (edit distance):

$$\begin{aligned} D_{LS}(w_{err}, w_i) = Min[D_L(w_{err}, w_i); D_L(w_{err}, w_{1space_i}) \\ +space + w_{2space_i}] \\ where\, D_L\, is\, the\, edit\, distance \end{aligned} \tag{2}$$

The scheduling of solutions is based on this new D_{LS} distance.

In the sequel, we will present the new approach we propose in this paper to correct errors in the insertion of space inside word, and then we will show how to integrate it with the previous approach in a single one. Then all types of spelling errors can be corrected (editing errors, errors due to deletion and insertion of space).

IV. The Approach to Correcting Space Insertion Errors

This approach is based on the edit distance and on the bi-grams language models. In the rest of this paragraph, we will give a little reminder on these two concepts.

A. The Edit Distance

The metric method introduced by Levenshtein [5] measures the similarity between two words by calculating an edit distance. The edit distance is defined as the minimum number of basic editing operations required to turn an erroneous word into another word in the dictionary. Thus, to correct a wrong word, we retain a set of solutions requiring as few editing operations as possible.

The procedure for calculating the distance of Levenshtein between two strings $X = x_1x_2\ldots x_m$ of length m and $Y = y_1y_2\ldots y_n$ of length n, consists of calculating from near to near in a matrix of order $(m*n)$ the edit distance between the different sub-chains of X and Y.

The calculation of the case (i,j), which corresponds to the editing distance between the sub-chains $X_1^i = x_1x_2\ldots x_i$ and $Y_1^j = y_1y_2\ldots y_j$, is given by the following recurring relationship:

$$D(i,j) = Minimum \begin{cases} D(i-1,j)+1, \\ D(i,j-1)+1, \\ D(i-1,j-1)+cost \end{cases} \tag{3}$$

with

$$cost = \begin{cases} 0 & \text{if} \quad x_{i-1} = y_{j-1} \\ 1 & \text{otherwise} \end{cases} \tag{4}$$

The limitation of such a spelling correction system using the edit distance is that it does not allow a good scheduling of suggested solutions for a set of candidates with the same edit distance.

B. N-gram Language Models

The importance of language models is quite clear. They are used in several areas of NLP, such as continuous speech recognition, machine translation, etc. The main goal in these different applications is to have some solutions weighed against others.

A n-gram language model shows the fact that the probability of a word appearing after a sequence of words can be given only on the basis of the last $n-1$ words [29].
This model verifies:

$$Pr(w_i/w_1, w_2..., w_{i-1}) = Pr(w_i/w_{i-n+1}, .., w_{i-1}) \tag{5}$$

In practice, the value of n does not exceed order 3.

- If $n = 1$, the model is called a uni-gram model. This type of model does not take into account any history of the word.
- If $n = 2$, the model is called a bi-gram model. This type of model only takes into account the previous word: $Pr(w_i/w_1, w_2..., w_{i-1}) = Pr(w_i/w_{i-1})$
- If $n = 3$, the model is called a tri-gram model. This type of model takes into account only the previous two words: $Pr(w_i/w_1, w_2..., w_{i-1}) = Pr(w_i/w_{i-1}, w_{i-2})$

For the construction of n-gram language models, learning is done on a corpus of texts that must encompass all possible successions of words belonging to the vocabulary of the language used. This construction consists of estimating all the probabilities already mentioned.

V. Processing Space Insertion Errors

The processing of this type of error normally goes through the following two steps: the detection that one has an error due to the insertion of space into a correct or erroneous word, and the phase of correction.

A. Detection of Errors Due to the Space Insertion

Here we cite methods that are not 100% correct to detect errors in inserting space into a correct or erroneous word. We have cases where the probability of having a space insertion error is very high.

Among these cases we cite:

- If two successive words w_1 and w_2 are erroneous, then the probability is very high to have inserted a space that gave us these two wrong words. In this case, we concatenate the two words, and we treat $w_1 - w_2$ as a single word that must be submitted to

the correction procedure. However, this is not always the case as we can have two successive erroneous words without having a space insertion error ("The wolrd vaxinated against Covid" instead of "The world vaccinated against Covid"

- If we have a word consisting of a single character, then this may be due to a bad insertion of space into a word ("v accination" instead of "vaccination".
- If we have some kind of erroneous word and the following word is correct, it may be due to a space insertion into a word ("vacci nation" instead of " vaccination").

So from what we have presented, it is very difficult to fix cases and say that they are the only ones that exist for space insertion errors.

There are even cases where you insert a space into a word and you get two sequences that are both correct ("foot ball" instead of "football").

For this, we will treat the problem of space insertion according to two methods:

- **Method 1**: The space insertion error is only addressed if we have two successive words that are wrong, working with an H1-rated hypothesis that will be defined afterwards. If we have a single erroneous word, we correct it in a simple way.
- **Method 2**: Once we have a wrong word and regardless of the next word, plus the simple correction of that wrong word, we add the corrections of the error due to the wrong insertion of space between that wrong word and the two neighboring words.

B. Correcting Space Insertion Errors using Method 1

This method uses the following hypothesis:

If we have a correct word, then we should not change it.

Be a text $T = w'_1 w'_2 \dots w'_n$ consists of a set of words typed in that order, and suppose that we have two successive erroneous words w'_i and w'_{i+1}. To also take into account space insertion errors, and use the H1 hypothesis, all the corrections proposed for these errors consist of two sets:

- All simple corrections of the two words w'_i and w'_{i-1} (assuming we don't have errors in inserting or deleting space). This set is given by the following rule:

$$S_i^1 = \underset{w_k \in Lexique}{\arg\min} \frac{D_L(w'_i, w_k)}{Pr(w_k / w'_{i-1})} \tag{6}$$

and

$$S_{i+1}^1 = \underset{w_k \in Lexique, w_i \in S_i^1}{\arg\min} \frac{D_L(w'_{i+1}, w_k)}{Pr(w_k / w_i)} \tag{7}$$

- we Concatenate w'_i and w'_{i+1} (w'_i+w'_{i+1}), i.e. assume that we have inserted a space in the word $w'_i + w'_{i+1}$ which produced the two wrong words w'_i and w'_{i+1}. For correction, we check if $w'_i + w'_{i+1}$ is in the lexicon of the system. If so, we keep the word $w'_i + w'_{i+1}$ as an ideal solution with edit distance equal to zero; otherwise we make the correction with the edit distance weighted by the bi-gram language model:

$$S_i^2 = \underset{w_k \in Lexique}{\arg\min} \frac{D_L(w'_i + w'_{i+1}, w_k)}{Pr(w_k / w'_{i-2})} \tag{8}$$

To take into account space insertion errors during the correction operation, we propose the distance rated D_{AL} which is defined as a follow-up:

$$D_{AL}(w'_i, w_k) = Min[\frac{D_L(w'_i, w_k)}{Pr(w_k / w'_{i-1})} + \frac{D_L(w'_{i+1}, w_k)}{Pr(w_k / w'_i)}, \frac{D_L(w'_i + w'_{i+1}, w_k)}{Pr(w_k / w'_{i-2})}] \tag{9}$$

The best corrections are those that check :

$$\min_{w_k \in Lexique} D_{AL}(w'_i, w_k) \tag{10}$$

C. Correcting Space Insertion Errors using Method 2

For this method, we do not use the H1 hypothesis; and in this case, we can modify words that were correct. The list of solutions or corrections for the erroneous word w'_i proposed is of three types:

- The set of all simple corrections of the word w'_i (assuming we have no errors in the insertion or deletion of space). This set is given by the rule given in equation number (6)
- we concatenate w'_{i-1}, correct word, and w'_i ($w'_{i-1} + w_i$) and check if $w'_{i-1} + w'_i$ in the lexicon of the system. If so, we keep the word $w'_{i-1} + w'_i$ as an ideal solution with edit distance equal to zero, otherwise the correction is made with the edit distance weighted by the bi-gram language model :

$$S_i^2 = \underset{w_k \in Lexique}{\arg\min} \frac{D_L(w'_{i-1} + w'_i, w_k)}{Pr(w_k / w'_{i-2})} \tag{11}$$

- We concatenate w'_i and w'_{i+1} (w'_i+w'_{i+1}) and we check if w'_i+w'_{i+1} is in the lexicon of the system. If so, we keep the word w'_i+w'_{i+1} as an ideal solution with distance equal to zero; otherwise the correction is made with the edit distance weighted by the bi-gram language model:

$$S_i^3 = \underset{w_k \in Lexique}{\arg\min} \frac{D_L(w'_i + w'_{i+1}, w_k)}{Pr(w_k / w'_{i-1})} \tag{12}$$

To take into account space insertion errors during the correction operation, we apply the D_{AL} distance, which this time is defined as follows:

$$D_{AL}(w'_i, w_k) = Min[\frac{D_L(w'_i, w_k)}{Pr(w_k / w'_{i-1})}, \frac{D_L(w'_{i-1} + w'_i, w_k)}{Pr(w_k / w'_{i-2})}, \frac{D_L(w'_i + w'_{i+1}, w_k)}{Pr(w_k / w'_{i-1})}] \tag{13}$$

The best corrections of the wrong word w'_i are given by the following formula:

$$\underset{w_k \in Lexique}{\arg\min}\ D_{AL}(w'_i, w_k) = \underset{w_k \in S_i^1 \cup S_i^2 \cup S_i^3}{\arg\min} [\frac{D_L(w'_i, w_k)}{Pr(w_k/w'_{i-1})}, \frac{D_L(w'_{i-1} + w'_i, w_k)}{Pr(w_k/w'_{i-2})}, \frac{D_L(w'_i + w'_{i+1}, w_k)}{Pr(w_k/w'_{i-1})}] \quad (14)$$

Its solutions belong to one of the sets of S_i^1, S_i^2 and S_i^3 :

1) If a solution belongs to S_i^1, we correct w'_i by this solution, and we go to w'_{i+1} to check whether or not this word exists in the lexicon; otherwise we repeat our correction approach quoted here on w'_{i+1}
2) If a solution belongs to S_i^2, we removew'_{i-1}, we correct w'_i by this solution, and switchto w'_{i+1}. We check w'_{i+1} whether we exist in the lexicon or not, or we apply our correction approach to w'_{i+1}.
3) If the solution belongs to S_i^3, we correct w'_i with this solution, we delete w'_{i+1}, and we move to w'_{i+2}. We check whether w'_{i+2} exists in the lexicon or not, otherwise we apply our correction approach to w'_{i+2}.

When the correction is completed, the new sentences are scheduled with the original sentence, $w'_1 w'_2 \dots w_n$ by the edit distance taking the space as a character: $D_L(w'_1 w'_2 \dots w'_n, w'_1 w'_2 \dots, w'_{i-2}, w_{i-1} \dots, w_k) \quad k \leq n$

Example:
"The world vaccinated against Covid"
We have two successive erroneous words, so we do the processing according to the two methods.

Method 1:

- The corrections of the two erroneous sequences "vacc" and "inated" are "vacc" ={ vaccine, vice, Vicki, vaccines..}, and "inated"={noted, anted, named, mated, hated...}. The best corrections are distance 1, so the sum 1+1=2.

- The corrections of the word "vaccinated", after deleting space between sequences "vacc"and "inated" we obtain this word which is a lexicon entry.
- Applying the distance D_{AL} the min between 0 and 2 is 0 and like that, the best correction is "vaccinated" ("The world vaccinated against Covid")

Method 2:

- The first wrong word is "vacc", so the three sets without taking into account the language models in the formulas, S1, S2, and S3 are:
  - S1- corrections of the wrong word "vacc" ={ vaccine, vice, Vicki, vaccines..}
  - S2- corrections of the wrong word "worldvacc"={$\varnothing$}, in reality no suggestion
  - S3- the corrections of the word "vaccinated", this word is a lexicon entry.

TABLE I. RECALL AND ACCURACY OF DIFFERENT METHODS

	Recall	Accuracy
Method 1	82%	91%
Method 2	76%	88%

Words in S1 have a distance greater than or equal to 1, and words in S2 have a distance greater than or equal to 2. So the words that check the rule in equation (14) is "vaccinated" that is, the solution belongs to S3, so we correct "vaccinated" and we delete "inated", So the new sentence after the correction is: "The world vaccinated against Covid".

VI. TESTS AND RESULTS

The corpus on which we conducted our test is composed of 100 paragraphs taken from the Wikipedia site, and in each paragraph, we randomly created space insertion errors in words in those paragraphs in addition with other types of editing errors.

In total, we have 1000 errors due to the insertion of space into words that are correct or erroneous. These errors are created according to the four types of space insertion errors cited in subsection (3.1.)

In order to evaluate the different methods used for spelling correction, we use the classic evaluation measurements by calculating recall and accuracy. The results obtained are cited according to these four types of error, and are as mentioned the Table I. In order to test the robustness of our approach with these two methods, we compared it to a widely recognized commercial spell checker.

The first results approved that our approach achieves a very high correction rate compared to this corrector: 89.5 % of the suggested correction for errors due to the insertion against only 19.12 % for the commercial corrector. this can be interpreted by the fact that this corrector does not take into account the existence of this type of error due to the insertion.

CONCLUSION

According to the results obtained, we can say that our new proposed approach is an effective method to correct errors due to space insertion comparing with other commercial spell checker. In other hand, our approach present an acceptable and better complexity level compared with other approach based only on n-gram language models.

***Abstract*—The aim of this paper is to avoid any future health crises by analysing COVID-19 data of Morocco using Time Series to get more information about how the pandemic is spreading. For this reason, we used a statistical model called Seasonal Autoregressive Integrated Moving Average (SARIMA) to forecast the new confirmed cases, new deaths, cumulative cases and deaths. Besides predicting the spreading of COVID-19, this study will also help decision makers to better take the right decisions at the right time. Finally, we evaluated the performance of our model by measuring metrics such as Mean Squared Error (MSE). We have applied our SARIMA model for a forward forecasting in a period of 50 days, the MSE reported was 62196.46 for cumulative cases forecasting, and 621.14 for cumulative deaths forecasting.**

Keywords*—COVID-19, machine learning, seasonal autoregressive integrated moving average, SARIMA, statistical modeling, time series forecasting

I. Introduction

Since the announcement of sars-cov2 outbreak as a public health emergency by the world health organization (WHO) in January 2020, The world didn't stop counting its damage due to the spreading of this virus. The incessant stream of new unpredictable cases has caused crises in many countries. For instance, in Italy, the death toll caused by COVID-19 raised dramatically in a short period of time making it the biggest crisis since the Second World War. To control the crisis, many decisions have been made all over the world. However, all these efforts lacked efficiency since we didn't yet predict what the world needs in terms of tools and information to make better decisions, to end the pandemic as fast as possible, or at least prevent some of its dire consequences.

In Morocco, the first case was detected on March 2020, and by July 2021 the total cases reached 552635 confirmed cases and 9427 deaths according to the Moroccan health ministry [1]. The situation has become critical especially when COVID-19 reaches its peak at the critical phase. To manage this, the Moroccan government has taken many decisions regarding the timeline development of the disease, but as the pandemic hasn't been stopped yet, we can expect other peaks that should be predicted beforehand to minimize the consequences.

Many studies have been done to decrypt the spreading mechanism of the mysterious virus that has caused vast damage in different sectors. It was important for mathematicians, epidemiologists, and data analysts to analyze and model the phenomenon using various models and methods such as compartmental models [2, 3, 4, 5], machine learning and artificial intelligence models[6, 7], or statistical methods [8, 9, 10, 11].

In this paper, we present a new SARIMA model to forecast the new cases and deaths in Morocco to help decision-makers to prevent any critical phases. We have chosen to forecast COVID-19 using time series analysis. In Section II, we will present the related work. Then Section III will present the time series approach for forecasting, and the process of this study. Afterward in Section IV, we will describe the materials and methods we used in this work. Section V will be devoted to presenting the numerical results that will be discussed in Section VI. Finally, we will end this article with a general conclusion.

II. Related Work

A. Compartmental Models

Compartmental models are mathematical modelling of infectious diseases. One of the most important and commonly used of these models is the "Susceptible-Infectious-Recovered or Resistant" model known also as the SIR model, a simplest compartmental model based on the research of Anderson Gray McKendrick and William Ogilvy Kermack in 1927[12]. This model divides the population into three compartments or categories and calculates the transition rate between compartments. Other models had been extended from the SIR model like the SEIR[13] model dividing the population into four compartments instead of three, by adding a new one named "Exposed" representing people highly exposed to the infection.

Several studies have adapted the SIR and SEIR models to investigate the new coronavirus. Chen et al. [2] created the Bats-Hosts-Reservoir-People (BHRP), a transmission network model describing the transmission chain of the virus, from bats to people passing by the hosts and the seafood market, using the SEIR model. While Euloge Mouvoh et al. [3]described the impact of different intervention strategies on the spread of COVID-19 in Morocco using a contact-structured and age-structured-SEIR model considering the interventions dynamic between different age groups. On the other hand, Ben Hassen et al. [4]combined the Poisson Markov process with a SIR model to build a hybrid model called SIR-Poisson model to estimate deaths number at a certain date t. However, the SIR model failed to forecast COVID-19 in Isfahan, because the

assumptions that the SIR model is based on are not seemingly true for COVID-19 [5].

B. Artificial Intelligence and Machine Learning Models

In addition to compartmental modelization, Artificial Intelligence and machine learning models are highly recommended in such problems it can be used in various aspects. Ahmed et al. [6] suggested some problems related to the pandemic where Artificial Intelligence can act efficiently and expected that studies using those models will increase significantly when more COVID-19 data will be available. In this direction, Mbilong et al. [7] proved the efficiency of Deep Learning models by using six models of machine learning and deep learning to forecast COVID-19 in Morocco during 7 days.

C. Statistical and Time Series Methods

statistical methods have been used to forecast, identify and measure the damage due to the COVID-19 pandemic. Shang et al. [10]used time series analysis to identify any change points using excess in the counts of COVID-19 caused excess death in Belgium. Salgotra et al. [9] have chosen to predict COVID-19 in India using models based on genetic programming and evaluated by statistical methods and metrics. Alsulami et al.[11] presented a statistical method to study the effects of various factors on the deaths due to COVID-19. ArunKumar et al.[8]have forecasted COVID-19 cases using the statistical models SARIMA and ARIMA for 60 days in 16 countries.

In this paper, we have chosen to use the statistical model SARIMA to forecast cases in Morocco. In the next section, we will present the model and the process of this work.

III. COVID-19 Propagation by using Time Series Approach

Time series analysis is the process of analyzing a sequence of data recorded at a specific interval of time. As its name indicates time is a crucial variable in this process. It shows us how the problem studied is adjusted over time, and it provides an additional source of information extracted from the dependencies established between data and the time variable. Time series analysis is usually utilized for problems that are highly affected by time, it can be used to analyze and forecast trading data, weather data, electricity data, etc. With a representative sample and cleaned data, Time Series analysis can provide a lot of information about the phenomenon in question, or even forecast the future with high accuracy.
The Time series process requires 5 principal steps as shown in Fig. 1:

- **Data collection**: It's the first thing to do when using time series analysis, data can be collected by observation, experimentation , simulation or simply derived.
- **Data-preprocessing**: In this step, we prepare data collected to be used for forecasting, the preprocessing consists of cleaning data and handling the missing values.
- **Selection of Time series model**: Many time series models are available, but their efficiency depends on the data used for the study. In this step, we analyze data to extract its characteristics, to choose the best model for this study.
- **Model tuning**: It's a process that creates a combination of a manually specified subset of the hyperparameter space and evaluates each model to choose the best combination of those parameters. It's called also grid search.
- **Forecasting and interpretation**: After specifying the best parameters of our model, we can finally fit it and forecast our variables.

After explaining briefly the process of a time series analysis, we propose in the next section a comparison between two time series models known as Autoregressive Integrated Moving Average(ARIMA) and seasonal Autoregressive Integrated Moving Average (SARIMA).

A. Time Series Generalities (ARIMA VS. SARIMA)

The Autoregressive Integrated Moving Average model (ARIMA), is one of the models that are most widely used to forecast a time series. It describes the autocorrelations in data by combining the autoregressive model (AR); a linear regression between past and future values; and moving average model (MA) that considers the past forecast error and future values of data. The added value of ARIMA is the Integrated component (I) that describes the order of differentiation used to make data stationary [14].

ARIMA model depends on 3 parameters:
p: trend autoregressive order, **q**: trend difference order, and **d**: trend moving average order.

When time-series data present a seasonality pattern, we use the Seasonal Autoregressive Integrated Moving Average model (SARIMA) instead of ARIMA. SARIMA is an extension of ARIMA that can deal with seasonality to forecast seasonal Time series. It is composed of four parts. In addition to the three components of ARIMA described before, SARIMA is composed of seasonal components describing the seasonality pattern in data [14].

SARIMA depends on 4 other hyper-parameters (P D Q s) in addition to the ARIMA's parameters (p d q):

- **P**: Seasonal autoregressive order
- **D**: Seasonal difference order
- **Q**: Seasonal moving average order
- **s**: The number of time steps for a single seasonal period.

SARIMA model is described mathematically as :

$$\boxed{\varphi_p(B)\Phi_p(B^s)\nabla^d\ \nabla_s^D y_t = \ \theta_q(B)\ \Theta_{\mathcal{Q}}(B^s)\varepsilon_t} \qquad (1)$$

where:
y_t: is the forecast variable
$\varphi_p\,(B)$: is the regular AR polynomial of order p
$\theta_q\,(B)$: is the regular MA polynomial of order q
$\Phi_p\,(B^s)$: is the seasonal AR polynomial of order P

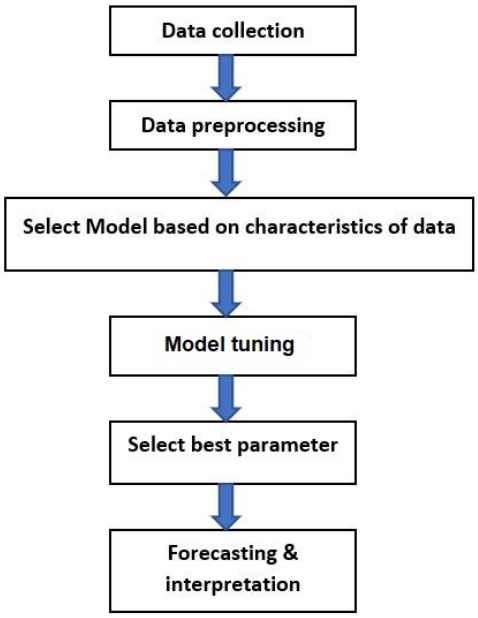

Fig. 1. SARIMA Process.

$\Theta_Q\,(B^s)$: is the seasonal MA polynomial of order Q
∇^d is the differentiation operator
∇_s^D is the differentiation operator
ε_t white noise process B back shift of y_t

To optimize our model and make sure that the parameters chosen are optimum, we used a process that creates a combination of a manually specified subset of the hyper-parameters space and evaluates each model to choose the best combination of those parameters. This process is known as grid search or model tuning.

IV. Materials and Methods

A. Methods and Data Preprocessing

We collected data from [15], it is a recording of corona cases in the whole world, for the period going from 24/02/2020 to 18/07/2021 with 103348 rows and 59 columns.

The data preprocessing in our case consists of creating new data for Morocco by using the global data collected, then cleaning this one by detecting the aberrant values in order to correct them, and finally dealing with the missing values by deleting some useless rows or filling them by fitting values. The specificity of time series data preprocessing is that we should also handle the trend and stationarity by de-trending data and making it stationary especially when using models like ARIMA or SARIMA.

The final dataset is new data recorded from 02/03/2020 (the date of the first case in Morocco) to 18/07/2021 with 504 rows (observations) and 29 columns. The new dataset is shown in Fig. 2

The new data was divided into two categories:

- Training data: is used to train and fit the model to find the best parameters.
- Testing data: is used for forecasting and assessing the performance of our model.

B. Time Series Analysis

In this section, we analyse the components of our data to extract the different characteristics of our time series data.

1) Trend: The first thing to check on time series data is the presence of a long-term movement called a trend in a cyclical context [16].

By plotting the data (Fig. 3), we observe the presence of a trend, but this should be proved by some tests. To test the presence of a trend in this time series, we used "pyMannkendal" a Python implementation of nonparametric Mann-Kendall trend analysis .

The mann-kendall test confirmed the existence of an upward trend on the data of new cases and new deaths with a significant p-value of p=5.329070518200751e-15 for new cases and 1.4821224705308111e-05 for new deaths. Before applying any model of forecasting, we should de-trend our data. There are many ways to do this, the most common method is differentiation.

2) Stationarity: Stationarity is one of the most important things to check before dealing with a time series. Stationary data means that the variance and the mean are constant over time. In other words, the data is stable [17]. However A non-stationary data is unpredictable data unless we make it stationary which is possible using some transformations. To test stationarity, we used two tests ADF and KPSS from the statsmodels package:

date	total_cases	new_cases	total_deaths	new_deaths	reproduction_rate	new_tests	total_tests	tests_per_case	total_vaccinations	people_vaccinated	...
2020-03-02	1	1	NaN	NaN	NaN	NaN	29.0	NaN	NaN	NaN	...
2020-03-03	1	0	NaN	NaN	NaN	4.0	33.0	NaN	NaN	NaN	...

2021-07-18	557632	2144	9450.0	16.0	NaN	NaN	NaN	NaN	20840340.0	11219675.0	...

504 rows × 29 columns

Fig. 2. Moroccan Data.

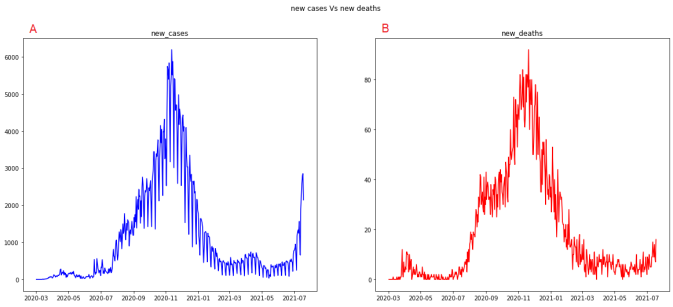

Fig. 3. A- Daily New Cases of COVID-19 in Morocco. B- Daily New Deaths due to COVID-19 in Morocco.

Fig. 4. A- Differencing Results of Original Series of New Cases. B- Differencing Results of Original Series of New Deaths.

- Augmented Dickey-Fuller test or ADF test: in which the null hypothesis admits the existence of unit root which means that the data is non-stationary [18].
- Kwiatkowski Phillips Schmidt Shin or KPSS test: unlike ADF the null hypothesis that we are testing in the KPSS is that our data is stationary [19].

The results of these two tests are shown in Table I.

Both ADF and KPSS tests confirm the non-stationarity of our data for the reasons below:

- For ADF:
  - The p-value is higher than the significance level of 0.05.
  - The ADF statistical test is higher than all the critical values.
- For KPSS:
  - The p-value is less than the significance level of 0.05.
  - The KPSS statistical test is higher than all the critical values.

It's indispensable to make data stationary before using it on a forecasting operation to make it predictable and to get relevant results. In our case, we have chosen the differentiation method to make it stationary. Fig. 4A and Fig. 4B show the data after 1st and 2nd order differencing, we can observe that our data had become stationary with the first differencing order and there is no need for a second one. To prove the stationarity of the new data, we have retested it with KPSS and ADF.

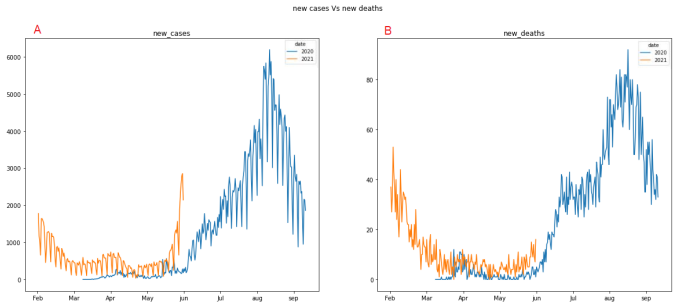

Fig. 5. A- Daily New Cases per Year in Morocco. B- Daily New Deaths per Year in Morocco.

3) Seasonality: The last component that we should verify is seasonality which means the presence of a pattern. In the Fig. 5A and Fig. 5B, we observe the existence of some pattern between 2020 (year of the appearance of COVID-19 In Morocco) and 2021. For example, the number of new cases increases between June and August, probably because of the school and summer vacations in which most people travel a lot and don't respect restriction policies. In contrast, the number of new cases decreases between November and February, and it is somehow stationary between February and January.

TABLE I. KPSS VS. ADF TEST RESULTS

		KPSS				ADF

V. NUMERICAL RESULTS

In this section, we present the results of COVID-19 daily new cases, new deaths, cumulative cases, and cumulative deaths forecasting using our proposed models.

After the model tuning, we have chosen the best parameters for each model. So we selected SARIMA (5,1,0)(1,0,1,7) to forecast new cases, and SARIMA (0, 1, 1) (2, 0, 2, 7) for the new deaths forecasting. The Fig. 6A shows the prediction of daily new cases, while figure Fig. 6C shows the prediction of daily new deaths for 104 days.

To measure the performance of our models, we calculated the Mean Equared Error(MSE), Root Mean Squared Error (RMSE), Mean Absolute Error (MAE) for 104 days in Table II, and we have compared our results with other persistent models.

In Fig. 6B and Fig. 6D we noted that the model fits very well at the first 50 days of forecasting and start deviating after, so we recalculated the errors for 50 days. Table III shows the metrics reported for the 50 days forecasting.

VI. DISCUSSION

In the present study, we developed a SARIMA model to fit the reported data of COVID-19 in Morocco. The proposed model was prepared to select the best parameters in order to predict cumulative cases and deaths, new daily cases, and deaths.

The results show that the proposed models fit very well at the first 50 days with a reported MSE of 316960.2267400527 for new daily cases forecasting, 8.28 for new daily deaths, 62196.46 for cumulative cases, and 621.14 for cumulative deaths. The model starts to deflect after 50 days and the error starts to become higher. We tested our model for a forecasting period of 104 days and have reported an MSE of 4881.384615384615 for cumulative deaths forecasting, and an MSE of 108689697.75 for cumulative cases.

The 104 days predictions results are good if we compare them to most of the reported results in [8] for 60 days forecasting in 16 countries, where the MSE variates between 6.63E+04 for cumulative cases in Bangladesh and 2.69E+09 for Brazil, while the MSE of cumulative deaths forecasting for the same number of days variates between 3.10E+00 in Spain and 2.24E+06 in India.

VII. CONCLUSION

Since the outbreak of COVID-19 in Morocco, the government has made many decisions regarding the real-time situation, therefore forecasting the COVID-19 impact could help in preventing any critical situation by making a well-informed decision.

In this paper, we used time series analysis, one of the most important aspects of data analytic to analyze Moroccan data by understanding components like trend and seasonality. The ultimate objective of this work was to predict cases (new confirmed cases, new deaths, cumulative cases, and cumulative deaths) for 104 days using the SARIMA model. The results of our proposed models matched with test data especially for the first 50 days of forecasting for both cumulative cases and deaths. Decision-makers should consider forecasting models like SARIMA in preventing any future critical situation.

Amrita Vishwa Vidyapeetham, India

***Abstract*—Synthesizing new images from textual descriptions requires understanding the context of the text. It is a very challenging problem in Natural Language Processing and Computer vision. Existing systems use Generative Adversarial Network (GAN) to generate images using a simple text encoder from their captions. This paper consist synthesizing images from textual descriptions using Caltech-UCSD birds datasets by baselining the generative model using Attentional Generative Adversarial Networks (AttnGAN) and using RoBERTa pre-trained neural language model for word embeddings. The results obtained are compared with the baseline AttnGAN model and conduct various analyses on incorporating RoBERTa text encoder concerning simple encoder in the existing system. Various performance improvements were noted compared to baseline Attention Generative networks. The FID score has decreased from 23.98 in AttnGAN to 20.77 with incorporation of RoBERTa model with AttnGAN.**

***Keywords*—Natural language processing; computer vision; GANs; AttnGAN; RoBERTa**

I. Introduction

Text to Image generation is an application of Generative Networks. The underlying problem comprises recognising the context of the text description and generating a realistic image that matches the caption. It is a multi-modal problem that challenges natural language Processing for context understanding and Computer Vision for Images. There are numerous applications in arts and design and have advanced considerably in recent years. Text to image generation can assist game developers to generate more distinct characters or skins with ease. Artists could use them to create starter comics from descriptions of the scene.

GANs are primarily used as generative networks for Image Synthesis from text and use Deep Convolutional GANs [1]. Recently, enormous progress has been made in synthesising images from texts for a single class of datasets like the Caltech-UCSD Birds-200-2011 dataset [2] or Oxford 102 Flower dataset. This paper uses the baseline AttnGAN model [3] that make use of Long Short term Memory for processing the text description. The latest language models developed lately has proved to be very efficient for text related problems. Thus it is required to utilize the latest transformer models so that better attention can be obtained within the natural language and hence increase the overall performance of the problem.

This problem can be divided into different parts and approached individually as a module. Text description is taken with details as input. The description includes features of its appearance, like the colour of particular body parts and its length. Text like, "this small bird has a short, pointy orange beak and white belly", are provided as input. The RoBERTa language neural model [4] to capture attention and understand the context of the description.

Fig. 1. Result of a Generated Bird from the Generative Model using RoBERTa Text Encoder and the Attention Captured during the Generation of Image at Epoch 600.

RoBERTa language model is used for embeddings words into a feature representation. Transform models use an attention mechanism to capture critical details associated with the word, and they can link them using the attention heads [5]. AttnGAN are used to train the generative networks. With each stage, higher resolution images are synthesized. Another component used in the AttnGAN is a Deep Attentional Multimodal Similarity Model (DAMSM). The attention mechanism and the DAMSM are used to find the similarity between the image generated by the GANs and the sentence using both the global sentence level and the fine-grained word-level information. The DAMSM component provides a fine-grained image and text comparison loss that can be used to train the generator [3].

The goal is to explore the current state-of-the-art model that can generate images based on the description from text using the Attention mechanism. RoBERTa language model is incorporated and experiments are performed on how the

existing system is affected. The same is analyzed and compare each result using the Fréchet inception distance (FID) score obtained from the base model. The focus is on the CUB Bird dataset for this paper, and the dataset also provides us with boundary box segmentation of bird images. Segmentation [6,7,8] can help train the model for generating a specific object in the boundary of images used from training . Analysis also performed on how RoBERTa embeddings have an effect in an interval of epochs on generating the images. The models are implemented using deep convolutional neural networks because they enhance the processed image [9,10]. The final output of the generative network is a high-resolution image matching the text description. Various attentions mapped are recorded with the experiments conducted and we obtain results as in Fig. 1.

The major benefits on exploring research on this problem lay in understanding the use of transformers with basic attention based generative system. This will help us explore how latest language models that uses attention heads can help understand the text association with the image better. A larger intuition could be developed in natural language association with text generation and scene prediction. This will help artists, game developers, animation industries to develop characters based on the textual description provided by the artists.

II. Related Work

Generative Adversarial networks are generative models that can synthesize images and are used for generative learning. In this network, a generator generates images based on the input from the embeddings and the noise. The discriminator help discriminate the picture as real or fake. Both generator and discriminator improve over time. The generator aims to generate images to fool the discriminator into thinking and classifying the images as real. These models were the first approach in generative networks [11] by Ian Goodfellow. There have been a variety of works on generative networks, and GANs have been able to generate photorealistic images with very high resolutions lately. Lately, generating images from text descriptions has been an area of research, and have few novel approaches to this problem.

The first approach to this problem was synthesizing low-resolution images from captions using Deep Convolutional GANs [1]. This system however could not completely produce image that looked realistic enough. Many images that were synthesised didn't exactly match the description either. This lead the author [12] to introduce Generative Adversarial What-Where Network (GAWWN). It exposed the control with the object's bounding box in the image and focused on particular parts. It modelled the distribution on various components like the tail and beak to obtain efficient results by focusing on that area. This proved to help identify key objects for generation but couldn't exactly focus on key details of objects like its poses or structure. A conditional Pixel Convolutional Neural Network (CNN) was used to synthesize images from text and used a multi-scale model structure. An image closer to the text description could be generated and a starting point to research the text to image using GANs. The image quality generated was an issue motivating Stack GANs, which used a stacked approach to improve the image resolution in different stages and generated 256 x 256 sized photorealistic images. The initial model was able to generate 64 x 64 resolution images. This approach generated an initial 64 x 64 images and was trained with GANs in two stages to get 128 x 128 images in Stage-I and 256 x 256 images in Stage-II. Each stage had an aim to improve the image quality to gain a photorealistic effect. StackGANs could generate photorealistic birds and flower images [13].

While this generated photorealistic images, proper context extraction was lacking. It paved the way to AttnGAN, which took a new approach by using an attention mechanism from the text description. Attention capturing helped the network to a closer understanding of context and better generation of images from text. AttnGAN used word embeddings and could capture important words from descriptions of birds [2] in the Caltech-UCSD Birds-200-2011 dataset. The attentional generative network could synthesize fine-grained details at various image subregions by providing detailed attention to the relevant words provided in the text description. This paper also introduced a deep attentional multimodal similarity model (DAMSM), used as the loss function and matched with text description and the generated image features. Word level condition selection was introduced to synthesize image details [3]. AttnGAN made use of bidirectional LSTM for the natural language processing. Similar to this work is the Controllable Text-to-Image Generation, which is used to synthesize high-quality images effectively by controlling parts of the image generation concerning natural language descriptions. In addition to the attention mechanism followed in AttnGAN, this paper used a channel-wise attention module and a word-level discriminator. It adopted a perceptual loss [14] in the text-to-image synthesis. Experimental researches have been performed by updating the architecture within the GANs by connecting generated image with the input description. The method of redescription was performed in MirrorGANs and Cycle GANs [15,16] using the BERT language model, where the authors obtained a great performance enhancement on complex datasets. Lately transformers have enhanced the neural language processing and is widely used in most of the latest intelligent systems. While the works performed till now has shown great result, it is very important to understand how these models could perform with the latest transformer models. This lead us to using latest neural language model RoBERTa as a pretrained model and incorporate it with the AttnGAN network instead of using basic LSTM system at language processing end. The aim of this paper is to analyze how well the AttnGAN model improves its performance using this system.

III. Dataset

Table I shows the Caltech-UCSD Birds-200-2011 (CUB-200-2011) [2] image dataset that contains 200 categories of birds were used for experiments. There are a total of 11,788 images with annotations. The images and annotations together size up to 1.1 gigabytes. This dataset is used as a benchmark dataset for all the text to image synthesis research works. The images along with them have boundary boxes provided and are of various sizes each.

This dataset [2] contains images of North American birds from 200 different species of ranges. The dataset (CUB-200) was created in 2010 and contains approximately 6000 photos of each of the 200 bird types. Additional label data, such as

TABLE I. STATISTICS OF DATASETS

Dataset	Train	Test
No: of Samples	8,855	2,933
No: of Captions	10	10

bounding boxes, crude segmentations, and additional features, accompanied this. The dataset was updated in 2011 (CUB-200–2011) to include new photos, bringing the total number of images in the dataset to around 12,000 (CUB-200–2011). 15 component locations, 312 binary attributes, and a bounding box per image were added to the accessible attributes . The photos and class labels will be used to create and train networks for predicting bird class for the majority of this series.

IV. METHODS

A. Attention GANs

Fig. 2 shows the architecture of the AttnGAN networks with RoBERTa neural language model. AttnGAN make use of an attention mechanism that embeds the generated caption from the Birds dataset and run through the RoBERTa model to generate word and sentence vectors. The text encoder takes the caption, which is a T words sentence. The sentence features contribute to the global vector, which is passed on to the noise vector. The sentence feature is the final hidden state with a dimension D.

$$\bar{e} \in R^D \tag{1}$$

Similarly, word features are extracted separately. It produces a hidden state from all timesteps for the T-word sentence.

$$e \in R^{DXT} \tag{2}$$

The conditioning augmentation has the randomly sample latent variables from the Gaussian distribution. So $\bar{e}$, which is received as an input to caption feature, is split into μ and σ with a fully connected linear layer. This is the mean and variance from the sentence embedding. The mean and variance generated are used to parameterize the normal distribution from which a sentence embedding sample gets generated to be passed on to the generative network.

It is combined with a noise vector so that the generated images show higher variation for a single caption. The c vector is concatenated with the Z noise vector, and this is used in further stages for the generation of various features of birds in the network. Similarly, word features are extracted separately. It produces a hidden state from all timesteps for the T-word sentence.

$$\begin{aligned} &\bar{e} \longrightarrow \mu, \sigma \\ &c = \mu + \sigma * \varepsilon, \varepsilon \sim N(0, I) \end{aligned} \tag{3}$$

The first generative network is mainly responsible for upsampling. The nearest neighbour interpolation is used to upsample with a scaling factor of 2. The output is generated with a 64 X 64 image. This stage does not use any word-level features that are extracted using the RoBERTa model. It utilizes the sentence level features, which is taken as input from the noise vector space.

$$\begin{aligned} &h \in R^{\hat{D} \times N} \\ &h_0 = F_0\left(z, F^{ca}(\bar{e})\right) \end{aligned} \tag{4}$$

The first attention model combines word features e, with the previous stage context h_{i-1}. The word features before combination are brought into a common space. This is represented using e' and obtained by adding a new perceptron layer. $e' = Ue$, where $U \in R^{\hat{D} \times D}$. Each column of h is a feature vector of a sub-region of the image.

$$s'_{j,i} = h_j^T e'_i \tag{5}$$

$$c_j = \sum_{i=0}^{T-1} \beta_{j,i} e'_i, \text{ where } \beta_{j,i} = \frac{\exp\left(s'_{j,i}\right)}{\sum_{k=0}^{T-1} \exp\left(s'_{j,k}\right)} \tag{6}$$

Combining them with the context, it generates a score for a particular sub-region j, and a word i. So a combination is brought out with a particular word with a sub-region and it's used for the word-context vector for that region. This process is repeated for each region. This provides us with the output of the attention network.

$$F^{attn}(e, h) = (c_0, c_1, \ldots, c_{N-1}) \in R^{\hat{D} \times N} \tag{7}$$

The second generator also is used for upsampling of the image and it obtains an image of 128 X 128. Here, along with the previous output as input from the first generator which carries the context vector, the word embeddings through the attention networks are also added which carries the word context vectors. The residual blocks here, make the network deeper and train them without degradation. Similarly, one more generator was used to upscale the image up to 256 X 256 and it takes input similar to that of the second generator.

In the end, 256 X 256 image is passed to an image encoder. In the image encoder, local image features can be extracted and this is converted to a common space to match the text encoder feature. These two are combined to make the Deep Attentional Multimodal Similarity Model (DAMSM) and this is trained with attention loss. The DAMSM model is pre-trained for stability in the system.

There are three discriminators each attached with its respective generators. The sentence level features is taken without noise vector as input to each discriminator. Two forms used in the network is the unconditional form that tells if the image is real or fake and the conditional form that tells if the image and caption are of the same pair. In unconditional pair, a result close to 1 is obtained if both the pair are matching.

1) Text Encoder: RoBERTa makes use of transformers that has attention mechanism which learns the contextual relationship between the words within the sentences.

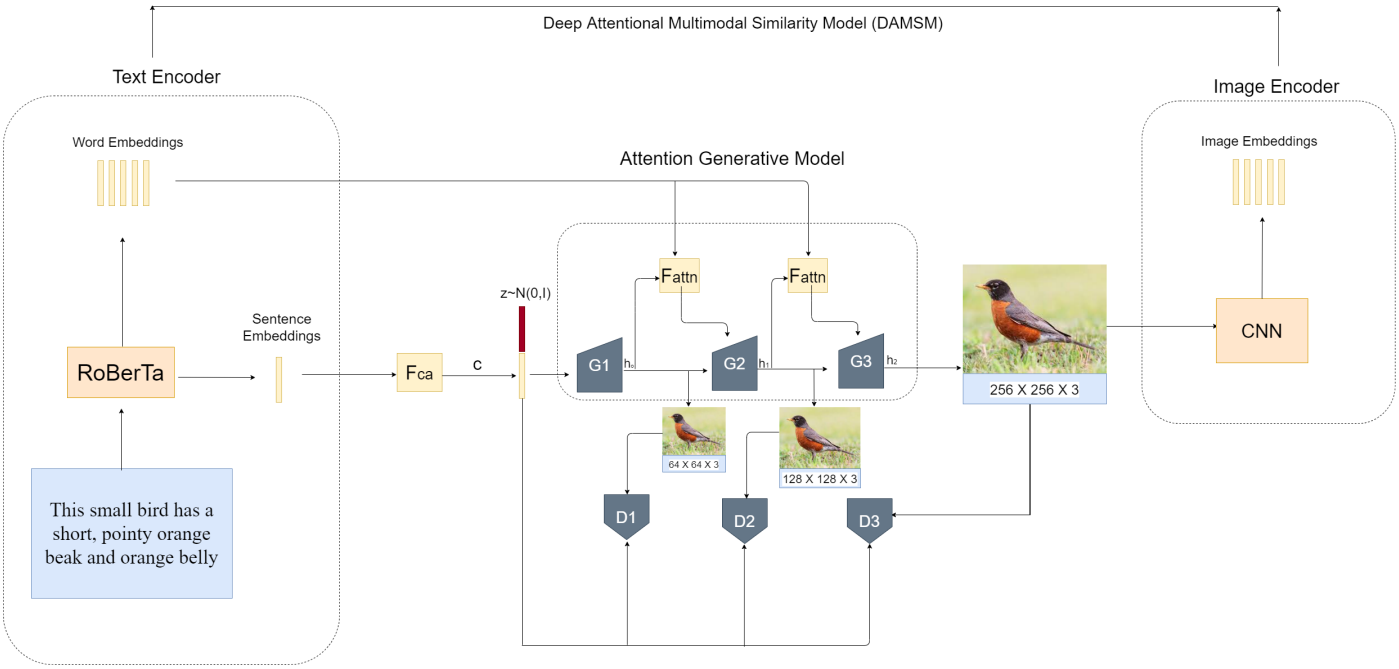

Fig. 2. Architecture of the Proposed System. RoBERTa Text Encoder is for Word Embeddings passed to Generative Network with Fine Grained Attention Networks; Text-Image Matching Loss Generated with DAMSM for the Generative Networks.

2) Image Encoder: The Image encoder is used with DAMSM as a convolutional neural network to extract the features out so that it can map to a common space. With CNN, the intermediate layers can learn various features associated with the different sub-regions of the image and the latter learns about the global features associated with them. A pre-trained Inception-v3 model on ImageNet was used as the image encoder. 768 is the local features dimension and it resizes the image to 299 X 299 pixels, to get 289 sub-regions in the image. In the end, these features are converted to similar space to that of the text encoder by adding perceptron layers.

3) Loss: For every generation, G_i a discriminator D_i and the loss is a combination of both conditional and unconditional at each stage. The embeddings of sentences is being conditioned on. The unconditional loss brings the generated images sampled from the generator of the particular distribution and is passed to the discriminator. The loss is minimized here so that the discriminator is fooled to think the image coming is real. For the conditional loss, passed $\bar{e}$ along with the generated image to the discriminator.

$$\mathcal{L}_{G_i} = \underbrace{-\frac{1}{2}E_{\hat{x}_i \sim p_{G_i}}\left[\log\left(D_i\left(\hat{x}_i\right)\right]\right.}_{\text{unconditional loss}} \underbrace{-\frac{1}{2}E_{\hat{x}_i \sim p_{G_i}}\left[\log\left(D_i\left(\hat{x}_i, \bar{e}\right)\right]\right.}_{\text{conditional loss}} \tag{8}$$

The discriminator uses cross-entropy loss and has data from the original distribution and the generated distribution. The discriminator will try to bring the original distribution close to 1 and the generated images output close to 0 to minimize the discriminator loss.

$$\mathcal{L}_{D_i} = \underbrace{-\frac{1}{2}E_{x_i \sim p_{\text{data}_i}}\left[\log D_i\left(x_i\right)\right] - \frac{1}{2}E_{\hat{x}_i \sim p_{G_i}}\left[\log\left(1 - D_i\left(\hat{x}_i\right)\right)\right] +}_{\text{unconditional loss}}$$
$$\underbrace{-\frac{1}{2}E_{x_i \sim p_{\text{data}_i}}\left[\log D_i\left(x_i, \bar{e}\right)\right] - \frac{1}{2}E_{\hat{x}_i \sim p_{G_i}}\left[\log\left(1 - D_i\left(\hat{x}_i, \bar{e}\right)\right)\right]}_{\text{conditional loss}} \tag{9}$$

B. RoBERTa

Attention GANs use basic RNN, which is a bidirectional LSTM. LSTM is used on the text description to extract the semantic vectors. With bi-directional LSTM, each word corresponds to two hidden states representing one for each direction [3]. RoBERTa: A Robustly Optimized BERT Pre-training Approach is the latest language model introduced by Facebook that optimizes the existing BERT architecture. It introduces the dynamic masking, hence the masked token changes during the training epochs. RoBERTa uses 160 GB of text for pre-training, including large Books Corpus and English Wikipedia are used in BERT. The additional data included CommonCrawl News dataset, Web text corpus and Stories from Common Crawl. The RoBERTa makes use of similar architecture as BERT Model but uses the byte-level BPE as the tokenizer [4]. The 'roberta-base' is the model used for prediction. The model was trained with an embedding dimension of 768. The pre-trained RoBERTa model is used to obtain the word and sentence embeddings and pass them with a fully connected layer before remaining in the Attention GANs architecture. The pre-trained model is 12 layered with

12 heads for the attention mechanism of the transformer and has around 125M parameters.

C. Deep Attentional Multimodal Similarity Model

Deep Attentional Multimodal Similarity Model (DAMSM) verifies if the generated image follows the description. It accompanies various steps to check this and update the network. The image features are brought f and $\bar{f}$ into a common space by adding a perceptron layer. The dimmension D is similar to the text encoders dimmension.

$$v = Wf, \quad \bar{v} = \bar{W}\bar{f} \tag{10}$$

$$v \in, R^{DX289}\bar{v} \in R^{D} \tag{11}$$

The matching score is driven by attention for the text and image features and calculate them as a pair The similarity matrix is calculated first for every pair in the sub-region of the image using

$$s = e^{T}v \tag{12}$$

In this equation, $s \in, R^{TX289}$ and i^{th} word in that sentence with the j^{th} sub-region available in that image. The normalized matrix for better result and stability,

$$\bar{s}_{i,j} = \frac{\exp\left(s_{i,j}\right)}{\sum_{k=0}^{T-1}\exp\left(s_{k,j}\right)} \tag{13}$$

Region-context vector c_i, is calculated. Earlier the interest was in generating the image, so it went through all the words and found the sub-region at each time. But, here it can be found if that particular word has any significance in the generation of that particular image. So for all the sub-region, it is needed to be checked one word at a time. This is summed here for all 289 sub-regions. $gamma_1$ is the attention scaling factor used in the equation and a score is generated for that and multiplied with the image features.

$$c_i = \sum_{j=0}^{288}\alpha_j v_j, \quad \text{where } \alpha_j = \frac{\exp\left(\gamma_1 \bar{s}i, j\right)}{\sum k = 0^{288}\exp\left(\gamma_1 \bar{s}_{i,k}\right)} \tag{14}$$

Word level relevance of i^{th} word is calculated with cosine similarity. It uses the current words, region-context vector and words vector. $R\left(c_i, e_i\right)$ tells us the score of each of those words on how important they are in generating the actual image.

$$R\left(c_i, e_i\right) = \left(c_i^{T}e_i\right) / \left(\|c_i\| \, \|e_i\|\right) \tag{15}$$

The word-level features are used to calculate the final global level scores. This image description score is calculated using word-level features with the hyperparameter γ_2, which signifies word to region context pair importance.

$$R(Q, D) = \log\left(\sum_{i=1}^{T-1}\exp\left(\gamma_2 R\left(c_i, e_i\right)\right)\right)^{\frac{1}{\gamma_2}} \tag{16}$$

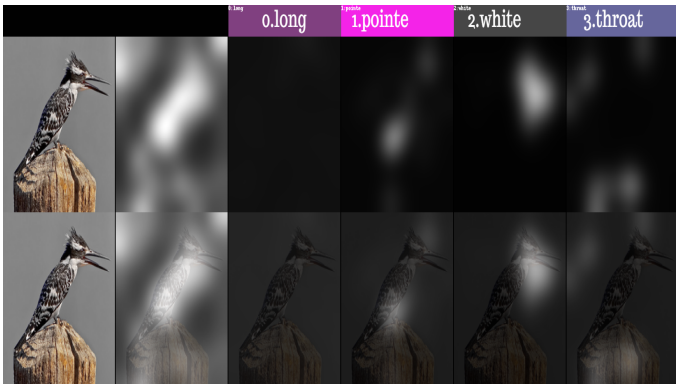

Fig. 3. Attention Map Generated by DAMSM on using RoBERTa Text Encoder. The Figure shows one Part of the Entire Caption Captured.

Similarly, using sentence-level features, using cosine similarity between global sentence and image features.

$$R(Q, D) = \left(\bar{v}^{T}\bar{e}\right) / \left(\|\bar{v}\|\|\bar{e}\|\right) \tag{17}$$

In the training process, calculation is done for the DAMSM loss for all the pairs. Thus with multiple descriptions and multiple images. The posterior probability is calculated of D_i matching with Q_i. So this gives a probability of how likely is that a description will be selected out of all the descriptions available. γ_3 is a hyperparameter for smoothing and stability in training the DAMSM. Similarly, it is also found the posterior probability when there is description and the images needs to be found.

$$P\left(D_i \mid Q_i\right) = \frac{\exp\left(\gamma_3 R\left(Q_i, D_i\right)\right)}{\sum_{j=1}^{M}\exp\left(\gamma_3 R\left(Q_i, D_j\right)\right)} \tag{18}$$

$$P\left(Q_i \mid D_i\right) = \frac{\exp\left(\gamma_i R\left(Q_i, D_i\right)\right)}{\sum_{j=1}^{M}\exp\left(\gamma_3 R\left(Q_j, D_i\right)\right)} \tag{19}$$

D. Total Loss

Total DAMSM loss in the network is calculated by

$$\mathcal{L}_{DAMSM} = \mathcal{L}_1^{w} + \mathcal{L}_2^{w} + \mathcal{L}_1^{s} + \mathcal{L}_2^{s} \tag{20}$$

L_1^{w} provides the word-level loss with respect to the description given the image and is the negative summation of log value of $P\left(D_i \mid Q_i\right)$. L_2^{w} provides the word-level loss with respect to the image given the description and is the negative summation of log value of $P\left(Q_i \mid D_i\right)$. L_1^{s} provides the sentence-level loss with respect to the description given the image. L_2^{s} provides the sentence-level loss with respect to the image given the description. Both the sentence level loss is same as word level loss except it use $\bar{e}$ instead of e.

Total loss in the entire network

$$\mathcal{L} = \mathcal{L}_G + \lambda\mathcal{L}_{DAMSM}, \text{ where } \mathcal{L}_G = \sum_{i=1}^{3}\mathcal{L}_{G_i} \tag{21}$$

Here, L_G is the generator loss summed with L_{DAMSM} multiplied by a hyperparameter λ for smooth training.

Fig. 4. Image of an Indigo Bunting Generated at Every 50 Epochs by the Model.

Fig. 5. Comparison of Image Generated by the Model and the Ground Truth Image.

Fig. 6. Bird Generated by the Model for the Caption "This Bird has Wings that are Black and has a Red Belly".

E. Frechet Inception Distance (FID)

To analyze the model generated images, the Frechet Inception Distance (FID) score [17] is used as the metric. FID score is the best metric that can be used for the evaluation of the system as it measures the distance between the feature vectors of both real and generated images. The baseline model's paper has used the inception score as a metric for evaluating the GANs. The problem associated with the inception score being taken as a metric is that it does not find how the generated images compare with the actual images. With FID, it evaluate the generated images based on the generation distribution with the actual image in that particular target domain. For the FID score, the lower, the better. A lower score indicates that the generated images are closer to authentic images and are higher quality images and features with real one's match.

V. Experiments and Result

Multiple experiments were performed with the proposed Generative network using a pre-trained RoBERTa language model. The comprehensive network was initially pre-trained for DAMSM up to 200 epochs. Tesla V100 GPU with 16GB VRAM and 24GB CPU RAM for training with worker set as 4 were used for experimentation. The batch size for training was kept at 48 with a learning rate at encoder at 0.00005, and gradient clipping of 0.25 was kept to make sure training was stable. Various smoothing parameters were set during training, which helps train the various losses in multiple steps followed at DAMSM. $\gamma 1 = 4$, $\gamma 2 = 5$, $\gamma 3 = 10$, respectively. The parameters choosen for experimentation are taken from AttnGAN model and used for direct comparison. (GF_DIM) is the number of conv filters in the first layer of the generator and (DF_DIM) is the number of conv filters in the first layer

of the discriminator.

Ten captions were taken per image for training with the number of dimensions for the latent representation of the text embedding as 768. In previous experiments that were conducted in AttnGAN used bidirectional LSTM, which only required 256 embeddings. the base size was set as 299 which captured the attention map generated while pretraining the DAMSM with the pre-trained RoBERTa text encoder. The text encoder model was adopted from the hugging face library, providing the tokenizer for RoBERTa. It was observed that word vectors like colours get clustered together in vector space. The training of the transformer started from the pre-trained 'roberta-base' model with a RoBerTa tokenizer. The training of CNN started from the ImageNet pre-trained Inception-v3 model. Fig. 3 shows an attention map captured from image of a bird. At each frame a part of bird is being captured based on the text assosiated with it. The language model finds the relationship linking the body part and the colour designated for it. Attention mechanism explicates how each word corresponds to synthesizing a selective part of the bird image. Once the pre-training is completed, the DAMSM model generates a text encoder and an image encoder. This is used in the training of the AttnGAN architecture. AttnGAN network was trained using RoBERTa text encoder for 600 epochs. Due to limited resource allocation, kept the number of convolutional filters in the first layer of the generator (GF_DIM) and the number of convolutional filters in the first layer of the discriminator (DF_DIM) as 32.

The batch size was restricted to 8. The discriminator and generator learning rate was set to 0.0002. The generator and discriminator models were saved at every 50 epochs for analysis. For performance comparison with the baseline AttnGAN model, which trained the model with λ set as 5. The dimension of the RoBERTa text encoder is 768, amidst ten captions per image. The number of dimensions of the Noise vector was kept as 100 throughout the training process. Fig. 4 shows an Image generated at every 50 epoch by the AttnGAN with RoBERTa language model network. It is observable that around 200 epochs, the generator learns to generate an image close to a real-life bird. Images generated after 400 epochs looks realistic. By 600 epochs, it concluded the training and the models were saved. Fig. 5 explicates how the image generated by the model resembles the ground truth image. The model has learnt well to capture the essential details of birds like the body parts like wings, beaks, eyes, and feathers and understand its colour. It has also captured the pose of a bird to a reasonable extent. With more GPU power, it can use more generative networks to convert the image to higher quality. Fig. 6 was generated by the model around 600 epochs. The text as "this bird has black wings and a red belly", were provided to the generator synthesized an image matching the text description. 'roberta-base' was used as the model for capturing the context from the text description. The natural language model's main idea is to find attention heads and associate words in a bidirectional way. Fig. 7 envision the attention head for essential words in the sentence and how the RoBERTa model builds the attention mechanism. With the hugging face xbert tool, visualizing how the roberta-base model works in associating each word within the sentence with each other is simpler. The 'roberta-base' model uses 12 attention heads for generating a semantic relationship between each word in any direction. The word "this" is associated with itself and many other words within the sentence. The RoBERTa model learns that bird is the best associated and predictable word as the model is trained. There can be seen a strong connection between "this" and "bird". The word "bird" with the other words in the sentence is associated with particular words like "wings", "black", and "belly".These are the semantic relationship found by RoBERTa, and these get correlated with each other.

This assists in image generation and particularly in developing the text encoder in DAMSM loss. The word "black" here is a colour, and "wings" and "belly" are the two strong words that "belly" correlates. Colours like "red" get strongly related to "belly" in the sentence. Fig. 6 shows us the generated image by the model. The belly is red, and have black wings. This shows us how the RoBERTa model associates each word and what level of attention is provided for each word which nurses in the generation of the image with that particular features like body parts or colour.

TABLE II. FID SCORE GENERATED FOR EVERY 50 EPOCHS

Epoch	FID Score
0	275.833490
50	45.298608
100	32.540591
150	29.566392
200	25.616694
250	27.216560
300	24.648624
350	26.616447
400	22.377503
450	23.709113
500	22.760225
550	**20.773709**
600	21.468151

The Frechet Inception Distance(FID) score was calculated as part of the validation to compare the results with previous models as shown in Table II. Multiple epochs were ran and the FID score for λ = 5 were recorded. The number of generated images used for FID calculation was 2928, and the number of real images to be used in FID calculation was 11788. For epoch 0, had initially got a score of 275.833490. As each epoch is being trained, it can be seen the FID score keep reducing (Fig. 9).

A lower FID score indicates the model can generate more realistic images and various distributions of images. Around 550 epoch, a score of 20.773709 was obtained, the lowest and best for this model. This shows a good improvement from the baseline AttnGAN module [3] that used bidirectional LSTM as it got an FID score of 23.98 around the same number of epochs. Experiments were conducted on different values for λ at 100 epochs. Table III shows how the model performed without DAMSM and, by altering values of DAMSM, how the FID score or generation of different results is affected. A score of 35.44 was obtained. While tuning in too much attention value, the stability is lost in training, and it ends up with a score of 54.77 for λ set to 100. λ value of 1 seems to be stable for training with the AttnGAN and generating the bird images. A λ value set to 1 seems to work well for the model with RoBERTa embeddings and AttnGAN network. The λ value may fit differently for different datasets and should be

FID Score	67.22	51.89	23.98	**20.77**

VI. CONCLUSION

This paper used the baseline AttnGAN model with the latest pre-trained language model RoBERTa. It used transformers with the generative network to analyze the fine-grained text to image generation. The generative network takes in captions in word and sentence embeddings level and uses the latent space of noise vector to synthesize birds images matching the text description. With the help of a deep attentional multimodal similarity model, and found the fine-grained image-text matching loss. This loss was further used to train the generator. Pre-trained Inception V3 model was used for the Image encoder along with pre-trained RoBERTa for Text Encoder. The baseline AttnGAN model had achieved a Frechet Inception Distance (FID) score of 23.98. The model with RoBERTa text encoder improved this performance and obtained a score of 20.77 on the CUB dataset. Various experiments were performed and recorded the results for the proposed architecture of generative networks.

***Abstract*—In mobile ad-hoc network (MANET) environment, routing of data packets is a challenging task due to rapid changes in mobility and network topology. In addition, the security aspect of routing is disturbed by attacks caused by malicious nodes. These attacks greatly affect the Quality of Service. To overcome the challenges faced in routing message packets, the Bayesian Directed Acyclic Graph (B DAG) Aided Blockchain model is proposed for clustered MANET environment. The proposed model encompasses the following processes: (i) Multi factor authentication of users by using BLISS algorithm. This step involves acquisition of user credentials and generates hash values for those credentials using Cube Hash algorithm. These hash values are further used to generate public and private keys by BLISS algorithm, (ii) Weighted sum computation for clustering to reduce complexity in the MANET environment. Cluster head (CH) and cluster member (CM) are classified based on energy status, geometric distance, link quality and direction, (iii) A secure AODV based routing protocol using Dolphin Swarm Optimization (DSO) algorithm. This step involves selection of reputed node based on link stability, relative velocity, available bandwidth, energy, queue length, and trust. The packet forwarding is based on the reputation value of the node, by which the trust provided by malicious nodes are eliminated to improve security and (iv) Bayesian DAG aided blockchain, in which the user authenticity, data integrity of packets and signature are verified to mitigate the routing attacks created by nodes in the MANET environment. The proposed model is experimented in NS 3.26 network simulator tool and its performance in terms of multiple QoS metrics is evaluated.**

***Keywords*—Mobile ad-hoc network; node authentication; BLISS algorithm; blockchain; Bayesian direct acyclic graph**

I. INTRODUCTION

The current mobile nodes highly necessitate the secure communication. The key goal of this secure communication is to facilitate Quality of Service (QoS) and reliable data transmission in mobile ad-hoc network (MANET) [1,2]. The secure communication in MANET can be established by the combination of trusted mobile nodes and trusted third party. In secure environment, trusted third party plays a crucial role in several disaster applications. The security far-sightedness requirement in MANET is essential because of the succeeding issues, such as vulnerable entities in MANET to the routing attacks (black hole, gray hole, timing and intruder attacks), false warnings in the network and false registered credentials with the transmitted message [4-6] [9]. These issues exemplify the importance of the security in the MANET security. Further, the QoS parameters are affected due to lack of security, stability, and scalability [3]. When the network meets these three factors, each mobile node can be obtained with high QoS by means of high packet delivery ratio, throughput and low packet loss, routing overhead, route acquisition delay, end-to-end delay, and energy consumption.

Authentication is a main process in MANET security that verifies the provided credentials during registration process [6]. Few works [1,2,7] have performed authentication with an aid of blockchain technology to overcome failure during centralized administration when group of attackers combined to target it. Here, the transactions/blocks signature process is performed to provide security in MANET. The public key infrastructure (PKI) based authentication process has performed in blockchain where the Elliptic Curve Digital Signature Algorithm is used to generate key for the data transmission [7,8,15]. In blockchain, elliptic cryptography based authentication is contributed in the MANET. It performs authentication by considering the identity based signature procedures. Routing plays a vital role in the mobile communication and hence, providing security is significant while selecting best next hop. To ensure this, trust based node selection procedures are emerged in the MANET network [10]. In general, source node considers the two trusts viz. direct and indirect trusts for next hop selection [11]. Two different algorithms have utilized for estimation of direct and indirect trusts [12]. In direct trust, recommendation trust is estimated by considering the dropped and forwarded counts of the nodes. The trust is estimated based on two factors that are reputation information collection and trust value estimation procedures. A secure and efficient routing protocol (AOMDV) is designed to provide secure routing in the mobile ad-hoc network [13,14]. The MANET is largely utilized in several sensitive and non-sensitive applications. However, proving security in the MANET is difficult because of the issues, such as dynamic topology, communication latency, network scalability, and high processing security algorithms [16]. These issues induce difficulties in proving security to the MANET. Hence, the main aim and scope of this work is to provide high level security to the MANET network with better data transmission.

Paper outline: The remaining part of the paper is structured as follows: Section II describes the related works in the field of MANET, Section III presents the major problem statements, Section IV briefly explains the proposed system design and architecture in a well-organized manner and section V presents the experimental settings for the proposed system design and also evaluates the comparison between the proposed as well as previous approaches. Finally, the conclusion is work prospects are presented and summarized in Section VI.

II. Related Work

In this section, the existing works of secure cluster based routing in MANET are discussed. In [17], topological change adaptive ad-hoc on demand multipath distance vector routing protocol (TA-AOMDV) is proposed. This protocol is highly adaptable for high speed node movement in support of QoS. In this protocol, shortest path selection is implemented which takes four parameters as inputs for routing i.e. residual energy, available bandwidth, queue length, and link stability. In general, the path selection is not always optimum due to nodes movement and thus stable path is selected for routing. It considers both path stability and node density, but does not adapt for high speed scenario under large scale environment. In [18], routing attacks (black hole and gray hole) are detected by proposing an intrusion detection system on mobile ad-hoc environment. In attack scenario, the malicious node does not cooperate with other mobile nodes and intentionally disturb data communication by sending false route request & response forwarding and also false data transmission. These behaviors are timely detected in this work through deployment of IDS in most legitimate node. This legitimate node is determined by the connected dominating set model, which considers node energy and blacklist status for deploying IDS entity into it. The proposed method connected dominating set can be applied for small scale region, which is not efficient in large scale region. Further, the IDS deployment is a crucial process that must be running in decentralized mode, since malicious nodes can change the blacklist and nodes energy status. So, the routing attackers cannot be eliminated.

In [19], authors presented graph structure for mobile nodes communication over the network environment. To consume less energy and ensure QoS while transmitting packets from the source to destination node, the graph kernel structure based clustering algorithm is proposed in this work. In graph kernel, all mobile nodes are connected and CH is elected by means of certain significant parameters for data transmission. In particular, there are two processes are executed including cluster head election phase and cluster head maintenance phase. Based on node stability, CH is selected and CH maintenance is initiated by solving K-hop problem and node's current situation (stability and connectivity to other nodes). Among the set of CHs, shortest path is selected. Graph theory consumes more energy where clustering alone can able to perform. Since more computations are required to select K-hop shortest path selection. In [20], a hybrid optimization is proposed for energy related parameters adjustment. As a result of topology changes in network, energy consumption and packet losses during packet transmission is more. To address this issue, chronological and earth worm optimization algorithms are combined as a hybrid algorithm. Clustering is built by graph model (Gabriel graph) where node's power, connectivity, mobility, link lifetime and distance are considered for CH elected. In the graph structured cluster model, data packets having high power and energy are transmitted through nodes. Due to lack of infrastructure, secure communication is the way to minimize errors and data loss for data transmission. This further optimizes power and energy parameters when topology changes exponentially. In [21], network topology is controlled by hybrid artificial swarm intelligence algorithms i.e., robotic Darwin particle swarm optimization with graph based algorithm (RDPSO-GBA). Obviously, transmission delay happens when number of hop counts increases. In graph constructed framework, node's mobility and link connectivity between nodes are predicted. With these criterions, optimal route is selected and routing problem is solved via optimization solution. For route selection, ant colony optimization (ACO) is proposed. However, packet drop rate and energy consumption rate are high. In [22], expected transmission count (ETX) metric is used as one of the metrics to evaluate routing overhead. Through this metric, light ETX, light reverse ETX, and power light reverse ETX that minimizes routing overhead and also improves other ad-hoc network performances. All three metrics are computed for AODV routing protocol and implemented using NS3 network simulator. In experiments, Throughput, Packet Delivery Ratio, Useful Traffic Ratio, Jitter and End-To-End Delay are evaluated. Eventually, ETX does not support for optimum routing because AODV protocol works well in other networks i.e., static network, but does not suit for dynamic networks like MANET.

In [23], author discusses the trusted environment for IoT assisted MANET. The presented trust scheme is a combination of two individual metric i.e., direct and indirect trusts. The sum of direct and indirect trust values is used for final trust value. To compute trust values, beta probabilistic distribution is applied for combining different trust evidences and compute direct trust is calculated. A recommendation trust is computed using ARMA/GARCH, which is predicted for ensuring reliable and secure end-to-end forwarding of packets. Trustworthy nodes are selected in the routing. In [24], author proposes QASEC security routing protocol for secure data communication in MANET. This is a simple and lightweight model for best link selection from the set of available links for packets transmission between nodes. This link must be of optimal transmission link and thus produces minimized end to end delay. To ensure node authenticity, a simple authentication scheme is proposed, which relies on symmetric encryption for each mobile device shared secret keys generation. In particular, device identity, unique session key, and authentication token are considered for legitimate nodes identification. The symmetric encryption requires high energy consumption and also large key size that led to high processing time.

In [25], authors proposed a model for smart packet forwarding based on game theory. This model was proposed to identify and eliminate self-centered nodes which tend to drop the packets thereby increase the retransmission rate and reduce the performance. This model identifies the malicious

nodes by considering two factors namely possibility of packet drop and reward factor. Once the node is identified as malicious, the model stimulates the nodes to cooperate in packet forwarding paradigm. The formulated game theory model controls the energy consumption during modulation and data transmission. Even though the proposed method reduces retransmission rate, the network burden and complexity of the method is increased when the number of nodes are increased. In [26], authors proposed a method to protect the packet drop by two major attacks namely black hole attack and grey hole attack. The proposed method uses Artificial Bee Colony optimization algorithm (ABC) based on intelligent swarm algorithm in Artificial Neural Network (ANN) as a deep learning algorithm. The ABC optimization segregates the normal node and attacker node based on the fitness value. The ANN is trained with the output of optimization algorithm and is used to identify the malicious nodes thereby reducing the energy consumption and increasing the security. The ANN used in this method has no determined proper structure; the appropriate structure of the network is achieved through experience and trial and error. The duration of ANN is unknown and this will affect the performance of the method. In [27], authors proposed a model to evaluate the credibility of the mobile nodes by using trust reasoning model based on cloud model and Fuzzy Petri Net (FPN). The routes with minimal trust are selected and added to the routing table. Finally, a routing algorithm based on trust entropy routing algorithm and optimized link state routing protocol is presented. Based on the output of the proposed algorithm, the trust value gets assigned to the nodes and the route selection is carried out on the trustworthy nodes. Fuzzy logic is not always accurate hence results are obtained based on assumptions and the number of rules in the fuzzy logic makes it time consuming. In [28], authors proposed a routing mechanism named Energy Efficient Cloud-Assisted Routing (EECRM), which consists of three phases that cloud assist routing mechanism for efficient employment of route discovery, energy consumption phase for efficient utilization of energy and cloud service update phase. Suppose if any packet drop occurs in data transmission the adjacent route for better transmission is selected and the routing is performed to reduce the energy consumption. The parameters considered for selecting the backup nodes are not sufficient for optimal data transmission. The proposed method does not address problems caused by network attacks but practically these attacks increase latency and reduces performance during data transmission.

III. Problem Statement

This section summarizes the specific problems on blockchain aids and secures routing protocol for MANET. A framework for secure data transmission was proposed in [29]. The blockchain for security data collection in mobile ad-hoc network (B4SDC) framework exterminates of two types of attacks, such as collusion and spoofing. With the use of cooperative receipt report, the collusion attack is detected via control information forwarding for selected routes nodes only and mitigated whereas, the secure digital signature is used for spoofing attacks detection via signing sent messages from source to the destination. Further, excessive message forwarding attack is mitigated through the spoofing attacker's detection. The problem existing in this work, such as blockchain structure is not scalable. As the mobile nodes are always moving dynamically throughout the network, the use of conventional blockchain chain structure is not suitable.

Transaction confirmation time is higher since ECDSA, and $(SHA\text{-}2)^2$) consumes more processing time. Furthermore, creating blocks for dense MANET consumes high energy compared to clustered environment. Authentication is implemented and security credentials are transmitted through public channel and secret keys are received by the same that may facilitate the receiving of key by the compromised and malicious nodes. The mining complexity is higher for verification of block transactions during message transmission. Hence, a secure routing protocol was proposed to defend against the popular network attack named black hole attack [30]. This work is called as Blackhole Protected AODV routing protocol (BP-AODV) for malicious nodes detection. In routing process, blackhole attackers are detected through nodes past behaviors. Here, the history of node is collected and stored in routing table. To ensure security in the routing process, Chaotic Map features (Ergodicity, Randomness, and Sensitivity) are added which control the conditions and control parameters. However, the above work contains the following significant problems: Chaotic Map is not efficient enough because it needs successive monitoring neighbors' nodes. Besides, it also consumes more bandwidth during data transmission. Further, challenge at source node and secret responses at destination node are not be optimal when nodes move at high mobility. The routing is performed through BP-AODV protocol, which is not efficient to find optimum route since trustworthiness of nodes are computed by historical behaviors. This requires more packet retransmission due to poor computations of trust. Thus, it causes high packet losses and requires optimized solution. To evaluate the trust of the node, a support vector regression based corrective linear program classification model was proposed [31]. The main aim of this work is to reduce minimum end to end delay and maximize packet delivery ratio. In the first step, Tanimoto kernelled support vector regression is proposed to predict node features, such as node history and current energy status. Based on the node examined information, nodes are classified into two classes as "Trusted & Non-Trusted Nodes".

Subsequently, linear program boost classifier is used for trusted node selection for secure data transmission. Here, routing is performed based on node history, current energy status, and cooperativeness. In MANET environment, mobility of the node is more important, since lack of mobility information leads to high data loss. Further, trust values can be easily modified by malicious users. Tanimoto kernel in SVM provides less accuracy in trusted node prediction so that packet losses by malicious nodes involvement and also it leads to poor accuracy when mobile nodes mobility at high rate. To improve the energy efficiency and reduce complexity clustering based protocol was proposed [32].

The fuzzy logic based clustering is presented for cluster formation and cluster head selection. The cluster heads are selected by energy status, node degree, distance, trust level, and node mobility. A standby CH is also presented in case of

CH dies, moving out of coverage, or CH comprises. After the CH selection, trusted nodes are determined for secure route determination. Nevertheless, 243 fuzzy rules are generated for CH election, which increases energy consumption in cluster formation and also CH election. The strong computation mechanisms are required to estimate the trust level of mobile node. Here, the trust value is estimated based on the public historical behaviors. Thus, it induces malicious node participation in data transmission and also introduces high packet loss. Message may be modified or false data packets can be injected by the malicious nodes in intermediate hops.

The problem statements of these researches insist the need of a secure data transmission protocol which routes data in the optimal way through the trustworthy nodes whose trustworthiness is evaluated with strong parameters. The problems stated are illustrated in Table I. In this way, our proposed system is carried out towards the solutions of these problems by improving the security and scalability of data transmission in MANET.

TABLE I. EXISTING PROBLEMS

Method/ Technique	Concept	Drawback
B4SDC [29]	Detects collusion and spoofing attacks	The existing blockchain structure is not scalable furthermore; creating blocks for dense MANET consumes high energy
BP-AODV [30]	Blackhole attackers are detected through nodes past behaviors	The routing is not efficient since trustworthiness of the nodes is computed by considering only the historical behavior
Tanimoto SVM based linear program [31]	Classification of nodes based on node history and current energy status	Lack of mobility information leads to high data loss
Fuzzy logic based Clustering [32]	The trust nodes are determined by the cluster head	The number of fuzzy rules generated for CH election will make the process time consuming

IV. PROPOSED METHODOLOGY

The proposed system addresses challenging issues present in current MANET security works. The mobile ad-hoc network has become more popular in wide variety of applications that eventually increases intruders. This section is categorized into sub-sections depending on hierarchy of process involved to provide highly confidential authentication and data security in MANET that avoids severe attacks in network. In the present study, we have employed BDAG method to detect the malicious attacks mainly because of its relatively minimum resource utilization, fast detection of attacks and high delivery ratio.

A. B-DAG CHAIN Architecture

The proposed system comprises of four processes. The processing handled in each process is user validation, clustering, optimal route selection and data packet verification. The entities present in the proposed MANET environment are Security Node, Bayesian Network Directed Acyclic Graph aided Blockchain Nodes, and Mobile Nodes. The malicious traffic is provoked with the objective of demolishing the performance of the network. Initially the network consists of both the legitimate users and malicious users. Let the users be $\{U_1, U_2, U_3 \ldots U_n\}$ in which the data transmission is to be done between the legitimate users so the authentication of the legitimate users is important in secure data transmission. The users who possess original security credentials are termed to be legitimate users. The security nodes present in the environment is denoted as $\{S_1, S_2 \ldots S_n\}$. The security credentials of the legitimate users are managed by the security nodes. Once the security node receives the credentials of the users it starts to compute the key for message signing process. The number of users in the MANET environment is huge and it is not possible to manage the users individually hence clustering of mobile nodes is introduced, this process significantly reduces the complexity of managing the mobile nodes. Fig. 1 depicts the system architecture of the proposed work. The cluster head is elected and it is managed by security node. In order to reduce the packet drops and retransmission of data packet the data packet transmission is to be done through trusted nodes. The reputation value of each node is estimated and the source node selects the forwarder based on the reputation. In the destination side, both the sender's authentication and integrity of data packets are verified and the timestamp is also checked for secure transmission of data. On designing the BDAG chain architecture, the malicious nodes are detected and several attacks caused by these nodes are defended. The user authentication is carried out by using CubeHash algorithm and bliss algorithm. Then clustering is done using weighted sum computing for clustering algorithm and finally the secure routing is carried out by using Dolphin Swarm Optimization. Fig. 1 shows the proposed BDAG chain architecture and the processing carried out in each process. All these processes are completely focused on mitigation of the attacks caused by the malicious nodes.

B. Multi-Factor Authentication

The U_n users of MANET environment are validated when the user requests with a service. User validation includes processing of two phases as (I) Registration phase and (II) Authentication phase. The steps in registration phase are given as follows.

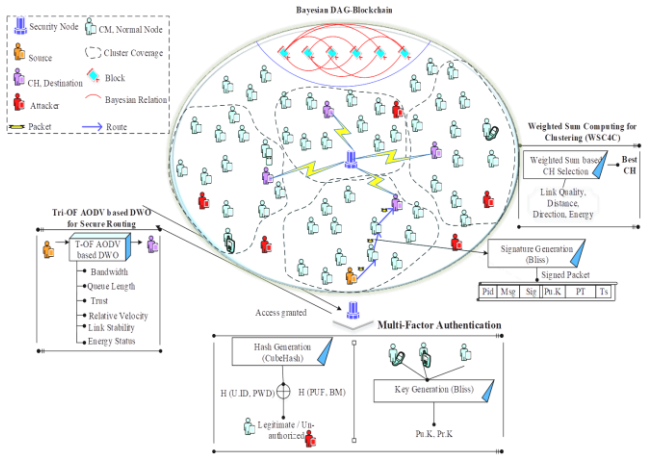

Fig. 1. System Architecture.

STEP 1: First assume U_1 be the user who requests the security node (SN) for registration with his / her unique Binary format of user finger vein, Physically Unclonable Function (PUF), Password and User ID. These credentials are submitted to SN for registration.

U_1 (BM||PUF||PWD||ID) ⟶ SN (1)

STEP 2: Then, receiving user credentials from U_1, the SN generates hash value for all user credentials by using CubeHash algorithm. The parameters involved in CubeHash algorithm are listed below:

- RD - The number of iterations in {1to 16}.
- Bpb – It is represented in bits per packet block {1 to 128}.
- O – The output bits range from {2 to 512}.
- Pkt - the actual message as a string of bits in size {0 to 2^{128-1}}.

The algorithm involves the stages listed below:

- The state S is initialized based on (O, Bpb, RD)
- The Pkt should be divisible by Bpb for that padding may be performed.
- The RD rounds of the ordering on state S is performed for every Bpb-byte block in the padded O xored with first Bpb- bytes of state.
- The state S is then finalized.
- The final result is delivered as the first O bits of state S.
- Each state is built of 32 bits. The first three values are set to O/8, Bpb, RD in the initialization stage. Further the state is ordered to 10RD rounds. Until the value of Pkt is divisible by Bpb the padding is carried out by appending the pkt by 1. The preserved symmetry is broken by performing the XOR operation to the last bit with the integer value1. Finally, the state is reordered through 10RD rounds once again. CubeHash seems to easily configure the input parameters such as BM, PUF, PWD and ID. The maximum security is obtained by deploying CubeHash 8/1-512 and the energy efficiency is obtained by deploying CubeHash 16/32. The hash values H is determined which is used to generate the unique signature.

Procedure for Key Pair Generation

1: Begin
2: Initialize nodes
3: $\boldsymbol{U_1}\rightarrow$ request key pairs to the $\boldsymbol{SN}$
4: SN (For U_1 generate key pairs)
hash value acquisition
Key pair generation(Pr.k, Pu.k)
5: End for
6: $\boldsymbol{SN}\rightarrow$ reply key pairs to U_1

Procedure Description: The U_1 requests the key pairs to the security node which will be generated from the hash values determined for the user credentials. Once hash values are obtained the two different keys Pr.k and Pu.k are generated. The security node assigns the Pr.k and Pu.k to the user here it is U_1. Further the keys from SN are stored in user's device.

The BLISS algorithm is used to generate the digital signature. First, the two different keys Pr.k and Pu.k are generated. The Pr.k is a (short) matrix $S \in Z_{2q}^{mxn}$ and Pu.k is given by the matrix $A \in Z_{2q}^{n\times m}$ such that AS = q**I**n (mod 2q). The security node assigns the Pr.k and Pu.k to the user here it is U_1.

SN ⟶ U_1 (Pr.k, Pu.k) (2)

STEP 3: Further the keys from SN is stored in user's device which is required during the authentication process. The registration phase for the device is completed.

Procedure for Message packet transmission

1: Initialization
2: $U_1 \rightarrow$ requests for connection with G_1
3: Timestamp verification by G_1
4: $G_1\rightarrow$ reply ack to U_1
5: U_1 (for message transmission)
Message $\boldsymbol{\mu}$ is generated
Signing of message with generated keys (Pr.k, Pu.k)
6: End for
7: $U_1\rightarrow$ Message transmission to G_1

Procedure description: U_1 requests for the connection establishment with G_1. The timestamp for the request message is verifies by G1 and the ack for connection is sent to U_1. For message transmission the message μ is generated and the digital signature is signed with the key. The signed message is then transmitted to G_1 in several hops. The steps followed in authentication phase are described below:

STEP 1: During authentication the request from U_1 is submitted to G_1 for data transmission. On receiving request, the timestamp T_1 freshness is verified. Then the G_1 replies the U_1 with the acknowledgment (ack). Once the ack is received by the U_1, the message μ is generated and the private key is used to sign the message. The signed message is denoted as δ which is sent to the destination G_1

$$U_1(\mu \oplus Pr.k) \longrightarrow U_1\ (\delta\ ) \quad (3)$$

Procedure for Message packet reception

1: Reception
2: G_1 (For key generation)
verification of sender identity (U_1)
verification of data integrity (δ)
Pr.k is generated for the destination node
3: End for
4: The message packet is decrypted

Procedure Description: After the reception of encrypted message packet the G_1 verifies the sender identity of the message and the data integrity of the packet. After the verification process, the private key is generated to decrypt the received message.

- STEP 2: The signed message packet is transmitted to the next reputed node and thus the message packet reaches the destination in several hops.

$U\_1\ (\delta) \longrightarrow G\_1$ (4)

STEP 3: Once the destination node receives the packet, the private key for the respective message packet is generated to the destination. This way of data transmission provides security to the transmitted data effectively.

$$G_1(\delta) \longrightarrow G_1(\mu \oplus Pr.k) \quad (5)$$

The authentication of users enables to withhold illegitimate user's access into the network. A system model without authentication process is much easier for attackers to initiate attack which degrades network performance. The authentication of user by private and public key ensures to allow access only for the legitimate users. The goal of our work is to defend the attacks and to perform the data transmission securely.

C. Weighted Sum Computation for Clustering

The mobile nodes in the MANET environment are clustered to minimize the computation complexity. The clustering of nodes undergoes two phases they are (I) cluster head election and (II) cluster formation. The nodes are grouped based on the factors such as Energy status, distance, link quality and direction. The resulting cluster will contain single cluster head (CH) and number of cluster members. The cluster head has complete information about the cluster members and link state details. Each and every node in the cluster is connected to the cluster head with a bi-directional link, through this each node in the cluster knows which cluster it belongs to. The proposed Weighted Sum Computation. For Clustering (WSC4C) performs well in optimal cluster formation in highly moving MANET environment. The proposed algorithm computes the weight score for each factor and then elects the optimal node as cluster head.

1) Energy status calculation: The energy status for each node in the MANET environment is obtained by finding the difference of the energy availability in two sub-phases. The energy spent on forming the topology is considered to obtain the correct energy status of the mobile node. For that the energy status before topology formation and the energy spent on topology formation. The energy status can be found by the equation as follows:

$$E_{status} = E_{Bt} - E_{St} \quad (6)$$

2) Geometrical distance calculation: The distance between each node is to be found to decide the cluster size and the optimal cluster head for the respective cluster. The distance calculation is carried out in meters (m). The optimal distance between the node and the security node is calculated. The reason to calculate distance is that when the distance between two nodes is small the energy required in transmitting the packet between the nodes reduces. The geometrical distance between two nodes is calculated as follows:

$$D(t) = \sqrt{A1 + A2 + \theta} \quad (7)$$

3) Link quality estimation: The link quality is one of the significant parameters to be considered in highly moving MANET environment. The estimation of link quality is carried out through number of transmissions expected (NET) and the path count expected (PCE). The number of transmissions expected (NET) between the transmission of packets between sender and receiver is used to calculate the link quality. Let node U(i) be the intermediate node which has the probability of receiving and transmitting the message packets of $\alpha(i) and\ \beta(i)$ respectively. The probability of packet delivery ratio between the nodes is calculated as follows:

$$\alpha(i) = \frac{n_w}{w/_\tau} \quad (8)$$

The probability that a previous node sends packet to the node U(i) is stated as $P_{pre} = 1 - \Pi_{i>s}(1 - \alpha_s\beta_i)$ and the probability that the next node receives a packet from U(i) is stated as $P_{next} = 1 - \Pi_{d>i}(1 - \alpha_i\beta_d)$. Then the number of transmissions expected is determined by

$$NET = \frac{1}{Ppre \times Pnext} = \frac{1}{(1-\Pi_{i>s}(1-\alpha_s\beta_i))(1-\Pi_{d>i}(1-\alpha_i\beta_d))} \quad (9)$$

The PCE value is calculated based on the probability of packet delivery ratio. This metric is calculated to find the optimal pair of the node U(i). The PCE value from sender to receiver is can be calculated as

$$PCE(s,d) = \frac{1+\sum_i PCE\ (c_i^{s,d},d)\ (1-\Pi_{i>s}(1-\alpha_s\beta_i))\Pi_{j-1}^{i-1}(1-\Pi_{d>i}((1-\alpha_s\beta_j))}{1-\Pi_{s>i}(1-\alpha_s\beta_i)} \quad (10)$$

The above determined NET and PCE metrics are used to estimate the link quality between the nodes in the MANET environment.

4) Direction estimation: The direction of nodes in a MANET environment can be estimated from the change in link quality between the nodes. If the link quality increases between the nodes, then they are moving towards one another and if the link quality degrades between the nodes, then they are moving away from one another. Thus, the direction of the nodes can be classified into two classes they are (i) moving toward (TW) and (ii) moving away (AW). The weighted sum computation for clustering is carried out with the above calculated factors and the clustering is performed in an optimal manner. From the nodes present in the cluster, the cluster head (CH) is elected based on the calculated weighted sum. Table II illustrates the formation of cluster and election of cluster head based on WSM score. The node $U3$ is elected as the Cluster Head (CH), as the Weighted Sum Computation (WSC) score for the respective node is greater when compared to other nodes.

TABLE II. CLUSTER FORMATION AND CLUSTER HEAD SELECTION

Nodes	Input parameters for clustering				WSC score	Role
	C_1	C_2	C_3	C_4		
$U1$	5	12	75%	*AW*	0.75	CM
$U2$	8	10	78%	*TW*	0.82	CM
U3	**11**	**3**	**90%**	***TW***	**0.91**	**CH**
$U4$	6	8	83%	*AW*	0.69	CM
$U5$	9	15	67%	*AW*	0.56	CM

Once the cluster is formed, each node in the cluster will broadcast its neighbor table for every periodic time period as a hello message. After receiving hello message from the neighbor node, the respective nodes ID and role (CH or CM) will be registered in the neighbor table. These clusters are managed by the security nodes. If any attack patterns found by the security node, it will immediately isolate the particular malicious node and inform this message throughout the network. This way of forming the cluster and electing the cluster head is efficient and this will greatly minimize the complexity and overhead in packets and control message forwarding.

D. TRI-OF AODV based DSO for Secure Routing

In the MANET environment, communication is done by sharing message packets from one node to another node. In this work, Ad hoc On-demand Distance Vector (AODV) protocol which is a significant routing protocol in MANET is used. The AODV protocol overcomes the issues of mobile network such as high mobility, packet loss, etc. The AODV routes the message packets to the next node based on the trust value of the respective node. The trust value is classified into two types they are (i) direct trust and (ii) indirect trust. The direct trust is estimated by using the past behavior and successful transaction of the node whereas the indirect trust is provided by the security node. In order to achieve more secure message packet routing, we use Dolphin Swarm Optimization (DSO) algorithm. The proposed algorithm computes the reputation value for each node and forwards the message packets to the most reputed node. The algorithm is classified into three stages which are as follows:

- Search stage.
- Call stage.
- Response stage.

Search stage: In the search stage, the mobile node searches its neighbor node from the neighbor table. The algorithm obtains two nodes one is, the node which is selected by the source node and the second is the node which is recommended by another neighboring node. For each node U(i) (i= 1, 2, 3…N), two corresponding possibilities X_i (i=1 to N) and Y_i (i= 1, 2, 3…N). Where, X_i is the node selected by the source node and Y_i is the node recommended by the neighbor nodes. First the node U(i) calculates the fitness for the node selected by itself and then for the node recommended by the neighbor nodes. The comparison of both the fitness value will help the source node to select the best node. The fitness value is calculated based on the factors such as link stability, relative velocity, available bandwidth, energy, queue length, and trust.

For the node X_i that node U(i) gets, its fitness F_{xit} is calculated as follows:

$$Fxit = Fitness\ (Xi) \tag{11}$$

Then the fitness value for node Y_i is calculated as F_{yit} is calculated as follows:

$$Fyit = Fitness\ (Yi) \tag{12}$$

$$\text{If } F_{yit} > F_{xit} \tag{13}$$

Then Yi is replaced by Xi. Otherwise, Xi which is selected by the source node itself does not change. After the updation of the reputed node, the DSO enters into next stage.

Call stage: In the call stage, the source node U(i) informs the neighbor node about the result obtained in the search stage and requests the connection from the selected reputed node for data transmission. The transmission time matrix (TM) gets updated as follows:

$$TM_{U(i)} = \left\lceil \frac{Dist}{speed} \right\rceil \tag{14}$$

After the updation of the transmission time matrix gets updated and the DSO enters the next stage.

Response stage: The reply for the request sent to the reputed node is received by the source node and the message packet is generated and sent to the respective node. The reputed node receives the message packet from the source node within the mentioned transmission time matrix. (TM). When the time becomes.

$$TMU(i) = 0 \tag{15}$$

The reputed node will no longer get the message packet, which means that the message packet will be transmitted to the reputed node within the time. This process gets looped until the destination node receives the packet. In this process the trust values provided by the malicious nodes gets eliminated and the message is transmitted through the reputed nodes and reaches the destination node in the optimal time. The objectives achieved by the Dolphin Swarm Optimization is listed below:

- Low Relative Velocity and High Link Stability.
- High Available Bandwidth and High Energy.
- High Trust and Low Queue Length.

The Procedure 4 presents the overall working of DSO based AODV for multi-hop routing. The above explained three stages along with the start and end phase is involved for fitness computation of each relay node. In the start phase the mobile nodes are initialized with its input parameters. This process is significant for the initialization of parameters for fitness evaluation.

The best fitness function is chosen for packet transmission. The end condition is achieved when the packet reaches the destination. The matrix updation is done in both call stage and response stage which is done to make the routing process within the labeled time period.

Procedure: Route selection by DSO algorithm.
1: initialization
Collects information about neighboring nodes from neighbor table
Nodes= {U1, U2, U3...} in the neighbor table.
2: begin loop
While the end condition is not satisfied **do**
2.1: search stage
Two nodes Xi and Yi are obtained.
Calculate fitness F_{xit} and F_{yit}.
Highest fitness node is selected.
2.2 Call stage
Request for connection
Update time matrix.
2.3 Response stage
Reply received
Packet generation
Update time matrix.
3 **If** packet reached destination then
End loop
Else
Increment loop
End if
End while
End

E. Attacks Mitigation by Bayesian DAG-Blockchain

In this section, the attacks associated with the routing in MANET environment is explained briefly and a model is proposed to defend against these routing attacks. Generally, routing in mobile ad-hoc network is to be performed in an optimal way to reduce the latency and increase the privacy of the mobile nodes. Some of the nodes try to bypass the message packet to steal the sensitive information embedded in it; these nodes are collectively called as malicious nodes. To mitigate the attacks occurring in routing process, the Bayesian Direct Acyclic Graph (B DAG) aided Blockchain model is proposed. The security of the routing protocol is increased by using blockchain technology. The blockchain makes use of asymmetric encryption and authorization processing. Fig. 2(a) illustrates the format of the data block; (b) describes the individual specification of the data blocks.

Version	Block Types	Previous Block Hash	Timestamp	Trust Value	Residual Energy	Bliss Signature	Index Record

(a)

version	Block version number
Block types	Node details
Previous Block Hash	Link for connecting block
Timestamp	Block creation time
Trust value	Node trust
Residual energy	Energy availability
Bliss signature	Public and private key
Index record	Holds index information

(b)

Fig. 2. (a) Format of Data Block, (b) Data Block Description.

The transaction of packets stored on the blockchain is public, but the identity of the nodes is encrypted and the key for encryption is provided to the data owner only thereby ensuring the privacy. Each and every action in blockchain is transparent and is available to every node of the block however the data cannot be deleted or changed. The decentralized management of network reduces a number of risks that emerge with data being managed centrally. This type of management has no central point of failure. The priority of trust is given equally to all the nodes. The verification of message packet is performed to find whether the source of the packet is a legitimate user and the data integrity of the packet. To do so each and every event of all the nodes are stored in a chain of blocks. To eliminate the problem of storage requirement, these events are converted into hash values and these hash values are table verification process. The previous hash of the block is stored in the current block therefore the security of the blockchain increases with the number of blocks. Traditional blockchain technologies arrange the blocks in a single chain. So, in order to verify the packet integrity, the hash values of source to destination are to be verified and this will lead to delay in the verification process. To overcome this delay the blocks are presented in Direct Acyclic Graph (DAG). This enables the verification process to check the needed blocks only. But in order to select the required block, all the blocks associated with the process is to be checked. Therefore, a Bayesian Network is used to estimate the probability of the hash value in the respective block. This significantly reduces the delay associated with the process. The Block Independence value (BI) is presented as a triplet of $J\ (x, y, z)$. Here the value x denotes the key of $J(x, y, z)$. The factors determining the Block independency is listed as follows:

- Symmetry
- Decomposition
- Weak union
- Contraction

The graph is plotted for the number of blocks in a hyper tree construction ordering. The hyper graph is denoted as.

$$\langle B, P\rangle = \{b_1, b_2 \ldots b_n\} \quad (16)$$

Where, $b_i \subseteq P$ is called a *hyper edge* of ⟨B, P⟩, and $P = b_1 \cup b_2 \cup \ldots \cup b_n$. the hyper graph B is determined as acyclic if $, si = bi \cap (b_1 b_2 \ldots b_{i-1}) \subseteq b_j, 1 \leq j \leq i-1,$ where s is referred to as segregator. Thus, an acyclic hypergraph is constructed and thereby removing the dependency between each block in the blockchain.

V. Results and Discussion

This section presents the simulation results with the detailed description of three sub-sections include simulation setup, comparison analysis, security & efficiency analysis for the proposed model in comparison with the existing approaches.

A. Simulation Setup

The Network Simulator version 3 (NS3) is used to evaluate our proposed model. The hardware and software requirements for the proposed model are illustrated in Table III.

The mobile node configuration is deployed to transmit the data by sensing the varied circumstances. The network simulator 3 tool has better features of network and provides all specifications of MANET. The proposed B DAG aided blockchain based secure routing model is experimented in 1000m × 800m simulation environment for evaluation of packet transmission by defending various attacks. The codes implemented for the construction of clusters, route establishment for transmission of data. Secure routing is a significant factor which is considered in many research works and our work also focuses on secure routing in MANET environment. Table IV describes the parameters associated in the experiment of proposed work in simulation tool. Fig.3 illustrates the flow of the proposed work in the NS3 tool.

B. Comparison Analysis

This sub-section presents the formulation of the proposed B-DAG aided blockchain secure routing model with respect to several QoS metrics. The proposed research work is compared with several existing works. Particularly, the following metrics are considered for performance analysis: attack prediction rate, end to end delay, packet delivery ratio, route acquisition delay, routing overhead, security strength and throughput. These metrics are described in the following in detail.

TABLE III. SYSTEM CONFIGURATION

Hardware specifications	Processor	NS3.26
	RAM	2GB
	Hard Disk	60GB
Software Specifications	Network Simulator	Pentium Dual Core and Above
	OS	Ubuntu 14.04 LTS

TABLE IV. SIMULATION PARAMETERS

Parameters	**Description**
Simulation area	1000 m*800 m
Number of nodes	100 with 10% of attackers
Node mobility model	Random waypoint model
Node speed (Max)	5 m/s
Forwarding capacity	2 Mbps
Number of flows	50
Transmission range	250 m
Packet transmission average rate (per flow)	1024 bytes/packet
Node buffer size	64 packets (fixed)
Queue type	Priority queue
Traffic type	TCP, UDP, and ICMP
Nodes distribution	Random
Interface type	Physical wireless
Neighbor nodes waiting time	0.3 s
Duration for packets carrying	1 s
Propagation delay mode	Constant speed
MAC type	Ad Hoc Wi-fi MAC

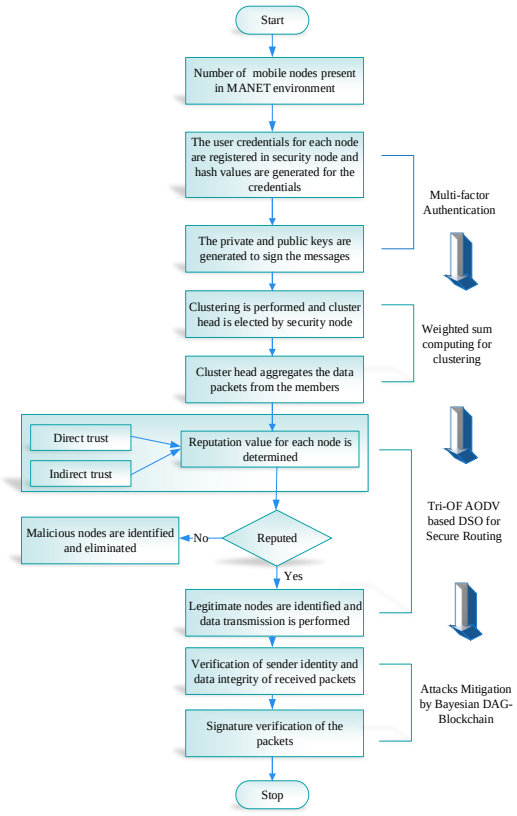

Fig. 3. Flow of B-DAGChain Simulation.

1) Impact of attack prediction rate: Attack prediction rate is defined as the number of attacks predicted for the given unit time. The true positive value is used to compute the attacks. It is defined as the number of packets which are determined correctly as normal for the total number of packets forwarded. It is calculated as.

$$APR = \frac{no.of.detected\ attacks}{no.of.attacks} \times 100\% \quad (17)$$

$$APR = TPV = \frac{TP}{TP+FN} \quad (18)$$

Fig. 4 depicts the attack prediction rate of three works including the proposed work with respect to number of malicious nodes. With the implementation of B DAG aided Blockchain model, attack prediction rate gets improved for the proposed research work which is evaluated for different number of malicious nodes. This work primly focuses on prediction attacks caused by the malicious node and mitigation of those attacks Table V. Firstly, the packets are signed with the digital signature and then packets are forwarded through reputed nodes and reach the destination. Existing works such as B4SDC and BP-AODV considers the trust values of the malicious nodes.

2) Impact of end-to-end delay: The End-to-End delay is defined as the delay of packets between two nodes. The end-to-end delay is calculated with respect to number of nodes.

Fig. 5 depicts the end-to-end delay the proposed method in comparison to the existing works for increasing number of nodes. The proposed work implements clustering of nodes

using Weighted Sum Computing for Clustering (WSC4C) algorithm which will reduce the complexity and delay associated with quantity of nodes Table VI. In the existing works [29], [30] the delay increases exponentially with increase in the number of nodes.

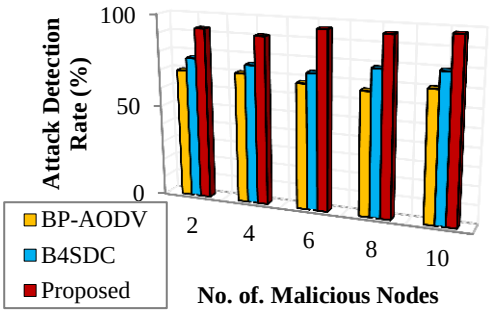

Fig. 4. Attack Prediction Rate vs. no. of. Malicious Nodes.

TABLE V. COMPARISON OF ATTACK DETECTION RATE OF PROPOSED METHOD WITH EXISTING METHODS FOR DIFFERENT NUMBER OF MALICIOUS NODES

No of Malicious Node	Attack Detection Rate (%)		
	BP-AODV	B4SDC	Proposed
2	69.7	76.7	92.9
4	70.5	75.3	90.8
6	67.8	73.5	96.3
8	66.5	78.3	95.7
10	70.3	79.4	97.7

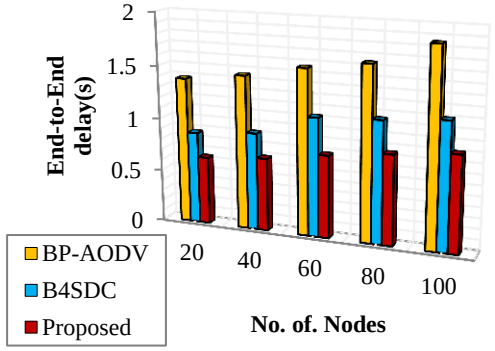

Fig. 5. End-to-End Delay vs. no. of. Nodes.

TABLE VI. COMPARISON OF END-TO-END DELAY OF PROPOSED METHOD WITH EXISTING METHODS FOR DIFFERENT NUMBER OF NODES

No. of Nodes	End-to-End Delay(s)		
	BP-AODV	B4SDC	Proposed
20	1.38	0.87	0.64
40	1.45	0.92	0.69
60	1.56	1.12	0.78
80	1.64	1.15	0.85
100	1.85	1.2	0.91

3) Impact of packet delivery ratio: Packet Delivery Ratio (PDR) is termed as the ratio between the numbers of packets delivered with respect to the number of malicious nodes present in the MANET environment. Fig 6 depicts the performance of proposed method in terms of packet delivery. With the increased number of malicious nodes, the existing systems [29], [30] fails to achieve better packet delivery ratio. The proposed work uses Dolphin Swarm Optimization (DSO) for reputed node selection and AODV protocol for secure route selection and this eliminates the trust provided by the malicious nodes thereby not affecting the packet delivery ratio Table VII.

4) Impact of security strength ratio: Security Strength is described as the level of security provided to the sensitive information embedded into the message packet. The security strength is improved by authentication of legitimate users and encryption of message packets during transmission of packets. Fig. 7 depicts the comparison of security strength provided by the proposed methods and other existing methods with respect to the packet size. The proposed method proves to be more secure even when the size of the packets is increased. The Bayesian Direct acyclic graph aided blockchain technology implemented in the proposed work improves the security of routing Table VIII. The existing works fails to focus on security when the packets and number of nodes increase which is a significant drawback.

5) Impact of throughput: Throughput is defined as the rate of successful reception of message packets by the destination node. It is one of the important factors in determining the accuracy and safety of the research work. Fig. 8 depicts the throughput achieved by the packets with respect to the increasing number of malicious nodes in three research works. This shows that the proposed work has higher throughput rate when compared with other research works. The proposed work uses DSO in selecting the reputed nodes thereby eliminating the malicious nodes which will reduce the number of packets drop and other adversary activities. The existing works are attracted by the smaller number of hop counts presented by the attackers and considers the trust value provided by them but the proposed work calculates the reputation value based on several features including the indirect trust provided by the security node Table IX. Therefore, it is able to differentiate the malicious nodes from the legitimate nodes. Thus, the proposed work has better throughput.

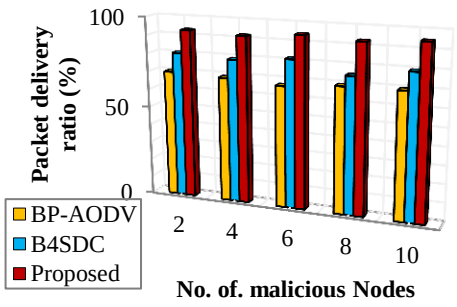

Fig. 6. Packet Delivery Ratio vs. no. of. Malicious Nodes.

TABLE VII. COMPARISON OF PACKET DELIVERY RATIO OF PROPOSED METHOD WITH EXISTING METHODS FOR DIFFERENT NUMBER OF MALICIOUS NODES

No. of Malicious Nodes	Packet Delivery Ratio(%)		
	BP-AODV	B4SDC	Proposed
2	69.8	80.5	93.2
4	68.7	78.9	91.9
6	66.8	81.3	94.3
8	69.2	74.9	92.8
10	69.5	79.4	94.7

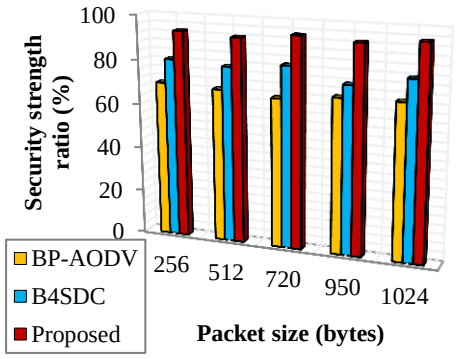

Fig. 7. Security Strength Ratio vs. Packet Size.

TABLE VIII. COMPARISON OF SECURITY STRENGTH RATIO OF PROPOSED METHOD WITH EXISTING METHODS FOR DIFFERENT NUMBER OF PACKET SIZE IN BYTES

Packet Size (Bytes)	Security Strength ratio (%)		
	BP-AODV	B4SDC	Proposed
256	69.8	80.5	93.2
512	68.7	78.9	91.9
720	66.8	81.3	94.3
950	69.2	74.9	92.8
1024	69.5	79.4	94.7

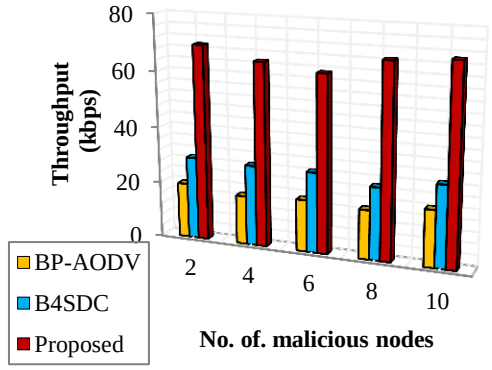

Fig. 8. Throughput vs. no. of. Malicious Nodes.

TABLE IX. COMPARISON OF THROUGHPUT OF PROPOSED METHOD WITH EXISTING METHODS FOR DIFFERENT NUMBER OF MALICIOUS NODES

No. of Malicious Nodes	Throughput(kbps)		
	BP-AODV	B4SDC	Proposed
2	19.6	29.4	69.7
4	17.4	28.7	65.3
6	18.5	28.6	62.9
8	17.5	25.8	68.7
10	20.2	29.2	70.2

6) Impact of routing overhead: Routing Overhead is defined as the ratio of number of packets generated to the number of packets transmitted in the established route. The routing overhead depends on the link stability and quality. The number of nodes and mobility of nodes also influences the routing overhead. Fig. 9 depicts the performance of proposed work in terms of routing overhead with respect to number of nodes. This shows that the proposed work has less routing overhead when compared to the other existing works, this is because the proposed work implements the clustering process by using Weighted Sum Computation for Clustering (WSC4C) to cluster the nodes in the MANET network thereby increasing the link quality between the nodes which will reduces the routing overhead Table X.

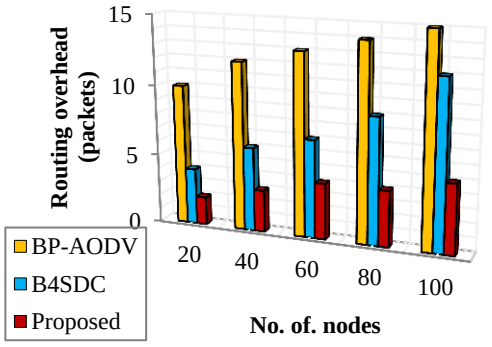

Fig. 9. Routing Overhead vs. no. of. Nodes.

TABLE X. COMPARISON OF ROUTING OVERHEAD OF PROPOSED METHOD WITH EXISTING METHODS FOR DIFFERENT NUMBER OF NODES

No. of Nodes	Routing Overhead (Packets)		
	BP-AODV	B4SDC	Proposed
20	10	4	2
40	12	6	3
60	13	7	4
80	14	9	4
100	15	12	5

7) Impact of routing acquisition delay: Route Acquisition is described as the establishment of route between two nodes for forwarding the data packets from source to destination. The delay associated with the route establishment is termed as route acquisition delay. This delay is occurred mainly due to lack of selection of neighboring nodes. Fig. 10 depicts the comparison of route acquisition delay in three research works including the proposed work with respect to the routing hops. Existing works focuses on only the selection of neighbor nodes based on the trust value but the selected node may not have sufficient energy level to forward the packet and this will lead to route acquisition delay Table XI. The proposed work selects the reputed neighbor node based on link stability, relative velocity, available bandwidth, energy, queue length, and trust. Hence the delay associated with route acquisition is decreased significantly.

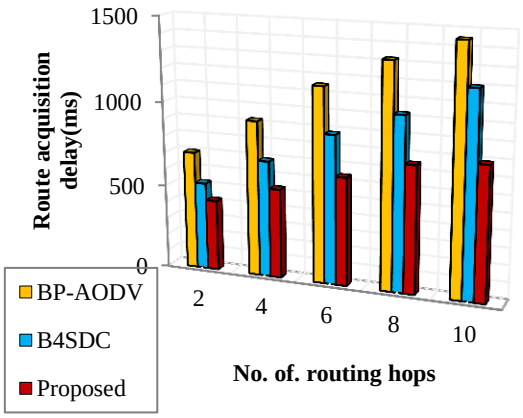

Fig. 10. Routing Acquisition Delay vs. no. of. Routing Hops.

TABLE XI. COMPARISON OF ROUTING ACQUISITION DELAY OF PROPOSED METHOD WITH EXISTING METHODS FOR NUMBER OF ROUTING HOPS

No. of Routing Hops	Routing Acquisition Delay(ms)		
	BP-AODV	B4SDC	Proposed
2	700	520	420
4	920	690	530
6	1150	880	640
8	1320	1024	750
10	1450	1200	790

C. Security and Efficiency Analysis

The packet transmission in the MANET environment carries sensitive data and the security of these message packets should be ensured. The malicious nodes in the network lead to routing issues. The attacks caused by these nodes will affect the performance of routing between the nodes and greatly affects the privacy of the nodes. Some of the important routing attacks and the process followed by the proposed work to overcome these attacks are explained below:

Black Hole attack: In this type of attack, the attacker will attract the source node with low hop routes. Once the sender begins to transmit data packets, the attacker will drop the packets without transmitting it to the next node. This increases the latency among the nodes. The proposed system selects the reputed node for pack forwarding by considering both the direct and indirect trust of each node thereby identifying the false trust given by the malicious nodes.

Grey Hole attack: This is an advanced level of black hole attack in which the malicious node will behave like a legitimate node. Not all the packets send through this node will be dropped, the attacking node drops only the sensitive packets. These types of nodes are difficult to identify. However, the indirect trust provided by the security node will identify the symmetrical pattern of packet drop through which the grey hole attacks can be identified and the proposed method will eliminate these nodes during packet forwarding.

Worm Hole attack: A tunnel like structure is created by two or more nodes thereby decreasing the hop count of the route. Once the source node begins to transmit the packet through this tunnel, the source node gets attacked resulting in denial of service and replay attacks. The proposed work performs clustering of mobile nodes and the cluster head is elected for each cluster. The cluster head will have the link details of each node by doing so the nodes involved in these types of attacks can be identified and are eliminated during packet transmission.

Timing attack: in this type of attack, the attacker alters the time slot of the packet passing through it thereby causing a delay to the packet in reaching the destination. Due to this manipulation the receiver may not receive the packets on time. The proposed work identifies the malicious node even before the attack takes place, hence these types of attacks can be avoided.

Intruder attack: In this type of attack, the attacker is from outside the network. These attackers enter the network by manipulating the user present in the network. Once the malicious nodes enter the network they start to attract the source nodes which will leads to packet drop and security threat to the sensitive information. The proposed method secures the authenticity of the user through multi factor registration and authentication. The credentials such as Binary format of user finger vein, Physically Unclonable Function (PUF), Password and User ID are registered hence the manipulation of malicious nodes is prevented.

The efficiency of the proposed work is expressed in terms of QoS, energy consumption and security which is depicted in Fig. 4 to 10. The proposed work has better performance when compare to existing works which is explained in terms of security strength ratio, routing overhead ratio, packet delivery ratio, attack prevention rate, end-to-end delay, throughput, route acquisition time. The summary of the proposed research work is briefed as follows:

- The user identity ID registered and the hash values for these credentials are generated by using CubeHash algorithm. These hash values are used to create the private and public keys for the encryption of the message packets during transmission.

- The network complexity and the transmission overhead are minimized by forming the cluster of nodes by using Weighted Sum computation for Clustering (WSC4C). Factors such as energy status, geometrical distance, link quality and moving direction are computed and the weighted sum of these factors is used for cluster formation and cluster head election.
- The routing of message packets is done through the reputed nodes which are selected using Dolphin Swarm Optimization (DSO) algorithm. The reputed nodes are estimated based on link stability, relative velocity, available bandwidth, energy, queue length, and trust. Through this algorithm the high link stability, low queue length and high bandwidth is achieved.
- The attack mitigation is carried out by Bayesian Direct Acyclic Graph aided Blockchain. The verification of the received packet is taken place by examining the user authentication and integrity of the data. Once the verification process is over the key to decrypt the received message packet is generated. The blocks in the blockchain technology are distributed in the hyper graph and the block independency of each block is determined thereby the proposed work improves the performance of the process.

VI. Conclusion

In this work, Dolphin swarm optimization is proposed to improve the secure routing in MANET environment. To achieve the highly secure routing of data packets the Blockchain technology is used. Each and every transaction of the nodes in the network gets stored in the blocks and the hash values for these events are generated in the blocks. The user legitimacy is verified by multi-factor authentication of user. The credentials such as Binary format of user finger vein, Physically Unclonable Function (PUF), Password and User ID are collected and hash values are created by using CubeHash algorithm. These hash values are used to generate the keys to encrypt the message packet. Then the mobile nodes are clustered by using Weighted Sum Computation for Clustering to minimize the complexity encountered in routing data packets. The node with the high WSM score is elected as the cluster head. The routing is taken placed through reputed nodes which are selected by using Dolphin Swarm Optimization (DSO) algorithm. In the destination side the packets are verified for user authentication and integrity of data and the decryption of message packets is carried out by using Bayesian Acyclic Graph aided Blockchain technology. The block independence of the blockchain is computed which will improve the security of the routing in MANET environment. In future, the work can be extended by implementing the present method in MANET-IOT and also in view of improving its performance further by integrating diverse DLT algorithms.
