Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Machine Learning Augmented Breast Tumors Classification using Magnetic Resonance Imaging Histograms

Ahmed M. Sayed
Biomedical Engineering Department, Helwan University, Helwan, Cairo, Egypt
EECS Department, MSOE University, Milwaukee, WI, USA

***Abstract*—At present, breast cancer survival rate significantly varies with the stage at which it was first detected. It is crucial to achieve early detection of malignant tumors to reduce their negative effects. Magnetic resonance imaging (MRI) is currently an important imaging modality in the detection of breast tumors. A need exists to develop computer aided methods to provide early diagnosis of malignancy. In this study, I present machine learning models utilizing new image histogram features using the pixels least significant bit. The models were first trained on an MRI breast dataset that included 227 images captured using the short TI inversion recovery (STIR) sequence and diagnosed as either benign or malignant. Three data classification methods were utilized to differentiate between the tumor's classes. The examined classification methods were the Discriminant Analysis, K-Nearest Neighborhood, and the Random Forest. Algorithms' testing was performed on a completely different dataset that included another 186 MRI STIR images showing breast tumors with verified biopsy diagnostics. A significant tumor classification efficiency was found, as judged by the pathological diagnosis. Classification's accuracy was calculated as 94.1% for the DA, 94.6% for the KNN and 80.6% for the RF algorithm. Receiver operating curves also showed significant classification performances. The proposed tumor classification techniques can be used as non-invasive and fast diagnostic tools for breast tumors, with the capability of significantly reducing false errors associated with common MRI imaging-based diagnosis.**

***Keywords*—Tumor classification; histogram analysis; magnetic resonance imaging; breast cancer; machine learning**

I. Introduction

Breast cancer is the most common cancer type in women worldwide. It is the fifth cause of female deaths due to cancer [1]. Around 300,000 new female cases is estimated to occur each year in the United States alone [2]. The survival rate for breast cancer have generally improved over the past few years, as diagnosis at an early and localized stage is now possible, because of the progressive improvement in treatment strategies [3]. Early diagnosis of malignant tumors is crucial to avoid tumor metastasis and subsequently elevate the survival rate of diseased cases. If the tumor was not diagnosed early, it may spread beyond the original breast organ to other distant organs. Currently the routine method for diagnosing suspected breast tumors is imaging using Mammography, the main imaging modality for the breast organ that is then followed by pathological diagnosis through extraction of a biopsy sample from the tumor invasively. Mammography breast cancer detection sensitivity is generally high [4], however, this sensitivity goes down to near 62% when imaging females with dense breasts [5]. Additionally, the costly biopsy procedure, the gold standard for diagnosis, is routinely performed under ultrasound guidance. However, about 75% of the performed biopsy procedures yield a benign diagnosis [6, 7], which is considered an unnecessary, costly, and time consuming and painful procedure to patients. In order to reduce the wasted biopsy procedures, other imaging modalities were proposed, such as magnetic resonance imaging (MRI) and ultrasound elastography [8-13].

Lately, MRI has become a useful and important modality to visualize and detect breast tumors in today's clinical practice [8, 14, 15]. This imaging modality is becoming increasingly in use to preoperatively evaluate DCIS tumors and define their extent [16, 17]. MRI has the advantages of not producing ionizing radiation, exhibiting high imaging contrast, good sensitivity rate, ability to show auxiliary nodes, and enjoying 3D imaging capabilities [18]. Additionally, Short inversion time Inversion Recovery (STIR) MRI scanning sequence provides a means for suppressing fat and inflammatory tissue from the normal tissue in the resultant images [19, 20]. If MRI is used in daily routine examinations, specific types of cancer would have been significantly diagnosed with higher sensitivity rates at an earlier stage [8], but cost remains a major impediment. Nevertheless, breast imaging using MRI exhibit relatively moderate specificity rates (down to 79%) that increase the erroneous false positive diagnostic percentages [15, 21-23].

One of the MRI imaging characterization methods is histogram analysis that is usually used to distinguish different anatomical and morphological regions, in addition to its more fundamental usage as an image enhancement tool [24, 25]. Some previous studies used histogram methods to illustrate the relation between the tumors physiological changes and their associated histogram parameters to achieve improved utilization of these histogram parameters as substitutive and representative markers describing heterogeneity of the tumor compositions [15, 26, 27]. In the past years, several studies have exploited histogram approaches in various imaging modalities [24, 27-32] with a growing emphasis on different MRI techniques and imaging sequences. Histogram processing methods showed its value for investigating various tumor parameter distributions, for example, in dynamic contrast-enhanced MRI (DCE MRI) it was possible to differentiate

between responder and non-responder groups in brain tumors radiotherapy [33], and in apparent diffusion coefficient (ADC) using diffusion MRI, it was also possible to detect specific types of cervical cancer [34] and endometrial cancer [35]. Despite that, information related to tumor's heterogeneities remain not fully scrutinized [15]. Along with the advances in high resolution MRI and its associated signal processing methods, histogram analysis of cancer tumors scanned using MRI will be used to a greater extent.

In this research, breast tumor's heterogeneity was investigated and described by the least significant byte histogram parameters calculated from STIR MRI imaging sequences for a number of clinically and pathologically verified patients diagnosis. The aim of this study is to differentiate between the two main breast tumors' classes; benign and malignant, with higher accuracy rates. Computer aided diagnosis was achieved using three classification algorithms to categorize the acquired data. Following that, the classification efficiency was calculated and compared with the outcomes of pathological tumor's diagnosis; consequently, the classification errors and receiver operating curves were calculated using two MRI data sets; one dataset for training the classifiers and the other dataset was utilized for testing. Throughout this study, it will be demonstrated that the proposed breast tumor classification technique has the potential as a noninvasive early diagnosis tool. This may lead to earlier and faster tumors characterization, and also may reduce the number of unnecessary biopsies performed pathologically to determine benignancy or malignancy; the applicable criteria that follow.

II. Materials and Methods

In this research, the used training dataset was an online imaging dataset made available for scientific studies. It was published by the Cancer Imaging Archive (TCIA) [36] under the Breast-Diagnosis collection [37]. Table I lists the mass types included in this training dataset and their pathologic diagnosis, as published in the clinical, pathology, and radiologist reports [37]. A different MRI dataset was used for classification testing purposes. This testing dataset was previously acquired from different health care faculties, where tumors diagnosis was also verified with histopathology, as it was used in a previously published study of the research team [38]. The dataset included 186 tumor images, as listed in Table I, and their biopsy results were also available.

TABLE I. Pathologic Diagnosis of the Examined Cases

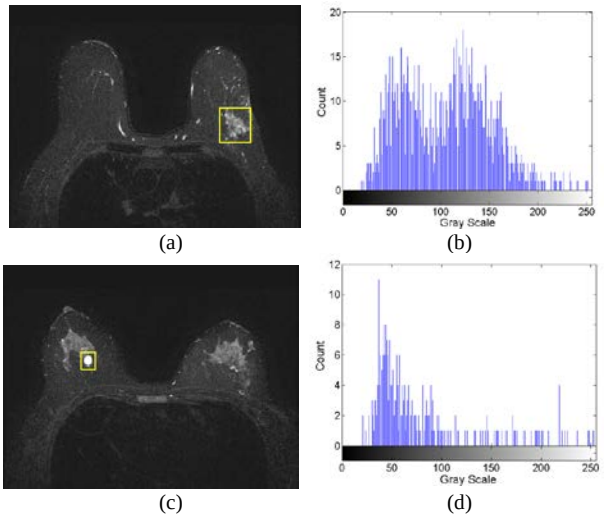
Case Diagnosis	**Pathological Diagnosis (count)**	
	Training Dataset	**Testing Dataset**
Benign	Fibroadenoma (27) Fibrocystic Change (22) Fibrosis (25) Stromal Hyperplasia (8)	Fibroadenoma (43) Fibrocystic Change (15) Cystic Lesion (14)
Malignant	Invasive Ductal Carcinoma (91) Ductal Carcinoma In Situ (19) Invasive lobular Carcinoma (35)	Invasive Ductal Carcinoma (114)
Total Numbers	**Training Dataset**	**Testing Dataset**
Benign	82	72
Malignant	145	114

A. Generating Histograms

The presented analyses in this study focus on obtaining tumor's histograms and identify the important classification features. Apparently, obtaining the whole image's histogram will degrade the classification overall accuracy by including imaging features that represent the surrounding non-tumorous tissue and healthy organs. Selection of the region of interest (ROI); i.e., delineating only the tumor, is a common practice in the routine radiology analysis. This is a particularly necessary step in this study to exclude non-tumorous features from the classification process.

Tumors' locations and pathological diagnosis were already determined in the training dataset's pathological reports. This information was used to manually select ROIs for all independent breast tumors in the dataset. Fig. 1(a) and Fig. 1(c) show selected ROIs for malignant and benign breast tumors, respectively. Following that the histogram for the selected image ROIs was generated for the least significant byte (LSB) only; the reason for that will be explained shortly. The corresponding histograms are presented in Fig. 1(b) and Fig. 1(d), in which the horizontal axes represent gray scale level variations, and the vertical axes represent the number of pixels for a specific gray scale level.

After generating all tumors' ROI imaging histograms, their classifying features were then computed. The classifying features were chosen to be ten histogram parameters. Those parameters were used to describe the shape and profile of a histogram. The ten histogram parameters were generally used in similar studies found in the literature [15, 26, 34, 38, 39] that aimed to differentiate tumors or identify various morphological regions based on imaging data. The used histogram features were: maximum, median, mean, mode, entropy, standard deviation, kurtosis, skewness, 75 percentile and the 25 percentile values. Entropy measures the degree of uniformity of a histogram. Kurtosis represents a measure of the histogram general shape. Skewness represents a histogram's data asymmetry about the mean value. Percentile values represent a value below a specified limit of the calculated histogram data.



(a) (b) (c) (d)

Fig. 1. MRI Imaging Examples of Breast Tumors' ROI and their Least Significant Byte (LSB) Associated Histograms: (a, b) Malignant Tumor; (c, d) Benign Tumor.

Statistically speaking, this study is an observational study, with no control over the classification features. Statistical testing was used to examine the classification significance of the chosen histogram parameters/features. First normality test had to be applied to select a suitable significance test. The Jarque–Bera normality test was utilized to examine the features normality. All features failed the normality test; therefore, the parametric t-test could not be used and the non-parametric Wilcoxon rank sum test was used instead. This test showed that some features had a significant classification power, provided that the alternative testing hypothesis of different features distribution medians for the two classes (benign and malignant) were different. Statistical significance level α of 0.05 was considered throughout this study.

For both training and testing data sets, only Short TI Inversion Recovery (STIR) MRI imaging were examined, which is an imaging procedure that aims at highlighting the breast mass's morphology and facilitates visualization of tumor's heterogeneity. Each pixel of the studied MRI images consists of two bytes; least significant bytes (LSB) and most significant bytes (MSB). Two types of histograms were generated: histograms based on the whole pixel size; LSB and MSB, and histograms based using LSB only. As shown in Table II, the number of significant histogram features using the full pixel size were only 6, compared to 8 significant features when using the LSB. Kurtosis and skewness were the additional significant features in the second case. For the full-length histograms, the mode was the most significant feature with P value of 0.0026, while for the LSB case, skewness was the most significant feature with 8.35E-05 P value.

Evidently, features based on the LSB histograms would provide more classification power between the two tumor types. The LSB's histogram information may have magnified the tumor's image heterogeneity and adherence pattern with the surrounding normal tissue. Fig. 1 shows benign and malignant examples along with their LSB histograms. The malignant LSB histogram has a greater content of low pixel values, in contrast to the benign LSB histogram that has larger content of high pixel values that has been truncated in the calculation of the LSB histograms. Therefore, this interesting and useful effect was encouraging to proceed the classification process using LSB histograms rather than full pixel length histograms, which according to my knowledge, has not been reported before.

B. Data Classifiers

Three classifiers were exploited to automatically categorize the examined images as either malignant or benign, according to the corresponding histogram features. The used classifiers were the discriminant analysis (DA), K-Nearest Neighbor (KNN), and Random Forest (RF) classifiers. The 227 data points were utilized to train and validate the three classifiers, judged by their consequent resubstitution error, and the leave-one-out analysis. The three classifiers were chosen for their popularity, implementation simplicity, and prior use in similar applications [40-42].

The DA classifier tries to find a combination of the classifying features that divides the two disease main classes; benign and malignant. The discriminant analysis as a parametric method, attempts to estimate a categorical or grouping dependent variable based on a number of continuous independent variables; i.e. predictor variables using a preselected discriminant function. The dependent variable in our application was the tumor diagnosis outcome, while the independent variables were the MRI imaging features. Previous studies show that this classification method has shown an acceptable classification performance, even with inappropriate features selections [41, 43].

KNN is a nonparametric classification method. A data point is classified according to the distance between it and its neighbors in the feature space, with the point being assigned to a class that is closest to its K nearest neighbors. The main parameter controlling the performance of such classifier is the number of neighbors, K. A common tradeoff in selecting the right value of the parameter K exists, where larger K values make classification outcomes less vulnerable to the effect of noise or data outliers but results in less distinct classification boundaries. On the other hand, lower values of K produce uneven and irregular classification boundaries [44]. Therefore, the classification analysis was repeated in the training phase for different values of the K parameter, and the resultant classification error was reported accordingly.

The third used classifier in this study was the RF which is also a nonparametric classification method. In this method, a group learning model is constructed using a large number of decision trees. Classification is performed according to the mode of the decision trees. Classification trees have the advantage of making a good fit to the training data [45, 46]. The main parameter in this method is the number of trees T used to build the classification model. Therefore, the classification analysis was repeated in the training phase for different values of the T parameter, and results were compared at each selected value. It is worth mentioning that it has been reported by Lin and Jeon [47], that a relationship exists between RF and KNN methods, where both belong to the weighted neighborhoods schemes.

After training each classifier using the training MRI dataset, the associated resubstitution error was calculated. Additionally, leave one out analysis (LOO) was performed as a validation step. In leave one out analysis each classifier was trained on the whole data set except for one data point, and classification was then predicted for this data point. This process is repeated until all points were diagnosed based on the model generated using the other trained data points. Both resubstitution and LOO analysis data were used to select the classifiers' parameters that generate the lowest false negative error with a high level of accuracy. Achieving low false negative errors is very crucial, as misclassifications of positive malignant tumors are so severe, as they lose the early detection and treatment privileges.

Following training, testing of the classification model follows using another independent dataset that consists of 186 testing images. Classification accuracy and receiver operating characteristic (ROC) curves were plotted for each classification model and analyzed accordingly. A flowchart summarizing the tumor's classification process is shown in Fig. 2.

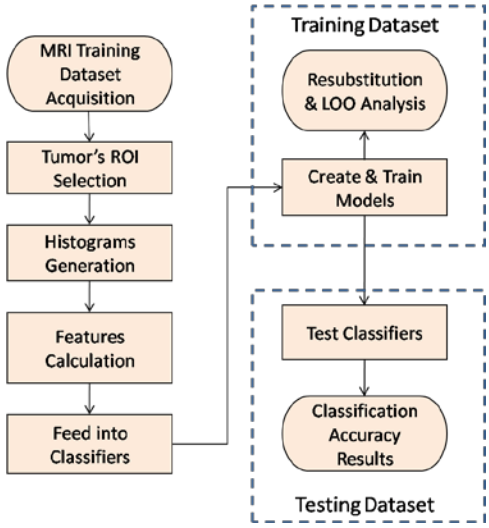

Fig. 2. Flow Chart of the Breast Tumor's Classification Process.

III. Results

Application of the described approach resulted in labeled histogram data points. The points were used for training and evaluation of the three classifiers. The classifiers where then tested, and classification was found to be significant, with different efficiencies according to the used classifier, as will be shown in the following subsections.

A. Classifiers Training Evaluation

1) DA classifier: Five DA discriminant functions were evaluated and the results of resubstitution error and leave one analysis are shown in Table III. The table lists the True Negative (TN), True Positive (TP), False Negative (FN) and False Positive (FP) values for each discriminant function. Sensitivity, specificity, and accuracy values are used to determine the classifier's performance. The sensitivity value provides a very important indication, as higher sensitivity values point out the classifier's ability to identify malignant tumors as malignant. It is ideal to have a false negative value of zero (sensitivity of 1). The Positive and Negative Likelihood Ratios (PLR and NLR respectively) are also reported in Table III. It is desirable to have a classifier with higher positive likelihood ratio > 2 and NLR < 0.5 for a better discriminatory classification [48].

From the table, it is evident that the Mahalanobis discriminant function provides satisfactory classification results with high sensitivity and low NLR reflecting the low possibility of producing false negative errors. Although the other functions provided a lower FP error, yet the severity of FN errors is much higher than FP errors.

2) KNN classifier: The KNN classifier was trained using the standard Euclidean distance metric. This classifier requires determination of the number of neighboring points; K parameter, to be included while creating the model decision boundary. A good value of K would provide a suitable compromise between the classifier's sensitivity to noise at low values of K form one hand, and the reduced classification accuracy at high values of K on the other hand. Therefore, different K values were examined, as shown in Fig. 3.

In Fig. 3, both the resubstitution and LOO analysis were performed for K values ranging from 1 to 100, to explore any potential useful values of K. Only the classification accuracy is being graphed to show the overall performance of the classifiers, but specificity and sensitivity are also reported and analyzed in Table IV. The resubstitution accuracy profile in Fig. 3(a) shows a rapid accuracy decline as K increases with a small peak that appears at K=15, then the curve declines again until it settles at an accuracy of 79% approximately. The LOO accuracy profile in Fig. 3(b) shows two peaks at K=5 and K=15, then the curve settles at about 79 % accuracy level. From both curves, it is rational to select the value of 15 rather than 5, to make the model more generalized and less sensitive to data outliers and data irregularities. For this value of K = 15, an overall training classification sensitivity of about 85.5% was achieved with a low NLR; which is an indication of a low possibility of producing false negative diagnosis.

3) Random Forest Classifier: In this classifier, the main parameter is the number of trees (T) composing the forest. The resubstitution and LOO analyses were performed for T values from 5 to 300, to explore potentially useful T values, as illustrated in Fig. 4. The resubstitution accuracy profile shown in Fig. 4(a), exhibits a steady accuracy of 100% for T values larger than 40 trees. The LOO profile in Fig. 4(b) shows accuracy fluctuations around the 79% accuracy level for almost all values of T. It can be noticed from the figure that the resubstitution error is infinitesimal and only occurs for small tree numbers. Nevertheless, the LOO analysis reveals the actual performance of the RF algorithm when data points not included in the training are tested, which indicates a model overfitting effect. Based on these results, a classifier with a decision trees number T of 100 was chosen for further testing, and the corresponding training evaluation calculations are listed in the second section of Table IV.

B. Classifiers Testing Evaluation

One contribution of this study is exploitation of trained classification models to classify an entirely different testing dataset that was not included in the models training. No further tuning or post processing was applied on the models, and testing was performed directly resulting in the following tumor diagnosis outcomes.

1) Testing DA classifie: A summary of DA testing outcomes is presented in Table V. The DA classified the tumors with a sensitivity of 99.0%, specificity of 87.8%, and accuracy of 94.1% with a very low NLR ratio.

2) Testing KNN classifier: The KNN classifier testing results are summarized in Table V for the same K value used in the training process. The testing accuracy of the algorithm was calculated for all values of K; from 1 to 100, as shown in Fig. 5(a). Two accuracy peaks appear at 15 and 23 and giving the same exact classification accuracy.

It is apparent that the KNN has a very close performance to the DA classifier, yet the sensitivity measure was found to be better using the KNN, as the calculated NLR was almost zero with no FN errors.

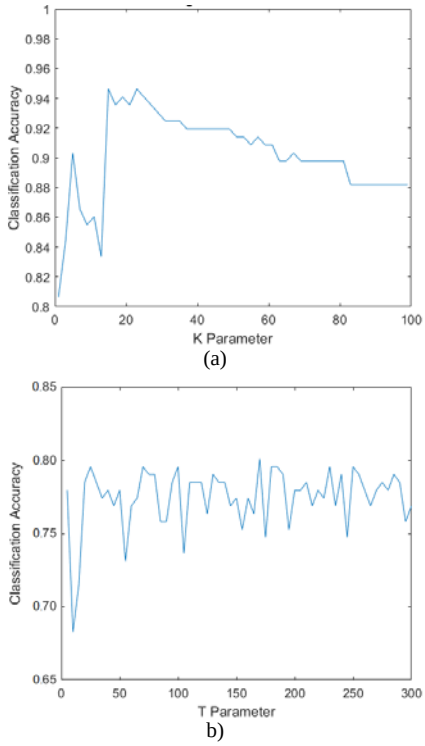

Fig. 5. (a) Accuracy of Classification Testing for all Values of K Parameter for the KNN Classifier. (b) Accuracy of Classification for all Values of T Parameter for the RF Classifier.

3) Testing random forest classifier: The RF algorithm tumor categorization outcomes were summarized in Table V for the same T value used in the training process. Once more, the testing accuracy of the algorithm was calculated for all values of T; from 5 to 300, as shown in Fig. 5(b). The accuracy profile does not show specific peaks or range of T values with higher accuracy levels. A fluctuating, yet steady performance is noticed for T values of more than 25, around the 77.5 % accuracy level. Yet, a sensitivity level of only 76% was noted, as the classifier failed to correctly categorize 25 malignant tumors. The RF testing profile is very similar to the RF LOO training profile. This observation is interesting, as it shows that the RF classifier performance can be accurately predicted based on the LOO training curve profile.

To compare the three classifiers' performance at the selected classification parameters, a combined ROC curve was plotted in Fig. 6. It is clear that the DA and KNN classifiers are superior to the RF classifier, in terms of sensitivity and specificity. The areas under the curves (AUC) were 0.956 and 0.953 for the DA and KNN, respectively, indicating a very good and significant classification performance. The AUC value for the RF model was calculated to be only 0.845 reflecting a moderate classification performance.

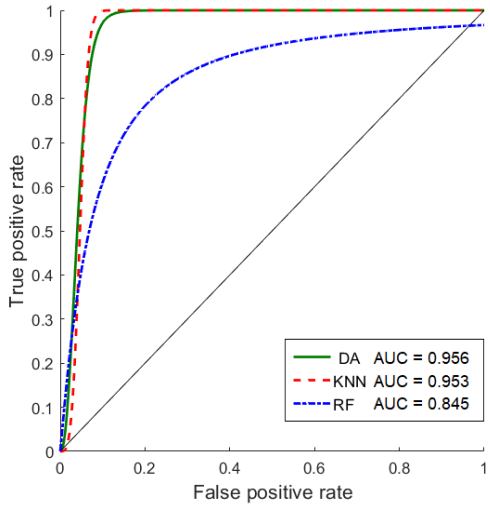

Fig. 6. ROC Curves showing Performance of the Three Breast Tumor Classifiers.

IV. Discussion

In this article, breast tumor classification methods based on MRI LSB histogram parameters were demonstrated. The selected histogram features were used to train three different machine learning methods as tumor classifiers, and their corresponding performances were compared. Previous studies in the literature used histogram parameters to characterize breast cancer and its response to therapy [27, 41, 49-51]. Their main goal was finding the statistical significance of histogram features to categorize the examined breast tumors, yet the usage of machine learning techniques for such a purpose was limited in the literature. The study reported by Vidić and coworkers presented a support victor machine algorithm to evaluate breast tumors classifications [50]. Although the authors showed an overall classification accuracy of up to 0.96, they reported only accuracy values without considering specificity nor sensitivity ratios, therefore, no information were provided about false positive or negative classification errors. Lee and associates reported five machine learning algorithms to predict prognostic biomarkers of breast cancer [51]. The authors reported an AUC value of 0.8 using a random forest

model, which is quite close to the RF AUC value we report herein, although higher AUC values were achieved using other algorithms, as demonstrated in the paper in hand. Additionally, usage of histogram features calculated using only the LSB imaging pixels has never been reported, according to my best knowledge, which have shown more significant differences between benign and malignant tumors. This effect can be explained as follows: important information pertaining to the tumor's heterogeneity, adherence to the surrounding normal tissue, and response to magnetic excitations may have been emphasized in the image's low gray scale values, due to the scanning nature of STIR MRI sequence that suppresses the fatty normal tissues, i.e., it nulls the signal from fat.

Herewith, two different breasts MRI dataset were exploited: one for training the classifiers and the other for independently testing them. One main contribution in this study is the application of a trained machine learning method on a totally different dataset from a different source. This strengthens the hypothesis that the described methods are generalized classification methods that could be efficiently used to classify any given STIR MRI breast tumor images. Furthermore, the described methods can be easily repeated and validated by other research groups on their own datasets.

Statistical analysis of the selected histogram features showed skewness as the most significantly different parameter between benign and malignant tumors, with a P value of 8.35E-05. In general, skewness represents the shape and asymmetry of a given histogram. Based on the training MRI dataset, the average skewness value for the benign images was 5.866, while for the malignant tumors the value was 2.001; approximately 3 folds. This indicates that benign histograms were quite asymmetric around the mean and more right-skewed towards the higher image pixel values as compared to malignant histograms.

As mentioned earlier the selection of the three classifiers was based on their inherent implementation simplicity and prior use in similar applications [40-42]. The aid of machine learning algorithms to improve diagnostic accuracy is of significant interest and utility, as human interpretation of MRI breast data is neither 100% sensitive nor 100% specific. Even though the DA algorithm assumes a multivariate normal distribution between the used features, which is not the case here, yet it was successful in categorizing the testing tumors data. It has been reported that violations of the normality assumption can be permitted in certain cases, and the algorithm outcomes can still be considered reliable, given that the non-normality violations are not caused by data outliers [52]. The other two algorithms; KNN and RF, do not assume normality for the input data points.

The KNN classifier was also very successful and specific in classifying the examined breast tumors. Selection of a certain K parameter was a compromise between good classification performance and robustness against noise and data outliers. Optimization techniques can be used to find the optimum KNN parameters by minimizing the cross-validation loss error. Readily available hyperparameter optimization methods (MATLAB, The MathWorks Inc., Natick, Massachusetts, US) was attempted using the training data and tested as well using the testing dataset. The optimization process recommended using the Spearman distance function (instead of the standard Euclidean method used throughout this study) and a K value of 38. In this case, the classification error occurred only for 1 FP and 1 FN data points out of the 186 testing points (sensitivity of 99% and specificity of 98.8%), which is a remarkable classification performance. Yet, the goal of this paper is to demonstrate the feasibility of using different machine learning techniques to categorize breast tumors and compare between their performances in a pilot study. The task of finding an optimal classifier for that purpose would need more investigation and testing using larger datasets, which is considered future work.

The DA and KNN classification performance metrics showed significantly better outcomes in categorizing testing data over the training data. Training outcomes showed an accuracy of approximately 83%, while testing data showed about 94% accuracy; more than 10% of accuracy increase. This effect can be explained by the fact that the training dataset was larger and more diverse than the testing dataset. As demonstrated in Table I, the training dataset included 227 independent images with 7 different tumor types, while the testing dataset included 186 images showing 4 types of common breast tumors. The training dataset included more tumor types, however, some of them were uncommon and rare tumor types, such as stromal hyperplasia and Ductal Carcinoma in Situ [53, 54]. The trained algorithms used a more generalized data than the testing data, which was the main cause behind the accuracy differences between the two situations. The lack of a more generalized testing dataset is considered another limitation of this study. Despite the encouraging results that have been shown in this study, testing the developed classification methods on a larger and more diverse MRI dataset is an ongoing work.

The RF algorithm had though a moderate classification performance with an utmost accuracy ratio of 80%. It has also the disadvantage of being expensive regarding the computational time. RF LOO analysis was completed in approximately 70 minutes to run using MATALB (The MathWorks Inc., Natick, Massachusetts, US) on a modern computer (Windows 10, 10th Generation Core I5, 2.11 GHz, 16GB RAM), while DA LOO and KNN LOO were completed in 2 and 6 seconds, respectively. Nevertheless, this method's testing performance may be directly predicted from the training LOO data analysis, as the RF algorithm behaved in a very similar and consistent way in both cases, with slight accuracy degradation under the testing mode. This was clear from the demonstrations in Fig. 4(b) and 5(b). Another interesting observation is that the three unoptimized algorithms had very close specificity ratios though; 87.8 for DA, 87.8 for KNN and 85.4 for RF, respectively.

TABLE V. TESTING RESULTS FOR THE BREAST TUMOR'S CLASSIFICATION USING THE THREE ALGORITHMS

Algorithm Parameter	TN	TP	FN	FP	Count	Sensitivity	Specificity	Accuracy	PLR	NLR
DA Algorithm										
Mahalanobis	72	103	1	10	186	0.990	0.878	0.941	8.121	0.011
KNN Algorithm										
K = 15	72	104	0	10	186	1	0.878	0.946	8.2	0
RF Algorithm										
T = 100	70	79	25	12	186	0.76	0.854	0.801	5.191	0.282

V. CONCLUSION AND FUTURE WORK

New breast tumors' classification methods based on MRI imaging were presented. The methods showed the potential to provide more accurate tumor's diagnosis non-invasively and timely efficient. This method may provide an alternative approach to the unnecessary biopsy procedures routinely performed to verify a breast tumor preliminary diagnosis. From the demonstrated results, it has been shown that the discriminant analysis and K nearest neighborhood methods can provide good tumor categorization performance with a significant sensitivity and accuracy levels. The random forest method proved to provide a moderate degree of classification accuracy, however, it showed consistent outcomes in both the training and testing data. The reported least significant byte histogram-based algorithms may be applied on other tumor types, but this requires further investigation to prove being valid. Future research projects include applying the described methods on larger and diverse STIR MRI imaging datasets to find an optimized tumors classification scheme.

ACKNOWLEDGMENT

This research did not receive any specific grant from funding agencies in the public, commercial, or nonprofit sectors. My sincere acknowledgment goes to Dr. Eman Zaghloul and her team for providing access to the testing dataset used in this study.

London, UK

***Abstract*—The total losses through online banking in the United Kingdom have increased because fraudulent techniques have progressed and used advanced technology. Using the history transaction data is the limit for discovering various patterns of fraudsters. Autoencoder has a high possibility to discover fraudulent action without considering the unbalanced fraud class data. Although the autoencoder model uses only the majority class data, in our hypothesis, if the original data itself has various feature vectors related to transactions before inputting the data in autoencoder then the performance of the detection model is improved. A new feature engineering framework is built that can create and select effective features for deep learning in remote banking fraud detection. Based on our proposed framework [19], new features have been created using feature engineering methods that select effective features based on their importance. In the experiment, a real-life transaction dataset has been used which was provided by a private bank in Europe and built autoencoder models with three different types of datasets: With original data, with created features and with selected effective features. We also adjusted the threshold values (1 and 4) in the autoencoder and evaluated them with the different types of datasets. The result demonstrates that using the new framework the deep learning models with the selected features are significantly improved than the ones with original data.**

***Keywords*—Financial fraud; online banking; feature engineering; unbalanced class data; deep learning; autoencoder**

I. Introduction

As the online payment system advances, fraud schemes have shifted from physical fraud actions using ATMs into an advanced technique that uses digital banking accounts. Unauthorized remote banking fraud is formed by three categories: Internet banking, telephone banking and mobile banking. A fraudster accesses a customer's bank account through these remote banking channels and steals money by making an unauthorized money transfer from the account. UK finance announced that total losses through remote banking in the United Kingdom have increased and reached £197.3 million in 2020, 31percent higher than in 2019. The annual number of cases of internet banking fraud and mobile banking fraud has been growing rapidly from 32,721 cases in 2019 to 66,150 cases in 2020. Other financial fraud losses such as payment cards and cheques decreased from £470.2 million to £452.6 million [1].

The fraud Detection System (FDS) used by many financial institutions, has not caught up with the advancement in fraudulent schemes on remote banking. To address constant changes in fraud behavior, some financial industries employ machine learning (ML) methods in FDS [2, 3], but it is still challenging to reveal new fraudulent behaviors by applying ML to raw data only.

Financial transaction data is also very unbalanced because legitimate transactions account for 90% and above of all transaction data and only less than 10% of the rest of the data is fraud. It is difficult to find fraudulent patterns out for ML algorithms specifically for supervised learning.

In the new feature engineering framework published in [19], we created and selected the effect features for fraud detection models built with ML algorithms: We selected Support Vector Machine (SVM) and Isolation Forest (IF) as fraud detection models.

Throughout this research, we apply the feature engineering framework on remote banking data for deep learning with the experimental dataset being provided by a European private bank.

Deep learning has been popularly used for image, audio and video recognition in terms of coping with big data in depth. It learns by dividing input data into a plurality of segmented data patterns through many hidden layers. Recently, it came to be used for classification issues such as fraud detection in the financial area. The original concept of deep learning will be traced to studies of artificial neural networks (ANN). Autoencoder is a type of ANN, an unsupervised deep learning algorithm [4]. It learns how to compress and decompress input data for representation of the original input data and consists of three layers: Encoder, latent (hidden) layer, decoder (Fig. 1). It discovers specific features from the given data during the process of data compression, also known as dimensionality reduction, and how to map the compressed features to the latent layer. The autoencoder finds out how to reconstruct the input data from mapping the features. The most advantage of using autoencoder for financial fraud detection is that autoencoder does not need fraudulent transaction data to learn fraud patterns. As mentioned above, the proportion of fraud transaction data is very little whereas the number of legitimate transaction data is very large. It is difficult to keep track of new fraudulent behavior and state-of-the-art fraud schemes from a few fraud samples because fraudulent actions are not carried out by one person. On the other hand, legitimate transactions are carried out by the same customer who holds his or her own bank account or credit card. Autoencoder can reconstruct customers' behavior patterns by learning from

specific features among large history transaction data. Autoencoder models judge fraudulent data by using loss function with mean squared error (MSE) that measures the error distance of variables in specific features between the learnt data and new input data. There are some related studies of fraud detection using the autoencoder model [5, 6, 7, 8] and they chose autoencoder techniques from the perspective of coping with unbalanced transaction datasets. They commonly use two popular techniques of feature engineering, which are principal component analysis (PCA) and standardization. PCA is a technique of dimensionality reduction and uses orthogonal transformation that computes covariance matrix which represents the correlation between two variables. Unlike machine learning models, deep learning is essential for data processing standardization as it standardizes and weight each attribute to measure how much specific features influence.

Standardization is an essential data processing for using deep learning because deep learning multiplies each attribute and sets the weighting coefficients. Deep learning has not implemented feature engineering on input data from the point of view of adding latent data patterns.

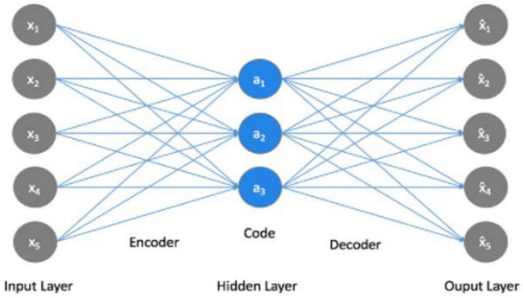

Fig. 1. Autoencoder with Hidden Layer.

In this paper, we propose a new feature engineering framework that newly creates features using feature engineering methods of feature aggregation and feature transformation and selects effective feature candidates for deep learning. In the experiment, the autoencoder is used for building a fraud detection model and verifying the effect of the paper. The rest of the paper is structured as follows: Section 2 reviews the recent development of feature engineering in financial fraud detection for deep learning. Section3 develops a new feature engineering framework that combines feature creation and feature selection processes, and section 4 introduces an autoencoder for fraud detection. Section 5 presents the experimental remote banking dataset, and the final section demonstrates a simulation of the framework for the deep learning model. Finally, section 6 presents results, discussions, and future work.

The main contribution of this study is around improving the accuracy of fraud detection models through using the engineered features produced with the framework, which are the combination of creation and selection processes.

II. Related Work

Until several years ago, the credit card was the great majority of transaction methods in financial services at ATMs, shops, and online shopping. In recent years, remote banking has also become a popular method for transferring money and at the same time, financial fraud losses through remote banking exceed fraud losses of using credit cards according to a report by UK finance in 2021 [1]. Despite the increase of the fraudulent cases of remote banking, there are still very few studies on using feature engineering for deep learning in remote banking.

A. Feature Engineering Framework for Financial Fraud Detection

There exist some similar works of feature engineering framework for financial fraud detection in [9,10,11,12] and they all use feature aggregation methods to create behavior attributes that reveal latent fraudulent patterns. J.S. Kalwihura et al. [11] and Zhang et al. [10] use the HOBA feature engineering methodology which groups into homogenous fraudulent patterns by using feature aggregations based on recency, frequency and monetary (RFM) for insurance fraud detection. The RFM is for behavior analysis which is popularly used in the marketing area. Feature aggregation methods in HOBA feature engineering consist of four aggregation categories related to behavior analysis based on a defined period during a transaction. HOBA also comprises a feature selection method which is a bootstrapped ensemble of bagged trees to select a subset of features from original data. They select random forest as an experimental model which demonstrates a 56.2% increase in the F1-score compared against the original data. Y. Lucas et al. [9] suggest using a feature engineering framework based on multi-perspective Hidden Markov Models (HMMs) for credit card fraud detection. The history of credit card transactions has the card holder's habits of the timing or the place of using a credit card in the last 24h. HMM is a sequence classification model which considers the sequential properties of transaction data. The multi-perspective HMMs categorize a symbol on transactions such as "merchant and amount", "timing", "fraud or customer"," genuine" and observe each symbol as the sequential event on transactions. The HMMs calculate the likelihood of sequences of observed symbols and create features of each event. To measure the effectiveness of the addition of the HMM features, they use perspective, recall and AUC metrics, and random forest as an experimental model. Consequently, the use of the HMM-based features improved the precision-recall AUC of the random forest model significantly compared with the use of the original features only. All the above studies have demonstrated the impact of using feature engineering methods on data with improved performance of machine learning models. In their works, they focused only on the feature aggregations side to reveal latent fraudulent patterns. A. Nagaraja et al. [14] introduced an approach for any network anomaly detection using feature transformation based on mathematical methods. They use feature clustering based on the Gaussian distribution function and a k-Nearest Neighbours (KNN) classifier as a detection model for finding the similarity between observations. The distribution function provides the equivalent deviation and threshold values to carry similarity calculation, and then the distance function of KNN measures the distance of the transformation features and determines if the input is fraud or a legitimate value. Using transformation features improves the detection accuracy in comparison with using the raw data only.

In the new framework [19], we use feature aggregation and feature transformation jointly to create important feature candidates. R. Wedge et al. [15] suggest Deep Feature Synthesis (DFS) that creates new attributes for machine learning models of credit card fraud detection using the relational structure of the dataset. In the processes of DFS, both feature aggregation and transformation methods are used to create new features using attributes of the related transactions. For instance, they applied the Hour in transaction time to determine when a transaction has occurred during the day and use statistical methods i.e., average, mean, sum and standard deviation to express the user behavior on the transaction time base. Timestamps in transactions are significant processes in DFS to compute features of every month and within 24 hours. Eventually, they generated 237 features (over 100 behavioral pattern features) for each transaction and reduced the false positive rate by 54%. However, in their study, they use all 237 generated features which may cause overfitting if the number of the training data is not enough.

In the work described in [19], we used the engineered features created through using the feature engineering framework which has improved the performance of machine learning models.

In this paper, we make use of the new feature engineering framework for deep learning, specifically for autoencoder neural network models.

B. Fraud Detection using Autoencoder Neural Network

Fraud transaction data is always imbalanced and needs to be carefully handled while using machine learning algorithms. Popular methods of coping with imbalanced datasets are oversampling and undersampling which are techniques to balance the class distribution. Oversampling is utilized to synthesize new samples of fraudulent classes but, it will take in noise. Undersampling removes samples from the majority class in the trained dataset but, it may remove useful information or important data. Autoencoder is good for coping with imbalanced datasets without considering the minority class issue because it only uses majority class samples. Some research for credit card fraud detection uses an autoencoder model [16, 17, 18]. P. Jiang et al. [16] designed a six-layer autoencoder for the dataset and selected SoftMax with cross-entropy as the loss function for final classification to detect credit card fraud. The autoencoder model improved the classification accuracy of the fraud class when the threshold was equal to 0.6. A. Pumsirirat et al. [17] used deep learning based on auto-encoder and restricted Boltzmann machine for credit card fraud detection because fraudsters gain new technology that enables them to steal money from customers. Their autoencoder applied backpropagation by setting the input data equal to the output data. Restricted Boltzmann machine can reconstruct legitimate transactions to discover fraudsters from legitimate patterns and holds two layers, input layer and hidden layer. They used the library of TensorFlow to implement autoencoder and restricted Boltzmann machine. The number of studies of financial fraud detection using autoencoder is not a few, but almost all studies use only raw data as the input data for autoencoder. They do not apply feature engineering methods to the raw data.

III. Feature Engineering Framework for Deep Learning Model

The main contribution of the new framework lies in joining two processes of feature creation and feature selection (Fig. 2). Whether machine learning or deep learning algorithms are selected, the processes of feature creation and feature selection in the framework remain the same. In the case of feature creation for deep learning, it is necessary to standardize variables in all features before building a model.

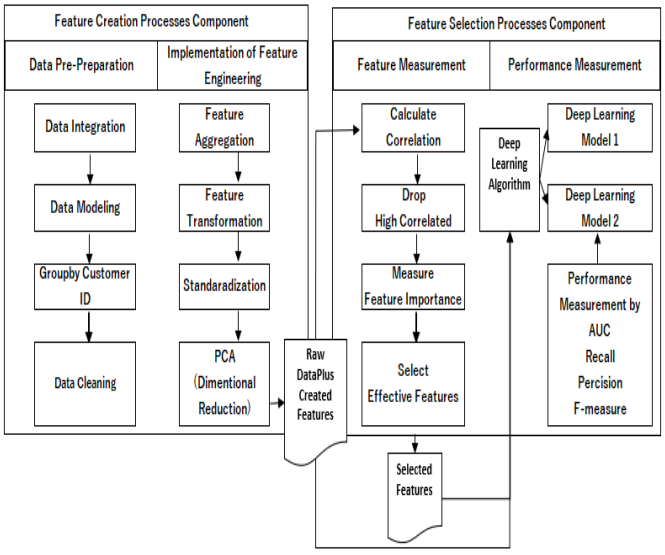

Fig. 2. Feature Engineering Framework.

A. Feature Creation Processes

In the feature creation component, there are two categories: data preparation and implementation of feature engineering. Data preparation contains four processes before the data are ready for implementation using feature engineering methods. The raw data collected from various sources are not clean and need to be maintained by handling missing data and unifying data formats. After the data preparation is made, feature aggregation and feature transformation are sequentially carried out. At this point, a first feature set candidate including all features which include newly created features and original attributes are prepared.

1) Feature aggregation based on customer behavior: Feature aggregation represents a customer's behavior when an online transaction occurs. Based on a unique customer ID, some action attributes e.g., amount, time, access device and network information are aggregated. Aggregation increases the dimensions that can express the data pattern in more detail. The created features by these aggregations represent latent customers' behavior from various angles of data. Table I describes some attribute candidates which can be aggregated with other action attributes for creating individual customer's journeys via online banking.

TABLE I. FEATURE AGGREGATION

Attributes	Combinations
Time	- Days since the last transactions - Hours since the last transactions - Minutes since the last transactions - Days since the last access by same device - Hours since the last access by same device - Minute since the last access by same IP address - Hours since the last access by same IP address - Days since the last event type occurred - Hours since the last event type occurred - Days since the last transaction occurred from specific location/ATM - Hours since the last transactions occurred from specific location/ATM
IP Address	- IP address of access device since last transaction
Amount	- Amount of the last transaction - Amount of the last transaction from specific location/ATM - Amount of the transaction via IP address
Channel	- Channel type when each event is occurred
Event Type	- Event type accessed via IP address - Event type accessed by a specific device

2) Feature transformation based on mathematical functions: There are some available mathematical functions and equations to transform a single attribute into other dimensions by mapping data. The purpose of using transformations is to generate features that discover implications in a given data from mathematical functions i.e., scaling (standardization), log transformation, binning, linear combination, count, on numerical attributes. Some of the functions which are used in the framework are described below:

a) Confidence Interval Formulas

Confidence interval (CI) is a statistic estimation formula that uses the normal distribution for observing a point estimate by calculating maximum, minimum, median, and mean.

b) Standard Deviation

Standard deviation is a method of scaling the values based on z-score which calculates the following equation:

$$Standard\ Deviation = \sqrt{\frac{\sum_{i=1}^{n}(X_i - \bar{X})^2}{N-1}} \quad (1)$$

Where:

X_i = Value of each data point

$\bar{X}$ = Mean

N = Number

c) Logarithm Transformation Formula

Log transformation is one of the popular transformation methods used to cope with skewed data because it can remove skewness adapting the formula below.

$$x_i' = \log(x_i) \quad (2)$$

$$x_i' = \log(x_i + 1) \quad \text{in case value can be zero} \quad (3)$$

$$x_i' = \text{sgn}(x_i) log|x_i| = \frac{x^i}{|x_i|} log|x_i|$$

in case value can be negative (4)

$$x_i' = \log(x_i + \sqrt{x_i^2 + \lambda}) \quad (5)$$

generalized log transformation

d) (Linear) Regression Function

This function adapts the concept of linear or multiple regression which classifies the data by fitting two or more attributes to determine the best line. Applying regression helps to discover a mathematical equation for adjusting the data and smoothing out the noise (Fig. 3).

The equation: Let A1, ……, An be n matrices having dimension K x L.

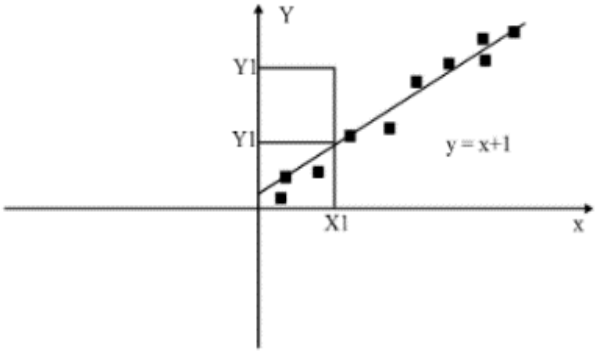

Fig. 3. Linear Regression Function.

$$B = \alpha_1 A_1 + \ldots + \alpha_n A_n \quad (6)$$

e) Clustering (K-Means)

The clustering is to group a set of spots into clusters based on a measured distance. Fraud will be recognised by locating spots out from similar clustering (see Fig. 4). All customers are classified into groups based on similar data patterns by using the K-means clustering method. K-means is an unsupervised learning algorithm that discovers the k number of clusters in a dataset. The K number of clusters are grouped by similarities based on a point at the centre of a cluster. All data are assigned to the closest cluster.

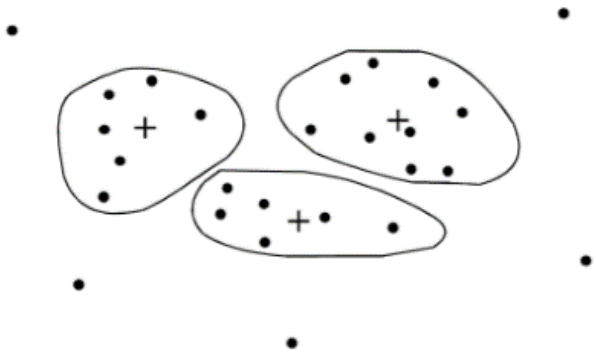

Fig. 4. Clustering.

f) Principal Component Analysis (PCA)

Principal component analysis (PCA) is an unsupervised method to reduce feature dimensions from the original feature dimensions but keeps the meaningful variation in the original attributions. PCA explores correlations among the given data and produces new aggregate variables which is a condensed dimensional feature, called principal components (PC).

In Fig. 5, the left side (plot A) shows the original data on the x-axis and y-axis. On the right-side (plot B), the 1st principal axis in the PC1 pivot displays the largest norms. PC2 pivot shows the 2nd principal axis and is orthogonal toward the pivot of PC1. The data in 2-dimension may be diminished to one dimension with extruding each element on the PC1.

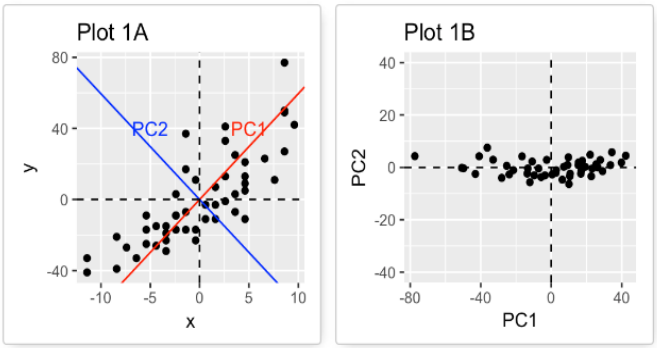

Fig. 5. Principal Component Analysis.

The mathematical approach of PCA is to maximize variances by converting a sequence of values as it is expressed in the following formula. Samples, $X_1, X_2, \ldots, X_N \in R_n$ of the variable X $\in R_n$ that was randomly selected.

$$V_{xx} = \frac{1}{N}\sum_{i=1}^{N}(X^i - \frac{1}{N}\sum_{j=1}^{N}X^j)(X^i - \frac{1}{N}\sum_{j=1}^{N}X^j)^T \quad (7)$$

$$\max_{|a|=1}\frac{1}{N}\sum_{i=1}^{N}(a^T(X^i - \frac{1}{N}\sum_j X^j))^2 = \max_{|a|=1} a^T V_{xx^a} \quad (8)$$

Where a is eigenvector corresponding to the maximum eigenvalue of a variance-covariance matrix of VX_iX_j.

B. Feature Selection Processes

In the feature creation component work introduced above, we created many additional new features. However, redundant features that correlate strongly with other features might be also included. Increasing high dimensional feature space impacts the model performance and causes overfitting, according to Mwadulo [13]. In the feature selection component, there are two main parts for selecting appropriate features from all features having both newly created features and the original data. The first part is feature measurement. In the feature measurement part, we calculate the correlation coefficient and measure feature importance, and then drop redundant features.

- Pearson Correlation Coefficient

When there are high correlations between two or more explanatory variables in the dataset, multicollinearity exists and will cause overfitting in a multiple regression model. The correlation coefficient is a statistical method to measure the degree of intensity of the relationship between feature variables. In the framework, Pearson correlation is selected to calculate the strength between two variables from different types of correlation coefficients. The range of the strength values of the correlation is expressed between -1 and 1. A value of -1 indicates the perfect negative relationship between the two feature values. On the contrary, a value of 1 indicates the perfect positive relationship between the two feature values. Values close to zero means weak or no relationship between the two values (Table II). The equation of the Pearson correlation coefficient is shown below:

$$\rho_{xy} = \frac{Cov(x,y)}{\sigma_x \sigma_y} \quad (9)$$

Where:

ρ_{xy} = Peason product-moment correlation coefficient

Cov (x, y) = covariance of variables x and y

$\alpha_x = standard\ dviation\ of\ x$

$\alpha_y = standard\ deviation\ of\ y$

TABLE II. BENCHMARK OF CORRELATION COEFFICIENT

Range of Correlation	Interpretation
±0.9 to ± 1.0	Very high positive (negative) corrlation
±0.7 to ± 0.9	High positive (negative) correlation
±0.5 to ± 0.7	Moderate positive (negative) correlation
±0.3 to ± 0.5	Low positive (negative) correlation
0.0 to ± 0.3	No correlation

- Feature Importance Measurement

As an evaluation method of relevant features, we select feature importance to measure the relative importance of each input feature. Scores are calculated by finding a rate of contribution indicating which features influence predictions. In a decision tree model, every node indicates a status of how to split values in an individual feature. The status depends on Gini impurity or information gain in the case of classification. While building a decision tree model, feature importance computes how much a single attribute contributes to reducing the weighted impurity.

IV. DEEP LEARNING ALGORITHM FOR FRAUD DETECTION

- Autoencoder

Autoencoders are unsupervised learning neural networks that learn to encode input data to specific features by reducing dimensions and discovering how the features can be reconstructed and decoded to the original data. In order to measure how well the input data can be reconstructed, a loss function is calculated for updating different weights and reducing the loss between the represented data and the original data. Autoencoder uses unlabeled training data {x (1), x (2), x (3), …}, where x (i) $\in$ Rn and applies backpropagation to learn how to approximate to a function h w, b (x) $\approx$ x displayed in Fig. 6. The output x^ is similar to x.

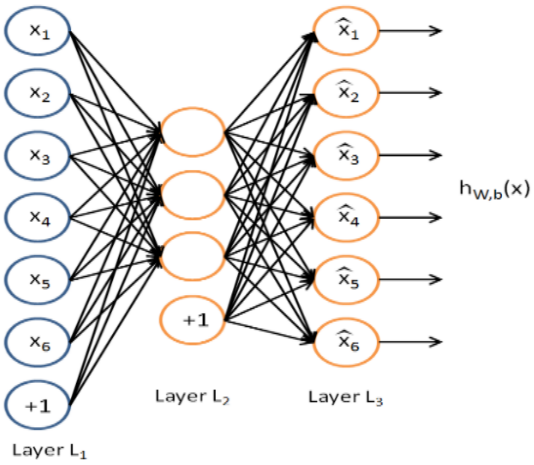

Fig. 6. Autoencoder.

There are three main layers of autoencoder: encoder, hidden and decode.

a) Encoder Layer

An autoencoder model learns how to reduce dimensions of input features and compress the given data into an encoded representation.

b) Hidden Layer

This layer holds the compressed representation of the given data and expresses the most compacted dimensional features.

c) Decoder Layer

The model learns how to reconstruct the compressed data to the original data by using the loss function and calculates the loss between the original data and the reconstructed data. The Mean square error is utilized to measure the error value shown below:

$$l(x, \hat{x}) = \frac{1}{n} \sum_{i=1}^{n} (xi - x^i)\hat{}2 \quad (10)$$

The equation of encoder and decoder are given as follows:

Encoder $h(x) = g((\alpha x))$

$$= \sum (Wx) or \ \tan h(Wx) \quad (11)$$

Decoder $\hat{x} = O(\alpha\hat{}(x))$

$$= \sum (W * h(x)) or \ \tan h(W * h(x)) \quad (12)$$

V. Online Banking Transaction Dataset

The online banking dataset is provided by a European bank for only academic purposes. The dataset contains about 130,000 transactions that occurred via online banking with each customer party ID. The dataset includes fraudulent actions which account for 5% of all transaction records and it is unbalanced labelled data (see Fig. 7).

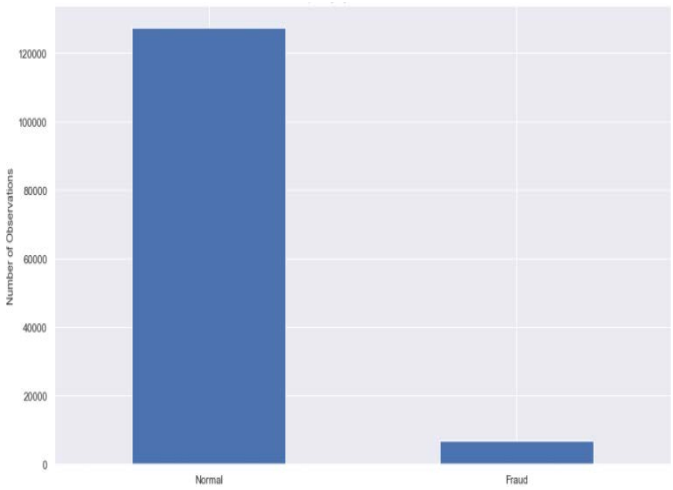

Fig. 7. An Unbalanced Target Data.

There are 39 attributes collected from various data sources such as customer information, bank account, online banking information, device information, network information, timestamp, as described in Table III. Before applying these attributes to the framework, fraudulent tendency from the point of view of transaction amount and timestamp is checked.

In the Fig. 8 shows two distributions of transaction amount frequency. One distribution (in green color) is fraudulent transactions whereas another one (in red) describes normal transactions. Both distributions show little difference between fraud and customer in this context only.

We used a logarithm function on this amount attribute, which is one of the popular mathematical functions. The histogram of log transformation is shown in Fig. 9. The distribution in green shows normal transactions while the one in red represents fraudulent transactions. From the diagnose in Fig. 8, it is shown that the fraudster in red does not steal large money at one time and seems not to be different from normal customers' transactions. It indicates that it is difficult to detect fraud transactions by the rule-based fraud detection system.

The timestamp is considered as an important feature to discover different behavior between a customer and a fraudster as customers will have their usual lifestyle patterns on a time-series basis. Days, Hours and Minutes plot transactions are shown in Fig. 10, 11, 12.

The timestamp in this dataset does not have a remarkable difference between fraud and non-fraud at a glance. Through our framework, this timestamp is segmentalized based on each customer by aggregating customer's information such as amount, network information and access information and creating new features which reveal latent customer behavior or fraudulent pattern.

TABLE III. DESCRIPTION OF ATTRIBUTES IN ORIGINAL DATA

Attribute Name	Description
ED_EVENTTYPETX	Type of event e.g., Customer Login, Make Payment etc
ED_TXNID	Transaction ID
ED_CHANNELIDENTIFIER	A way that customers can interact with a bank. This can be via the telephone, internet banking, branch, mobile.
ED_FINANCIALINSTITUTENM	Financial Institute name
ED_SUBCHANNELNM	Sub-channel name
CUSTD_PARTYID	Customer Party ID
CUSTD_EMAILADDRESSTX	Customer's email address
EVENT	Event of transaction
AUTO_RESPONSE	Auto-response
LATENCY	Latency
IDVD_LOGINTYPE	Login Type
ACTD_BANKACCTNO	Account's bank account number
ACTD_ACCTTYPENM	Account type
ACTD_AVAILABLEBL	Available balance
TRNSD_BENEFICIARYSORTCD	Beneficiary sort code
TRNSD_BENEFICIARYACCTNO	Beneficiary account number
TRNSD_TRNSAM	Transaction amount
TRNSD_PAYMENTDT	Transaction Datetime
TRNSD_TXNREFERENCETX	Transaction reference
TRNSD_PAYMENTDT	Transaction Date Time
IDVD_AUTHENTICD	Authentication code
IDVD_INTESESSIONID	Internet session ID
IDVD_IPADDRESSID	IP address
IDVD_CLIENTSCREENRESOID	Client screen resolution
IDVD_USERAGENTTX	User-agent
IDVD_DEVICEID	Device ID
IDVD_INTESESSIONID	Internet session ID
IDVD_CLIENTSCREENRESOID	Client screen resolution
IDVD_USERAGENTTX	User-agent
IDVD_BROWSERLANGTX	Browser language
IDVD_IPADDRESSID	IP address
IDVD_DEVICEID	Device ID
IDVD_TELSESSIONID	Telephone session ID
IDVDATA_TRNSTS	Transactions timestamps
EVENT	Event of transaction
AUTO_RESPONSE	Auto-response
Last_LATENCY	Latency
IDVD_LOGINTYPE	Login Type
IDVD_AUTHDETAILS1	Authentication details
Is Fraud	Fraud flag whether fraud or not

VI. Experiments and Results

A. Experiments

From our previous published work in [19], it has been demonstrated that the performance of fraud detection models with prepared feature sets, performs better than the models with original data only.

The purpose of the experiments in this research is to verify the effectiveness of using a feature set that is created through the processes using our framework for deep learning. The online banking dataset described in Section 3 is used. Target attributes in original data that are used for implementation of feature aggregation and transformation methods are almost fixed specifically for online banking transaction data. This is because the banking system has common attributes in some tables such as customer information, banking information, network information. According to processes in the feature creation component, we apply feature engineering methods on the original data and create 65 new features after aggregating features and transforming features (see Table IV).

The result of feature importance measurement is presented in Table V. We measured the feature importance of all features both original and the created features and recognized that the most of features with higher importance rate are the new features created via the feature engineering framework. Based on higher scores, we selected 57 features among all 104 features and the rest of feature's importance rate were nearly equal to zero.

Now, three different deep learning models are built with three types of feature sets: (1) original dataset only, (2) original dataset plus newly created features, (3) only selected features following feature importance scores (see Tables VI to VIII).

We then use Tensor Flow which provides a simple autoencoder program from Python libraries.

Autoencoder requires the setting of some parameters and we manually determine optimal parameter values. The Autoencoder algorithm is applied in the settings below:

1) The data are divided into 80% training data and 20% testing data. The training data consists of customer transactions only excluding fraudulent data. In the testing, the autoencoder encodes and compresses the input data and tries to represent the original data based on leaned dimensional reduction and reconstruction. Then, it can distinguish a fraudulent transaction if it cannot represent the data again.

2) The number and size of layers are set from left to right 57-18-10-6-6-10-18-57 in the case of the selected feature set. These numbers show how to encode and decode in the neural networks. From the fifth to the eighth layers the data is reconstructed, and the mean squared error as a loss function is calculated. The significant point in the layers is that the number of input data size is the same as the output data size.

TABLE VI. PARAMETERS OF AUTOENCODER

Parameter Name	Value
Optimizer	Adam Optimize

B. Performance Metrics for Fraud Detection Models

Classification problems using unbalanced labelled data cannot be evaluated by the accuracy only. Especially in the case of financial fraud detection, we should evaluate and compare the model performance with plural metrics because the classification problem is necessary to be considered as a balance between the true positives ratio (TP) and the false-positive ratio (FP). TP is the number of predictions as fraud where the actual result is also fraud. FP is the number of predictions as a legitimate transaction where the actual result is the customer. The true negatives (TN) and the false negatives (FN) are also significant metrics when measuring the performance of recall and precision. A recall is the ratio of frauds that are perfectly classified whereas precision is the ratio of the accuracy of fraud predictions. When the score of recall is high, it indicates a poor rate of FN which is the number of predictions as a legitimate transaction where the actual result is fraud. When the score of precision is high, it indicates a poor rate of FP which is the number of predictions as fraud where the actual result is the customer.

F1-Measure is the harmonic mean of precision and recall. The best score is 1 whereas the worst score is 0. This metric seeks the balance between precision and recall (see Table IX).

TABLE IX. PERFORMANCE METRICS DEFINITION

Precision	TP/(TP+FP)
Recall	TP/(TP+FN)
F1-measure	2*Precision*Recall/ (Precision + Recall)

The confusion matrix shows a matrix describing the performance of the model using True Positives (TP), False Positives (FP), True Negatives (TN) and False Negatives (FN) (see Table X).

TABLE X. CONFUSION MATRIX

# of Observations	**Predicted Normal**	**Predicted Fraud**
Actual Normal	TN	FP
Actual Fraud	FN	TP

C. Results and Evaluations

The effectiveness of the feature engineering framework is measured by comparison with the performance of the autoencoder model with the original data only. As stated in the previous section, in order to evaluate the efficiency of the created and selected features, the model performance is assessed by AUC, recall, precision, and F-measure. The following Table XI shows the comparison of autoencoder models with two threshold values (Threshold=4 and 1) with three different types of datasets.

TABLE XI. COMPARISON OF AUTOENCODER MODELS WITH THRESHOLD VALUE =4 IN THE DIFFERENT DATASETS

Threshold=4	**AUC**	**Recall**	**Precision**	**F-measure**
Model1 with only original data	0.65	0.058	0.188	0.0896
Model 2 with original data plus new features	0.83	0.064	0.215	0.0986
Model 3 with the selected features	0.92	0.064	0.215	0.0986

The results in Table XI shows that model 3 with the selected features and model 2 with original data plus newly created features are higher in all performance metrics than model 1 (with original data only). Model 3 has a higher AUC than Model 2.

Different threshold values are chosen based on the situation shown in Fig. 13. We can adjust the threshold value to a better classification part.

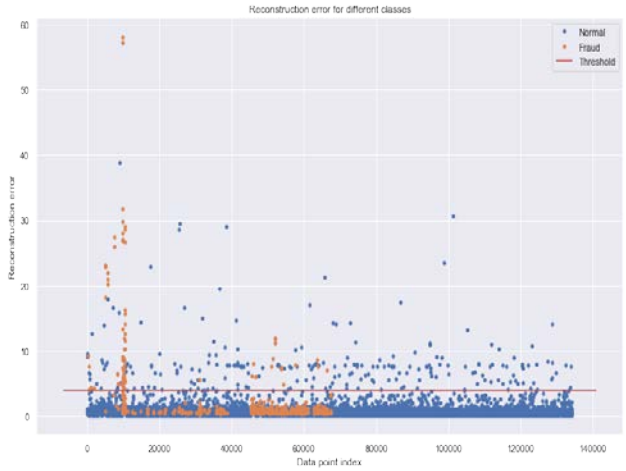

Fig. 13. Data Distribution in Threshold 4.

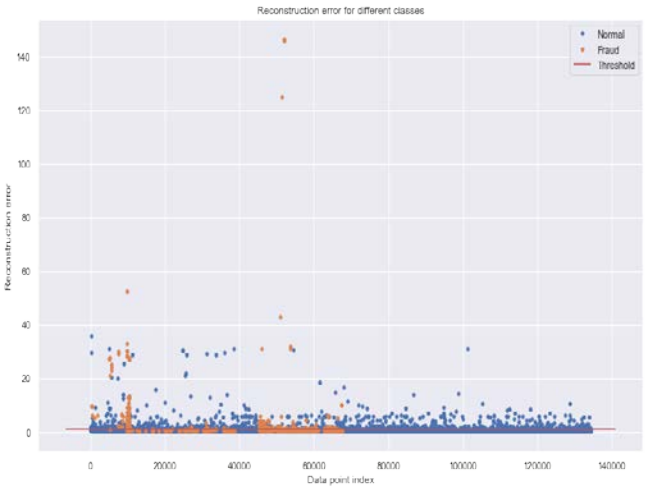

Fig. 14. Data Distribution in Threshold 1.

The data distribution presents the thresholds between fraudulent data and legitimate data. In the case of threshold 4, most fraud transactions are not classified well with the confusion matrix confirming this. Now let's change the threshold value from 4 to 1. Fig. 14 shows the data distribution when the threshold value is equal to 1.

It appears that fraud transactions with the threshold value of 1 are better classified than the ones with a threshold equal to 4. The performance of the models with a threshold value of 1 becomes as described in the table below:

TABLE XII. COMPARISON OF AUTOENCODER MODELS WITH THRESHOLD VALUE=1 IN THE DIFFERENT DATASETS

Threshold=1	AUC	Recall	Precision	F-measure
Model1 with only original data	0.73	0.161	0.104	0.1263
Model 2 with original data plus new features	0.91	0.358	0.451	0.3994
Model 3 with the selected features	0.96	0.648	0.430	0.5167

Table XII demonstrates the superiority of Model 3 with selected features.

From the above results two suggestions are drawn. First, the performance of the autoencoder models significantly improves when the new features are created based on the proposed feature engineering framework. The experiments indicate that it is efficient for a deep learning model (for classification) to implement feature engineering on original data before inputting the data. Second, adjustment of threshold in autoencoder also made an impact on the model accuracy. A combination of an appropriate setting of threshold and optimal feature set can improve a deep learning model performance for fraud classification.

Another point of view from the experiments is about scores of Recall and Precision of each model. Recall has an impact on huge money loss whereas Precision influences customer satisfaction and confidence. All measurements of the models using the selected feature set are the highest scores than model 1. Precision in model 2 is higher than the precision in model 3 which indicates that a balance between precision and recall is a trade-off. As mentioned above, a high score of recall indicates the model can identify fraudulent activities without mislabeling them as actual customers. On the other hand, a high score of precision means the model can identify actual customers' transactions without mislabeling them as fraud. In either case, using the created features in the newly built feature engineering framework could improve the model performance and detect fraudulent transactions based on the reconstruction of the input data.

VII. CONCLUSION

A fraud detection system in recent years adopts machine learning models which learn anomaly data patterns from past transaction records. However, the total losses through online banking in the United Kingdom have been increasing because fraud schemes continue to further evolve as the online payment system advances. Feature engineering is a key to improving the accuracy of fraud detection models and can reveal latent data patterns by transforming raw data into another dimension. In the paper, we used the feature engineering framework which creates new features and selects effective features through feature engineering techniques for autoencoder, a deep neural network, this time. As a result, the performance of the autoencoder models built with selected features from the framework was better in comparison to the performance of the autoencoder models built with raw data only.

Deep learning methods have a function of feature extraction to reduce the number of features in an input data and automatically learns features at multiple levels by combining the input features. Although they already have a part of feature engineering function in the algorithms, using the prepared dataset including new features created through the feature engineering framework was more effective for improving the deep learning model performance.

In this paper, we used an autoencoder as a deep learning model and presented the effectiveness of using the feature engineering framework. In further work, we will use other deep learning algorithms such as recurrent neural network (RNN) and convolutional neural network (CNN) which are often used for financial fraud detection. Moreover, the feature selection component in the framework will be studied and improved.

Multifractal Analysis of Heart Rate Variability by Applying Wavelet Transform Modulas Maxima Method

Evgeniya Gospodinova, Galya Georgieva-Tsaneva, Penio Lebamovski
Institute of Robotics, Bulgarian Academy of Sciences, Sofia, Bulgaria

***Abstract*—The analysis of heart rate variability is based on the intervals between the successive heartbeats and thanks to it information about the functional state of the person can be obtained and the dynamics of its change can be traced. The nonlinear dynamics methods provide additional, prognostic information about the patient's health, complementing traditional analyses and are considered potentially promising tools for assessing heart rate variability. In this article, studies have been carried out to identify the mono- and multifractal properties of two groups of people: healthy controls and patients with arrhythmia using Wavelet Transform Modulas Maxima Method. The obtained results from the studies show that for healthy subjects the multifractal spectrum is broader than the spectrum of patients with arrhythmia. The value of the Hurst exponent is lower in healthy controls, and in patients with arrhythmia this parameter tends to one. For the healthy subjects, the scaling exponent showed nonlinear behaviour, while for patients with arrhythmia it was linear. This indicates that heart rate variability in healthy controls has multifractal behaviour while patients with arrhythmia have monofractal behaviour. The finding may be useful in diagnosing subjects with cardiovascular disease, as well as in predicting future diseases, as the heart rate variability changes at the slightest deviation in the health status of subjects before the onset of relevant signs of the disease.**

***Keywords*—RR time series; heart rate variability; wavelet transform modulas maxima method; monofractal; multifractal**

I. Introduction

The effectiveness of the modern medical technologies is closely linked to the improvement of the methods and the instruments for monitoring and analysing the condition of patients during their treatment. In medicine the problem with patients' clinical surveillance occupies a special place, as the monitoring of their current state can be of vital importance.

The use of electrocardiographic data for analysis of the cardiac activity of the patient is a generally accepted method. The presentation of heart rhythm as a dynamic row of RR time intervals (the distances between the R-tops of the electrocardiogram) and the mathematical analysis of this data [1] is widely used in the research of the cardiac activity. Based on the RR interval series, heart rate variability (HRV) is determined, which is one of the most accessible physiological parameters [2] reflecting the processes of autonomic regulation in the cardiovascular system. The dynamic characteristics of the heart rate make it possible to assess the severity of changes in the sympathetic and parasympathetic activity of the autonomic nervous system in changing the patient's health. The sympathetic branch reduces the intervals between heartbeats [3], while the parasympathetic branch increases them.

In modern cardiology, more and more attention is paid to the analysis of heart rate variability and more specifically to the changes in heart rate intervals [4]. Heart rate is the most objective characteristic of the functional state of the human body and depends on several factors: age, gender, environmental conditions, stress, body temperature, etc. [5, 6]. HRV analysis is a unique diagnostic technique that allows not only to assess the functional state of the human body, but also to monitor its dynamics and to identify the occurrence of pathological conditions when they are at a very early stage. The heavy physical work, the psychological stress, as well as the disease states of the human body lead to an increase in heart rate and to a decrease in HRV. Conversely, when the body is at rest, the heart rate is usually lower and the HRV is higher.

The mathematical methods for assessing the functional state of the human body through the study of HRV are combined into the following two groups: linear and nonlinear methods.

The linear methods include time-domain analysis and frequency-domain analysis. These methods are standardized, knowing the reference values of the studied parameters, but this is often not enough to characterize the complex dynamics of the RR time series of heart rate.

The nonlinear methods such as: Poincare plot, Detrended Fluctuation Analysis (DFA), Multifractal Detrended Fluctuation Analysis (MFDFA), Wavelet Transform Modulas Maxima Method (WTMM), AppEn, SampEn [7, 8, 9, 10] and others are not standardized, which is the reason for their limited use in clinical practice. The nonlinear methods for HRV analysis are based on the theory of chaos and fractals. These methods are in the process of active research, and it is expected that in the near future they will be able to give a new idea of the dynamics of heart rate in the context of physiological changes in patients with cardiovascular disease. Practically, each cardio interval contains elements of nonstationarity (fractal components) and for their evaluation in recent years methods of nonlinear dynamics are actively applied. These methods provide additional prognostic information of the studied signals, which complements the traditional analyses in the time and frequency domains.

This article is funded by the National Science Fund of Bulgaria (BNSF).

To be able to deal with the problem of the accurate HRV assessment of the studied cardiac signals, it is necessary to choose an appropriate method of analysis that represents the dynamics of the heart rate.

The aim of this article is to analyse and evaluate HRV in two groups of people: healthy controls and patients with arrhythmia, using the Wavelet Transform Modulas Maxima method. The effectiveness of the method used was evaluated by statistical t-analysis.

The rest of the paper is organized as follows: Section II provides an overview of related research in the scientific literature. Section III focuses on the Wavelet Transform Modulas Maxima Method used in this paper for HRV analysis. Section IV describes the data used for the analyses performed. Section V presents the results and discussions. The final section (Section VI) of the article contains the conclusion that can be made from the obtained results.

II. Related Work

In recent years, there has been an active introduction of the mathematical methods of analysis in the medical practice. Many scientists have studied the complex nature of the changes in the parameters of electrocardiographic (ECG) signals using nonlinear dynamic methods. The fractal and multifractal approach in the analysis of the cardiological data allows to obtain new knowledge and assessments that give an idea of the nonlinear dynamic processes taking place in them. As a result of the work of [11] on the heartbeat dynamics, the multifractal analysis has become a widely used tool for applied research, in cases where the non-stationary processes are limited by the application of the classical methods of analysis.

The multifractal analysis expands the possibilities for cardio-diagnostics based on the wavelet theory. The proposed approach by [12] for multiresolution wavelet analysis of heartbeat intervals allows distinguishing healthy patients from those with cardiac pathology. This universal approach is applicable in the analysis of non-stationary processes in the physical and biological sciences, including the analysis of ECG signals.

The authors in [13] proposed a technique for multifractal analysis to determine the degree of multifractality of the heart rate of patients suffering from partial seizures. The results show that the degree of multifractality varies depending on the severity of the disease.

The authors of [14] advise physicians to interpret the results obtained from fractal and traditional methods with caution, as they are still in the process of research and the measurements obtained are not fully described as biomarkers for clinical use.

In [15], the authors show how the entropy and the multifractal analysis can depict the dynamics of heart rate when students performed selective inhibition tasks. The results show that the entropy and the fractal markers outperform markers in the time and frequency range of the heart rate variability in distinguishing the cognitive tasks.

The WTMM method presented by Arneodo et al. [16] can be used to study the structures of inhomogeneous processes of various natures, based on wavelet and multifractal analysis.

Recent studies [17, 18] have shown that HRV changes in individuals infected with Covid-19 even before the onset of symptoms of the disease. This indicator can be useful for early detection of this disease.

The need to study HRV through the application of mathematical methods is determined by the fact that it accurately reflects the state of regulatory processes in the human body and provides information that is important in the diagnosis, prognosis, treatment, and prevention of diseases of various kinds.

III. Methodology

The choice of an appropriate mathematical method for time series analysis is determined by its flexibility and ability to be effectively applied to real processes. Among such universal methods for time series analysis, the WTMM method, which is discussed in this article, can be applied.

The WTMM method [19, 20, 21] is based on the mathematical tools of wavelet, fractal and multifractal analysis, which can reveal the hidden dynamics of the studied time series of heart rate in the context of mono- and multifractality.

The wavelet theory allows the studied signal to be analysed in more detail than Fourier analysis [22]. The wavelets are localized at both frequency and time, while the standard Fourier transform has only frequency localization.

The continuous wavelet transform (CWT) is used to decompose the continuous wavelet function. Unlike the Fourier transform, CWT provides the ability to build a time-frequency representation of the signal [23, 24], which achieves very good localization in time and frequency.

The dynamic characteristics of the RR interval series have fractal and in some cases multifractal properties [25, 26]. The fractal concept is related to processes (objects) that meet the following two criteria:

- Self-similarity: The process consists of many segments that are similar to each other and to the whole object.
- Fractional dimension: According to this criterion the fractal objects are distinguished from Euclidean ones, which are characterized by a dimension that is an integer.

The fractal processes are of two types: monofractal and multifractal [25]. The monofractal process is homogeneous in the sense that it has the same scaling properties, which both locally and globally can be characterized by a single scale indicator, such as: fractal dimension and Hurst exponent. Unlike the monofractal processes, the multifractal processes decompose into a large number of homogeneous fractal subsets, whose properties can be characterized by a spectrum of local fractal dimensions or Hearst exponents.

The behaviour of the studied signal by applying the WTMM method is performed in two stages [27, 28, 29, 30]. In the first stage, a continuous wavelet transform is performed according to the following formula:

$$W(a,b) = \frac{1}{a}\int_0^T x(t)\psi^*\left(\frac{t-b}{a}\right)d \quad (1)$$

Where:

- W are the wavelet coefficients;
- a is a scale parameter, $a \in R^+$;
- b is the translation coefficient, $b \in R$;
- x(t) is the input signal;
- ψ^* is a continuous function in the field of time and frequency, called the mother wavelet, which is complexly conjugated. The main purpose of the mother wavelet is to provide a function to generate daughter wavelets;
- T is the maximum value of time.

The scale parameter **a** can stretch or contract the signal under study. When the value of this parameter is small, the signal is compressed, which in turn leads to a more detailed graph. On the other hand, when the scale parameter is higher, the signal is stretched, which means that the resulting graph will be presented in lower detail.

To determine the singularity of the function, it is sufficient to use only the information about the maximum of the obtained wavelet coefficients, constructing the skeleton of the wavelet transform [31,32]. Following the lines of the skeleton, the behaviour of the singularities of the function x (t) can be traced [33].

The second stage of the WTMM method consists in the creation of partition functions Z(q, a), which allow to obtain reliable estimates of the characteristics of the studied process:

$$Z(q,a) = \sum_{l\in L(a)}(\sup_{a'\le a}|W(a',x_l(a'))|)^q \quad (2)$$

Where:

- L(a) is a set of all lines;
- l are the local maxima of the modules of the wavelet coefficients that exist for the scale a.

Equation (2) shows that the maximum value of the modulus is selected for each line at scales smaller than a set value of a. As a rule, it is expected that at small values of a, the partition function will have a power dependence, which will quantitatively characterize the scaling exponents τ(q):

$$Z(q,a) \sim a^{\tau(q)} \quad (3)$$

The scaling exponent τ(q) is defined by the following expression:

$$\tau(q) \sim log_{10}Z(q,a)/log_{10}a \quad (4)$$

By selecting different values of the parameter q, a linear or nonlinear dependence of τ(q) can be obtained, depending on the type of the studied process [34]:

- if the process is monofractal, then the function τ(q) is linear and the exponent h(q)=dτ(q)/dq=const;
- if the process is multifractal, then the function τ(q) is nonlinear and the exponent h(q)=dτ(q)/dq≠const.

By analogy with thermodynamic formalism, the spectrum of singularities is calculated on the basis of the Legender transformation:

$$D(h) = qh(q) - \tau(q) \quad (5)$$

The spectrum D (h) is determined by the set of values of the fractal dimensions of the original time series. The maximum of the spectral curve corresponds to the Hurst parameter. The following conclusions about the signal behaviour can be made from the value of the Hurst parameter:

- if $0<h<0.5$, then the signal has anticorrelation dynamics;
- if $0.5<h<1.0$, then the signal has a correlation behavior;
- if h=0.5, it lacks correlation in the signal.

IV. Data

The application of wavelet and fractal analysis of the studied RR interval series is designed to determine and visually assess the degree of harmonization of the studied time series that have fractal-like structures. The purpose of this analysis is to identify functional and pathological changes, as well as to predict changes in the health status of patients.

To test whether HRV can provide information outside of linear indices, the following two groups of people were examined in this study:

- healthy controls (10 men and 10 women aged 56 ± 4).
- patients with arrhythmia (10 men and 10 women aged 58 ± 3 years).

V. Results and Discussion

The software for the analysis of the fractal and multifractal properties of the test signals was created with MATLAB.

On Fig. 1A and Fig. 1B are shown RR interval series corresponding to the heart rate variations in a healthy individual and a sick patient with arrhythmia. Variations in a healthy individual are greater than those of a sick patient. This property can be used as a criterion in cardiovascular diagnosis. In practice, heart rate dynamics can be investigated using the linear methods by applying methods in the time- and frequency domains. The obvious shortcomings of these methods are that they can only be applied only to stationary time series and the heart rate shows heterogeneity and non-stationary of its fluctuation.

On Fig. 1C and Fig. 1D are shown the results of the wavelet transform and the graphics obtained have tree structures. The tree structure is more pronounced in the healthy patient. This property allows revealing the structure of the RR interval series and can also be used as a diagnostic criterion. The colour code of the graphics presents the values of wavelet

coefficients. The light colours correspond to the higher absolute values of the coefficients and darker colours correspond to the lower values.

Important information about the behaviour of the studied RR interval series is also contained in the wavelet skeleton of the local maxima lines on each scale of wavelet coefficients matrix (Fig. 1E and Fig. 1F). The local maximum modules of wavelet transformation |W(a, в)| there are the greatest values in those points of the analysed function in which it undergoes the most significant changes (jumps).

On Fig. 2A and Fig. 2B are shown the partition functions Z(q,a) for a healthy subject and for a patient with arrhythmia. The calculation of the Z(q,a) allow the signal fluctuations to be monitored. Positive values of the parameter q accentuate the large fluctuations of the signal (strong inhomogeneity), while the negative values of q accentuate on small fluctuations.

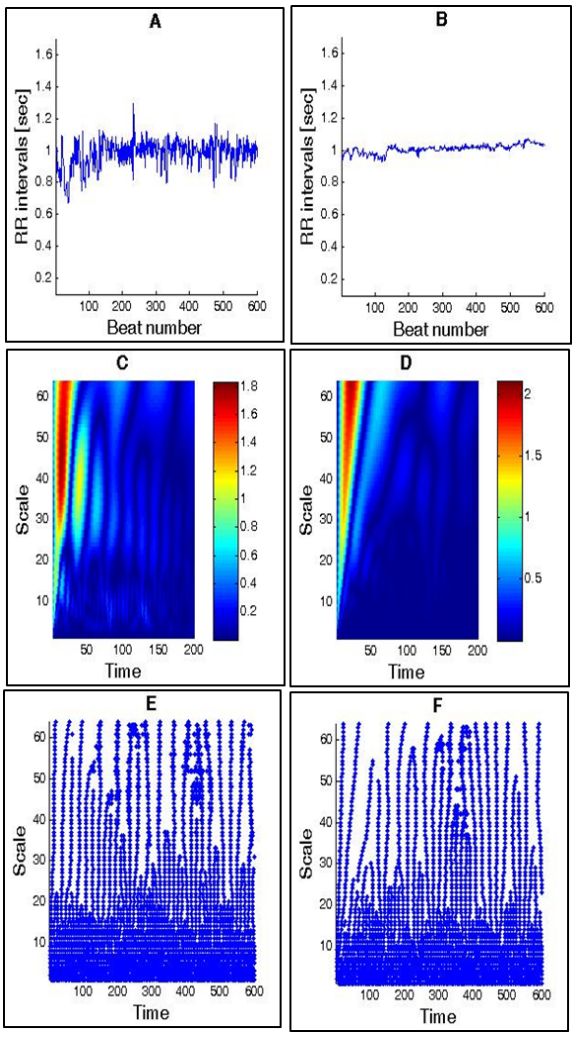

Fig. 1. RR Time Series for Healthy Subject (A) and for Subject with Arrhythmia (B); CWT Coefficients Plot in the Case of RR Intervals for Healthy (C) and Subject with Arrhythmia (D); WTMM Skeleton Plots for Healthy Subject (E) and Subject with Arrhythmia (F).

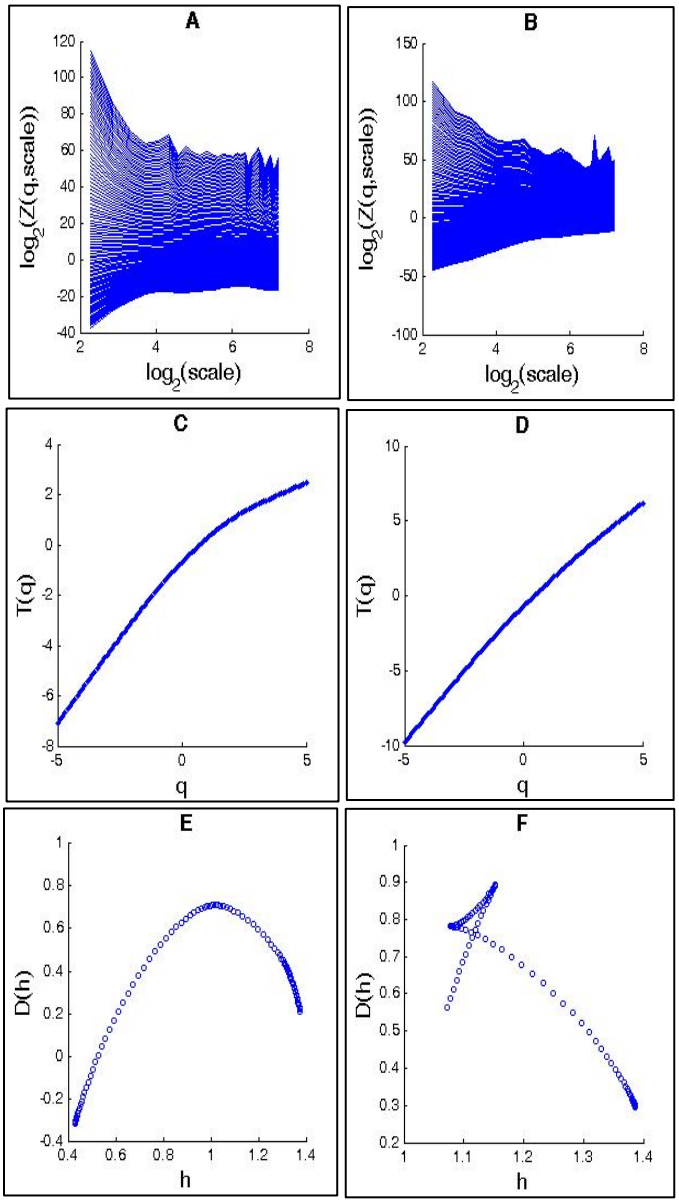

Fig. 2. Partition Functions for Healthy Subject (A) and for Subject with Arrhythmia (B); Scaling Exponent τ(q) for Healthy Subject (C) and for Subject with Arrhythmia (D); Multifractal Spectrum for for Healthy Subject (E) and for Subject with Arrhythmia (F).

The function τ(q) characterizes the fractal properties of the RR time series investigated. The graphics of the scaling exponent τ(q) have been shown on Fig. 2C and Fig. 2D for a healthy subject and for a patient with arrhythmia. For the healthy subject, the τ(q) spectrum has nonlinear behaviour and for the patient with arrhythmia this function is linear.

The statistical differences for multifractal spectrum between the RR time series of the two investigated subjects have been shown on Fig. 2E and Fig. 2F. The key characteristics are: the width of the spectrum of the singularity and the value of the exponent corresponding to the maximum value of the spectrum (Hurst exponent). For healthy people, the singularity spectrum is wide with non-zero singularities. On the other hand, for the patient with arrhythmia the singularity

spectrum is a very narrow range. In Table I is shown the values of the multifractal spectrum parameters: h_{max}, h_{min}, $\Delta h=h_{max}-h_{min}$ and the value of the Hurst exponent observed for healthy subjects and patients with arrhythmia. The results show that the width of the multifractal spectrum of the group: healthy controls are greater than the group: patients with arrhythmia. The value of the Hurst exponent is lower in healthy subjects. The studied parameters determined by t-test have statistical significance (p-value <0.05), therefore with these parameters the two studied groups can be distinguished.

The obtained results show that the heart rate of the healthy people is characterized by uneven dynamics in the form of multifractal behaviour, which cannot be detected by traditional methods, but can be observed using the WTMM method. In the pathological cases, the uneven dynamics of HRV is destroyed, which reflects the state of the cardiovascular system.

The results demonstrate the effectiveness of applying the WTMM method for HRV analysis as an additional measure that can expand and improve the information obtained from the RR time series in the diagnosis and prognosis of cardiovascular disease.

TABLE I. MULTIFRACTAL SPECTRUM PARAMETERS AND HURST EXPONENT

Parameter	**healthy controls N=20**	**patients -arrhythmia N=20**	**p-value**
	mean±std	*mean±std*	
h_{max}	1.42±0.12	1.31±0.15	0.01
h_{min}	0.30±0.20	0.8±0.14	0.0001
$\Delta h=h_{max}h_{min}$	1.0±0.22	0.6±0.20	0.0001
Hurst	0.72±0.10	0.93±0.3	0.01

VI. CONCLUSION

The results obtained in this article confirm the hypothesis that monofractality is a marker of pathological dynamics of heart rhythm in the case of cardiovascular disease such as arrhythmia. Conversely, it has been shown that multifractality is an indicator of a healthy individual. Therefore, HRV analysis using the WTMM method can be a useful approach to distinguish healthy controls from patients with arrhythmia, as the parameters studied have statistical significance (p-value<0.05). Interpretation of the results of this type of analysis may be useful before the possibility of using this method for physiological or clinical studies.

ACKNOWLEDGMENT

This research work was carried out as part of the scientific project “Investigation of the application of new mathematical methods for the analysis of cardiac data” No KP-06-N22/5, date 07.12.2018, funded by the National Science Fund of Bulgaria (BNSF).

Neural Network Model for Artifacts Marking in EEG Signals

Olga Komisaruk, Evgeny Nikulchev
MIREA — Russian Technological University
Moscow 119454, Russia

***Abstract*—One of the main methods for research of the holistic activity system of human brain is the method of electroencephalography (EEG). For example, eye movements, blink, hearth activity, muscle activity that affects EEG signal interfere with cerebral activity. The paper describes the development of an intelligent neural network model aimed at detecting the artifacts in EEG signals. The series of experiments were conducted to investigate the performance of different neural networks architectures for the task of artifact detection. As a result, the performance rates for different ML methods were obtained. The neural network model based on U-net architecture with recurrent networks elements was developed. The system detects the artifacts in EEG signals using the model with 128 channels and 70% accuracy. The system can be used as an auxiliary instrument for EEG signal analysis.**

Keywords*—Artifacts in EEG signal; neural network model; recurrent neural network; U-net architecture

I. Introduction

Electroencephalography provides quantitative and qualitative analysis of human brain functionality and its reactions to stimulants. Electroencephalogram (EEG) is important for brain activity and behavior recognition, but there are always artifacts in electrical activity records that have influence on EEG signal analysis.

Measuring instruments, including defective electrodes, disturbances and high electrode resistance can be the reason of artifact occurrence. These artifacts can be recognized by more accurate recording system, but physiological artifacts are more complex. The eye movements, blink, hearth activity, muscle activity that affects EEG signal interfere with neural activity and can be used as normal phenomenon [1].

Artifact is a signal, caused by an extracerebral source, observed during EEG recording. They identify physical and physiological causes of artifacts [2]. Artifacts obtained during an electroencephalographic investigation represent a recording defect [3]. Modern electroencephalographic equipment records extremely small values of changes in bioelectric potentials, and therefore the true EEG recording can be distorted due to the influence of a variety of physical (technical) or physiological artifacts [4]. In some cases, such artifacts can be removed using analog-digital converters and various filters, but if the artifact effect coincides in characteristics of wave frequency with a real EEG recording, then these methods become ineffective.

The most common physical artifacts are mains frequency, phone artifact, wire breakage, poor electrode contact, high resistance artifact.

The following physiological artifacts are often recorded: ECG artifact, vascular artifact, galvanic skin artifact, oculomotor artifact, electrooculogram, myographic artifact - electromyogam [2]. The appearance of such artifacts is due to various biological processes occurring in the patient's body.

An ECG artifact most often occurs in the examined patients suffering from increase in arterial pressure, mainly in monopolar and transverse biopolar leads [5]. Usually, its occurrence is associated with an increase in the activity of the sympathetic nervous system, which facilitates the conduction of an ECG signal to peripheral tissues. Galvanic skin artifact occurs due to the activation of the patient's parasympathetic nervous system and increased sweating. As a result, there is a general cyclical change in the resistance of the skin and the skin-electrode system [1]. An oculomotor artifact, an electrooculogram (EOG), appears as slow-wave oscillations in the frontopolar leads with a frequency of 0.3–2 Hz. The appearance of EOG is associated with a change in the position of the eyeball (retina). Myographic artifact occurs when the frontal, chewing and occipital muscles are strained. The appearance of such an artifact can be both a spontaneous stress of the patient and involuntary reaction to an overly tightly put on fixing electrodes system [6].

The use of machine learning methods and neural networks determines promising research in the field of automatic artifact detection. In neurocomputer technologies, there is a general training scheme [7], which is divided into a training set, in which optimization of parameters is carried out, and a test set, according to which the quality of the resulting model is assessed. At the stage of training, it is necessary to understand the signs by which the classifier will be trained [8].

The paper contains six sections. The second section presents the overview of the approaches used. The third section describes the source data for current study. The fourth section presents methods used in the study including the description of software and the types of the neural network architectures. In the fifth section, conclusions of the study are given. This section presents the result of the searching for effective architecture for a qualitative solution to the problem of searching for artifacts. The sixth section contains general conclusion.

II. Related Work

EEG is a tool for psychophysiologic researches. However, the record filtering is often accomplished by high qualified professionals and takes a lot of resources and special filtering techniques [9]. Under these conditions development of effective EEG data filtering methods is an urgent task.

Fast development of cheap high parallel computation infrastructure, powerful machine learning algorithms and big data caused a huge progress in deep learning. The modern approaches of automatic interpretation of EEG use modern techniques such as neural networks and support vector machine.

Machine learning and neural network techniques in particular [2] determine perspective in researches in the automatic artifact recognition domain.

There are five basic algorithms [10] that are widely used in classifiers:

- Linear classifier [11]. It is more popular in online applications including real-time applications. One of the most effective method is support vector machine that usually better than other classifiers.
- Neural networks [12]. The most frequent methods for time series analysis are such architectures as convolutional neural network and recurrent neural network.
- Non-linear classifier [13]. Common methods are hidden Markov models and Bayesian classifiers.
- K-means [14]. These classifiers are based on neighbor distance values.
- Classifier combinations [15]. This method combines different classifiers and demonstrates good efficiency for autonomous applications.

Due to real-time classification, described classifier methods are more optimal for EEG signal analysis.

The task of the machine in unsupervised learning is to find relationship between individual data, to identify patterns, to select patterns, to organize data or describe their structure, and to classify data.

One of the most known drawbacks of machine learning methods is that the source data for training and data for test belong to the same feature space and follow the same probability distribution.

The aim of the research is development of intelligent tools based on neural network technologies that can recognize artifacts in EEG obtained via 64-channel electroencephalograph.

III. Data

EEG data is recorded using electroencephalograph Brain Products, containing 128 channels, 64 sensors placed on the international system “10-10%”.

The aim of the experiment was analyzing brain activity zones in resting state and nonverbal intelligence dependencies.

The study was conducted in a sound-attenuated and electrically shielded dimly lit room. Impedance was kept under 25 kOhm with high conductive chloride gel. The time of EEG settling was approximately 15 minutes.

The BrainProducts PyCorder system was used as a data collection system. This system allows continuous recording without any filtering and continuous sampling at 500 Hz. The reference electrode was located at Cz. The data was re-referenced to the common reference after the recording and downsampled to 256 Hz. The data were filtered from 0.1 Hz to 30 Hz and then re-referenced to an averaged reference and manually cleaned from artifacts, with noisy channels excluded.

To remove blink and vertical eye-movement artifacts, independent component analysis (ICA) was performed on the following electrodes: VEOG — Fp1, HEOG — FT9 and FT10. After ICA, the excluded channels were topographically interpolated, and semiautomatic artifact rejection was conducted.

Dataset contains two types of files:

1) Edf files are source data of EEG recording process (see example in Fig. 1)

2) “Markers” files contain description of artifacts (see example in Fig. 2):

- type - type of interval;
- description - artifact description (for example, “Blink”);
- position - time of artifact appearance (unit of time represented in “SamplingInterval” field, that equals to 3.90625 ms);
- length - artifact duration;
- channel - channel name, representing the location of artifact (Fp1, Fp2 – “Blink”, All - artifact that appeared in all channels).

There are only two types of artifacts. Thereby, neural network will classify three classes: “Blink”, “Global artifact” and “Resting state” (when there are no artifacts).

IV. Methods

To select a neural network model, it is necessary to conduct experimental studies of various architectures. An intelligent EEG signal analysis circuit has been developed (Fig. 3). Intelligent analysis of EEG signals consists of the process of recording and forming a database, processing signals and training a neural network model.

Recording process consists of taking readings using an electroencephalograph, the data of the electrodes located on the surface of the head are sent to the BrainProductsPyCorder data acquisition system. Next, expert analysis and processing of the generated database is carried out, in which different types of artifacts are marked, and then a new database is formed containing information about artifacts in each .edf file.

Based on the Database analysis, the size of input and output of neural network was determined. Pre-processing block reads Markers Database. Then, Data analyze block analyzes it. After that, train and test samples formed.

It is necessary to determine input and output. To find the solution, data was analyzed where distance between artifacts and maximum duration of every type of artifact were found. Also, quantity for every type of artifact was analyzed for data balance. For that, Data_analyzer.py library was created. The library consists of the following methods:

- max_artifact_length - returns maximum length of the artifacts;
- max_type_length - returns maximum length of the artifact of the specific type;
- channel_stats - based on markers data, it returns quantity of artifacts for every channel;
- normal-state-lengths - returns distances between artifacts (lengths of «resting state»);
- getMaxMin_by_edf - returns maximum and minimum values of frequency in edf file;
- getMaxMin_by_train - returns maximum and minimum values of frequency in input samples.

Using the described methods, the most optimal time window was selected for determining artifacts, based on the maximum length of the artifact Blinking (1.8 seconds) [16].

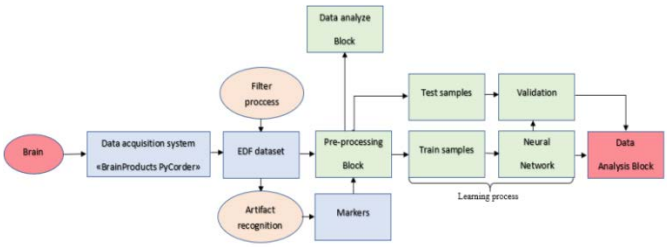

Fig. 3. EEG Signal Intelligent Analysis Scheme.

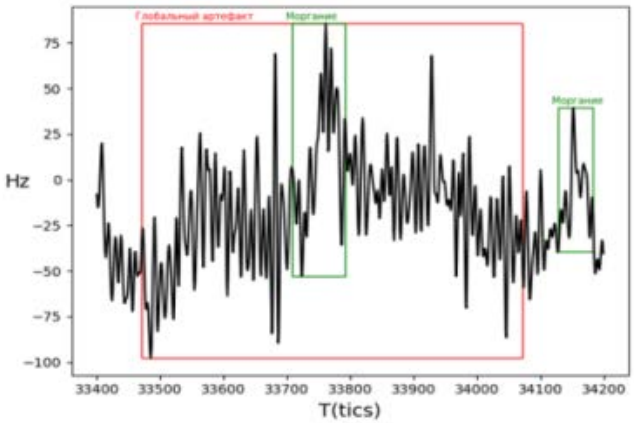

Fig. 4. Signal Graph with Artifact Marking.

It is necessary to determine number of channels that will be included in classification. Based on fact that most «Blinks» appear in Fp1 sensor, neural network can be trained only on one sensor. There are two artifacts: Blink and global artifact. Output of neural network consists of three classes: «Blink», «Global artifact» and «Resting state».

Samples were formed based on Markers database. Blink artifacts are put randomly in samples (Fig. 4).

Raw data in dataset still has noise. To filter the signal Fast Fourier Transform was implemented. The result is showed in Fig. 5.

Based on the developed mining analysis scheme presented in Fig. 4, it is necessary to develop an environment for conducting experiments. The interaction of software is shown in Fig. 6. Number of neural network models were trained.

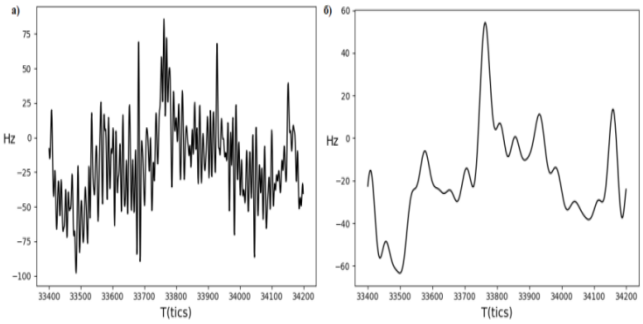

Fig. 5. Result of FFT: a) EEG Signal; b) EEG Signal with FFT.

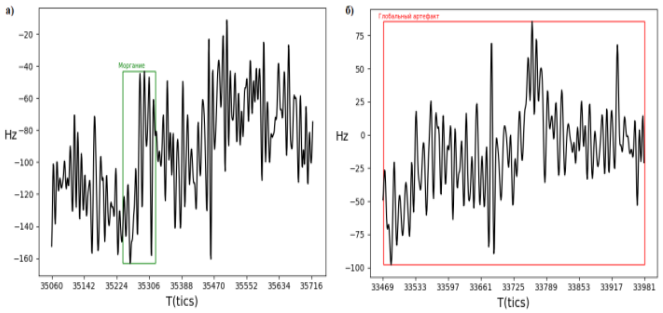

Fig. 6. Train Sample.

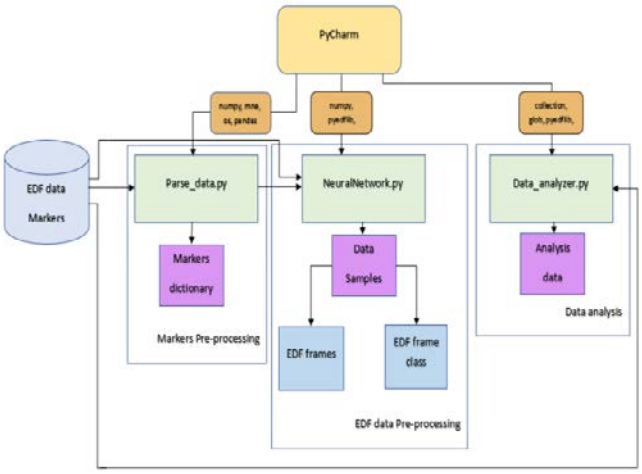

Fig. 7. Software Structure for the Analysis and Formation of Training Samples for a Neural Network Model.

In the PyCharm development environment, the main source code was developed to analyze and process the input values of the neural network model. The software tools interaction is shown in Fig. 7. The Parse_data.py library is used to convert Markers files into an associative array containing all the artifact information for each record in .edf files. The library contains the artifacts_supression method, which is used to translate the Position and Length format in seconds. In the read_markers_from_dir method, an associative array is formed from the specified directory using the pandas data analysis library containing the file name and its information about artifacts: the position of the artifacts, their description and length. This approach is used to obtain data in the function of generating training samples for a neural network.

The NeuralNetwork.py library allows creating samples for training a neural network based on arrays that are generated using the Parse_data.py library. The main method is prepare_data, which is based on information about artifacts, a database of EEG signals, used channels, and the size of the input window (in seconds) and a given ratio of samples with a normal state to samples with artifacts forms training samples for a neural network. Since the window size is larger than the maximum length of the Blinking artifact, this class is added to the selection completely. This takes into account the random shift of the artifact relative to the start of the sample. The Global artifact class is divided into several samples, from the beginning of the artifact to the sample that captures the end of the artifact and part of the signal without artifacts. In the process of recording samples with artifacts, the distance between them is calculated, and samples with the "normal state" class are taken, located between the artifacts. The Data_analyzer.py library contains the methods for analyzing the database described previously. An executable file "main.ipynb" was created in the Colaboratory environment, which contains the interactions of the libraries shown in Fig. 7, and also contains the architecture and process of training a neural network. The implementation scheme of an intelligent system for determining artifacts in an EEG signal is described in Fig. 8.

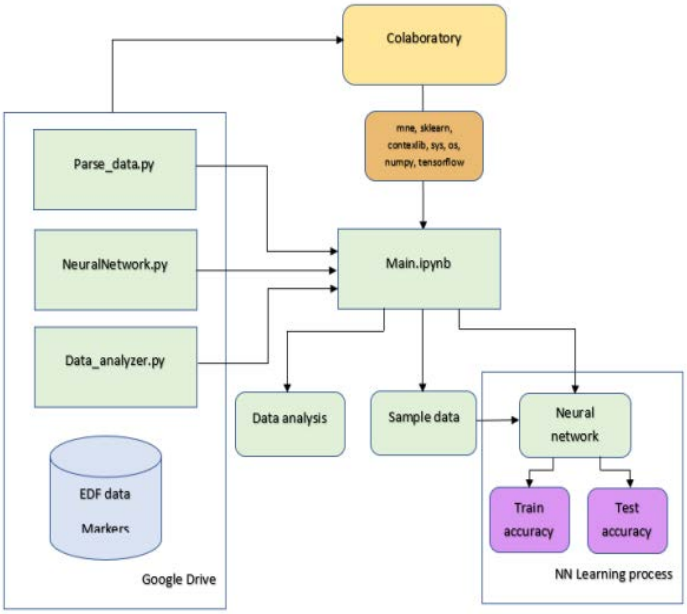

Fig. 8. Neural Network Training Scheme.

The neural network training scheme is an interaction of the libraries described earlier in the executing part of the Main.ipynb program. The executable file contains methods from the libraries for processing the database, conclusions of analytical data, sampling, the architecture of the neural network and its learning process located in the GoogleDrive cloud storage. The training process was conducted on the Colaboratory platform.

V. Experimental Selection of Neural Network Architecture

After analyzing the results of studies related to signal processing using neural networks, the architectures were selected based on convolutional and recurrent neural networks. Thus, 4 architectures were obtained:

- Batch_normalization + CNN + Dense using spectrograms;
- RNN (LSTM) + CNN + RNN (LSTM) + Dense;
- Batch_normalization + CNN + Dense;
- LSTM + NN based on "U-net"

1) Batch_normalization + CNN + Dense using spectrograms: The signal was converted to a spectrogram, a corresponding function was created using the fast Fourier transform (performed using the spectrogram method of the Scipy library) (Fig. 9).

A neural network model was applied to this type of data (Fig. 10), which is based on the convolutional neural network (CNN) [17]. The architecture was selected experimentally. It is the input data that comes to the normalization layer (BatchNormalization) with the aim of uniform learning.

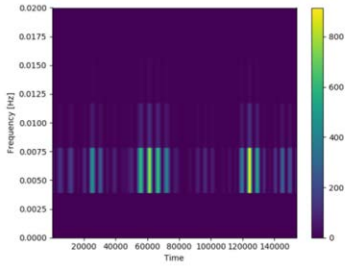

Fig. 9. Spectrogram of the EEG Sensor Signal.

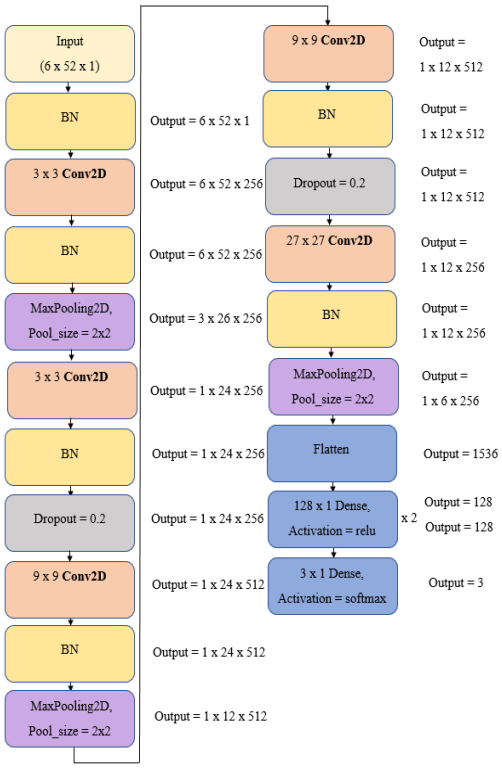

Fig. 10. Architecture of CNN.

BatchNormalization is a method for deep learning accelerating that solves a problem of learning efficiency. Normalization is implemented before every neural network layer [18]. Further, the convolutional neural network [19] receives normalized data at the input, and convolutional layers form 3x3 feature maps from it. During the experiment, it was revealed that a gradual twofold increase in the convolution core is two times more optimal for this architecture. With pooling (MaxPooling), the sample of the input space is being reduced by half (2x2), after that the "Dropout" layer is used to exclude a certain percentage of random neurons, since the neural network was overtrained during training. Then data is being converted to a one-dimensional vector using the Flatten layer. Classification is performed by the fully connected layer.

Based on the results obtained from experimental studies of the first model, several neural network models have been developed. The difference between the second and the third models (Fig. 11, 12) are that the data of the neural network model were presented in the form of a sequence, which were also converted using the fast Fourier transform.

2) RNN (LSTM) + CNN + RNN (LSTM) + Dense: A neural network model is shown on Fig. 11, the basis of which is a convolutional neural network (CNN) [20], that uses time convolutional layers (Conv1D). This layer creates a convolution core, which is convoluted with the input layer in one time dimension [21]. The architecture is as follows: in the second experiment, the input data comes to the recurrence layer (LSTM) with the maximum number of neurons, depending on the GPU capability, then the data goes to a time convolution layer in which a window of size 3 was specified empirically, after that the data is normalized by normalization layer (BatchNormalization). Based on the first experiment, the "Dropout" layer was applied, in which 20% of neurons are randomly turned off to exclude overtraining of the neural network. Then the data is transferred to the recurrent neural layer and converted into a one-dimensional vector using the "Flatten" layer. Classification is performed by the fully connected layer (Fig. 11).

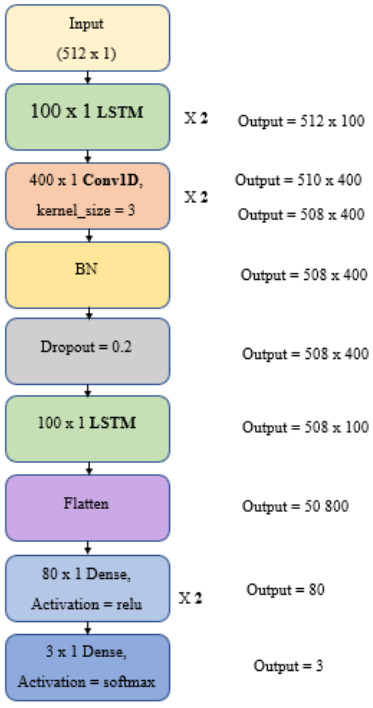

Fig. 11. Neural Network Architecture of the RNN (LSTM) + CNN + RNN (LSTM) + Dense Type using the Fourier Transform.

3) Batch_normalization + CNN + Dense: The difference between the architectures of the third model and the second model is that before the data is going to be transferred to the convolutional layer, it is being normalized. A normalization layer (BatchNormalization) was applied, before each time convolutional layer, then similarly, the data was converted into a one-dimensional vector, using the Flatten layer for fully connected layer and classification (Fig. 12).

4) LSTM + NN based on "U-net": fourth model was developed based on “Unet” (Fig. 13), using a time convolution, due to fact that database is small. The architecture of model 4 is shown in Fig. 14.

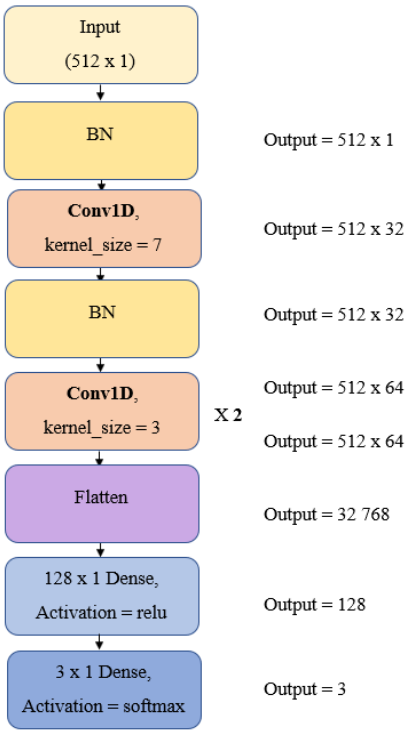

Fig. 12. Neural Network Architecture of Type Batch_Normalization + CNN + Dense using Fourier Transform.

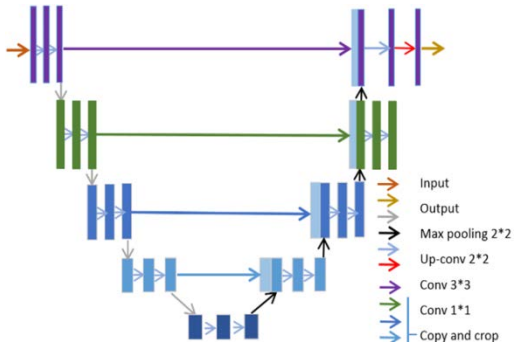

Fig. 13. The Architecture of the Neural Network “U-net".

For signal preprocessing, the fast Fourier transform method was used. Also, to improve the quality of training, a function was created (blink_augmentation), where several positions are generated for each "Blink” artifact, where this artifact will be recorded. The result is number of "Blink" samples with the same artifact but the different location in samples.

During the study, the U-net architecture was used (Fig. 13), which consists of an encoder (narrowing part), a bottleneck and a decoder (expanding part). This architecture is used for the analysis of R-grams, MRI and other medical images.

The first part of U-net is the classical architecture of a classification convolutional neural network [22]. It consists of repeated applications of two convolutional layers, with a 3–3 kernel, followed by the ReLU activation function and the MaxPooling operation, which reduces the input representation by the maximum value in the window (poolsize, in this case the value is 2).

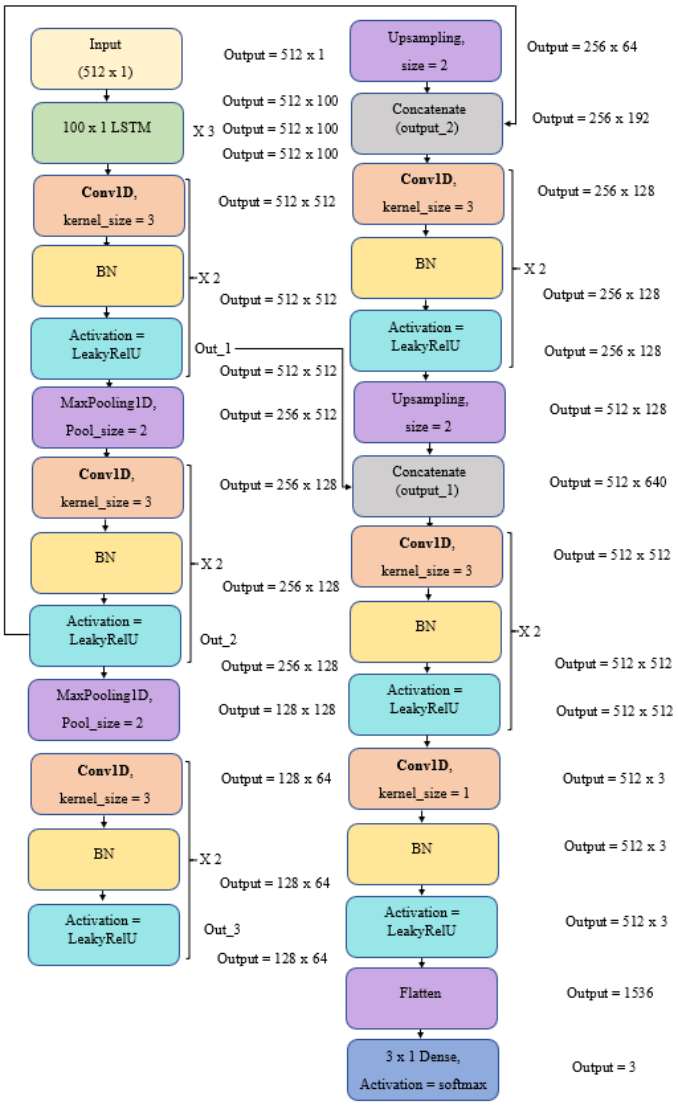

Fig. 14. The Architecture of the Neural Network Type LSTM + NN based on "U-net" using the Fourier Transform.

"Bottleneck" is a part of the network located between the contracting and expanding parts [23]. The second part consists of reverse convolution (deconvolution), which contains two convolutional layers with a 3–3 kernel and the Relu activation function, then concatenation is performed. At the last level,

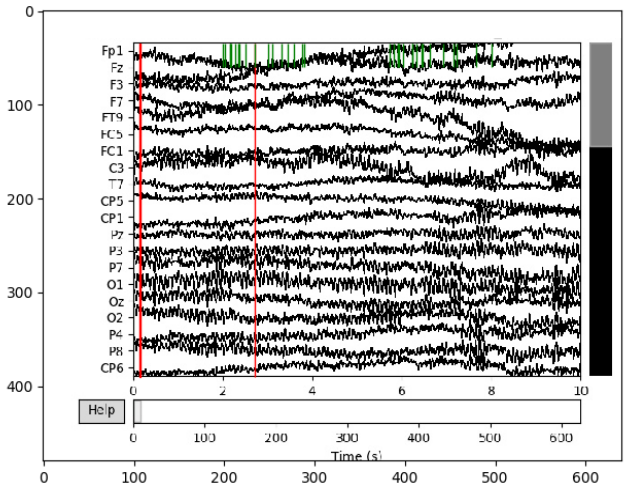
convolution 1x1 is used to match each vector with class attributes. Then the data is converted into a one-dimensional vector using the Flatten layer and the classification is performed by a fully connected layer [23].

In all experiments, the "fit" method was used for training. The number of samples, the gradient and the number of epochs for the model as well as compile method "Adam optimization function" and the error calculation function "categorical_crossentropy" were determined for each neural network model. It was revealed empirically that categorical_crossentropy is the most suitable error calculation function to optimize Adam parameters. To assess the quality of training, the Accuracy metric was chosen.

TABLE I. LEARNING OUTCOMES OF CLASSIFICATION MODELS WITH VARIOUS PARAMETERS

No.	Neural network architecture	Epochs	Batch_size	Accuracy	
				train	test
1	Batch_normalization + CNN + Dense with spectrogram	20	128	0.68	0.67
2	RNN (LSTM) + CNN + RNN (LSTM) + Dense	20	256	0.81	0.60
3	Batch_normalization + CNN + Dense	50	16	0.94	0.49
4	LSTM + NN based on U-Net model	10	300	0.70	0.70

A comparison of the results of an experimental study of four models is given in Table I. The training graph of neural network models was analyzed. The developed neural network based on the U-net architecture with recurrent layers demonstrates the best result of artifact recognition. 70% accuracy were acquired on test samples. Fig. 15 shows the results of automatic search for artifacts.



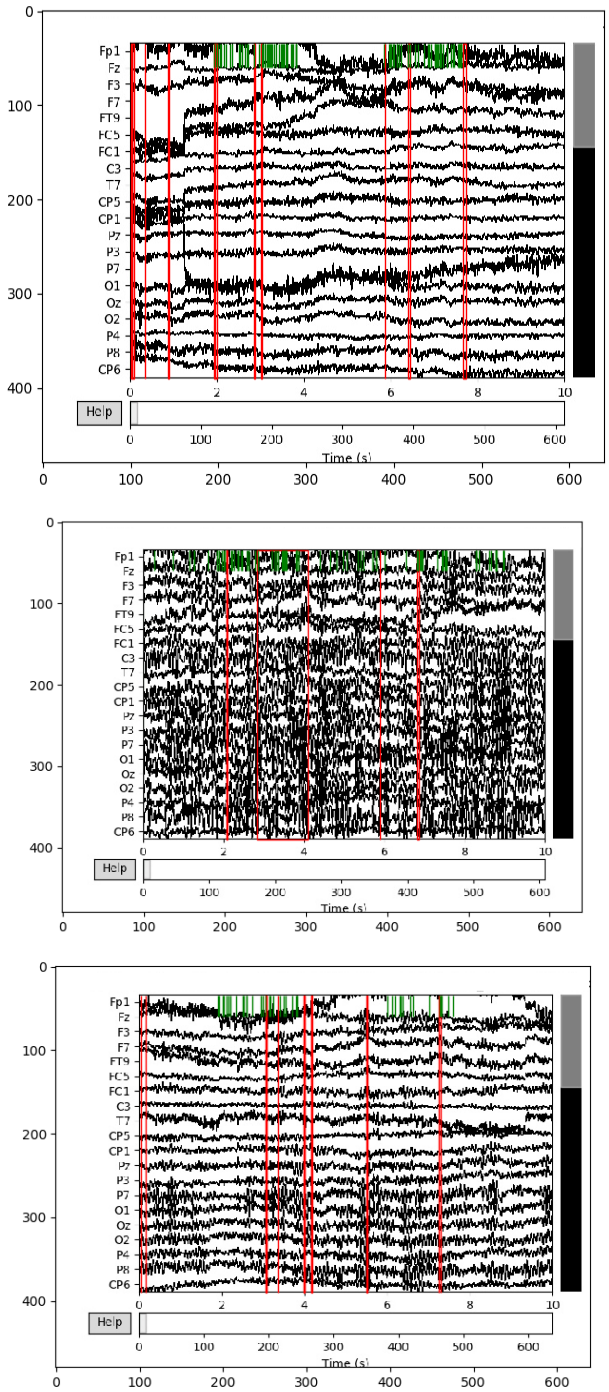


Fig. 15. The Result of Neural Network Activity. Examples of Highlighted Neural Network Artifacts: Blink Artifact is Green, Global Artifact Artifact is Red.

VI. CONCLUSION

A neural network model capable of recognizing artifacts in the process of recording EEG has been developed. Experimentally LSTM + U-net architecture was formed. To solve the problem, the U-net architecture, which is a two-dimensional convolution, was modified - a one-dimensional temporary convolution was used, the input of which received data from LSTM layers. Ensuring the required accuracy (70%)

is achieved due to the properties of the LSTM layers (trained to determine the signal state) and qualitative symmetric analysis (tension / compression) of the modified U-net layer.

Data analysis was carried out, in which the distance between artifacts in the signals, the maximum duration of each type of artifact was found. Using analytical functions, an optimal time window was allocated for artifact recognition, based on the maximum length of the "Blink" artifact. Since the data was manually filtered from the artifacts, and the database was small (9574 samples with artifacts), there was a problem with the quality of training of the neural network. The database was expanded using augmentation method, which partially influenced the learning process (28,722 samples with augmentation).

An analysis of existing architectures of neural networks, as well as an experiment with a training set was conducted. As a result, a neural network was developed based on recurrent neural network and U-net. The resulting neural network model is capable of detecting artifacts in the converted signal with an accuracy of 70%. The developed intelligent system can be used as an auxiliary tool for the analysis of the EEG signal.

During the study, the methods using libraries of applied software packages were developed for selecting an artificial neural network model of defects in digital signals, such as blinking artifacts in an EEG signal. Selected tools are able to create an environment for research and modeling of various signals.

The study showed the prospects for using the identified types of neural network architectures for analyzing EEG signals. The architectures selected during the study can be used in future studies aimed at modeling and clustering EEG signals.

Changing Communication Path to Maintain Connectivity of Mobile Robots in Multi-Robot System using Multistage Relay Networks

Ryo Odake, Kei Sawai
Graduate School of Engineering
Toyama Prefectural University, Toyama, Japan

***Abstract*—Mobile robots are being increasingly used to gather information from disaster sites and prevent further damage in disaster areas. Previous studies discussed a multi-robot system that uses a multistage relay backbone network to gather information in a closed space after a disaster. In this system, the mobile robot explores its search range by switching the connected nodes. Here it is necessary to maintain the communication quality required for the teleoperation of the mobile robot and to send and receive packets between the operator PC and the mobile robot. However, the mobile robot can become isolated when it is not able to maintain the communication quality required for teleoperations in the communication path after changing the nodes. This paper proposes a method to change the communication path of a mobile robot while maintaining its communication connectivity. In the proposed method, the mobile robot changes its route while maintaining communication connectivity without any communication loss time by connecting to two nodes.**

Keywords*—Multi-robot; multistage relay network; communication connectivity; changing communication path

I. Introduction

After a disaster occurs, disaster reduction activities are performed in the affected area to prevent the damage from spreading. In the implementation of disaster reduction activities, information needs to be gathered to determine the damage status [1–2]. Existing infrastructure, such as surveillance cameras, drone aerial photographs, and rescue teams, can be used to gather such information [3–6]. However, in some cases, the existing infrastructure cannot be used because of infrastructure malfunction or lack of power supply. Also, it is difficult for people to control the drone based on the camera images. Therefore, the use of drones is not effective in enclosed spaces after a disaster. Moreover, there is a risk of endangering human lives or inducing secondary disasters during information gathering by rescue teams. Therefore, the use of mobile robots is widely preferred for gathering information in enclosed spaces after disasters [7–11].

Two communication methods are adopted for mobile robots: wired and wireless. Wired communication helps maintain a stable communication quality and power supply to the mobile robot by using cables [12]. However, cables can get disconnected and communication with the mobile robots can be interrupted when cables become tangled with obstacles or the wheels of the mobile robot. Wireless communication has a high runnability because of the absence of physical restrictions using cables [13–14]. However, in wireless communication, mobile robots may become isolated when radio waves are hindered by obstacles. Therefore, in an enclosed space after a disaster, it is necessary to use the communication method that best matches the purpose and the situation of the disaster area [15–16]. This paper discusses a method for gathering information using wireless communication in environments where it is difficult to explore with a mobile robot using wired communication.

Robot wireless sensor networks (RWSNs) involve the teleoperation of mobile robots using wireless communication [17–19]. In an RWSN system, a mobile robot expands its search range by deploying a relay node called a sensor node (SN) in its path (Fig. 1). Therefore, the RWSN can gather information without depending on the existing infrastructure. In a network that uses multistage relaying, such as RWSN, the communication quality decreases as the number of relays and the distance between the nodes increases. Therefore, it is difficult to maintain communication connectivity of mobile robots in a multistage relay network; these networks are mainly operated by single robots. However, there is a limit to the range searched by a single robot in a large-scale facility. Therefore, this study discusses a multi-robot system that uses a multistage relay backbone network (Fig. 2).

In the proposed multi-robot system, a static multistage relay network is constructed by deploying SNs equipped with a single mobile robot first. Then, this system connects the mobile robot to the constructed network, and the mobile robot explores the search range by switching its connection between the nodes. Then, the mobile robot exhaustively explores within the network construction range while changing the search range by switching between the nodes. However, when changing the node to be connected, the operator experiences communication loss time with the mobile robot and cannot obtain environmental information from the mobile robot. Moreover, there is the risk of isolation when a mobile robot fails to connect to a node or is unable to reconnect. In addition, the operator cannot determine whether the communication quality required for the teleoperation of the mobile robot can be maintained in the communication path after changing the node to which the robot needs to connect. Therefore, there is a risk that the mobile robot becomes isolated without maintaining the communication quality.

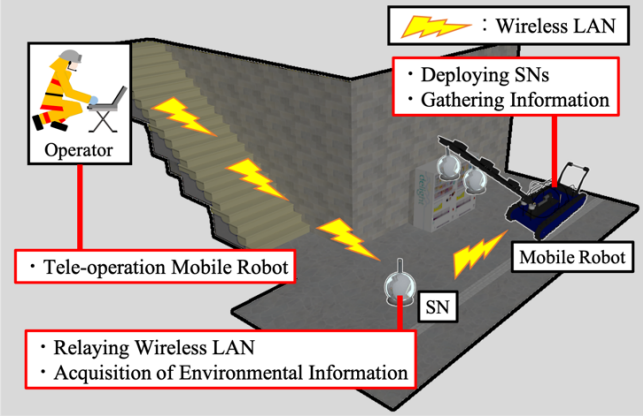

Fig. 1. Gathering Information by Mobile Robot (Robot Wireless Sensor Networks : RWSN).

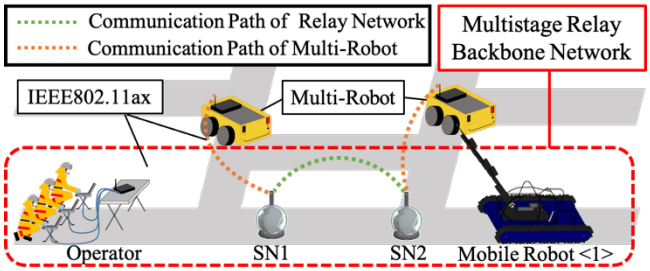

Fig. 2. Multi-Robot System using Multistage Relay Network.

To solve these problems, this paper proposes a method to change the communication path so that the communication connectivity of mobile robots is maintained. In the proposed method, the mobile robot teleoperates with two communication paths to eliminate any communication loss with the mobile robot. The communication quality required for the teleoperation of the mobile robot in the communication path is maintained after changing the nodes to be connected to; this method obtains the communication quality of the changed communication path before changing the communication path. The experiment in this paper confirmed that the required communication quality can be maintained in the communication path after changing the connected node using the proposed method. And the experiment showed the effectiveness of the proposed method.

II. Multi-robot System using Multistage Relay Network

A. Multi-robot Information Gathering

Many wireless teleoperation systems for mobile robots are based on the transmission control protocol/Internet protocol (TCP/IP). TCP/IP is highly compatible with mobile robot communication because most control systems of mobile robots use PCs. Therefore, socket communication is often adopted for mobile robot communication, and information communication is typically done by packet transmission and reception. Therefore, RWSN adopted the wireless LAN as the communication method. The operator receives packets containing information about the camera and sensor, which is acquired by the mobile robot, and this information is used to teleoperate the mobile robot (Fig. 3).

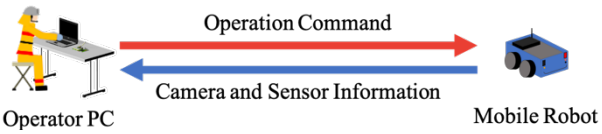

Fig. 3. Teleoperating Mobile Robot.

In previous research, there are systems that distribute and explore a large number of robots in the environment [20–21]. However, this system dynamically changes the route to send the information to the operator, which results in a misalignment of the reception intervals of the operation command packets. In addition, it is difficult to send large amounts of data, such as videos, using this system. These problems limit the operability and the ability of the mobile robot to gather information. Therefore, in this paper, the mobile robot is explored by connecting it to a static multistage relay network, such as the RWSN.

B. Flow and Requirements for Information Gathering by Multi-robot System using Multistage Relay Network

The process of the multi-robot operation using the multistage relay network is shown below (Fig. 4).

- Construction range of a multistage relay backbone network is expanded with the mobile robot <1> such as RWSN.
- Multiple mobile robots are connected to the constructed backbone network.
- Mobile robot <1> and the other mobile robots search within the network construction range while switching the nodes to be connected.

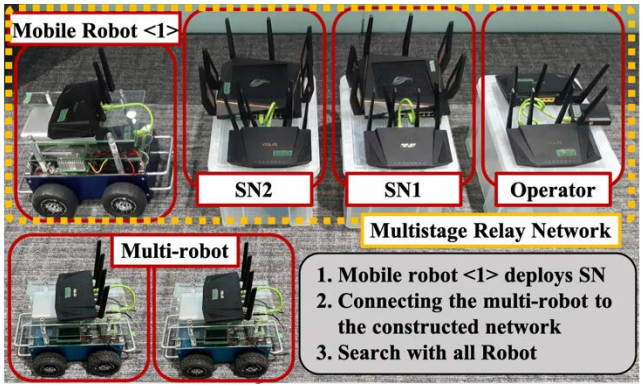

Fig. 4. Device of each Node that Constitutes Multi-robot System.

Based on the results of the operations of the robots at the damaged nuclear power plant, this study defined the network requirements of the multi-robot system as below.

- Teleoperation of a total of three or more mobile robots.
- Maintaining a throughput of 20 Mbps or higher in the communication path between each operator PC and each mobile robot.

The teleoperation of a multi-robot requires a throughput of 20.0 Mbps or higher in the communication path between each operator PC and each mobile robot. However, the theoretical value of IEEE802.11b/g used in RWSN is 54.0 Mbps, which is

insufficient throughput for multi-robot operations. This study constructs a network using IEEE802.11ax, which has a theoretical value of approximately 1,200 Mbps.

C. Topology of Multistage Relay Network

Based on the process flow and requirements of multi-robot systems, this paper proposed a multistage relay network topology for the construction of multi-robot environments. The network topology shown in Fig. 5 is characterized by the fact that each node in the multistage relay network has an access point (AP) and multiple mobile robots can be connected to a single node. Therefore, in this topology, each node constructs a network, and multiple mobile robots can explore the network construction range exhaustively while changing the APs to be connected.

D. Problems in Changing Communication Path

In this multi-robot system, the mobile robot changes the search range while switching the connected nodes, and exhaustively explores within the network construction range (Fig. 6). However, when the mobile robot changes the node to be connected, the below problems occur.

- There is communication loss between the operator PC and the mobile robot while changing the node to be connected to.
- There communication quality is unknown in the communication path after changing the node to be connected.

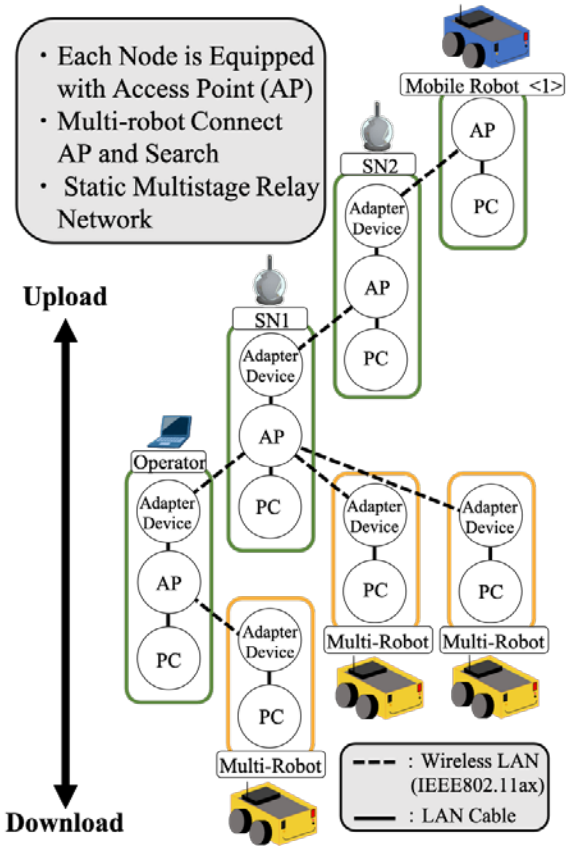

Fig. 5. Network Topology of Multi-robot System.

Fig. 6. Switching Nodes to Be Connected.

When the environment changes around the mobile robot during the communication loss time, the operator cannot receive sensor and camera information and cannot send operation command packets; consequently, it becomes difficult to respond to environmental changes. Moreover, when the connection change fails, the mobile robot becomes isolated. When the node to be connected is changed, the operator cannot determine whether the communication quality required for the teleoperation of the mobile robot can be maintained in the communication path after the node is changed. Therefore, there is a possibility of the mobile robot becoming isolated because of its inability to maintain communication connectivity after connecting to a new node. An isolated mobile robot is an obstacle to other mobile robots and affects their ability to explore the scene of disaster; they could also become a cause of secondary disasters because of their battery ignition. Therefore, this multi-robot system requires a method to change the node to which it is connected without losing the communication connectivity of the mobile robot. This paper proposes a communication path change method to maintain the communication connectivity of mobile robots.

III. Requirements for Changing Communication Path in Multi-robot System

Given the problems described in Section 2.2, the following specifications are required for the mobile robot to change the communication path in this multi-robot system.

1) The capability to send and receive packets between the operator PC and the mobile robot.

2) The capability to switch the communication path even when the operator does not know the exact location of the SN and the mobile robot.

3) Capable of obtaining the communication quality required for teleoperation of a mobile robot on the changed communication path, before switching the path.

During the exploration, it is possible to reduce the risk of isolation of the mobile robot by monitoring the changes in the environment and by being able to respond to them while the communication path was being changed. Therefore, as stated in specification (1), the system needs to be able to send and receive operation commands and camera/sensor information between the operator PC and the mobile robot during the communication path change.

After a disaster, a closed space would have an environment with multiple obstacles. In such cases, the SN and the mobile robot might not be able to see each other with a camera, or it might be difficult to measure the distance with a sensor because of the various disturbances. In such cases, there is a possibility of the mobile robot not being able to connect to the appropriate node and becoming isolated because of the lack of

location information. Therefore, as stated in specification (2), the communication path is changed without depending on the location information.

Some studies have used the electric field strength as a method for switching the routing [22]. However, the teleoperation of mobile robots sends and receives packets; therefore, it is necessary to maintain the communication quality at the packet level. Therefore, specification (3) requires the maintenance of the throughput required for the teleoperation of the mobile robot in the changed communication path before changing the node. As described in Section 2.2, the throughput required for the teleoperation of the mobile robot in this system is 20.0 Mbps; therefore, in this paper, the throughput to be maintained in the communication path after the change was set to 20.0 Mbps.

IV. Method for Changing Communication Path while Maintaining Communication Connectivity for Mobile Robots

This paper considers a method for changing the communication path of a mobile robot while maintaining communication connectivity in a multi-robot system using a multistage relay backbone network. This chapter proposes a method to obtain advance information about the communication quality of the changed communication path; this method will ensure that there is no communication loss time when the path is changed. In this method, apart from the main communication path, there is a sub-communication path that connects in advance to the next node. We also include a "judgment communication path" that monitors the communication quality. Section 4.1 describes a method to change the communication path without causing any communication loss; two communication paths were used here. Section 4.2 describes a method to determine in advance whether the communication quality required for the teleoperation of a mobile robot can be maintained in the communication path after changing the connecting nodes.

A. Communication Path Changing Method using Sub-communication Path

The proposed method used a mobile robot connected to two APs (IEEE802.11ax), as shown in Fig. 7. The steps for changing the communication path of a mobile robot using two communication paths are given below. Here, this paper assume that the node number is *n* (Fig. 8).

1) The mobile robots connect to the *n*th and *n+1*th nodes and teleoperate via the main communication path.

2) The communication quality of the judgment communication path is used to determine whether to switch between the main communication path and the sub-communication path.

3) The sub-communication path is changed to the main communication path.

4) The path that was originally the main communication path is changed to a sub-communication path. (The adapter device that was connected to the *n*th node is changed to the *n+2*th node).

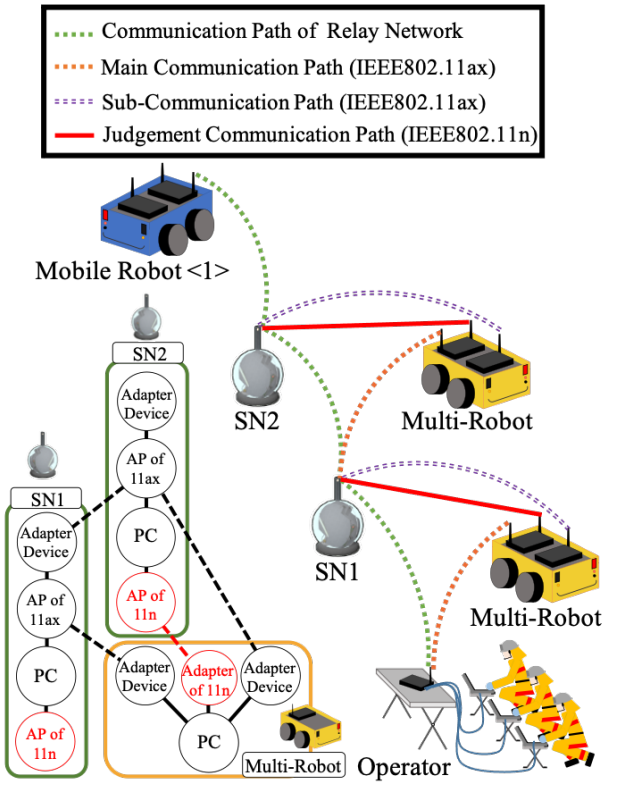

Fig. 7. Method for Changing Communication Path while Maintaining Communication Connectivity for Mobile Robots.

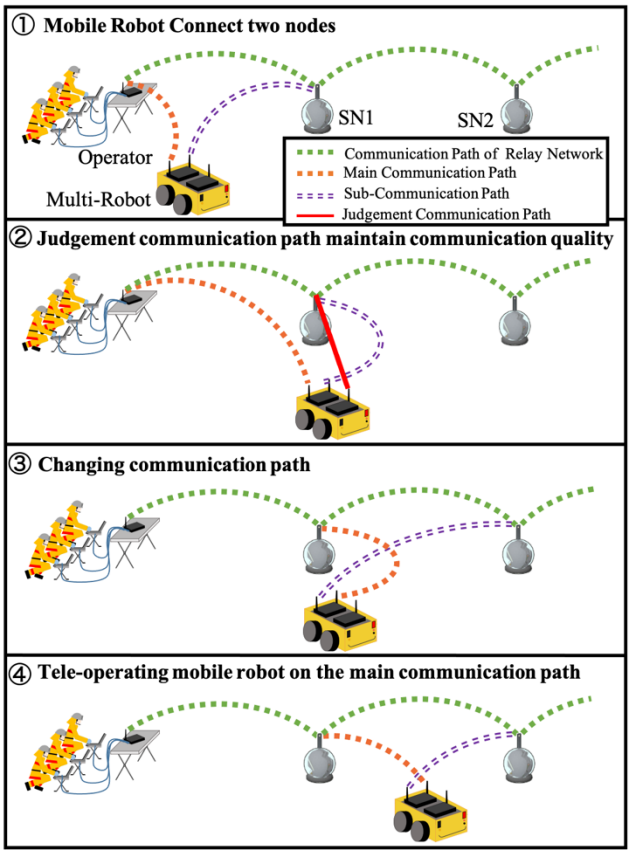

Fig. 8. Flow of Changing Communication Path.

Two communication paths were used: one with a large number of relays and the other with a small number of relays. This paper consider the decrease in communication quality due to the increase in the number of relays, and use the communication path with a small number of relays as the main communication path for sending and receiving teleoperation packets. Then, the sub-communication path becomes the next main communication path, as shown in Fig. 8. The packets are sent and received to confirm that the communication has not been interrupted. The operator can communicate with the mobile robot on the path via the *n*th node when changing the sub-communication path to the main communication path. Then, when changing the main communication path to the sub-communication path, it is possible to communicate with the mobile robot via the *n+1*th node. In this way, packets can be sent and received between the operator PC and the mobile robot while the communication route is being changed. Therefore, the mobile robots switch between the main communication path and the sub-communication path and can explore the disaster site without any communication loss even when there are changes in the communication path.

B. Monitoring Communication Quality using Judgment Communication Path

In the proposed method, in order to obtain in advance whether the communication path after changing the node to be connected can maintain the throughput required for teleoperation of the mobile robot, we construct a judgment communication path between the next node to be connected to and the mobile robot, as shown in Fig. 7. The judgment communication path is constructed by mounting an AP of IEEE802.11n, which is in the same frequency band as IEEE802.11ax, on the SN and an adapter device on the mobile robot. To obtain the throughput of this judgment communication path, the measurement packets are sent and received between the SN and the mobile robot <1>. This communication path is constructed in a separate network from the network of the multi-robot system, so that the throughput between the SN and the mobile robot can be measured without placing a load on the path used for teleoperation.

When the communication quality between an SN and a mobile robot of IEEE802.11n is maintained for the teleoperation of the mobile robot, the communication quality between an SN and a mobile robot of IEEE802.11ax can also be maintained for teleoperation of the mobile robot due to IEEE802.11n is in the same frequency band as IEEE802.11ax. This multi-robot system has also confirmed that the throughput between the operator PC and the SN is maintained required for the teleoperation of multiple mobile robots during the multistage relay network range is expanded. Therefore, if the communication quality required for the teleoperation of the mobile robot is maintained in the judgment communication path, it is assumed that the communication quality required for the teleoperation of the mobile robot is also maintained in the main communication path after switching the node to be connected. Therefore, in this method, the communication path is changed when the communication quality required for the teleoperation of the mobile robot can be maintained in the judgment communication path.

V. Evaluation of Communication Quality using Throughput Measurement

This chapter describes a method for measuring the communication quality characteristics when teleoperating a mobile robot. As described in Section 2, the teleoperation of a mobile robot sends and receives packets; therefore, it is necessary to evaluate the communication quality at the packet level. This paper evaluates the transmission speed in a TCP/IP-compliant communication path as the throughput at the packet level. The throughput [bps] specifies the transmission received per second by the PC. Therefore, the following experiments continue to send measurement packets from the mobile robot at a transmission speed of 25.0 Mbps and confirm whether a throughput of 20.0 Mbps or higher can be maintained at the receiving side. Therefore, the experiments in next chapter send measurement packets from the mobile robot side and confirm that the receiving side can maintain the throughput required for the teleoperation of the mobile robot.

VI. Changing Communication Path while Maintaining Communication Connectivity using Proposed Method

This experiment was conducted to confirm whether the proposed method can be used to change the communication path of a mobile robot while maintaining the communication connectivity. The experiment setting is shown in Fig. 9, and the equipment used is shown in Fig. 10. This experiment used Raspberry Pi 4 Model B as the PC, ASUS RT-AX3000 as the adapter device, GT-AX11000 as the AP of IEEE802.11ax, WN-AC433UA as the antenna of IEEE802.11n, and CAT8 LAN. The experiment was conducted in the following steps:

1) Deploying nodes equipped with AP of IEEE802.11n so that the distance between each node is 90 m. (Constructing a 270m network with 3hop).

2) Move the mobile robot and measure the throughput in the judgment path of IEEE802.11n at 10 m intervals (Between each SN and the mobile robot).

3) Move the mobile robot and measure the throughput in the communication path of IEEE802.11ax at 10 m intervals. (Between operator PC and mobile robot via each node).

This experiment selected 10 throughput values measured at each location and shows the average of them. In the multistage relay network constructed in this experiment, the nodes are deployed so that the distance between each node is 90 m (270 m in total), and the network is capable of maintaining a throughput of more than 60.0 Mbps between the operator PC and the mobile robot <1>. Fig. 11 shows the results of measuring the throughput on the judgment communication path (between SN and mobile robot). Fig. 11 shows that the throughput between SN1 and the mobile robot is more than 20.0 Mbps in the range of 60-130 m. Therefore, the proposed method changes the sub-communication path to the main communication path in that section. The throughput between SN2 and the mobile robot is more than 20.0 Mbps in the range of 150-210 m. Therefore, the proposed method changes the sub-communication path to the main communication path in that section.

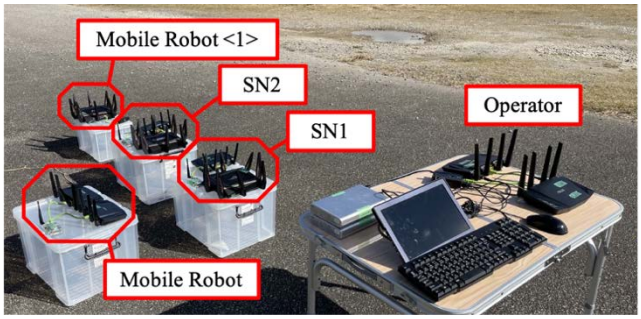

Fig. 9. Experimental Environment.

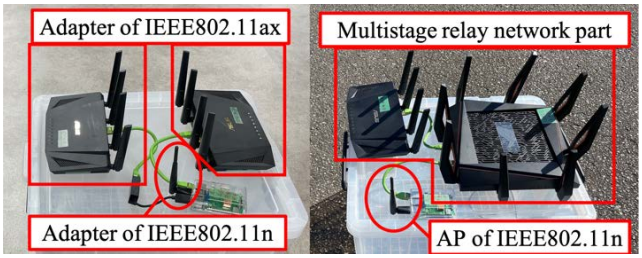

Fig. 10. Device of IEEE802.11n and IEEE802.11ax. (Left : SN, Right : Mobile Robot).

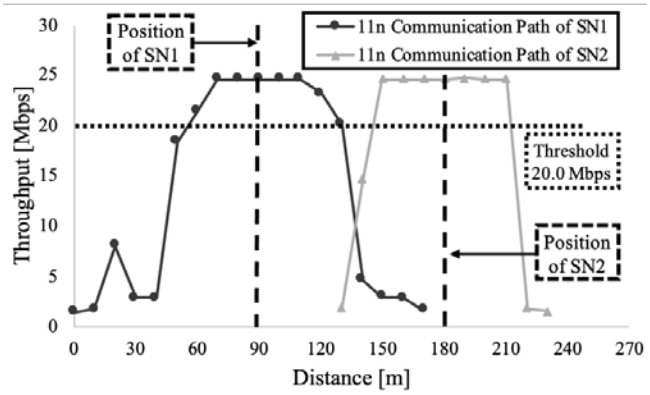

Fig. 11. Throughput of Judgment Communication Path (IEEE802.11n).

From the results shown in Fig. 11, we measured the throughput between the operator PC and the mobile robot so that the 60-130 m and 150-210 m sections overlap in this experiment, and confirmed whether the main communication path can be switched while maintaining the communication connectivity. The throughput in the communication path of IEEE802.11ax between the operator PC and the mobile robot via each node is shown in Fig. 12. As shown in Fig. 12, both communication paths have a throughput of more than 20 Mbps in the 60-130 m section, so it was possible to switch the main communication path while maintaining the communication connectivity. Also, in the 150-210 m section, both communication paths are maintained at more than 20 Mbps, so it was possible to switch the main communication path while maintaining the communication connectivity. As a result, when the proposed method was used to teleoperate a mobile robot, the communication path could be switched while maintaining the communication connectivity. Therefore, this method is effective for changing the connected nodes in a multi-robot system using a multistage relay backbone network.

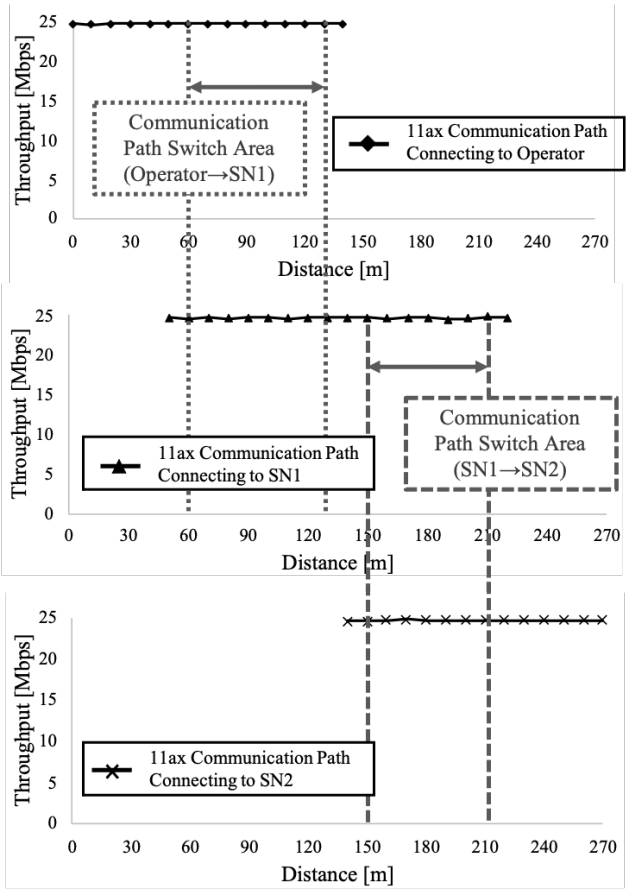

Fig. 12. Throughput between Operator and Mobile Robot. (Top : Mobile Robot Connecting to Operator, Middle： Mobile Robot Connecting to SN1, Bottom： Mobile Robot Connecting to SN2).

VII. Discussion

In the judgment communication path of this experiment, the throughput between SN1 and the mobile robot is more than 20 Mbps in the 60-130 m section, and the throughput between SN2 and the mobile robot is more than 20 Mbps in the 150-210 m section. The experimental results show that the IEEE802.11ax communication path can maintain a throughput of more than 20 Mbps in those sections, so it is possible to change the main communication path after confirming the communication quality in the judgment communication path in advance. Therefore, proposal method can obtain the communication quality of the changed communication path in advance, without communication loss time when the path is changed. Additionally, switching between the sub-communication path and the main communication path does not depend on distance information, but on the throughput of the judgment communication path, which is effective even in environments with many obstacles.

VIII. Conclusion

In a multi-robot system using a multistage relay network, multiple mobile robots were connected to the constructed network, and the mobile robots changed the search range by switching between the nodes. However, a mobile robot can be isolated when changing the node because of the loss of

communication or the poor quality of the communication in the new communication path. This paper proposed a method to change the communication path of a mobile robot using multiple paths so that communication connectivity is maintained.

The proposed method uses a sub-communication path, which connects in advance to the next node so that the communication path can be switched without any communication loss between the operator PC and the mobile robot. In addition, the proposed method constructs a judgment communication path between the nodes that constitute the sub-communication path; the main communication path and the sub-communication path are changed when the communication quality is maintained on the judgment communication path. Therefore, even when the sub-communication path is changed to the main communication path, the communication quality required for the teleoperation of the mobile robot can be maintained in the new main communication path. This study measured the throughput of the judgment communication path connected to each node and confirmed the section that can maintain the communication quality required for the teleoperation of the mobile robot. This experiment confirmed that the communication quality required for the teleoperation of the mobile robot could be maintained in the communication path of IEEE802.11ax in that section. The experiment results confirmed that it was possible to maintain the communication quality required for the teleoperation of the mobile robot in the new main communication path even when the main communication path was switched. The communication quality required for the teleoperation of the mobile robot was maintained in the judgment communication path. Therefore, the judgment communication path could monitor the communication quality of the changed path before changing the main communication path; this experiment proves the effectiveness of the proposed method.

In these experiments, the nodes to be connected to the mobile robot were changed manually. In the future, we will create a program that will automatically switch the communication path.

***Abstract*—Conceptual design represents a critical initial design stage that involves both technical and creative thinking to develop and derive concept solutions to meet design requirements. TRIZ Scientific Effects (TRIZSE) is one of the TRIZ tools that utilize a database on functional, transformation, parameterization of scientific effects to provide conceptual solutions to engineering and design problems. Although TRIZSE has been introduced to help engineers solve design problems in the conceptual design phase, the current TRIZSE database presents general scientific concept solutions with a few examples of solutions from patents which are very abstract and not updated since its introduction. This research work explores the derivation of a novel framework that integrates TRIZ scientific effects to the current patent information (USPTO) using data mining techniques to develop a better design support tool to assist engineers in deriving innovative design concept solutions. This novel framework will provide better, updated, relevant and specific examples of conceptual design ideas from patents to engineers. The research used Python as the base programming platform to develop a conceptual design software prototype based on this new framework where both the TRIZSE Database and Patents Database (USPTO) are searched and processed in order to build a Doc2Vec similarity model. A case study on the corrosion of copper pipelines by seawater is presented to validate this novel framework and results of the novel TRIZSE Database and patents examples are presented and further discussed in this paper. The results of the case study indicated that the Doc2Vec model is able to perform its intended similarity queries. The patent examples from results of the case study warrant further consideration in conceptual design activities.**

Keywords*—TRIZ; patent mining; natural language processing; product design

I. Introduction

TRIZ is a Russian Acronym which translate to the "Theory of Inventive Problem Solving" which was first initiated by Genrich Altshuller in 1946 [1]. TRIZ represents an engineering theory consisting of many problem-solving tools derived from compiling and analyzing utility patents to find general solutions and trends, which will be used to solve complex engineering problems that can be further decomposed into their individual problems and components.

One of the main TRIZ tools is the contradiction matrix which is well-established and is used to improve an engineering system based on solving engineering contradictions. According to TRIZ, there will always be engineering contradictions that need to be resolved in all inventive problems [2]. Contradiction matrix will recommend inventive principles derived from years of study of patent information to assist engineers resolve these contradictions. However, these inventive principles are very general and abstract for most engineers and interpreting these inventive principles in the context of specific solution concepts are challenging because expertise knowledge and experience are required. The other TRIZ tools including TRIZ scientific effects (TRIZSE) and system of standard inventive solutions also recommend solution concepts which are very general and abstract [1]. Therefore, research have explored into extending and improving existing TRIZ tools and proposed new patent extraction system such as Inventive Design Method (IDM) and extracting design information from patent documents and focus on assisting engineers to overcome their psychological barrier [3]. The proposed IDM has its limitations and deficiencies in issues related to duplicated information. This research work acknowledges the importance and criticality of defining design problems described in the form of function, parameter, transform and a real-time link to patent documents in patent offices to provide accurate relevant examples to assist engineers.

Therefore, this research work will explore the derivation of a framework to link TRIZSE to patent documents to support engineers in conceptual design and investigate the potential of enhancing TRIZSE with patents database. By developing this

*Corresponding Author.

link, TRIZSE may provide a better and clearer solution to each of their effects. The main objectives of this paper are:

1) To introduce the preliminary conceptual design system using TRIZSE which is enhanced by utilizing a similarity model built on a patent database to provide sufficient examples suggested by TRIZSE.

2) To build a Graphical User Interface (GUI) to allow a user to provide their input and queries for a single functional statement.

3) Conduct a case study to assess the performance of the program in factors of user input, data accuracy and its relevance.

The rest of the paper will cover the extraction of information, development of Doc2Vec model, and a case study. The proposed process model will be presented in the methodology section. This is followed by validation of the Doc2Vec model for feature extraction from the patent database for a use case. The report will then be concluded with recommendation for future improvement.

II. Background

TRIZ Scientific Effects (TRIZSE) is one of the TRIZ tools which is applied in the conceptual design phase that utilizes a database based on three types of search query; Functional, Parameterization, and Transformation to recommend a list of solution concepts (for e.g., if a user desires to constrain gas, one suggestion effect from the Functional aspect is Glassy Carbon which has high temperature resistance, extreme resistance to chemical attack, and impermeability to gases and liquid [4]). However, these suggestions lack suitable examples to support the recommended list of solution concepts and fail to inspire conceptual design ideas. Nonetheless, these deficiencies of the TRIZSE database offer a unique opportunity to explore the possibility of applying appropriate data mining techniques to search for examples related to the recommended list of solution concepts based on available online patents information with the intention of retrieving relevant patents as examples for any given recommended solution concepts by TRIZSE. To link the recommended solution concepts of TRIZSE to patent information, it is necessary to develop a suitable framework (with a user-friendly user interface) that integrates data analysis and mining technique (also known as patent mining) based on TRIZSE.

Using similar initiative to enhance a TRIZ technique, TRIZ Scientific Effects (TRIZSE) are comprehensive descriptions of effects based on sciences which provide good conceptual solutions which can potentially link patent information to obtain sufficient relevant real examples from TRIZSE database. In conceptual design activities, TRIZSE plays a role of redefining each function in a system and provides a set of suggestions of functional solutions as shown in an online database developed by Martin [4]. TRIZSE itself serves as a basis of creative idea generation in solving an engineering problem. Access to TRIZSE databases is limited due to subscriptions or memberships [5, 6], and third party state-of-the-art patent mining and analysis software [7]. However, the TRIZSE database provided by Martin [4] is available for public usage.

For the conceptual design framework development, the user must first define the engineering problem to be solved. The user-defined problem should be decomposed from complex problems into simple sentence structure before being used as an input. This not only simplifies the problem but also provides a clearer view of expected results from the query. There are vast selections of problem analysis tools such as Causal Loop diagram [8] that identify the polarity influences, Functional Decomposition and Morphology [9] decompose complex systems and re-merges as well as Systems Dynamics [10] that can simulate potential design changes. However, a simple and direct tool should be selected as it can provide more direct input for the model to manipulate. Hence, Functional Analysis (FA) [11] which maps component relationships can be selected for deployment. FA fosters problem statement formulation that could be further decomposed into a simple solution statement consisting of Subject-Action-Object. This facilitates better transition to the parameters of the TRIZSE database.

The linkage between TRIZSE to a patent database can be implemented through text mining techniques. A text mining Python library called Gensim is widely popular amongst patent mining research and has diverse range of data mining models. One of the models is a similarity model Doc2Vec inspired by vector representations of words using neural networks known as Word2Vec [12]. The Word2Vec model has a disadvantage as it does not consider the word order of each text document [12]. It functions similarly to a bag-of-words model where only the frequency of each word in the patent document is accounted for [12]. The proposed Doc2Vec is an improved model that can assess the word and neighboring words in the sentence to properly gauge the semantics of the entire sentence. Doc2Vec is compared to other similarity models such as Term frequency-inverse document frequency (TF-IDF) which calculates the importance of a word based on the frequency in the patent document and Global Vectors for Word Representation (GloVe) just like TF-IDF but with word embeddings to discover word contexts [13]. The result of comparisons shows that Doc2Vec is superior and capable of handling higher amounts of data entries (in millions) [13].

The patents database is sourced online. There are major databases such as the United States Patents and Trademark Office (USPTO), the Japanese Patent Office (JPO), the European Patent Office (EPO) [14]. For the ease of database extraction, the USPTO database is selected.

III. Methodology

A. Data Extraction

The TRIZSE database is extracted from the online database [4]. A third party free-to-use software called ParseHub is shown in Fig. 1. It performs as an automated user-action and data collector. Parsehub is utilised to extract every combination of the database and its results. The data extracted is stored into a Comma-Separated Values (csv) file.

Patent documents are unstructured texts with sections of irregular word limits and formatting. Thus, this paper makes use of one of the consistent sections of a patent document, the abstract. Sections such as claims would range from few sentences to several pages.

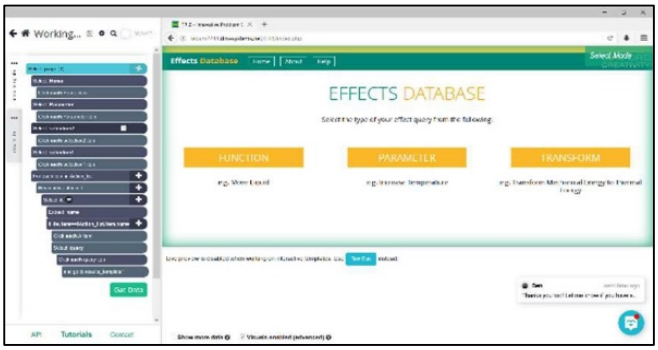

Fig. 1. Brief Interface of Parsehub.

B. Data Processing

The main data processing involves handling of millions of patents in the database. In USPTO, there are multiple types of patents such as utility, design, plant. Utility patents are patents that contain a feature or solution whereas design patents are typically drawings. Only utility patents are added value documents for this study. The total number of utility patents from the year 1971 to 2020 numbers is approximately 6.8 million. The abstracts of patents are useful for feature extraction in patent mining as there is a word limit and crucial information is present. Hence, each patent document's abstract undergoes a pre-processing stage, where words will be separated, and reformatted. The pre-processing steps involve removal of special characters, lowercasing capitals, and removal of redundant words [15, 16]. The pre-processing technique is adapted from the Gensim code examples [17]. The patent documents are tagged by simple indexing for accessing the documents in later stages.

C. Similarity Model Technique and Concept

Similarity models encompass supervised and unsupervised techniques, each with their own advantages and disadvantages. Supervised techniques involve high percentage of manual sorting and tagging that yields better overall results. On the other hand, unsupervised techniques do not have manual inspection. However, it is preferable over supervised techniques when dealing with massive number of documents. The Doc2Vec model is an unsupervised technique model. The data is fed into the algorithm and all unique words will be extracted from the patent documents into a vocabulary dictionary. The Doc2Vec model starts training with a vocabulary size and input texts. The Doc2Vec modelling can be simplified (as shown in Fig. 2).

```
Doc2Vec(abstracts, min_count=2,
window=3, vector_size=100,
epochs=20, workers=7)
```

Fig. 2. Modelling of Doc2Vec.

The description of the arguments for Doc2Vec is as follows: abstracts represent the input of patent abstracts; min_count the removal of words with frequencies less that the value f (in this example, 2); window is N (3 in this example), number of neighboring words that can affect the word of interest; vector_size shows the number of numerical elements that an abstract vector can attain. The higher the number of vector size, the higher the number of features of an abstract that can be captured; epochs are the number of training iterations of the model; workers are the number of computer cores for processing. With the vector generated, it can be compared numerically with a cosine similarity approach [14][17].

D. Process Chart of the Conceptual Design Framework

Once trained, the model can produce and predict a vector for new inputs to reflect similarity results. This can be used to evaluate similarity of a TRIZ Scientific Effect concept with real patent examples. The development of a Graphical User Interface (GUI) using PySimpleGUI library is to facilitate user input. The activities are depicted in Fig. 3. The processes and output is visible to the user through Graphical User Interface. The user inputs their problem in a Functional statement which will be a guide to invoke suitable TRIZSE settings. TRIZSE database will return results from the inputs which are fed into the similarity model individually by each effect. The model results are compiled in a descending order of patent similarity.

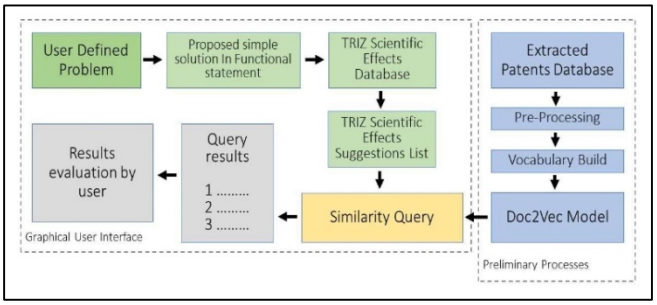

Fig. 3. Process Chart of the Conceptual Design System Framework.

IV. Results and Discussion

A. TRIZSE Database Extraction

This work starts with extraction and analysis of the TRIZSE database. The database extracted from the source website takes approximately 15 hours to parse through all combinations. The CSV file saved is checked and validated for accuracy. Fig. 4 shows the sample of the data extracted from the database. Each combination of TRIZ Scientific Effect yields a set of results which are suggestions of Effects along with brief description of the concept.

Absorb	Divided Solid	Effect	17 suggest	Amphiphiles	A chemical compound poss
Absorb	Divided Solid	Effect	17 suggest	Bingham Plastic	A viscoplastic material that
Absorb	Divided Solid	Effect	17 suggest	Diffusion	The movement of particles
Absorb	Divided Solid	Effect	17 suggest	Electret	An Electret is a dielectric m
Absorb	Divided Solid	Effect	17 suggest	Fractal Forms	A fractal is generally 'a roug
Absorb	Divided Solid	Effect	17 suggest	Gel	A gel is a solid, jelly-like ma
Absorb	Divided Solid	Effect	17 suggest	Ostwald Ripening	An observed phenomenon
Absorb	Divided Solid	Effect	17 suggest	Oxidation	A chemical reaction that in

Fig. 4. A Snapshot of Extracted TRIZSE Database.

The data extracted undergoes data elimination of duplicated data. For example, a combination of Absorb and Divided Solid in Function section can have three types of results which are

Framework, Effect, or Both. The results that are repetitive can be merged. For example, the Functional section containing 21,175 rows of effect suggestions is merged into 10,589 rows, which is 50% smaller. Similar process is applied to Parameter and Transformation section which yields similar reduction.

The Effects in TRIZSE database are obtained through the various combinations of inputs. Each Effects accommodates multiple combinations, and the total of Effects is approximately 1000. The concept description of each Effects will be assessed by the Doc2Vec model to identify similar concepts in patents.

B. USPTO Patents Extraction

The USPTO patents are downloaded from PatentsView website in a compressed ZIP file. A Python code parses through the ZIP file to extract the desired information which comprises the following: utility patents' number, title, and abstract. The process has taken 5 hours for 7.5 million patent documents and 6.8 million utility patents are extracted and stored.

C. Doc2Vec Model Code Development

The Doc2Vec modelling follows the stages of Preliminary processes in Fig. 3. The first stage is the pre-processing of each patent abstracts. In this stage, abstracts will undergo tokenization. Tokenization splits the abstracts, a paragraph of words, into individual words while keeping the order of the sentence. Each individual word is converted to lowercase and stop words are removed. Stop words are words that do not add to sentence context such as "a", "of", "and", "also". The duration of the pre-processing stage is 2660 seconds. Prior to Doc2Vec modelling, the abstracts undergo a vocabulary building phase which identifies unique words and stores it into a dictionary. This phase identifies the weight of each word. Heavier word weight shows higher importance. The process is 4340 seconds. The Doc2vec modelling uses the settings from Fig. 2, frequency of words less than 2 will be removed since they are uncommon words. The window size of 3 influences the target word with 3 nearby words. The vector_size is also known as feature size that captures the feature of a document and converts it into a vector of numbers [12] that is calculated from the weights of words in the vocabulary dictionary. The vector_size is set to 100 which balances between memory usage and feature uniqueness. Epochs are set at 20 with each iteration taking 40 minutes. By running multiple iterations on the data, the Doc2Vec model learns and re-calibrates features in a document. The Doc2Vec model is successfully built into 6.8 million abstract vectors in a process that has taken 17 hours. The model loaded within the Python workspace is displayed in Fig. 5 showing it has been successfully booted.

The unique tokens and the number of documents vectorized in the model is shown in Fig. 6.

D. Doc2Vec Model Validation

The model can be validated by a similarity query of a random patent abstract section from USPTO. Typically, the result of similarity in the model will proceed with high similarity documents, followed by lower similarity documents. The output in Fig. 7 shows that the behavior is as predicted.

The output seen in Fig. 7 uses a section of the abstract as input to find similar documents. The first result has a similarity of 88.57% and on online inspection, found to be the correct patent. Thus, the model can provide accurate similarity. A similarity tolerance test is conducted by running 10 times on the same query shown in Fig. 8. The graph shows that the average similarity value is at 0.885825 with a range of ± 0.000144. Since the value of the range is significantly small, it will not affect the order of top documents in similarity results.

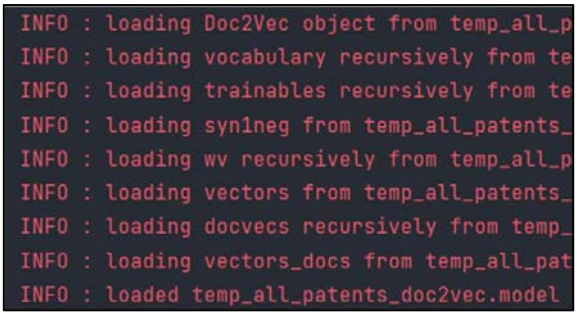

Fig. 5. Doc2Vec Model Logs.

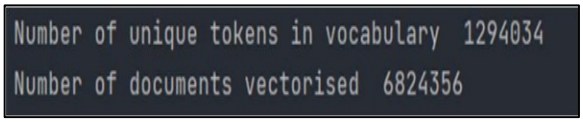

Fig. 6. Output of Token and Vectors Computed.

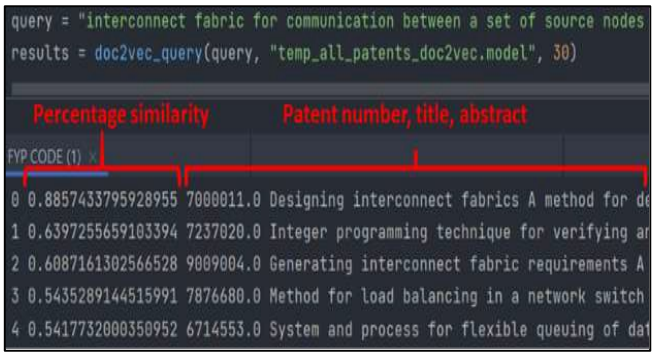

Fig. 7. Similarity Query of a Patent Abstract.

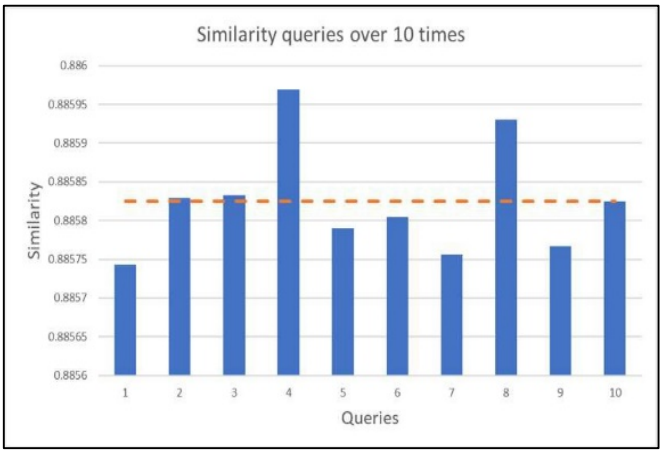

Fig. 8. Plotted Percentages of Similarity Query.

E. Graphical user Interface (GUI) Development

Once the fundamental operation of the program is developed, a GUI is built to accommodate user input. The interface contains the user input of their Functional Statement in three text boxes: Subject, Action, Object. With the guidance of the proposed Functional statement simple solution input, the rest of the TRIZSE database can be selected. The TRIZSE database is laid out with Function, Parameter and Transform sections clearly indicated. The user may select the applicable selections from the available options as well as the ability to exclude un-used sections. The GUI is coded and loaded as shown in Fig. 9, provides enough information to users to perform their input activities.

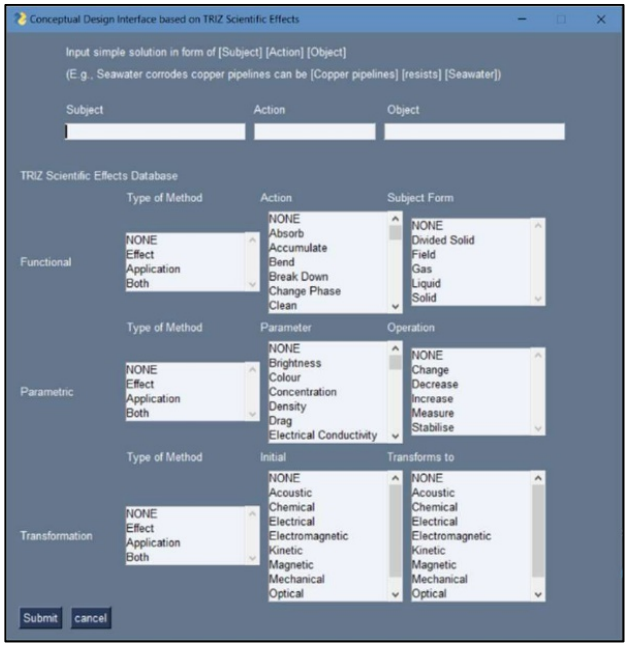

Fig. 9. Graphical user Interface of the Conceptual Design Software Prototype.

F. Case Study on the Corrosion of Copper Pipelines caused by Seawater

Copper alloys are used in ships as pipelines, heat exchanges, screw propellers, valves [18] and most components are often exposed to seawater which is corrosive. In marine engineering applications, copper alloys have an innate seawater corrosion resistance, but will be vulnerable under heavier load conditions [18] such as pressure generated from propeller torque or oscillating temperature in pipeline cooling systems. The case study aims to discover methods to prevent the corrosion of copper pipelines in a marine boat's cooling system. The problem first is approached by using Functional Analysis to identify and break down the problem into a simple problem statement of Subject-Action-Object as shown in Fig. 10.

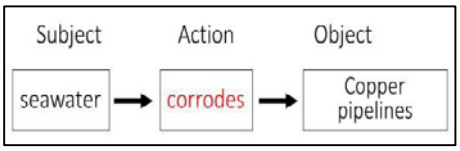

Fig. 10. Problem Statement in Functional Analysis Form.

The simplified problem statement is transformed into a simple solution statement by reversing the subject, object, and providing a counteraction. The solution statement is presented using the same format as shown in Fig. 11.

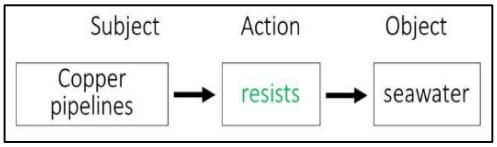

Fig. 11. Solution Statement in Functional Analysis Form.

With the defined solution statement, the GUI can be filled together with the TRIZSE options. Corrosion is an electrochemical reaction that requires surface contact and seawater is a form of liquid. Thus, in the Functional section, the best combination will be to resist liquid as an application. To prevent contact between copper and seawater, the surface finish should not degrade and should have high wear resistance. This can be used in the parameterization section with stabilize surface finish as an application. In the final section, it is unnecessary as the solution should be a preventive measure and thus, assumed to have no transformation of energy in copper pipelines. With the information gathered, the software prototype can be launched and have the input arranged in the GUI as displayed in Fig. 12. From the input screen, it is then submitted and the results of the TRIZSE database are shown in Fig. 13 and Fig. 14 which will be used with the Doc2Vec model to discover similar patent examples.

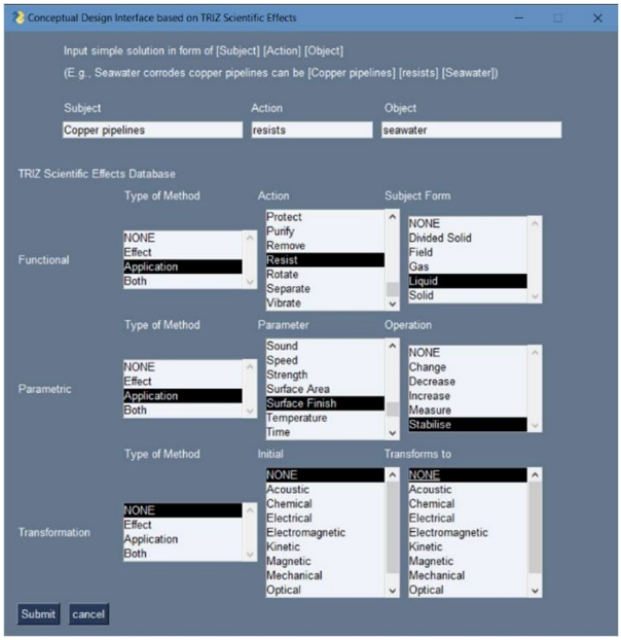

Fig. 12. GUI Interface with Case Study Settings.

As observed in Fig. 13, the list of suggestions from TRIZSE database provides a brief description of each effect with limited examples. A brief review will be conducted to reduce the redundant effects generated. Effects such as Valve and Tesla Valvular Conduit can be removed from consideration as it is an interest of internal volume. The effect Intumescent materials will also be removed as temperature should not be a factor in corrosion resistance. Another similar

review will be conducted on the results of the Parametrization section shown in Fig. 14. From the results of the Parametrization section, some effects can be removed to refine the patent results. Effects such as Redundancy may be considered as a last resort stage and will be removed. The effect Thin Films is also present in the list in Fig. 13 and will be removed since both lists will be compiled before loading into the Doc2Vec model. Using each TRIZSE obtained from the input, it is used together with the subject as a query input to the Doc2Vec model.

Input		TRIZ Scientific Effects	Effect Descriptions
Resist	Liquid	Diamond-like Carbon	(DLC) exists in seven different forms of amorphous carbon materials that display some of the unique properties of natural diamond. They are usually applied as coatings to other materials. All seven contain significant amounts of sp3 hybridized carbon atoms. As well as excellent hardness and wear resistance, DLC is claimed to have the lowest coefficient of friction of any known solid material.
Resist	Liquid	Ferrofluid	A liquid which becomes strongly magnetized in the presence of a magnetic field. Ferrofluids are colloidal mixtures composed of nanoscale ferromagnetic, or ferrimagnetic, particles suspended in a carrier fluid, usually an organic solvent or water. The ferromagnetic nanoparticles are coated with a surfactant to prevent their agglomeration (due to van der Waals and magnetic forces).
Resist	Liquid	Intumescent Materials	An intumescent is a substance which swells as a result of heat exposure, thus increasing in volume, and decreasing in density. Intumescent are typically used in passive fire protection.
Resist	Liquid	Polytetrafluoroethylene (PTFE)	A synthetic fluoropolymer. As fluorocarbons are not as susceptible to van der Waals force (due to the high electronegativity of fluorine) water and water-containing substances, and oil and oil-containing substances, like most foods do not wet PTFE. PTFE is very non-reactive. PTFE's coefficient of friction is 0.1 or less, which is the second lowest of any known solid material.
Resist	Liquid	Solenoid	A coil wound into a tightly packed helix. In physics, the term solenoid refers to a long, thin loop of wire, often wrapped around a metallic core, which produces a magnetic field when an electric current is passed through it. Solenoids are important because they can create controlled magnetic fields and can be used as electromagnets.
Resist	Liquid	Tesla Valvular Conduit	A one-way valve with no moving parts, using the geometry of the fluid path to redirect the flow of the fluid to oppose its own motion in one direction, but offering little resistance in the other.
Resist	Liquid	Thin Films	Thin material layers ranging from fractions of a nanometer to several micrometers in thickness. Electronic semiconductor devices and optical coatings are the main applications benefiting from thin film construction.
Resist	Liquid	Valve	A device that regulates the flow of a fluid (gases, liquids, fluidized solids, or slurries) by opening, closing, or partially obstructing various passageways.

Fig. 13. Output of Functional Section Effects Database.

Input settings		TRIZ Scientific Effects	Effect Descriptions
Stabilize	Surface Finish	Coatings	A covering that is applied to an object. The aim of applying coatings is to improve surface properties of a bulk material usually referred to as a substrate. One can improve amongst others appearance, adhesion, wettability, corrosion resistance, wear resistance, scratch resistance, etc. They may be applied as liquids, gases or solids.
Stabilize	Surface Finish	Electroplating	The process of using electrical current to reduce cations of a desired material from a solution and coat a conductive object with a thin layer of the material, such as a metal. Primarily used to bestow a desired property (e.g., abrasion and wear resistance, corrosion protection, lubricity, aesthetic qualities, etc.) to a surface that otherwise lacks that property. Also used to build up thickness on undersized parts.
Stabilize	Surface Finish	Epitaxy	The method of depositing a monocrystalline film on a monocrystalline substrate. Epitaxial films may be grown from gaseous or liquid precursors. Because the substrate acts as a seed crystal, the deposited film takes on a lattice structure and orientation identical to those of the substrate.
Stabilize	Surface Finish	Feedback	A circular causal process whereby some proportion of a system's output is returned (fed back) to the input. This is often used to control the dynamic behavior of the system.
Stabilize	Surface Finish	Ferromagnetic Powder	Ferromagnetic material in a powdered or finely divided form. Ferromagnetic materials (such as iron) form permanent magnets and/or exhibit strong interactions with magnets. Ferromagnetic materials lose their ferromagnetic properties above a characteristic temperature (the Curie Point).
Stabilize	Surface Finish	Physical Vapor Deposition	A variety of methods used to deposit thin films by the condensation of a vaporized form of the material onto various surfaces
Stabilize	Surface Finish	Preservative	A naturally occurring or synthetic substance that is added to products such as foods, pharmaceuticals, paints, biological samples, wood, etc. to prevent decomposition by microbial growth or by undesirable chemical changes.
Stabilize	Surface Finish	Redundancy	The duplication of critical components of a system with the intention of increasing reliability of the system, usually in the case of a backup or fail-safe.
Stabilize	Surface Finish	Sintering	A method for making objects from powder, by heating the material below its melting point (solid state sintering) until its particles adhere to each other. Traditionally used for manufacturing ceramic objects. Most, if not all, metals can be sintered - especially pure metals produced in vacuum which suffer no surface contamination. Many nonmetallic substances also sinter, such as glass, alumina, zirconia, silica, magnesia, lime, ice, beryllium oxide, ferric oxide, and various organic polymers.
Stabilize	Surface Finish	Thin Films	Thin material layers ranging from fractions of a nanometer to several micrometers in thickness. Electronic semiconductor devices and optical coatings are the main applications benefiting from thin film construction.

Fig. 14. Output of the Parametrization Section Effect Database.

Each query has been set to have an output of the first 10 patents and this setting can be customized as a preference. However, since the similarity of documents is highly saturated in the first few results, the similarity of the rest of the documents may be too broad to provide substantial design support. The output results are compiled, and the top 5 results are shown in Fig. 15. From displayed results in Fig. 15, the outcome of the top 5 highest similarity in patent documents have the effect Physical Vapor Deposition in majority. Analysis of the first patent (10115603) reveals that the patent describes a method of removing passivation films. Passivation film is a coat of protective material typically able to protect against corrosion [19]. However, the patent suggests removal of the said film instead. This displays the model inaccuracy of polarity checking, although being accurate to the topic of corrosion. The second patent (5514414) discusses the deposition of heated flux vapor by condensing onto the subject. The role of flux vapor in corrosion resistance is by removing impurities and oxidation layer [20]. The third patent (9859218) is not applicable towards pipelines as its application is focused on reinforcement of interconnected structures. The fourth patent (5352331) focuses on electroplating a thin film cermet; a composite of ceramic (cer) and metal (met). A thin layer of cermet is capable of producing corrosion resistance and protecting the internal material [21]. The fifth patent (4927472) discusses the formation of tin phosphate on metal surface which creates a layer of corrosion resistance. The idea of phosphating a base material with solution of phosphate ions can provide for corrosion resistance against highly corrosive environments such as seawater [22]. From the first 5 results of the Doc2Vec model, although not all results have the intention of offering corrosion resistance, it is still relevant to the topic scope of the model input.

Effect	Similarity Number	Patent	Title	Abstract
Physical Vapor Deposition	63.45%	10115603	Removal of surface passivation	Methods for removing a passivation film from a copper surface can include exposing the passivation film to a vapor phase organic reactant for example at a temperature of 100° C. to 400° C. In some embodiments the passivation film may have been formed by exposure of the copper surface to benzotriazole such as can occur during a chemical mechanical planarization process. The methods can be performed as part of a process for integrated circuit fabrication. A second material can be selectively deposited on the cleaned copper surface relative to another surface of the substrate.
Physical Vapor Deposition	61.86%	5514414	Solvent-less vapor deposition apparatus and process for application of soldering fluxes	Apparatus and method for condensing a solderless flux vapor onto a work surface to be soldered such as an electronic circuit board. The flux vapor is created by heating flux in a liquid state to a temperature greater than the temperature of the work surface. Flux is applied to the work surface without the use of any volatile organic chemicals.
Physical Vapor Deposition	58.86%	9859218	Selective surface modification of interconnect structures	Semiconductor structures including copper interconnect structures and methods include selective surface modification of copper by providing a CuxTiyNz alloy in the surface. The methods generally include forming a titanium nitride layer on an exposed copper surface followed by annealing to form the CuxTiyNz alloy in the exposed copper surface. Subsequently the titanium layer is removed by a selective wet etching.
Electroplating	58.29%	5352331	Cermet etch technique for integrated circuits	An etching process for patterning thin film cermet (14) on a semiconductor substrate (10) using a mild room temperature acid solution as the etchant. The semiconductor substrate (10) has a glass passivating layer (12) such as silicon dioxide deposited thereon. The cermet layer (14) is deposited on the silicon dioxide layer (12). A photoresist layer (16) is deposited and patterned on the cermet layer (14) followed by the deposition of a layer of aluminum (18). The cermet (14) is then preferentially etched with a mild room temperature hydrofluoric acid solution diluted with hydrochloric acid to form the desired cermet resistance pattern.
Physical Vapor Deposition	56.67%	4927472	Conversion coating solution for treating metal surfaces	A conversion coating predominantly consists of tin phosphate can be deposited on steel or tin-plated steel surfaces by contact with a solution containing phosphate ions tin ions an oxidizing agent such as chlorate and a chelating agent for the tin ions the latter to prevent the rapid loss of tin from the solution that otherwise would occur. A coating that confers excellent resistance to corrosion in hot water is formed on drawn and ironed thinly tin-plated cans.

Fig. 15. Output of the Doc2Vec Model.

V. Conclusion

This research has demonstrated the potential of linking TRIZSE to USPTO patents pool to provide additional support for conceptual design related activities. With the successful building of the Doc2Vec model, a case study has been conducted on the corrosion of copper pipelines in seawater. The concluded discussion of the results of TRIZSE and Doc2Vec model shows that:

- The model provides a majority of relevant examples that ought to be further investigated for the case study.
- The Doc2Vec model does not account for semantics and thus, could not differentiate polarity of relevant examples.
- The improvement of Doc2Vec model can be conducted in stages of pre-processing, feature size, and semantic analysis.

Although the results of patent relevancy are not sufficiently accurate, the linkage of TRIZSE database with USPTO patent pool shows the potential of assisting conceptual design activities. In conclusion, TRIZSE when combined with patent mining provides a viable support means to engineers in developing conceptual solutions by providing relevant examples of solutions in patent documents. Future explorations of the similarity model may be able to provide better accuracy and feature extraction along with semantic analysis. Enhanced accuracy is

necessary as the current search results from the similarity model include accurate relevant concept solutions as well as somewhat inaccurate concept solutions. Future work should only yield search outputs that are only directly relevant patents.

ACKNOWLEDGMENT

The authors would like to thank Universiti Kebangsaan Malaysia (which is part of the EMJMD Genial Consortium) for supporting this work through the Research University Grant GUP-2018-124.

***Abstract*—Cognitive diagnosis models (CDMs) have been shown to provide detailed evaluations of students' achievement in terms of proficiency of individual cognitive attributes. Attribute hierarchy model (AHM), a variant of CDM, takes the hierarchical structure of those cognitive attributes to provide more accurate and interpretable measurements of learning achievement. However, advantages of the richer model come at the expense of increased difficulty in designing the hierarchy of the cognitive attributes and developing corresponding test sets. In this study, we propose quantitative tools for validating the hierarchical structures of cognitive attributes. First, a method to quantitatively compare alternative cognitive hierarchies is established by computing the inconsistency between a given cognitive hierarchy and students' responses. Then, this method is generalized to validate a cognitive hierarchy without real responses. Numerical simulations were performed starting from an AHM designed by experts and responses of elementary school students. Results show that the expert-designed cognitive attribute explains the students' responses better than most of alternative hierarchies do, but not all; a superior cognitive hierarchy is identified. This discrepancy is discussed in terms of internalization of cognitive attributes.**

Keywords*—Cognitive diagnosis model; attribute hierarchy model; cognitive hierarchy; model validation

I. Introduction

A. Cognitive Diagnostic Models

Learning analytics has attracted much attention recently, as more data become available for educators and learners [1]. Vast amounts of data are generated in the field of education, due to the widespread adoption of online education systems, such as massive open online courses [2]. By utilizing more data, a more accurate and detailed assessment of learning achievement is possible [3], resulting in enhanced learning experience [4]. For instance, teachers could offer individualized learning strategies tailored to needs of the target students, such as university students [5], under-represented students [6] or foreign language learners [7].

Cognitive diagnosis models (CDMs) have been actively studied as a useful tool for assessing students' knowledge states in terms of multiple cognitive attributes [8]. CDMs incorporate multiple cognitive attributes that are required to understand a concept or to perform a task. Items that require different combinations of cognitive attributes are developed, and the degree of proficiency for each cognitive attribute is estimated from the students' responses to these items. The quantitative assessment of a student's proficiency of individual cognitive attributes allows a more detailed evaluation of a student's achievement, compared to a total score-based learning diagnosis.

CDMs are largely divided into two groups: compensatory models and non-compensatory models [9]. Compensatory models assume that one cognitive attribute could compensate for another. Thus, even if a particular cognitive attribute is not mastered by the examinee, they may solve an item by using other cognitive attributes. For instance, reading comprehension requires numerous cognitive attributes, such as grammar and vocabulary. Even if there are a few words that a reader is not familiar within a given text, the reader could postulate the meanings of the words from the grammatical structure and solve related items correctly. In such cases, grammar plays a compensatory role for vocabulary.

In contrast, non-compensatory models assume that the lack of a cognitive attribute is not compensated for by other cognitive attributes [10]. Therefore, if one fails to master any of the cognitive attributes required, an item cannot be solved. For example, according to the non-compensatory model, an item requiring the concepts of logarithmic function and algebraic function could only be correctly solved by those who have mastered both concepts. If any one of the two concepts is lacking, they will not be able to correctly solve the item.

B. Related Work

Among early non-compensatory models, the rule-space model (RSM) was explored and established by Tatsuoka [11]. The relationship between an item and the cognitive attributes required to solve the item is represented by a matrix, called the Q-matrix. Each row of the Q-matrix corresponds to an item, while each column corresponds to a cognitive attribute; Q_{ij} is one if the j^{th} cognitive attribute is required to solve the i^{th} item. Otherwise, Q_{ij} is zero. The RSM was developed to estimate students' knowledge states from their item responses and a corresponding Q-matrix.

In this study, we adopt a variant of the RSM, called the attribute hierarchy model (AHM) [12] to quantify elementary school students' learning achievements in arithmetic operations. Similarly to CDMs, the AHM aims to represent the relationship between items and cognitive attributes. Furthermore, the AHM includes hierarchical relationships between the cognitive attributes in the model. This hierarchical structure of cognitive attributes is represented by a graph, in which each node corresponds to a cognitive

*Corresponding Author.

attribute, and an edge between two nodes implies that one cognitive attribute is a prerequisite for the other cognitive attribute. Therefore, the AHM is suitable for evaluating the achievement of mathematics subjects, where the hierarchy of cognitive attributes is important [13].

A precise relationship between cognitive attributes and items is crucial for the accurate measurement of learning achievement. However, in practice, developing a Q-matrix and corresponding items, requires months of intensive collaboration between modeling experts and teachers in the field.

To assist the development of the Q-matrix, several quantitative tools have been proposed. First, de la Torre [14] proposed to validate a given Q-matrix by the degree of agreement with the response data using the EM algorithm [15]. Such quantification provides an objective measure to compare multiple Q-matrices. However, it remains elusive which Q-matrices should be compared. To address this gap, DeCarlo proposed a Bayesian framework to validate individual elements of a given Q-matrix [16]. However, the flexibility of the Bayesian model comes with an increased complexity of the validation procedure because the reliability of each element of the Q-matrix must be provided in advance. Last, Chiu proposed a simpler nonparametric method to identify misspecified entries of a Q-matrix [17].

However, those validation methods are applicable only to RSMs, not to AHMs. The hierarchical structure of the cognitive attributes is not considered for the validation of a given Q-matrix. Therefore, adopting AHMs in practice requires extention of the validation framework and more careful consideration of the structure of the cognitive attributes of interest.

C. Contributions of the Study

We propose quantitative tools for validating the hierarchical structures of cognitive attributes, to aid the development of AHMs. Whereas the current validation methods quantify the validity of each element of the Q-matrix, we explore alternative hierarchical structure of the cognitive attributes. Thus, the search space of out method is a graph rather than a matrix.

Our approach would provide a more natural way to validate AHMs in conjunction with the experts' domain knowledge. For instance, the current methods provide a refined Q-matrix with some elements flipped from the initial Q-matix. However, such a refined Q-matrix may contradict to the hierarchical structure of cognitive attributes developed by the experts. Instead, our method starts from the experts' knowledge in terms of the hierarchical structure and validate individual associations of cognitive attributes.

The rest of this paper is organized as follows: the Methods section describes the AHM model, as well as the data collection and evaluation of alternative hierarchies of cognitive attributes. In the Results section, we show numerical simulations; finally, in the Conclusions and Discussions section, we discuss the results and their implications, with concluding remarks.

II. Methods

A. Modeling and Data Collection

An AHM model for arithmetic operations with natural numbers was designed as follows. First, seven cognitive attributes were chosen based on the elementary school mathematics curriculum – addition (A1), subtraction (A2), multiplication (A3), division (A4), carry (A5), borrow (A6), and '0' in multiplication (A7). Thereafter, the hierarchy of the seven attributes (H_0, Fig. 1A) was designed by experts. In brief, the root node (A1) represents addition, which is the prerequisite for all other cognitive attributes. The descendant nodes of the root node are A2, A3, and A5, which correspond to subtraction, multiplication, and carry, respectively. To understand a leaf node (A4, A6, or A7, corresponding respectively to division, borrow, and "0" in multiplication), one should master all the preceding cognitive attributes up to the root node. For example, A4 (division) requires A1 (addition), A2 (subtraction), and A3 (multiplication).

Based on the expert-designed hierarchical structure (H_0, Fig. 1A), alternative hierarchical structures ($H_1, H_2, \cdots, H_7$) were created by removing an edge from H_0 (Fig. 1B). For example, H_1 was generated by removing the edge between A1 and A2 (dashed line in Fig. 1B) from H_0. Similarly, the removed edges in H_k for $k = 2, 3, \cdots 7$ are indicated by (H_k).

Next, thirty items involving the seven cognitive attributes were developed. Our participant sample comprised 977 fourth graders who participated in the test; their responses to individual items were coded as either correct (1) or incorrect (0).

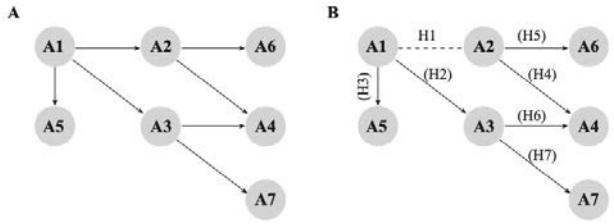

Fig. 1. (A) The Hierarchical Structure (H_0) of the Seven Cognitive Attributes (A1, A2, ⋯, A7) Designed by the Experts. (B) Alternative Hierarchical Structures ($H_1, H_2, \cdots, H_7$) were Created by Removing One Edge from H_0. For Example, the Graph in Panel B shows H_1, Generated by Removing the Edge between A1 and A2 (Dashed Line) from H_0. Similarly, other Hierarchical Structures (in Parentheses) are Generated by Removing the Corresponding Edges.

B. Validating the Hierarchies of Cognitive Attributes

The alternative hierarchies were validated by quantifying the degree to which a given hierarchy is in agreement with students' actual responses. The block diagram in Fig. 2 summarizes the quantification steps, each of which is explained as follows.

First, a different attribute hierarchy (H_k) implies a different structure of students' knowledge states. For the seven cognitive attributes, $2^7 = 128$ combinations of the seven attributes are enumerated. Among all the potential combinations, those that are in conflict with H_k are eliminated (Leighton et al., 2004) and the remaining attribute combinations comprise the set of valid knowledge states S_k.

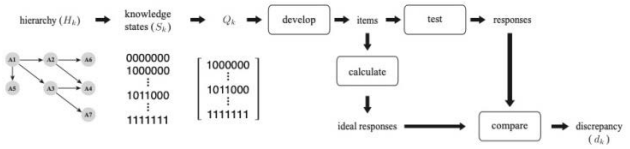

Fig. 2. A Schematic Diagram of the Quantitative Validation of a Hierarchical Structure. For any given Hierarchical Structure H_k, Corresponding Knowledge States S_k (Combinations of Attributes Consistent with H_k) and a Q-matrix Q_k are Generated. Items Corresponding to the Rows of Q_k are Developed and Students' Responses (r) to these Items are Collected. Ideal Responses (r_{ideal}) are Theoretically Calculated from the same Items. Comparing r and r_{ideal} Produces a Discrepancy Value d_k, which Quantifies the Validity of H_k; a Lower d_k Implies Higher Validness.

Next, the Q-matrix Q_k is defined by taking all the valid states in S_k—except the all-zero state (0000000)—as its rows.

Three statistical characteristics of each Q_k-matrix are then measured. First, the sum of each column of Q_k (column sum) indicates the number of items that require the corresponding cognitive attribute. Second, the sum of each row of Q_k (row sum) indicates the number of attributes included in the corresponding item. Third, the sparsity of Q_k is defined by the number of ones divided by the number of elements of Q_k, which corresponds to the frequency of attributes examined in the test set.

Next, we develop an item involving corresponding attributes for each row of Q_k, and students' item responses (r) to the items, which are collected through tests. The set of all the item responses is called R.

The ideal responses (r_{ideal}) to the items are theoretically generated. Here, *ideal* means that the response is solely based on the mastery of the cognitive attribute, excluding guessing or mistakes. For each knowledge state $s \in S_k$, an ideal response r_{ideal} is calculated by Equation 1.

$$r_{ideal} = \sim((\sim s){Q_k}^T), \quad (1)$$

where $\sim$ and T mean the logical NOT operator and the matrix transpose, respectively. The set of ideal responses for all the states in S_k is called I_k.

Last, the discrepancy between the ideal responses (I_k) and the actual responses (R) is calculated as follows. A lower discrepancy value indicates that H_k provides a better account for actual students' responses. First, the discrepancy for each response $r \in R$ is defined by the Hamming distance (the number of mismatches) between r and the closest r_{ideal} in I_k, presented as $h(r, I_k)$. The average discrepancy of responses is normalized by the number of items and defined as the discrepancy for H_k (Equation 2).

$$d(H_k) = \frac{\sum_{r \in R} h(r, I_k)}{N_R N_I}, \quad (2)$$

where N_R and N_I are the numbers of responses and items, respectively.

C. Generating Virtual Responses from an Existing Dataset

Ideally, a different test set would be developed and responses for each hierarchical structure H_k would be collected. However, this would be costly and require too much time. Developing a test set for H_k requires determining the combinations of cognitive attributes based on H_k and developing corresponding items; each of these steps requires repeated feedback from experts. Recruiting test takers for multiple test sets is also costly. Repeating multiple test sets involving the same set of cognitive attributes for a fixed target group would be impractical. Students might learn to recognize patterns during the sequence of similar tests or become bored by the similarity of multiple tests. In either case, collecting unbiased responses for each H_k is a challenging task. Furthermore, if each test is performed on a different group of students, it is unclear whether any difference in item responses is due to the different hierarchical structure or the heterogeneity of the student groups.

To overcome this limitation, we propose to generate virtual responses to each H_k by employing random sampling using a common dataset (Fig. 3). Specifically, for each item, corresponding attributes (each row of Q_k) are used as a query to retrieve responses to items that require attributes similar to the query from the existing database. To simplify, attributes that have the smallest Hamming distance to the query attribute are chosen as candidates first. Thereafter, if there are multiple candidates, one is randomly selected with equal probability. Otherwise, (if there is only one item with the smallest Hamming distance), the candidate response is the virtual response. Repeating the above procedure for all the items (all the rows of Q_k) comprises an iteration of simulation. Subsequently, the average discrepancy is measured for 1,500 iterations for each H_k. Additionally, the statistical significance of the discrepancy is measured by repeating the above calculations, starting from 10 different random seeds.

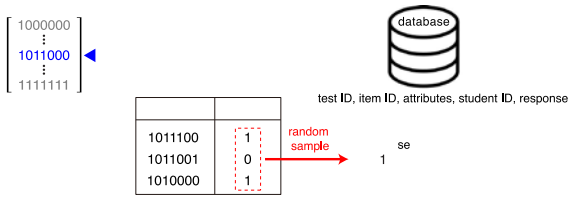

Fig. 3. Virtual Item Responses are Generated from an Existing Database. Each Row of Q_k is used as a Query to Retrieve Candidate Responses to Items with Similar Attributes. among these Candidate Responses, One Response is Randomly Sampled and used as a Virtual Response.

III. Results

A. Statistical Characteristics of the Q-matrix

Even with the same set of cognitive attributes, different hierarchical structures necessitate items with different combinations of cognitive attributes; these result in different numbers of rows in the corresponding Q-matrices. Removing an edge from H_0 increases the number of rows of Q_k (27 ~ 33) for $k = 1, 2, \cdots, 7$ (Fig. 4). This is because more items are needed to determine participants' mastery of independent attributes than what are needed for related attributes. More specifically, Q-matrices corresponding to H_5 and H_7 had the largest number of rows (33). Compared with H_0, H_5 and H_7 have independent nodes A6 and A7, respectively; these nodes had many preceding attributes in H_0.

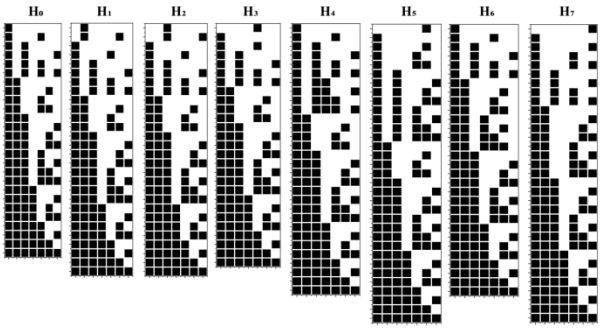

Fig. 4. The Q-matrices (Q_k) for different Hierarchical Structures (H_k). The Rows and Columns of each Q_k are Associated with Items and Attributes, Respectively. Each Row of Q_k Represents Cognitive Attributes Required for each Item in Black.

Even though the number of rows of Q_k differ, the frequencies of ones in Q_k are similar. The average numbers of items per attribute did not differ significantly ($p = 0.970$, one-way ANOVA). Similarly, the average numbers of attributes per item did not differ significantly ($p = 0.998$, one-way ANOVA). Finally, the average sparsity of Q_k was $0.571\ (\pm 0.012)$. Thus, on average, hierarchies (H_k) are homogeneous in terms of the number of items per cognitive attribute and the number of cognitive attributes per item.

B. Comparison of the Discrepancy for Each Hierarchy

The hierarchy designed by the experts (H_0) had a lower discrepancy than all the alternative hierarchies, except for H_2 (Fig. 5); this indicates that H_0 explains students' responses better than most alternative hierarchies, except for H_2. The increase in the discrepancy between the alternative hierarchies implies that the removed edge is important for explaining the actual students' responses.

In contrast, $d(H_2)$ was lower than $d(H_0)$ (Fig. 6). The *t*-test for 10 simulations with different random seed numbers confirmed that there was a significant difference between $d(H_0)$ and $d(H_2)$ ($p = 4.18 \times 10^{-18}$). This result implies that H_2 explains the students' real item responses better than H_0. There is thus a hierarchy of cognitive attributes that better describes responses than the hierarchy designed by the experts.

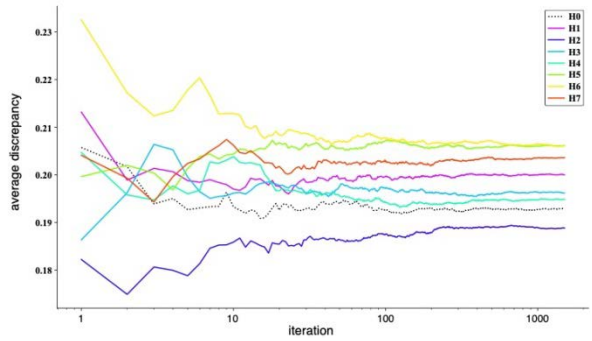

Fig. 5. Average Discrepancy (d_k) of each Hierarchy (H_k) as a Function of Iteration. During Early (< 10) Iterations, d_k Fluctuates Considerably; However, it Stabilizes after about 500 Iterations. After 1,500 Iterations, the Value of d_k was Measured for each H_k. The Hierarchy H_k, which was Designed by the Experts, showed Lower d_k (Black, Dotted) than Most of the other H_k, Except for H_2 (Purple).

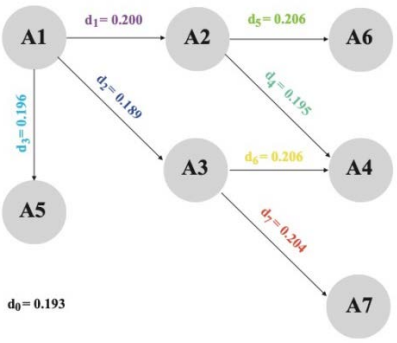

Fig. 6. The Discrepancy (d_k) of each Hierarchy (H_k) is shown on the Removed Edge (for $k > 0$). The Hierarchy without the Edge between A1 and A3 (H_2) showed the Lowest d_k, even Lower than that of the Expert-Designed Hierarchy (d_0).

IV. Conclusion and Discussion

In this study, we propose a method to quantitatively validate the hierarchy of cognitive attributes of a CDM and corresponding Q-matrices. The hierarchy designed by experts (H_0) was compared with alternative hierarchies ($H_1, H_2, \cdots, H_7$) with an edge removed. The discrepancy for each hierarchy was defined by the distance between the real and ideal responses (r and r_{ideal}), the inverse of which is interpreted as a quantitative indicator of how well a hierarchy and the corresponding Q-matrix describe the students' item responses.

Virtual responses were generated from an existing database, rather than directly collecting responses for each hierarchy and its corresponding Q-matrix. After generating a Q-matrix that corresponds to each hierarchy, we selected the items with the closest Hamming distance ($d_{Hamming}$) to each row of Q by comparison with the existing datasets, and one of the responses to these items was randomly selected as a virtual response.

The hierarchy of cognitive attributes designed by the experts (H_0) had generally lower discrepancy than alternative hierarchies; however, one hierarchy (H_2) had a lower discrepancy than H_0. The difference between H_0 and H_2 was the edge between addition (A1) and multiplication (A3), which is present in H_0, but absent in H_2. This implies that the link between addition and multiplication might be weaker than was expected by the experts.

Our interpretation of this gap is that multiplication, once acquired as a separate skill, may not require the concept of addition. The concept of multiplication can be divided into three categories: repetitive addition, multiples, and product set [18]. The first concept of multiplication—repetitive addition—is utilized to teach multiplication to first-time learners. It is therefore reasonable to assume that understanding or performing multiplication also relies on the knowledge of addition, in agreement with the hierarchy designed by the experts (H_0). However, the other aspects of multiplication may play more important roles for students who mastered the concept of multiplication. In other words, after acquiring the knowledge of multiplication, they may perform multiplication as an independent skill, rather than repeating

addition multiple times. Therefore, we posit that the relationship between addition and multiplication may be important for learning, but that it is less so for practicing the actual skill of multiplication.

We propose a scalable validation tool for comparing alternative hierarchies, which could encourage more teachers to utilize CDMs for learning achievement analyses. Selecting relevant cognitive attributes and designing the hierarchy among them requires experts' knowledge and experience, which could hinder wider uses of CDMs. When a user wants to validate a chosen hierarchy or explore alternative hierarchical structures, item responses are sampled from an existing database, without having to develop new items and collect responses for each candidate. The proposed quantitative validation of alternative hierarchies could be used as objective indicators of the validity of established hierarchies.

Our future work will generalize the proposed framework to more complex cases. In this study, we considered only seven attributes with rather simple associations. In general, presence of loop a graph hinders theoretical analysis as well as numerical calculations based on the graph. The hierarchical structure in this study has only one loop. It is of great interest to explore a more complex attributes structure with multiple loops.

Gabor Descriptor for Representation of Spatial Feature

Comparison Between the Proposed Descriptor and the Conventional Fourier Descriptor

Kohei Arai
Information Science Department
Saga University, Saga
Japan

***Abstract*—New spatial feature descriptor based on Gabor wavelet function is proposed. The proposed method is compared to Fourier descriptor. The experimental results with Advanced Earth Observing Satellite: ADEOS / Advanced Visible and Near-Infrared Radiometer: AVNIR image show an effectiveness of the proposed method. It is found that the restored image quality, in terms of root mean square error between the original and the restored images depends on the support length of the mother wavelet and is much better than that with the conventional Fourier descriptor method for spatial feature description.**

Keywords*—Spatial feature; Gabor wavelet descriptor; Fourier descriptor; wavelet transformation; ADEOS (advanced earth observing satellite); AVNIR (advanced visible and near-infrared radiometer)

I. Introduction

There are various examples of applying wavelet analysis to the processing analysis of earth observation satellite images. A method of superimposing a plurality of visible images after wavelet transform [1], a method of superimposing a plurality of SAR: Synthetic Aperture Radar images with different off-nadir angles after wavelet transform [2], and an annual fluctuation pattern of sea surface temperature estimated from satellite data. Method [3] that applies wavelet transform to extract its features, method [4] that applies wavelet transform to the extraction of surface roughness of sea ice, method [5] that extracts spatial features from images extracted from soil moisture, etc. There are [6], [7]. As a report on image processing analysis using the Gabor transform, a report on compression [8] – [11], a report on texture analysis [12] – [15], a report on reconstruction [16] – [21], and a report on feature extraction [22] – [25], there are reports on classification [26] – [28].

However, as far as the authors are aware, there is no example of applying wavelet analysis to the method of describing the geometrical features of an image. The Fourier descriptor is well known as a method of describing the geometrical features of an image [29] – [31]. The Fourier descriptor is the one that the contour line (closed curve) extracted from the image is Fourier expanded, and the closed curve is described by a finite number of Fourier expansion coefficients. The Fourier descriptor does not describe the characteristic points of the closed curve in detail but describes all points using the sin function (cos function). Also, some proposals have already been made for the method of applying the Fourier descriptor to open curves.

On the other hand, the Gabor descriptor proposed in this paper takes advantage of the characteristics of Gabor transformation and is devised so that it is possible to describe the complicated part of the contour line in detail. The author considered that the Gabor descriptor enables the description of geometrical features with less information than the Fourier descriptor with less deterioration [32] – [34]. Furthermore, remote sensing satellite image database system allowing image portion retrievals utilizing principal component which consists spectral and spatial features extracted from imagery data is proposed recently [35].

In this paper, the author tries to extend the descriptor by Fourier expansion and opening to the descriptor by Gabor expansion. The proposed method was applied to the Visible and Near Infrared Radiometer: VNIR data of the Advanced Spaceborne Thermal Emission and Reflection Radiometer: ASTER sensor mounted on the Terra satellite to confirm that it is superior to the existing method and to change the support length in Gabor conversion. The author also confirmed the effect of the proposed method.

The next section describes theoretical background and the proposed method for spatial feature descriptor based on Gabor wavelet function. Then some experiments are described followed by conclusion together with some discussions.

II. Theoretical Background and Proposed Method

A. Fourier Expansion and Gabor Wavelet Expansion

The Fourier transform of the complex function f given the contour line (closed curve etc.) extracted from the image is defined by the equation (1).

$$F(\omega) = \int_{-\infty}^{\infty} \overline{e^{\iota\omega t}} f(t)dt \tag{1}$$

The Gabor transform is defined by equations (2) and (3).

$$W(\omega,\sigma,k) = \int_{-\infty}^{\infty} \overline{\exp\left(-\frac{(t-k)^2}{\sigma^2}\right)e^{\iota\omega t}}) f(t)dt \tag{2}$$

$$= \int_{-\infty}^{\infty} \overline{e^{\iota\omega t}}\exp(-\frac{(t-k)^2}{\sigma^2} f(t)dt \tag{3}$$

However, $\overline{e^{\iota\omega t}}$represents the complex conjugate of $e^{i\omega t}$ and $\overline{\exp\left(-\frac{(t-k)^2}{\sigma^2}\right)e^{\iota\omega t}}$ expresses the complex conjugate of $\exp(-\frac{(t-k)^2}{\sigma^2})e^{i\omega t}$. ω is a parameter in the frequency axis direction, and σ and k are parameters in the time axis direction.

The Gabor transform is a Gaussian function with a window function introduced into the Fourier transform. That is, the Gabor transform is a kind of Fourier transform with window function. In particular, when *k*=0, equation (2) becomes equation (4).

$$W(\omega,\sigma,0)=\int_{-\infty}^{\infty}\overline{\exp\left(-\frac{(t)^2}{\sigma^2}\right)e^{\iota\omega t}}\,f(t)dt \quad (4)$$

When σ = ∞, equation (2) becomes equation (5).

$$W(\omega,\infty,k)=\int_{-\infty}^{\infty}\overline{e^{\iota\omega t}}\,f(t)dt \quad (5)$$

Therefore, it can be seen that it does not depend on the parameter *k*.

According to Eq. (2), if the value of the parameter σ is large, the influence of the parameter *k* on *W(ω,σ,k)* is small. If the value of the parameter σ is small, the influence of the parameter *k* on *W(ω,σ,k)* is large.

The Gabor transform is not restored to the original data when the inverse transform is performed because it is not an orthogonal transform. However, even in the Fourier transform which is the orthogonal transform, for example, when the inverse transform is performed through the low-pass filter, the original data is not restored. The reason why Gabor transform is not orthogonal transform is that it introduces window function into Fourier transform. In other words, it is necessary to consider the effect of the window function when performing Gabor transformation.

B. Fourier Descriptor and Gabor Wavelet Descriptor

In the Fourier descriptor, the extracted spatial feature information is Fourier expanded and the expansion coefficient is used as the descriptor. In the Gabor descriptor, the extracted spatial feature information is Gabor expanded, and the expansion coefficient is used as the descriptor. The Fourier descriptor requires operations from -∞ to ∞ according to Eq. (1). The Gabor descriptor proposed in this paper does not require operations from -∞ to ∞ by introducing the window function (Gaussian function) in Eq. (2). However, it is assumed that the tail of the Gaussian distribution is regarded as zero. From the viewpoint of the above calculation amount, the author thinks that the Vega ball descriptor is superior to the Fourier descriptor.

The number of non-zero Gabor expansion coefficients is called the support length. It can be seen from Eq. (2) that the support length depends on the parameter σ.

C. Gabor Descriptor for Closed Curve

Let *Z(l)=(x(l), y(l))* be the closed curve. *Z(l)* is a point that has advanced a distance *l* on the closed curve from a certain start point on the closed curve as shown in Fig. 1.

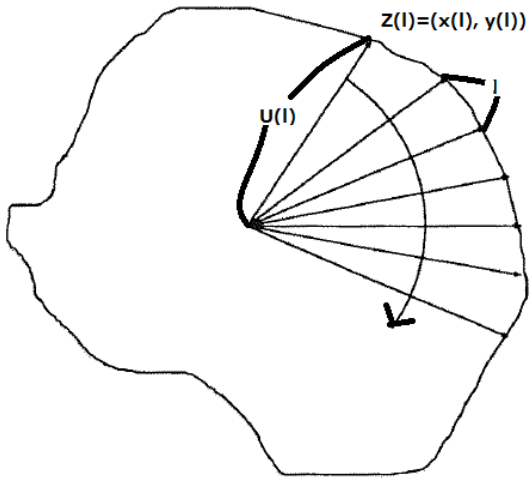

Fig. 1. Concept of the Proposed Wavelet Descriptor.

Here, if the complex function *u(l)* is defined as follows,

$$u(l)=x(l)+iy(l),\left(i=\sqrt{-1}\right) \quad (6)$$

The complex function *u(l)* is the total length *L* of the closed curve which is a periodic function. The Gabor descriptor is realized by performing Gabor expansion on the complex function *u(l)*.

D. Feature of the Proposed Gabor Wavelet Descriptor

The proposed method considers the information of the edge of the closed curve of the image as a periodic complex function and describes and saves the geometrical feature of the image using the information of the position of a certain starting point on the closed curve and the Gabor expansion coefficient. The proposed method has the following features,

1) When compared with the method of saving edge information as a binary image (method of saving as "face" information), it is superior in terms of the amount of saved data. That is, information of pixels that are not edges is not included.

2) The Fourier descriptor requires operations from -∞ to ∞, but the Gabor descriptor does not require operations from -∞ to ∞.

III. Experiments

A. Experimental Method

The data used this time are actual observation images near Mt. Usu acquired by the sensor AVNIR onboard the ADEOS satellite. Fig. 2 shows the aerial photo of Aza-Nakanoshima island near the Mt. Usu while Fig. 3 shows the acquired Advanced Visible and Near Infrared Radiometer: AVNIR (onboard on Terra Satellite) image.

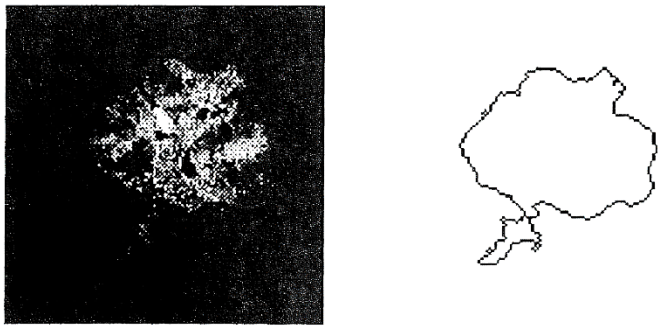
Fig. 3(a) shows an actual observation image, and Fig. 3(b) shows an image resulting from contour extraction. In this experiment, the experiment is performed using Fig. 3(b). Fig. 4 shows the distance from a certain point inside the closed curve in Fig. 3(b) to a point on the closed curve. The purpose of this experiment is to compare the effectiveness of the wavelet descriptor with that of the Fourier descriptor and to

confirm it by evaluating the restoration accuracy. Therefore, the result obtained by halving the number of Fourier expansion coefficients by a low pass filter is used in the Fourier descriptor, and the result obtained by only the low frequency component is used in the wavelet descriptor. At the same time, the impact of the support length of the wavelet will be examined. In addition, equation (7) is used to evaluate the restoration accuracy.

$$J_1 = \sqrt{\frac{\sum_{s=1}^{N}\{(\widehat{x(s)}-x(s)\}^2+\{(\widehat{y(s)}-y(s)\}^2}{N}} \qquad (7)$$

Note that from Fig. 4, N=256.

Fig. 2. Google Map (Aerial Photo Image) of Aza Nakanoshima near the Mt.Usu of Intensive Study Area.



(a) Original AVNIR Image. (b) Detected Edge.

Fig. 3. Acquired AVNIR Image of Aza-Nakanoshima Island near the Mt. Usu and the Detected Edge Image.

Fig. 4 is an example of constructing a complex function *u(l)* based on Fig. 3(b). The vertical axis in Fig. 4 is the time axis. The result of projecting the complex function *u(l)* on the two-dimensional plane orthogonal to the time axis agrees with Fig. 3(b). Since the complex function *u(l)* is composed of a closed curve, Fig. 4 shows one cycle of the complex function *u(l)*.

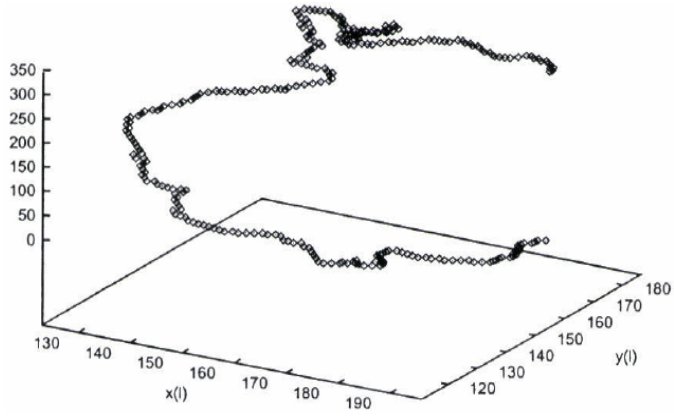


Fig. 4. The Complex Function u(l).

B. Experimental Result

Fig. 5 shows the real and imaginary parts of Fourier spectrum and the power spectrum when the Fourier expansion is applied to the complex function *u(l)*. Fig. 6 corresponds to the result of the Gabor expansion coefficient when σ=5-40. Fig. 7 shows the number of non-zero Gabor expansion coefficients (support length) when the parameter σ is changed. Fig. 8 shows the restoration accuracy J_1 when the parameter σ is changed. Fig. 6 shows an example of a restored image when the parameters σ = 10 and 20. Table I shows the restoration accuracy J_1 when the parameter σ is fixed and the Gabor expansion coefficient with a large parameter ω is forcibly set to zero (the restoration accuracy J_1 is shown when the number of coefficients forcibly set to zero is changed.

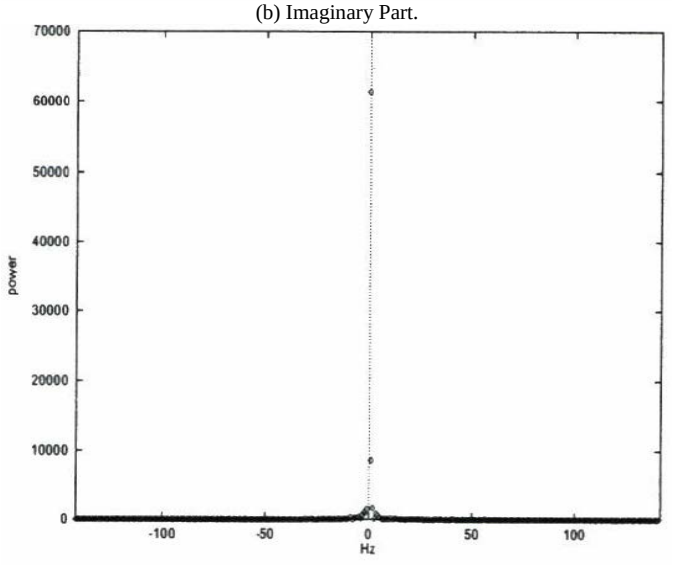
(b) Imaginary Part.



(c) Power Spectrum.

Fig. 5. Real and Imaginary Parts of the Fourier as well as Power Spectrum of *u(l)*.

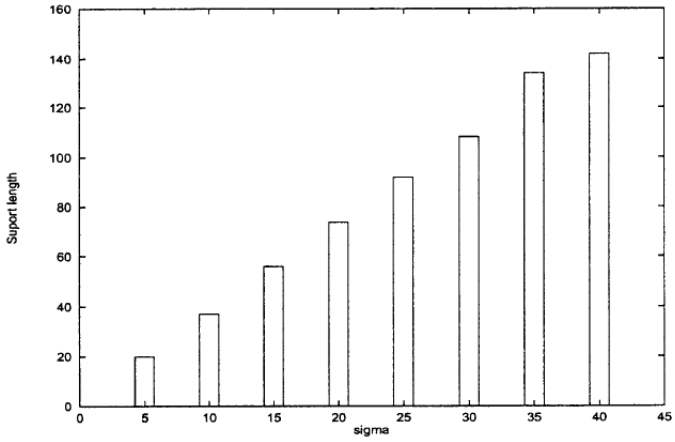


Fig. 6. Support Length for the Designated Parameter σ.

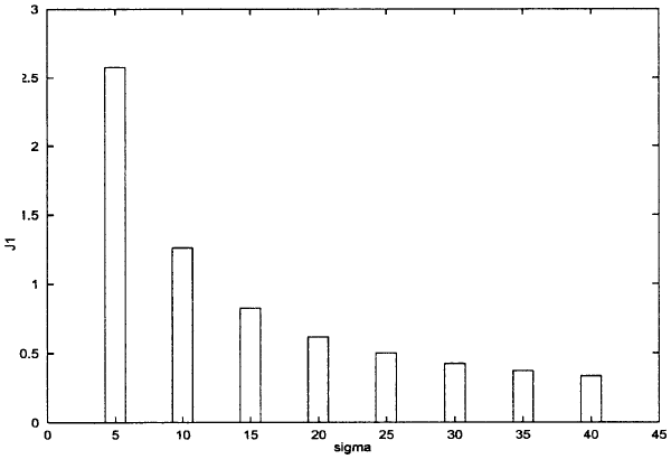

Fig. 7. Error J_1 for the Designated Parameter σ.

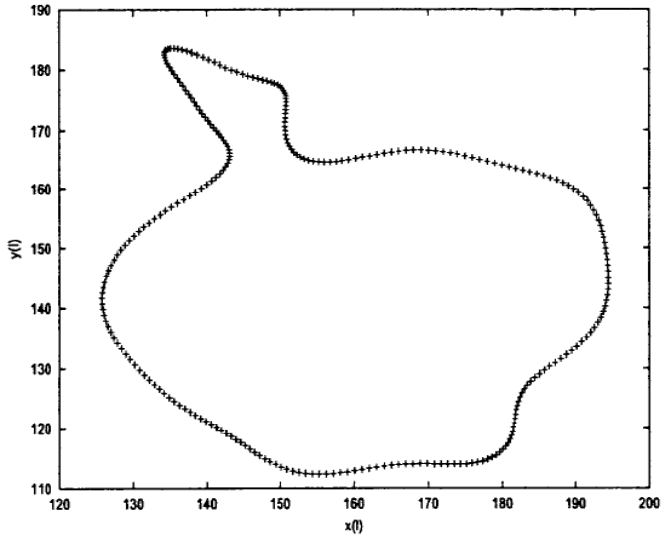
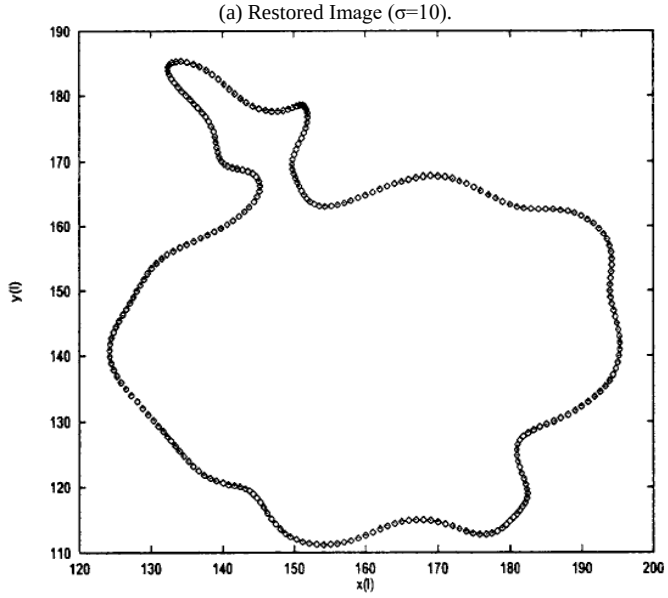
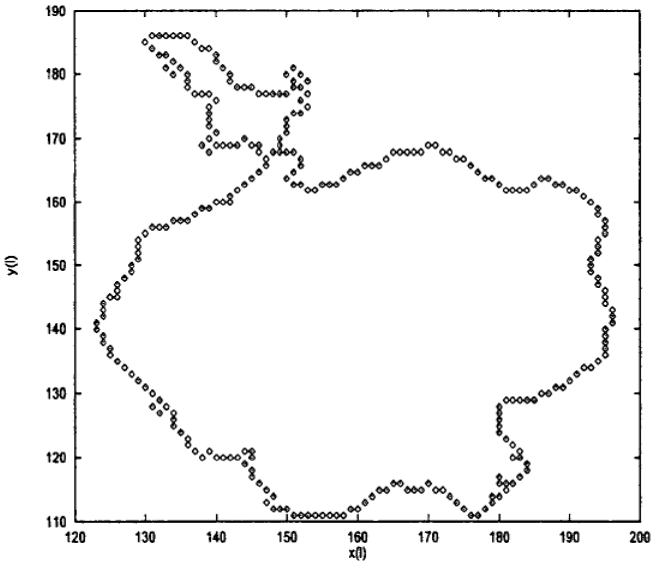


(a) Restored Image (σ=10).



(b) Restored Image (σ=20).



(c) True Contour (the Detected Edge).

Fig. 8. Example of Restored Image for σ=10, 20.

TABLE I. RESTORATION ACCURACY J1 BY THE NUMBER Γ OF COEFFICIENTS

σ|γ	20	40	60	100	160
10	1.374	1.267	1.266	1.266	1.266
20	1.08	0.656	0.622	0.618	0.618
30	1.056	0.531	0.453	0.427	0.424
40	1.051	0.5	0.401	0.348	0.335
50	1.05	0.491	0.382	0.312	0.282
80	1.05	0.485	0.369	0.28	0.216
100	1.049	0.484	0.368	0.276	0.195
150	1.049	0.483	0.367	0.273	0.183

That is, the accuracy J_1 is shown which is obtained by applying the low pass filter to the result of the Gabor transform of the parameter σ and restoring it. Table I shows the restoration accuracy J_1 by the number γ of coefficients that are not forced to zero. The parameter γ is a parameter in the frequency axis direction for the low-pass filter, and the parameter σ is a parameter in the time axis direction.

C. Remarks

As for the relationship between the restoration accuracy and the parameter σ, it can be seen from Fig. 4 that the support length depends on the parameter σ. That is, the support length increases as the parameter σ increases. From Fig. 7, the restoration accuracy J_1 depends on the parameter σ. That is, the restoration accuracy J_1 improves as the parameter σ increases. From Fig. 8, the restoration accuracy of the restored image depends on the support length.

On the other hand, regarding the relationship between the restoration accuracy and the parameter ω, from Table I, the restoration accuracy J_1, when the number of coefficients that force the Gabor expansion coefficient with a large parameter ω in each parameter σ to zero, is changed is zero. The smaller the number of coefficients to be set, the better.

IV. CONCLUSION

New spatial feature descriptor based on Gabor wavelet function is proposed. The proposed method is compared to Fourier descriptor. The experimental results with an ADEOS (Advanced Earth Observing Satellite) / AVNIR (Advanced Visible and Near-Infrared Radiometer) image show an effectiveness of the proposed method.

Through experiments with actual remote sensing satellite imagery data, it is found that the proposed description of geometric features of images based on the wavelet transform based on the Daubechies basis is more reproducible than that by existing Fourier descriptors under the condition of the same bandwidth. This is because, when the image space domain is transformed into the Fourier frequency domain and the wavelet frequency domain by the Fourier transform and the wavelet transform, respectively, if the band is halved to the maximum image frequency, the high frequency component disappears in the former case.

On the other hand, in the latter case, it can be said that the high frequency reproducibility is excellent because the high frequency component is preserved even when the latter is divided into the low frequency component. Moreover, it was found that this reproducibility depends on the support length of the basis function in the case of the wavelet descriptor, and when the support length is 2, it exceeds the Fourier descriptor in all cases of 4 or more. From the above, it can be said that the reproducibility of the geometrical description of the image by the wavelet descriptor under the same band limitation exceeds that of the Fourier descriptor.

V. FUTURE RESEARCH WORK

Further investigations are required for the validation of the proposed spatial feature extraction method with a variety of imagery data.

ACKNOWLEDGMENT

The author would like to thank Dr. Kaname Seto (former student of the Saga University) and Mr. Taroh Nakao (former student of the Saga University) for their contributions on this study. The author, also, would like to thank Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

Comparative Analysis of National Cyber Security Strategies using Topic Modelling

Minkyoung Song, Dong Hee Kim, Sunha Bae, So-Jeong Kim
National Security Research Institute, Daejeon, South Korea

***Abstract*—Comprehensive comparative analyses of national cyber security strategies (NCSSs) have thus far been limited or complicated by the unique nature of cybersecurity, which combines various areas such as technology, industry, economy, and defense in a complex manner. This study aims to characterize the NCSSs of major countries, quantitatively considering the time series, and identify further cybersecurity agendas for the benefit of NCSS revision in South Korea, by applying topic modelling to the analysis of eight NCSSs from the US, UK, Japan, and EU. As a result, fifteen agendas were identified and grouped into four sectors. We determined from the agenda distribution that the approach of each country to cybersecurity was different. In addition, additional agendas worthy of consideration for future NCSS revisions in South Korea were proposed, based on a comparison of the 15 aforementioned agendas with those of South Korea. This study is significant for cybersecurity policy in terms of enabling quantitative analysis in a single framework via latent dirichlet allocation (LDA) topic modelling, and deriving further cybersecurity agendas for future NCSS revisions in South Korea.**

Keywords*—*Cybersecurity policy; national cyber security strategy (NCSS); policy analysis; quantitative analysis

I. Introduction

Even in the midst of the COVID-19 pandemic, many of us were able to maintain our daily lives and national activities through the use of cyberspace. Cyberspace has become a new existential dimension for individuals and society to access the world via the transcendence of the physical limits of time and space. However, as dependence on cyberspace increased through digitalisation across the world, cyber threats have also become more diverse, complex, and menacing. Furthermore, malicious cyber activities on critical infrastructure such as electrical utilities, banking systems, and telecommunications networks could threaten the national security of almost any country. Therefore, at least 100 countries have established national strategies to secure their cyberspace.

A national cybersecurity strategy (NCSS) is one of the most concise documents for understanding the national approach to securing cyberspace. Analysing NCSSs is essential for determining the response stances at a national level and for understanding international cybersecurity trends. However, NCSSs endogenously include multidimensional agendas such as technology, industry, economy, and defence, which make it difficult to perform consistent and systematic analysis of NCSSs and to discover which agenda should be addressed in the development or revision of an NCSS. Meanwhile, text analysis has emerged as a new method for the analysis of large amounts of descriptive data, such as in NCSSs. Text analysis is useful for enabling empirical and quantitative analysis of descriptive data by identifying the keywords of documents and understanding content from relationships between words. Recently, even though text analysis has begun to be introduced into the analysis of NCSSs, there is still room for improvement, such as through the inclusion of time series in the analysis, which can lead to further agendas for future NCSS development.

This study aims to determine the cybersecurity agendas of leading countries and derive their implications using topic modelling, a text analysis technique, to prepare their NCSSs for development and/or revision. To accomplish this objective, we focused on the eight NCSSs of the US, UK, Japan, and EU, who have attempted to assert their leadership in cyberspace by establishing their NCSSs earlier, and by constantly improving their NCSSs in consideration of the changing threat environment. Furthermore, the aforementioned four countries are suitable for inspiring the design of a domestic cybersecurity agenda for South Korea because these countries have similar cybersecurity approaches and similar or higher technology levels with respect to South Korea.

The remainder of this paper is organised as follows. The first part consists of a literature review on topic modelling and NCSS analysis. The second part presents an analysis of target NCSS documents. The third part provides information on 15 cybersecurity agendas and their trends by nation and period as a result of topic modelling analysis, and the last part reveals the conclusion and future direction of research.

II. Literature Review

A. Topic Modelling

Unstructured data such as NCSSs have been analysed mainly using qualitative methods rather than quantitative methods because of the nonlinear relationship between cause and effect, the importance of historical reasons, and path-dependent development. However, as natural language processing (NLP) techniques are applied to existing data mining processes, empirical and quantitative analyses of unstructured text data increasingly gain attention in the field of policy analysis. In its early stages, this type of text analysis was used primarily for library and information science and computer engineering, whereas nowadays, it is used for a greater variety of purposes as part of quantitative content analysis.

Topic modelling is a statistical technique used to discover hidden structures from collections of documents. In policy research, topic modelling has been used to discover policy

agendas or issues from news articles, speeches, and petitions, and to monitor research trends through the analysis of research papers in time series. Furthermore, research applying topic modelling to policy evaluation has recently emerged. Table I shows a list of these studies with descriptions of the methodology.

TABLE I. A LIST OF POLICY ANALYSIS STUDIES APPLYING TOPIC MODELLING

Research Area	Study	Year	Purpose	Dataset	Algorithm
Policy Agenda Analysis	[1]	2013	Monitoring public opinion	all posts by top 2,000 'LiveJournal' (blog platform in Russia) users (2011–2012)	LDA
	[2]	2015	Understanding citizens' direct policy suggestions	2,850 petition texts (2011–2014)	LDA
	[3]	2017	Analysing political agenda of European Parliament	English language legislative speeches in European Parliament plenary (1999–2014)	NMF
	[4]	2019	Policy requirement at citizens' level	173 posts in social media	LSA
	[5]	2019	Identifying relation between mass media and public attention	news articles, Google trends query, Twitter keywords (Jul. 31st to Nov. 5th, 2017)	NMF
Research Trend Analysis	[6]	2017	Discovering themes and trends in transportation research	17,163 papers (1990–2015)	LDA
	[7]	2018	Exploring research trend of smart factory	2,488 international papers and 404 Korean papers (1995–2016)	LSA
	[8]	2019	Analysing research topics in cybersecurity and data science	48 papers (2012–2018)	LDA
Impact Analysis	[9]	2021	Assessing temporal patterns of newspaper coverage	6,645 articles on German Renewable Energy Act (2000–2017)	LDA

As shown in Table I, researchers could determine policy implications by selecting appropriate datasets and algorithms according to their research purposes and interpreting the topic modelling results. Specifically, Table I shows that policy agendas could be discovered from SNS postings, petitions, speeches, articles, etc., research trends from research papers, and policy impact from the contents of articles on specific issues. On the other hand, algorithm selection does not depend on the research purpose or area. Some algorithms for categorising topics from words in documents include latent semantic analysis (LSA), non-negative matrix factorisation (NMF), and latent dirichlet allocation (LDA), among which LDA is the most widely used for topic modelling in social science. This is because LDA assumes that multiple topics exist in a single document, which is in harmony with the social science assumption that a single body of text does not reflect only a single point of view, but that multiple competing points of view can appear within the same document. Therefore, this study attempted topic modelling using LDA, the algorithm that is most widely used for policy analysis.

B. National Cybersecurity Strategy

A national cybersecurity strategy (NCSS) is a document that reflects cybersecurity policy direction and stance on cyber threats at the national level. Because the NCSS sets national strategic objectives and priorities for a specific period, it is essential to consider the evolving cyber threat environment and the national approach to cybersecurity in a timely manner. For example, Japan has a cybersecurity policy structure that is revised every three years, and the EU every seven years. However, because of rapid technological changes and the short technological life cycle of information and communications technology (ICT), NCSS revision cycles need to be shorter in the future. For nations that want to properly establish or revise their NCSSs, analysis of the NCSSs of countries that have leadership in cyberspace or similar approaches to cybersecurity is important. This strategy will help with identifying new policy agendas that have not yet been considered and with uncovering any issues that may require cybersecurity cooperation.

Studies on NCSSs have usually aimed to discover common structures or identify further agendas that need to be considered. However, prior to the application of data analysis such as topic modelling to the cybersecurity policy area, qualitative methodologies, which forced reliance on the opinions of experts, were used in the analysis of NCSSs. Qualitative analysis not only consumes large amounts of time, but also is prone to inconsistencies because of the likelihood of differing opinions among these experts. Therefore, it is necessary to establish an automated quantitative analysis system to work alongside qualitative analysis. NCSS analysis using topic modelling has thus far focused only on analysing more countries and more data, which is unsuitable for studies aiming to discover cybersecurity agendas for the establishment or revision of NCSSs. Of course, it is important to examine global cybersecurity trends practically and academically, but in any research for the purpose of establishing or revising an NCSS, it is necessary to limit the scope of analysis to NCSSs in like-minded countries or in advanced countries. Table II outlines prior studies on NCSS analysis.

TABLE II. A LIST OF NCSSS ANALYSIS STUDIES USING TOPIC MODELLING METHOD

Study	Year	NCSSs	Methodology	Description
[10]	2013	19 NCSSs	(Qualitative) comparison based on 11 categories	Identifying formal structures for NCSS development
[11]	2015	3 NCSSs	(Qualitative) comparison based on 7 categories	Finding NCSSs, in general, changed from voluntary self-regulation to enforced self-regulation
[12]	2016	10 NCSSs	(Qualitative) content analysis	Finding 8 main components of NCSSs
[13]	2019	6 NCSSs	(Qualitative) cross-section analysis using 8 comparison elements	Evaluating robustness of existing cyber security strategy of Bangladesh
[14]	2017	60 NCSSs	(Quantitative) clustering and topic modelling	(Initial attempt to compare NCSSs using topic modelling method) Identifying 10 topics in NCSSs
[15]	2020	101 NCSSs	(Quantitative) topic modelling	Identifying 4 critical agendas in NCSSs

Topic modelling has contributed to the understanding of international trends in cybersecurity by enabling massive data analysis and extending NCSS analysis to quantitative and empirical areas. However, the limitations of not considering the time series and the scope of analysis remain, rendering these past analyses insufficient for deriving policy implications for future NCSSs. Therefore, this study focuses on characterising the NCSSs of the US, UK, Japan, and EU, tracking changes in their topic distributions over time, and then identifying critical national cybersecurity agendas through comprehensive comparative analysis of the results of topic modelling.

III. DATASET

South Korea launched its first national cybersecurity strategy in 2019. Although this strategy is not the first official document to reveal the response stance of South Korea to cyber threats, it is the first cybersecurity strategy document established in accordance with the national security strategy. This strategy contains six strategic tasks, the titles of which are listed in detail in Table III.

To implement the NCSS, South Korea has announced an action plan at the agency level to support these six strategic tasks until 2022. This suggests that the policy demand for NCSS revision would increase, such as in identifying additional policy agendas worthy of consideration but not covered by existing NCSSs. Therefore, this study selected the NCSSs of the US, UK, Japan, and EU for comparative analysis to derive additional considerations for revising the NCSS of South Korea. Two criteria were considered in the selection of the target of analysis. For the first criterion, the target must have similar approaches to cyberspace in terms of international relationships, while also having similar ICT research and development level, to that of South Korea. For the second criterion, the target should have published an NCSS more than once, such that its NCSS transition in time series can be tracked. This target selection enables a direct comparative analysis of cybersecurity agendas derived from topic modelling results and the strategic tasks of the South Korean NCSS; it is also suitable for examining NCSS trends by country and period, which have not been provided by prior studies that used topic modelling. The dataset for this study is presented in Table IV. Prior to analysis, the aforementioned eight NCSSs were subjected to pre-processing: synonyms were extracted into single words, and unnecessary words with general meaning were eliminated. As a result, 1,287 words remained for the actual LDA topic modelling analysis.

TABLE III. STRATEGIC TASKS PRESENTED IN NCSS OF SOUTH KOREA

1. Increase Safety of National Core Infrastructure	
1-1	Strengthen security of national information and communications networks
1-2	Improve cybersecurity environment for critical infrastructure
1-3	Develop next-generation cybersecurity infrastructure
2. Enhance Cyber Attack Response Capabilities	
2-1	Ensure cyber attack deterrence
2-2	Strengthen readiness against massive cyber attacks
2-3	Devise comprehensive and active countermeasures for cyber attacks
2-4	Enhance cybercrime response capabilities
3. Establish Governance Based on Trust and Cooperation	
3-1	Facilitate public–private–military cooperation system
3-2	Build and facilitate nation-wide information sharing system
3-3	Strengthen legal basis for cybersecurity
4. Build Foundations for Cybersecurity Industry Growth	
4-1	Expand cybersecurity investment
4-2	Strengthen competitiveness of cybersecurity workforce and technology
4-3	Foster growth environment for cybersecurity companies
4-4	Establish principle of fair competition in cybersecurity market
5. Foster Cybersecurity Culture	
5-1	Raise cybersecurity awareness and strengthen cybersecurity practice
5-2	Balance fundamental rights with cybersecurity
6. Lead International Cooperation in Cybersecurity	
6-1	Enrich bilateral and multilateral cooperation systems
6-2	Secure leadership in international cooperation

TABLE IV. ANALYSIS TARGET DOCUMENTS

Nation	Year	Document (NCSS)	Version
U.S.	2003	National Strategy to Secure Cyberspace	Previous
	2018	National Cyber Strategy	Current

	2018	Cybersecurity Strategy	Current
EU	2013	EU Cybersecurity Strategy: An Open, Safe and Secure Cyberspace	Previous
	2020	EU Cybersecurity Strategy for the Digital Decade	Current

IV. Data Analysis and Result

A. Result of Topic Modelling

A total of 15 agendas were identified, as shown in Table V. Although there are a few tools available for determining topic sets, such as the minimum perplexity approach, the suitable approach is not yet clear. Therefore, we designated an optimal number of topics by reviewing the keywords constituting each agenda in a way that minimised duplication, and maximising the explanatory power of the agendas from a holistic point of view.

Table V consists of the columns Sector, Agenda, Keywords, and Proportion. The naming of each agenda is based on its constituent keywords. Furthermore, the agendas are grouped into four sectors: Infra Stability (I), Protection and Response Capability (II), Industry and Technology (III), and International Cooperation (IV), in accordance to their strategic or operational objectives. Lastly, the rightmost column of Table V presents the proportion of each agenda.

TABLE V. Fifteen Cybersecurity Agendas of US, UK, Japan and EU and their Proportion

Sector	Agenda	Keyword (Top 15)	Prop.
Infra Stability (I)	① Network and System Vulnerability	**cyber-attack**, **network**, **system**, **vulnerability**, **software**, computer, internet, actor, **damage**, attacker, critical infrastructure, **malware**, **hardware**, attention, **disruption**	7.93
	② Cyber Security Role and Responsibility	**security**, **agency**, **system**, **responsibility**, cyber space, **role**, **risk**, state, investment, **control**, IT, procurement, **administration**, **asset**, effectiveness	5.86
	③ Risk Assessment and Management	**risk**, **cyber threat**, **vulnerability**, cyber-attack, **critical infrastructure**, **assessment**, **priority**, operation, challenge, company, nation, damage, **risk management**, **resource**, opportunity	7.13
	④ Information Communication Network Access Control	**system**, **information**, **network**, **security**, infrastructure, **communication**, **access**, **control**, **information system**, computer, AI, internet, trustworthiness, knowledge, integrity	6.29
Protection and Response Capability (II)	① Privacy and Intellectual Property Security	**internet**, information, **right**, **freedom**, **citizen**, **privacy**, **protection**, **security**, business environment, **society**, **DNS**, **online**, **intellectual property**, **breach**, **human right**	7.04
	② Cyber Defence Capability	**capability**, **cyber-attack**, **defence**, **cyber threat**, **national security**, nation, **critical infrastructure**, **state**, actor, **cyber terrorism**, **adversary**, network, infrastructure, **ability**, **operation**	7.85
	③ Incident Response and Information Sharing	**cyber-attack**, **incident**, **response**, information, **cyber threat**, **capability**, **coordination**, **information sharing**, damage, sharing, **detection**, **recovery**, knowledge, **situational awareness**, **monitoring**	8.40
	④ Cyber Crime Law Enforcement and Investigation	**cyber-crime**, **law**, **enforcement**, **capability**, agency, cyber threat, **intelligence**, **response**, **investigation**, **authority**, tool, force, child **protection**, resource, **capacity**	8.61
Industry and Technology (III)	① Standard, Certification and Supply Chain Security	**system**, **security**, **operation**, **IoT**, **business environment**, **critical infrastructure**, **standard**, information, **industry**, **assurance**, safety, **certification**, **supply chain**, connection, collaboration	6.75
	② ICT Innovation	**information**, **internet**, **society**, **security**, **economy**, infrastructure, **progress**, **innovation**, **multi-stakeholder**, governance, **ICT**, **market place**, communication, country, culture	4.22
	③ Public Private Partnership (PPP)	**industry**, cyber awareness, **research**, **R&D**, security, **coordination**, **standard**, public, role, **partnership**, collaboration, company, information, state, **innovation**	4.61
	④ Security Awareness and Knowledge	**business environment**, **market place**, **company**, **investment**, **personnel**, **cyber awareness**, risk, cost, judiciary, solution, opportunity, **knowledge**, role, **human resource**, demand	7.90
International Cooperation (IV)	① International Norm and State Behaviour	**state**, **rule, behaviour**, **principle**, **national security**, **peace**, **law**, **norm**, **stability**, **international community**, **international law,** society, safety, actor, **alliance**	8.18
	② EU Member State Cooperation	**member**, **state**, **cooperation**, **defence**, authority, progress, agency, **NIS directive**, **ENISA**, **coordination**, **incident**, **resilience**, role, framework, capability	3.99
	③ International Partnership	**country**, **partner**, **cooperation**, cyber threat, **partnership**, **industry**, challenge, capability, information, **ally**, border, network, communication, **participant**, NATO	5.26

B. NCSS Agenda Transition

1) Topic distribution by nation: The results of topic distribution for the four nations are presented in Table V. This section aims to identify the differences in cybersecurity approaches by nation. In Fig. 1, which was derived from the current NCSS of each country that was analysed, the blue bar represents the percentage of each agenda, whereas the orange line represents the percentage of each sector, which is the sum of the percentages of agendas constituting that sector (I–IV). According to the results, the NCSSs of the US and UK focused on improving cybersecurity response capability, whereas those of Japan and the EU vitalised the cybersecurity industry and international cooperation, respectively.

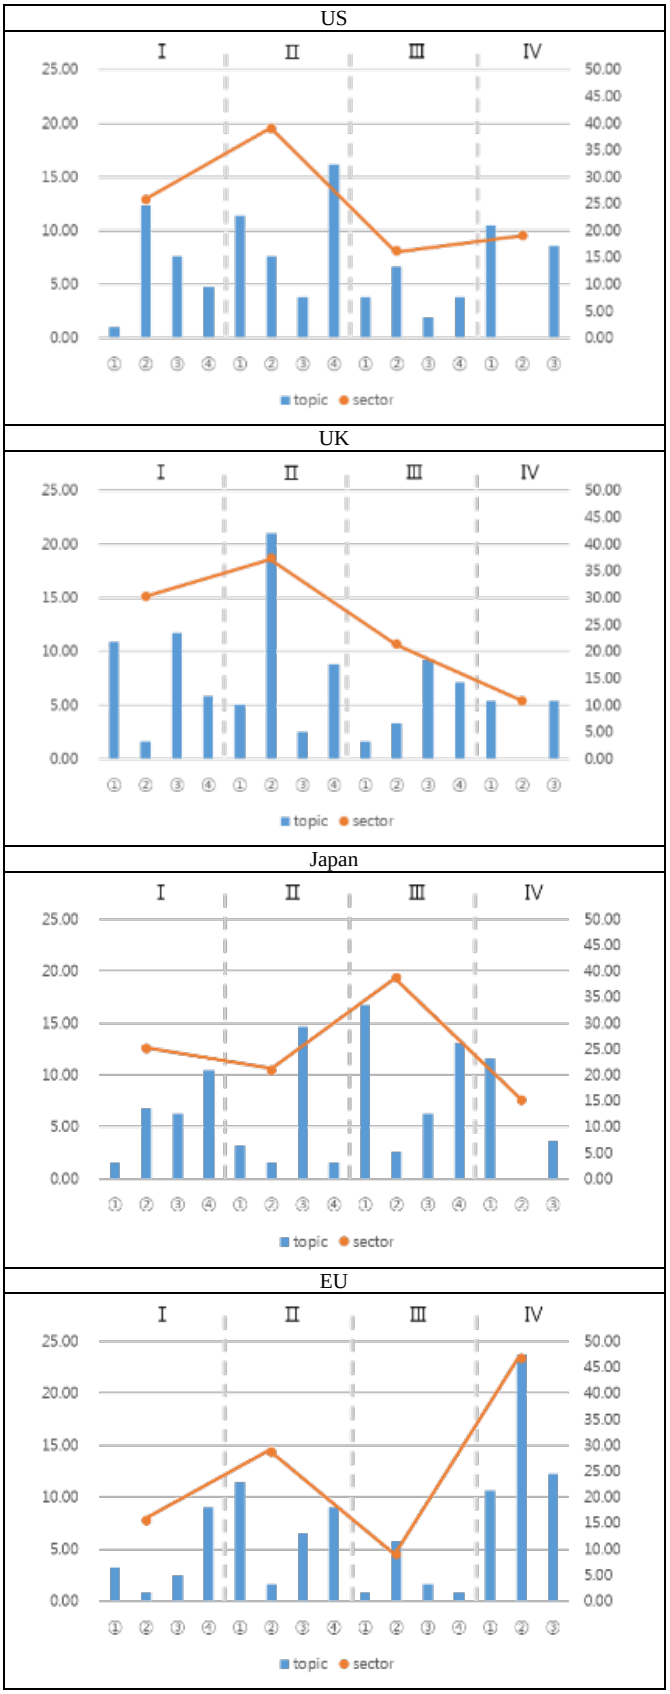

Fig. 1. Topic and Sector Distribution Derived from the Current NCSS of each Country.

The NCSS of the US (2018) emphasised improving incident response capabilities (II), especially cybercrime law enforcement and investigation capabilities (II-④), and establishing cybersecurity governance (I-②). In addition, intellectual property security (II-①) had a relatively higher proportion compared with in other NCSSs, which means that the US, with its world-class technology levels in a wide range of emerging technology areas such as IT, aerospace, and defence industries, likely regard the technological and economic aspects of its cyberspace from a national security perspective.

Similar to the US, the UK (2016) prioritised protection and response capability (II). However, unlike the US, the UK highly concentrated on cyber defence capability (II-②). This may reflect the concept of traditional defence power in cyberspace, and is consistent with the creation of a National Cyber Force, which is known to provide offensive and defensive capabilities in pursuit of national security objectives, and operation of an Active Cyber Defence (ACD) programme, which is meant to reduce harm from commodity cyber-attacks by providing necessary tools and services. Moreover, the UK was also shown to be discussing both vulnerability mitigation (I -①) and risk assessment and management (I -③) to improve infrastructure stability. A risk-centric approach to cybersecurity could be the basis for establishing concretised security measures according to asset or information-specific importance and the level of risk exposed; therefore; the NCSSs of the US, Japan, and UK covered this type of approach at high proportions.

On the other hand, the NCSS of Japan (2018) was characterised by a relatively high proportion (39%) for the cybersecurity industry and technology sector (III). This observation is consistent with the objective of its strategy; the first objective of Japan, unlike in the other analysed countries, was to enable socio-economic vitality and sustainable development. Their suggested policy approach to achieving this objective was to advance cybersecurity, establish a secure supply chain, and build a secure IoT system. This approach to cybersecurity was clearly different from those of the other analysed countries, which prioritised the protection of critical infrastructure and enhancement of deterrence in cyberspace. In addition, their National Information Security Center (NISC), which is responsible for information security policy, announced the necessity to protect the supply chain against dependence on excessive foreign technologies, to drive data accumulation and utilisation using emerging technologies such as AI, and to accomplish international standardisation of related technologies. Based on a comprehensive view of these considerations, the focal point of the cybersecurity policy of Japan seemed to be the revitalisation of future technological industry and economy.

Finally, the topic modelling results characterised the NCSS of the EU as emphasising international cooperation. In particular, the EU sought to improve levels of cyber resiliency and consistency across Europe through cooperative responses in cyberspace based on the NIS Directive, as shown by the word composition of the topic regarding EU member state cooperation. In particular, according to the contents of the EU

cybersecurity strategy, the EU would strengthen the interoperability of information systems, establish a security operations centre (SOC) network, and expand the use of the EU Cyber Diplomacy Toolbox to achieve their objectives of improving the level of resiliency and consistency in cyberspace. Therefore, the strategy of the EU would have been devised based on a very high proportion of international cooperation.

2) Topic distribution by period: The topic distributions of the analysed NCSSs are shown in Table VI.

As presented in Table VI, there were no significant increases or decreases in the NCSS agenda transitions in time series. This observation indicates that in setting their cybersecurity agendas, each country considers its own threat environment and its geopolitical characteristics rather than the agenda trends at that time. In other words, in the establishment or revision of an NCSS, an understanding of the threat environment facing the country should be obtained, and a clear analysis of their own approach to solving it should be conducted.

The agenda that exhibited the biggest distribution gap in the US strategies was network and system vulnerability. Although the previous strategy of the US prioritised this agenda (which had the highest proportion, at almost 20%), that proportion was significantly reduced to less than 1% in the current strategy. This observation could reflect a change in response posture against cyber-attacks, crimes, or even threats, from passive protection that mitigates critical vulnerabilities in their own network or system, to an active response posture that includes law enforcement in anti-cybercrime efforts and cooperative responses with like-minded countries.

These trends could also be observed in the UK, which addressed strengthening defence and response capabilities in both their 2011 and 2016 strategies. In particular, in their current strategy, the weight of the agenda on cyber defence capability has increased (+12.68%), suggesting that defensive and even offensive operations could be conducted based on an understanding of cyberspace as a military domain.

Meanwhile, the NCSSs of Japan had the smallest change in topic distribution over time, because the three-year NCSS establishment cycle of Japan is not only short compared to those of other countries but also established with the basic act on cybersecurity as a legal basis. On the other hand, because Japan is constantly emphasising the revitalisation of the cybersecurity industry, it is necessary for them to continuously grasp related standards and supply chain security trends in the future.

The EU also had a small change in their distribution of cybersecurity agendas by period. However, a noticeable difference was that the proportion of EU member state cooperation slightly decreased, whereas the proportion of agenda on international partnership somewhat increased. For context, Europe has recently continued to discuss European capability building from the security and defence standpoint and the 'strategic autonomy' based on it. As the need to work together with international partners to achieve these goals is emphasised, it is necessary to observe how Europe will strengthen its international partnerships to secure strategic autonomy in the future.

TABLE VI. TOPIC DISTRIBUTION IN EACH NCSS DOCUMENT

Topic (Agenda)	Topic distribution (%)							
	US 2003	UK 2011	EU 2013	JP 2015	UK 2016	JP 2018	US 2018	EU 2020
Network and System Vulnerability	19.42	5.30	1.15	4.04	10.92	1.57	0.95	3.28
Cyber Security Role and Responsibility	13.04	0.00	1.15	4.04	1.68	6.81	12.38	0.82
Risk Assessment and Management	12.17	3.03	1.15	1.79	11.76	6.28	7.62	2.46
Information Communication Network Access Control	8.70	0.76	2.30	2.69	5.88	10.47	4.76	9.02
Privacy and Intellectual Property Security	7.54	12.12	10.34	3.14	5.04	3.14	11.43	11.48
Cyber Defence Capability	8.99	8.33	1.15	2.24	21.01	1.57	7.62	1.64
Incident Response and Information Sharing	6.96	2.27	11.49	17.94	2.52	14.66	3.81	6.56
Cyber Crime Law Enforcement and Investigation	5.22	29.55	13.79	1.79	8.82	1.57	16.19	9.02
Standard, Certification and Supply Chain Security	2.90	2.27	2.30	18.83	1.68	16.75	3.81	0.82
ICT Innovation	2.61	5.30	4.60	6.28	3.36	2.62	6.67	5.74
Public Private Partnership(PPP)	3.48	3.03	1.15	4.48	9.24	6.28	1.90	1.64
Security Awareness and Knowledge	6.38	14.39	5.75	9.87	7.14	13.09	3.81	0.82
International Norm and State Behaviour	0.87	10.61	9.20	14.80	5.46	11.52	10.48	10.66
EU Member State Cooperation	0.00	0.76	31.03	0.00	0.00	0.00	0.00	23.77
International Partnership	1.74	2.27	3.45	8.07	5.46	3.66	8.57	12.30

C. Comparative Analysis of NCSS Agendas with Coverage in South Korea

As discussed earlier, NCSS agendas had different distributions depending on the threat environment and approach to cybersecurity of each country. However, the US, UK, Japan, and EU have close cooperation in cybersecurity and in related technologies and research areas, and thus identifying the cybersecurity agendas of these countries is essential for future cooperation or diplomacy. Furthermore, analysing the agendas of like-minded countries is valuable as a method for determining suitable NCSS agendas for a given country because it provides an understanding of global cybersecurity trends in the context of cooperative response. Therefore, this section identifies agendas worthy of consideration for future NCSS revisions in South Korea by comparing the strategic task of the current NCSS with the 15 agendas previously derived.

Table VII is the result of comparing the 15 agendas derived from this analysis with the contents of the NCSS of South Korea. This analysis reveals two agendas that were not covered (marked with ×) and one agenda partially covered (marked with △) in the NCSS of South Korea.

First, one agenda on risk assessment and management in sector I was not covered in the NCSS of South Korea. Because cyber threats tend to be increasingly diverse and sophisticated, a single way of managing security vulnerabilities in systems or networks may not be sufficient for preventing cyberattacks that use social engineering techniques. However, the current NCSS of South Korea has been focused on vulnerability management in the infra stability sector, and not on risk assessment and management. Here, cyber risk is a concept that considers not only vulnerabilities in the system itself but also the possibility of manipulation, disruption, or destruction of specific assets [16].

Moreover, cyber risk management refers to a series of actions that identify the value and importance of individual assets, evaluate the impact of vulnerabilities or risks of exploiting them, and prepare and implement appropriate countermeasures for the assessed risk. Therefore, efforts should be made to ensure the stability of critical infrastructure in a dynamic cyber threat environment through the establishment of a framework for assessing and managing risk to critical assets in addition to vulnerability management [17].

Furthermore, the NCSS of South Korea has no discussion on the protection of intellectual property rights. Competitiveness in science and technology is becoming more important in both cybersecurity and economic aspects compared to in the traditional security perspective. Whereas many countries are making great efforts to secure technological competitiveness, the number of malicious cyber activities targeting the intellectual property (IP) of research institutes or universities has been increasing. Accordingly, countries with high levels of technology, such as the US and UK, are implementing strict measures against such technology theft to maintain their technological and economic superiority [18]. In particular, the US government is using name-and-shame processes, such as public indictments on IP theft, to inform countries about these malicious activities and continue efforts to strengthen relevant law enforcement capabilities. For future NCSS revisions in South Korea, there is a necessity for multilateral discussions to protect future cybersecurity R&D achievements through close cooperation between science, technology, and industry, to secure the technological advantage of the country.

Finally, a discussion on supply chain security is necessary. The supply chain refers to the overall system of organisations, resources, human resources, and information in the process of providing products or services to customers. The supply chain is particularly complex for ICT products and services, and includes processes of S/W and H/W design, deployment, acquisition, operation, and maintenance. Supply chain security issues, which began to be discussed in earnest after the US sanctions against Huawei, are currently being embodied in policies for developing supply chain risk assessment tools or systems, and diversifying or internalising 5G suppliers [19]. However, in the case of the NCSS of South Korea, discussions on overall supply chain risk management, including all ICT products and services such as 5G, IoT devices, and cloud services, are limited, and are covered only through standards and certification systems and the security-by-design concept. Therefore, it is necessary to establish and realise a supply chain security system across the country to analyse supply chain risk and prepare for global supply chain reorganisation under US–China trade tension.

TABLE VII. THE RESULT OF COMPARING THE 15 AGENDAS WITH THE CONTENTS OF NCSS OF SOUTH KOREA

Sector	Agendas	Comparison Result	
		(○/△/×)	Related tasks # of Table III
Infra Stability	Network and System Vulnerability	○	1-1,2
	Cyber Security Role and Responsibility	○	3-1
	Risk Assessment and Management	×	-
	Information Communication Network Access Control	○	2-2
Protection and Response Capability	Privacy and Intellectual Property Security	×	-
	Cyber Defence Capability	○	2-1,3
	Incident Response and Information Sharing	○	2-2, 3-2
	Cyber Crime Law Enforcement and Investigation	○	2-4
Industry and Technology	Standard, Certification and Supply Chain Security	△	1-3
	ICT Innovation	○	4-3
	Public Private Partnership (PPP)	○	3-1, 4-1,3
	Security Awareness and Knowledge	○	4-1,2
International Cooperation	International Norm and State Behaviour	○	6-2
	EU Member State Cooperation	○	6-1
	International Partnership	○	6-1

V. Conclusion

Cybersecurity has more complex and multidimensional characteristics compared to those of traditional security, and involves a combination of hyper-connected cyberspace, rapid development of ICT, and double-use issues of cyber technology. In addition, differences in the approaches to cyber space and cyber threat environments in different countries contribute to further increasing this complexity, which in turn complicate the macroscopic perspective analysis of national cybersecurity policies. Therefore, this study aimed to derive the national cybersecurity policy agendas of major countries from a macro perspective by using the topic modelling method.

The study was divided into two parts. The first part was to use a topic modelling method to identify national cybersecurity policy agendas in major countries, and the second part was to determine policy agendas that could be further considered for future NCSS revisions in South Korea. Thus far, policy research in the field of cybersecurity with the use of topic modelling has focused on expanding the scope of analysis to observe the global cybersecurity landscape. Therefore, this study is meaningful in that it used topic modelling to explore critical agendas and quantitatively compare the focal points of various NCSSs for the benefit of future NCSS revisions in South Korea.

As a result of this study, 15 agendas were derived from words that compose the NCSSs of the US, UK, Japan, and EU. These agendas were grouped into infrastructure stability, response capability, industrial revitalisation, and international cooperation, in accordance to their attributes. Based on the agenda distribution, we observed that the approach to cybersecurity differed by country: the US and UK focused on response capability, whereas Japan and the EU focused on the cybersecurity industry and international cooperation, respectively. Furthermore, the distribution of NCSS agendas depended only on the perceived cyber threat environment and approach to cybersecurity by country, and no agenda exhibited a significant increase or decrease in proportion over time, regardless of country. On the other hand, we highlight the necessity for discussions on risk assessment and management systems, intellectual property theft, and supply chain security systems, to diversify cyber security management systems at a national level, based on a comparison of the 15 agendas with the NCSS strategic task of South Korea.

This study provides a comprehensive understanding of the cybersecurity policy agenda from the perspective of South Korea. However, because the scope of the analysis was limited to NCSSs and to deriving implications for future NCSS revisions, we propose discovering policy agendas from a wider variety of sources and comparing them in future research. As presented in the previous literature review, policy agendas could be derived from a variety of sources, including publicly published reports, news articles, research papers, petitions, and even SNS postings. In particular, because of the multidimensional nature of cybersecurity policy, multilateral cooperation efforts across society, government, science, technology, industry, and academia are essential for building global cybersecurity resiliency beyond national security. Therefore, it would be meaningful to comprehensively compare cybersecurity policy demands from various perspectives.

Stefan cel Mare University of Suceava
Suceava, Romania

Corneliu Octavian Turcu[2]
Computers, Electronics and Automation Department
Stefan cel Mare University of Suceava
Suceava, Romania

***Abstract*—The aim of this paper was to obtain data and information on the digital transformation of human resource (HR) processes in small- and medium-sized enterprises (SMEs) with the help of robotic process automation (RPA), in order to increase competitiveness in the digital age. Romanian businesses are attempting to close the gap with companies in developed countries by implementing projects that allow the adoption of emerging technologies in HR departments. This paper presents some of the preliminary findings, resulted from a collaboration between a university and an SME, for the efficient implementation of specific HR processes using RPA. The paper provides a brief introduction of the RPA concept as well as a list of HR processes that can be automated within enterprises, with the benefits brought to the enterprise and employees presented in both qualitative and quantitative terms for each HR process. In addition, a case study for the automatic collection of candidates' documents and extraction of primary information about them was considered. Further on, the problems encountered during implementation were listed, along with potential solutions. Given the benefits offered, RPA could play an important role in transitioning HR functions into the digital era.**

***Keywords*—Robotic process automation (RPA); small- and medium-sized enterprises (SME); human resource (HR); digital HR; recruitment**

I. Introduction

We are currently witnessing multiple challenges for companies, such as demographic and social changes, technological advances, etc. In order to meet these challenges, companies need to be agile and adaptable. An important role in fulfilling these expectations, in the conditions of ongoing and massive disruptions, is played by human resources. The good organization of human resources allows the optimization of the employees' work, even in the conditions of the disturbances introduced by the COVID pandemic.

If before the global pandemic, "digital technologies did not find a strong and widely based application in the small- and medium-sized enterprises (SMEs) sector", "due to the COVID-19 disruption, SMEs are now trying to avoid a total shut down of economic activities by introducing digital technologies" [1].

In all US industries, according to the research conducted by the McKinsey Global Institute in 2016, approximately 17% of work consists of data collection and 16% of data processing - tasks that at the time of the study were largely performed by human workers [2].

In small- and medium-sized businesses, human resource (HR) departments typically suffer from aging IT systems. Employees of these departments often need to:

- Enter data into multiple systems;
- Toggle between different applications, entering in one application data retrieved from another one.
- Reconcile data across two or more systems.

To quickly streamline these routine tasks without upgrading or replacing existing old systems, Robotic Process Automation (RPA) technology offers solutions. Thus, much of the manual work involved in these tasks can be automated using RPA.

RPA adoption is growing every year. According to Gartner, in 2020 RPA was, for the second year in a row, the fastest-growing segment in the enterprise software market, with a 38.9% increase to $1.9 billion in revenues [3]. Several studies worldwide estimated an increase in the use of RPA in various fields. Thus, for example, Transforma Insights expects total market spending for RPA will increase from $ 1.2 billion in 2020 to $ 13 billion in 2030 [4].

Over the past few years, we are witnessing the digital HR transformation, “the application of advanced technologies and analytics, digital traits and behaviors, and HR customer centricity through the lens of the organizations HR Operating Model to optimize HR to deliver sustainable organizational performance” (Fig. 1) [5].

Analysts from McKinsey & Company called robotic process automation technology a “third arm” for HR organizations because it works with HR to amplify the department’s capacities [6].

According to a survey conducted by PwC on HR technologies, 45% of respondents (approx. 600 HR and HR information technology leaders on six continents) intend to invest in hyper-automation or robotic process automation (RPA) technology in the following 12-24 months [7].

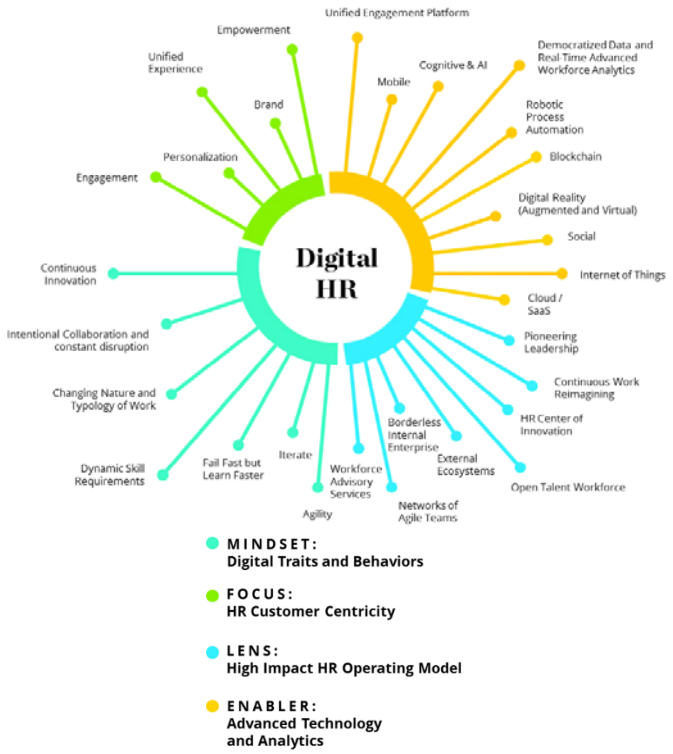

Fig. 1. Digital HR [5].

Published studies on the adoption of RPA in companies refer mainly to large companies. Small- and medium-sized enterprises are often overlooked. Our research seeks to fill a gap in the scientific literature on robotic process automation in human resource departments of SMEs, aiming to ensure the potential transfer of knowledge from academia to industry.

In this regard, we try to provide answers to the following research questions (RQ):

RQ1. What is Robotic Process Automation (RPA)?

RQ2. What are the HR processes in SMEs that can be automated with RPA?

RQ3. What advantages would the adoption of RPA bring in the HR departments of small- and medium-sized enterprises (SMEs)?

RQ4. What are the challenges HR departments are faced with when adopting RPA-based solutions?

To capture relevant knowledge on the topic, we conducted a literature review considering six of the databases frequently used by researchers: Web of Science, Springer, Science Direct, IEEE Xplorer, Scopus, and Google Scholar. In order to gain more insights for this paper, we also conducted a backward-and-forward search.

A further step in our research was the expert interviews, used to confirm and strengthen the list of use cases identified in the literature. Thus, we conducted a semi-structured in-depth interview with senior HR personnel from various SMEs. During the interviews, we considered the following topics: RPA objectives in HR, types of projects, benefits, impact on jobs, challenges. We reviewed the interview responses to obtain key insights that are summarized in the present paper.

The remainder of this paper is organized as follows. In the next section we present some definitions of the term Robotic Process Automation. Section III refers to several achievements in the field, while Section IV presents the processes of HR departments in SMEs where RPA can be incorporated along with their benefits that SMEs and employees can obtain by using RPA tools. The next section presents the flow of an application under development within a national project, mentioning some issues encountered during implementation. Further on, authors highlight the future scope of the technology, and in the last section of the paper we formulate the conclusions of our research.

II. Theoretical Background

A. Robotic Process Automation (RPA)

In order to answer the first research question and to clarify the concept of Robotic Process Automation (RPA), we present some selected definitions that we believe are relevant to our discussion.

IEEE Corporate Advisory Group defines RPA as the use of a "preconfigured software instance that uses business rules and predefined activity choreography to complete the autonomous execution of a combination of processes, activities, transactions, and tasks in one or more unrelated software systems to deliver a result or service with human exception management." [8].

RPA could be described as an "emerging form of business process automation technology based on the notion of software robots or artificial intelligence (AI) workers. RPA has become the new language of business. This technology is more powerful among the 21st century technologies" [9].

RPA technology is non-invasive for existing systems; it does not replace them, but interacts with them. In fact, it's a new layer above the organization's applications and cloud services that must integrate easily and efficiently with all of these.

The concept of robotic process automation is becoming increasingly integrated into various domains as a means for improving productivity, compliance, product quality, etc. In the gray literature, many key use cases are examined, presenting the experience of various organizations that have adopted RPA. The use of this technology allows the emulation of actions taken by human users, so that work processes can be automatically implemented in many business functions, such as: Human Resource, Finance & Accounting, Production, Sales & Marketing, Supply Chain, and Information Technology.

In this paper, authors focus on human resource departments. HR professionals deal with many processes and sub-processes, such as hiring, onboarding, employee benefits administration, managing complex workplace situations, enforcing regulatory changes. This usually means working with multiple software platforms, spreadsheets, documents, etc. Various studies highlight that 33% of companies have more than ten HR systems. 47% of companies have HR software that is over seven years old [10]. According to Center for Effective

Organizations and a study conducted by G&A Partners, HR professionals spend about 73.2% of their time dealing with tedious administrative tasks [11]. But some of these HR operations could be automated with RPA-based solutions. But a successful implementation depends on several factors, including the RPA tool.

B. RPA Tools

Currently, there are many RPA tools available on the market, some of them free, others commercial, such as, Automation Anywhere, Blue Prism, EdgeVerve, Microsoft, NICE, UiPath, WorkFusion, etc.

RPA market solutions offer various capabilities, as presented in numerous studies and scientific papers, such as, for example, [12]. It should be noted that providers of robotic process automation platforms quickly and continuously update their offers to meet the developing needs of their clients. Thus, for example, various RPA providers announced further development of their RPA platforms, by incorporating new breakthroughs in artificial intelligence and machine learning. Given the multitude of existing RPA platforms that offer powerful functionality, as well as their continued development, choosing the best automation tool for an organization could be a real challenge.

III. Related Work

Recently, because of the difficulties caused by the COVID-19 pandemic, many companies have turned to robotic process automation solutions to help them overcome the challenges of the pandemic. Thus, they can "automate repetitive tasks across multiple business applications without altering existing infrastructure and systems" [13].

Many publications present the strengths and weaknesses of the RPA. However, the reviewed literature highlights a predominantly positive assessment of RPA, given that its strengths outweigh its weaknesses [14]. Adopting RPA in enterprises offers many benefits, including higher productivity, improved business efficiency and accuracy, data security, scalability, auditability, low printing and storage [13]. The promises of RPA for enterprises include easy implementation at a relatively low cost compared to other solutions.

Some authors consider that RPA is suitable for processes with high levels of i) standardization, ii) volume of transactions, iii) maturity, iv) approach to business rules ([13], [15], [16], [17]). Other authors recommend the RPA approach for standardized and repetitive processes that i) follow business rules, ii) take longer to complete, iii) are performed on a regular basis, and iv) require manual interaction with information systems [18]. Furthermore, many authors advocate RPA adoption for processes involving structured data, low variance and logic-driven procedures [19].

IV. Discussion

The analysis of scientific and industry publications shows that RPA has been used moderately in the human resource departments of large enterprises and less in SMEs. A single enterprise can have hundreds or thousands of processes and sub-processes and the selection of those that could be automated with RPA is a difficult task.

We examined case studies that are related to the aforementioned research questions. Following an examination of these case studies, and an analysis of the academic and industry papers it can be highlighted that the processes suitable for RPA have several common features. Thus, the considered process should have clearly defined inputs and outputs. Workforce tasks that are rule-based, predictable, high-volume, time-consuming, repetitive, or prone to human error are good candidates for RPA.

Despite the vast potential of RPA technology, experts point out that it is not suitable everywhere. Thus, if a process is dynamic, requires creative thinking, deals with unexpected events or involves decision-making on a case-by-case basis, RPA can fail.

Various studies have shown that RPA projects failed initially in a proportion of 30% to 50% [20]. In order to determine which processes are suitable for RPA, an evaluation can be performed considering the criteria specified above.

As we can see, there are many opportunities to use RPA in human resource management. Below we present some HR processes in SMEs that can be automated with RPA, in response to the RQ2. Table I summarizes the HR use cases found in the literature and validated by some HR experts.

TABLE I. The RPA Opportunity for HR Departments

HR Process to be automated	Benefits	SME	Employee
CV Screening and recruitment	Facilitating employment	X	
	Identifying the best candidates	X	
	Keep candidates informed with better, automate communication	X	X
	Faster cross verification of candidates' details	X	
	Automatic data concatenation from multiple input sources	X	
	Behavior reference check	X	
	Criminal record checks	X	
	Correct evaluation of candidates	X	X
	Minimizing delays in hiring process	X	
	Reduction in hiring costs	X	
Onboarding	Smooth onboarding process		X
	Data integration capacity	X	
	Faster onboarding process		X
	Low-cost onboarding process	X	
Employee training	Accelerated employee skill acquisition		X
	Better alignment of employee skills with the organizational certification requirements	X	
	Enhanced learning experience		X
Employee data management	Better management of data of current/former employees etc.	X	
	Consistent actions across various systems/ databases/departments	X	
	Elimination of data entry errors	X	

	Employee data protection	X	X
	Efficient allocation of office space in the hybrid-work conditions	X	
Tracking attendance	Better calculation of employee salaries		X
	Workflow disruption prevention	X	
	Accurate time records	X	
Payroll management	Avoiding delay in salary payments		X
	Lower payroll costs	X	
	Reduced risk of multiple errors	X	
	Simplified payroll processing	X	
Expense management	Fast processing of expenses		X
	Correlation of individual expenses with company regulations and spending rules	X	
Maintaining compliance	High accuracy of the maintaining compliance process	X	
	Ensuring an error-free compliance maintaining process	X	
Exit management	Exit process consistency	X	
	Ensuring data privacy	X	
Performance management	Faster data collection for the calculation of performance indicators	X	
	Automatic report generation/ updating/ deletion	X	
Qualitative	Quantitative		

The general hire-to-retire (H2R) process integrates several disparate systems that often require swivel-chair work to migrate employee data between different systems. These processes are good candidates for RPA. Various studies have shown that recruitment is one of the most time-consuming key tasks for human resources. On average, recruiters spend 60% of their time for candidates sourcing and screening. Implementing an RPA-based solution can take over manual and repetitive work involved, such as filtering resumes, scheduling interviews, and simplifying the integration process.

RPA can significantly reduce inefficiencies on management reporting. Thus, an RPA-based solution can gather information from multiple sources and generate a report or save it into consolidated XLS.

The implementations we studied showed a significant decrease in process time and in errors, and a high potential for scalability.

Successful use cases will continue to emerge with the increasing development of RPA platforms and as more businesses expand their use of RPA, demonstrating the wide variety of issues that can be addressed.

Further on, we attempt to answer the RQ3 research question, presenting the benefits of adopting RPA. RPA has great value to offer for improving the human resource management system in small- and medium-sized enterprises. The benefits we mean are not only for the company, but also for employees. Thus, RPA-based solutions could offer SMEs important benefits, including increased productivity, improved accuracy, faster digital transformations, higher employee engagement, improved data security and quality, etc. Once an RPA layer has been added within an SME for HR processes, each individual employee can access and exploit it. RPA-based solutions could offer employees [13] a wide variety of benefits in laborious or tedious manual processes. We presented some of the qualitative and quantitative benefits identified following the analysis of the academic and industry literature.

After conducting the overview of various possibilities, the main conclusion is clear. RPA could play an important role to shift the HR functions to enter the digital era.

Next, based on literature research, we present some of the challenges that SMEs face in implementing RPA within HR departments (RQ4).

An important challenge for many SMEs is how to add automation to workflows. There can be a large number of processes and sub-processes within the HR departments of SMEs [21], so choosing which ones could be automated with RPA, as well as the order in which they can be automated can prove to be a big challenge.

Other challenges focus on human resource management, given that workforce need to adapt to new work, as RPA-based solutions can take on important parts of their daily tasks [22].

The challenges can also be considered from a legal viewpoint, analyzing, for example, questions such as "who has the control over the intellectual property robots handle and generate" and "who is responsible if the robot fails" [23]. Unfortunately, these two questions have not yet been answered.

V. Case Study

Recruitment is one of the most promising use cases for adopting RPA-based solutions. Processes in this area involve a large volume of repetitive, time-consuming tasks that are still manually operated by human force. Thus, a significant amount of time is spent screening resumes and application forms submitted by candidates for open positions. Software robots can make this process considerably easier by gathering applications quickly and comparing all of the data to a list of precise job requirements. These requirements can be viewed as predetermined rules that influence the whole selection method while using RPA technology.

Candidates for a position in an SME scan their documents and send them to the SME for processing. Most of the times the documents sent by the candidates are in pdf format. These include diplomas, identity card, certificates, CV, letter of intent, etc. Some documents may have a format imposed by SME, in this case the centralization of information from several candidates is much simplified. For example, an SME can request the completion of important information in editable pdf files with PDF tagged order features. But, retrieving information from candidates' scanned documents is a tedious, repetitive, time-consuming process that involves a multitude of copy-paste activities and requires manual interaction with information systems.

To eliminate these disadvantages, we proposed an RPA-based solution. For this case study, we have opted for the

UiPath platform. Thus, we developed a solution based on RPA enhanced with Optical Character Recognition (OCR) that can recognize and extract the information needed by the HR department from scanned documents and then enter it into the HR database. HR staff can run this solution on their laptop while handling more important activities. Then, the only operation to be performed by the HR department staff is to verify the veracity of the information entered in the system by the RPA solution.

The flow chart of this application is depicted in Fig. 2.

Fig. 2. The Flow Chart of the RPA-based Solution.

The proposed solution has been verified to ensure proper processing. Thus, we evaluated the implemented application with documents of different formats. In our experiments we used pdf files and image / picture files (JPEG, BMP, GIF, PNG, etc.). The extraction of information from the files sent by the candidates is one of the most significant difficulties to be handled. This problem becomes even more acute when the documents are edited in a language with special characters, as the Romanian language. Thus, the information on the applicants' documents may contain diacritics in Romanian. The correctness of the extracted information depends a lot on the OCR engine.

We have developed and tested several OCR engines available in UIPath, such as: Microsoft OCR, Google OCR, Abbyy OCR and other OCR software like: Convertio [24], Online OCR [25], Free Online OCR [26], i2OCR [27]. The best results were obtained using Convertio and Abbyy FineReader. Even if the developed application is in a beginning form, we consider that it is necessary to test as many OCR engines as possible and to select the one that provides the best recognition rate for Romanian characters.

One way to reduce the number of errors in extracting information from scanned files is to use OCR engines that are based on artificial intelligence. One such example is Abbyy FineReader, which has the latest OCR technology based on artificial intelligence and performs a variety of operations such as digitizing, retrieving, editing, protecting and sharing documents of various types in the same workflow [28].

A limitation of the research is the use of only one RPA platform (UIPath) for the case study. To create meaningful solutions for HR departments in SMEs, further research employing different RPA platforms is required.

The authors of this paper intend to continue research in the near future, considering further explorations of RPA in the field of human resource management in SMEs. Attention will be paid to combining solutions developed using RPA tools with solutions based on blockchain, Internet of Things, etc.

VI. Conclusion

This paper aimed to explore the robotic process automation technology and to identify the promising application of RPA in human resource management within SMEs. In the near future, human resource departments that rely on manual, paper processes will need to re-examine their processes and consider whether RPA technology can benefit them. Through this paper, the authors want to support SMEs that aim to streamline the HR department by adopting RPA.

In the analysis of numerous publications and case studies, various authors' observations on how companies and business people are trying to reorganize the company's human resources for an accelerated economic recovery after being affected by the pandemic crisis, we tried to find answers to some of the basic problems of HR digitization, which would contribute to a profitable and sustainable business for SMEs. The adoption of RPA can bring important benefits in the HR departments within SMEs for laborious or tedious, repetitive, time-consuming manual processes.

Through the case study implemented and presented, it was demonstrated that RPA can fulfill some of the basic pre-processing tasks undertaken by human resources departments in recruiting candidates.

The RPA platform used has an important role in the successful implementation of an RPA-based solution. There are various vendors on the market that offer RPA solutions. Choosing the best solution to meet the specific requirements of an SME's HR department is not an easy task, an in-depth analysis must be performed by taking into account several criteria.

Thus, for example, a developer must consider the type of analyzed documents when implementing RPA-based solutions for managing candidates' documents (scanned or generated, with or without images, with or without tagged order features, etc.). The correctness of the extracted data is also dependent on the ability of OCR tools to recognize the specific characters of the language used in the elaboration of documents. In many cases, processing data that has been extracted incorrectly can be time-consuming.

Although some HR processes require human intervention to correct extraction errors, RPA can be considered a viable candidate for streamlining HR processes, which can lead to a rapid improvement in a business's overall value.

Computerization of Local Language Characters

An Innovative Model for Language Maintenance in South Sulawesi, Indonesia

***Abstract*—The objective of this study is to provide innovative model for the approach of language preservation. It is necessary to maintain indigenous languages in order to avoid language death. Script applications for indigenous languages are one of the solutions being pursued. This script program will facilitate communication through writing between speakers of indigenous languages. Additionally, the study illustrates the implementation of the Lontara script (Bugis-Makassar local language letters and characters). This script application is compatible with the Microsoft Windows operating system and the Hypertext Transfer Protocol (HTTP). This study employed the research and development (R&D) approach. Six stages are followed in this R & D study: 1) doing a requirements analysis to determine the viability of Bugis-Makassar indigenous languages in everyday life and also to determine ways to retain them 2) designing and constructing Lontara scripts with hypertext-based applications, 3) producing Lontara scripts with hypertext-based applications, and 4) validating the hypertext-based applications through one-to-one testing, small and large group testing. 5) Lontara application revision; and 6) Lontara application as a finished product. This product is designed to be used in conjunction with other interactive applications.**

***Keywords*—Innovative model; language maintenance; Lontara script; Makassarese; local language; hypertext-based application**

I. Introduction

Indonesia is a multi-ethnic and multilingual country. The Indonesian Central Bureau of Statistics [1] revealed that Indonesia consists of 1,128 ethnic groups. Besides, BPS also presents ethnographic data and records about 700 local languages owned by Indonesia's state. The diversity of ethnic groups in Indonesia is caused by various factors, including historical and natural isolation factors. The old nature isolation factor also influences Indonesia's condition, which various ethnic groups inhabit. Therefore, ethnics are diverse and have their characteristics in terms of language and culture, although they all belong to the same language family, the Austronesian. On the other hand, there are 7,117 languages in the world that are spoken today, and it has estimated in the year 2020 that 40-90% of them will disappear during this century [2]. However, 20-50% of this amount is no longer used by the younger generation of its native [3].

The picture of the vitality of local languages in Indonesia, in South Sulawesi, is still unclear. It is still challenging to obtain accurate data on local language vitality in South Sulawesi. However, this condition can be seen by a glance at native speakers of Makassarese, one of the local languages in South Sulawesi. The vitality of the Makassar language can be seen by the Extended Graded Intergenerational Disruption Scale (EGIDS) rubric that has been developed by Simons and Lewis [4] and [5]. Based on EGIDS, the Makassar language is at level 6b [6], [7].

The vitality of local Indonesian languages is more easily recognized by the EGIDS than other scales, for example, the Fisman scale [8]. Fishman's Graded Intergenerational Disruption Scale (GIDS) and UNESCO's five steps endangerment framework. EGIDS is a union of the Fishman scale and the UNESCO scale. The EGIDS scale can be seen as in the following Table I.

Based on EGIDS, we can assess the vitality of the Makassar language. However, before assessing its vitality, we should first understand the local language environment in Indonesia. Indonesia's local language environment is the pressure most like in China, both vertical and horizontal pressure [9]. The pressure on Indonesia's local languages generally comes from Indonesian and its dominant or more native languages. This pressure is due to prestige for Indonesian speakers, educational interests, and even economic factors. Another is the Indonesian language pressure, which comes from international languages, Arabic and English.

On the other hand, regional languages are under the position of Indonesian. Therefore, horizontal pressure can occur from other regional languages with a better sociolinguistic status [10]. This condition further weakens the vitality of local languages in Indonesia.

Ethologically, this condition can be understood that Indonesia's local languages are very worrying [4], [11], [12].

Based on the above Table II, it can be seen that almost half of Indonesia's languages are "in trouble or worse." The number of languages that are rated "Vigorous" (260) compared with those that are "In trouble" (272) can be concluded that the local languages in Indonesia are in trouble. We can also have an alternate assessment and visual representation to obtain local language vitality in Indonesia through UNESCO"s. "Interactive Atlas of the World's Languages in Danger" classifies 144 of Indonesia's languages as "Vulnerable" or worse. Ethnologue website has stated that:

"The number of individual languages listed for Indonesia is 719. Of these, 707 are living, and 12 are extinct. Of the living

languages, 701 are indigenous, and six are non-indigenous. Furthermore, 18 are institutional, 81 are developing, 260 are vigorous, 272 are in trouble, and 76 are dying [13].

Based on this fact, the research question is, "How to design an innovative model of local language maintenance?"

TABLE I. EXPANDED GRADED INTERGENERATIONAL DISRUPTION SCALE

Level	***Label***	***Description***	***UNESCO***
0	International	The language is used internationally for a broad range of functions.	Safe
1	National	The language is used in education, work, mass media, government at the national level.	Safe
2	Regional	The language is used for local and regional mass media and governmental services.	Safe
3	Trade	The language is used for local and regional work by both insiders and outsiders.	Safe
4	Educational	Literacy in the language is being transmitted through a system of public education.	Safe
5	Developing	The language is used orally by all generations and is effectively used in written form in parts of the community.	Safe
6a	Vigorous	The language is used orally by all generations and is being learned by children as their first language.	Safe
6b	Threatened	The language is used orally by all generations, but only some child-bearing generation transmit it to their children.	Vulnerable
7	Shifting	The child-bearing generation knows the language well enough to use it among themselves, but none are transmitting it to their children	Definitely endangered
8a	Moribund	The only remaining active speakers of the language are members of the grandparent generation.	Severely endangered
8b	Nearly Extinct	The only remaining speakers of the language are members of the grandparent generation or older who have little opportunity to use the language.	Critically endangered
9	Dormant	The language serves as a reminder of heritage identity for an ethnic community. No one has more than symbolic proficiency.	Extinct
10	Extinct	No one retains a sense of ethnic identity associated with the language, even for symbolic purposes.	Extinct

TABLE II. EGIDS OVERVIEW OF THE VITALITY OF LANGUAGES OF INDONESIA

Languages	Institutional (EGIDS 1-4)	Developing (EGIDS 5)	Vigorous (EGIDS 6a)	Threatened (EGIDS 6b-7)	Dying (EGIDS 8a-9)	Extinct (EGIDS 10)
719	18	81	260	272	76	12

II. RELATED WORK

Language maintenance programs, language shift, and endangered language are topics that have never-ending debate. The linguists are always looking for alternative plans to maintain minority languages that a language shift has caused. Language researchers often face people who leave their mother tongue due to political and economic pressures [14]–[16]. A language preservation program is carried out in legal recognition of the minority language [17], [18]. Other researchers propose a theory for heritage language, literacy, and identity processes to maintain minority languages [19]. Other language researchers make breakthroughs in maintaining minority languages by using a smartphone [20].

Other studies have shown that sometimes a language appears suddenly, spreads quickly, and quickly disappear. This case challenges linguists to document, describe, preserve, and revitalize languages [21], [22]. Another linguistic phenomenon that often affects decreasing local language speakers is the influence of strong language used on daily life, both informal and non-formal [10]. Preservation of minority languages can survive because it is a language preservation policy [23].

In his book on global paradox, John Naisbitt reiterated that globalization promotes a paradoxical tendency [24]. John Naisbitt's view is proven at present. Technological advances in transformation and the informatics revolution have led to human beings' tendency to a one-tier, modern, and global world. On the other hand, modern humans also long for past histories in ethnic romance, values, and primordial styles. The point of these tendencies can cause conflict, friction, and shock.

If John Naisbitt's view is compiled with ethnological data, modern world-class and ethnic romance and primordial values are inevitable. Our society is undoubtedly inseparable from cyberspace and connectivity that can no longer be encountered. At the same time, the use of local languages is decreasing. The shortcomings can be seen in the number of websites or sites that provide local language information.

The clash of these trends creates implications for the use of local languages. The local language users are more likely to use Indonesian as their daily language. This condition cannot be avoided because Indonesian is the national and official language, both oral and written. It is understandable if people use Indonesian to communicate daily, both at work and sharing information. The local language is only used at the oral or spoken level and rarely uses local language in written form.

The shift in language utilization from the local to the Indonesian language is caused by various factors, including economic factors, migration, and marriage. Economic factors caused Makassar speakers (for example) in Gowa Regency's highlands to use the Indonesian language. Javanese speakers and other tribes who trade in this area use the Indonesian language. The influence is quite crucial, which appears from the public began to get used to speaking Indonesian. On the other hand, the Indonesian language is considered prestigious and proud of society's expression when using the Indonesian language. When we as researchers met Ngawing, one of an elder in this village, he said in Makassarese that "*abbicara*

malayu tauwwa," which means "Wow, they speak Indonesian." This sentence is an expression of those who can speak Indonesian [25]. The Indonesian language is forced to be used as a communication language in the commerce sector. Although it unwittingly has shifted the attitude of the language of some highland communities of Gowa Regency, especially in the Tompobulu district, this condition is very reasonable.

Population migration to Makassar City is another factor that contributing to the shift of language use from Makassar to the Indonesian language. Some Gowa highland residents in Tompobulu Sub-district moved to Makassar city looking for work after harvesting in the dry season. Young people in their productive ages left home to earn a living. Some of them migrated to the island of Borneo and the country of Malaysia. When returning to the village or returning home, they generally use the Indonesian and Malay languages. Not infrequently among them "back home" to meet their relatives and back again to the island of Borneo and the State of Malaysia. They prefer to speak Indonesian or Malay rather than Makassar [25].

Inter-tribal marriage also became the cause of the shift of language use from Makassar to Indonesian. Some Gowa highlands residents have been married to other tribes like Bugis, Mandar, Toraja, and Java. Families who are married to other tribes use Indonesian in their daily conversation. Makassar language is used only if their relatives who use it visit them, but when other relatives visit them from mixed-marriage status, they use Indonesian.

Shifting the use of language from this local language to the Makassar language needs to be addressed. If the shift has taken place at the oral language level, it can be expected that the use of local languages in writing may be more severe. More severe in the sense that as majority speakers of local languages, in this case, speakers of Makassar, they no longer use the language of Makassar in writing. This condition is worsened by the digital era that does not provide characters or lontara letters required in various applications, for example, on the hypertext level or the website page.

Various attempts at writing Lontara script have been made, including typewriters, machine-set photos, and computers. The recording of Lontara script making was once presented by Barbara Friberg [26] at a Makassar Golden Hotel seminar. Barbara is evident in the exposition of the history of the digitization development of the Lontara script.

In 1985, the Consulate General of Japan in Makassar sponsored the manufacture of the Lontara typewriter. This device is good enough, and it can produce a good letter. However, typewriters have some weaknesses, including the letters' size is small and the same width. This size results in less than perfect spaces. Whatever the outcome, Taufik Sakuma's efforts should be rewarded for speakers of languages that use the Lontara script [26].

Five years following, in 1990, at Language Center in Ujung Pandang, Ms. Astuti Hendrato from Jakarta collaborated with Monotype Typography in England and worked on Lontara script using LASERCOMP the photo-set machine. A year later, in 1991, USI / IBM, for the guidance of the former Rector of Hasanuddin University and South Sulawesi Governor, Prof. Dr. Ahmad Amiruddin, and Makasar community leaders, provided a computer with a scanner to preserve the Lontara texts. As a result, the manuscripts can be stored on a computer that can then be published quickly. This effort means preserving the Lontara manuscripts in the file image form on the computer. Thus, the systems (font/font types, such as TrueType Font types compatible with Windows) used to write computer-assisted Lontara scripts did not exist yet [26].

Barbara Friberg has also done a person who works on writing Lontara script. She once applied to Monotype Typography in the United Kingdom to help the Makasar community acquire fonts-computers that can be used in various personal computers, not just on specific machines. In 1991, Barbara Friberg's colleague in Singapore was willing to help prepare the Lontara font used on similar IBM-PC and Microsoft Word programs. With the help of Drs. Djirong Basang, Barbara Friberg sent a picture for every Lontara letter used in the Makasar language. The effort was running, but eventually, Barbara Friber's colleague in Singapore could not complete making the Lontara font as expected. In 1994, Barbara Friberg then tried to build the Lontara script font. She continued to develop the program, which was not finished in Singapore. The program that Barbara Friberg used to build the font was the FONTMONGER program. With this program, she created a Lontar21 font with type, True-Type, later known as Lontar21.ttf. The file size is 28 kb. This font was presented in Makassar Golden Hotel in October 1995 [25].

In the same year, precisely in December 1995, Andi Mallarangeng and Jim Henry made Lontara font volume one with BugisA (also with True Type type). BugisA.ttf font file size is 16 kb. However, BugisA font is often experiencing constraints or unstable in Office Word (Windows). An example of a common obstacle is that the Lontara script's initial letters often turn into Latin or boxes in the first word in each paragraph's first sentence. The two types of fonts, both Lontar21 and BugisA fonts, do not add specific numbers to Lontara. Both types of fonts can only be run and used on Windows-based operating systems. Both of these fonts also cannot be used in hypertext-based platforms. In other words, both types of fonts cannot be used to write messages in emails (email) and social media Facebook. The two fonts are also not prepared a consonant marker (diacritic) to facilitate Lontara character speakers reading the Lontara script. Thus, this hypertext-based Lontara font is a development of the previous font.

The character development history triggers the addition of numeric characters and consonant markers to the Lontara script application. The researchers found it essential to add the character of numbers and consonant markers in the Lontara script after seeing the Hijaiyah script's development (Arabic). At first, the Arabic script did not recognize a point and was without a vowel. The example of letters that do not have dots are [ج] ,[ح], and [خ]. These three letters are the same; both have no dots in the form [ح]. It is similar to the other letters, for example, ,[ت] ,[ب] and [ث]. These three letters are initially in the same form, i.e., [ب], but without dots. In this era, not many people can read and write in Arabic script.

History records the development of Arabic script mastery through the punishment for prisoners of the Badr war. After the war, the Muslims captured the Quraysh army. Umar bin Khattab r.a asked that they should be beheaded. However, Abu Bakr r.a. disagreed and proposed that the ransom of literate prisoners teach ten Muslims' sons. As for those who cannot read and write, redeemed in the form of payment. Both ransoms are indispensable for the Muslims at that time.

At the time of Ali bin Abi Talib came the scholar Abu al-As'ad al-Du'ali [27], who added dots to the Arabic character. Furthermore, the addition of marking (harakat) or the line is done by other scholars, namely Ahmad al-Khalil [28]. The addition of this vowel made it easier for non-Arabic speakers to read the Qur'an and hadith correctly. However, for educated and able to read Arabic script without a vowel, the additional marking is no longer needed. Therefore, the Hijaiyah script's development is the idea that inspires writers to add Lontara characters, numbers, and consonant markers.

It should be noted that the Lontara script is syllable and has no consonants. This condition makes a word written in the Lontara script sometimes difficult to read, not only by foreign speakers of the Makassar language but also the native speakers. The word "*paja*" /paja/ can be read /paja/ which means butt and can also be read /pa'ja/ which means salty. This condition is like an Arabic character with no marking (harakat) and can be read according to the position of words in a sentence. This condition has inspired the research team to modify or additions to the characters in the Lontara script.

III. Methodology

This study uses research and development (R & D) methods [29]–[31]. According to Borg and Gall, "R & D method is a process used to develop and validate educational products." Therefore, this sentence can be interpreted that the R & D method is developing and validating educational products. Thus, R & D has a series of cyclical research and development steps. Additionally, each step to be performed should refer to the results of the previous step. Therefore, a new educational product will be obtained at the end of every stage or step applied.

Borg and Gall have presented a series of stages to be followed in this R & D approach: research and information collecting, planning, preliminary proof of form, preliminary field testing, primary product revision, main field testing, operational product revision, operational field testing, final product revision and dissemination and implementation.

R & D research stages, both discovered by Borg and Gall and by Dick and Careys, have ten steps. Of course, this stage of the R & D model always culminates with a product or output. However, in this research, R & D steps are modified in such a way as required. According to the end of the research stage, the researchers determine that other researchers can continue these steps. Whatever stage is chosen at the end of the research stage, the result remains a product.

Research development of Lontara script application with this hypertext-based ends at the sixth step called the final product. The following are the steps:

- Needs analysis. The researchers have conducted a needs analysis and literature review.
- Design of the lontara character application. In this step, the researchers designed a model of the lontara script application. Again, the researchers focused on software, hardware, and humanware characteristics.
- Development of the lontara script application. By this step, the researchers have developed true type font for windows and a lontara character application for HTML called Yusring Keyboard.
- Formative evaluation step. This formative evaluation stage consists of expert validation, one-to-one testing, small group testing, and large group testing. In addition, participants who participated in this stage filled out an instrument called the Technology Acceptance Model (TAM).
- Revision of the lontara character application. Based on the instrument from participants, researchers revised bugs that occur during the stage of formative evaluation.
- Final Product. Thus, this application (yusring keyboard) has been tested in the small and large groups test phase of Formative Evaluation or the fourth stage. The yusring keyboard is ready to use.

In brief, the stages of this method can be seen in the following Fig. 1:

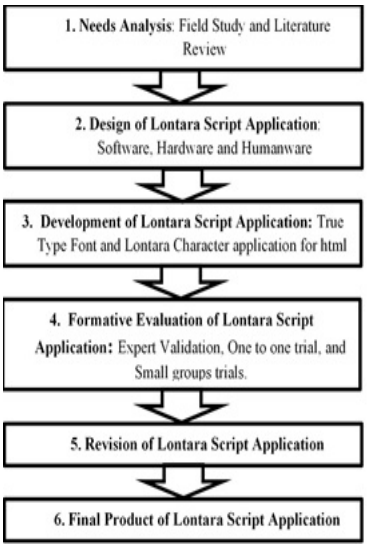

Fig. 1. R & D Steps.

IV. Result and Discussion

This research was conducted for three years, from 2017 to 2019. Application tests were carried out by speakers of Bugis and Makassar languages, two local languages in South Sulawesi, Indonesia. Since the beginning of 2020, this application has been free to download on the Hasanuddin University website, https://web.unhas.ac.id/arab/

Referring to previous research methods, in the first stage, the researchers have conducted a needs analysis and literature review since 2018. This R and D research continues previous

research that has produced a True Type Font (TTF) called Lontara Yusring. The Lontara Yusring is limited to use on Windows Operating Systems only. Along with the times, Lontara Yusring's user community needs a script application that can be used to communicate with popular media, including email, Facebook, and smartphones. The researcher then developed an application to meet the Lontara script user's needs based on this need.

The development of communication technology is the main reason for local language teachers in South Sulawesi to use the latest media to support the learning process. The research team conducted depth interviews in three groups. The first groups are the teacher group in the Tompobulu sub-district, Gowa Regency. Secondly is the Local Language Teachers Association in Parepare City. Furthermore, the third group is the teachers at the As'adiyah Islamic Boarding School Sengkang, Wajo Regency. Based on this dept interview, the researchers obtained information that they urgently need a local language application to be used in the learning and communication process.

In this in-depth interview, those groups explained that in the learning process, writing a lontara script as a local script was not enough; it had to be supported by technology that could be used to write the lontara script. For writing needs on a Windows-based laptop, Lontara Yusring has fulfilled these needs. However, for general communication purposes, another application is required. Based on this need analysis, the research team plans to develop the Lontara Yusring into an application that can be used on HTML and Android platforms.

To meet the needs mentioned in the first stage, the research team then designed the Lontara application. In this step, the researchers designed a lontara script application model focused on software, hardware, and humanware characteristics. This application model is designed to be integrated with the HTML and Android platforms. However, the Lontara characters' position on the keyboard is maintained according to QWERTY as in Yusring Lontara. Thus, the users of Lontara Yusring will remain familiar with the standard of the Lontara Yusring keyboard.

In the third stage, the lontara application design was developed. The research team agreed to give this application a name with Yusring Keyboard. This naming is intended to establish sustainability between the Lontara Yusring and the Yusring Keyboard Application. Therefore, the Lontara Yusring and Yusring keyboard will be combined in one term, namely the lontara application.

The Lontara Yusring, which is intended to be developed in this research, is as shown in the following Fig. 2.

Formative evaluation is the fourth step. This formative evaluation stage consists of expert validation, one-to-one testing, small group testing, and large group testing. Respondents who participated in this stage filled out an instrument called the Technology Acceptance Model (TAM). This TAM instrument is used to measure the acceptability of a technology product marketed to the public. The TAM instrument is also used to determine the ease with which technology is adopted and used by the community [32]–[36].

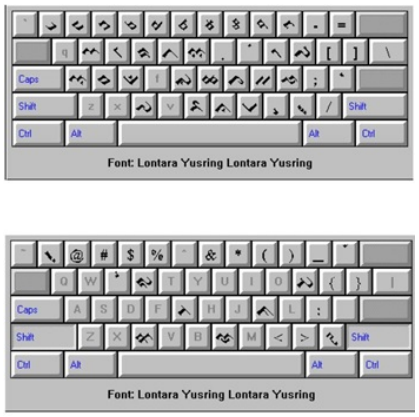

Fig. 2. The TTF Lontara Yusring.

The research team used three TAM instrument constructs: perceived ease of use, perceived usefulness, and attitude toward using. In addition, the team provided instruction that helped the respondent qualify how to interpret the scale (1 being terrible, ten being excellent).

- Perceived Ease of Use
  - How would you rate your experience using the lontara application on MS Office?
  - How would you rate your experience using the lontara application on the HTML Platform?
  - How would you rate your experience using the lontara application on WhatsApp or Telegram for Windows?
- Perceived Usefulness
  - This application is quickly used in writing Lontara characters
  - Users get the benefits of the Lontara application
  - This application is more effectively used in compiling local language learning materials
- Attitude Toward Using
  - The position of the QWERTY keyboard is easily recognized on a laptop
  - The Lontara Yusring is obtained quickly at the Theme Fonts of MS Office

Expert validation is done by giving this application to developers. The research team included additional requirements that the expert can speak either in Buginese or in Makassarese. This competency is needed because speakers of these two local languages will use the Lontara Yusring and Yusring keyboards. At this stage, two experts used the Lontara Yusring and Yusring Keyboard. One of them is the teaching staff at the Geophysics Study Program, Faculty of Mathematics and Natural Sciences at Hasanuddin University. Another expert is a lecturer at the faculty of computer science at the Indonesian Muslim University. The first expert can speak the Bugis language fluently. The second expert speaks fluently in Makassar.

The next stage is a one to one test. At this test, the lontara application is given to respondents to use on MS Office, email, Facebook, WhatsApp, and Telegram for Windows. In this stage, the application was addressed to three lecturers within the Faculty of Culture Science at Hasanuddin University and three students in the same environment. In selecting respondents, the research team required that they communicate either in Buginese or Makassarese languages. Also, the respondents had learned to write using the lontara script in elementary or middle school. These respondents were asked to use the lontara application then give a rating according to the TAM instrument.

The small group test is the third test in this fourth stage. Respondents involved in this test must also meet the requirements, namely speaking either Buginese or Makassarese. Also, they are teachers of Bugis or Makassarese languages. Another requirement is to use MS Office, send an email, and write on Facebook, WhatsApp, and Telegram.

In this test, two groups of language teachers were involved. The first group is the Makassar language teaching group. They are twenty teachers and live in the Tompobulu sub-district, Gowa regency. The second group is the Bugis language teaching group in Parepare, where twenty-four teachers participated in this application test. These two groups were chosen because the Lontara script is used by speakers of the Makassar language and Bugis language. However, the level of Makassar language in EGIDS is lower than that of Bugis.

The research team assisted the two groups in installing the Lontara application on their laptops. First, the research team explained how to use the Lontara application in MS Office, email, Facebook, and social media. Then they were asked to use the lontara application to write some local language vocabulary in MS Word. After that, they emailed the vocabulary to one of the teachers. Messages in emails must use the local language in Lontara characters. At the end of the meeting, the two groups were asked to rate the TAM instrument.

The fourth phase in the formative evaluation stage is the large group test. Respondents who participated in this phase had the same requirements as the previous small group test. The difference between small and large groups is only in the number of people involved, and they are not necessarily local language teachers.

The first group is the teachers of the As'adiyah Islamic boarding school in Sengkang, Wajo district. Forty-five teachers participated in this test. The second group is elementary school teachers in the Tompobulu sub-district, Gowa district. Eighty-one teachers were involved in this test.

The application test results in these two groups can be seen in the following Table III.

Revision of the lontara application. Based on the instrument from participants, researchers revised bugs that occur during the stage of formative evaluation. The respondents' suggestions are generally not related to this application, but rather on its socialization to users of this application. Another suggestion is that a guide to installing the Lontara application on the website that provides this application and a guide on using it on MS Office, HTML and Whatsapp for Windows has also been prepared.

Final Product. Thus, this application has been tested in the small and large groups test phase of Formative Evaluation or the fourth stage.

The need to present information in local languages must be well prepared, especially in local languages. The needs of these communities must be aligned with the development of information technology. The digital era has forced humans, including regional language speakers, to interact with other humans through cyberspace. The internet in various electronic mail and social media on Facebook is one of modern humans' most widely used media today.

Although Lontara literature is often marginalized with Latin characters in literacy, it does not mean that the Lontara script should be abandoned. However, some efforts to bring Lontara character to the young generation of the Bugis-Makassar community must be implemented through information technology in the form of Lontara-based hypertext applications. This Lontara application's readiness is undoubtedly expected to stimulate Lontara users' interest in the HTML platform.

The model of the Lontara application is still referring to the Lontara Yusring. However, this hypertext-based Lontara application has been adapted to the characteristics of the Lontara script itself. Also, the characteristics of software, hardware, and human ware remain to be considered.

TABLE III. LARGE GROUP TEST

TAM Instrument Constructs	Average scale of Gowa group	Average scale of Wajo group
a. Perceived Ease of Use		
How would you rate your experience using lontara application on MS Office?	8	8
How would you rate your experience using lontara application on HTML Platform?	10	9
How would you rate your experience using lontara application on WhatsApp or Telegram for Windows?	9	10
b. Perceived Usefulness		
This application is quickly used in writing Lontara characters	10	9
Users get the benefits of the Lontara application	8	9
This application is more effectively used in compiling local language learning materials	9	8
c. Attitude Toward Using		
The position of the QWERTY keyboard is easily recognized on a laptop	8	10
TTF Lontara Yusring is obtained quickly at the Theme Fonts of MS Office	10	9
AVERAGE	9	9

The Lontara Yusring is still paying attention to the QWERTY keyboard model. However, this Lontara Yusring can only run on a Windows-based operating system. In the browser application, some treatments on settings need to be done. The treatment is required after the hypertext-based Lontara Yusring is installed. This need should be done because this Lontara letter's application does not include the Windows operating system's default fonts. Thus, a personal computer or laptop that has not been installed with a Lontara application cannot recognize the character.

Via email, Bugis-Makassar speakers can send messages using this research product. Indeed, to read these lontara characters on personal computers and laptops, the user needs to install the lontara application since the Lontara Yusring is not the official default of the Windows operating system. Therefore, lontara script users must install this application. So, both the message's sender and the lontara script's message must first install the lontara application. If it is not installed, lontara characters will appear on the personal computer screen or laptop users in the form of boxes.

Users of the lontara application can communicate either when sending messages via email or Facebook or creating interactive applications. Of course, it is expected that the younger generation of Bugis-Makassar knows and utilizes this lontara application. Using the lontara application, both oral and written, can be maintained in the writer's view. Thus, on the other hand, there is a local language sustainability action in place in this country expressing their ideas using the local language. Sometimes past romanticism has been just right and appropriate if it is expressed in the local language. Of course, local characters such as lontara characters should be able to support the speakers' wishes. In other words, the local script's character should be integrated with the development of information technology.

The same procedure can be done when the lontara application will be used on Facebook or social media. For example, an essential step for Facebook users (Facebooker) is to change the keyboard system from a standard keyboard to a lontara keyboard. The trick was relatively easy, that is, by choosing the lontara keyboard. In other words, this stage is the same if the user of the lontara application will send a message via email. An example of the lontara script on Facebook social media can be seen in the following picture.

The users of the lontara application can also take advantage of creating interactive material questions. Various applications can make this type of interactive exercise or interactive questions, including Hot Potatoes [37]. Hot Potatoes [38] is one of the most popular closed-circuit maker applications. This app is used to create multiple choice questions, match, crosswords, short stuffing, and composing sentences—result or output of this application in HTML-based file. The language characters that can be used in this Hot Potatoes application are all characters that are the default Windows operating system. Thus, the lontara application must be installed first for a personal computer or laptop user lontara application.

Lontara Application can also be used on other social media, for example, Whatsapp and Telegram. In this case, the lontara application must be used on the keyboard of a laptop or personal computer (input) and not on a smartphone. However, Whatsapp or Telegram, where the lontara application is used, can still be seen (output). For example, the lontara application, which is inputted on Whatsapp and Telegram laptop but seen on mobile, can be seen in the following Fig. 3:

Fig. 3. Lontara Yusring on Whatsapp.

Although the Lontara application can be utilized in Microsoft Office, the HTML platform can be seen on android. It does not mean maintaining the local language ends at this stage. The central and local government policies are essential to maintain regional languages. Without this policy, the local language observers, including language researchers, will face many potential challenges. For example, government policy requires every elementary and secondary level to continue studying their local languages, which is very important. However, the policy is not enough. The government of society must create space and a stage to display regional languages and literature. Government policy can be implemented by preparing columns in local newspapers once or twice a week. Publication of language and literature and local wisdom written in the local language familiarize the speakers of local languages accustomed and aware of the region's local wealth and wisdom.

To sustain the local language is a joint effort of various nation components. The government has a role in making policies and preparing budgets to support the policy. On the other hand, educators should teach the important role of regional and literary languages in life, especially in primary and secondary schools. Do not miss the local language users to use the local language in everyday conversations, especially non-formal events. Communication in the local language is not intended to undermine the national language's function since Indonesian can be found in every segment of communication, both formal and informal. This condition makes the Indonesian nation, directly and indirectly, use the Indonesian language in both oral and written forms.

This condition is somewhat different from the existence of local languages. Besides, local language characters should be brought closer to the development of technology. Space and stage use must also be considered. The writer expects that the lontara application with hypertext-based can be utilized by both tribes Bugis and Makassar, in expressing their ideas using the local language. Of course, local characters such as the

lontara application should support the speakers' wishes. In other words, the local script's character should be integrated with the development of information technology.

With this lontara application, the researchers hope that Bugis-Makassar speakers and other Lontara script users can communicate using this application, either when sending messages via email or Facebook or creating interactive applications. Of course, it is expected that the younger generation of Bugis-Makassar knows and utilizes this Lontara application. Only by using the Lontara script, both oral and written can be maintained in the writers' view. Thus, on the other hand, there is a local language sustainability action in place in this country expressing their ideas using the local language.

V. Conclusion

The lontara application model has been created. This application has been tested on a one-to-one test, small groups test, and large groups test. The participants from groups were very enthusiastic and were happy with this lontara application. This application helps them in teaching the local language. Also, they find it easy to prepare lontara script learning materials through this application.

The next step is launching this application for lontara users. The researchers recommend that the government issue a policy to implement learning lontara manuscripts in elementary to high school officially. Policies in the form of regulations will be a guide for local language teachers. This policy can be called a real, maintaining the local wisdom of South Sulawesi. Optimizing the use of this application is expected to be one of the concrete actions to maintain the local language in South Sulawesi.

Trend of Bootstrapping from 2009 to 2016

Paulin Boale Bomolo, Eugene Mbuyi Mukendi, Simon Ntumba Badibanga
Department of Computer Sciences and Mathematics
University of Kinshasa, Kinshasa, Democratic Republic of Congo

***Abstract*—The pedestal of fully homomorphic encryption is bootstrapping which allows unlimited processing on encrypted data. This technique is a bottleneck in the practicability of homomorphic encryption. From 2009 to 2016, the execution time of bootstrapping decreased from several hours to a few thousandths of a second for processing a logic gate on two encrypted bits. This paper makes a comparative study of the evolution of bootstrapping during the period. An implementation of multiplication on 16-bit integers on an Intel i7 architecture through three schemes whose libraries are respectively DGHV, FHEW and TFHE makes it possible to corroborate the trend that to date the best bootstrapping on bits is that of the TFHE which executes this processing in 29 seconds improving that of the FHEW 30 times despite the multiplication algorithm used.**

Keywords*—Bootstrapping; homomorphic encryption; binary multiplication; logic gates

I. Introduction

Encryption is said to be probabilistic if a plaintext message is encrypted in several ciphertexts. This feature is found by adding a random value during the encryption operation. It is said to be homomorphic if it allows performing processing on ciphertexts with corresponding results on plaintexts. If it performs only additions [1, 2], multiplications [3] or binary operations [4] it is called partial homomorphic otherwise if it performs additions and multiplications in a limited number then it is somewhat homomorphic [5, 6, 7]. On the other hand, if it performs processing on unlimited number it is said to be fully homomorphic [5, 6, 7, 8, 9, 10, 11].

Fully homomorphic encryption was a breakthrough made by Gentry [6] in his thesis in response to the conjecture state in [12]. This breakthrough is based on the bootstrapping technique that evaluates its own decryption circuit to refresh noise in the ciphertexts thus allowing an unlimited number of processing in the encrypted domain. Initially, it requires the squashing technique and an additional security assumption to reduce the complexity of the decryption circuit [9, 10, 11, 13, 14]. With the advent of fully homomorphic encryption schemes based on the difficult problem of LWE [15] which belongs a low-complexity decryption algorithm, squashing was eliminated in bootstrapping [8, 9,10, 11,13, 14].

The removal of squashing allows in [9,10] to use a second homomorphic encryption scheme in the homomorphic evaluation in the decryption algorithm. This consideration improved performance of the homomorphic processing of gate NAND on two-bits encrypted in less than a second [9]. This processing was improved to 13 milliseconds by [10, 11].

N-bits arithmetic operations such as multiplication or addition can be built from the universal gate NAND. While knowing that an addition or multiplication operation performed on encrypted bits can respectively multiple or raise to the power the noise by the number of operations. We seek to know in this paper whether the performance of bootstrapping on a multiplication on two encrypted integers of 16 bits through an implementation carried out with three libraries of the comparative schemas that each marked a period in this trend is in the same order of processing as on the encrypted bits.

Roadmap. Section II presents the literature review of the encryption scheme from gentry's breakthrough to the period under review. Section III establishes the criteria for comparison through bootstrapping with a focus on the concepts behind them and presents a comparative study based on the concepts between the relevant algorithms of each period. Section IV shows three multiplication algorithms on two 16-bit integers and a shifter. Finally, section V extends the bootstrapping processing of said algorithms to integers of 16 to perform homomorphic multiplication. Discussions close this comparison.

II. Literature Review

In 2009, Gentry published the first homomorphic encryption scheme based on ideals lattices. This scheme is characterized by too large parameters and additional security assumptions. Two schemes improved respectively the reduction of the size of encrypted keys and messages and the removal of the additional security assumptions [16, 17, 18, 19]. The majority of schemes in this category are unusable in everyday applications.

To facilitate an understanding of gentry blueprint, an integer-based homomorphic encryption scheme was published in 2010[7]. It is based on the difficult assumptions of Approximate Greatest Common Divisor [20]. Several integer-based schemes have been proposed to improve the efficiency of DGHV. These improvements could be achieved based on different variants of the AGCD security assumptions to reduce the size of the public key in security parameter and the expansion of this schema in [21, 22, 23,24 ,25].

The hardness of implementing homomorphic encryption schemes based on hard problems mentioned above have steered the research towards another security problem. Thus, the first complete homomorphic encryption scheme based its security on the assumptions of LWE that removes squashing was presented by Brakerski and Vaikuntanathan [13]. Said scheme is based on two procedures which are the relinearization and the reduction of the module or dimension. Relinearization is a technique that reduces the size of ciphertexts from $n^2$to $n + 1$. It starts from a quadratic function

in a secret key $s$to a linear function in a secret key $t$dependent on s. Reducing the module or dimension naturally reduces the complexity of the decryption function and also reduces the size of the digits. Then, Brakerski and Vaikuntanathan also proposed a version of their schema based on the assumptions RLWE [14,26,27]. Many homomorphic schemes by levels or complete was introduced [8, 27]. Each new scheme brings techniques aimed essentially at reducing the size of the parameters and increasing the multiplicative depth. But relinearization is still a bottleneck for the majority of these schemes.

Of all these schemes, [8] stood out. It relies on assumptions of approximate vectors to perform a homomorphic operation of gate NAND on encrypted messages. Encrypted messages are square matrices, addition and homomorphic multiplication is addition and multiplication matrix respectively. The author in [8] removes relinearization which is an expensive technique used in other LWE schemes in favor of the eigenvector approximation technique. The author in [9] uses a variant of the [8] to improve its bootstrapping based on gate NAND in less than a second. The author in [10, 11] introduces the external product in a variant of the [8] to reorganize bootstrapping of [9] and achieve 30 times better performance.

Our goal is to establish the criteria for comparing bootstrapping in three schemes which are the DGHV scheme [7], the Ducas Micciancio [9] scheme and the scheme in [10, 11]. In addition, use the libraries that implement them to corroborate the trend of bootstrapping in a 16-bit binary multiplication.

III. BOOTSTRAPPING

It is a technique that was introduced by Gentry [6] to solve the open problem stated in 1978 by [12] which consists in carrying out the processing on the encrypted data. Before Gentry's breakthrough, the noise increases with the circuit depth to be evaluated. The consequence is that decryption fails. The solution to this concern for inefficiency was through the encryption technique to reduce noise in the encrypted message and a homomorphic evaluation of the decryption algorithm.

A. The reencryption [6]

1) Definition of reencryption: reencryption is a noted function $\mathrm{Rencrypt}_\varepsilon$ that converts a message encrypted under a key $\mathrm{p_{k1}}$ into another message encrypted under an another key $\mathrm{p_{k2}}$ without revealing any information about the private key $\mathrm{s_{k1}}$ or the plain text m it is clear that $\mathrm{Rencrypt}_\varepsilon(\mathrm{c}) = \mathrm{Encrypt}_\varepsilon(\mathrm{p_{k2}}, \mathrm{m})$ where $\mathrm{c} = \mathrm{Encrypt}_\varepsilon(\mathrm{p_{k2}}, \mathrm{m})$ [2].

2) Reencryption algorithm: A reencryption can be evaluated in the following steps:

Generate a key pair (s_{ka}, p_{ka}) and (s_{kb}, p_{kb}) respectively belonging to A and B.

Evaluate A reencrypting key A between B and as follows $r_k = Encrypt_\varepsilon(p_{kb}, s_{ka})$.

Calculate a ciphertext $c = Encrypt_\varepsilon(p_{ka}, m)$ where m is plaintext.

Redefine the decryption function $Decrypt_\varepsilon$ as follows $f_c(s_{ka}) = Decrypt_\varepsilon(s_{ka}, c)$.

Evaluate the reencryption as follows $Evaluate_\varepsilon(p_{kb}, f_c, r_k) = Encrypt_\varepsilon\big(p_{kb}, f_c(s_{ka})\big) = Encrypt_\varepsilon(p_{kb}, m)$.

Reencryption allows to A to designate B by giving it the ability to encrypt the plaintext that it has encrypted with another key. B is called proxy.

3) One-way reencryption: Given a pair of keys (s_{k1}, p_{k1}) and (s_{k2}, p_{k2}). A one-way reencryption is a conversion from $Encrypt_\varepsilon(m, p_{k1})$ to $Encrypt_\varepsilon(m, p_{k2})$ by the evaluation of $Evaluate_\varepsilon(p_{k2}, f_c, r_k)$ where $r_k = Encrypt_\varepsilon(p_{k2}, s_{k1})$, not the inverse $Encrypt_\varepsilon(m, p_{k1}) = Evaluate_\varepsilon(p_{k1}, f_c, r_k)$ where $Encrypt_\varepsilon(m, p_{k2})$ and $r_k = Encrypt_\varepsilon(p_{k1}, s_{k2})$. The reciprocal of this assertion is false.

B. Hard Problems of Homomorphic Encryption

1) The problem of learning with error: The Problem of Learning With Error (LWE) was introduced by Regev in 2005 [15]. The Ring version of this problem called RingLWE, was introduced by Lyubashevsky, Peikert and Regev in 2010[28]. All variants are widely used nowadays in the construction of lattices-based homomorphic encryption schemes.

a) The Regev problem: For a security setting λ, Either $\mathrm{n} = \mathrm{n}(\lambda)$an integer dimension, an integer $\mathrm{q} = \mathrm{q}(\lambda) \geq 2$, and a distribution $\chi = \chi(\lambda)$ under $\mathbb{Z}$. The hard problem of $\mathrm{LWE}_{\mathrm{n,q},\lambda}$ the is to distinguish two following distributions:

In the first distribution, the sample $(\overrightarrow{a_i}, b_i)$ drawn uniformly from $\mathbb{Z}_q^{n+1}$;

In a second distribution, draw $\vec{s} \leftarrow \mathbb{Z}_q^{n+1}$and $(\overrightarrow{a_i}, b_i) \in \mathbb{Z}_q^n$ then a sample by drawing uniformly $\overrightarrow{a_i} \leftarrow \mathbb{Z}_q^n$ and $e_i \leftarrow \chi$ respectively, and initializing $b = \langle \overrightarrow{a_i}, \vec{s}_i \rangle + e_i$. The assumptions of $LWE_{n,q,\chi}$ are such that the problem of $LWE_{n,q,\chi}$ is hard.

b) The RLWE problem: For a secret $s \in R_q$, the RLWE distribution under $R_q \times R$ is drawn by respectively a uniform and random $a \in R_q$ and $e \leftarrow \chi$, and gives the output expression $(a, b = \langle s, a \rangle) + e \bmod q$.

RLWE is said to be decisional if given m independent samples $(a_i, b_i) \in R_q \times R_q$ where each sample is distributed either $A_{s,\chi}$ for random and uniform $s \in R_q$ (fixed for all samples) or the uniform distribution, distinguish which is the case (with a significant probability).

c) The General Problem of the LWE (GLWE) [26]: For a security parameter λ, that is $f(x) = x^d + 1$, where $d = d(\lambda)$ is a power of 2. Let be two integers respectively the modulus $q = q(\lambda)$ and the dimension n, let $R = \mathbb{Z}[x]/f(x)$ and $R_q = R/qR$. Let be $\chi = \chi(\lambda)$ a distribution on R. The problem with GAAE is to distinguish between the following two distributions:

The first distribution is a uniform sample $(a_i, b_i) \in R_q^{n+1}$;

In the second uniformly drawn distribution $a_i \leftarrow R_q^n$, $s \leftarrow R_q^n$ and $e_i \leftarrow \chi$, the second distribution is the sample $(a_i, b_i) \in R_q^{n+1}$ where $b_i = \langle a_i, s \rangle + e_i$. The assumption of GLWE is that the GLWE problem is hard.

If $d = 1$ then the LWE problem is that of the LWE problem. If n = 1 then the GLWE problem is that of the RLWE problem.

The author in [8] based on assumptions of LWE, it constructs its schema with a plaintext space $\mathbb{Z}_4 = \{0, 1, 2, 3\}$, an encrypted message space $\mathbb{Z}_q$ with an error or noise $E < \frac{q}{16}$ where q is the modulus that determines the key space from which the secret key s is taken and n is the encrypted message dimension.

To encrypt a plaintext $m \in \mathbb{Z}_2 \subset \mathbb{Z}_4$, draw $a \leftarrow \mathbb{Z}_q^n$, $e \leftarrow \chi$ and output the ciphertext c as follows $LWE_s^{4/q}\left(m, \frac{q}{16}\right) = \left(a, a.s + \frac{2m}{4} + e\right) \in \mathbb{Z}_q^{n+1}$.

The authors in [10, 11] redefines the problem of LWE and RLWE on the real torus $T = \mathbb{R} \, mod \, 1$ and the torus of polynomials $T[X] = T[X] \, mod \, X^N + 1$ respectively. This redefinition produces three types of ciphertexts for this schema. It also generalized and improved the encryption scheme based on the [8] and several of its variants.

To encrypt a plaintext $m \in T$, pick a secret key $s \in \mathcal{B}^n = \mathbb{Z}_2^n$ and calculate $c = (a, b) \in T^{n+1}$ where $a \in T^n$ is a random mask, $b = a.s + \varphi$ and $\varphi = e + m$ where e is a parameter that is drawn in a Gaussian distribution.

To encrypt the plaintext $m \in T_N[X]$, draw a key $s \in \mathcal{B}_N[X]$ and calculate $c = (a, b) \in T_N[X]^2$ where a is a random mask and $b = s.a + e + m$ where $e \in T_N[X]$.

To encrypt the plaintext $m \in \mathbb{Z}_N[X]$, pick the secret key $s \in \mathcal{B}_N[X]$ as in the RLWE and calculate $c = Z + m.G_2 \in T_N[X]^{2l \times 2}$ where Z is a list of ciphertexts of type RLWE of 0 and G_2 is the matrix with $\begin{pmatrix} g & 0 \\ 0 & g \end{pmatrix} g^T = (2^{-1}, \dots\dots\dots\dots\dots\dots\dots, 2^{-l})$.

2) The problem of the Approximation of the Greatest Common Divisor (AGCD)[20, 29].

The AGCD's problem with the parameters (γ, η, ρ) is the problem of finding the secret integer p given several samples $x_i = pq_i + r_i$ of arbitrarily provided where:

The secret integer p has bits η;

The terms noises r_i are uniform samples from the interval $[-2^\rho + 1, 2^\rho - 1] \cap \mathbb{Z}$;

The terms q_i are uniform samples of $[0, 2^{\gamma-\eta}] \cap \mathbb{Z}$.

[7] is the first known scheme applying the AGCD problem in cryptography to produce a homomorphic encryption scheme. In its symmetric version, it encrypts the plaintext $m \in \{0, 1\}$, two random integers are drawn uniformly to evaluate the encrypted message as follows $c = pq + 2r + m$. In other words, a sample of AGCD is calculated by adding the even noise $2r$ to the product pq which is added to m.

C. Bootstrapping [6]

1) Fundamental properties: In Gentry construction, bootstrapping is based on three fundamental properties that belong a partial or somewhat homomorphic encryption scheme that make it fully homomorphic encryption. These properties are listed and noticed below:

The complexity of the decryption algorithm is greater than that of the circuits to be evaluated. Given d the maximum degree of the decryption algorithm $Decrypt_\mathcal{E}$ and p the maximum degree of the function or polynomial to be evaluated by scheme. If $d < p$ then the decryption algorithm $Decrypt_\varepsilon$ is been useful in homomorphic evaluations. If $d > p$ then the complexity of this algorithm is reduced to $Decrypt'_\varepsilon$ for homomorphic evaluations hence $f_c(s_k) = Decrypt'_\varepsilon(s_k, c)$ where $c = Encrypt_\varepsilon(p_k, m)$.

Bootstrappability is a critical property of an encryption scheme that allows you to homomorphically evaluate your own decryption algorithm under an encrypted decryption key. Given an encryption scheme $\mathcal{E}$, $\mathcal{E}$ is said to be bootstrappable if $Evaluate_\mathcal{E} = (p_{k1}, f_c, e_k) = Encrypt_\mathcal{E}(p_{k1}, m)$ where $f_c(s_k) = Decrypt_\mathcal{E}(c, s_k)$, $c = Encrypt_\mathcal{E}(m, p_k)$ and $e_k = Encrypt_\mathcal{E}(p_{k1}, s_k)$ it is obvious that $\mathcal{E}$ evaluates homomorphically its decryption algorithm.

Circular security is a property that an asymmetric (symmetric) encryption scheme has to encrypt one's private key securely (secretly) by its corresponding public (secret) key. A homomorphic encryption scheme $\mathcal{E}$ has the circular security property if for a couple of given keys, (s_k, p_k) the bootstrapping key is evaluated as follows $e_k = Encrypt_\mathcal{E}(s_k, p_k)$: it is obvious that the private key is securely encrypted by its public key.

2) Definition of bootstrapping: Bootstrapping is a technique for reducing noise in the ciphertext c and getting noise b' in a refreshed ciphertext c' such as $b' < b$ where $b' \supset Encrypt_\varepsilon(p_k, m) \leftarrow Evaluate_\varepsilon(p_k, f_c, e_k)$ and b is the original noise in the ciphertext c by the homomorphic evaluation its own decryption circuit $f_c(s_k) = Decrypt_\varepsilon(s_k, c)$ on a decryption key called bootstrapping key$e_k = Encrypt_\varepsilon(p_k, s_k)$.

3) Bootstrapping algorithm: Given two pairs of keys (p_{k1}, s_{k1}) and (p_{k2}, s_{k2}) generated by a homomorphic encryption scheme ε.

Let be two ciphertexts c_1 and c_2 evaluate as follows: $c_1 = Encrypt_\varepsilon(p_{k1}, m_1)$ and $c_2 = Encrypt_\varepsilon(p_{k1}, m_2)$ where $m_1 \, and \, m_2$ are plaintexts.

The bootstrapping key e_k is calculated as follows $e_k = Encrypt_\varepsilon(p_{k2}, s_{k1})$. And the decryption function $Decrypt_\varepsilon$ is redefined in the following way $f_{c_1,c_2}(s_k) = NONET\big(Decrypt_\varepsilon(s_k, c_1), Decrypt_\varepsilon(s_k, c_2)\big)$ where is the private key s_k.

A homomorphic evaluation of f_{c_1,c_2} on c_1 *and* c_2 is carried out as follows: $Evaluate_{\varepsilon}(p_{k2}, f_{c_1,c_2}, e_k) = Encrypt_{\varepsilon}\left(p_{k2}, NONET\left(Decrypt_{\varepsilon}(s_{k1}, c_1), Decrypt_{\varepsilon}(s_{k1}, c_2)\right)\right) = Encrypt_{\varepsilon}(p_{k2}, NONET(m_1, m_2)) = NONET(Encrypt_{\varepsilon}(p_{k2}, m_1), Encrypt_{\varepsilon}(pk_2, m_2)) = NONET(c_1', c_2')$ where c_1' *and* c_2' are refreshed ciphertexts of c_1 *and* $c_2$whose noise $b' \ll b$.

4) Squashing: Squashing is a procedure that consists of expressing the decryption algorithm $Decrypt_{\varepsilon}$ into a polynomial or function $p_c(s_k)$ whose variables are the ciphertext c and the secret key sk. $p_c(s_k)$ is equivalent to a shallow circuit.

In [3], the decryption algorithm is expressed by the function $c^d \bmod N$. The complexity of the operation of exponentiation does not make it possible to rewrite this function into an equivalent function of low degree.

In the [7], the decryption algorithm is expressed by the expression $c \bmod p \bmod 2$ (1) which is not a low complexity. To do this, it is transformed into a circuit of expression $[c]_2 \oplus \left[\left\lfloor c.\left({}^{1}/_{p}\right)\right\rfloor\right]_2$ (2). ${}^{1}/_{p}$ is replaced in the evaluation (2) by the expression $\sum_{i=1}^{\Theta} s_i z_i$ which represents the sum of the subsets where $s_i = {}^{u_i}/_{2^{\kappa}}$. Evaluation (1) becomes $\left[c - \sum_{i=1}^{\Theta} s_i z_i\right]_2$ (3). (3) is the equivalent function of (1). (3) is an expression that has a low complexity.

5) Concept of Bootstrapping from 2015 [8 9, 10, 11]: Bootstrapping of scheme based on the problem of assumptions of LWE and its variants removes squashing. The decryption algorithm has a complexity that allows it to be evaluated homomorphically in the reencryption. This reencryption is carried out by a homomorphic accumulator which makes it possible to refresh the encrypted message into an equivalent encrypted message containing a small noise.

A homomorphic accumulator is a quadruplet of algorithms $Encrypt_{\varepsilon}$, Init, Incr and msbExtract. $Encrypt_{\varepsilon}$ is an encryption scheme that uses a key and is different from the first. It is called an internal scheme.

Init is the algorithm that initializes the contents of the accumulator. More briefly, this operation is written as follows: $ACC \leftarrow Encrypt_{\varepsilon}, (v)\ pour\ ACC \leftarrow Init(Encrypt_{\varepsilon}, (v))$.

Incr is the algorithm that allows you to add a value to the contents of the accumulator. This operation is written as follows: $ACC \overset{+}{\leftarrow} Encrypt_{\varepsilon}$ for $, (v) Incr\left(ACC,\ Encrypt_{\varepsilon}, (v)\right)$.

$msbExtract$ calculates with high probability from the contents of the homomorphic accumulator to produce a valid number. This operation is summarized by the expression $c \leftarrow msbExtract(ACC)$ with $c \in LWE_s^{t/q}\left(msb(v), e(l)\right)$ where e is the noise.

6) Type of bootstrapping: There are two types of bootstrapping that bootstrapping by squashing or by homomorphic accumulator.

A bootstrapping is said by squashing if a new security assumption is added in the reduction of the complexity of the decryption algorithm to ensure optimal security in the encryption scheme during the refresh of the noisy message.

Refreshing the ciphertext c with the addition of the assumption of the sum of subsets to re-encrypt c using the encrypted secret key $\sum_{i=1}^{\Theta} s_i z_i$ of $\frac{1}{p}$ which is used to obtain the ciphertext $c^* = \left[c - \sum_{i=1}^{\Theta} s_i z_i\right]_2$ [7].

A bootstrapping is said by homomorphic accumulator if a homomorphic accumulator is used to refresh a ciphertext in the reencryption operation.

a) Homomorphic accumulator in [9]: In [9], the homomorphic accumulator is based on the encryption scheme [8] defined under the assumptions of the Ring LWE. Let be a message m and the key $z \in \mathbb{Z}$, $Encrypt_{\varepsilon_z}(m)$ encrypts as described below:

Pick Randomly and uniformly the vector $a \in \mathcal{R}_Q^{2dg}$ and $e \in \mathcal{R}_Q^{2dg}$ into a Gaussian distribution χ of parameter ζ where $\mathcal{R}_Q^{2dg} = \mathbb{Z}_Q^{2dg}, N = 2^k$;

Calculate $Encrypt_{\varepsilon,z}(m) = [a, a.z + e] + uY^m G\ de\ \mathcal{R}_Q^{2dg\times 2}$ where m is encoded as the root of the unit $Y^m \in \mathcal{R} = \frac{\mathbb{Z}_N}{X^N+1}$ of where $N = 2^k$.

To upload the accumulator with the ciphertext $v \in \mathbb{Z}_q$, the function $Init(ACC \leftarrow v)$ uploads the content of accumulator with v as follows $ACC := uY^v G\ de\ \mathcal{R}_Q^{2dg\times 2}$;

To add an ciphertext to the contents of the accumulator, a decomposition of $u^{-1}.ACC$ in the base B_{dg} is performed as follows: $u^{-1}.ACC = \sum_{i=1}^{d_g} B_g^{i-1} D_i$ where the $D_i \in \mathcal{R}^{2dg\times 2}$ with the coefficients $\left\{\frac{1-B_g}{2}, \ldots\ldots, \frac{B_g-1}{2}\right\}$ and then perform $Incr(ACC \overset{+}{\leftarrow} C)$ where $ACC, C \in \mathcal{R}_Q^{2dg\times 2}$ to output $ACC := \left[D_1 \ldots\ldots D_{dg}\right]$.

Finally, use the msbExtract function with two entries that are a switch key $\mathfrak{R}$, a test vector $t = -\sum_{i=0}^{{}^{q}/_{2}-1} \vec{Y}_i$ to find $c \in LWE_s^{4/q}\left(m, \frac{q}{16}\right)$.

In [10], bootstrapping by accumulator is performed on the one-bit encrypted message $m \in \mathcal{B}$, $(a, b) \in T^n \times T = LWE_q^s(m, e)$ where $\mathcal{B} = \{0, 1\}$ and $e < \frac{1}{4}$ for valid decryption. Said message is first rounded to $\left(\bar{a}, \bar{b}\right) \in \mathbb{Z}_{2N}^n \times \mathbb{Z}_{2N}$ where $\bar{b} = \lceil 2Nb \rfloor$ and $\overline{a_i} = \lceil 2Na_i \rfloor$.

Given a test vector $testv = (1 + X + \cdots\ldots\ldots + X^{N-1}).X^{N/2}.u'$ where $u' = \frac{m}{4} \in T$, the result of the expression $X^{\bar{b}}.(0, testv)$ is loaded into ACC: $ACC \leftarrow (0, X^{-b}, testv)$. The evaluation of the

expression $[h + (X^{-\bar{a}_i} - 1)] \odot ACC$ update the content of ACC: $ACC \leftarrow X^{\bar{b}-\bar{a}s}.testv$.

An extraction is performed with the function $SampleExtract$ that receives as input the contents of: $ACCX^{\bar{b}-\bar{a}s}.testv$. It extracts the terms of said polynomial in a sample $msg((a', b'))$ where $(a', b') = (coefs(a''(X)), b'') \in T^n \times T$ where $coefs(a''(X))$ is the coefficient of the vector $a'' \in T_N[X]$ and $b_0'' \in T$ is the constant term of the polynomial $b'' \in T_N[X]$.

Key switching allows you to find a sample $TLWE(a, b) \in T^n \times T$ of the message $\frac{m}{2} \in T$ under the secret key s. It receives as input the result of the expression $msg(u) = u' + msg(SampleExtract(ACC))$.

7) Processing bootstrapping [9, 10]: There are two types of processing bootstrapping which are logic gate bootstrapping and logic circuit bootstrapping.

It is said that a homomorphic encryption scheme supports logic gate processing bootstrapping if a refresh is performed after each logic gate it is obvious that $Evaluate_\varepsilon(p_k, f_c, e_k)$ where f_c is a logic gate of the type AND, OR, NOT, ...

In [8], the homomorphic NAND gate is defined by $HomNAND: LWE_s^{4/q}(m_0, {}^{q}/_{16}) \times LWE_s^{4/q}(m_1, {}^{q}/_{16}) \rightarrow LWE_s^{2/q}(m_0 \overline{\wedge} m_1)$ where $m_0 \overline{\wedge} m_1 = 1 - m_0 m_1$ and $c_i = LWE_s^{4/q}(m_i, {}^{q}/_{16})$ with $i \in \{0, 1\}$. The refresh is performed on the result as follows: $LWE_s^{2/q}(m, {}^{q}/_{4}) \longrightarrow LWE_s^{4/q}(m, {}^{q}/_{16})$.

It is said that a homomorphic encryption scheme supports circuit processing bootstrapping if a refresh is performed after each logic circuit it is obvious that $Evaluate_\varepsilon(p_k, f_c, e_k)$ where f_c is a circuit that includes more than one logic gate of the type AND, OR, NOT.

In [8], let be a circuit for calculating the retention in an n-bit adder of two numbers a and b and an incoming retention c_0= 0, the expression (2). $c_i = (a_i \oplus c_{i-1}).(b_i \oplus c_{i-1}) \oplus c_{i-1}$ where $\oplus$ is XOR logic gate. From the Table I which is table of truth below of this expression a bootstrapping by circuit can be performed from a function majority with three variables noted $Maj(m_1, m_2 m_3)$ gives a value equal to 1 if the majority of bits is 1 otherwise 0.

Specifically, given three encrypted messages; Expression (1) can evaluate these three ciphertexts and produce a resulting ciphertext. Being calculated modulo 4, this makes it possible to homomorphically process the majority function described above. $c_1, c_2\ et\ c_3$.

This addition modulo 4 of the encrypted messages makes it possible to find the encrypted $Encrypt_\varepsilon(m)$, $m \in \{2,3\}$ with if majority is equal to 1 or if $m \in \{0,1\}$ the majority is equal to 0. An affine transform of $\frac{9q}{8}$ is performed to find the majority function in $\mathbb{Z}_4$. The circuit retained out of three is illustrated with the majority function noted maj as follows:

$$Maj\left(LWE_s^{4/q}(m_0, {}^{q}/_{16}), LWE_s^{4/q}(m_1, {}^{q}/_{16}), LWE_s^{4/q}(m_2, {}^{q}/_{16})\right) \rightarrow LWE_s^{2/q}(m, {}^{q}/_{4}).$$

The refresh is carried out on the result of the circuit as follows: $LWE_s^{2/q}(m, {}^{q}/_{4}) \longrightarrow LWE_s^{4/q}(m, {}^{q}/_{16})$.

8) Bootstrapping: Analysis and comparison of algorithms: Table II shows that TFHE bootstrapping performs better than bootstrapping performed and executed in the other two schemes. This fact is due to the removal of the decomposition step in any basis of the vector a of assumptions LWE [10, 11].

TABLE I. TRUTH TABLE OF THE SELECTED FUNCTION OF THE THREE BITS

a_i	b_i	c_{i-1}	$a_i \oplus c_{i-1}$(1)	$b_i \oplus c_{i-1}$(2)	1 ⊕ 2(3)	3 ⊕ c_{i-1}	Maj

IV. Applications: Binary Multiplication

The operation of multiplying two integers is described in Fig. 1, for any calculation basis (binary, decimal, etc.) by the following two steps:

The calculation of partial products;

The sum of the partial products obtained.

The product of two numbers of n digits can be given by a number of $2n$ digits. In the binary system, the gate AND is used to generate the partial products $a_i b_i$ between each bit of the two multiplicandes. A binary addition is performed on each column of partial products.

				a_3	a_2	a_1	a_0
				b_3	b_2	b_1	b_0
				a_3b_0	a_2b_0	a_1b_0	a_0b_0
			a_3b_1	a_2b_1	a_1b_1	a_0b_1	
		a_3b_2	a_2b_2	a_1b_2	a_0b_2		
	a_3b_3	a_2b_3	a_1b_3	a_0b_3			
p_7	p_6	p_5	p_4	p_3	p_2	p_1	p_0

Fig. 1. Example of Multiplying Two Numbers at 4 Bits.

A. The Classic Multiplication Algorithm[30]

Let a and b be two numbers of k bits, expressed as a basis:$\beta = 2$

$$a = (a_{n-1}a_{n-2} \dots \dots \dots \dots a_0) = \sum_{i=0}^{n-1} a_i \beta^i \quad (1)$$

$$b = (b_{n-1}b_{n-2} \dots \dots \dots \dots b_0) = \sum_{i=0}^{n-1} b_i \beta^i \quad (2)$$

Where the and a_i are b_i in the interval $[0, 1]$. The classical algorithm of multiplication of a and b consists in calculating partial products by multiplying the b_i of the multiplier by b the whole number a and then adding these partial products in order to obtain the final product p which is a number of $2n$ bits.

Note p_{ij} the pair (carry, Sum) obtained from the partial product $a_i b_j$. Fig. 1 illustrates the results p_{ij} of multiplication of a and b at 4 bits.

The last rank denotes the total sum of the partial products which is also the product $a\ by\ b$ represented by a number of $2k$ bits.

Algorithm 1: Classical Multiplication MC

Input: a, b
Output: p = ab
Initialize $p_i \coloneqq 0$ for $i = 0, 1, \dots \dots, 2n-1$
for $i = 0\ to\ n-1$
r
for $j \coloneqq 0\ to\ n-1$
$(r, s) = p_{i+j} + b_i a_j + r$
$p_{i+j} = s$
End For
$p_{i+n} \coloneqq r$
End for
Return $(p_{2n-1}p_{2n-2} \dots \dots \dots \dots p_0)$

This algorithm requires $O(n^2)$ bit-level operations to multiply two n bit encrypted numbers.

B. Horner's Algorithm

It was originally introduced to effectively evaluate the value of a polynomial $p(x) = \sum_{i=0}^{n} a_i x^i$ for a given value α. It is based on the following rewrite:

$$p(x) = a_0 + a_1 x + \cdots \dots + a_n x^n \quad (3)$$

$$= a_0 + x\left(a_1 + x\left(a_2 + \cdots \dots \dots \dots . . + x\left(a_{n-1} + x(a_n)\right) \dots \dots .\right)\right) \quad (4)$$

The expressions below evaluate a polynomial $p(x)$ at a given point α by performing n multiplications and n additions to calculate $p(\alpha)$.

$$ab = a.\sum_{i=0}^{n-1} b_i 2^i = ab_0 2\left(ab_1 + 2\left(ab_2 + \cdots . . + 2\left(ab_{n-2} + 2(ab_{n-1})\right) \dots \dots \dots \dots\right)\right) \quad (5)$$

The equation below can be written in the following recursive form:

$$p_0 = 0$$

$$p_i = 2p_{i-1} + b_{i-1}a \quad (6)$$

From these equations, Horner's algorithm (2) for multiplying binary integers is written as follows:

Input: $a_0, a_1, \dots \dots \dots, a_{n-1}$ and $b_0, b_1, \dots \dots \dots \dots \dots \dots, b_{n-1}$
Output : $p = ab$
$p_0 \coloneqq 0$
For $i = n - 1\ to\ 0$
Do
$p_i \coloneqq 2p_{i-1} + b_{i-1}a$
End do
End for
Return p

This algorithm has the same complexity as the classical multiplication algorithm is $O(n^2)$.

C. Karatsuba's Algorithm

The Karatsuba algorithm is a recursive algorithm introduced by the Russian mathematician Karatsuba in 1962. This algorithm requires $O\left(n^{\log_2 3}\right)$ to multiply two numbers of n bits. Its complexity is reduced by method of the divide-and-conqueror which uses fewer multiplications than the classical algorithm.

Let a and b be two integers of n bits and $l = \lceil n/2 \rceil$. Karatsuba initially breaks down $a\ and\ b$ into two equal parts:

$$a = 2^l a_1 + a_0\ , b = 2^l b_1 + b_0 \quad (7)$$

Such as a_1 is the l high-weight bits of a and a_0 is the l low-weight bits of a. Note that the 2^lvalue thus constitutes the basis of the representation β.

1) Naïve recursion method: The naïve recursion method reduces the multiplication of a and b multiplication of their components $a_1, a_0, b_1\ et\ b_0$ including the size of the initial integers as shown in the following equation:

$$p = a.b = (2^l a_1 + a_0)(2^l b_1 + b_0)$$

$$= 2^{2l}(a_1b_1) + 2^l(a_1b_0 + a_0b_1) + a_0b_0$$

$$= 2^{2l}p_2 + 2^lp_1 + p_0 \quad (8)$$

Said formulation reveals that the multiplication of two numbers of k bits require 4 multiplications of $l = \frac{k}{2}$ bits. Its complexity is not far from that of a classical algorithm.

2) Karatsuba algorithm: Its algorithm improves the performance of equations in (1). By reducing the number of multiplications to three but adding four additional additions. A rearrangement of the terms of the product $p = a.b$ makes it possible to obtain:

$$p_0 = a_0b_0 (9)$$

$$p_1 = (a_0 + a_1)(b_0 + b_1) - p_0 - p_2 \quad (10)$$

$$p_2 = a_1b_1 \quad (11)$$

Of these equations, a remark is made of the presence of three multiplications, two bits n and $n + 1$ one bit. The karatsuba algorithm requires $O(n^{1.59})$ operations to give the product of two numbers.

Algorithm 3: Karatsuba multiplication.MK

Input: a, b, k
Output : $p = a.b$
If (is small) then k
Return: Call the classic algorithm.$MC(a, b)$
Finsi
$l := k/2$
$a_0 := a/2^l$
$a_1 := a \ mod \ 2^l$
$b_0 := b/2^l$
$b_1 := b \ mod \ 2^l$
$p_0 := MC(a_0, b_0)$
$p_1 := MC(a_1, b_1)$
$temp := MC(a_0 + a_1, b_0 + b_1)$
$p_1 := temp - p_0 - p_2$
Return $2^{2l}p_2 + 2^lp_1 + p_0$

The version of the algorithm that has been implemented in this paper is iterative. It performs operations on 8-bit encrypted integers.

D. The Shifter

A shifter is formed of n + 1 inputs d_1, d_2, ..., d_n, c and n outputs s_1, s_2, ..., s_n and operates an offset of 1 bit on the inputs if c = 1, it is an offset to the right and if c = 0 then it is an offset to the left.

Algorithm 4: shifting to left or right.

```
Input: a: n-bit encrypted integer, right or left Boolean: offset direction
Positions: Number of offset positions
b: encrypted integer shifted by offset over n bits of positions.
cx1, cx2 two null encrypted integers of n bits
i: integer counter
flag: A Boolean integer that determines the offset direction.
if flag = 0 then
 right = 1;
 left = no(right)
otherwise
 right = 0;
 left = no(right)
finsi
for i of 1 to positions
do
 for k from 0 to n – 1
do
 if k > 0 and k < n – 1 then
 cx1k = and(ak-1, left);
 cx2k = and(ak+1, right);
 bk = or(cx1k , cxk2);
 otherwise
 if k = 0 then
 bk = and(ak+1, right)
 finsi
 if k == n then
 bk = and(ak-1, left);
 finsi
 finish
end do
return b
```

Algorithm 4 has a complexity of $O(p \times n)$ where p is the number of offset positions and n is the bit size of the number to be shifted.

V. Implementation and Interpretation of Results

A. Implementation

The implementations were tested on the Intel® core™ i7-5500 CPU @2.4 GHZ processor of a laptop with a cache memory of 4019 kilobytes, a clock clock clock of 1100 MHZ and a volatile memory of 8 Gigabytes that supports extensions of the following instruction sets: MMX, SSE, SSE2, SSE4_1, SSE4_2, FMA, AVX and AVX2.

The DGHV code was implemented in Python with Sage and GMP (GNU Multi Precision). These two libraries provide machine compiled mathematical libraries that are fast in their executions. We have not been optimal to work with these tools in the implementation of multiplication.

The FHEW library that is written in C/C++ language. An optimization to quickly perform convolution was achieved by an implementation of the Fourier transform FFTW3 to process bootstrapping. Functions useful for performing multiplication have been added to the FHEW.cpp source file [31].

The TFHE library is written in C/C++ language and an optimization has been implemented for the fast processing of bootstrapping with the data parallelism of fused-multiply add and as an Advanced Vector eXtensions assembler through a SQLIOS fast Fourier transform parameterized in either AVX or FMA. Useful functions have been added to the cloud file.c and alice.c [32].

Synthesis and comparison:

In Table III, the columns represent the circuit type used in the implementation of multiplication operations and the type of logic gates. As for the rows, they represent the implementation of different types of multiplication. The intersection between the row and the column gives the number of circuits or gates implemented to achieve each type of multiplication.

TABLE III. Circuit used in each Type of Multiplication

	Adder	Subtractor	Shifter	And	Multiply	Weighting
Horner	1	0	1	1	0	N
Classic	2	0	0	1	0	N^2
Karatsuba	4	4	4	1	3	1

The implementation of Karatsuba is less expensive in circuits and logic gates than the other two implementations are about three offsets respectively of 8 bits on 8 bits and 16 bits on 16 bits, two subtractors on 8 bits which represents the modulo 2^8, four additions respectively two on 8 bits and two on 16 bits and three multiplications on 8 bits. And on the other side, the classic implementation takes 512 complete additions on one bit and 256 multiplications with the door and on one bit. And in the same proportion as Horner's is 16 offsets of 1 bit by 16 bits, 256 multiplications on 1 bit with the door and 16 additions on 16 bits.

B. Interpretation of Results

In Table IV, the columns represent the implementation library and the rows represent the type of multiplication implemented. The intersection is the second execution time of a type of multiplication of two 16-bit numbers with one of the column libraries.

TABLE IV. PERFORMANCE TABLE OF MULTIPLICATION BY DGHV, FHEW OR TFHE

	DGHV	FHEW	TFHE
Horner	NA	671	41
Classic	NA	649	39
Karatsuba	NA	483	29

The library implemented for the DGHV did not provide results in a reasonable time to be taken into account in this paper. As for the FHEW and TFHE libraries, the theoretical results corroborated the theoretical hypotheses in memory and time complexity. It appears that the choice made in the design and implementation of the TFHE makes its bootstrapping more efficient.

VI. DISCUSSION

TFHE bootstrapping improves 15 times that of FHEW for this homomorphic multiplication on two 16-bit encrypted integers. This multiplication deteriorates the performance of the TFHE compared to the FHEW by halving the starting assumptions for a logic gate on ciphertexts bits. But in practice, this improvement is negligible if we consider that a binary multiplication of two 16-bit on plaintext numbers on the same architecture is carried out in less than 1 nanosecond. The ratio of improvement of the TFHE by adding the decryption time of the result is close to zero. This observation is also valid for the FHEW.

VII. CONCLUSION

Bootstrapping is the basis of unlimited homomorphic processing on encrypted data. This study compared bootstrapping through three patterns to identify its evolution from 2009 to 2016. It emerges from this comparison that the best design and implementation is that of the TFHE which is based respectively on the problem of the LWE on the real torus modulo 1, the bootstrapping by accumulator, on the fast Fourier transform coupled with the parallelism of FMA and AVX data. One avenue to explore is to study the performance of the implemented FHEW with a rapid transform based on the stockham algorithm, optimized throttle calculation and data parallelism.

A Hybrid Similarity Measure for Dynamic Service Discovery and Composition based on Mobile Agents

Naoufal EL ALLALI, Mourad FARISS, Hakima ASAIDI, Mohamed BELLOUKI
Department of Computer Science, Mohammed First University
FPD Nador Laboratory MASI
Nador, Morocco

***Abstract*—With the ever-present competition among companies, the prevalence of web services (WSs) is increasing dramatically. This leads to the diversity of the similar services and their developed nature, which makes the discovery of a relevant service during the composition phase a complex task. Since most of the competition companies aim to discover high-quality services with minimum charges in order to increase the number of customers and their profit. The semantic WSs allow performing dynamic service discovery through the entities software and intelligent agents. However, the solutions provided to the discovery process are limited to their performance in terms of the quickness to respond to the request in real-time, without considering the constraints such as the accuracy in the discovery phase and the quality of the similarity mechanism evaluation. They usually are based on the similarity measure of distance between concepts in the ontology instead of taking into consideration the relationships semantically and the strength of the semantic relationship between concepts in the context. In this paper, we proposed a novel hybrid semantic similarity method to improve the service discovery process. The hybrid method is applied to an architecture based on mobile agents, where cooperative agents are integrated to facilitate and speed up the discovery process. In the first hybrid method, we defined the Latent Semantic Analysis (LSA) with a semantic relatedness measure to avoid the ambiguity of the terms and obtain a purely semantic relatedness at level of the service description. The second one is defined to analyze the relationships at the level of the I/O service based on the subsumption reasoning, called IO-MATCHING. Experimental results on a real data set demonstrate that our solution outperforms the state-of-the-art approaches in terms of precision, recall, F-measure, and consumed time of the service discovery.**

Keywords*—IO-MATCHING; latent semantic analysis; mobile agents; OWL-S; semantic web services; semantic similarity; semantic relatedness

I. INTRODUCTION

Over the last years has become widely popular as the number of Web services deployed in the world is rapidly increasing owing to their low-cost and cross-organizational construction of distributed applications in heterogeneous environments [1]. In another term, as the number of WSs increases, the discovery of web services needed by the user becomes more and more critical [2, 3]. However, the requested information and knowledge from the data remain difficult to obtain precisely. Since there are some conventional approaches based on WSDL [4] as the description of Web Service, it provides limited results due to lack of semantic service description. Contrary to other service descriptions such as OWL-S [5], WSMO [6] and SAWSDL [7], which are based on the semantic description of web services. Thus, The Semantic Web Services (SWS) concept is the result of integrating Web services and Semantic Web technologies [8].

The key point behind integrating Web Service and Web semantic is developing intelligent service-based applications and carrying out high-precision semantic discovery and automated service composition based on formal ontology-based service semantics representations [9, 10]. These service-based applications can reason based on such formal service semantics. This can support not only semantic interoperability between services, but also planning of their logic-based automated composition and more precision service discovery [11]. Thus, the process of service discovery and composition is generally based on service description, increasingly beyond syntactic descriptions to incorporate the semantics of the service to enable more accurate analysis.

With the advancement of semantic technology in web services has become more attractive to researchers in recent years due to the importance of existing web services on the Internet [12]. However, that does not mean there are no complex challenges confronting researchers to improve web service discovery in real-time. Since some solutions [13–15] aim to minimize the execution time of web service discovery but generally lead to low productivity with marginal performance, they do not target semantic analysis of the request to achieve an accurate solution, making it challenging to realize the semantic web discovery process. Most of these solutions are based on the distance between two concepts of the ontology to measure the degree of similarity rather than to consider the semantic relatedness existing between these two concepts in a contextual way.

The crucial issue in the discovery process is that consists on the way to measure the correspondence ratio between the request and the service concepts, and also the semantic correlation strength between both. So that the semantic similarity and the semantic relatedness are two different concepts, because the semantic relatedness includes the strength of relationship between two concepts in a context, while the concept of semantic similarity is more specific than the semantic relatedness [16]. The semantic similarity is done by evaluating two concepts in a taxonomy or ontology, which are constructed only by "is a" relations. For example, "book" is similar to "novel", but is also related to "author" and "publication". Thus, more the similarity between two concepts

is higher, more the relatedness is increased in the given context [17]. For this reason, there are some semantic discovery methods based on simple matching of the concepts annotated to services and requests, without considering the relationship of these concepts to the desired service context, rather than a simple semantic matching of terms that are related to I/O. This is considered to be insufficient to improve performance either in the semantic discovery process or during composition, producing results according to the similarity ratio between terms without taking into account the semantic relatedness of the terms to the desired service.

In this paper, we proposed a novel approach that addresses the service discovery problem based on a cooperative system by mobile agents developed in [18]. This approach aims to analyze the semantic services in a contextual way. The provided approach takes into account all the constraints discussed in the above paragraphs. In particular, the novelties of our proposal are:

- The use of the parallelism of the agent technology to make the service discovery process more efficient and dynamic.
- The cooperative agents enable the semantic analysis of the request autonomously to improve the accuracy rate.
- The integration of a semantic analysis agent in order to facilitate the retrieval of ontology relationships between concepts and to enhance the performance of the discovery process. This integration provided to the proposed module by [18], which allows reinforcing in a robust and more flexible in responding to any point of the execution, enables to achieve better performance and lower memory consumption to select the composition of the services dynamically.
- The support of a secondary database to improve the quickness and reliability of semantic analysis without reproducing the extraction of ontological relations between concepts.
- The semantic analysis agent targets to extract the semantic relatedness strength between the wanted keywords and the service description, in order to return the service in context for responding the desired request to be realized.
- The use of a hybrid similarity method proposed to maximize the matching process between the query and service.
- The first hybrid similarity measurement method is a classical tool to retrieve the description services similarities automatically; through dimensionality compression, it is known as Latent Semantic Analysis [19]. In addition, the semantic relatedness between the concepts and the desired service is performed to support the LSA.
- The second hybrid method is based on the relationship between the input/output (I/O) concepts in their OWL ontologies; it is known as IO-MATCHING [20].

The experimental results on a real dataset demonstrate that our solution outperforms the state-of-the-art approaches in terms of precision, recall, F-measure and consumed the time of the service discovery.

The remainder of this paper is organized as follows: Section 2 introduces the related works, Section 3 presents our proposal approach, Section 4 demonstrates the experiment results and discussion, and the final section concludes the paper and the future work.

II. Related Work

With the radical proliferation occurring in web services technology, it is becoming difficult to discover a service that is adequate to the user's requirements. For that reason, there are many solutions to reinforce the service discovery problem in terms of functionality and QoS. In this regard, we present only related works to achieve a better understanding of the advantages that can be obtained and put our contributions in context.

The technique suggested in [18] provided a method for discovering and composing SWSs in a distributed environment. This technique is based on a mobile agent, which has the characteristics of self-reliance, social capability, self-learning, and, most importantly, mobility. It is a technology suitable for autonomously exploiting SWSs to provide end-user applications. The mobile agent aims to discover the SWS desired from different locations and the generated graphs to perform the composition process. Despite a sufficient result provided by the discovery process, it may provide relevant services, but it does mean that there is no accurate measure to find a service that satisfies the user's requirement.

The authors [21] suggested an approach to automatically compose web services based on multi-agent systems and an algorithm to dynamically select an optimal solution as a service that responds to the customer's requirements. This composition is based on the quality and composition-capacity of the participating services. They aim to design, deploy and manage distributed systems more efficiently by combining, reorganizing, and adapting the services. Despite the efficiency feasibility provided by their proposed module, it does not cover some evaluation metrics and the performance of the similarity semantic method during composition.

The work of [22] proposed a new WSs discovery method based on semantic matching and service clustering for effective and practical web services discovery, which integrates functional similarity with process similarity. Their suggested approach is based on the knowledge available from the semantic description model, based on improving Lin's [23] semantic similarity measure to include opposition or degree of contrast as specified in [24]. Their vision is to develop a practical WS discovery approach based on pre-clustering that enable them to perform semantic and scalable WS discovery in a short period and thus minimize the search space. However, their method similarity proposed is not accurate to describe semantically due to the ignorance of the two concepts' antisense relationships.

A new semantic similarity method is proposed by the authors [25] that may be performed on both the textual

description and the interface of WSs. Their proposed semantic similarity method incorporates multi-conceptual relationships for service discovery. It is based on the relational semantic distance between concepts in WordNet and other ontologies. This method provides a more accurate estimation of the similarity between the terms, the web services and the query. Although the experimental results are promising in terms of precision, recall and f-measure, but it is limited to the semantic similarity of the terms based on the generic WordNet ontology.

In [26], a proposed method for discovering and selecting WSs that use OWL-S to represent web services, quality of service, and customer demand. This architecture is built on system-multi-agent approaches that make use of semantic web services. Their proposed technique discovers services similar to the consumer request based on functional and QoS parallels and reputation computing. Their model is based on four-layers: the web service and request description layer, the functional match layer, the QoS computing layer, and the reputation computing layer. Their Future work includes combining several Web services into an atomic service (service composite) and composes Web services based on customer preferences and QoS.

The authors in [27] suggested an automated approach to discovering semantic Web services. It is characterized by an ontology-based service preprocessor, a reasoning-based service filter, and a parameter-based matcher of the service. The first uses the ontology defined by services and requests to reduce the number of candidate services. The second one consists basically on a reasoning-based service filter to extract the concepts tagged to the input and output parameters of the selected services from the SAWSDL set of documents. Consequently, it logically deduces the concepts and filters out the services that are insufficient to satisfy the user's parameter needs. Finally, the third one is a parameter-based service matcher based on the measure of semantic similarity in the matching algorithm (PBSM_R). This semantic similarity measure is mainly based on the relationship between the concepts of the domain ontology. Lastly, it returns services adequate to the requirements of the user. Although the results achieved in performance of the runtime through the narrowing the search space, but it lacks on one side precision and recall.

The authors [28] proposed a novel service discovery scheme based on a combination of similarity methods using the WSDL specification and ontology to make the service discovery process more automated, discover the best match rapidly, and improve the Hungarian algorithm [29] is used. This method combination includes the structural similarity, the semantic similarity and the concept similarity based on bipartite matchmaking techniques used to discover web services. This suggested scheme includes two phases to discover the most suitable services to the request. In the first phase, measuring similarity between the requested service and a set of advertised services. In the second phase, a bipartite graph of nodes defined based on the ontology is used to describe semantic Web service matching. The obtained experimental results are better than other existing schemes using the Hungarian algorithm in terms of precision, recall and f-measure, but it is lacked parallelizing some steps in the discovery process.

III. The Proposed Approach

This section presents an approach for supporting the discovery process during web service composition using the cooperative agents, which targets the minimization of the discovery performance overhead without requiring the memory pre-loading of service registries. Moreover, the maximization of the matching algorithm by the hybrid method proposed. This method consists in retrieving the context of the terms in the service description, where the service context can provide more accurate information regarding the services that are relevant to the request. The main novelty of our proposed discovery system aims to be self-adapting to unexpected variations, particularly in a heterogeneous environment.

Service discovery is a crucial issue to accomplish at each major step of the composition generation process. However, the increasing number of services on the Internet, the dynamic and unstable nature of these entities makes the composition tasks more difficult. Therefore, it considers the process of discovering a service during composition most important to ensure the system has the ability to semantically parse, respond to a request quickly and accurately in real-time. In order to have an efficient system for identifying the best solutions, we adopted the architecture developed by the authors [18], but with the incorporation of our hybrid semantic similarity measurement method and an agent to analyze ontological relationships as illustrated in Fig. 1, it can lead to successful results as detailed in the next section. This architecture is based on system multi-agent (SMA) for the discovery of Web services. Our contribution to this architecture is to improve the semantic similarity method's efficiency in the service discovery process.

Fig. 1 represents an improvement of the author's architecture [18], based on a primary agent in the distributed environment called a Mobile agent. This agent is used to discover the desired SWS in different locations and graphs to accomplish the composition process. This architecture includes the main entities to support the discovery process through the exploitation of the ontology domain used and facilitate the search process, which is corresponding between the request and the service offers. In the following, we will explain more details what happens in each entity.

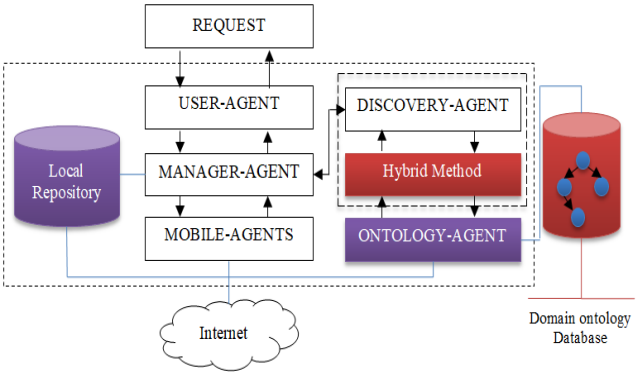

Fig. 1. Integration of the Proposed Solution for Mobile Agent Architecture to Discover and Compose SWS.

- USER-AGENT: is a point to interact between the request and the service discovery system. This agent is responsible for providing the user with an OWL-S standard semantic module [5] to express the request. The user's request is composed of inputs/outputs, a reference to the domain ontology to be used, and after the processing returns the desired results to the user.
- MANAGER-AGENT: Checks the availability of the desired service index in the local repository or whether the service can be composed of the local repository services. In the absence of the desired service, it is up to a set of mobile agents to search in different locations on the web to find the desired service.
- MOBILE-AGENTS: are responsible for retrieving the semantic web services from different websites instead of using a crawler due to their speed performance and low network overhead. It satisfies the needs of "MANAGER-MOBILE" to reinforce these services during the composition.
- ONTOLOGY-AGENT: is designed to facilitate the semantic analysis of the I/O of the service required by the discoverer agent (as illustrated in Fig. 2). It is considered as a cooperative agent. It analyzes the ontology domain that corresponds to the request of the discovery agent. Thus, it extracts the classes and their links to deduce the generalization relations between the concepts, which means a concept is more general than another in the arborescence (as shown in Fig. 3). These domain ontologies are stored in the domain ontology database.

This agent can exploit the relations already deducted in advance that are stored in the secondary database. This database is developed as a memory cache to avoid spending more interaction and extract these relations quickly without reproducing the operation of processing analysis.

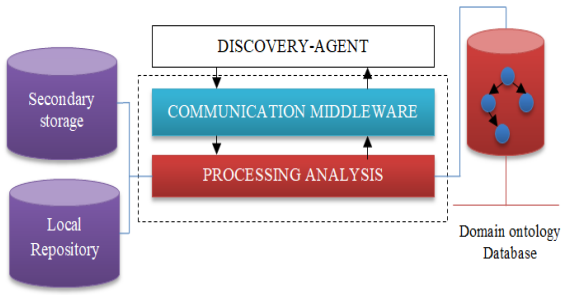

Fig. 2. Components of "ONTOLOGY-AGENT".

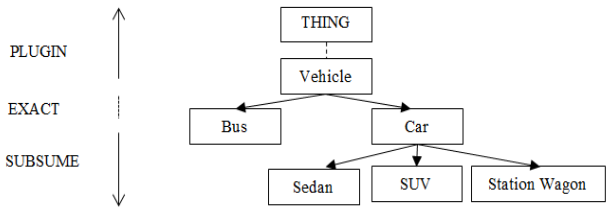

Fig. 3. A Vehicle Ontology Fragment [20].

- DISCOVERY-AGENT: allows discovering semantic web services that fulfills the requirements of the manager agent. The discovery process is based on the mobilization of the hybrid measurement similarity method and the "ontology-agent". The hybrid method integrated into the discovery agent are the following: The first method, based on the LSA, aims to investigate the relationships between a set of service descriptions and the terms embedded, by producing a set of concepts related to the service descriptions and the terms. In addition, to analyze the semantic relatedness between the concepts and the desired service. The second method, based on IO-MATCHING, intends to describe the degree of matching between two I/O concepts using the ontology agent.

To maximize the contextual similarity of service discovery, we propose a hybrid method which focuses on the semantic similarity between the input/output concepts of services, and to find the semantic relatedness between the service description terms in a contextual way. This is intended to facilitate the performance of "ontology-agents" to cooperate in a more intelligent and explicit sense with other agents. In the following, we will describe in more detail the different definitions to clarify the mechanism of similarity provided.

Definition 1 (Request): the request of the user is defined as $R = \langle R_{in} | R_{out} | R_{des} \rangle$, where R_{in} denotes the set of required input parameters, R_{out} denotes the set of required output parameters , and R_{des} denotes the required service description.

Definition 2 (Web Service): A web service is described by the OWL-S ontology. The service defined as a 3-tuple: $S = \langle S_{in} | S_{out} | S_{des} \rangle$, where S_{in} and S_{out} are the input and output concepts respectively, S_{des} is the description of the service.

Definition 3 (LSA): Latent Semantic Analysis is used to discover the hidden and subjacent (latent) semantics of words in a corpus of documents by constructing "concepts" related to documents and terms. It is a standard technique to extract automatically similarities between documents, by reducing the dimensionality. A word-document matrix is packed with weights according to the extent of the word in the specific document and is then reduced by singular value decomposition to a reduced dimensional space called conceptual space. The LSA process includes four steps illustrated in Fig. 4 as follows.

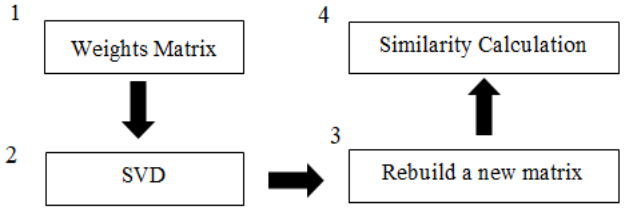

Fig. 4. The LSA Algorithm Processing Steps.

Step 1: Before building a weights matrix, the short text of the service description must be treated in the pre-processing phase as normalization of the service description to reduce the information ambiguity. The next phase is the tokenization task,

which consists of transforming the short text existing in S_{des} to a set of separate terms as a set of tokens. After finishing the tokenization task, it will be the stemming task to convert different forms of terms into a similar canonical form. Before finishing the pre-processing task, the terms must be sorted alphabetically. This step can be completed by building a weigh matrix as illustrated in equation (1) bellow.

$$A=\begin{pmatrix} & t_1 & \cdots & t_j \\ s_1 & w_{1,1} & \cdots & w_{1,j} \\ \vdots & \vdots & \ddots & \vdots \\ s_i & w_{i,1} & \cdots & w_{i,j} \end{pmatrix} \quad (1)$$

where $W_{i,j}$ represents the weight of the term i in the service j. The Term Frequency-Inverse Document Frequency (TF-IDF) can be calculated as:

$$W_{ij} = TF_{i,j}(T,S) \times IDF(T) = \frac{n_{i,j}}{\sum_k n_{k,j}} \times \log\left(1+\frac{N}{df_i}\right) \quad (2)$$

where $n_{i,j}$ is the number of occurrences of the term t in the service, N is the total number of services in the corpus, and df_i is the number of services where the term T_i occurs.

Step 2: After the generation of weight matrix, it follows the step of decomposition of matrix A by SVD as illustrated in equation (2),

$$A=U\sum V^T \quad (3)$$

where,

U Term matrix.

$\sum$ Descriptions service matrix.

V^T Singular value matrix.

Step 3: Once the matrix A is decomposed by SVD, we have to reduce the vector space to an approximation with a rank of $k=4$, it becomes to find a service description closest to the request. A request is represented in the k-dimensional vector space as a service. A request (R) can be represented as follows:

$$R_{des} = R_{des}{}^T U_k \sum\nolimits_K^{-1} \quad (4)$$

Step 4: Then, we need to measure the cosine similarity to evaluate the similarity between the query description and the service description. The cosine similarity measure is defined as follows.

$$sim(R_{des}, S_{des}) = \frac{R_{des} \cdot S_{des}}{\| R_{des} \| \| S_{des} \|} \in [0,1] \quad (5)$$

Definition 4 (Description Similarity): A service description S_{des} is a short text which describes the typical properties of a service. The service descriptions include rich information to be evaluated semantically. To calculate the description similarity (DS) will be evaluated by the similarity of the hidden topics using the LSA method as mentioned in definition 3, additionally evaluating the correlation rate to the I/O concepts with the service description. These concepts are considered essential keywords to improve the precision rate. The description semantic similarity is defined as follows.

$$sim_{DS}(R_{des}, S_{des}) = \delta \times sim(R_{des}, S_{des}) + (1-\delta) \times Relatedness(R_{des}, S_{des}) \quad (6)$$

where $\delta \in [0,1]$ is weight factor of the LSA similarity and $Relatedness(R_{des}, S_{des})$ is the semantic relatedness.

To infer the semantic relatedness between the wanted keywords and the service description, our ontology method mentioned in definition five correlates the I/O concepts to get the diversification of the service description related to these concepts in a semantically precise way. We define the semantic relatedness method as follows.

$$Relatedness(R_{des}, S_{des}) = \begin{cases} e^{-((1-\frac{\ln(1+n_k)}{1+\ln(n)})\times(\frac{T(T_R,T_S)}{\max(W_{T_R},W_{T_S})}))} & \text{if } T(T_R,T_S) \neq 0 \\ 0 & \text{otherwise} \end{cases} \quad (7)$$

where $Relatedness(R_{des}, S_{des})$ is normalized in the range [0,1], n_k is the number of occurrences that a combination of terms appears in the service descriptions, and n is the number of services in the corpus. $T_R = R_{in} \cup R_{out}$ is a set of I/O concepts of the request, and $T_s = \{t_1, t_2, ..., t_n\}: t_1, t_2, ..., t_n \in S_{des}$ is a set of terms of the web service description that are semantically related to concepts of the T_R request. Also, w_{T_R} and w_{T_S} are the term weights of the wanted keywords T_R and T_s respectively.

To analyze the semantic compatibility between the wanted keywords T_R and the concepts of T_s, the semantic matchmaking method is used, which is in charge to assess the degree of compatibility between the concepts included in the keywords with the concepts of the S_{des}. This method uses semantic reasoning (subsumption reasoning) to analyze the relationship between concepts. These ontology relationships allow extracting the concepts compatible to the T_s concepts, and this allows improving the performance of the LSA method semantically. So, to retrieve the web service which is related to the wanted keywords T_R, we determine the subsumption relationship as follows.

$$T(T_R, T_S) = \begin{cases} 1 & if\ T_R = T_s \\ \frac{1}{2} \times \left(\frac{\sum_{c \in T_R} max_{t \in T_S}\{Match(t,c)\}}{|q_{T_R}|} + \frac{\sum_{t \in T_S} max_{c \in T_R}\{Match(c,t)\}}{|q_{T_s}|}\right) & otherwise \end{cases} \in [0,1] \quad (8)$$

where c and t are any concepts of wanted keywords T_R and the service description T_s respectively. Moreover, $|q_{T_R}|$ and $|q_{T_S}|$ are the total number of the ontology relationships that have the maximum value and greater than zero.

As illustrated in the formula (8), if the all concepts of T_R appear in T_s, at this point the value of $T(T_R, T_S)$ is 1. In otherwise, the concepts of T_R are adjusted by other related

concepts using the ontology-agent, these concepts are different than the initial concepts T_R, in order to identify of the different keywords that are closer to the desired service description. It leads to avoid the ambiguity of the terms frequency and to enrich the terms which have a purely semantic relatedness with the service description. Thus, more the value of $T(T_R,T_S)$ is higher, more the concepts of keywords T_R are suitable to the concepts of T_s, that's means the value of semantic relatedness will be maximized.

Definition 5 (Interface Similarity): Interface similarity (IS) is determined by the semantic compatibility between S_{in} and S_{out}. This compatibility is evaluated by the degree of semantic matching between concepts, which is called IO-MATCHING. The relations of these concepts are deduced by the "ontology-agent" analyzer. This degree of semantic matching uses 4 types of matching score: Exact, Plugin, Subsume, and Fail to measure the matching between two S_{in} / S_{out} concepts as follows:

$$Match(C_i,C_j)=\begin{cases}\text{EXACT } if\ C_i \equiv C_j \\ PLUGIN\ if\ C_i \sqsubseteq C_j \\ SUBSUME\ if\ C_i \sqsupseteq C_j \\ FAIL\ otherwise\end{cases} \in [0,1] \quad (9)$$

where C_i and C_j are the request and service concepts respectively. The interface similarity between the request *R* and the service *S* is calculated as shown in the equation below.

$$sim_{IS}(R,S)=\frac{\sum Match(C_i,C_j)}{max\{Card(S_{in}\cup S_{out}),Card(R_{in}\cup R_{out})\}} \in [0,1] \quad (10)$$

In the literature [20], the different degrees of matching that are often considered are as follows:

- EXACT ($C_i \equiv C_j$): if the concepts C_i and C_j belong to the same ontology class.
- PLUGIN ($C_i \sqsubseteq C_j$) : where the C_j concept in the ontology is a sub-class of C_i, the concept C_i is more specific than the desired concept C_j
- SUBSUME ($C_i \sqsupseteq C_j$) : if the class of C_i is more general than the class of C_j, it indicates that the class of C_j is a sub-class of C_i.
- FAIL ($C_i \perp C_j$): when there is no subsumption relationship in ontology between C_i and C_j.

Definition 6 (Functionality semantic similarity): The functionality semantic similarity measure (FSM) includes two main components: description similarity and interface similarity. Functionality semantic similarity is defined as follows.

$$sim_{FS}(R,S)=\alpha\times sim_{IS}(R,S)+\beta\times sim_{DS}(R,S) \in [0,1] \quad (11)$$

where α and β are the interface similarity weight and the description similarity weight, respectively.

Table I represents the best-desired services to fulfill the request. As the desired service which should return a book price. It demonstrated the semantic relatedness/ similarity performance, which reinforces the LSA and IO-MATCHING similarity method to identify the hidden relationships in the service description rather than to focus the semantic analysis of the I/O. Although the similarity at the input/output level is similar, it provides different functionalities than expected. For example, the similarity at the interface level in the service "Cheapest Book Service" provides different request requirements. On the contrary, "BookPrice" and "BookPriceService" services respond to the users' same needs. As a result, it is crucial to measure similarity at the level of service description to extract hidden semantic relations and increase accuracy. This experiment is done by the weight of the interface similarity $\alpha=0.5$ and the description similarity $\beta=0.5$.

TABLE I. AN ILLUSTRATION OF THE RESULTS OBTAINED FROM THE SIMILARITIES BETWEEN THE SERVICES AND THE REQUEST

Service name	Inputs	Outputs	Text description	FSM
Cheapest Book Service	#_BOOK	#_PRICE	A Service that searchest the cheapest Price for a book	0.94
BookPriceService	#_BOOK	#_PRICE	Return price of a book	0.98
Bamzon RecommendedPriceService	#_BOOK	#_RECOMMENDERPRICEINDOLLAR	Bamzon is a popular service to return recommended price of a book	0.87
BookPrice	#_BOOK	#_PRICE	Uses the ISBN to return price of a book	0.96
BDe RecommendedPriceService	#_MONOGRAPH	#_RECOMMENDERPRICEINEURO	BDe is a competitor web service to return recommended price of a monograph in Euro	0.70
BookPriceTaxedPriceService	#_BOOK	#_TAXEDPRICE,#_PRICE	This service informs the taxed price of a book	0.88

IV. Experiment Results

In this section, we present our analysis that includes two main parts: In the first part, an overview of the experimental settings. The second part discusses the experimental results obtained by comparing the performance provided to another work [27].

A. Experimental Setup

To improve the performance mentioned in the last Section, we have been implemented our proposed approach in JADE Platform and OpenNLP Framework [30], which are based on the java language using an Intel® Core (TM) i7-4770 processor with 8 GB of main memory running Windows 10. Our experimental data is from the OWLS-TC version 3.0 dataset, which contains 1007 indexed OWL-S services, most of which were collected from public IBM UDDI registries semi-automatically transformed from WSDL to OWL-S. Table II below summarizes the features of the experimental environment.

To analyze the correctness and performance as discussed in our contribution, we carried out two experiments in different weights to prioritize each aspect of similarity (interface similarity and description similarity) as shown in the Table III. These parameter weights are scaled according to the importance of the similarity parameter in two different scenarios, these two scenarios will be experimented in order to understand the value added in our solution will be illuminated in the next Sub-section. Furthermore, the value of the weight factor δ=0.3 , which indicates a high importance of relatedness semantic than the LSA similarity, to reinforce the relatedness to cover the limitations of the LSA similarity.

TABLE II. The Experimental Environment

Environment	Description
Operating System	Windows 10
CPU	Core (TM) i7-4770
RAM	8 GB
Software Framework	JADE
NLP Toolkit	OpenNLP
Programming Language	JAVA
Dataset	OWL-S TC Version 3.0

TABLE III. The Weights of different Methods (Hybrid and IO-MATCHING Method)

Experiments	Method	Weight name	Parameter	Value
1	IO-MATCHING	Interface Similarity	α	0.50
	Hybrid Method LSA-IO	Description Similarity	β	0.50
2	IO-MATCHING	Interface Similarity	α	1
	Hybrid Method LSA-IO	Description Similarity	β	0

B. Results and Discussion

In order to carry out a standard and comparable analysis, we selected a set of 29 test queries (OWLS-TC3) associated with pertinence sets to lead performance evaluation experiments. These experiments are analyzed in more detail by comparing the precision, recall, and F-measure of the services retrieved by the two experiments, as illustrated in Table III. Then, the processing time is evaluated in function of the rising number of services, which are varied in each test (from 50 to 1007 services). It allows us to measure scalability according to the average speed to fulfill the query's requirements. For more analysis, we compared our solution with another method [27] to evaluate the system's performance in terms of scalability to clarify our system's success in dealing with all these constraints, as mentioned previously.

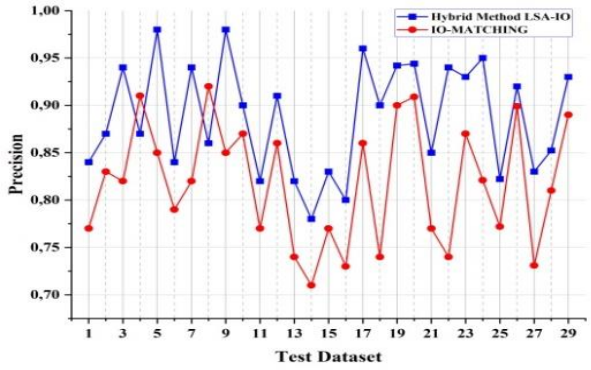
1) Evaluation metrics: As mentioned earlier, the experimental results should be analyzed in advance regarding the precision, recall and f-measure of the services retrieved by the hybrid and IO-MATCHING method. Precision is the ability to retrieve the most precise services. Higher precision means better relevance and more precise results but may imply fewer results returned. Recall means the ability to retrieve as many services as possible that match or are related to a query. F-Measure evaluates a weighted harmonic mean of precision and recall. As we used it for the evaluation process, it is then defined as follows.

$$precision = \frac{A_{Relevant} \cap B_{Retrieved}}{B_{Retrieved}} \quad (12)$$

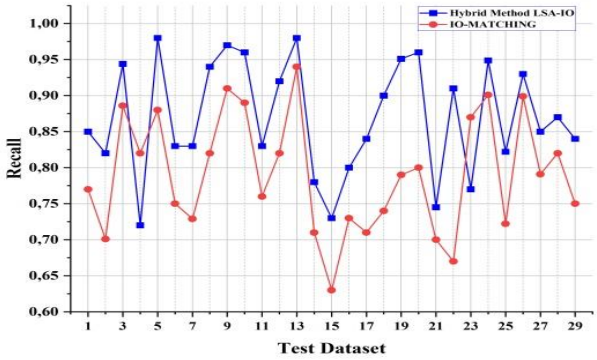
$$recall = \frac{A_{Relevant} \cap B_{Retrieved}}{A_{Relevant}} \quad (13)$$

$$F - measure = 2 \times \frac{precision \times recall}{precision + recall} \quad (14)$$

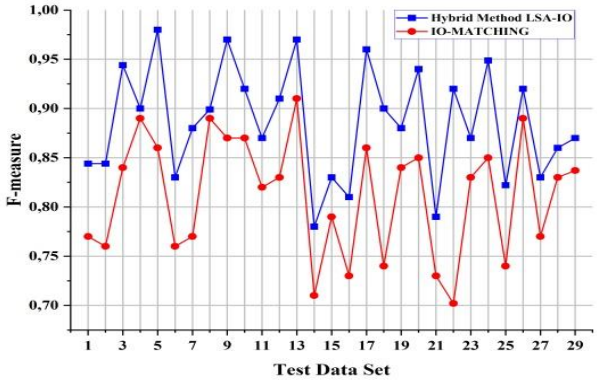
Where $A_{Relevant}$ is the set of relevant services, and $B_{Retrieved}$ is the number of relevant services retrieved. As indicated in the experimental results below, we run 29 test queries (OWLS TC-3) simultaneously to measure precision, recall, and F-measure in each experiment in Table III. The Fig. 5 demonstrates the efficiency of the interface similarity over description similarity as well as the performance provided by just the similarity measure at the I/O interface level. This proves that the hybrid method has a high value of precision, recall, and F-measure in all the query tests as compared to the traditional method (IO-MATCHING), which is purely based on the ontological relationships at the I/O level. With the exception of the query test 4 and 8, which record higher precision rate in concerning the IO MATCHING method. Relative to the query test 4 and 23, it also shows higher value of recall than the hybrid method.



(a) Precision.



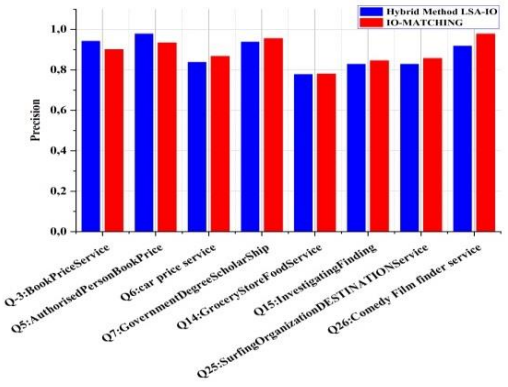
(b) Recall.



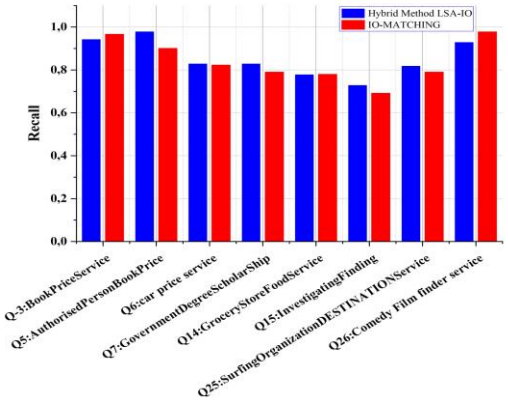
(c) F-measure.

Fig. 5. The Performance Measures for each Query in the Testing Dataset OWLS TC-3 for Both IO-MATCHING and Hybrid Method.

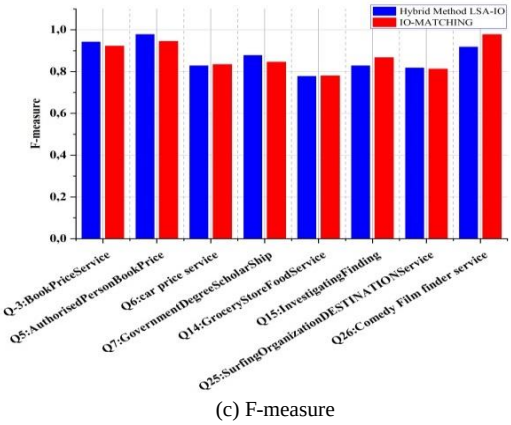
For more explicit the results obtained above, the Fig. 6 represents more in details by the selected test queries (OWLS TC-3), to clarify well the powerful hybrid method proposed in terms of the different evaluation metrics. It is the same criteria that we mentioned previously concerning the query tests, which are the identical to those shown in the Axis-x Fig. 6. These selected query tests indicate the challenges chosen to understand our hybrid method dominated by the IO-MATCHING method regarding precision, recall and F-measure. It was analyzed in Table III, the " Q3:BookPriceService" query can retrieve services similar but not as meaningful to the query in the case of experience 2. We deduced that it is not sufficient to just rely on the I/O interface instead of relating the concepts contained in the inputs/outputs with the description. But with Experimental 1, the hybrid method leads to relevant services to the query, due to the reinforcement provided to the LSA method by the semantic relatedness, which allows to improving the correlation ratio between the terms and the desired service instead of related to the frequency of terms. For example, the query "Q7:Government Degree ScholarShip " which requires the information on scholarships offered by a given government according to degree and government. Thus, the concept "#degree" can be related semantically to "#Academic-Degree" or "#Award", while the concept "#Government" can be related to the concept "#GovernmentOrganization". This is why the hybrid method is robust in terms of correlating these concepts with the service requested in the context.



(a) Precision



(b)Recall



(c) F-measure

Fig. 6. Evaluation of different Queries of OWL-S Dataset in Terms of Precision, Recall and F-measure.

Fig. 7 indicates the number of services retrieved via the hybrid or IO-MATCHING method for each query test (OWL-TC 3). These query tests vary in the number of inputs/outputs and related functionality desired to be achieved, in order to make a real challenge to the discovery systems concerned. As illustrated below, the significant number of services retrieved to satisfy the request set by our proposed system. Moreover, due to the performance provided by cooperative agents such as mobile agent and ontology-agent, that is proved in terms of different evaluation measures, to find a relevant service.

In addition, the comparison illustrated in Fig. 8 indicates the average precision-recall curve between the hybrid method and the IO-MATCHING method in order to expand the evaluation measures of the performance system proposed in retrieving a relevant service. In this experiment, we run 29 test queries in order to compute the average precision and recall. This demonstrates in the average precision-recall curve that the hybrid method excels considerably in the retrieval accuracy for relevant services based on the semantic correlations between the query concepts and the desired service. Consequently, the hybrid method has a higher precision value in service retrieval than the IO-MATCHING method.

2) Runtime performance comparison: To validate and evaluate the speed up performance for the proposed architecture, we compared our system with other works in the same scope [27] . To perform this comparison, we computed the average runtime according to each service set for different test queries. These sets vary in number of services to provide the scalability with a growing set of services (from 50 to 1007 services) and the response of the system in real time. This is demonstrated in Fig. 9, the results obtained in comparison with another work. The work [27] suggested to be compared, based on Ontology filtering and parameter matching relied on the discovery of function-oriented Web services to reduce the space of matching preprocessor and filter. While, we focused on the semantic analysis and the inter-relatedness between the concepts and the desired service, combined with the privileges provided by the agent ontology, which allows to exploit the pre-existing solutions in the second database, as discussed in Section 3, that facilitate the discovery of semantic relations and to reduce the consumption of reproducing the analysis of the operations required. This makes the discovery more flexible and rapid.

According to the results shown in Fig. 9, both approaches do not spend more time to the first sets of services (between 50 ms and 110 ms), while the OFPM method spends more run-time than the hybrid method when the number of services is scaled up. This is due to the cooperation of agents in the environment in order to make the discovery task and to respond in a real-time. This provides for a more flexible process of composition to accomplish its tasks.

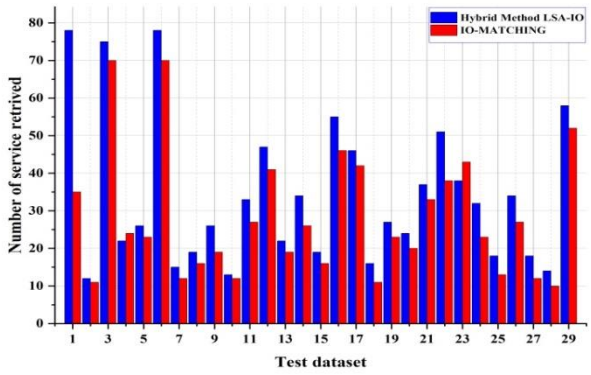


Fig. 7. The Number of Services Retrieved by the Hybrid Similarity Method and IO-MATCHING.

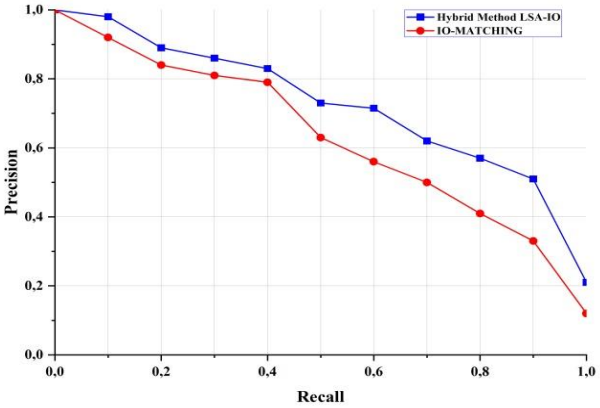

Fig. 8. Average 11-Points Precision-Recall Curve Across 29 Test Queries for the Hybrid Method and IO-MATCHING.

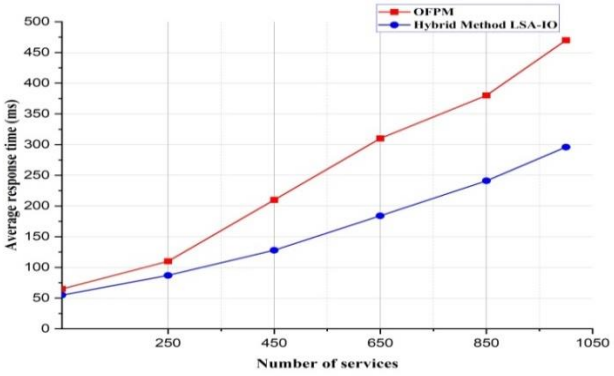

Fig. 9. Runtime Performance Comparison for Both Hybrid Method and OFPM [27].

V. Conclusion

This paper demonstrates the performance dynamicity provided to the architecture proposed. This allows handling the service composition more flexibly and quickly, with autonomous to find services accurately. Thus, it is proved in terms of the scalability and flexibility to respond in a real-time. This is due to the integration of the proposed hybrid method and the ontology analysis agent, which makes the architecture to be more dynamic in terms of autonomy, reliability and robustness. In addition, the proposed hybrid method makes the

system to meet the requirements of the query in the context of the semantic relatedness between the requested concepts and services. This leads to the high retrieval precision, recall and F-measure discovery process.

As future work, we will focus on integrating Micro-services and multi-agent systems (MAS) to reduce the time and complexity of composite semantic web services. Furthermore, we intend to enrich our system with the semantic descriptions of other functional aspects such as pre-conditions/post-conditions.

Linear Mixed Effect Modelling for Analyzing Prosodic Parameters for Marathi Language Emotions

Trupti Harhare, Milind Shah
Dept. of Electronics and Telecommunications
Fr. C. Rodrigues Institute of Technology, Navi Mumbai, India

***Abstract*—Along with linguistic messages, prosody is an essential paralinguistic component of emotional speech. Prosodic parameters such as intensity, fundamental frequency (F0), and duration were studied worldwide to understand the relationship between emotions and corresponding prosody features for various languages. For evaluating prosodic aspects of emotional Marathi speech, the Marathi language has received less attention. This study aims to see how different emotions affect suprasegmental properties such as pitch, duration, and intensity in Marathi's emotional speech. This study investigates the changes in prosodic features based on emotions, gender, speakers, utterances, and other aspects using a database with 440 utterances in happiness, fear, anger, and neutral emotions recorded by eleven Marathi professional artists in a recording studio. The acoustic analysis of the prosodic features was employed using PRAAT, a speech analysis framework. A statistical study using a two-way Analysis of Variance (two-way ANOVA) explores emotion, gender, and their interaction for mean pitch, mean intensity, and sentence utterance time. In addition, three distinct linear mixed-effect models (LMM), one for each prosody characteristic designed comprising emotion and gender factors as fixed effect variables, whereas speakers and sentences as random effect variables. The relevance of the fixed effect and random effect on each prosodic variable was verified using likelihood ratio tests that assess the goodness of fit. Based on Marathi's emotional speech, the R programming language examined linear mixed modeling for mean pitch, mean intensity, and sentence duration.**

Keywords*—Prosodic parameters; a marathi language prosody model; a two-way analysis of variance; linear mixed-effect models; r programming language

I. Introduction

The COVID-19 pandemic has drastically altered people's lifestyles in many parts of the world. The lockdowns and social distancing norms eventually increased human-machine interaction applications. If computers can recognise emotions, they can communicate in a human-like manner. The prosodic features employed for emotion recognition play an essential role in the quality of the human-computer interaction that replicates human speech emotions. Supra-segmental features or the prosody features such as intensity, pitch, duration, etc., contribute additional information to speech known as paralinguistic information [1-4] and characterize the emotional speech. Developing a prosodic model for emotional utterances for less-studied languages is very challenging. It entails a lot of work, such as creating a database, processing it for analysis, investigating the fluctuation of prosodic elements about emotions using acoustic analysis, and establishing the relevance of these aspects using statistical analysis. In India's Maharashtra and Goa states, the Marathi language is spoken by over 73 million people. In comparison, in the Marathi language, there is less research on prosody aspects for emotional speech. Few of them includes, the syudy of the effect of focus shift in Subject-Object-Verb type Marathi sentences on prosodic features such as F0, duration, and intensity variations[5]. Authors analyzed that the speakers consistently provide acoustic cues with increased duration, higher mean F0, and higher intensity, differentiating focus location. The authors of [6] used broadcast radio transmission Marathi news that are available to the general public to investigate the significant prosodic aspects of the Marathi news-reading style. The authors observed prominence and boundary as the important prosody cues for Marathi's news reading style. Acoustically, the boundaries showed pre-boundary lengthening and pitch contour slope on the final syllable, and the prominence correlated with maximum F0 and maximum intensity and lesser duration. The authors analyzed MFCC features and energy ratios in [7] to investigate the Marathi emotion recognition for anger and happiness. The authors observed the anger emotion recognition rate higher than happiness and neutral emotions. However, the authors suggested generating more emotional speech databases from skilled Marathi speakers.

Considering comparatively less work towards prosody features of Marathi language and lack of emotional database from trained speakers, the paper focuses on emotion analysis for the Marathi language. We constructed a Marathi emotion database from professional speakers with a theatre background in a recording studio expressing anger, fear, happiness, and neutral emotions. The detailed study of the relationship between acoustic features such as mean intensity, mean pitch, sentence duration, and the emotions such as anger, happiness, fear, and neutral for Marathi's emotional speech showed various prosodic cues based on the emotions. Also, a comprehensive statistical analysis was conducted to construct a practical framework for assessing emotional speech data. A two-way ANOVA test for emotion, gender, and their interaction for mean pitch, mean intensity, and sentence time, as well as a linear mixed-effect analysis, were used in the statistical study. The LMM analysis is used to examine the relationship between the emotions and prosodic features data while considering the impacts of fixed and random effect variables and their connection. The two-way ANOVA analysis and a linear mixed model (LMM) analysis contributed while selecting the optimal prosodic features for constructing a

prosody model.There is no comparable effort for the Marathi language that we are aware of.

This prosody model for the Marathi language using the acoustic and statistical investigation will help develop a human-machine interaction application such as emotion recognition from speech can help interpret students' answers and fit pupils with various learning abilities, Text-to-Speech systems (TTS) for Marathi storytelling, speaker recognition, speech recognition, online education etc. among other things.

The remainder of the paper is structured as follows: Section 2 contains a literature review, Section 3 explains the methodology and implementation for creating a Marathi database for various emotions and calculating prosodic features using the PRAAT speech analysis framework, Section 4 focuses on the results and discussion based on acoustic and statistical analysis to prepare a Marathi prosody model, and Section 5 summarises all of the discussions.

II. Literature Review

Speech is an important channel for the communication of emotion, yet studied little in the context of emotion. Speech conveys linguistic messages and includes a major paralinguistic part, prosody. The prosody of speech is defined in the linguistic literature as the suprasegmental properties of speech and include the pitch/F0, loudness/intensity, and rhythm/duration aspects (Brown 2005). Analyzing prosody features based on emotional speech is central to a few emotions. Although emotion classifications, in reality, are much larger, the majority of emotional speech statistics comprise four or eight emotions. Variations in prosodic elements concerning emotions, on the other hand, differ among languages and are dependent on culture and speaking style. As a result, it is vital to investigate the prosodic features for the emotional expressions specific to the language and culture. Fundamental frequency (F0), intensity, and duration are the essential acoustic characteristics influencing prosody. Fundamental frequency (F0) or pitch is the number of vibrations per second produced by the vocal cords, and the relative highness or lowness of a tone perceived by the ear determines pitch in speaking. The length of time a sentence, word, or syllable exists is called its duration. The intensity of a sound measures the energy contained in a given waveform signal. It is essential to analyze the prosodic features of emotion expression specific to the language and culture as emotions differ according to the cultural backgrounds, several international and national languages; the researchers are looking for acoustic correlates of prosody. Table I compares various prosody features studied in different languages based on distinct emotions and the corresponding dominant emotional signaling in the respective language.

Researchers often analyzed the database statistically after acoustic analysis to validate the acoustic analysis results and then select the best prosodic features to construct a prosody model [14-19]. Analysis of variance (ANOVA) findings investigate statistical discriminations of prosodic properties between various emotion classes. The success of ANOVA in identifying the best prosodic qualities to model the emotion recognition system has significantly reduced signal evaluation time. Hence, we have carried out a a two-way ANOVA analysis and linear mixed model (LMM) statistical analysis to design a prosody model for various emotions for Marathi. The LMM refers to using both fixed and random effects on the variables in the same analysis [20-23]. Due to the differences in prosodic variation patterns based on emotions, we examined three separate LMM models, one per prosody feature.

TABLE I. Comparison of Acoustic Feature Variations based on Various Emotions in different Languages

Reference	Language Studied	Emotions	Prosody Features	Emotional Signaling
Bansal S., Agrawal, S., Kumar, A., 2019[8]	Hindi	neutral, fear, anger, surprise, sadness, and happiness	pitch, intensity and duration	The most intense emotion is anger, followed by neutral, happy, surprise, sadness, and fear. For all emotions, the pitch fluctuates in accordance with the intensity feature of speech.
J. Kaur, K. Juglan, V. Sharma, 2018.[9]	Punjabi	happiness, anger, fear. Sad, neutral	Mean Pitch, Intensity and formants	Mean pitch highest for happiness and lowest for sad, Intensity is highest for anger and lowest for fear.
Swain, M.; Routray, A., 2016.[10]	Odia	anger, fear, happiness, disgust, sadness, surprise.	pitch, energy, duration, and formant	In both males and females, the feeling "happy" has the greatest mean pitch value, followed by "surprise" in a close second. All other emotions have significantly lower energy levels than disgust and fear. Female respondents showed no discernible differences in the amount of energy levels for distinct emotions.
Hellbernd, N.; & Sammler, D., 2014.[11]	German	Criticism, naming, suggestion, doubt, warning, wish	Mean duration, mean intensity, mean F0, Pitch rise, harmonic-to-noise ratio	The loudest and most arching pitch contour were seen in warning stimuli. Naming stimuli having a low mean pitch, flat pitch contour, and low intensity.
Rao, K.; Koolagudi, S., 2013.[12]	Telugu	Anger, Disgust, Fear, Compassion, Neutral, Happiness, Sarcasm, Surprise	Mean duration, mean pitch, mean energy	Anger emotion with the highest energy Anger, happiness and neutral have high pitch values
Liu, P., Pell, M.D. 2012.[13]	Mandarin	anger, sadness, happiness, disgust, fear, pleasant surprise, neutrality	mean fundamental frequency, amplitude variations, speech rate (in syllables per second). mean harmonics-to-noise ratio, HNR variation	Anger and pleasant surprise had comparatively high mean f0 values and significant f0 and amplitude variations, but sadness, disgust, fear, and neutrality had relatively low mean f0 values and minor amplitude variations, while pleasure had a moderate mean f0 value and f0 variation.

III. Methodology and Implementation

Because prosody varies by language and speaking style, studying the relationship between emotions and the accompanying prosody variants is vital for all languages. This study aims to see how the prosodic aspects of Marathi's speech change with emotions, and four sub-questions are investigated concerning it as below.

1) Do Marathi speakers employ changes in prosody elements to help them communicate the emotion they want to convey in their speech?

2) If so, what precise variations in an utterance's prosody are used by speakers to differentiate one emotion from another?

3) Is it possible to create a predictive statistical model of prosody variation based on emotions in Marathi that can be utilized as a prosody model for a variety of applications such as emotion recognition, speaker recognition, speech recognition, text to speech synthesis systems, etc.?

4) Is it possible to consider neutral emotion as a baseline and analyze variations of prosodic features concerning neutral emotion and be used for emotion conversion applications?

The workflow for conducting out the research is depicted in the steps below.

1) Collection of sentences.

2) Selection of trained speakers.

3) Recording the sentences in anger, happiness, fear, and neutral read-out style emotions.

4) Collecting the database in .wav format.

5) Processing the .wav files with segmentation, annotation, and creating corresponding text grid files in the PRAAT speech processing toolbox.

6) Calculating the mean pitch, mean intensity, and sentence duration for all the .wav files.

7) Calculating and analyzing acoustic behavior of the above prosodic features based on the emotions, gender, speakers, and sentences.

8) Statistial analyzation of these prosodic features using two-way ANOVA and LMM analysis.

The corpus was constructed by identifying the sentences for the recordings, finding expert Marathi speakers, practicing, and recording their acted utterances in a recording studio. Each line was deliberately crafted to avoid provoking any emotion. There were three to nine words in each sentence. Eleven Marathi professional artists, four females and seven males with experience in drama and television, aged 18 to 40, participated in the experiment. The research objective was conveyed to the speakers, and two practice sessions were arranged to get acquainted with the sentences. The participants were paid incentives for this work. The selected ten sentences from different Marathi storybooks listed in Table II along with their English translations.

TABLE II. The English Translation of Ten Marathi Sentences used for Recording

	Marathi Sentences	**English Translation**
1.	*आम्ही पण दहा बाय दहाच्या खोलीत राहतो .*	We stay in 10 by 10 room.
2.	*लेकीला सांगा तिचा बाबा आलाय.*	Tell daughter that her father has come.
3.	*मन मोठं असलं की सारं काही सामावून घेता येतं.*	Big heart accommodates everything.
4.	*अन्न वाया घालवू नये, त्याची किंमत कमवायला लागल्यावर कळेल.*	You will value food when you start to earn.
5.	*प्रत्येक दगड हा देव होतोच असं नाही.*	Every stone does not become God.
6.	*अंथरुण पाहून पाय पसरावे.*	Spend as per your earning.
7.	*गरीब माणसाची गम्मत करू नये.*	Do not make fun of poor people.
8.	*भाकरीची किंमत घाम गाळल्याशीवाय कळत नाही.*	You never understand value till you won't work for it.
9.	*डोकं शांत असेल तर निर्णय चुकत नाहीत.*	A calm mind takes always the right decision.
10.	*तुमचं बरोबर आहे.*	You are right.

Each speaker repeated the given sentences with different emotions such as anger, happiness, fear, and neutral. The speakers recorded the utterances in a recording studio with a condenser microphone and a digital audio tape (DAT) recorder using a lossless 44kHz, 16bit audio format and saved at a sampling rate of 16kHz. Each speaker initially recorded ten sentences in a single emotion during the recording. Between the two sentences, the speakers left a reasonable pause. After recording all ten sentences in one emotion, the speakers took a short rest before recording all ten sentences in another emotion. The recording procedure took over three months to complete. Each speech file was an a.wav file with 2-4 seconds duration. The entire database of 440 sentences (eleven speakers, ten sentences, and four emotions) was available for further study. Each line was listened to by fifteen people (twelve Marathi native speakers and three non-Marathi speakers). They were able to identify emotions such as anger, happiness, fear, and neutrality in each recorded voice recording. The perceptually verified sentences were segmented in a PRAAT Text Grid. The .wav file of all the sentences is annotated manually in a sentence and word level for better accuracy. We observed variations in pitch contour, intensity contour, and duration for the same sentence comprising four emotions uttered by every speaker. It showed that there is some relationship that exists between the emotional utterances and corresponding prosodic features even for the Marathi language. The mean values of mean pitch, mean intensity and sentence duration of 422 sentences were calculated using the PRAAT speech analysis framework. The mean pitch was calculated by 'getting the Pitch' command and the mean intensity was calculated by 'getting Intensity (dB)' by selecting the sound interval in the PRAAT editor window. Sentence duration is calculated by selecting the portion of the utterance and reading the duration of the selection (in seconds) from the duration bar from the PRAAT editor window.

IV. Result and Discussion

A. Acoustic Analysis

The mean and standard deviations of prosodic parameters such as mean pitch, mean intensity, and sentence duration were determined for all 422 utterances to check for variation in mean pitch, mean intensity, and sentence duration for distinct emotions. Table III shows the overall descriptive statistics for the three prosodic variables for all four emotional utterances.

From Table III, we can see that the amount of variation or standard deviations (SD) are high for the mean pitch with 25.58% and the sentence duration with 27.62%, while mean intensity appears fairly consistent with the amount of variation (SD) of 6.6%. The standard deviation provides some insight into the patterns of variation occurring within the data. We analysed the variations of means and SDs of all three prosodic variables independently of anger, happiness, fear, and neutral emotions to acquire a clear picture of the prosodic variations based on emotional utterances, as shown in Table IV.

Table IV shows that the mean and standard variation values of all the three prosodic features for anger and happy emotions, and fear and neutral emotions, are nearly identical. To understand variations of prosody features for emotions, other factors such as gender, speakers and sentences are also important. Fig. 1 gives the analysis of variations of mean pitch, mean intensity and duration for gender, speakers and sentences.

Fig. 1a demonstrated substantial differences in mean pitch values by gender, with males having lower values than females. Fig. 1b showed that males have variability in mean intensity than females, and Fig. 1c showed that both genders with similar observations for utterance duration. Fig. 1d, 1e, and 1f showed the variations of mean pitch, mean intensity, and sentence duration among the multiple speakers of the same gender. Fig. 1g, 1h, and 1i show the variations of the prosodic features concerning the ten different sentences. Fig. 1 shows that in the Marathi language, prosodic features vary for emotion change as well as variations in gender, speaker, and sentence. In Fig. 2, gives variation of prosodic features based on emotion and gender.

TABLE III. Descriptive Statistics for the Three Prosodic Variables

Prosodic Variables	Mean	Std. Deviation	Percentage
Mean pitch	217.70 Hz	55.69 Hz	25.58%
Mean intensity	69.74 dB	4.615 dB	6.6%
Sentence duration	2.69 sec.	0.743 sec.	27.62%

TABLE IV. Summary of Means and SDs of Each Prosodic Variable by Emotions

Emotion	Mean pitch (Hz)		Mean Intensity (dB)		Duration (sec.)	
	Mean	*S.D.*	*Mean*	*S.D.*	*Mean*	*S.D.*
Anger	254.7	46.6	73.69	2.58	2.27	0.57
Happiness	241.4	51.5	71.02	2.86	2.64	0.63
Fear	193.9	43.3	67.40	4.15	2.86	0.73
Neutral	179.5	42.2	66.77	4.71	3.01	0.82

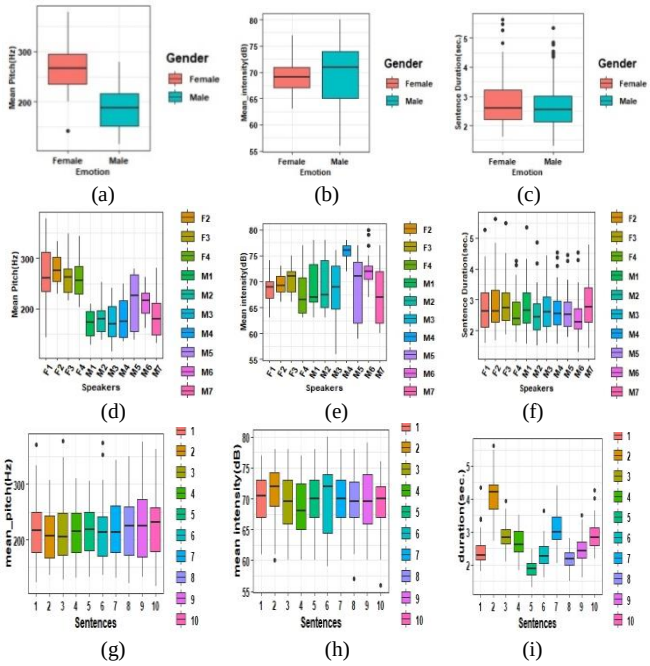

Fig. 1. Box Plots Showing Variations in mean Pitch mean Intensity and Sentence Duration (Figure 1a, 1b, and 1c) for Gender, Speakers (Fig. 1d, 1e, 1f) and Sentence Duration Due to Multiple Speakers (Fig. 1g, 1h, 1i).

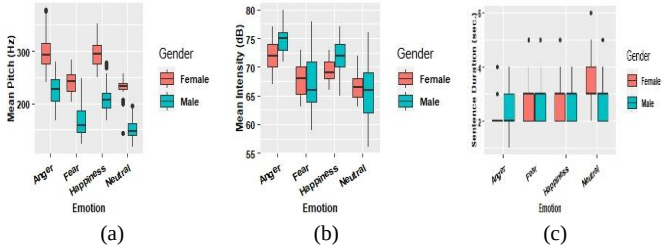

Fig. 2. Variations in (a). Mean Pitch, (b). Mean Intensity, (c). Sentence Duration for Emotions and Gender.

Fig. 2a and 2b showed variations in mean pitch and mean intensity for gender for all the emotions. There was little change in mean intensity levels for the fear emotion between male and female speakers. Each gender takes the same amount of time to speak the lines in fear and happiness observed in Fig. 2c. Female speakers took less time to express anger than male speakers, whereas female speakers' utterance duration was higher for neutral speaking style sentences. As a result, acoustic analysis of mean pitch, intensity, and duration revealed that prosodic features behave differently for emotions and gender.

For Hindi language, acoustic correlation of emotions were analysed for prosodic parameters such as pitch, intensity and duration in [24]. Authors have generated Hindi speech database with 10 speakers in all six emotions such as anger, Fear, Happy, Neutral, Sad and Surprise. Comparison between the prosodic parameters related to the emotions for Marathi and Hindi language given in Table V.

From Table V, comparing the prosodic variation patters for anger, happiness, fear and neutral emotions the pitch, intensity

and duration features observed with the following order by taking neutral emotion as reference.

Pitch : Neutral > Anger > Happiness > Fear (for Hindi).

Pitch : Anger > Happiness > Fear > Neutral (for Marathi).

Intensity : Happiness >Anger > Neutral > Fear (for Hindi).

Intensity : Anger > Happiness > Fear > Neutral (for Marathi).

Duration : Fear > Happiness > Neutral >Anger (for Hindi).

Duration : Neutral > Fear > Happiness > Anger (for Marathi).

When the behavior of variations of prosodic elements dependent on emotions is compared for the two Devnagari languages of India, Hindi, and Marathi, the relevance of studying each language separately for prosodic patterns based on the emotions becomes clear.

B. ANOVA Analysis

A two-way ANOVA analysis explored the impact of emotions and gender and their interaction on the mean pitch, mean intensity, and duration. Both emotion ($F = 205.7$, $p < 0.0001$) and gender ($F=872.1$, $p < 0.0001$) were significant for mean pitch, suggesting that gender is more responsible for mean pitch variations. The p-value for the interaction between emotion and gender was non-significant ($F =1.468$, $p=0.223$) indicated that the relationships between gender and mean pitch was independent of the emotion. For mean intensity, emotion ($F = 104.2$, $p< 0.0001$) and gender ($F= 9.528$, $p <0.001$) were statistically significant with emotion as the most significant factor variable. The p-value for the interaction between emotion and gender for mean intensity observed to be significant ($F =7.274$, $p <0.0001$) indicated that the relationships between gender and mean intensity depends on emotion. For sentence duration, emotion factor observed to be statistically significant($F = 16.142$, $p< 0.0001$) but gender as non-significant ($F= 0.923$, $p =0.337$). The p-value for the interaction between emotion and gender non-significant ($F =0.709$, $p = 0.547$) indicated that the relationships between gender and sentence duration depend on emotion.

TABLE V. THE PROSDIC FEATURE VALUES FOR MARATHI AND HINDI LANGUAGE FOR ANGER, HAPPINESS, FEAR AND NEUTRAL EMOTIONS

Prosodic Parameters	Emotions	Marathi	Hindi
Mean pitch (Hz)	Anger	254.7	303
	Happiness	241.4	300
	Fear	193.9	295.5
	Neutral	179.5	304.4
Mean Intensity (dB)	Anger	73.69	84
	Happiness	71.02	84.5
	Fear	67.40	81
	Neutral	66.77	83
Duration (sec.)	Anger	2.27	1.39
	Happiness	2.64	1.67
	Fear	2.86	2.8
	Neutral	3.01	1.66

C. LMM Analysis

Differences in prosodic features in Marathi are attributable to emotion fluctuations and gender, speaker, and sentence variations. Also, even if the independent variables such as emotions and gender have a somewhat consistent impact on prosodic feature variations, it can vary amongst speakers of the same gender or even between the different sentences. Linear mixed models are a type of regression model that takes into account variation explained by the independent variables of interest, known as fixed effects, and variation not explained by the independent variables, known as random effects [22]. The model is mixed since it combines both fixed and random effects. Thus, to calculate variations in prosodic features, emotion and gender factors are of primary interest and added as fixed effect variables. The emotion factor with four factors: anger, happiness, fear, and neutral emotions and gender factors included males and females: the speaker and the sentence considered random effect variables. Each prosodic feature was then verified for the model fit considering these factors. The goodness of fit of prosodic features for fixed-effect and random-effect variables, as shown in equation (1).

$$\text{Prosodic feature} = \text{emotion} + \text{gender} + (1/\text{speaker}) + (1/\text{sentence}) \quad (1)$$

Equation 1 shows the variations in the prosodic feature for the variations in emotion and gender as fixed effect variables and speakers and sentences as random effect variables with 1/speaker and 1/sentence as random intercept different for each speaker and each sentence individually.

The likelihood ratio tests to assess the goodness of fit to verify the significance of the fixed effect and random effect for each prosodic variable. The goodness of fit test confirmed the relevance of the fixed and random effect variables for prosodic feature variations.

1) Modeling mean pitch: The impact of fixed-effect variables on the mean pitch calculated by comparing the null effect models with fixed effect = 1 and two models with emotion as a fixed effect factor and the other model with emotion and gender as two fixed-effect elements shown in equation (2), (3) and (4) respectively.

$$\text{Mean pitch} = 1 + (1/\text{speaker}) \quad (2)$$

$$\text{Mean pitch} = \text{Emotion} + (1/\text{speaker}) \quad (3)$$

$$\text{Mean pitch} = \text{Emotion} + \text{Gender} + (1/\text{speaker}) \quad (4)$$

Chi-square difference tests showed the significant p-value of emotion with $\chi2(1) = 434$, $p < 0.001$ and of gender with $\chi2(1) = 23$, $p < 0.001$. Both emotion and gender observed to be significant with $p<0.001$ and considered fixed effect variables for mean pitch modeling.

In addition, likelihood ratio tests examined the goodness of fit and confirmed the relevance of the random effect variables' influence on the mean pitch. We compared the two null effect models, with fixed effect = 1 and one without sentence intercept, and sentence intercept with the following equation (5) and (6) respectively.

$$\text{Mean pitch} = 1 + (1/\text{speaker}) \quad (5)$$

Mean pitch = 1 + (1/speaker) + (1/sentence) (6)

Comparing the models with Chi-square difference tests, resulted $\chi 2(1) = 0$, $p > 0.01$. It showed that the inclusion of a sentence is not significant for mean pitch calculation since it does not improve the model fit.

The final design of the model fit to calculate the mean pitch model for Marathi emotional speech calculated as shown in equation (7) as below,

Mean pitch = Emotion + Gender + (1/speaker) (7)

As in equation (7), emotion and gender factors are fixed effect variables, and the speaker is a random effect variable for calculating the mean pitch model for Marathi's emotional speech. Table VI shows the impacts of fixed effect variables such as emotions (angry, happiness, fear, and neutral) and gender (male and female) on computing mean pitch values.

TABLE VI. FIXED EFFECT SUMMARY OF MEAN PITCH

Emotions	Estimate	Std. Error	t- value
Intercept (Neutral)	228.19	7.257	31.45***
Anger	75.51	3.19	23.64***
Fear	15.47	3.2	4.84***
Happiness	61.49	3.19	19.30***
Male	-77.40	8.756	-8.840***

*** =p< 0.001

The neutral emotion is used as an emotion baseline, while the female gender is a gender baseline. The estimate of the intercept value of 228.19 indicates that the mean pitch value for neutral emotion and female gender is 228.19Hz. The mean pitch values for other emotions were calculated from Table V based on the neutral emotion mean pitch value estimates. The estimate for the mean pitch value of anger emotion is 228.19+ 75.51= 303.7Hz, which is significantly higher than for neutral emotion ($t= 31.45$, $p<0.001$). Similarly, the estimate for the mean pitch value of fears emotion is 228.19 + 15.47= 243.66Hz, which is significantly higher than for neutral emotion ($t=4.98$, $p<0.001$). Similarly, the estimate of the mean pitch value for happy emotion is 228.19 + 61.49= 289.68 Hz, and this is significantly higher than for neutral emotion ($t= 19.30$, $p<0.001$). Also, the estimated value of the mean pitch of males of -77.40 based on a baseline of female gender means the pitch of males is lower than that for females by 77.40Hz. With this we can calculate mean pitch values for male gender for each of the emotion as; anger = 303.7 – 77.4 = 226.3Hz, happiness = 289.68 – 77.4 = 212.28Hz and fear =243.66 – 77.4 = 166.26Hz.

The Fixed Effects table, similar to most methods such as ANOVA, MANOVA, multiple regression analyses only focuses on group differences in changes in mean pitch values for emotions and gender. Understanding the mean pitch change at both the group and individual levels will be helpful to capture a complete overview of developmental changes in mean pitch values. Table VII summarizes the random effect of individual speakers on the mean pitch model design below.

TABLE VII. RANDOM EFFECT ANALYSIS FOR MEAN PITCH

Groups Name	Variance	Std. Dev.
Speaker	181.3	13.46
Residual	534.5	23.12

The variance due to the speaker is 181.3 and hence the standard deviation of 13.46Hz. This means that there can be variations in the fixed effect values due to variability between the individual speakers. The residuals are the random deviations from the predicted values that are due to some factors outside of the purview of the experiment. The estimate of the residual variance, with a standard deviation equal to 23.12Hz, represents the variability in individual emotion pitch values due to unknown factors.

2) Modeling mean intensity: The relevance of fixed effects on mean intensity was established by comparing null effect models with fixed effect = 1 to two models, one with emotion as the fixed effect factor and the other with emotion and gender as fixed effect factors as shown in equation (8), (9) and (10).

Mean intensity = 1 + (1/speaker) (8)

Mean intensity = Emotion + (1/speaker) (9)

Mean intensity= Emotion + Gender + (1/speaker) (10)

Chi-square difference tests showed the significant p-value of Emotion with $\chi 2(1) = 274.63$, $p <0.001$ and gender with $\chi 2(1) = 0.48$, $p > 0.1$. This means, emotion factor is significant for variations in mean intensity, but gender is non-significant.

A chi-square difference test calculated the inclusion of a random effect structure with random intercepts for speakers and sentences as shown in equations (11) and (12), respectively.

Mean intensity = 1 + (1/speaker) (11)

Mean intensity = 1 + (1/speaker) + (1/sentence) (12)

Comparing the models with Chi-square difference tests, we conclude that sentence inclusion is not significant for mean intensity calculation since it does not improve model fit, $\chi 2(1) = 0$, $p > 0.01$.

The final design of the model fit to calculate the mean intensity model for Marathi emotional speech calculated as shown in equation (13) as below.

Mean intensity = Emotion + (1/speaker) (13)

Table VIII gives the summary of fixed effect variables for calculating the mean intensity.

TABLE VIII. FIXED EFFECTS SUMMARY FOR ANALYSIS OF MEAN INTENSITY

	Estimate	Std. Error	t value
Intercept (Neutral)	66.76	0.73	91.39***
Anger	7.02	0.41	17.31 ***
Fear	0.68	0.41	0.096
Happiness	4.22	0.40	10.44 ***

*** =p< 0.001

The estimate of the intercept value of 66.76 indicates that the mean pitch value for neutral emotion 66.76dB. The estimates of mean intensity values for other emotions are calculated based on the estimates of intercept, i.e., neutral emotion mean intensity. The estimate for mean intensity of anger emotion is 66.76 + 7.02= 73.78 dB and this is significantly higher than for neutral emotion (t= 17.31, p<0.001). The estimate for mean intensity for fear emotion is 66.76 + 0.68 = 67.44 dB and this is not showing any significance with neutral emotion (t=0.096, p > 0.1). Similarly, the estimate for mean intensity for happiness emotion is 66.76 + 4.22 = 70.98 dB and this is significantly higher than for neutral emotion (t= 10.44, p<0.001).

Table IX summarizes the random effect of individual speakers on the mean intensity model design below.

TABLE IX. RANDOM EFFECT ANALYSIS FOR MEAN INTENSITY

Groups Name	Variance	Std. Dev.
Speaker	4.956	2.226
Residual	8.619	2.936

The variance due to speaker is 4.956, indicating the standard deviation in mean intensity is 2.23dB in the fixed effect values due to variability between the speakers. The residuals are the random deviations from the predicted values, with a standard deviation equal to 2.96dB representing the variability in intensity apart from speakers.

3) Modeling duration: The significance of fixed effects on the sentence duration was determined by comparing null effect models, where fixed effect = 1 and the two models one with fixed effect factor as emotion and the other with fixed-effect factors as emotion and gender as shown in equation (14), (15) and (16) respectively.

$$\text{duration} = 1 + (1/\text{speaker}) \quad (14)$$

$$\text{duration} = \text{Emotion} + (1/\text{speaker}) \quad (15)$$

$$\text{duration} = \text{Emotion} + \text{Gender} + (1/\text{speaker}) \quad (16)$$

Chi-square difference tests for duration showed the significant p-value for emotion with $\chi2(1) = 640.8$, $p < 0.001$ but non-significant for gender with $\chi2(1) = 2$, $p = 0.15$. This suggests that the variation in sentence duration is due to emotion rather than gender.

Also, the two null effect models, one without speaker intercept and the other with a sentence and speaker intercept, compared to determine the duration model fit for random effect variables as shown in equation (17) and (18) respectively.

$$\text{duration} = 1 + (1/\text{speaker}) \quad (17)$$

$$\text{duration} = 1 + (1/\text{speaker}) + (1/\text{sentence}) \quad (18)$$

The Chi-square difference tests showed that inclusion of sentence as one of the random effects is significant for the mean duration and it improved model fit, $\chi2(1) = 410.73$, $p < 0.001$.

The final design of the model fit to calculate the sentence duration model for Marathi emotional speech calculated as shown in equation (19) as below.

$$\text{duration} = \text{Emotion} + (1/\text{speaker}) + (1/\text{sentence}) \quad (19)$$

Table X gives the summary of fixed effect variables for calculating the duration given by the final design to calculate the duration for emotions equation.

TABLE X. FIXED EFFECTS SUMMARY FOR ANALYSIS OF DURATION

	Estimate	Std. Error	t value
Intercept (Neutral)	2.99	0.19	15.52***
Anger	-0.73	0.04	-16.42 ***
Fear	-0.14	0.04	0.002**
Happiness	-0.36	0.04	-8.104 ***

*** =p< 0.001, ** =p< 0.01

The estimate of the intercept value of 2.99 indicates that the mean sentence duration for neutral emotion is 2.99sec. The estimates of mean sentence duration values for other emotions are calculated based on the estimates of intercept, i.e., the mean sentence duration for neutral emotion. The estimate for the sentence duration anger emotion is 2.99 - 0.73= 2.26 sec and this is significantly lower than for neutral emotion duration (t= -16.42, p<0.001). The estimate for the sentence duration for fear emotion is 2.99 -0.14 = 2.85 sec and this is not showing any significance with neutral emotion (t=0.002, p = 0.01). Similarly, the estimate for the mean sentence duration of happy emotion is 2.99 -0.36 = 2.63 sec and this is significantly higher than for neutral emotion (t = -8.104, p<0.001).

Table XI, giving the summary of the random effect of individual speaker and individual sentence on the sentence duration model design as below.

TABLE XI. RANDOM EFFECT ANALYSIS FOR DURATION

Groups Name	Variance	Std. Dev.
Speaker	0.119	0.014
Sentence	0.59	0.35
Residual	0.32	0.10

The variance due to speaker is 0.014, and hence standard deviation of 0.119 sec. in the fixed effect values can be due to variability between the speakers. The variance due to the sentence is 0.35 and hence standard deviation of 0.59 sec. in the fixed effect values can be due to variability between the sentences. The residuals are the random deviations from the predicted values, with a standard deviation equal to 0.32 sec. represents the variation in duration values apart from speaker and sentence.

V. CONCLUSION

This work explains how to investigate acoustic clues for Marathi emotions, including anger, happiness, fear, and neutral. Eleven Marathi professional artists created a database of 440 words in anger, happiness, fear, and neutral emotions in a recording studio. According to an acoustic experiment, the features of mean intensity, mean pitch, and sentence duration

vary depending on the emotions. A two-way ANOVA and a linear mixed-effect analysis provided a valuable framework for studying emotional speech data and, as a result, best practices for generating an emotional speech corpus.

The following is the prosodic model for emotions in the Marathi language, with emotion and gender as fixed effect variables and speaker and sentences as random effect variables.

Mean pitch = Emotion + Gender + (1/speaker).

Mean intensity = Emotion + (1/speaker).

duration = Emotion + (1/speaker) + (1/sentence).

A detailed analysis of Marathi's emotional speech will help develop a prosody model. This model will help select appropriate input features for machine learning algorithms used in emotion classification applications. In the future, it will be beneficial to examine some more prosodic aspects for the Marathi language emotions. Sadness, surprise, and sarcasm are examples of other basic emotions that may be investigated for Marathi speech. Children, young adults, and the elderly can all be studied separately in a similar way. When these meticulously generated prosodic elements are fed into a machine learning model, they can aid in emotion recognition, text-to-speech synthesis, and other human-machine interaction applications in the future.

Kigali, Rwanda

***Abstract*—Spam emails have recently become a concern on the Internet. Machine learning techniques such as Neural Networks, Naïve Bayes, and Decision Trees have frequently been used to combat these spam emails. Despite their efficiency, time complexity in high-dimensional datasets remains a significant challenge. Due to a large number of features in high-dimensional datasets, the intricacy of this problem grows exponentially. The existing approaches suffer from a computational burden when thousands of features are used (high-time complexity). To reduce time complexity and improve accuracy in high-dimensional datasets, extra steps of feature selection and parameter tuning are necessary. This work recommends the use of a hybrid logistic regression model with a feature selection approach and parameter tuning that could effectively handle a big dimensional dataset. The model employs the Term Frequency-Inverse Document Frequency (TF-IDF) feature extraction method to mitigate the drawbacks of Term Frequency (TF) to obtain an equal feature weight. Using publicly available datasets (Enron and Lingspam), we compared the model's performance to that of other contemporary models. The proposed model achieved a low level of time complexity while maintaining a high level of spam detection rate of 99.1%.**

Keywords*—Machine learning; feature selection; feature extraction; parameter tuning

I. Introduction

Email is an online application that enables the exchange of data using electronic devices [1]. Email communication is quick, inexpensive, easy to duplicate, and widely available. Email can extremely be beneficial to businesses and organizations because it allows for the efficient, productive, and effective transmission of all types of electronic data [2]. Email communication began in the 1960s with the restricted functionality of sending information to users within the same computing environment only [3]. Recently, email has become the most common way of communication [4], serving users across computing platform environments. The average number of emails exchanged per day reached 293 billion in 2019 and is forecasted to reach 347 billion by the end of 2023 [5].

Despite its importance, email has become a vehicle for a variety of malicious programs [6]. It is estimated that 50% of all emails are spam [1]. Email spam, also known as junk mail, refers to any form of undesired, uninvited digital communication sent in large quantities [7]. Spam is usually sent via email [8] but can also be delivered via text messages, phone calls, or other social media platforms. Spam has been a big challenge, disturbing users and consuming their time. Spam also leads to phishing attacks, storage space misuse, decreased internet speed, and theft of critical information [5]. The financial losses caused by email spam are estimated to reach a total of USD 257 billion between 2012 and mid-2020 [9]. As a result, substantial negative impacts on the global economy, such as lower productivity have been identified. These factors hinder the development of the communication sector that can benefit governments, individuals, and business companies [10].

To combat the problems, various scientific research studies have been conducted, including the application of machine learning [11]. Previous scientific studies were categorized into three approaches, single-based machine learning, hybrid, and feature engineering [12]. In the first classification, a specific single machine learning algorithm was used to build a spam detection method [12]. Some popular classifications of machine learning algorithms include Naïve Bayes, Random Forest, Support Vector Machines (SVMs), and K-nearest neighbor (KNN) [5].

Support Vector Machines are supervised learning models, which are mostly used to analyze data for regression analysis and classification [13]. Every data item is plotted as a point in n-dimensional space where n is the number of features present with the value of each feature being that of a certain coordinate in the SVM algorithm. The classification is accomplished by finding the hyper-plane that best differentiates the two classes. Support Vector Machines achieves great accuracy on small, clear datasets but performs poorly on larger, noisy datasets with overlapping classes [14].

Naive Bayes is a machine learning classification algorithm commonly used for binary and multi-class classification problems. This algorithm is based on the Bayes Theorem, which states that given the known independent probability of each event and the reverse conditional probability of the pair of events, one may compute an unknown conditional probability of the pair of events [15]. The disadvantage of this method is that it makes assumptions that all attributes are independent, which is incorrect. In fact, by recognizing that some attributes are related, one can create patterns or common attributes from related attributes to minimize the number of features, hence reducing storage consumption.

Random Forest is a classifier that uses the number of decision trees on separate subsets of a dataset and averages their results to enhance its predicted accuracy [16]. Instead of

relying on one decision tree, Random Forest collects the forecasts from every tree and calculates the final output based on the majority vote of predictions. The technique is well-suited to classification problems with small datasets because a large number of trees may make it slow for real-time prediction.

K-nearest neighbor, also called Lazy Learner is another learning algorithm that works well in simple classifications [17]. When an email is classified, KNN tries to find the K-nearest neighbors by calculating the distance in each prediction. In high dimensional datasets, it becomes challenging for the KNN algorithm to compute the distance in each dimension resulting in poor performance.

A combined machine-learning (hybrid) algorithm generates a new line of spam detection methods. The approach combines a specific machine learning algorithm and other methodologies [12]. Wijaya [18] proposed a hybrid decision tree with logistic regression with a focus on reducing noisy data. Another researcher Dedeturk [5] introduced a model which uses logistic regression combined with an artificial bee algorithm. However, this model faces high computation costs.

The feature engineering classification focuses on offering a new set of features. Farisa [19] proposed an intelligent spam detection method and recognizes the relevant features by categorizing spam features into three categories. These are payload, head features, attachment features. Payload features are those that involve the email body, readability, and lexical features [19], while attachment features are the files that are combined within an email. Despite its benefits, this methodology cannot be used when there is an imbalanced dataset [19].

As reviewed, we identify that machine learning is an efficient method for detecting email spam. However, most of the existing models failed to consider the number of features in high-dimensional datasets, leading to high time complexities. Nevertheless, the finding by Majeed [20] shows that time complexity is an important factor to be considered in model development since it reduces the training speed and decreases the importance of the model to be used in online spam filtering [11]. Time complexity depends on the number of features required in a given model as well as whether the proposed method is linear or nonlinear [21]. Xia [22] proposed an approach based on reducing time complexity in rule-based filtering. Nonetheless, this is not currently a recommended approach due to inefficient results that require every time to change the rule.

High-dimensional datasets are datasets with many features. It is the excess number of features that leads to a high time complexity and sometimes a low detection rate (meaning low accuracy) [23], as illustrated in (1) - (8).

Recall formula for finding accuracy of the model [24].

$$Accuracy = \frac{Number\ of\ correct\ prediction}{Total\ number\ of\ prediction} \quad (1)$$

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (2)$$

Key: TN=True negative, TP=True positive, FN=False negative, and FP=False positive.

Example: Let us take 10,000 features for a high dimensional dataset and 2605 features for a low dimensional dataset with a test size of 0.34. For a high dimensional dataset, the number of correct predictions is described by the confusion matrix Table I.

Then from Table I, TP=1521, TN=1700, FP=136, FN=43.

$$Accuracy = \frac{1521+1700}{1521+1700+136+43} \quad (3)$$

From (3); $Accuracy = \frac{3221}{3400}$ (4)

Therefore, the accuracy of a high-dimensional dataset obtained from (4) = 0.947 (5)

For a low-dimensional dataset, the number of correct predictions is described in Table II.

Then from Table II, TP=98, TN=768, FP=0, FN=10

$$Accuracy = \frac{98+768}{768+0+41+98} \quad (6)$$

From (3); $Accuracy = \frac{866}{907}$ (7)

Therefore, the accuracy for a low-dimensional dataset obtained from (7) = 0.955 (8)

So, from (5) and (8), the accuracy of a high-dimensional dataset seems to be low compared to a low-dimensional dataset.

Therefore, this paper proposes an efficient hybrid model [25] of logistic regression, with the consideration of the time complexity in a high dimensional dataset. Our methodology combines feature extraction, feature selection, and parameter tuning methods. This approach will reduce the time complexity on high-dimensional datasets. It will equally reduce equal feature weight, overfitting, increase training speed and boost performance. The model uses the Big O notation to find the time complexity of different existing models with accuracy starting from 90%. The evaluation involves a calculation of time complexity in terms of the steps required to operate an input.

TABLE I. CONFUSION MATRIX FOR A HIGH DIMENSIONAL DATASET

Spam	43	1521

TABLE II. CONFUSION MATRIX FOR A LOW DIMENSIONAL DATASET

Actual	Predicted	
	Non-spam	*Spam*
Non-spam	768	0
Spam	41	98

The rest of the paper is structured as follows: the materials and methodology are presented in Section II while the results are discussed in Section III. Finally, the conclusion and future research direction are presented in Section IV.

II. Materials and Methods

A. Experimental Setup

The model was developed using Python (v3.7.1) in the Google Colab (GCC 7.5) environment on a 64-bit Windows operating system, equipped with 8GB of computer Random Access Memory (RAM).

B. Dataset

The experiments were carried out using two datasets derived from a public repository. This helped to validate the accuracy of the model for spam detection. The first dataset was obtained from the Kaggle repository, which was the Enron dataset with 10,000 samples, half of which were spam and half legitimate emails. The second dataset was the Lingspam with 2605 samples, out of which 433 were spam and 2172 legitimate emails. We analyzed the dataset in relation to their balance ratio which is computed by dividing the total number of genuine emails by the total number of spam emails. The balance ratios of Enron and Lingspam were 1 and 5 respectively. The dataset was then split into two, 67% for training and 34% for testing as described in Table III.

C. Pre-Processing

This step involved cleaning the data by removing missing values; transforming the data into a direct format that could be used by machine learning and splitting them for training and testing. Data transformation is a data mining approach that involves changing raw data into a usable format. This is because real-world data is usually inconsistent, inadequate, lacking in specific behaviors or patterns, and rife with mistakes [26]. Data preparation is a tried-and-true approach for overcoming such difficulties. Building a high-performing model needs a careful evaluation of the input data quality. Therefore, the dataset was pre-processed for the suggested model to perform intelligent diagnosis by extracting suitable characteristics from the data. The preprocessing involved several steps such as importation of the data and libraries, cleaning the data by removing missing values; converting the data into a direct format that could be used by machine learning, and splitting them for training and testing. The process of removing missing values and stop words is very important because of their non-informative in the email spam detection process. Apart from removing stop words, characters must also be converted to lowercase before tokenization. In our datasets, no missing values were found, and tokenization was done through the Sklearn library. The splitting test size was 0.34, meaning that 3400 samples of emails for the Enron dataset were used for testing and 6600 for training. For the Lingspam dataset 886 were used for testing and 1719 for training as shown in Table III.

D. Feature Extraction

This step involved converting email messages into a format that could be processed by a machine learning algorithm. Email spam features are obtained from three different methods, namely, the Heuristic approach, Term frequency (TF) analysis, and behavior approach [27]. In the first approach, emails are mined to discover and generate patterns and rules, while in the TF analysis; every word in an e-mail is specified as a feature. The behavior approach builds features based on knowledge about spammers' behavior. This is often gathered via header, attachment, and email flows between groups of e-mail users.

In this study, the Term Frequency Inverse Document Frequency (TF-IDF) method was employed as a feature extraction method. It is a combination of TF and IDF [28]. According to Kadhim [29], this helps to capture features that are more important within the body of an email. The importance of this method is that it reduces the limitation of equal feature weight obtained when TF is used. Term frequency is how many times a term appears in an email and IDF is how many times a term appears in all emails. Suppose an email contains 50 terms, where the term "none" occurs 10 times. Term frequency is obtained as shown in (9) and (10):

$$TF(t) = \frac{\text{Total no.of times a term occur in an email}}{\text{total number of terms in an email}} \quad (9)$$

$$TF(t) = \frac{10}{50} = 0.2 \quad (10)$$

Now let's say we have 5000 emails, and the term "none" occurs 50 times in all emails. Then TF-IDF is obtained as shown in (11) and (12):

$$IDF(t) = log\frac{500}{50} = 2 \quad (11)$$

$$TF - IDF(t) = 0.2 \times 2 = 0.4 \quad (12)$$

Therefore from (12) our TF-IDF (t) is 0.4

E. Feature Selection

Due to the presence of many features in a high-dimensional dataset, feature selection is an important step. This step involves picking up items that are more important to be used in model development [5]. Feature selection leads to less time complexity that increases the potential application in online spam filtering. Training an algorithm using all the features requires a large amount of memory and high time complexity [30]. Hence, reducing the number of features is very important, since it permits the machine learning algorithm to train faster due to the reduction of the number of steps taken to train the model. Additionally, reducing the number of features also eliminates overfitting [31]. This happens when the model fits more data than it needs and starts catching noisy and inaccurate data. Hence, the efficiency and accuracy of the model decrease.

To reduce the time complexity problem, our research used the Sklearn library, which implements the SelectKBest feature selection method. This method only selects the highest scoring features. It is a wrapper method that uses the score function of Chi-square to obtain the features. By using Chi-square only 450 features were selected. Chi-square is a mathematical formula used to determine if there is a relationship between the features and select those with the highest score only as indicated in (13).

$$\text{Chi-square formula} = \sum \frac{(O_{I-E_i})^2}{E_I} \quad (13)$$

TABLE III. DATASET SAMPLE, TRAINING AND TESTING SIZE

Dataset type	Sample size	Training	Test
Enron	10,000	6600	3400
Lingspam	2605	1719	886

Whereby O_i is the number of the class observed and E_i is the number of expected classes when there is no relationship between the feature and the target [32].

F. Proposed Model

Logistic regression is among the most commonly used algorithms for classification [33]. It is an efficiency model with low time complexity [25]. It is used to determine discrete data from a set of variables [34]. In logistic regression, instead of applying a line, we apply an "S" shape that determines the two largest values [35]. The "S" shape is called the logistic function [36] as shown in Fig. 1. It is used to convert every real value between 0 and 1 into another value [37]. The function uses the threshold value, which determines the likelihood of either 0 or 1. A value beyond 0.5 is 1 and below 0.5 is 0. A logistic regression formula can be formed from the linear equation as indicated in (14) – (16).

However, in logistic regression, y can be 0 - 1, so we divide (14) by 1-y. When y=0 we get 0, and when y=1 we get infinity. To match the equation, we need to transform (15) into a logarithm.

$$y = c + m_1x_1 + m_2x_2 + \cdots + m_nx_n \quad (14)$$

$$\frac{y}{1-y} = c + m_1x_1 + m_2x_2 + \cdots + m_nx_n \quad (15)$$

$$log[\frac{y}{1-y}] = c + m_1x_1 + m_2x_2 + \cdots + m_nx_n \quad (16)$$

After transformation, the formula obtained in (16) can be used for logistic regression.

In this research, the logistic regression was trained with 450 features obtained from the SelectKBest as identified in Fig. 2. The results were then optimized using random search with several parameters as shown in Table IV.

G. Parameter Tuning

When training the models in this study, the hyper-parameters were searched to find the ones with the best performance. A random search was used with the parameters as described in subsections 1-3 and values are presented in Table IV.

1) Penalty: This parameter has two options; ridge (L2) or lasso(L1). Both parameters are used in a regression method to reduce the time complexity of the model. However, while ridge is better for a high-dimensional dataset, lasso is better for a low-dimensional dataset.

2) Solver: This parameter has five solvers which are lbfgs, liblinear, sag, saga, and newton-cg. Liblinear is a decent choice for small datasets, while sag and saga are quicker for big ones [38]. Only lbfgs, sag, newton-cg, and saga can handle multinomial loss in multiclass issues.

3) The Inverse of Regularization Strength (c): It is a logistic regression trade-off parameter that affects the intensity of regularization. The larger values of c correlate to less regularization (where we can specify the regularization function).

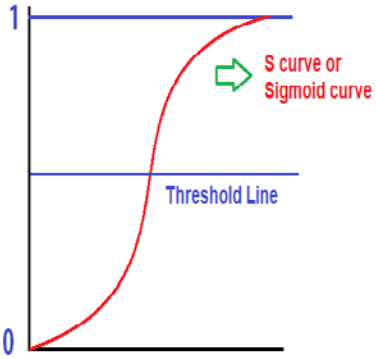

Fig. 1. Logistic Regression Graph [39].

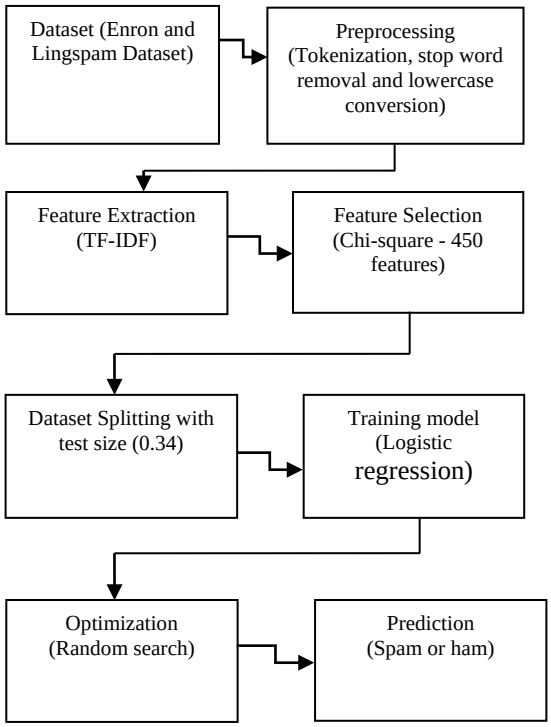

Fig. 2. A Proposed Logistic Regression Model Diagram.

TABLE IV. HYPERPARAMETER USED

Parameter	**Value**
Penalty	L1 and L2
Solver	Saga, sag ,lbfgs, newton-cg, liblinear
C	0.001,0.01,0.1,10,1000

H. Evaluation of the Classifiers

The evaluation of the classifier was evaluated by analyzing the model performance and time complexity during the training and testing procedures. In this study, evaluation was carried out by employing the confusion matrix and Big O notation. The evaluation measures utilized were accuracy, precision, recall, and time complexity each of which is described in subsections 1 – 4 below.

1) Confusion matrix: This is a table that defines the model's overall performance and displays the proper and wrong classifications for each class. Confusion matrix plots are used to show the trained model's ability in guessing the classes of data included in the set of test data. The test set evaluates a model's expected future performance. Table V shows the structure of the confusion matrix using our proposed model. Where TP = True Positive: the number of emails with spam and grouped as having spam, TN = True Negative: the number of emails without spam and grouped as not having spam, FP = False Positive: the number of emails with no spam and grouped as having spam, and FN = False Negative: the number of emails with spam and grouped as not having spam.

a) Accuracy: It computes the frequency with which predictions and labels are equivalent. The accuracy is calculated as shown in (17).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (17)$$

b) Precision: The number of correctly identified results divided by the total number of positive outcomes results. Equation (18) describes how precision is obtained.

$$Precision = \frac{TP}{TP+FP} \quad (18)$$

c) Recall: The number of accurately recognized positive findings by the total number of samples that should have been positive. A recall is obtained as indicated in (19).

$$Recall = \frac{TP}{TP+FN} \quad (19)$$

2) Big O notation: This is a mathematical study used to describe the complexity of different algorithms [40]. Time complexity is divided into two categories: the number of inputs an algorithm takes to operate and if the algorithm is linear or nonlinear [21]. Each algorithm in machine learning has its formula for finding the time complexity in terms of the steps used to operate an input. This research uses a logistic regression formula to find the time complexity of the proposed model due to its low time complexity compared to others. Table VI presents the formula for finding the time complexity of the different algorithms in machine learning [41]. Given:

O=growth rate of a model.

C=number of the class label for spam is 2spam or ham).

d=number of input/features.

k=number of neighbors, number of support vector.

e=number of epochs.

n=number of neurons.

III. Result and Discussion

This section discusses the results of the proposed model as obtained from the experiments carried out in this research. The results are divided into two parts, the first part shows the time complexity obtained using the Big O notation method as identified in Table VII. The second part shows the performance of the logistic regression when combined with TF-IDF and feature selection method in terms of precision, accuracy, F1-score, and recall as presented in Tables VIII and IX for Enron and Lingspam, respectively.

A. Complexity Result

In machine learning, the time complexity of the model is measured by two things; the type of algorithm used and the number of inputs an algorithm takes to operate. In our model, we used logistic regression which is linear. The advantage of a linear algorithm is its low time complexity relative to non-linear algorithms. Furthermore, when considering the number of inputs, the study used the Big O notation to describe the time complexity of the model as described in Table VI. The result shows that the proposed model attained low time complexity compared to other conventional models as shown in Table VII.

B. Performance Result Analysis

The classifier was evaluated by analyzing the model performance during the training and testing the outcomes. In this study, evaluation was carried out using the confusion matrix as shown in Fig. 3 and 4 whereby 0 represents non-spam and 1 represents spam. The evaluation measures utilized were accuracy, precision, F1 score, and recall. The results showed that saga and L2 parameters are very resourceful parameters in a high-dimensional dataset compared to other solvers because of their performance. Nevertheless, the results show that the feature selection method is an important part to be considered in model development since it reduces the computation time while the optimization process increases model accuracy. The proposed model was compared to other conventional methods and the results showed that the performance of the proposed model was higher than other models as indicated in Table X.

TABLE V. Confusion Matrix Structure

Actual	Predicted	
	Non-spam	*Spam*
Non-spam	TN	FP
Spam	FN	TP

TABLE VI. Formula for Time Complexity

Algorithm	Formula
K-nearest neighbor	O (knd)
Logistic regression	O (nd)
SVMs	O (n^3)
Decision tree	O (n*log (n)*d)
Naïve Bayes	O (n*d)
Deep learning	O(c*d*e*n)

TABLE VII. RESULTS AND COMPARISON ANALYSIS FOR TIME COMPLEXITY

Author	Algorithm and Accuracy obtained	Number of features selected	Time complexity in the training phase(step used)
[5]	Logistic regression- 98.4%	500	O(cd)=2*500 1000 steps
[42]	Deep learning-96.43%	3000	O(c*d*e*n)=2*3000*2*2 24000 steps required
[43]	Naive Bayes-96.87 %	1319	O(c*d)=2*1319 2628 steps required

Model	Accuracy
[5]	98.4%
[44]	96.63%
[11]	96.7%
Proposed model	99.1% and 98.3 respectively

IV. CONCLUSION

In this paper, a hybrid logistic regression model was proposed to reduce the time complexity in a high-dimensional dataset that will increase the potential of the model in online spam detection. The model performs three different tasks that are feature extraction, feature selection, and parameter tuning. TF-IDF was used during feature extraction to replace the drawbacks of equal feature weight obtained when TF is used. To increase the training speed in the high-dimensional dataset the model uses Chi-square that helps to select the feature which is related to each other with the highest score only. A random search was used to optimize the model performance. The performed task help to reduce time complexity by decreasing the number of features in a high-dimensional dataset. The model also uses the TF-IDF feature extraction method to reduce the disadvantage of equal feature weight obtained when TF is used. The experiment shows that a better performance of 99.1% is achieved when feature selection is combined with parameter tuning. Overall, it can be concluded that feature selection is an important part of a high-dimensional dataset that helps to reduce an excessive number of features. Nevertheless, for future work, more research is needed in other feature selection and parameter tuning methods.

ACKNOWLEDGMENT

I would like to sincerely thank the Government of the United Republic of Tanzania for funding this research through the Ministry of Education, Science, and Technology (MoEST).

Furthermore, I would like to acknowledge my supervisors, Dr. Jema David Ndibwile and Dr. Anael Sam for their excellent guidance and supervision of this research. Also, I would like to thank my colleague Stephano Amoni for his constant support in this research.

***Abstract*—The emphasis of this work is image encoding based on permutation as well as changes that utilize Latin cube as well as Latin square image cipher meant for both color and gray images. Generally, multimedia data are transmitted in the network as well websites, numerous methods have been established for securing the information without any negotiation. Security of information in all the areas is required to ensure that the information sustains privacy, is presentable for recovery as well as governance purposes. These data can be secured by taking CIA (confidentiality, Integrity, and Availability) to realize information like confidentiality about the data that can be reserved as undisclosed from an illegal user of source, the integrity of the data is maintained unaffected for unauthorized font, availability of resources for official personal to retrieve data for access the information. Authentication of a person is by identification, conserving information and its validation of data. Implementing this authentication will store the data in the required format that is either exchanged or transmitted for the internet application. By breaching the misuse of data is can be protected for confidential as well as sensitive data. To achieve security and maintain confidentiality cryptographic methods are implemented.**

***Keywords*—Decryption; encryption; Latin square generator; sequence generator**

I. INTRODUCTION

In the current scenario security of data is the main issue to maintain confidentiality as well as privacy. The main concern is managing the data while communicating as well as storing data from stealing as well as exploiting the data. For this purpose, an appropriate method has been employed for securing the data while transmitting as well as storing the data by utilizing the technique of cryptography. The information is utilized in the form of a plaintext image. The encryption technique converts this plaintext image into an unidentifiable form that cannot be easily decoded. By employing the decryption process, it is possible to get back original information by utilizing the Cipher text method. The main solicitations of this image encryption are many, some of them are military application, medical images, communication via the internet and many more. In this electronic era, cryptography is applied to provide various types of security to different electronic devices [1]. New encryption for images that utilize permutation-substitution network and chaotic systems has provided a better result in terms of both qualitative and quantitative studies that is superior to other techniques [2]. Generally, an intelligent technology that can protect the information from unauthorized person to hack or decode, that the data is immune to attack. This will implicate various techniques such as decipherment in symmetric and asymmetric keys [3] [20]. This process uses the decryption and encryption of data that is equivalent to electronic locking of knowledge [4]. This technique uses a private or secret key that can be shared only with receive for decoding as well as encoding the information. A novel technique based on memristive chaotic for random behavior is used for encryption has resulted in effective results in the decryption and protecting the data [5] [16]. The behavior of chaotic systems is mainly categorized using sensitivity based on dependence on primary situations. By using this chaos for self-synchronization has ignited a huge work in the field of cryptography [6] [15]. For certain initial conditions, some nonlinear functions can generate chaotic or random numbers. By utilizing a one-time pad system and replacing it with proper chaotic function cryptographic results can be improved [7]. Encryption of probabilistic image for LSB plane using random noise provides better diffusion as well as confusion properties with error tolerance [8] [10]. The security analysis is tested for different types of attacks [9] [18]. Decipherment of plain text is called secret information of plain text p and cipher text C is encrypted [11]. Latin square and CNN, for the input image are implemented bitwise and encrypted and decomposed to obtain encrypted image [12] [17]. Input image based on Latin Square creates 256 bits' key, which is operated by ex-or with Latin square to obtain encrypted images [13]. Latin rectangle scrambling using chaotic map reduces the number of iteration for achieving better security [14]. Latin square with S box and chaotic system results in better security [19]. For decryption, decoding the cipher image accompanying lookup table with index numbers results in effective and secured results [21]. Images of multimedia and its application are focused on efficient encryption and decryption to obtain better results [22].

This article is organized as follows, Section 2 provides the background of encryption methods. Section 3 explains the methodology of implementation of Latin square that generates and Substitution for cipher image as well as Whitening of premature images. Whereas Section 4 provides and evaluates the results and Section 5 concludes this paper.

II. Background

With the evolution of information technologies and pandemic situations, present days, people have started to use the internet and images in their daily routine. So encryption of images is gaining huge momentum for the present situation. For security reasons, image encryption converts the original images into unrecognizable images, Medical images, military services as well as its affair application, e-commerce, telecommunication, and many applications that gains the prominence of image encryption. In the present scenario, usage of text data has been reduced because of the advantages of the security in the digital images, since a different enormous amount of information like wide content, maximum data, as well as monotony and an exceptionally authoritative correlativity, can be obtained by the neighborhood pixel.

A. The Objective of the Work

Cryptography deals with mainly three core capacities like integrity, authenticity and confidentiality, which defends the digital data from hackers or unauthorized users from theft. By using encoding, the confidentiality of information is hidden is known as data privacy. The private key is used to extract the image at the transmission of the data. For the decryption of information, the same private key is used that has been used for encryption. Authenticity assurances that a person or a process can be identified receiver by their identification method. If the same data has been transmitted to the receiver ensure that data is integrated, without loss of any information sent by the transmitter.

III. Methodology

Misuse and theft of information are the main threat while storing and transmitting images, to a major amount of care has to be taken to maintain confidentiality and privacy. A technique based on cryptography can be utilized to store information as well as communication of data in plain text data. The process regarding hiding a given message as a fragment of a specific kind with accurateness to protect the data is encoding. The technique of converting cipher content back into plain text without any loss is deciphering.

As a part of security and confidentiality, the encrypting technique has gained momentum in the present situation. Information safety is a significant subject as part of communication purposes and for image storage, encryption is a distinct behavior that can secure the information. For this purpose, encrypting has enormous applications Image encoding includes a huge number of applications Encrypting text messages may lead to unrecognizable information or trash data known as cipher content. This technique is utilized to guarantee that data hidden from others of concern is not intended to, furthermore, individuals can recognize the encoded data. The technique of recovering the cipher text to its reliable plaintext is known as decryption.

A. Latin Square

A Latin Square is a collection N*N is jumble-sale of demonstration of N different elements, that all the elements representation considering exactly just the once in each distinct row along with each distinct column. Fig. 1 represents an example of a Latin square.

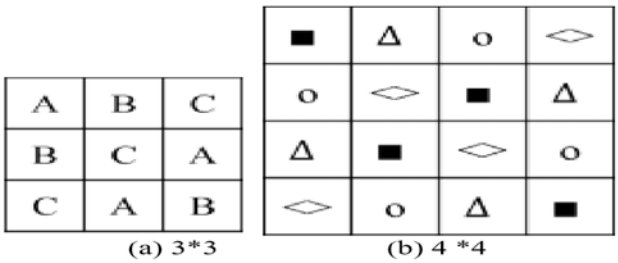

Fig. 1. Latin Square with Dissimilar Sets and Orders.

B. Latin Square Generator

A Latin square is created by using two structures of identical length. If P1 and P2 are two sequences of length equal to N arrangements [11].

LS=LSG (P1, P2)

P1 and P2 are input sequence

Ensure: - LS is a N order Latin square

S1 = Sort Map function (P1)

S2 = Sort Map function (P2)

For i=0 to N-1

LS (i,:)=Row shift(S1, S2(i))

End

P1 and P2 are two input sequences that are aimed to generate a pseudo-random number generator. Sort Map function (S1, S2) is classifying function with index in the middle of an S1 and S2 series, as a sequence of acclivitous order can be obtained by transformed edition S1*, and operated on Row Shift is through (S1, v) which is a periodic transfer of the S1 arrangement with v elements to the left [9][10][11].

C. Substitution-Permutation Network

Input information in cryptography is represented as plaintext and the resultant output information is called cipher text. A substitution-permutation network (SPN) is a sequence of cipher that includes various iterations, for each iteration includes a replacement, a variation and an additional key. It is a sequence of mathematical equations utilized for block cipher or different algorithms. Block ciphers algorithms are designed employing replacing and variation in various forms of SPN. Throughout the N-iteration variation and replacement of the given network, a plaintext will be converted into a new bit series and symbolized as P, which is primary and source content that has to be encoded. SNP that has been encoded to obtain the cipher text in the bit sequence C, by using this technique. Fig. 2 represents the substitution permutation network. A commonly used procedure to persistently synthesis with a given key for the plaintext is known as Latin square

whitening. Replacement of one byte to other bytes in the input sequence is known as Latin Square Substitution. Whereas shuffling bit location in the input sequence is done in Latin Square Permutation. Similarly, the reverse will be implemented in the decryption process of a substitution and permutation network cipher.

D. Latin Square Image Cipher

In the encoding and decoding technique for cipher, the treatment block is by splitting (32*32) bytes of segmented grayscale, for which its definite pixel value with the intensity of 256 levels (1byte). In this algorithm P is a plaintext image is to be defined by (32*32) byte, whereas cipher image C is denoted by (32*32) byte, Latin Square is denoted by L (32 bytes), and the encoding key is denoted by K (32 bytes) encoding key. This suggested technique iterates for 4 and 8 rounds of substitution as well as permutation network structure respectively. Fig. 3 represents Latin square image Cipher with 8-round SPN.

E. Latin Square Whitening

By utilizing a typical SPN method for ciphers block, the mixing of the content of plain text P along with key using rotation is implemented by using logical operations such as XOR procedures. In this proposed algorithm plain text P is composed of 1byte per pixel for the encoding process. In a normal predictable technique, logical whitening using XOR turns out to be intolerable, because of unsuccessful of information in images. Mixing the content of plaintext with that of a sequence is the to generate the Latin square is intended in whitening, for this purpose cipher is reorganized through Finite field or Galois field for plain text image that can be represented as

f = [r + l] 2^8

The reverse of whitening technique to obtain Latin square can be obtained by using this equation,

r = [f + l]2^8

Where f is the whitening result in the byte.

l is the Latin square in the byte.

r is a plain text image in the byte.

2^8 is used to calculate Galois or finite field.

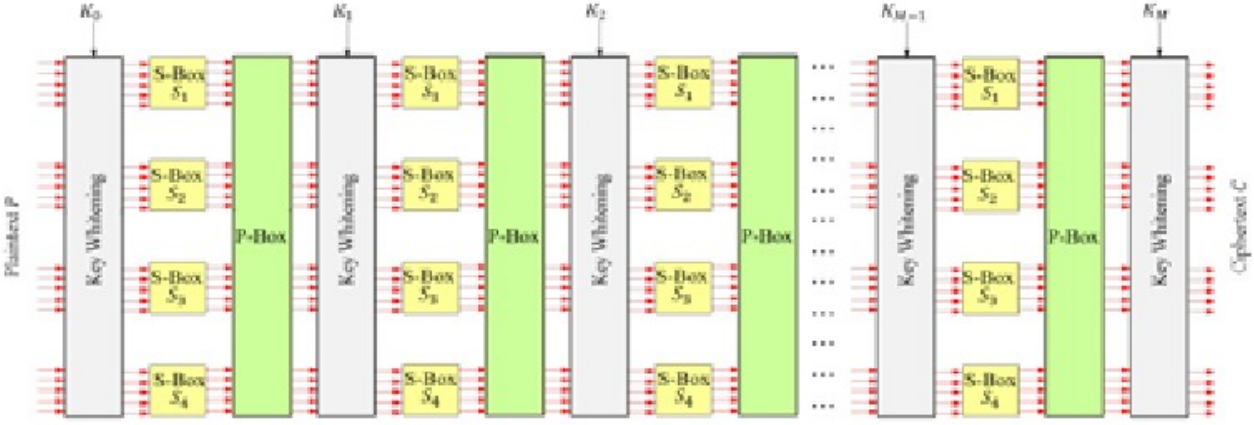

Fig. 2. Substitution-Permutation Network.

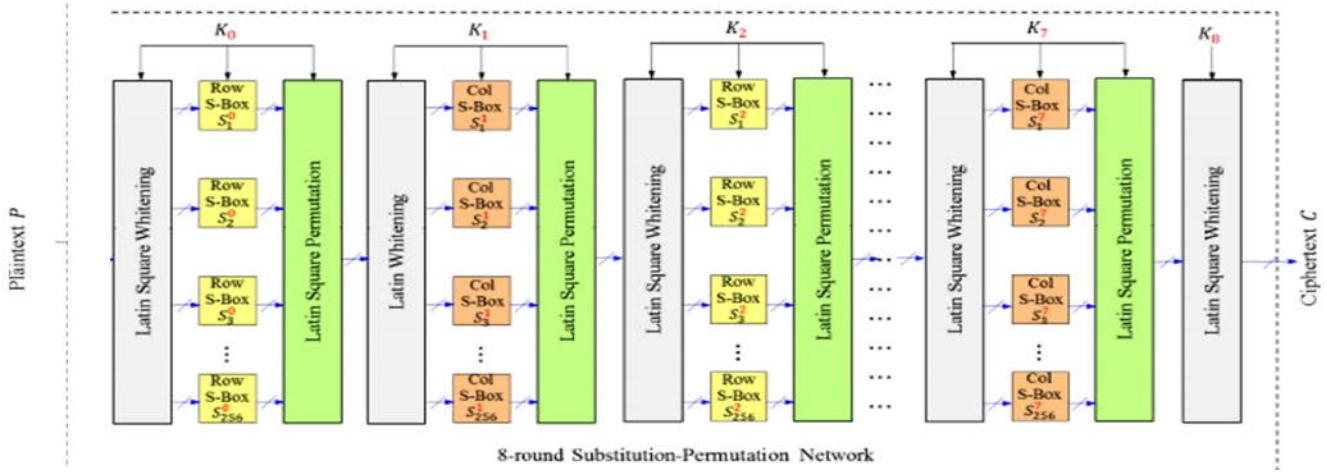

Fig. 3. Block Diagram of Latin Square Image Cipher with 8-round SPN.

F. Latin Square Substitution

S-box is frequently applied to accomplish byte substitution in the calculation of cryptographic images. All S-Box is recognized as bijection, furthermore a definite function that can be mapped as one-to-one. In the encoding process, image pixels are associated with the image as 8-bit or byte. That is a grayscale image of 8-bit that contains intensity with a grayscale of 32-byte along with every intensity is essential of 8-bit. Normally there is a presence of forwarding row and column mapping, this forward column along with row mapping will map to Latin square. Byte replacement is achieved in image cipher by the corresponding mapping which is termed as Latin Square S-box of replacement.

$$\text{LSRS:}\begin{Bmatrix} C = Ecr(L,P) \\ P = Dcr(L,C) \end{Bmatrix}_{ROW}$$

LSRS function in form of a pixel in cipher image is represented in row forwarding plotting function merely by Latin Square L via a function restriction to have cipher text, similarly, IRM is the reverse function to obtain plaintext.

ECR_s^{row}:

$$C(r,c)=\begin{Bmatrix} FRM(L,C(r-1,c),P(r,c)), if\ r \neq 0 \\ FRM(L,0,P(r,c)), if\ r = 0 \end{Bmatrix}$$

DCR_s^{row}:

$$P(r,c)=\begin{Bmatrix} IRM(L,C(r-1,c),C(r,c)), if\ r \neq 0 \\ IRM(L,0,C(r,c)), if\ r = 0 \end{Bmatrix}$$

$$\text{LSCS:}\begin{Bmatrix} C = Ecr(L,P) \\ P = Dcr(L,C) \end{Bmatrix}_{COL}$$

Similarly, for the column pixel function of LSCS, cipher image is represented utilizing FCM function over Latin Square L to obtain ciphertext. Similarly, ICM is a reverse function to obtain the plain test and is represented as.

ECR_s^{col}:

$$C(r,c)=\begin{Bmatrix} FCM(L,P(r,c),C(r,c-1)), if\ c \neq 0 \\ FCM(L,P(r,c),0), if\ c = 0 \end{Bmatrix}$$

DCR_s^{col}:

$$P(r,c)=\begin{Bmatrix} ICM(L,C(r,c),C(r,c-1)), if\ c \neq 0 \\ ICM(L,C(r,c),0), if\ c = 0 \end{Bmatrix}$$

After implementation of Latin square substitution, input plaintext image P will have converted in an unidentifiable image, by applying LSRS and LSCR, the resultant output will be in histogram pattern.

G. Latin Square Permutation

The permutation is mainly required to use P-box for its implementation. This P-Box is referred to as bijection, which specifies one-to-one mapping. This P box of Latin square will plot corresponding integer numbers to each row or column that permutes a series of data in integer. Latin square permutation can achieve both forward and reverse plotting for both row and column mapping function for the r^{th} row and c^{th} column respectively and represented as:

$$\begin{Bmatrix} y = FRM(L,r,x) = L(r,x) \\ x = IRM(L,r,y) = argmax(f(r,z,y)) \end{Bmatrix}$$

$$\begin{Bmatrix} y = FCM(L,x,c) = L(x,c) \\ x = ICM(L,y,C) = argmax(f(r,c,y)) \end{Bmatrix}$$

where x and y, represent input and output relating to plotting function, respectively.

IV. Result and Discussion

Implementation of this work for Encryption as well as Decryption was using MATLAB R2014a, results were simulated and are explained as provided. The results have been divided into four parts as shown below.

A. Encryption and Decryption for 8 Round Grayscale Image

Encryption of grayscale Latin Square Cipher image block for 8 rounds, requires a 32-byte K key, 32*32 bytes, 1byte image block (grayscale) for P to determine C that is of 32*32 byte of grayscale with 1 byte of the block, Fig. 4 represents a Latin square grayscale cipher image block for 8 rounds of encryption.

Similarly, for 8 rounds of decryption value P is determined for the grayscale 1 byte of 32*32 bytes by utilizing the key (K) and Cipher images (C) that is of 32-byte key and grayscale of 1 byte of 32*32 byte. Decryption for 8 round grayscale cipher image using Latin Square is as shown in Fig. 5. For this purpose ship image available in MatLab is utilized for encryption as well as decryption.

B. Encryption and Decryption for 4 Round Grayscale Image

Encryption of grayscale Latin Square Cipher image block for 4 rounds, requires a 32-byte K key, 32*32 bytes, 1byte image block (grayscale) for P to determine C that is of 32*32 byte of grayscale with 1 byte of a block, Fig. 6 represents a Latin square grayscale cipher image block for 4 rounds of encryption.

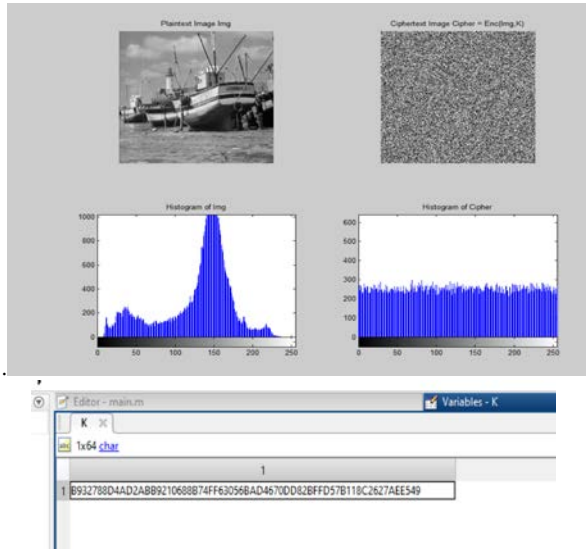

Fig. 4. Encryption of Latin Square Grayscale Cipher Block Image after 8 Rounds.

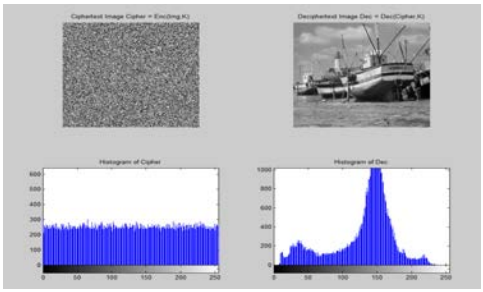

Fig. 5. The Decryption of Latin Square Grayscale Cipher Image after 8 Rounds.

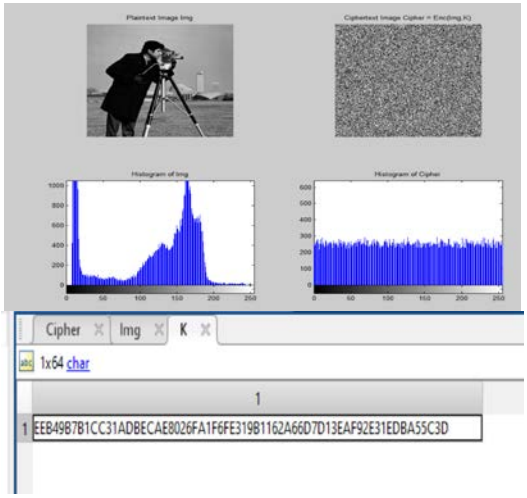

Fig. 6. Latin Square Grayscale Image Cipher block- Encryption for 4 Rounds.

Similarly, for 8 rounds of decryption value P is determined for the grayscale 1 byte of 32*32 bytes by utilizing the key (K) and Cipher images (C) that is of 32-byte key and grayscale of 1 byte of 32*32 byte. Decryption for 8 round grayscale cipher image using Latin Square is as shown in Fig. 7. For this purpose, in internet-based cameramen image utilized that is available in Mat lab for both encryptions as well as decryption.

C. Latin Cube Color Image Cipher block- Encryption and Decryption

Encryption and decryption of grayscale Latin cube color Cipher image require a 32-bit K key, 32*32 bytes, image block (color) for P to determine C and for decryption, it is to find back P image with Key K, Fig. 8 represents a Latin cube color cipher image block for both encryption as well as decryption.

D. Key Change Analysis

1) Encryption and decryption process for Latin Square Grayscale Image Cipher block with the same key (8 rounds): Encryption of grayscale Latin Square Cipher image block for 8 rounds, requires a K key, plain text image P to determine C. For decryption P is determined with the same key and C block, Fig. 9 represents Latin Square Grayscale Image Cipher block- Encryption and Decryption for 8 Rounds. After applying the same key for encryption and decryption with the same K (32 bytes) the resultant image is obtained and is as shown. Fig. 10 represents Latin Square Grayscale Image Cipher block- Encryption and Decryption for 8 Rounds (when a key is same). So the distortion at receive is minimum when data is retrieved.

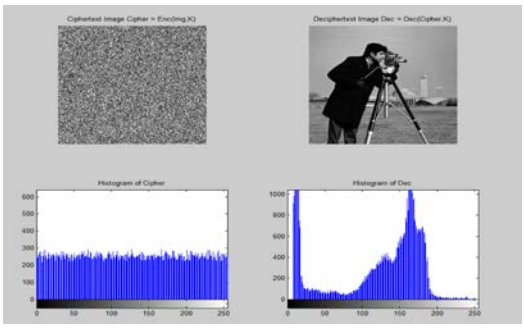

Fig. 7. Latin Square Grayscale Image Cipher for block- Decryption for 4 Rounds.

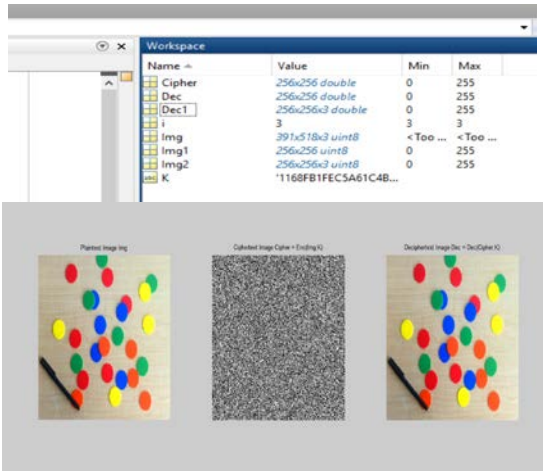

Fig. 8. Latin Cube Color Image Cipher block- Encryption and Decryption.

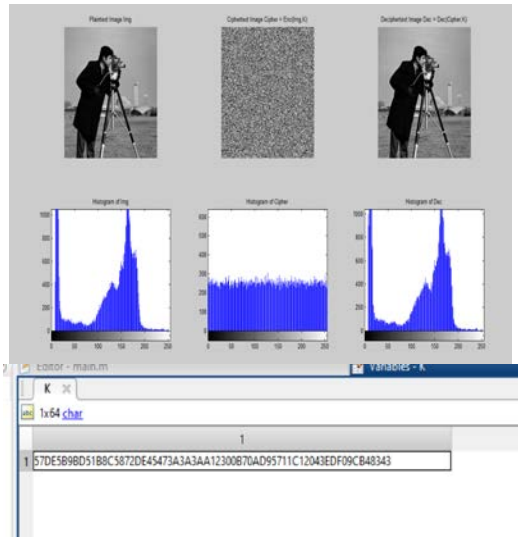

Fig. 9. Latin Square Grayscale Image Cipher Block- Encryption and Decryption for 8 Rounds.

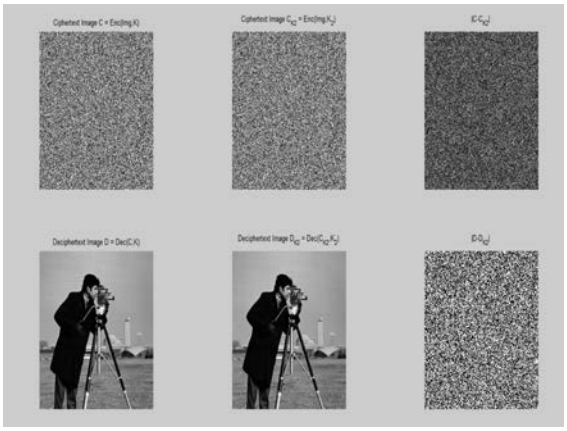

Fig. 10. Latin Square Grayscale Image Cipher Block- Encryption and Decryption for 8 Rounds (When a Key is same).

2) Encryption and decryption process for Latin Square Grayscale Image Cipher block with a different key (8 rounds): For encryption K1 key is required that is of 32 bytes, it is used to determine the value of C that is of size 32*32 bytes by using the cipher image P of size 32* 32 bytes. Similarly, in the decryption stage the value of plain text P employing cipher image C and different key K2, the result is as shown in the diagram. Fig. 11 shows different keys used for encryption and decryption for Latin Square Grayscale Cipher image for 8 rounds. The results can be compared with the images decryption with the same as well as different keys. The images obtained from different key has shown that is similar salt and pepper noise, which shows that the image that has been decrypted is unrecognizable when compared to that of decryption using the same key. The image decryption obtained from the same key has shown a better result when compared to that of a different key.

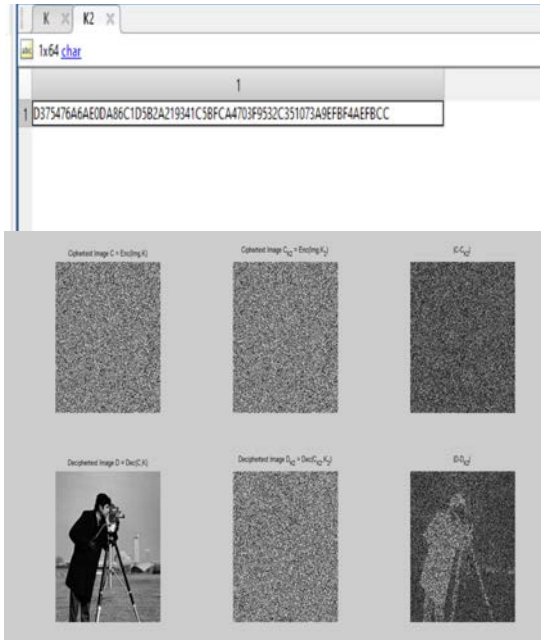

Fig. 11. Different Keys were used for Encryption and Decryption for Latin Square Grayscale Cipher Image for 8 Rounds.

The result can be tabulated as shown in the comparison table. Table I represents the difference between the plain images and deciphers images after decryption image, where decipher images have shown a better result when compared to the normal decipher images. Table II shows the comparison between the present work as well as the base paper for both correlation and entropy are better when compared to the results [1].

TABLE I. COMPARISON RESULTS

Features	Plain image	Decipher image
Contrast	0.587162	0
Correlation	0.922726	Nan
Energy	0.18037	1
Homogeneity	0.8952	1
Mean	118.73	118.73
Standard deviation	62.44	62.35
Entropy	7.009	0

TABLE II. COMPARISON WITH BASE PAPER

Feature	Base paper	Proposed result
Correlation	0.9227	0.9315
Entropy	7.997	7.0097

V. CONCLUSION

In this work, a unique image is constructed that is cipher based on Latin square as well as Latin cube. By using a grayscale image of Latin square plaintext P of 32*32 bytes is encrypted using key K to obtain cipher images of size 32*32, with histogram where Latin square is n*n 2 dimensional attribute. Implementation of Latin cube for the color image is implemented using P and K key, the color image has shown better performance for the Latin cube that has a 3-dimensional attribute. The results obtained are compared with the implementation of the paper by Xu [1] has shown a better performance both in correlation as well as entropy. By using the different keys of the image is decrypted the results have shown a salt and pepper image that cannot be recognized as the original image. Simulation results have shown that the developed algorithm will preserve better security as well as advanced efficiency appropriate for real-world application. LSIC analysis has shown that Latin cube and Square in the cryptographic application have a better safety portion in terms of security as well as privacy from hackers with the change in key. Experimental security analysis with comparison between the plain image as well as decipher image is shown in the table. The distinction between plain image and decode image for the same key was 0.0037%. This result shows same data has been transmitted to the receiver to ensure that data is integrated, without loss of any information sent by the transmitter

A Review of Feature Selection Algorithms in Sentiment Analysis for Drug Reviews

Siti Rohaidah Ahmad, Nurhafizah Moziyana Mohd Yusop, Afifah Mohd Asri, Mohd Fahmi Muhamad Amran
Department of Science Computer, Faculty of Defence Science and Technology
Universiti Pertahanan Nasional Malaysia, Sungai Besi
Kuala Lumpur, Malaysia

***Abstract*—Social media data contain various sources of big data that include data on drugs, diagnosis, treatments, diseases, and indications. Sentiment analysis (SA) is a technology that analyses text-based data using machine learning techniques and Natural Language Processing to interpret and classify emotions in the subjective language. Data sources in the medical domain may exist in the form of clinical documents, nurse's letter, drug reviews, MedBlogs, and Slashdot interviews. It is important to analyse and evaluate these types of data sources to identify positive or negative values that could ensure the well-being of the users or patients being treated. Sentiment analysis technology can be used in the medical domain to help identify either positive or negative issues. This approach helps to improve the quality of health services offered to consumers. This paper will be reviewing feature selection algorithms, sentiment classifications, and standard measurements that are used to measure the performance of these techniques in previous studies. The combination of feature extraction techniques based on Natural Language Processing with Machine Learning techniques as a feature selection technique can reduce the size of features, while selecting relevant features can improve the performance of sentiment classifications. This study will also describe the use of metaheuristic algorithms as a feature selection algorithm in sentiment analysis that can help achieve higher accuracy for optimal subset selection tasks. This review paper has also identified previous studies that applied metaheuristics algorithm as a feature selection algorithm in the medical domain, especially studies that used drug review data**.

Keywords*—Sentiment analyis; drug reviews; feature selection; metaheuristic

I. Introduction

Sentiment analysis (SA) or opinion mining is a field that analyses opinions, comments, expressions, and views on different entities, such as products, services, organisations, and individuals. It is subjective in sentiment analysis to analyse each comment to identify the types of sentiment polarity, as either positive, negative, or neutral. According to [1], sentiment analysis is widely implemented in the domains of products, restaurants, movies, etc. However, this technique is not widely used in the medical domain, which could probably be due to privacy and ethical issues [1].

The current widespread use of social media has allowed users the freedom to speak their mind by giving their opinions or views in various aspects, such as medical quality, services they received, the effectiveness and side effects of drugs, and medical costs. Users would use social media platforms as a place for them to express their dissatisfaction or satisfaction with the goods or services provided. According to [2], medical documents are classified into six types, namely, nurse's letter, radiological report, discharge summary, drug reviews, Medblogs, and slashdot interviews.

This study has specifically focused on drug reviews, namely, users' comments on drugs in terms of effectiveness, side effects, symptoms, facilities, and the value of the drugs. The main problem in sentiment classification is that features extracted from user comments often contain data that are redundant, irrelevant, or even misleading [3], [4].

According to [5], there are three levels of SA, namely, feature, sentence, and document. The focus of this study has been on feature, which is to identify features embedded in customers' comments, as either positive, negative, or neutral. This study has also identified previous studies that were conducted on the medical domain, which were specifically related to drug reviews. This study has focused on identifying feature selection techniques and techniques for classifying sentiments in customers' comments on drug use. Several combinations of keywords were used ("feature selection + sentiment analysis + drug review or drug) during the search process in standard databases, such as Elsevier, ACM, Google Scholar, Science Direct, Elsevier, SpringerLink, Scopus, Taylor & Francis; and IEEE Xplore.

II. Background Research

According to [2], drug reviews refer to comments on drugs, which are related to their effectiveness, side effects, convenience, and value. User comments can help other users find the best businesses, destinations, or services by sharing opinions and ratings on these drugs.

It is important to analyse these drug reviews and identify users' views or opinions on these drugs, whether they are good or vice versa. The results of this analysis could contribute insights related to the health field to the stakeholders of this field [1]. Apart from that, the results of this sentiment analysis could also help the community understand the effects of drugs on human health. This paper will describe drug reviews, sentiment analysis and feature selection in detail.

A. Drug Review

According to [6], drug reviews consist of posts in social media, where patients express their experiences and opinions about treatments or medicines. According to [7], the

Pharmaceutical Care Network Europe (PCNE) defined medication review as a structured evaluation of a patient's medicines, with the aim of optimising medicine usage and improving health outcomes, in terms of drug-related problems and recommended interventions. As reported by [2], a drug review can be defined as a user's personal perceptions on several drug-related categories, including effectiveness, side effects, convenience, and value. According to [8], a drug review is a patient-written review on various drugs based on their experiences and preference. This kind of review provides a lot of information that can lead to accurate decisions about public health and drug safety.

B. Sentiment Analysis

Sentiment analysis (SA), also referred to as opinion mining, is the area of research that analyses the perceptions, thoughts, opinions, evaluations, behaviour, and emotions of people on anything, for example, products, services, organisations, people, concerns, activities, topics, and their attributes [5]. SA is the process of evaluating a word or a sentence based on their sentiment. Any opinion or emotion expressed in the form of a text would contain a negative, positive, or neutral element [9]. As stated by [2], SA could be used to gather information on the effectiveness of a treatment or medication from social media and health records. According to [6], drug manufacturers could also benefit from SA, particularly in pharmacovigilance, as particular adverse effects of a drug can be found more easily from public repositories or social media posts. A drug review may contain a high proportion of sentiment terms formed from personal impressions and feelings [2]. Therefore, SA can be used to collect useful information that can assist in making accurate decisions on public health and drug safety.

C. Feature Selection

Features are topics or keywords found in users' comments. A feature can be a topic that is being discussed or things that users made comments on. An example of a user's comment sentence: 'This camera is very good': the feature in this sentence is 'camera' and the word sentiment is 'good'. Various definitions of feature selection have been provided by previous studies [10 –14]. Based on studies by [4, 9, 15], it is important to produce an optimal feature subset by reducing feature size to increase classification accuracy. In conclusion, feature selection is a process of selecting and identifying features that are not redundant and relevant to reduce the size of feature dimension and improve the accuracy of sentiment classification. Therefore, this study aimed to identify feature selection techniques used in previous studies to select features in drug review datasets.

III. A Review Feature Selection Algorithms used in Sentiment analaysis for Drug Reviews

The world of social media is full of people who would make various comments, either positive or negative. Social media is full of information regarding users' preferences and experiences when using products or services. This type of information should be utilised by identifying valuable insights in such comments using artificial intelligence technologies, such as sentiment analysis. Big-sized and high-dimensional data are a major problem that can decrease the accuracy of classification performance and complicate the process of obtaining an optimal feature subset. Feature selection in SA is an important step to produce an optimal feature subset [14], without having to change the original meaning of the feature. This study will identify feature selection methods, feature extraction, sentiment classification, data sets, and evaluation standards that are being used to measure the performance of the methods used.

NLP concepts, such as part of speech tagging, n-gram, content words, and function words have also been used to extract features from tweet data [16]. The Penguin Search Optimization (PeSOA) algorithm [16] was also used as a feature selection technique to select optimal features based on the keywords of drugs and cancer in tweet data. The K-Nearest Neighbour (KNN), Naïve Bayes (NB), and Support Vector Machine (SVM) methods were used through MATLAB simulation software to classify the tweet data. The performance metrics used were processing time, accuracy, precision, recall, and F-Measure to measure the performance value of each proposed method. Based on the combined feature selection techniques, which consisted of PeSOA and three classification methods, namely, PeSOA-KNN, PeSOA-NB, and PESOA-SVM, it was found that the combination of PeSOA-SVM was able to produce high accuracy, precision, recall, and F-Measure values compared to the other combinations. Similarly, PeSOA-SVM required less processing time to complete the classification process compared to other combinations. This increased performance was due to the ability of the combined SVM and PeSOA to classify larger data sizes from the search process from multiple dimensions. Their study had only focused on comments that contain the keyword drug, regardless of the type and effect of the drug. According to [1], the Bag of Words (BoW) technique or the term frequency-inverse document frequency (TF-IDF) technique were used to extract important words in a document. Once the keywords have been extracted from the document, the next process was to select an optimal feature subset using the Fuzzy-Rough Quick Reduct (FRQR) technique. By using BoW to determine the value of a feature, the feature selection process was able to significantly reduce the generated feature space. FRQR was able to select 43 optimal features from the 903 original features using the forward search strategy. Meanwhile, 56 optimal features were selected using the backward search. These two resultant feature subsets were tested using four classification methods, namely, the Ripper, Naive Bayes, Random Forest, and Decision Tree. The performance of these methods was measured based on training accuracy, performance of running independent hold-out test, and the time required to build the model. The experimental results showed that the FRQR technique was able to increase sentiment accuracy, as well as reduce the complexity of feature space, and the classification of run-time overheads.

According to [17], machine learning methods are insufficient to address the complex grammatical relationships between words in clauses. Their study applied a linguistic approach to overcome weaknesses in machine learning approaches. The advantage of using a linguistic approach is that this method can determine sophisticated rules for dealing

with various grammatical relationships between words in sentences or clauses. New rules based on linguistics can also be added to the system at certain levels. A comparison between SVM (a machine learning method) and linguistic approach was conducted using a dataset obtained from DrugLib.com. Experimental results showed that the linguistic approach was more effective compared to the SVM method. However, several problems have been identified based on the error analysis. This situation showed that the proposed linguistic approach required improvement.

Satisfaction with drug use was analysed based on drug reviews from www.askapatient.com [18]. Several experimental analyses were conducted on the performance of Probabilistic Neural Network (PNN) and Radial Base Function Neural Networks (RFN) using two different datasets, namely, cymbalta and depo-provera. The results showed that the Neural Network approach surpassed the SVM method in terms of precision, recall, and F-Score values. The RFN method showed a higher performance value compared to the PNN method.

In their research [19] used the Probabilistic Aspect Mining Model (PAMM), which is a method to identify the relationship between features and class labels. Due to the unique features of PAMM, it focuses on finding features related to one class only rather than simultaneously finding features for all classes in each implementation. Apart from finding features, it also has properties that can be distinguished by the class. This means PAMM can be used to differentiate between classes, which help reduce the likelihood of features being formed from mixing different class concepts. Thus, the identified features would be easier to construe. Researchers have argued that this method can avoid features that have been identified as having contents mixed from different classes. Better and more specific features can be identified by focusing on the tasks in one class. This approach is also different from the intuitive approach, whereby reviews were grouped first according to their class label and followed by features for each group. The proposed model used all reviews when finding features that were specific to the target class. This approach helped to distinguish reviews from different classes.

Various sentiment categories for consumer review on drugs have been identified for the introduction to Adverse Drug Reactions (ADRs) [20]. The Weakly Supervised Model (WSM) was introduced using data labelled as weak to pre-train model parameters. Then, WSM was combined with the Convolutional Neural Network (CNN) and the Bidirectional Long Short-term Memory (Bi-LSTM) to produce another model, known as the WSM-CNN-LSTM to implement the sentiment classification process. The experiments showed that the proposed model was able to improve ADR recognition based on accuracy, precision, and F-Score values compared to other models.

According to [8], two deep fusion models have been proposed based on the three-way decision theory to analyse drug reviews. The first fusion model was known as the 3-way fusion of one deep model with traditional models (3W1DT). In 3W1DT, each classic algorithm is combined with a deep learning method separately. For example, Naïve Bayes (NB) was combined with Gated Recurrent Unit (GRU), Convolutional Neural Network (CNN), and Three-Way Convolutional Recurrent Neural Network (3CRNN), and known as GRU-NB, CNN-NB, and 3CRNN-NB, respectively. The second combination models were known as the 3-way fusion of three deep models with traditional models (3W3DT) to improve the performance of the deep learning methods. This second model combined three learning algorithms, namely, GRU, CNN, and 3CRNN with traditional algorithms, which were NB, Decision Tree (DT), Random Forest (RF), and K-Nearest Neighbour (KNN). These combinations were known as 3W3DT-NB, 3W3DT-DT, 3W3DT-RF, and 3W3DT-KNN. Data sets from Drugs.com were used to test these two models. The 3W1DT and 3W3DT methods showed better results compared to the stand-alone traditional and deep learning methods. Meanwhile, a comparison between 3W1DT and 3W3DT showed that 3W3DT was able to produce higher accuracy and F1-Score values compared to 3W1DT. The study [8] had also intended to apply a metaheuristic feature selection technique and evolutionary algorithm to improve the performance of the proposed fusion models in the future.

In their study, [21] implemented two feature extraction methods, namely, Word Embedding and Position Encoding in Vector Representation to extract features from drug review datasets. The obtained features were tested using four sentiment classification methods, namely, NB, SVM, RF, and Radial Basis Function Network (RBFN). They compared the sentiment classification of the original SentiWordNet (SWN) lexicon with the medical domain-based SentiWordNet lexicon (Med-SWN). Experimental results showed the effectiveness of the proposed method in the feature selection process. Meanwhile, an assessment on the performance of sentiment classification has proven that the features extracted from Med-SWN outweighed those from SWN.

Based on the summary in Table I, the use of metaheuristic techniques as part of feature selection techniques is still in its infancy. Therefore, further research must be conducted to prove that metaheuristic techniques are able to produce optimal feature subsets and help improve the performance of sentiment classification accuracy. The use of metaheuristic feature selection techniques was suggested by [8] to improve the performance of sentiment classification accuracy. However, this situation depends on the data training sets. Tests based on domains could also play an important role in each study.

TABLE I. A SUMMARY OF FEATURE SELECTION ALGORITHMS AND FEATURE EXTRACTION METHODS FOR DRUG REVIEWS

Author	Feature Extraction	Feature Selection	Classification	Measurement
[1]	Bags of Words (BoW) or term frequency-inverse document frequency (TF-IDF)	Fuzzy-Rough Quick Reduct (FRQR).	Ripper, Naive Bayes, random forest and decision tree	Performance based on training accuracy, performance of running independent hold-out test, and the time required to develop the model.
[8]	Not mentioned in paper.	Not mentioned in paper.	CNN-NB, GRU-NB dan 3CRNN-NB. 3W3DT-NB, 3W3DT-DT, 3W3DT-RF dan 3W3DT-KNN	Precision, recall, and F-Score
[16]	Part of speech tagging, n-gram, content words, function words	Penguin Search Optimization (PeSOA)	K-Nearest Neighbour (KNN), Naïve Bayes (NB), and support vector machine (SVM)	Accuracy, precision, recall, and F-Measure
[17]	Not mentioned in paper.	Not mentioned in paper.	Rule-based Linguistic	Precision, recall, accuracy, and F1-score
[18]	Not mentioned in paper.	Not mentioned in paper.	Probabilistic neural network (PNN), and radial basis function neural networks (RFN)	Precision, recall, and F1-Score
[19]	The specific type of feature extraction was not mentioned.	Not mentioned in paper.	Probabilistic aspect mining model (PAMM)	Mean Pointwise Mutual Information (PMI) and accuracy
[20]	Not mentioned in paper.	Not mentioned in paper.	Weakly supervised model (WSM), convolutional neural network (CNN), and bidirectional long short-term memory (Bi-LSTM)	Accuracy, precision, and F1-Score
[21]	Word embedding and position encoding in vector representation	Not mentioned in paper.	Naive Bayes, SVM, RF, and RBFN	Precision, recall, and F-Score

IV. A SURVEY OF FEATURE SELECTION USING METAHEURISTIC ALGORITHMS IN SENTIMENT ANALYSIS

This section will briefly present feature selection techniques that use metaheuristic algorithms in sentiment analysis. Metaheuristic techniques can solve various problems with satisfactory solutions in a reasonable time. According to [22], metaheuristic techniques have been used for over 20 years in numerous applications. Most applications that use this technique demonstrated efficiency and effectiveness for solving large and complex problems.

These techniques are a high-level strategy and iteration generation process, which can guide the process of exploring the search space using different techniques. Metaheuristic techniques may include ant colony optimization (ACO), artificial immune system (AIS), bee colony, genetic algorithm (GA), particle swarm optimization (PSO), and genetic programming [22], [23]. According to the study by [23], metaheuristic characteristics are as follows:

1) A strategy that provides guidance in the search process.

2) Able to effectively explore the search space and find the optimal solution; and.

3) A simple local search procedure for complex learning processes.

Metaheuristic techniques have been used as feature selection techniques by [4], [24], [25], and [26]. Table II lists several studies in other domains that similarly used metaheuristic algorithms, such as particle swarm optimization, ant colony optimization, hybrid cuckoo search, and artificial bee colony that have been proven to show good results based on precision, recall, F-measure or accuracy values.

TABLE II. A SUMMARY OF FEATURE SELECTION USING METAHEURISTIC ALGORITHMS IN SENTIMENT ANALYSIS

Author	Feature Selection	Domain	Result
[4]	Ant Colony Optimization	Customer Review	Precision = 81.5%; Recall = 84.2%; and F-score = 82.7%
[26]	Multi-Swarm Particle Swarm Optimization	Online Course Reviews	Micro-F-measure = 88%
[27]	Particle Swarm Optimization	Movie review	Accuracy level from 71.87% to 77%.
[28]	Multi Objective Artificial Bee Colony	Movie Review	Accuracy 93.8%
[29]	Particle Swarm Optimization	Laptop and Restaurant	F-measure values = 81.91% and 72.42% for aspect term extraction classification. Accuracies = 78.48% (restaurant) and 71.25% (laptop domain).
[30]	Fitness Proportionate Selection Binary Particle Swarm Optimization	Hotel Reviews And Laptop Reviews	Accuracy = 93.38%
[31]	Particle Swarm Optimization	Cosmetic Products Review	Accuracy from 82.00% to 97.00%
[32]	Hybrid Cuckoo Search	Twitter Dataset	Not mentioned the value of accuracy.
[33]	Ant Colony Optimization	Twitter Dataset	Accuracy = 90.4%

Next, the search for research papers on feature selection using metaheuristic algorithms that use drug review data was based on the following combinations of keywords:

1) ("Feature selection + sentiment analysis + metaheuristic + drug review);
2) ("Feature selection + sentiment analysis + optimization + drug review); and
3) ("Feature selection + sentiment analysis + swarm intelligence + drug review).

Searches in benchmark databases, such as ACM, IEEE Xplore, Elsevier, SpringerLink, Scopus, Google Scholar Taylor & Francis; and Science Direct showed no results. However, when the keyword combination has no 'sentiment analysis' and 'drug review', several papers were found containing the following keywords:

1) ("Feature selection + swarm intelligence + medical);

and

2) ("Feature selection + swarm intelligence + health).

Brief descriptions on each paper are given in the following section. In their work, [34] studied feature selection techniques for the classification of medical datasets based on Particle Swarm Optimisation (PSO). Their research was focused on multivariate filter and wrapper approaches, combined with PSO using medical dataset. PSO was used as a filter and CFS was used as a fitness function. They also proposed using the wrapper approaches with PSO on five classifiers, namely, decision tree, Naïve Bayes, Bayesian, radial basis function, and k-nearest neighbour to increase classification accuracy. This method had been tested for feature selection classification on three medical datasets, which were the breast cancer dataset, the Statlog (Heart) dataset, and the dermatology datasets. A comparison was performed between the proposed approaches with the feature selection algorithm based on genetic approach. The results showed that the PSO_CFS filter was able to improve classification accuracy, while the proposed wrapper approaches with PSO showed the best classification accuracy. However, two studies had identified that GA_CFS is more reliable than the proposed method, which would be when KNN and RBF classifiers were applied to the to Statlog (Heart) datasets.

Confidence-based and cost effective feature selection (CCFS) methods were proposed using binary PSO on UCI lung cancer dataset [35]. The results showed that the proposed algorithm demonstrated effectiveness in terms of accuracy and cost of feature selection. Additionally, [36] applied the Binary Quantum-Behaved Particle Swarm Optimisation (BQBPSO) algorithm as a feature selection technique for selecting optimum feature subsets for a microarray dataset that contains five types of data set, namely, Leukaemia, Prostate, Colon, Lung, and Lymphoma. The BQBPSO showed more significant results in terms of accuracy and optimal feature subset compared to two comparison algorithms, namely, Binary Particle Swarm Optimization (BPSO) and Genetic Algorithm (GA).

An ontology-based two-stage approach to medical text classification, with feature selection using particle swarm optimization research was conducted by [37]. They developed a two-stage methodology to analyse domain principles and identify which concepts are discriminatory to a classification problem. This research used a set of clinical text, known as the 2010 Informatics for Integrating Biology and Bedside (i2b2) dataset. This dataset must go through an ontology-based feature extraction during the first stage. The MetaMap tool was then used to send the document to Unified Medical Language System (UMLS) to extract all features with meaningful phrases. A simple idea was applied in the concept section set and finally, a tf-idf measure was used to transform the feature into a vector. In the second stage, PSO was used to further remove redundant and unwanted features. To test the accuracy of the suggested method, five classifiers were used, namely, Naive Bayes (NB), Linear Support Vector Machine (LSVM), K-Nearest Neighbour (KNN), Decision Tree (DT), and Logistic Regression (LR). The results showed that the two-stage approach was able to extract meaningful features, reduce the number of features, and improve classification accuracy.

Based on the summary of previous studies in Table III, metaheuristic algorithms have been used as a feature selection algorithm in the medical or healthcare domain. However, these experiments had only included other disease datasets, such as breast cancer, lung cancer, and leukaemia. Experiments using drug review data were not found in this literature review.

Therefore, further research should be conducted using drug review datasets as research data to implement the use of metaheuristic algorithms. Additionally, studies should be conducted to identify metaheuristic algorithms that would be appropriate for drug review datasets.

TABLE III. A SUMMARY OF FEATURE SELECTION USING METAHEURISTIC ALGORITHMS IN MEDICAL OR HEALTHCARE DOMAIN

Author	Feature Selection	Domain	Dataset
[34]	Particle Swarm Optimization	Medical	Breast Cancer, Heart, Dermatology
[35]	Binary Particle Swarm Optimization	Healthcare	Lung Cancer
[36]	Binary Quantum-Behaved Particle Swarm Optimization	Medical	Leukaemia, Prostate, Colon, Lung, and Lymphoma
[37]	Particle Swarm Optimization	Medical	Medical Notes
[38]	Confidence-based Cost-effective + Binary Particle Swarm Optimization	Healthcare	UCI datasets

V. CONCLUSION AND FUTURE WORK

The literature review in this research paper was conducted in three parts. The first part was to identify which feature selection algorithms were used for drug review data in

previous studies. Table I shows the results of the first search, whereby natural language processing, machine learning, and metaheuristic algorithms were used. However, several studies did not state the type of feature selection techniques used in their study. Table I also shows that the use of metaheuristic algorithms as a feature selection technique is still lacking in the domain of drug reviews. Next, this study identified the use of metaheuristic algorithms as a feature selection technique in sentiment analysis in general. The results are summarised into Table II, which shows several studies in different domains using metaheuristic algorithms as a feature selection technique. Table II also shows excellent experimental results based on the measured values. Next, this study searched for previous research papers in a list of standard databases that applied metaheuristic algorithms as a feature selection technique in the drug review domain. However, no matches were found. Then, the keyword combinations were changed, which were "feature selection + swarm intelligence + medical" or "feature selection + swarm intelligence + healthcare". Several research papers have been found using these keywords, as listed in Table III. Table II and Table III show that metaheuristic algorithms can be used as a feature selection technique in the domains of movies, customer reviews, tourism, medical, and healthcare, with excellent experimentation results. SA plays an important role in the decision-making process. Health-based organisations or services would have to make decisions on the use of drugs, side effects or services provided based on user comments. Numerous approaches can be used in SA. Metaheuristic-based feature selection techniques can assist in the selection of optimal features, with higher accuracy. The literature review has shown that research to implement metaheuristic algorithms as feature selection in the medical domain have great potential which would benefit from further studies on drug review data. Researchers also need to identify the advantages and disadvantages of metaheuristic algorithms that would be used as feature selection algorithms in further studies. More studies are needed to identify previous studies that applied metaheuristic techniques. More experiments should be conducted to identify metaheuristic techniques that are appropriate for future drug review data.

ACKNOWLEDGMENT

The authors gratefully acknowledge Universiti Pertahanan Nasional Malaysia, and the Skim Geran Penyelidikan Jangka Pendek Fasa 1/2021 for supporting this research project through grant no. UPNM/2021/GPJP/ICT/1.

***Abstract*—Covid-19 is declared a global pandemic by WHO due to its high infectivity rate. Medical attention is required to test and diagnose those with Covid-19 like symptoms. They are required to take an RT-PCR test which takes about 10-15 hours to obtain the result, and in some cases, it goes up to 3 days when the demand is too high. Majority of victims go unnoticed because they are not willing to get tested. The commonly used RT-PCR technique requires human contact to obtain the swab samples to be tested. Also, there is a shortage of testing kits in some areas and there is a need for self-diagnostic testing. This solution is a preliminary analysis. The basic idea is to use sound data, in this case, cough sounds, breathing sounds and speech sounds to isolate its characteristics and deduce if it belongs to a person who is infected or not, based on the trained model analysis. An Ensemble of Convolution neural networks have been used to classify the samples based on cough, breathing and speech samples, the model also considers symptoms exhibited by the person such as fever, cold, muscle pain etc. These Audio samples have been pre-processed and converted into Mel spectrograms and MFCC (Mel Cepstral Coefficients) are obtained that are fed as input to the model. The model gave an accuracy of 88.75% with a recall of 71.42 and Area Under Curve of 80.62%.**

Keywords*—Coronavirus; cough sounds; mel frequency cepstral coefficients; convolutional neural network; reverse transcription–polymerase chain reaction (RT-PCR)

I. Introduction

Covid19 is caused by the SARS-CoV2 Virus and was declared a pandemic across the world on the 11th of February 2020. Majority of Covid-19 patients experienced fever, dry cough and fatigue. Other symptoms experienced by the patients include aches and pains, sore throat, diarrhoea, conjunctivitis, headache, loss of taste or smell, a rash on skin, or discoloration of fingers or toes. This pandemic has affected more than 17 crores worldwide and has resulted in the death of 38 lakhs as of June 2021. Testing has become one of the most important requirements for starting the treatment, allocation of Beds, procurement of specific medicines etc. The current methods which are RT-PCR tests are conducted and samples are sent to a lab for disease detection. While Lateral Flow Tests (LFTs) can diagnose Covid-19 immediately, it is not as precise as RT-PCR. Antibody tests also cannot effectively detect Covid-19, but can determine an individuals' immunity to Covid-19. There could be false negatives up to 30% in RT-PCR tests. It means the presence of an infection could be done in far better way than giving a patient the all-clear negative report. There is possibility of false positive results because of detecting dead and deactivated viruses in the body of a pateint recovered from Covid-19.

The paper focuses on using deep learning techniques to detect Covid 19 using methods that don't involve any incision or wound to the patient while still finding ways to detect Covid-19. Cough and breathing based analysis to isolate cough sound snippets and convert this data that can be used for analysis and training a model based on the characteristics obtained. Convolutional neural network is used to analyze the images which are derived after preprocessing and Ensemble of models are used to increase the accuracy. For testing performed the performance will be measured based on the recall and accuracy rates. The applications would include testing methods within web applications, and sophisticated testing without one's aid.

The rest of the paper is organized as follows: Section II highlights the contemporary works carried out for Covid-19 detection in various countries. Section III discusses the materials and methods used in this work. Section IV gives the results obtained on carrying out the work. Section V summarizes the work carried out for Covid-19 detection.

II. Literature Review

In [1], the authors had analyzed the features for cough breathing and voice of the patients. Long term dependencies can be remembered in LSTM. Dataset consists of 60 healthy speakers and 20 Covid-19 patients. In comparison between the three through performance metrics, it is found that patients cough and breathing sounds are effective to diagnose infection as they have high recall. The Limitations of the papers include inefficient preliminary results due to time constraints, collected data is small and lacks control on other patients suffering from other kinds of respiratory illness.

In [2], a CNN model to detect Covid-19 from breath and cough sounds was proposed. Spectrogram extraction to obtain visuals of audio frequencies against time. CNN variant CIdeR is based on ResNets which alleviates the vanishing gradient problem. The output is later given to a sigmoid layer. A score, thus obtained can be used to determine if a person is Covid-19 positive or not. Dataset used is 517 coughing and breathing recordings from 355 people, of which 62 participants had tested positive within 14 days of the recording. The Technique used is CNN-ResNet. The prime limitation of this study is size and demographics of the dataset.

The proposed work in [3] identified coughing is not just one predominant symptom of Covid-19 but a symptom of more than 100 diseases. Machine learning techniques can be applied on global smartphone recordings to detect Covid-19. Dataset used for training is the Coswara dataset and the Sarcos dataset. Techniques used are Logistic regression, SCM, MLP, LSTM, Resnet50.

In [4], the authors suggested that the only screening method for Covid-19 is a thermometer but only 45% of the mild-moderate patients had fever, their study suggested that Covid patients who are especially asymptomatic could be classified with a good accuracy as positive or negative with just the forced-cough recordings. The data was collected from opensigma.mit.edu and it had 5320 cough recordings. The cough recordings were converted using Mel Frequency Cepstral Coefficient (MFCC) and later on, fed into CNN containing one Poisson biomarker layer with biomarkers like Muscular degradation, Vocal cords, Sentiments, Lungs and Respiratory Tract and 3 pre-trained ResNet50's in parallel; 4256 recordings were used for training and the remaining 1064 was used for testing. The model had a recall of 98.5% and a specificity of 94.2%. For asymptomatic persons, it achieved recall of 100% with a specificity of 83.2%.

It was proposed in [5] that the lung volume and oxygenation can be modelled and approximated with a good accuracy. Energy of acoustic signal of respiration in each phase of airflow to/from the lungs from the breathing sounds is considered. Rhonchus, squawk, and stridor are also considered in the inspiration phase. All of the above characteristics are extracted from the lung function augmentation graph which is calculated against time and amplitude.

In [6], the authors have analyzed the computation of Mel spectrogram from cough sounds. Deep transfer learning based multi class / binary classifier along with classical machine learning based multi class classifier were applied to differentiate cough due to Covid-19 from cough due to other respiratory infections.

In [7], the authors have proposed a Radiographic scoring model applied by assessing disease severity using severity score. Score was given based on the extent of lung infection. Statistical analysis was performed by applying Student's T test, Mann Whitney's test, Chi-square test and Fisher's exact test. Some limitations were lack of retrospective analysis and correlation between CXR severity score and patient co morbidities.

The authors in [8] have made a comparative study of twelve deep learning algorithms using a multi-center dataset, including open-source and in-house developed algorithms. The 12 methods which are Benchmarked and compared include Lung segmentation for severe pathologies, 3D Lung segmentation Lobe segmentation, CT Angel software for lung segmentation and binary lesion, CovidENet, 2D Unet, 3D multiclass segmentation, Inf-Net, WASS, UNWM and Majority voting.

In [9], it was proposed that RT-PCR is probably a more accurate and sensitive strategy. GradCAM mappings and 3-D model were applied. Pretest background prevalence determines test success metrics. Testing practices may differ depending upon exposure rates and pandemic phases. The work was limited in truly evaluating the generalizability of this model to an independent population, because positive and negative cases were obtained from separate populations.

In [10], the authors have proposed some Non Clinical techniques such as machine learning, data mining, expert system and other artificial intelligence techniques must play significant roles in diagnosis and containment of the Covid-19 pandemic to detect asymptomatic cases and for accelerating the testing process. Supervised ML models were developed using decision tree, logistic regression, Naive Bayes, SVM and ANN.

Detection of Covid-19 by using both cough recording and the uttering of the vowel sounds was proposed in [11]. Many classifiers like decision trees, support vector machines, K-Nearest-Neighbor, Random Forest (RF) and XGBoost were used. The best performance was shown by the weighted XGBoost classifier. A larger number of X-ray images with a wider distribution could have been used.

The authors in [12] have proposed detection of Covid-19 using cough and breathing sounds. Crowdsourced dataset was used for analysis. The model was trained using two feature sets - one was the handcrafted features like the MFCC (Mel Frequency Cepstral Coefficients) and other statistical features and the other feature set was obtained from the pre-trained models [14] [17][21].

III. Materials and Methods

A. Materials

The proposed solution provides a web application that takes cough, breathing and speech sounds along with the symptoms shown by the person as input and predicts the likelihood of him/her having Covid-19. The training process of the machine learning model begins with pre-processing techniques like loading the audio samples and removing null values. The features of the audio samples like MFCCs and Mel Spectrogram images are further extracted from the audio samples and given to the input generator function. Mel-Frequency Cepstrum Coefficients (MFCCs) are coefficients that provide a representation of the short-term power spectrum of a sound.

A Mel spectrogram is a spectrogram where the frequencies are transformed to Mel scale. This converts the audio samples to image form. The input generator function divides the training data into batches and shuffles the order of the examples so that batches between epochs do not look alike. The data generated from the input generator function is then fed to the machine learning model. Next, an ensemble of three convolutional neural network models and four dense neural network models are used to analyze the pre-processed data and predict the desirable output. Each CNN model consists of 3 2D convolutional layers, average pooling, batch normalization, Relu activation function and a dropout model. Further, the input is flattened using the Flatten class. Glorot Uniform initializer is used to initialize layer weights. Each dense neural network consists of two dense layers using Relu

activation function and Glorot Uniform initializer and a dropout layer. The concatenated ensemble model is then fed through two hidden layers and an output layer to finally generate the output.

The outline of the overall Workflow of the model from start to finish is as follows: The flow starts with the user recording his voice and the symptoms shown by him, the application after receiving the sample runs separate pre-processing steps for voice and categorical features, audio features are converted to Mel spectrograms, MFCC, along with the binary symptoms are fed into the ensemble model which tells if the patient is positive or not.

Fig. 1 gives a brief overview of the Machine Learning model employed in the proposed work. It is an ensemble model of 3 CNN models and 4 dense neural network models. The 3 CNN models take Mel Spectrogram images as input, 3 dense neural network models take MFCCs as inputs and the other dense neural network takes symptoms as input. The ensemble model is then fed through the two hidden layers and an output layer to derive the output. The model consists of an ensemble model of 3 CNN models and 4 dense neural network models. The 3 CNN models each consist of 3 Conv-2D layers, 3 Average Polling 2D layers, 3 Batch Normalization layers, 3 dropout layers and 3 Relu activation functions. The CNN models flatten the input before sending the input through the final dropout layer, dense layer and activation function. The 4 dense neural network models consist of 2 dense layers and 2 dropout layers [16],[18],[26].

Three CNN models were selected because out of the 7 inputs,

The inputs were image inputs i.e Mel spectrogram images of Cough, Breathing and Speech. Since CNN's are very effective in Image classifications because Images have higher dimensions and CNN is very good at reducing the number of parameters without reducing the quality makes it the best option to consider as the model. The 3 CNN models take images as input, 3 dense neural network models take MFCCs as input and the other dense neural network models take symptoms as input. Glorot Uniform is used as the initializer for each of the models. The ensemble model is then passed through 2 dense hidden layers which then feed the input into the dense output layer. The hidden layers use Relu activation function. The output layer finally makes the prediction for the input. The output layer uses the sigmoid activation function.

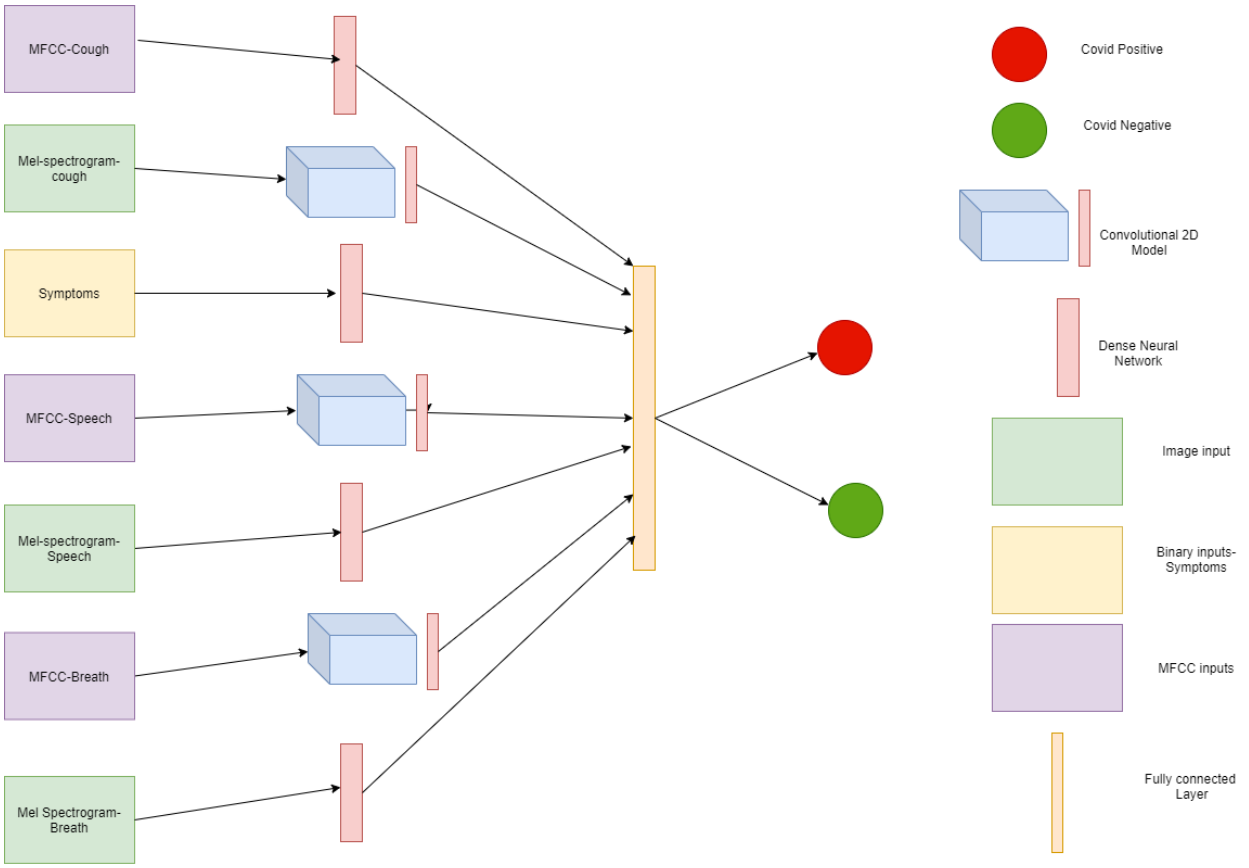

Fig. 1. Brief overview of the Model.

B. Dataset

DiCOVA challenge employs a dataset for respiratory heath diagnosis by speech and audio processing [13]. In this paper, the data used is taken from Coswara data which was collected by Indian Institute of Science (IISc) Bangalore. The dataset includes voice samples including fast and slow breathing sounds, deep and shallow cough sounds, phonation of sustained vowels, and counting numbers at slow and fast pace. Collected metadata includes the participant's age, gender, location country, state/ province of the participant, current health status that could be healthy, exposed, cured or infected and the presence of comorbidities like pre-existing medical conditions. The dataset consists of 1645 samples of individuals. The data was sampled from all the continents except Africa and more than 88% of the samples were from India.74% of samples are male and around 26% are females. 76.8% of samples are healthy individuals; 8.4% of samples are positive and the rest can't be identified. Majority of the samples are those between 20-30 years of age followed by 30-40 years and followed by 40-50 years. Fig. 2 shows Pearson's correlation heatmap for the dataset. It can be inferred from the above figure that the most important symptoms of Covid-19 status are asthma, fever, cough, sore throat, breathing difficulty, cold, fatigue, muscle pain, loss of smell and pneumonia in that order.

C. Data Preprocessing

Sound, represented as an audio signal possesses characteristics like frequency, bandwidth, decibel, etc. Usually, such signals are given as a function of amplitude and time. Audio processing involves extraction of acoustics features relevant to a task. Librosa [19][23][24], a Python for music and audio analysis facilitates various options to construct music information retrieval systems. A Mel spectrogram is a spectrogram where the frequencies are transformed to the Mel scale. The Fourier transform maps continuous time into a frequency spectrum, but an inverse is performed over its log to make it perceptible by humans. General data preprocessing is finally done using Python libraries [22]. In brief, the process of obtaining Mel – Spectrogram is as follows:

1) The samples of air pressure are collected at different instances of time and the same digitally represents an audio signal.

2) The audio signal is transformed from time domain to frequency domain using the Fast Fourier transform.

3) Frequency on y axis is converted to a log scale and amplitude is converted to decibels and the spectrogram is subsequently formed.

4) Frequency is again mapped onto Mel scale and Mel spectrogram is obtained.

D. Mel-Frequency Cepstral Coefficients (MFCCs) and Feature Extraction

MFCCs consist of 10–20 features usually. These features give the general shape of a spectral envelope and models the characteristics of the human voice. To get MFCC, DCT on the Mel-spectrogram is computed. To obtain MFCC, the following steps could be carried out.

1) A windowed excerpt of a signal is taken and Fourier Transform is applied on it.

2) Powers of the spectrum thus obtained are mapped onto Mel scale using triangular overlapping windows.

3) Logarithms of the powers at each Mel frequency are computed.

4) DCT of such MEL log powers is calculated.

5) Amplitudes of the resulting spectrum give MFCCs

Fig. 3. Psuedocodes (A) Data Generation (B) Feature Extraction.

The following is the six step process to obtain the features.

1) The signals are split into short-time frames.

2) Windowing is applied.

3) An NN-point FFT on each frame is applied and frequency spectrum also called Short-Time Fourier-Transform (STFT) is obtained.

4) Filter Banks are applied. Actually, a set of 20–40 triangular filters is employed.

5) Logarithm of these spectrogram values is applied to get log filter bank energies.

6) DCT (Discrete Cosine Transform) is applied.

E. Convolution Neural Network

In Covolutional 2D filters, Keras Conv2D parameter determines the number of kernels to convolve with the input volume resulting in a 2D activation map. Average Pooling calculates the average value for patches of a feature map and creates a down sampled (pooled) feature map.

```

```

Fig. 4. Psuedocode (C) Model Training.

In Average Pooling layer the average for each block is computed rather than a max value, which is the case with max pooling. Batch Normalization (BN) is performed as a solution to speed up the training phase of deep neural networks through the introduction of internal normalization of the input values within the neural network layer. Dropouts can prevent overfitting in the model and can be added to randomly switch some percentage of neurons of the network. When the neurons are switched off, the incoming and outgoing connection to those neurons is also switched off. The dense layer is a deeply connected neural network layer with each neuron in the dense layer receiving input from all neurons of the preceding layer. Thus the dense layer results in an 'm' dimensional vector.

```

Fig. 5. Psuedocode (D) Processing.

Units are the fundamental parameter that takes positive integers usually. This parameter determines the size of the weight matrix along with the bias vector. The activation parameter helps to apply element-wise activation function in a dense layer. By default, Linear Activation is used but any of the options that Keras [16][18][24] provides can be used for this. In the model Relu has been used as the activation function and it is used for activation to avoid gradient descent,

It also avoids vanishing gradient problem from sigmoid function. The rectified linear activation function or ReLU for short is a piecewise linear function that maps input to output for positive values. The initializer parameter deals with initialization of values in the initialization layer. In the Dense Layer, the weight matrix and bias vector has to be initialized. The initializer used here called glorot_uniform draws samples from a uniform distribution within [-limit, limit] where,limit=sqrt(6/fan_in+fan_out) where, fan_in is the number of input units in the weight tensor and fan_out is the number of output units. The algorithms employed in this work are mentioned in Fig. 3, Fig. 4 and Fig. 5.

IV. Results and Discussion

Through the analysis of the Pearson's correlation matrix we found that a few symptoms are particularly highly correlated and other symptoms didn't have much weightage so only highly influential symptoms were provided as the option. The inclusion of the 7 inputs in itself has the information equal to that of many inputs because the inputs like Mel spectrogram and MFCC have a lot of parameters associated with them , each parametre represent different feature which makes it so that we are considering enough inputs without getting to the scale of overfitting. The 7 inputs include Mel spectrogram and MFCCs of cough, speech and breathing samples respectively along with another input that included symptoms. MFCC inputs further have 39 coefficients each.

The user interface for the web application is developed [15] [20]. It shows the input given to the Covisound-Covid detection website. Symptoms are given as inputs. The symptoms considered are fever, muscle pain and respiratory problems (asthma, breathing difficulty, cold and cough). It also shows the result displayed on the Covisound-Covid detection website. The website displays the result of the Covid-19 test, negative in this case and how likely it is that the person has Covid-19 is 5.82%.

Fig. 6 shows the input given to the Covisound-Covid detection website. Breathing sounds, cough sounds, speech sounds and symptoms are given as inputs. The application shows the result displayed on the Covisound-Covid detection website. 60% of the samples were used for training, 20% for testing and 20% for validation. The total number of samples considered after preprocessing are 1605. Therefore, the number of training and testing samples is 963 and 321 respectively. The website displays the result of the Covid-19 test, negative in this case and the likelihood of the person having Covid-19 is 72.37%. Evaluation metrics considered here include accuracy, recall, AUC Score, ROC Curve, False Positive Rate and False Negative Rate [25]. The five models used for analysis have a few attributes and parameter changes between them; this is performed to see how the prediction varies based on the values set. We set a different training environment for the data to deduce the best possible trade-off over different variations.

Five models are trained by having a binary cross entropy loss function with different metrics for optimising the model. The first model uses Area under the curve as the metric for optimising the model and thereby maximising the same parameter. For imbalance data handling, class weights parameter was provided in the ratio of 1:10 (each negative sample gets ten times the weightage of a positive sample). A high AUC value is obtained here. In our second model the metric that was tuned used is accuracy so that the model focuses on the accuracy of each function and it maximises the same in each iteration. Here the trade-off made is recall which was very low and not favourable for this particular paper as the main aim is to have a high recall to reduce false negatives. In the Third model, the metric tuned was true negatives, the model gave considerable high accuracy and true negatives but it had one of the lowest recall when compared to all the other models. The false negatives rates obtained were also high, so this model was not very favourable. In the fourth model the metric used for optimising the model is recall, this attribute describes the number of positive predictions determined out of all True positive predictions. Recall also shows how well the positive class is covered in the predictions. The fifth model uses Area under the curve as the metric for optimising the model and maximises the parameter. The reason being this parameter shows the true variance between true positives and true negatives which leads to better distinguishability between them. Higher AUC means the model is able to deduce the right class it belongs to. Scoring metrics for different models are tabulated below in Table I. In Fig. 7A, ROC curves of a few models trained on the dataset in different epochs is shown. It also shows the AUC for the respective models. Fig. 7B shows the variation in AUC values vs different epochs for the model. The graph shows a steady improvement in AUC value as the epoch number increases.

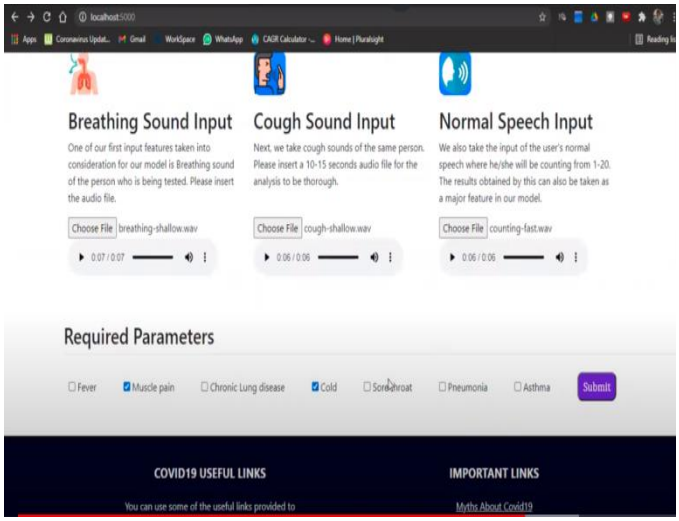

Fig. 6. Covisound- Covid Detection Website Inputs-Positive Sample.

TABLE I. Scoring Metrics for different Models

Model	Accuracy	Recall	AUC-Score	False positive rate	False negative rate
Model-1	88.75%	71.42%	80.62%	10.18%	28.57%
Model-2	95%	44.44%	71.77%	0.9%	55%
Model-3	92.91%	60%	77.95%	4%	40%
Model-4	83.75%	75%	79.86%	15.27%	25%
Model-5	90.42%	63.16%	77.96%	7.23%	36.84%

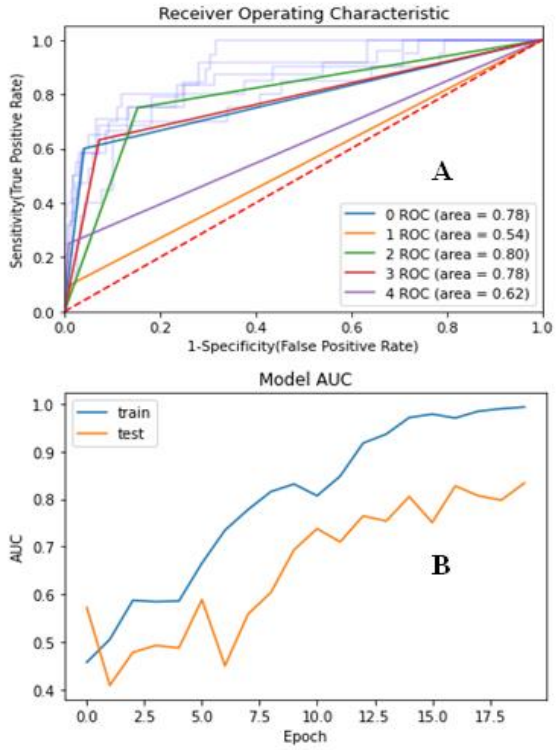

Fig. 7. (A) ROC Curves of a Few Trained Models (B) AUC Value vs epoch Numbers.

The following are the observations made after analysing the results: The best model for the paper was chosen based on AUC and recall. Model 1 gave the best recall and AUC values of 71.42% and 80.6% respectively. It gives an accuracy of 88.75%, a false negative rate of 28.57% and a false positive rate of 10%. A slight trade-off between accuracy and recall was observed while choosing the best model. Some of the models had an accuracy of 96.67% and 97% but had low recall whereas some of the other models had a high recall of >80% and close to 90% but they had low accuracy. So, the best model had to be chosen in such a way that it gave decent values for both accuracy and recall. AUC was chosen as the metric while training the model. Training AUC of 99.8%, validation AUC of 91% and a test AUC of around 81% were observed.

Binary cross entropy was chosen as the loss function while training the model. As the epoch number increased, the AUC value increased and the loss value-binary cross entropy decreased for test, train as well as the validation data. Choosing class weights while training increased the overall performance of the models but the best model was obtained while training without the class weights. The model performs much better than the baseline model in which had an AUC of 70%. The work shows that Covid-19 can be determined using the characteristics of an individual related to speech, breathing and cough sounds. The symptoms and existing conditions can further help in determining Covid-19 status. The model is able to predict the Covid-19 status of an individual reasonably and also the likelihood of the individual having Covid-19.

V. Conclusion

The proposed work showcases the possibility of using an ensemble of Convolutional Neural Networks as a testing method for Covid-19. An encouraging result was obtained in the paper by taking speech, cough and breathing sounds as inputs. Coswara data has been used in this work. MFCCs and Mel spectrogram images were obtained to extract features from the audio samples.

Seven inputs were fed to the model- MFCC cough, MFCC speech, MFCC breath, Mel spectrogram cough, Mel spectrogram breath, Mel spectrogram speech and symptoms. An ensemble of three CNN models and four dense neural network models was used for the purpose of classification. The machine learning model is able to identify Covid-19 patients with a recall of 71.42% and an AUC of 80.62%. The model performs much better than the baseline model in which had an AUC of 70%. An easy-to-use web application with a friendly user interface has also been developed as part of the work. The web application predicts whether the individual is Covid-19 positive or negative and also determines the likelihood of the individual having Covid-19. The tradeoffs between recall and the overall accuracy have also been compared in this paper. Some models had high accuracy but low recall whereas some had high recall but low accuracy. So, the best model was chosen in such a way that both recall and accuracy had decent values. Use of class weights was also attempted as part of the work to improve data imbalance handling. This work is able to reduce false negative rate and improve recall appreciably and is a good preliminary analysis tool for distinguishing Covid-19 affected individuals from healthy individuals.

Recall and false negative rate can be improved further. Dataset used is relatively small and imbalanced; a larger dataset may lead to improved results. As the dataset size increases, the model can be retrained with new data. Dataset was heavily imbalanced with positive samples contributing to less than 9% of the total data and less than 150 samples. Imbalanced data handling can be further improved in the future.

***Abstract*—With the revolution that happened in electronic gadgets in the past few years, information sharing has evolved into a new era that can spread the news globally in a fraction of minutes, either through yellow media or through satellite communication without any proper authentication. At the same time, all of us are aware that with the increase of different social media platforms, many organizations try to grab people's attention by creating fake news about celebrities, politicians (or) politics, branded products, and others. There are three ways to generate fake news: tampering with an image using advanced morphing tools; this is generally a popular technique while posting phony information about the celebrities (or) cybercrimes related to women. The second one deals with the reposting of the old happenings with new fake content injected into it. For example, in generally few social media platforms either to increase their TRP ratings or to expand their subscribers, they create old news that happened somewhere years ago as latest one with new fake content like by changing the date, time, locations, and other important information and tries to make them viral across the globe. The third one deals with the image/video real happened at an event or place, but media try to change the content with a false claim instead of the original one that occurred. A few decades back, researchers started working on fake news detection topics with the help of textual data. In the recent era, few researchers worked on images and text data using traditional and ensemble deep and machine learning algorithms, but they either suffer from overfitting problems due to insufficient data or unable to extract the complex semantic relations between documents. The proposed system designs a transfer learning environment where Neural Style Transfer Learning takes care of the size and quality of the datasets. It also enhances the auto-encoders by customizing the hidden layers to handle complex problems in the real world.**

Keywords*—Transfer learning; GANS; glove algorithms; word2vec; ensemble techniques; auto encoders; pre-trained models; word embeddings; BERT models

I. Introduction

A few decades back, researchers started working on fake news detection topics with the help of textual data. In the recent era, few researchers worked on images and text data using traditional and ensemble deep and machine learning algorithms, but they either suffer from overfitting problems due to insufficient data or unable to extract the complex semantic relations between documents. The proposed system designs a transfer learning environment where Neural Style Transfer Learning takes care of the size and quality of the datasets. It also enhances the auto-encoders by customizing the hidden layers to handle complex problems in the real world. The identification of fake news or phony news does treat as a sort of "Spam Detection," for which the reliability or accuracy of the model generally depends on the processing of the textual and image data. In this section, article will discuss a few popular textual and image pre-processing techniques. Initially, for the multi-media content, system have to work with images first. The dataset consists of three types of images, namely, a) Fake Image (tampered or morphed), b) Pristine Image (Resizing operation does perform to maintain standard size for all images), c) Image Splicing (it adds new content to the image either in image or text). The samples of fake news about celebrities that are have posted on Facebook does represent in Fig. 1. One of the fake news here is posted about celebrity with name "Tina Turner" stating that she is one of the top most among the haters list released by reputed organization, which is later found to be false. Like this many fake stories are released by few media and social networks to get the attention of viewers. The popular example for these type of examples is you tube people post false thumbnails on their videos irrespective of the content that might be displayed in the videos.

Any algorithm for working with these type of images, any model first need to separate the text and image as shown in Fig. 2.

Fig. 1. Fake News Published on Facebook.

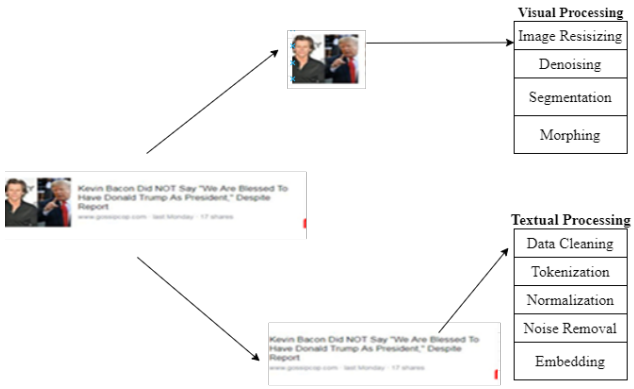

Fig. 2. Working with Multi-Media Content.

A. Image Pre-processing Techniques

This section will discuss mainly four types of processing techniques, as shown in Fig. 2. The image resizing does perform to standardize all the images to equal width and height because different articles will have different dimensions, then it becomes difficult for the neural network to give training based on the dimensions. The Denoise removal of noise steps helps the system improve the image's quality, majorly for the images captured with a low-quality lens or blur images posted due to the motion that occurred while capturing the image. Noises can exist in multiple forms, as shown in Fig. 3.

The segmentation process [22] helps find the interesting regions in the image to subtract the unwanted or uninterested parts from the original image. This process reduces the complexity as well as time to work with the image. The major pre-processing in the phony news detection system is finding the linkage or sequence in between the articles with the same headlines or continuing to a news article published a long back. These scenarios are taken care of by defining the transformation and morphing points or lines across the different images available in the dataset. All these methods mentioned are traditional, so to achieve an excellent accurate system, the researchers can replace these mechanisms with deep learning techniques like CNN [23], LSTM, and others, which are described in Table I.

Apart from these possible techniques, the best way to determine the quality of model is usage of GAN's to generate the duplicate images of different orientations by defining two types of layers one for generator and second layer for discriminator. The purpose of the generator is to create more number of relevant images and discriminator tries to identify the fake images.

B. Related Knowledge

In the implementation of GAN, there exists two components, namely, generator and discriminator. The major focus of the generator is to make the discriminator to believe the information generated about the fake images it has created. Since, the proposed model involves both text and images; the best case of GAN to implement is neural style GAN [21] because style GANS majorly focus on the tampered or morphed images rather than the real objects that exists in the image. The shape, color and edges are the crucial elements in the image processing. The extraction of these features should not impact the other layers of the network, so it's better to take the help from encoding mechanisms.

C. Text Pre-processing Techniques

In this section, the article discusses the basic techniques of NLP to deal with textual data extracted from the image. Data cleaning deals with removing stop and abuse words from the content, handling special characters, emojis, performing either stemming or lemmatization so that important base words are maintained, and others eliminate them from the content. The next step is to count the occurrences or frequencies in various new articles starting from character to sentence because the higher the frequency higher the priority to maintain the element in the content. The crucial text processing step is normalization because the semantic relation between the words (or) sentences does establish. The popular normalization technique is "POS Tagging," which labels each word in the sentence with parts of speech so that all the words might not be reduced, and sometimes over lemmatization might change the meaning of the entire sentence. The word embedding tries to find similar words with different representations and merge them to have a unique representation in the entire article so that the reader finds fewer complications with the interchange of similar words. The overall tentative proposed system does represent in Fig. 4, which can solve the major difficulties identified in the previous systems.

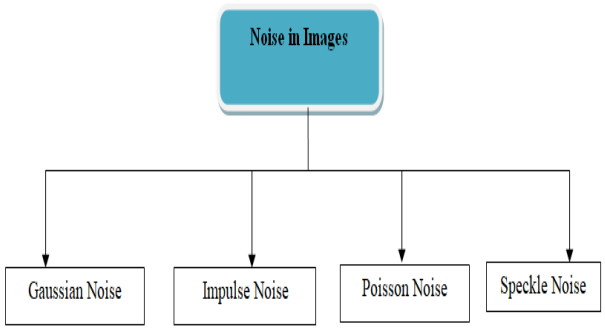

Fig. 3. Types of Noises in Image Processing.

TABLE I. DESCRIPTION OF NEURAL NETWORK TECHNIQUES

S.NO	Name	Description
1	CNN	In general images are represented in the form of 2D matrix, to explore all possible features; the CNN represents them as a 3D matrix. The extraction of features are performed with the help of hidden layers
2	LSTM	It tries to identify the features from the previous predictions which are arranged in an sequential manner taking the help of circuit gates
3	MLP	It is a fully connected layer and data units are transferred through all the layers for processing. These type of networks are applied for applications where speech act as input and to work with complex classification systems
4	RBFNN	In this model, the input vectors are compared to find the similar data points and every vector is compared against all the possible classes of the neural networks.

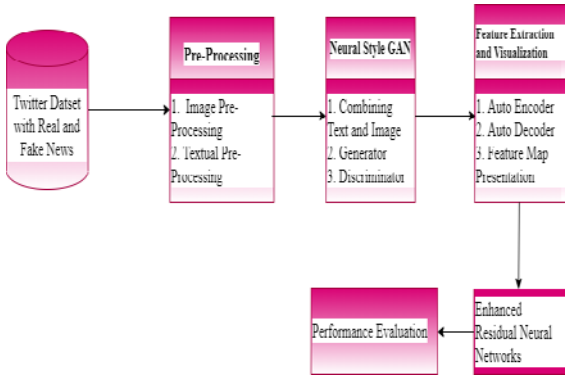

Fig. 4. Brief Overview of the Fake News Detection System.

In the below sections, the paper is organized as follows, the literature survey provides a glance of all the previous existing mechanisms and results and discussion section discusses their advantages and disadvantages to find the limitations that exists in the previous works along the datasets they have used. The observations section identifies the accuracies of all the models and describes about the best model it identified.

II. Literature Survey

In [1], Xinyi Zhou et al. explored a multi-modal analysis to detect fake news using both text and images. First, it extracts the information from the image and runs the similarity matching algorithm with different types of contents. The textual features extract using the text-CNN, in which a fully connected layer does attach to the normal CNN, and the important contents did extract after passing through each layer. For processing the images, a pre-trained model known as "image2sentence" is implemented. An independent model is developed by performing the cross-entropy modal. Every image does label with multiple classes, and the probability distribution function access the correct prediction label by using the concept of majority voting schema.

In [2], Priyanshi Shah et al. designed a framework by analyzing the tweets, which are made available in public datasets. The textual extraction performs sentiment analysis, i.e., by identifying the polarity value for all the tweets. In visual extraction, segmentation is applied by combining wavelets with K-Means and extracting nine important images. The features extracted from text and visual are represented as a matrix and passed as input to the optimal algorithm proposed by the author. Then it identifies the relevant contents and is passed to the SVM classifier with RGBF kernel function to classify the image.

In [3], Anastasia Giachanou et al. have studied multi-model evaluation using two datasets and by combining the neural networks with semantic search. The tags on images were observed and did pass as input for the local binary patterns algorithm, which finds the similarity between the text and images. The model can identify the different images with the same content. In [4], Deepak Mangal et al. proposes text cues to extract features from images by implementing the LSTM technique in neural networks. It removes the information from tag line and compares it with various news articles by using the cosine similarity mechanism. The visual features do train using VGG, and text features do train using word2vect corpus. The LSTM uses three gates to generate the classification by using useful information. The non-linearity function helps the layer identify any short sequences that occur but has a great role to play in predicting.

In [5], Tong Zhang presented a novel approach known as "BERT" implementation in neural networks for identifying the essential domain features. In this model, a component called "BDANN" identifies irrelevant features and integrates with the remaining modules to focus on the event-specific tasks. The model works in both forward and backward directions, and it works on the domain classifier by making them into sub-groups with defining specific patterns for each group to identify in the future quickly. This model has achieved an accuracy of 98.1% and presented well even in the case of true label prediction.

In [6], SomyaRanjanSahoo et al. experimented with an automatic system that can detect multiple features to identify the fake news posted on social networks. This model first analyzes the profiles of the users through a web crawler attached to the browser to get the features associated with the user. These extracted features apply machine learning like KNN, SVM, Logistic Regression, and deep learning techniques like LSTM to classify real and fake news. The model has divided features into two significant categories: contents related to profile and contents newly created, and tries to generate a mapping technique between the previous posts and new ones.

In [7], Aman Agarwal et al. explored a new approach in neural networks by blending different deep learning algorithms. The model tries to establish a relationship in terms of language by constructing a word vector using a novel algorithm known as "GLOVE" to process the textual data. The beauty of word embedding lies in its representation of sentimental meaning and their corresponding relation in geometric shapes, which helps visualize the vector space. The reason behind this shape utilization is, it marks how far two different words did match one against the other. Later, these different vector spaces are organized into a bag of words, using Keras as a pre-trained model to construct a sequential model. The major work in this system focuses on turning the parameters associated with convolution and recurrent neural networks. Using the CNN model and embedded trained matrix, N-gram higher-order representation does construct to find the co-relations between the different sequences to construct a feature vector map. With this matrix, there is a possibility of obtaining non-linear transformations in the model, which the LSTM helps classify the temporal and essential features among the text data available. This model also helps in handling the unlucky data that might be present in the model by any chance by defining the threshold values, by adding the generalized layers like dropout, normalizations, and others.

In [8], Juan Cao et al. discussed detecting fake news in different multi-media channels. The model has designed deep learning techniques incorporated with image processing compression techniques to identify the manipulations or

tampered text within the images. The major role of CNN is to extract the semantic and content features associated with the images, and later it performs statistical measures to perform feature engineering. In this system of adversarial image reconstruction, the first part of the algorithm deals with metadata generation from the top k-features extracted from the reference dataset, and the second part of the algorithm act as a consistency verifier to generate the evidence that is against the tampered image because it is essential to know the relationship between the image and text to make some inferences and decisions.

In [9], Yin-Fu Huang et al. modeled an Adaptive Harmony based genetic algorithm using ensemble techniques of deep learning. The highlight associated with this model is, it has successfully processed data based on their dimensions. For example, suppose the tokenization of words has to perform, then the embedded LSTM takes care by extracting the semantics in the form of 300 dimensions. Similarly, the depth of the sentence and parsing of grammar is taken care of by depth LSTM. From these different LSTM's, an optimized LSTM with minimum weights is constructed. The classification of news is taken care of by heuristic genetic algorithm, which consists of first random selection, whose performance computed using the objective function, which defines as the minimum weight of the output node then in the second step, the value of the node updates if and only if the memory consideration accepted. In every iteration, it adjusts the pitch such that every time it selects the elements that are less than the threshold value and simultaneously reduces the loss function by wrapping the MSE error function with a harmony algorithm.

In [10], AnshikaChoudhary et al. designed a framework based on language to detect fake news. This system uniquely concentrates on syntax related to the sentence instead of semantics by computing the density of each word. During this process, it takes three statistical measures into account; one is count, which computes the occurrence of each word, second one deal with sentences to extract the sentiment associated with it in the form of polarity, which represents the negative and positive words and subjectivity, which assigns the score as either 0 or 1. The last one takes care of the properties associated with grammar by computing the readability of the sentence based on the pattern of writing. In deep learning algorithms, all the features are standardized and passed as input to the network with two hidden layers, which designs a variant of LSTM by taking the input gate's input because it determines the number of updated values do add to the four neurons. The layer might feel some of the features are unimportant in the next phase, so the forget gate can control this. Finally, using the activation function tanh and the dot product of weighted sums, the memory gate computes the final value at the output node.

In [11], JiangfengZeng computed deep semantic correlations between the textual data and multi-media images by using pre-trained models like VGG to deal with variations in hierarchical representation systems. The model knows the complexities involved in training with the machine learning model, so it has opted for the computation of Eigenvectors to train the model, which in turn helps in the image enhancement process. The system takes news articles, i.e., text documents and the image, associated with annotated labels as input. The system uses the concept of word embedding for processing the textual data, for converting the words which are semantically closer as a group of vectors, and VGG-19 to train the features related to the images in the transfer learning environment because, in the end, they produce the output as an encoded image. The bi-directional LSTM integrated with soft attention encodes the word to extract the complete sentence in terms of grammar and other notations and represents them in a hierarchal format known as "DOM"; these can traverse in both directions. At last, the visual content connects with two dense, fully connected layers to perform decoding of both textual and visual features.

In [12], Rohit Kumar Kaliyar et al. designed a tensor decomposed matrix to work with the BuzzFeed dataset by integrating the machine learning algorithm "eXtreme Gradient Boost" algorithm with a proposed algorithm known as "DeepFake." This system involves only detecting fake in terms of social context, the construction of which needs two major inputs is contents related to the article, and the second is a matrix that defines the relation of users with different communities. The contents convert into an N-grams count vector, representing the occurrence of a particular word in different news articles. The relationship matrix converts into couple matrix factorization and mode-1 participation by constructing echo chambers, where people share their opinions about it a particular post. These matrices help compute the interests of different communities based on their comments and relationships in the network. The DeepFake architecture has designed a 4-layered network with correct regularizations.

In [13], Muhammad Umer et al. experimented with stance detection using multi-classification techniques with the help of neural networks. The headlines associated with the news article are converted into a 100-dimensional vector so that all the details about the report are stored clearly and projected into n-dimensional space, which is geometrically represented as a dense shape and is taken care of by chi-square PCA model, to reduce the low latent space vectors. The covariance, a relation between the dimensions and observations, helps the PCA reduce the number of features considered for constructing a classifier. The content in the images is categorical data, so the computation of statistical measures is done by chi-square test. The model has to predict one output out of 4 class labels, so; the last constructs, with the help of a densely connected layer, attach with softmax activation function, which is popular in handling the multi-classification, reduces the burden of the overfitting problem.

In [14], Stephane Schwarz et al. designed EMET, which considers users' responses for a particular post by performing multi-classification as true, false, and unknown. These three values are projected onto a latent space using NLP techniques; corresponding transformers did generate. The author has chosen LS representation to draw the inferences, decisions, and finally to construct a two-dimensional matrix between the post, comments, and users. The input signal transformation has marked its place in the NLP world because it generates bitextual pairs, draws the semantic relations between the closest words, and answers for a particular search query

displays with the rules that match with expert system shells. The model has used a hyper tuned CNN to classify the images by finding the best number of filters, strides, filter size, and several neurons.

In [15], SawinderKaur et al. used the concept of voting at multi-levels to identify fake news. This model has experimented with three features extraction techniques implemented as a step in ML algorithms LR and Linear SVC. All the traditional cleaning steps take care of initial processing, and mean values for different types of articles present in different datasets are measured. The System generates features; a sparse matrix does publish, using different computations like TF-IDF, hashing, and count vectors. In the TF-IDF vector, the relationship does base on the count and its associated weight; for every word, the probability of word occurrence in each document is represented in the interaction cell.

In contrast, the count vector is a numerical representation. The hashing is a novel approach implemented to store the values in buckets based on the calculated remainder value; the major advantage of this approach is that it efficiently handles the memory space during the extraction process. The reason for selecting a multi-level algorithm is to reduce the training time and to generate the outputs in parallel by using the voting classifier. The voting classifier picks the top 3 algorithms with high false rates and ensemble them because the higher the false rate, they are weak the classifiers. The model once again constructs the soft voting classifier and predicts the label based on their false positive rate from the obtained results.

In [16], Mohammad HadiGoldani et al. incrementally designed a margin loss CNN. This research aims to create a less error-prone function that reduces the cross-entropy generated by the softmax activation function. In general, the softmax functions don't adapt to the new environment, so to overcome this drawback; this research has extended the activation function with reinforcement learning. This mechanism helps in generating related featured during the process of adaptive learning. The model uses intracluster property while performing the compaction technique and inters cluster property for separating the dissimilar characteristics. The defined lambda value specifies the margin value empirically predicts the class labels.

A. Gaps Identified

Few researchers worked on the textual data to identify the fake news and few worked on both images and text. The working on images and text involves complex operations so to simplify the model, it is needed a design an architecture which reduces the cost of operations that are involved in image processing. It is observed that most of the systems find difficulty in finding the semantic relation between the different images along with their text. The popular technique for feature reduction is PCA, but it cannot handle the images where the text is embedded in the image so the usage of variant auto encoders and decoders might help the system to expose both the image features and textual features. Most of the researchers utilized the predefined architectures due to which sometimes it may suffer from bottle neck problem. The solution to this problem might be provided with the usage of transfer learning.

III. Results and Discussion

All the existing systems have successfully implemented the detection of fake news in different social media platforms. Table II compares the methods used in previous case studies and their usage of datasets and identifies the limitations found to address the research gap for implementing a better system with efficient metrics in terms of all objective functions that a deep learning system needs.

To understand the flaws and advantages in terms of various metrics, article has tabulated all the results obtained from different old research systems in Table III.

TABLE II. Comparative Study on Existing System of Fake News Detectors

Author	Approach Implemented for Feature Extraction	Algorithms Implemented for Classification	Dataset (s) Used	Limitations
Zhou[1]	Multi-Modal	Similarity Aware Capture Model	1. PolitiFact 2. GossipCop	Articles that are in pair format from different sources but published differently are not taken care
Shah[2]	Cultural Algorithm	SVM	1. Weibo 2. Twitter	The model cannot handle the complex relations between the text and visual, if any
Giachanou[3]	Google Word Embedding Layer + LBP	Inception+Xception	1. PolitiFact 2. GossipCop 3.MediaEval	It is not able to produce the decision with neutral polarity.
Mangal[4]	Textual- word2vec Visual- VGG Net	LSTM+ Cosine Similarity	Twitter	Semantically irrelevant data didn't consider here.
Zhang[5]	Multi-Modal	Domain Classifier (BDANN)	1. Weibo 2. Weibo Filtered	The domain classification rate further extended by computing the probability rate
Sahoo[6]	Web Crawler in browser	1. Group of ML Algorithms 2. Group of DL Algorithms	Own Dataset	In ML algorithms, ensemble techniques, and the DL algorithms, Hyper tune parameters can yield better results.
Agarwal[7]	N-gram through Convolution	LSTM	Kaggle	The dataset with an early annotation mechanism helps in the good clustering of characteristics.
Cao J[8]	CNN+word2vec	LSTM with multiple packages, AIRD	Own Dataset	The Metadata generator takes much more time.
Yin-Fu Huang[9]	Ensemble LSTM+ N-Gram CNN	Self Adaptive HS	Cross-Domain Dataset	It deals with only headlines mentioned in the image.

Choudhary[10]	Syntax+ Semantics+ Readability+ Correlation	Feature based sequential neural networks	BuzzFeed	The memory and temporal data should do taken into consideration for efficient implementation
Zeng[11]	Multiple Components Encoder with Soft Attention	LSTM	1.Twitter 2.Weibo	Usage of GANS can improve the Size and Quality of the dataset.
Kaliyar[12]	Tensor Formation	XGBOOST+CNN	1.Buzzfeed 2.PolitiFact	The activation function selected suffers from a zero gradient problem.
M. Umer[13]	PCA	CNN+LSTM	FNC	PCA is the traditional approach. Advanced techniques like variational autoencoders can extract high-quality and related features.
S. Schwarz[14]	Signal transformations	EMET	Twitter	Data augmentation techniques did fail in the case of an image with side annotations.
Kaur[15]	TF-IDF, Count, and hashing vectors	Multi-level voting system	1. NewsTrends 2.Kaggle 3. Reuters	Further research should control Impulsive data at an early stage.
Goldani[16]	Embedding Layer	CNN	LIAR	The embedded layer used is static.
Kaliyar[17]	Glove+Pre-trained word embeddings	Deeper CNN: HCNN+HLSTM	Kaggle	Instead of traditional neural networks, residual or transfer learning neural networks can handle complex relations and associations**.**
Hamdi T[18]	Twitter API	Node2vec selection classifier	CREDBANK	It has to generate synthetic works to handle the abnormal relations findings.
Masciari E[19]	Word Embedding	Google BERT	1. LIAR 2.PolitiFact	Diffusion mechanisms integrated with BERT improve the space complexity of the environment.
A. Agarwal[20]	N-Grams	Different Algorithms in ML & DL	LIAR+Kaggle	Hyper turned LSTM with enhanced activation functions is needed.

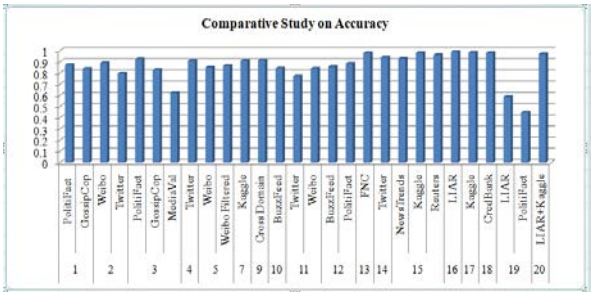

Fig. 5. Comparative Study on Accuracy Metric.

Fig. 5 describes the comparative study on accuracy metric, and from the figure, it has been found that author [16] has achieved nearly 99.9% accuracy on the Liar dataset, which is highest in terms of both similar and non-similar datasets [20][21]. The author has implemented a simple static word embedding technique to extract the features. Still, in further research, one can try to implement the non-static and redundant dimensions to improve the learning rate and other adaptability parameters because accuracy alone cannot justify the model's reliability.

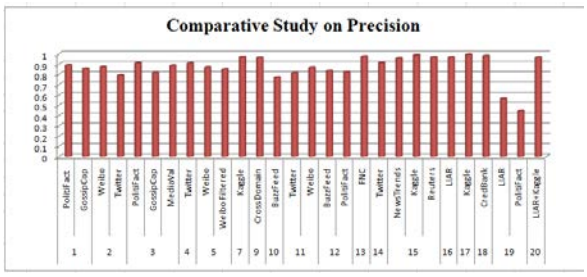

Fig. 6. Comparative Study on Precision Metric.

Fig. 6 clearly states that the author [17] [22-24] has achieved the highest precision rate, “99.4%,” by working on the Kaggle dataset. The model has successfully implemented hyper-turning of estimators inclemently, which involves checking of 2**n combinations, increasing the execution and training time. So, in further research, the selection of combinations can be reduced by creating a transfer learning environment.

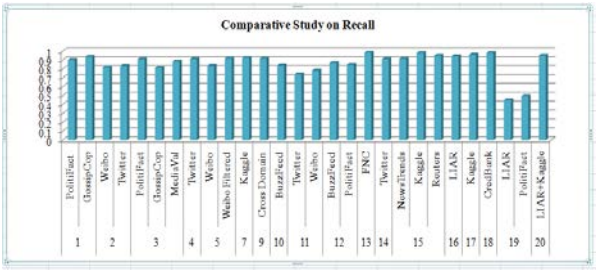

Fig. 7. Comparative Study on Recall Metric.

Fig. 7 states that the author [13] has achieved the highest recall rate, “98.2%”, by working on the FNC dataset. Still, it has applied traditional PCA algorithms for feature reduction and extraction, which further improves by defining the ensemble or variational autoencoders, which has proved its capability in extracting the visual features from multimedia content.

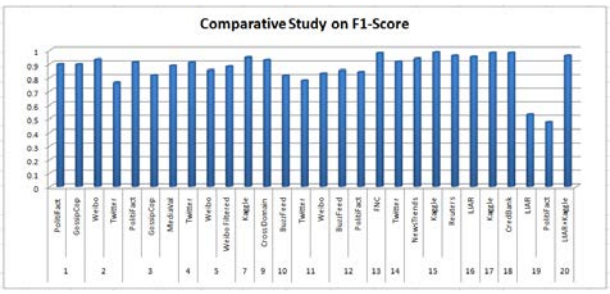

Fig. 8. Comparative Study on F1-Score Metric.

Fig. 8 showed that the author [15] had obtained an F1-score of “98.3%” on the Kaggle dataset by experimenting with three types of feature vectors and designed its classification algorithm, but it suffered when the data, either images or text are in impulsive nature so, in the early stages of model designing, one has to take care of these type of persistent relations.

IV. Observations

Table II inferences that [19], [3c], and [11] are inferior in performance in terms of all metrics. So this problem can be addressed by neural style transfer learning GANS because they can handle both images and text very effectively. The reason for selecting GANS does explain in two situations, one where the pre-processing step fails to separate the visual and text and the second where the number of images is significantly less to design a model. Next, the proposed system from the above study identified that [16] and [17] are the top two systems in identifying phony news. From these limitations, the system identified the second research gap has to take care of feature extraction with the latest deep learning techniques like autoencoders, by hyper turning and by integrating an enhanced activation function at its output layer, which is dense as fully connected layers. So that the high complex features propagate to the next layers as a simple linear input, finally, to improve the overall capability of the system, the latest transfer learning approach implements by incorporating residual neural networks with pre-trained models to reduce the time for training and to define the correct lambda values to predict the correct output labels associated with the annotated images.

V. Conclusion

This extensive literature survey helps the system to identify the drawbacks associated with the previous methodologies. From this study, the system has identified that Natural Language Processing tools like N-grams, SVD decomposition, Lemmatization’s and other simple processing techniques are efficient to work on the text extracted from the images. To work with the images, instead of simple CNN techniques, it is better to design modified auto encoders which can efficiently solve the problem of bottle neck in linear amount of time. The feature extraction is the crucial step in fake news detection because the text objects in the image play a vital role in deciding whether it is real or fake news. For the classification of news, it is better to implement ensemble algorithms or Meta classifiers, which achieves good accuracy and true positive rates. The ensemble algorithms have proved

their efficiency in terms of AUC and Kappa Statistics measurement. In future, to detect fake news detection, the proposed research first implements GANs to increment the size of data then it extracts the features using AEDECNN and then it performs classification using ensemble mechanism.

GLOSSARY

S.No	Term	Full Form
1	CNN	Convolution Neural Networks
2	GAN	Generative Adversial Networks
3	LSTM	Long Short Term Memory
4	RBFNN	Radial Bias Function Neural Network
5	MLP	Multi Layer Perceptron
6	SVD	Single Value Decomposition
7	AUC	Area Under Characteristics

Information Systems, King Abdulaziz University, Jeddah, Saudi Arabia[2, 3, 4, 5]

***Abstract*—Littering contributes significantly to environmental pollution. Previous studies have noted that children are more likely to litter than adults. This target age group can be easily reached through mobile applications and games. Therefore, this study aims to investigate the effect of a gamified application in raising awareness on the effect of littering in the environment. We developed a gamified app, called DoItRight to promote an environment friendly behavior and improve the littering behavior of children. The DoItRight app is in Arabic language and targets children between 5 and 13 years old. It is a gamified application that enables kids to learn the importance of picking up litters and dropping it in trash cans. The app was evaluated using the System Usability Scale (SUS) standardized instrument which was administered on the target audience. The results of the evaluation showed that the DoItRight app has an SUS score of 93.25 which represents an A+ grade and a percentile range of 96 to 100. This indicates that the DoItRight app is technically usable and can potentially serve the purpose of increasing kids' awareness about the downsides of littering on the environment.**

***Keywords*—Littering; mobile application; gamification; children intention; raise awareness; behavior change Saudi Arabia**

I. Introduction

Over the years, human practices have caused several environmental hazards which can inhibit future growth and wellbeing. The collective impact of human behaviors on the environment further threatens our ecosystem [1] – [3]. One of such behaviors is littering which can either be accidental or intentional. Therefore, identifying factors responsible for high rate of littering is critical to design an efficient littering-reduction intervention. A study carried out in 2020 used the Motivation, Opportunity, Ability and Behavior (MOAB) framework to examine the individual littering behaviors of Saudi citizens. It conducted twenty-five semi-structured interviews on individuals between 20 and 40 years in Saudi Arabia. The outcomes of the study showed that the lack of knowledge, at the individual level, influences littering behavior. Other factors found include social norms and the built environment. Therefore, any plan to reduce littering must include the implementation of an individual-level strategy [4].

Additional individual and environmental factors influencing littering behavior in Saudi Arabia have also been unraveled. Recent research observed 362 individuals and their surrounding environments for twelve days in Saudi Arabia [5]. Findings revealed that littering rates were higher in environments that were less attractive and where trash cans were far from individuals. Also, the study found out that younger people are more likely to litter than older people.

Meanwhile, the global increase in the use of smartphones has led to the emergence of mobile applications being developed and deployed for education and enlightenment on several issues including environment and health (for instance, mhealth systems) [6]. Also, researchers have acknowledged the effectiveness of mobile applications in educating children. Therefore, the use of a mobile app to raise children's awareness of the threats posed by littering can prove to be an effective litter-reduction strategy [7]. Therefore, this research designs, and evaluate an Arabic gamified mobile application following user-centered design approach, called "DoItRight" to increase children's awareness and intent towards littering. It targets children from 5 to 13 years.

A. User-Centered Approach

As the name implies, a user-centered design (UCD) approach puts the user at the center of the design process. That is, the designer of a product or application considers the needs, limitations, and interests of the end users and designs a product that meets those needs. Having an understanding of who we design for, what they need, and their environmental circumstances is an effective way to ensure that a product or design is successful. It is also a good way of preventing a bad design that can potentially frustrate users [8]. The UCD approach involves understanding user context, defining requirements, developing solutions, and evaluating the outcomes with respect to the users' requirements and contexts [9]. In this study, we adopted a user-centered design approach to develop the DoItRight application.

The rest of this paper is organized as follows: Section 2 explores the related work in the existing literature. Section 3 presents the methodology adopted in conducting the research. Results are presented and discussed in Section 4 while Section 5 concludes the paper and sets the direction for future work.

II. Related Work

A. Improving Children's Littering Behavior

Education in different forms can be used to improve children's behavior towards the environment. Reference [10] reported outcomes of the "We Love Reading Program" that

leveraged the reading of social stories to address littering and environmental issues across different communities in Jordan. The results indicated that the program improved children's knowledge of littering issues and created a positive change in the behavior of the kids.

The author in [11] explored 5th grade children's solutions to littering and environmental pollution using the kids' drawings. Forty children at the age of 10 and 11 years, including 25 girls and 15 boys, completed drawings to provide solutions and future plans to littering and environmental pollution. The study utilized three themes to analyze the drawings; these include persuasion, physical action, and political action. However, most of the children found it difficult to visually express their thoughts on persuasion and political action. The major solutions common in the drawings include collecting litters, dropping litters in the trash can, and planting saplings [11]. The children in the research knew littering is a great environmental challenge that needs to be addressed with more than one strategy.

In a recent publication [12], researchers echoed the fact that a proper upbringing of a child potentially represents a great beginning towards developing a good littering behavior. A survey administered by the study recorded responses from 2,349 individuals. The outcome of the survey showed that low-income households need support in terms of quality education and disposal facilities while high-income households need support in terms raising awareness on the problems of littering. Though self-initiative and parental guidance constitute a good approach towards improving the littering behavior of children, they are not sufficient [12]. The researchers suggested that future research should explore the effectiveness of religious education on the littering behavior of children.

To find a lasting solution to the littering problem, it is important to understand the factors that motivate people to dump litters in the environment or in the bin [13]. Researchers [13] explored these motivating factors by conducting a survey that asked people to indicate what motivates them to drop litters in the bin. An analysis of the survey responses divided the motivators into intrinsic and extrinsic motivators. The results showed that sense of morals, ethics and upbringing were the highest-level intrinsic motivators while the highest-level extrinsic factors were the presence of kids, being in a clean place, and recycling programs. Therefore, to create a successful anti-littering campaign in developing countries, stakeholders should combine intrinsic and extrinsic motivators. The study [13] noted that, for the intrinsic motivators, authorities should remind people of their core values, morals and ethics. For the extrinsic factors, authorities should create a convenient infrastructure, recycling programs, rewards, and penalties.

B. Use of Digital Technologies to Address Littering Issues

Some existing research works have explored the possibility of leveraging digital technologies and mobile applications to improve the littering behavior of children. Researchers [14] concluded that it is extremely important to raise children's awareness towards making sustainable choices when buying, using or dismissing products. One of the solutions proposed was the development of Contact from the future, a digital game focusing on plastic pollution education of children. After defining the requirements and objectives of the game, the study designed and developed the game application. The ultimate goal was to raise awareness and stimulate pro-environmental behaviors in children.

Another study [15] identified inadequate environmental education or awareness at the early age as a critical cause of littering and environmental problems. To address the issue, the study developed an Android-based sorting waste game to teach children the different kinds of waste, (i.e., organic and inorganic) and the appropriate litter box to drop each waste. The Waterfall Development Model was adopted meaning that the development of the sorting waste game followed a 4-step process including analysis, design, implementation, and testing. The functionality of the game was tested and the outcome indicated that the game is user friendly, runs smoothly on Android, and can serve as an effective medium of gaining environmental education.

Also, an exploratory study [16] was conducted to understand how children's use of digital technology, especially iPads, can impact outdoor environmental education programs. In particular, iPads were integrated into water quality education for 5th grade children. The qualitative observations obtained from the study were analyzed and seven major themes emerged. They include children's reaction to mobile devices, digital natives versus immigrants, group interactions, mobile devices in the hands of kids, instruments for learning, nature prevails, and introduction of mobile devices. These themes offered new insights to understand best practices for technology integration into littering and environmental education.

The author in [17] examined the effectiveness of web-based animation videos in the environmental education of elementary school pupils. The research [17] developed web-based animation video pages for climate change, waste recycling, mangrove forest, ozone depletion, and biodiversity. The impact of the intervention was measured via pupils' level of natural curiosity, improvement in environmental awareness, and the pupils' level of pro-conservation values. The outcome of the evaluation revealed that the use of web-based animation videos has positive effect on pupils' littering and environmental education.

Moreover, other researchers [18] have equally emphasized the urgent need to consider the use of virtual and augmented realities, videoconferencing, and mobile apps to engage primary school children with the ultimate goal of preventing littering and restoring the environment. The research [18] indicated that these technologies can capture children's interest while enabling them to learn important practices in preventing littering and protecting the environment. Quick Response (QR) codes are another example of a technology that can be integrated into mobile learning technology in littering education [19]. When attached to an object, the QR codes can add a layer of digital functionality thereby empowering users of mobile devices to access information without any restriction.

III. Methodology

A. DoItRight App Intervention Design and Development

We followed four main stages in the design and development of the DoItRight App:

1) Understanding user context

2) Obtaining requirements from parents and families of children who are target audience of the proposed application.

3) Creating a prototype of the app features based on the requirements collected in stage 2 as well as a review of similar mobile applications in the market.

4) Deploy and test the DoItRight app for evaluation; create a formative evaluation protocol to get feedback that can be used to further refine the app.

In stage 1, we determined the target audience in terms of who they are, their access to smartphones, age group, level of education etc. In stage 2, we administered a survey filled by parents and families to enable us to identify and define user requirements while also exploring the operational feasibility of the proposed DoItRight app.

In stage 3, the team reviewed existing mobile applications in the market with similar features and target audience to DoItRight app. The team also developed all necessary features to meet the requirements obtained in stage 2 and fill the gaps in the existing similar mobile applications. In stage 4, the team prepared and administered a survey on children between 5 and 13 years (target audience) to evaluate the usability, reliability, and response time of the DoItRight app. The design and development stages of the DoItRight app can be seen in Fig. 1.

B. Requirements: Increasing Children Awareness and Intention about Littering

In stage 1, preliminary studies and review of the existing literature indicate that kids are more likely to litter than adults. These children also have little awareness on the consequences of littering. Therefore, the target audience of this study is determined to be 5 to 13 years. In stage 2, we defined a survey to obtain user requirements of the target audience. The questionnaire was administered using Google Forms, distributed via WhatsApp and filled by parents and families of the target audience. In total, 161 responses were recorded.

- Demography of Participants: 87.6% of participants are female while 12.4% are male. 20.5% of them are less than 20 years, 51.6% are between 20-40 years, and 28% are over 40 years. Also, 46% of the participants have children with the age of 5 years.
- Results: 90.7% of participants reported facing the problem of littering in different public places, thereby confirming the significance of the littering problem that the DoItRight app aims to address. Also, 16.8% of the respondents reported that their children have bad littering behavior and throw wastes on the floor rather than the trash can, even at home. When asked about the causes of littering, 39.1% chose "lack of education", 54.5% chose "no responsibility" and 6.4% chose "others". This indicates that the lack of adequate awareness (education) contributes significantly to the menace of littering. In addition, 98.8% of participants are willing to allow their children use a mobile application that can increase their level of awareness and intent on littering. Also, 98.8% will appreciate a solution that is highly interactive, can improve the children's motivation towards dumping litters correctly and can help them apply whatever they learn.

C. DoItRight App Description

In stage 3, a prototype of the DoItRight app was developed while ensuring that there the features address the user requirements identified in stage 2. The mapping of the requirements to the features and the anticipated techniques to increase children's awareness and intention is provided in Table I. The DoItRight app is an education gaming mobile application targeting Saudi children between the age of 5 and 13 years. To access the application, a child needs to create an account which includes providing a username and creating a password of not less than 8 characters. The game consists of 3 levels; each level has specific tasks.

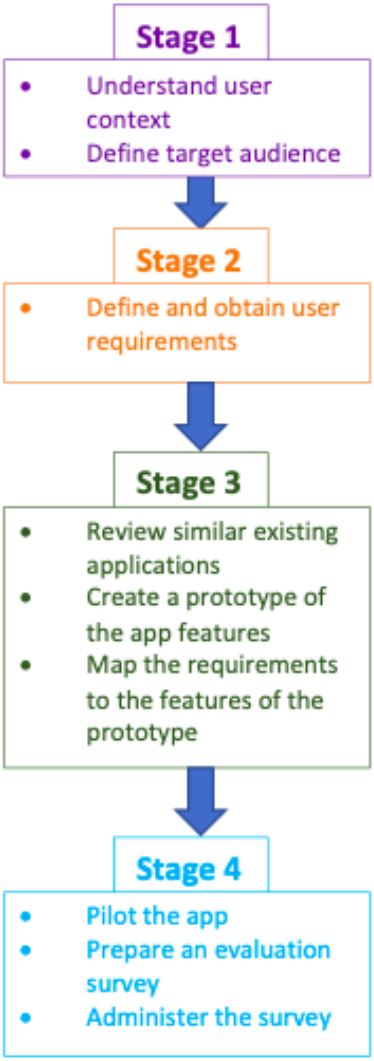

Fig. 1. Shows the Major Highlights of all the Four Stages in the Design and Development of the DoItRight App.

TABLE I. MAPPING USER REQUIREMENTS TO DOITRIGHT APP FEATURES AND AWARENESS/INTENTION TECHNIQUES

User requirements	App features	Increasing awareness and intention techniques
A means of raising awareness on littering	Levels 1 to 3 of the game, food items in the reward and evaluation stage of the game	Instruction on how to perform the behavior
Highly interactive	Use of visuals (videos and pictures), sounds, texts	Information provision
Motivation for children to drop litters appropriately	Food reward after level 3 (candy, banana, juice, and chips), stars, accumulation of points	Rewarding
Ability to apply what is learnt	Evaluation task on the empty candy bag, banana peel, empty can and empty chips bag on the floor	Feedback on the behavior; prompts
Understanding the importance of good littering behavior	Videos displaying positive and negative impacts of varying actions on the environment	Feedback on the behavior

1) First level (the beach)

- The game starts with a child carrying a bag in the beach.
- The child must collect 50% of the litter at the beach.
- In this first level, the child's speed will be medium.

2) Second level (the park)

- The second level starts with a child carrying a bag in a park.
- The child must collect 50% of the litter in the park.
- Here, the child's speed will be faster than the first level's speed.

3) Third level (the city streetss)

- The third level starts with a child carrying a bag in the city streets.
- The child must collect 50% of the litter in the streets.
- The child's speed will be faster than the speed in the second level.
- Throwing the dirtbag into the waste bin completes level 3 while the game proceeds to the reward and evaluation stage.

For completing all three levels successfully, the child is rewarded with food which includes a candy, banana, a can of juice, and a bag of crispy chips. While the food items serve as a reward for a job well done in levels 1 to 3, they are equally serving as a means to assess the child's level of awareness about littering having played the game. Therefore, after eating the food, the empty candy bag, banana peel, empty can, and empty chip bag are all thrown on the floor. Afterwards, a creative character will appear on the screen to ask the child a question; "what are you going to do now?" If the child picks up the litters and drop in the waste bin, he has passed the test. A congratulatory message will appear. However, if he did not drop the litters in the waste bin after 10 seconds, he will lose and repeat the game.

D. Key Highlights of the DoItRight App

1) Methods of collecting points: In each level, the child gets the maximum points obtainable if he collects the highest possible amount of litter that comes his way in the course of the game and successfully drops them all in the waste bin before the end of the level.

2) Difficulty: The child's walking speed will increase after each level, potentially allowing him to collect all the litters before reaching the waste bin.

3) Motivation: Aside from the food reward given to the child at the end of level 3, encouraging sound and objects will appear during the child's walk e.g., stars or clapping sound.

4) Videos at the end of each level: The first video congratulates the child who gets the required number of points and scales through the evaluation test. The video will show the positive impact of the child's act on the environment. Then, it also shows the negative effects of leaving litters on the floor.

The second video shows the child who did not get the required number of points or who did not pass the evaluation test. It shows the negative effects of the litter on the environment. Then, it ends with the positive impact of collecting litters and throwing them in the appropriate waste bin. This helps the child to visualize the positive change his efforts could have brought to the environment if he had dropped the litters in the waste bin.

5) Activity diagram: An activity diagram shows the flow of the interaction between a system and the user in a sequential order. The activity diagram for the DoItRight app is shown in Fig. 2.

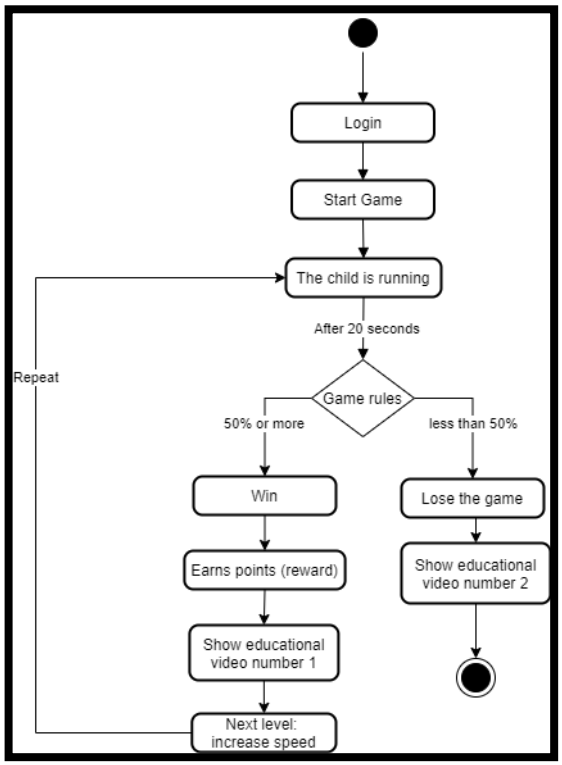

Fig. 2. The Activity Diagram of the DoItRight App Showing the Flow of Interaction between the System and the user.

6) User interface: The Graphics User Interface of the DoItRight app was designed using JustInMind. Some of the snapshots of the interface like welcome page, education video page, and game page are shown in Fig. 3-5.

Fig. 3. A user Interface that shows the Welcome Page of DoItRight App.

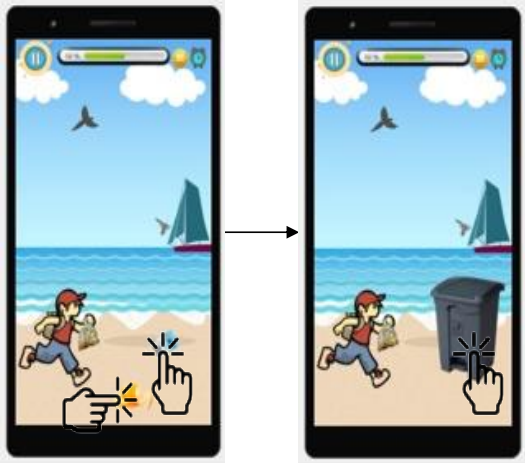

Fig. 4. Two user Interfaces with the First One showing 50% Progress made in the Level 1 of the Game and the Second Interface Showing a Child Throwing the Dirtbag into the Waste bin.

Fig. 5. The Interface Shows an Educational Video on the Positive Environmental Impact of Dropping Litters in the Waste Bin.

E. Testing and Evaluation

To test and evaluate (stage 4 of UCD) the effectiveness of the DoItRight app, three techniques were implemented namely unit testing, integration testing, and usability testing. These steps help to test the application for quality assurance, both technically and in terms of user satisfaction.

1) Unit testing: Unit testing is a software testing method by which each part of an application (known as a unit) is tested to ensure it is fit for use and meets the desired goal. Part of the objective is also to identify and solve any problems that may arise [20]. In the DoItRight app, we performed unit testing for several units of the app, such as the signup function and the login functions. In the login unit testing, for instance, we tested several cases like leaving the username and password fields blank, filling the password field alone, filling username field alone, and filling correct username and password in their respective fields.

2) Integration testing: While unit testing involves testing a part of the application, integration testing involves testing a combination of units. It is carried out to check if specific units of an application work and interact together as expected. It is usually carried out after the unit testing [21]. For the DoItRight app, we implemented seven different integrated testing objectives. The results are shown in section 4.0.

3) Usability testing: Here, we adopted the Arabic version of System Usability Scale (SUS) which is known as the most popular and widely used standardized questionnaire for assessing perceived usability [22]. SUS consists of a 10-item questionnaire; each question has five response options which include strongly agree, agree, neutral, disagree, and strongly disagree [23]. This evaluation was carried out to determine whether the DoItRight app meets the needs and expectations of the major stakeholders who are the target audience. The questionnaire was deployed using Google Forms. The ten questions include the following:

i. I think that I would like to use this system frequently.
ii. I found the system unnecessarily complex.
iii. I thought the system was easy to use.
iv. I think that I would need the support of a technical person to be able to use this system.
v. I found the various functions in this system were well integrated.
vi. I thought there was too much inconsistency in this system.
vii. I would imagine that most people would learn to use this system very quickly.
viii. I found the system very cumbersome to use.
ix. I felt very confident using the system.
x. I needed to learn a lot of things before I could get going with this system.

Ten children between the age of 5 and 13 were selected as participants in this survey. The full consent of the parents was secured before selecting a child or administering the questionnaire. As per the demography of study participants, we recorded 7 boys with age ranging from 5 to13 years and 3 girls

with age ranging from 8 to 13. Age 8, 11, and 13 recorded 2 children each while age 5, 6, 7, and 10 recorded one child each.

IV. Results and Discussion

The outcome of the integrated testing implemented on the DoItRight app is shown in Table II. As it can be seen in the table, all the test cases gave positive results.

After analyzing the responses recorded for the System Usability Scale questions, the following results were obtained:

i. 30% strongly agreed that they would like to use the DoItRight app frequently, 50% agreed while 20% were neutral.
ii. 80% of respondents strongly agreed that the system was easy to use while 20% agreed.
iii. 30% strongly agreed that they found the various functions in the system well integrated, 60% agreed and 10% were neutral.
iv. 70% strongly agreed that they would imagine that most people would learn to use the system very quickly; 30% agreed.
v. 60% strongly agreed that they felt confident using the system while 40% agreed.
vi. All respondents strongly disagreed that the system was unnecessarily complex or that there was too much inconsistency in it or that the system was too cumbersome to use or that they needed to learn a lot of things before they could get going with the system. They all strongly disagreed!
vii. 90% strongly disagreed that they would need the support of a technical person to be able to use this system while 10% agreed.

Also, based on the responses, we computed the SUS score for the DoItRight app. The SUS score of the app was found to be 93.25. This falls between 84.1 and 100 on the Sauro-Lewis grading scale for SUS scores [24]. Therefore, the DoItRight app falls into the grade A+ category and a percentile range of 96 to 100 on the Sauro-Lewis. As a result, it can be concluded that the DoItRight app is highly acceptable among users.

There are some existing apps that have some similarities with the DoItRight app. Such applications include Watten Games, Garbage Truck, Trash Stash and Littering Game. A comparative analysis between the DoItRight app and the four identified similar apps revealed that the DoItRight app offers better and superior features to address the challenge of littering than any of the other four applications. It supports Arabic language, has several levels and scenarios, rewards players with points, and provides realistic images of characters. This puts the DoItRight application in a position to change the behavior and intent of children towards littering in Saudi Arabia, much better than any other application.

TABLE II. Results from the Integrated Testing Carried Out on Doitright App

Test Case ID	Test Case Objectives	Test Case Description	Expected Results	Remark
1	To check the interface link between the first page and the signup page.	The user clicks the " أنشأ حسابك الان" button.	DoItRight directs the user to the signup page.	Positive test
2	To check the interface link between the first page and the login page.	The user clicks the "سجل دخولك" button.	DoItRight directs the user to the login page.	Positive test
3	To check the interface link between the signup page and the start page.	The user enters name and password, confirms it, and clicks the "أنشأ حسابك" button.	DoItRight application creates a user account and directs the user to the start page.	Positive test
4	To check the interface link between the login page and the start page	The user enters name and password and clicks the " سجل دخولك" button.	DoItRight application allows the user to access the app and directs user to the start page.	Positive test
5	To check the interface link between the start page and the first page	The user clicks the " تسجيل الخروج" button.	DoItRight directs the user to the first page.	Positive test
6	To check the interface link between the start page and game page	The user clicks the "ابدأ اللعب" button.	DoItRight directs the user to the game page.	Positive test
7	To check the interface link between the stop page and the start page	The user clicks the "انهاء اللعب" button.	DoItRight directs the user to the start page.	Positive test

V. Conclusion and Future Work

To the best of our knowledge, the DoItRight app is the first mobile application aimed at increasing awareness level and intention of Saudi children about littering. The app features meet all user requirements identified and defined during the UCD process such as the potential to educate a child on the proper way to dump litters, motivation, and the application of knowledge gained in real-life. A survey conducted to determine the acceptability of the DoItRight shows that the app has a high acceptability rate among the target audience having recorded a System Usability Scale score of 93.25%.

In the future, we would like to explore the following areas:

i. Conduct a more comprehensive evaluation of the DoItRight app by getting feedback from more children. To get this done, we intend to get approval from the Institutional Review Board (IRB) in Saudi Arabia.
ii. Add more levels to the DoItRight game with varying degrees of difficulty and duration.
iii. Connect the application with the Internet and GPS such that the stages can appear on the map and give a child the feeling of cleaning his current living environment.

iv. Create a dashboard where users can track their performance with respect to other players using the DoItRight app in their areas.
v. Add multiplayer stages to allow users compete with nearby players and friends.

The DoItRight app can have a significant positive impact on Saudi's public environment if widely adopted among children across the country.

Noise Cancellation in Computed Tomography Images through Adaptive Multi-Stage Noise Removal Paradigm

Jenita Subash, Dr.Kalaivani S*
School of Electronics Engineering (SENSE)
Vellore Institute of Technology, Vellore, Tamil Nadu, India

***Abstract*—Image de-noising is a noise removal approach, which is utilized to remove noise from the noisy image and is utilized to protect the significant features of images namely, corners, edges, textures, and sharp structures. For medical diagnosis Computer tomography (CT) images are mainly utilized. Due to acquisition and transmission in CT imaging, the noise that appears leads to poor image quality. To overcome this problem, an efficient Noise cancellation in computed tomography images using adaptive multi-stage noise removal paradigm is proposed. The proposed approach consists of three phases namely, Optimal Discrete Wavelet Transform, first stage noise removal using Block Matching, and 3D filtering (BM3D) filter and second stage noise removal using the bilateral filter (BF). Initially, Discrete Wavelet Transform (DWT) is applied to the input image to diminish noise in CT images. In this method, co-efficient ranges are optimally selected with the help of Crow Search Optimization (CSO) algorithm. Secondly, to remove the noise present in the bands, BM3D algorithm is applied. Finally, bilateral filter is applied to the BM3D output image to further enhance the image. The performance of the proposed methodology is analyzed in terms of Peak signal-to-noise ratio (PSNR), Root Mean Square Error (RMSE), and Structural Similarity Index (SSIM). Furthermore, the multi-stage noise removal model obtained gives the best PSNR values compared to other techniques.**

Keywords*—*De-noising; computer tomography; discrete wavelet transform; crow search optimization; bilateral filter

I. Introduction

An image is a collection of dimensions in two dimensional (2-D) or three dimensional (3-D) spaces [1]. Computer tomography (CT) images usually have noise due to faults in image holding methods. Noise will be removed from images so that the analysis of image elements (e.g., blood vessels, inner folding, or tumors in the human brain) can be completely observed and the upcoming image researches are trustworthy. The image restoration presented appears to be the sharpest possible among the multi-scale image smoothing methods by preserving uniqueness and stability [2]. The medical imaging technology is fetching a valuable section of a huge amount of purpose namely research, diagnosis, and treatment. It has enabled doctors to construct images of patient body for medical objectives [3]. Basically medical images namely X-Ray, CT, MRI, and PET contain the information of

Heart, brain, and nerves but these images are suffered from huge shortcomings, which include the acquisition of noise [4].

The noise is irregular fluctuations that accompany a transmitted signal that tend to obscure the signal that has to make the data to slow down or reduce the clarity or accuracy of the data. Medical images may be clear, sharp, noisy and vague. Usually computed tomography (CT) images are distorted by Gaussian noise and salt and pepper noise [5]. The Gaussian noise, which increases due to acquisition and it can be reduced by using spatial filters. Salt and pepper noise, which rarely occurs in form of white and black pixels, can be effectively eliminated by the morphological filter. Two approaches Empirical Mode Decomposition (EMD) and Dual-Tree Complex Wavelet Packets (DTCWP) are used for de-noising the CT-images. All noisy algorithms are based on the local or global noise model and the generalized image softness model [6]. In modern hospitals, X-RAY and CT images are mostly used because these have several importance, but it may lead to potential radiation hazard to patient because x-rays could cause hereditary harm and actuate malignant growth in likelihood identified with radiation portion [7].

A lot of filtering methods for example median filter, mean filter, bilateral filter, Gaussian filter, linear filters, non-linear filters, spatial filters and transform domain filters are used for remove the noise present in the CT images. Moreover, edge-preserving approaches are utilized for reducing undesirable effects on images [18]. In [9] nonlocal means filtering based CT image de-noising is explained in [8] 3D collaborative filtering based de-noising. A lot of methods are available for de-noising even though an efficient de-noising method is urgently needed.

The important goal of this paper is to eliminate noise existing in CT image with the help of multi-stage noise removal paradigm model. The proposed multi-stage noise removal paradigm model consists of two stages of the noise removal process. The first stage noise removal is done with the help of the BM3D filtering algorithm and second stage noise removal is done with the help of a bilateral filter. These two stages have improved the quality of the image. The contribution of the research work is listed below:

- DWT is applied to the input image to convert the spatial domain image into a transform domain. In this, coefficient ranges are optimally selected with the help of CSO algorithm.

*Corresponding Author.

- To evacuate the noise present in the input image BM3D channel is connected to the input image. The BM3D channel accomplishes the dependable PSNR and resolves difficulties of related methodologies when tending to the distinctive level of noise.
- To further progress the input image quality, a bilateral filter is accomplished to output of the BM3D image.
- The performance of proposed technology is scrutinized in conditions of various metrics and performance is in comparison with a different algorithm.

The remainder paper sorted out as pursues; the background of the proposed method is analyzed in Section II and the proposed image de-noising methodology is analyzed in Section III. The performance analysis is discussed in Section IV. Finally the article is concluded in Section V.

II. Background

A lot of researchers had elucidated the image de-noising technique. Among them some of the methods are analyzed here; Elhoseny et al. [10] had proposed a medical image de-noising using optimal bilateral filter (OBF) and convolution neural network (CNN). For the noise removal process optimized bilateral filter (OBF) is utilized. In this filter, Gaussian and spatial weights are the parameter used in the OBF. To increase the characteristic of the de-noised image, the parameters are excellently selected with the help of a combination of dragonfly (DF) and modified fruit fly algorithm. After the filtering process, the normal and abnormal images are classified using CNN classifier. Manduca et al. [11] proposed a novel locally adaptive projection space denoising algorithm for a low dose CT image. Similarly, Katsuhiro et al. [12] have developed an edge preserving based noise reduction using three-dimensional cross-directional bilateral filter (3D-CDBF) in CT images. The filtering process is mainly used for noise removal and edge preserving process. The bilateral filter is a mixture of two types of filters namely spatial and Gaussian filter. Finally, the noise spectrum is calculated for all the de-noised image and performance are analyzed.

In [13], Wojciech and Ewa have explained a medical image noise cancellation and edge preserving based on a granular filter. Here, two different methods namely, crisp and fuzzy are developed. For experimentation, CT and US breast images are utilized. The granular filter performance is compared with different filters namely, relating to space balancing and median, bilateral filter, anisotropic diffusion. Moreover, Hsuan and Chieh [14] have explained a kernel-based image de-noising technique for developing parametric image creation. To eliminate the noise in input image, general-threshold filtering method is combined with a whole variation and this method was investigated. The mathematical explanation of improved intravoxel incoherent motion (IVIM) method based de-noising is proposed. The suggested method was effective than IVIN method.

Manoj and Pardeep, [15] have explained a CT image de-noising using the bilateral method with the concept of Bayes Shrinkage rule in the wavelet domain. Initially, the image is filtered with the help of the bilateral filter. After the noise removal process, wavelet packet based thresholding is applied. Then, to attain the efficient de-noised image, the threshold output image is added with the bilateral filter. The performance of the presented technology is analyzed in conditions of the PSNR and similarity measures. Similarly, in [16], Manoj et al., have explained CT image de-noising in the curvelet domain. In high frequency coefficients, inter- and intra-scale responsibilities are used in side by side. From the high frequency coefficients, correlation values are obtained. Then, both the high frequency coefficients, aggregation are performed. After aggregation, the inverse curvelet transform is applied to get a de-noised image. Moreover, Bing et al. [17] have explained a Coupling de-noising methods depends on individual wavelet transform and modified median filter for medical image. The method consists of four phases namely, image acquisition, image storage, image processing, and image reconstruction. Initially, the image is captured from the patient that contained the noise. Then the collected images are stored on the cloud. In the third phase, the medical image is breakdown into four modules namely, LL, LH, HL, and HH. Then, for further processing, high frequency co-efficient are utilized. Then the changed median filter is applied to three high frequency sub bands. Finally, they have obtained the de-noised image. The performance is analyzed in terms of PSNR measures. Jenita Subash et. al. [19], Shyna.A et.al.[20], Devinder Singh et. al. [21] introduced improved fuzzy based approach for noise removal.

III. Adaptive Multistage Noise Removal Methodology

In this work, a novel multi-stage noise removal paradigm to deal with noise is proposed. The overall architecture of proposed method is shown in Fig. 1. For de-noising process, at first, images are decomposed with the help of DWT. To enhance the sensitive regions with higher visual quality, initially, DWT is employed to input image; while optimal coefficients are selected using the Crow Search Optimization algorithm. After decomposition, BM3D filtering algorithm is applied to high frequency sub bands of DWT output. Then at the subsequent stage, the bilateral filter is used to take out the noise cleanly and it retains the uncorrupted information. The overall concept is compressed into three phases:

A. Crow Search Optimization Algorithm

The most important goal of this section is to segregate the input image into four sub divisions, that is, LL, LH, HL, and HH. To increase the image quality in terms of PSNR, this methodology optimally selects the wavelet coefficient. For wavelet co-efficient optimization, CSO algorithm is utilized. CSO is a recently developed metaheuristic algorithm and also developed based on crow's behaviour.

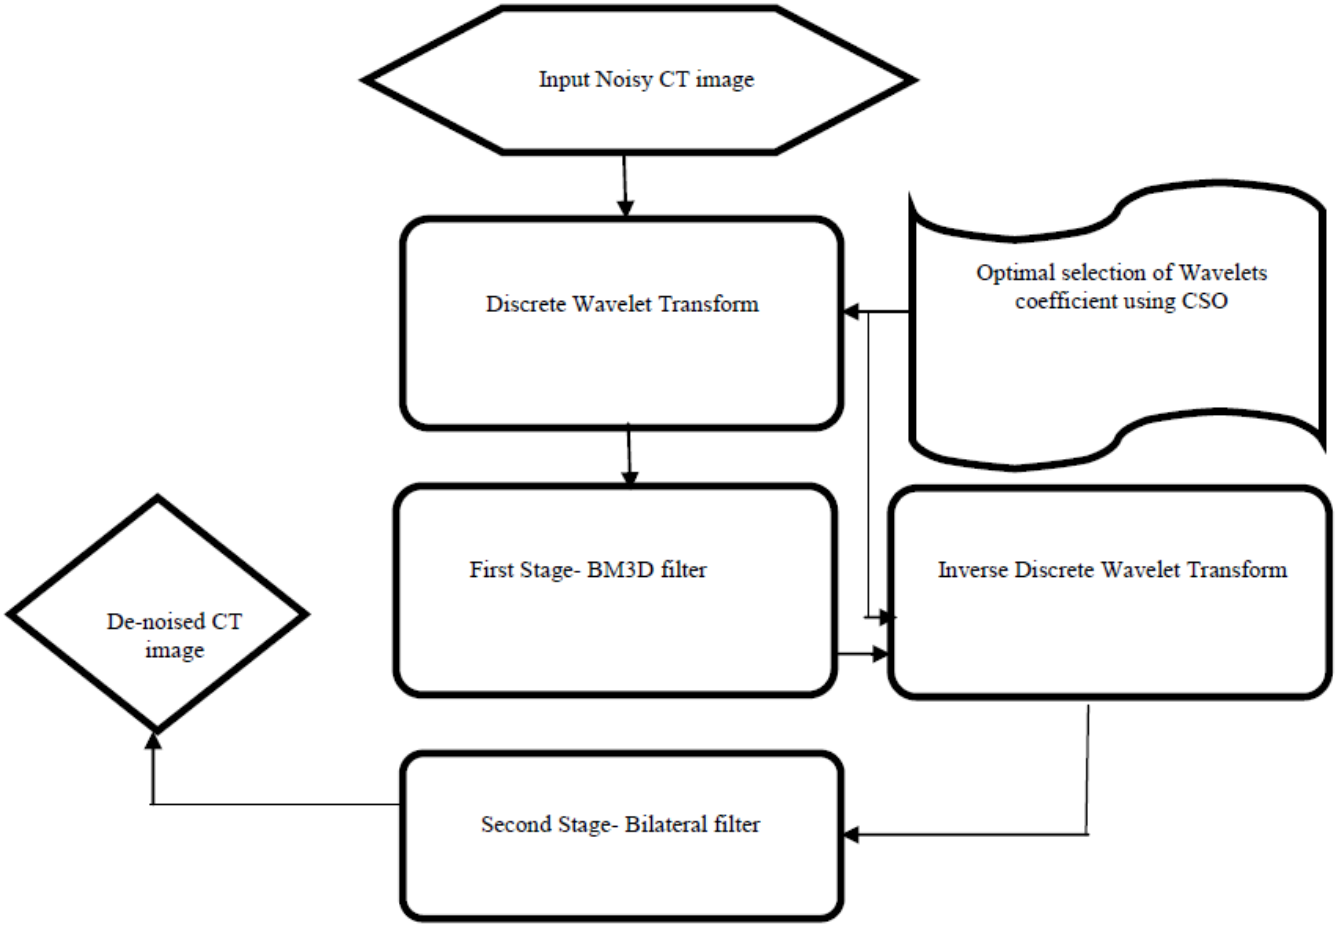

Fig. 1. Overall Architecture of Proposed Method.

B. *First Stage Noise Removal using BM3D Filtering Algorithm*

After image de-composition, BM3D procedure is used to eliminate the noisy contents present in image. BM3D filtering algorithm is mainly applied to LH, HL and HH frequency subdivision bands of DWT image outputs. The BM3D algorithm is divided into two fundamental step ladders. In the initial stage the main focus is on producing essential image estimation and it's widely less noise than the noisy image. In the second stage the fundamental estimate is utilized as a block matching base for pragmatic wiener filtering. The second step could be empirically confirmed to get better quality of an image compared with the initial stage of output.

The principal step is termed as basic estimation, which emphases on eliminating noise present in the image. This step consists of three phases namely, Block-matching (BM), Collaborative filtering (CF), and Aggregation:

1) Block Matching (BM): Initially, the image I is converted into a number of blocks size of $a \times a$. Consider the reference block A. Blocks have been a high similarity with the reference block is formed as a group. Then, the blocks are converted into the 3D array. The similarity of the reference block A and other block O are calculated using equation distance function which is given in equation (1).

$$S(A_i, O_j) = \frac{\|A_i - O_j\|}{N_1^2} \quad (1)$$

Where A_i represent the 2D array of reference block A, O_j represent the 2D array of similar blocks. After the similarity calculation, blocks are grouped.

2) Collaborative filtering: At present, the most equivalent blocks of reference blocks are recognized and might be gathered to frame a 3D Array S_1 size is $a \times a \times |S_1|$ .After that, every 3D array is converted to a frequency domain using a 1D and 2D intra-block transform. From transferred data the valuable data is placed in the utmost huge coefficients. Therefore it is conceivable towards decreasing the noise through disposing of little coefficients. The procedure of CF can be represented as:

$$C_F = K_{3D}^{-1}\left(R\left(K_{3D}(S_1)\right)\right) \quad (2)$$

Where C_F denotes the collaborative fitter output, K_{3D} is the 3D linear transform is usually actualized by isolated 2D

and 1D linear transformation, R represent the hard thresholding operator, which is used to regulate the transform coefficient. The threshold is calculated using equation 3.

$$R(x)=\begin{cases}0, & |x|\le\sigma.\chi_{3D}\\ x, & |x|>\sigma.\chi_{3D}\end{cases} \quad (3)$$

Where

χ_{3D} →Hard-thresholding parameter

σ →Standard deviation

Meanwhile, noise is found in the little coefficients and it is feasible to lessen noise and safeguard best subtleties in the images over the hard-thresholding administrator. Simultaneously CF understands the separation of image signal and noise deprived of expending energy.

3) Aggregation: After filtering, overlapped blocks of the image are to be recovered to their unique positions. Then weighted average (WA) measure based images are estimated. In common, the WA is apprehended by conveying suitable weighting components to the groups of blocks and the weight W_ρ can be displayed as:

$$W_\rho=\begin{cases}\dfrac{1}{N_c}, & N_c\ge 1\\ x, & N_c<1\end{cases} \quad (4)$$

Where

N_c →Quantity of the persisted non-zero coefficient

We obtain the small number of non-zero co-efficient implies the number of noise detached using collaborative filter since its weight of the block is superior. The basic estimation of the de-noised block D_{basic} is given in equation (5).

$$D_{basic}(i)=\frac{\Sigma_{Op}\,\Sigma_{Q\in O_p}W_i.R_{PQ}}{\Sigma_{Op}\,\Sigma_{Q\in O_p}W_i.x_Q}\quad \forall i\in I \quad (5)$$

Where

Q → Similar block of the present operational block comprises the pixel i

O_p →Set of entirely available blocks

R_{pQ} → Estimation of the block Q

$$R_{pQ}=\begin{cases}R_{PQ}, & i\in Q\\ 0, & i\notin Q\end{cases} \quad (6)$$

The characteristic function x_Q is symbolized as follows;

$$x_Q=\begin{cases}1, & i\in Q\\ 0, & i\notin Q\end{cases} \quad (7)$$

*4) Final estimation:*In this stage, final estimation is done with the help of a wiener filter which is used to improve de-noising performance. Initially, the basic estimation output is given to the input of the block BM. In the BM, two groups arrive which is from a noisy image (TP1) and other one from the basic Estimation (TP2). The attained basic estimation output is the same as the actual image. The final weight is calculated using equation (8).

$$W_{final}=\frac{|K_{3D}(T_{P2})|^2}{|K_{3D}(T_{P2})|^2+\sigma^2} \quad (8)$$

The final estimation F_{final} is attained using equation (9).

$$E_{final}(i)=\frac{\Sigma_{Op}\,\Sigma_{Q\in Op}W_{final}.R_{PQ}}{\Sigma_{Op}\Sigma_{Q\in Op}W_{final}.x_Q}\quad \forall i\in I \quad (9)$$

Compared with the mutual modest hard-thresholding process, Wiener filtering is more effective and the outcome is more precise.

C. Second Level Noise Removal using the Bilateral Filter

After the initial stage of noise removal, bilateral filter (BF) is applied to the first stage output image to improve the image quality. The BF has established its potential for image de-noises with edge protection related to additional spatial domain filtering. It is a very simple and non-iterative filter. BF is based on domain filtering as well as range filtering.

Let f(x) be the input image the low-pass domain filter is applied to the input as well as the output is given by the condition 10-13,

$$f(z)=\ k_d^{-1}(z)\iint f\ (\alpha).e(\alpha,z)d\alpha \quad (10)$$

where, e (α, z) = geometric distance among centre x also close by point α .likewise,range filtering is given in the subsequent equation 11 as,

$$\text{h (z) } k_r^{-1}(z)\iint f(\alpha).s\big(f(\alpha)f(z)\big)d\alpha \quad (11)$$

Whereas s(f (α)f(z)) = “photometric distance” in the middle of center x and close by points ε.

While the bilateral filter is a mixture of both domains filter as well as range filtering, its production could be characterized as (12).

$$h(z)=\ k^{-1}(z)\iint f(\alpha).e(\alpha,z).s\big(f(\alpha)f(z)\big)d\alpha \quad (12)$$

At this point, k (z) = normalization constant is defined by the subsequent equation,

$$K(z) = \iint e(\alpha, z)s\big(f(\alpha)f(\alpha)f(z)\big)d\alpha \quad (13)$$

Bilateral filters are mostly utilized to remove noise exactly or precisely. Here first we prefer the window size then we pre-compute the distance weight. Later the bilateral filter is applied to remove noise accurately that is the first step in local region extraction and the next step is intensity value calculation and then the subsequent step calculates the bilateral filter response. Later the de-noised image is obtained.

IV. SIMULATION RESULT

The performance of proposed image de-noising method is analyzed in this section. For experimentation CT images are utilized. The adaptive multi-stage noise removal methodology is implemented in the platform of MATLAB.

A. Data Set Description

The CT lungs images are efficiently occupied in the innovative image segmentation and classification technique that is attained from therapeutic facility just as web sources. The corresponding gathered image dataset have 1000 CT lungs images. Here 750 lungs images acquired from TNMSC kudangulam CT scan center, Tamil Nadu and Marthandam MRI and CT scan center, Tamil Nadu. The remaining images are collected from web resources. Datasets are collected during June 2018- July 2019. It has CT images of females, males and an infant. Fig. 2, 3, and 4 provide some input images.

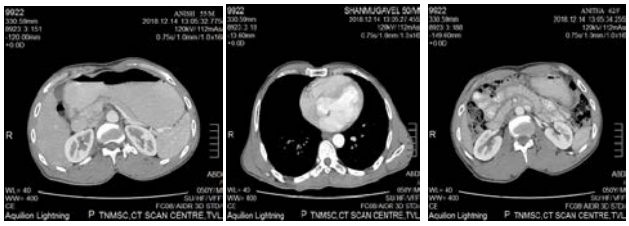

Fig. 2. Sample Images Collected from TNMSC CT Scan Center Tamil Nadu.

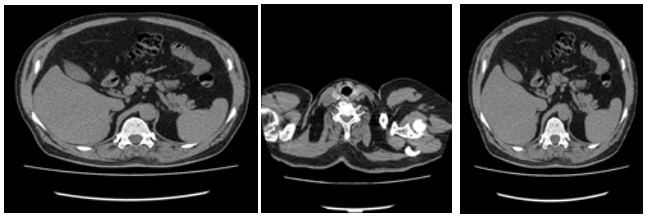

Fig. 3. Sample Images Collected from Marthandam MRI and CT Scan Center Tamil Nadu.

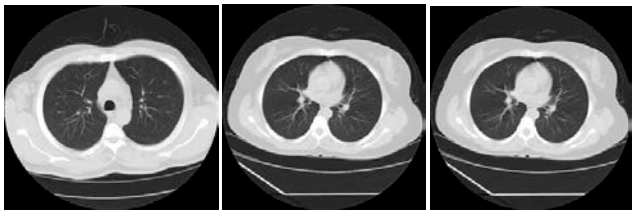

Fig. 4. Experimentally used Sample Images Collected from a Web Source.

B. Evaluation Metrics

The performance of adaptive multi-stage noise removal method is analyzed in terms of various metrics namely peak signal for the noise ratio (PSNR) and Root-Mean-Square error (RMSE), and structural similarity index are explained as below:

1) PSNR: This measure is utilized to measure de-noised image quality. The PSNR is the ratio among the input image and the noise image. Higher PSNR value is given a good quality image.

$$PSNR = 10\log_{10}\left(\frac{255^2}{MSE}\right) \quad (14)$$

$$MSE = \frac{1}{M * N}\sum_{x=1}^{M}\sum_{y=1}^{N}\left[I(i,j) - I'(i,j)\right]^2 \quad (15)$$

Anywhere;

$I(x,y)$ → Input image.

$I'(x,y)$ → De-noised image.

2) RMSE: RMSE minimizes the error rates. It serves to summative the magnitudes of the errors in predictions for a variety of times into a solitary measure of predictive power. RMSD is the square root of the mean of the square error. *RMSE Formula* is given by:

$$\text{RMSE} = \sqrt{\frac{\sum_{i=1}^{n}(P_i - O_i)^2}{n}} \quad (16)$$

3) SSIM: The structural similarity index which is used to measure the comparison among several images. It is a sensitivity based model, that considers the image,

$$\text{SSM}(x,y) = \frac{(2\mu_x 2\mu_y + c_1)(2\sigma_{xy} + c_2)}{(\mu_x{}^2 + \mu_y{}^2 + c_1)(\mu_x^2 + \sigma_y^2 + c_2)} \quad (17)$$

Where,

μ_x →Specifies the middling of x,

μ_y →Specifies the middling of y,

μ_x^2 →Specifies the variation of x, σ_y^2which specifies the variation of y

Experimental results are attained from the adaptive multi-stage noise removal methodology. The following Fig. 5 to Fig. 7 displays the comparative outcomes of existing methodology as well as adaptive multi-stage noise removal methodology for de-noising CT medicinal images.

The principal goal of this article is to perform image de-noising utilizing a blend of BM3M and bilateral filter. Initially the images are decomposed using DWT. To improve the final de-noising performance the coefficient range of DWT is optimally selected with the help of Crow Search Optimisation Algorithm.

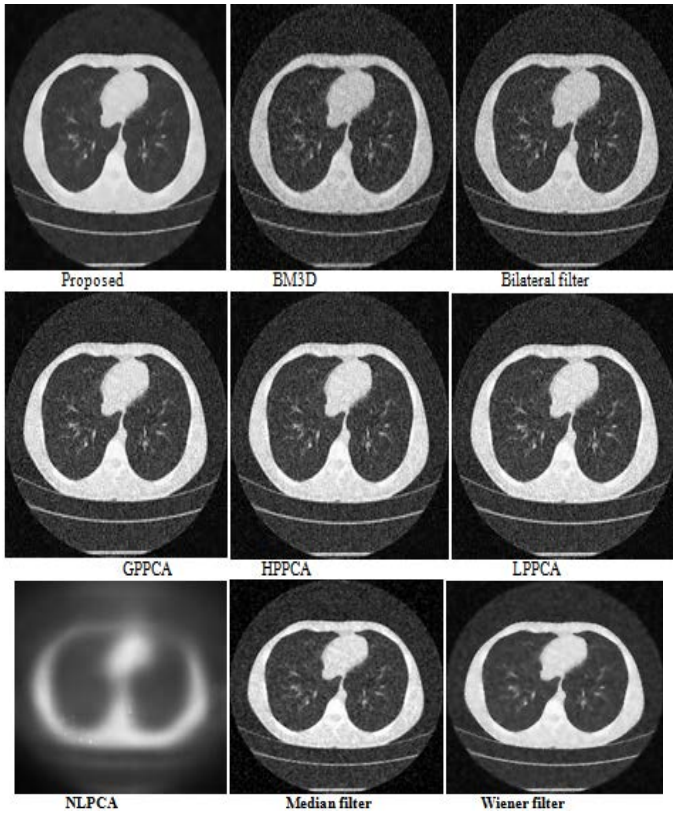

Fig. 5. De-noising Result of Images Collected from Internet Source.

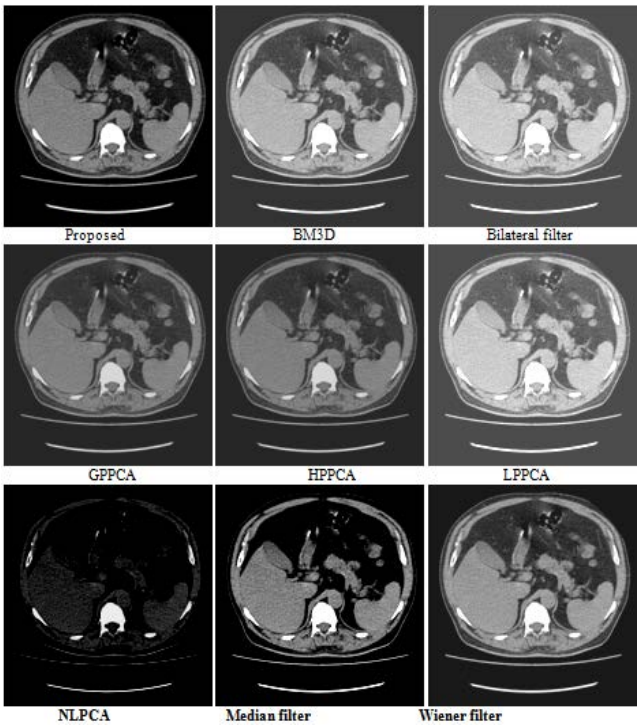

Fig. 6. De-noising Result of Images Collected from Marthandam MRI and CT Scan Center.

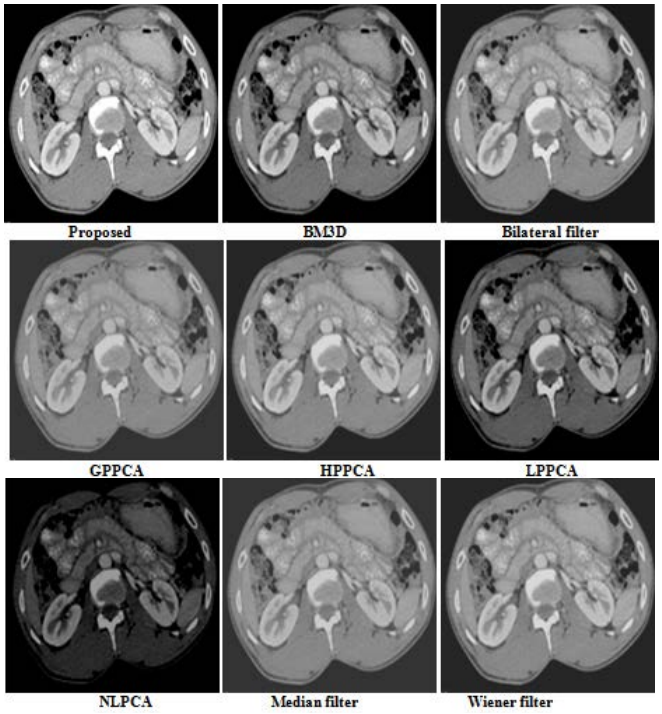

Fig. 7. De-noising Result of Images Collected from the TNMSC CT Scan Center.

Once the optimal coefficients are selected, the BM3D algorithm is applied to the LH, HL and HH frequency bands of DWT image output, and then the bilateral filter is applied to eliminate the noise clearly and to retain the uncorrupted information. In this section, the above Fig. 5 to Fig. 7 shows the comparison results of existing and proposed de-noising CT medicinal images. To evaluate the performance of our adaptive multi-stage noise removal methodology approach, we examine our results with other existing approaches. In this we compare our work with the following existing techniques which is named as BM3D, Bilateral filter, Global Patch Principle Component Analysis (GPPCA), Hierarchical Patch Principle Component Analysis (HPPCA), Local Patch Principle Component Analysis (LPPCA), Non-Linear Principal Component Analysis (NLPCA), Median filter and Wiener filter based image de-noising approaches. Compared to the existing approach our proposed adaptive multi-stage noise removal methodology achieve a better result because of our proposed strategy using the de-noising process in two steps applying BM3D filter the noise is almost removed clearly in the first step and for more exactness and precision bilateral filter is applied, which removes the noise clean and clearly in CT medical images.

Fig. 8 demonstrates the performance analysis of the proposed method using PSNR measure. The maximum PSNR is considered as a good quality image. To demonstrate the efficiency of proposed adaptive multi-stage noise removal methodology based de-noising approach, we compare our algorithm with different algorithm namely BM3D, Bilateral filter, Global Patch Principle Component Analysis (GPPCA), Hierarchical Patch Principle Component Analysis (HPPCA), Local Patch Principle Component Analysis (LPPCA), Non-

Linear Principal Component Analysis (NLPCA), Median filter and Wiener filter based image de-noising.

When analyzing Fig. 8, our algorithm attains the average PSNR of 42.25 db, which is 41.25 db, 41.25, 21.53, 22.32db, 32.025 db, 25.50db, 25.47db and 25.44 db for using BMSD, Bilateral filter, Wiener filter, median filter, NLPCA, GPPCA, HPPCA, and LPPCA respectively. From the PSNR value, we precisely realize our proposed methodology is superior to existing methodology because our proposed scheme prefer optimal co-efficient at the same time it uses filters in two stages in 1st stage BM3D filters are used to remove noise among several CT images. Applying BM3D filter the noise is almost removed clearly in the first step and for more exactness and precision we use bilateral filter to remove noise clearly in CT medical images. Fig. 9 shows a comparative analysis based on RMSE measures. Of these, minimum value of RMSE gives better results of de-noising because the quality of a resultant image is being measured by using RMSE. Comparing to the existing techniques, RMSE measure minimize the error rates of our proposed methodology. When examining Fig. 9 our proposed adaptive multi-stage noise removal methodology achieves the minimum RMSE of 0.7157348629. Here the proposed approach attains maximum SSIM of 0.9110654649, which is highly compared to other existing algorithms. In this, the maximum value of SSIM measure gives better results because SSIM measures the similarity among several images when examining Fig. 10 our proposed adaptive multi-stage noise removal methodology accomplish the utmost SSIM measure of 0.9110654649. From the experimental outcomes, we obviously understand our proposed methodologically gives out enhanced results compared to other existing approaches and the performance comparison is shown in Fig. 11 using mean of PSNR(dB) values. Fig. 12 shows the intensity variation of noise and de-noised CT image. Table I shows the performance of proposed approach by altering noise level. Here, the performance is analyzed based on three level noises like as 0.02, 0.04 and 0.06. When analyzing Table I, after applying noise also our proposed approach attains the excellent PSNR value. This is because of two level filtering approaches. As a result, it is clear to us that our proposed method produced an excellent result compared to other methods. To prove the effectiveness of the proposed methodology, we compare our algorithm with different methods as shown in Table II. In this performance analyze, we compare our proposed method with already published literatures like Dual Tree Complex Wavelet (DTCWT) [22], Curvelet Transform (CT) [22], Harris and DWT [23], Harris Operator and Wavelet Domain Thresholding (RDTDWT) [24], SRTW [25]. When analyzing the above table our proposed method achieves a higher accuracy and higher PSNR of 42.05 because in our work multilevel denoising is performed as well as adaptive bilateral filter is used. Comparing these existing techniques our proposed method achieves a high quality results.

Proposed Method	42.05

V. CONCLUSION

In our paper, another new innovative image de-noising is proposed using optimal discrete wavelet transform, BM3D as well as the bilateral filter. In our work, the proposed strategy consists of two phases, which are named as discrete wavelet design and image denoising structure.

To improve the delicate regions with higher visual quality the DWT domain transform is applied; where the optimal coefficients are selected using the crow search optimization algorithm. Once the optimal coefficients are selected, the BM3D filtering algorithm is applied to the frequency sub-division bands of DWT image output. At the next stage, the bilateral filter is applied to take away the noise clearly as well as to keep the uncorrupted information well. Experimental results on CT medicinal images are obtainable to estimates presentation of a proposed filter. Our adaptive multi-stage noise removal methodology beat other methodologies based on PSNR, RMSE and SSIM measures.

Smart Tourism Recommendation Model: A Systematic Literature Review

Choirul Huda, Arief Ramadhan*, Agung Trisetyarso, Edi Abdurachman, Yaya Heryadi
Computer Science Department, BINUS Graduate Program – Doctor of Computer Science
Bina Nusantara University, Jakarta, Indonesia

***Abstract*—The tourism industry has become a potential sector to leverage economic growth. Many attractions are detected on several platforms. Machine learning and data mining are some potential technologies to improve the service of tourism by providing recommendations for a specific attraction for tourists according to their location and profile. This research applied for a systematic literature review on tourism, digital tourism, smart tourism, and recommender system in tourism. This research aims to evaluate the most relevant and accurate techniques in tourism that focused on recommendations or similar efforts. Several research questions were defined and translated into search strings. The result of this research was promoting 41 research that discussed tourism, digital tourism, smart tourism, and recommender systems. All of the literature was reviewed on some aspects, in example the problem addressed, methodology used, data used, strength, and the limitation that can be an opportunity for improvement in future research. This study proposed some references for further study based on reviewed papers regarding tourism management, tourist experience, tourist motivation, and tourist recommendation system. The opportunities for a further research study can be conducted with more data usage especially for a smart recommender system in tourism through many types of recommendation techniques such as content-based, collaborative filtering, demographic, knowledge-based, community-based, and hybrid recommender systems.**

Keywords*—*Systematic review; tourism; smart tourism; digital tourism; recommender system

I. Introduction

The tourism industry sector has become a potential sector for economic growth in various regions. The World Tourism Organization (UNWTO) reported in January 2020 that the international tourism arrival reached 1.5 billion with a growing percentage of 4% in 2019 [1]. This growth will certainly take place in line with the discovery of various new tourist destinations in various regions. In China, the tourism market growth of inbound and outbound tourism changed markedly in the past few years [2]. This potential tourism industry growth was also found in Thailand [3].

Tourism industries have faced a hard challenge since the coronavirus disease 2019 (COVID-19) pandemic. This pandemic has hurt the global economy, causing unprecedented global health and social emergencies [4]. Some studies have stated that this pandemic will end in the next few years so that it can help the growth of the tourism sector as in the previous year. Every country has a different level of rebound from the COVID-19 pandemic according to the numbers of daily confirmed COVID-19 cases [4]. Tourism managers should establish marketing strategies and improve their service [5].

As the tourism industry gets an opportunity to rebound, it is necessary to prepare adequate strategies and activities to be able to provide good service for every tourist and all stakeholders. This preparation needs to involve all stakeholders by paying attention to their respective roles. Intrinsic motivation and extrinsic motivation had a highly positive impact on perceived trust in the tourism industry [6]. The aim of this study is to conduct a literature review that supports the preparation of a tourism recommendation model that focuses on two aspects, namely tourist attractions, and tourist smart services. Along with the development of information technology, today we are faced with the flow of information that floods various media regarding searching for some tourism information. Information on various attractions in various locations can be obtained through various media. Some of the media or sources of information that we conventionally use to find information related to tourism include travel agents, brochures, and social media [7].

Human lifestyle in the tourism and hospitality areas has been influenced by Information and Communication Technologies (ICT) [8]. Today, ICT has become a strategic platform for business and other purposes. Digital technologies as a part of ICT have introduced important innovations in many human aspects of life such as factories, hospitals, hotels, cities, and territories [9]. By using a mobile device, as a popular digital technology, many people can get information easily. They can brow some web site, search engines, social media, and any other digital platform to get the needed information. In some cases, they get private messages or notifications for some uninteresting information. The flooding of information sometimes harms some people because of unsuitable information. For getting tourism information people can use some search engine manually. Of course, this searching is not efficient yet because they will get the flooding of information even though they have used keywords for searching. Frequently mobile devices have been used by contemporary travelers for making decisions in traveling and managing travel itineraries [8]. Furthermore, travel, tourism, and hospitality companies have started to adopt some digital technologies such as Artificial Intelligence (AI), robots, and service automation (RAISA) through chatbots, delivery robots, the concierge of a robot, conveyor restaurants, self-service kiosks, and many others [9].

Regarding the trend of smart ICT especially in intelligent systems and location detection, the tourism industry has the

*Corresponding Author.

opportunity to improve better services for stakeholders. Through smart ICT Tourist as a user of tourism industry needs more smart system and dynamics recommendation for specific recommendation in tourism in order to improve tourism experience and tourism service. Smart tourism is various changes driven by the application of some new technologies in tourism and it is a modernization of providing tourism service, innovating tourism management, improving tourism experience, and optimizing the tourism resources usage [10]. It would be important for managers of destinations to make greater development in the tourism destination resources, in order to provide a competitive advantage and enhance experiences [11]. Interactive solution through online media is needed for potential tourist for improvement of their tourism experience [12]. The smart technology solution in tourism should consider some effectiveness and healthy of tourism experience related to digital well-being experienced [13]. Search strings as the form of research questions translation were used in this Systematic Literature Review (SLR) method regarding the need for appropriate search results.

II. METHOD

For achieving the objective, this SLR has three main phases: Planning the Review, Conducting the Review, Reporting the Review [14]. Additional explanation of these main phases and the sub-phases is showed in Fig. 1.

All the stages listed in Fig. 1 may appear to be sequential, but practically some of the stages can be repeated for further review. This review is conducted to summarize the existing literature related to the relevant and accurate techniques for recommender systems in tourism through the defined problem, method, data usage, strength, and limitation.

This review protocol is built to reduce bias from the researcher in the selection of individual studies that may be influenced by researcher intentions [14]. The SLR activities also adopt several approaches in [15]. The review protocol is shown in Fig. 2. The steps of the review protocol are slightly modified to achieve the aim of this research.

There are ten steps of the review protocol according to Fig. 2. The activities are arranged in sequence as a guideline before the review of papers conducted. The first step of the review protocol is defining or formulating the research question (RQ) as the most important activity during protocol [14]. The research questions are showed in Fig. 3.

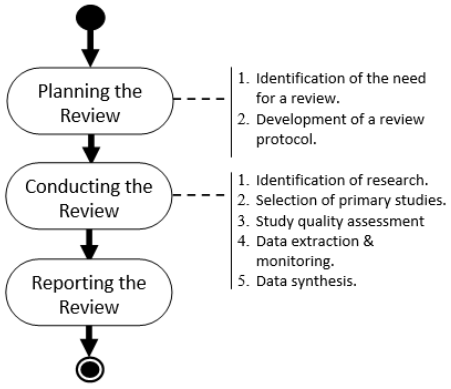

Fig. 1. The Phases of SLR.

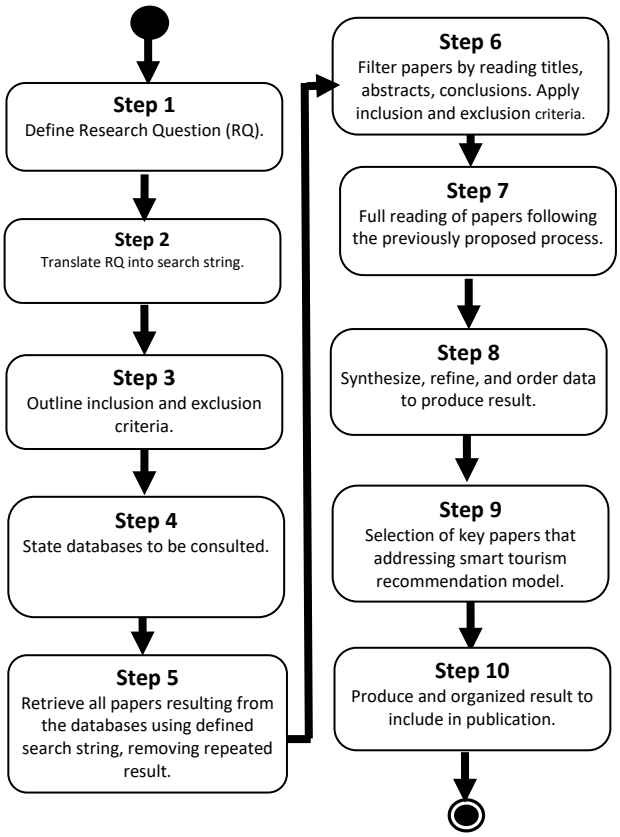

Fig. 2. Steps of the Review Protocol.

RQ1	What is the problem to be solved?
RQ2	What kind of data is being used?
RQ3	What kind of methodology is being used?

Fig. 3. Defined Research Questions.

The second step is translating the RQ into search strings such as: “Tourism”, “Digital Tourism”, “Smart Tourism”, “Recommender System”. The complete search strings can be seen in Fig. 4. The third step is to outline the inclusion and exclusion criteria to specifying the selected paper according to the inclusion aspect and exclusion aspect. The inclusion is intuition aspect that is considered for further process, while the exclusion is the aspect that should be consideration of rejection. The further explanation of the inclusion aspects, exclusion aspects, and justifications are showed in Table I.

String1	“Tourism”
String2	“Digital Tourism”
String3	“Smart Tourism”
String4	(“Recommender System” AND “Tourism”)
String5	(“Recommendation System” AND “Tourism”)

Fig. 4. Search Strings.

TABLE I. CRITERIA (INCLUSION, EXCLUSION), AND RELATED JUSTIFICATION

Inclusion criteria	**Justification**
Published papers in 2016 to 2021 in journal or conference proceedings.	Use the most recent findings only.
Papers present tourism study regarding smart tourism recommendation model.	The opportunity of smart tourism recommendation model development in the future.
Exclusion criteria	**Justification**
Not in English written papers.	Standardization of international language in English.
Paper is a secondary (review) or tertiary study.	Focus on primary studies.

The fourth step is stating the reputable databases to be consulted for the source of papers. Several databases were classified into four groups according to authors' experiences and authors' decisions. The first group consists of IEEE, Elsevier, Science Direct, Springer, ProQuest, Emerald, Wiley, and UNWTO. The second groups consist of Routledge, IOP, MDPI, ICCT, and IJTC. The third group consists of ACIS, AITM, E3S, ICEB, and SAGE. The fourth group consists of CBUNI and Pertanika.

The review process was started by the first group and followed by the second group, third group, and finally fourth group. The searching process was conducted through the "Publish or Perish" application developed by Prof. Anne-Will Harzing [16], and Mendeley software applications. The fifth step is the retrieval of all papers resulting from the searching process and also removing repeated results. The sixth step is filtering papers by reading part of papers starting by reading the titles, abstracts, conclusions and then applying the inclusion and exclusion criteria. The seventh step is conducted by a full reading of papers following the reviewing part of papers, i.e. introduction, methodology, result and discussion, and any other part of papers. This step is conducted manually by reading every statement from all parts of the paper to find more implicit and explicit ideas and the relationship between every section in existing research. The eighth step is to synthesize, refine, and order extracted data to produce the result in some figures and tables. The result of this study is presented based on some aspects, and be analyzed based on the process, the database used, topics, and years of publication or conference. The ninth step is the selection of key papers that addressing the smart tourism recommendation model. The tenth step is producing and organizing the review result to be submitted in international publication.

III. RESULTS

The results in some topics seemed on a small number because of the specific requirement on searching proses and the result of the review protocol. Some papers were retrieved but many of them were not providing the recommender system in tourism through computer science research.

Steps of filtering papers were conducted through searching from the databases according to the defined search strings. The summary of this process is presented in Table II. Because of similarity in content, the result from searching by using ("Recommender System" AND "Tourism") and ("Recommendation System" AND "Tourism") as search strings are summarized become one-row label: "Recommender System" at Table II.

Summary of publication period and related databases used on searching based on steps above are presented in Table III.

The locations of selected research were distributed into many regions or continentals with the majority of research were established in Asia (China, Indonesia, Japan, India, and Hong Kong). Further information on distributed research by region is displayed in Table IV. This discussion consists of some topics according to the topics in the searching process. The discussion was sequentially be arranged through Tourism, Digital Tourism, Smart Tourism, and Recommender Systems. The questions of what, why, how, when, where, and who were considered on every discussion based on the available information on each paper.

IV. Discussion

A. Tourism

Thirteen papers were selected for this topic discussion below and introduction above. The authors in [1] and [4] provide the contribution, opportunity, and challenge of the tourism industry. How is the pandemic will rebound was stated in [4]. The first paper being analyzed is the paper produced by The World Tourism Organization (UNWTO) for the global tourism industry based on January 2020 report. Tourism industries face a hard challenge on Pandemic COVID-19, but it will be rebound for the next period according to research from [4] with various recovery levels for each country.

This sub-topic was discussed in [17] and [18]. The author in [17] used Exploratory Factor Analysis (EFA), T-test, and ANOVA analysis to explore tourists' motivations in China, and involvement in adventure tourism activities, and also the kinds of personality and location affect their motivation and involvement in 2019. This research provided the reasons for preferred adventure activities and key requirements of adventure activity but using a relatively small sample size and only focus on adventure tourism in Chengdu and Xiamen, China.

Lindberg et. al. in [18] describe the integrated analysis of individual characteristics, such as attitudes and demographic factors, and situational characteristics, such as interpretive center features through discrete choice models use random utility theory in Norway in 2019. This paper gave an excellent aspect of analysis based on respondent characteristics according to basic demographic data (gender, education, age, and income) but has limitations on the generalization of the demographic factor for other locations like Asia. The author in [19] explains tourist experience regarding the judgment of tourists' willingness to pay to increase the public managers' income to produce policies through binary logistic regression and decision. This paper used travel characteristics and variables of sociodemographic of tourists visiting Andalusia (Spain) in 2021.

Based on the research question and discussion in tourism, the selected papers have some various problems to be solved. All of them can be seen in Table V.

Based on the research question and discussion in tourism, the selected papers have some various data used, and methodologies used. All of them can be seen in Table VI.

Based on the research question and discussion in tourism, the selected papers have some various methodologies used. All of them can be seen in Table VII.

B. Digital Tourism

The next topic discussion is digital tourism that is a fundamental platform for smart tourism recommendation models through digital technology. Digital tourism is a part of digital transformation in the tourism industry that used digital technology as a strategic platform for transformation from the traditional approach to digital. The digital platform offers a better solution for tourism rather than the traditional approach through a more effective and efficient service for stakeholders in tourism. Some various approach was conducted at the existing research in different regions. Ten papers were selected at final review: [8], [9], [10], [21], [22], [23], [24], [25], [26], [27].

In [8], it was addressed the problem of overuse in technology-related addiction issues and mental health regarding tourism context has been explored through literature review and exploratory study about the perception of 17 participants on 2020. On the other hand, the impact of the digital revolution on tourism, the different and common work between tourism 4.0 and smart tourism through a conceptual approach is addressed in [9].

The author in [10] used blockchain technology to develop a tourism information intelligent service platform for tourism enterprises, tourists, government and promoted tourism management and service coordination, and economic development in China. In [21], it was developed a system to automatically recommend tourists to visit a particular tourist destination through an ontological approach. This approach included current situation detection such as location, existing fixed schedule, time, means of transportation, place accessibility to visit Japan in 2019.

Veloso et. al. in [22] identified the main challenges within tourism crowdsourcing platforms through a comparison of existing models. They detect future research trends to ensure the quality and authenticity of tourism-related crowdsourced data by using published papers about tourism crowdsourcing

platforms. The author in [23] developed a software architecture that can be specified in a web application based on the proposal of a management model of the NTS-TS 002 standard through conceptual software design in Columbia. Paper [24] conducted IoT-based research on tourism industrial clusters and information platforms through niche principles and its theoretical framework in China.

Briciu in [25] use Virtual Reality and mobile application for city development in terms of cultural tourism solutions and evaluation on cultural heritage sites through descriptive analysis in Romania. The author in [26] conducted comparative and content analysis for tourism zone development in Russia's economic space through tourism technology platforms implementation. Paper [27] conducted a Blackwell-Miniard-Engel model to develop a customer journey map creation in Russia.

Based on the research question and discussion in digital tourism, the selected papers have some various problems to be solved. All of them can be seen in Table VIII.

TABLE VIII. PROBLEM TYPES IN DIGITAL TOURISM

Problem	∑ Papers	Selected Papers

Conceptual Model	5	[21], [10], [9], [23], [24]
TOTAL	**10**	

C. Smart Tourism

Further topic discussion is smart tourism that used various approaches in research and model development. Some papers used an intelligent approach while others used some different approaches. It was explored in [28], a tourist preference methodological approach of Smart Tourism Attractions (STA), and comprehensive review for the weaknesses and strengths of an STA through related study site, literature on Hongshan Zo in China, data collection by questionnaire for collecting the travel experience, and FCEM-AHP evaluation in 2016. The authors in [29] have addressed a definition comparison between traditional and smart tourism information services based on published papers.

Ramadhani in [30] explained the creation of the automatically rating system of tourism destination based on a travel blog through an automatic approach by a new semantic analysis algorithm in Indonesia in 2017. However, in [31], it was found the important factors for the tourists' preferences to visit the Vredeburg museum in Yogyakarta, Indonesia in 2018. This research provided the preferences of tourists towards smart tourism and having challenges for a more general purpose.

The author in [32] provides a better user travel experience of smart tourism in China in 2021. On the other hand, Dey in [33] focused on a literature study on Indian tourism sectors providing online services and talking about the current Artificial Intelligent used in India in 2020. It briefed technology usages in tourism and needs more introductions for implementation of recommender system in tourism.

A system is developed in [34] to arrange professional game rangers for a visitor in a particular tourist destination using machine learning through Google's TensorFlow based on animal mages in South Africa in 2018. The author in [35] introduced available datasets for the public in Europe regarding the area of tourism demand prediction for future comparisons and experiments using Pearson correlation analysis for features extracted from the environmental, social media, and official datasets.

Li in [36] extracted useful search query data and construct relevant econometric models. However, in [37] it was proposed the incorporation of reliable traditional methodologies with text analytics and machine learning to facilitate a deeper understanding of concepts and theory building through a step-by-step methodological and analytical framework based on an analysis of online reviews of existing research.

The author in [38] provided an understanding of the aspirations of people with visual impairments in terms of tourism and explore how smart tourism destinations could potentially enhance the tourism experience they offer. Qualitative research was adopted at this research through in-depth expert interviews and multisensory observation and implemented the PERMA model as a framework for designing the app in Hong Kong. The author in [39] provides definitional clarity and a comprehensive approach to the smart tourism city anatomy regarding smart tourism and smart city through a conceptual approach. The author in [40] provided the relationship among smart tourism technology attributes, travel satisfaction, happiness, and revisit intention regarding travel experience satisfaction through the structural equation method in China. The questionnaire was conducted for Chinese tourists' travel satisfaction analysis.

Based on the research question and discussion in smart tourism, the selected papers have some various problems to be solved. All of them can be seen in Table XI.

TABLE XI. PROBLEM TYPES IN SMART TOURISM

Problem	∑ Papers	Selected Papers

D. Recommender Systems

The final topic discussion is about Recommender Systems according to the selected papers: [7], [41], [42], [43], and [44]. In [7], it is offered a travel recommender system for the effects of automating Word-of-Mouth (WOM) and established personalized travel-planning services to tourists through Collaborative Filtering (CF)-based recommender using WOM communication. This research used tourists' preference ratings on some destinations through interpersonal communication in South Korea in 2019. The author in [41] provide a framework of a travel recommender system by combining knowledge-based filtering and hybrid recommendation methods with decision-making theory in China in 2020.

Sagar et al. in [42] developed a hotel recommender system based on collaborative filtering and regression. Whereas Roy and Dietz in [43] develop a travel recommender system based on the content-based recommender system method. This research used user information and preferences such as home region, destination region, traveler type, and maximum travel duration and fondness for different types of venues in a city through Twitter social media in 2021.

The author in [44] proposed a solution for detection of tourist implicit preferences based on photos from social media on Facebook, Instagram, and Google Plus, and recommend a set of emerging techniques for tourism such as Convolutional Neural Network (CNN) and fuzzy logic to classify tourists and provide the recommendation at Brazil on 2018. This research provided two recommendation types: item-based and user-based.

Based on the research question and discussion in recommender system in tourism, the selected papers have one type of problem to be solved. All of them can be seen in Table XIV.

TABLE XIV. PROBLEM TYPES IN RECOMMENDER SYSTEM.

Intelligent Model (AI, ML, CNN, FL, CF)	5	[7], [44], [41], [43], [42]
TOTAL	**5**	

This research found that motivation and preference in tourism should become a concern for a better tourist experience. Digital technology offers some efficiency and flexibility for the tourist experience. Implementation of digital tourism offers better integration for stakeholders for maintaining, searching, and decision making of tourism factors such as facility, attraction, location. Some approaches for digital tourism can be adopted from [10] and [9]. For further smart experience, a smart tourism solution should be conducted. Smart tourism development through any type of

data format and intelligent models that will improve the tourist experience and management can be adopted from [34], [35], and [40]. A personal recommendation for a better tourist experience can be provided by a recommender system in tourism through various approaches. Recommender system improvement through Collaborative filtering and Content-based Recommender systems can be adopted from [43], and [7] with further personalization and generalization for other attractions.

V. Implication and Conclusion

This study provided 41 selected papers from various data sources, regions, and years that were reviewed and promoted as references for the next study on tourism, digital tourism, smart tourism, and recommender systems. This research found opportunities for further research in tourism based on the review and discussion of existing research through their addressed problems, methodologies, data usages, research times and locations, strengths, and limitations. The next study can be conducted on a different aspect of what, why, where, and how to solve the problem based on previous studies and the enhancement in the future. Due to the conceptual model provided from this research, some steps or development and result were provided on some figures that need further discussion.

The result of this study will help decision-makers in the tourism industry to improve their service for stakeholders in the tourism industry. Findings in tourism, digital tourism, smart tourism, and recommender system will help different approaches to decisions. Providing public policy in tourism and excellent facilities by local government will contribute to tourist experience and willingness to pay. The available personal recommendation will help the tourist to make a good decision in traveling. This study found some guidelines for tourism management to government through existing study. The opportunity of the tourism industry rebound after a pandemic should be prepared with adequate strategy although every country has a different scale of time to rebound.

Limitations of the current research regarding the scalability of data usage and quality of data usage and their methodologies can be enhanced to the next research. This study proposed some references for further study based on reviewed papers regarding tourism management, tourist experience, tourist motivation, and tourist recommendation system. The opportunities for a further research study can be conducted with more data usage especially for a smart recommender system in tourism through many types of recommendation techniques such as content-based, collaborative filtering, demographic, knowledge-based, community-based, and hybrid recommender systems. The tourist recommendation system in the future can be started with a study in link and match of personal demographics with available attractions on dynamic location through machine learning model, and location detection technology regarding available data in social media.

***Abstract*—User experience is imperative for the success of interactive products. User experience is notably affected by user preferences; the higher the preference, the better the user experience. The way users develop their preferences are closely related to personality traits. However, there is a void in understanding the association between personality traits and aesthetic dimensions that may potentially explain how users develop their preferences. This paper examines the relationship between the Big-Five personality traits (Openness to Experience, Conscientiousness, Extraversion, Agreeableness, and Neuroticism) and the two dimensions of aesthetics (classical aesthetics, expressive aesthetics). Two hundred twenty participants completed the Big-Five questionnaire and rated their preference for each of the ten images of web pages on a 7-point Likert scale. Results show Openness to Experience, Conscientiousness, Extraversion, and Neuroticism were not significantly correlated with aesthetic dimensions. Only Agreeableness showed a significant correlation (although weakly) with both classical and expressive aesthetics. The finding conforms to literature that personality traits have influence on the preference of individual design features in lieu of aesthetic dimensions. In other words, personality traits are inapt predictor of aesthetic dimension. Therefore, more studies are needed to explore other factors that potentially help to predict aesthetic dimensions.**

Keywords*—User experience; aesthetic dimensions; personality traits; big-five

I. Introduction

User preferences play a significant role in improving the quality of user experience; the higher the preference, the better the user experience [1][2][3]. Many factors can influence user preferences, and among the most important factors is interface aesthetics [4][5][6]. The author in [7] suggested in their influential work on the dimensionality of aesthetics that aesthetics in interface design consisted of two dimensions: classical aesthetics and expressive aesthetics. Classical aesthetics emphasise clarity, orderly, symmetrical and clean design and is closely related to many of the design rules advocated by usability experts. Conversely, expressive aesthetics accentuate creativity, originality, exquisiteness, and the ability to go against design conventions. The aesthetic dimensions of classical and expressive aesthetics have been discussed thoroughly in the literature. However, little is known about which of these two aesthetic dimensions highly correspond with user preferences.

According to [8][9][10][11], user preference is influenced by overall aesthetics during the initiation stage and followed by individual design features on the latter. Wood and Keller [11] explained that preference is the result of how the visual system organises and groups the incoming information. This conclusion corroborates [9]'s finding, where only 50 milliseconds are required to react to overall aesthetics. This spontaneous reaction time was found to be consistent throughout the system utilisation by [10], who studied the consistency of immediate aesthetic perceptions. Furthermore, [8]'s work on web usability using eye-tracking concludes that users looked at the overall design first, followed by specific design features afterwards. Therefore, aesthetics is arguably the by-product of the overall design effect rather than the details comprising it.

Despite the notion that aesthetics is a result of the overall design, several works report that aesthetic preferences are closely related to personality traits through the users' mental model [12]. The mental model explains how users simplify the complexity and details of external reality into a proportional representation applicable for decision making. This process of representation reduces individual details to fewer relevant entities with relationships between them, useful for decision making at hand. Since personality is integrated within the mental model, personality traits are likely to affect users' preferences.

User preferences over interface design can at some point be predicted by personality traits, where certain personality traits trigger preferences for specific design features (e.g. buttons, font, icons, information density, menu structure, navigation, theme, etc.) [13][14][15][16][17][18][19][20]. Personality traits as classified by the big-five also known as Five-Factor Inventory (FFI), categorised human characteristic patterns into five broad dimensions, represented by the acronym OCEAN or CANOE: Openness to Experience (O) or sometimes abbreviated as Openness, Conscientiousness (C), Extraversion (E), Agreeableness (A), and Neuroticism (N) [21]. Openness to experience is defined as the tendency to actively seek and appreciate new experiences and tolerate novel situations. This personality trait is manifested by curiosity, imagination, and being untraditional [22][23][24].

Conscientiousness is defined as the tendency to be cautious, consistent, and organised; manifested by self-regulation and adherence to norms [25] [26][27]. Extraversion is defined as the tendency to be extrovert, manifested by assertiveness, talkativeness, and optimism [28][29] [30]. Agreeableness is defined as altruistic, tolerant, and trustworthy. This personality trait exhibited gullible, meek, and selfless behaviours and other prosocial behaviours [31][32][33]. Finally, Neuroticism is defined by the tendency to experience negative emotions exhibited through anxious, depressive, and insecure behaviours [34][35].

While previous research findings confirmed the relationship between personality traits and users' preferences, there is limited work that studies the association between personality traits and aesthetic dimensions. Most of the research studies focused on specific design features, neglecting the aesthetic dimensions. This research gap raises a question of whether personality traits affect user preference on aesthetic dimensions as it does with specific design features. Addressing this gap will present an opportunity to explore the predictive role of personality traits in determining which dimension of aesthetics has a strong influence on user preference. Therefore, this study was undertaken to fill the gap by analysing the correlation between the big-five personality traits and users' preferences over screenshots of web pages (homepage) representing classical and expressive aesthetics.

The rest of this paper is organized as follows. Section 2 discusses related works associated with the big-five personality traits and aesthetic preferences. Section 3 describes the methodology used in this study. Sections 4 and 5 present the finding and discussion, respectively. The conclusions are given in Section 6.

II. Related Work

This section provides some references to previous work related to the big-five personality traits and aesthetic preferences.

According to [36], visual aesthetic sensitivity is independent of personality whilst others indicated that people high in Conscientiousness, Extraversion, and Agreeableness preferred common elements of design, such as the contrast between background and text, straightforward information display with the typical organisation of menu bar, scroll bar, and buttons [13][37][38]. These design elements are literally the execution of affordance and design convention. Affordance solicits users' actions without mental effort, whilst design convention influences users' expectations in the absence of affordance. Deviating from such intuition-centric would cause confusion and frustration for people high in Conscientiousness. People high in Conscientiousness further demonstrated positive inclinations toward conventional, clean, and orderly interface design features [39][40] and detest intense design style; complex and unconventional designs with irregular shapes of features [41].

Despite the fact that Openness to Experience has been widely examined, only a few empirical studies address its locus in design preference [12]. The author in [42] reported that people with high Openness to Experience tend to focus and adapt more inquisitively to an unconventional style of interface. Their preference for imaginative, untraditional, and personalised features allows them to quickly adapt to a new interface style. They relatively are not concerned with convention and are eager to explore new design features [43]. The consistent findings on unconventional design elements may explain the disposition towards expressive design in people with high Openness to Experience. However, unlike people high in Extraversion, people with high Openness to Experience are generally deterred by persuasive designs. Fear and stress are the reasons that discourage them from persuasive design [44].

Unlike Openness to Experience, which desires uniqueness, Extraversion desires extravagance, that is, the extreme continuum of design [45]. According to [46], Extraversion correlates with the desire for status, leading to a preference for extravagant designs. This is induced by the assertiveness trait in people high in Extraversion. People high in Extraversion prefer high colour contrasts, saturated hues, and bold or sharp-edged shapes of the graphical interface [13][20]. Concerning utilisation of the adaptive interface, [47] revealed that the approach does not benefit Extraversion. In other words, people high in Extraversion do not respond well to monotonous interface set up by adaptation design.

On the other hand, people high in Agreeableness are relatively easy to accept any design presented to them [48]. They tend to be more receptive to design that generates a sense of certitude in relation to their personality traits defined by altruistic, tolerant, and trustworthiness. According to [49], Agreeableness is generally considered as an adaptive trait and correlates with the preference of authority figures. This is evident in a study to explore how personality features affect compliance towards recommendations, where they found that people high in Agreeableness follow the editor's suggestions. In other words, people high in Agreeableness cope with individuals who have reliable and verifiable qualities in related disciplines [50][51]. This might explain why they are easily more satisfied aesthetically compared to other traits [48]. Nevertheless, [52] revealed that people high in Agreeableness have a high preference for classical, representational art and less preference for abstract art.

Compared to the rest of the traits, Neuroticism is strongly associated with sensitive, obsessive, and anxious characters. Neurotic individuals exhibit an inclination towards asynchronous media as it enables higher situational control and avoids direct interactions with others [53][54]. They are concerned with the visual clarity and readability of interface design [13][15]. A study by [44] reported that people high in Neuroticism have a low preference toward designs that utilise persuasive strategies (i.e., competition, simulation, self-monitoring and feedback, goal setting and suggestion, customisation, reward, social comparison, cooperation, punishment, and personalisation). These findings imply that people high in Neuroticism respond poorly to unconventional design features. Considering the immense magnitude of paranoia embedded in these individuals, it is very unlikely that they will advocate for expressive aesthetics.

In general, the five personality traits of the big-five; Openness to experience, Cautiousness, Extraversion, Agreeableness, and Neuroticism, have unique characteristics that can influence their preferences towards classical or expressive aesthetics of interface design. Both Openness to experience and Extraversion individuals have shown novelty-seeking behaviour that corresponds to unconventional design, seemingly reflecting preference over expressive aesthetics. On the contrary, Conscientiousness and Neuroticism individuals have exhibited non-receptive behaviour towards novel-centric design concurrently with a positive response to design convention. These inclinations are apparently in agreement with an exposition of classical aesthetics. In comparison to other personality traits, Agreeableness individuals inhabit disparate behaviour that is highly flexible to both conventional and non-conventional design. The absence of preference over particular design categories implicates that Agreeableness individuals are receptive to both classical and expressive aesthetics.

The unique characteristics of each personality trait and their preference for specific design features, as discussed above, are useful to predict aesthetic dimensions. However, empirical evidence to support the accuracy of the prediction has been lacking. This study aims to provide an empirical evidence to confirm the predictive role of personality traits in predicting preference for aesthetic dimensions.

III. Method

The study consisted of two phases. Phase 1 was designed to classify website homepages into classical and expressive aesthetics. The selected web pages in phase 1 were used as stimuli in phase 2 to examine the relationship between aesthetic preferences and personality traits.

A. Phase 1

1) Participants: 128 undergraduate students of Universiti Malaysia Sabah voluntarily participated in the study. Of the 128 students, 98 (77%) were students of the Faculty of Computing and Informatics, and 30 (23%) were students of the Faculty of International Business and Finance. 86 (67%) of the participants were female, and 42 (33%) were male, with ages ranging from 19 to 26 years (Mean=22.69, SD=1.515). 46 (36%) participants identified themselves as Chinese, 34 (27%) as Native Borneo, 31 (24%) as Malay, 16 (12%) as Indian, and one (1%) as others. The majority of the participants (65 (51%)) spent more than 8 hours per day on computer/ internet, while 43 (34%) spent 5-8 hours per day, 17 (13%) spent 2-5 hours per day, and the remaining 3 (2%) spent less than two hours per day.

2) Instrument: An online questionnaire administered via Google form and advertised through Facebook group pages and WhatsApp served as the main instrument of the experiment in phase 1. The questionnaire was composed of three sections. Section 1 consisted of the consent form and instruction of the experiment. Section 2 was the demographic questions on age, gender, ethnicity, faculty, and duration of computer or internet use per day. Section 3 begins with definitions of classical and expressive aesthetics, followed by 30 screenshots of web pages, each accompanied by a 7-point Likert scale (1, classical aesthetics; 7, expressive aesthetics). The 30 screenshots were arranged vertically, one above another and presented in a different random order for each participant to avoid the order effect.

3) Task and procedure: The participants were required to complete all three sections of the questionnaire, starting from Sections 1 to 3. In Section 1, the participants were required to read the instruction and give their consent to participate. If the participants consented, they can click on the “Next” button to proceed to the next section. Otherwise, they can click on a “Cancel” button to withdraw from the experiment. In Section 2, the participants were required to answer five demographic questions related to age, gender, ethnicity, faculty, and the duration of computer/internet use per day. Upon completing Section 2, the participants proceeded to Section 3 by clicking the “Next” button. In Section 3, the participants were required to rate their perceived aesthetic dimension on each of the 30 screenshots of web pages on a 7-point Likert scale (1-classical aesthetics, 7-expressive aesthetics). A definition of classical and expressive aesthetics was provided to ensure that all participants understood the term and rated the screenshots based on the same definition. The experiment ended when the participants click the “Submit” button.

4) Measure: The ratings of each web page were summed and ordered from lowest to highest score. Five web pages with the lowest scores and five with the highest scores were selected, and the remaining 20 were discarded to create a proper gap between the lowest and the highest. The five web pages with the lowest scores and five with the highest scores were classified as classical and expressive aesthetics, respectively, and used as stimuli in phase 2.

B. Phase 2

1) Participants: A total of 220 undergraduate students of Universiti Malaysia Sabah voluntarily participated in the study. 153 of the total participants were students of the Faculty of Computing and Informatics, and 67 were International Business and Finance students. In terms of gender distribution, 70% (146) were females, and 30% (71) were males with ages ranging from 20 to 27 (Mean=22.43, SD=1.41). Ethnicity wise, 41% (91) participants identified themselves as Native Borneo, 30% (66) as Chinese, 20% (44) as Malay, 7% (16) as Indian, and 1% (3) as others. In terms the duration of computer/ internet use per day, 53% (116) of the participants reported that they spent more than 8 hours a day, 23% (50) spent 5 – 8 hours, 16% (36) spent 3 – 5 hours, 7% (16) spent 2 - 3 hours, and 1% (2) spent less than an hour.

2) Instrument: An online questionnaire administered via Google form and advertised through Facebook group pages and WhatsApp served as the main instrument of this study. The questionnaire was composed of four sections. At the bottom page of Sections 1, 2 and 3, there was a “Next” button to move to the next section, whereas in Section 4, there was a

"Submit" button to finish the questionnaire. The first two sections were identical to the first two sections in phase 1. The third section consisted of 10 items of the Big Five Inventory (BFI-10) [51] (Table I). Each item of the BFI-10 was accompanied by a 5-point scale ranging from 1 (disagree strongly) to 5 (agree strongly).

TABLE I. BFI-10 [55]

I see myself as someone who ...	Disagree strongly	Disagree a little	Neither disagree or agree	Agree a little	Agree strongly
1)... is reserved	1	2	3	4	5
2)... is generally trusting	1	2	3	4	5
3)... tends to be lazy	1	2	3	4	5
4)... is relaxed, handles stress well	1	2	3	4	5
5)... has few artistic interests	1	2	3	4	5
6)... is outgoing, sociable	1	2	3	4	5
7)... tends to find fault with others	1	2	3	4	5
8)... does a thorough job	1	2	3	4	5
9)... gets nervous easily	1	2	3	4	5
10)... has an active imagination	1	2	3	4	5

The fourth section contained 10 screenshots of web pages (see Appendix) derived from phase 1, five screenshots each for classical and expressive aesthetics. Each screenshot was presented with a 7-point Likert scale, anchored by 1 (I don't like it) and 7 (I like it a lot). The ten screenshots were arranged vertically, one above another and presented in a different random order for each participant to avoid the order effect.

3) Task and procedure: The participants were required to complete all four sections of the questionnaire, starting from Sections 1 to 4. Upon completing Section 1, the participants can move to the next section by clicking on the "Next" button. This process continued until all sections were completed. The experiment ended when the participants clicked on the "submit" button in Section 4.

The task and procedure of sections 1 and 2 were similar to that of Sections 1 and 2 in phase 1. In Section 3, the participants were asked to answer all 10 items of BFI-10 by giving a rating from 1 (disagree strongly) to 5 (agree strongly) to each item. In Section 4, the participants were asked to indicate the extent of their preference from 1 (I don't like it) to 7 (I like it a lot) for each of the 10 screenshots of web pages.

4) Measures: Personality traits were measured using BFI-10 [55]. BFI-10 is a shorter version of the well-established BFI-44 [56]. Compared to BFI-44, which consisted of 44 items with 8 to 10 items per trait, BFI-10 consisted of only 10 items with two items per trait (Table I). Although short, this shorter version of BFI-44 claimed to predict almost 70% of the variance of the scales [57]. Each item of BFI-10 was rated from 1 (disagree strongly) to 5 (agree strongly). Scale score was obtained by the average rating of 2 items where 1 item was reversed-scored (Extraversion: 1R, 6; Agreeableness: 2, 7R; Conscientiousness: 3R, 8; Neuroticism: 4R, 9; Openness to experience: 5R, 10, R=item is reversed-scored). The internal consistency reliability of the scales was not reported in this study. A small number of items always yielded inadequate internal consistency reliability; thus, internal consistency is not an adequate measure for BFI-10 [58]. Preference for classical and expressive aesthetics was measured using a 7-point Likert scale; 1 reflects the least preference, and 7 reflects the greatest preference. Fig. 1 shows the hypothetical model of this study.

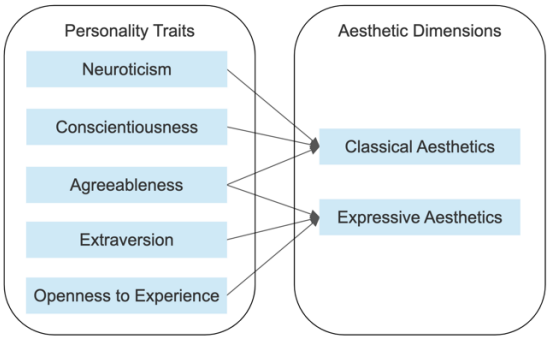

Fig. 1. Hypothetical Path Model.

IV. Result

This study used SPSS (version 26) for Windows to perform the statistical analysis of the questionnaire data. The statistical analysis used, including Pearson's correlation and multiple regression analysis with the stepwise method, to identify a possible association between aesthetic preferences and personality traits. Table II shows the overall results of this study.

TABLE II. Correlation Matrix

Personality / Dimension	μ	σ	Classical aesthetics		Expressive aesthetics	
			r	α	*r*	α
O	3.1000	.5564	-.029	.664	-.118	.081
C	3.0068	.7207	-.010	.883	.075	.265
E	2.8250	.6908	-.041	.549	.075	.271
A	3.5614	.7132	**.161***	.017	**.133***	.049
N	3.1318	.8335	-.042	.537	-.056	.407
Classical aesthetics	3.9291	1.0128				
Expressive aesthetics	5.2327	.7938				

*Correlation is significant at the 0.05 level (2-tailed).

The result of the Pearson product-moment correlation showed that Agreeableness was significantly correlated, albeit weak, with classical aesthetics (r=.161, p=.017, n=220) and expressive aesthetics (r=.133, p=.049, n=220) (Fig. 2). The

strength of correlation of Agreeableness on classical aesthetics was slightly higher than on expressive aesthetics; but clearly the numbers are too small to make the differences meaningful. Other personality traits (i.e., Openness to Experience, Conscientiousness, Extraversion, Neuroticism), however, were found not significantly correlated with either classical or expressive aesthetics (Fig. 2).

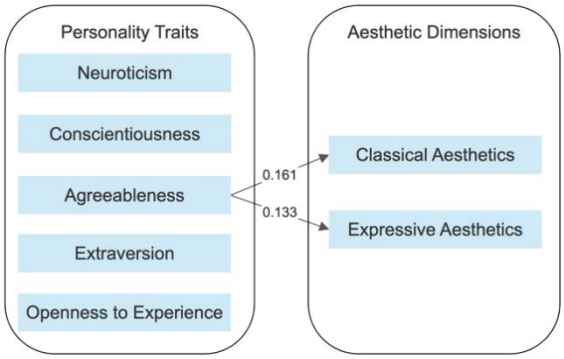

Fig. 2. Data-driven Path Model.

The result of a series of stepwise linear regression analyses with preferences as criteria showed that Agreeableness was the only personality trait that survived the stepwise procedure for classical and expressive aesthetics. For classical aesthetics, a significant regression equation was found ($F(1, 218) = 5.794$, $p<0.05$) with an R^2 of .026. Participants' predicted classical aesthetics is equal to 3.115 + .228 (Agreeableness) when Agreeableness is measured on a Likert scale. Classical aesthetics increased .228 for each point of Agreeableness. For expressive aesthetics, a significant regression equation was found ($F(1, 218) = 3.909$, $p<0.05$) with an R^2 of .018. Participants' predicted expressive aesthetics is equal to 4.707 + .148 (Agreeableness) when Agreeableness is measured on a Likert scale. Expressive aesthetics increased .148 for each point of Agreeableness.

The personality traits' contribution to being able to predict preferences for aesthetics of different dimensions was relatively low, with all predictors together accounting for only 2.8% of the variance for the classical aesthetics and 4.2% of the variance for the expressive aesthetics. As in the case of aesthetic preference, Agreeableness was shown as the most important characteristic of the big-five personality traits. Agreeableness was predictive of classical and expressive aesthetics whereas the others were not.

V. Discussion

The study demonstrates that among the big-five personality traits, Agreeableness was the only trait that significantly, albeit weakly, correlated with classical and expressive aesthetics. A closer look at the correlation of Agreeableness on classical and expressive aesthetics revealed that the strength of correlation between Agreeableness and classical aesthetics (r =.161) was slightly higher than between Agreeableness and expressive aesthetics (r =.133). This result can be interpreted in two ways. First, people with Agreeableness prefer classical aesthetics over expressive aesthetics. This interpretation is in line with [52], who conducted a study in visual art and found that people with Agreeableness prefer representational arts over abstract arts. Second, people with Agreeableness prefer both classical and expressive aesthetics. This interpretation is based on the trivial difference in the correlation coefficient between classical and expressive aesthetics (i.e., 0.028) and is aligned with our hypothesis that people with Agreeableness are receptive to any form of aesthetics presented to them.

Conversely, the absence of a significant correlation of Openness to Experience, Conscientiousness, Extraversion, and Neuroticism on both classical and expressive aesthetics implies that these four personality traits have no influence over user preference on aesthetic dimensions. This finding correlated well with [36], who claimed that visual aesthetic sensitivity was independent of personality. Our work extends their study by employing a website interface with all adult subjects (21-27 years) in comparison to using artwork as stimuli with mostly children (10-15 years) in assessing the independence of visual aesthetic sensitivity from personality traits. This finding adds to the literature suggesting that aesthetic preference is independent from personality across computer or non-computer interface and age groups (i.e. children and young adults).

Apart from the immediate results, the findings of this study should also be considered within the context of its limitations. As in most empirical studies, the study conducted here was limited by the measure used to examine user preferences. Since user preferences were measured using static screenshots of web pages, the results may only apply to non-interactive interfaces, whereas the use of interactive interfaces as stimuli may potentially alter the results. This is an interesting aspect to be carried out in prospective work.

In addition, the subjects in this study were undergraduate university students. This restricted sample of subjects may hinder the generalizability of the findings across the populations. The opportunity to evaluate other populations may provide insight into interpopulation perspectives of user preference. Replicating findings in different contexts and with different populations may possibly benefit the knowledge-building process, theoretical refinement, and applicability in other situations [59][60].

VI. Conclusion

This study examined the relationship between personality traits and aesthetic dimensions. The results showed a weak relationship between personality traits and aesthetic dimensions, thus suggesting that personality traits are not a good predictor of aesthetic dimension preferences. Previous literature and our findings collectively illuminate the fact that personality measures appeared more useful in predicting aesthetic preference of individual design features than the aesthetic dimension of interface. In the future, other than using different stimuli and populations, further study should consider inductive research design to gain a qualitative understanding of underlying reasons and motivations for aesthetic preferences.

An Ontology-based Decision Support System for Multi-objective Prediction Tasks

Touria Hamim, Faouzia Benabbou, Nawal Sael
Laboratory of Modeling and Information Technology
Hassan II University, Faculty of Sciences Ben M'sik, Casablanca, Morocco

***Abstract*—Student profile modeling is a topic that continues to attract the interest of both academics and researchers because of its crucial role in the development of predictive or decision support systems. It provides platforms to build intelligent systems such as e-orientation, e-recruitment, recommendation, and prediction systems. The purpose of this research is to propose an ontology-based decision support system that can be used for multi-objective prediction tasks such as prediction of failure/abundance, orientation or decision-making. Two major contributions are proposed here: a new domain ontology that models the profile of a student and a system that is based on this ontology to perform multiple prediction tasks. The proposed approach relies on the efficiency of the ontology to ensure semantic interoperability and the benefits of machine learning techniques to build an intelligent system for a multipurpose decision support objectives. The proposed system uses Decision Tree algorithm (C5.0), but other machine learning models can be added if they prove to be more efficient. Furthermore, the performance of the developed method is computed using performance metrics and achieved 83.6% for accuracy and 81.9% for recall.**

***Keywords*—Profile modeling; student; ontology; machine learning; academic domain**

I. Introduction

In the educational field, student can be described over different information that changes over time and which constantly evolves. The profile model is the way to represent and cover the different dimensions describing accurately different features of the student such as personal, academic, social, psychological information and some others [1]. The reliability or quality of the profile description is very crucial to have efficient understanding of students. Profile modelling has the advantage of encompassing several aspects of the student that can be exploited for different purposes such as course recommendation, orientation, outcome prediction, recruitment, etc.

The education sector is a great field of promise for the uses of artificial intelligence. Artificial intelligence (AI) has the capacity to meet some of the greatest challenges facing the field of education today to develop innovative teaching and learning practices. Machine Learning (ML) can be used in many ways in the field of education, either for adaptive learning which, depending on the abilities and learning mode of each student, allows to choose personalized techniques and optimized techniques to the individual scale, or for improving student performance by identifying the cause of the problem and helping to remedy it and the institutions themselves can identify their weaknesses and find areas for improvement to maximize their students' results, or for predicting student success or failure. ML techniques have also shown their power to help students choose their path, where based on the data, the system can suggest a student to work in the industry or sector that best suits him, guidance can therefore be based on these results to better guide those who are struggling to find their way. Machine learning-based systems are used to design complex models and algorithms that lend themselves to prediction or decision support. These models allow researchers, scientists, engineers and analysts to "produce reliable and repeatable decisions and results" and to uncover "hidden information" by taking advantage of historical relationships and trends in data. To learn, these systems receive huge amounts of data, which they then use to learn how to perform a specific task. The quality and size of this dataset is important to building a system capable of performing the task assigned to it with precision. Researchers turned their attention to the possibilities of standardizing the representation of knowledge. Ontology is one of the approaches that allow concepts to be represented explicitly, it determines the concepts that exist or may exist in the area of interest [2-3].

In addition to representing knowledge, a machine learning-based system must encode the knowledge into a form that can be processed efficiently. The Ontologies are currently among the most talked models in Knowledge Engineering aiming to establish representations through which machines can manipulate the semantics of information, integrate new concepts according to the evolution of the system and use different data sources. Ontologies offer knowledge sharing facilitated by the use of a common conceptualization (vocabulary and semantics) and the adoption of a standard ontological language. The integration of machine learning (ML) techniques in ontologies makes it possible to enrich and broaden the context of use, from an ontology that offers a common conceptualization, to an ontological system of decision support. Several research studies combine ontologies with machine learning techniques for different purposes [4-5]. This combination can be used for the enrichment of the data available to a Machine Learning model, and this comes from the fact that ontology, offers in addition to raw data, a whole chain of associations and relations between data.

This paper presents two major contributions. The first one is the creation of a new Generic Student Modeling ontology (GSMonto) that aims to describe several student features in different levels while remaining extensible and scalable. The second contribution is the exploitation of GSMonto to build an

ontology-based decision support framework for multi-objective tasks. The objectives are numerous such as to offer adapted learning content, to predict student failure, success or dropout, to propose student orientation, or recommendation, etc.

This article is organized as follows. In Section 2, the authors present the background concept of ontology and machine learning techniques. Section 3 is a comparative study of the different researches dealing with student profile modelling using ontologies and dealing with the integration of Machine Learning with ontologies. The proposed generic student model ontology (GSMonto) is detailed in Section 4. Section 5 develops the proposed ontology-based machine learning system for student profile. Section 6 presents an experiment of the proposed system. At last, the authors give a discussion, conclusion and perspectives.

II. Background Concept

A. Ontology

The definition of ontologies is inherited from a philosophical tradition which is concerned with the science of "Being". Today, it means the "science of beings" that is to say the set of objects recognized as existing in a domain. It is a structured set of concepts that make sense of information [6]. Its primary objective is to model a body of knowledge in a given field.

The advantage of ontologies is the separation of knowledge. The ontological knowledge being separated, it can be reused in several applications, and these re-uses (total or partial) can form the basis of interoperability between different systems. For example, integrating an ontology into a ML based system therefore makes it possible to formally declare a certain amount of knowledge used to characterize the information managed by the system and to be based on these characterizations and the formalization of their meaning in order to automate data processing tasks. Ontologies are employed as a form of representation of knowledge in Artificial Intelligence, semantic web, software engineering, biomedical domain, and information architecture. Among the constraints of the use of ontologies is their creation difficulty as well as the visualization limits and the difficulty of finding ready-made ontologies to meet user needs.

There are several knowledge representation languages, as RDF (Resource Description Framework) [7] and RDF Schema [8] which have tried to solve the problem of the absence of the semantics of XML schemas by associating simple semantics with identifiers, RDF and RDFS were designed to be as generic as possible, this simplicity of language is also accompanied by an insufficient expressiveness for the description of complex situations. The OIL (Ontology Inference Layer) [9] and DAML (DARPA Agent Markup Language) languages were developed to fill the gaps of RDF, OIL allows defining classes and relations and a limited number of axioms and DAML intervenes to allow agents to share semantics. These two languages were then merged to give a DAML+OIL language that is based on the RDF and RDF Schema languages by enriching them with new primitives [10]. Based on the DAML + OIL language, OWL was defined based on the basic primitives defined by RDF schemas. However, far from being a simple extension of RDF, OWL provides all the semantics necessary for the description of knowledge especially for publishing and sharing resources on the semantic web, structuring them in an understandable and standardized way, and making them accessible by adding Meta information. For this, OWL is chosen to lead this study, given that OWL has more powerful means of expressing meaning and semantics than XML, RDF, and RDF-S. In addition, OWL allows information to be gathered from distributed sources, including allowing the import of information from other ontologies. OWL is developed as an extension of the RDF vocabulary and is derived from the DAML + OIL ontology language [11]. OWL has three increasingly expressive sub-languages. OWL Lite is a sub-language that supports users who mainly need a classification hierarchy and simple constraints, which makes the calculation time of inference processes limited. The advantage of OWL Lite is that is both easier to grasp (for users) and easier to implement (for tool builders). The disadvantage is its restricted expressivity. OWL DL, a sub-language of OWL that supports maximum expressiveness needs while guaranteeing the completeness of calculations and decidability necessary for reasoning systems. The advantage of OWL DL is that it permits efficient reasoning support but loose full compatibility. And OWL Full sub-language which gives the user maximum expressiveness, but there is no guarantee as to the completeness and completion of the procedures inference, the advantage of OWL full is its maximum expressiveness without sacrificing computational completeness and the inconvenient is that it is so powerful in expressiveness that it became undecidable. OWL DL is the language chosen to drive the proposed approach.

B. Machine Learning Techniques

Machine learning is an artificial intelligence (AI) field that enables systems to learn and improve automatically from the experience itself without being explicitly programmed. Machine learning focuses on the development of computer programs that can access data and use it to learn on their own. In general, two main types of machine learning algorithms are used today: supervised learning and unsupervised learning. In supervised Learning all data is tagged and algorithms learn to predict the outcome of the input data. Unsupervised Learning uses an unlabeled data set, the machine is then asked to create its own responses. It thus offers answers from analyses and grouping of data.

In the proposed system of this paper, Decision Tree (DT) is used, which is an algorithm that estimates a target concept by a tree representation, where each internal node corresponds to an attribute, and each terminal node (or leaf) corresponds to a class. It is widely known and used in many fields to aid the decision-making. In the academic field, it was shown in author's previous study [12], that it is counted among the algorithms that give the best performance for the prediction of the academic performance of the students. There are several automatic algorithms for building decision trees like ID3, C4.5, C5.0 and CART, etc. ID3 (Iterative Dichotomiser 3) was developed by Ross Quinlan. It can be applied only on the nominal characteristics. It is used for ranking. Therefore, if the data contains continuous characteristics, then discretization should be applied. C4.5 is an extension of ID3 by Ross Quinlan

that can be applied on all types of features. Among the improvements of C4.5 regarding ID3, is the transformation of continuous (digital) characteristics into nominal characteristics dynamically, features without values are ignored when calculating entropy and information gain and pruning trees after creation. C5.0 is a commercial and vastly improved version of the C4.5 algorithm, which applies in large databases. Among the improvements that are added in the C5.0 algorithm is the addition of new data types such as dates and the improvements in efficiency, memory and data processing speed. And CART algorithm, which is similar to that of C4.5 with a few differences like supporting regression, representing the decision tree by a series of binary divisions leading to terminal nodes which can be described by a set of specific rules. The attractive presentation of the CART tree makes it easy to interpret.

III. Related Works Review

A. Ontology Construction in Educational Domain

In several research studies, ontologies were used to master the information resources of learners, and to facilitate their organization and exploitation. Ontologies is now one of the most important bases of the Semantic Web approaches in the educational field, whether for online or traditional learning. When building a model in adaptive e-leaning, several questions arise, such as which information will serve to represent a better the learner? Which formalism to choose for representing and managing the learner model? To answer these questions, authors in [13] proposed an ontology-based approach for the representation of learner profile and learning styles to simply use them for a personalized E-learning and to allow greater flexibility and reusability. The proposed approach collects personal information about the learners, their learning styles, prerequisites, preferences, objectives, online behaviors, etc.

In adaptive e-learning, the student information can be traced and used by systems to provide adaptive content, the authors in [14] addressed the involvement of digital library in the e-learning process and proposed a student model that adopts technologies, applications and standards from the Semantic Web by using OWL ontology language based on six main classes: Personal data, Background, Motivation state, Learning goal and Preferences. In adaptive learning, the content is adjusted to the learner's profile to respect their learning style. In [15], authors proposed to establish an ontological relationship between the formation of learner models with adaptive learning systems. As well, the authors in [16] presented an OWL learner ontology that supports personalization based on three learner style models: Felder-Silverman, Honey-Mumford and Kolb. While an ontology-based approach with six learning style model to adapted learning systems was presented in [17]. In [18], authors proposed a Framework for adaptive learning ontology to retrieve learning resources according to the learner style and knowledge level. The ontology captures information about learner's personal information, prior knowledge, and learning styles. In [19], proposed an ontology to model learners enrolled in distance learning. The proposed ontology arranges learner model characteristics into facets. The Learner class is the key concept of our hierarchy and it includes all specific details regarding learners. It's associated with the corresponding sub-classes through has Profile, has Education and has Personality.

One of the biggest challenges of adaptive e-learning systems is learner modelling. To create a model that meets the requirements, the authors in [20] proposed a novel adult learner's knowledge model using ontologies and rule reasoning. The proposed model takes into account different elements of the learner's knowledge. In [21] a ubiquitous lifelong user model ontology called LifeOnto is proposed, which meets the requirements of adaptive learning systems. Authors in [22] proposed a model based on OWL-DL ontology language that can provide support for recommended activities and personalization of educational context in Adaptive Educational Systems (AES) by grouping the chosen characteristics into four classes: Personal Information, behavior, context and progress/knowledge. An ontology-based learner modelling approach is proposed in [2] to adapt learning contents to learner. Four main classes were proposed, namely: Personal data, context, cognitive data and activity data.

In order to adapt the learning profile to the learning environment, the authors in [23] focus on the following behavioral analysis and evaluation, the detection of learning styles, the development of the learner's profile that takes into account the knowledge, preferences and attitude of the learner for learner profile modeling. Authors in [24] proposed an approach based on the semantic student profile to predict learning preference of the students based on their learning interest and style. With the advent of e-learning, even school orientation starts to be done remotely. The author in [25], proposed a framework of an ontology system called for personalized course recommendation. The approach aims to integrate the information from multiple sources based on the hierarchical ontology similarity with a view to enhancing the efficiency and the user satisfaction and to provide students with appropriate recommendations. The proposed user profile consists of two main parts. The first part is the personal attributes and education attributes of the user and the second is the user's rating of the previously recommended course.

The links between higher education and the world of work are the most controversial. Most of the controversy revolves around the mismatch between higher education opportunities and the needs of the word of work. A better understanding of the relationship between education and the world of work helps to pinpoint the reality of the problems that higher education encounters. Studying the gap between the results of higher education and the needs of industry was the author's objective in [26], by establishing an ontological relationship between the skill requirements of market occupations and the profile of learners of higher education to ensure continuous alignment between student profiles and industry. The classes used by the author to establish the ontology of the student profile are divided into five sub-models: Common model, Education model that represents the education profile, Student model, Application model and Occupation model. Table I presents a second comparison of the research studies dealing with the construction of ontologies in the academic domain for different objectives. Each research study is presented in a row of the table, including the reference, publication year, ontology language used, the tool and the main ontology model classes

used (to define and categorize the different concepts used, to a standardization of concepts is proceeded).

B. Integration of Machine Learning Techniques with Ontologies in Different Domains

ML learning integration with ontologies has proven to be successful in many decision-support systems. For this, artificial neural network methods, logical rules based techniques like decision tree, mathematical functions based ones like SVM, probabilistic methods like naive Bayesian classifier and some others, are used over ontologies concepts or data. The author in [27], used an environmental ontologies of lakes with the K-means clustering algorithm to group lakes according to the average nitrogen concentration into two groups (PoorIn and RichIn). In [28] and [29], the authors proposed an artificially intelligent predictive model for a manufacturing network by developing an ontology model based on decision tree algorithm. In [30], the main goal of the research is enhancing ontology matching by using techniques coming from different fields such as ML, Information Retrieval and Graph Matching to discover correspondences between semantically related entities of ontologies by transforming the ontology matching task into a classification task in ML (match or not match category) using Decision Tree J48 model. Authors in [5], proposed an ontology-based decision tree where the principle was using characteristics of the elements and the relations between them to find the feature super-class with the highest information gain instead of using a single vector of characteristics in the model. These classes are used as decision on tree node to obtain more information on the preferences of the user. The relation between ontologies and ML techniques can be described as a reciprocal benefit relationship. In addition to the advantage of the application of ML techniques within the ontology for decision support, the ontology also carries a benefit for Machine Learning techniques especially in the data processing due to its organized structure which is especially the case for Text classification issue. As for the authors in [4] who used a Human Disease Ontology, and tried to carry out a classification problem with and without the use of ontology. The authors found that the ontology based classification stands at a higher level than the classification without ontology by using various ML classifiers.

The study of the research studies cited in the educational field shows that researchers are interested in constructing the ontology for a specific objective, either to adapt the content of e-learning to the profile of each student, or to predict the drop-out or the performance of the student, or for recommendation or guidance. According to this objective, the system is modelled to meet the given purpose. In what follows, a multi-objective decision support system is proposed, developed from an ontology which covers the different concepts of the student with the integration of ML techniques.

TABLE I. COMPARISON OF CONSTRUCTED ONTOLOGIES FOR EDUCATIONAL PURPOSES

Ref	Ontology language	Tool	Ontology Main Classes
[13]	-	-	Personal data, Prerequiste, Preference, learning style, online behavior, social data, psychological data.
[14]	OWL	Protégé	Personal data, Learning style, knowledge, Course information

[26]	OWL	Protégé	Common model, Education model, Student, Application model, Occupation model.

IV. GSMONTO: GENERIC STUDENT MODEL ONTOLOGY

A. GSMonto Creation

Based on state of the art and different data sources, the authors build a domain ontology that covers the different aspects of the student needed in building intelligent systems, in the context of keeping up lifelong learning processes, go beyond guaranteeing interoperability between different educational systems or applications via the web, capable of satisfying users educational needs, and that can be used for different purposes (prediction of failure, dropout, orientation, etc.). OWL DL language is used for its ability to be distributed across many systems and its scaling for Web needs with reasonner support. The generic student model ontology (GSMonto) is based on expert knowledge and documentation on the educational field and mainly covers different classes that can be scalable for future perspectives. The ontology creation goes through two fundamental stages, which are the acquisition and the modelling of knowledge. During the construction of ontology, a semantic reasoner is used to deduce logical consequences from a set of facts or asserted axioms (Hermit and Pallet are two Protégé reasoners examples).

The proposed ontology defines a set of 12 upper level classes, namely:

- Student: the main class of the proposed ontology.
- Personal Identity: defines the student in a unique way (first name, family name, personal address, etc.).
- Social Identity: Derived from the belonging of a student to a social group (Nationality, marital status, etc.).
- Digital Identity: Student Identity in Social Media and Web World (digital signature, twitter account, etc.).
- Family Background: Describes the family size, parents' education, parents' job, family structure (if the student has no parent, single parent or two parents), etc.
- Personality: Encompasses information about the psychology (if the student has a normal psychology or suffers from addiction, depression or anxiety), skills and personality type of the student (intuitive, extraverted or introverted).
- Professional Experiences: Internships and jobs that has been done by the student.
- Physical Limitation: student's physical limitation as visual, verbal, hearing, amputation, paralysis, etc.
- Knowledge Profile: Records if the student has general, theoretical or practical knowledge in a specific topic.
- Learning Profile: Encompasses information about the student's learning in presential and online learning platforms, like learning style, interaction preferences (practice, example or principle oriented), learning media (audio, text or video oriented), etc.
- Academic Background: Detail about the formal education that the student has received including high school background, university background (graduate education, certified formations or PhD formation).
- Cognitive Profile: Describes the range of mental processes relating to the manipulation of the information like memory level, intelligence level, etc.

Fig. 1 describes the schematic representation of the proposed ontology. Each class can include data type properties to connect a single subject with some form of attribute data, and object properties to provide the relationships between two individuals from given class.

B. GSMonto Scalability and Instanciation

To ensure the update and the scalability of the ontology, an enrichment of the latter has to be done periodically. This enrichment can be defined following either the knowledge of experts in the educational field, or by the collection of a dataset which carries new concepts from different sources, whether from learning management systems (Moodle, Blackboard, etc.), Enterprise Resource Planning (like Apogee, XML, etc.) or traditional databases. Then, a mapping process is necessary, to convert dataset components or new discovered concepts to the corresponding ontology components. When it comes to the data source, a Metadata analysis is done, to obtain a description of the data. This metadata analysis will be used to create mapping rules, which, for each database component, generate the correspondence in ontology components with the objective of creating an ontological model from a database. If the concepts drawn from the mapping rules and those of the constructed ontology are aligned, an automatic instantiation of the constructed ontology is done in the third. Nevertheless, if the mapping rules shed light on new concepts that don't exist in the ontology already established, and which are supposed to be important, an update must be done so that the ontology is up to date, as shown in Fig. 2 that describes the process of updating and instantiating the ontology.

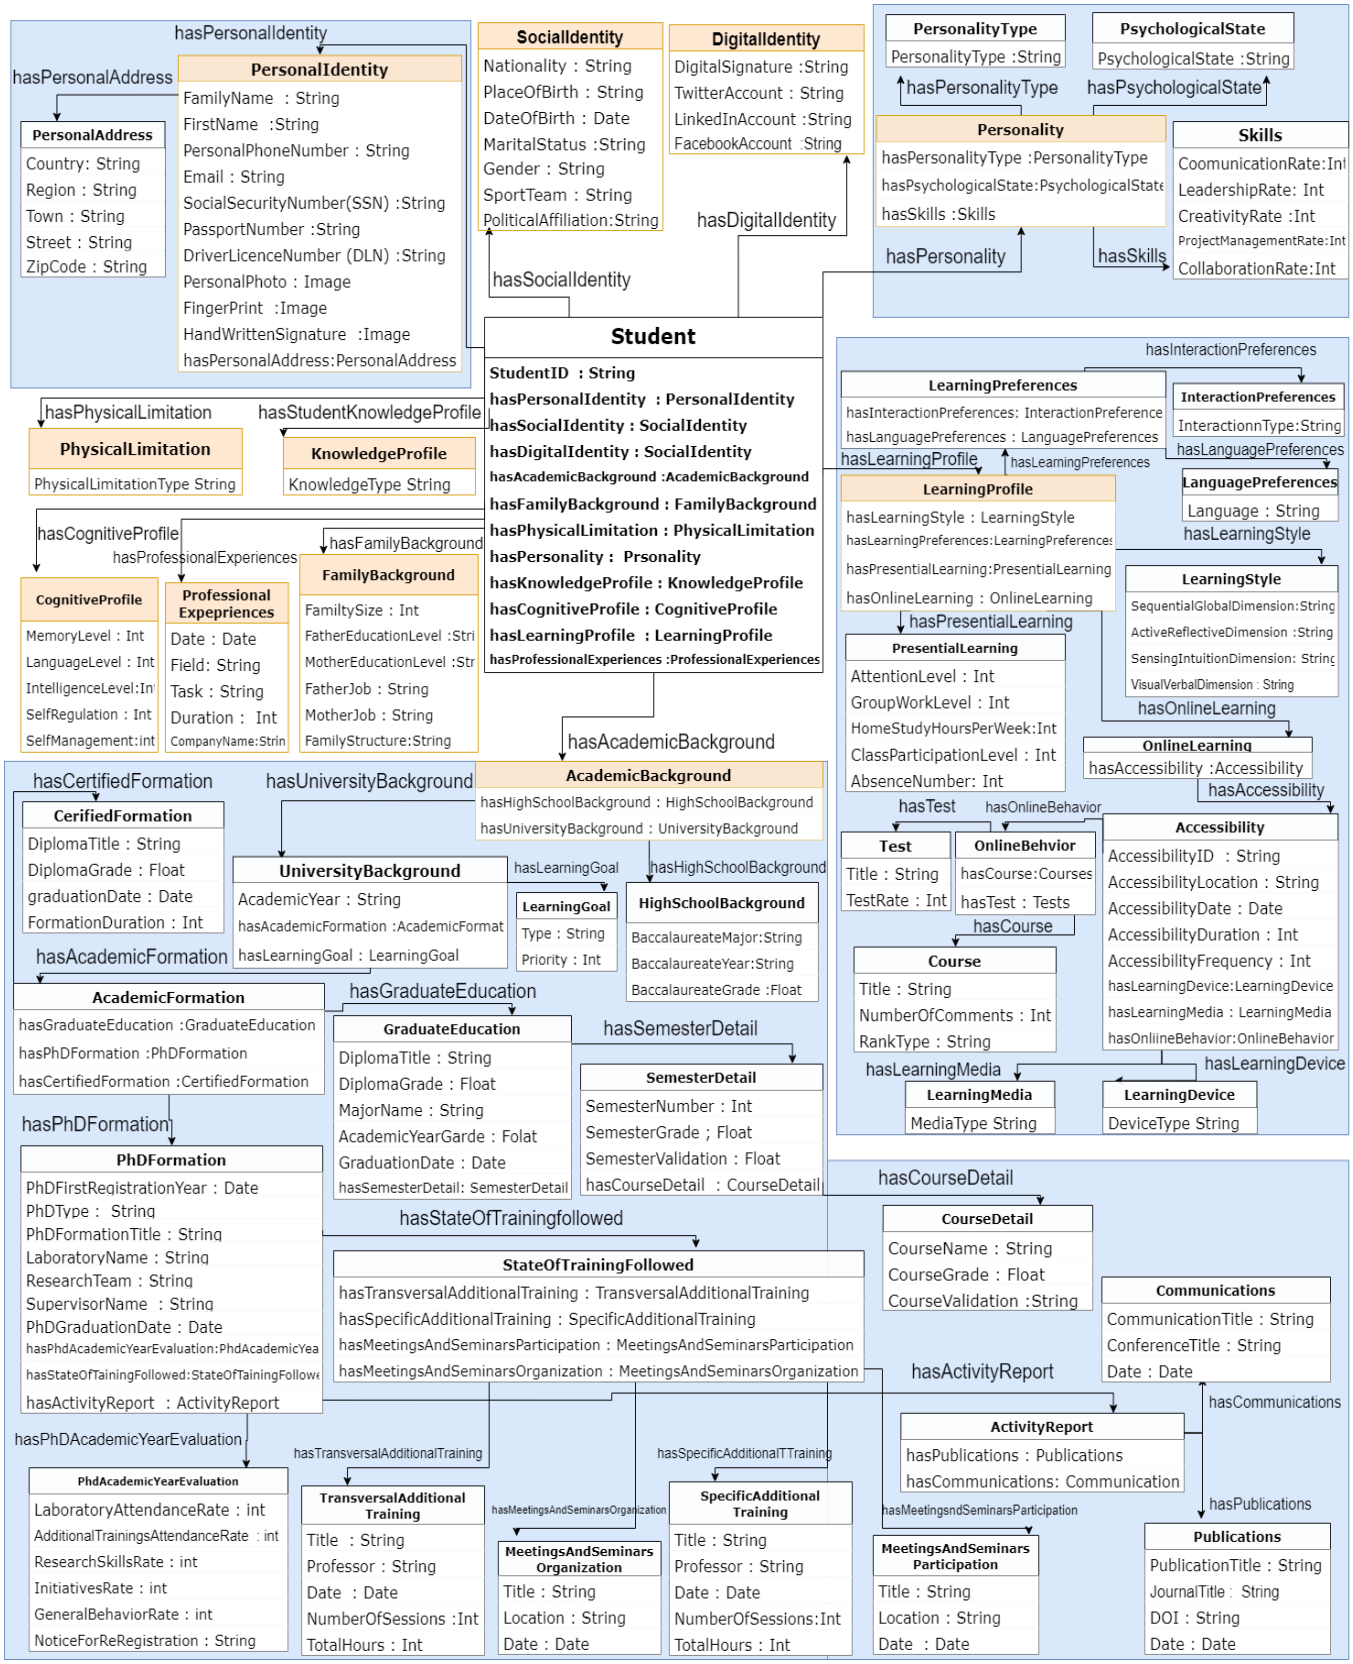

Fig. 1. GSMonto Overview.

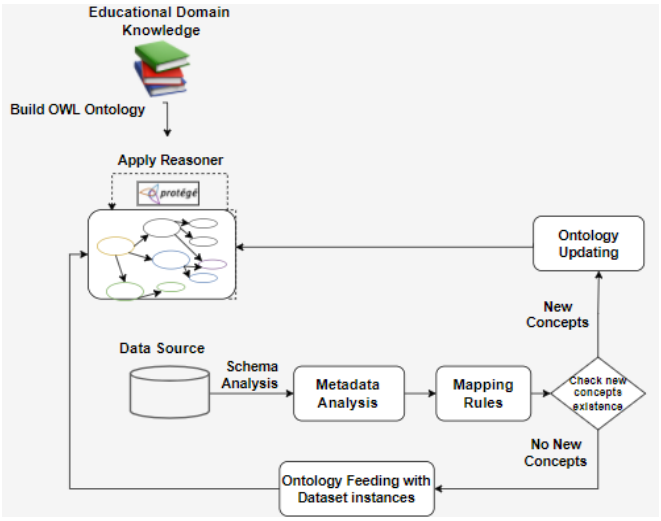

Fig. 2. Ontology Update and Instantiation Process.

V. Proposed Ontology Based Machine Learning System for Student Profile Modeling

This paper proposes an ontology based Machine Learning system using an ontology that covers the different aspects of the student. The proposed system process of the can be divided into four levels. The first level concerns the exploitation of the constructed ontology. According to the objective (prediction of failure, dropout, orientation or other objective) and to the available data, a selection of relevant concepts of the ontology is made to generate a sub-ontology. The second level is the conversion of the created sub-ontology to a dataset using mapping tools. These are based on the use of defined rules to transform the concepts of ontology (classes, individuals, data type properties, etc.) to their equivalents dataset that can be used for the application of ML techniques.

In the third level, the ML process is applied on the generated dataset, starting with data pre-processing, in the case of the presence of anomalies or incorrect values that compromise the quality of the dataset, knowing that the initial ontological presentation of the data already offers the advantage of avoiding the majority of inconsistencies, conflicts and contradictions. Then, a feature selection is carried out to reduce the number of input variables and the computational cost of modelling and, in some cases, to improve the performance of the model. In addition, data partitioning is followed to prepare for the application of the appropriate ML technique. The final level consists in converting the ML algorithm results into Semantics Web Rule Language (SWRL) to be easily integrated into the ontology, thus enriching its expressive power and increasing knowledge about individuals, so the ontology will be more consistent and can include in addition to knowledge, integrated predictive models. Fig. 3 shows the proposed ontology based ML system process for student profile modelling.

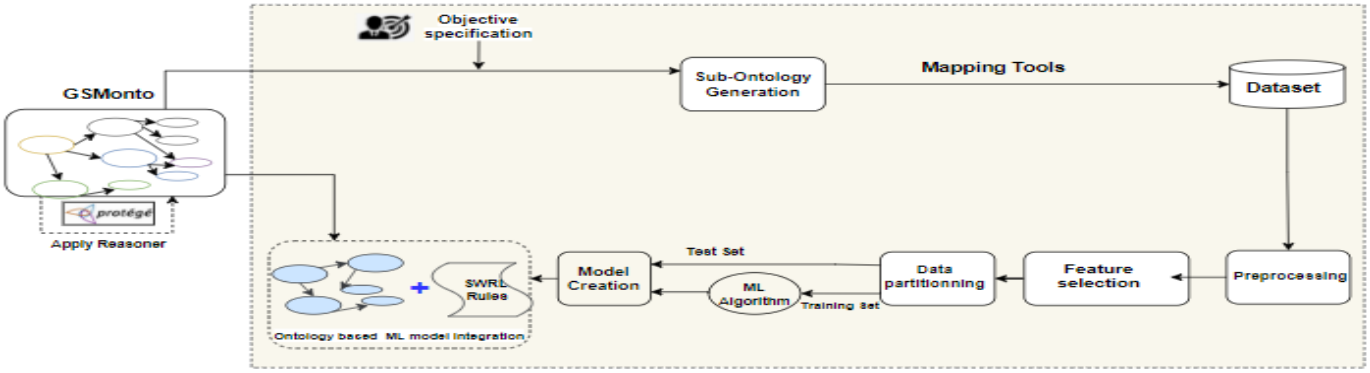

Fig. 3. The Proposed Ontology-Based Decision Support System for Multi-objective Prediction Tasks.

VI. Experiment and Results

In this section, a case study that illustrates the application of the proposed system described in the previous section is presented. The aim of this case study is to apply the proposed system in real situations, whether they are new and/or complex or to extend knowledge. The implementation process of the GSMonto ontology is accomplished with the aid of Protégé tool, which is a free and open source ontology editor for building intelligent systems.

A. Data Source and Metadata Analysis

The dataset used is extracted from the Apogee (Application For Organization and Management of Teaching and Students) database and transferred to a spreadsheet, including 20 academic performance features of 3911 student [31].

One feature relates to the validation result of the academic year (100) and two features relate to the validation of each semester of the two semesters (110 and 120), and the rest of the attributes give the validation results of the courses.

B. Ontology Updating and Feeding

In this case study, no new general context is detected, but detailed sub concepts must be presented in the established ontology, these are the courses studied in each semester. The semester class is divided into two classes (semester 1 and semester 2) and each course column title from the Spreadsheet is transformed to a subclass of each Semester class. To carry out this mapping, Cellfie is used, which is a Protégé Desktop plugin for importing spreadsheet data into OWL ontologies with the intermediary of the mapping rules. The updating process of the ontology includes information about the new courses. For example, a transformation rule expression can be defined to take the name of the spreadsheet cell G1 (column name SemesterOne) and declare an OWL named class that is a subclass of an existing YearResultDetail class which defines

that the SemesterOne class is a subclass of the class YearResultDetail , as follows:

Class: @G1 SubClassOf: YearResultDetail

Fig. 4 illustrates the proposed ontology with the update undergone in relation to new concepts in Protégé.

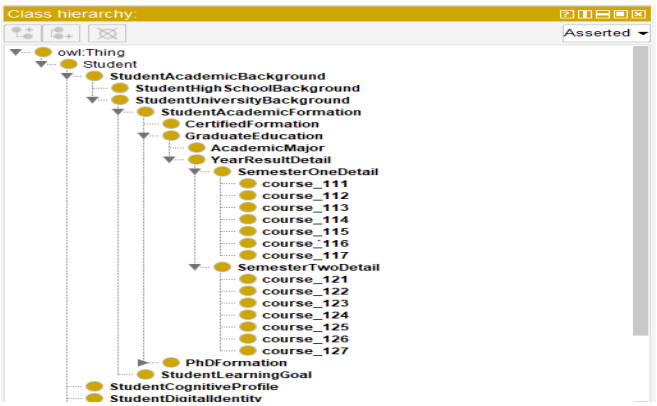

Fig. 4. GSMonto overview after the Updating Process as Diplayed in Protégé.

After updating the new concepts under the GSMonto, Pallet reasoned is used to ensure the compatibility between the concepts. Finally, the ontology feeding is carried out.

C. Machine Learning Integration

The Third step of the proposed process concerns the integration of ML within the ontology created.

An example of prediction concerns the same dataset with which the authors instantiated the proposed ontology. The validation of the academic year is the class to be predicted. The independent variables used for the prediction concerns the validation result of the first semester and its related courses. The algorithm used in this case study is C5.0. R software is used for the implementation of the model. The model performances achieved are 83.6% in accuracy and 81.9% in recall. To implement the proposed model within the ontology, the rules deduced from the decision tree are converted into SWRL rules, using a Python code that maps each rule in the decision tree to its equivalence syntax on Protégé SWRL. The generated decision tree rules are converted into SWRL rules. An example the conversion method is presented in the Fig. 5.

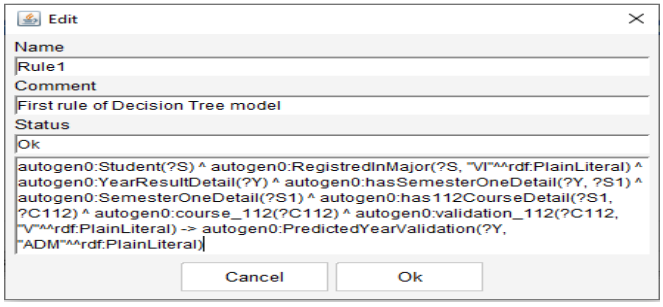

Fig. 5. SWRL Rules Implementation.

For each new student registered with the information of his academic performance in the first semester, the model gives the academic year result prediction. Fig. 6 shows the prediction result for a student: PredictedYearValidation: "ADM", which means that the student will succeed in the academic year according to the model prediction.

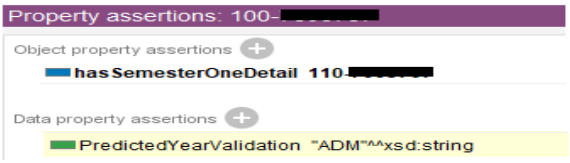

Fig. 6. Prediction Results view in Protégé.

VII. Discussion

In this study, the authors were able to implement a generic ontology that dissects the majority of students' characteristics. The authors were also able to bring together the benefits of standardization of the concepts provided by the ontology with the benefits of machine learning techniques to meet several predictive tasks. As an experiment, the decision tree algorithm was used for predicting student performance, and the results of the algorithm were transformed into SWRL rules to build an ontology-based decision support system.

VIII. Conclusion

The authors have presented a generic ontology proposed for modelling the student profile, which differ from the existing ontologies by its generic aspect that can be adapted to several objectives in the educational field. The authors also proposed a system that combines the proposed ontology with machine learning, using an algorithm based on decision trees and SWRL rules to achieve several objectives such as prediction of failure/abundance, orientation or decision-making. As a future perspective, authors plan to optimize the update process of the ontology by automatically detecting and integrating new concepts. Another goal is to implement other machine learning techniques to meet other objectives and to benefit from the AHP (Analytical Hierarchy Process) technique implemented in a previous paper to propose a module in the system dealing with the missing data as in the case of school dropout.

Towards a New Metamodel Approach of Scrum, XP and Ignite Methods

Merzouk Soukaina, Elkhalyly Badr, Marzak Abdelaziz, Sael Nawal
Department of Mathematics and Computer Sciences, Hassan II University- Casablanca
Faculty of Sciences Ben M'sik, Casablanca, Morocco

***Abstract*—The agile approach is a philosophy that aims to avoid the traditional management approach problems. It concentrates on the collaborative approach, using iterative and incremental development. The client receives a first production version (increment) of his software, faster thanks to agile methodologies. Project needs are influenced by the rapid expansion of technologies, particularly after the emergence of the Internet of Things (IoT). They are becoming larger and more complex. IoT provides a standardization and unification of electronic identities, digital entities, and physical objects. Consequently, interconnected devices can retrieve, store, send, and process data easier from both physical and virtual worlds. Scalable methods such as SAFe, LeSS, SPS, and others are existing methodologies ameliorated and dedicated to large projects. These methods are tough to adopt and do not consider the physical side of the project, according to IoT enterprise teams. Based on their managerial and IoT expertise, they suggest their own methods (Ignite | IoT Methodology and IoT Methodology). Model Driven Architecture (MDA) was coined by the Object Management Group (OMG) in 2000 to develop perpetual models that are independent of the technical intricacies of the execution platforms. The purpose of this paper is to propose a metamodel for each methodology among: Scrum, XP, and Ignite.**

Keywords*—*Agile software development; scrum; extreme programming; XP; internet of things; IoT; Ignite | IoT Methodology; IoT Methodology; metamodel; MDA; OMG

I. Introduction

For decades, projects have been managed with the classic (or traditional or predictive) approach, which is characterized by gathering the requirements, defining the product, developing, and testing it before the delivery. This is the "waterfall" model [1] or its adaptation, the "V" model [2].

One of the main weaknesses of 'waterfall' approach is that the design errors are often not discovered until the time of deployment. At this time, the project is almost complete, and errors are often costly to recover.

Agile methods avoid this weakness by executing iterative and incremental development that is carried out in a collaborative spirit, with the right amount of formalism. They generate a high-quality product while considering the modification needs of the customers.

Thanks to agile methods, the client participates in the realization of the project (prioritize, select items to be implemented on current iteration, do the functional tests, etc.) and obtains very quickly a first production release of his software, by using one of these methods: the XP method, the SCRUM method, the DSDM method, the FDD method, etc. [3].

Projects are becoming larger and complicated as the technology industry expands, especially after the emergence of the Internet of Things. The latter is defined as a network of interconnected electronic devices, which enables electronic identities, digital entities, and physical objects to be standardized and united. As a result, being able to recover, store, transmit, and process the associated data without interruption across the physical and virtual worlds [4].

The technology evolution leads project management experts to try different management methods or to improve existing ones. SAFe [5] [6], LeSS [7], SPS [8] and others are among the methods dedicated to large projects. IoT experts find that these methods, despite being dedicated to large and complex projects, they are complex in use and do not address the physical part of the project. At this level, IoT companies' teams propose their own methodologies based on their managerial and IoT experience. These methodologies are Ignite | IoT methodology (Ignite) [9] and IoT Methodology [10].

In 2000, the Object Management Group (OMG) coined the term Model Driven Architecture (MDA) to create perennial models that are independent of the technical minutiae of the execution platforms. This approach necessitates the use of a variety of models, including CIM, PIM, PSM, and others. As a result, the various formalisms that enable the building of models that are both sustainable and productive had to be explicitly specified. The MetaObject Facility (MOF [16]) standard, which was designed by OMG specifically for this purpose, supports the establishment of modeling formalisms in the form of metamodels. These are made up of a collection of metaclasses linked together through meta-association [11].

This article aims to present first of all the Scrum, XP and Ignite methodologies, describing their processes, artifacts, and roles. Then, it proposes a metamodel for each of these methods using MOF standards.

The rest of the paper is organized as follows: Section 2 presents the research work related to the field of project management and model engineering. Section 3 describes the methodology followed in this work. Section 4 is specific to the definition of the metamodel principle, the presentation of the proposed metamodel, and finally the description of the method

components that are the basis of the proposal. Section 5 presents the paper's discussion and conclusion.

II. Related Work

During this work, there are research works related to the metamodels of project management methods.

Many companies that use agile processes might benefit from using a process measurement framework, for example, to evaluate their process maturity. Ernesto et al. [12] offer a metamodel for the construction of specialized data models for agile development processes in their study. Then, they demonstrate how their metamodel can be utilized to derive a Scrum process model.

The traditional approaches of software development (e.g., RUP, waterfall) and agile approaches (e.g., Scrum, XP) are the two most popular software development strategies nowadays. Hybrid methods can also be used because both approaches offer advantages. Darko and Zeljko's work [13] demonstrates how to use metamodels to create new hybrid software engineering methodologies. They build a common metamodel by combining the metamodels of the traditional waterfall method with extreme programming. The new hybrid method development and development workflow are then built on top of this shared metamodel.

Given the rapid advancement of technology, the necessity for project management in terms of methodology and new concepts continues to develop. Hamzan and Belangour [14] constructed a framework for generating a metamodel that they used to project management to provide a generic metamodel of project management. This approach is founded on two project management methodologies which are "PRINCE 2" and "Scrum". The goal of this research is to validate and apply this methodology to all aspects of IT governance, then merge the metamodels to build a global metamodel that covers all IT governance domains.

The Agile Project Management Framework (APMF) is a collection of fine-grained project management techniques used in agile methodologies that is quickly gaining traction as a viable alternative to traditional project management frameworks. However, both frameworks have flaws that prevent developers from improving one in order to accept the other. Merging the two systems into a Unified Project Management Framework (UPMF) is a reasonable option. In order to achieve this goal, Mahsa and Raman [15] propose a project-management technique metamodel as a common abstract substrate for fusing the traditional framework with its agile counterpart. By abstracting the fine-grained parts of APMF, the proposed Agile Project Management Methodology Metamodel (APM3) was created. An analytical analysis of the project management procedures of seven important agile approaches was undertaken using APM3's generic agile metamodel.

A standardization of the methods concerning Scrum, XP and Ignite is proposed. This standardization is a metamodeling of the phases, the artifacts, and the whole ecosystem.

III. Methodology

The carrying out of the work is done by applying the Scrum methodology as shown in the Fig. 1. The first step consists in defining a list of tasks in the form of user stories that should be carried out throughout the work and to refine them. This list is not definitive, as it will be updated during the work. The next step is prioritizing the list according to the importance of the user stories and its sequence. The second step is to select the user stories to be done for each sprint. Finally, an increment is produced, and the next sprint is started, and so on.

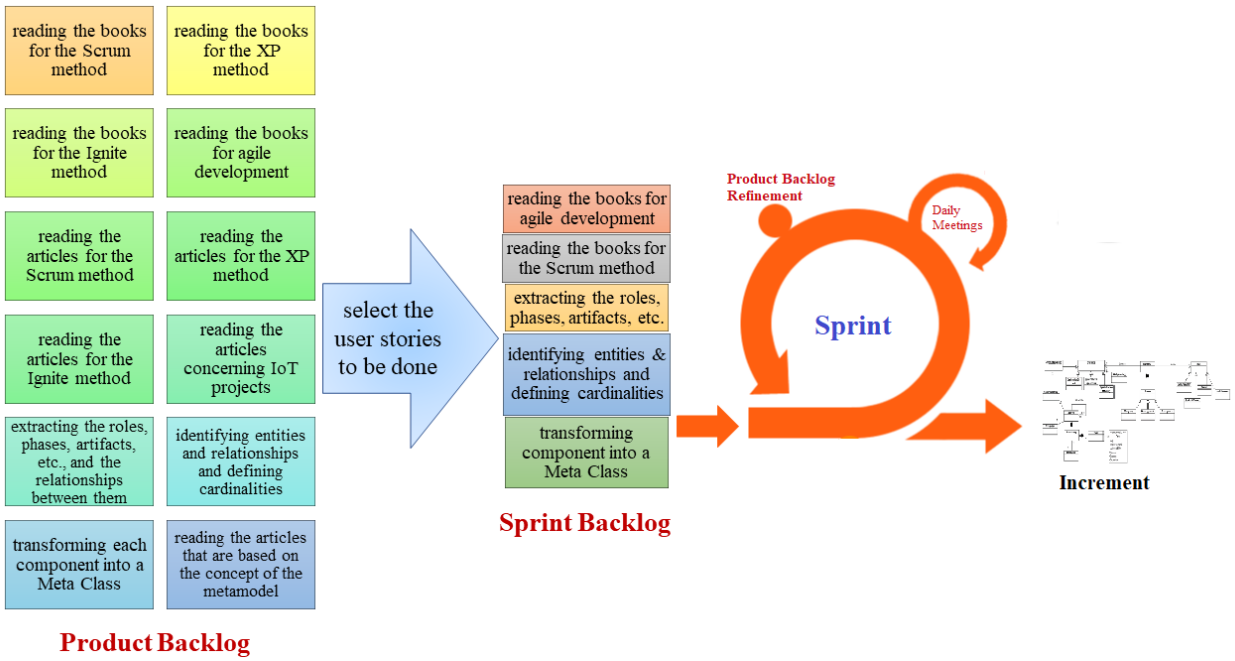

Fig. 1. The Work using Scrum Process.

The list of user stories contains: reading the books for the Scrum method; reading the books for the XP method; reading the books for the Ignite method; reading the books for agile development; reading the articles for the Scrum method; reading the articles for the XP method; reading the articles for the Ignite method; reading the articles concerning IoT projects; extracting the roles, phases, artifacts, etc., and the relationships between them; identifying entities and relationships and defining cardinalities; transforming each component into a Meta Class; reading the articles that are based on the concept of the metamodel.

- The first Sprint concerns the realization of the Scrum metamodel.
- The 2nd Sprint concerns the realization of the XP metamodel.
- The 3rd Sprint concerns the realization of the Ignite metamodel.
- The 4th Sprint concerning the proofreading, writing and correction of the proposed metamodels.

Moreover, daily meetings are held for the discussion regarding the work and the problems encountered in the realization of the current activity.

IV. Metamodel Approach

A. Definition

The Object Management Group (OMG) defined Model Driven Architecture (MDA) in 2000.

This approach advocates the massive use of models and offers the first answers to how, when, what and why to model. It includes the definition of several standards, notably UML, MOF, and XMI. The main objective of MDA is the development of perennial models, independent of the technical details of the execution platforms, in order to allow the automatic generation of the entire application code and to obtain a significant gain in productivity.

MDA necessitated the employment of a variety of models. As a result, it was necessary to explicitly specify the many formalisms that permit the construction of models that are both sustainable and productive. The MOF [16] standard, created by OMG for this purpose, provides support for establishing modeling formalisms in the form of metamodels. According to MOF, any model must respect the structure defined by its metamodel. A metamodel is thus composed of a set of metaclasses. The latter has a name and contains attributes and operations, also called meta-attributes and meta-operations. A meta-association is a binary association between two metaclasses. A meta-association has a name, and each of its ends can have a role name and a multiplicity [11].

B. Extreme Programming Methodology

1) Definition: Extreme programming, or XP, is a method proposed by Kent Beck that applies the old development principles to the extreme. It divides the project into subprojects applying the traditional development steps in each subproject in an iterative way and continuous integration (incremental) which reduces the change cost [17] [18] [19] [20]. Fig. 2 shows the evolution of the Waterfall model towards extreme programming.

2) XP Metamodel: Fig. 3 shows the metamodel of the XP method. This metamodel is based on the transformation of the method's components into metaclasses and the relationships between them into meta-associations.

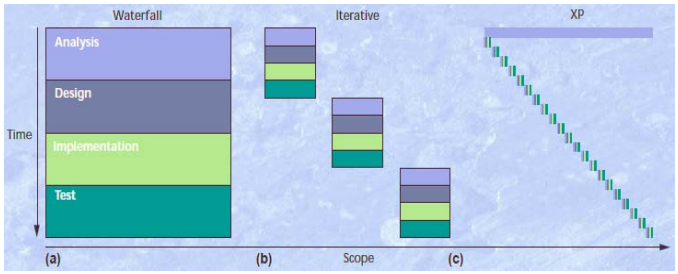

Fig. 2. Evolution towards XP Method: (a) Waterfall Model, (b) Spiral Model, (c) XP [18].

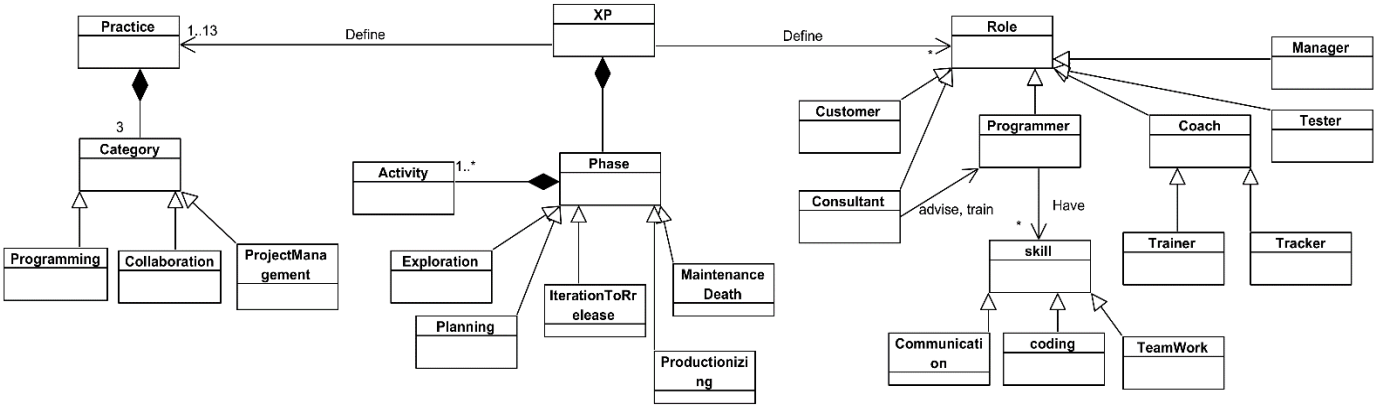

Fig. 3. Proposed Metamodel for XP Method.

3) Component:

a) Phases: The XP method consists of five phases viz., exploration, planning, iteration to release, productionizing, maintenance, and death. Each phase consists of a set of activities. These phases are described according to [20], [21], and [22].

- Exploration: The customer uses index cards to write user stories presenting his needs, as shown in the Fig. 4. These user stories are estimated by developers one by one in terms of the time needed to implement them and the implementation risk. This phase should take a few weeks to a few months and defines the technologies, tools and architectures that will be used in the project. Fig. 4 shows an example of a user story card used in the C3 project.

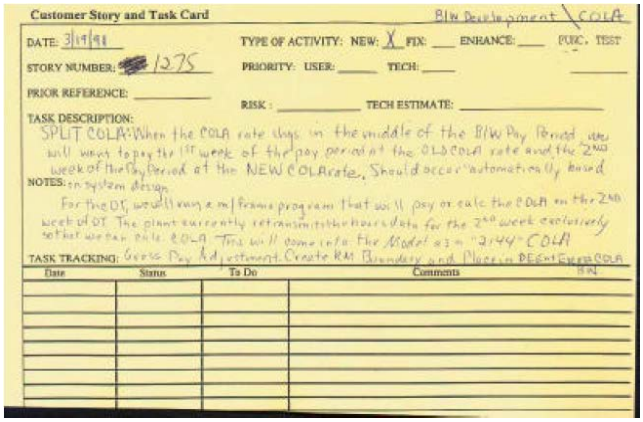

Fig. 4. C3 Project user Story Card [21].

- Planning: Commitment schedule meeting is done, after all user stories are written by the customer and estimated by the developers, to define the priority of each story and which ones are needed for the current release. In addition, the customer writes the functional tests based on the user story cards. The team transforms these cards into tasks with an estimate of each (the Fig. 5 shows a task card used in the C3 project). The meeting ends when the list of stories and the schedule are validated.

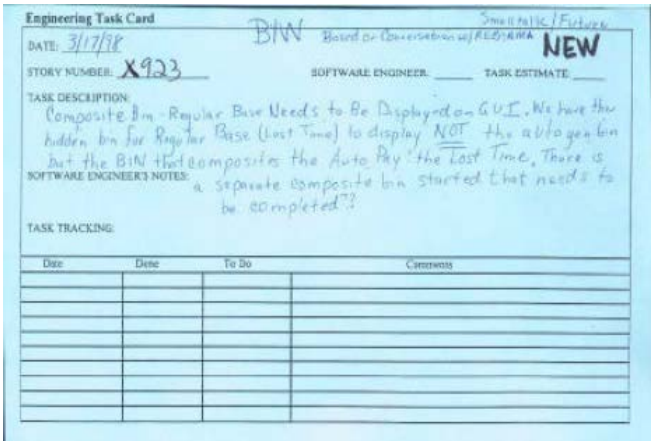

Fig. 5. C3 Project Engineering Task Card [21].

- Iteration To Release: This phase consists of breaking down the schedule of commitments set in the previous phase in a series of iterations. Each iteration follows the phases of the classical approach (designing, coding, testing, and integration). Furthermore, functional tests are applied at the end of each iteration to verify the functioning of the story.

- Productionizing: The system is ready for production at the end of the last iteration. In this case, it is necessary to ensure the performance of the system before delivering it to the customer. To do this, extra testing is done. The ideas and proposals reported are documented for later implementation during, for example, the maintenance phase.

- Maintenance and Death: The maintenance phase is triggered after the first release to the customer. The team must keep the system running in production while the new iteration is in production. It may also require the integration of new people into the team and the modification of the team structure. The death phase is the phase that describes the end of the project when the customer is satisfied and has no stories to implement. At this point, the system documentation is written. This phase also consists of closing down the system if it does not deliver the desired results or if it becomes too costly for further development.

b) Roles: Furthermore, XP defines six roles viz., Customer, Consultant, Programmer, Coach, Tester, and Manager that are described according to [18], [21], and [22]. The consultant is responsible for advising and training the programmer that having communication, coding, and teamwork skills.

- Customer: The client is responsible for defining the requirements because he writes the user stories. In addition, he defines the priority for each card and writes the functional tests which are used at the end of the iteration to check that the stories work. There is a special role in the XP method called on site customer. This is often a domain expert representing the customer.

- Consultant: In most XP projects, there are no professionals due to the rules and practices. A consultant will be employed in these circumstances to supply this information. The consultant's job is to provide expertise. One or two team members will meet with the consultant and ask several of the technical questions before attempting to fix the problem.

- Programmer: The programmer is responsible for the analysis of the design code, etc. He writes the program code as simple as possible. He is required to be competent in communication, coding, and teamwork.

- Managing part of XP project: The project management part of XP is divided into two roles such as coach and tracker Coach: The system manager participates in the management meetings. His role is to guide the team away from the process. It is necessary to be calm; to understand alternative practices that need it and could

help the current set of problems; what the ideas behind XP are; how it relates to the current situation and how other teams use XP. Tracker: Acts as the conscience of the team. He/she must track to determine if the Iteration Schedule and Commitment Schedule can be met. This work gives him data that is used to give feedback to developers on the quality of their estimates. Also, it helps him get feedback on the team's next estimates. In addition, the tracker is required to be proficient in collecting the necessary information without disrupting the whole process.

- Tester: The programmers have a large portion of the duty of testing, so the role of the tester in an XP team is particularly customer-centric. However, someone needs to run all the tests regularly, disseminate the test findings, and guarantee that the testing instruments are in good working order.
- Big Boss: Courage, confidence, and the occasional insistence that they do what they say they will be what the team most needs from the Big Boss. They aren't complaining; they genuinely aren't. They want Big Boss to know as soon as possible if things aren't going as planned, so he can react as quickly as feasible. If it works, he will be golden because he will have a team that's productive, satisfied with its clients, and does everything they can to avoid surprising him.

c) Practices: The method's practices are grouped into three categories, such as programming, collaboration and project management, which are described according to [21], [22], [23], and [24].

Programming category

- Simple design: The simplest solution that will work is always implemented by developers. They do not, for example, design generic mechanisms if the urgent necessity does not necessitate it.
- Refactoring: Developers are not hesitant to go back over the written code to make it "cleaner," to remove any unused components, and to prepare it for the addition of the next feature. More generally, this practice suggests a continuous design approach that highlights the application's structure as it develops.
- Test-first programming, unit tests, developer tests: Even as they are writing the code, developers generate automated tests for it. This enables them to gain a deeper understanding of the problem before creating the code. In addition, to gradually build up a battery of tests that enables them to make changes to the application fast and with confidence.
- Acceptance Tests, Customer Tests: Through participating in the writing of acceptance tests, the client expresses his wants and the programmers' objectives very explicitly. Acceptance tests, like unit tests, must be automated in order to ensure that the product does not regress on a daily basis.

Collaboration category

- Pair Programming: The developers always work in pairs on the same machine when coding for the application - this is an "extreme" type of code review that both developers actively collaborate to resolve issues they discover. The pairs change regularly, so everyone must work with all other team members early or later.
- Collective code ownership: All developers in the team may be required to work on all parts of the application. Furthermore, they have a duty to improve the code they work on, even if they are not the original authors.
- Coding standards: Developers follow coding rules defined by the team itself. This ensures that their code is consistent with the rest of the application, and therefore facilitates the intervention of other developers.
- Metaphor: Developers do not hesitate to use metaphors to describe the internal structure of the software or its functional issues. This facilitates communication and ensures a certain homogeneity of style throughout the design, the ideal being to describe the system in its entirety by a single metaphor.
- Continuous integration: Developers synchronize their work as frequently as feasible, at least once a day. This decreases the frequency and severity of integration issues, while also ensuring that a current version of the software is always available.

Project Management Category

- Frequent releases: The team delivers software releases at a regular rate, as high as possible, depending on the client's preferences. This enables both the team and the client to guarantee that the product meets the client's expectations and that the project remains on schedule.
- Planning game: In dedicated sessions done on a regular schedule throughout the project, the client and the development team collaborate on project planning.
- On-site customer, whole team: The customer is literally incorporated into the development team, allowing him to set priorities and specify his wants clearly, notably by directly addressing programmers' inquiries and taking advantage of the instant feedback provided by a frequent-delivery application.
- Sustainable pace: The team adopts schedules that allow it to keep the energy required to create high-quality work and efficiently follow other project procedures.

C. Scrum Methodology

1) Definition: The word "scrum" and the method's idea are derived from a rugby strategy that entails "bringing an out-of-play ball back into the game" through collaboration [25] [26]. The method was created in the early 1990s to manage the systems development process. It is a framework that focuses on how team members should work together and always ready to reorient so as to create a flexible system in an ever-changing environment. Scrum helps an organization's existing

engineering processes by requiring frequent management activities to systematically identify gaps or impediments in the development process, as well as the techniques that are employed [27] [19].

2) Scrum metamodel: The Fig. 6 shows the metamodel of the Scrum method. This metamodel is based on the transformation of the method's components into metaclasses and the relationships between them into meta-associations.

3) Component:

a) Phases: Scrum process consists mainly of three phases viz; Pre-Game, Development and Post-Game, which are described according to [20] and [22].

- Pre-Game: Pre-game consists of two sub-phases, the planning phase, which serves to define the system being developed. Defining the customer requirements and estimating the effort needed to implement each requirement. The list of requirements is always updated with new requirements. This phase ends with the definition of the project team, tools, and resources. The architecture phase consists of the high-level design of the system based on the requirements determined in the previous phase and the preparation of preliminary plans for the content of the releases.
- Development: The development phase or game phase is a black box where the system is developed in sprints that comprise the traditional software development phases. In addition, Scrum identifies environmental and technical variables. Then, aims to control them through various Scrum practices during the sprint, which is planned to take from one week to one month.
- Post-Game: The closing phase of the release after the customer has reached his goal, and he has no change or other requirements. Release preparation includes the integration, testing, and documentation of the final system.

b) Roles: Scrum defines the roles, described according to [28], which are Scrum Master, Product Owner, Team, and Stakeholders.

- Scrum Master: He is the team leader and at the same time a team member, he helps the team to understand the Scrum methodology, to create a high-value increment. He ensures that there are no obstacles that stop the progress of the product and that the team respects the work schedule. It helps the product owner to define and manage the product backlog. Then, facilitates the collaboration of stakeholders according to the demands or needs and to remove the barriers between them and the team [27].
- Product Owner: This is the most important role in this method. For the reason that it is the representative of the customer and responsible for defining the product vision and following its transition to the product backlog list. The latter is used by the product owner to check that the requirements are developed. The most significant skill that the product owner is supposed to have is written and oral communication [29].
- Team: Responsible for the project from planning to delivery of an increment. It is self-organized, works together, and takes account of the probability of change in requirements.
- Stakeholder (s): It is a person or a group of people or organizations that have a relationship with the project who are the clients [30].

c) Practices: It also defines seven practices divided into two categories, events, and artifacts to be applied in different phases to avoid chaos caused by the unpredictability and complexity. The practices, which are described according to [22], [27], and [31], are: Daily Meeting, Sprint Planning Meeting, Sprint Review Meeting, Effort Estimation, Sprint, Sprint Backlog, Product Backlog. Sprint has a Velocity based on the Sprint Backlog, which is produced from the Product Backlog. In addition, it consists of a set of User Stories that contain Elements and contain Tasks of different types.

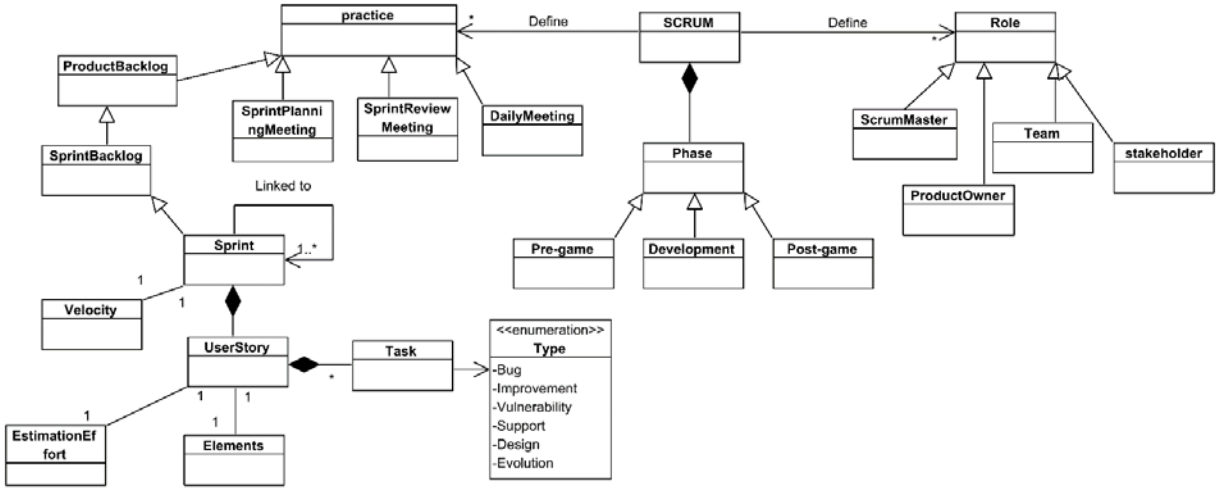

Fig. 6. Proposed Metamodel for Scrum Method.

Events category

- Daily Meetings: Scrum meetings are led by the Scrum Master. In addition to the Scrum team, management can also attend the meeting. The Scrum Team's Developers attend the Daily Scrum, which lasts 15 minutes. Developers are those who are actively working on Sprint Backlog items, such as the Product Owner or Scrum Master. Daily Scrums improve communication, identify barriers, stimulate quick decision-making, and thereby avoid the need for additional meetings.
- Sprint Planning Meeting: The Scrum Master organizes a Sprint Planning Meeting that is a two-section meeting. In the primary section of the meeting, customers, users, management, the Product Owner, and the Scrum Team determine the objectives and functionalities of the subsequent Sprint. The Scrum Master and the Scrum Team hold the second section of the meeting, which focuses on how the product increment is implemented in the course of the Sprint.
- Sprint Review Meeting: The Sprint Review's goal is to examine the Sprint's results and make recommendations for future changes. In an informal meeting, the Scrum Team and Scrum Master present the outcomes of their work to management, customers, users, and the Product Owner. The participants evaluate the product increment and make decisions about the next steps. The review meeting may result in the addition of new Backlog items and possibly a change in the system's direction.

Artifact's category

- Sprint: The procedure of adjusting to changing environmental variables is known as sprint (requirements, time, resources, knowledge, technology, etc.). In a Sprint, where ideas are becoming valuable, the Scrum Team arranges itself to generate a new executable product increment over the course of thirty calendar days. Sprint Planning Meetings, Sprint Backlog, and Daily Scrum meetings are the team's working tools. Each Sprint may be in concept of as a small project. Burndowns, burn-ups, and cumulative flows are all techniques for forecasting progress. While they have proven to be valuable, they do not take the place of empirical evidence. What's going to occur in complicated environments is unknown. Only what has already occurred can be used to make decisions in the future. If the Sprint Goal is no longer relevant, the Sprint may be cancelled. Only the Product Owner has the right to terminate the Sprint. During the Sprint, no modifications are made that might endanger the Sprint Goal; quality is maintained; the Product Backlog is adjusted as required; and, as additional information becomes available, with the Product Owner, the Scope can be clarified and renegotiated.
- Sprint Backlog: A Sprint Backlog is created at the start of each Sprint. The Sprint Backlog is made up of the Sprint Goal (why), the Product Backlog items chosen for the Sprint (what), and an actionable plan for producing the Increment (how). The Sprint Backlog is a strategy created by and for developers. The items are chosen in the Sprint Planning meeting by the Scrum Team, in collaboration with the Scrum Master and the Product Owner. Which are based on prioritized items and Sprint Goals. The Sprint Backlog, in contrast to the Product Backlog, is stable until the Sprint is finished. A new iteration of the system is deployed once all the items in the Sprint Backlog have been accomplished.
- Product Backlog: Based on existing knowledge, the Product Backlog describes everything that is required in the final product. As a result, the Product Backlog describes the project's tasks. Features, functionality, bug fixes, issues, requested improvements, and technology upgrades are all examples of backlog items. The list also includes issues that must be resolved before other Backlog items may be completed. Product Backlog items can be created by a variety of actors, including the customer, project team, marketing and sales, management, and customer support. The Product Owner oversees keeping the Product Backlog updated.
- Effort Estimation: The Product Owner and the Scrum Team oversee effort estimation, which is an iterative procedure. The Product Owner collaborates with others as the backlog is generated to predict how long it will take to develop. He or she consults with developers, technical writers, quality assurance staff, and others who are familiar with the product and technology in order to arrive at the estimate. Because the product owner and the team are experienced in estimating, the estimate will be accurate. The Product Owner develops estimates for every item, beginning with the highest priority backlog.

D. Ignite Methodology

1) Definition: Originally from industry. The founders of this methodology are based on the analysis of manufacturing and industry, connected vehicles, Smart Energy and Smart Cities. Through collecting best practices of IoT strategy management and project execution. It is open source and covers all aspects of IoT development. It addresses various IoT stakeholders, namely product managers, project managers, and solution architects [9] [32] [33] [34] [35].

2) Ignite metamodel: Fig. 7 shows the metamodel of the Ignite method. This metamodel is based on the transformation of the method's components into metaclasses and the relationships between them into meta-associations.

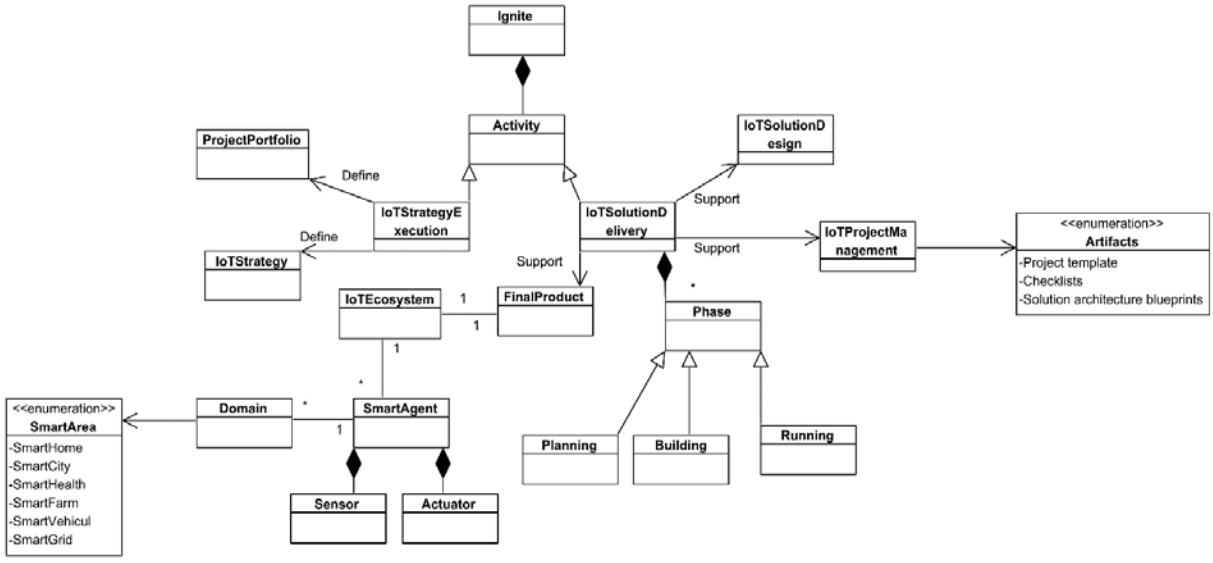

Fig. 7. Proposed Metamodel for Scrum Method.

3) Component: All components of this methodology are described according to [9].

a) Phases: Two activities make up the Ignite process (as shown in Fig. 8). The first is to define the strategy and prepare the organization to adopt IoT, then create and manage the portfolio of IoT projects to support the IoT Strategy. This activity is called IoT Strategy Execution. The second activity, called IoT Solution Delivery, is used to execute the famous three phases such as Plan, Build and Run to deliver a solution.

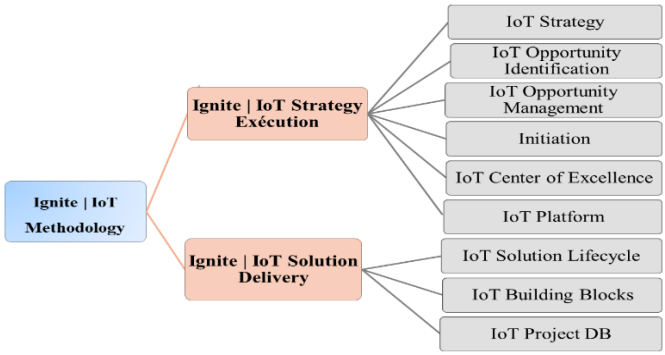

Fig. 8. Ignite | IoT Methodology Activities.

Ignite | IoT Strategy Execution

IoT Strategy, IoT Opportunity Identification, IoT Opportunity Management, Initiation, IoT Center of Excellence, and IoT Platform are the six domains of the Ignite | IoT Strategy Execution framework.

- IoT Strategy: The extent and speed with which a corporation should migrate toward IoT should be reflected in its IoT strategy. The Internet of Things strategy must have a vision, goals, and guiding principles. It should also provide a high-level overview of how IoT-related business areas should create strategic alliances and partner ecosystems. Finally, it must oversee the portfolio of IoT prospects and projects, as well as budgeting and IoT roadmap management.
- IoT Opportunity Identification: The generation of IoT solution innovation ideas, can take two forms: an open process that taps into the creativity of employees, customers, and developers, or a more structured approach in which ideas are derived from a specific context, such as the company's value chain. Ideas that show the most promise should be fleshed out further, perhaps using idea refinement templates.
- IoT Opportunity Management: The most promising ideas are then improved as part of the IoT Opportunity Management process after passing the first quality gate. In order to examine the utility and the business case, a more complete business model must be created. The following Impact & Risk Assessment step guarantees that all conceivable results of the business model are taken into account.
- Initiation: An IoT opportunity can be moved to the Initiation stage once it has been authorized. Management must decide how to best set up the effort at this stage, e.g., as a dedicated internal project, a spin-off, or even an M&A project. These activities connect to the Ignite | IoT Solution Delivery for internal initiatives.
- IoT Center of Excellence: An IoT Center of Excellence (CoE) can assist new projects in gaining traction faster. For instance, by offering IoT consulting and alter management support, IoT maturity evaluations can assist a company in determining where it stands in terms of IoT adoption.
- IoT Platform: Large enterprises may find it beneficial to provide a shared IoT Platform that many projects can use to create their solutions. An IoT application platform, connectivity solutions, and technical and functional standards are typically included.

Process

- Generate Idea: In a large company, there are usually two approaches to produce ideas: open idea generation (green field technique) or a more structured idea generation approach. The latter approach is generally carried out in a top-down manner. It typically entails a thorough market investigation by an internal strategy team or an external consulting agency. Open idea creating is more likely to produce disruptive ideas. As a result, companies should have numerous channels in place to collect these ideas, including employees, consumers, and even developers.
- Refine Idea: Many good ideas aren't particularly attractive when they're initially formed. Before they will really persuade potential stakeholders, they need care in order to grow and mature. Thankfully, there is no shortage of ideation methodologies that promote idea refining, such as the St. Gallen Business Model Navigator™ and the Innovation Project Canvas. The detailed idea sketch, which is the product of the idea-refinement phase, can be used for presentations at the next quality gate level. It can be used to develop the business model after it has been approved.
- Business Model Development: it consists of four phases (shown in the Fig. 9) viz., Strategic embedding (it lays the foundations of the business model and ensures consistency with the IoT strategy or the company's IoT vision. The implementation of "future proofing" should indicate how the business model intends to address future challenges.); Value proposition (To increase the attractiveness of the offer for customers, the proven approach of segmentation of target groups, formulation of the value offer and definition of customer channels can be used.); Customer journey (The explanation of the end-to-end solution from the customer's perspective serves in highlighting the characteristics of the proposal that the consumer finds important. Another benefit of establishing the customer journey is that it guarantees that all relevant consumer channels have been identified.); Value added (The value added can be demonstrated once the solution has been defined. The capabilities of the parties are the network's constituent elements: they are a combination of technology, resources, and know-how that they can bring in to assist the solution.); Business case (There are numerous techniques and templates for calculating business cases, but the recommendation is to use the same one for all IoT activities, as this makes comparing business models easier.); Strategic impact and subsequent business models (The house's chimneys represent two non-monetary effects of a business model that must be considered alongside the business case. The second chimney, “subsequent business models” is extremely specific to the IoT: it is very usual for teams to come up with exciting new ideas on how to utilize the data. Additionally, build new services while designing the business model and gathering all the associated data with connected devices.).

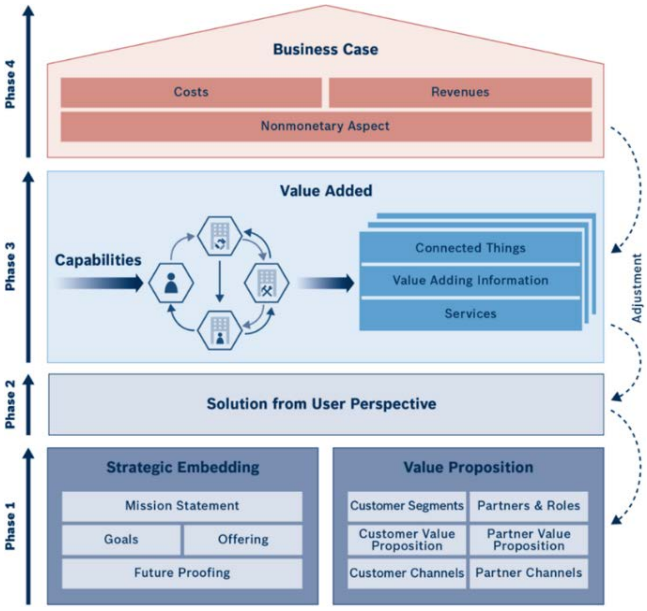

Fig. 9. Builder of IoT Business Model [9].

- Impact And Risk Analysis: Business models, and business cases in particular, deal with future value flows, so they are subject to uncertainty. To promote transparency for decision-makers and to generate the tasks necessary to resolve these uncertainties, it is critical to underline the degree of uncertainty within the business model. Various future scenarios are suggested that support the provided parameters. Trends or cause-and-effect relationships can be used to accomplish this. In the context of the strategy, it is crucial to check those aspects of the business model that create effect and value.

2 Ignite | IoT Solution Delivery

- By providing project templates, checklists, and solution architectural blueprints, the mission is to make IoT best practice applicable in the form of a technology-independent, reusable, open-source methodology that supports IoT solution design as well as the implementation and management of IoT projects. The following is a breakdown of Ignite | IoT Solution Delivery.
- The IoT Solution Lifecycle focuses on the planning, development, and execution of IoT solutions encloses the following elements. Initial Project Design: The elements established as part of the generic IoT Building Blocks, such as project self-assessment employing IoT Project Dimensions, solution architecture employing IoT Architecture Blueprints, and technology selection employing IoT Technology Profiles, are all used in this design blueprint. Project workstreams and project organization: The top-level organization and workstreams generally found in an IoT solution project are defined in this blueprint. There is a checklist for every workstream, as well as a list of common dependencies between them.

- IoT Building Blocks includes reusable artifacts such as IoT Project Dimensions, IoT Architecture Blueprints, and IoT Technology Profiles from successful projects.
- IoT Project DB is a repository of reference projects that have been analyzed in order to identify best practices for the IoT Solution Lifecycle and Building Blocks.

Process

- IoT Project Initiation: A requirements study, which is more in-depth than the analysis performed during the business model building phase, is a significant factor in the Ignite | IoT Project Initiation phase. A tiny team of subject matter specialists is generally in charge of project initiation. A business analyst with strong domain expertise and a clear vision for the solution's functional features should also be part of the team.
- Initial Solution Design: Initial Solution Design consists of a collection of key artifacts that include analysis, projections, and planning, as well as functional and technical design artifacts. Even though they might be developed concurrently, it is generally more practical to group them, as shown the Fig. 10. Analysis, Projections, Planning: It was created to aid with analysis, projections, and planning. They contain: Problem Statement, Stakeholder Analysis; Site Survey; Solution Sketch; Project Dimensions; Quantity Structure; Milestone Plan.

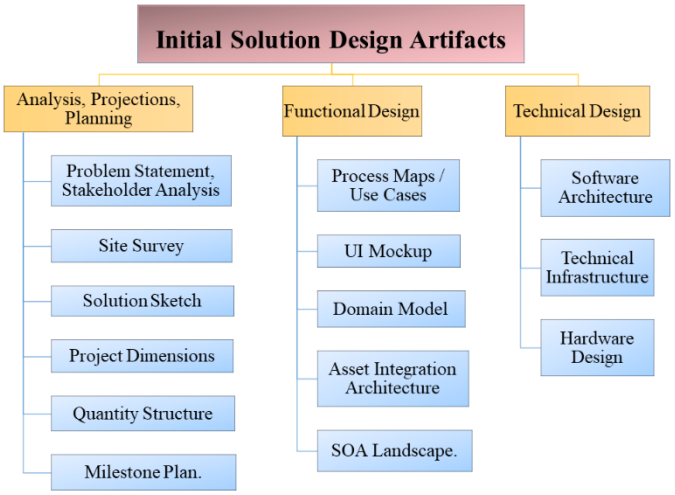

Fig. 10. Initial Solution Design Artifacts.

Functional Design contains: Process Maps / Use Cases; UI Mockup; Domain Model; Asset Integration Architecture; SOA Landscape. Technical Design contains: Software Architecture; Technical Infrastructure; Hardware Design.

- Plan: After the funding decision on Ignite | IoT Strategy Execution, this phase begins. A small, but devoted team usually creates an initial project plan, which includes a solution definition, based on the ideas and criteria from the business planning phase. This could be an RFP (Request for Proposal) document or the initial list of high-level epics that will need to be broken down into more detailed user stories later in the Build phase. The initial team will often oversee sourcing (internally or externally) the larger team that will eventually create the solution during the planning phase.
- Build: A larger team or teams often execute the build phase. Keep in mind that, particularly in the IoT, the work is frequently with various, multidisciplinary teams. It's worth noting that, due to the often highly dynamic nature of IoT projects, planning continues during the build phase. Each sprint will be meticulously planned, especially if an Agile approach is used. The higher-level papers developed during the planning phase will frequently need to be updated to reflect new or changing needs, as well as lessons gained from prior sprints.
- Run: The project team is typically disbanded, and the solution is handed over to a line organization around the time of the IoT solution's Start of Production (SOP). This line organization will set up an integrated DevOps organization in modern enterprises, which will deal with both the solution's continuous development and operations. DevOps for IoT can be more challenging than typical DevOps due to the potentially extremely distributed nature of IoT systems.

V. Discussion and Conclusion

The previous section presents the Scrum and XP agile methods and the dedicated IoT project method Ignite. Moreover, it presents the metamodel of each one with their components that have been translated into metaclasses and meta-associations.

The Scrum and XP methods are based on almost the same principles, with a very clear definition of roles, unlike the Ignite method.

Furthermore, another difference between Ignite and the Scrum and XP methods is that Ignite divides the project realization process into two sub-processes called Strategy Execution and Solution Delivery activity, whereas Scrum and XP have an ecosystem whose components are chained.

To sum up, the paper presents the standardization of the Scrum, XP and Ignite methods as metamodels based on their components and the fundamental MDA principles. These metamodels are the beginning of the forthcoming contribution concerning a Framework used for Industry 4.0.

Towards a Computational Model to Thematic Typology of Literary Texts: A Concept Mining Approach

Abdulfattah Omar
Department of English, College of Science & Humanities
Prince Sattam Bin Abdulaziz University, Al-Kharj 11942, Saudi Arabia
Department of English, Faculty of Arts, Port Said University, Egypt

***Abstract*—In recent years, computational linguistic methods have been widely used in different literary studies where they have been proved useful in breaking into the mainstream of literary critical scholarship as well as in addressing different inherent challenges that were long associated with literary studies. Such computational approaches have revolutionized literary studies through their potentials in dealing with large datasets. They have bridged the gap between literary studies and computational and digital applications through the integration of these applications including most notably data mining in reconsidering the way literary texts are analyzed and processed. As thus, this study seeks to use the potentials of computational linguistic methods in proposing a computational model that can be usefully used in the thematic typologies of literary texts. The study adopts concept mining methods using semantic annotators for generating a thematic typology of the literary texts and exploring their thematic interrelationships through the arrangement of texts by topic. The study takes the prose fiction texts of Thomas Hardy as an example. Findings indicated that concept mining was usefully used in extracting the distinctive concepts and revealing the thematic patterns within the selected texts. These thematic patterns would be best described in these categories: class conflict, Wessex, religion, female suffering, and social realities. It can be finally concluded that computational approaches as well as scientific and empirical methodologies are useful adjuncts to literary criticism. Nevertheless, conventional literary criticism and human reasoning are also crucial and irreplaceable by computer-assisted systems.**

Keywords*—Computational linguistics; concept mining; data mining; empirical methodologies; semantic annotators; text clustering; typology

I. Introduction

Despite the wide applications of computational and statistical approaches in different disciplines in humanities, many critics still argue against the usefulness of these approaches in literary studies. So far, most literary critics reject the use of computer technology and statistical and computational methodologies in the analysis and interpretation of literary texts [1]. In light of this argument, this study seeks to evaluate the reliability of computational and statistical approaches to literary studies, and more specifically to the thematic typologies of literary texts. In other words, it seeks to see whether computational and statistical approaches, which have long been rejected by many literary critics, can be usefully used in generating typologies that best reveal the thematic features within these texts.

The study takes Thomas Hardy's prose fiction production as an example. The great reputation Hardy received as a novelist and the thematic richness of his texts have always made his novels and short narratives a target for critics and commentators [2]. From the time Hardy published Wessex Edition, where he provided a broad classification of his works, a critical response has focused on the questions of thematic classification of his work. Critics have adopted different approaches for investigating Hardy's thematic treatment of his texts [3-5]. Nevertheless, questions are often raised regarding the reliability of these classifications. In this regard, Hardy's prose fiction represents a good opportunity to test the reliability of computational and statistical methods in the thematic typology applications to literary texts.

To carry out the objectives of the study, concept mining is used. The rationale is that concept mining methods have been usefully used in text clustering and text classification applications. They have been effectively used for generating reliable clustering and classifications that explored the underlying meanings and themes within texts. Unlike conventional text clustering approaches including vector space clustering (VSC), concept mining focuses on identifying the patterns that are associated with concepts in similar texts [6, 7]. The underlying premise is that concept mining can be usefully used for identifying and recognizing the thematic patterns which can thus be used in developing a thematic typology that expresses the thematic interrelationships within literary texts.

The remainder of this article is organized as follows. Section Two surveys the literature on the thematic typology of literary texts. Section Three proposes the research questions. Section Four describes the methodological framework of the study. Section Five describes the data collection and processing procedures. Section Six reports the results of the study. Section Seven is a discussion and interpretation of the results. Section Eight is conclusion.

II. Literature Review

Different critical approaches have been used in the thematic typology studies of literary texts. These have usually been traditionally based on qualitative methods that tended to focus on identifying and revealing the underlying meanings that are

conveyed within the texts [8]. In this regard, thematic classifications have been carried out according to different concepts including purpose, content, and period [9]. Despite the popularity of the concepts of content and purpose, typologies based on these two concepts are always associated with subjectivity being largely based on the intuitive readings and making general observations based on such readings. One major problem with the adoption of these concepts in the identification of themes is that they are based on personal thoughts and emotional reactions, and thus they are subjective.

The period concept, on the other hand, is one of the most dominating methods in the thematic classification of literary texts. The underlying premise of this concept is that every period has its characteristic thematic features that can be usefully used in grouping texts through time. Taking English literature as an example, it is usually classified under the headings the Anglo-Saxon Literature, the Medieval Literature, the Elizabethan Literature, the Neoclassical literature, the Romantic literature, the Victorian literature, the Modernist literature, and the Postmodern literature.

Following this tradition, different thematic typologies have been developed in the critical study of Thomas Hardy's prose fiction. According to Plietzsch [10], the first person to suggest a general classification of Hardy's novels is thought to be Edmund Gosse in 1890. Gosse's classification included only ten novels, which were all that Hardy had written so far [11]. In this regard, Gosse's study misses many of the themes Hardy was to develop in subsequent work. With its limitation, Gosse's classification was nevertheless a step forward in generating a broad classification of Hardy's works.

Following Gosse's attempt, Thomas Hardy provided a broad classification of his prose and verse works. In the Wessex Edition, Hardy [12] classified his novels and short stories into three categories: (1) Novels of Character and Environment, (2) Romances and Fantasies, and (3) Novels of Ingenuity. One obvious observation about Hardy's classification is that there is no clear-cut relationship between the thematic accounts Hardy himself suggested for this classification and the way the texts were finally classified. Plietzsch [13] argues that it seems that Hardy ranked his texts in this particular order as a result of the responses from the public and literary critics which he had received.

The implication for the present study is that the reliability of such a classification is thus questionable. First, Hardy did not provide definite criteria for his classification. Second, some of the texts that used to be regarded as minor by the public and critics in Hardy time are now regarded as major works [14, 15]. Furthermore, the classification does not include all of Hardy' works. A Changed Man and other Stories, for instance, was published one year after the Wessex Edition. In view of this, it excludes some important works that represent the thematic development of Hardy's career as a novelist.

In response to Hardy's work, Abercrombie [16] classified the novels and short stories based on their artistic significance into four categories: (1) Minor Novels, (2) Annexes, (3) Dramatic Form, and (4) Epic Form. In spite of its success in drawing connections between texts, Abercrombie's classification, however, raises many questions concerning replicability and objectivity, since his criteria are subjective and undefined.

Harvey [14] suggested an alternative typology where he divided Hardy's prose works into three main categories: major novels, lesser novels, and short stories. The main criterion of this classification is subject matter. Harvey considered only the social and realistic novels to be major novels. Other novels were classified under the category of minor novels. Once again, the classification lacked any objective criteria [15, 17].

Another approach to the typology of Hardy's prose fiction texts can be traced in grouping Hardy's novels and short stories based on literary criticism perspectives. The underlying principle is that critics have come to classify Hardy's works under different headings including tragedy, women, religion and philosophy, Wessex and regionalism, nature and landscape, social change, and pastoral. One major problem with these critical discussions is that their perception of Hardy's work is very narrow in the sense that they are almost restricted to what Hardy calls 'Novels of Character and Environment'. Furthermore, they ignore important thematic concepts within the texts as they usually focus on just one aspect of his writings. Equally important, such reviews are always based on some biographical elements or historical accounts which again raise questions regarding the objectivity and reliability of such typologies and classifications.

In the face of the problems associated with the conventional classifications of Hardy's prose works, recent studies built on the advances in the application of computational data processing for analyzing and classifying novels and short stories in a way that is both objective and replicable [18, 19]. Motivation has been to understand Thomas Hardy better as a literary artist in an objective, replicable, therefore scientific way. In a recent study, Omar [20] employed centroid-based lexical clustering methods for identifying the thematic structures in Hardy's prose fiction. The novels and short stories were clustered into four classes, where each class or group of texts share the same thematic features based on the lexical profiles of each class.

Despite the reasonable success of such classification in drawing a thematic mapping of Hardy's novels and short stories based on objective grounds, questions regarding the use of vector space clustering (VSC) in exploring the salient thematic features of the texts are often raised. VSC is based on what is known as bag of words techniques where context is not considered at all. In this regard, VSC is not capable of accounting for all the linguistic and contextual features of texts. In the face of these limitations, this study proposes the use of concept mining methods for generating a thematic typology that best captures the underlying meanings, concepts, and thematic patterns of literary texts taking the novels and short stories of Thomas Hardy as an example.

III. Research Questions

Despite the extensive literature on the thematic typology of literary texts including Thomas Hardy's prose fiction writings, almost all of the relevant work is theoretically driven. That is, classification criteria are selected by the critic based on some critical theory or framework supported by personal knowledge

and evaluation of the texts. Moreover, many existing accounts follow the stereotypical classifications of what might be called Hardy Critical Industry. In other words, many of Hardy's commentators are willing to agree with conventional, well-known evaluations of Hardy even though such evaluations conflict with their critical presuppositions. Two examples of this are given. First, many commentators have favored the idea of classifying Hardy's works into major and minor novels in relation to subject-matter, and many studies use such dichotomy without giving reasons for its adoption. Second, many thematic reviews of Hardy use the term 'Wessex novels' in reference to nine or ten of Hardy's novels without explaining why these nine or ten texts should constitute variants of the same theme apart from the fact that they are about Wessex [21].

It can also be claimed that many of the classifications of Hardy's work followed Hardy's own classification of his works. The problem is that Hardy did not set clearly defined criteria for his classification. Furthermore, some classifications based on philological methods are greatly biased. In the face of this problem, this study seeks to answer the following research questions:

- Can computational linguistic methods be usefully used in addressing the limitations of the conventional approaches of literary criticism regarding thematic typologies of literary texts?
- How can computational models in general and concept mining methods in particular be used in developing a thematic typology of literary texts with reference to the prose fiction writings of Thomas Hardy?
- What is the future of computational approaches and scientific and empirical methodologies in literary studies?

IV. Method

In different natural language processing (NLP) applications including text clustering and text classification, concept mining is a process that has been used to provide an automated categorization of documents based on their content [22, 23]. It is a workflow that is used to discover implicit and explicit relationships, useful associations and groupings in a set of documents or data collection with the purpose of detecting similar documents in a large corpora and classifying them by topic [24, 25]. It can provide thus powerful insights into the meaning, provenance, and similarity of documents [26-28]. The assumption is that each word in a given document relates to several possible concepts which make it possible to cluster documents based on their content. The underlying principle of concept mining is the conversion of words into concepts. This is done in two subsequent steps. First, documents are reduced into a sequence of words that describes the content. Second, these words are mapped into concepts [29].

In this way, given that we have a number of documents on generative grammar; concept mining is possible by identifying relationships and generating facts based on the data within collection and the dimensions of the subject. These can be something like Chomsky and generative grammar, theoretical linguistics and generative grammar, Phrase Structure Rules (PSR) and Generative grammar, deep and surface structures in generative grammar, etc. Documents can also be classified by topic as WH-movement, linguistic competence, etc.

In this way, concept mining is based on clustering or grouping semantically-similar texts together. Text clustering is the process of automatically grouping natural language texts according to an analysis of their information/semantic content. In other words, clustering is a task of dividing given data into defined set of clusters and it is the task of classification to structure these clusters and sort them into categories according to a group structure known in advance [30, 31]. In concept mining processes, text clustering starts by discovering and finding groups that have similar content, and then organizing our perceptions of these groups into categories. In other words, clustering places documents into natural classes and generating taxonomies that best describe the patterns within the datasets [32].

V. Data Collection Procedures

For generalizability purposes, the study is based on all the novels and collections of short stories written by Thomas Hardy. Three sources were used for data collection. These are shown as follows.

- Chadwyck-Healey Literature Collections is a commercial product with authoritative full-text databases that offers coverage of English literary works from 1477 to the present.
- The Gutenberg Project is the oldest producer of free e-books on the Internet with a large volume of collections produced by thousands of volunteers. The project was founded in 1971 by Michael Hart.
- The Thomas Hardy Short Story Page (http://darlynthomas.com/hardyshortstories.htm-) includes all collection of short stories and the individual, excluded and collaborative stories written by Thomas Hardy.

Hardy has 14 published novels. These are listed below.

1) Desperate Remedies
2) Under the Greenwood Tree
3) A Pair of Blue Eyes
4) Far from the Madding Crowd
5) The Hand of Ethelberta
6) The Return of the Native
7) The Trumpet-Major
8) A Laodicean
9) Two on a Tower
10) The Mayor of Casterbridge
11) The Woodlanders
12) Tess of the D'Urbervilles
13) Jude the Obscure
14) The Well-Beloved

In his life time, Hardy also published four collections of short stories. These are A Group of Noble Dames [33], Life's Little Ironies [34], Wessex Tales [35] and A Changed Man and

other stories [36]. These account for "thirty-seven stories in all [37]. For the first three collections, texts were abstracted from the Wessex Edition [12]. A Changed Man and other stories was published one year after the publication of the Wessex Edition. So it was not included in that edition. The data was abstracted from Macmillan & Co 1913 edition which includes as well the novella The Romantic Adventures of the Milkmaid.

A. Wessex Tales

The short stories used in this study are the contents of the Wessex Tales collection of the 1912 *Wessex Edition*. These are shown as follows.

The Three Strangers
A Tradition of Eighteen Hundred and Four
The Distracted Preacher
The Withered Arm
Fellow-Townsmen
Interlopers at the Knap

B. Life's Little Ironies

The stories in this collection had been written at different periods but were assembled in 1893 for publication under the title given. In 1912, Hardy reassembled the stories for the Wessex Edition as indicated below. The texts used for the data of the study are the ones in the Wessex Edition. The stories in this collection are listed below.

An Imaginative Woman
For Conscience's Sake
The Fiddler of the Reels
To Please His Wife
On the Western Circuit
A Few Crusted Characters
A Tragedy of Two Ambitions
The Son's Veto

C. A Group of Noble Dames

In his preface to *A Group of Noble Dames*, Hardy [38] indicates that the tales were first published in periodicals six or seven years before being collected and published in 1891. Hardy published the tales once again in the same form in which they appeared in the 1891 edition for Wessex Edition in 1912. The stories in this collection are shown below.

The First Countess of Wessex
Barbara of the House of Grebe
The Marchioness of Stonehenge
The Lady Icenway
The Duchess of Hamptonshire
Anna, Lady Baxby
Lady Mottisfont
Squire Petrick's Lady
The Honourable Laura
The Lady Penelope

D. A Changed Man and other Stories

Although the tales in this collection represent an important stage in Hardy's development, they were not collected in one volume until 1913. Interestingly, Hardy used the expression minor novels instead of short stories. This may suggest that the short story was not a fully-fledged literary genre yet. Stories in this collection are shown below.

A Changed Man
Alicia's Diary
A Tryst at an Ancient Earthwork
A Committee-Man of 'The Terror
The Waiting Supper
The Grave by the Handpost
What the Shepherd Saw
Master John Horseleigh, Knight
A Mere Interlude
The Duke's Reappearance
Enter a Dragoon
The Romantic Adventures of a Milkmaid

E. Excluded and Collaborative Stories

These are the stories which were not included in the collected volumes published during Hardy's life. They were collected and edited by Pamela Dalziel [39] in Thomas Hardy: The Excluded and Collaborative Stories. Dalziel argues that although the stories occupy a significant position in the professional career of Hardy as a novelist, they have not received due critical treatment from critics and biographers. She also stresses that these stories are not thematically coherent: "Each story is an individual work, meriting treatment as such, and its unique conditions of composition and publication (or non-publication) have been carefully considered, in so far as they are now recoverable, when making editorial decisions" [39]. In making these stories available in one volume, Dalziel addresses some limitations in Hardy scholarship.

F. A List of Hardy's Excluded and Collaborative Stories

This collection consists of 10 stories including both excluded and collaborative stories of Hardy. The Spectre of the Real is the only story acknowledged by Hardy to be a collaborative tale [39]. It was written in collaboration with Florence Henniker. Blue Jimmy: the Horse Stealer and The Unconquerable were written in collaboration with his wife Florence Dugdale-Hardy. However, Hardy never admitted Florence's role in the two stories [39]. The texts in this collection are listed below.

How I Built Myself a House
The Thieves Who Couldn't Help Sneezing
The Doctor's Legend
Our Exploits at West Poley
Destiny and a Blue Cloak
Old Mrs. Chundle
The Spectre of the Real
The Unconquerable
An Indiscretion in the Life of an Heiress
Blue Jimmy: The Horse Stealer

G. Unpublished Work

The Poor Man and the Lady is Hardy's first novel. He sent the manuscript of the novel to Macmillan who refused to publish it on the grounds that the book creates a world which is entirely dark. Accordingly, Hardy took it to Chapman & Hall where George Meredith recommended him not to publish it. Meredith thought that the text was socialist, injudiciously

provocative, and full of indiscriminate satire. As a result, Hardy gave up the idea of publishing it and it is commonly said that he burned it [40]. Nevertheless, many critics often have argued that the novel may have been partly drawn on for the short story An Indiscretion in the Life of an Heiress [41, 42]. However, Hardy always stressed that the short story is different from the novel [43]. The text of this work is based on Weber's edition of Hardy' lost novel. Weber [44] claimed that there was an earlier record for the novel Hardy destroyed. He realized that the novel deserves a critical attention; therefore, he revived it. He gathered information from six sources together which equipped him, as he claims, with a detailed knowledge of The Poor Man and the Lady and used it for the synopsis of the novel he produced.

A corpus was thus built from the electronic texts of the novels and short stories. Codes were used in reference to the texts as shown in Table I.

TABLE I. THE CORPUS

Code	Title
Hardy01	Desperate Remedies
Hardy02	Under the Greenwood Tree
Hardy03	A Pair of Blue Eyes
Hardy04	Far from the Madding Crowd
Hardy05	The Hand of Ethelberta
Hardy06	The Return of the Native
Hardy07	The Trumpet-Major
Hardy08	A Laodicean
Hardy09	Two on a Tower
Hardy10	The Mayor of Casterbridge
Hardy11	The Woodlanders
Hardy12	Tess of the D'Urbervilles
Hardy13	Jude the Obscure
Hardy14	The Well-Beloved
Hardy15	The Poor Man and the Lady
Hardy16	Wessex Tales
Hardy17	Life's Little Ironies
Hardy18	A Group of Noble Dames
Hardy19	A Changed Man and other Stories
Hardy20	Excluded and Collaborative Stories

It was decided to consider each of the collection of short stories as a single document. Short stories were not considered as separate documents. The rationale is that concept mining is more effective with long documents. In this regard, it was thought that concept mining would work better with the collections of short stories than individual stories.

VI. DATA ANALYSIS

For the extraction of the concepts, concept-based text representation was used. The documents were converted into clauses or what is referred to as 'bag of concepts'. Documents were represented as strings of concepts, where each document was represented by a given number of vectors. For this purpose, the study adopts the extraction model developed by Kim, et al. [45] shown in Fig. 1.

Given the high dimensionality of the corpus, it becomes impossible for any concept extraction or mining system to deal with these huge datasets effectively. In concept extraction applications, just like other clustering applications, high dimensionality is a serious problem that has adverse impacts on the reliability of the clustering performance [46]. With high dimensionality data in the clustering applications to literary texts, semantic similarity or relatedness is not accurately computed [47].

In the face of this problem, dimensionality reduction is carried out. The purpose is to keep only the distinctive features or variables. Also, concept-frequency inverse document frequency (CF-IDF) is used. CF-IDF is a weighting scheme for discovering the key concepts within datasets that is based on term-frequency inverse document frequency (TF-IDF) that tends to rank the concepts based on their frequency in relation to document frequency [48-50].

As a final step, semantic similarity between the texts is computed. Thus is a process whereby metrics are used for weighting or ranking similar concepts based on a concept taxonomy [51]. Semantically similar concepts can be thus grouped or classified together as shown in Fig. 2.

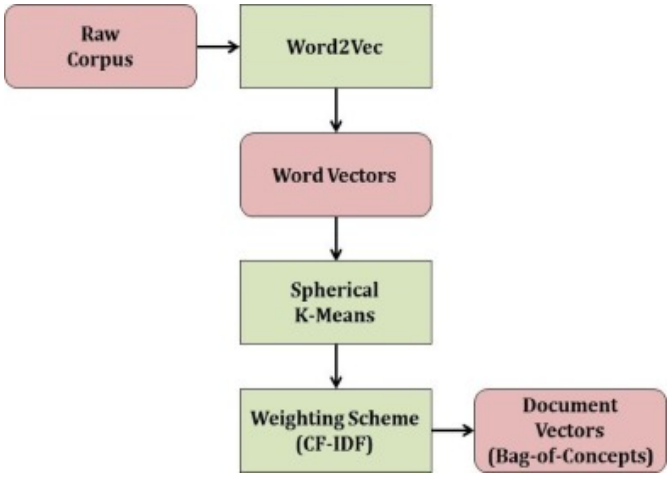

Fig. 1. Bag of Concepts Model Developed by Kim, et al. [45].

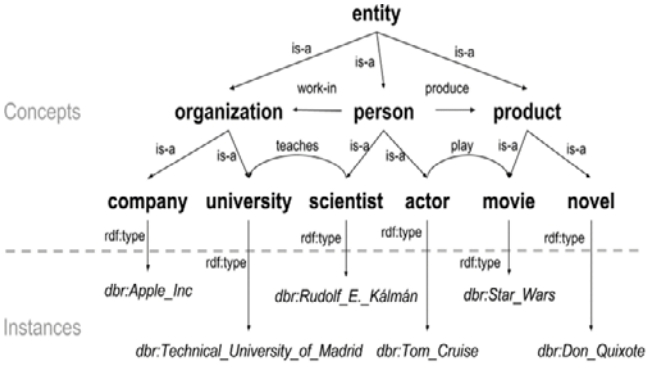

Fig. 2. An Example of Computing Semantic Similarity [51].

Most of metrics are designed for computing the semantic similarity with focus on the structure of the semantic network between concepts (e.g., path length and depth), or only on the Information Content (IC) of concepts [51]. These metrics, however, are not appropriate for the thematic typologies of literary texts which require identifying the conceptual similarities within texts. In so doing, the method developed by Zhu and Iglesias [51] for computing the conceptual similarity within texts is used for clustering and categorizing the selected texts based on their type concepts.

The selected texts are categorized based on their conceptual similarity into five categories. These are class conflict, Wessex, religion, female suffering, and social realities. First, the concept of class conflict is represented through romantic relations, mismatched marriages, elopement, and inequalities. Texts in this group included The Poor Man and the Lady, Life's Little Ironies, Far From the Madding Crowd, and A Group of Noble Dames. Second, the concept of Wessex is associated with a number of other concepts including rural life, local traditions, and industrialization. The concept of Wessex is extensively represented in Desperate Remedies, Under the Greenwood Tree, A Pair of Blue Eyes, The Hand of Ethelberta, The Trumpet Major, A Laodicean, and The Well-Beloved. Third, the concept of religion is represented through Christian beliefs and rituals, faith, morality, human existence, spiritual doubt, Evangelicalism and biblical references. Texts grouped under the concept of religion included Jude the Obscure, Tess of the D'Urbervilles, and Wessex Tales. Fourth, the concept of female suffering is represented through divorce, sexuality, struggle of women, oppression, and loss of chastity. Texts in this group included Two on a Tower, An Indiscretion in the Life of an Heiress, and A Changed Man and Other Tales. Finally, the concept of social realities is represented through poverty, social security, inequalities, and forces of oppression. Texts categorized under the heading of social realities included The Woodlanders. The Return of the Native and The Mayor of Casterbridge.

VII. Analysis and Discussions

Based on computing the conceptual similarity within the datasets, the texts were grouped into five main categories. These included class conflict, Wessex, religion, female suffering, and social realities. These are shown as follows.

A. Class Conflict

Class conflict is one of the central concepts in Hardy's novels and short stories including The Poor Man and the Lady and A Group of Noble Dames. In The Poor Man and the Lady, for instance, Hardy describes the ugly face of class conflict. This is represented in the love story between Miss Allamont and Will Strong. Miss Allamont is the squire's daughter and his heiress and Will Strong is a son of a peasant working on the estate of the Squire. In spite of the class gap between both, Miss Allamont takes a romantic interest in Will, and this is strongly rejected by her parents. Being rejected, Will moves to London where he achieves a striking success and becomes a public figure. However, he is still rejected by the family. This leads the two lovers to marry in secret and live away from her family. Soon her life is endangered and she dies. It was thus obvious that Hardy did not like class differences of his age and tended to represent the hypocrisy of the Victorian age in his books. Hardy describes the sufferings of the lower classes and the severe laws that threaten their lives in these books [52].

B. Wessex

Wessex is a dominating theme in many of Hardy's novels and short stories. In these texts, Hardy stressed the death of England's rural life along with its old customs and local traditions. Many critics consider Hardy as the greatest novelist in the form of regional fiction, and they think that the best example of regional fiction is Hardy's Wessex novels [53-55]. In the Wessex texts, Bullen [56] argues, Hardy succeeded at linking human behavior with the physical world. He adds that the works of Thomas Hardy to the historic place he was concerned with in his writings indicating that he was nostalgic for the past of England and that he distrusted modern civilization.

C. Religion

Religion is one of the central themes in Hardy's prose fiction. In his novels and short stories, the Bible and biblical names are obviously frequent. Influenced by controversies of the age, Hardy used what came to be known as the evolutionary narrative envisaged an alternative to a narrative which assumes that God created the world in its present state. Hardy expressed morality in a unique way. Morality is not based on traditional Christian beliefs. Rather, it is a social construct enforced by human intelligence rather than divine authority [57].

Many critics claim that any thematic discussion of Hardy's works has to consider religion as a crucial element in understanding and interpretation [58]. Hardy's texts cannot be fully understood without critical considerations of religious background and influence. According to Fergusson [59], the avoidance of such religious dimensions in thematic discussions results in interpretative gaps and loss of many thematic concepts in the literary texts.

D. Female Suffering/Tragedy

The texts included in this category reflect Hardy's preoccupation with the Victorian women and their sufferings. Hardy's women are destined to suffer. They are victims to the merciless conditions of the age. Women's suffering was deeply rooted in the hypocrisies of the Victorian society which was male dominated and obsessed with the idea of woman virginity. Many critics have advocated the idea that the texts of Hardy address the low position of women in the Victorian society and the strict laws that tended to deprive them of their independence. Morgan [60] argues that Hardy's texts reflect his sympathy towards women and his deep concern with their sufferings. Hardy introduces the sufferings of his women with a peculiar pathos and shows them as victims of male-dominated society. Likewise, in her book The Feminist Sensibility in the Novels of Thomas Hardy, Kaur [61] stresses that Hardy had sympathy for the women's cause and their sufferings. She stresses that Hardy is 'feministic', an artist with feminist sensibilities.

The results of the study agree with different feminist readings of Thomas Hardy that consider the writings of Hardy as a cry against the injustices done to the Victorian woman,

and an assertion her rights. The feminist investigations of Hardy's work often involve a discussion of sexuality and the sensual dimensions of the texts [60, 62, 63]. The main assumption of feminist readings of Hardy is that his texts reflect in one way or another the individual and social pressures the Victorian woman had to experience [61, 64-67]. The central concept in such reviews is that Hardy's works both depict and resist the male-centered culture and the oppression of the Victorian woman. At this point, much of the feminist reading of Hardy's prose fiction praises his progressive exploration, understanding, and support of women issues at a time of social crisis and change [66, 68].

E. Social Realities

In this class of novels and short stories, Thomas Hardy was concerned with depicting the contemporary social issues of his age. Levine [69] argues that that Hardy was a Victorian social critic since his writings depict the sufferings of England's working class and society's responsibility for their tragic fates. That is, Hardy's mind was preoccupied with improving conditions of society. He marks Hardy as a realistic writer who thought his role to express the joys and woes of the victims of merciless conditions of life. Likewise, Reid [70] argues that Hardy's works represent a cry against the excesses of modern civilization and injustices of modern societies.

It can be concluded that concept mining methods can be used for identifying the conceptual similarities within texts and generating reliable typologies of the novels and short stories of Thomas Hardy. Texts were successfully categorized based on their thematic concepts of class conflict, Wessex, religion, female suffering, and social realities. Although the thematic typology of Thomas Hardy based on the concept mining methods agrees in principle with the previous classifications based on fundamental philological approaches, the results reported here are testable, replicable, and thus reliable.

VIII. Conclusion

This study reviewed the literature regarding the thematic typologies of literary texts focusing on the thematic classification of Thomas Hardy's novels and short stories. It was obvious that the typologies of literary texts including those of Thomas Hardy have been traditionally based on philological methods with no consideration of empirical methodologies. With the development of computational approaches, quantitative and statistical methods have come into use. The majority of these typologies, however, are largely based on standard clustering methods or more specifically VSC theory. Despite the effectiveness of this methodology in generating classifications that are based on objective and replicable methods, underlying meanings and concepts were not fully explored. This is attributed to the absence of context in VSC applications which are largely based on 'bag of words' methods. In the face of these limitations, this study proposed a thematic typology based on concept mining methods. The findings indicated that concept mining was usefully used in generating a thematic typology of the novels and short stories of Thomas Hardy that revealed the thematic patterns of the texts. These thematic patterns would be best described in these categories: class conflict, Wessex, religion, female suffering, and social realities. Although the study was limited to the novels and short stories of Thomas Hardy, the results can be extended to other literary texts. It can be finally suggested that the computational and quantitative methods will be central components in the future of thematic typology research.

Acknowledgment

I take this opportunity to thank Prince Sattam Bin Abdulaziz University in Saudi Arabia alongside its Scientific Deanship, for all technical support it has unstintingly provided towards the fulfilment of the current research project.

AUTHORS' PROFILE

Abdulfattah Omar is an Associate Professor of English Language and Linguistics in the Department of English, College of Science & Humanities, Prince Sattam Bin Abdulaziz University (KSA). Also, he is a standing lecturer of English Language and Linguistics in the Department of English, Faculty of Arts, Port Said University, Egypt. Dr. Omar received his PhD degree in computational linguistics in 2010 from Newcastle University, UK. His research interests include computational linguistics, digital humanities, discourse analysis, and translation studies. ORCID: 0000-0002-3618-1750.

Educational Data Mining in Predicting Student Final Grades on Standardized Indonesia Data Pokok Pendidikan Data Set

Nathan Priyasadie, Sani Muhammad Isa
BINUS Graduate Program – Master of Computer Science
Bina Nusantara University, Jakarta
Indonesia, 11480

***Abstract*—Educational Data Mining has been implemented in predicting student final grade in Indonesia. It can be used to improve learning efficiency by paying more attention to students who are predicted to have low scores, but in practice it shows that each algorithm has a different performance depending on the attributes and data set used. This study uses Indonesian standardized students' data named Data Pokok Pendidikan to predict the grades of junior high school students. Several prediction techniques of K-Nearest Neighbor, Naive Bayes, Decision Tree and Support Vector Machine are compared with implementation of parameter optimization and feature selection on each algorithm. Based on accuracy, precision, recall and F1-Score shows that various algorithm performs differently based on the high school data set, but in general Decision Tree with parameter optimization and feature selection outperform other classification algorithm with peak F1-Score at 61.48% and the most significant attribute in are First Semester Natural Science and First Semester Social Science score on predicting student final score.**

Keywords*—Educational data mining; student performance; classification models; feature selection; parameter optimization

I. Introduction

Educational data mining is a rapidly growing multidisciplinary area of study devoted to studying and developing techniques for extracting useful information from enormous amounts of data generated in educational settings [1]. Because information technology has been significant in improving the area of education over the last decade, nearly every institution now maintains a student information system [1]. This information includes student demographic, parent information, scores etc. Applying data mining techniques to educational processes can be beneficial in identifying important trends, performance summaries, and insights, which will assist students in identifying areas for improvement. An institution's academic performance, life cycle management, course selection, retention rate measurement, and grant money management may all be considered [2].

Predicting student grades is one of educational mining's applications. Grades are critical components of education since they act as a barometer of a student's competency and performance within that institution. Predicting a student's final grade might also encourage a school to improve its teaching techniques and create a more pleasant learning environment [1]. By providing additional support to students who were previously projected to have lower grades, it is possible to enhance learning efficiency and the overall student grade [3]. Finally, a high score improves a student's chances of admission to a more prestigious higher education program.

Data from Organization for Economic Co-operation and Development (OECD) shows that Indonesian student ranked 72 out of 77 countries on Programme for International Student Assessment (PISA) report in 2018, and this rank tends to stagnate for the last 10-15 years. It can be concluded that education in Indonesia is still lagging compared to other countries.

The purpose of prediction is to determine the value of an unknown variable that correspond to the student [1]. In Indonesia there have been several researches that investigate student performance prediction using Naive Bayes (NB) [4], Decision Tree (DT) [5], Support Vector Machine (SVM) [6], K-Nearest Neighbor (K-NN) [7] and Regression Analysis [8] but there is no research that predicts student grades by using standardized national socio-demographic aspects of students such as the Data Pokok Pendidikan (DAPODIK).

The purpose of this study is to find the best algorithm to predict student final score using standardized DAPODIK data combined with student historical grade from three public junior high schools in Indonesia. With standardized data, schools throughout Indonesia can determine the best method to predict student grades in their schools. It can be used to improve learning efficiency by providing additional support to students who were previously projected to have lower grades. This study will compare four different algorithms, Naive Bayes, Decision Tree, K-Nearest Neighbors and Support Vector Machine with two data mining optimization methods, parameter optimization (PO) and feature selection (FS).

II. Related Work

Mengash [9] in their study found that using Artificial Neural Networks to predict student performance of 2039 Computer Science students at a Saudi Public University from 2016 to 2019 had an accuracy rate of greater than 79%, outperforming other classification techniques such as Decision Trees, Support Vector Machines, and Naive Bayes. It compares various pre-admission criteria (high school grade average, Scholastic Achievement Admission Test score, and General

Aptitude Test score). The findings indicate that the Scholastic Achievement Admission Test score is the most reliable predictor of future student performance of any pre-admission criteria. As a result, admissions systems should give this score a higher weight.

Rifat et al. [10] perform research to predict students' performance using transcript data from a Bangladeshi institution. The authors utilized six cutting-edge classification algorithms (Gradient Boosted Tree, Random Forest, Tree Ensemble, Decision Tree, Support Vector Machines and K-Nearest Neighbor) to forecast students' final grades. The findings indicated that the Random Forest algorithm performed the best, with an accuracy of 94.1%, followed by the Tree Ensemble method.

Yao et al. [11] perform research to determine the final score of secondary school students utilizing their personal data. The data set contains a variety of factors, including parent information, student health status, financial status and. attendance etc. With feature selection, the J48 algorithm achieved the highest accuracy of 84.39%, whereas without feature selection, the OneR algorithm achieved the highest accuracy of 84.19%.

Saa et al. [12] gathered data on student demographics, course teacher information, student general information, and prior performance from a private institution in the United Arab Emirates using various algorithms (Decision Tree, Random Forest, Gradient Boosted Trees, Deep Learning, Naive Bayes, Logistic Regression and Generalized Linear Model). With 75.52% accuracy, the Random Forest method topped the other classifiers, followed by the Logistic Regression technique.

Fairos et al. [13] conduct research to predict student performance using Universiti Technology Cawangan Kelantan and Universiti Teknologi MARA Cawangan Negeri Sembilan student data with total 631 transcript from 2013 to 2016, with various attributes such as gender, all the course enrolled by student including the course grade. They develop a model to predict student performance using K-Nearest Neighbor, Naive Bayes, Decision Tree and Logistic Regression Model. It shows that Naive Bayes outperform other classification algorithm with 89.26% accuracy.

Based on previous study shows that data set plays a big role in determining which algorithm is the best for predicting student final score. On this research a standardized data set is used to determine which algorithm is best to be applied throughout high school in Indonesia.

III. Methodology

This research uses The Cross Industry Standard Process for Data Mining (CRISP-DM) [14]. CRISP-DM is the most used methodology for developing Data Mining projects; it consists of six steps as visualized in Fig. 1. The first step is business understanding where the purpose is to provide context for the objectives and data. The second step is data understanding where its purpose is to determine what can be expected and accomplished from the data. The third step is data preparation where it involves cleaning, integrating, and formatting the data [15]. The fourth step is modelling where the Naive Bayes, Decision Tree, Support Vector Machine and K-Nearest Neighbor algorithm are used then optimized using feature selection and parameter optimization method to produce the best prediction model. The last step is Evaluation of each model based on accuracy, precision, recall and F1-Score.

A. Data Understanding

The first step is to collect data from various sources, locate and gather data for training and validate the algorithm, which may be spread over many spreadsheets, databases, or webpages. This research uses data from 3 high schools from the Jakarta class of 2020 and 2019. With a total of 926 student data each with 33 variables, in xlsx format with Table I attributes.

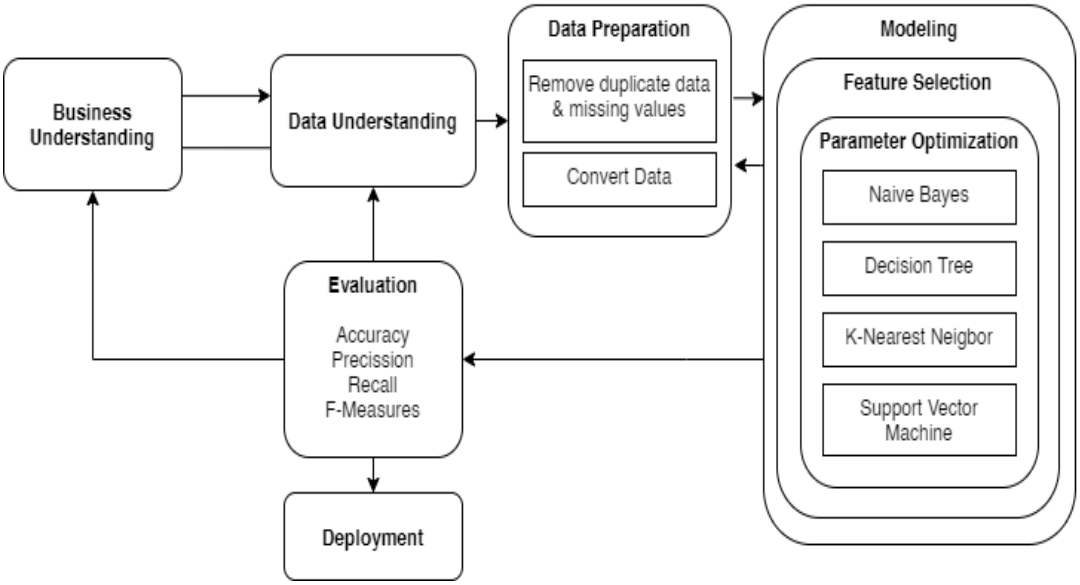

Fig. 1. CRISP-DM Methodology.

TABLE I. DATA ATTRIBUTES

Variables	***Description***	***Possible Value***
Final Grades	Average of Student's Final Grade	A, B, C, D, E, F, G
Entrance Grades	Student's Final Grade in Primary School	A, B, C, D, E, F, G
Gender	Student's Gender	Male, Female
Type of living	Student's living types	Living with Parents, Boarding House, Living with Guardian Others
Transportation Method	Student's Transportation Method to School	Car, Motorcycle, Bicycle, Public Transportation, Taxibike, On Foot, Others
Father's Education	Father's latest Education	None, Primary School, Junior High school, Senior High school, Diploma, Bachelor's Degree, Master's Degree
Father's Occupation	Father's latest Occupation	General employees, Entrepreneur, Merchant, Deceased, Laborer, Government Employees/Soldiers/Police, Others
Father's Income	Father's Monthly Income	No Income, <Rp 500.000, Rp 500.000 - Rp 999.999, Rp 1.000.000 - Rp 1.999.999, Rp 2.000.000 - Rp 4.999.999, Rp 5.000.000 - Rp 20.000.000, >Rp 20.000.000
Mother's Education	Mother's latest Education	None, Primary School, Junior Highschool, Senior Highschool, Diploma, Bachelor's degree, Master's degree
Mother's Occupation	Mother's latest Occupation	General employees, Entrepreneur, Merchant, Deceased, Laborer, Government Employees, Soldiers/Police, Others
Mother's Income	Mother's Monthly Income	No Income, <Rp 500.000, Rp 500.000 - Rp 999.999, Rp 1.000.000 - Rp 1.999.999, Rp 2.000.000 - Rp 4.999.999, Rp 5.000.000 - Rp 20.000.000, >Rp 20.000.000
First and Second Semester's Grades	Grades in Religion, Civic, Bahasa Indonesia, English, Mathematics, Natural Science, Social Science, Art and Culture, Sports	A, B, C, D, E, F, G

After being collected, the data is combined into a single data set.

B. Data Preparation

This step is to delete duplicate data or have empty attributes leaving 759 student data remaining. Then, numerical attributes are converted into categorical attributes based on Table II rules.

TABLE II. MAPPING RULES

Numerical Values	**Categorical Values**
Above 95	A
90-94	B
85-89	C
80-84	D
75-79	E
70-74	F
Below 70	G

Then the data is divided into two categories: training and testing, The training data set comprises 80% of the total data will be used to train the algorithm for classifying student data, whereas the testing data set comprises 20% will be used to evaluate the trained model's performance.

C. Modelling

Classification is a concept that refers to the act of classifying things according to information about one or more of its attributes, as well as categorizing them according to a collection of already classified items [16]. This research uses RapidMiner software which has a large collection of classification and optimization methods [17].

Naive Bayes is one of the simplest and most frequently used classification methods [18]. This method is based on Bayesian theory of probability, which assumes that a class is independent of each other [19]. With a simple concept, Naive Bayes uses a conditional probability model with P(six) as the probability of the class and assumes that the value of a predictor (x) in a particular class (c) does not depend on the value of other predictors. Naive Bayes can be described in the following equation 2.2.

$$ax(t) = Ax(t) + Bu(t) + B1w(t) \quad (1)$$

Naive Bayes has the advantages of being fast and efficient in using memory, able to handle quantitative data and discrete data, resilient to noise and only requires a small amount of data for classification and can handle missing values by ignoring values during probability calculations [20].

Decision Tree is a method for classifying by looking for differences between classes and dividing them using attributes by making a diagram in the form of a tree. This method uses a divide-and-conquer approach, one of the advantages is the ease of reading the model that has been made, with this convenience, information related to the identification of important attributes and relationships between classes can be used for analysis and research in the future [21]. By splitting to determine branches, there are several ways that can be used, such as Gini Impurity which looks for branches that have the most homogeneous results, which means that the results of the division have similar characteristics.

K-Nearest Neighbor performs classification by comparing input with training data like it, each data consists of n-attributes represented by a point on the n-dimensional graph, if given a data whose class is not known then K-Nearest Neighbor will look for several k training data closest to the location with the data [19] . After knowing the number of closest samples, the algorithm can estimate the class of the data based on the number of closest samples, the distance can be measured using several formulas such as Euclidean Distance. The advantage of K-Nearest Neighbor is that it can group a lot of data efficiently and in a fast time [20], but it has the disadvantage that it can become significantly slower with an increasing amount of data.

Support Vector Machine is a method that can be used to classify linear and non-linear data [22]. The way it works is by doing non-linear mapping to change the training data to a higher dimension, in this dimension he looks for the most optimal linear hyperlane separator. With enough nonlinear mappings that have high dimensions, data from the two classes can always be separated by hyperlane. Support Vector Machines finds hyperlane using support vectors and margins [19]. The advantages of Support Vector Machines are that it works well if there is a clear distance between class differences, effective for cases where the number of dimensions is more than the number of sample data, but the disadvantages are that it is not suitable for large data sets and does not perform well for data sets that have a lot of noise.

Feature selection reduces the number of dimensions of the data set thereby reducing processor and memory usage [23]. With this feature selection removes irrelevant attributes from the data set and improves the accuracy of the algorithm. For this study forward selection is used where it starts with an empty attribute set and adds attributes in it until the stopping criterion is met [24]. This method allows avoiding the use of additional memory and processor and improves the accuracy of the algorithm by removing irrelevant attributes from the data set.

Parameter optimization is a technique used to find the best combination of parameters to get the optimum performance of each algorithm. In the approach there are several ways such as through the grid, evolutionary and quadratic. By running iterations according to the provisions, then trying to calculate new parameters that may be between the previous parameters, and after that compare the results of the accuracy of the initial parameters and the parameters of the calculation results. The grid search is originally an exhaustive search based on defined subset of the hyper-parameter space. The hyper-parameters are specified using minimal value (lower bound), maximal value (upper bound) and number of steps [25]. In this case the grid search is used since those best ranges and dependencies are known.

D. Evaluation

In this research method the evaluation will be carried out using multi-class confusion matrix to evaluate each model accuracy, precision, recall and F1-Score.

E. Result and Analysis

Tables below summarizes the algorithm performance for Naive Bayes, Decision Tree, Support Vector Machines and K-Nearest Neighbor without any optimization, and with both feature selection and parameter optimization on different high school testing data set. For more concise tabulation the methods Naïve Bayes, Decision Tree, Support Vector Machines, K-Nearest Neighbor, combined feature selection and parameter optimization are abbreviated to NB, DT, SVM, K-NN and FS+PO, respectively.

On Table III shows result for high school A data set, Decision Tree with optimization shows to be the best overall algorithm and with best F1-Score at 54.01% and the most significant attribute on that algorithm is *First Semester Social Science*, *Second Semester English* and *Gender*, while K-Nearest Neighbor with optimization achieved best accuracy score at 77.36% while Naive Bayes with optimization achieved best recall score at 52.41%.

On Table IV shows result for high school B data set, Decision Tree with optimization shows to be the best overall algorithm and with best accuracy at 85.71% and precision at 64.40% and the most significant attribute is First Semester Religion score, First Semester Natural Science score, First Semester Sports score, First Semester Arts score, First Semester Social Science score and Second Semester Arts score while Naïve Bayes without optimization achieved best recall score at 61.11%.

On Table V shows result for high school C data set, Naive Bayes with optimization shows to be the best overall algorithm on all measurements and the most significant attributes are First Semester Natural Science score, First Semester Social Science score and Gender.

TABLE III. PERFORMANCE ON HIGH SCHOOL A TESTING DATA SET

Algorithm	Optimization Method	Accuracy	Precision	Recall	F1-Score
NB	-	69.81%	60.60%	48.72%	54.01%
	PO + FS	76.92%	55.47%	52.41%	53.89%
DT	-	62.26%	55.90%	39.12%	46.02%
	PO + FS	73.58%	62.46%	50.63%	55.92%
SVM	-	66.04%	32.72%	36.22%	34.38%
	PO + FS	71.70%	60.58%	44.37%	51.46%
K-NN	-	67.92%	58.58%	42.29%	49.11%
	PO + FS	77.36%	38.54%	44.57%	41.33%

TABLE IV. PERFORMANCE ON HIGH SCHOOL B TESTING DATA SET

Algorithm	Optimization Method	Accuracy	Precision	Recall	F1-Score
NB	-	76.79%	53.12%	61.11%	56.70%
	PO + FS	83.93%	60.60%	61.01%	60.80%
DT	-	66.07%	43.75%	42.56%	43.14%
	PO + FS	85.71%	64.40%	58.83%	61.48%
SVM	-	66.04%	32.72%	36.22%	34.38%
	PO + FS	82.14%	60.91%	57.54%	59.17%
K-NN	-	69.64%	47.62%	44.15%	45.81%
	PO + FS	78.57%	53.08%	57.00%	54.97%

TABLE V. PERFORMANCE ON HIGH SCHOOL C TESTING DATA SET

Algorithm	Optimization Method	Accuracy	Precision	Recall	F1-Score
NB	-	48.78%	42.39%	51.62%	46.55%
	PO + FS	79.41%	66.62%	66.62%	66.62%
DT	-	63.44%	50.91%	50.86%	58.88%
	PO + FS	70.73%	57.30%	64.93%	60.87%
SVM	-	60.98%	42.00%	36.70%	39.17%
	PO + FS	68.75%	41.86%	45.56%	43.63%
K-NN	-	58.54%	39.78%	38.17%	38.95%
	PO + FS	75.61%	45.65%	51.49%	48.39%

In general, the experiment shows that feature selection and parameter optimization improve the accuracy of the classifier algorithm up to 62.79%. However, it also shows that various algorithms show different accuracy results with different high school data set. Decision Tree with optimization shows to be the best overall combination to predict student performance on A and B high school data set with peak F1-Score at 61.48%, meanwhile Naive Bayes with optimization shows to be the best combination on high school C data set with 66.62% F1-Score And in almost every data set shows that the most significant attributes are First Semester Natural Science, First Semester Social Science score on predicting student final score.

IV. CONCLUSION

The result of this study found that: (a) Overall best F1-Score is achieved by Decision Tree with feature selection and parameter optimization. (b) In general parameter optimization and feature selection show to improve algorithm performance. (c) The most significant attributes in predicting student score are First Semester Natural Science score and First Semester Social Science score. (d) Even with the same attributes from different schools' data set each algorithm performs differently. With these results it can be concluded that the research has achieved its objectives. But there is a room of improvement on this research since there are lack of data varieties because we're only using data from single province in Indonesia.

***Abstract*—Cyberbullying is the use of technology to harass, threaten or target another individual. Online bullying can be particularly damaging and upsetting since it is usually anonymous and it's often hard to trace the bully. Sometimes cyberbullying can lead to issues like anxiety, depression, shame, suicide, etc. Most of the cyberbullying cases are not revealed to the public and the number of cases reported to the legal system is only few. Certain victims do not reveal their bully experiences out of shame or due to difficult procedures for reporting to the legal system. Our cyberbullying detection system aims to bring cases involving cyberbullying under control by detecting and warning the bully. Such cases are also reported to appropriate authorities, which can then be verified and necessary actions can be taken depending on the situation. The technology stack used for implementation include Flask, Scikit learn, Chat application APIs, Firebase, HTML, Javascript and CSS. The model was tested on classifiers like SVM, KNN, Logistic regression and Random Forest. F1 score was used as a metric to assess the four models. While analyzing the performances of these models, it was observed that Random Forest Classifier outperformed all the models. F1 score of 93.48% was achieved using the Random Forest Classifier.**

***Keywords*—Cyberbullying detection; support vector machine (SVM); kNN (k nearest neighbor); logistic regression; random forest classifier**

I. Introduction

The most common type of online bullying is mean comments which includes use of aggressive and pejorative words, threats, profile hacking etc. [11][12][13][14]. Nearly 8 out of 10 individuals are subject to the different types of cyberbullying in India. Out of these around 63% faced online abuses and insults, and 59% were subject to false rumours and gossip for degrading their image. 64% of victims receive an aggressive instant message when they are bullied. 7 in 10 young people experience cyberbullying before they hit the age of 18. About 37% of children between 12 and 17 years experienced cyberbullying at least once. One in four children fall victim to cyber bullies. In just one year, cyberbullying of teenagers and Indian women has increased by 36%. Only 4.6% of the cases are reported to the authorities and the rest go unnoticed or are hidden by victims to save themselves from further damage. Cases of cyber stalking or bullying of women or children increased by more than 36% from 2018 to 2020, data released recently by the National Crime Records Bureau showed.

Most of the comments that are posted on social media are noticed by people, but a large number of cases involving cyberbullying in messages are not shown in the public by victims to protect themselves from shame. These events can severly impact the one getting bullied and can sometimes lead to suicide. Currently studies and projects that are carried out in this area only include models to classify single sentences as a comment on bullying or not. What differentiates our model from existing ones is that we capture the message, the context and details of the bully and report it to authorities. With the use of our cyberbullying detection system, messages indicating cyberbullying can be detected and reported so that such events do not go unnoticed.

The rest of the paper is organized as follows: Section II summarizes contemporary research works carried out in cyberbullying detection. While Section III elaborates the methodology employed, Section IV discusses the results as an outcome of our work carried out. Section V concludes the findings and details the future work.

II. Literature Review

Many existing approaches were proposed in [1]. Authors have worked on the detection of Cyberbullying over comments posted on Instagram. Preprocessing techniques performed include unimportant character removal and removal of stop words. The machine learning model used was the Linear Support Vector Machine (LSVM). The metrics used for evaluation were accuracy, precision and recall. The model was designed only for detection of highly negative social media posts, more features and detailed labelling surveys can improve accuracy. In [2], authors have worked on identifying tweets related to cyberbullying by using PHP and HTML with MySQL and Twitter API. The preprocessing steps carried out were removal of punctuations and emotional icons. The detection of cyberbullying in tweets was done using a simple keyword search, in which each word present in the tweet was compared with the words in the dataset. The model did not consider the context of tweet, accuracy, informal language and abbreviations.

In [3], authors worked on the detection of cyberbullying on ASKfm which is a platform that allows users to ask and answer questions anonymously. Data cleaning steps done were removal of white spaces and replacement of abbreviations. The preprocessing steps consisted of tokenization, POS tagging and lemmatization. The machine learning model used was SVM (Support Vector Machine) and the evaluation metric considered was F1 score. The model only detected cyberbullying, it did not warn the bully or report the same to authorities. In [4], authors worked on identification and classification of Cyberbully Incidents using Bystander Intervention Model. The proposed model focused mainly on the analysis of direct intervention by bystanders. The dataset used consisted of posts and activities from facebook. Data preprocessing steps included were removal of whitespaces and

stop words. The machine learning model used for implementation was Random Forest Classifier. A limited dataset with limited accuracy was used for binary classification. In [5], the authors worked on the design of Semantic Framework for detecting Cyberbullying on social media. The main focus of the paper was detection of cyberbullying using Semantic learning. Removing stop words and Tokenization were the preprocessing steps performed. Sentiment Analysis was done on comments from posts. The model concentrated only on binary classification of comments and did not include reporting of comments related to cyberbullying to authorities. In [6], the authors' approach is validated on a dataset of over 3000 images along with peer-generated comments posted on the Instagram photo-sharing network, running comprehensive experiments using a variety of classifiers and feature sets. In this work, methods for detecting cyberbullying in commentaries following shared images on Instagram are developed. Classification of images and captions themselves are potential targets for cyberbullies. Standard k-fold validation technique is used to train data. It is a lengthy process. The training algorithm has to be rerun from scratch k times, which means it takes k times as much computation to make an evaluation. In [7], the paper proposes a supervised machine learning approach for detecting and preventing cyberbullying. Several classifiers are used to train and recognize bullying actions. The evaluation of the proposed approach on cyberbullying dataset shows that Neural Network performs better. Preprocessing is done, and then feature extraction is performed. The extracted features are fed into a classification algorithm to train, and test the classifier and hence use it in the prediction phase. Two classifiers, namely, SVM and Neural Network are used. This model of detecting cyberbullying patterns is limited by the size of training data. Thus, a larger amount of cyberbullying data is needed to improve the performance. In [8], authors worked on aggressive text detection for cyberbullying. The proposed model automatically maps a document with an aggressiveness score, thus treating aggressive text detection as a regression problem and explores different approaches for this purpose. These include lexicon-based, supervised, fuzzy, and statistical approaches. The different methods were tested over a dataset extracted from Twitter and compared them against human evaluation. The results favored approaches that considered several features particularly the presence of swear or profane words. The approaches used could be refined to better handle difficult cases, testing more supervised approaches using a larger dataset and building a framework for cyberbullying automatic identification. In [9], the authors have focused on detection and mitigation of cyberbullying in English and Arabic. The dataset was taken from Facebook posts and Twitter feeds. Their preprocessing involved removing tweets other than English and Arabic. Naive Bayes and Support Vector Machine were used to build the model. Recall and Precision were used as a metric for evaluating the built model. Enhancing the performance measures achieved by the system by using hybrid training models, such as combinations of Distance Functions, NB and SVM would make the model more effective in detecting cyberbullying. In [10], the authors have used methodologies to extract texts sent by the user and network based attributes are used to study the properties of bullies and aggressors. Dataset was taken from youtube comments and Twitter handles. The preprocessing includes replacing abbreviations with full phrases. Multiple models were used such as Logistic Regression, SVM and Gradient Boost. These models were only able to achieve an accuracy between 70 and 75% and it was only able to give a binary classification.

Some gaps were identified in the works discussed in this section. In [1], cyberbullying detection is limited only to English and Arabic. In [2][3][8], reporting to authorities is not done at all. In [6][7], only a limited dataset was employed. The works mentioned in [5][6] performs only with limited accuracy. Hence, in our paper, we have focused on working with large dataset and improving accuracy. We have also worked on reporting to authorities.

III. METHODOLOGY

The system consists of two main parts, a backend that captures messages on a chat application and calculates the probability that the sent message belongs to categories like toxic, severe toxic, obscene, insult or identity hate and a front end which displays messages that have a high probability of the message belonging to one of the six categories mentioned. The system is designed with the following objectives.

- Detection of cyberbullying in text messages.
- Reporting to appropriate authorities for initiating suitable action.

The technology stack used for backend are Flask, Scikit learn and Firebase. Flask is a micro web framework written in Python which contains third-party python libraries used for developing web applications. Flask was considered for this system since it was easy to integrate it with the machine learning model which was also written in python. Scikit Learn is one of the most useful libraries for machine learning in python and contains several tools and implementations of many machine learning algorithms. This has been used to determine the probabilities of messages being a bully message with the help of a random forest classifier.

Firebase which is a Backend-as-a-service provided by Google was chosen as the database to store all the details related to cyberbullying messages sent on the chat application. Email notifications are also triggered when database updates are made. The front end web application that displays the dashboard is built using HTML, CSS and Javascript. This dashboard is used by authorities to view details associated with the cyberbully messages.

A. Dataset

Toxic comment dataset was chosen for this purpose which was sourced from Wikipedia's talk page edits. This dataset was posted on Kaggle by the Conversation AI team, a research initiative founded by Jigsaw and Google. It essentially consists of 1,59,571 rows and 7 columns. Each row has a unique comment along with its comment id and the labels that it belongs to. Various labels that describe the comment in the dataset are - toxic, severe_toxic, obscene, threat, insult and identity_hate. Libraries used include numpy, re, panda, nltk, Matplotlib, wordcloud, sklearn, pickle.

B. Exploratory Analysis

Exploratory analysis is the process of analysing the dataset and displaying it in the form of graphs for better understanding of how the data is structured. A bar graph is plotted to see the unique comments that fall under different categories.

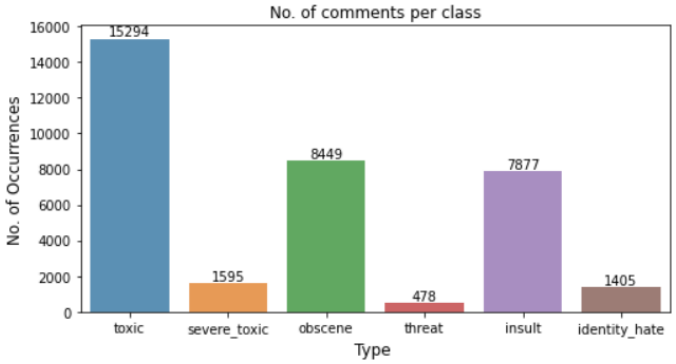

Fig. 1. Bar Chart Showing Number of Comments Per Class.

Fig. 1 shows that there are 15,294 toxic messages, 1595 severe_toxic messages 8449 obscene messages 478 threat messages, 7877 insult messages and 1405 identity_hate messages.

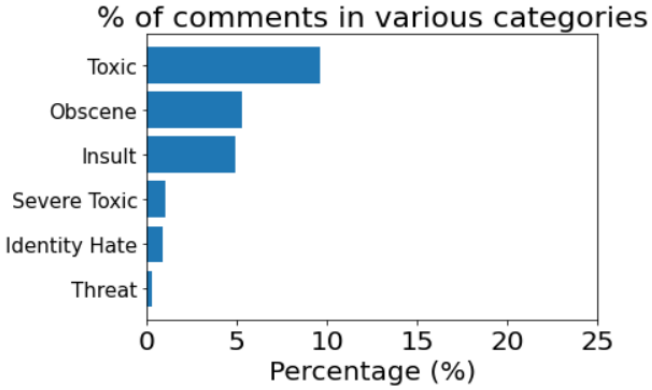

Fig. 2. Percentage of Comments in Various Categories.

Fig. 2 represents the percentage of comments that belong to a particular hate label. As we can see that only about 30% of comments fall under one of the given labels and a certain set of preprocessing has to be done in order to avoid class imbalance problems, see Fig. 3.

Fig. 3. Word Cloud.

C. Data Preprocessing

Data preprocessing is a technique that involves transformation of raw data into a format that can be utilized by machine learning models. The comments present in the dataset contain characters that are not essential in determining if a message is related to cyberbullying, hence such characters must be removed to increase the efficiency of the machine learning models. Various preprocessing steps have been carried out to clean the raw data. They include removal of numbers in combination with letters, replacing punctuations with white spaces, conversion of the comments to lower case, removal of escape sequences and replacing it with white spaces, removal of non ascii characters, removal of stop words, etc.

Since the data has lot of non-toxic comments and less toxic comments, training the model can make it prone to identifying more non-toxic comments rather than toxic comments. Hence, balancing of non-toxic and toxic comments has been done. After the basic preprocessing of the data, the dataset was separated into six sections. Each section contains the comments along with one of the categories in the dataset. Comments that were toxic or belonged to other forms of toxicity made up for less than 10% of the comments in the dataset. This led to a class imbalance problem where the class distribution was unequal or skewed. To overcome this issue, we took a subset of the data where the proportion of comments related to toxicity was at least 20% in relation to non-toxic comments. In order to make the subsets first the number of comments under each category was counted. If the category had 5000 rows, another 5000 rows of comments not belonging to the category were considered and the two were combined to form a new section. In case, a category did not have 5000 rows, then 20% of the comments belonging to the category and 80% of the comments not belonging to the category were chosen for the combination. In this manner six different sections or data frames were made per category.

Fig. 4 gives an overview of the data frames after eliminating the class imbalance problem. After the dataset was balanced, it was vectorized using Tfidf vectorizer which tokenizes the documents, learns the vocabulary given in the dataset and calculates the document frequency weighting which is essential in building a machine learning model. As machine learning models do not understand words or letters, they are converted to a machine understandable format using this method. 1-gram is used to split and tokenize the data, where it breaks the sentences into individual words and calculates the document frequency weight using Tfidf vectorizer.

	DF name	No. of pts (1)	No. of pts (0)	Total data pts
Toxic	data_tox_done	5000	5000	10000
Severe Toxic	data_sev_done	1595	1595	3190
Obscene (8449)	data_obs_done	5000	5000	10000
Threat (478)	data_thr_done	478	1912	2390
Insult (7877)	data_ins_done	5000	5000	10000
Identity Hate (1405)	data_ide_done	1405	5620	7025

Fig. 4. Overview of the Dataframes.

D. Backend

The backend was built using Flask, the database used was Firebase and Telegram API. SMTPLib (Simple Mail Transfer Protocol) module, which defines an smtp client session object is used to send emails.

When the server is run, the vectorizer and Random Forest model for each category is unpickling and loaded into the memory. We have used the Telegram API to capture messages sent by users. These messages are first vectorized and then passed to the machine learning model. These models return their respective names and the associated probabilities. The returned probabilities are compared with a threshold to identify bully messages. If the probability exceeds the threshold of 0.7, the model with the highest probability is chosen as the category that identifies the type of bullying. A warning is sent for the first bully message in the conversation, if more of such messages are sent further actions are taken.

A message queue is maintained to hold a few messages before and after the second bully message in the conversation. This queue is used to store the context of the messages being sent. The details of the messages and users such as username, chat id, time stamp, etc., are also stored in the message queue. Once the message queue is filled, the queue is pushed to the database along with the type of bullying and its probability. This event also triggers an email to the authority which alerts them about the update of the database so that they can review the conversation. This service is hosted on Heroku where the service is kept running so that messages can be monitored in real time.

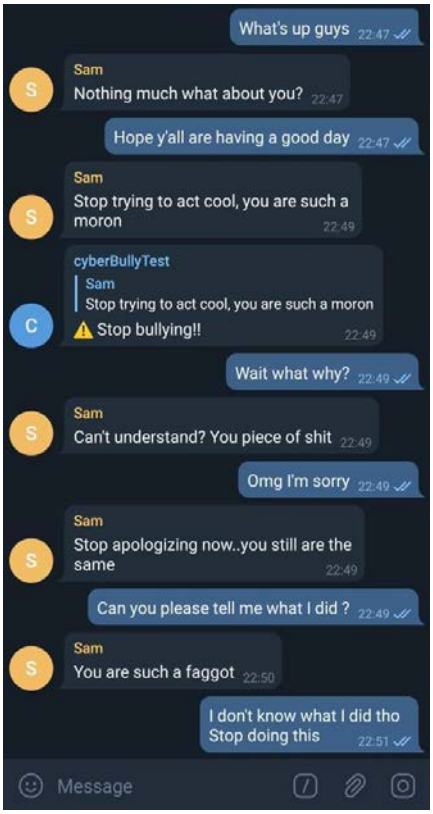

Fig. 5. Snapshot of a Cyberbullying Conversation.

Fig. 5 is a snapshot of a conversation that involves bullying. A warning is sent by the bot as a reply to the first bully message. If the user responsible for sending the message continues to do so by ignoring the warning, the messages are captured as evidence along with their details and these are saved to the database.

E. Frontend

The email that is sent to the authority notifies the authority when the database has been updated and it consists of the dashboard URL. On clicking the URL mentioned in the email for dashboard, the user lands on the login page where the person has to login using the official cyber cell credentials. Firebase authentication was used for this purpose.

Upon successful login, the authority is redirected to the pending page as shown in Fig. 6 which consists of all the conversations along with details like the type of toxicity, level of toxicity, name and user Id of the bully. The authority is given an option to either delete the conversations or approve them if they are legitimate. Approved messages are displayed under the approved tab.

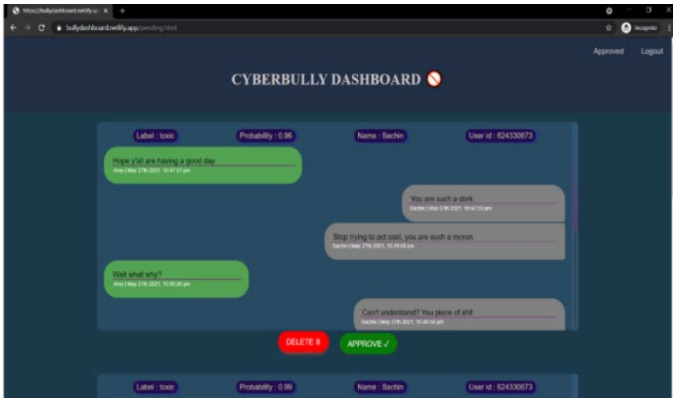

Fig. 6. Pending Reports Displayed in the Dashboard.

IV. Result and Discussion

The evaluation metric chosen was F1 score. F1 score was selected since it takes into consideration both False Positive and False Negative values, our goal was to minimise these values. A table comparing the F1 scores obtained using each of the machine learning models for the six data frames is shown below in Table I.

TABLE I. Comparison of F1 Score for the Models Used

Measure	Logistic Regression	KNN	SVM	Random Forest
F1 Score (Toxic)	0.861234	0.185120	0.876133	0.838055
F1 Score (severe_toxic)	0.927879	0.857416	0.926004	0.934874
F1 Score (obscene)	0.908655	0.519056	0.921378	0.909091
F1 Score (insult)	0.896599	0.257992	0.902619	0.883993
F1 Score (threat)	0.628821	0.720000	0.786765	0.795539
F1 Score (identity_hate)	0.699029	0.230159	0.797516	0.768448

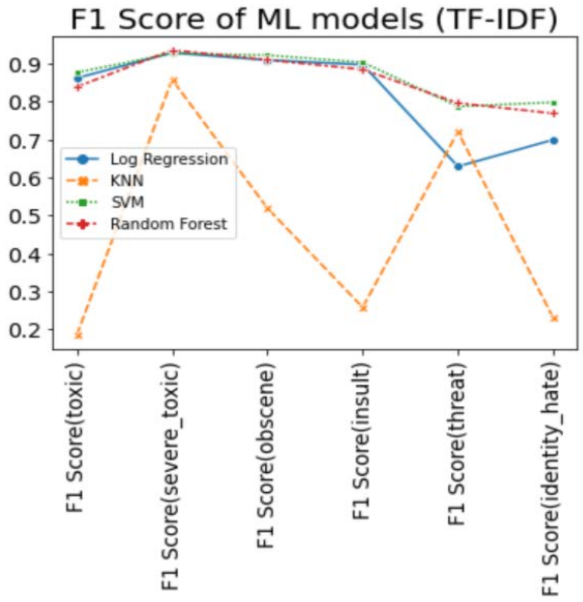

Fig. 7. F1 Score Comparison Plot.

By observing the values in Fig. 7, we see that SVM and Random Forest perform comparatively better than Logistic Regression and KNN classifiers. The plot in Fig. 7 shows that Random Forest represented by the red line and SVM represented by the green line perform better than the rest. So, Random Forest is chosen as the best performing model since results are returned in probabilities which were useful for our cyberbully detection system. Random Forest also makes use of multiple decision trees and hence gives a more accurate result.

V. Conclusion and Future Work

There are many people who are falling prey to cyberbullying, which goes unnoticed. It is high time that a system is made which helps in preventing these crimes. Our cyberbullying detection system aims to bring all these cases of cyberbullying under control by detecting and warning the bully. Then these cases are also reported to appropriate local authorities, which can be verified and required steps and actions can be taken depending upon the situation. Our model is built by using Chat application APIs, Firebase, Flask, Scikit learn, HTML, CSS and Javascript. It also gives high accuracy compared to the existing projects. It can be feasibly used and would show appropriate information whenever one is cyberbullied.

In future, CNN will be applied. Also, the algorithm will be applied on huge datasets and accuracy can be improved further. Certain issues like reducing false alarms, educating the users of the usability feature of cyberbullying detection and reporting to authorities, framing of privacy features of the platform and having moderators to review the conversations will be addressed in future work.

***Abstract*—Mobile telecommunication companies in Malaysia have been widely used in the recent decade. There is intense competition among them to keep and gain new customers by offering various services. The reviews of the services by the customers are commonly shared on social media such as Twitter. Those reviews are essential for mobile telecommunication companies to improve their services and at the same time to keep their customers from churning to another company. Hence, this study focuses on the public sentiment on Twitter towards mobile telecommunication services in Malaysia. Data on Twitter was scraped using three keywords: Celcom, Digi, and Maxis. The keywords used to refer to Malaysia's top three mobile telecommunication companies. The timeline for the tweets was between December 2020 until January 2021 and was based on the promotion sales commonly used by the organisation to boost their sales which is called Year End Sales. Corpus-based approach and Machine Learning model using RapidMiner were used in this study, namely, Support Vector Machine (SVM), Naïve Bayes, and Deep Learning. The corpus determines the sentiment from the tweets, either positive, negative, or neutral. The models' performances were compared in terms of accuracy, and the outcome shows that Deep Learning classifiers have the highest performance compared to other classifiers. The results of this sentiment analysis are visualised for easy understanding.**

Keywords*—Sentiment analysis; predictive analytics; RapidMiner; mobile telecommunications

I. Introduction

Sentiment analysis determines a writer's attitude toward a topic or the overall contextual polarity. The author's attitude could be based on his or her judgment or evaluation, affective state (i.e., the author's emotional state at the time of writing), or the intended emotional communication (that is to say, the emotional effect the author wishes to have on the reader) [1]. In other words, sentiment analysis is the classification of text documents, such as user reviews, newsgroup postings, and blogs, based on the polarity of their opinions.

Twitter, Facebook, and Instagram are examples of online social media that allow users to communicate with people worldwide. People can spread data, opinions, statements, and behaviour via social media [2]. They express their thoughts about items or share personal experiences, and they even can influence politics and businesses [3]. For example, practically every large corporation has a Twitter account to keep track of client comments on their services or products. Twitter is a powerful microblogging platform that allows users to post status updates (called "tweets"). These tweets contain a lot of human expressions, such as likes, dislikes, and contributions to many issues [3].

Malaysia's mobile telecommunications services sector has exploded in the recent decade. The competition among existing and new telecommunication service providers has intensified as they aim to keep and gain new consumers by offering a variety of eye-catching promotions and seasonal events. Customers frequently compare the promotions on Twitter. Opinions expressed on Twitter are frequently more influential than other social media because they are made public for all to see and compare. Hence, the motivation of this paper is to develop a model that could predict which telecommunications companies in Malaysia provide the top mobile services for the users.

The following are the contributions of this paper:

- This research proposes a Sentiment Analysis on customers' opinions for mobile telecommunication services in Malaysia.
- A corpus-based approach and several state-of-the-art machine learning models are compared to get the best model.
- The findings are visualised using Microsoft Power BI to understand the results better.

The remaining of this paper is structured as follows: Section II discusses the related works on mobile communications and sentiment analysis, while Section III describes the study's methodology. Section IV highlights the results, and Section V concludes the paper with future works.

II. Literature Review

A. Mobile Telecommunication Services in Malaysia

Mobile telecommunications are the process of sending, transmitting, and receiving information over a distance to communicate [4]. This type of signal transmission is carried out using a mobile device, such as a cell phone, computer, or other wired or wireless devices. Mobile telecommunications have a generation of network standards which are 1G, 2G, 3G, 4G, and 5G. 1G and 2G only give a means of speaking and texting over mobile phones. 3G allows mobile phone users to

connect to the internet and send or receive any multimedia transmissions. 4G increases the bandwidth significantly while 5G is still under development to improve 5G [5].

A study by Dagli and Jenkins [5] stated that mobile phone services are one of the most prominent growing areas in the telecommunication industry while currently holding more than 1.7 billion customers worldwide and targeting around 80% of the world population as its potential customers. Five (5) big companies dominate the telecommunication industry: Maxis, Celcom, Digi, U Mobile, and Unifi. However, there are three major mobile service providers in Malaysia, namely Maxis, Celcom, and Digi [6]. Smaller carriers with limited coverage in Malaysia and mobile virtual network operators are the rest (MVNOs). Each of these significant corporations has its own set of colours that signify its respective brands. Maxis represents green (post-paid), red (prepaid), blue represents Celcom, and yellow represents Digi.

B. Sentiment Analysis

Sentiment analysis (SA), also known as opinion mining or contextual mining, is a technique used in Natural Language Processing (NLP), computational linguistics, and text analysis to discover, systematically extract, and quantify subjective data. According to Singh et al. [7], the most common approach is machine learning, a method that needs an essential data set for training and learning the aspects and sentiments associated. Sentiment analysis can be used on any material or object in the form of a customer's voice, such as reviews or responses. For example, if a consumer wants to buy something online, they would usually read reviews on the item or product first, which will help them make the best selection possible [8]. Sentiment analysis allows businesses to understand a user's feelings about a product, service, or brand by converting internet comments into emotion and categorising it as positive, negative, or neutral [9].

Machine learning and lexicon-based approaches are the two most utilised techniques in sentiment analysis [10]. The lexicon-based technique generates flawless dictionaries, whereas the machine learning technique concentrates on feature vectors. The general workflow of sentiment analysis consists of a few processes: goal setting, text preprocessing, parsing the content, text refinement, and analysis and scoring [11].

C. Machine Learning Algorithms

1) Support Vector Machine (SVM): Support Vector Machine (SVM) is a supervised machine learning algorithm capable of performing classification, regression, and even outlier detection. The linear SVM classifier works by drawing a straight line between two classes. SVM is a supervised machine learning model for two-group classification issues that uses classification techniques. SVM models can categorise new text after being given labelled training data sets for each category. It is mainly used in text classification, and it comes with a dataset for high-dimensional training [3].

2) Naïve bayes: Naïve Bayes is the supervised machine learning algorithm that uses Bayes theorem for classification problems [11]. The Bayes' Theorem is used to create a collection of classification algorithms known as Naive Bayes classifiers. In Almonajed and Jukić's paper [3], the researchers mentioned that the Naïve Bayes classifier is a popular supervised classifier, furnishes a way to express positive, negative, and neutral feelings in the web text. Naïve Bayes classifier is valuable and efficient for classification purposes [12]. A family of algorithms share a similar idea: each pair of features being classified is independent of the others. It is a numerical-based approach with easy, fast, and high accuracy [13].

3) Deep learning: Deep Learning is a subfield of machine learning concerned with algorithms inspired by the structure and function of the brain called artificial neural networks [6]. Deep learning has emerged as a powerful machine learning technique that learns multiple layers of representations or features of the data and produces state-of-the-art prediction results. Along with the success of deep learning in many application domains, deep learning is also used in sentiment analysis in recent years [6]. Deep Learning is based on a multi-layer feed-forward artificial neural network taught via back-propagation and stochastic gradient descent.

III. Research Methodology

Machine learning and lexicon-based approaches are the two most utilised techniques in sentiment analysis [11]. The lexicon-based technique generates flawless dictionaries, whereas the machine learning technique concentrates on feature vectors. The general workflow of sentiment analysis consists of a few processes: goal setting, text preprocessing, parsing the content, text refinement, and analysis and scoring [14].

A. Data Collection

Data was collected by extracting tweets from Twitter using a python tool called Twint. Python is a general-purpose language. It can build anything using Python [15]. Twint is a Python-based Twitter scraping tool that allows scraping tweets from Twitter profiles without using Twitter's API. Twint makes use of Twitter's search operators to scrape tweets from specific people, scrape tweets related to specific themes, hashtags, and trends, and shift out sensitive information from tweets such as e-mail addresses and phone numbers. Twint also uses Twitter to make unique queries that allow it to scrape a Twitter user's followers, tweets they have liked, and whom they follow without requiring any login, API, Selenium, or browser emulation. Tweets scraped were between 1st December 2020 until 31st January 2021. Three keywords are used to scrape the tweets: Celcom, Digi, and Maxis. Any tweets posted on Twitter that contained the keywords and within the durations mentioned above will be automatically scrapped by Twint.

B. Data Preprocessing

1) Data cleaning: There were seven operators used to clean the datasets. The first operator is called the Retrieve operator. After the datasets had been successfully scraped using Python tools, the datasets were stored in a CSV file. Then the CSV was stored in the RapidMiner repository. The

Retrieve operator is used to access the stored datasets in the repository and load them into the RapidMiner's process. Then, the second operator is called Filter Examples. The raw datasets collected consist of multiple languages. Since RapidMiner only detects English, only English tweets were chosen. Python tools used in the data collection phase provided a language detector of the tweets. The tweets were labelled by each detected language in the language attribute. Therefore, the Filter Examples operator selected only data labelled as "en", which means English. After only tweets in English were chosen, the following operator used was called the Select Attributes operator. Only four important attributes from 36 common attributes were selected. The selected attributes were time, date, tweet, and username attributes. Then, the operator will keep only the four attributes selected and remove the remaining 32 attributes.

The next operator used was called Replace operator. The value of tweet attributes might contain special characters or punctuation characters. Those characters cannot be processed to perform a Sentiment Analysis. So, those characters need to be removed. Remove Duplicate operator was the fourth operator used in the data preprocessing process. It might be a spamming situation where the customers spam with the same tweets in the real world. Therefore, the operator will remove duplicate data and only keep one. The last operator used in the data preprocessing process was the Filter Examples operator. The operator was used again but with a different purpose. After the datasets go through several processes, the missing values appear. The values were removed due to some factors, including those from a special character or just a punctuation character. Therefore, the operator will remove data with a missing value. Fig. 1 shows a RapidMiner's operator used in the data cleaning process.

2) Data labelling: Fig. 2 shows a RapidMiner's operators used to extract sentiment. The data labelling process is the process to extract the sentiment and classify the texts as either positive, negative, or neutral. The cleaned datasets have been called by using the Retrieve operator. Then, the Extract Sentiment operator was used to extract the tweet's sentiment. A few models can be used to extract the sentiment, and the VADER model has been used in this project. VADER model will produce a compound score for each sentence. The compound score is a metric that calculates the sum of all the lexicon ratings, which have been normalised between -1(most extreme negative) and +1 (most extreme positive). Table I shows a compound for each sentiment class.

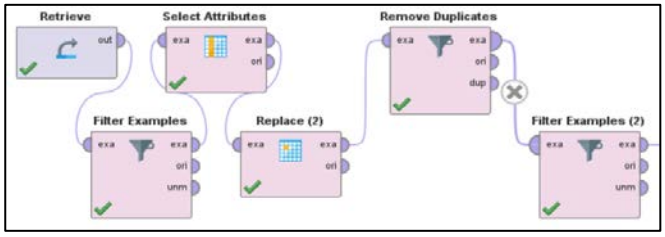

Fig. 1. RapidMiner's Operators used for Data Cleaning.

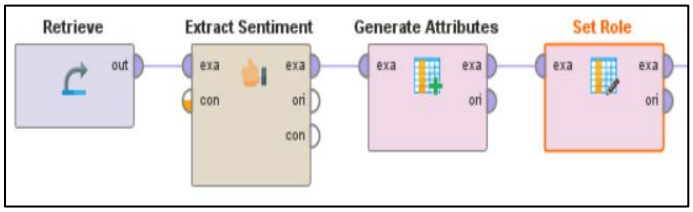

Fig. 2. RapidMiner's Operators use to Extract Sentiments.

TABLE I. COMPOUND SCORE

Sentiment	***Compound Score***
Positive	>= 0.05
Neutral	> -0.05 and < 0.05
Negative	<= -0.05

After three classes of sentiment have been successfully extracted, the following process sets the role for the sentiment attribute. RapidMiner's operator used was called the Set Role operator. The role of the attribute that has been set will describe how other operators handle the attribute. This operator also will transform the sentiment attribute into a special attribute.

3) Data transformation: Fig. 3 shows the operators applied in the Process Document operator. Only attributes that focused on sentiment analysis were involved in this stage, which is tweet attributes. There are five processes involved in the data transformation stage. The first process was Transform Cases. Transform Cases operator has been applied to transform all characters in the tweet attribute into lower case. The second process was stopped word removal. All stop words, such as frequent terms like a and the, are deleted from multiple word queries to improve search performance. The third process was the tokenisation process, where the Tokenize operator was applied. For this project, non-letter characters have been used as a method for the splitting points. The fourth process was the stemming process, where the Stem operator has been applied. This operator stems from English words using the Porter stemming algorithm, which employs an iterative, rule-based substitution of word suffixes intending to shorten the words to a minimum length. The last data transformation process was generating n-grams by using the Generate n-Grams operator. This operator generates the word n-Grams, which refers to all series of consecutive tokens of length n.

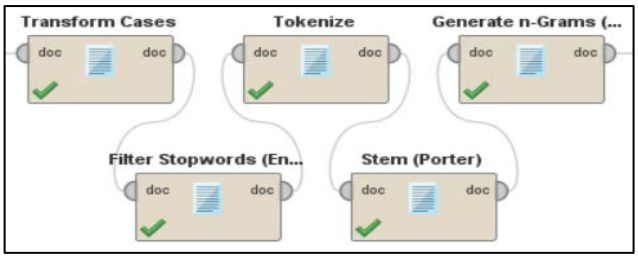

Fig. 3. Operators Applied in Process Document Operator.

C. Model Development

In this project, three machine learning models were compared. The classifiers used were Support Vector Machine (SVM), Naïve Bayes, and Deep Learning. Deep learning is a class of machine learning algorithms that uses multiple layers to progressively extract higher-level features from the raw input [16-17]. Those Machine Learning models will be applied using RapidMiner. After the datasets had been successfully labelled, the result showed an imbalanced class. Datasets are said to suffer the Class Imbalance Problem when highly imbalanced class distributions. The datasets must be equally distributed for each class to get higher accuracy. There are a few methods that can be used to handle imbalanced data. This study used the under-sampling method to obtain an evenly dispersed amount of data to a model. This method investigates the class with the smallest number. Fig. 4 shows RapidMiner's operators used in the modelling process.

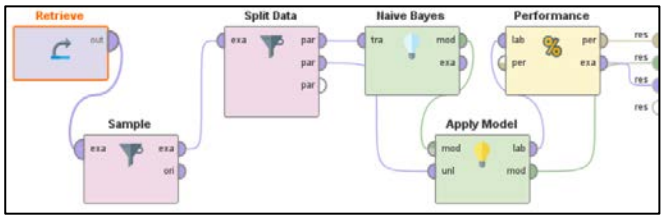

Fig. 4. RapidMiner's Operators used in the Modelling Process.

The first operator used in the modelling process was the Retrieve operator. This operator is used to call the datasets saved in the RapidMiner repository. The second operator used was the Sample operator. This operator was used to solve the imbalanced class problem. The size of the sample has been specified with an absolute sample. Then, the size per class has been set by the smallest number of sizes per class for each dataset. The next operator applied was the Split Data operator. The operator is used to split the datasets into two parts: train data and testing data. The split ratio used in this project was 70:30, 80:20, and 90:10 percent. The three ratios were used to find the best ratio which produced the highest accuracy. After the Split Data operator splits the datasets into training and testing data, the training data will be passed to the classifier operator. In contrast, the testing data will be passed to the Apply Model operator. Since this project will compare three different Machine Learning models, three different classifiers will be used.

After the training data has been successfully processed in the classifier operator, the training data also will be passed to the Apply Model operator like the testing data. Therefore, the Apply Model operator will receive both parts of data: training and testing data. Apply Model operators have two types of input received: Model and Unlabeled data. Model input will be received data that model has been trained, while Unlabeled data input will be received testing data. This operator also will apply a model used on the datasets. Not only receive two types of inputs, but this operator will also produce two types of output: Labelled data and model. The input of the Model type was passed without changing to the output through the output of the model type. While the datasets delivered from the output of the labelled type will be passed to the Performance operator. The last operator applied in the modelling process was a Performance operator. This operator is used to evaluate the performance of classification tasks statistically. This operator will return a list of classification task performance criteria values.

D. Dashboard Development

The goal for developing the dashboard in this project was to visualise customers' reviews and comparisons between each telecommunication company's customers based on Twitter data. This section goes through the visualisation that may be derived from the sentiment data that has been extracted. The subject under discussion is customers' reviews on Malaysia's top three telecommunication services, and the dashboard was developed using Microsoft Power BI.

IV. Result and Discussion

A. Split Ratio Selection

There are three split ratios used in this project which is 70:30, 80:20, and 90:10 percent ratio. Each split ratio produces a different accuracy, and the split ratio which produces the highest accuracy was selected. Table II until Table IV presents the accuracy result by different split ratios for each dataset. Table II shows the accuracy result for the Celcom dataset. As shown in Tables II to IV, generally, the performance of the three classifiers increases as the sample size increases. In Table II, the Deep Learning classifier appears to be the best model, followed by the Naive Bayes and Support Vector Machines classifier. Similar performance can be seen in Digi and Maxis datasets, in which Deep Learning consistently gave the highest accuracy results.

Based on the accuracies in Table II until Table IV, the 90:10 percent split ratio produced the highest accuracy for each classifier and each dataset. Therefore, the 90:10 split ratio will be used for the following process: finding the best N-gram for the better accuracies produced.

TABLE II. Accuracy Result for Celcom Dataset

Classifier	**70:30**	**80:20**	**90:10**
SVM	49.87%	49.94%	50.93%
Naive Bayes	60.84%	61.52%	61.59%
Deep Learning	79.17%	77.81%	81.22%

TABLE III. Accuracy Result for Digi Dataset

Classifier	**70:30**	**80:20**	**90:10**
SVM	37.86%	38.31%	38.72%
Naive Bayes	52.93%	51.31%	55.49%
Deep Learning	65.03%	69.73%	83.73%

TABLE IV. Accuracy Result for Maxis Dataset

Classifier	**70:30**	**80:20**	**90:10**
SVM	44.84%	44.21%	45.86%
Naive Bayes	52.84%	52.60%	53.19%
Deep Learning	76.89%	76.91%	78.25%

B. Model Comparison

1) Support Vector Machine (SVM): The first classifier tested was the Support Vector Machine. Table V shows the accuracy for the SVM model with three conditions: without n-Grams, n-Grams set to 2, and n-Grams set to 4.

TABLE V. ACCURACY RESULT FOR SVM MODEL

Dataset	Accuracy		
	Without n-Grams	**n-Grams = 2**	**n-Grams = 4**
Celcom	50.93%	52.28%	45.18%
Digi	38.72%	49.44%	53.98%
Maxis	45.86%	55.40%	54.99%

For the conclusion, after the three different datasets have been tested using the SVM classifier, by applying the change of parameter with n-Grams equal to 2 has been set, the accuracy for the classifier for Celcom and Maxis datasets were the highest. While for the Digi dataset, by applying the change of parameter with n-Grams equal to 4 has been set, the accuracy for the classifier was the highest.

2) Naïve bayes: The second classifier that has been tested was Naïve Bayes. Table VI shows the accuracy for the SVM model with three conditions: without n-Grams, n-Grams set to 2, and n-Grams set to 4.

TABLE VI. ACCURACY RESULT FOR NAÏVE BAYES MODEL

Dataset	Accuracy		
	Without n-Grams	**n-Grams = 2**	**n-Grams = 4**
Celcom	61.59%	62.44%	63.62%
Digi	55.49%	56.23%	43.49%
Maxis	53.19%	56.58%	48.73%

In conclusion, after the three different datasets have been tested using the Naïve Bayes classifier by applying the change of parameter with n-Grams equal to 2 has been set, the accuracy for the classifier for Digi and Maxis datasets will be the highest. While for the Celcom dataset, n-Grams equals 4 produced the highest accuracy.

3) Deep learning: The final classifier that has been tested was Deep Learning. Table VII shows the accuracy for the SVM model with three conditions: without n-Grams, n-Grams set to 2, and n-Grams set to 4.

TABLE VII. ACCURACY RESULT FOR DEEP LEARNING MODEL

Dataset	Accuracy		
	Without n-Grams	**n-Grams = 2**	**n-Grams = 4**
Celcom	81.22%	78.00%	66.33%
Digi	83.73%	81.22%	41.67%
Maxis	78.25%	74.39%	59.33%

For the conclusion, after the three different datasets have been tested using Deep Learning classifiers, applying the change of parameter with n-Grams equal to 2 and n-Grams equal to 4 has been set, the accuracy for the classifier will be decreased. While without the n-Grams, the classifiers will perform better. It was different from the SVM and Naïve Bayes classifier.

C. Dashboard Visualisation

The dashboard of customers' reviews on Malaysia's top three telecommunication services was developed in 2 pages. Fig. 5 shows the first page of the dashboard. This page was aimed to give a clear view to the readers about the comparison between the top three telecommunication services in Malaysia based on customers' reviews on Twitter. The results are related to customer satisfaction. When the customers feel satisfied, they believe in the brand and become loyal [18]. Based on the visualisation on page 1, it can be concluded that Digi telco has the highest number of positive reviews, while the second-highest was Celcom telco. From that, the readers can decide where the readers might be tended to choose a telco with the highest positive reviews. The readers also were able to read the reviews given by previous users in the table visualisation.

Fig. 5. Page 1 of the Dashboard.

Fig. 6 shows a second page of the dashboard. This page was aimed to provide profound information about the reviews. The readers from the background as a telco's customers might not be interested in this page because most of the telco's customers just want to know the information that can help them decide. At the same time, this page was more focused on telco companies' sites. Based on the line chart on the second page, the telco companies can identify a specific time the reviews were given in the duration selected. From that information, the telco companies might gain new knowledge about the customer's behaviour or what has been suffered by the customers in that time so that the telco companies can decide to maintain customers satisfaction.

Fig. 6. Page 2 of the Dashboard.

V. Conclusion

This study has demonstrated SVM, Naive Bayes, and Deep Learning using a corpus-based approach and machine learning algorithms. Our results showed that the Deep Learning model without n-Grams provides the highest accuracy. The highest value produced for the Celcom dataset is 81.22% which is 17.6% better than the Naïve Bayes model and 28.94% better than the SVM model. Meanwhile, for the Digi dataset, the Deep Learning model produced 83.73% accuracy, 27.5% better than the Naïve Bayes model and 29.75% better than the SVM model. Lastly, for the Maxis dataset, the Deep Learning model produced 78.25% accuracy, which is 21.68% better than the Naïve Bayes model and 22.85% better than the SVM model. The future researcher may consider using a more extensive dataset for better generalisation. This work would reach a wider audience with a mobile application since smartphones are widely used nowadays. Further future work could also include the Malay language during sentiment extraction since Malay is the highest population in Malaysia.

Acknowledgment

The authors would like to thank the Faculty of Computer and Mathematical Sciences, Universiti Teknologi MARA, Malaysia, for the support throughout this research.

***Abstract*—Server-side request forgery (SSRF) is a security vulnerability that arises from a vulnerability in web applications. For example, when the services are accessed via URL the attacker supply or modify a URL to access services on servers that he is not permitted to use. In this research, various types of SSRF attacks are discussed, and how to secure web applications are explained. Various techniques have been used to detect and mitigate these attacks, most of which are concerned with the use of machine learning techniques. The main focus of this research was the application of deep learning techniques (LSTM networks) to create an intelligent model capable of detecting these attacks. The generated deep learning model achieved an accuracy rate of 0.969, which indicates the strength of the model and its ability to detect SSRF attacks.**

Keywords*—Server-side request forgery (SSRF); machine learning (ML); deep learning (DL); long short-term memory (LSTM)

I. Introduction

With the development and increasing number of applications on the World Wide Web, security violations have increased, as these applications are characterized by being public, making them vulnerable to attacks [1]. Despite the great progress in methods to protect web applications, hackers are searching using advanced technology for loopholes to overcome these protection methods [2]. These applications inherently contain huge and sensitive data that must be protected from intrusion. SSRF attacks exploit any vulnerability within the web application to enter the server and obtain data in illegal ways, so we need mechanisms to defend against these attacks. Web applications use Authentication Systems to confirm the identity of the client communicating with the web application on the server. The username and password are sent from the client to the server in an encrypted form via HTTP, this information can be compromised while it is being sent. One of the main characteristics of the web applications is that it should work without interruption, so when designing these applications, you must take into account that it works even if it is attacked by hackers. Therefore, several security rules and controls must be put in place to protect web applications from attacks that are widespread with the development of technology. The development of technology helps hackers search for potential vulnerabilities in web applications, making the web application vulnerable with the data contained within it being corrupted, lost, or hijacked. There are now basic plans and concepts to reduce the risk of these attacks and protect data [3]. Web applications are exposed to multiple attacks, the most common of these attacks is Cross-Site Scripting (XSS), SQL Injection, DDoS Attack, Malware, Bots, Cross-Site Request Forgery (CSRF) and Server-Side Request Forgery (SSRF). To detect and mitigate attacks against web applications, machine learning techniques are used because of their ability to learn from data. Server-side request forgery (SSRF) is a security vulnerability that arises from a vulnerability in web applications**.**

In this research, different methods are presented in several literatures to detect SSRF attacks that use URLs to perform the attack. in addition to, the LSTM deep learning network was used to build an intelligent model for detecting SSRF attacks. The training of this model was based on a set of data that represents normal data and others infected with attacks. The test results of this model were good, with an accuracy of 96%.

A. Background of SSRF

In a Server-Side Request Forgery (SSRF) attack, the attacker reads and controls internal server resources by using the available functions on the server through web applications [4], as shown in Fig. 1.

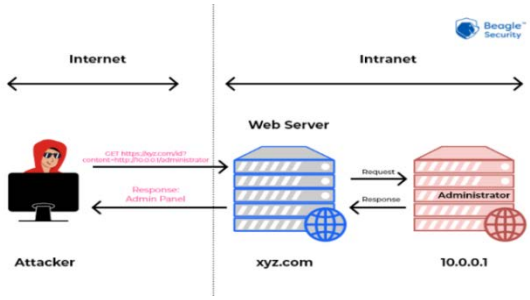

Fig. 1. Server-Side Request Forgery (SSRF) Attack [**4**].

Internal servers behind firewalls can be accessed by the attackers by submitting a URL within a web request to the web application.

A real example of an SSRF attack is the Capital One breach, where the database of Capital One Bank was hacked, and the information of more than 100 million customers was stolen. The attacker uses the Amazon Web Services credentials that were then used to access the Capital One database. Now a list of the main three types of SSRF attacks are explained [5].

- Non-Blind SSRF: As shown in Fig. 2, an attacker can access the data via the HTTP response. Server retrieves the contents of the resource located at the URL submitted, without verification, in an HTTP response to the user is given.

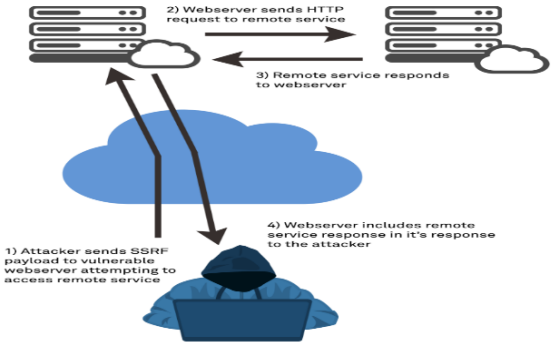

Fig. 2. Non-Blind SSRF [5].

- Blind SSRF: Fig. 3 illustrates this type of SSRF attack. When a web application has SSRF vulnerability but at the same time there is no HTTP response to the attacker. Here the attacker sends his own URL, he can access it, and the server sends an HTTP response to this URL. However, this method detects vulnerability, but it is possible that sensitive data will not be obtained.

Machine learning techniques greatly support artificial intelligence, as computer systems learn to perform human tasks such as classification and prediction. There are many machine learning algorithms and statistical models that are used to analyze data and extract knowledge from it. The process of training machine models produces a system capable of making decisions or recognizing objects. Machine learning algorithms are divided into several types according to the training method and the data available for this process.

Deep learning is a machine learning technique, and it is also considered as developing neural networks by adding new layers to them. Compared to neural networks, deep learning networks improve classifiers, especially as the volume of data increases [6]. As shown in Fig. 5, the performance of deep learning networks generally improves with increasing amounts of training data, unlike other types of machine learning techniques [7].

- Semi-Blind SSRF: Fig. 4 illustrates this type of attack. In the HTTP response, the server does not display all the details but only some of them. Data can be contained in error messages that enable the attacker to learn more information such as request response times, allowing the attacker to validate if a request succeeds.

Deep learning techniques are now used in all areas of artificial intelligence, recognition of voices, faces, text analysis, etc. The process of training deep learning networks often takes longer compared to other machine learning techniques, due to the presence of many parameters in deep learning algorithms.

The difference between neural networks and Deep learning is mainly found in the hidden layer structures. Neural networks contain one layer while deep learning contains several hidden layers. These multiple layers enable deep learning to recognize features in the data without human intervention [8]. Deep learning techniques vary according to several factors, as shown in Fig. 6 [9].

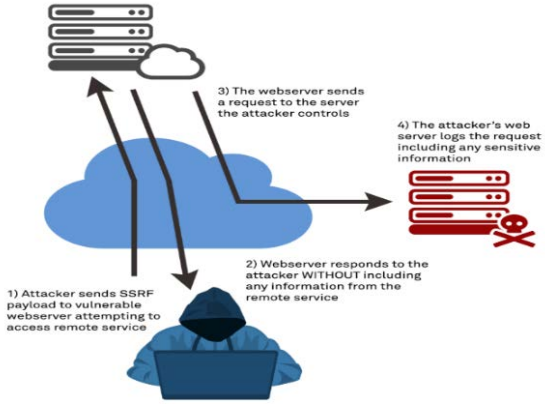

Fig. 3. Blind SSRF [5].

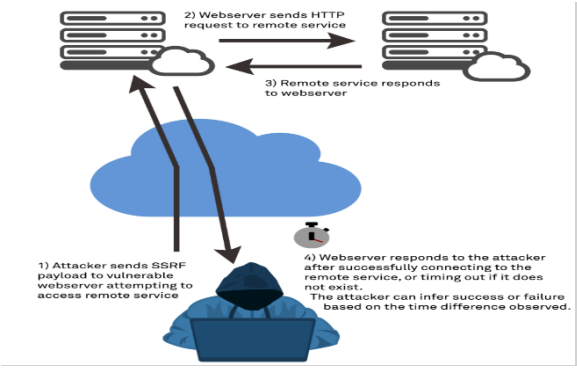

Fig. 4. Semi-Blind SSRF [5].

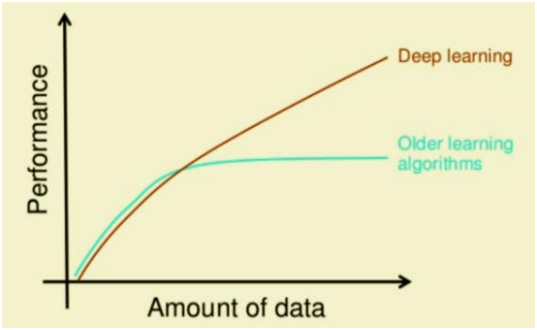

Fig. 5. Machine Learning Techniques Scale with Amount of Data (source [7]).

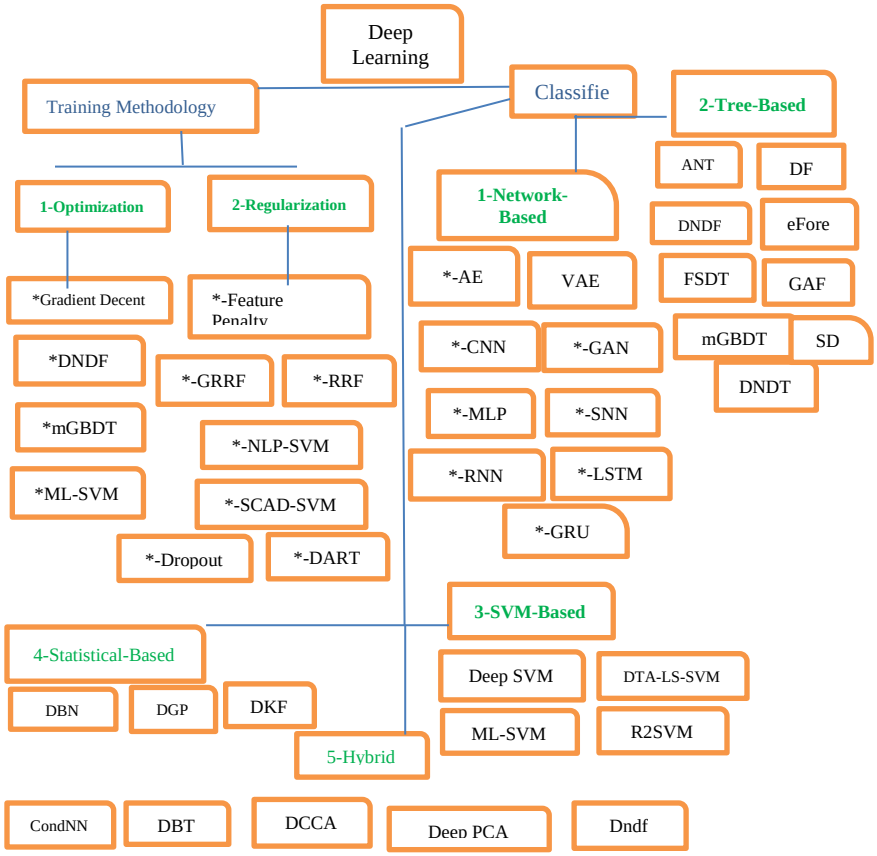

Fig. 6. Deep Learning Methods (source [9]).

II. Related Work

There are several studies concerned with how to detect attacks against web applications, as well as how to face these attacks and overcome them. Various techniques have been used to detect and mitigate these attacks, most of which are concerned with the use of machine learning techniques. we discuss many of the researches concerned with Preventing Server-Side Request Forgery Attacks by discovering them and preventing them from making any threat. Several methods have been used to detect this type of attack. Most of this research was based on artificial intelligence techniques because of their flexibility in application.

In [10], a defensive method was shown to protect web servers from SSRF attacks, and the researcher divided this method into several steps as shown in Fig. 7.

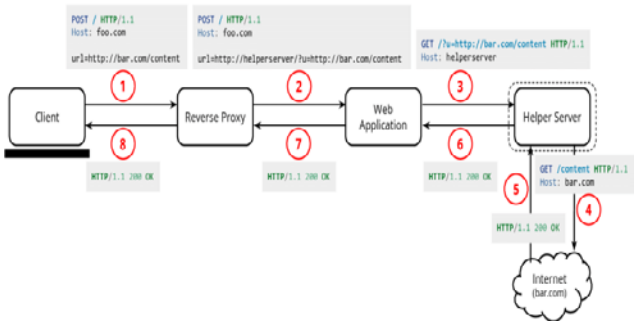

Fig. 7. Overall Architecture to Defenses from SSRF [10].

The reverse proxy located in front of the web application server, in the first step of the methodology, checks all the signals received from service seekers before allowing them to log in and use the application. If the reverse proxy finds a URL embedded in the request from the client to log in to the web application services, it automatically modifies the address and transfers this modified address to the web application server. Helper service takes the original value of the URL and executes it on the server since it cannot use services that are running on the internal network Experimental results show that the proposed solution can prevent all in-band SSRF attacks. Only one of them requires minimal developer collaboration In fact, little increase is observed in the response time in applications for the rest of the applications in the response time.

The researcher at [11] presented a deep learning-based model to discover attacks against web application. This model uses a deep learning technique which is an auto-encoder that is able to learn from the presence of a sequence of words while giving weight to these words according to their presence in the sequence. The model receives an entry request for the web application and then decodes and encodes the requests vector and calculates the reconstruction or loss error. If the loss error value is large then it classifies this request as anomalous requests, and conversely if the value is low then the request is classified as normal requests. The threshold θ is set to determine how small or large the loss error is. The experimental results show that the proposed model can detect web applications attack with low false positive rate and true

positive rate is 1. Because of less volume of labeled categorized anomalous dataset, the proposed classification engine is not 100 percent accurate; however, the classification can be improved with optimized training with a large volume of dataset, which is left as the future scope of the work.

In [12] end-to-end deep learning is applied to detect cyber-attacks astronomically in real-time. The intelligent part of the proposed framework is illustrated in Fig. 8. Authors evaluate the feasibility of an unsupervised/semi-supervised approach for web attack detection based on the Robust Software Modeling Tool (RSMT), which autonomically monitors and characterizes the runtime behavior of web applications. RSMT operates as a late-stage (post-compilation) instrumentation-based toolchain targeting languages that run on the Java Virtual Machine (JVM). It extracts arbitrarily fine-grained traces of program execution from running software and constructs its models of behavior by first injecting lightweight shim instructions directly into an application binary or byte code. These shim instructions enable the RSMT runtime to extract features representative of control and data flow from a program as it executes, but do not otherwise affect application functionality. shows the high-level workflow of RSMT's web attack monitoring and detection system. This system is driven by one or more environmental stimuli, which are actions transcending process boundaries that can be broadly categorized as either manual or automated.

In [13], an accurate and light-weight Android malware detection method is proposed. This method takes an APK-formatted Android app and passes it on to a deep learning network (1-D CNN) to be analyzed to discover the extent of the app's damage. The training and testing steps for this method are shown in Fig. 2. The training process is dependent on 5,000 malwares and 2,000 good wares. We confirmed our method using only the last 512-1K bytes of APK file achieved 95.40% in accuracy discriminating their malignancy under the 10-fold cross-validation strategy as shown in Fig. 9.

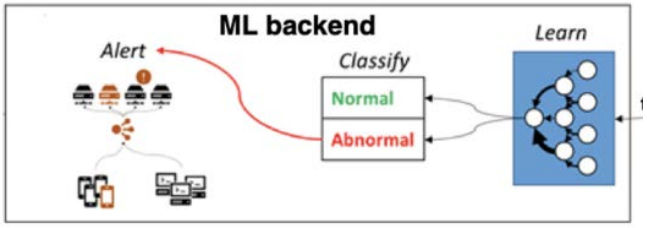

Fig. 8. Train the Classifier to Detect [12].

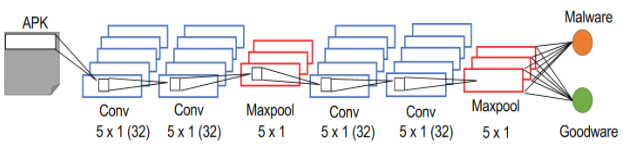

Fig. 9. 1-D CNN Model for Malware Discrimination [13].

In [14] a strategy is presented to discover real-time SSRF activities in the Amazon Web Services environment. This strategy consisted of several steps as follows:

- Detection using VPC Traffic Mirroring
- Detecting SSRF using Zeek
- Detecting SSRF using Suricata
- Detection using iptables

In [15], the researcher introduced a network-based intrusion detection system (NIDS) based on deep learning and machine learning techniques. This system is aimed at detecting intrusion on the network by examining the traffic through it. The general AI-based NIDS methodology for this paper is illustrated in Fig. 10 [16]. Table I covers the literature review evaluation.

III. METHODOLOGY

In this Paper, Long Short-Term Memory (LSTM) is used as a deep learning technique to build a model to detect SSRF attacks. Long Short-Term Memory (LSTM) architecture overcomes vulnerabilities in RNN networks [17]. In the first part of our methodology, we collect a dataset. Dataset obtained from the Canadian Institute for Cybersecurity of the University of New Brunswick. This dataset contains many features; we can mention some of them.

This dataset covered all types of SSRF attacks:

- Domain token count, avgpathtokenlen, tld, Arg URL Ratio.
- Number of DotsinURL, Arguments Longest Word Length.
- Spchar URL delimeter Doman, delimeter path, Number Rate.

- Directory Name, Symbol Count Domain, Entropy Domain.

Pre-processing and transformation the data before it is used to train and test machine learning algorithms is essential for creating high-accuracy models. Also, the data that determines whether there is an attack or not, be converted from text to numerical form to facilitate the training process of the deep learning algorithm. Then The text 'benign', 'Defacement' values have been converted to (0-1) to fit the LSTM deep learning network training process Among the important processes of data processing in this Paper is the transformation of data into a form suitable for analysis. Where scaling techniques were used to improve the possibility of recognizing data patterns by deep learning model. All data items is scaled to (-1,1) to enhance the training process.

A. *Learning Methodology*

The LSTM network that used to build the model in this Paper be explained in Fig. 11.

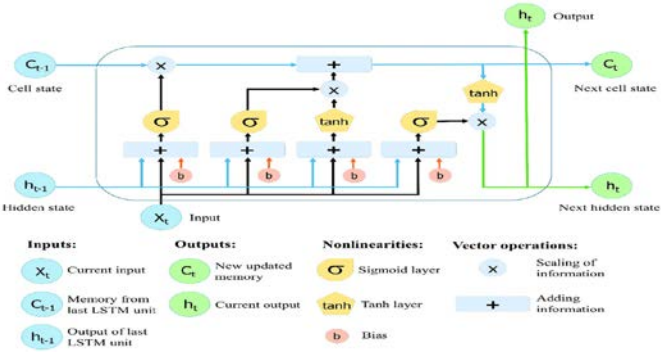

Fig. 11. LSTM Network.

LSTM networks are specifically designed to learn long-range dependencies and avoid problems with RNN. The idea of this type of network is to have a repeating edge inside each cell with weight w = 1. This eliminates the problem of the vanishing gradient problem, since repeated multiplication by 1 neither diverges nor converges to zero. Information flows on two levels from one step to the next while updating the weights is controlled by so-called gates. Gateways use various activation functions to redirect or stop the flow of information. The central change within the LSTM model as opposed to the RNN model or the feedforward model is a more complex type of hidden neuron. LSTM recursive networks contain 'LSTM cells' which have an internal repeat (self-loop), in addition to the external redundancy of the RNN. As can be seen from the previous figure, each element represents a vector with multiple properties that are placed across the grid showing three time steps and a dataset containing three sequential data samples (xt-1, xt, xt+1). The central LSTM cell is shown in detail to reveal the processes within it. The grid appears only until the hidden layers are output (ht-1, ht, ht+1).

LSTM network be used in this Paper to design an intelligent model to predict the SSRF attacks.

In the part of our methodology, we learn a deep learning model to be able to detect SSRF attacks as illustrated in Fig. 12.

In the part of our methodology, we will learn a deep learning model to be able to detect SSRF attacks as illustrated in Fig. 12. To train the deep learning model, the dataset is divided into two parts, the first for the training process and the second for the testing process. The percentage of training data was 80% of the entire dataset, while the percentage of test data was 20%. Then the Feature scaling method was applied to normalize the range of independent variables, where the data range became between -1 and 1. Data now is ready to train and test the model.

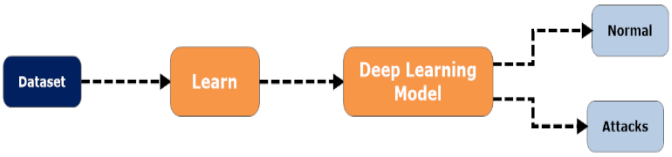

Fig. 12. Training Deep Learning Model.

After that, we can use our proposed model to detect any attacks in the HTTP Request and allow or block this entry according to the absence or presence of an attack as illustrated in Fig. 13.

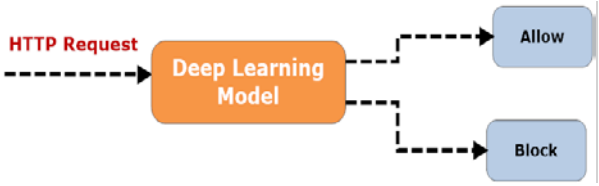

Fig. 13. Use Deep Learning Model to Detect SSRF Attack.

B. *Metrics Measures*

We rely on a set of measures to evaluate the model presented in this Paper, which is based on deep learning techniques. These measures can be summarized as follows:

1) True Positive (TP): The data instances correctly predicted as an Attack by the classifier.

2) False Negative (FN): The data instances wrongly predicted as Normal instances.

3) False Positive (FP): The data instances wrongly classified as an Attack.

4) True Negative (TN): The instances correctly classified as Normal instances.

The confusion matrix, which is generated at the end of the above-mentioned training and testing process, is used to calculate the preceding metrics. The four types (true positives, false negatives, false positives, and true negatives) as well as the positive and negative classifications are used in the template for any binary confusion matrix. Table II shows a 2x2 confusion matrix that can be used to express the four outcomes.

TABLE II. CONFUSION MATRIX PARAMETERS

Actual class	**Predicted class**		
		Class= yes	***Class=no***
	Class =yes	True positive	False negative
	Class=no	Fales positive	True negative

IV. Result and Discussion

Request Forgery (SSRF) attacks on web applications. The basic architecture of web applications and how this architecture is threatened are explained. Also, the types of SSRF attacks are described in this Paper. The proposed system is based on a technique of machine learning, which is deep learning technique, as it has the ability to learn, especially with the availability of a large amount of data.

A. Methods and Tools

The software and libraries needed to construct the LSTM model, which is utilized to identify SSRF assaults, will be detailed in this section. The programming language used is Python, which contains a huge number of external libraries. The diversity of these libraries and their easy handling of data has led to the widespread use of the Python language in all research Paper. Among these libraries used in the proposed Paper:

1) Numpy: This library is for scientific computing to work on the creation, editing and calculation of N-dimensional array objects.

2) Pandas: This library is used to handle large numerical tables with high performance. It can handle data that contains more than 2000 columns.

3) Scikit-learnrn: This library contains many methods that are used for data processing and evaluation of machine learning and deep learning models. It has been used in this Paper to evaluate the proposed deep learning model, using accuracy, precision, Recall, F1 score metrics.

4) Keras: It is an interface for programming neural networks and deep learning applications, by accessing the top of TensorFlow to create, train and test models. This interface supports the training of neural network models on the CPU or GPU. It also supports most types of deep learning networks such as CNN, RNN, and LSTM. In this Paper, keras was used to build an LSTM model for detecting SSRF attacks [18].

B. Development of the LSTM Model

In this part, a description of how to develop, train and evaluate an LSTM network be presented. At first, the data be read from the file that contains the dataset, then a figure be drawn showing the percentage of the data containing the attack as shown in Fig. 14.

After that, the data is scaled between 1 and -1 to enhance the accuracy of the deep learning model. To prepare dataset for training and testing process, it split to the training and testing parts using the following python code [19].

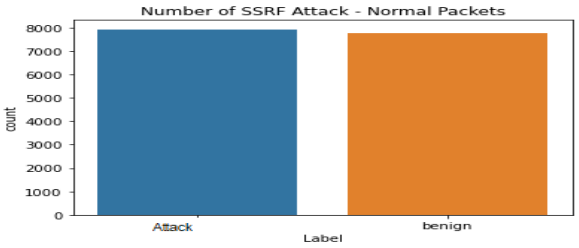

Fig. 14. Attack and Benign Percentage in the Dataset.

As a result of this code, the first 70% of the dataset is classified as training and the last 30% is used as testing data. The `X_train, X_test, Y_train, Y_test = train_test_split(X,y,test_size=0.3, random_state=6)` parameter values of LSTM network is optimized by testing its values for many times, and the final values are:

Batch size: 25

Epochs: 100

Hidden units: 20

Learning rate: 0. 005

Loss Function: MSE

A loss function quantifies how "good" or "bad" a given predictor is at classifying the input data points in a dataset. If the gap between training loss and validation loss is large its means that your model is overfitting and if training loss is large its means your model is underfitting. If your training loss and validation loss are overlapping or close to each other means your model is now good for prediction. Here the model is look good as illustrated in Fig. 15.

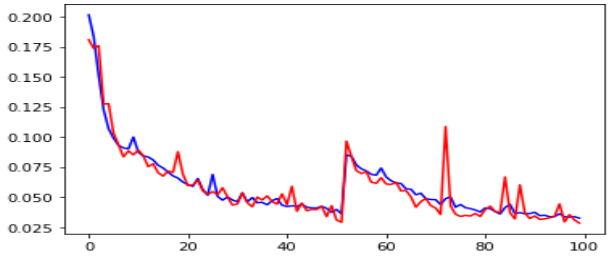

Fig. 15. Training and Validation Loss through Epoch Values.

C. Evaluation of the LSTM Model

The results of the attack detection on dataset are shown in Fig. 16 (Confusion matrix). The values of TP, FN, FP, TN is obtained from confusion matrix and can be summarized as follows:

1) True Positive (TP): 3015
2) False Negative (FN): 80
3) False Positive (FP): 112
4) True Negative (TN): 3078

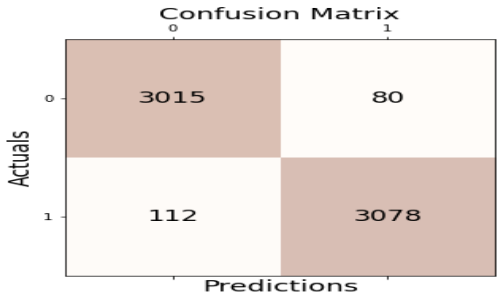

Fig. 16. Confusion Matrix for the Testing Results for LSTM Model.

From these values the metrics for evaluation the proposed model can be calculated as follows:

Precision: 0.975

Recall: 0.965

Accuracy: 0.969

F1 Score: 0.970

V. Conclusion

Server-side request forgery (SSRF) is a web application vulnerability that attackers exploit to access services on servers that an attacker is not allowed to use. In this paper a comprehensive review of the types of SSRF attacks and how they occur is presented. How to protect against these attacks is also explained with a review of literature reviews that provide various solutions to counter these attacks. Some machine learning and deep learning techniques have been demonstrated with an emphasis on the LSTM deep learning network. The LSTM network was used to design a deep learning model to detect SSRF attacks contained in URLs. This network was trained using a set of data after preprocessing operations were performed on it, and the data was scaled between values 1 and -1. This model was tested using several metrics such as accuracy to measure the accuracy of the proposed model in this Paper. The results of the deep learning model test were good, reaching 96%.

VI. Future Work

In the future, we will try to design other machine learning and deep learning models and compare them to get the most accurate model. Also, searching for another preprocessing operation to increase the accuracy of the deep learning model will be the focus of our next work.

***Abstract*—Due to environmental changes, including global warming, climatic changes, ecological impact, and dangerous diseases like the Coronavirus epidemic. Since coronavirus is a hazardous disease that causes many deaths, government of Egypt undertook many strict regulations, including lockdowns and social distancing measures. These circumstances have affected agricultural experts' presence to help farmers or advise on solving agricultural problems. For helping this issue, this work focused on improving support for farmers on the major field crops in Egypt Retrieving solutions corresponding to farmer query. For our work, we have mainly focused on detecting the semantic similarity between large agriculture dataset and user queries using Latent Semantic Analysis (LSA) based on Term Frequency Weighting and Inverse Document Frequency (TF-IDF) method. In this research paper, we apply SVM MapReduce classifier as a framework for paralleling and distributing the work on the dataset to classify the dataset. Then we apply different approaches for computing the similarity of sentences. We presented a system based on semantic similarity methods and support vector machine algorithm to detect the similar complaints of the user query. Finally, we run different experiments to evaluate the performance and efficiency of the proposed system as the system performs approximately 77.8%~94.8% in F-score measure. The experimental results show that the accuracy of SVM classifier is approximately 88.68%~89.63% and noted the leverage of SVM classification to the semantic similarity measure between sentences.**

***Keywords*—Agricultural system; semantic textual similarity; text classification; latent semantic analysis; part of speech**

I. Introduction

The semantic similarity of sentences has many real applications like Intelligent Question Answering (IQA) system. When a question is asked, the existing answer can be returned if a similar question is found in the database. In this paper, we provided a solution for calculating semantic similarity between sentences that based on vectoring sentences using their syntactic and semantic features. Semantic Textual Similarity (STS) is focusing on finding the similarity between two sentences. Similarity between the sentences is based on the explicit or implicit semantic relationships between them[1]. These relationships can be identified or measured by finding semantic relations among them. Many algorithms are presented for textual similarity. We can group them based on the algorithm or method that we used to perform the semantic similarity process.

Agriculture has a huge impact in the economy of countries. Since over a huge number of the population in Egypt is dependent on agriculture. Moreover, it considers to be one the source national economy, foreign currency, Livelihood, and food supply [2]. Further, it creates job opportunities to a large scale of the population.

This paper uses the an English approach based on latent semantic analysis [3],[4] for measuring the semantic similarity between English sentences of agricultural data and user query to find the appropriate solution for the complaints of farmers. The proposed system used SVM classification in MapReduce Hadoop environment to classify the agricultural dataset complaints based on crop name to improve the efficiency of the semantic similarity process.

Therefore, the aim of the approach is providing the support for experts and farmers in the system in Egypt. The complaints' associations are distributed over around 4242 villages and 198' centers' across Egypt [5]. In Arabic script format, these complaints' are submitted to support for farmers in their agriculture problems. Storage all farmer agriculture problems stored on a public cloud which hosting analytics toolkits [6], [7].

In our approach, first; the farmer submits his agriculture problem in the Arabic language; then, Google machine translation is used to translate the problem from Arabic into English. Second, Analyses of the complaints through data analytics techniques to extract (most) term frequency and classify the query to which crop class using support vector machine in map/reduce model. The classification process might take some time to correctly classify the crops. Third, Building an automated support response by searching for similar complaints within the agriculture complaint datasets. We saved our dataset on the public cloud to store massive data or the number of complaints as big data. Our key focus has been on calculating the semantic similarity between Arabic and English cross-language sentences using LSA. We consider different methods like term frequency weighting and inverse document frequency to identify words in each complaint. The rest of the paper is presented as follows: Related Work in Section II describes a few Semantic Textual Similarity approaches. In Section III, Proposed System, we present our proposed LSA with SVM classification. Section IV, Discussion and Results describe the experimental results of

these methods. Finally, the Section V, Conclusion will be presented.

II. Related Work

Words can be similar in two ways lexical or semantical. Similar lexical words, if the words have the same sequence of character. Similar semantical words, if they have almost the same meaning, used in the same way, used in the same context. The String-Based algorithm is based on lexical similarity. Corpus-Based and Knowledge-Based algorithms are based on Semantic Similarity. String similarity measures operate on word sequences and character composition. It can be categorized into two sets: Character-Based Similarity, Term-based Similarity Measures. Character-Based Similarity like longest Common SubString (LCS) algorithm. N-gram algorithm Smith-Waterman [8]. Term-based Similarity Measures like Cosine similarity measure, Euclidean distance, Jaccard similarity, and Block Distance that also called Manhattan Distance.

Corpus-Based Similarity: Latent Semantic Analysis (LSA) [3] is the most popular technique of Corpus-Based Similarity. Hyperspace Analogue to Language (HAL), Generalized Latent Semantic Analysis (GLSA), Explicit Semantic Analysis (ESA), Normalized Google Distance (NGD). Knowledge-Based Similarity can be categorized into three groups like: (1) node-based/ information content (IC): like Resnik (res), and Conrath (jcn), (2) edged-based like Lesk, and vector pairs, and (3) hybrid where it combines both node and edge-based. We used LSA corpus-based algorithm in our work that depending on the corpus and word embedding to compute the semantic similarity degree between the sentences.

Nagoudi et al. [9] presented a word embedding representations for calculating the semantic similarity between Arabic and English sentences. This paper used machine translation and word embedding approach to get the properties of words like semantic and syntactic. Machine translation is used to translate English complaint into the Arabic one for applying a classical monolingual comparison. Word embedding methods are applied to measure the semantic similarity. The proposed method is used Bag-of-word alignment, IDF, and part of speech weighting to determine the most descriptive words in each sentence. The performance of this approach is evaluated on the four datasets of the shared task of SemEval in 2017. The results achieved the best accuracy rate compared to the other systems in the semantic text similarity in Arabic-English cross-language of SemEval 2017.

Wafa Wali et al. [4] proposed several methods for calculating the semantic similarity among two English sentences, which consider semantic and syntactic knowledge. It presented a technique for measuring sentence similarity, which combined the three components: lexical similarity, semantic similarity, and syntactic-semantic similarity. Lexical similarity included the common words, the semantic similarity used for finding the synonymy words, and the syntactic-semantic similarity based on common semantic arguments, thematic role, and semantic class. The word-based semantic similarity is measured for estimating the semantic degree among words by exploring the WordNet "[10] is a" taxonomy. Furthermore, the semantic argument is determined by the VerbNet database. The experiments are applied on the Microsoft Paraphrase Corpus and shown the metric F-score compared to other metrics. The results are shown that the proposed technique could support using several sentence features like semantic arguments and properties in measuring the sentence similarity. Therefore, this technique can be applied in many applications, such as plagiarism detection.

The author in [11] presented both the design and implementation of an evaluation system for English short answers. Handwritten Short Answer Evaluation System (HSAES) is an automated short answer system for determining the answer in answer papers and testing each short answer's marks depending on the model's knowledge during training. The proposed system was used the Optical Character Recognition (OCR) tools for extracting handwritten texts. Natural Language Processing is applied to retrieve the main feature from person tested datasets for answer keys and the handwritten of answer papers. The proposed system was used the cosine similarity approach for measuring the semantic similarity among sentences. Marks were given to each sentence in the evaluated answer paper. The developed model was applied for assessing the un-scored short answer marks.

Chandrathlake et al. [12] focused on providing an accuracy level for English news posts written on social media. The proposed system performed many functions: extract the news item's content, search the Internet for finding the similar posts in online articles sources, match the returned content with the online article sites' content and finally generate the accuracy level. Many Natural Language Processing techniques are used for developing this model like web scrolling, text summarization, URL ranking, and semantic similarity methods like Word2vec, part of speech, and cosine similarity. This system achieved an accuracy of 70% for the news posts on social media comparing with the trustable online news in the social media.

Taieb et al. [13] proposed a Features-based Measure of Sentences Semantic Similarity (FM3S) approach for computing the semantic similarity between English sentences. The proposed method combined three methods: the noun semantic similarity, the verb semantic similarity and the common word. This approach used the information content-based measure in computing similarity between keywords using the WordNet [14]. The experiments are performed and tested on the Microsoft Paraphrase Corpus (MPC) and scored the best results compared with other metrics for high similarity thresholds. The results showed that FM3S proved the importance of syntactic information, compound nouns, and verb tense in computing the semantic similarity.

Xiaolin Jin et al. [10] proposed a model based on Word2vec for measuring the semantic similarity between English sentences. This method was presented to solve the low universality problem and the contextual information's absence in calculating the word based on the dictionary. This method improved the approaches based on the Chinese dictionary, e.g., HowNet and Tongyici Cilin. It also used the word vector model as a weighing parameter for measuring the word

similarity after comparing the words' similarity by giving different weights to the three methods. The experiments were conducted on this algorithm and achieved a high Pearson coefficient. The proposed method could include most words that could effectively solve the word similarity calculation problem in the dictionary.

Many work related to SVM in the parallel environment (or distributed system) have introduced in Ngoc et al. [15], Wen et al [16], and Rao [17] . There are many researcher papers using Cloudera and Hadoop [18] Map/reduce. Studies using SVM [19] in parallel environment for semantic classification are proposed. However, there isn't work which combine them such as: Hadoop Map/ Reduce, SVM classification, parallel system, and semantic similarity. Our new system uses all of them.

III. Proposed System

This section presents the proposed system main steps as shown in Fig. 1. The proposed system has five steps: (1) translate the user query (farmer complaint) from Arabic into English language (2) preprocessing the farmer query; (3) classification method using SVM in map/reduce model (4) Finding the word vector, building the sentence vectors matrix using LSA; and computing the similarity between sentence vectors by using vector similarity methods like cosine similarity (5) The problems are ranked and then select the one with the highest semantic score.

A. Translation

In this step, the complaint text is translated into English language. We used Google Cloud translator API [20] to translate the Arabic sentence into English one.

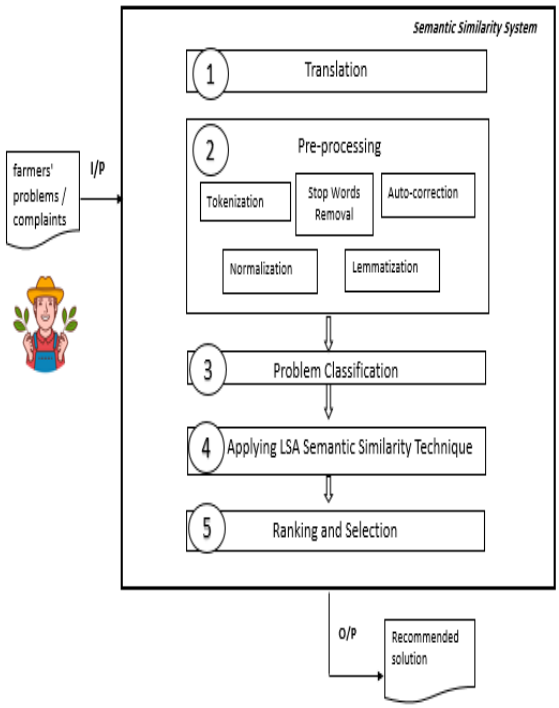

Fig. 1. The Proposed System.

B. Preprocessing

The farmer who describes the problem information like: the crop name, planting and watering method, and soil type. The farmer's query may contains useful words that effect the text processing phase. Pre-processing is important for removing the noise rows or data from historical complaint/response. It is focused on the historical agriculture dataset and farmer query to be used in this step [21]. Data pre-processing has many steps, like as: "tokenization", "stop words removal", "auto-correction", "normalization", and "lemmatization".

1) Tokenization : is the process of dividing written text into units (tokens) [21].White spaces, commas, semicolon and punctuations are used as a segment point in various languages especially in Arabic and English.

2) Stop words removal: is the process of removing unnecessary words. There are some words that are less importance, less useful, and less informative. These words are called stop words such as words in English complaints like "the", "is", "and", "an","a", etc. To enhance and generate a better solution, it is necessary to eliminate and remove these words using a predefined list. We also used the WordNet database that has a list of all English words. WorldNet is a huge lexical database of English verbs, nouns, pronouns, adjectives, and adverbs that are used for knowledge-based semantic similarity. WordNet's Relations make it a useful tool for natural language processing and computational linguistics.

3) Auto-correction: is used to correct errors made by the farmer when entering the complaint text. The complaints can also contain words written in a slang language. Auto-correction is used to solve such problem by replacing the incorrect word with the correct one.

4) Normalization: is the process of transforming the input text into a standard form. It focuses on removing inconsistent variations or unwanted data such as: "riice" is transformed to "rice".

5) Lemmatization: is the process of finding the base form of words, such as: "fruits" is transformed to "fruit".

C. Classification

In this phase, the classification is made semantically using SVM map reduce approach which is applied on the agriculture dataset and the farmer query in a parallel manner. The classification is paralleled between several machines using a Hadoop cluster with MapReduce [19], programming model for our work. Our approach is based on the English data set. The dataset is classified into a number of crop names like Wheat, Rice, Cotton, Local Bean, Tomato, Corn, Onion, and Beet Each group contains the SVM using Hadoop Map (M)/Reduce (R) is applied to classify the farmer query based on which crop class belongs to find the suitable solution.

D. LSA

Once the farmer complaint text and historical agriculture dataset are pre-processed and classified, and word vectors, the next step is to build a semantic model to compute the semantic similarity between the farmer query and the historical

agriculture dataset. LSA Algorithm builds in three main steps, Input Matrix Creation, Singular Value Decomposition (SVD), and Sentence Selection. Almost all previous works perform the first two steps of latent semantic similarity algorithm are in the same way. There is some difference in the word weighs like term-frequency and part of speech tagging which used to fill in the input matrix. Another difference is that they select words in the two sentence to measure the similarity [3] , [22]. The developed semantic model is based on LSA. LSA [23] is one of the most and important corpus-based techniques used for measuring semantic similarity. It consist of three steps are input matrix creation, singular value decomposition (SVD), and sentence selection.

A word co-occurrence matrix is calculated where the rows filling with the main words and columns filling with the sentences and the cells values have word occurrence counts. This matrix has an important underlying corpus so SVD dimensionality reduction is applied using a mathematical techniques. Such dimensionality reduction is highly used to: (i) minimize the output dimensionality and (ii) increase overall performance. Finally, the semantic score is calculated for each farmer complaint; then the sentences are ranked according to the semantic score to select the closest solution to the farmer query.

In this phase, an input matrix is computed for the farmer query and historical agriculture dataset. Each row in the matrix represents the word or term in the farmer query. Each column represents the problem. The cell value is the result of the intersection between term and problem. There are two ways that are used for filling the cell values, which are Term Frequency-Inverse Document Frequency (TF-IDF) or Term Frequency (TF). In TF-based LSA, the cells are filled with the term frequency (TF_i) of terms in the complaint query (C_j) according to Eq. 1.

$$W(t_{ij}) = tf_{ij} \quad (1)$$

Where $W(t_{ij})$ the weight of a term (i) in each problem (j), and tf_{ij} is the frequency of a term (i) in each problem text (j). In LSA bas based on TF, the cells are filled with the weight of term (i) in

problem statement (Cj) according to Eq. 2.

$$TF - IDF_{ij} = TF_{ij} * IDF_{ij} \quad (2)$$

Where TF-IDFij is TF is the frequency of a term (i) in each complaint statement (j), and IDF explain the importance of N terms between all problems.

E. Ranking and Selection

The semantic similarity is measured as the cosine value output between these sentences vectors. LSA system is generalized by changing rows with texts and columns with samples and can be used to compute the similarity between sentences, paragraphs, and documents. After applying the SVD matrix, the cosine similarity method will be calculated between the user complaint and each historical data problem to find the most suitable answer to identify the similarity among them. The cosine is calculated as Eq. 3:

$$\text{cosine similarity}(X, Y) = \frac{X.Y}{\|X\|.\|Y\|} \quad (3)$$

Ordering the agriculture problems based on to the semantic similarity result as shown in Fig. 2 decision function, and then select the problem (complaint) with the highest score based on the semantic similarity score.

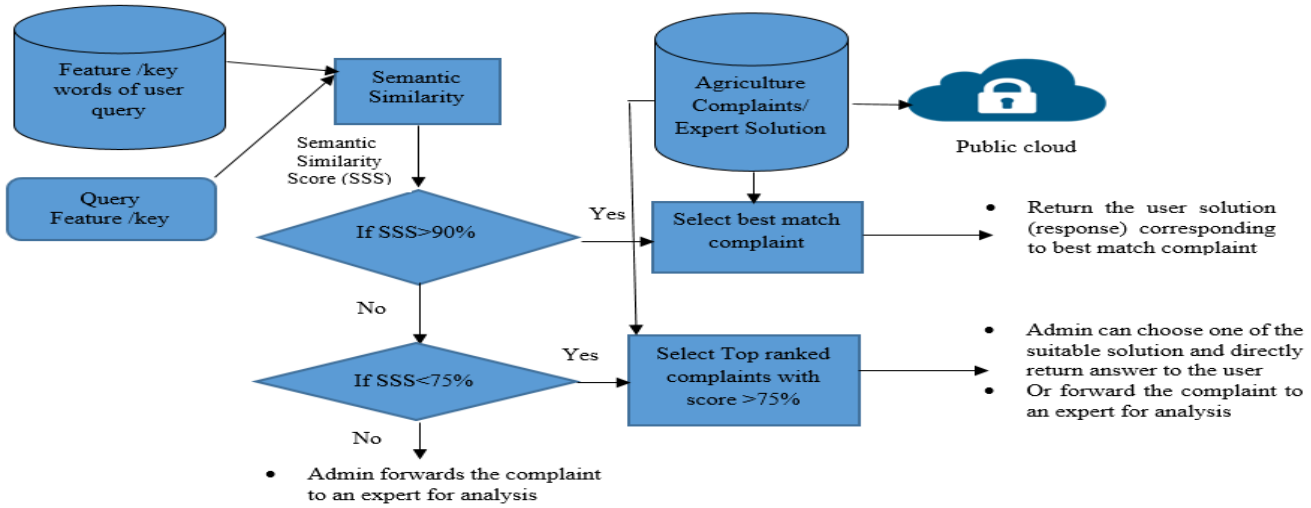

Fig. 2. Decision Function.

IV. Decision and Results

A. Environmental Setup

We used python programming language to implement our LSA model. The dataset is divided into 80% training and 20% testing with 10 experiments. We train the agriculture data set. The experiments are performed in devices with the following properties as shown in Table I.

B. Dataset

The dataset collected from Egypt's Virtual Extension Research Communication Network(VERCON) [5] and Agriculture Research Center (ARC), it contains historical complaints and solutions provided by the experts in text forms in English language complaints. The agricultural dataset was deployed on a public Cloud. The dataset is important because it has complaints/solutions from different agricultural problems that contain data for the main crop like: corn, cotton, wheat, and rice, also problem categories like environment, irrigation, pest, weed, diseases, and farming. Table II shows some examples of VERCON dataset. Table III presents the number of complaints in VERCON dataset in each crop.

C. Result Analysis

Consider the farmer query example: as presented in Table IV; firstly the farmer query is translated into English using google API. Secondly we apply preprocessing on the farmer query. Third, classify farmer query based on crop name by using SVM classifier in Hadoop Map/Reduce. Fourth create term frequency matrix. Fifth; compute semantic similarity score from the generating LSA matrix using TF-IDF or TF as shown in Tab. 3. The semantic similarity using TF-IDF achieved better result than the TF, because TF-IDF method shows the important features in each complaint however TF shows the number of term occurrence that appears in a complaint. Finally, ranking the complaints according to the semantic similarity score, and return solution of the farmer query with the highest similarity result.

We apply accuracy measure is to calculate the accuracy of SVM classification before semantic process. SVM is also used to predict the farmer query belongs to which crop class before being combined with semantic similarity process. The results show that the performance of classification with accuracy is approximately 88.68%~89.63%, as shown in Table V.

We proposed semantic similarity approach when using TF-based LSA and TF-IDF-based LSA. The work was evaluated using different measures like F-measure, precision and recall. F-measure expresses a trade-off between the two measures, precision, and recall as shown in Tables VI, VII and VIII. We compare our proposed results with the other models like POS (Part of Tagging) [24], [25]. The work was tested and evaluated on our agriculture data set. We test our dataset on different crop such as Wheat Rice, Cotton, Local Bean, Tomato, Corn, and other crops as shown in the following tables.

The F-measure in Table VI using TF-IDF weights scores the highest one about 0.939 in cotton crop, then the TF (term frequency) about 0.899 in the TF in Table VII while part of speech (POS) in Table VIII is 0.889. We run different kind of queries and get the average of F-measure, precision and recall. The F-measure in in Table VI using TF-IDF weights of F-score approximately 77.8%~94.8%, then the TF (term frequency) approximately 75.7%~92.3 while part of speech (POS) is approximately 73.3%~91.4%.

TABLE I. Environmental Setting

Item	Description
programming language	python
Processor	dual-core processor
CPU	Pentium CPU speed of 6.00 GHz
GPU(Graphics processing unit)	Tesla V100-SXM2-8GB
RAM (Random Access Memory)	8GB

TABLE II. Example of Dataset Complaints

Complaint	Solution
How to treat piercings with rice	Fyuridan is used at a rate of 6 kg per acre.
Yellowing of the lower leaves and the drying of the edges of the leaves in wheat.	Yellowing of the leaves at this time is normal, especially the lower one, to reach the ripening stage of the crop.
White spots on the leaf, spikes and stems feel cotton.	These symptoms of microflora disease, and if the infection requires severe chemotherapy, is spraying with a sumateite at a rate of 35 cm / 100 liters of water.

TABLE III. numer of complaints in historical dataset

Crop Name (English)	#of Complaints	Crop Name (English)	#of Complaints
Wheat	1073	Mango	435
Rice	1021	Citrus	254
Cotton	937	Grapes	247
Local Bean	783	Eggplant	227
Tomato	757	Green Pepper	199
Corn	648	Cucumber	178
Onion	546	Zucchini	168
Beet	461	Orange	153
Potato	440	Garlic	151
Clover	321	Guava	146

TABLE IV. An Example of System Process

Process	An example
Farmer query	يقع صفراء على أوراق نباتات البصل.
Translation	Yellow spots on the leaves of onion plants.
Tokenization	Yellow, spots, on, the, leaves, of, onion, plants
Stop word removal	Yellow, spots, leaves, onion, plants
Lemmatization	Yellow, spot, leaf, onion, plant
Classification	Onion class
Solution	These are the symptoms of onion thrips infection and it is treated with a 50% Acylac pesticide at a rate of 500 cm/100 liters of water, or a 72% silicron pesticide at a rate of 750 cm/f.

TABLE V. THE EVALUATION OF THE SVM CLASSIFICATION IN DATASET

Crop Name	# of records	Correct classification	Incorrect classification	Accuracy
Wheat	1073	955	118	89.19%
Rice	1021	909	112	89.03%
Cotton	937	834	103	88.98%
Local Bean	783	691	92	88.23%
Tomato	757	668	89	88.50%
Corn	648	572	76	88.43%
Onion	546	482	64	87.13%
Beet	461	407	54	89.23%
Potato	440	388	52	88.23%
Clover	321	282	39	88.58%
Mango	435	383	52	89.36%
Citrus	254	224	30	88.41%

TABLE VI. EVALUATION MEASURES FOR USING TF-IDF FOR EACH CROP

crop name	TF-IDF		
	Precision	**Recall**	**F-score**
Wheat	0.849	0.855	0.852
Rice	0.841	0.856	0.848
Cotton	0.926	0.952	0.939
Local Bean	0.864	0.853	0.858
Tomato	0.893	0.866	0.879
Corn	0.867	0.899	0.883
Onion	0.955	0.941	0.948
Beet	0.902	0.895	0.898
Potato	0.925	0.915	0.921
Clover	0.822	0.856	0.839
Mango	0.785	0.795	0.793
Citrus	0.796	0.813	0.804
Grapes	0.773	0.784	0.778
Eggplant	0.899	0.875	0.887
Green Pepper	0.866	0.879	0.872
Cucumber	0.866	0.879	0.872
Zucchini	0.942	0.954	0.948
Orange	0.864	0.855	0.861
Garlic	0.941	0.948	0.938
Guava	0.796	0.813	0.804

The results show that the proposed text similarity LSA model using the TD-IDF method resolves the problem of the low recall of words in traditional semantic approaches well, and high the similarity performance of relevant words more than using only term frequency (TF) as shown in Tables VI, VII and VIII. The tables show the different measures for using TF-IDF, TF and POS for weeds, pests, diseases and irrigation categories.

TABLE VII. EVALUATION MEASURES FOR USING TF FOR EACH CROP

crop name	TF		
	Precision	**Recall**	**F-score**
Wheat	0.773	0.795	0.784
Rice	0.891	0.874	0.882
Cotton	0.902	0.896	0.899

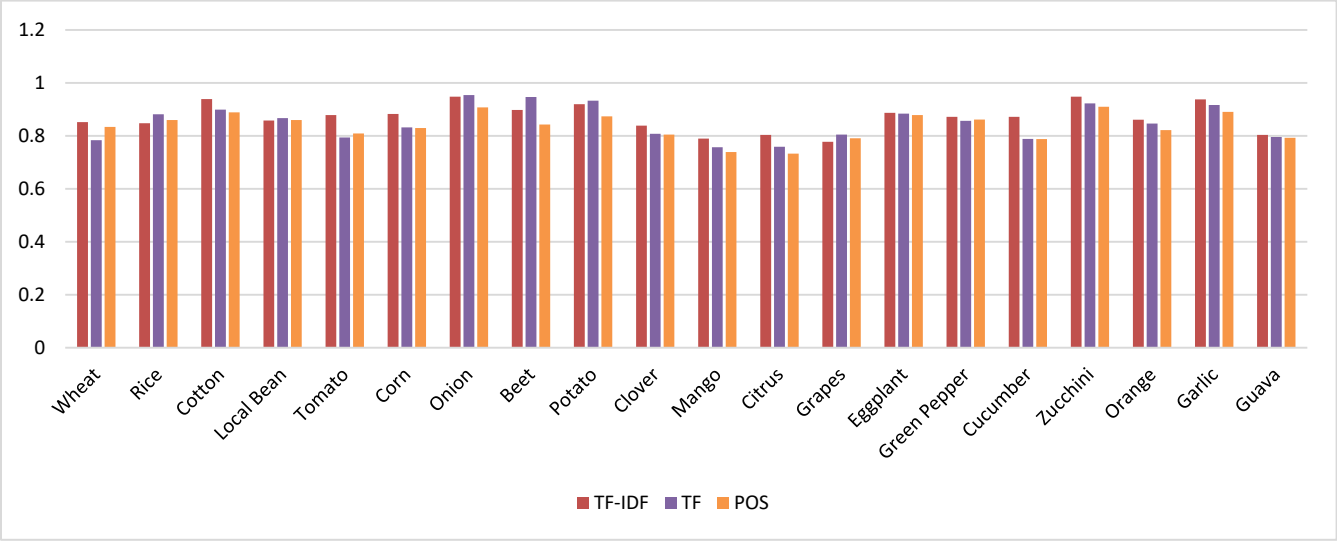

Fig. 3. F-score Values for different Metrics.

As a result, by evaluating the different experimental results of TF, TF-IDF and POS weight, we summarized that the results of LSA approach based on TF-IDF have the highest average F-measure as presented in Fig. 3.

V. Conclusion

Our work in this paper focused on building a semantic model for the available agricultural data, the design of interfaces and features for the system to ensure timely advice, easy access, consistency, and broadcasting service possible to farmers. We used MapReduce SVM classifier in Hadoop MapReduce to classify agricultural dataset into crops names. The performance of the system achieved better results than previous work. Also, we propose English semantic system for farmers' complaints that based on Latent Semantic Analysis depend on TF-IDF term to calculate similarity between user query and the complaints in the agriculture database. The results are tested on twenty different crops and also different complaint queries are applied on each crop. The system performed F-score with 0.939 using TF-IDF, then about 0.899 in the TF. The developed system with LSA based on TF-IDF achieved better results than the TF. The support provided by the system will be quickly and reliable not only for farmers but also for the 'research centers' and 'agricultural units' with minimal resources and training needs.

In the future work we will use different methods in semantic similarity process to enhance the system performance and also classify the dataset base on problem categories like pest, weed and irrigation.

Multi-objective based Cloud Task Scheduling Model with Improved Particle Swarm Optimization

Chaitanya Udatha, Gondi Lakshmeeswari
Department of Computer Science and Engineering
GITAM (Deemed to be University)
Visakhapatnam, India

***Abstract*—Now-a-days, advanced technologies have emerged from the parallel, cluster, client-server, distributed, and grid computing paradigms. Cloud is one of the advanced technology paradigms that deliver services to users on demand by cost per usage over the internet. Nowadays, a number of cloud services have rapidly increased to facilitate the user requirements. The cloud is able to provide anything as a service over web networks from hardware to applications on demand. Due to the complex infrastructure of the cloud, it needs to manage resources efficiently, and constant monitoring is required from time to time. Task scheduling plays an integral role in improving cloud performance by reducing the number of resources used and efficiently allocating tasks to the requested resources. The paper's main idea attempts to assign and schedule the resources efficiently in the cloud environment by using proposed Multi-Objective based Hybrid Initialization of Particle Swarm Optimization (MOHIPSO) strategy by considering both sides of the cloud vendor and user. The proposed algorithm is a novel hybrid approach for initializing particles in PSO instead of random values. This strategy can obtain the minimum total task execution time for the benefit of the cloud user and maximum resource usage for the benefit of the cloud provider. The proposed strategy shows improvement over standard PSO and the other heuristic initialization of PSO approach to reduce the makespan, execution time, waiting time, and virtual machine imbalance parameters are considered for comparison results.**

Keywords*—Cloud computing; task scheduling; cloud service provider; virtual machines; PSO; multi-objective; cloud service broker

I. Introduction

The rapid growth of internet data processing prompted the creation of cloud computing systems. Cloud computing is critical for providing technology-based services through the use of the internet. It gives access to computing resources like storage, network and data without requiring active user control. Cloud environments can provide three distinct services: SaaS, PaaS, and IaaS. SaaS (Software as a Service) is the top layer service that distributes software to consumers. SaaS allows users to utilize software straight from the cloud without the need to install anything locally; you can access it immediately from the cloud.

The middle one is PaaS (Platform as a Service), it allows users to develop and deploy their own applications on top of the provided platform. Finally, IaaS (Infrastructure as a service) is the bottom layer service, the capability to deliver services as servers, storage and operating system and compute resources. Cloud providers use virtualization technology to provide consumers with computational resources virtually. Optimal task scheduling strategy is essential in the multi-tenant cloud computing model for enhancing the performance of a cloud environment. An efficient scheduling strategy enables the best virtual machine (VM) allocation to the required tasks in a way that to attain the required quality of service. The purpose of optimal allocation of tasks to VMs that fits certain criteria to obtain a specific objective as a result, the scheduling algorithm is a vital part of any cloud architecture.

A. Scheduling in Cloud Environment

Nowadays, everyone is trending towards advanced technology to save management efforts, time, and personnel. Cloud Computing is a new paradigm for hosting services and delivering those through the internet. Cloud dynamically provisions platform, infrastructure, and software applications as services to the cloud users based on the pay-as-you-go model, which means charging per usage. The cloud is a metaphor for the internet and virtualization technology is the key concept used to deliver services through the cloud by maintaining data integrity. Cloud environment is a pay as you go service model and it is an important aspect to business owners to compute huge amounts of data. Scheduling helps in better utilization of resources optimally. Thus, scheduling is the heart of cloud computing for the management of resources effectively.

Scheduling is categorized into two distinct levels:

1) The first level of Scheduling under IaaS is the Task or Workflow scheduling

2) The next level is the Virtual machine scheduling under IaaS.

Fig. 1 indicates that the primary type of scheduling technique used in cloud computing is further divided into two types: workflow task scheduling and independent task scheduling.

- Workflow task scheduling enables the tasks in a specific order because the tasks are interdependent, like a parent-child relationship.
- Independent task scheduling is converse to workflow scheduling in which all tasks are independent and there is no dependency among the set of tasks.

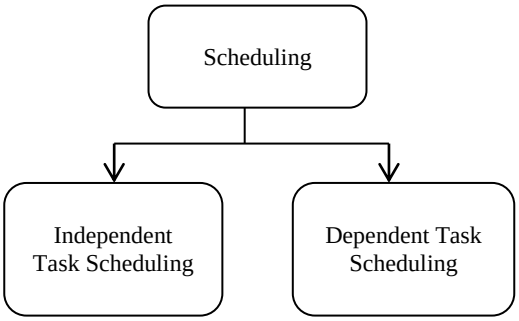

Fig. 1. Task Scheduling Categories.

Scheduling can be achieved with either static or dynamic scheduling approaches. The resources and scheduling strategy is pre-determined in static scheduling. Whereas in dynamic scheduling, the resources are allocated at the time of execution according to requirement and resource allocation can be modified during execution. Each scheduling technique can be achieved through different categories of heuristic, meta-heuristic, and combination of both approaches. Heuristic scheduling techniques are the most common type of scheduling methodology. Static scheduling is done by using heuristic methods, to give a single static solution. Cloud task allocation strategy is a type of NP-hard problem. Meta-heuristic algorithms are required to solve problems that are multidimensional in nature. They provide multiple solutions dynamically. Several researchers proposed multi-stage hybrid meta-heuristic algorithms to obtain better performance, combining heuristic and meta-heuristic approaches.

The following is a proposed work summary of the key contribution of task scheduling to the current literature:

- MOHIPSO solution for optimum task scheduling strategy employs a hybrid approach that combines two heuristic methodologies such as shortest job first and minimum execution time, to initialize the particles in PSO with a good starting point to explore the search space more efficiently instead of random values.
- Creating a multi-objective scheduling technique that reduces both task execution and waiting time for the benefit of the user in reducing the cost of application based on pay per usage policy and improving resource utilization, maximizing the profit for cloud provider by reducing makespan and degree of VM imbalance.
- The proposed method was implemented in CloudSim framework by extending JSwarn package and validating the proposed method with multi-objective-based standard PSO and SJF-PSO methods.

Section II focuses on the literature review, Section III focuses on the proposed MOHIPSO model for scheduling, the outcome of the proposed method is compared and analyzed in Section IV, and the conclusion in Section V.

II. Related Work and Background

Researchers sought to discover acceptable scheduling mappings in the cloud environment using various methodologies based on heuristic and meta-heuristic approaches. Many authors have improved scheduling strategy by novel variants in nature-inspired algorithms to enhance the global search capability of traditional standard techniques to avoid premature convergence. However, the focus on scheduling using multi-objective-based algorithms was minimal.

Bangyal, Waqas Haider, et al. [1] survey provides a complete overview of the different PSO and DE initialization procedures based on the Sobol, Halton, and random distribution families of quasi-random sequences. The fundamental purpose of the proposal was applied to various meta-heuristic approaches. It provides future work directions for the researchers.

Alsaidy et al. [2] proposed heuristic initialized PSO [3] [4] [5] outperforms among other approaches by considering of convergence and load balance, but it is a single objective based solution not able to satisfy the targets of multiple objectives by considering both cloud provider and user.

Bangyal et al. [6] proposed an enhanced version of bat algorithm using torus walk instead of uniform walk for improving local search and chaotic mapping [7] introduced for inertia weight to explore more in global search space for hyper dimensional global optimization problems. TW-BA is useful for the researchers to propose a new variant to all traditional nature-inspired algorithms.

Zhou, Zhou, et al. [8] introduced a unique variation of GA using a greedy approach to optimize scheduling strategy, which converges solution with very few iterations. This approach had considered only the makespan as a fitness function.

Ngatman et al. [9] survey on modified PSO compared to traditional PSO to solve issues of random initialization of population for convergence of best solution by exploring the search space effectively. This survey is useful for many authors to propose the advancement of PSO by considering the study.

Zhang et al. [10], [11] survey provided a thorough examination of PSO. PSO advancements by initializing with chaotic and quantum behavior, analyzed PSO with different population topologies, hybridization and extensions by discussing multiple objectives [12] and theoretical analysis of PSO were considered in various computing environments for targeting researchers from all engineering fields.

MOPSO [12] [13] [15] based new task scheduling model by E. S. Alkayal et al. [14] on a ranking strategy to achieve minimum waiting time and maximum throughput for only heterogeneous tasks but there is a chance of performance degradation for homogeneous tasks.

The proposed scheduling technique makes three main assumptions:

- The first assumption is that each task is an independent task.
- The second assumption is that users can submit n tasks, and are executed on m virtual machines, mapping tasks to VMs.

- The final one is that there is no task migration across virtual machines. That is a task cannot be assigned to multiple virtual machines at the same time.

A major challenging issues of scheduling is to schedule, distribute varying number of tasks to multiple virtual machines (VMs) and minimizing the turnaround time of a task. In the cloud environment which consists of number of data centers.

Each datacenter (DC) consists of hosts , i = 1, 2, . . ., N are presented and it can represented as:

$$DC = [H1, H2, \dots Hi \dots . HN]$$

Host(Hi) consists of VMs , i = 1, 2, . . ., N are presented in each host and it can represented as:

$$Hi = [VM1, VM2, \dots, VMi, \dots . VMN]$$

Similarly each VMi consists of tasks, i = 1, 2, . . ., N are executed on each virtual machine based on task scheduling algorithm as shown in Fig. 2.

$$VMi = [T1, T2, \dots, Ti, \dots, TN]$$

Each cloud user submitted job is considered as a task. The cloud broker acts on behalf of the user in a data center environment and abstracts VM management functions like VM creation, cloudlet assignment to these VMs, and VM destruction. CIS(Cloud Information Service) is one of the cloud entities which performs cloud resource registry and indexing. The datacenter informs CIS that they are ready to process the cloudlets. The cloud broker can communicate with this entity, which returns a list of all the VM IDs that have been registered and allocated to the tasks.

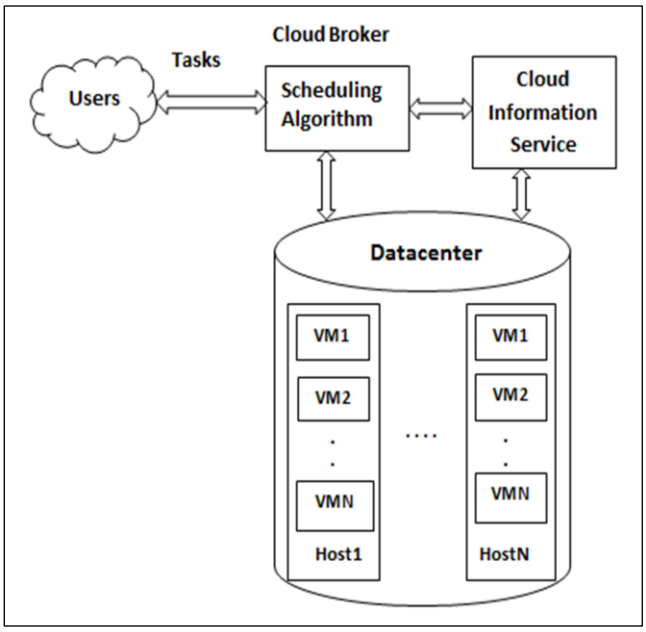

Fig. 2. Cloud Task Scheduling Model.

III. Problem Description for Proposed Methodolgy

In this section, the primary discussion is about the standard PSO method and MOHIPSO algorithm.

TABLE I. MOHIPSO Parameters

PSO Parameter	Value
Population	50
Iterations	100
α	0.05
β	0.7
γ	0.25
ω	0.9
$k1, k2$	2.0
$r1, r2$	[0,1]

Table I lists the PSO parameters considered for implementing MOHIPSO model. The PSO algorithm is a meta-heuristic population-based strategy for finding food sources in an optimal way influenced by the social behavior of birds flocking. PSO quickly gained popularity as a general purpose global optimizer. In this method, particles are moved across a multidimensional solution search space to find their destination. Each particle position changes in response to its own experiences as well as the experiences of others around it based on particle fitness value denoted by fit(X). The symbol $X(p)_i^{(t)}$ represents the location of particle position *i* at iteration *t*. It is possible to change the location of particle position $X(p)_i^{(t)}$ by adding the new random velocity $U(p)_i^{(t+1)}$ to the current position, as shown in the below equation:

$$X(p)_i^{(t+1)} = X(p)_i^{(t)} + U(p)_i^{(t+1)} \quad (1)$$

The particle velocity reflects the movement of particle position that is socially exchanged is given by the equation:

$$U(p)_i^{(t+1)} = \omega * U(p)_i^{(t)} + k1r1 * \left(X(p)_{pbesti}^{(t)} - X(p)_i^{(t)} \right) + k2r2 \left(X(p)_{gbesti}^{(t)} X(p)_i^{(t)} \right) \quad (2)$$

In (2), k1 and k2 are used as constant factors of a particle for personal and global influence, respectively. In this equation, ω denotes the inertia weight of a particle, which is used to control the movement of the particle velocity.

$$X(p)_{pbesti}^{(t+1)} = \begin{cases} X(p)_i^{(t+1)}, if\ f\left(X(p)_i^{(t+1)}\right) < f(X(p)_{pbesti}^{(t)}) \\ X(p)_{pbesti}^{(t)}\ otherwise \end{cases} \quad (3)$$

$X(p)_{pbesti}^{(t)}$ denotes local best position of the particle, $X(p)_{gbesti}^{(t)}$ denotes the particle best position of the entire swarm globally and $r1 \& r2$ denotes pseudo random values within the range between 0 and 1 at each iteration i.

B. Proposed MOHIPSO Model

One of the criteria used to classify the meta-heuristics algorithms for optimization problems by considering the no. of objectives, they are single objective, multi-objective [12] [13] and many objectives [11].

The propsed Multi-Objective based Hybrid Initialization of Particle Swarm Optimization (MOHIPSO) algorithm determines which virtual machines are most ideal for scheduling tasks and finds the most efficient task scheduling

schema. Total n tasks t1, t2, . ., tn are defined in the task scheduling model, and they must be allocated to m virtual machines (vm1, vm2,...,vmm) in order for them to be executed.

Algorithm 1: Pseudocode for MOHIPSO

Input: Tasks, Task length, VMs ,VM Processing rate
Output: Task scheduled on VM
Start:
Initialize particles Xi with SJFP-MET algorithm
For each iteration i
For each particle Xi
calculate TET , MS and DI applying Eqs. 3, 4 and 5.
calculate the fitness function fit (X) applying Eq. 6.
Find X(p)pbesti and update the velocity value by 2
Update the position of the particle according to Eq. 1.
End
Find X(p)pbesti
End
Output the optimal task scheduled with X(p)gbesti

In the proposed MOHIPSO, particles are initialized with a good starting point with the help of hybrid strategy of using minimum execution time (MET) [16] and shortest job to fastest processor (SJFP) [2] to explore the search space effectively instead of random selection. In each iteration multi-objective fitness value is used to find the particle local and global best values by updating velocity randomly and tasks are scheduled on VMs based on $X(p)^{(t)}_{pbesti}$.

C. Task Scheduling Problem Description

The scheduler determines which task should be assigned to which machine.

Cloud Task Scheduling helps in:

- Reducing operational cost.
- Reducing waiting time.
- Increasing resource utilization.

Table II lists cloud simulation parameters considered for the proposed task scheduling strategy implemented on the CloudSim framework. The simulation initially starts by initializing the CloudSim clock instance and creating a data center and datacenter broker. VM and cloudlet specifications as per Table II were created and submitted to the cloud broker. MOHIPSO model is used to schedule the tasks to specific VMs based on resource availability.

The proposed work improves the PSO algorithm for scheduling tasks in a cloud environment with a multi-objective decision problem. This context mainly considers the three objectives: execution time, makespan, and degree of imbalance. It is expressed as follows:

Execution Time (ET): The time required for processing a task on a particular virtual machine.

$$ET_{ij} = \frac{TLeni}{VMj}$$

TABLE II. CLOUD SIMULATION PARAMETERS

Cloud Parameter	Value
No.of Tasks/ Clouldets	10-50
Task Length (MI)	1100-2000
Cloudlet file size	300
Cloudlet output size	300
No.of VMs	5
VM Processing rate (MIPS)	500-900
VM RAM (MB)	512
VM Bandwidth (Mbps)	1000
Vmm Name	Xen
VM Pes Number	1
Data Center	1
Host	1

ET_i denotes Task i execution time on VM_j and T_{Leni} denotes ith task length specified in MI (Million Instructions).

Total Execution Time (TET): It is the summation of all tasks processing time.

$$TET = \sum ET_{ij} \quad (3)$$

Makespan: It is the last task finishing time on virtual machine.

$$MS = Max\ \{ ET_{ij} \} \quad (4)$$

MS is the maximum make span of all VMs.

Degree of Imbalance (DI): The difference between the maximum and minimum execution time and the total execution time.

$$DI = \frac{Max\{ ETij \} - Min\{ ETij \}}{TET} \quad (5)$$

The fitness function in (6) is calculated based on TET, MS and DI using weighted sum method for MOHIPSO method as follows:

$$fit(X) = Min\{\alpha * TET + \beta * MS + \gamma * DI \} \quad (6)$$

Where parameter α refers to the weight of total execution time, β refers to the weight of makespan and γ refers to the weight of degree imbalance. fit(X) function is considering three parameters specified in the equations (3),(4) &(5) and three control parameters such as α, β and γ with in the range of [0,1] and sum of α+β+γ=1 and these parameters values are specified in Table I.

IV. RESULTS AND COMPARISION

MOHIPSO algorithm is compared with two other variants of PSO algorithm. The first variant of PSO is a multi-objective based PSO algorithm by considering MS, TET and DI objectives for finding the fitness value of a particle and the second variant of PSO is called as SJF-PSO, in which initialization of particles with SJFP algorithm and multi-objective based fitness value is calculated to map the tasks to VMs. Finally proposed MOHIPSO is a combination of Standard PSO with MET and SJF-PSO gives better performance compared with existing algorithms.

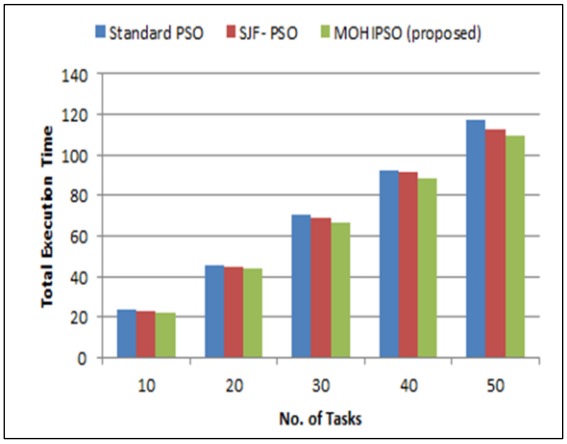

Fig. 3. Comparision of Total Execution time between PSO Varients.

Fig. 3 indicates the number of tasks vs. total execution time, in which the proposed algorithm MOHIPSO shortens the execution time compared other standard PSO and variant of PSO.

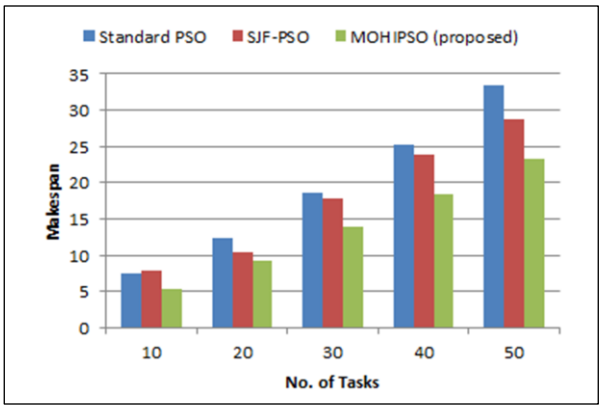

Fig. 4. Comparision of Makespan between PSO Varients.

In Fig. 4, the comparison between nuber of tasks and makespan, the proposed algorithm reduces the makespan compared to the standard PSO and SJF-PSO

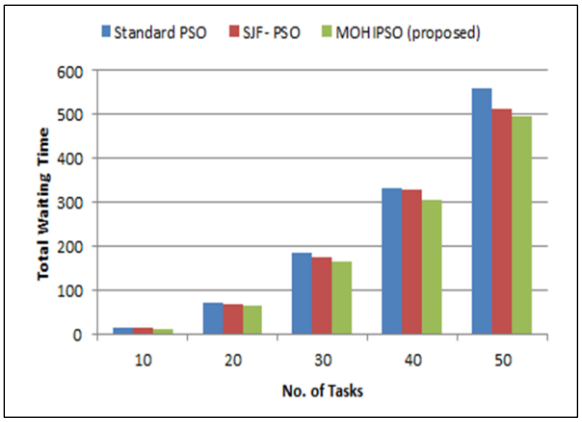

Fig. 5. Comparision of Total Waiting Time between PSO Varients.

Fig. 5 indicates the number of tasks vs. total waiting time of all tasks. The proposed algorithm reduces the waiting time compared to the standard PSO and SJF-PSO.

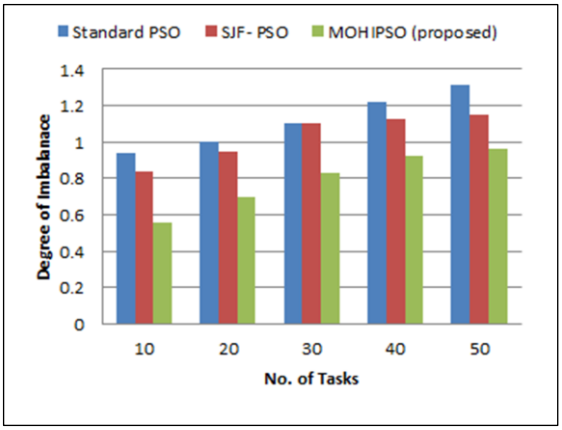

Fig. 6. Comparision of Degree of VM Imbalance between PSO Varients.

Fig. 6 shows the graph between tasks and degree of VM imbalance, it clearly shows that as the number of tasks increases then DI is increased. In order to reduce this, MOHIPSO algorithm considers the best way of scheduling tasks to the given resources on efficient way.

V. Conclusion and Future Work

Scheduling plays a crucial role in the cloud environment for effective distribution of tasks to enhance the quality of service. The MOHIPSO satisfies multiple objectives and provides obvious improvements in terms of makespan, execution time, waiting time, and degree of VM imbalance compared to traditional PSO and SJF-PSO.The simulation results show that the MOHIPSO has improved.

Task scheduling is not a multi-objective solution but it is to be a many-objective based solution by considering multiple objectives on both sides of the cloud provider and user. In future, the proposed algorithm can be extended to appraise other quality parameters like energy consumption and cost apart from makespan, execution time, waiting time, and degree of imbalance.

GML_DT: A Novel Graded Multi-label Decision Tree Classifier

Wissal Farsal, Mohammed Ramdani, Samir Anter
Computing Laboratory of Mohammedia (LIM)
FSTM, HassanII University of Casablanca
Morocco

***Abstract*—The goal of Graded Multi-label Classification (GMLC) is to assign a degree of membership or relevance of a class label to each data point. As opposed to multi-label classification tasks which can only predict whether a class label is relevant or not. The graded multi-label setting generalizes the multi-label paradigm to allow a prediction on a gradual scale. This is in agreement with practical real-world applications where the labels differ in matter of level relevance. In this paper, we propose a novel decision tree classifier (GML_DT) that is adapted to the graded multi-label setting. It fully models the label dependencies, which sets it apart from the transformation-based approaches in the literature, and increases its performance. Furthermore, our approach yields comprehensive and interpretable rules that efficiently predict all the degrees of memberships of the class labels at once. To demonstrate the model's effectiveness, we tested it on real-world graded multi-label datasets and compared it against a baseline transformation-based decision tree classifier. To assess its predictive performance, we conducted an experimental study with different evaluation metrics from the literature. Analysis of the results shows that our approach has a clear advantage across the utilized performance measures.**

Keywords*—Graded multi-label classification; algorithm adaptation; decision tree classifier; label dependencies

I. Introduction

Multi-label classification (MLC) has become an extensively researched and prominent field in machine learning. This is attributed to various real world applications that the traditional task of classification could simply not cover. Instead of predicting one class at a time, MLC predicts multiple classes at the same time. The classes are predicted based on a relevance/non relevance paradigm, while this task has proven to be useful, it remains limited as to the information it provides. Hence, an extension of MLC called Graded Multi-label Classification (GMLC) was proposed in [1].

GMLC assigns a degree of relevance or membership for each label to an instance. The degrees of relevance are gradual memberships in the sense of fuzzy set theory. A Covid-19 article, for example, may belong to three classes {health, economy, society} at the same time. However, the degree of membership to each class differs. The article can fully belong to the class health while it remains somewhat socio-economical.

In this light, all multi-label problems are graded multi-label problems, where the membership degrees are reduced to two binary values, relevant/non relevant. However, the reverse is not true, and reducing the graded multi-label problem to a standard multi-label problem was shown to decrease the predictive performance [1]. Hence the need of graded multi-label classifiers that can generalize the multi-label learning to encompass graded multi-label learning tasks.

Research on multi-label learning in recent years provided solutions in a variety of real-word problems where the traditional learning paradigms were not applicable, ranging from text categorization [2], automatic video and image annotation [3] [4] [5], web mining [6], information retrieval [7] to medical research and bioinformatics [8] [9] [10]. The different algorithms and approaches proposed exploited the transformation and the adaptation methods [11]. The diversity of these approaches is necessary to answer various real-world applications. In bioinformatics, for example, and more specifically genomics, the adaptation of the decision tree classifiers was proven to be very important in deducing comprehensible and readable rules predicting the functional classes of the genes.

Similarly, the ongoing research on Graded multi-label classification aims at developing solutions for real-world problems where the multi-label learning paradigm is not applicable or not optimal. For this purpose, some graded multi-label classifiers were proposed [1] [12] [13] [14]. However, to the best of our knowledge, there are no adaptation-based classifiers for GMLC in the literature.

In this paper, we propose a novel adapted decision tree classifier (GML-DT) that is suited for the graded multi label setting. The main advantages of this approach are its ability to fully model the label dependencies which improves the quality of its predictions. Furthermore, this algorithm is the first adapted tree-based model which makes it the most interpretable existing approach in GML. It is the only model in the literature that constructs a single decision tree from which a set of intelligible and accurate rules can be easily extracted.

The rest of the paper is organized as follows: Section II reviews previous works on GMLC and adapted decision trees in MLC. Section III presents the GML-DT algorithm. Section IV displays the experimental results on real-world graded multi-label data. Finally, Section V concludes this work and introduces future perspectives.

II. Related Work

In this section, we go over related work in both graded multi-label classification and multi-label classification.

A. Graded Multi-label Classifiers

Graded multi-label classification [1] was formalized as an extension of multi-label classification [15] [16], to predict the degrees of relevance of the labels rather than the set of relevant labels. By extension, graded multi-label classifiers fall within two main categories, problem transformation and problem adaptation. The former transforms the multi-label problem into a combination of regular classification tasks for each class label, whereas the later modifies directly the classifier to deal with graded multi-label data.

Cheng et al. [1] proposed a solution by decomposing the problem into an ordinal classification problem and a multi-label classification problem. They introduced two transformation methods, namely the vertical reduction, which predicts the membership degree for each label, and the horizontal reduction which predicts a subset of labels on each grade level. The authors also proceeded to prove the usefulness of graded multi-label classification, by deploying and comparing their approach on both GML data and ML data. Although the model proved to be effective in this setting, it does not model label dependencies. Brinker et al. [12] applied pairwise decomposition using three variants of Calibrated Label Ranking [17], to model the preferences between labels. While these approaches outperformed the predictive model developed in [1], they can only model pairwise dependencies. Lastra et al. [13] proposed a non-deterministic learner based on binary relevance that returns an interval whenever the classification is uncertain for a label. This method relies on a tradeoff between the size of the interval and the improvement of the accuracy.

Laghmari et al. [14] introduced an approach for learning label dependencies and label preferences. This is achieved by using the horizontal decomposition to reduce the problem into a combination of multi-label learning tasks, and then combining pairwise comparisons and classifier chains [18], which is an extension of binary relevance consisting of adding the labels as descriptive attributes.

While transformation methods can be easily implemented with the existing algorithms, their inability to fully model label dependencies and their run time can render them inefficient. This is especially true in cases where an interpretable model is needed, specifically a tree-based one capable of inferring accurate rules, which is the focus of this article. In fact, if one is interested in a model that produces rules identifying the features relevant for the prediction, these approaches would be inefficient and even inapplicable. The approaches in [1] can only identify the features relevant for one class label. Pairwise comparisons are not sufficient to fully model label dependencies. Classifier chains method is not applicable in this setting since it includes the labels as features, which would result in unintelligible rules. Furthermore, these approaches have to build a number of learners, proportional to the number of class labels, which affects their run time and interpretability.

B. Multi-label Decision Tree Classifiers

Clare et al. [19] adapted the c4.5 algorithm to handle multi-label data. The authors modified the formula of the entropy to account for the existence and non-existence of each label, and thus producing a decision tree capable of predicting all the class labels at once. The multi-label entropy is calculated as follows:

$$Entropy(S) = -\sum_{i=1}^{N} p(c_i)\log p(c_i) + q(c_i)\log q(c_i) \quad (1)$$

Where $p(c_i)$ is the probability of the class label c_i

$$q(c_i) = 1 - p(c_i)$$

Blockeel et al. [20] proposed a hierarchical multi-label decision tree, based on predictive clustering trees [21]. The tree is built by recursively partitioning the data into smaller clusters. This is achieved by finding the best attribute-value that reduces the intra-cluster variance. Where the variance is calculated based on the weighted Euclidean distance. Following this work, Vens et al. [22] presented an empirical study confirming the findings in [19] [20] and thus proving the ineffectiveness of transformation-based decision tree learners in comparison to adapted multi-label decision trees.

III. Graded Multi-Label Decision Tree

A. Formal Task Description

In graded multi-label classification, we have a number of training examples from which we build a classifier that assigns a grade or membership degree to each class label. An instance is represented as a vector x of d attribute values $x = [x_1, \dots, x_d]$ drawn for an input domain $A_1 \times \dots \times A_d$. Given $L = \{\lambda_1, \dots, \lambda_n\}$ a finite set of predefined labels and $M = \{\mu_1, \dots, \mu_m\}$ a finite set of predefined ordered membership degrees such that $\mu_1 < \mu_2 < \cdots < \mu_m$ ranging from complete irrelevance to full relevance. An instance x is assigned a vector of membership degrees $y_x = [y_x^1, \dots, y_x^n]$, where y_x^i corresponds to the degree of relevance of the ith label λ_i for the instance x.

We define a graded multi-label classifier H: $A_1 \times \dots \times A_d \to M^n$ as $(x) = \hat{y}_x$, where $\hat{y}_x = [\hat{y}_x^1, \dots, \hat{y}_x^n]$ corresponds to the set of predicted membership degrees for each label $\lambda_i \in$ L and an instance x.

B. GML_DT: Graded Multi-label Decision Tree

To deal with graded multi-label learning tasks, we propose a novel graded multi-label decision tree algorithm (GML-DT), capable of predicting the membership degrees of all target labels simultaneously.

The GML_DT, given in Algorithm 1, is a greedy model that follows a top-down induction approach for building decision trees. The algorithm takes as input the training set. It starts by searching for the best attribute-value test for the root node. It proceeds to splitting the training set based on the selected test into two partitions, one for which the test succeeds and one for which the test fails, and then calls itself recursively on each partition to construct the left and right subtrees.

Algorithm 1 GML_DT

Input: an attribute-valued training set S
If stopping criterion is True then terminate
End if
For each attribute A do
For each split value v do
Compute overall entropy for splitting on (A, v)
End for
End for
$(A, v)_{best}$ = Best attribute-value that reduces the overall entropy
Create a node in the Tree with the best test $(A, v)_{best}$
S_1, S_2 = Induced sub-datasets from S based on the test $(A, v)_{best}$
Sub_Tree_1 = GML_DT(S_1)
Sub_Tree_2 = GML_DT(S_2)
Add Sub_Tree_1 and Sub_Tree_2 to the corresponding branches of the Tree
Output: Tree

The best attribute-value test is selected by considering all possible split values for each attribute. If the attribute is categorical, the algorithm constructs a test of the form $a_i = v_j$, if it is continuous the test takes the form $a_i \leq v_j$. For each node, the algorithm computes the heuristic values of all the possible attribute-value tests. The heuristic calculates the overall entropy induced by splitting the node on an attribute-value test. The overall entropy as defined in equation (2) is the sum of the weighted entropy of the two partitions created by the split according to their size.

The algorithm then selects the test that reduces this heuristic to put in an internal node. It splits the instances based on the test into two partitions and constructs the subtrees as explained above.

$$Overall\_Entopy = \sum_{i\in\{1,2\}} \frac{|S_i|}{|S|} Entropy(S_i) \quad (2)$$

$$Entropy(S_i) = \frac{1}{n}\sum_{j=1}^{n} Entropy(S_i, \lambda_j) \quad (3)$$

Where $Entropy(S_i, \lambda_j)$ is defined as follows:

$$Entropy(S_i, \lambda_j) = -\sum_{k=1}^{m} p(\mu_k)\log p(\mu_k) \quad (4)$$

We modified the formula of the entropy in order to handle graded multi-label classification tasks. We propose a graded multi-label entropy that is computed as the averaged sum of the entropies of class labels. This definition ensures that instances with similar degrees of relevance to the set of labels go in the same subset and thus allowing the prediction of a set of membership degrees for the set of labels in the leaves. We use the majority vote on each class label, to predict its corresponding relevance degree.

The algorithm builds the tree until a stopping criterion is triggered. The stopping conditions are:

- The partition is pure, meaning that all instances have the same degree of relevance for each class label.
- The number of instances in the node are less than a predefined threshold.
- The tree reaches a maximum depth.

C. A Toy Example

To demonstrate the process of building a graded multi-label decision tree, we use a toy example. Table I displays 10 samples of the toy dataset, which originally contains a total of 35 instances described with 3 attributes. a_1 is a categorical feature, a_2 and a_3 are continuous features. The set of class labels is constituted by $\{c_1, c_2, c_3\}$ and the set of degrees is $\{0, 1, 2, 3\}$. This set is equivalent to a set of descriptive nominal counterpart for each degree {not at all, somewhat, almost, fully} characterizing the ordinal levels of relevance of the class labels.

TABLE I. GRADE MULTI-LABEL TOY DATASET

Instances	a_1	a_2	a_3	c_1	c_2	c_3
x_1	A	63	7	3	0	0
x_2	C	29	5	3	3	1
x_3	A	69	13	1	2	3
x_4	B	49	11	1	0	2
x_5	C	51	7	2	1	0
x_6	B	61	5	1	0	2
x_7	C	43	17	2	1	0
x_8	A	69	9	3	0	0
x_9	C	27	13	3	3	1
x_{10}	B	10	14	1	0	2

First, we find the best split by iterating over the attribute columns to get potential split values. The potential split values of a continuous attribute column being the middle values between each consecutive values of the attribute. Then we calculate the overall entropy induced by splitting on an attribute a and a potential split value v.

For example, according the samples in table 1, the potential splits for the attribute a_1 are $(a_1 = A)$, $(a_1 = B)$ and $(a_1 = C)$

Based on these samples, the overall entropy induced by the test $(a_1 = A)$ is calculated as follows:

By applying Equations (2) and (3), we obtain:

$$Overall\_Entropy = \frac{3}{10} \times Entropy(S_1) + \frac{7}{10} \times Entropy(S_2)$$

$$Entropy(S_1) = \frac{1}{3} \times [Entropy(S_1, c_1) + Entropy(S_1, c_2) + Entropy(S_1, c_3)]$$

Where S_1 is the set of instances for which $a_1 = A$, and S_2 is the set of instances for which $a_1 \neq A$.

By applying Equation (4), the entropy of the subset S_1 for the class label c_1 is calculated as follows:

$$Entropy(S_1, c_1) = -\,p(0) \times \log p(0) - p(1) \times \log p(1) - p(2) \times \log p(2) - p(3) \times \log p(3)$$

$$= 0 - \frac{1}{3} \times \log\frac{1}{3} - 0 - \frac{2}{3} \times \log\frac{2}{3}$$

$$= 0.918$$

After computing $Entropy(S_1, c_2)$ and $Entropy(S_1, c_3)$ following the same process, we get the entropy of the subset S_1:

$$Entropy(S_1) = 0.918$$

In the same way, we calculate the entropy of the subset S_2 and we obtain:

$$Entropy(S_2) = 1.556$$

The overall entropy for splitting on the test $(a_1 = A)$ is 1.364

The overall entropies for the remaining potential splits of the attributes a_1, a_2 and a_3 can be computed following the same process. The potential tests for the continuous features are determined by considering the middle values between each consecutive values.

Fig. 1 displays the decision tree built by GML_DT based on the toy dataset (35 instances). We can infer the five following rules from this decision tree:

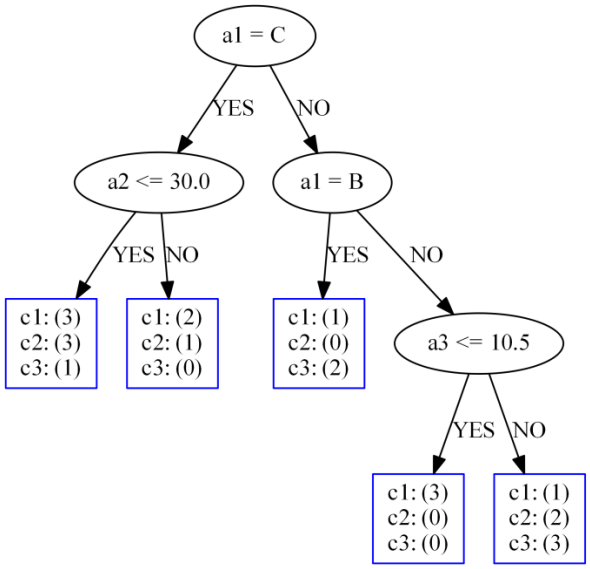

Fig. 1. A Graded Multi-label Decision Tree Constructed by GML_DT.

R_1: IF $a_1 = C$ AND $a_2 \leq 30$ THEN $<Degree(c_1) = 3, Degree(c_2) = 3, Degree(c_3) = 1>$

R_2: IF $a_1 = C$ AND $a_2 > 30$ THEN $<Degree(c_1) = 2, Degree(c_2) = 1, Degree(c_3) = 0>$

R_3: IF $a_1 = B$ THEN $<Degree(c_1) = 1, Degree(c_2) = 0, Degree(c_3) = 2>$

R_4: IF $a_1 \notin \{C, B\}$ AND $a_3 \leq 10.5$ THEN $<Degree(c_1) = 3, Degree(c_2) = 0, Degree(c_3) = 0>$

In this toy dataset the attribute a_1 has three possible values A, B or C. Hence, the condition $a_1 \notin \{C, B\}$ is equivalent to $a_1 = A$. Therefore, the fourth rule becomes:

R_4: IF $a_1 = A$ AND $a_3 \leq 10.5$ THEN $<Degree(c_1) = 3, Degree(c_2) = 0, Degree(c_3) = 0>$

R_5: IF $a_1 = A$ AND $a_3 > 10.5$ THEN $<Degree(c_1) = 1, Degree(c_2) = 2, Degree(c_3) = 3>$

As demonstrated above, the new developed graded multi-label model yields rules that are intelligible and interpretable.

IV. Experimental Study

We conducted an experimental study on real-world datasets, comparing our approach with binary relevance (BR) applied with a state of the art decision tree classifier, under the evaluation metrics from the literature [12] [1]. Cheng et al. [1] generalized some of the common loss functions used in multi-label classification for the graded multi-label setting and introduced the benchmark dataset BeLaE. These performance metrics were then used in the experimental study in [12], which compares the previous work in [1] and three new implemented approaches. This study was carried out on the benchmark dataset BeLaE and two additional real-world graded multi-label datasets curated by the authors, which makes it the most extensive work on GMLC compared to the rest of the work in the literature. For the purpose of conformity, we used the same datasets in our experimental study, along with three of the evaluation metrics from this previous work.

The experimental study is obtained by carrying out 10-fold cross validation on each single dataset. The same folds were used for both experiments on GML_DT and a baseline decision tree classifier applied with binary relevance approach (BR_DT).

We developed the GML_DT algorithm proposed in this paper from scratch using Python. The baseline BR_DT is implemented using the Scikit-learn library [23].

A. Evaluation Metrics

We evaluated the predictive performance of the algorithm based on three metrics; the hamming loss, which corresponds to the mean deviation of the predicted membership degrees to the true membership grades:

$$E_H(\hat{y}_x, y_x) = \frac{\sum_{i=1}^{n} AE(\hat{y}_x^i, y_x^i)}{(m-1)n} \quad (5)$$

Where AE is the absolute error of the predicted membership degree and it is defined as:

$$AE: M \times M \to L, AE(\mu_i, \mu_j) = |i - j|$$

The vertical 0-1 loss measures the percentage of class labels with incorrectly predicted degrees of relevance:

$$E_{0/1}(\hat{y}_x, y_x) = \frac{1}{n}\sum_{i=1}^{n} I(\hat{y}_x^i \neq y_x^i) \quad (6)$$

Where I is the indicator function.

The C-index measures the pairwise ranking errors between the true membership set and the predicted membership set.

$$E_{CI} = \frac{\sum_{i<j}\sum_{(\lambda,\lambda') \in M_i \times M_j} S(h_x(\lambda), h_x(\lambda'))}{\sum_{i<j} |M_i| \times |M_j|} \quad (7)$$

Where $M_i = \{\lambda \in L | L_x(\lambda) = \mu_i\}$

$L_x(\lambda)$ is a function returning the degree of membership of the label λ for an instance x.

$h_x(\lambda)$ is the predicted degree of membership of the label λ for an instance x.

and $S(u, v) = I(u > v) + \frac{1}{2} I(u = v)$

B. Datasets

The datasets used for the experimental study are the BeLa-E which is a benchmark dataset introduced in [1] consisting of 100 variants, 50 datasets predicting 5 labels and 50 datasets predicting 10 labels. BeLaE was constructed based on a survey conducted with 1930 students, in order to grade on a finite ordinal scale the importance of different job properties.

Movies [12] is a dataset collected from 1967 movies where each movie is graded on its level of membership to five descriptive categories, e.g. its level of humor, action, suspense.

Medical [12], based on 1953 radiology reports, annotated with a set of ICD-9-CM disease/diagnosis classification codes. This dataset was adapted from the multi-label dataset by taking into account the level of agreement of the annotators.

Table II summarized the different properties of the aforementioned datasets.

C. Results

Table III displays the experimental results of GML_DT in comparison to BR_DT. We averaged the evaluations across the 10-fold cross validation for each single dataset. For the benchmark datasets, BeLaE (n=5) and BeLaE (n=10), we averaged the performance over the 50 variants of each. We summarize their predictive measures in terms of the mean and the standard deviation.

The experimental study conducted reaches the following conclusions:

GML-DT outperforms the baseline classifier BR_DT in terms of predictive performance according to all three evaluation metrics used in this experiment for all four datasets.

The performance metrics used in these experiments evaluate the results along three dimensions depicting the disparity, accuracy and pairwise ranking errors between the true membership set and the predicted membership set. Hence, GML_DT yields more accurate rules across all these different dimensions.

TABLE II. OVERVIEW OF THE GRADED MULTI-LABEL DATASETS, AND THEIR PROPERTIES: NUMBER OF INSTANCES, NUMBER OF ATTRIBUTES, NUMBER OF CLASS LABELS AND THE NUMBER OF GRADES

Datasets	Instances	Attributes	Labels	Grades
BeLaE n=5	1930	45	5	5
BeLaE n=10	1930	40	10	5
Movies	1967	27002	5	4
Medical	1953	1602	204	4

TABLE III. EXPERIMENTAL RESULTS FOR EACH DATASET ACCORDING TO THE HAMMING LOSS, THE VERTICAL 0/1 LOSS AND THE C-INDEX

Datasets	Evaluation Measures	GML_DT	BR_DT
BeLa-E n=5	Hamming Loss	0.168 ±0.018	0.257 ±0.026
	Vertical 0-1 Loss	0.526 ±0.039	0.689 ±0.032
	C-Index	0.264 ±0.047	0.374 ±0.055
BeLa-E n=10	Hamming Loss	0.174 ±0.011	0.259 ±0.017
	Vertical 0-1 Loss	0.540 ±0.020	0.690 ±0.023
	C-Index	0.263 ±0.030	0.361 ±0.040
Movies	Hamming Loss	0.172	0.253
	Vertical 0-1 Loss	0.424	0.536
	C-Index	0.247	0.368
Medical	Hamming Loss	0.002	0.010
	Vertical 0-1 Loss	0.006	0.017
	C-Index	0.135	0.448

Furthermore, GML_DT has a smaller model size compared to BR_DT. In fact, GML_DT is a single model that predicts the membership degrees relative to the set of class labels simultaneously. It builds a single decision tree that identifies the attribute-value conditions relevant for the prediction of the complete set of degrees associated to the label set. On the other hand, BR_DT runs $|L|$ times, and results in $|L|$ constructed decision trees, one for each class label, which not only affects its execution time and complexity but also its interpretability. The higher the number of labels, the more complicated the model gets and therefore the less effective it becomes for retrieving useful and comprehensible rules.

Moreover, if we were to compare GML_DT to the state of the art approaches solely based on the results reported in [1] and [12], we can deduce that GML_DT outperforms the model in [1] across all three metrics. Furthermore, it has better results for the hamming loss and the vertical 0-1 loss compared to the full CLR and Joined CLR while it remains very competitive against the Horizontal CLR [12].

V. CONCLUSION

We present a graded multi-label decision tree classifier, GML_DT, which generalizes the multi-label setting by predicting the membership degrees of the target labels instead of the binary relevance/non relevance. This approach utilizes the interpretability of decision tree classifiers and produces readable and comprehensive trees, which can be translated into useful, homogenous rules. GML_DT is also the first adaptation algorithm in the literature that fully models label dependencies, resulting in an increase of the predictive performance and the quality of the deduced rules.

The proposed algorithm is based on a new adapted graded multi-label heuristic that allows the algorithm to split based on the homogeneity of the combined set of labels, and ultimately retuning a vector containing the majority grade in each class label. We carried out an experimental study on real-world graded multi-label datasets, and evaluated our approach against a state of the art transformation-based decision tree classifier.

Our model is more interpretable and has the best predictive quality according to a variety of performance measures from the GMLC literature.

This paper constitutes a preliminary presentation of GML_DT, we are currently investigating further adaptations of the heuristic to the GML setting in order to improve the predictive performance of the model. Moreover, we are working on reducing the complexity of the generated tree via an adapted post pruning method.

***Abstract*—Object detection technology aims to detect the target objects with the theories and methods of image processing and pattern recognition, determine the semantic categories of these objects, and mark the specific position of the target object in the image. This study generally aims to establish a recognition method for Cassava Phytoplasma Disease (CPD) real-time detection based on transfer learning neural networks. Several methods and procedures were conducted, such as the testing of two methods in transmitting long-distance high definition (HD) video capture; establishment of a compact setup for a long-range wireless video transmission system; the development, testing of the real-time CPD detection and quantification monitoring system, providing the comparative performance analysis of the three models used. We have successfully custom-trained three artificial neural networks using transfer learning: Faster Regions with Convolutional Neural Networks (R-CNN) Inception v2, Single Shot Detector (SSD) Mobilenet v2, and You Only Look Once (YOLO) v4. These deep learning models can detect and recognize CPD in actual environment settings. Overall, the developed real-time CPD detection and quantification monitoring system was successfully integrated into the wireless video receiver and seamlessly visualized all the incoming data using the three different CNN models. If the consideration is the image processing speed, YOLOv4 is better compared to other models. But, if accuracy is the priority, Faster R-CNN inception v2 performs better. However, since CPD detection is the main purpose of this study, the Faster R-CNN model is recommended for adoption to detect CPD in a real-time environment.**

***Keywords*—Cassava phytoplasma disease; faster regions with convolutional neural networks (R-CNN) inception v2; you only look once (YOLO) v4; object detection; precision agriculture**

I. Introduction

The agricultural industry plays an important role in the economy. Plant illness is also caused by climatic circumstances, exacerbated by the exponential trend of population growth. The major challenges of sustainable development include reducing pesticide use, the expense of preserving the environment, and the cost of building quality. Exact, exact, and timely decisions may reduce pesticide use [1]. Cassava is a key crop that has been produced in the Philippines. Nowadays, innovation is commonly used for plant disease prediction. The concept of image processing combined with information mining improvements aids in identifying plant diseases. With the development of intelligent devices, the data bulk on Internet has grown with high speed. As an important aspect of image processing [2][3][4], object detection has become one of the popular international research fields. In recent years, the powerful ability with feature learning and transfer learning of Convolutional Neural Network (CNN) has received growing interest within the computer vision community, thus making a series of important breakthroughs in object detection [5][6]. So, it is a significant application to apply CNN to object detection for better performance.

Real-time object detection is the task of doing object detection in real-time with fast inference while maintaining a base level of accuracy [7]. Object detection technology aims to detect the target objects with the theories and methods of image processing and pattern recognition [8][9], determine the semantic categories of these objects, and mark the specific position of the target object in the image. It is a very challenging task in the actual application to use computer technology to detect objects automatically. Complex background, noise disturbance, occlusion, low-resolution, scale, and attitude changes, and other factors will seriously affect the object detection performance. The conventional object detection method was based on the hand-crafted feature. It is not robust to illumination change, lacking good generalization ability. Using Google's TensorFlow and YOLOv4 as well as transfer learning, we were able to custom-trained three separate artificial neural networks [10]. These deep learning models can detect and recognize CPD in actual environment settings.

This study established a recognition method for Cassava Phytoplasma Disease (CPD) real-time detection based on transfer learning neural networks. Specifically, this paper is presented to test the two methods in transmitting long-distance high definition (HD) video capture. Likewise, it established a compact setup for a long-range wireless video transmission system. Furthermore, the project developed a real-time CPD detection and quantification monitoring system, performed a wireless video transmission test, and compared the test results in each model used.

As compared with the recent papers and technologies related to plant disease detection, this paper presented a disease detection technology specifically for Cassava

Phytoplasma Disease. It demonstrated which real-time detection technology is the most appropriate to use, which is more practical and can have a great impact on society. This research provides a visual object identification framework capable of processing pictures at high detection rates while processing images at a fast pace.

Hence, the authors conducted a thorough experiment on what innovative technology will be used. To befittingly implement the selected technology to our partner agency, the EDCOR, a cassava development cooperative located in San Guillermo, Isabela. Their cassava farms are situated in remote locations where internet connectivity is scarce. We developed a remote image processing server system utilizing digital First-Person View (FPV) [11]. This remote server can perform real-time image processing for CPD detection and recognition with a dedicated ground station for long-range high-definition video transmission without using the Internet.

The next sections discussed the related works, methods, and results that transpired during the conduct of the study. It explained the details on how the entire project was done and the results of the undertakings.

II. Literature Review

Cassava plants exhibiting characteristic phytoplasma signs, such as witches' broom, general stunt, chlorosis, distortion, and decreased size [12], were seen in farms near San Guillermo, Isabela. CPD is a severe danger to cassava producers' food security [13].

Object detection is a critical computer vision problem that involves detecting visual objects in digital photos of a specific type (such as humans, animals, or autos). Object detection aims to create computational models and approaches that give one of the most fundamental bits of data required by computer vision applications [14]. Object detection is essential in identifying the disease type in the specific video sequence performed in agricultural farming. Object detection reduces computing time while increasing detection accuracy [15].

Several popular deep learning-based object identification algorithms are available that can accurately identify which section of a farm field is infected with Cassava Phytoplasma Disease. Some frameworks will need a lot of computing power, while some will provide less accuracy. By surveying several neural network frameworks, the authors identified the following frameworks with the best performance in object detecting technology.

Transfer learning is the enhancement of learning in a new task by transferring knowledge from a previously learned related activity [16]. While most machine learning algorithms are designed to solve particular tasks, the development of algorithms that promote transfer learning is a continuing area of study in the machine-learning field. The following are the transfer learning neural networks considered in this paper:

A. Faster Regions with Convolutional Neural Networks (R-CNN) Inception v2

The Region Proposal Network (RPN) is a fully convolutional network that predicts object limits and objectness scores at each place simultaneously. RPNs are trained from start to finish to create high-quality region suggestions, which Fast R-CNN uses for detection [17]. RPN and Fast R-CNN may be taught to share convolutional features using a simple alternating optimization. RPN was added to the design of faster R-CNN. It means that it uses a quick neural network to handle a sluggish search selection process.

RPN comes after the last convolution layer of a Convolutional Neural Network. Inception V2 was a module created to minimize the complexity of a convolution network. This module causes the convolution network to be broader rather than deeper. There are three types of modules in Inception V2 [18].

B. You Only Look Once (YOLO) v4

YOLO is a cutting-edge, real-time object detecting technology. It is a real-time object identification system that recognizes several items in a single frame. YOLO takes a completely new approach to earlier detection methods. It uses a single neural network to process the entire picture. This network separates the picture into regions and predicts each bounding boxes and probabilities. The projected probabilities are used to weigh these bounding boxes [19]. YOLO offers excellent real-time performance in multi-scale object recognition [20].

C. Single Shot Detection (SSD)

Single Shot Detection is a technique for detecting objects in a single shot. By capturing a single photograph, you can analyze many items. A single frame is used to recognize and analyze several items in a picture. Compared to Convoluted Neural Networks, this is a considerably faster analysis. For p channel analysis, a feature layer of m*n is obtained. For each of the k areas, a bounding box is generated. SSD is sometimes called a Multibox detector since it computes each bounding box and offsets relative to the initial bounding boxes [21].

III. Methods

A. Conceptual Framework

The different processes and methodologies in the wireless video transmission system, its establishment, the development of a real-time CPD detection monitoring system, the performance testing were realized based on the conceptual framework of the study as presented in Fig. 1. The Real-time CPD detection and quantification Framework Model.

B. Methods in Transmitting Long-distance High Definition Video Capture using the Long-Range Wireless Video Transmission System

We have used two methods in transmitting long-distance high definition (HD) video capture. These methods involve using 2.4Ghz and 5Ghz frequencies. Both had their advantages and disadvantages. 2.4GHz offers a wide network coverage and is superior at bypassing substantial impediments like trees. However, it has a smaller data rate and is more susceptible to interference; more devices normally utilize this frequency. 5Ghz, on the other hand, offers a greater data rate and is less susceptible to interference; it is typically used by

fewer devices. However, it has a smaller coverage area and is not performing well when penetrating solid/thick layered obstacles.

To implement the 2.4Ghz concept, we adapted the method called Wi-Fi Broadcast illustrated in Fig. 2. Wi-Fi-broadcast activates the monitor mode on the Wi-Fi cards. This mode allows you to transmit and receive arbitrary packets without having to associate them with anything. Furthermore, it is possible to get incorrect frames (where the checksum does not match). In this method, a real unidirectional connection is produced, simulating the benefits of an analog link. They comprise the following: the transmitter broadcasts data regardless of whether or not there are any receivers nearby. As a result, there's no possibility of video stalling due to a loss of association; the receiver gets video as long as it's within range of the transmitter. The video quality declines as it moves out of range, but it does not stall. Even if frames are incorrect, they will be shown rather than discarded; the classic "one broadcaster – numerous receivers" method will function right out of the box. Bystanders who wish to view the video stream on their devices only need to "shift to the correct channels"; Wi-Fi-broadcast permits the simultaneous use of numerous low-cost receivers and the combining of their data to enhance the likelihood of correct data reception. This so-called software diversity enables the use of identity and complementary receivers to increase dependability (imagine one reception with a 360° omnidirectional antenna and multiple directional antennas for long distances, all functioning in tandem). To archive high dependability at minimal bandwidth needs, Wi-Fi-broadcast employs Forward Error Correction. It can recover packets that have been lost or corrupted at the receiver.

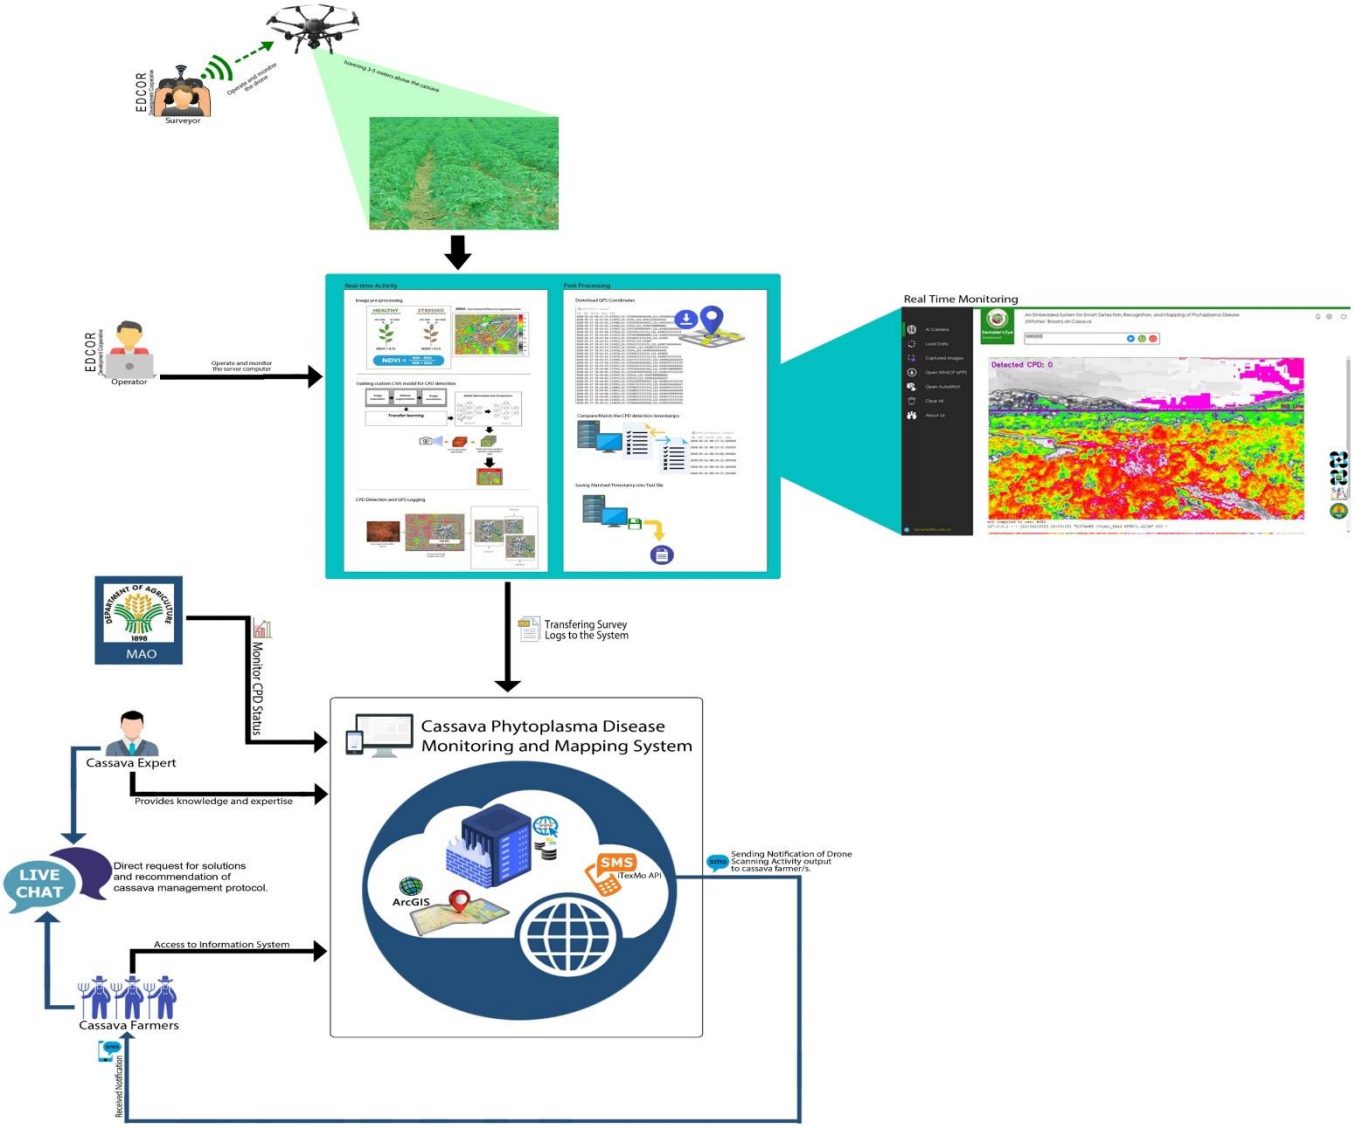

Fig. 1. The Structural Framework of Faster R-CNN(a), YOLOv4(b), SSD Mobilenet v2(c).

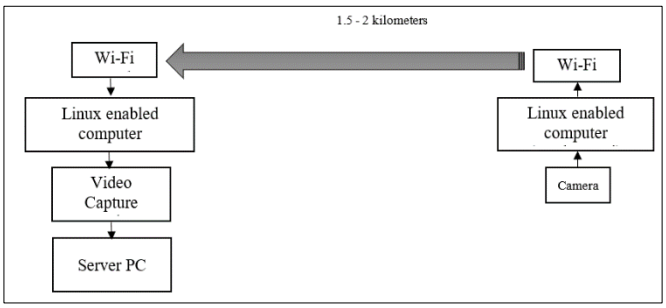

Fig. 2. Wi-Fi Broadcast Block Diagram.

Using standard Wi-Fi dongles with Atheros AR9271 802.11 chip for the transmitter and receiver, and a 2.4Ghz Yagi antenna for our ground station presented in Fig. 3 and 4. This setup can process camera feed from either USB Video or through RTSP/TCP URLs.

The ground station uses a sturdy tripod with a height of 2.5 meters. The Wi-Fi dongle, Yagi antenna, and a single board computer are securely installed on it, as shown in Fig. 5 and 6.

Fig. 3. Atheros AR9271 802.11 Wi-Fi Dongle.

Fig. 4. 2.4Ghz Yagi Antenna.

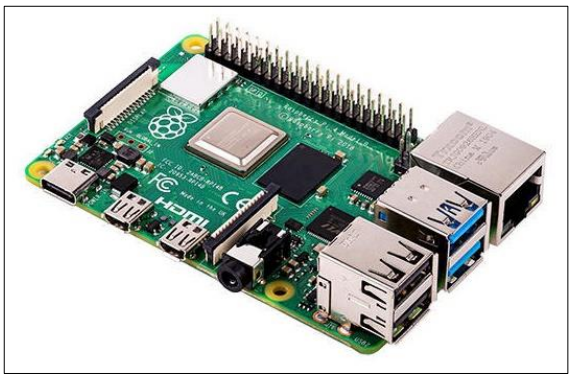

Fig. 5. Single Board Computer; Raspberry pi 4.

Fig. 6. A 2.5 Meters Tripod Stand where the Wi-Fi Dongle, Yagi.

On the other hand, we used a commercially available FPV high-definition video transmitter using 5Ghz presented in Fig. 7, which also supports HDMI all format video input up to 1920*1080@60fps, and output is up to 1920*1080@30fps. A 5dB omnidirectional antenna is installed on the ground unit (standard). According to the manufacturer, the effective transmission distance is over 2km with an output delay of 80ms/0.08s.

Fig. 7. Commercially Available full HD Digital Video System.

The receiver/ground unit is also installed on the tripod, just beside the 2.4Ghz Yagi antenna. This method takes advantage of the commercially available HD Video TX/RX and its dedicated windows application. The commercially available video TX/RX works perfectly fine using its dedicated application (Insight.exe) on a windows computer. However, the downside is that we cannot tap on the video feed from the transmitter into our developed system. Given that its dedicated application is not open-source and there is no available software development kit (SDK) for this device, it is hard to analyze and reverse engineer. On the other hand, the RTSP URL that supposedly works based on its documentation turns out to be incorrect (or, if not, maybe they no longer support this feature).

The alternative concept uses the "HD Video Capture" method, as illustrated in Fig. 8, which works by connecting the NDVI camera through HDMI into the Video TX and connected to the Video RX wirelessly (5Ghz band). The Video RX will also act as a Wi-Fi access point using the 5Ghz band. A lightweight, small single-board computer (SBC) running Windows 10 Pro x64 with Insight.exe configured will be linked to the Video RX over Wi-Fi (5Ghz) and display the live camera feed from the TX side. Then a video capture device will be used to mirror the preview display on the SBC and send it to our server computer via wired connection in digital HD resolution (720P - 1080P) in real-time (or near real-time).

After which, our developed Demeter's Eyes Monitoring System will then be able to adapt to this alternative method and process each frame from the incoming digital HD resolution camera pass through our custom-trained CNN model for CPD detection and quantification. These two different videos transmission configurations work independently of each other, and only one setup can be used at a time since there is only one camera installed to the transmitter.

C. Establishment of a Compact Setup for a Long-Range Wireless Video Transmission System

The long-range wireless video transmission system is equipped with 16 megapixels NDVI camera, GPS module, a single-board computer, and a swappable video transmitter (2.4Ghz and 5Ghz), as shown in Fig. 9. This compact setup also includes a portable power supply, mini-fan, and LED light indicators. The LED lights indicate the status of each component on this embedded system. It is very useful when conducting pre-flight checkups and during troubleshooting.

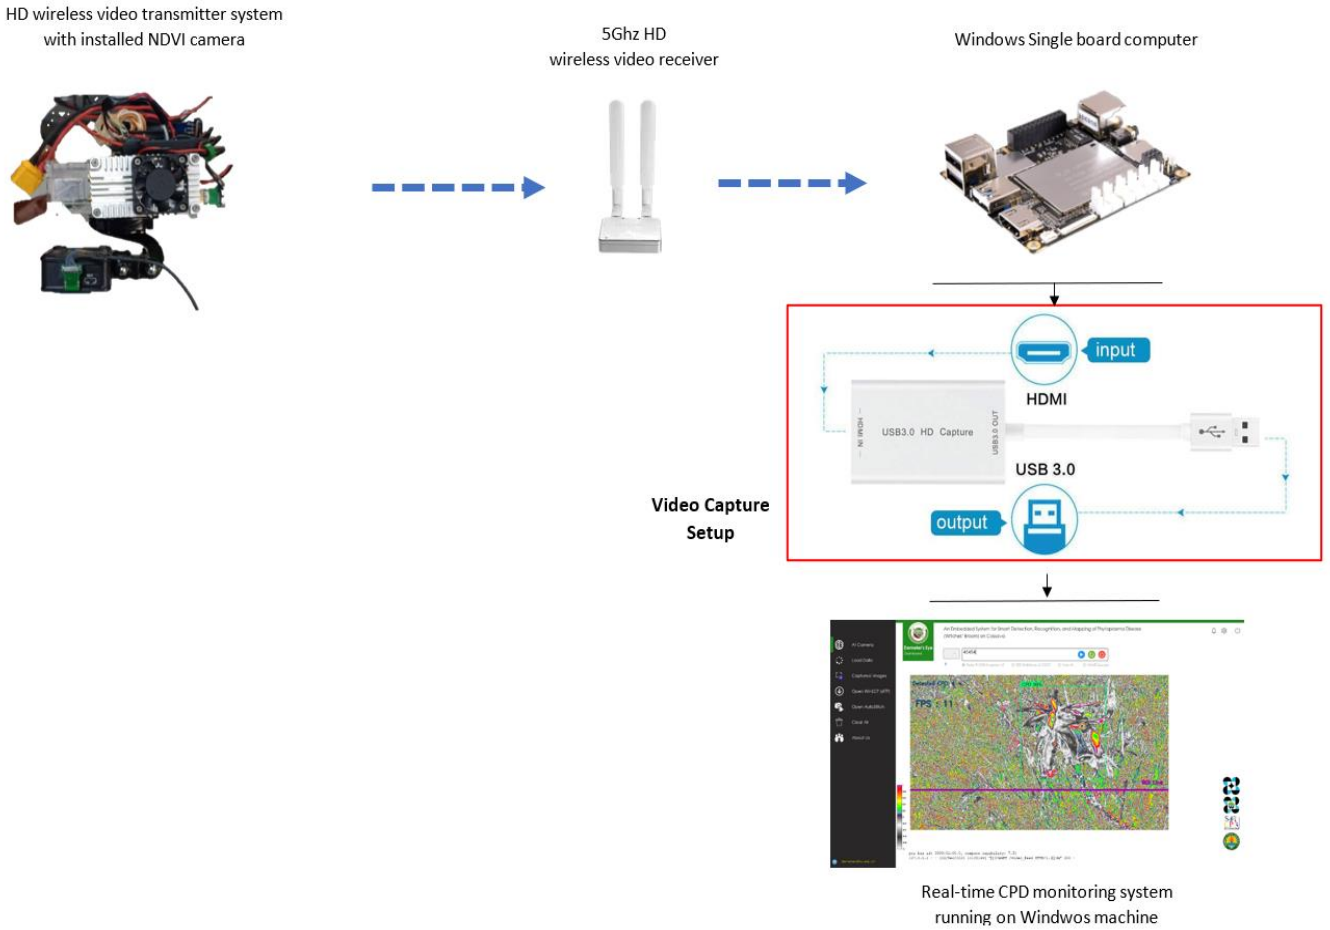

Fig. 8. Video Capture System Layout.

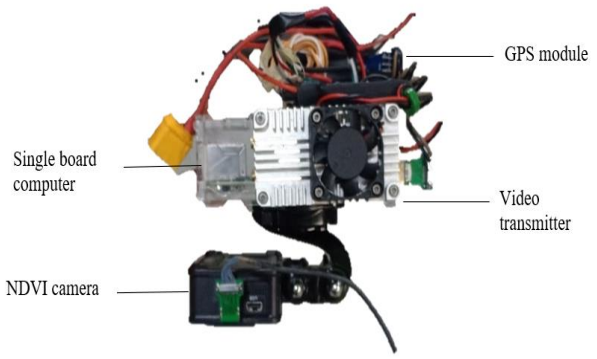

Fig. 9. HD Wireless Video Transmitter System with Installed NDVI Camera and GPS Module.

D. Development and Testing of the Real-Time CPD Detection and Quantification Monitoring System

The real-time CPD detection [22][23] and quantification system work by switching on the NDVI camera, video transmitter and receiver (including the single-board computer from the ground station), GPS logging module (will automatically start logging time stamps and GPS coordinates once switched on and successfully linked to a satellite) and, the drone itself. After which, the video transmitter and receiver will automatically link each other (the green light indicator for data on the video receiver must be steady).

On the server-side, the CPD real-time monitoring system should now be able to detect and preview incoming live camera feed from the video transmitter, as shown in Fig. 10.

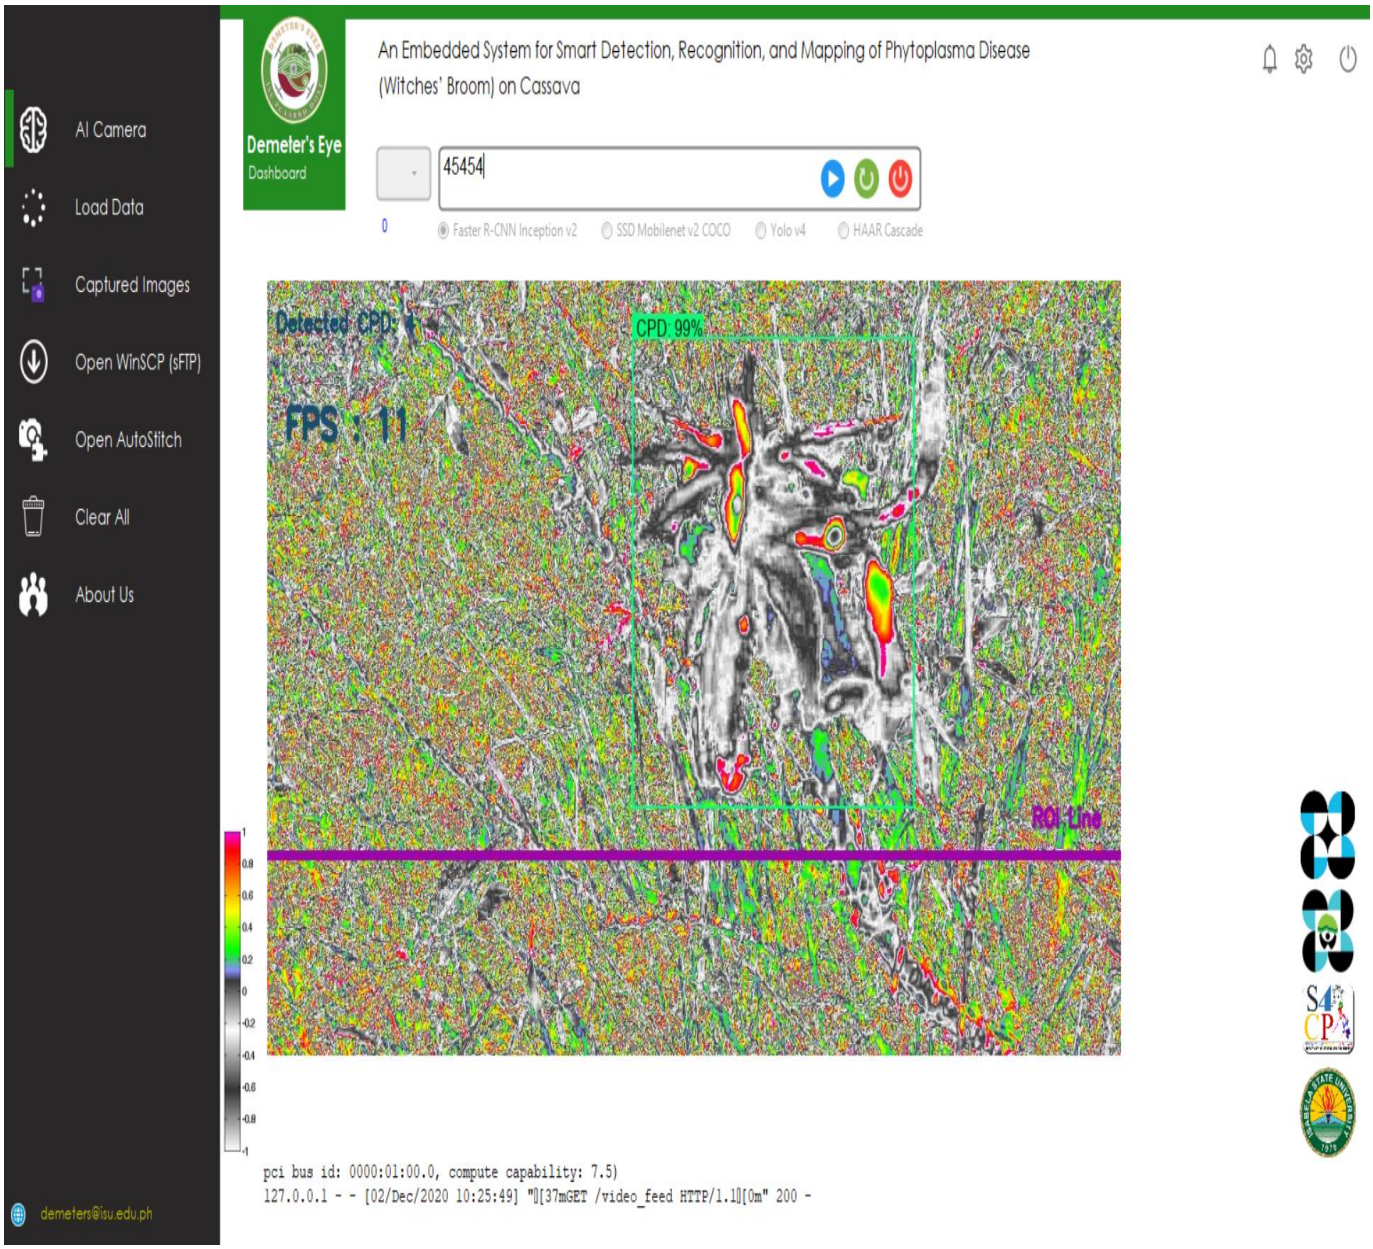

Fig. 10. Real-Time CPD Detection and Quantification System Dashboard.

Once the video link is established, the surveyor can now start hovering above the cassava field (3-5 meters above the cassava). While hovering over the cassava field, the CPD real-time monitoring system performs image pre-processing procedures on each incoming frame. This includes applying a Fastie color map to visualize the NDVI values in the image. The pre-processed frame(s) is passed through our CNN model (custom trained CPD detection model using transfer learning with Faster RCNN for prototype 2, SSD MobileNet V2 [1] COCO for prototype 3, and YOLO v4 for prototype 4) for CPD detection and quantification based on the TensorFlow object detection API. The real-time CPD detection is displayed on the system preview window with an overlaid running count of CPD detected. The system also automatically records each CPD detected timestamp (the latency between the transmitter and receiver was considered; thus, an adjustment with the time delay was done).

After completing the survey and the drone has returned, the GPS logging module will automatically connect to the access point located on the operator side. This will allow the operator to download GPS coordinates and corresponding timestamp Logs from the drone onboard GPS logging module through sFTP and upload it into the server computer. The system will now compare/match the CPD detection timestamps from the server computer and the timestamps from the GPS logging module. For each timestamp that matches, save its corresponding GPS coordinate into a .txt file. This .txt file will be uploaded into the web-based information system for visualization. These processes are illustrated in our conceptual framework shown in Fig. 1.

E. Testing the Long-range Wireless Video Transmission System

To verify the actual performance of the video transmission system, we conducted a stress test to determine the following: working time per battery charge of the NDVI camera; working time per battery charge of the video receiver; the actual working distance of the video TX/RX; actual latency of the video transmission; actual latency of the video transmission when adapted into the monitoring system.

We conducted the test at an open field inside the Isabela State University located at San Fabian, Echague, Isabela, as shown in Fig. 11 and 12. The test location is ideal since it has an almost identical topography with the actual cassava farms. It has a combination of wide-open fields with surrounding trees in various heights and densities.

F. Portable Handheld Prototype Field Testing

With favorable weather, we conducted the onsite pilot testing of our prototype at Villa Teresita, San Guillermo Isabela, on a cassava farm owned by one of the EDCOR members between 10:00 in the morning up until 3:00 in the afternoon. The planted cassava was at around three months old at the time of testing. We used PVC pipes to hold the prototype steady, facing the camera down at a height of 2-3 meters from the top-most part of the cassava. Thus, mimics the drone altitude and flight movement.

Fig. 13 shows the actual field testing of the prototype. This was performed in the cassava farm in Villa Sanchez, San Guillermo, Isabela. This testing makes sure that the prototype works well as per its functionalities.

G. Drone and Prototype Payload Field Testing

After the initial test, we embedded the prototype as a payload into our custom-built drone and went back to the same site to conduct another series of tests. This milestone is presented in Fig. 14 and 15.

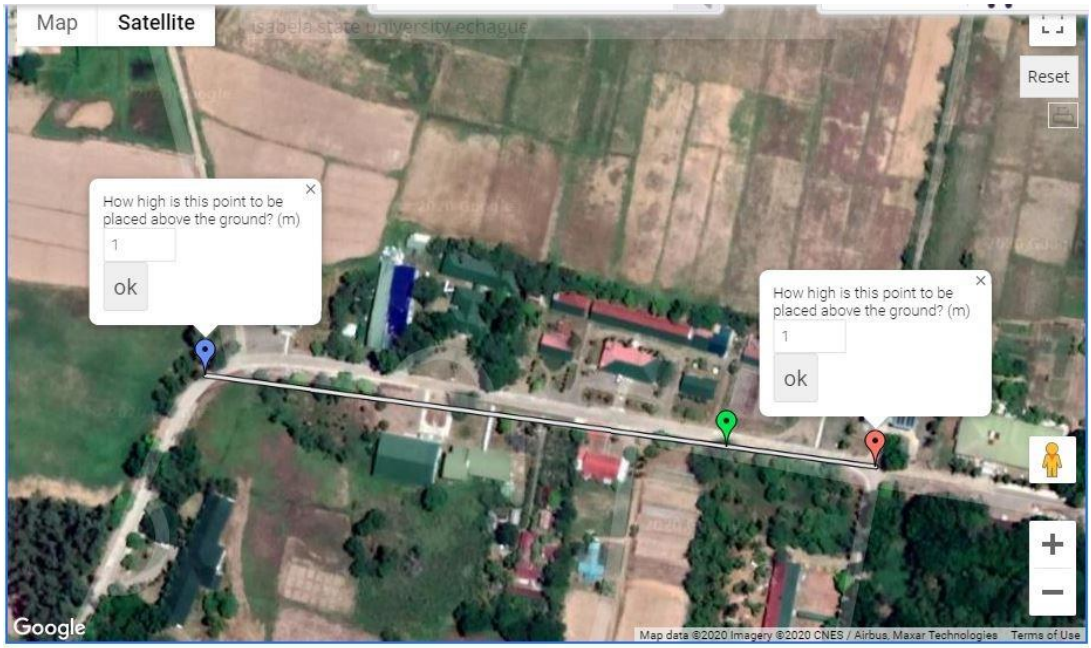

Fig. 11. Testing Site.

Fig. 12. Actual Wireless Video Transmission Test Conducted.

Fig. 13. Actual Field Testing of the Prototype.

Fig. 14. Installed Prototype as Payload underneath the Drone.

Fig. 15. Actual Field Testing using the Drone with the Prototype Payload on it

H. Comparison of the Test Results in each Model used

The ground-truthing [24] procedure was done on a selected area from a cassava farm with identified CPD infection. Our plant pathologist selected two lanes of planted cassava by which our prototypes camera can cover at one pass at a height of 2-2.5 meters. The cassava planted on the selected test area was counted manually. We got a total of 40 cassava stalks, wherein our plant pathologist identified 18 as CPD infected, and 22 were healthy/normal/or with a different disease. As the prototype passes through each cassava plant, our plant pathologist verifies if it can detect CPD infected or has no detection.

IV. Results and Discussion

For objective one, on testing two methods in transmitting long-distance high definition (HD) video capture. The wireless video transmission results show that the working time per battery charge of the NDVI camera (while installed in the video TX/RX) is capable of reaching three hours on preview mode with a remaining one bar on the battery indicator. Actual working distance of the Video TX/RX. Both 2.4Ghz and 5Ghz setups reached 900 meters in the actual ground test with few trees in between. Also, both setups lose connection after a total loss of line of sight between the TX and RX. The actual latency of the video transmission is at 90-100 milliseconds.

The second aim is to construct a small configuration for a long-range wireless video transmission system. The tests conducted between the two wireless configurations showed promising results with the given environmental condition during the field testing. However, we opt to use the 5Ghz setup moving forward simply because it is very straightforward to deploy both its transmitter and receiver. Also, given the fact that the end-users are not technically knowledgeable on setting up the 2.4Ghz configuration, which may be too complex for non-technical users, using it may pose problems during the turnover and maintenance of the system.

The creation and testing of a real-time CPD detection and quantification monitoring system and wireless video transmission test performance are goals 3 and 4. The developed real-time CPD detection and quantification monitoring system was successfully integrated into the wireless video receiver and seamlessly visualized all the incoming data using the three different CNN models, as shown in Fig. 16.

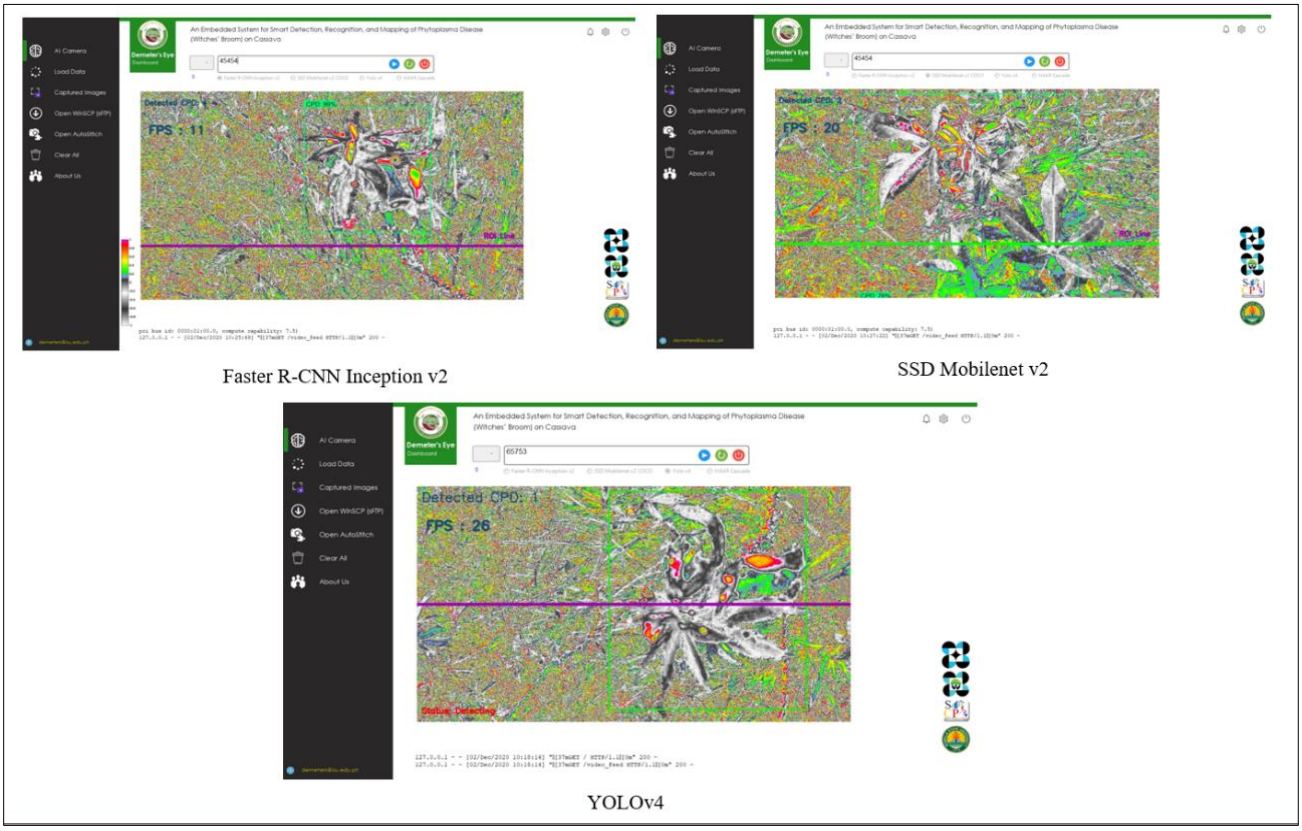

Fig. 16. Deploying the Three Custom Trained CNN Models (Faster R-CNN, SSD Mobilenet v2, and YOLOv4.

For objective 5, the comparison of the test results in each model used, the tabulated results using each custom-trained CNN model at different frame resolutions presented in Tables I to VI show that the Faster R-CNN model has the highest detection accuracy across different frame resolutions with a top detection rate of 13 out of 18 CPD samples. However, this has the lowest processing frame count among the three CNN models used. On the other hand, the YOLOv4 model has a top processing speed of 25 frames per second and a 9 out of 18 detection rate on CPD samples. In contrast, the SSD Mobilenet v2 model has a top processing frame count of 20 frames per second, which is second to the YOLOv4 model in terms of processing speed. However, it has the lowest detection rate, with just 6 out of 18 CPD samples being detected.

Table I shows the detection results using Faster R-CNN Inception v2. The video resolution was 1080 x 720 at eight frames per second (FPS). Negative samples mean that during the detection process of the system, these are samples that are not infected with CPD. In contrast, those positive samples are samples that were infected with CPD. This particular table showed that from the 25 negative samples, it recognized 20 True Negative (TN) from the samples while only 5 were False Negative (FN). Furthermore, the Faster R-CNN framework recognized 13 True Positive (TP) and 2 False Positive (FP) samples from 20 samples infected with CPD.

Table II is the detection tests using Faster R-CNN Inception v2 960 x 640 at 11FPS. The 24 negative samples recognized 17 as TN and seven as FN. From the 16 positive samples, the result is 11 as TP and five as FP.

Table III shows the result of tests using YOLOv4 1080 x 720 @22FPS. From this table, 18 were detected as TN while nine were detected as FN from the 27 negative samples. For the positive samples, the system saw nine as a TP, while 4 were FP.

Table IV also presented the results using YOLOv4 960 x 640 @25FPS. The result is not much desirable since from the 26 negative samples. It only detects 14 as TN, which is close to detection of FN, which is 12. The same is through with its detection on positive samples. It detects 8 FP and 7 FP from 15 positive samples.

Table V presents the results using SSD Mobilenet v2 1080 x 720 @18FPS. From this table, the detection accuracy can be seen as low. It has 13 TN and 12 FN from 25 negative samples, while 9 FP and 6 TP from 25 positive samples.

Table VI shows the result using SSD Mobilenet v2 960 x 640 @20FPS. Its accuracy is less good than the previous methods. From the 25 negative samples it detects 11 TN and 14 FN. While from the 15 positive samples, it detects 11 FP and 4 TP.

Based on these results, if the image processing speed is considered, YOLOv4 is better than other models. Faster R-CNN inception v2 performs better if accuracy is a priority. Hence, these two models can be used depending on the purpose of the detection of the CPD. However, the most important factor to be considered must be its accuracy since CPD detection is the main objective of this study.

V. CONCLUSION

During the field testing/actual testing, the 5Ghz set-up was used because it is straightforward to deploy both its transmitter and receiver. The developed real-time CPD detection and quantification monitoring system was successfully integrated into the wireless video receiver and seamlessly visualized all the incoming data using the three different CNN models. If the consideration is the image processing speed, YOLOv4 is better compared to other models. Faster R-CNN inception v2 performs better if accuracy is a top requirement. Hence, these two models can be used depending on the purpose of the detection of the CPD. However, the most important factor to be considered must be its accuracy since CPD detection is the main objective of this study.

VI. RECOMMENDATION

The test's discussed results using the three methods - SSD Mobilenet v2, Faster R-CNN Inception v2, and YOLOv4, shows that Faster R-CNN Inception v2 has the highest accuracy. However, the accuracy rate needs to be improved to achieve optimal accuracy. The suggestion is to increase the training datasets and modify the hyperparameters to achieve maximum accuracy.

ACKNOWLEDGMENT

We want to extend our sincerest gratitude to the Department of Science and Technology (DOST) for funding this project under the Science for Change Program, particularly under the CRADLE PROGRAM. The Philippine Council for Agriculture, Aquatic and Natural Resources Research and Development (PCAARRD) as the monitoring body, particularly the Agricultural Resources Management Research Division (ARMRD). To the Isabela State University, Quirino State University, EDCOR Cassava Development Cooperative, and the LGU San Guillermo, Isabela.

***Abstract*—The ubiquity of smartphone use nowadays is undeniable exponentially growing, replaced cell phones, and a host of other gadgets replaced personal computers to a certain degree. Different smartphones specifications and overwhelmed smartphone advertisements have caused broader choices for the customer. Many qualitative and quantitative criteria need to consider, and customers want to select the most suitable smartphones. They face difficulties deciding the best smartphone according to their budget and desire. Thus, a new method is needed to recommend the customer according to their preferences and budget. This study proposed a method for optimizing the recommendation system of the smartphone using the genetic algorithm (GA). Moreover, it is implemented with a progressive web application (PWA) platform to ensure the customer can use it on multiple platforms. They can choose the platform to input any specification of smartphone preferences besides the budget. Functional testing results showed the achievement of the study's objectives, and usability testing using UEQ managed to receive feedback of 93.64%, with an overall average mean of 4.682. Therefore, according to the outcome, it can be concluded that optimizing the smartphone recommendations through GA enables the customer to ease the comparison based on the obtained optimum result.**

Keywords*—Genetic algorithm; progressive web application; recommendation; smartphone introduction

I. Introduction

In this modern era, smartphones are one of today's most necessary and personal technologies [1]. Smartphones can drastically alter how humans communicate, consume information consumption, and use their time. Smartphones are used to make calls, read or send emails, view and upload images and videos, play games, and listen to music [2]. Besides, it reacts as a personal diary to record reminders or schedules and contacts, browses the internet, speech searching, verify the latest news update and the current or predicted climate. It also uses text chatting applications such as Facebook, Twitter, and WhatsApp and connects on social networks [3].

The selection of smartphones compatible with consumers' needs has motivated our research topic. Molinera et al. [4] claimed that whenever it comes to purchasing a new smartphone model, customers can easily get lost in the midst of hundreds of advertisements from different companies. We have surveyed 100 respondents, and it shows that 89% of respondents have trouble choosing the right smartphone. Also, 94% of respondents of the same survey claimed that it is more convenient to recommend a list of smartphones within their budget and preferences. Furthermore, they were having difficulties comparing the preferences of the smartphone features within the budget. They have to search manually through dozens of reviews on the overwhelming information on the internet. 77% of respondents claimed that they read reviews or comment on the smartphone before making a decision. It is time-consuming and puts much effort into cognitive while manually searching the rating and feedback based on user preferences [5]. The consequences of relying on reviews will be a combination of negative and positive feedback, and consumers feel difficult to seek a cogent response. Besides, the unauthorized review may be a scam too.

Nonetheless, most comparison approaches use the specific meaning of the attribute. Sometimes, customers may not accurately describe the artifacts in which they are interested. They do not entirely understand the level or degree of specific attributes and hard to locate a precise analysis for a specific service feature [6]. The recommendation of the product's latest features in an adaptive manner is not successful due to the high-end products' short life cycles. It has caused inappropriate reviews and obsolete scores rated by other users [7].

Sponsored by Indonesian Ministry of Research and Technology and Universitas Pendidikan Indonesia.

Cha & Seo [8] claimed an average of 54% estimated that 21 developing and emerging countries such as Malaysia, Brazil, and China had at least one internet or smartphone by 2015. The ubiquity of smartphone use nowadays is undeniable exponentially growing. Smartphones have become a host of other gadgets, replaced cell phones, to a certain degree, replaced personal computers [9]. In 2017, 5 billion individuals possessed smartphones, and by 2025, this number is predicted to rise to 5.9 billion. 95% of the population in the United States owns a smartphone. Through new features, smartphones are constantly evolving, becoming cheaper and faster each year at the same time. Therefore, it is essential to consider the quality and quantitative requirements to select the most preferred smartphones. For example, pixel density, the camera resolution, RAM, battery power, stand-by time, memory built-in, weight, thickening, scaling, type of the processor, processor, and costs are quantitative parameters. In the meantime, consistency requirements include longevity, reliability, aesthetics, and branding. Thus, Chen et al. [10] indicated that customers' purchasing decisions are different because their perceptions and desires vary. Customers would feel satisfied with the criteria leading to an informed decision to make one-hand purchases and meet their expectations.

Now-a-days, humans have been very dependent on mobile phones since developing robust mobile applications. Besides, mobile applications thrived originally aimed for productivity assistance and information retrievals such as emails, calendars, and contact databases. Due to the rapid advancement of technology and public demands, it is essential to implement an effective development of mobile applications as there is a need to overcome many challenges [11]. Unfortunately, every invention comes with limitations where mobile applications need to be compatible with the platform of the devices to work.

As a solution, in this study, the system will be a progressive web application (PWA) which is application software that can cross any platform. This enhancement of PWA does not force users to download the application to experience the features. However, the functionality remains the same [12]. Besides, this recommended system research optimization technique focuses on adapting a GA. The selection method works by using each member's fitness function according to the fitness value calculated. Resulting the fittest member is more likely to be selected based on the selection likelihood. This study outcome, SRcS, which stands for Smartphone Recommendation System, helps recommend which smartphone is affordable for the customer to purchase that follows customer preferences within the budget. This paper's organization begins with a brief introduction in Section 1. Section 2 explained the literature review and followed by methodology in Section 3. Section 4 elaborates on results and discussion. Finally, Section 5 concludes the study and briefly mentions future enhancement.

II. Literature Review

This section describes the smartphone preferences, recommendation technique, and progressive web application on the related issue.

A. Smartphone Preferences

A smartphone merged some electronic devices and became a miniature of a computer. It supports mobile or portable computing technology and applications with efficient operating systems [13]. The opportunities provided by the internet eventually makes smartphones often provide qualitatively different service. Smartphone has become a part of human life basic needs nowadays. Rotondi et al. [14] claimed that the smartphone's advent has significantly changed how information is accessed, allocated time, and interacted with others. The consumer's decision-making process depends on the product attributes. Price is the most obvious concerning the attribute of smartphones [15]. Due to that, a smartphone's price plays a vital role in a company's market strategy. Customers will also compare their needs and want between various products to buy their products inside their budget fit [16]. Therefore, the product quality must match the price to find that it is worth investing in a smartphone.

Next, consumers' need for multi-function cell phones drives the smartphone's development [17]. There are plenty of platforms for development, but the two famous and excellent platforms are iPhone Operating System (iOS) from Apple and Android from Google. Up until now, Android and iOS remain to dominate the market share of smartphones worldwide. Despite that, the Android operating system is considerably newer than iOS. Android utilizes iOS weaknesses and promotes a tangible cross-platform development operating system [18].

Furthermore, [19] agreed that organizations will always find ways to be different, especially in the smartphone industry, which continuously changes technology. The brand name can be an organization's brand and exclusivity. The brand name can be a title, word, logo, and design to differentiate its rivals such as Acer, Amazon, Apple, Samsung, BlackBerry, Nokia, Huawei, Lenovo, Microsoft, One Plus, Oppo, ZTE and Sony, and. Marketers were trying to create brand equity to improve customer response to win consumer preference and loyalty. Brand equity represents how the brand thinks, feels, and behaves. Thus, it becomes the products and services value-added [20].

Smartphones will only become more and more popular. Most people depend on their mobile devices to run their lives nowadays. Thus, smartphone brands need to thoroughly understand the current use and future adoption. The brand presence is essential, as it ensures that the business has a specific role in the markets and has established its reputation in the consumer's view [21]. However, [22] claimed that choice depends on the consumer's different variables, calculated by the utility. This proposed project focuses on the top five smartphone model brands in Malaysia: Samsung, Vivo, Oppo, Huawei, and Xiaomi. Purwanto [23] revealed a study outcome during the covid 19 pandemic where sales promotion and brand image influenced smartphone purchasing.

Besides, there are many high technology smartphones features available in the market today. Therefore, different individuals can choose a specific smartphone to meet their needs and desires—the smartphone features, including software and hardware. Hardware is a system concept that can

be physically touched; meanwhile, software, for instance, computer programs, procedures, and documentation are the general terms. Hardware is the smartphone's size, design, color, body, and weight, whereas software consists of the documentation and application. Rahman et al. [24] alleged that many consumer choices could be rational, such as time management, communication, and emotional, such as camera, games, music, and application features.

Cost, reliability, battery's lifespan, special promotions, camera resolution, size, storage offered, networking, or connectivity options affect customers' features when purchasing any smartphone. People believed that the smartphone's size connects with the screen's resolution and is inversely linked, such as the bigger the phone, the higher the resolution, and the harder it to carry. Therefore, with the enormous open doors within a short period in the smartphone showcase, smartphone suppliers need to understand factors that satisfy the customer decisions on which model to buy [25]. All of these demands in preferences become the input. Then, the system processed the algorithm and produced a list of smartphones that matched the most input preferences.

B. Recommendation Technique

Artificial intelligence (AI) approaches have become more prevalent in a variety of fields. For instance, recommender systems provide consumers with recommendations for selecting different items from a massive pool of items [26]. Consequently, it creates a program that can allow people to select requirements and remove the dilemma. Numerous options allow humans to be uncertain about what is best for them or fulfil their needs. The recommendation helps customers reduce the time and difficulty of searching for the information required. The methods promote customers towards the product by collecting and evaluating feedback from other buyers, implying reviews from specific establishments and even the customer [27].

Consequently, many new researchers have embarked on this study to develop more recommended research and techniques. Several techniques have been evaluated based on the accuracy, ability to receive multiple inputs, and simplicity—for instance, fuzzy logic, content-based filtering, and genetic algorithm. Table I explains the details of the comparison.

TABLE I. FEATURES COMPARISON BETWEEN RECOMMENDATION TECHNIQUES

Technique / Features	**Content-Based Filtering**	**Fuzzy Logic**	**Genetic Algorithm**
Accuracy	Medium	Low	High
Receive many inputs and run in a single run	Yes	No	Yes
Simplicity	No	No	Yes

In conclusion, GA has been chosen because simple programmability and efficiency features offered. GAs is a robust optimization system widely applicable since it requires users to give many inputs to run in a single run [28]. The GAs maintained the population of an individual's chromosomes along with their fitness scores. It gave more opportunities for individuals with better fitness scores to reproduce than others. Thus, GA can give the best optimization solution to the smartphone buyer. No matter what the user may input into the system, GA will always provide one recommendation instead of null.

C. Progressive Web Application

PWA is an abbreviation for Progressive Web Application. It is also a cross-platform with a new approach that modern web capabilities provide a user experience. PWA uses the most recent technology to incorporate the best of web and mobile apps. PWA hence unifies the browsing web experience on mobile and other devices of various pixel sizes, including laptops, tablets, and other devices [29]. The web-based framework is designed using HTML, CSS, and JavaScript standards. It is compatible with any platform that supports standards-compliant browsers. Besides, the PWA development and evolution is not a new framework or technology. It allowed the mobile expansion externally for cross-platform [30]. With the advantage of a mobile app's features, PWA enhances user retention and execution without complicating a mobile application's maintenance. Biørn-Hansen et al. [31] declared that the service worker sits at the heart of a PWA because, without a service worker, support will cause PWA not to work correctly. A service worker helps give the consumers of a web application an offline experience. A service worker is a client-side script that operates on a different JavaScript thread and is independent of the web application. It helps developers programmatically store and preload data so that the code can be loaded from the user cache if the network connection fails.

Furthermore, PWA requires a manifest file. The JSON file is the manifest file for the web application that applies to the user-installable home screen. A manifest file configures the application includes name, short name, icons, background color, view, width, and theme color. It manages to change the behavior and design of PWA. The PWA platform adapts in developing this recommendation system because it is understandable, reliable, and faster to access. Besides, PWA is a regular application on a computer. The ability to run it from a uniform resource locator (URL) makes it easy for users with a browser to use the program [32]. Therefore, it is unnecessary to maintain an application programming interface (API) with backward compatibility. Each user uses the same website version of the code, unlike the version fragmentation of native apps, making it easier to deploy and manage the software. Meanwhile, web-based information systems offer easy and cost-efficient resources to facilitate usability, effective delivery, efficient administration, and cross-platform versatility.

III. METHODS

Four subsections describe the flow in implementing the proposed idea: system use case, system flowchart, the phases of GA implementation, and PWA implementation.

A. System use case for SRcS

The overall system use case illustrated in Fig. 1 demonstrates using the UML on users' interaction. We identify ten use cases for this system: seven use cases handled by the admin and three by the user.

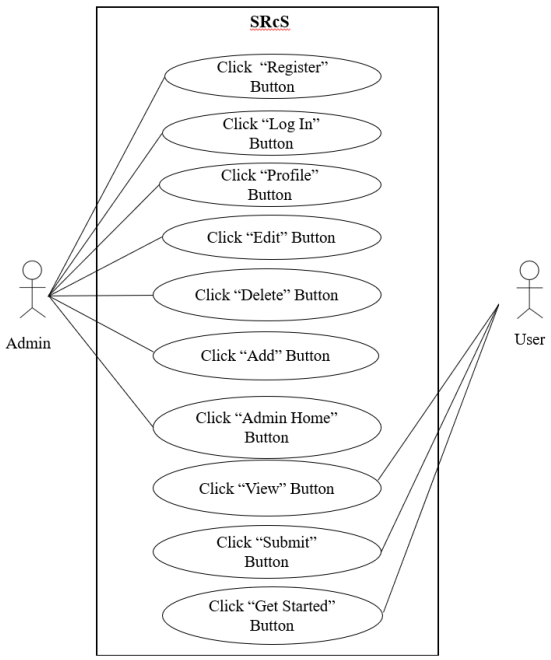

Fig. 1. SRcS use Case Diagram.

B. Flow Chart for SRcS

A visual representation of the series of steps and decisions or a flowchart requires a system using different symbols containing information. It is essential in design phases to avoid any obstacle and clearly describe the system. The flow of the recommendation process for SRcS shown in Fig. 2. The user must provide 16 specifications of their preferences into the system, including the budget. The chosen specification will then go through the five GA processes to get the smartphone's highest match with the user's input. Lastly, resulting in the top three smartphone recommendation lists.

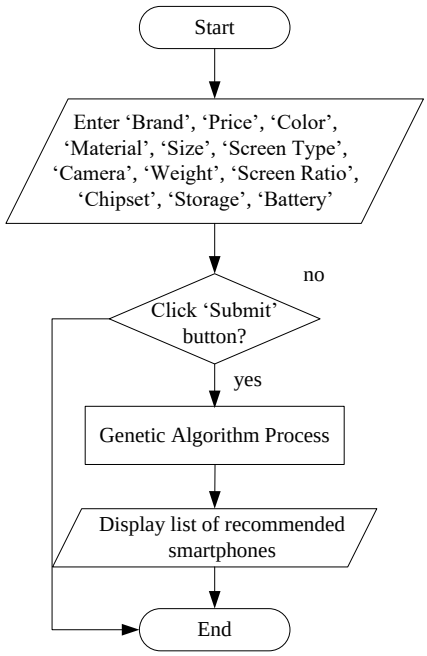

Fig. 2. Process flow for SRcS.

C. Genetic Algorithm Implementation

As mentioned, GA involves five processes that start with initializing the population, followed by fitness calculation, crossover, mutation, and convergence. All user information is stored in the system as input. This sub-section presented a detailed description of each process involved and how GA produces the final result. Fig. 3 shows the basic process of GA, which consists of six main steps: 1) initialize population, evaluate fitness, 2) create a new population through the selection of the individuals, 3) process the crossover and mutation, 4) test the condition and if satisfied, return the best individual of the current population. Else, repeat the process.

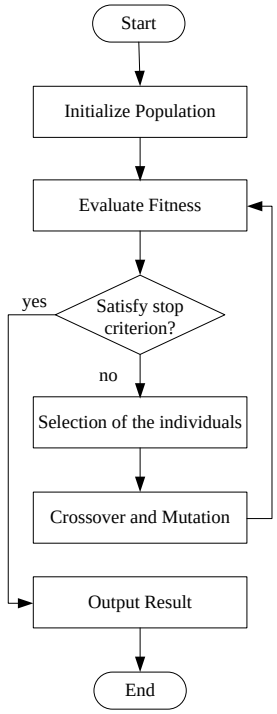

Fig. 3. Process for Genetic algorithm

1) Step 1: Initialize population: GA begins with an initial population of typically randomly formed phenotypes. The GA needs to continue to evolve new genotypes from the population and evaluate each genotype's fitness at each iteration. The population will create chromosomes up to 150 generations as their stopping condition is defined in for loop. Each chromosome encodes three types of smartphones. Each smartphone contains information like the brand, price, colour, material, size, year release, display, camera, weight, chipset, CPU, GPU, RAM, memory, and battery, as in Fig. 4.

2) Step 2: Evaluate fitness: The next phase is calculating each chromosome's fitness by comparing the user with database chromosomes. Each smartphone holds an equal percentage of totalling 100%. The fitness function is the inverse of the input given, for example, using three variables: a, b, and c. Fitness means the best result for the input given for a, b and c, so we can assume the value will be d as in (1).

$$a + b + c = d \quad (1)$$

Smartphone23	Smartphone67	Smartphone09	Fitness
Brand	Brand	Brand	
Price	Price	Price	
Color	Color	Color	
Material	Material	Material	
Size	Size	Size	
Release Year	Release Year	Release Year	
Screen Type	Screen Type	Screen Type	
Camera Number	Camera Number	Camera Number	
Rear Camera	Rear Camera	Rear Camera	
Front Camera	Front Camera	Front Camera	
Weight	Weight	Weight	
Resolution	Resolution	Resolution	
Chipset	Chipset	Chipset	
GPU	GPU	GPU	
RAM	RAM	RAM	
Storage	Storage	Storage	
Battery Capacity	Battery Capacity	Battery Capacity	
Battery Type	Battery Type	Battery Type	

Fig. 4. Chromosome Encoding.

The process of fitness function declares as the inverse of | a + b + c – d | because of the need to reduce the sum of the three variables from deviating from d. Thus, the fitness function identifies as in (2).

$$\text{Fitness Function} = 1/ | a + b + c - d \quad (2)$$

3) Step 3: Crossover and mutation: After calculating the value of fitness, the best fitness value is chosen and arranged to descend from the highest fitness-to-lowest. The crossover and mutation operation uses the first three highest fitness values for chromosomes. Then, it follows by sorting out the fitness value. Fig. 5 shows the crossover example between chromosome X and Y. The GA process chooses and displays the highest fitness value data to the user.

D. Progressive Web Application Implementation

A PWA requires a web manifest and service worker file. The manifest file allows the system to execute the full-screen web application as a standalone application. It can assign an icon to show when finishing the application and assign a theme and background colour app on the computer. Furthermore, this application also has implemented an installation banner that makes it easier to be download on any device.

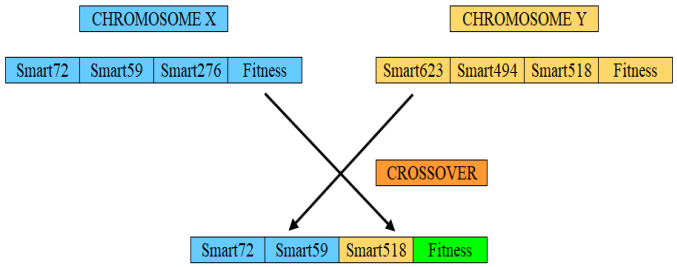

Fig. 5. Example of Crossover Process.

Next, service workers are the mastermind of PWA, in which it reacts as middleware by intercepting each request. It responds instantly to the cached request or performs the channel recovery. There are two caches implemented in this system, which are dynamic and static. In static stores, every single asset while in dynamic fetches all previously requested assets while users online limit to 20 requests to be stored. Inside service worker also implements install and activate event code. An event code fires when the service worker is mounted and occurs once. If the service worker is installed and activated, the device will use the currently installed service worker. The caches are deleted whenever there are changes to cache the latest version of code. Therefore, every declared asset will be cached automatically.

E. Evaluation and Acceptance

In this study, two types of tests were performed, which are testing on functionality and usability. Functionality evaluation is testing to verify the outcome for each use case module. Every module is evaluating whether it could generate the predicted result. Usability testing is about bringing actual people to connect with the system and watch their behavior and reactions. The key benefit of usability testing is to detect usability problems with a design as early as possible before the design is adopted. This step ensures that the program built is convenient for someone with no computer science experience to use. Therefore, we do the evaluation using the User Experience Questionnaire (UEQ). UEQ is a quantitative survey proposed by [33] [34], and we test it according to the SRcS functionality. UEQ consists of 26 dimensions, but we chose five dimensions related to the study as in Table II.

TABLE II. FIVE UEQ DIMENSION AND DESCRIPTION FOR USABILITY TEST

Dimension	Description
Attractiveness	Overall impression of the product. Do users like or dislike the product?
Perspicuity	Is it easy to get familiar with the product? Is it easy to learn how to use the product?
Efficiency	Can users solve their tasks without unnecessary effort?
Usefulness	Is it useful? Helpful? Beneficial? Rewarding using the application?
Novelty	Is the product innovative and creative? Does the product catch the interest of users?

Our research respondents consisted of 30 public participants who randomly took part in the application testing. Firstly, we briefed the participants on project details and what they were required to do with the application. Then they tried the application until they were satisfied with the recommendation given by the system. Once they finished it, we issued the UEQ using the Google Form.

IV. RESULTS AND DISCUSSION

A. Functionality Testing

Functionality evaluation is testing to verify the outcome for each use case module. Every module is evaluating whether it could generate the predicted result. Fig. 6 and Fig. 7 indicate the SRcS snapshot, the user filling up the form with the questions that began with the brand, price, and specification preferences question. Then, SRcS shows the user's smartphone recommendation result, as in Fig. 8.

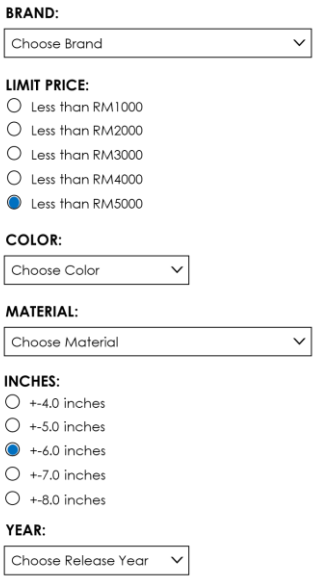

Fig. 6. Snapshot of SRcS submenu 1

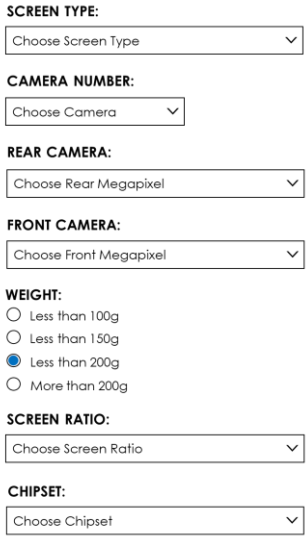

Fig. 7. Snapshot of SRcS submenu 2

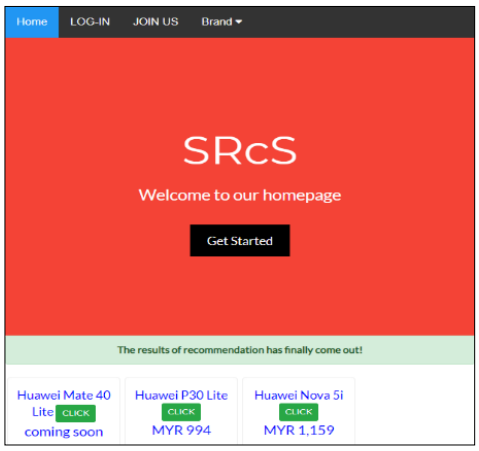

Fig. 8. SRcS recommendation result

The evaluation of the functionality test follows according to the use case of SRcS, and Table III displays the SRcS outcome on the functionality test to ensure that it works according to the proposed.

TABLE III. SRCS FUNCTIONALITY TEST RESULT

Use Case	Description	Remark
Register Button	Allows a new admin to register into the system	Successful
Log In Button	Allows admin to log in to the profile page	Successful
Profile Button	Allows admin to view their account information	Successful
Edit Button	Allows admin to update their account information	Successful
Delete Button	Allows admin to delete smartphone details system	Successful
Home Button	Allows both user and admin to view all smartphones available in the database	Successful
Find Button	Allows both users to find a smartphone that matches with user's preferences	Successful
Profile Button	Allows admin to view their account information	Successful

B. *Usability Testing*

We evaluate the feedback given by the 30 respondents and summarize the UEQ results for the five items. Each of the dimensions has a related and specific questionnaire to get a quantified value. Table IV shows the overall average value of the UEQ with the specific result for mean and average mean.

For the first dimension attractiveness, feedback shows that respondents felt that the SRcS shows the highest average mean of 4.800 for four questionnaires that asked whether the application is enjoyable, good, pleasant to use and user friendly. Item A2 get the highest average mean among the rest dimension with 4.933, and we get direct feedback that the application is good. Item A4 get the lowest average mean of 4.667 for the first dimension due to not all specification being well-known by some respondents. We further analyze the second dimension, perspicuity, which is related to the ease of using the application with an average mean score of 4.711. We guest the same issue for item P2 with A4, where not all users have deep knowledge about the smartphone specification. Dimension three is dependability asked on the application's reaction to the user input, whether predictable and meets expectations. Item D1 gets the lowest mean among the rest with 4.433, but item D2 shows a contra result that the input and command meet the user's expectations. The fourth dimension is related to the usefulness of the application. Item U1 until U3 managed to get the result more than 4.500 mean with the average mean of 4.750. We can assume that the system is really useful to the respondents. The last dimension is novelty involved in the idea behind the application into four different criteria: creative, inventive, leading edge and innovative. Although we got the lowest mean for item N3, we managed to get an average mean of 4.533, which is more than 4.500. In summary, the average overall mean score for SRcS is 4.682 or 93.64% conclude that the system considers received a 'High' level of usability acceptance.

TABLE IV. MEANS, STANDARD DEVIATION AND CONFIDENCE INTERVALS UEQ FOR SRCS

Dimension	Item	Question	Mean	Average Mean
Attractiveness	A1	In your opinion, the application is enjoyable	4.767	**4.800**
	A2	In your opinion, the application is good	4.933	
	A3	In your opinion, the application is pleasant to use	4.833	
	A4	In your opinion, the application is user friendly	4.667	
Perspicuity	P1	In your opinion, the application is easy to understand	4.833	**4.711**
	P2	In your opinion, the application is easy to learn	4.533	
	P3	In your opinion, using the application is easy	4.767	
Dependability	D1	In your opinion, the reactions of the application to your input and command is predictable	4.433	**4.617**
	D2	In your opinion, the reactions of the application to your input and command meets expectations	4.800	
Usefulness	U1	You consider using the application as useful	4.533	**4.750**
	U2	You consider using the application as helpful	4.767	
	U3	You consider using the application as beneficial	4.867	
	U4	You consider using the application as rewarding	4.833	
Novelty	N1	In your opinion, the idea behind the application and the designs are creative	4.567	**4.533**
	N2	In your opinion, the idea behind the application and the designs are inventive	4.500	
	N3	In your opinion, the idea behind the application and the designs are leading edge	4.433	
	N4	In your opinion, the idea behind the application and the designs are innovative	4.633	
Average Overall Mean Score			**4.682**	
Average Percentage of Mean Score			**93.64%**	

V. CONCLUSION

This study aims to develop a smartphone recommendations system (SRcS) using a GA adaptation with innovative PWA. With the GA advantages, SRcS helps users seek out and purchase a smartphone according to specification preferences, needs, and allocated budget. Tacitly, it helps to ease the time-consuming manual survey and comparison via websites. The outcome performed from the functionality testing by assessing and testing the use case function proves the SRcS functions work correctly. The usability testing using the five scale in UEQ shows a good result with a positive evaluation value mean scores that indicate the majority of the respondents preferred using the SRcS. The benchmark result also shows an excellent trend and prove the acceptance of SRcS. For the next improvement, SRcS can expand the fitness of the brand's choices, view the smartphone's picture in a 3D rotation image, and recommends the authorized seller.

SG-TSE: Segment-based Geographic Routing and Traffic Light Scheduling for EV Preemption based Negative Impact Reduction on Normal Traffic

Shridevi Jeevan Kamble, Manjunath R Kounte
School of Electronics and Communication
REVA University, Bengaluru-560064, India

***Abstract*—Emergency Vehicles (EVs) play a significant role in giving timely assistance to the general public by saving lives and avoiding property damages. The EV preemption models help the EVs to maintain their speed along their path by pre-clearing the normal vehicles from the path. However, few preemption models are designed in literature, and they lack in minimizing the negative impacts of EV preemption on normal vehicle traffic and also negative impacts of normal vehicle traffic on EV speed. To accomplish such goals, the work proposes a Segment-based Geographic routing and Traffic light Scheduling based EV preemption (SG-TSE) that incorporates two mechanisms: Segment based Geographic Routing (SGR) and Dynamic Traffic Light Scheduling and EV Preemption (DTSE) for efficient EV preemption. Firstly, the SGR utilized a geographic routing model through the Segment Heads (SHs) along the selected route and passed the EV arrival messages to the traffic light controller to pre-clear the normal traffic. Secondly, the DTSE designs effective scheduling at traffic lights by dynamically adjusting the green time phase based on the minimum detection distance of EVs to the intersections. Thus, the EVs are passed through the intersections quickly without negatively impacting normal traffic, even the signal head in the red phase. Moreover, the proposed SG-TSE activates the green phase time at the correct time and minimizes the negative impacts on the EV preemption model. Finally, the performance of SG-TSE is evaluated using Network Simulator-2 (NS-2) with different performance metrics and various network traffic scenarios.**

I. Introduction

The Vehicular ad hoc networks (VANETs) enable real-time communication among the roadside vehicles with the support of roadside infrastructure [1]. The VANETs receive high popularity among researchers owing to the application diversity [2]. The VANET applications are mainly categorized into safety and infotainment. In infotainment applications, the vehicles exchange messages about parking areas and hotels and make the journey very comfortable. In contrast to infotainment applications, the safety applications alert the drivers about hazardous situations such as crash warning, accident warning, EV preemption, and others. Hence, the safety applications require strict delay bounds compared with comfort applications. The Emergency Vehicle (EV) preemption is one of the prime VANET applications in which the emergency vehicles are quickly navigated from the approaching lane and intersections [3]. The EVs such as ambulances, fire fighting vehicles, police vehicles, and other defense fighting vehicles receive high priority on roads, as they have to reach their destination on time to save human lives and property losses. The traffic lights integrate various preemption methods and assure desired speed to EVs along its selected path to the incident location to benefit such EVs [4].

The Emergency vehicle preemption system (EVP) interrupts the signal timings of normal traffic at the signalized intersections and provides a green band to the EVs along its routes [5]. Thus, the preemption assists the EVs to pass without stopping or waiting at intersections. It potentially minimizes the travel time and shrinks conflicts with other vehicles in the traveling route [6]. However, it may also negatively impact the general vehicle traffic in the approaching lane. It suffers the vehicles not only in the corresponding intersection but also on other neighboring intersections of coordinated signal control. Hence, it is essential to activate the traffic light green phase at the correct time to reduce the negative impact of EV on normal traffic and also pre-clear the roads in an efficient way to minimize the negative impacts of normal traffic on EVs. Owing to the high dynamic nature and frequent link failure, the geographic routing protocols are highly fit for the VANET environment [7]. Therefore, this work proposes a novel EV preemption model in which segment-based geographic routing and effective traffic light scheduling pass the EVs at intersections quickly with the desired speed.

By designing efficient EV preemption with timely green phase activation, the proposed SG-TSE diminishes both negative impacts, such as the negative impact on normal traffic due to EV preemption and the negative impact on EV due to normal traffic. The conventional methods handle only negative impact issues, resulting in inappropriate EV preemption and traffic light control. Thus, it leads to losses of human life and property damages. Hence, crucial green phase activation is required with optimal routing strategies. The SE-TSE solves such an issue significantly by splitting the vehicle density of highly congested scenarios into multiple segments and organizing the vehicles with accurate green phase activation. For that the SG-TSE utilizes a geographic routing

method. Compared to existing preemption methods, the performance of the proposed model is highly superior in terms of EV preemption speed, especially under a high vehicle density scenario. By navigating the emergency vehicles quickly along its path even the road is congested, the SG-TSE saves human lives and prevents property losses from a hazardous situation.

A. Contribution

The main contributions of the proposed work are as follows.

- To guarantee the desired speed of EVs at intersections under feasible traffic conditions, this work proposes an SG-TSE protocol that includes two different mechanisms, SGR and DTSE, to achieve its objective.
- To announces the EVs arrival to the traffic light controller, the SGR divides the EV approaching lane into many segments and elects an SH in each segment for geographic message routing.
- The DTSE uses an effective traffic light scheduling model in which the green phase time is adjusted based on the minimum detection distance of EVs from the intersection that effectively diminishes the normal traffic impacts on EV speed and also EV preemption impact on normal vehicles.
- Finally, the effectiveness of the proposed SG-TSE is evaluated using NS-2. The performance is analyzed with various metrics like packet delivery ratio, overhead, throughput, delay, and EV preemption speed under different network traffic conditions.

B. Paper Organization

The remaining part of the SG-TSE is organized as follows. Section 2 survey the paper related to EV preemption models and analyzes the gaps in the existing works. Section 3 provides an overview and network model of SG-TSE. Further, it clearly describes the two mechanisms such as SGR and DTSE. Section 4 describes the performance evaluation by applying the simulation parameters and performance metrics for SG-TSE performance analysis. Finally, Section 5 concludes this paper.

II. Literature Survey

For a clear view, the survey is categorized into two types that are geographic routing methods and EV preemption methods.

A. Geographic Routing Methods

A Predictive Geographic Routing Protocol (PGRP) in [8] maximizes the connectivity to deal with VANET dynamicity. The PGRP instructs the vehicles to assign a weight to their neighboring vehicles based on the direction and the angle of the corresponding vehicles. The PGRP can predict the position information of the vehicles at the time with the help of hello packets according to the acceleration information of vehicles. The work in [9] proposes a Maxduration-Minangle GPSR (MM-GPSR) routing protocol that defines a cumulative communication duration in greedy forwarding to obtain the node stability of neighbor nodes. Further, it selects the nodes with maximum cumulative communication duration as next-hop nodes for communication. If the greedy routing is failed, the MM-GPSR utilizes the perimeter mode with the minimum angle method. The node location information is used to estimate the angles. Moreover, the MM-GPSR successfully transmits the packets to the destination with optimal forwarder nodes. The work in [10] proposes a novel geographic routing protocol named Geo-LU to enhance the VANET routing performance. It elaborates the local view of the network topology at the current forwarder by incorporating two-hop neighbor information. It exploits a link utility (LU) measure to measure the utility of a two-hop neighbor link. Further, it takes into account the minimum residual bandwidth on that link and its packet loss rate. Moreover, the Geo-LU effectively reacts to high network traffic and frequent link disconnections by including the two-hop neighbor information with LU measurement. The work in [11] proposes a dissemination mechanism with reroute planning for exchanging the emergency vehicle information.

B. EV Preemption Methods

Several research works have been designed for emergency vehicle route selection and pre-clearing by integrating the real-time traffic and travel time information [12] [13]. An emergency vehicle pre-emption strategy has been proposed in [14]. Such a preemption model can reduce the delay of emergency vehicle arrival caused due to wide network traffic. It utilizes a connected vehicle infrastructure and efficiently manages the time delay in emergency vehicle arrival. Further, the pre-emption model considers the worst-case non-emergency vehicle's waiting time issues. The work in [15] utilizes an emergency vehicle signal coordination method to offer a green wave to the emergency vehicles. The signal coordination method effectively clears the queue traffic on the road and creates a green phase for quick navigation of emergency vehicles. The work in [16] considers daily emergency vehicle routing issues in a specified network with high spatial resolution and offers effective decision support for emergency vehicular systems. The spatial resolution introduces two advanced technologies that are pre-hospital screening and lane pre-clearing.

The pre-hospital screening offers injury diagnosis of patients and lane pre-clearing assures that the ambulance is moved with desired speed in all lanes. Such a model exploits three various ambulances which can support first aids based on the pre-hospital screening. Moreover, it presents mixed-integer linear programming (MIP) strategy to allocate emergency vehicles to the patient location and navigate the vehicles promptly by planning the shortest traveling routes. Thus, it manages the ambulance fleet properly. A Virtual Traffic Light plus for Emergency Vehicle (VTL+EV) has been proposed in [17] to prioritize the emergency vehicles in an intersection. The VTL+EV is a decentralized and self-coordinated traffic control system in which the movement of emergency vehicles is expedited, and the normal vehicle waiting time is also minimized.

The work in [18] proposes a Global Positioning System (GPS) based traffic light preemption model to diminish the travel time delay of emergency vehicles. With the GPS data,

the emergency vehicle can become aware of its position and destination position. The GPS assists the preemption model by incorporating software programs with GPS technology and developing electronic maps to determine the shortest paths. Thus, the emergency vehicle selects the shortest paths based on GPS information and arrives on time. Also, the GPS-based preemption model clears the normal vehicles on the emergency vehicle path by effectively managing the traffic lights of intersections using transmitters. An innovative traffic signal control model in [19] diminishes the response time of emergency vehicles by utilizing connected vehicle infrastructure. Based on the beacons received from an emergency vehicle, such a model instructs the traffic signal to adjust the green phase earlier to reduce the arrival delay of emergency vehicles. The work in [20] proposes a priority signal control algorithm with transit signal priority to improve the emergency vehicle preemption. The transit signal priority model is a proven technique to offer an enhanced public transit operation quality in urban scenarios. The priority model tunes the traffic signal phases based on transit signal priority and serves quick preemptions to an emergency vehicle. Thus, it assists in alleviating the delay in emergency vehicle arrival and minimizing the impact of preemption on general road traffic. An emergency vehicle pre-clearing model in [21] prioritizes the emergency vehicle on the corresponding path by employing the cooperative driving of connected vehicles in a particular area. Such a model converts the connected vehicle cooperative driving issue as a mixed-integer nonlinear programming (MINP) to guarantee the emergency vehicle desired speed and to minimize the impact of pre-emption on connected vehicles. The MINP achieves the objectives by formulating a bi-level optimization model. Initially, the connected vehicles proceeding of the emergency vehicle are divided into various blocks. Further, an emergency vehicle sorting algorithm is applied in each block to sort vehicle trajectories. Thus, the MNP is solved based on the sorting trajectories, and the emergency vehicles are allowed with desired speed on the corresponding path. A novel traffic light-assisted emergency vehicle preemption method at an intersection has been introduced in [22]. Such a model employs wireless vehicles to infrastructure communication among the emergency vehicle and the traffic lights controller for preemption. It estimates the vehicle density at the intersections based on the messages and builds a dynamic mathematical model to discharge the vehicles in the queue.

The work in [23] utilizes a multi-objective programming model for emergency vehicle pre-emption at intersections. The main intention of such a model is to clear the emergency vehicles quickly at the intersection and increase the passing rate of normal vehicles by minimizing the emergency vehicle preemption impact. The work in [24] mainly focuses on constructing better routes for emergency vehicles by designing a realistic traffic-based optimization model. It obtains real-time traffic knowledge from the Google Maps Distance Matrix API. Finally, it finds the best shortest emergency vehicle path with less congestion. The real-time traffic flow-based dynamic and efficient traffic light scheduling algorithm in [25] adjusts the finest green phase time at the signalized road intersection based on realistic traffic information. It also considers the emergency vehicle presence in green phase time adjustment and assists for quick emergency vehicle passing. A multi-agent preemptive longest queue first system has been proposed in [26] to handle the emergency vehicle crossings at interrupted intersections. Further, an efficient preemption strategy is selected to diminish the negative impact of preemption on general traffic in [27]. It utilizes the VANET communication through the emergency vehicle path. Thus, it clears the entire route of an emergency vehicle in advance without disturbing the normal traffic flow. The work in [28] utilizes the internet of things technology to facilitate emergency vehicles crossing the intersections quickly. Such a model gathers the EV data along its route periodically and intermittently and provides high priority to the EVs, especially at intersections. A signal priority algorithm in [33] develops a queue length-based green signal activation model in which the signal green phase is extended to the specific road that experiences a high delay. The priority algorithm considers queue length to solve the arrival time issues of the emergency vehicle and reduce the impact on normal vehicles along the emergency vehicle route. The smart emergency vehicle plan model in [30] designs an efficient EV communication model by utilizing app monitoring and a centralized network. The vehicles in the traffic control system have a unique identity number to establish a connection with a centralized server around the traffic signal. The centralized network maintains the vehicular network data, and it plans effective routes to the emergency vehicles. A novel EV preemption method in [31] exploits the advantage of the vehicle to infrastructure communication and vehicle density queue information to manage the traffic light controller. However, it lacks to consider the negative impact of EV preemption on normal traffic.

C. Research Gap and Problem Statement

Numerous emergency vehicle preemption and route selection methods are designed in the existing literature to pass the emergency vehicles quickly to the destination. Most of the emergency vehicle route selection model considers the traffic congestion and route length in the emergency vehicle path discovering. However, an emergency vehicle may be delayed due to the signalized intersections along its selected shortest path in urban scenarios. A minute of emergency vehicle delay causes tremendous loss of lives, and hence, it is crucial to minimize the impact of intersection delay caused due to inefficient traffic light scheduling. With aiming to solve such issues, the later researches utilize efficient preemption methods in which the vehicle and infrastructure communication are used to clear the emergency vehicle path or lane in an advanced manner. Such models allow the emergency vehicles to take high priority at the intersections even the signal is in the red phase. In such situations, there is a chance of accidents due to inexperienced and careless driver behaviors. Therefore, it is crucial to activating the signal preemption at the right time using appropriate scheduling methods. The proposed work attempts to design an efficient emergency vehicle preemption model in which geographic routing and timely traffic light scheduling are used to quickly navigate the emergency vehicles and reduce the impact of normal traffic.

III. Design Overview of SG-TSE

Generally, a less congested route with a short travel time is suggested for emergency vehicles. However, the suggested best routes may be suffered by normal vehicle traffic flows and the hindrances of normal road topology. This work proposes an emergency vehicle pre-emption method with the assistance of vehicular geographic routing and traffic light scheduling to reduce the negative impacts of normal vehicle traffic on emergency vehicle speed. Fig. 1 shows the block diagram of the proposed methodology. Initially, the traffic light and RSU detect the EV on the selected less congested and shortest traveling route based on the routing messages disseminated by EV. The disseminated messages include information about EV presence and speed. Thus, the EV is detected based on the messages. The pre-emption distance measurement is applied to compute the distance between the EV and road intersections in which the normal vehicle traffic is high. Secondly, the multi-criteria-based preclearance is utilized to clear the normal vehicles quickly in the approaching route and minimizes the disturbances associated with emergency vehicle speed. Further, the normal vehicles are cleared rapidly from the approaching route based on green phase adjustment. Moreover, the proposed methodology minimizes the negative impacts on emergency vehicle speed and provides timely help to the public.

A. Network Model

The vehicular network is modeled as a communication graph G (N, E), where N refers to the number of nodes classified into emergency vehicles, non-emergency vehicles, RSUs, and traffic light controllers. It is assumed that the virtual traffic lights are installed at every intersection, referred to as RSUs. The term N refers to the communication link between any two entities. The vehicles in SG-TSE move with the desired speed S. The speed of EV is high than normal vehicles $S_{EV}>S_{NV}$. The EV does not change its speed along its path using geographic routing and traffic light scheduling-based preemption. Every vehicle in the SG-TSE is equipped with GPS, and it updates its location itself. The other vehicles knew the location of emergency vehicles based on dissemination messages. The vehicles are also equipped with On-Board Units (OBUs) for enabling wireless communication. The emergency vehicles disseminate the beacons to the others in the corresponding segment by using OBUs. Each vehicle has a road map for path selection. The shortest and less congested traveling route of EV is suffered by normal network traffic in urban scenarios. To reduce the negative impact of normal vehicles on the EV route, the SG-TSE divides the EV approaching lane into multiple segments $S=\{S_1, S_2,.....S_n\}$. In each segment, a Segment Head (SH) is selected for centric-based geographic routing. Further, the signal head green phase adjust time t_g is computed using the minimum detection distance metric.

B. Segment based Geographic Routing (SGR)

Initially, the emergency vehicle selects the best traveling route with minimum congestion and short travel time [32]. However, the shortest route includes some normal traffic that influences the desired speed of emergency vehicles. Therefore, it is essential to create an alert about the emergency vehicle arrival to reduce the negative impacts of normal vehicles. The TG-TSE utilizes the SGR to inform the emergency vehicle presence and speed to the traffic controllers along its selected path. The SGR exploits segments to accomplish information dissemination segment-based routing. The SGR routing decision depends on vehicle location information, direction, vehicle density, and link quality among the two communicating parties. Initially, the SGR separates the selection path into multiple segments and inaugurates the geographic routing through the head node elected in each segment. The SGR routing decision is based on the segment data with a look ahead of the next segment data. The message is forwarded through the segment heads until it reaches the traffic controller.

Segment Formation: The SGR is based on various routing parameters like location information, direction, link quality, and traffic density of road networks. The main intention of SGR is to quickly inform about its presence to the traffic controller for efficient preemption. The EV routes the messages in two ways. Firstly, the EV straightly informs the traffic controller when the EV and traffic controller is in the same segment. Otherwise, the EV divides the corresponding path into multiple segments based on the location information and road map data for multi-hop forwarding. In Fig. 2, the segment formation of the proposed SGR is depicted. The SGR forms the segments based on the road trajectory and the number of intersections of the EV vehicle path [29].

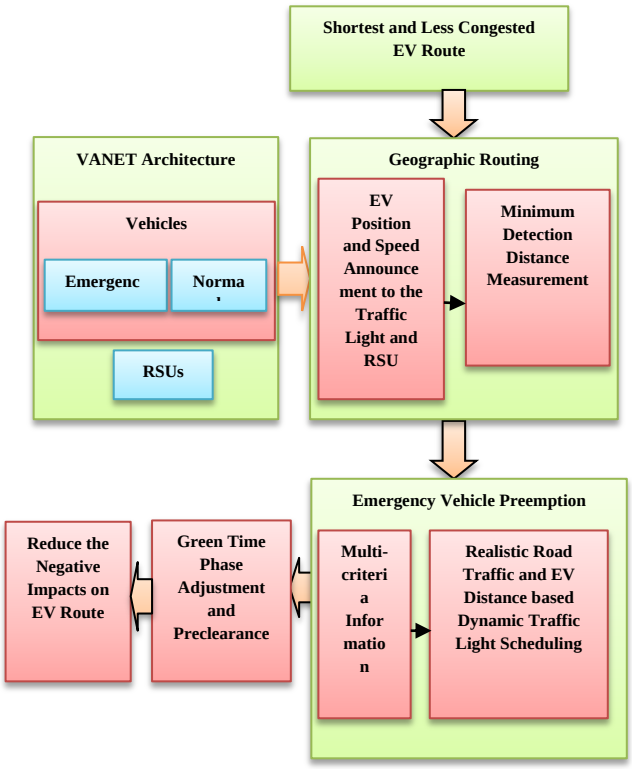

Fig. 1. Block Diagram of Proposed Methodology.

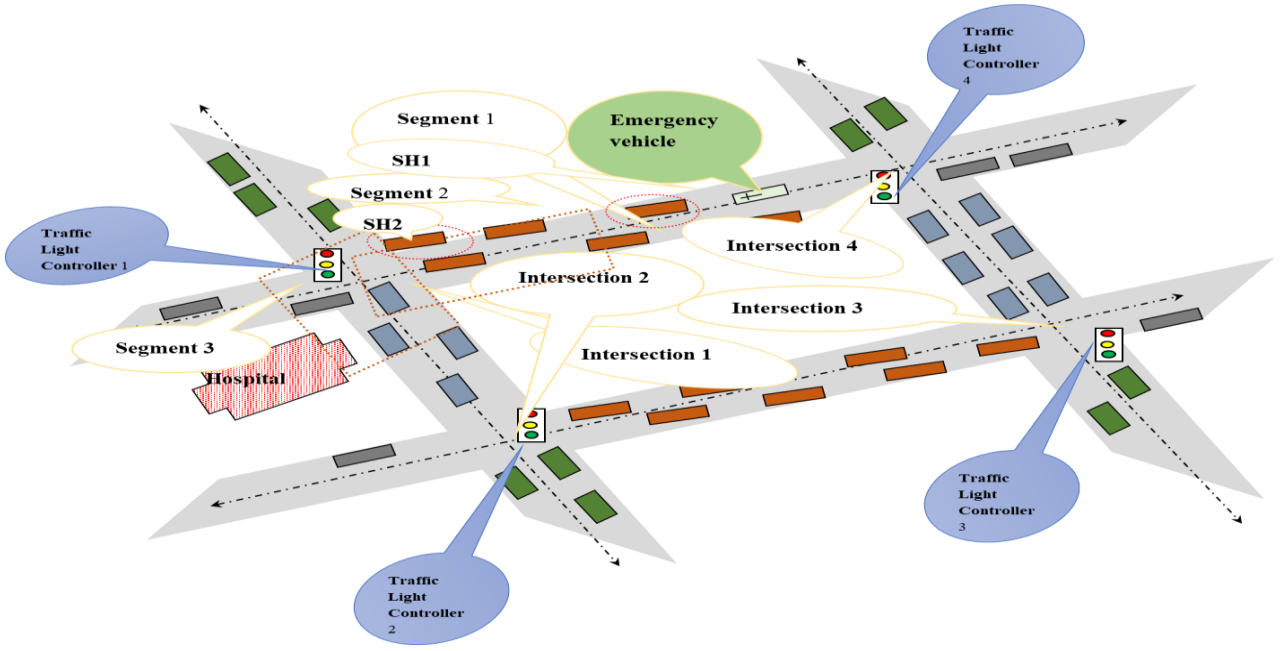

Fig. 2. SGR Segment Formation and Routing.

Segment Head Selection: The segment head is a crucial forwarding node in SGR, as the emergency vehicle arrival is informed through the head to the traffic light controller for preemption. The segment head (SH) selection is initiated after segment formation. Every vehicle announces its position, speed, direction, and link quality through its beacon messages in VANETs. The segment centric distance of a node D(c) is measured using the location information of the node n at t and t+1 time intervals. It is estimated as follows.

$$D(c) = L(t+1) - L(t) \quad (1)$$

The terms $L(t+1)$ and $L(t)$ are location coordinates of (x2, y2) and (x1, y1), at t+1 and t time, respectively. Further, the SGR utilizes the Pythagoras theorem to estimate the location of the SH node, as depicted in equation (2).

$$D_{c\to n} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \quad (2)$$

More than one nodes are presented near the centric location. Therefore, the SGR considers the link quality and direction parameters in SH selection to speed up the message delivery rate without compromising the reliability. Consequently, the SGR computes a score value for the nodes that are suitable for SH. The first metric is location information, in which the node should have to present near or exactly in the central position of the segments. Further, the progressive distance towards the destination is an essential routing metric in which the vehicles are moving in the same direction of EV is selected as SH. The direction difference score is estimated using the following equation.

$$S_{DD} = \begin{cases} 1; & \text{Same Direction} \\ 0; & \text{Opposite Direction} \end{cases} \quad (3)$$

Finally, the SGR computes the overall score value of the SH nodes using the following equation (4).

$$S_{SH} = \alpha * D_{c\to n} + \beta * S_{DD} + \gamma * L_Q + \varphi * S_v \quad (4)$$

In equation (4), the terms $D_{c\to n}, S_{DD}, L_Q$ snd S_v are the distance, direction, link quality, and speed values of the vehicle suitable for SH. The terms $\alpha, \beta, \gamma,$ and φ are weighting factors. The summation of weighting factors is equal to 1. Finally, the SGR selects the node that has high S_{SH} value as SH. This process is performed in all the segments of the EV traveling path. Further, the EV informs the traffic controller about the arrival through the selected SH vehicles.

C. Dynamic Traffic Light Scheduling and EV Preemption (DTSE)

After receiving the EV arrival information, the traffic light controller in SG-TSE initiates the traffic light scheduling process DTSE. The traffic light controller has to identify the EV in advance with a minimum detection time to pre-clear the approaching lane before the EV arrival and neglect the EV waiting time at the intersection. Hence, efficient scheduling is essential to minimize the impact of the normal vehicle on EV preemption. For traffic light scheduling, the DTSE uses the minimum detection distance metric, which is a type of distance measurement applied between the emergency vehicle location and the traffic light intersection. The controller receives the location and speed information of EV from the SH node, and it starts to calculate the minimum detection distance between the EV from the intersection using equation (5).

$$t \geq t_{switchover} + t_{min} + STI \quad (5)$$

Where the term $t_{switchover}$ is the switchover time of the signal head and the term t_{min} is the discharge time of the signal. The term STI is the safety time interval to pre-clear the vehicles in the approaching lane of EV. The switchover time is the interval of switching the signal state. The discharge time t_{min} is estimated from the average queue length and the queue discharge speed of the EV approach using historical information. The STI value is kept at the constant of 2 s. The t

value and speed information are used to calculate the minimum detection time. Thus, the TSE preemption method inaugurates the preemption phase at the correct time using minimum detection distance. Thus, the TSE avoids the hindrances of EV traveling path and minimizes the impact of the preemption on normal vehicular traffic. Further, the TSE starts the green phase adjustment for quick EV navigation through the corresponding intersection.

1) Green phase adjustment: Based on the distance measurement and multiple criteria like congestions and road conditions, the EV preemption is timely activated in the SG-TSE. A significant parameter is the signal head green time requirement (t_g) on the EV preemption, which is computed as follows.

$$t_g = t - (t_{switchover} + t_{min} + STI) \quad (6)$$

By using the t_g value, the SG-TSE effectively pre-clears the vehicles in the EV approaching lane and assists the EVs to maintain their desired speed in the corresponding intersection. In the coordinated route intersections case, the TSE assumes that the distance between two successive intersections is smaller than the detection time of EV detection distance. The EV detection point suffers the first intersection. To rectify such an issue, the SG-TSE considers the notification period of the discharge time of both consecutive intersections. In other words, the SG-TSE treats the two consecutive intersections as a single intersection. Otherwise, the distance between the two consecutive intersections is high than the minimum detection distance, and the SG-TSE re-estimates the detection distance for the second intersection by using the TSE model for preemption. Moreover, the green phase of the traffic light is scheduled at the correct time according to the emergency vehicle distance from the intersection. The SG-TSE protocol process is explained in algorithm 1.

Algorithm. 1. SG-TSE Protocol Process

//SG-TSE Protocol Process//

Input: Selected less congested and shortest EV travelling route
Methods: SGR and DTSE
Output: EV preemption
SG-TSE Do {
Inputs the EV travelling route and initializes the network;
Starts the SGR and DTSE;

SGR Do {
Initiates the segment formation for geographic routing;
Divides the approaching route into multiple segments;
Elects an SH in each segment based on a multi-criteria value;
Passes the EV arrival messages to the traffic light controller through SHs;
}

DTSE Do {
Measures the minimum detection distance using equation (5);
Initiates green phase adjustment;
Calculates signal head green time requirement (t_g);
Switchovers the green phase at right time;
Pre-clears the EV route;
EV preemption;
}};

IV. Performance Evaluation

The SG-TSE performance is analyzed using NS-2. The performance of the proposed work is compared with existing MDRP [11], PGRP [8], MM-GPSR [9], and Geo-LU [10] for performance evaluation. The simulation parameters are demonstrated in Table I.

TABLE I. Simulation Parameters

Parameter	Value
Simulation Tool	NS-2
Network Area	1000x1000
Number of Nodes	10 to 30
Number of EVs	1-3
Vehicle Communication Range	50m
RSU Communication Range	250m
Routing Protocol	SG-TSE
Traffic Simulator	SUMO
Transport Protocol	UDP, CTP
Speed of Normal vehicles	45 Km/hr
Speed of EVs	60 Km/hr
Propagation Model	Two Ray Ground
Simulation Time	2 Seconds
Application Type	CBR
Packet Size	128 Bytes
Data Rate	3 Mbps

A. Performance Metrics

The efficacy of SG-TSE is analyzed in terms of packet delivery ratio, overhead, throughput, delay, and EV preemption speed.

- Packet Delivery Ratio (PDR): It is the percentage of successfully delivered packets to the total number of generated packets.
- Overhead: It is the number of extra packets used to perform network operations.
- Throughput: It is the rate of data delivery.
- Delay: It is the time taken to deliver a packet from a source to a destination.
- EV preemption Speed: It is the speed maintained by the EVs on the approaching lane.

B. Simulation Results

Fig. 3 portrays the comparative PDR results of SG-TSE, MDRP, PGRP, MM-GPSR, and Geo-LU observed under different node density scenarios. From the results of Fig. 3, the SG-TSE increases the PDR from vehicle density 10 to 20, whereas the PDR is decreased after the point of 20 node density scenario. It is caused due to the adequate number of vehicles offer better connectivity to packet forwarding, and the high number of nodes competes to access similar links, resulting in some packet loss in the network. For example, the

SG-TSE accomplishes 99%, 99.6%, and 98% of PDR for 10, 20, and 30 node densities, respectively. However, the PDR of SG-TSE is higher than the other four geographic routing protocols from 10 to 25 node densities. For instance, the SG-TSE improves the PDR by 1.4%, 3%, 1.9%, and 1.5% than the existing MDRP, PGRP, MM-GPSR, and Geo-LU protocols, respectively, when 10 nodes are present in the network. The figure shows that the SG-TSE and Geo-LU accomplish 98% and 99.4% of PDR in 30 node scenarios. The link utility aware geographic router node selection in Geo-LU improves the PDR than the proposed SG-TSE. However, the SG-TSE attains better PDR values than the MEDRP, PGRP, and MM-GPSR protocols, when 30 numbers of vehicles are presented in the network.

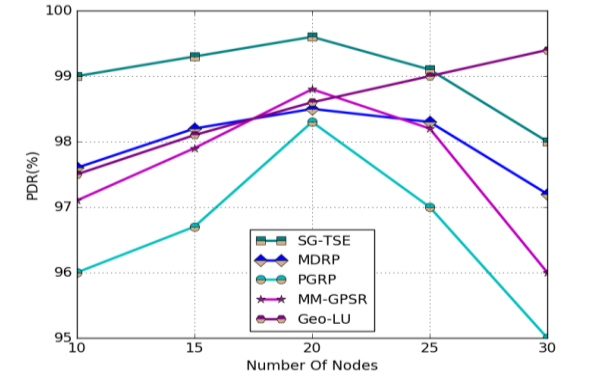

Fig. 3. Number of Nodes vs. PDR.

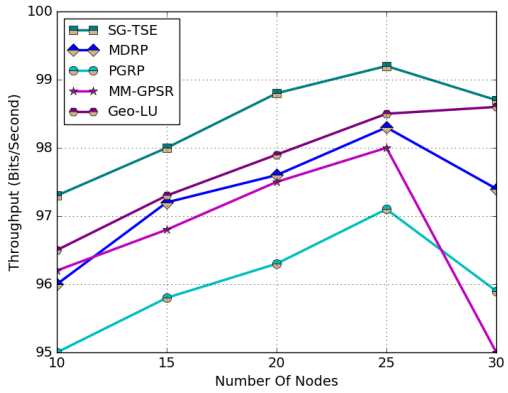

Fig. 4. Number of Nodes vs. Throughput.

Fig. 4 demonstrates the throughput comparison results of SG-TSE, MDRP, PGRP, MM-GPSR, and Geo-LU geographic routing protocols. All protocols increase the throughput from the point of 10 node densities to 25 node densities. For example, the SG-TSE obtains 97.3% and 99.2% of throughput under 10 and 25 number of nodes scenario, respectively. It is high in the range of 1.9%. After point 25, the throughput value of SG-TSE is decreased, as the link may fail due to high competition nodes. The SG-TSE minimizes the throughput by 0.5% after the point 25 number of nodes. However, the SG-TSE attains better throughput performance than the other existing protocols. The main reason is that the SG-TSE selects the best SH nodes for data forwarding using multiple parameters that are position, speed, direction, and link quality. Thus, it maximizes the throughput even the network is highly congested. For instance, the SG-TSE improves the throughput by 1.3%, 2.3%, 1.1%, and 0.8% than the existing MDRP, PGRP, MM-GPSR, Geo-LU when 10 numbers of vehicles are present in the network.

Fig. 5 shows the delay results of SG-TSE, MDRP, PGRP, MM-GPSR, and Geo-LU obtained with different numbers of nodes. The SG-TSE escalates the delay by adjusting the number of nodes from 10 to 30. The main reason is that the nodes have to retransmit the packets frequently due to high packet loss under a high vehicle density setting. For example, the delay of SG-TSE is 0.35 seconds and 1.7 seconds for 10 and 30 nodes scenarios. However, the delay performance of SG-TSE is better than the other four geographic routing methods. The segment-based geographic router selection assists the SG-TSE to diminish the delay even the highly congested network. Also, the SG-TSE selects the best SH node by taking into account the position, speed, direction, and link quality parameters. Thus, it minimizes the delay in packet delivery and motivates the traffic lights for timely green phase activation, resulting in minimum EV arrival delay. For instance, the SG-TSE reduces the delay by 30%, 58.8%, 78.1%, and 63.2% than the MDRP, PGRP, MM-GPSR, and Geo-LU under 10 nodes scenario. It is varied by 69.6%, 51.4%, 63%, and 57.5% for 30 number of nodes scenario.

Fig. 6 illustrates the overhead comparison results of SG-TSE, MDRP, PGRP, MM-GPSR, and Geo-LU by adjusting the number of nodes from 10 to 30. All protocols increase the overhead by varying the node density from low to high. This is caused due to the utilization of a high number of control packets under the high-density scenario that maximizes the overhead in the network. For instance, the SG-TSE accomplishes 110 and 310 packets of overhead for 10 and 30 numbers of nodes, respectively. However, the SG-TSE diminishes the overhead than the MDRP, PGRP, MM-GPSR, and Geo-LU, as demonstrated in Fig. 6. The main reason is that the segment-based geographic routing along the EV route limits the control packets within the segment, resulting in minimum overhead. For example, when 30 nodes are present in the network, the SG-TSE, MDRP, PGRP, MM-GPSR, and Geo-LU attain 310, 350, 375, 410, and 375 packets of overhead, respectively.

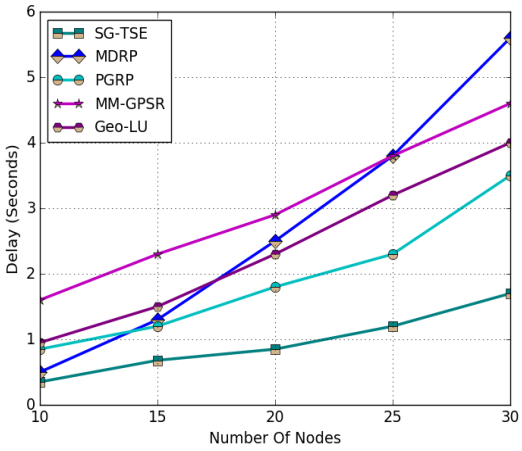

Fig. 5. Number of Nodes vs. Delay.

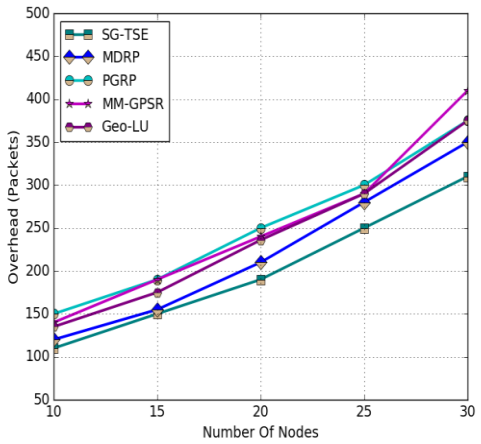

Fig. 6. Number of Nodes vs. Overhead.

The EV preemption speed results of SG-TSE obtained by varying the Number of Intersections (NoI) are depicted in Fig. 7. The EV preemption speed is diminished when varying the vehicle density from 10 to 30. The main reason is that the traffic controller requires a long time to pre-clear the vehicles under a high vehicle density scenario, impacting EV preemption speed. For instance, the speed of EV is 60 and 55 Km/Hr for 10 and 30 node density scenarios under one intersection. The SG-TSE design considers the NoI into account, and there is a need to recalculate the minimum detection distance when more than one intersection is presented along the EV route. Thus, it creates some impact on EV speed. For instance, the speed of EV is diminished by 8.3% for 20 nodes with two NoI scenarios. However, the timely green phase activation with minimum detection distance measurement in SG-TSE speeds up the EV at intersections rapidly and minimizes the arrival delay even the network is congested.

Fig. 8 obtains the PDR comparative results of SG-TSE, MDRP, PGRP, MM-GPSR, and Geo-LU by varying the vehicle speed from 20 to 60Km/hr. The results show that the SG-TSE decreases the PDR by adjusting the vehicle speed from 20 to 60 Km/Hr. It is caused due to the frequent link disconnections of high-speed vehicles in the network. For example, the SG-TSE accomplishes 99% and 97.1% of PDR when the nodes move with speed 20 Km/Hr and 60 Km/Hr, respectively. However, the SG-TSE obtain better PDR results by selecting the SH nodes with multi-criteria information like position, speed, direction, and link quality than the existing protocols. Thus, it effectively handles the frequent link disconnections and boosts the PDR even when vehicles move at high speed. For instance, the SG-TSE increases the PDR by 0.3%, 1.1%, 4.1%, and 2.6% than the existing MDRP, PGRP, MM-GPSR, and Geo-LU protocols under a high vehicle speed scenario of 60 Km/hr.

Fig. 9 shows the delay results of SG-TSE, MDRP, PGRP, MM-GPSR, and Geo-LU protocols. The results are accomplished by adjusting the speed values of the vehicles from 20 to 60 Km/hr. All protocols increase the delay by varying the vehicle speed from low to high. The main reason is that the nodes have to retransmit the packets frequently due to link disconnections. For example, the delay of SG-TSE is 0.5 seconds and 2.3 seconds for 20 and 60 Km/Hr of vehicle speeds, respectively. However, the delay performance of SG-TSE is better than the other existing MDRP, PGRP, MM-GPSR, and Geo-LU protocols. For instance, the SG-TSE reduces the delay by 54.5%, 37.5%, 58.3%, and 66.7% than the MDRP, PGRP, MM-GPSR, and Geo-LU when the vehicles move with 20 Km/Hr speed. The reason is that the multi-criteria-based SH router selection assists the SG-TSE to diminish the delay even the highly congested network. Thus, it maximizes the green time activation accuracy. Moreover, the SG-TSE minimizes the negative impact on normal vehicles owing to EV preemption by activating the green phase at the right time.

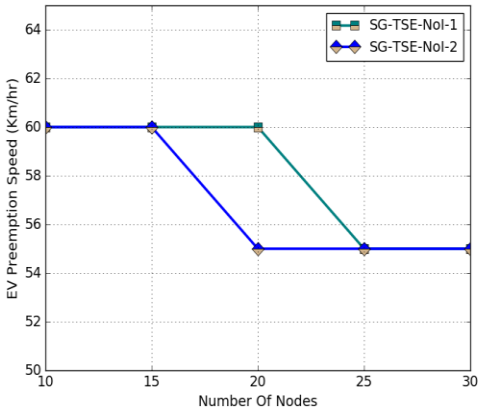

Fig. 7. Number of Nodes vs. EV Preemption Speed.

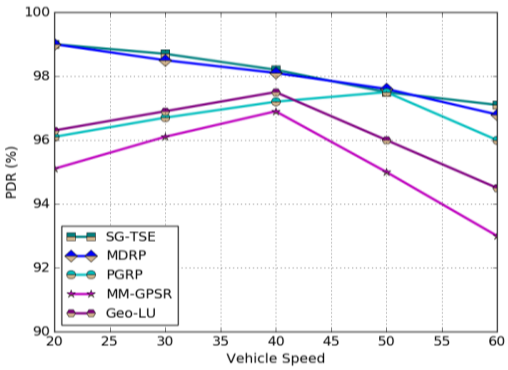

Fig. 8. Vehicle Speed vs. PDR

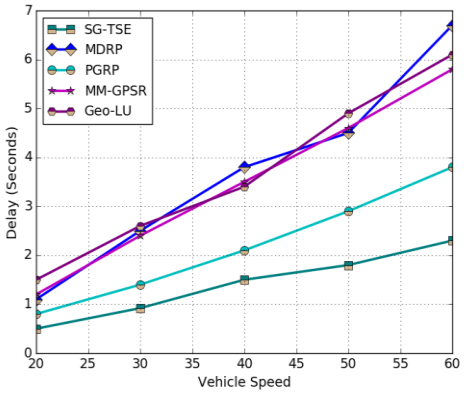

Fig. 9. Vehicle Speed vs. Delay.

V. Conclusion

In this paper, a novel EV preemption method SG-TSE has been proposed to reduce the negative impacts of normal vehicles on EV speed. To achieve the objective, the SG-TSE includes two mechanisms that are SGR and DTSE. By dividing the approaching route into multiple segments and performing segment-based geographic routing, the SGR instructs the traffic light controller about EV arrival. The minimum detection distance measurement based green phase adjustment in DTSE reduces the negative impacts of normal traffic on EV speed and neglects the EV preemption negative effects on normal traffic. Moreover, the NS-2 based simulation depicts the effectiveness of the proposed SG-TSE with different performance metrics like PDR, overhead, delay, throughput, and EV preemption speed. From the results, the EV maintains its speed in the approaching lane without disturbing the normal traffic conditions.

***Abstract*—With the growth in the distributed data processing and data being the fuel for each of the processes, the query processes of the data are expected to be significantly lower. Hence, the distribution of the data is highly expected and during the distributing of the data, the chances for data leakage increases to a significant extend. The data leakage problems are not generally caused by intentional errors, rather this is caused by the higher visibility of the data over multiple clusters. Henceforth, the detection process is also very critical. Many of the parallel research attempts have demonstrated various methods for the detection and as well as the prevention methods. The works in the direction of the detection of the data leaks are highly dependent either on the historical information of the leaks or depends on the contextual importance of the data. In both the cases, the outcomes of the detection process accuracy cannot be ensured. In the other hand, the preventive measures can also turn into a reactive process for detection by reversing the principles proposed in these research outcomes, but the computational complexities are significantly higher. Thus, this work proposes a novel strategy for detection of the data leakages after the data distribution during the query processing events. This work proposes an initial Occurrence Based Rule Set Extraction method using Adaptive Threshold for generating the rulesets, further for reducing the time complexity and reducing the loss of dataset attribute information, this work introduces yet another algorithm for Dynamic Inference-based Rule Set Reduction. After the inferences are generated, finally this work deploys the Attribute Subset Equivalence-based Leak Detection mechanism for final detection of the clusters with data leaks. This work demonstrates nearly 89% accuracy for the detection process.**

Keywords*—Distributed query processing; distributed data leak; data leak detection; attribute subset equivalence; dynamic inference; adaptive threshold model introduction

I. Introduction

Leakage of the data during centralized or distributed query processing environment is one of the primary concerns in the recent cyber security domain. Number of professionals and researchers have aimed to define the problem of data leakage in the past decade and aimed to provide solutions considering the higher number of cases are reported for data leakage, which leads to data breaches. As per the reports by Breach Level index [1], a gigantic volume of data, as close to 4.5 Billion, are compromised only in 2018.

The empirical study by C. Missaoui et al. [2] have critically analysed the data leakage situations and formulated the correct sequence of events, which might lead to the data breach. The common reason for data leakage, as per this study, showcased that the use of unused data stored in the centralized or distributed storage solutions leads to data leakage. The example also demonstrated that the data, which is left unattended or not in motion, must be revoked or should be distributed with a specified life time and expiry to be restricted for reuse.

Yet another case study presented by IBM showcased that the cost of recovery of stolen or leaked data can be as high as 3.86 Billion dollars [3].

Thus, the demand for data protection and data leakage detection is one of the primary demands from the current research trends and must be addressed. Also, the parallel research outcomes have demonstrated that the security concerns are higher in case of the distributed data sources for the obvious reasons. Thus, this work focuses on the distributed query processing environments to detect the data leaks.

The rest of the work is furnished such as in Section – II, the fundamentals of the distributed query processing is discussed and understood, in Section – III, the outcomes from the parallel research attempts are analysed, in Section – IV, the problem is formulated using mathematical model, in Section – V, the proposed solution is again formulated using mathematical modelling method, in Section – VI, the proposed algorithms are furnished and elaborated, in Section – VII, the obtained results are analysed, in Section – VIII, the comparative analysis is presented and in Ssection – IX, the final conclusion of the research is presented.

II. Distributed Query Processing Fundamentals

In this section of the work, the fundamental of distributed query processing method is discussed in order to realize the recent outcomes from the parallel research attempts.

Assuming that, every query Q is the collection of relations and predicates as R and P respectively. This relation can be formulated as,

$$Q \rightarrow \sum R . \sum P \tag{1}$$

Or for example, the above relation can be re-written as,

$$Q \rightarrow [R_1 \cap R_2] \cup R_3 \tag{2}$$

Also, assuming that the relation R, is distributed over the cluster set C[], where each and every cluster can be identified as C_X for "n" number of clusters. Thus, can be represented as,

$$C[] \leftarrow \sum_{x=1}^{n} C_x \tag{3}$$

And,

$$R[] \rightarrow C[] \tag{4}$$

Further, assuming the data distribution is as follows,

$$\{R_1, R_2, R_3\} :: \{\langle C_1, C_2, C_3 \rangle, \langle C_2, C_3 \rangle, C_3\} \tag{5}$$

During the query processing for distributed systems, the primary objective is to find the allocation and minimum distribution of the relations. As,

$$\{R_1, R_2, R_3\} :: \{C_3\} \tag{6}$$

Further, the optimization possibilities for predicates can also be identified and performed. Once the optimization task is completed, the result of the query can be return to the queue buffer.

Henceforth, this fundamental understanding of the distributed query processing shall help in realizing the parallel research outcomes, which are discussed in the next section of the work.

III. Parallel Research Outcomes: Survey

After the fundamental understanding of the distributed query processing and chances for the data leakages, in this section of the work, the parallel research outcomes are discussed.

In the recent years, multiple organizations have aimed to provide the complete solution for the detection and up to some extend prevention of the data leakages problems. The primary working principles of these systems are to manual perform exhaustive search with the previously leaked data on the existing shared data for finding the leakage. The point to be mentioned here is that, the data leakage may not be an intentional issue every time. Many of the times, it is been observed that, the wrong distribution of the data attributes leads to the data leakages. Thus, the search option of the previous information may demonstrate machine learning characteristics, but eventually leads to failure in case of insufficient previous or historical data; thus, the other approaches getting popularity in the practice.

One of the major benchmarks in the domain of data leakage detection was the research outcome by P. Papadimitriou et al. [4]. This work demonstrates the data leakage detection by introducing watermarking methods to identify the source of leakage. However, this method was highly criticised by many other researchers due to the higher complexity of the computational models. Also, the size of the actual data, which is distributed, increases to a significant extend because of the replication for each watermarking information and the second issue was that the digital watermarking process is fragile as because of the pre-processing methods used by many algorithms can lead to the loss of watermarks and making the complete process again vulnerable.

The other parallel research outcome by L. Cheng et al. [5] has demonstrated another method to data leakage problem solution. This method demonstrates an approach to classify the content based on the sensitivity of the information and manage the distribution of the higher sensitive data with maximum care. This work is also criticised by the parallel researchers due to the facts that, firstly, the data sensitivity also depends on the context of the data, which is highly variable in all the instances of the query, and secondly, the higher time complexity and chances of low data visibility is also a challenge.

Further, in the complete other direction from these solutions, the work by S. Liu et al. [6] have demonstrated and listed the principles of data leakage preventions. This direction, in contract to the detection of the data leakage, promotes the prevention methods. Elaborating this fact, the work by B. Hauer et al. [7] have also showcased the functional rules for making the data leakage preventions. The set of mentioned rules can also be reversed to identify the leakage sources. Nevertheless, it is natural to realize that, the computational time complexity can be very high for this detection method and also for the distributed environments, this method is prune to errors. The next method is one of the extensions, proposed by T. Malderle et al. [8]. This work elaborates the mechanisms for collecting evidences of the data leakage and further validates the evidences against the prevention principles.

The data leakages are not only limited into the scope of centralized data, rather also extended in higher scale for distributed data. The work by J. Schütte et al. [9] has elaborated on the challenges of data leakage for distributed mobility devices.

The work by S. Trabelsi et al. [10,11,12] provides the summery of the challenges and failure points of each of the above-mentioned mechanisms.

Henceforth, in order to provide the solution to data leakage detection, in the next section of the work, the mathematical model of the actual problem is furnished for better identification of the solution possibilities.

IV. Problem Formulation

After the fundamental understanding of the query processing and the review of the parallel research outcomes, in this section of the work the research problem is formulated.

Assuming that the complete data schema is denoted as DSC[] and every attribute is denoted as AR_X. Thus, for n number of attributes, the total relationship can be formulated as,

$$DSC[] \leftarrow \sum_{i=0}^{n} AR_i \tag{7}$$

Also, one of the attributes in the total attribute set must be identified as the class variable and can be denoted as AR_C. This can be formulated as,

$$\prod_{i=0}^{n} AR_i \cup \prod_{j=1}^{n-1} AR_j \rightarrow AR_C \tag{8}$$

It is natural to realize that the class variable or the class attribute can also be retrieved using other attributes as well and can be denoted as,

$$\prod_{x=0}^{n} AR_x \cup \prod_{y=1}^{n-1} AR_y \rightarrow AR_C \tag{9}$$

In case of a distributed query processing environment, the data is expected to be distributed over multiple clusters, denoted as C[] and each and every cluster can be identified as, C_i. Thus, this relation for k number of clusters can be identified as,

$$C[] \leftarrow \sum_{i=1}^{k} C_i \tag{10}$$

The data is expected to be distributed over the clusters from the initial schema sets and can be realized as,

$$\prod_{i=1}^{n} DSC[i] \Rightarrow \prod_{j=1}^{k} C[j] \tag{11}$$

This can be re-written as,

$$\prod_{i=1}^{n} AR_i \Rightarrow \prod_{j=1}^{k} C[j] \tag{12}$$

It is often to be realized that during the query processing, the similar information can be generated from different attributes and the data leaks can happen.

For example, as the attribute sets AR_i, AR_x and AR_j, AR_y can contain similar information, thus these sets if become part of same clusters during data distribution, then the data leakage is obvious and cannot be prevented.

$$\langle AR_i, AR_x \rangle \neq C_\alpha \tag{13}$$

And

$$\langle AR_j, AR_y \rangle \neq C_\beta \tag{14}$$

Or,

$$C_\alpha \neq C_\beta \tag{15}$$

Henceforth, detection of the data leakage from the distributed schema is the identified problem to be solved. In the next section of this work, the proposed mathematical model for the data leak detection is proposed.

V. Parallel Research Outcomes: Survey

After the fundamental understanding of the parallel research outcomes and the formulation of the problem, in this section of the work, the mathematical model for solution is elaborated.

Assuming that the complete data schema is denoted as DSC[] and every attribute is denoted as AR_X. Thus, for n number of attributes, the total relationship can be formulated as,

$$DSC[] \leftarrow \sum_{i=0}^{n} AR_i \tag{16}$$

Also, one of the attributes in the total attribute set must be identified as the class variable and can be denoted as AR_C. This can be formulated as,

$$\prod_{i=0}^{n} AR_i \cup \prod_{j=1}^{n-1} AR_j \rightarrow AR_C \tag{17}$$

Further analysing the item set frequency for each data item sets, the ruleset, R[] can be generated for "d" number rules and each rule in the ruleset can be considered as R_X. Thus, this relation can be formulated as,

$$R[] \leftarrow \sum_{i=1}^{d} R_i \tag{18}$$

Also, assuming that two different rules, R_X and R_Y, implies the same class variable data instance, AR_C, as,

$$R_X \rightarrow AR_C \tag{19}$$

And,

$$R_Y \rightarrow AR_C \tag{20}$$

However, the rules can contain different attribute sets, as,

$$R_X = \langle AR_i, AR_{i+1}, AR_{i+2}, ...AR_n \rangle \tag{21}$$

Or,

$$R_X = AR'[] \tag{22}$$

And,

$$R_Y = \langle AR_j, AR_{j+1}, AR_{j+2}, ...AR_m \rangle \tag{23}$$

Or,

$$R_Y = AR''[] \tag{24}$$

Finally, in order to detect the data leak based on the large-scale distributed query processing, both the attribute sets, must not coexist on the same cluster, as formulated as,

$$(AR'[], AR''[]) \rightarrow C_{\alpha} \tag{25}$$

If the above situation is detected, then the data leakage can occur, and the security challenges can be increased.

Further, in the next section of this work, based on the problem formulation, the proposed algorithms are furnished and elaborated.

VI. Proposed Algorithms

Furthermore, in this section of the work, based on the proposed mathematical model of the solution in the previous section, the proposed algorithms are furnished.

The first algorithm is designed to generate the rulesets from the given schema and the dataset items. The algorithm is furnished here:

Algorithm - 1: Occurrence Based Rule Set Extraction using Adaptive Threshold Model (**OBRSE-ATM**)

Input: {Read the schema definition for attribute sets, A[] and Class variable, ARC}
Output: {Rulesets, FR}
Process:
Step - 1. Accept the list of attributes as A[]
Step - 2. Accept the class variable as ARC
Step - 3. For each item sets
  a. For each attribute value as A[i]
    i. If A[i] and A[i+1] generates ARC[i]
    ii. Then, count the number of occurrence as O[i] and Rule[i] = A[i] and A[i+1]
  b. End
Step - 4. For each occurrence as O[i]
  a. Calculate the mean as OM = {Sum(O[])}/{Count(O[])}
  b. Calculate the position of the OM as O[k]
  c. Calculate the adaptive threshold as AT = K/{Count(O[])}
Step - 5. For each occurrence as O[j]
  a. If O[j] > OM * AT
  b. Then, Accept R[j] as final rule and add to FR[i]
Step - 6. Report FR[]

To instigate the best principles dependent on a given perception, RULES family start by choosing (isolating) a seed guide to assemble a standard, condition by condition. The standard that covers the best models and the least negative models are picked as the best principle of the present seed model. It permits the best guideline to cover some negative guides to deal with the expansion adaptability and lessen the over fitting issue and uproarious information in the standard enlistment.

The second algorithm is designed to reduce the redundant rule sets and build the final reduced rulesets.

This articulation expresses that at whatever point over the span of some legitimate inference the given premises have been gotten, the predetermined end can be underestimated too. The specific conventional language that is utilized to portray the two premises and ends relies upon the real setting of the determinations.

Algorithm - 2: Dynamic Inference-based Rule Set Reduction (**DI-RSR**)

Input: {Rulesets, FR}
Output: {Reduced Rulesets, FRR}
Process:
Step - 1. Accept the rule sets as FR
Step - 2. For each FR[i]
  a. Generate the attribute set as AR[j]
  b. If AR[j] is subset of AR[j]
  c. Then, remove the AR[j] and FR[i]
  d. Else, Keep FR[i] into FRR[k]
Step - 3. Build the final rule set as FRR[]

The final algorithm is built for detecting the leaks in the distributed query situations and as furnished here.

Algorithm - 3: Attribute Subset Equivalence-based Leak Detection (**ASLD**)

Input: {Final Rulesets, FRR and Cluster Sets, CS}
Output: {Leaked Clusters, LC}
Process:
Step - 1. Accept the final rule sets as FRR[]
Step - 2. Accept the cluster distributions CS[]
Step - 3. For each FRR[i]
  a. Identify the attribute sets as AR[j]
  b. For each AR[j]
    i. If AR[j] infers to ARC[k] and AR[j+1] infers to ARC[k]
    ii. Then, Check AR[j] and AR[j+1] cluster allocation
      1. If AR[j] -> CS[r] and AR[j+1] -> CS[r]
      2. Then, detect data leakage at CS[r] and CS[r]->LC[]
      3. Else, Continue
Step - 4. Report the final leaked clusters as LC[]

Quite a bit of science is grounded in the investigation of equivalences, and request relations. Cross section hypothesis catches the scientific structure of request relations. Despite the fact that equality relations are as omnipresent in arithmetic as request relations, the mathematical structure of equivalences isn't too known as that of requests.

The working flow of the proposed algorithms as a framework is furnished here [Fig. 1].

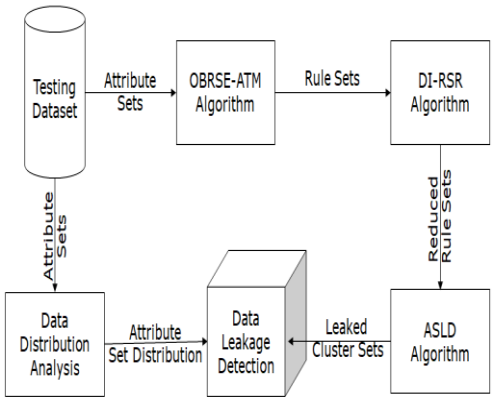

Fig. 1. Working Model of the Proposed Algorithms.

The obtained results from the proposed algorithms are highly satisfactory and discussed in the next section of the work.

VII. Result and Discussion

After the detailed discussed on the mathematical model and the proposed algorithms, in this section of the work, the obtained output from the algorithms are discussed here.

Firstly, the rule extraction results are discussed [Table I].

TABLE I. Rule Extraction Results

Test Number	Number of Rules Extracted	Time Complexity (Sec)
Test Run - 1	329	8.065
Test Run - 2	321	8.301
Test Run - 3	303	8.199
Test Run - 4	326	8.802

The number of extracted rules is the indications of the detailed understanding and deep consideration of all the attribute sets from the dataset. The greater number of rules in this phase of the result defines that most of the attributes are considered and further detection of the leaks can be performed more efficiently.

The results are analysed graphically here [Fig. 2, Fig. 3].

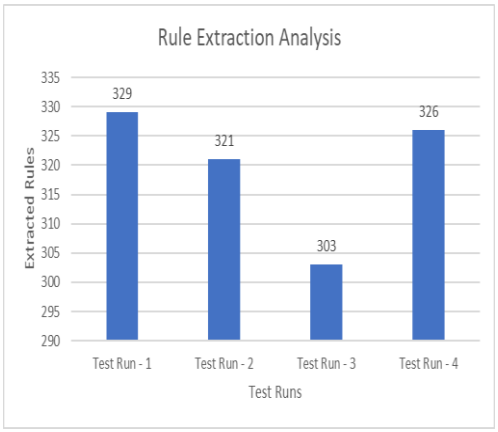

Fig. 2. Rule Extraction Analysis.

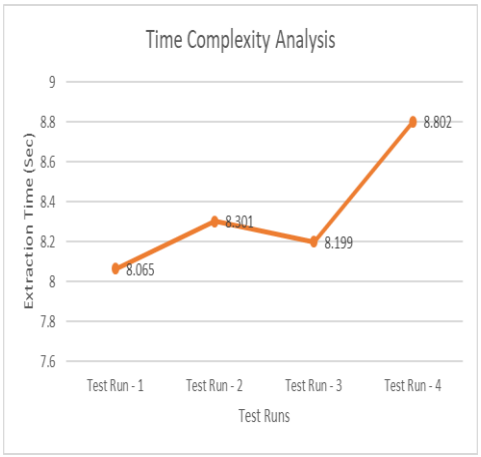

Fig. 3. Rule Extraction Time Complexity Analysis.

However, a greater number of rules can lead to higher time complexity for detection of data leakages. Thus, the reduction of the rulesets is highly expected here. Also, during the rule set reduction process, the point of caution is to maintain the attribute inference properties and relations, which will be helpful in deep detection of the data leakages. Henceforth, the rule set reduction results are discussed here [Table II].

TABLE II. Rule Reduction Results

Test Number	Number of Rules Extracted	Number of Rules after Reduction	Percentage of Reduction (%)	Time Complexity (Sec)
Test Run - 1	329	136	58.66	0.118
Test Run - 2	321	133	58.57	0.120
Test Run - 3	303	126	58.42	0.121
Test Run - 4	326	135	58.59	0.164

The results are analysed graphically here [Fig. 4, Fig. 5, Fig. 6].

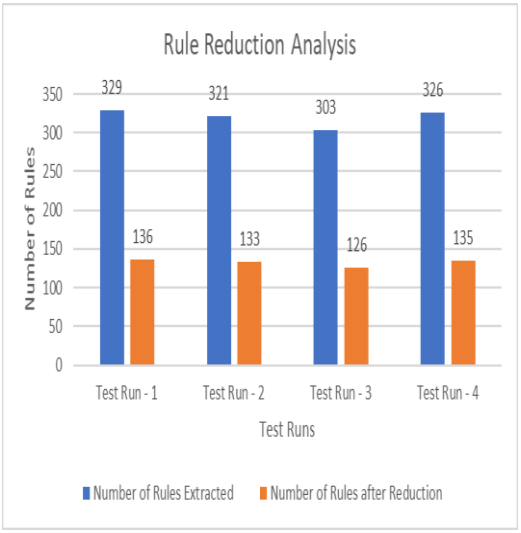

Fig. 4. Rule Reduction Analysis.

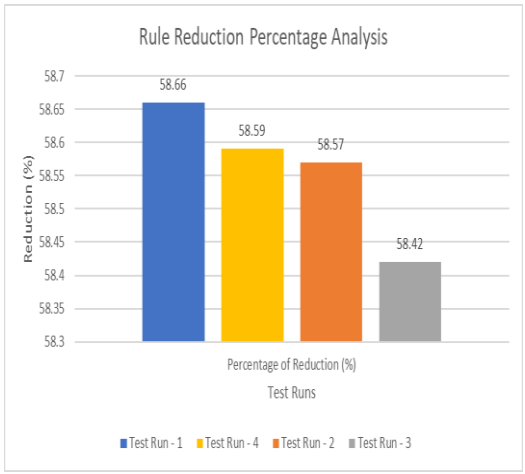

Fig. 5. Rule Reduction Percentage Analysis.

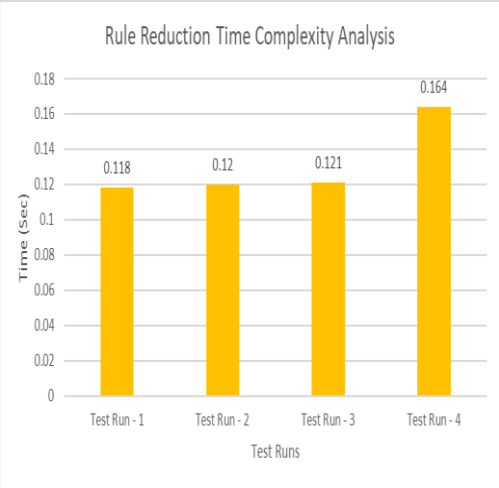

Fig. 6. Rule Reduction Time Complexity Analysis.

Once the rulesets are reduced and the inference properties are extracted, the actual distribution of the data must be analysed as the number of attributes distributed over the test clusters are the key points for detection of the leakages. Hence, the data distribution is analysed here [Table III].

TABLE III. DATA DISTRIBUTION ANALYSIS RESULTS

Test Number	Number of Clusters Detected	Number of Attributes (Mean) stored	Time Complexity (Sec)
Test Run - 1	5	4	0.023
Test Run - 2	4	7	0.022
Test Run - 3	4	7	0.022
Test Run - 4	5	6	0.023

Further after the analysis of the data sets, which are distributed over multiple clusters, finally the data leakages are detected, and the result is furnished here [Table IV].

TABLE IV. DATA LEAKAGE DETECTION ANALYSIS RESULTS

Test Number	Number of Clusters Detected	Number of Clusters with Leakage	Time Complexity (Sec)	Detection Accuracy (%)
Test Run - 1	5	2	0.010	89.55
Test Run - 2	4	3	0.012	89.55
Test Run - 3	4	3	0.009	89.55
Test Run - 4	5	4	0.018	89.32

It is natural to realize that, the higher accuracy of the detection process leads to higher security of the data distribution during the distributed query processing.

The results are analysed graphically here [Fig. 7, Fig. 8].

Henceforth, with the detailed analysis of the obtained results, in the next section of this work, the results are compared with the parallel research outcomes.

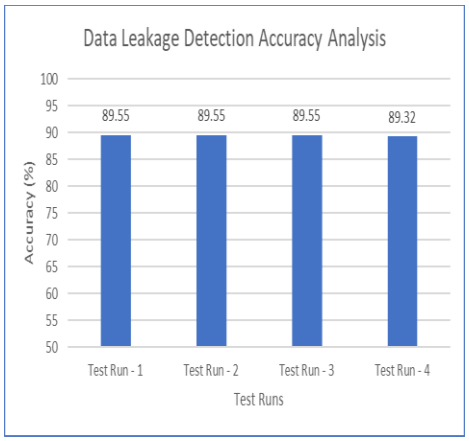

Fig. 7. Data Leakage Accuracy Analysis.

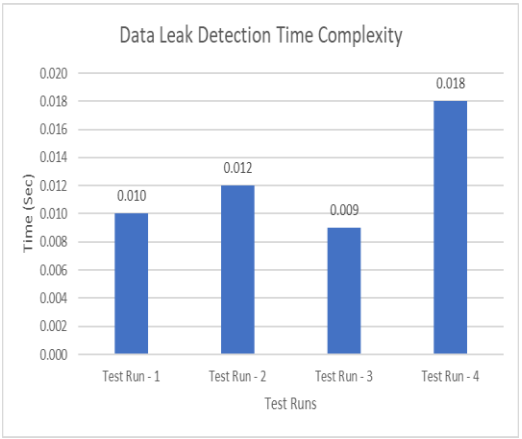

Fig. 8. Data Leakage Time Complexity Analysis.

VIII. COMPARATIVE ANALYSIS

In order to establish the believe that the proposed model is better performing than the other parallel research outcomes, the comparative analysis is most important. Thus, in this section of the work, the proposed algorithms are compared with the parallel research outcomes [Table V].

Hence it is natural to realize that, the proposed algorithms have outperformed the other parallel research attempts. The detailed reason for this achieved benefits are discussed in the previous sections of this work.

Further, with the analysis of the results and comparative analysis, in the next section of the work, the research conclusion is presented.

TABLE V. COMPARATIVE ANALYSIS

Proposed Methods	Year	Fundamental Mechanism	Detection Accuracy (%) [Mean]	Time Complexity (Sec) [Mean]
Appcaulk by J. Schütte et al. [9]	2014	Distributed Data & Taint Tracking	80	0.37
Proactive Warning by T. Malderle et al. [8]	2018	Centralized Data & Historical Data Analysis	88	0.40
Monitoring Methods by S. Trabelsi et al. [10]	2019	Centralized Data & Cost-Based Analysis	85	0.24
OBRSE-ATM, DI-RSR & ASLD Method [12]	2020	Distributed Data, Adaptive Threshold Model, Dynamic Inference & Subset Equivalence Analysis	89.49	0.01

IX. CONCLUSION

The distributed query processing is an essential part of today computing and the challenges of the distributed query processing is the leakage of the data. The data leakage can lead to critical security issues. Thus, this work identifies the solutions to detect the data leaks, which can further be used to ensure data distribution carefully. As mentioned in the previous sections of this work, the detection of the data leakages is highly difficult and demands a deep machine learning based approach. Thus, in order to solve the data leakage detection this work demonstrates a step by step process as initially the data relation between the data set attributes are extracted in form of rulesets. During the further processing, it is been observed that, due to higher number of rulesets in the system, the computational complexity is increasing to a greater extend, thus, this work again deploys a novel mechanism for reduction of rulesets. The deployed algorithm for rule reduction is designed carefully not to lose any inference properties. The rule reduction algorithm demonstrates a nearly 50% reduction in rulesets. Further, the data distribution is analysed, and the number of clusters are detected. Finally, this work deploys yet another novel machine learning based algorithm for detection of the data leakages based on data information equivalence and demonstrates a nearly 89% accuracy. The algorithms designed in this case are highly generic and can be applied for any data distribution scenarios and can be considered as a benchmark in this field of research for making the distributed query processing domain safer and faster.

Knowledge Graph-based Framework for Domain Expertise Elicitation and Reuse in e-Learning

Jawad Berri
Information Systems Department
King Saud University, Saudi Arabia

***Abstract*—Reusing knowledge expertise of different domains in e-learning is an ideal approach to sustain knowledge and disseminate it throughout the different organizations' processes. This approach generates a valuable source for instruction which can enrich significantly the quality of teaching and training as it uses effortlessly expertise from its original sources. It is also very useful for teaching activities since it connects learners with real-life scenarios involving field experts and reliefs instructors from the tedious task of authoring teaching material. In this paper we propose a framework that allows gathering automatically expertise from domain experts while doing their activities and then represents it in a form that can be shared and reused in e-learning by different types of learners. The framework relies on knowledge graphs that are knowledge representation structures which facilitate mapping expertise to e-learning objects. A case study is presented showing how inspector reports are handled to generate on-demand e-courses specifically adapted to learners' needs.**

Keywords*—Knowledge graph; domain expertise; e-learning; knowledge elicitation; learning web

I. Introduction

Expertise is a valuable asset in today's competitive world. Organizations are striving to safeguard and make the most of their expertise to sustain development and maintain an advantage with competitors. Expertise is retained by human experts; it is the set of know-how and skills developed through practicing and experiencing their knowledge in a specific domain [1]. Identifying, representing and sharing expertise requires the development of knowledge management systems that are able to sustain knowledge and disseminate it through the different organizations' processes. These two requirements represent a twofold challenge facing the development of knowledge management systems. First, acquisition of expertise is not a straightforward task; it requires specific settings and work context to obtain it from experts. Most of the methodologies that have been proposed to acquire expertise relied mainly on eliciting expertise manually or by using elicitation systems that rely on the availability of experts where meetings are organized to acquire their expertise [2]. This ends up generally with additional load for experts which is not always in line with their daily commitments and duties resulting in less involvement and motivation. Second, transferring and reusing expertise requires that the representations of knowledge have the articulacy and flexibility to smoothly transfer it from an initial domain to another domain and to adapt it to different contexts and users. The ability to reuse expertise remains the ultimate goal of organizations. e-Learning systems can contribute a great deal to reuse expertise by mapping it to e-courses for on demand learning and training [3]. In order to provide such e-learning environment for organizations, these systems should be able to handle expertise in a mechanistic way so that to not add a burden on experts while transferring their expertise and also on instructors while preparing e-courses for learners.

In this research we propose a framework that is designed to transfer domain expertise through e-learning systems which can generate and adapt the learning material to different target learners. The framework maps conceptual representations of expertise acquired during normal experts' activities while on duty into learning material that can be used by different types of learners. Expertise is represented as knowledge graphs that are knowledge representation structures which facilitate mapping expertise to e-learning courses. Knowledge graphs capture the expertise concepts and their relationships offering a semantic organization of concepts which allow a fluent mapping into an e-learning course where concepts are prerequisite of other concepts. Also, accessing concepts over the web is facilitated by available technologies that allow querying remotely knowledge graphs which opens the possibility to share and reuse all knowledge graphs on the web. The transition from knowledge graph representation to a e-course is made possible by the learning web constructor algorithm, proposed in this research, which is used to structure e-learning material as a tree of concepts that are adapted to fit the learner's context and profile. A case study is presented to illustrate a real life application of the proposed framework. It shows a company that employs experts who write inspection reports that are automatically represented as knowledge graphs during the report elaboration phase. Domain knowledge and reports are stored into a knowledge graph base that is used to generate on-demand e-courses specifically adapted to learners' needs. The knowledge graph base is then queried to retrieve the necessary concepts which are used to generate a e-course for two types of learners: inspection trainees and new recruits.

This paper is organized as follows: Section 2 provides a background on knowledge engineering and knowledge graphs. Section 3 presents research works in relation to the present research. The following section presents the knowledge management framework and explains the different stages to handle expertise. Section 5 details the inspector report case study that illustrates how expertise is acquired and reused. Finally, we conclude this research and provide future potential research paths to investigate.

II. Background

A. Knowledge Engineering

Knowledge engineering is a critical task and a bottleneck facing any knowledge management system aiming to handle human expertise. During this task expertise is acquired from domain experts by specialized knowledge engineers. Many methodologies have been suggested and used to perform this task and the majority relies on the availability and willingness of experts to transmit their tacit knowledge to the knowledge engineer who encodes it into the knowledge base of a knowledge management system [4], [5]. Unfortunately, experts are not always available and experience has shown that classical knowledge engineering could not be applied at large scale. Indeed domain dependence of the developed systems was not easy to bypass towards flexible and domain independent systems. In order to circumvent this difficulty and make this phase at large scale, knowledge engineering should be transparent to experts relieving them from the burden of eliciting knowledge for every domain from scratch [6], [7]. Also knowledge engineers should focus more on the development of knowledge management systems which serve the daily tasks of experts and at the same time can detect, acquire and represent knowledge into knowledge bases that can be reused and shared effortlessly. Such systems can be developed with the widespread of mobile technologies and context-aware mobile systems which are able to adapt to complex context situations and recommend sophisticated solutions to users. This has been the target of many research such as in the medical, engineering and manufacturing fields [8]. In these domains experts have mobile applications that facilitate their work and at the same time perform a great management work on the background such as efficient storage and retrieval of information, efficient context management to adapt information to users and recommendation systems to guide them through the best and optimal solution [9].

B. Knowledge Graphs

Knowledge graphs are graphs of data intended to accumulate and convey knowledge of the real world [10]. Knowledge Graphs involve interlinked descriptions of entities – objects, events or concepts. These are semantic graphs which can capture subtle meanings that can enhance inference in knowledge management systems. The implementation of knowledge graphs and their use in different applications can also foster the development of intelligent systems able to reason and recommend knowledge. Knowledge graphs can use ontologies to provide an abstract representation of a domain where graph concepts and relationships are concisely defined. Besides, available technologies allow accessing concepts over the web which facilitates sharing and reusing remotely knowledge graphs. Also, query languages, such as SPARQL, have been defined to query knowledge graphs which opens the possibility to search and retrieve knowledge graphs easily [11].

A knowledge graph is defined as a graph G = {E, R, F}, where E is a set of entities, R a set of relations and F a set of facts that have the form of a triple (e, r, e') [12]. For instance, (Tom, FriendOf, Jerry) is a triple denoting a relationship FriendOf between two objects Tom and Jerry. This simple fact can be represented in predicate calculus as: FriendOf(Tom, Jerry). Predicate calculus is a language which handles knowledge graph representations in the form of facts, rules for inferring new knowledge and allows expressing queries for retrieving knowledge. For instance, the query FriendOf(Tom, X) retrieves all friends of Tom by instantiating X with all objects that match similar predicates and hence knowledge graphs.

III. Related Work

Sharing and reusing expertise is a broad research field which involves many disciplines such as knowledge management to elicit knowledge of experts, artificial intelligence to represent knowledge and use it in reasoning, computer information systems to develop applications able to diffuse knowledge to the right user in the right context. e-Learning is an ideal application domain that can contribute to reuse expertise as it transfers tacit knowledge to explicit knowledge through learning, training, coaching, or mentoring [2]. e-Learning systems developed for education or training implement instructional material into user-friendly sophisticated systems that have the ability to adapt to learners in need of domain expertise in a specific context [9]. Knowledge representations are naturally used in teaching and learning in the form of concept maps and taxonomies to categorize concepts and to illustrate them through concept visualization. In this section we present research works that have used concept graphs in education from different perspectives.

Shi et al. in [13] propose a learning path recommendation model which uses specific semantic relationships and knowledge graphs to propose learning objects to learners. The objective of the proposed framework is to increase learning efficiency and recommend personalized learning paths. This framework has been applied to learn machine learning algorithms. Learning objects are categorized into three classes namely: basic knowledge, algorithm, and task. A recommendation algorithm is then used to recommend the optimal learning path for learners based on scores of learning algorithms features such as publication time, citation count, search frequency and impacts of the publisher and author. While this approach seems to work well in the specific domain of machine learning algorithms, it has two major limitations: i) it needs a manual elicitation of the domain knowledge to identify and categorize learning objects for every domain, and ii) some of the semantic relationships defined to link learning objects such as: Ori-algorithm (current LO was improved from an original algorithm), ApplyToAlgorithm and ApplyToTask, are local to this particular domain and can hardly applied to another domain. In [14] a system is developed based on knowledge graphs to provide personalized learning content to learners that are categorized by their learning abilities skill set. Knowledge graphs are constructed based on the concepts extracted from learning objects and relationships are set between concepts. Based on the core concepts and the relationships semantic of the knowledge graph, graphs are generated automatically to the three categories of learners. Accordingly, slow learners are given only the core concepts, then additional graph relationships are considered to generate learning content for moderate learners, and finally highly skilled learners are offered more learning objects based on an

extended knowledge graph. In [15] authors developed a learning path generator based on knowledge graphs to provide guidance for learners. The method uses a topological ranking algorithm to generate a topological structure of the learning path and then learning objects are serialized using ant colony optimization. Evaluation of the method shows that the generated learning path is comparable to expert learning path in terms of learning outcomes. Authors in [16] propose KnowEdu, a system that construct educational knowledge graphs that can be used for online learning in school. The system uses pedagogical data and learning assessment data to extract instructional concepts of courses and then identifies significant relations holding between these concepts. Concepts and relations are extracted using respectively neural sequence labeling algorithm on pedagogical data such as textbooks and course tutorials, and association rule mining on learning assessment data to identify the relations such as prerequisite and inclusion. The authors present a case study where the system was used to build a knowledge graph for mathematics course.

IV. Knowledge Management Framework

The framework depicted in Fig. 1 shows the different stages that allow handling knowledge from its source till its utilization in e-learning systems. The framework exhibits four main phases namely: Elicitation, Management, Reuse and Sharing, for converting knowledge expertise as it is acquired from experts till it is shared by learners in various learning systems.

A. Knowledge Elicitation

Knowledge is sought through daily expert activities such as coaching, auditing, brainstorming, training, consultation and mentoring. Knowledge undergoes a four step process: Identify, Extract, Validate, and Represent. Knowledge identification is done from resources such as videos, audios, manuals, reports, regulations, procedures, etc. produced by the expert and made available for performing the activities. These resources are either available internally within the organization and are queried from databases or are retrieved using web services for activities that are posted on the web or online social networks. Knowledge is then extracted automatically from these resources and then validated to make sure that it fits with the objectives set for reusing and sharing learning content. In the last process step knowledge is represented into the knowledge base for further use. This process is supported by the Elicitation Model which specifies what knowledge is sought, from where to get it and how to extract it and validate it. It is also supported by the knowledge representation language which allows representing knowledge into the knowledge graph base.

B. Knowledge Management

Knowledge Management step handles mainly the storage of knowledge in the knowledge graph base and provides a reasoning engine to infer new knowledge or to adapt knowledge according to the user's context. For this purpose, context is constantly gathered and updated to allow adaptation of learning content. Knowledge is also scored which is necessary in order to retrieve quality knowledge in response to requests of learners.

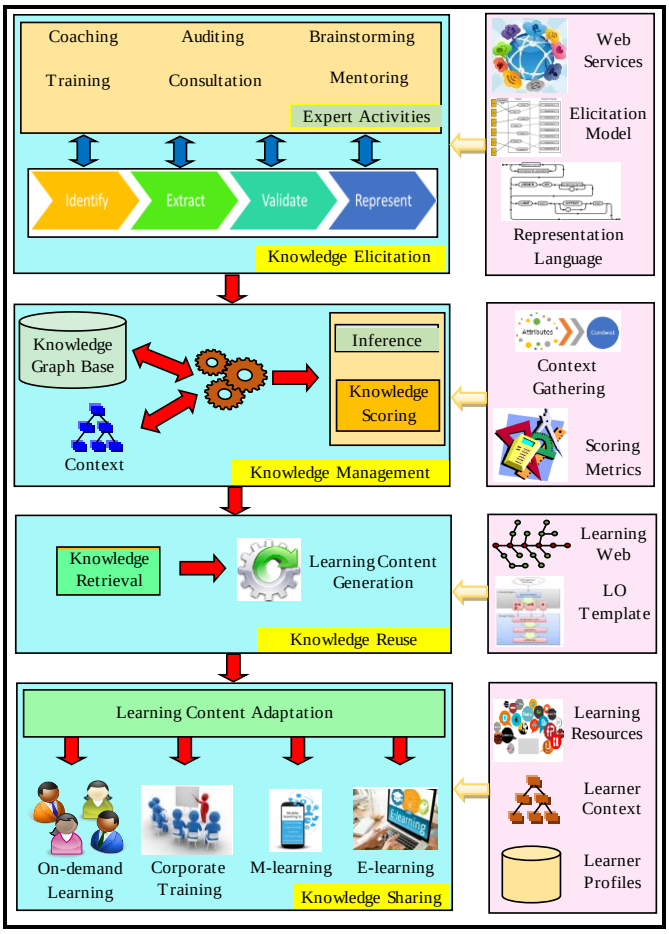

Fig. 1. Knowledge Management Architecture.

C. Knowledge Reuse

This step provides the necessary modules for retrieving knowledge and generating the learning material. Reusing knowledge for learning relies on two components: the Learning Web (LW) and the Learning Object Template. LW is the main learning structure which organizes the learning material. LW is generated by the Learning Content Generation module. It is similar to a tree of nodes where the root is the first learning object and the other nodes represent LOs available for the learner to visit to complete the learning requirements. LOs are learning units including a set of resources that are organized into specific templates. Algorithm ConstructLW in Fig. 2 takes three parameters Le, KG and LW. Le is an input list of ordered concepts in the knowledge graph base selected by an instructor to deliver a particular e-course. This list should be ordered according to the pre-requisite teaching precedence. KG is the input knowledge graph base as described in Section 2; it is defined as {E, R, F}. LW is the learning web which is initially set to an empty list and which will include a list of ordered concepts in relation with the concepts in Le. ConstructLW retrieves all direct concepts e' in relation with concepts e in Le and adds them to LW. It is noted that the union set operation (Line 9) prevents the duplication of concepts already in LW. The complexity of ConstructLW is in $O(n^2)$ where n is the maximum number of concepts e' that can be in relation with a concept e in LW.

```
1. ConstructLW (Le, KG, LW)
2. input: Le                          is a list of concepts in the
                                      knowledge graph KG
3. input: KG = {E, R, F}              is a knowledge graph;
4. output: LW = ∅                     is the Learning Web
5.    for each e ∈ Le do
6.    {
7.     LW = LW ∪ {e}                  add e to LW
8.     for each e' such that (e, r, e') ∈ KG do
                                      e' is a concept in relation with e
9.          LW = LW ∪ {e'}            add e' to LW
10.   Le = Le – {e}    remove e from Le
11.   }
12. return LW
```

Fig. 2. Learning Web Generator Algorithm.

D. Knowledge Sharing

In this phase learning generated is adapted to fit different learners according to their context and profiles. Sharing knowledge is vital for organizations. It should be a daily integral part of a learning organization which must develop clear strategies for diffusing knowledge and define the appropriate use of the transmitted knowledge. In order to be able to share and adapt knowledge this phase uses three components namely learning resources, learners' profile and context which allow content adaptation to different types of learners.

V. Case Study

The Inspection Report case study presented in this section illustrates the knowledge management architecture (Fig. 1) and shows how expertise is elicited and reused. A petroleum and gas company has many natural gas processing plants which includes satellite stations that treat Liquefied Natural Gas (LNG). These stations have specialized maintenance engineers who monitor the station's devices (such as piping systems, storage tanks, vaporizers, control devices, pressure regulating valves, etc.) in order to conduct risk assessment, predict deficiencies and propose corrective maintenance actions. The objective is to improve operational efficiency, guaranty safety and protect the environment. Engineers perform regular on-site visits and write reports about the station devices. In case there is a deficiency they propose the repairing to be done and the devices to replace. Reports have a specific template which include an identification section, a description of the problem (if any), reference to previous reports about the same device (or problem), corrective actions proposed and possible maintenance (replacement, reparation, …) to be done on the device along with the execution schedule. While on-site engineers can access all the reports stored in the database to check the maintenance history and evaluate the progress of previous defects. They can also communicate with each other seeking advice or corroboration of their diagnostics. Reports are recorded using a mobile tablet through a template allowing the engineer to write text, take pictures and record audios and videos. Also communication with peers is recorded and added to the report.

A. Eliciting Knowledge Reports

Reports represent a valuable source of expertise that is consulted by managers, experts, maintenance engineers. Also trainees and new recruits can learn and practice their knowledge from inspector reports. When inspectors do their inspection task a knowledge graph is created based on the report attributes such as the inspector ID, the task name, and the component inspected. Fig. 3 shows part of the knowledge graph including two types of concepts: domain knowledge concepts about Refrigeration Piping (green colored circles), and task related knowledge (blue colored circles) which captures the inspection tasks done by inspectors to check pressure of a specific Refrigeration Piping. The figure shows a superposition of concepts for *Inspection Report* and *Inspector* exhibiting the fact that multiple reports have been done by many inspectors for the same task that is to check pressure of component Piping GNL 225-R3674. Knowledge elicitation is done in a transparent manner without intervention of inspectors. While performing their tasks, the task related knowledge is acquired whenever an inspector creates an inspection report to inspect a component. The report is then added automatically as a subgraph in the knowledge graph base as a task related knowledge.

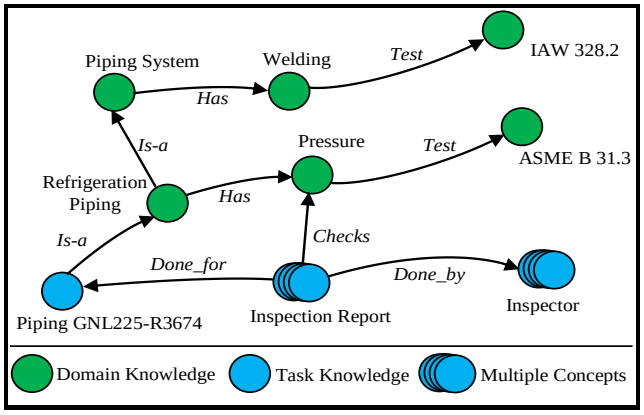

Fig. 3. Piping System's Knowledge Graph.

B. e-Learning Content Generation

Inspection reports expertise represented as knowledge graphs is used by experts, inspectors, and engineers to plan on-site inspections and to follow up on maintenance. It is also exploited by the training and development unit to provide learning content for trainees and new recruits. Training material is generated, as e-learning courses, by querying the knowledge graph base for both inspection trainees and new recruits for the plant. These two types of learners have different backgrounds and different learning objectives and hence require different learning material. Inspection trainees are company employees who need to be trained on inspecting the site, they are knowledgeable about the plant processes. They need to be trained on testing the refrigeration piping system by using the test specification ASME B 31.3. New recruits are engineers who need to acquire knowledge about the plant processes and get some practice on the unit piping system. In order to cover the learning needs of these two types of learners, two different learning webs are generated as shown in Fig. 4.

1) Learning web generation: The learning web is a learning structure organized as a tree of units including the building blocks of learning called Learning Objects (LO) [3]. LW represents the e-course that is traditionally designed by instructors. In our case LW is automatically generated from the

knowledge graph base which is queried to retrieve the knowledge subgraph containing the necessary knowledge concepts to fulfill the requirement of learning for a specific learner [17], [18]. These concepts are then ordered to form a tree of concepts. Each concept is materialized by a LO (or set of LOs) that includes the necessary learning resources to be exposed to the learner [9].

Both LWs in Fig. 4 are generated by *ConstructLW* algorithm (Fig. 2). They include mandatory and elective LOs. Mandatory LOs represent the required knowledge that is essential in any learning course. They correspond to domain knowledge concepts in the knowledge graph (Fig. 2). Elective LOs are supporting learning units which are not essential to achieve the learning outcomes but they can support learners to understand, practice or have examples about the core concepts. Elective LOs correspond to task knowledge concepts in the knowledge graph.

Trainees' LW (TLW) is focused on a specific task that is to check and maintain the refrigeration piping system. They need to learn about this system and also be able to elaborate a report using the test specification ASME B 31.3. The input list of concepts Le for generating TLW is Le = {Refrigeration Piping, Pressure}. Algorithm ConstructLW generates LW by including the following: i) mandatory LOs: Refrigeration Piping, Pressure, and ASM B 31.1 representing the necessary domain knowledge and ii) elective LOs: Piping GNL225-R3674 and all reports that have been done for this particular component of the refrigeration piping. The new recruits' LW (RLW) is generated to acquire knowledge about the piping system and get some practice about the regular system maintenance. The input list of concepts Le is Le = {Piping System, Welding, Refrigeration Piping, Pressure}. In this case, ConstructLW generates RLW including the following: i) mandatory LOs: all domain knowledge concepts to allow engineers to learn about the piping system and ii) elective LOs: Piping GNL225-R3674 and the inspection and maintenance reports to allow engineers to have practical sessions on the piping system.

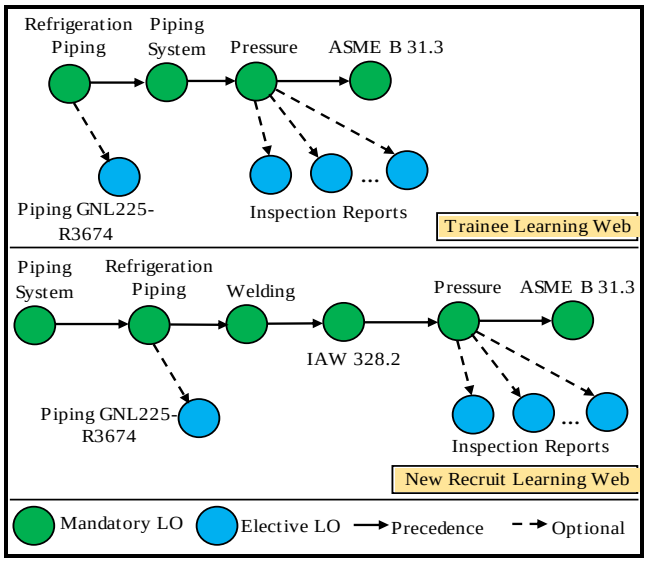

Fig. 4. Generated Learning Webs for Inspector Trainee and New Recruit.

2) Learning objects generation: Once the LW is built learning object are generated for each concept. During the elicitation phase resources are gathered and stored. These resources are then retrieved and packaged as LOs using specific templates. An example of a domain concept, the *Piping System LO*, is illustrated in Fig. 5. The generated LO includes a text description about the concept *Piping System*. It includes also a video, an image and a list of topics organized the same way as the LW, i.e. a sequence of domain concepts and task concepts supporting domain concepts.

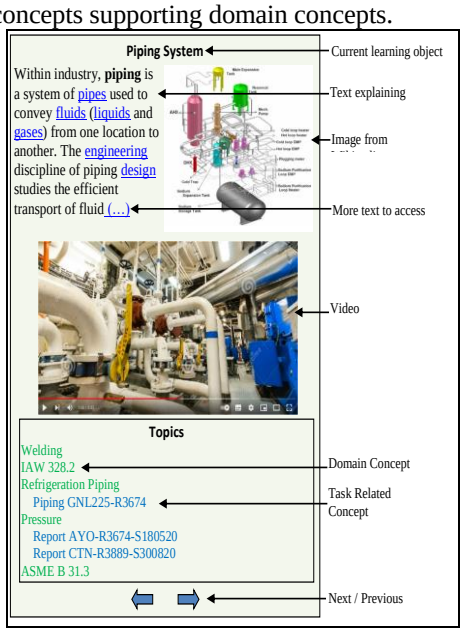

Fig. 5. Piping System Learning Object.

Navigation in the LW can be done in two ways. The first possible navigation is to use *Next* and *Previous* arrows at the bottom of the LO. This allows a sequential navigation in the LW moving forward (or backward) to the next (or previous) domain concept triggering the generation of the corresponding LO. The second possibility is to navigate freely in the LW by clicking on any LO listed in the *Topics* area. This gives more freedom to the user to focus on the concepts he is more interested in and do not waste his time with concepts already known.

VI. Discussion

The framework presented in this paper is designed to safeguard expertise and promotes a smooth transition from expertise represented as knowledge graphs to e-learning courses adapted to different learner types. Usually experts (such as doctors, consultants and auditors) in organizations perform their daily duties using computer programs or applications to facilitate their tasks. While these activities are generally recorded in databases (such as the inspection reports) rarely this expertise is shared and reused within or outside the organization. The framework contributes to not only gather expertise during experts' activities but explicitly turns expertise recorded into e-learning material for sharing by learners in the organization. The representation of expertise using knowledge graphs offers a clear flexibility to the web learning generation algorithm which allows to extract a subgraph on-demand. The

proposed algorithm extracts the target concepts and their related concepts to generate the learning web used for e-learning. Although the algorithm in its actual version is restricted to the first level related concepts, it can be easily updated to consider additional levels offering more learning depth and more adaptation to learners.

VII. Conclusion

Reusing expertise is e-learning opens many opportunities for organizations to exploit and share efficiently their know-how and skill set. The framework presented in this paper supports such fluent transition from expertise elicitation till its reuse for learning and training. Expertise is represented as knowledge graphs which provides two advantages: i) concepts are semantically organized which allows an inherent mapping in e-learning where concepts are prerequisite of other concepts, ii) accessing concepts over the web is facilitated by available technologies that allow querying remotely knowledge graphs which opens the possibility to reuse all knowledge graphs on the web. The transition from knowledge graph representation to a learning web is made possible by the learning web constructor algorithm which maps concept graphs into a tree-like structure of learning objects composing a e-course. This gives the possibility to adapt knowledge to different learner types based on their needs and context. The case study presented illustrates the framework's feature while the same knowledge graph has been queried for Inspection Trainee and New Recruit to generate learning material to both learners taking into account their context and learning needs. Future research plans are to develop the scoring function which scores learning resources according to diverse criteria such as author profile, resource creation time, resource popularity (such as number of likes, number of views). This will promote the use of the most interesting resources to fulfill effectively the learning requirements.

Leveraging Artificial Intelligence–enabled Workflow Framework for Legacy Transformation

Abdullah Al-Barakati
Faculty of Computing and Information Technology
King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—The rapid advancement of web technologies coupled with evolving business needs make legacy transformation a necessity for enterprises around the world. However, the risks in such a transformation must be mitigated with an approach that is flexible enough to allow for a gradual and low risk transformation process. This paper presents a Service Oriented Architecture (SOA) workflow-based legacy transformation approach that allows for phased transformation in which a legacy system is first transformed into self-contained modular services accessible via a dedicated service layer. These modular services are managed through an AI-enabled workflow management layer that interacts with improved UI frontend for the system's end users. This paper presents a hypothetical prototype in which an Oracle 5 legacy system is transformed using the proposed architecture. ASP .NET Core MVC as well as Pega business process management platform are utilized to practically assess the feasibility of the proposed approach.**

***Keywords*—Legacy systems; service oriented architecture; workflow management; legacy transformation; digital transformation; artificial intelligence (AI)**

I. Introduction

Legacy systems can be defined as applications that were built with old technology but are still in use in many business environments [1]. Despite the apparent advantages of transformation from legacy systems to modern web-based solutions, government and private enterprises consider the process risky and challenging and, therefore, show reluctance in initiating the change. Such reluctance can be attributed in part to the heavy investments that were associated with developing legacy applications [2]. Furthermore, enterprises incur heavy costs to train their employees and tailor their processes to benefit from legacy systems [3]. On the other hand, the legacy transformation and modernization process itself can be lengthy and costly. Major risks include the inherent complex designs of legacy systems [4], tightly coupled components, system performance issues, and difficulties in mapping current systems to target architectures and platforms [5]. Additionally, the underlying knowledge about such systems is usually scanty due to limited documentation and the unavailability of the developers who originally built these systems [4]. As a result, most legacy modernization tenures tend to begin with lengthy reverse engineering periods to document current systems before paving the way for technology transformation.

It can be argued that legacy transformation is inevitable with the rapid advancements that technology is witnessing, especially the digital transformation phenomenon. Digital transformation places special emphasis on legacy transformation as one of the cornerstones of successful transformation strategies [6]. While legacy transformation and modernization processes can be lengthy and costly as mentioned earlier, they can offer long term cost savings, increased efficiency, better resource utilization and the ability to adapt to the dynamic business needs of any given enterprise [7]. Therefore, enterprises need an optimal transformation approach that will enable them to part with legacy systems and take advantage of the possibilities offered by modern web-based technologies [8].

In this paper, we propose a legacy modernization approach that aims for gradual technology upgrade from legacy systems to modern web-based solutions without disturbing business operations. It is based on a Service Oriented (SO) architectural approach that wraps exciting legacy applications with an AI-enabled workflow management layer. The workflow management layer acts as a service orchestrater that reduces the risks of inadequate service mapping when migrating from legacy systems to target modernized systems. Workflow management functionality is achieved via Business Process Management Solutions (BPMS) that can sit on top of the legacy system services. This approach emphasizes service orientation where business logic is captured and managed in a dedicated middle service layer that can potentially integrate with any future core systems that may replace current legacy systems. While this approach can be technology agnostic, we are showcasing a hypothetical case study where Pega BPMS is utilized to manage the workflows of an Oracle 5 form-based legacy system while having ASP.Net Core MVC as the main technology for a dedicated service layer.

The reminder of this paper is organized as follows. Section II sheds light on some of the research in legacy system transformation approaches. Section III outlines the overall architectural approach, its layers, and the integration points with legacy systems. Section IV introduces the suggested technology stack related to the proposed architecture. Section V showcases a practical implementation of the proposed approach as a hypothetical proof of concept. Section VI presents the findings of this paper and highlights possible areas of future work.

II. Legacy Transformation Approaches

Due to the importance of legacy system transformation, several studies have focused on finding the best way for a safe and fast transformation process. In this context, the work produced by [9] examines several options for legacy system

transformation in which replacement is considered the best option for old systems which are undocumented, outdated, or not extensible. However, authors in [9] note that the replacement of such systems is often a resource-intensive and risky process. On the other hand, [6] present a lightweight agile approach for effective low-risk legacy transformation as opposed to waterfall-based transformation approaches. Such an approach can potentially address the technical and procedural complexities associated with legacy transformation.

In the work presented by [10], the authors showcased the process of transforming a legacy social services information system to a modern digital platform. This platform capitalized on advanced technologies (Artificial Intelligence [AI] and Machine Learning) for analyzing and processing big data. From an architectural perspective, this transformation was enabled via the utilization of cloud computing, big data innovations, and the emerging microservices architectural principles. In a similar manner, [8] proposed a tiered architectural approach for legacy system transformation. In this approach, component configuration is specified in Extensible Markup Language (XML) files to facilitate legacy service wrapping and integration. The work presented by [11] is in conformity with the approach presented by [8] as the author argues that legacy systems can be transformed by exploiting modern, faster, and cheaper technologies such as Java and XML. He also indicates that such an approach can shift focus to functionality not technology, hence allowing for better response to the evolving business requirements of any given enterprise. Furthermore, [11] presented a legacy transformation software tool (RescueWare) that acts to decompose business knowledge into self-contained e-components tasked with performing certain business functionalities. These components are defined within standard Application Programming Interfaces (APIs) which can be accessed by other systems and interfaces that can potentially replace the legacy system in question.

The work done by [1] emphasized a component-based approach for legacy transformation. Their methodology includes a reengineering process to transform legacy systems into new components with upgraded software architecture design. They adopted a reverse engineering approach that is based on the extraction of architectural information from the existing codebases of legacy systems. Based on the extracted information, in conjunction with business domain knowledge, modular system components were to be developed to replace the existing legacy system. Similarly, [12] present an interactive tool to extract database and business logic components from legacy systems. The aim is to minimize the complexity of the migration process by introducing a decomposition step. This step can help slice the legacy system into encapsulated components that can be migrated into a client-server platform.

The work in [13] encompasses a legacy migration approach based on the conversion of legacy system architecture into Service Oriented Architecture (SOA) within a systematic predefined process. The process that they suggest is feature oriented as it focuses on a reengineering approach to transfer existing legacy services into web services facilitated by the Web Services Composition Language (WSCL). The author in [13] validated their approach with a case study which presented a prototype based on a layered architecture comprising three main layers: Interaction Layer, Translation Layer, and Repository Layer.

Much of the previous research focused on the concepts of modularity and service orientation for successful transformation. However, to our knowledge, integration of workflow management layers as a part of the legacy transformation process is an area that is not yet fully examined. For this reason, we propose an AI-enabled workflow-based approach for legacy system transformation.

III. Proposed Architecture

To counter the risks and complexities that accompany legacy transformation tenures, a layered SOA-based architectural approach is proposed. SOA can play the role of a transformation and integration enabler for legacy systems [7]. Exposing legacy services in a service-oriented manner will provide for modular services that can be exploited by a variety of interfaces. Such interfaces can be frontend systems or other core systems that benefit from the services of the legacy system. Furthermore, Service Orientation - as a concept and a transformation enabler - will allow for greater interoperability for legacy services. More importantly, business logic transformation to a service layer will lead to decoupling the services of the core system to further facilitate legacy replacement/enhancement.

In addition to the advantage of transformation to service-oriented components, this model is complemented with a dedicated workflow management layer which is tasked with orchestrating the different business services of the legacy system in transformation. Such a model aims to facilitate the process of managing the usually complex services and workflows of a typical legacy system. Additionally, by having a dedicated workflow management layer, it will be possible to gradually move the legacy services from the core system to a service layer. In such a scenario, the workflow management layer will orchestrate uninterrupted business operations by managing the right mix of legacy services, external integration on the one hand and user interactions on the other.

Two main architectural principles will govern and shape the proposed legacy modernization architecture. Firstly, a microservices approach will allow for rapid delivery of the system's business services [14]. Microservices will also be an enabler for a robust technology stack that can be enhanced or modified when and if needed. Enhancement can be achieved by plugging in more service layers to cover any evolving business needs. In conjunction with the utilization of microservices architecture, the proposed solution focuses on the development of domain-specific services. Hence, the legacy application's services will be divided into self-contained modules based on business areas. This approach adheres to the principles of Domain Driven Design (DDD). Thus, business context will be divided into individual areas that can be developed and managed separately. Greater modularity and manageability can be considered as important advantages of this approach. Based on the proposed approach, the following architectural layers will be required as illustrated in Fig. 1.

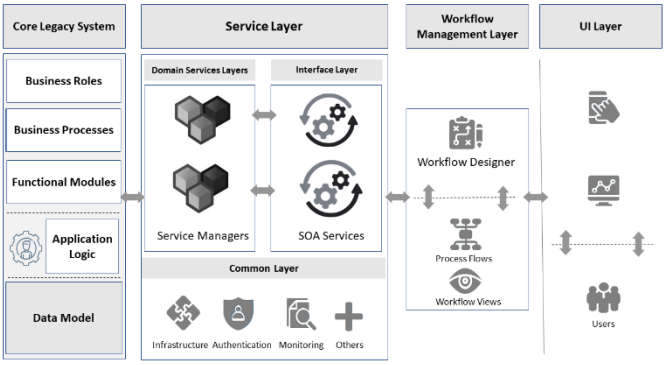

Fig. 1. Proposed Architecture.

A. Core Legacy System Layer

In the initial phases of transformation, the core legacy system will be considered as a backend system that the other system layers will be interacting with. As is the case with typical legacy systems, this layer will comprise application software and any associated databases.

B. Service Layer (Middle Layer)

To be able to adopt a service-oriented approach, most business logic should be separated from the core system into a dedicated API-based Service Layer (middle layer). This layer will contain the business logic such as all validations and custom roles related to the core legacy system. The service layer will be divided into the following sub-layers:

1) Interface Layer (API): This layer will be dedicated to exposing the services of the core legacy system into Representational State Transfer (RESTful) APIs that are consumable by the Workflow Management Layer. Furthermore, RESTful APIs will be exposed as web services that can be accessed by either internal or external systems.

2) Domain services layer: Following the principles of Design Driven Design (DDD), the Domain Services Layer will contain a number of business-oriented modules. These modules will correspond to the respective business areas in the core legacy system. Hence, each module will encapsulate several microservices that provide business-specific functions. In line with DDD implementation patterns, each module will have a service manager to manage its microservices. Moreover, the service manager will enable collaboration among the business modules as required. Service calling in this instance is achieved via the communication between the service managers of the different system modules.

3) Common layer: The Common Layer will provide generic services required by the application. For example, user management and authentication, integration with external parties, and data access. This layer will also comprise a dedicated Data Access Layer (DAL) that will provide all the data connectivity and access functionalities. Having a separate DAL is vital in the context of legacy transformation as it will enhance the adopted SOA approach by avoiding native access to databases.

C. Workflow Management Layer

One of the important elements of the proposed architecture is based on wrapping legacy solutions with Business Process Management (BPM) functionality. BPM functionality will be managed via a Workflow Management Layer that will act as an orchestration tool to manage the interactions between the legacy core system and its related end points. Following the proposed layered approach, a workflow management software component will sit on top of a dedicated service middle layer. Hence, the Workflow Management Layer will comprise three main components as follows:

1) Process workflows: The process workflows capture the workflows of the legacy system and manage the system services accordingly. It should be noted that domain driven workflows will not only capture the business-level models of the legacy system, but the approach adopted by [15] will be employed in which IT-level models will also be captured for effective workflow management. Hence, in addition to capturing the workflows of business processes, IT-level models will also be captured to address specific technical requirements such as infrastructure considerations and user access and authentication.

2) Workflow and data views: Workflow models constitute process models (views) that capture the actual sequence of activities/validations that a typical workflow process contains [16]. Workflow views will be used to create and manage the workflows that map the legacy system's functionality. Another layer of workflow modelling within the proposed architectural model is the data models (views). Data views contain the data objects required to define data fields, data field mapping, and connections to database. Hence, they bridge the connection between the backend database systems.

3) Artificial intelligence (AI) Layer: This layer will aim to streamline the system's workflows, reduce redundancies by intelligently handling large amounts of data, reduce user errors and increase the efficiency of routine tasks. It will offer the greater advantages of the legacy transformation process.

D. User Interface Layer

The User Interface (UI) Layer will provide users with the ability to interact with the backend legacy system to achieve the required business functionality. Frontends can be in the form of purpose-built desktop applications communicating with the Workflow Management Layer. They can also be in the form of web-based applications whether it be a website, web portal, tablet, or mobile applications.

IV. Technology Stack

There is a variety of technology solutions that can support a gradual transformation from legacy systems to modern web-based solutions. Based on the proposed workflow-managed SOA approach, the following software technologies can be utilized for a prototype implementation:

A. Pega Platform

Since one of the pillars of the proposed approach is the utilization of a Workflow Management Layer, the use of Pega

as a Business Process Management (BPM) platform is suggested. The low-code nature of Pega coupled with its App Studio that allows for business and IT cooperation in the design stage makes it a powerful tool for transformation and modernization projects [17].

Another reason to choose Pega is its wide range of data and integration capabilities that allows connecting Pega applications with distributed backend systems. The Pega platform also supports a wide spectrum of integration standards and protocols allowing for high connectivity levels with external systems [18]. Additionally, Pega offers a wide range of AI and machine learning tools that allow for optimized workflows and increased efficiency [19]. These capabilities are particularly important in relation to the proposed architecture which emphasizes communication with legacy systems via dedicated integration layers.

B. ASP.Net Core MVC

ASP.Net Core MVC is a modular and cross-platform development framework for developing web-based applications [20]. It provides a concrete framework for developing RESTful web services that can expose data operations [21]. This development framework was selected for the prototype implementation due to its ability to expose backend services as RESTful web services that can be consumed by other software layers (namely, the Workflow Management Layer in our proposed architecture).

Developing a middle layer using ASP.Net Core MVC can provide the required flexibility in terms of transforming a legacy system to a web-based system. Within this context, the main advantage of ASP.Net Core MVC is its ability to provide headless web services [21]. Headless API services do not have User Interface (UI) as they are meant to be consumed by other systems that may have their own UI elements. This approach provides the necessary flexibility to expose system services via different interfaces such as websites, web portals, and mobile applications.

C. Devart

Devart is a database connectivity tool that supports a variety of database platforms. To avoid direct (native) access to the legacy database, Devart can be a good tool for building Data Access Layers (DAL) that can provide the necessary interfaces to the service layer to access legacy databases. Furthermore, Devart's developer tools support reverse and forward engineering which makes it a suitable tool for legacy modernization implementation [22].

V. Solution Implementation

To identify the exact components of the proposed architectural approach, a hypothetical proof of concept is presented in this paper. We examine the effectiveness of the proposed approach through a prototype based on one of the common legacy transformation scenarios. This scenario is represented in the transforming of an Oracle forms-based system (Oracle 5) to a web-based application. In this proof of concept, the scenario of exposing a legacy HR system to the web is highlighted through the implementation of the proposed transformation approach.

A. Transformation Steps

A piece-by-piece transformation process is followed as opposed to a risky big bang approach where all system components are migrated at once to a new system/platform. Based on this gradual approach, two main transformation stages can be envisaged:

1) Phase I: Transformation to Service Orientation (SO): The main goal of this phase is to transform legacy services into modular services that can be accessed from a service-oriented middle layer (service layer). To achieve this goal, the legacy system will be analyzed and documented on an as-is basis. Then, business logic will be captured in the service layer that will directly interact with the legacy system and its database (acting as a backend system in this instance).

2) Phase II: Legacy system replacement: Since Phase I will separate business logic from the legacy core system, it will be relatively a lower risk process to replace the backend legacy system with a new system that will interact with the existing service layer. In such a scenario, business operations and end-user experience will not be interrupted as they will still be interacting with the same frontend systems. Such frontend systems can be either a workflow management interface as manifest by the proposed architecture, customized desktop applications or web-based applications.

B. Case Study

The prototype system includes four layers (Core Legacy System, Service Layer, Workflow Management Layer and UI Layer). In this context, it is assumed that the Legacy System's services were mapped into several clearly defined APIs that can loosely integrate with other systems. As illustrated in Fig. 2, the API services act as an entry point and perform the required services using the business modules' service managers. Furthermore, the API service layer will use the Common Layer for generic functions such as the management of user authentication, getting database context, etc. Additionally, API services will share the database context with all business services allowing the system activities to be handled in a few database transactions.

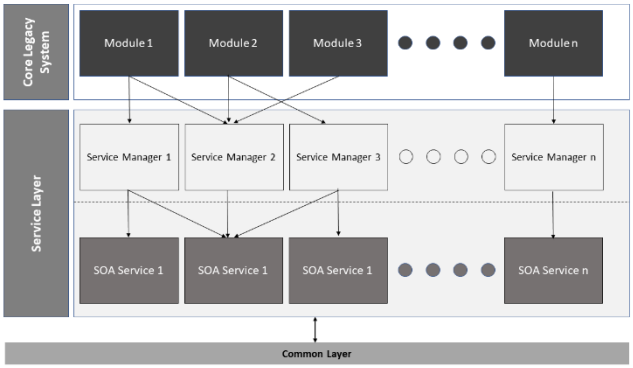

Fig. 2. Modules and Service Managers' Interactions.

C. System Services

Table I summarizes the main API Layer services that require the basic HR system functionality. If we take the example of a simple service to enter the details of a new employee, several RESTful API services can be used to populate the dropdown menus used in the data entry form within the system's UI. These services will be called via the designated service manager to pull the required data for use in the UI. Furthermore, business validation can be performed using services from several modules based on the action being performed by the end user.

D. Workflow Management

The legacy system functionality is decomposed into service-oriented workflows managed by the Workflow Management Layer. In our prototype, the Workflow Management Layer is represented in Pega BPMS, which is a low code workflow management platform that has the flexibility to integrate with a variety of backend systems. Fig. 3 illustrates the Pega-designed workflow for the employee addition process within the prototype HR system. This workflow contains three main steps: identification of employee details, employee addition, and closure.

TABLE I. API LAYER SERVICES

System Functions	**Service APIs (CommonDBContext = InfraSrctureManage.GetDatabaseContext)**
Search Function	API. Search Employee In this service, the user inputs the search attributes and then calls the following service to fetch the required results: HRSrvcMngr.GetEmployeeList
Add New Employee	API.NewEmployee: A data entry form allows the user to enter the attributes related to a new employee. The following services are used to fill the dropdown lists associated with employee attributes. For example: RefSrvcMngr.GetEmployeeTypes(CommonDBContext) RefSrvcMngr.GetContractTypes(CommonDBContext) RefSrvcMngr.GetContractTypes(CommonDBContext) RefSrvcMngr.GetDepartmentsList(CommonDBContext)
Update Employee Details	There are two steps in this process: 1. Show employee details, attributes are initiated by fetching the current employee data by using the service: HRSrvcMngr.GetEmployeeByID 2. Users can update the employee's details and then either save the record or cancel the process.
Delete Employee Details	API. DeleteEmployee The API.SearchEmployee can be used to fetch the employee details. Once an employee record is selected, it can be deleted by using the following service: SgnSrvcMngr.DeleteEmployee(CommonDBContext)
Save Details	API. SaveEmployee Saving an employee's details can be done through either of two processes: 1. Adding a new employee: HRSrvcMngr.CreateEmployee(CommonDBContext) 2. Updating employee details: HRSrvcMngr.UpdateEmployee(CommonDBContext)
Cancel Operation	This functionality will be achieved via the UI level by clearing the data entry form

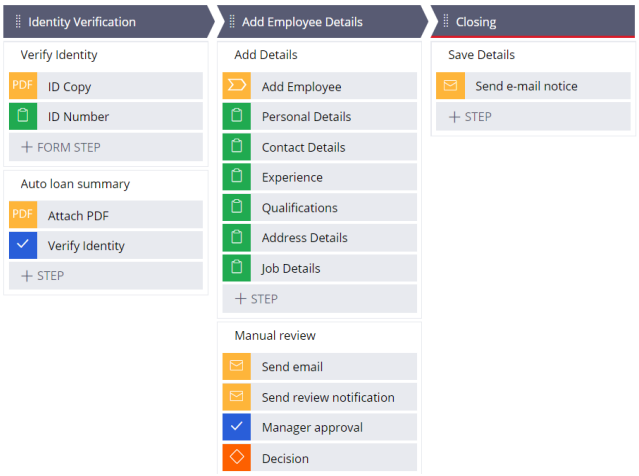

Fig. 3. Proposed Architecture.

The first step in the workflow involves the verification of the employee's identity before adding his details to the system. To verify the identity, it is assumed that Pega will integrate with a third-party provider to validate the employee's ID. In our prototype implementation, Pega capabilities are utilized to create the system's frontend in the form of a series of HyperText Markup Language (HTML) pages that correspond to the designed workflow.

Once the employee's identity is validated, the "Add Employee Details" step is invoked which will involve displaying the employee addition data entry form shown in Fig. 4. The different drop downs in the entry form will be populated with dynamic values pulled from the legacy system database. For example, the following services will be called to fetch Employee Types, Contract Types and List of Departments:

RefSrvcMngr.GetEmployeeTypes(CommonDBContext)

RefSrvcMngr.GetContractTypes(CommonDBContext)

RefSrvcMngr.GetDepartmentsList(CommonDBContext)

Once the employee details are added, they can be saved by invoking another service from the Service Layer:

HRSrvcMngr.CreateEmployee(CommonDBContext)

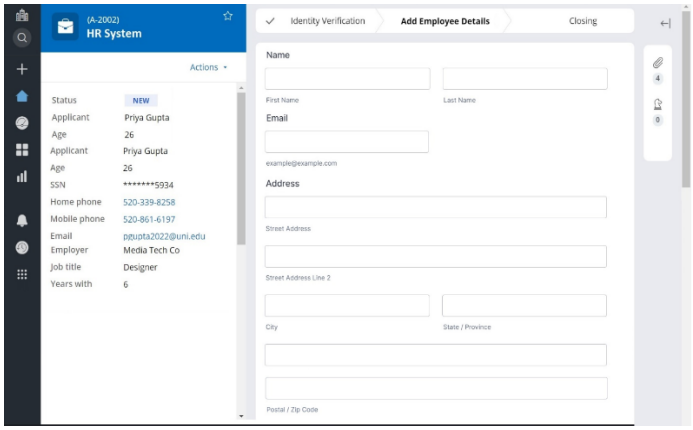

Fig. 4. Employee Addition Form.

E. Integration

Pega integration capabilities with RESTful APIs were utilized to integrate with the services provided by the Service Layer. In this scenario, Pega acted as a client application that uses HTTP protocols to access GET or POST methods to achieve the required functionality. An example of RESTful service consumption is the process by which the list of contract types is fetched to populate the relevant dropdown list in the employee addition form. HTTP GET requests are passed through service HTTP query strings that contain the required operations. In this example, GetContractTypes service is used:

https://www.legacyhr.com/GetContractTypes.php?operation=fetchtypes

The fetched data is formatted into JavaScript Object Notation (JSON) string that can be easily used in the system's frontend as illustrated in Fig. 5. Similarly, when there is a need to write data to the legacy system's database, HTTP POST operations can be used to pass the required data (for example, new employee's details) to the core system.

```

VI. Conclusion and Future Work

A. Conclusion

The rapid advancement of web technologies coupled with evolving business needs make legacy transformation inevitable for enterprises around the world. However, the risks of such a transformation should be mitigated with an approach that is flexible enough to allow for a gradual and low risk transformation.

The proposed SOA workflow-based transformation approach offers several benefits in terms of legacy system transformation into web-based applications. The key advantage here is the adoption of a microservices architecture where the legacy system's functionality is decomposed into self-contained functional units. On top of that, an AI-enabled Workflow Management Layer orchestrates the system's functionality by calling the required legacy services from a dedicated Service Layer (middle layer). In our prototype implementation, we utilized ASP.Net Core MVC for the Service Layer implementation and Pega BPMS for the Workflow Management Layer.

B. Future Work

Future work will involve progressing further with the transformation approach by examining the process of replacing the legacy backend system with a new core system. The aim here will be to validate the success of full transformation by utilizing the suggested architectural approach and transformation steps.

Developing the Mathematical Model of the Bipedal Walking Robot Executive Mechanism

Zhanibek Issabekov, Nakhypbek Aldiyarov
Satbayev University, Almaty
Kazakhstan

***Abstract*—The paper considers the accuracy of footstep control in the vicinity of the application object. The methodology of forming a simulation of the executive electro-hydraulic servomechanism is developed. The paper presents control algorithms in the dynamic walking mode. The issues of stabilization of the sensors installed in the soles are investigated. The description of the laboratory model and simulation of the main links of the exoskeleton, approximated to human parameters, allowing to insert the studied algorithms of motion of the executive mechanism into the program of automation of calculations of the links of motion are given. The authors for the first time simulated the bipedal walking robot using modern digital technologies, including the joint use of pneumatic electric drive. This paper proposes an automated control scheme for manipulators controlling immobilized human limbs. Considering the functions of the leg and the phases of movement, the structure scheme is chosen so that the same actuator performs several functions. This construction partially reduces the load on the person, because the drives of the various links due to their gravity can overturn a person. Using the kinematic structure of the model and the method of adaptive control of the manipulator, as well as replacing some movement parts with plastic material, the authors were successful in reducing the total weight by three times compared with foreign analogues, which is important for a sick person.**

Keywords*—Exoskeleton; manipulator; model; kinematics; dynamics

I. Introduction

In the 21th century, there arise more and more situations that demand from people with disabilities to perform a wide variety of works related to daily life. To help people, mobile robotics tools are being created which can be controlled via radio or cable. Relating to a person, being near the power source, he can control his functions by cable. However, as life shows, in order to expand human capabilities associated with his movement, control can be carried out by radio channel. Many scientists work for creation of the motion control algorithms of bipedal walking robots that move in various dynamic modes of movement: walking, running, jumping, etc., in other words, human motion simulation, which formed the basis for the study of using the theory for creation of mechanisms for energetically optimal regulation of human walking [1-2].

For these reasons, scientists develop exoskeletons that represent a technical device designed for physical relief of a person who performing different works thanks to load accommodation by the exoskeleton, provided that it repeats human biomechanics [1-3]. As one reason for the growing popularity of these devices, it is necessary to mention the areas of their possible application:

1) Military sphere.
2) Use by people with disabilities.
3) Elimination of consequences of various emergencies.
4) Use of heavy equipment in conditions of inapplicability.
5) Use in operations where it is possible to replace heavy equipment with human labor.

Exoskeletons are classified according to the following [3-5].

1) According to the power source and the drive operating principle: passive exoskeletons, active exoskeletons;
2) According to the drive: electric, pneumatic, hydraulic.

Exoskeletons of today are becoming a very powerful tool to assist soldiers and medical staff of specialized clinics with rehabilitation of patients who have suffered from limb diseases. It was found that the most of designed exoskeletons cannot be used for rehabilitation of patients with limited functions of the upper and lower limbs due to the large mass of the structure, dependence on external power sources and their significant cost. For designing the exoskeleton, it is necessary to solve a lot of technical problems, among which are the following: the problem of walking control; designing the executive mechanism using original design solutions; designing the system of interconnected drives; designing the power source with a high specific power; designing the system of sensitivity, orientation and navigation; designing the control system and designing its algorithms. As of today, there is a lot of versions of exoskeletons built using various drives (electric drive, hydraulic drive, pneumatic drive), but their practical use is very limited due to difficulties associated with an on-board energy source that can provide the exoskeleton with autonomy. However, this fact only serves as the progress accelerator and leads to the constant appearance of more and more new versions of exoskeletons [4-6]. The purpose of the research is the use of exoskeletons in medicine for the rehabilitation of patients with musculoskeletal direction. This article describes the mechanisms for controlling the feet and the center of mass of a human robot.

II. Relevance

The works of many scientists considered the problems of foot elasticity when modeling human movements [5-6], [5-6],

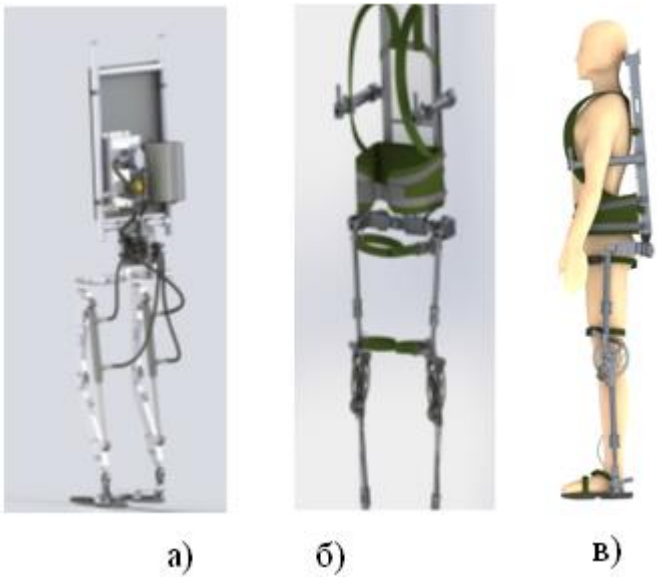
dynamic motion of the manipulator based on the closed kinematic chain with coordinate-parametric control, two-engined electric drives of coordinated rotation based on an asynchronous-valve cascade, dual-power machines [7-8], etc., developments of which facilitated the development of investigations in the field of the manipulator use for replacing the human legs. There are many examples in the world of using the developments of scientists to improve the situation of persons disabled from childhood and work, to return them to normal life, their participation in the Paralympic Games, etc. Fig. 1 shows the development of scientists of Moscow universities, active and passive exoskeletons, as well as the exoskeleton appearance on a man simulator.

It is of interest the ReWalk exoskeleton developed in Israel by ARGO Medical Technologies which allows people with paralysis of the lower half of the body (lower paraparesis) to stand on their feet and walk using sticks (Fig. 2).

The design of ReWalk exoskeleton is based on sensors that detect the body tilt ahead and transmit a signal to devices supporting the legs [4-7]. The power source is provided by a battery placed in a special backpack. It has 2 degrees of mobility. The structure operation is possible only for persons with preserved functions of the upper limbs.

A special feature of this layout diagram is installing 4 electric motors in the knee and hip joints of the exoskeleton, the ankle position is regulated by the springs that allow the foot to naturally stand on the ground (Fig. 3b).

A significant disadvantage of ReWalk exoskeleton is the complexity of ensuring the mechanism balance and hereto related safety problems of operator`s motion [9]. In most cases, these structural versions of exoskeletons are used as simulators for people undergoing rehabilitation.



(a) active exoskeleton; (b) passive exoskeleton; (c) exoskeleton on a man simulator.

Fig. 1. D-model of Active and Passive Exoskeleton.

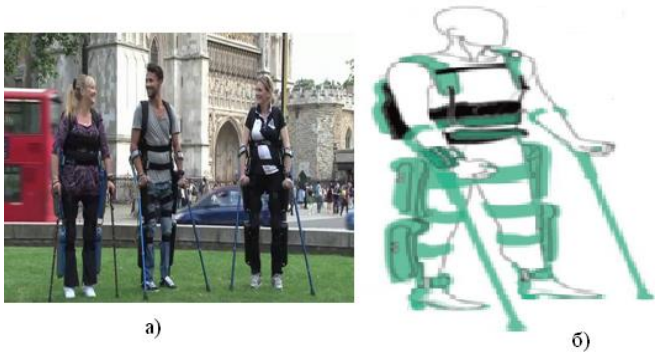


Fig. 2. ReWalk Exoskeleton (a) and its Layout Diagram (b).

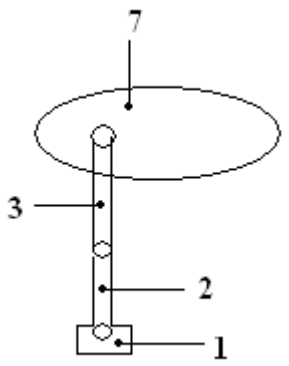
As far back as 1948, the Russian professor N. A. Bernstein drew a man with prosthetics copying the leg skeleton but with electric motors, which was the development of the Prosthetics Research Institute. It is interesting to note that just after the war ended, it was a very vital invention which, unfortunately, had no practical continuation in future. In the 60`s, General Electric developed this idea but in a version of a full-fledged skeleton with hydraulic control. The same attempt was made by the Russian side in Russia (Leningrad, 1970) [5-6]. In Kazakhstan, such works are under development, so the study presented in this article is very relevant.

III. Methodology

A large number of investigations were devoted to the study of kinematics and dynamics of manipulation robots [7-9]. The manipulator executive mechanism has the treelike kinematical structure, a large number of mobility steps, does not properly secure to the fixed base, and during movement, it is connected with the supporting surface and ambient objects [10-11]. The authors for the first time develop a similar model with the use of modern digital technologies including the joint use of pneumatic-electric drive. This paper offers the automated control scheme for manipulators that control the immobilized human limbs. It is known that human manner of walking just as a robot determines by trajectories of the pelvis (main but dependent movement) and feet (auxilliary but forced movements). The main movement is carried out as a result of moving the legs [12-13]. The schematic structure of human musculoskeletal system is similar in many ways to the movement of bipedal walking robot which contains a system of solids and is in the form of closed kinematic chains with rotating and translating kinematic pairs connected to the body. Fig. 3 shows the model of human foot control in which relative movements of segments are carried out by drives. The leg mechanism has several degrees of mobility. Taking into account the leg functions and movement phases, schematic structure is chosen so that one and the same drive performs several functions. This construction partially reduces the load on the person, because the drives of the various links due to their gravity can overturn a person.



1- foot; 2-lower leg; 3-upper leg; 7- pelvic bone

Fig. 3. Human Leg Model.

Methods for describing the kinematic structure (KS) were developed for formation of mathematical models of the executive mechanism [1, 11].

To set the kinematic structure and write the kinematic expressions, the designations and indices given below were used. Kinematic connections of each segment are characterized by:

- number of one of the previous segment;
- numbers of one or more of subsequent segments;
- its sequential number for the previous segment.

Each segment is associated with as many coordinate systems as there are subsequent segments but not less than one. One of them is taken as the main one, which is assigned the number 1, the rest are auxiliary. All of them are assigned in accordance with the traditional Denavit-Hartenberg rules for robotics [1, 9]. Vector values can be set in different coordinate systems (CS). Its upper left index indicates in which CS the given vector is specified. If this index is missing or null, then the vector is set in the base CS. If a nonzero number is specified, then the vector is specified in the main coordinate system of the segment, number of which is the specified number. If two numbers separated by commas are - ${}^{i,j}\overline{X}$, then the vector is specified in j^{-th} the auxiliary coordinate system i. Let us denote by $L = \{1,2,3 \dots n\}$ an unordered set, the elements of which are the numbers of the executive mechanism segments.

The following index functions are introduced: [11-13].

1) f(i) - segment number that is the parent segment for segment i.

2) s(i,k) –segment number that is k-th son segment for segment i.

3) dg+ (i) – semidegree of segment i that defines the number of son segments of i segment.

4) D(i) – cortege of numbers-links that are son segments for i segment$\left(\Gamma(i) = \left\{\left(s(i,1), s(i,2), \dots, s(i,k), \dots, s\left(i,i,dg^{+}(i)\right)\right)\right\}\right)$;

5) ns(i) –defines what number as son segment has i segment for its father segment (sequence number of i segment in the cortege. $\Gamma\left(f(i)\right)$.

6) nan(i) — defines the number of ancestors of i segment.

7) an(i,j) — determines the number of the j-th from the root of the ancestor of the link i.

If i segment is more than 0, it is possible to write:

$$ns\left(s(i,k)\right) = k\ ; i = f\left(s(i,k)\right);\ k \in \{1,2,3 \dots dg^{+}(i)\} \qquad (1)$$

As it is for each segment$i(i \in L)$, we define the vector connecting the beginning of the father segment with the beginning of the son segment; the vector of the centre of mass (CM) position; the coefficient defining the type of articulation of main segment i with father segment; the type of ancestor of segments – the rotary joint 1; the type of articulation of segments - the telescopic joint 0.

This is how the exoskeleton robot segments are described and defined. However, if you transfer this system to a person, then you need to note the following: if the robot can turn and rotate according to the operator's instructions, then the person is limited in his motions. For example, the human foot (especially a sick person) cannot turn to 180°, as well as the knee and other parts of the lower limbs. Therefore, it is necessary to develop the motion algorithm limiting turns of feet from zero to 90°.

The method for describing kinematics of the bipedal walking robot executive mechanism was proposed by Denavit and Hartenberg with compatible coordinate systems all parameters of whose are presented in Fig. 4 [11-13].

The calculation system [4] is based on the use of homogeneous transformations matrices (4×4), which give unambiguous and clear rules for constructing a mathematical model of the robot's executive mechanism. At the same time, the number of parameters included into the matrix relative to the position of the successive segments of the executive mechanism is minimal. The matrix form Ai is identical both for rotational and translational joints.

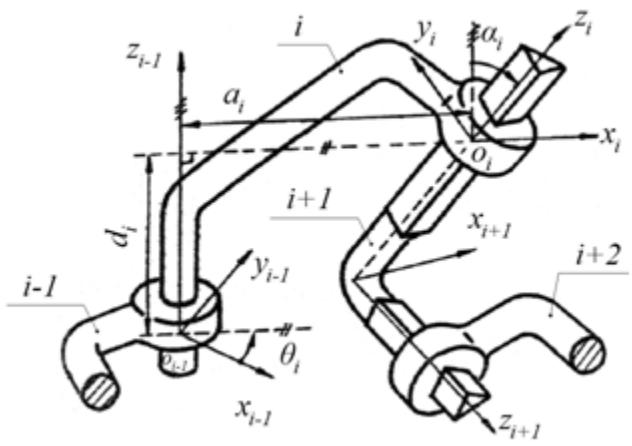


Fig. 4. Denavit-Hartenberg Compatible Coordinate Systems.

The advantage of this method of constructing connected CS is that you can specify only four parameters that determine the relative position of two consecutive CS i-1 and i, and, consequently, the conversion matrix Ai. Two consecutive coordinate systems of segments, for example, $i-1$ and i, can be always coincided using a rotation [14], two transfers and another rotation carried out by the $i-1$ coordinate system in the following order:

- Rotate by an angle θ_i around the axis z_{i-1} in the positive direction until the axes x_{i-1} and x_i become parallel and equally directed. If the joint is rotational, then the angle θ_i coincides with the generalized coordinate.
- Relocation over the distance d_i along the axis z_{i-1} until the axes x_{i-1} and x_i will coincide. If the joint is translational, then the d_i coincides with the generalized coordinate.
- Relocation over the distance a_i along the axis x_i until the coordinate origin will coincide. Parameter a_i is the constructive constant of the mechanism (depends on geometry of the structure).
- Rotation by the angle α_i αi about the axis x_i until all axes coincide.

Note that angles are positive if they are counted counterclockwise around the specified axes, and linear displacements are positive if they coincide with the positive directions of the corresponding axes.

IV. Result and Discussion

As a result of these movements the coordinate system $O_{i-1}x_{i-1}y_{i-1}z_{i-1}$ sequentially take up the possitions $O'_{i-1}x'_{i-1}y'_{i-1}z'_{i-1}$, $O''_{i-1}x''_{i-1}y''_{i-1}z''_{i-1}$, $O'''_{i-1}x'''_{i-1}y'''_{i-1}z'''_{i-1}$, and finally reaches the position $O_ix_iy_iz_i$. Moreover, each subsequent coordinate system is characteristed in the previous coordinate system by 4x4-coordinate transformation matrices sequentially.

From the four parameters θ_i , d_i , a_i , α_i (Fig. 4), two parameters a_i and α_i are always constant and determined by the design of the robot executive mechanism. One of two other parameters (θ_i or d_i) is a variable parameter. For the rotational joint, the value θ_i characterizes the angle of relative rotation of i-1 and i segments, and the liner value d_i is constant. Reverse, for the telescopic connection, d_i is a variable. The variable of i-th joint (θ_i or d_i) is usually called the generalized coordinate of the robot executive mechanism [15-18].

Each limb has three degree of freedom and is derived by an engine with mechanism (transmission, gearbox, reduction unit). In the lower part of the limb there are three force sensors for measuring the leg force response.

Using the methods of describing the kinematic structure there were made the prerequisites for adaptive control of the executive mechanism for motion of any part of the human body. The authors considered the akinetic human limbs as a non-stationary object (NO). Some scientists propose to use the adaptive identification of NO with Markov parameters on the example of the bipedal walking robot. However, this NO is considered as a non-stationary dynamic multi-dimensional multi-loop controlled object with inputs p and outputs q (Fig. 5) [19-21].

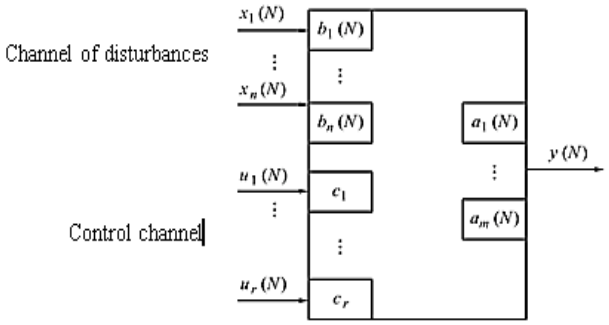

Fig. 5. Scheme of Non-stationary Dynamic Multi-dimensional Multi-loop Controlled Object.

There are two fundamentally different types of input channels at the object input. The perturbation channel is formed from n observed inputs:

$X^T(N) = (x_1(N), \ldots, x_n(N))$, multi-loop controlled object $X \in R_1^n$ where R_1^n is a set of alloweble inputs with unobserved unknown parameters bj (N), $j = \overline{1, n}$.

The control channel is also observed: UT(N) = (u1(N), ..., ur(N)), $U \in R_2^r$ where R_2^r − a set of acceptable controls, but unlike the perturbation channel, all its parameters are known: $a_1(N) \ldots a_m(N)$, then $Y \in R_3^q$, where R_3^q − a set of acceptable outputs [13,22].

Using Denavit-Hartenberg method and the adaptive method of controlling the executive mechanism of human movement, the authors developed two variants of variables for the human exoskeleton changing d or Q parameter.

These models were put into Program of calculation and received (Table I).

The table shows the results of eight from 21 steps.

TABLE I. Values of Simulated Parameters of Exoskeleton Segments

No. of step	Q, rad	d, м	a, м	α, rad	$f(i)$	$ns(i)$
1	$-\pi/2$	0	0	$-\pi/2$	0	1
2	$-\pi/2$	0	0	$-\pi/2$	1	1
3	$-\pi/2$	0	0	$-\pi/2$	2	1
4	$\pi/2$	0	0	$\pi/2$	3	1
5	$\pi/2$	0	0	$\pi/2$	4	1
6	0	−0,39	0	$-\pi/2$	5	1
7	$\pi/2$	−0,1	0,17	$\pi/2$	6	1
8	0	0	0	$-\pi/2$	7	1

It can be concluded from the table that angle Q changes from $-\frac{\pi}{2}, \frac{\pi}{2}, 0 \ldots d - 0{,}39; d = -0{,}1; d = 0$, etc.

TABLE II. RESULTS OF ARBITRARY POINTS OBTAINED ON MATLAB

$No.of\ step$	Q, rad	d, м	a, м	α, rad	$f(i)$	$ns(i)$
6	-π/2	0	0,237	- π/2	5	1
7	0	0,196	0,163	π/2	6	1
8	π/2	-0,109	0	- π/2	7	1
9	π/2	0	0,487	0	8	1
10	0	0	0,669	π/2	9	1
11	π	0,195	-0,097	π/2	6	1
12	π/2	-0109	0	- π/2	11	1
13	π/2	0	0,475	0	12	1

It can be concluded from the Table II that angle Q changes from $-\frac{\pi}{2}, \frac{\pi}{2}, 0 \ldots d + 0{,}196; d = -0{,}109; d = 0$.

The authors developed and applied the Program to the model in Fig. 3.

***Abstract*—Over the past several years, the traditional approaches of managing and utilizing hybrid Wide Area Network (WAN) connections, between sites across geographical regions, have posed many challenges to enterprises. Software-Defined Wide Area Network (SD-WAN) has emerged as a new paradigm that can overcome the traditional WAN challenges like the lack of visibility for WAN bandwidth utilization and the inefficient usage of expensive WAN resources. The flexibility and agility brought to WAN by applying the SD-WAN paradigm helped to improve the efficiency of bandwidth utilization and to address the surge of bandwidth demands. The SD-WAN capabilities become essential for meeting the heavy inter-data center's traffic exchange required for business continuity and disaster recovery operations. In this paper, a data backup approach is introduced using SD-WAN that makes the network centrally programmable. This will leverage the ability to make fine-grained traffic engineering for different data flows over WAN to optimize the bandwidth utilization of the expensive WAN resources by balancing the traffic load across network links between data centers and to minimize the time required to transfer backup data to disaster recovery sites. The proposed approach proved its efficiency according to the bandwidth utilization if it is compared to the other related works.**

Keywords*—Wide area networks; software defined network; software defined wide area network

I. Introduction

The Wide Area Network (WAN) is essential nowadays for large enterprises and businesses. It is a critical component to connect between data centers and different sites across geographies [1]. The first public WAN was deployed in early 1980 [2] and designed to connect between different sites using leased lines that had limited speeds and high cost.

In the previous decades, different WAN technologies have been developed to provide better service quality in terms of cost and speed such as VPN (Virtual Private Network), ATM (Asynchronous Transfer Mode), and MPLS (Multi-Protocol Label Switching). Despite the improvements in the bandwidth and speed of WAN networks and internet services, they are still congested with high traffic loads that cause data loss and jitters [3] which impact the performance and quality of the provided services.

During the COVID-19 pandemic, network traffic spikes have increased obviously and start to impact the services provided by different internet and cloud companies such as Amazon, YouTube, and Netflix [4]. To address these challenges and the surge in bandwidth demand, enterprises start to use technological innovations such as Software Defined Networks.

Software-Defined Networks (SDN) has emerged over the past years as a new promising model that simplifies network management. SDN aims to provide centralized management for multiple network devices like routers, switches, and firewalls by separating the control plane from the data plane [5]. The SDN framework consists of three layers. The lowest layer is the data plane layer that contains the network elements and devices responsible for packet forwarding. One layer above, the control plane is located where network intelligence is logically centralized to maintain a global view of the network.

The SDN controllers communicate with network devices to guide them in handling data packets and to execute network policies and rules. The application layer contains the network applications that introduce new network features and applications such as load balancing, network statistics monitoring, and security [6]. The application layer makes use of the holistic view of the network provided by controllers to get information about different data flows and give the appropriate guidance to the control layer for enhancing the network performance. Currently, there are several SDN controllers provided such as OpenDaylight [7], POX [8], NOX [9], and Beacon [10] that can simplify the management of network devices.

For the southbound interface, the OpenFlow protocol is the most used open protocol for the interaction between the SDN controllers in the control plane and SDN OpenFlow compliant switches in the data plane [6]. The OpenFlow SDN controller will insert flow entries on the OpenFlow compliant switches to instruct them for forwarding the incoming data packets. The OpenFlow switches will follow the basic packet forwarding mechanism to handle the incoming packets. They will check the packets header and match it to the entries inserted by the SDN controller in the flow table. In case no flow entry matches the incoming packet header, the OpenFlow compliant switch will notify the controller to identify the correct action for the packet and install the appropriate flow entries for it. The SDN controller can also interact with OpenFlow switches [11] to retrieve statistical information about data flows.

On the other side, the northbound interface is provided by the SDN controller to the application layer for network programmability. Applications neither have direct interaction

with data plane devices nor are aware of network topology [12]. They interact with controllers to make fine-grained traffic engineering, based on the data flow statistics controller can retrieve, and guide them with the path layout of the data flows [13].

The SDN paradigm is usually used in data centers local area networks (LAN) but recently it is used in wide area networks (WAN) to mitigate the challenges mentioned before. The Software-Defined Wide Area Networks (SD-WAN) is built on the concepts of SDN. The WAN networks will obtain many technical advantages by using the SDN concepts [14] that will help to leverage its performance, utilization, and efficiency to handle the massive data transmissions.

Multinational technology companies like Microsoft and Google used SDN concepts to deploy their SD-WAN solution for inter-data center connections. They have multiple data centers distributed across the planet that are exchanging data traffic extensively for communication between subsystems and data backup activities [5]. Gartner anticipates that by 2024 60% of enterprises will implement SD-WAN [15].

SD-WAN can play a big role in the enhancement of business continuity strategies. Data backup and disaster recovery mechanisms focus on what needs to be done to keep the business running when disasters hit. The long-distance WAN networks play a key role in disaster recovery operations that require a large amount of data to be exchanged over the long distance between primary and secondary sites. They are restricted by limited bandwidth and the high latency of WAN networks. SD-WAN can handle these issues [16] and cope with the increasing network demands to enhance the data backup and disaster recovery operations.

In this paper, an approach for data backup and replication is proposed using the concepts of SD-WAN. The main objective of the proposed approach is to use SD-WAN capabilities to increase the efficiency of WAN network utilization and the adaptation to network demands. This should help to minimize the time needed for data backup between sites by shrinking the recovery point objective down to meet business continuity demands for enterprises.

In the proposed approach, SD-WAN centralized management and programmability are used to run applications that can check the network statistics of data flows like throughput across various links in real-time, and based on these measurements, decisions are taken to meet the demands of other data flows and guarantee the fair utilization of the available WAN links. The OpenNetMon open tool [17] is used in this research to get data flow statistics and to make fine-grained traffic engineering. This will be discussed in the methodology and the results sections.

The remainder of this paper is structured as follows: In Section II, related works to this research are discussed. In Section III, the methodology and algorithm used for balancing the traffic load across all available WAN links are presented. Sections IV and V summarizes the results after applying the proposed approach on the test topology. Finally, Section VI concludes this paper and presents the future works.

II. Related Work

SD-WAN shows great potential in improving the performance and utilization of WAN networks. Currently, many SD-WAN vendors in the market provide different mature products for traffic management and real-time analytics to improve network performance and availability such as Cisco SD-WAN (Viptela), VMware SD-WAN, and Silver Peak. In the past several years, many pieces of research were published showing the benefits of deploying SD-WAN and how it can improve the performance of businesses' workflows and services. Some approaches that aim to improve bandwidth utilization will be reviewed in this section.

Tech giants like Google and Microsoft who have multiple data centers across the planet deployed their SD-WAN solutions for interconnection between data centers. B4 is Google's software-defined inter-data center WAN solution. It uses OpenFlow protocol to manage individual network switches with centralized controllers that run traffic engineering applications. In [18], the authors discuss their experience with deploying B4 in production and achieving better bandwidth utilization for WAN links to perform large-scale data copies between sites.

The second deployment is SWAN from Microsoft that aims to achieve highly efficient and flexible WAN interconnection between data centers. It also improves the fairness to meet different traffic demands when WAN links are utilized with background traffic [19]. It is obvious that both B4 and SWAN, use the capabilities of SD-WAN like the controller's global vision of the network and the easiness to retrieve network statistics for traffic engineering, to maintain better utilization for the WAN expensive resources.

In [20], the authors introduced a software-defined traffic load balancing (SD-TLB) module that is embedded into the ingress nodes at the edge of carrier networks. It is built on the CPU of the physical ASIC-based (Application Specific Integrated Circuit) SDN switches. The SD-TLB performs per-flow scheduling in a round-robin manner over the optical paths besides detecting any path outage or failure using a global network controller based on per-port statistics.

This research showed by experiment that the SD-TLB module is better than the link aggregation group (LAG) for optimizing the bandwidth utilization for optical paths in carrier networks. However, it doesn't abstract completely the control plane and forwarding plane as SD-TLB is still running on the CPU of the edge network switches.

In [21], the authors proposed the implementation of a wide area network defined by software, which guarantees a predefined quality of service (QoS) and traffic prioritization between Software-Defined Datacenters.

The proposal deploys an experiment test scenario based on the concept of the living lab which measures the performance of the network when Voice Over IP (VOIP) services are provided and verified that an adequate level of QoS of Bandwidth can be guaranteed by providing traffic priority in an SD-WAN network between Software-defined data centers (SDDCs).

However, this approach focuses only on maintaining QOS by prioritizing traffic based on the source and destination IPs by a policy/rules introduced by the SD-WAN OpenFlow controller Floodlight (by using OpenFlow flow tables that help OpenFlow switches to steer traffic) and it doesn't introduce any approach that can balance traffic or steer for flows to another transport link in case of having poor bandwidth or high packet loss which can highly impact the quality of VOIP services.

In [22], the authors proposed a simple implementation for SD-WAN using open source tools like OpenDaylight SD-WAN controller and Open vSwitch as virtual switches. They developed applications to run on top of a centralized SD-WAN controller to manage and improve the quality of service (QoS) of the interconnecting WAN network between headquarter and branch offices. The two applications used in this implementation are for monitoring and path switching. The monitoring module will collect real-time statistics for network metrics like packet loss, packet delay, and jitters by injecting traffic into the network paths to evaluate the network links and confirm if they will meet the required QoS. After that, the path switching module will install the path that meets the enterprise QoS thresholds on network switches.

This implementation helped to guarantee the QoS requirements for enterprise applications and services while transferring data between sites. However, the usage of active monitoring and injecting traffic to measure network statistics in real-time may introduce additional network load that impacts the accuracy of measurements.

In this research, fine-grained traffic engineering is enabled in the proposed approach using the real-time measured network metrics for each data flow. The per-flow throughput is measured using an opensource tool OpenNetMon by querying per-flow counters from source and destination switches without injecting extra packets through the network between sites to avoid any overhead that may be introduced. The measured throughput metric will provide an advanced bandwidth utilization monitoring for all available links between sites which will enhance routing decisions for new data flows in a way that can improve the traffic load balancing and the efficiency of utilizing the available bandwidth.

III. Methodology

SDN and SD-WAN are based on the same methodology of separating the control plane from the data plane. Both are using controllers and OpenFlow switches, the main difference is that SDN controllers manage every network device including switches and core switches in LAN networks while SD-WAN controllers manage and interact only with edge devices [23].

In this research, topology in Fig. 1 is suggested to simulate the WAN connection between two sites using different paths (simulating WAN links with different speeds/bandwidth).

Edge devices act as gateways that allow data centers to communicate with other sites through WAN links that can be served by different WAN providers. SD-WAN controllers can't manage or interact with intermediate devices that are under the control of WAN service providers but still can be programmable to interact with sites' edge devices to prioritize and control WAN traffic between different locations.

OpenNetMon software is used in the proposed approach, an open-source software that runs on SD-WAN controller for network monitoring. The OpenNetMon monitoring software will interact with edge OpenFlow switches to monitor TCP flows in real-time and gather statistical info about them. The real-time monitored information will leverage the ability to make fine-grained traffic engineering and hence make more efficient routing decisions. This will enhance data transfer operations through WAN between different sites which is essential for WAN-based backup.

OpenNetMon software is composed of two modules, the forwarding module, and the monitoring module. The forwarding module will discover paths between source-destination pairs when an un-matched TCP flow connection or packet arrives and install path on switches instructing them to route packets for this TCP flow. The monitoring module will monitor flow metrics (throughput/delay/packet loss) between source-destination pairs.

In this proposed approach, the per-flow monitored throughput metric is used for traffic engineering to enhance the bandwidth utilization and balance the traffic load across WAN links between sites while transferring data for WAN-based data backup operations.

Pox controller eel branch is used on Ubuntu Linux 3.13.0-24-generic virtual machine with 8 processor cores and 4GB RAM to run the OpenNetMon software, and mininet version 2.2.1 is used to build testing topology.

The TCP flow throughput metric is periodically measured by querying flow statistics via OpenFlow protocol. The SD-WAN controller will interact with edge Openflow switches to get individual flow statistics on a timely basis to measure the TCP flow throughput in real-time. Equation (1) is used to measure the TCP flow throughput in a given time [24].

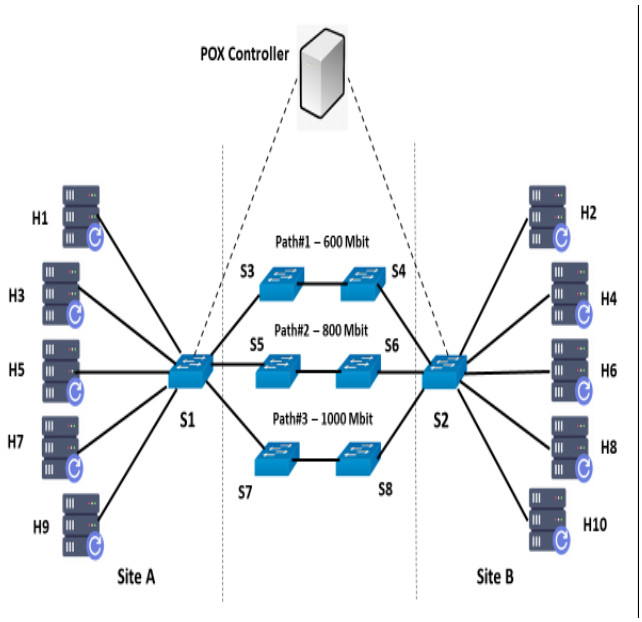

Fig. 1. Test Network Topology.

$$\text{Throughput (tp)} = \frac{\sum_{j=1}^{t} r_j}{t} \quad (1)$$

r_j Number of bytes processed for the TCP flow

t Time

The measured throughput metric of each TCP flow is used to find out the bandwidth utilization of each WAN link and based on this SD-WAN controller will select the least utilized link to be used by the newly initiated TCP flows for transferring data.

By calculating the average throughput of all TCP flows, it can be predicted if the WAN link used by each flow is highly loaded or has room for a new TCP stream. Equation (2) is used to measure the average throughput where tp donates to the measured throughput records for a specific TCP flow and n donates to the number of readings [24].

$$\text{Average throughput} = \frac{\sum_{i=1}^{n} tp_i}{n} \quad (2)$$

tp_i Represents measured TCP flow throughput at a specific interval.

n Represents the number of measured throughput records.

The Flow chart in Fig. 2 explains the proposed approach algorithm to select the least utilized path when new TCP flow starts:

In a nutshell, the following is a step-by-step implementation methodology for the proposed approach:

- Emulate the testing network topology in Fig. 1 on mininet for two sites with edge OpenFlow switches that have three WAN links each one has different Bandwidth (Path#1 600 Mbit – Path#2 800 Mbit – Path#3 1000 Mbit).
- Start running the OpenNetMon software on Pox Controller.
- Initiate three TCP flows at the same time using iperf tool between source-destination pairs H1-H2, H3-H4, and H5-H6 to transfer 10 Gig of Data.
- The three TCP flows will utilize the three WAN Links between the two sites.
- The forwarding module in OpenNetMon software was modified to discover all available paths between source-destination pairs.
- When the OpenNetMon software starts running on the POX controller, all paths between the two sites are in the ideal state. An index variable (i = 0) is used and will increment every time a new TCP flow starts.
- If 'i' is smaller than the number of available paths between source-destination pair, the controller will select one of the ideal paths to the new TCP flow.
- The aim of this is to generate traffic and flow congestion on all available paths.
- The monitoring module will keep a record of throughput for TCP flows on each path and calculate the average throughput for each link between 2 sites.
- After 30 seconds, a new TCP flow was initiated between source-destination pair H7-H8 to transfer 5Gig data using iperf.
- After 60 Seconds new TCP flow was initiated between source-destination pair H9-H10 to transfer 5 Gig of data using iperf.
- In the proposed approach, the forwarding module will select the path with the largest average throughput that will be the least utilized path and will have room to transfer more data.

In the next section, results for the proposed approach are highlighted regarding the throughput and the completion time needed for each TCP flow. Also, a comparison was made between the proposed approach and the Round-Robin approach [25].

Round-Robin: TCP flows are distributed among available paths in a sequential manner. In other words, the chosen path for the new TCP flows for source-destination pairs H7-H8 and H9-H10 is always the path of the next round in the available paths.

Proposed approach: The controller will direct TCP flows for source-destination pairs H7-H8 and H9-H10 to the least utilized path the moment a new flow is initiated based on real-time monitoring.

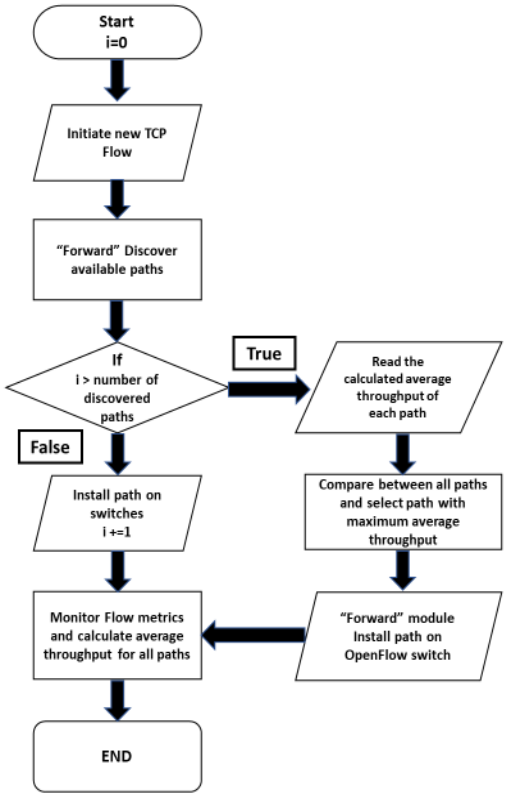

Fig. 2. Flow Chart for the Algorithm used in the Proposed Approach.

IV. Experimental Results

The two approaches were tested on the topology in Fig. 1 while transferring data (simulating data backup operations) between two sites.

The first approach used is Round-Robin. This approach will use all available paths with different Bandwidth (that simulates WAN links) in a sequential manner. Data was transferred between hosts/backup servers from site A to site B using iperf tool and Table I shows the path used by each source-destination pair in the Round-Robin approach.

Fig. 3 shows the throughput of all TCP flows on the 3 paths between source-destination host pairs. As it can be observed from the Round-Robin approach, the TCP flows from source-destination pairs H7-H8 and H9-H10 use path#1 and path#2 to transfer data, however, Path#3 has higher bandwidth, and this can be seen in the high throughput of H5-H6 TCP flow that utilizes this path in the graph (c). The usage of a single path by multiple TCP flows will impact the throughput share of each flow as shown in graphs (a) and (b).

The second approach tested is the proposed approach. Table II shows the path used by each source-destination pair while testing. In Fig. 4, the TCP flow for source-destination pair H7-H8 (that starts after 30 Seconds) uses path#3 based on the average throughput calculation done by the controller for the three paths that are utilized by TCP flows for source-destination pairs H1-H2, H3-H4, and H5-H6.

After 60 Seconds when a new TCP flow was initiated for H9-H10, path#2 was selected by the controller for it. The average throughput for path#2 shows better real-time results the moment this flow was started compared to path#3 that was already utilized by 2 TCP flows for H5-H6 and H7-H8 and path#1 that has the least bandwidth.

TABLE I. Paths used by each Flow in the Round-Robin Approach

Src-Dst pair	Data Transferred	Path	Path Bandwidth
H1-H2	10 Gig	Path#1 - S1 > S3 > S4 > S2	600 Mbit
H3-H4	10 Gig	Path#2 - S1 > S5 > S6 > S2	800 Mbit
H5-H6	10 Gig	Path#3 - S1 > S7 > S8 > S2	1000 Mbit
H7-H8	5 Gig	Path#1 - S1 > S3 > S4 > S2	600 Mbit
H9-H10	5 Gig	Path#2 - S1 > S5 > S6 > S2	800 Mbit

TABLE II. Paths used by each Flow in the Proposed Approach

Src-Dst pair	Data Transferred	Path	Path Bandwidth
H1-H2	10 Gig	Path#1 - S1 > S3 > S4 > S2	600 Mbit
H3-H4	10 Gig	Path#2 - S1 > S5 > S6 > S2	800 Mbit
H5-H6	10 Gig	Path#3 - S1 > S7 > S8 > S2	1000 Mbit
H7-H8	5 Gig	Path#3 - S1 > S7 > S8 > S2	1000 Mbit
H9-H10	5 Gig	Path#2 - S1 > S5 > S6 > S2	800 Mbit

V. Results and Discussion

As it can be observed in the comparison between the 2 approaches in Fig. 5, for the average throughput and time taken by each TCP flow for completing data transfer, the proposed approach shows that a fair share and better utilization of the bandwidth resources can be achieved in challenging network conditions beside reducing the time needed to transfer backup data between sites.

In Fig. 5(a) it is clear that the total time required for the 5 data flows that are initiated between the 5 source-destination pairs to transfer 40Gig of data, has been reduced significantly using the proposed approach compared to Round-Robin. The total time required for transferring 40Gig using the Round-Robin approach is 389.3 seconds across the 3 available links used to connect between the two sites A and B. While in the proposed approach, using traffic engineering based on SD-WAN capabilities to balance the traffic load across network links, the time required to complete data transfer is reduced to 293 seconds.

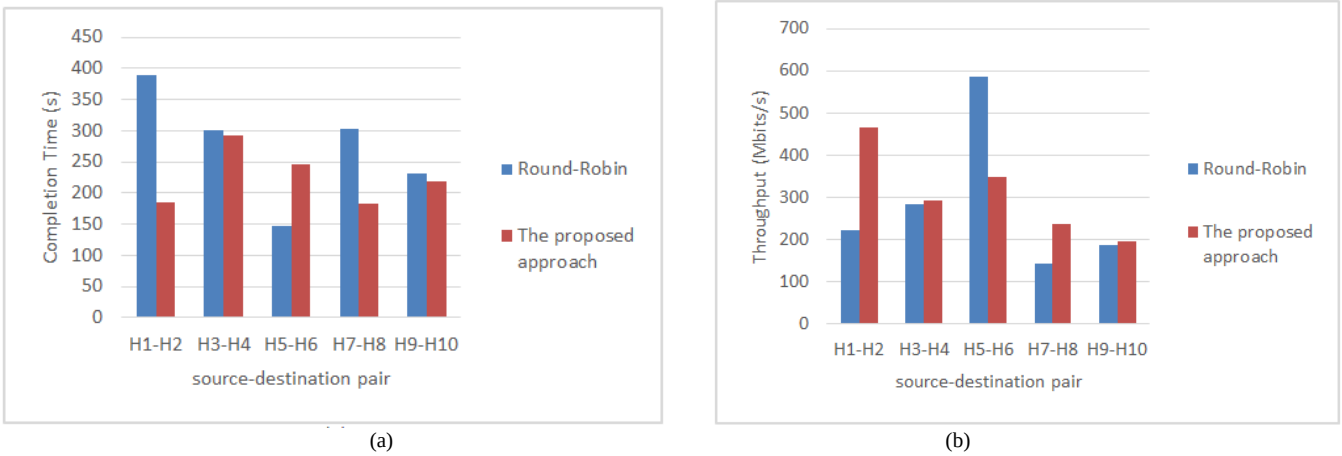

Fig. 5. Comparison between the Two Approaches for (a) Completion Time and (b) Average throughput of each TCP Flow.

These numbers reflect the bandwidth utilization enhancement between the data flows as shown in Fig. 5(b). The traffic load balancing mechanism introduced in this research, based on real-time measured network throughput, helps to improve the fairness in bandwidth utilization between the different data flows. The focus on background traffic initiated by the data flows (H1-H2, H3-H4, H5-H6) that initially utilized the three available network links, helps to make better routing decisions for newly initiated flows (H7-H8 and H9-H10). The average throughput for H7-H8 data flows while using the proposed approach is 236 Mbit/sec compared to round-robin 142 Mbit/sec. This enhancement occurs because of a better routing decision to use network Path#3 (bandwidth 1000 Mbit) and to share it with data flow (H5-H6) instead of sharing Path#1 (that has the least bandwidth 600 Mbit) with data flow (H1-H2). On the other hand, data flow (H1-H2) average throughput has improved to be 466 Mbit/sec, instead of 221 Mbit/sec in the round-robin case, after utilizing the limited bandwidth resources of Path#1 (bandwidth 600 Mbit) without having another competing data flow that tries to share resources on this network link.

It is obvious that the average throughput of H5-H6 data flow (transferring 10Gig of data) has been reduced from 587 Mbit/sec to 349 Mbit/sec after using the proposed approach for balancing data. This reduction is acceptable in the interest of improving fairness between all data flows and meeting the traffic bandwidth demands. This flow was using individually Path#3 (bandwidth 1000 Mbit) to transfer 10Gig of data in the round-robin approach, leaving the other four data flows to share the remaining two available network links Path#1 (bandwidth 600 Mbit) and Path#2 (bandwidth 800 Mbit) for transferring 30 Gig of data. After applying the proposed approach to balance traffic load, Path#3 is shared between two data flows (H5-H6 and H7-H8) to transfer 15 Gig of data.

The average throughput results for data flows H9-H10 and H3-H4 are nearly similar in the two approaches. The reason is that both data flows have shared the same network link Path#2 (bandwidth 800 Mbit) when applying the round-robin approach and the proposed approach as shown in Table I and Table II.

The results show that the aim of this research has been achieved by deploying fine-grained traffic engineering using SD-WAN to balance the traffic load across all available WAN links between data centers in a way that improves the bandwidth utilization and minimizes the time required for transferring data. The centralized traffic engineering used in the proposed approach helps to overcome the poor efficiency and sharing capabilities of WAN. This was achieved by considering the current state of the available WAN links before initiating new flows. The average throughput measurements are used to identify the reliability of each WAN link to handle new TCP flow without impacting the current running flows. From the test results, it is obvious that Round-Robin can cause an unplanned over subscription for some WAN links which degrades the performance of the competing TCP flows using them while other links are underutilized. On the other hand, the proposed approach helps to overcome the under and over subscription swinging state for available WAN links by enhancing the routing decisions for new data flows in a way that improves the fairness in sharing WAN resources and the utilization of bandwidth.

These enhancements are blessings for data backup and replication operations that are not a basic one-time function and they need to overcome many network limitations like latency for transferring data over long-distance networks. By minimizing the time required to transfer data through the network to the disaster recovery sites, the efficiency of data protection and business continuity will improve, and enterprises will be able to minimize their downtime.

VI. Conclusion and Future Work

In this work, the Software-Defined Network paradigm has been applied to achieve traffic load balancing across the hybrid WAN links available between data centers. The centralized programmable interface introduced by SD-WAN leverages the ability to make advanced network measurements for data flows that are propagating across network WAN links. An open-source network monitoring tool OpenNetMon is used to measure network throughput metrics for data flows based on SD-WAN capabilities. The measured network throughput metrics were used to balance the traffic load across available network links and to improve the efficiency of bandwidth utilization while transferring data between data centers.

The aim of this proposed approach is not to confirm or confute the performance improvement that can be achieved by other approaches that are used for traffic load balancing or to improve the bandwidth utilization, but the primary goal instead is to develop a new approach based on an open-source tool that was introduced in previous research to monitor per-flow metrics in real-time and provide the network statistical information essential for traffic engineering purposes.

By testing the proposed approach on a network topology simulated using mininet and compared it to the round-robin approach, the results showed that the approach developed in this research has shown an improvement in utilizing the bandwidth resources and helped to minimize the time required for transferring data between two sites. This will improve the efficiency of business continuity applications and helps the data backup operations to overcome network latency limitations that impact the time required to backup data between production and disaster recovery sites.

In the future work, it is planned to develop the used algorithm to add other network metrics like packet loss and latency to measure the reliability of available paths and to ensure meeting adequate quality of service policies before making routing decisions for new data flows. It is intended to extend the proposed approach by integrating algorithms to apply fault tolerance. The aim of fault tolerance is to failover data flows to use another WAN link in case of link failure or severe degradation in the link performance and throughput.

Critical Data Consolidation in MDM to Develop the Unified Version of Truth

Ms. Dupinder Kaur*, Dr. Dilbag Singh
Department of Computer Science and Engineering
Chaudhary Devi Lal University, Sirsa, India

***Abstract*—Organization seeking growth and competitive lead should use Master Data Management (MDM) as a foundation for efficient decision making. An MDM framework creates a trusted and reliable continuous record of customers, products, suppliers and other shared data sets. In master data, the critical data is consolidated to portray essential business entities into a Unified version of Truth. To create trusted view of master data challenges like quality, identity resolution, analytics and investment are faced. In proposed research, a technique has been designed to generate Master Data to assist the policy maker to address the said issues. In this paper, four steps have been taken for master data creation namely: Data Enrichment, Data Matching, Data Merging and Data Governance. To achieve legitimate data quality TALEND open studio has been used for data pre-processing and enrichment. An algorithm is designed to match and merge the master records. To validate the designed approach, results are evaluated using Pandas Data Frame on Python platform. This paper will assist the policy makers of the organizations in formulating the business strategies.**

***Keywords*—Master data management (MDM); master record; TALEND; data matching and merging**

I. INTRODUCTION

Data Management is concerned, with the entire lifecycle of a data resource from the creation to retirement, with advances and changes. Data Management comprises the procedures, practices, ideas and measures for proficient utilization of data resources. An enlargement of the data size, in many folds, makes the organizations to adopt the data management practices to maintain the quality. The transformation, integration and cleaning of data is needed for efficient handling of data [1]. The new challenge for maintaining the quality of most essential assets of business demands Master Data Management (MDM) program. MDM comprises of technologies, processes and disciplines to incorporate the cleaning, administration and controlling all shared data assets. An MDM arrangement formulates a single accurate set of data populated across different frameworks by ensuring the consistency and accuracy of organization's shared data assets. [2]. The core benefits of MDM includes informed decision making, reducing data duplication, better data compliance and handling change requests.

Master data deals with the critical data entities of a company such as clients, items and resources that are shared across value-based applications. It additionally enables the development of a 'single version of truth' [3]. The technical operations assisted by MDM activities include Data quality improvement, Master Data creation and Data engineering [4]. MDM is significant for a wide range of applications to make a complete beginning to end plan that drives progression and achieves better business results. A viable MDM execution enables better usage of basic data present in organization [5]. Relevant to Master data Management, various data taxonomies used in an enterprise are:

- Transactional Data: The inner or outer exchange or transaction that happen including sales, orders, purchase orders, card payment, etc.
- Reference Data: It addresses set of qualities that are referred by frameworks, applications, information store just as by transaction and master data, such as status codes, state contractions, segment fields and so forth [6].
- Reporting Data: The aggregated data compile for the purpose of analytic and reporting. For example: order status (Accept or Reject).
- Meta Data: The data that describe label or characterize other data. For example: properties of media file: its size, type, resolution and author, etc.
- Master Data: The persistent, non transactional data that defines primary business entities such as customer, product, employees and inventory. Master data is the unified version of common data that are often duplicated across the enterprise. The figure below depicts various categories of Master Data [7].

Master Data of an organization can include all entities involved in financial structure, transactions done by organization or locations such as address. If master data quality does not meet expectations, it can affect the efficiency of business operations [9]. Thus, there is need to manage this data. Master Data Management ensures complete, consistent, and accurate data in different areas of organization's activities MDM includes process of data collection, cleansing, consolidation and distribution in the organization ensuring the control of use in various analytical and operational applications [10]. The underlying driver for execution of MDM is to deal with data quality issue frequently emerges across data entities and information systems [13]. MDM is implemented in most of organization with aim to guarantee that master data includes reference details that reflects the present state of business [11].

*Corresponding Author.

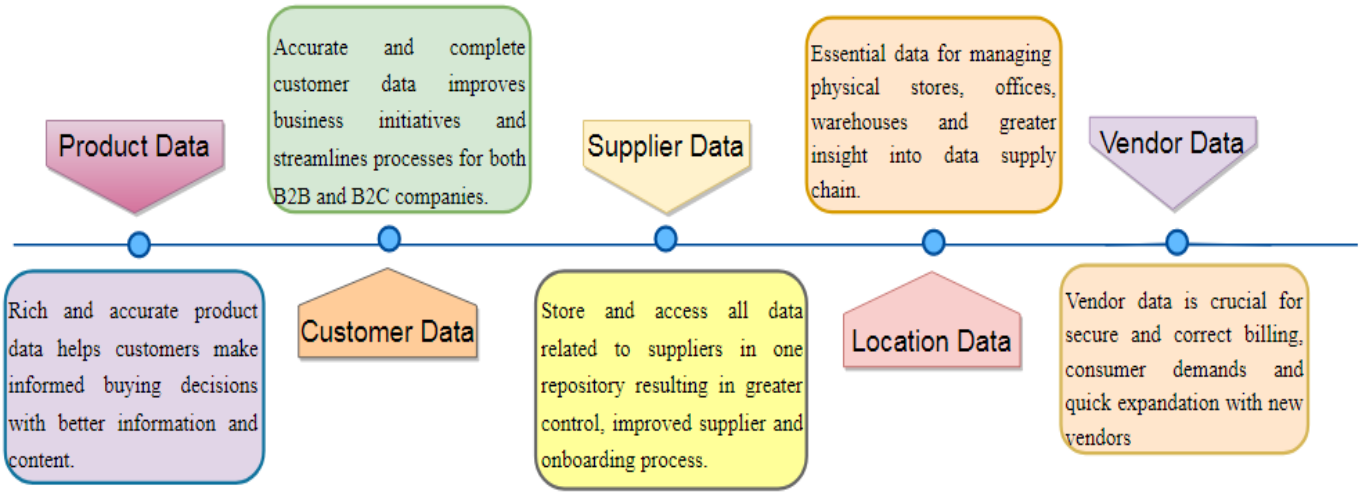

Fig. 1. Categories of Master Data [9].

Fig. 1 illustrates various categories of Master data. On the basis of need of an enterprise, Master data can be an employee data, party data, asset data or ledger data [8].

A Master Data Management program may provide an option to the industry with new ways to handle the data quality issues that the industry has struggled for few years and help prevent the "information rich and data poor" dilemma [14].

The main activities required for implementing MDM in an organization consist of following activities:

- Discover the need of master data management in organization and reference data.
- Categorize the sources and contributors of data.
- Define and maintain data architecture [12].

In light of the examination and investigation, following are the major contributions of this paper.

- To study the management, categories and related terms of Master Data.
- Designing of an algorithm for generating Master Record.
- Estimation and fixing of Data Quality using TALEND MDM tool.
- Use of Pandas Data Frame for creating Master Record.

The remaining part of the paper is organized as follows:

In Section 2, the related literature is reviewed. Section 3 elaborates the research methodology used for present research work. Section 4 is about the design of the proposed algorithm for generating Master records. Section 5 presents the Input dataset. Section 6 shows implementation and results of the proposed algorithm. Last section discusses the findings of implementation of the proposed method for creating qualitative and accurate master data to assist the organizations in decision making.

II. Literature Review

Radachirkova [1] et al. analyzed the usability of the existing data transformation tools for their utilization to achieve the desired quality characteristics in business measures. The focus was to enhance the data quality using existing tools instead of adopting a novel data transformation procedure for every data analytics task. Tending to this issue; Data cleaning, migration and transformation tools were summarized as black box procedure by exposing some properties such as applicability requirements, portion of data modified and constraints satisfied by data over applied procedure. The formal study revealed that these primary outcomes could be applied for accomplishing desired data quality outcomes in data analytics.

PanagiotisLepeniotis [2] integrated the MDM platform with Business Transformation Programme for decision making. The examination revealed that the Management of the Master Data and the never-ending confirmation of the Data Quality are crucial for any organization despite of having a BTP or not. An MDM impacted BTP decision model has been presented in the research. On the basis of case study audits and interviews, the research identified an improved indulgent into decision making process of a BTP concerning MDM and the way, these decisions affect the fruitful execution of a BTP.

Fernando Gualo [3] et al. assessed the "Functional Suitability" of MDM applications by considering useful necessities from section 100 to 140 of ISO 8000 and proposed a solution by considering the appraisal and affirmation of Functional Suitability of MDM applications. In addition to basic requirements, test cases are also designed required for the evaluation. In order to infer the prerequisites from ISO 8000, all the parts are covered except of ISO 8000-115, ISO 8000-116 and ISO 8000-150. Application of assessment method for existing master data based application is also featured.

Shreya Mrigen [4] et al. proposed a method for singular data management in pharmaceutical company. Hierarchies and type of problem faced in managing MDM solution in

pharmaceutical company has been examined in this research. The examination revealed that MDM is an essential activity for creating singularity, improving data consistency and data processing and market examination in pharmaceutical companies.

Dilbag Singh [5] et al. provided an MDM solution for building frameworks. A strategy to pilot the implementation process of MDM has been provided with a Framework, Roadmap and a DFD design. This strategy described complete description of step wise approach to have a better view point on generating, handling, validating and monitoring master data. A study on existing work and Gartner's Hype cycle has been performed to know the latest technical trends in MDM.

Chun Zhao [6] et al. designed a model for assessing the viability and rationality of master data network. Set Pair Analysis (SPA) design of MDM has been presented in the research. Data network based on master data and data keys are established using MDM system. In association with master data, the main concern was to assess the effectiveness and rationality of the network. Contextual analysis showed convenient update of information, distribution and active response are significant elements in cloud fabricating climate.

On the basis of literature review, it can be concluded that designing of policies and standards are required to evaluate the functional suitability of MDM based applications. Further, the identity resolution, business rules and MDM solution is required for data consistency and security. Data governance and stewardship is of utmost importance for managing the data.

III. Research Methodology

Identity resolution technique is significant in MDM as it integrates two or more data identities into one object. To allow data citizens to access the right information, a productive identity resolution technique is required. In MDM, Identity resolution finally determines the master record. To realize this need, a methodology has been proposed in the present research for identity resolution in MDM. Research begins with exploring, analyzing and enrichment of input data set on TALEND tool for legitimate quality of data. The characteristics of relevant attributes of input data sets like matching score, threshold value and merging condition are considered. Finally, the experimental study has been performed to generate Master Table using Pandas data frame. Hence, an exploratory, descriptive and experimental research methodologies are used in this research. This concrete motivation for generating an MDM solution arises from everyday needs of global identification, linking and synchronization of master data across heterogeneous data sources.

IV. Proposed Algorithm for Consolidating Critical Data Entities

In the present research; data is collected from various sources in different formats, therefore, the consolidation has been carried out. Consolidation amalgamates all the data, remove redundancies and inaccuracy before combining it into single place. Critical data consolidation enables 360-degree-view of data assets, efficient plan, implementation and execution of a business process. Data consolidation in MDM initiates with data collection from the significant sources, utilizing business rules to build up a unique data source, data governance and transmission to the concerned departments. To consolidate critical data entities over collected data set, an algorithm has been proposed in this research as shown in Fig. 2.

Input: Data Set collection from relevant sources.
Output: Master Table - Unified version of Truth.
Steps:

1. Collect data from multiple sources
2. Build a standardized data model for integration as per data set requirements.
3. Evaluates data quality with predefined standards and polices.
4. If data quality is not legitimate as per defined rules, do
5. Apply data cleaning and standardization techniques
6. End if
7. Design a model for resultant Master Table
8. Select the desired attributes to be matched from input data files.
9. For each record in input do
10. Apply fuzzy matching technique on corresponding attributes of input files
11. Set m = similarity score of attributes
12. Set k= threshold value
13. If m>=k
14. Set the record for best match and automatic merge.
15. End if
16. If m>=0 && m<k
17. Set the record for manual merge using data stewardship
18. Else
19. If m<0
20. Set the record as worst match and not pertinent for merge.
21. End if
22. End if
23. End for
24. Generate Master Table as T
25. Perform automatic and manual merge of records into T
26. Select a record as Instance I
27. If I is new record
28. Add it to T by following step 3.
29. Else
30. Repeat step 8
31. Apply Data Governance technique on T
32. Deploy T as final master table: Unified version of truth

Fig. 2. Algorithm for Generating Master Data through Consolidation.

The above algorithm is proposed for creating master data. Initially, data is gathered from heterogeneous sources. On the basis of the data set requirements, Data Model-1 is created. The quality of consolidated data is verified by keeping into account the policies and rules of the organization concerned. In case the data is adequate, it will be processed further, failing which quality improvements techniques like Data Cleaning, Enrichment or scrubbing are applied to ensure the data consistency, accuracy and timeliness. Once the data is

enriched, the attributes to be matched are selected from the input files. For each record, a similarity score (m) is generated. The corresponding attributes are matched and a score is generated by using fuzzy matcher. A threshold value (k) is selected on the basis of matching score for categorizing the matching and merging process. The attributes of the input files are compared to find out the match. For each record, a matching score is calculated by applying fuzzy matcher.

On the basis of matching score, a threshold value is selected. Matching score of a record, greater than or equal to threshold value, will lead to the best match and the data is automatically merged. However, if matching score is greater than or equals to zero or less than threshold, it is considered as average match and processed for manual merge using Data stewardship. For worst match, matching score is negative and thus the data is not considered for a merge. In the proposed strategy, master table is generated by applying automatic and manual merge. In case there is a new record, it will be directly added to Master table and if a record already exists in the table then the entire process of matching and merging is again carried out. Data Governance polices are applied continuously on master data to ensure the quality of the data.

The resultant Master record should correctly match and merge using identity Resolution technique. Variation in data will adversely affect the search process and quality of data. For example: A Person may use Ritesh as a name at one place but Ritesh Kumar or Retish K. at another places. The variation in names may be due to use of nick names sometimes, aliases or initials. Change in address of roads, areas, billings, mailing etc may lead to variations. Such variations are overcome while merging the data using proposed algorithm. Table I describes range of variations for designed Identity resolution.

Table I explains the range of Variation for identity Resolution using designed algorithm. Identity matching allows correct result focusing on standard and quality of key data elements such as address, phone and email address. It allows enrichment of customer profiles to improve the accuracy of matching.

TABLE I. RANGE OF VARIATION FOR DESIGNED IDENTITY RESOLUTION TECHNIQUE

Type of Data	Potential Variants on a Data Type	Priority
Name Variation	Ashwani, Ashwini, Ash, Aswani	High
Abbreviation	Mohammad, Muhammad, Mohd, Mhd	High
Phonetics /Spelling Variation	Ritesh, Reetesh, Ritish	High
Date Format	9/01/2020, 09/01/2020, Jan 09, 2020, 09 Jan 2020, 01/09/2020	High
Suffix Variation	Ranjeet Singh, Ranjeet S. , Ranjeet	Medium
Null Values	Not known, Unknown, ?, 000, N/A, [Blank],NaN	Medium
Organization Name	Chaudhary Devi lal University, CDLU, Chaudhary devilal University	Medium
Department Name	Department of Computer Science & Engineering, DCSE, Deptt. of Compt. Sc. &Engg.	Medium
Titles	Mr. Pawan, Dr. Pawan, Pawan MD	Low

V. INPUT DATASETS

To implement the proposed work, data set has been collected from University Computer Science & Engineering department, Library section and Account section. The information of student is submitted to department during admission of a course while a separate form is filled by student for issuing the books in Library. As for master data, two or more sources of same information is required The figure below represents the screenshot of input data files.

Fig. 4 describes second dataset as Input_File_2 taken from library. The attributes L_Reg_no, L_Name, L_Father_Name represents the Registration No, Name and Father Name of student as recorded in Library and so on.

VI. IMPLEMENTATION AND RESULTS

The schema diagram designed for present work comprises of four steps: Data Enrichment, Data Matching, Data Merging and Data Governance as shown below.

Fig. 5 illustrates the schema design for data consolidation process in MDM. A sequential flow of execution from Data enrichment to Data Governance has been employed in this research.

For the implementation, the quality of input data is verified first. As Fig. 3 addresses the problem of Data redundancy (Duplicate records for Registration No 130036), domain integrity constraint violation ('SC' value in FEES attribute) and incompleteness (Null entries in Subject and Category attribute). Before creating Master data, all these issues must be resolved to make data clean. Thus, in present research, data enrichment is performed on TALEND tool. The following sections describe the modules Data Enrichment, Data Matching, Data Merging and Data Governance in detail.

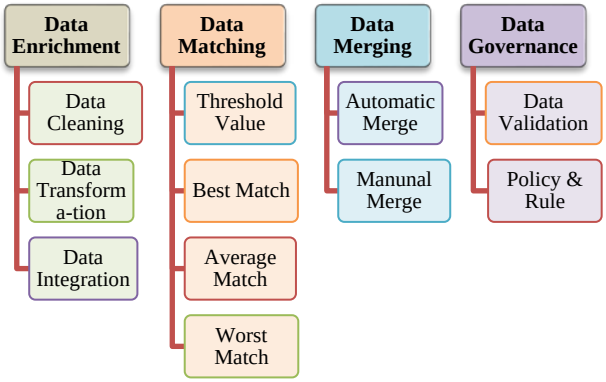

Fig. 5. Schmea for Methodology used in Research.

A. Module 1: Data Enrichment

Data Enrichment is characterized as enhancing or appending the collected data by supplementing incomplete, missing or inaccurate data. The subsequent enriched data empowers organizations in effectively customizing the data. To implement Data Enrichment, TALEND open studio for MDM has been used in present research as shown below.

Fig. 6 illustrates TALEND window with two input data files as Dept_data and Lib_data taken from University department and library. The results of TALEND tool are shown through Python platform for bringing together the results with further implemented result.

1) Data cleaning: Data cleaning is the process of removing or fixing inaccurate, corrupt, outdated, and incorrect formatted, duplicate entries from data sets. Data Cleaning is performed on input files Dept_data and Lib_data using predefined components in TALEND. The following figure represents the screenshot of Clean Data in Output_Flow_1 file.

Fig. 7 signifies that Unique Row and Replacement components are used for removing redundancy; null values, inaccurate and domain integrity constrain violation on input data source. The contents of Output_Flow _1 file shows that the above said problems are resolved in this step. Similarly, the same procedure is applied on library data and clan data is stored in Output_Flow_2 file.

2) Data transformation: The way toward changing over data from one format or construction into another is known as Data Transformation. In the present research, Python language has been used to execute the MDM solution. Python, being case sensitive language; lower case sentences are required to be converted into upper case sentences. Hence, data transformation is performed under mapping section of TALEND tool.

Fig. 8 indicates the Mapping process performing both Data Transformation and Integration. A mapping component takes two input as Main (department) and Lookup (Library) as shown above. The records are mapped on the basis of registration number of student. The attributes: Student Name, Father Name and Email id are converted into upper case under this section.

3) Data integration: Data Integration refers to the process of consolidating data from multiple sources into single or unified view. This technique helps analytic tools to generate effective and actionable business intelligence.

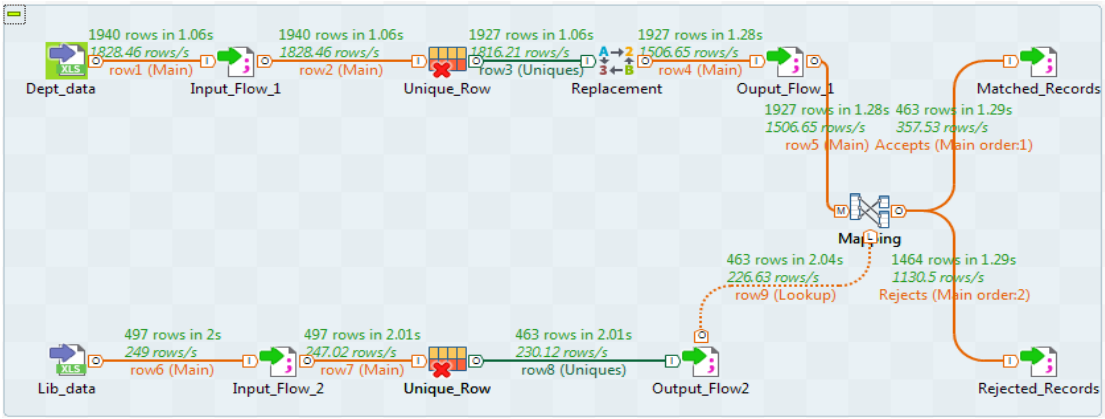

Fig. 6. Data Enrichment using TALEND.

Fig. 7. Clean Dataset- Output_Flow_1.

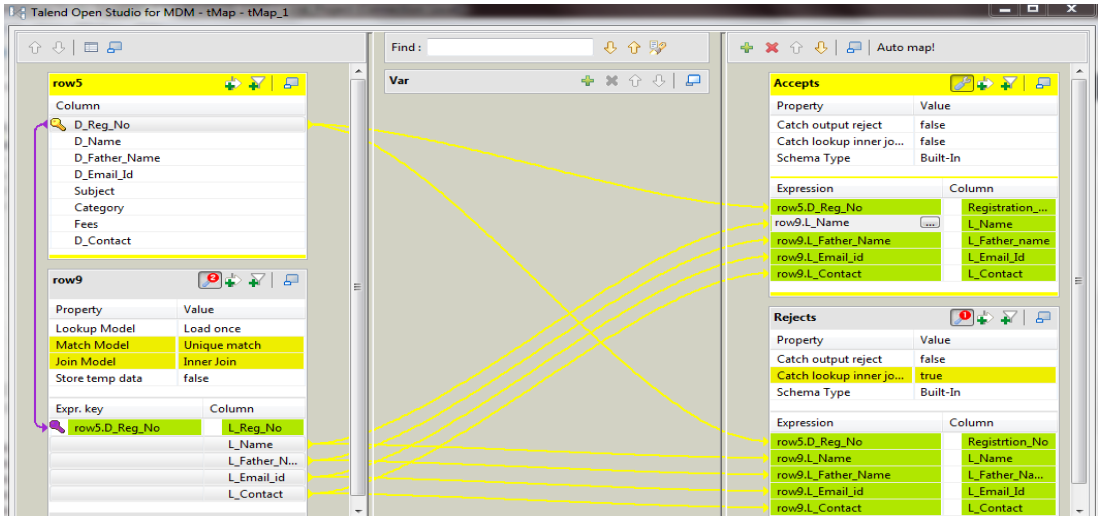

Fig. 8. Data Transformation using Talend Mapping Window

Fig. 9 describes the integrated result of mapping component as Matched records common to both department and library. In mapping, department and library records are mapped to generate a single copy of matched records by considering "Registration No". In above table, the attribute: registration number taken from department, whereas Name, father Name, Email and contact are taken from library record. The matched records are common records to library and department. Rejected records are not taken for analysis in present study.

Fig. 10 shows the Rejected records. The records of student which are not present in the library are rejected.

B. Module 2: Data Matching

Matching refers to the method of comparing different data sets and matching them against each other. The objective is to find the data that refers to same entity. To implement matching process, Python Fuzzy Match library is used to evaluate the matching score of records. A fuzzy match represents a match that is not exact. This technique identifies two elements of string, text or entities that are approximately same but not exact. In order to find a match score, four attributes: Name, Father Name, Email Id and Contact are considered for comparison in present research. Following values are evaluated on the basis of matching score of records.

1) ThresholdValue: Threshold value is considered on the basis of maximum matching of attributes. The Figure below illustrates the threshold value taken in the present research for merging of records in Final master Table.

In Fig. 11, the attribute best_match_score represents the matching score of the records. Matching score value 0.561963 is taken as threshold value. The records above or on threshold are considered as best match whereas below threshold and positive match score are average matched.

Fig. 11. Data on the basis of Threshold Value.

2) Best match: The record for which the matching scores value is greater than or equal to 0.561963 are categorized as best match records as shown below.

Fig. 12 shows the best matched records. The highest matching score is 0.947167. All the records above than or equal to threshold value are categorized as best matched records.

3) Average match: The record for which the matching scores value is greater than zero but less than 0.561963 are categorized as average match records as shown below.

Fig. 13 represents the screenshot of records below threshold value and greater than zero. There is need to manually determine which records are to be merged. Hence, these are categorized as Average matched records.

4) Worst match: The record for which the matching scores value is less than zero are categorized as worst match records as shown below.

Fig. 14 describes the worst matched records. All the records with negative matching score are considered as worst match records.

C. Module 3: Data Merging

Merging process allows merging the source data record into destination data record. Two base object records are merged to form a single consolidated base object. For merge operation, the attributes: Name, Father Name, Subject, Category, Fees are taken from department table whereas Email id, Contact are taken from library table.

Considering, k=Threshold Value, m=Matching score

Merge Condition =
- m>=k — Best Match → Automatic Merge
- m>0&&m<k — Average Match → Manual Merge
- m<=0 — Worst Match → Rejected

1) Automatic merge: The records for which matching scores is greater than or equal to threshold value are categorized as best match and considered for Automatic merge. Automatic merge is simply performed by merging corresponding attributes from two datasets. The result is Final Master Table containing Master record or Unified version of Truth for each record.

2) Manual merge: The records for which matching score is below than threshold value or greater than zero are categorized under average match and considered for manual merge. Data Steward helps to manually determine which records should be considered for a match. A data steward is accountable for carrying out data usage and security policies as determined through organization. The resultant records are stored into Final Master Table.

Fig. 15 depicts the Master Table after applying data enrichment, matching and merging. The content of the master table represents the Golden copy of each record stored in a single table. The attributes of table D_Name, D_father_Name, Subject, category, Fees are taken from department and L_Email_Id, L_Contact are taken from library. Thus, it represents a unified version of truth consolidated from multiple sites. It is essential to adopt an MDM strategy as master data represents the most valuable business objects and agreed upon the information that is shared among the organization.

D. Module 4: Data Governance

Data Governance is the set of policies, roles and standards that guarantees high quality throughout the lifecycle of data. It is the process of governing how data is used, by whom and when. Data Governance ensures that data accessibility, security and management rules are followed consistently, every working day. Services provide by data governance are: aligning rules and policies, establishing accountability and decision rights, specifying data quality requirements and performing data stewardship. An optimized data governance program will underpin the business transformation toward operating on digital platform at many levels. MDM requires Data governance activities for agreement on business and technical resources, data to be mastered, business rules and policies, consolidation rules and data quality. Thus, implementation of MDM is irrelevant without doing the significant bit of data governance.

1) Data validation: The purpose of Data Validation is to envelope accuracy: "The degree of similarity of an action to a standard or a genuine worth" and validity: “the degree to which data conforms to defined business rules”. It ensures that information present in the system is correct. Thus, in this study, the scope of Data validation is specified to figures out what data to validate, when to validate data and how to manage data that fails validation. Thus, Data Validation being an integral part of governance improves data quality and efficiency of the system.

Fig. 15. Master Table.

2) Policies and rules: The significance of Data governance policy is tied straightforwardly to the significance of a solid data governance program. A committee or governance team establishes policies and rules over collection, storage, usage and security mechanism of organization's data programs. Following functions are articulated in this study for making a governance policy.

- Reliable, proficient and successful administration of the information resources all through the organization and over the long run.
- Designing of Laws and regulation specifically designed for organization's data program.
- Proper assurance and security levels for various classifications of information as set up by the governance team.

In present paper, an algorithm has been designed to create Master data, with input data sources containing number of records: 1940 and 497, respectively. The records of these data sets are matched to find the similarity score using fuzzy matcher. On the basis of score and threshold considered, the input data set is classified into three types as shown.

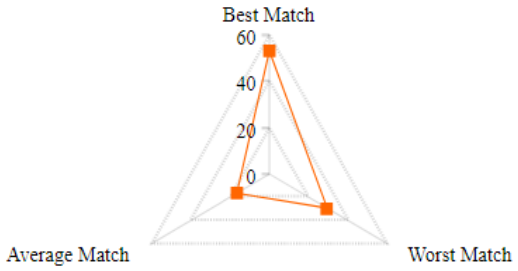

Fig. 16. Threshold based Classification of Input Data Sets.

The above Fig. 16 categories the input data set as: Best match, Average match and Worst match records. Matching is performed using fuzzy matcher to find a similarity score of a record. On the basis of match score, threshold value is considered to define the merge condition. The records above the threshold are taken as best matched records whereas below threshold and greater than zero are average matched records. Matching score with negative value are categorized as worst matched records. It is examined that the records in best, average and worst matching are: 53.2 %, 16.6% and 29.48% respectively for above said input. Master Table has been created using best and average matched records by automatic and manual merge process. It ultimately helps in improving data quality, business operation and analytics.

VII. Conclusion

In present study, an algorithm for critical data consolidation in MDM has been designed for small organizations. As Small and mid-sized organizations do not have the required capabilities to support best practices in MDM. They often underestimate complexity, cost, the flexibility to easily add attributes, and level of collaboration required for MDM program. Thus, to realize this target, a holistic approach for resolving and managing critical data entities in MDM has been presented in the present paper. In addition to data consolidation, Identity Resolution technique is also designed which helps in assessment of records while making "Unified version of truth". To discover and assess the quality of the identifying attributes, TALEND tool for MDM has been used in this research. Data quality over collected dataset is enriched with TALEND tool. By using fuzzy matcher, the matching score of corresponding attributes of input datasets is calculated. On the basis of threshold value, records are categorized as: Best match, Average match and Worst match. Best and average matched records are merged to generate Master Table while worst match records are rejected. Thus it is concluded that this approach is an optimal fit solution in small organization which enables users to integrate and circulate single standard view of master data across the frameworks like ERP, CRM, Apps, and systems. An effective MDM technique helps the business over wide variety of activities like reporting, up-selling and cross-selling of decision making and observance. The chances of being business successful, increases with significant implementation of master data.

Pipatpong Saephoo[2]
Department of Business Digital
School of Information and Communication Technology
(ICT), University of Phayao (UP)

***Abstract*—Digital identities, also known as virtual influencers, are created by humans through the creation of digital tools that mimic human behavior through the use of creative design. As a result of this, it has resulted in the creation of a group of people who are very fond of and trendy called "virtual influencers", particularly in the modern day. With the rise of virtual influencers, they must be used as tools in marketing and media, particularly in the online world. Because such a character is able to overcome a variety of limitations that humans are unable to provide, character styles, which do not need to have the same look or composition as people, are factors that make these characters popular, but the development of the virtual influencer depends on the social and cultural factors of the people of that era, as well as relying on technology to play a role for humans to be able to apply and use these elements to integrate with the existing virtual influencer to grow and develop more.**

Keywords*—Virtual influencer; online social; virtual character; media

I. Introduction

Today's technology and creative innovations, such as the development of multimedia technologies, including visual and entertainment innovations, have greatly expanded human imagination and creativity. Today's technology makes it possible to create realistic images of people. The general public can create images and video materials using design software or programs from their personal computers, as well as the tools used to create them. Humans began to study and create until humans in today's society encountered and became accustomed to virtual images and 3D designs in everyday life. It appears that these computer-generated images or characters are a part of the social and media lifestyle that we see and consume daily without feeling alienated.

Human society has advanced in computer technology, which has resulted in the advancement of computer graphics, and 3D technology as byproducts of development, as well as technology in the filmmaking, animation, and game industries. Beginning the creation of 3D works, and pushing the field of 3D computer graphics to people, with the release of Star Wars in 1977, a movie that the world recognized as a visual effect work of the world. The art of creating three-dimensional works has progressed to the present day since then.

Creating an imaginary world entails much more than simply building a structure or purchasing an object. Because technology has progressed to the point where tools can generate characters or simulate people from 3D programs. Furthermore, simulated people are now easily achievable, allowing people to create and simulate characters or objects, as well as create a fictional character. "Avatar" is a term for a fictional character that is processed by software to make it more intelligent. Furthermore, this effect contributes to the creation of a more realistic display for imaginative characters. Today's technological advances have created worlds, games, and applications in which people can meet, talk, and socialize without physically being present. Individuals create virtual avatars, or representations of themselves, to represent the user in those environments [2]. Not only can the characters take on the form of people, but they can also take on the form of monsters, imaginative characters, and characters created by the creators.

II. Problems of the Study

The purpose of this research paper was to investigate the popularity of virtual influencers as well as the factors that contributed to the popularity and support of the technology trend. This includes factors that will strengthen the current trend and encourage it to progress and develop further.

III. Method

The researcher used a method to analyze data from popular virtual influencers in various forms, such as analyzing the strengths that are regarded as supporting factors in the modern era in various aspects related to lifestyle and human media use. The current technology study has the potential to help drive the technology of the digital society of virtual influencers and summarize the issues by using this method.

IV. Character Development and Creation of Fictional Characters

Humans have long worked together in designing, thinking, and imagining. We have discovered imaginations of fictional deities dating back to recorded history, ranging from fictional paintings on cave walls to oil paintings of imaginary gods on the walls of famous artists' palaces. Visual stereotypes can appear in many different media formats: photos, movies, paintings, drawings, comics, animated movies, etc. Some of these formats allow different degrees of visual naturalism, which in the context of stereotypes is a feature of interest [1]. Visual Stereotypes and Virtual Pedagogical Agents Rather than using narrative, belief bonding, or even communication, characters are created by imagining gods or characters. The

attentive presence of a virtual character appears to be effective in reducing subjective stress responses, especially when the user believes the virtual other is controlled by a human [9]. This is accomplished by imagining fictional characters and transforming them into images for public broadcast. For a long time, humans have been modeling the shape of creating an ideal appearance, whether it is the nature of the gods and goddesses who have a beautiful appearance according to the ideals of each nation. For a long time, stereotypes or fictional examples have existed in human society to represent the archetype of strength, beauty, and perfection that is not found in the average human being. Virtual influencers bring new scenarios to digital marketing and more; if most analyses point to more convergence than divergence between real and virtual and between human and non-human [2].

In today's world, graphic design has become more straightforward. Creating the ideal character to represent or communicate the creator's imagination or the need for a person with the desired characteristics. The use of media technologies is growing increasingly prevalent around the world; within these technologies, users are finding ways to portray themselves. The more frequently our social interaction occurs via mediation, the more common the use of avatars will become [3].

CGI (computer-generated imagery) has been a popular tool in the entertainment industry for many years. Animated graphics, figures, and characters in films and video games have changed our perceptions of our surroundings [4]. In today's world, graphic design has become more straightforward. Creating the ideal character to represent or communicate the creator's imagination or the need for a person with the desired characteristics. CGI has been a popular tool in the entertainment industry for many years. Animated graphics, figures, and characters have altered our perceptions of our surroundings, whether in film or video games [5]. Character creation, or character design, maybe another way of reflecting one's identity and the need for a human appearance can be conveyed and presented through imagination and innovation in each era.

V. Creating a Digital Identity to Meet the Requirements of the Digital Market

The media in which humans see animated characters, monsters, and fictional characters have become the norm in today's communication and media world with the creation of human-made characters, thanks to the advancement of digital multimedia technology. There was a previous love trend when the trend of characters or cartoons flourished due to the appearance of anime characters. The following is an example of a trend that has sparked interest in the animation industry around the world, particularly in Japan, the East's leader. It is a mascot created for the Japanese voice-editing software Vocaloid, also known as Humanoid. The character's name is Hatsune Miku. A teen girl of 158 cm height and 42 kg weight appears. Her hair was turquoise, and her outfit was a short white skirt. She was adorable. This character was born in the year 2007. The Anime style, which is a technique used to create two-dimensional characters, was used to create her. The characters' popularity has spawned a massive industry phenomenon, including the ability for fans to organize their concerts utilizing 3D holographic character presentations. Furthermore, another response was their superior ability to humans' in communicating in a frequent way. This enhanced the level of intimacy with virtual influencers, showing that there were tendencies into developing bonds with them [6]. It was a way for the character to interact with her fans in person in 2014. This is yet another phenomenon in the digital world that demonstrates and conveys the fandom's affection for young girls. A large number of people also follow her on social media. More characters based on Miku's approaches and prototypes were created to satisfy the growing fan base as the character's popularity grew. This popularity has also spread outside of Japan to several other countries. This is reflected not only in the mashup of musical styles and aesthetics that underpin Hatsune's image as a performer but also in the numerous contributors to her live performance as well as her growing discography, which was created using synthesizer software [7]. Miku's success was most likely due to more than just the use of adorable new characters. Other factors that contribute to this character's popularity include Japanese culture, technology, sound, performance, release timing, appropriate publicity, and a variety of other factors. This phenomenon implies that the characters created are not always realistic, humanoid, or human representations.

The competition format and digital creations have become more realistic as we move into a more advanced era of virtual reality technology. We get to see the film characters, as well as the setting and fictional characters. In the entertainment industry, virtual reality graphics are widely used to create a more realistic appearance layout. Producers and cinematographers can express their imaginations in films by using characters created with graphics rather than human limitations. The images created by using these fictional characters are no different than those created by using real stars, people, or by creating and stimulating locations. The props are more realistic as well. It demonstrates digital characters' ability to transcend physical limitations or meet needs that humans are unable to meet. When such tools are capable of creating or producing people in such a way that it is difficult to tell them apart, creating fictional identities brings them to life. A variety of factors support and drive these factors. It is possible to make friends or form friendships in the modern era, as well as to make oneself known through a variety of social media channels. As a result, birth in the online world is regarded as a channel for presenting or informing birth. To present these digital characters, the majority of digital influencer channels currently emphasize the use of social media. Famous digital influencers were all discovered on Instagram, which is significant in and of itself. People consume content quickly on this platform, and the dimensions of the screen dictate how visual information is processed. At the start of their careers, digital influencers frequently use side channels. The online world is the primary channel for birth notification.

A persona that aligns with the target audience should be thoughtfully developed and executed. The content creators should develop an identity for the CGI that would include all components of a belief system, unique to the CGI. The CGI

should ultimately mock a human, physically, emotionally, mentally, and spiritually. Just as the CGI and brand must align for effective advertising, as in all advertising, the brand and target audience must align. Therefore, the brand, CGI, and target audience must align [8]. Furthermore, Virtual Influencers may emerge from well-known and popular virtual characters in the digital world, such as characters from computer games, animated movies, brand characters, mascots, and so on. "It is clear that the virtual aesthetic of video games dominates this collection." When we consider heroines, or what might constitute the nature of a woman whose actions can be so courageous that she becomes superior and iconic, it becomes clear that a virtual entity integrates with Maison's founding principles. Lightning is the ideal avatar for a global, heroic woman, as well as for a world in which social networks and communications are now inextricably linked. She is also a representation of new pictorial processes. How do you create an image that deviates from traditional photography and design principles? Lightning signals the beginning of a new era of expression." Nicolas Ghesquière [9]. It not only brings popular characters from niche platforms, such as computer games, such as Final Fantasy's Lightning, but it also brings this distinct character to the world of fashion. It is also expected to continue the trend and raise awareness among other consumer groups, as well as establish a link between the brand group and the game player. This is a good way to connect relationships and create marketing channels, such as when creating the Kumamoto mascot, a black bear with red cheeks who represents Kumamoto Prefecture in Japan. Kumanmon is regarded as a pivotal figure in Kumamoto. Kumamon travels all over the world as the prefecture's sales manager, introducing people to the wonders of his hometown and its abundance of nature, seafood, and delectable fruits [10]. When people are recognized as representatives in the character, the character is a representative or image of the place, implying that the character is a representative by default. Items associated with a particular character are well-received and desired by both fans and customers when a fan base develops for that character. Kumamon's popularity has had its impact, with merchandise sales reaching approximately 29.3 billion Yen in the first year of its promotion into the local budget flow. This result was very close to the total income of Kumamoto Prefecture, which is well-known for its agricultural products [11].

VI. The Social Development of Digital Influencer

The number of Virtual Influencers is growing, and the typical influencer model is to penetrate a specific market segment, such as being an influencer in one area such as travel, fashion, gaming, performances, sports, and so on. Countries or regions that wish to present language-specific content, however, the content presented retains the concept of coexistence with the characters' real life by referring to the current and imitating real life to reach or be closer to the person, for example, living like a normal person, interest in the online world like a normal person, expressing feelings or creating imitation behavior in real life based on people's age and character. It is likely that many brands will find the use of CGI as influencers appealing. The benefits are not limited to the potential of increased sales, more reach, and a reputation as an innovator. Should this be the new normal, brands may need to adjust and more CGI influencers may be needed [8]. It is thought that the character should be presented to get as close to and reach the person as possible. Although CGI allows for far more possibilities than photographic or realistic representation, these accounts attempt to depict scenes that are somewhat similar to or resemble real-life environments and scenes (Dovile Dudenaite). Human behavior may be imitated in the performance or presentation. Virtual Influencers want to sense the physical presence of the characters in the real world. After getting to know these characters, even fans and aficionados realize they are not real. The appreciation style in personality, stereotypes, or expressions, on the other hand, is most likely a big part of how people follow or become a fan base and support. CGI influencers are having an impact on the influencer marketing landscape and have the potential to change how brands communicate with their audiences [4].

VII. Strengths of Virtual Influencer that Aid in its Growth

A. Physical and Medical Limitations

Creating a virtual influencer is certainly a character regardless of physical use or physical health, and creators can accordingly customize the character's physical characteristics, as well as the content presentation or gestures. Because computer-generated influencers are not constrained by energy levels, family commitments, or overtime legislation, they are essentially available for brand use 24 hours a day, seven days a week [12]. Clients or employers can then select one of these influencers to provide an unlimited supply of product work. These Virtual Influencers have an advantage in being a good choice for today's entertainment or advertising business due to rest or physical factors. Characters with a creative streak can take risks or create images in dangerous or difficult-to-access environments. Traditionally, brands and advertisers have used real-life models as influencers to promote their brand or product. Fashion models were chosen to be slim and beautiful. These models came with overhead costs such as hair and makeup, lodging, transportation, their own reputations and sometimes a troubled past or future. With the advent of computer-generated images (CGIs), all of those overhead costs and potential public relations crises can be eliminated [8].

B. Workplace, Travel, and Time

In today's world, where traveling or moving is difficult due to the travel health influencers' safety epidemic, visual influencers are digital information that can be displayed on modern computers and mobile phones. As a result, the budget for Virtual Influencer-related expenses has been cut. We can change the character's position to suit the task or information to be presented. The presence of software assistance and computing capabilities allows for a more realistic display, removing the need for scheduling or job queuing. We could meet Virtual Influencers on the other side of the world and then vanish in an instant. These abilities could be one of the characteristics that make influencers more appealing to their followers.

C. Additional Customizations to fit the Content

Creating value or content for an influencer is simpler and less expensive than it is for the average person, as changing outfits and adding accessories around the body can change the composition in a very short time depending on the difficulty of creating a 3D piece for assembly. As a result, the new customizing influencer method saves money and time when creating content. Each image publicity for Influencers or singers, in general, necessitates a significant investment in terms of resources, expenses, and personnel. Creating content for these Virtual Influencers necessitates not only the use of computers to create images but also the character creators' skills and abilities.

D. Bypassing Legal Constraints

The media, labor, and the common man at work are all protected in advertising circles, as is the scope of the population's legal protection. Each region or country has its own set of specifications. They are rules that humans use to control and protect themselves to reduce problems and protect their rights. Many of these concerns are alleviated by virtual influencers: because they are not humans, there is no ethical issue of branding attached; the image can remain consistent; and the risk of indiscretions is minimized because they do not exist offline, allowing their "behavior" and image to be calibrated in the background (J. Tan). The rise of the artificial intelligence influencer: are they simply easier to work with? August 27, 2019, Marketing Interactive [13]. However, there is no specific law that governs Virtual Influencer. Despite their appearance and elements that are difficult to distinguish from the real person, the preliminary images are interpreted as a type of PR medium. The work and the virtual influencer continue to be fictitious characters, akin to cartoons or animated characters. Communication or overwork will work with these characters, so the style of content that appears with Virtual Influencers is much broader and more flexible than we've seen before. However, the requirements of different countries' media laws vary. Virtual Influencer characters are still regarded as media. Laws governing the public presentation of media also govern the rating of published media. Although CGI influencers provide brands with new ways to express themselves, the newfound power must be managed [4]. The creation of Virtual Influencer content necessitates knowledge of the countries and community's laws and customs. Even if the characters are real people, cartoons, or made-up. Although CGI influencers provide new avenues for brands to express themselves, the newfound power must be managed [12]. It is critical to have a regulatory and review body, as well as legal content related to Virtual Influencers, such as the Federal Trade Commission (FTC), whose mission is to protect consumers and competition by preventing anticompetitive, deceptive, and unfair business practices through law enforcement, advocacy, and education while not unduly burdening legitimate business activity. When receiving media, including communication from both Virtual Influencers, it is aware of information presentation and consumer protection.

VIII. Accelerating the Future Virtual Influencer

Although Virtual Influencers are gaining popularity in many parts of the world today. The character creates a distinct identity and persona to gain recognition and love from the online world as a gateway, as well as people's and brands' attention. Virtual, or rather artificial, influencers operate online in the same way that real ones do. Brands want to collaborate with them to design their fan base. Even if they are not intended to be brand ambassadors, their popularity will almost certainly attract companies looking for endorsement deals [14].

Popularity and trend in the online world are thought to be another driving factor of influencer identity, but with current trends and developments in many areas of technology, especially nowadays, it is evolving quickly. The advancement of computer graphics, as previously stated, has fueled the trend of Virtual Influencers. Online media is a factor that contributes to the trend's popularity. The Virtual Influencer's form and characteristics can be modified and developed further through the use and support of technology, which can be supplemented in the following ways.

A. A.I.(Artificial Intelligence) System Development

It is a type of technology that is vital in today's world and is used in all industries. It was created to be a simulation of the human nervous system, which processes information from learning and optimizes itself. Furthermore, it can analyze and process on its own in the process of thinking and self-development by relying on digital tools and computer systems. A field of study that seeks to explain and emulate intelligent behavior in terms of computational processes [15]. The advancement of digital human technology has a positive impact on the AI system development model. The seemingly infinite number of technologies, techniques, and applications that fall under the AI umbrella can be usefully divided into two categories. The first consists of knowledge-based systems that are "committed to the notion of generating behavior through deduction from a set of axioms" [16].

Which AI technology drives innovation in a variety of areas, including ways to accelerate advancement that can be combined with Virtual Influencer, a computer graphics applied science that can bring AI technology to promote this industry and society? In the future, the project Baby X will be developed as a clear example of the use of multimedia technology combined with AI processing. Dr. Mark Sagar created Baby X, a digital artificial intelligence mixed reality installation. It is a neuro-behavioral computational model with emergent behaviors that are actively used for neuroscientific research and, at times, a public media art installation [17]. Based on the Baby X project's experiments, we can anticipate the emergence of a new type of virtual influencer in the future - a framework for interaction that could serve as a model for the next great relevant project. We can predict and see the direction of the development of existing virtual influencers or new virtual influencers from such an intriguing project, which is likely to be a tool to help foster the ability to create interactions and allow virtual influencers to meet and greet fans. Virtual Influencers, on the other hand, do not have this capability. Bringing these incredible AI systems and

capabilities to Virtual Influencer could add augmented reality to the characters, charisma, and senses, bringing the virtual influencers to life in ways never seen before. AI is now being used by digital character creation companies to create characters for businesses, organizations, and even individuals. It was created by Soul Machines. The company is a pioneer in the field of character innovation or the simulation of real-life people.

This is a first step toward bringing Virtual multimedia and AI into the industry in the future by customers who have joined the corporate character creation when combined with the application of AI technology to be able to interact with people and study the needs of interactions to be the most similar to human personality. Vodafone ("Kiri"), NAB's UBank ("Mia"), the Ministry of Primary Industries ("Vai"), ASB Bank ("Josie"), UBS Bank ("Daniel Kalt"), and, more recently, BMW, Southern Cross, and BCG are among its customers (and digital humans) [18] and respond in an emotionally appropriate manner, providing the embodiment of the to the brand and developing brand loyalty and advocacy, bringing "humanness" into digital experiences, increasing sales conversions and customer advocacy (Monica Collier Scott Manion). Artificial Intelligence in Action: Digital Humans [18] as well as creating identity and recognition for the Brand's personality for customers and visitors. Currently, more and more such services are being born in other companies to create these digital characters, increasing the opportunity for Ai Digital Influencer to expand and widen the market, which benefits the consumer side. Consumption rises when competition in these markets rises. Nevertheless – this portrayal of the ideal can be taken one step further with interactive computer media. A key difference lies in what is otherwise seen as a central potential of virtual characters – not the least in pedagogical terms – namely their interactivity: Virtual characters may communicate, respond, and answer, thus establishing a dynamic, mutual social relation [1].

B. Robotics Advancements in Industrial Technology

We are familiar with the visualization and perception of virtual influencers' presence when viewing a digital display through a screen, but what if these influencers could transform into real people? They're just as real as robots or characters from science fiction movies. The task of perception is another important application of AI in robotics. Robots can sense their surroundings using integrated sensors or computer vision [19]. By mentioning the introduction of an AI system to manipulate and work with characters in the Virtual Character format to create a fictional character with a system that mimics human interactions as closely as possible. Virtual influencers who are unable to meet and interact with real people and followers will benefit from the adoption of this technology. Furthermore, the virtual influencer's difficulties in considering the specific context in real life were identified [6] and when considering the study and production of robots as another science that complicates. In fact, the development of these robots entails a plethora of subtleties and techniques. Humanoid robots should share the same working space as humans and should respond in a human-like manner. As a result, they require a light-weight body, high flexibility, a wide range of sensors, and a high level of intelligence [20].

Structuring is an important part of imitating and simulating a wide range of structural features, such as muscles, organs, hair, and skin, all of which necessitate the use of technology, science, engineering, art, and beauty in the creation of the humanoid. This is yet another feature that improves the Virtual Influencer industry while also introducing a new presentation style. In the future, having a unique digital identity or simply seeing these characters on screen may not be enough to meet the needs of fans, so creating a virtual influencer in the form of a robot that looks like a real person, known as a humanoid, may be required. A significant amount of difficulty is also involved, with the key being to create characters that allow for as natural an interaction and movement as possible. Robotics is a challenging field, both in terms of engineering human-like movements and expressions and the challenges that arise when a robot assumes human form. With this format, the social and emotional aspects of interaction take precedence [21]. Realbotic, a technology company focused on developing interactive and immersive virtual robots using AI and machine learning processes, as well as the development of external components, is currently developing augmented reality robotics in the industry. The movement and appearance of the characters create a sense of intimacy and an experience similar to meeting a real person for those who interact with them. Humanoid’s creation market has grown since the company's inception. Humanoid robotics labs around the world are working to develop robots that are one step closer to the androids of science fiction. Building a humanoid robot is a difficult engineering task that necessitates a combination of mechanical, electrical, and software engineering, computer architecture, and real-time control [22]. Humanoid's growing popularity has aided the industry and related technologies in improving their capabilities in these fields. In addition to enhancing and driving the virtual influencer industry, Humanoid is involved in promoting and driving other related industries such as entertainment, film, acting, service, helping, and the puppet industry. In a variety of situations, these virtual machines can play the roles of real people.

There are also various factors that support the opportunity and development of the Virtual Influencer to increase and leap forward, such as The development of Internet sensitivity is laying the foundation for today's global systems such as technology internet 5G, Internet of thing (IoT). The presence of a new online community Social media that will support the development and innovation of multimedia technology to make it more accessible to the way of life such as the world of Metaverse. Some believe that virtual worlds will comprise a metaverse, combining immersive VR with physical actors, objects, interfaces and networks in a future form of Internet [23] a social, virtual world that parallels – and in some respects, replaces – the real world [24]. which is regarded as space and the digital world in a new platform born from the development and pushing of the future simulation technology. It also consists of many factors such as the more people have time to dive into the online world. Everyday activities are more involved in the virtual world. Creating a wide range of technological innovations increased research or the price of technology products is more accessible to each individual, etc.

IX. Discussion

The study's design demonstrates that the popularity of the virtual influencer's identity is driven by the trend of online technology, which provides a means to promote recognition and popularity. Today, each of the channels is becoming more widely distributed. Popular social media platforms of choice for influence are Instagram, Facebook, Snapchat, and YouTube. An influencer has the power to affect the purchase decisions of others because of their authority, knowledge, position, or relationship with their audience. It is important to note that these individuals are not simple marketing tools, but rather social relationship assets with which brands can collaborate to achieve their marketing objectives [25]. It is regarded as a factor in promoting human beings' closer and more connected relationships with virtual influencers. As the number of online media channels grows, so does the number of people who like them. The more opportunities for relationships and interactions are better.

The technology is linked to the character's development style. As processing technology and character creation have advanced, the creation of such fictional characters, such as anime, has become more feasible. However, with the advancement of digital technologies, computer generated images (CGI) are becoming more and more human-like, and virtual agents are increasingly capable of simulating human content [26]. It is thought to be another factor that has contributed to the increase in popularity and likes, as well as the broadening of its target audience, possibly including groups of fans of technology, games, cartoons, sci-fi movies, and so on. Furthermore, other factors in the creative technology industry will help promote and create success through virtual influencers by utilizing technologies throughout the world. The development of information and computer technology allows modern man to live a double or triple life, and therefore, one reality will be superimposed on another. Perhaps in the future, the virtual world and the real world will be inseparable, but these are only predictions [27].

X. Conclusion

A study of the factors and successes of virtual influencers, the phenomenon of popularity and emergence, discovered that what helps virtual influencers create characters is also due to nature's imitation and the presence of a virtual influencer. A real person can become the main character of a story or combine or improve the strengths of a variety of personalities to create a unique character. It could be a design based on the character's appearance that matches popular trends and people's preferences, or it could be designing a character that isn't necessarily based on anything that is considered personal. Virtual influencers are created by interested parties, and followers are drawn to the style and uniqueness of the content presented. Influencers are the factors that contribute to people's preferences being met. These virtual influencers are options for people who like and have an attitude toward a character's lifestyle, despite the fact that virtual influencers are not always realistic, humanistic, or display any form of perfection. That is, it could be a new social group that addresses the needs and attitudes of people who have ideas or suggestions in an era when the line between people and the digital world is almost indistinguishable. Existing influencers may be unable to replace virtual counterparts. In a technologically influenced world, it's simply a new subset of preferences and approaches. Virtual influencers are characters whose attitudes and imaginations are enriched by the attitudes or influence of a society that has adopted human-born attitudes and ideas. According to the study, the factor that contributes to popularity could be the form of popularity in appearance and the liking of the ideal character that has been with humans for a long time, such as what we see in the visualization of gods, mythological and mythological characters created to meet the needs and attitudes of demanding physical traits and desired traits. Overall support in both technology and infrastructure is an important factor that will make a difference or drive a virtual influencer's social group to gain popularity and more likes than before. The use of computers and creative technology has gained popularity for the creation of virtual influencer identities, which create beautiful characters that are similar to real people or can be conveyed as closer to humans. People's interest in information technology today coincides with a period in which both social and technological conditions are becoming increasingly involved in human daily life through active lifestyles. The media has changed, and there is still room for growth due to the rate of growth and the number of internet and electronic device users. A computing system in the field of AI that will assist virtual influencers in learning and becoming smarter. Fast Internet connection systems, IOT (Internet of Things) applications, or the robotics industry are also becoming increasingly intelligent. Furthermore, many future academic and creative innovations will help drive the combination of development with the creation of Virtual Influencer characters to grow and progress. The benefits of a virtual influencer to humans also include a variety of computer tweaks and corrections, reduced stress, and a number of physical and mental limitations that real-life celebrities face. At this point, a virtual influencer may be appropriate for activities or areas where relevant trends are likely to occur. Although a variety of factors contribute to the rise in popularity of virtual influencers, there are still many factors that virtual influencers cannot replace today. A distinct way of life in which the naturalness and presentation of content to those who follow is rather unique and communicated directly to the audience. Human development and growth continue to be so enticing that virtual influencers fail to convey these feelings to the viewers. Although virtual influencers can be customized and corrected in body proportions to be perfect or according to societal trends, the charm of change and the development of human growth is still a strength that virtual influencers cannot replace and enhance the strengths that are the hallmark of human evolution. It is an option for those who admire and sympathize with the character's way of life. That is, it could be a new social group formed to meet the needs and attitudes of people with ideas in an era when the line between people and the digital world has almost vanished. It cannot be separated, which means that the popularity of virtual influencers is derived from social behavior, attitudes, technological processes, social trends, and responses to the needs of people who are satisfied with their character and will be able to influence trends and the development of the virtual influencer

society. In terms of living a way of life, conducting social sciences, and pushing themselves to be modern and comfortable, they are consistent and similar to humans. Because of technological advancements, life has become more convenient. Existing ones may not be able to be replaced by virtual influencers. It's simply a new subset of preferences and approaches added to the audience's options. Virtual influencers can only exist because of the encouragement and support of people who value those characteristics. Perhaps the ideal representation of the individual is where a society of virtual influencers and a variety of communication sciences collide to create new forms of self and character that satisfy and delight humans.

Modified Deep Residual Quantum Computing Optimization Technique for IoT Platform

Rasha M. Abd El-Aziz, Alanazi Rayan, Osama R. Shahin, Ahmed Elhadad, Amr Abozeid, Ahmed I. Taloba
Department of Computer Science, College of Science and Arts in Qurayyat
Jouf University, Saudi Arabia

***Abstract*—Internet of Things (IoT) is defined as millions of interconnections between wireless devices to obtain data globally. The multiple data are targeting to observe the data through a common platform, and then it becomes essential to investigate accuracy for realizing the best IoT platform. To address the growing demand for time-sensitive data analysis and real-time decision-making, accuracy in IoT data collecting has become critical. The Res-HQCNN is a hybrid quantum-classical neural network with deep residual learning. The model is qualified in an end-to-end analog method in a traditional neural network, backpropagation is used. To discover the Res-HQCNN efficiency to perform on the classical computer, there has been a lot of investigation into quantum data with or without noise. Then focus on the application of the artificial neural network to analyze the dangers to these IoT networks. For data recording purposes, to undertake in-depth analysis on the threat severity, kind, and source, a model is trained using recurrent and convolutional neural networks. The intrusion detection system (IDS) explored in this study has a success rate of 99% based on the empirical data supplied to the model. Due to irregularly distributed robust execution, larger affectability for the introduction of authority dimension, steadiness, and the extremely large crucial area, a quantum hash function work has been proposed as an amazing method for secure communication between the IoT and cloud.**

***Keywords*—Internet of things (IoT); cloud; Res-HQCNN; intrusion detection system (IDS); optimization**

I. Introduction

Artificial neural networks (ANN) are one of the most successful computational approaches. Neural network-based machine learning algorithms are improving and advancing [1]. In the machine learning sector, neural networks are currently enjoying remarkable success and have a wide range of applications, including pattern recognition, video analysis, medical diagnosis, and robot control. Quantum neural networks (QNN) appear in parallel with the development of artificial neural networks (ANNs), with the promise of overcoming classical computation limits using quantum computing [2]. The paper shows a quantum feed - forward neural network made up of genuinely quantum neurons. It has a remarkable capacity to study an unknown homogeneous and a high level of robustness when dealing with noisy training data. Due to a decrease in the number of coherent qubits, this process is essential for noisy approximate quantum computers. The adherence among a pure quantum system and an arbitrary quantum state is selected also as cost function in this study. However, as the number of network layers grows larger, the convergence rate of a cost function slows, and the value of convergence even fails to deliver the highest for clean data is shown in Fig. 1(a). In the case of noisy data, Fig. 1(b) shows it as the system gets deeper, the strength for noisy data weakens. As a result, guess if the cost function's efficiency can be enhanced both for clean and noisy data. To show the number of convolution layers in the corresponding layer, use a one-dimensional list of real numbers.

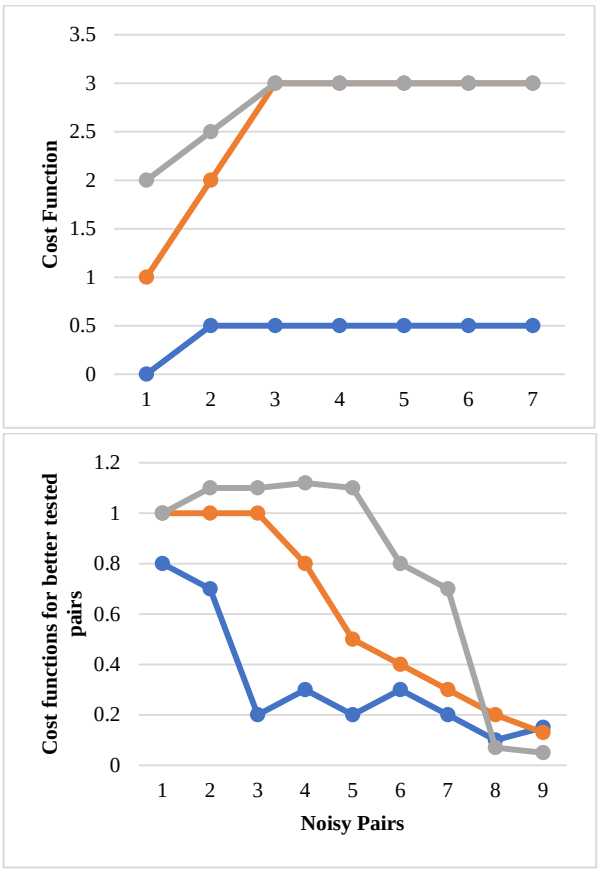

Fig. 1. QNN Numerical Results for Clean and Noisy Data.

To enhance the novel quantum-classical neural network with the deep residual learning (Res-HQCNN) to attain a goal, inspired by the deep residual efficiency learning. This is a novel concept and no work has been attempted as far as know. To find the efficiency incorporate a residual scheme into QNNs. It is not a simple task [3]. The amount of residual block structures, levels of the network count, and whether or not to skip the layer all have an impact on the parameter updating method. Because the informing parameters of the

matrix are derived from the function of derivative formulation, the updating parameters matrix for each network is unique. Res-HQCNN now outperforms previous QNNs on both fresh and loud quantum data while requiring only a conventional machine to build. Discuss a different way for incorporating quantum neural networks with residual block structure so that they can be executed on quantum computers.

Networks intrusion continues to occur. This is even though numerous artificial intelligence techniques have been created throughout time to prevent such incidents [4]. Various advancements and modifications are made to network configuration protocols daily to improve them, but in reality, there is a weakening risk of the protocols with or without understanding. Malware and other intrusions frequently take advantage of minute alterations made to the original core development codes that serve as the foundation for running and maintaining networks. The changes are vital, but they come at a high price. It's time to rethink your threat management strategy [5]. IoT and Cloud Computing benefit in the same way and Cloud Computing is constantly encouraged to improve the introduction to the level of high resource usage, accumulation, necessity, and processing capability.

However, network intrusions continue to occur. This is regardless of the fact that multiple artificial intelligence techniques have been developed over time to prevent such incidents. Various progressions and modifications are made to configuration management protocols on a daily basis in an effort to improve them, but in reality, there is a risk of decimating the procedures with or without knowledge [6]. Malware and other intrusions frequently take benefit of minute changes respect to the design foundational development rules that serve as the foundation for operating and maintaining networks. The changes are needed, but they come at a high cost.

Cloud is a ground-breaking platform that can provide additional features as an information distribution delegate. When an IoT client has valid requests for specific information to be acquired, stored, and accessed, he can simply designate the requests to the cloud whenever with more remarkable comfort. A couple of incites linked to contraption disillusionment are addressed by cloud and IoT applications developed in resource-constrained conditions. A QHF is proposed to address IoT security concerns. It converts an old-style message to a Hilbert space, preventing programmers from obtaining too much information about the old-style message. Safety issues are of extreme importance, and they must be addressed without exacerbating the system's or devices' dimensions [7]. A few calculations concerning safety issues have been published in prior studies. The U-2 hash work is the largest class of hash capacity groups among known hash capacity groups, assuring good safety.

The number of residual block structures, the number of network layers, and whether or not to skip layers all have an impact on the variable propagation algorithm. Because the updating parameters structure is derived from the description of the derivative feature, the updating parameters structure for each network structure is unique. The updating parameters matrix becomes more complex as the network structure becomes more varied. As a result, this investigation is both challenging and intriguing. This hope that our paper will serve as a useful resource in this field of study. The following are some of the contributions made as a result of this paper:

- Develop a new residual learning structure that is focused on QNNs.
- Calculate the current training algorithm using the Res-HQCNN model. Examine the performance from the level of information propagation feedforward and backward, subset of the training algorithm.
- concentrates on using Artificial Neural Networks to evaluate the risks to such IoT networks. For data acquisition reasons, a classifier is constructed using recurrent and convolutional neural networks to perform effective analysis on threat intensity, type, and source.
- Res-HQCNN has better performance across both clean and noisy quantum information than previous QNNs at the cost of implementation.

The remaining part and the aim of this paper have explained the RES-HQCNN optimization technique for IoT; Section 2 defines the highlight of the previous effort that can be done by the scholars in this domain; Section 3 offering the methodology architecture model and its mechanism, Section 4 represents the result and discussion and Section 5 represents the work achieved in conclusion and future work.

II. Related Work

The author in [8] evaluates Quantum Computing (QC) has grown in popularity as a result of its unique characteristics, which, in terms of performance and operation methods, differ from typical computers This research proposes hybrid models and approaches for large-scale mixed-integer programming issues that successfully combine the complementary strengths of deterministic algorithms and quality control techniques to solve a combinatory difficulty. Large-scale instances of these application problems across multiple dimensions, ranging from molecular design to logistics optimization, are computationally demanding for deterministic optimization algorithms on classical computers. To address the computing challenges, hybrid QC-based approaches are suggested, with comprehensive computational experimental results demonstrating their pertinence and productivity. The suggested QC-based solution approaches offer high computational efficiency in terms of solution quality and computation time by leveraging the unique properties of both classical and quantum computers.

The author in [9] introduces a Deep residual network with adequate depth but bounded width has recently been proven to be capable of universal approximation in the sense of the supremum norm. Illustrate to adapt existing deep residual network training methods to establish approximation bounds for the test error in the supremum norm based on the training error using these results. This technique is based on control-theoretic interpretations of these networks in discrete and continuous time, and they show that constraining the set of parameters to be learned in a way that is consistent with most commonly used training procedures is sufficient.

The author in [10] is proposed to use a combination of modified deep learning and reinforcement learning in an incentive-based demand response (DR) algorithm. A modified deep learning model based on recurrent neural network (MDL-RNN) was initially suggested to forecast future environmental uncertainties by projecting day-ahead wholesale energy price, photovoltaic (PV) power output, and power load. Then, using reinforcement learning (RL), researchers looked at the best incentive rates for each hour that would maximize earnings for both ESPs and EUs. When compared to other methods, the findings demonstrated that the proposed upgraded deep learning model can produce more precise forecasting predictions A short-term DR program was developed for peak electricity demand periods, and trial results show that peak electricity demand can be reduced by 17%. This helps to improve power system security by reducing supply-demand imbalances.

The author in [11] improve the feature mapping process, introduce a hybrid quantum-classical convolutional neural network (QCCNN), which is based on convolutional neural networks (CNNs) but is optimized for quantum computing. In terms of both the number of qubits and the depths of the circuits, QCCNN is favorable to existing noisy intermediate-scale quantum computers, while keeping crucial aspects of classical CNN, such as nonlinearity and scalability. Also, offer a methodology for computing the gradients of hybrid quantum-classical loss functions automatically, which may be extended to other hybrid quantum-classical algorithms directly. By using a Tetris dataset to demonstrate the architecture's capabilities, show that QCCNN can perform classification tasks with learning accuracy that exceeds that of standard CNN.

The author in [12] analyze in classical systems, Control parameter optimization is frequently achieved using supervised machine learning and reinforcement learning; however, in quantum systems, parameter optimization is primarily accomplished using gradient-based greedy methods. To use differential evolution methods to avoid the non-convex optimization stagnation problem. To improve quantum control fidelity for noisy systems by averaging across the objective function. To reduce processing costs, this paper proposes methods for early run termination and adaptive search subspace selection. The implementation is massively parallel and vectorized to further reduce execution time. Quantum phase estimation and quantum gate design are two instances where these methods outperform greedy algorithms in terms of fidelity and scalability.

III. Proposed Methodology

In this section, the Res-HQCNN architecture model is defined based on QNN. According to the mechanism Res-HQCNN is defined based on a training algorithm.

A. Architecture Model of Res-HQCNN

In Res-HQCNN describe a residual block structure. The Res-HQCNN structure with many layers is offered. Thus offer Res-HQCNN examples with a unit hidden layer to further understand the mechanism [1]. Finally, examine the difference between the past QNNs and the Res-HQCNN. Thus, Fig. 2 shows the residual block diagram. In Res-QCNNN, a new residual block diagram is defined as follows by including a few assumptions and notations at the start for your convenience.

The procedure for combining the residual block structure with the quantum neural network in Res-HQCNN layer k defines a quantum perceptron as an arbitrary unitary operator with U_{k-1} input qubits and one output qubit. For L=1,2,…U_k the quantum perceptron Q^k_L is a $(U_{k-1}+1)$ for qubit unit. Quantum perceptron's with K hidden layers make up the Res-HQCNN. It uses the layer unitary operator Q^k in the form of a matric product of quantum perceptron's to work on an input state $\rho^{k_{in}}$ of input qubits and obtain a mixed state k+1 out for the output qubits: $Q^k = Q^k_{u1} Q^k_{u1-1} \ldots . Q^k_1$. For 1,2,…$Q_{k,}$ acts on the qubits in layers k-1 and 1, because the unitary operators are arbitrary and do not always commute, the layer unitary order is critical. The residual block structure provides the new input state for layer k+1 by adding the input state with the output state of layer k for k=1,2, …. During the processing of information from 1 into K+1 out and K.

In Fig. 3, "Res" denotes the Res-HQCNN residual block structure. The "Res" can be connected not just layer by layer continuously, but also by skipping one or more levels [13]. Res-architecture HQXNN propagates data from input to output, progressively passing through a network of quantum feeder neurons.

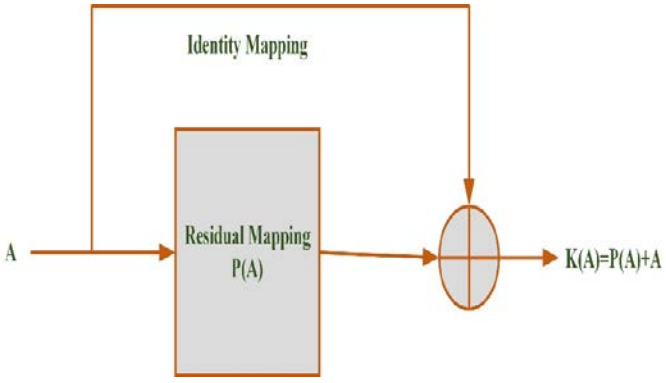

Fig. 2. Residual Block Diagram.

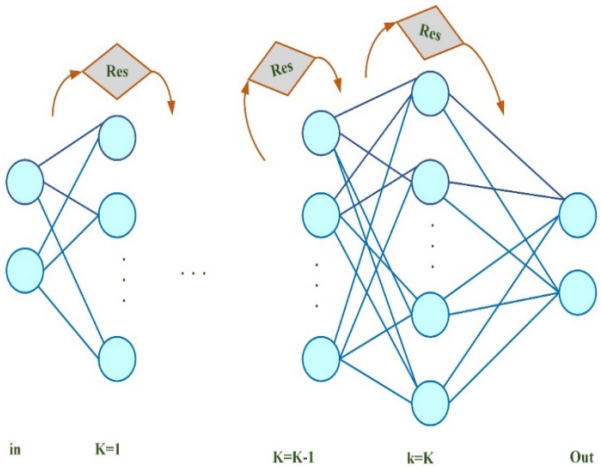

Fig. 3. Res-HQCNN Architecture.

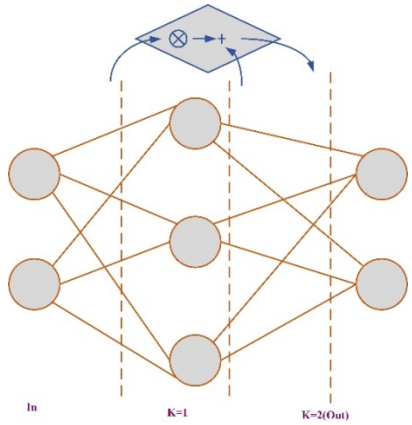

Fig. 4. Res-HQCNN Architecture with unit Hidden Layer.

The mechanism example for Res-HQCNN with one hidden layer in Fig. 4 helps with the comprehension. $Q^1 = Q_3^1 Q_2^1 Q_1^1$, which is a matrix product of quantum perceptron. The layer unitary between the input layer and the hidden layer is defined as $Q^2 = Q_2^2 Q_1^2$. The quantum perceptron's are applied layer by layer from top to bottom in the first stage, and the output state ρ^{1out} of the hidden layer is then computed as;

$$\rho^{1out} = is_{in}(Q^1(\rho^{1in} \otimes |000\rangle_{hid}\langle 000|)Q^{1^+})$$

Then, apply the residual block diagram to ρ^{1in} and ρ^{1out} to get a new input state for the output layer:

$$\rho^{2in} = \rho^{1out} + (\rho^{1in} \otimes |0\rangle\langle 0|)$$

In the following step, to obtain the final output state of Res-HQCNN from Fig. 5:

$$\rho^{1out} = is_{hid}(Q^2(\rho^{2in} \otimes |00\rangle_{out}\langle 00|Q^{2^+})$$

When comparing the previous QNNs to Res-HQCNN, that notice the trace value of the input state ρ^{k+1in} for some k changes as a result of the addition operation in the residual block structure [14]. Indicate k=2, $\rho^{2in} = (\rho^{1in} \otimes |0\rangle_{u_1-u_0}\langle 0|) + \rho^{1out}$, and $\rho^{3in} = (\rho^{2in} \otimes |0\rangle_{u_2-u_1}\langle 0|) + \rho^{2out}$, next trace values of the ρ^{2in} and ρ^{3in} are the 2 and 4, respectively. In theory, ρ^{2in} and ρ^{3in} are not density matrices, hence the training procedure cannot be used in a quantum computer. Every coin, however, has two sides. The residual block structure increases the cost function's performance, especially for deeper networks, as shown in the experiment section. It's also worth noting that the residual block structure can be applied to all concealed layers except the last output layer. Assumed $U_{k-1} \leq U_k$ for k = 1,2,….k and $U_0 = U_{k+1,}$ then the qubits in layer k in general. The final output of the network will be $\rho^{out} = \rho^{k+1in} + \rho^{k+1out}$ if the residual block structure is applied to the ρ^{k+1out} because the dimension of the ρ^{k+1in} is the equal to the dimension, that should use the partial trace on the ρ^{k+1in} to maintain the matrix addition rule.

The previously stated, the Res-HQCNN residual block structure has trouble similar to individuality mapping. But, by doing it will lose some ρ^{k+1in} information, which is incompatible to adopt the residual technique [15]. This also highlights the inefficiencies of applying residual block structure to the last output layer via an experiment.

B. Res-HQCNN Training Algorithm

N number pairs of training statistics, that are possibly unknown by the quantum states, are randomly generalized in the form of $(|\emptyset_a^{in}\rangle, |\emptyset_a^{out}\rangle)$ with a=1, 2,….., and N. It is also permissible to employ adequate copies of a training pair $(|\emptyset_a^{in}\rangle, |\emptyset_a^{out}\rangle)$ of a given a to avoid quantum projection noise, when compared to the cost functions derivative [16]. The intended output $|\emptyset_a^{out}\rangle$ as $|\emptyset_a^{out}\rangle$ = T $|\emptyset_a^{in}\rangle$ is choose to consider with an T as unknown unitary operation.

The cost function is used based on the mean fidelity of the Res output HQCNN and the expected results for all training data. However, to define the Res-HQCNN cost function to divide 2v, where v is the residual block number structures in Res-HQCNN, according to the residual block definition structure and fidelity linear fidelity:

$$R(f) = \frac{1}{2^v N}\sum_{a=1}^{N}(\emptyset_a^{out}|\rho_a^{out}(f)|\emptyset_a^{out}\rangle$$

To know the near network output state and the desired output state are, the higher fidelity. If the cost function equals 1 and 0, consider the Res-HQCNN to be the best performer to be the worst. As a result, the goal in the training process is to maximize the cost function. For each Res-HQCNN layer, that denote $\rho_a^{l_{in}}$ as the layer input state l and $\rho_a^{l_{out}}$ as the output layer state l with l=1,2,….L and a = 1,2,…….N. Consider the scenario in which each layer is added with a residual block structure and there is no skipping layer, then v=L. The Res-HQCNN training algorithm is explained in the following flow chart in Fig. 5.

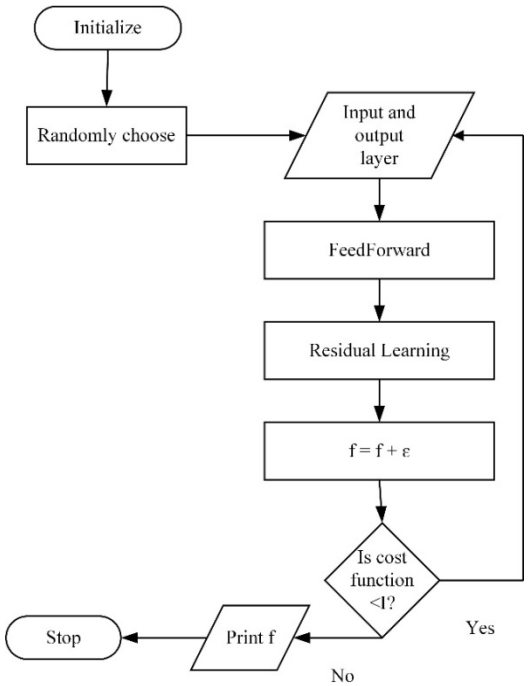

Fig. 5. Training Algorithm Flowchart.

Using a quantum hash function secure the data communication with encryption and decryption. They may occur some threat intrusion. Some types of threats and intrusion are following.

C. Types of Threats

By encrypting and decrypting data using the quantum hash function, data communication can be secured. They may be subjected to some sort of danger incursion [17]. Threats and intrusions of all kinds are on the way. Threats come in various forms:

- Malware.
- Data Loopholes.
- Feeble IoT network outlines.
- Service Denial.

D. Types of Intruders

The types of intruders are trying to intoxicate the network are following:

1) Outer intruder: This is an intruder from a different network from the one they're attempting to intoxicate. They use other networks, but they come to the network to distribute threats and recover data, among other things.

2) Inner network: This is an invader from a network other than the one they're trying to infect. They use other networks, but they come to the network for a variety of reasons, including propagating threats and recover data.

The internet connectivity of intruders on both online and offline:

1) Online Intruder: A danger has been identified as emanating from an internet source. This is particularly prevalent because they take advantage of relatively common IP addresses and can simply steal information from users of the addresses by messing with the network's coded backdrop.

2) Offline intruder: This is an invader who has gained access to the network but does not have internet access. There is virtually little technology available to deal with and counter this type of intrusion threat, yet this is a highly dangerous group of people.

E. Threat Proximity

This information is necessary to demonstrate the degree to which a network user is close to the threat described in the studies [18]. Unfortunately, this method can only be accessed by users of the same network. Due to differences in the functioning of the network, it would be more difficult to draw such a conclusion in the case of an external incursion.

To carry out the threat analysis, the input threat is exposed to a combination architecture of RNN and CNN that chucks the data into bits [19]. The data has a gaussian relationship, and it is assumed that the eventual output, after categorization and regrouping, will be a Gaussian distribution in a very precise manner. The following algorithms were used on the training model:

- Levenberg-Marquardt Algorithm: This approach has been utilized for neural network optimization and is highly useful because the threat is measured on a summation basis [20]. The intrusion is described as a collection of minor threats that add up to a level that is regarded as a threat numerically. Because desire a predefined category of various clusters, the neural network was trained with an input that specifies a certain objective.
- Feed Forward Algorithm: The connections employed in the node do not establish a rotating back dependence, which is ideal for the study. This algorithm is used to train the nonlinear optimization model [21]. It is represented in mathematical as:

  $$f(a) = \frac{1}{1+e^{-a}}$$

  $$f'(a) = f(a)\big(1 - f(a)\big)$$

- Backward learning algorithm: Sensitivity to the impacts of the feed-forward approach for model training. As a result, the feed-forward is primarily reliant on derivative functions, resulting in anticipation. Backward training is a strategy for optimizing a model that involves integration techniques [22]. It minimizes J and so optimizes the cost function for the Jacobian Matrix application.

F. Quantum Hash Function

The hash capacity is presented just in one-way great detail. Selecting the work verification, all single-direction QW work is considered [23]. The single path, solid impact opposition, and fragile crash obstruction are the main characteristics of H-work. The following are the quantum hash attributes capacities:

1) One-direction: It is possible to process the S regard S(G) by giving a data G, but it is computationally impossible to discover the basic data G with a given S regard S(G).

2) Frail crash obstruction: Based on the G data, it is impossible to find another data by computer G1 so that S(G)=S(G1).

3) Solid effect opposition: It is computationally impossible to locate the optional two unmistakably data G and G1 such that S(G)=S(G1). When grasping an S work, these three qualities are key models to consider. Quantum hash work, in comparison to old-style hash work, has more favorable circumstances, such as simple execution and a higher degree of security. Our information verification strategy will become more secure over time. the quantum hash work's nitty-gritty technique is depicted in the diagram below.

Parameter to be selected are [c, $\theta 1, \theta 2, \tau$] under the requirements: c is an odd number and $\{0< \theta 1, \theta 2, \tau < \frac{\pi}{2}\}$ here τ – coin state$|0\rangle = \cos\tau|0\rangle + \sin\tau|1\rangle$, c- number of cycles. In addition, $\theta 1$ and $\theta 2$ are the two controllers of C-QW. The two-coin admin controllers are $\varphi^1 and\ \varphi^2$.

$$\varphi^1 = \begin{bmatrix} \cos\theta 1 & \sin\theta 1 \\ \sin\theta 1 & -\cos\theta 1 \end{bmatrix} \quad \varphi^2 = \begin{bmatrix} \cos\theta 2 & \sin\theta 2 \\ \sin\theta 2 & -\cos\theta 2 \end{bmatrix}$$

The underlying one-information bit selects "0" as its value of φ^1 chooses φ^2. The likelihood dispersion is created by rolling one coin and walking DTQW on a cycle substantially influenced by information G [24]. To frame a twofold H computation, multiply all qualities in the following likelihood circulation by 10i times and maintain only their entire number component modulo 2j with a ≥ b. The S respect has a bit length of mj. This is the methodology used in the most recent QH works conspire, which has a higher level of safety than previous ones. To deservedly chose this QH capability as the approval work.

G. Encryption

The encryption framework works with given data and is a key to creating a figured data that may be delivered through insecure channels without risk of being deciphered by anyone that doesn't have the interpreting key. The key was initially subject to two sets of keys, one open and one private, for security concerns [25]. Initially, to encode, then to untangle, and finally in a different way; this is achievable due to the usage of particular mathematical constraints, which have non-reversible features.

Encryption = S (amount of A/T, S, \open key, A/T)

Decryption = ((m^k) | modified A/T (W)\) * open key

Hash efficiently communicates on little information to produce a string with a known length of G. The IoT sight and sound data are validated by the quantum value, open keys, and restricted irregularity has been able to abuse reduced the S-esteem in light of this worth [26]. The quantum value, open keys, and restricted irregularity have been able to exploit bargain the H-esteem in light of this worth to certify IoT sight and sound data.

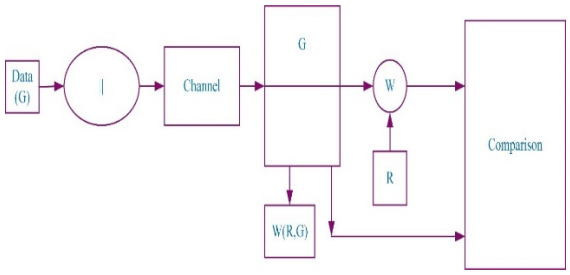

Fig. 6. Hashing Mechanism for Data Authentication.

Fig. 6 demonstrates the general information procedure confirmation. G is the data that will be transferred from the sender to the recipient. W is denoted as verification work is used to scramble the primary information of G. "| |" is a technique for teaching the underlying knowledge as well as the figure script. During correspondence, the square edge is used to symbolize the channel. The key that is utilized to encrypt the underlying data is R.

IV. Result and Discussion

The result examines the Res-HQCNN robustness to noisy quantum data. To compare to employ the same rule to test the robustness. The numerical output from running the two neural networks, RNN and CNN, is shown in the results. As can be seen, the entire input is fed into two robust neural platforms, which optimize the model that has been trained using learning algorithms, and the output is a classification of threats with subfolders indicating the severity of the threats. The level of threats is shown in Fig. 7.

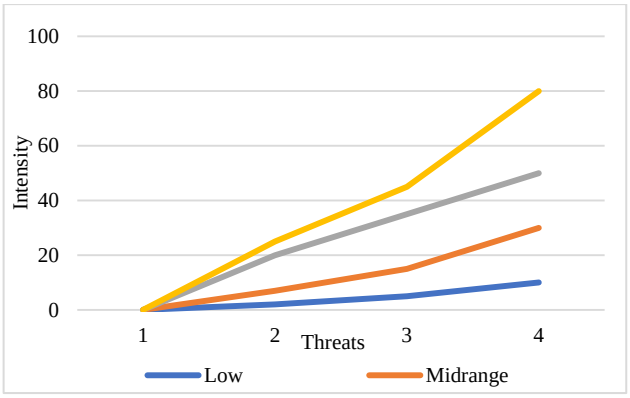

Fig. 7. Threat Ranges.

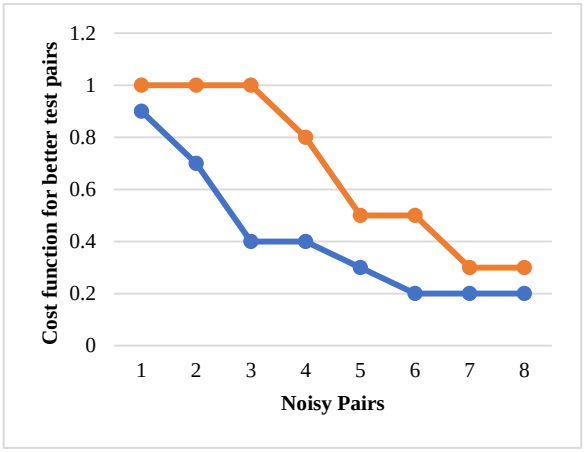
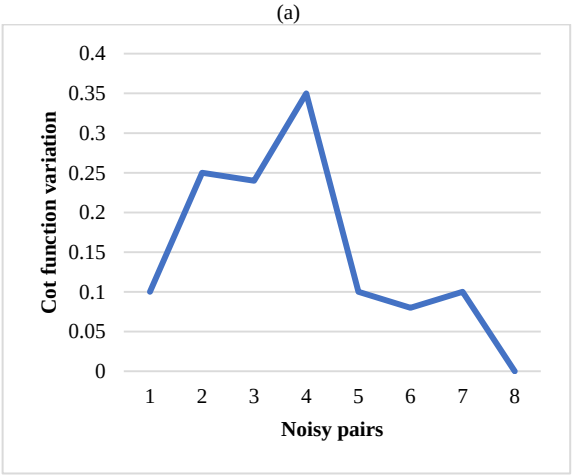
To produce an N better training pairs as $(|\emptyset_a^{in}\rangle, T|\emptyset_a^{in}\rangle)$, then n destroy by changing them with the training noisy pairs. At each period the changed subgroup is selected arbitrarily. Then, the cost function is measured for all the better test pairs. By select the example, Res-HQCNN [4, $\bar{5}$, 4], with η = 1/1.8 and ε = 0.1 is represented on Fig. 8.



(a)



(b)

Fig. 8. Noisy Training Data Behavior.

In Fig. 8(a), the orange line is the Res-HQCNN results and the blue line are the results, respectively. The Fig. 8(b), plots the cost function variations between the orange lines and blue lines. The x-axis in Fig. 8 demonstrates the number of better training pairs is changed by noisy pairs. Assume a small number of training rounds and pairs, for example, 50 training rounds and 30 training pairs. The cost value for both [4, $\bar{5}$, 4] and [4,5,4] decrease as the amount of noisy pairs raises and the cost value variation is always positive. This demonstrates the [4, $\bar{5}$, 4] superiority for noisy training data with the minimum training rounds and the minimum training pairs. Next, assume the amount of training rounds and pairs are increases as training rounds are 200 and training pairs in 100. Res-HQCNN and QNNs both offer robust toughness to the noisy quantum data when the number of noisy pairings is modest, such as less than 35. The cost values for the orange and blue lines begin to decrease at the same time as the number of noisy pair increases.

When the number of noisy pairings hits 60, the cost variation increases, reaching a maximum when the number of noisy pairs reaches 70. This contains three unstable points (55, -0.0115), (90, -0.0161) and (100, -0.0012) then the variation is negative. There are 21 orange line pairs and blue lines. For every period, the better training data ($|\emptyset_a^{in}\rangle, T|\emptyset_a^{in}\rangle$), and ($|\emptyset_a^{in}\rangle, |\emptyset_a^{out}\rangle$) as noisy training data are produced randomly. The ($|\emptyset_a^{in}\rangle$ *and* $|\emptyset_a^{out}\rangle$) elements are casually chosen out a normal spreading before regularization. The training data randomness produces some uneven ideas, it is shown on comparable results. Then, the Res-HQCNN [4, $\bar{5}$, 4] it shows better robustness to the noisy data than [4, 5, 4] QNNs.

To detect the deeper network as [4,$\bar{5}$,$\bar{6}$, 4] to noisy data is shown in Fig. 9. When the amount of training pairs and rounds are minimum like training rounds as 150 and training pairs as 30 on the figure. To notice a sign of improvement from the figure. The cost function variances are always positive. With an increase in the number of noisy pairs, the variation reduces. There is an amount of training rounds and pairs are large, like training rounds as 600 and training pairs 100 in Fig. 10. It's great to have all cost function variances are always positive and there are no unstable points. The greatest variance value is greater than 0.35, but the one in the figure is less than 0.12. This noisy data is deeper as [4,$\bar{5}$,$\bar{6}$, 4] it shows great improvement than [4,$\bar{5}$, 4]. It going via the studies for Res-HQCNN with or without noise and found that it outperforms QNNs in terms of cost function performance. Although this does not exhibit an outcome for Res-HQCNN with the four or more hidden layers, believe that due to the mechanism of its training method, deeper Res-HQCNN would increase cost function performance more.

Fig. 10 and Table I depicts the final results of the presented parameters in the evaluation. To find the encryption size, disentangling size, memory, and execution time as a function of record size. The result shows that as the archive size grows, so does the encryption and unscrambling size. As a result, the execution time grows as well. The result shows that as the archive size grows, so does the encryption and unscrambling size. As a result, the execution time grows as well. In any event, the given paradigm, which differs from various methodologies, secures IoT data in a high-level manner.

Fig. 11 depicts the throughput rate as a function of database size. For every information base size, the QH work provides an ideal level of safety. In QH work, the level throughput is normally excessive, averaging 90%.

V. CONCLUSION

In this research, to enhance the routine of the cost function for the deeper networks, a quantum-conventional hybrid neural network with deep residual learning was used. Based on the QNNs, a new structure of residual blocks in the quantum concept was developed. Then, the Res-HQCNN training algorithm was also made for different cases. The residual block structure, from the standpoint of information propagation, is similar to the ANN mechanism with deep residual learning in that it permits information to travel from the input layer to any deeper layer. The replications are demonstrated by Res-HQCNN's although it can only work on a regular computer. Due to its non-linear disordered dynamic execution and large key space, quantum hashing work has been proposed as a phenomenal tool for secure IoT communication. The benefits of quantum hashing work have been presented in this research effort as the latest breakthroughs in achieving secure data distribution and information assurance based on Q advancements. For the IDS system, a solution result was modelized using RNN and CNN. It consists of all learning models requested by various network providers. The provided approaches are characterized in terms of increased precision, safety, throughput, and toughness over a few well-known assaults, making them suitable for use in a variety of IoT and cloud applications. In the future, use simulation to investigate the QCNN model, which is more cost effective and has best performance. It is necessary to develop an effective data encoding principle for quantum systems and real information. Finding a way to evaluate threats authorized by offline cyber-attacks is a future suggestion. This study was limited to just online attacks that would be heavily discussed.

ACKNOWLEDGMENT

The authors would like to thank the Deanship of Scientific Research at Jouf University for supporting this work by Grant Code: (DSR-2021-02-0378).

Funding Statement: This work was funded by the Deanship of Scientific Research at Jouf University under grant No (DSR-2021-02-0378).

Conflicts of Interest: The authors declare that they have no conflicts of interest to report regarding the present study.

Adding Water Path Capabilities to QWAT Databases

Bogdan Vaduva, Honoriu Valean
Automation Department, Technical University of Cluj-Napoca, Cluj-Napoca, Romania

***Abstract*—The main purpose of this article is to show how to extend an existing open source database, namely QWAT (Acronym from Quantum GIS Water Plugin), by using pgRouting (PostgreSQL routing extension) in order to achieve the ability to find the water flow in a water network. The water path in a water network is a key information needed by any water supplying company for different activities such as customer identification, meter the water flow or isolating areas of the water network. In our environment an open source database was used and that database didn't have any means to identify the water path, so our research is intended into that direction. Once a water path is found, our next goal was to show that identifying customers for a water supplying company is just a click away (by using no directional graphs). Another key information needed by the water supplying companies is to know which valves should be closed in order to shut off the water for an area of the water network. As result, the second purpose of the article is to show how to identify the necessary valves, to be closed or open, in order to shut off or on the water (within the pipe network).**

***Keywords*—Relational database; graphs; water network; water path; open source; QWAT**

I. Introduction

Water supplying companies all over the world needs to know who their customers are and this task is a very important one, for reasons like: knowing to whom they will invoice, knowing how much water was used and if a leak occurs to identify which valves needs to be closed in order to shut off the water. In a previous paper we presented a way of predicting leakage in QWAT[1] databases, but identifying and predicting leakage is not enough, because, any existing or future leakage has a negative impact on the water supplying company's image [1].

QWAT databases are relational databases [2] that models water network pipes, by keeping information like: pipe attributes and geographical position, valve attributes and geographical position, meters, hydrants, network elements, subscribers, leaks. Pipes are kept in a table (within a schema called qwat_od) and have a set of attributes from whom we will focus on two, first node (fk_node_a) and second node (fk_node_b).

In the abstract of this paper, we said that we want to show a way of finding the water path within QWAT databases, but if the pipe table does have a first and a second node, why QWAT model doesn't have a water path function until the final consumer? Or does it? The answer is given by QWAT designers, into their documentation, where they presented how the QWAT model should be used. In that documentation they recommend that pipes should be broken whenever the pipes change their material, function, type or diameter. Other recommendations are:

- Pipes should only be coupled to the right of each intersection with another pipe (Fig. 1).
- Pipes should only be coupled to the right of each intersection with a branch (Fig. 1).
- Pipes should not be coupled in any case to the right of a private branch (Fig. 1).

Those recommendations were put into a picture as in Fig. 1.

If a QWAT database is filled the way described above, the water path should be available, but not actually to the final user/consumer, because, usually, water supplying companies have their own software for customer management and invoicing. We have to outline that, at the time this article was written, there wasn't any function within QWAT database, that allowed to find the water path or extracts the customers for some parts/sections of the water network and we came up with some proposals formulated into a document in 2017. [3].

When it comes to valves they also did some recommendations (Fig. 2):

- Do not cut the pipe on the right of each valve.
- Place the valves on the vertices of the pipe line.

Fig. 1. Example of How to Break Pipes at Intersections in QWAT Databases.

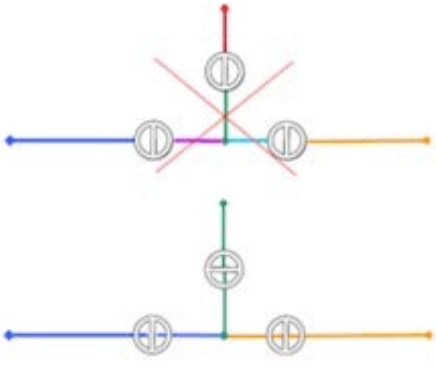

Fig. 2. Example of How to Place Valves in QWAT Databases.

In our case we begin using the QWAT model and we start entering data into that model, which uses a PostgreSQL [4]

[1] QWAT – Acronym for QGIS Water Plugin – http://www.qwat.org

database server. After a few months, we found that even if we somehow link customers, to a water distribution pipe, we can't actually differentiate between customers and all of that, because of the initial recommendations and the way our water network was drew. In our case, the colleagues from GIS (Geographic Information Systems) department, responsible with drawing the water network, were not splitting the pipes every time a pipe intersects a private branch.

We have to clarify what an intersection means from a GIS standing point: two or more pipes that actually connect to each other and not pipes that traverse other pipes (on top or under).

On other hand, getting outside on the field and looking at an actual private branch connection, we found that private branches are directly coupled to the distribution pipe (Fig. 3).

Fig. 3. Example of How a Private Branch is Actually Connected to the Distribution Pipe.

The current paper will continue with the following chapters: Database Background, Database Proposed Changes, Applied Research, Results and Conclusions.

II. Database Background

We started to study the QWAT model and see how and if, can be changed in order to accommodate our needs.

The QWAT model has a table called "pipe" which holds information for each water pipe. That information refers to attributes like: pipe id, pipe function, install method, material, bedding, precision, installation year, node a, node b, parent id, geometry and a few other that are not relevant to our paper. Let's consider a real street, which has a distribution pipe and each private branch is connected to that distribution pipe the way presented in Fig. 3. From a QWAT database standing point, the data is as in Fig. 4 and Table I.

Fig. 4 presents a distribution pipe, on which we placed, one node of the private branches, on its vertices (distribution pipe's vertices). That means that distribution pipe is not fragmented as in Fig. 1 right section and it means that we can't have a path (water flow) from node 38578 (placed on a private branch) to node 38529 (placed on distribution pipe), for example. In order to be able to do that a parallel water network should be created and kept within QWAT database. By having that parallel water network, we will actually create a graph that will contain nodes and edges for describing the water flow.

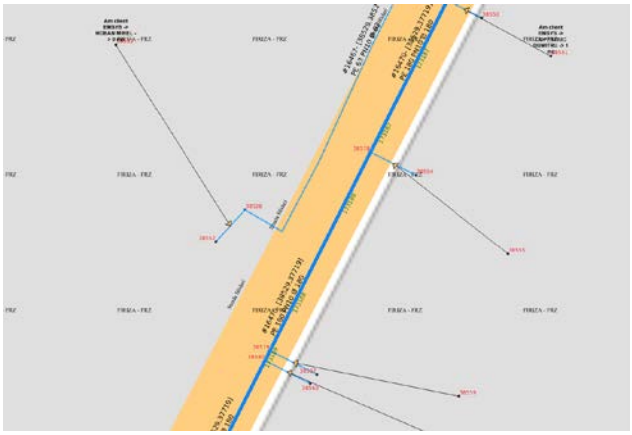

Fig. 4. Example of How a Private Branch is Actually Connected to the main Pipe.

TABLE I. Example of Data Kept in the Pipe Table

Pipe ID	**Pipe Table**				
	Function	***Material***	***Node A***	***Node B***	**…**
16470	Distribution pipe	Steel	38529	37719	…
18900	Private branch	Polyethylene	38580	38560	…
17898	Private branch	Polyethylene	38579	38557	…
14567	Private branch	Polyethylene	38578	38554	…
….					

In the current database model, we can achieve this water path goal only by fragmenting the distribution pipe every time it intersects a private branch. Doing so in a real-life scenario is unrealistic because of the amount of work and can't be achieved.

III. Database Proposed Changes

Analyzing the above data, we came with some initial conclusions and to do list, such as:

1) We need to (somehow) connect private branches to the distribution pipe without redrawing the water network pipes.

2) We need to know/change the valve state in order to be able to have a water path to the final consumer.

3) We need to match a private branch to a consumer.

4) We need to be able to show the water path from the source(s) to any consumer. Knowing that, we will be able to determine which valves should be closed in order to shut off or on the water to a specific customer.

We stated above that we need to address at least four database improvements in order to make it water path friendly. The first improvement on that list: "connect private branches to the distribution pipe without redrawing the water network pipes", it is the one that will allow us to determine the water flow within the water network and further to achieve the other goals on our list.

The first thought we had was to somehow split the distribution pipe, but in real world those distribution pipes are not split (Fig. 3) and our next idea was to build a parallel water

network that will have the desired format. The newly parallel water network will be fragmented as in Fig. 5. Furthermore, that parallel network should be created without asking the user to redraw the network in the format presented in Fig. 1.

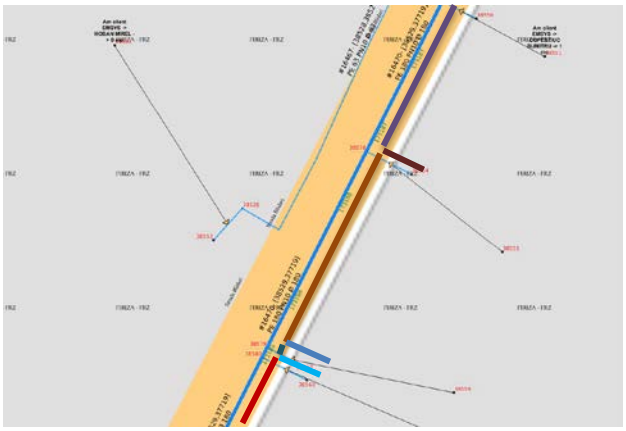

Fig. 5. Example of How we want to Build the Parallel Water Network. We used different Colors just to show that we will have Different Segments.

The parallel network should be built at the same time the user draws the water network in it's usually way, Fig. 4 and 5, where the user does not split the distribution pipe every time it intersects a private branch but places one end of a private branch on the vertices of the distribution pipe. In addition to this goal we figured out that a refresh button that creates that parallel water network for the current bounding box is acceptable and probably necessary.

Once the parallel network will be built we planned to add an existing PostgreSQL extension, called pgRouting [5] to QWAT database.

The first change to the QWAT model was to add a new table, which we called it "pipe_reference" and has the following fields:

- id, integer – an id for each pipe segment that will be generated/created,
- fk_pipe, integer – a reference to the initial pipe,
- fk_node_a, integer – a reference to the first node of the new segment,
- fk_node_b, integer – a reference to the second node of the new segment,
- geometry, geometry – the geometry of the newly created segment.

The reason behind the "pipe_reference" table is to keep the parallel water network saved, for a later use. At this point, we designed the "pipe_reference" table, but that one needed data and we planned to populate it with the help of a new function, called "fn_pipe_reference_update". Further we will present what that function does.

We imagined the function to have as input parameter the ID of the pipe (distribution pipe) that we want to split (ex. 16470 – Table I, Fig. 5). The function works as follow:

- For the input ID we delete all the records from "pipe_reference" having the fk_pipe field equal to the input parameter.
- We select all the pipes (usually private branches) that have one end placed on or near the vertices of the inputted pipe. For all the selected pipes we keep only the nodes placed on the vertices of the inputted pipe.
- Using all the nodes placed on the inputted pipe (distribution pipe), together with the first and second node of it (distribution pipe), we insert the missing rows into "pipe_reference" table (Table II).

TABLE II. EXAMPLE OF WHAT THE PIPE_REFERENCE TABLE WILL HOLD

Pipe Reference ID	**Pipe Reference**			
	Fk_pipe	***Node A***	***Node B***	***Geometry***
1	16470	38529	38577	…
2	16470	38577	38578	…
3	16470	38578	38579	…
4	16470	38579	38580	…
5	16470	38580	38581	…
6	16470	38581	38582	…
7	16470	38582	42086	…
8	16470	40286	37719	…
…				

The next envisioned step was to make a union between the content of the "pipe_reference" table with the records from the "pipe" table for whom the ids cannot be found in any of "fk_pipe" values of "pipe_reference" table. By doing so, we will have the parallel water network (automatically generated), labeled in green, that will be pgRouting friendly (Fig. 6).

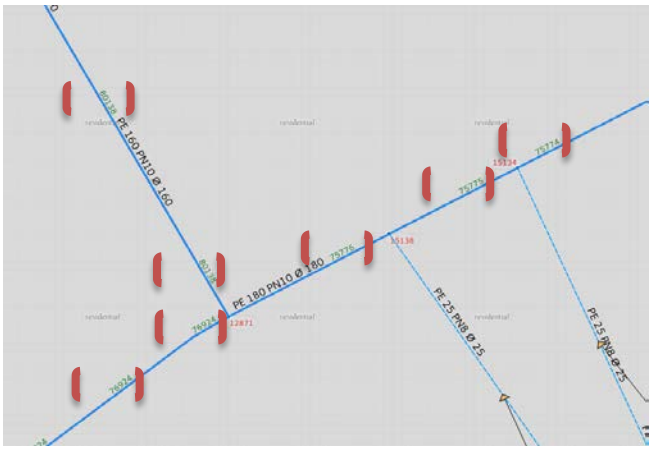

Fig. 6. Example of How the Parralel Water Network was Overlapped with the Pipe Table. Observe the Green Labels in between Orange Brackets on Top of some Pipes.

IV. Applied Research

After envisioning the parallel water network design, we moved forward by adding the new "pipe_reference" table into the QWAT database and the function named "fn_pipe_reference_update" that will construct / fill the parallel network. At the same time, we installed pgRouting in our database server. The new extension, gave us some new routing functions, from which we used "pgr_dijkstra". This function returns the shortest path using Dijkstra algorithm. In 1956 Edsger Dijkstra created a graph search algorithm (graph with non-negative edge path costs) for determining the shortest path [6]. Because the function works on graphs with non-negative edge path costs and because there are valves on pipes (which could be open or closed) we also added a function which we called "fn_element_valve_status". This function checks, if there are valves on a pipe and if one valve is closed on that pipe we consider the cost as being negative.

The example of running the function between node 38557 and node 38529 can be viewed in Fig. 7.

To this point, we addressed only the first and second item on our to do list, but we said that we want have a match between a private branch and a consumer and thus the path from the water source to the final user.

On our map (Fig. 7), we have outlined that each private branch serves a household. At some point the owners can change and we have to take that into consideration. On other hand the information about consumers is kept in a different database that is not by default accessible to QWAT database.

One of the last changes done to our QWAT database was to link the data about consumers into QWAT by adding a new table called "qwat_od_subscriber_location" which has two fields fk_subscriber and fk_location. The first field is a foreign key to "subscriber" table, which is native to QWAT model. The second field is a foreign key to "location" view, in a foreign database that keeps the consumer information and invoices. Regarding the foreign databases that keeps the consumer information and could be linked to QWAT, the only restrictions are related to the fact that those databases should be addressable by a PostgreSQL feature called Foreign Data Wrappers. The "location" view should always give us the information about the current consumer for a specific location.

We built that function that displays basic information about the current consumer at a specific location and the result can be seen in Fig. 7.

We succeed in solving another point in our to do list, but one item was still on that list. It is about the ability to find out if the water flows from one source of the water network to one final consumer.

Knowing which the clients are will allow the water supplying company, to send customized information, to its customers and thus improving its image. Water can flow in either directions on a pipe and as result, we have a no directional graph when it comes to water network pipes. We have implemented the extraction of this graph, in JAVA, on the server side of our web-based application. The result of this tool can be seen in Fig. 8.

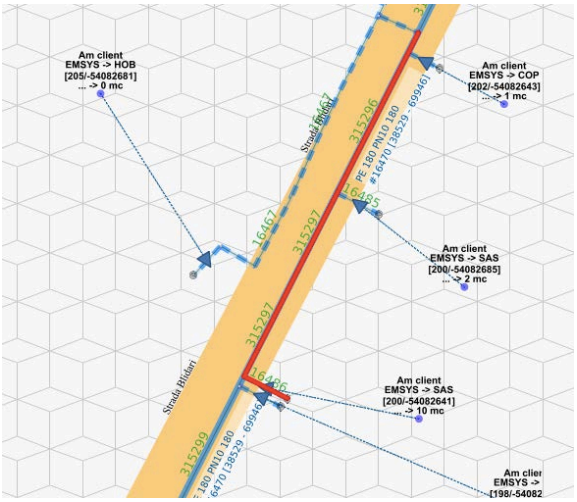

Fig. 7. Example of the Path between Node 38557 and 38529.

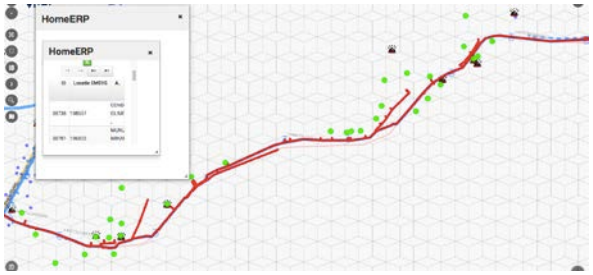

Fig. 8. Example of Determing/Identifying Clients/Customers.

To solve the last item in our to do list, we created a new function within QWAT database that we called "fn_valve_to_close". The new function takes as input parameter, the subscriber, which translates as the end node of consumer's private branch and determines all the water paths from the sources, defined for that water network, to that subscriber/consumer. For all the paths we outline the valves and we color the closest one with green. The result of running the function, on subscriber corresponding to the node 38557 can be seen in Fig. 9.

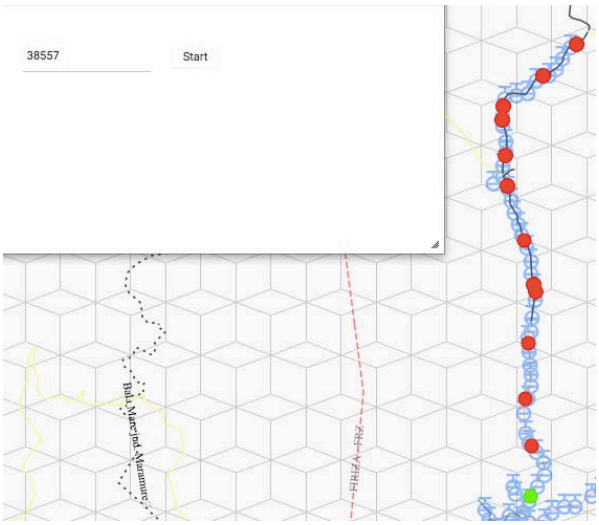

Fig. 9. Example of the Valves that Needs to be Closed for Node 38557.

We have to make a note here, related to "pipe_reference" table. The "pipe_reference" table has to be kept in synchronization with the "pipe" table, which means, that every time a user makes changes, to a pipe geometry, the "pipe_reference" table has also to be updated, to keep up with the modifications.

Regarding the hydraulic analysis that can be done on the water network [8] we have to note that are applications that already do that very well. From those applications we will mention the one called EPANET[2] (software application used throughout the world to model water distribution systems) given freely by the government of USA [9] [10].

V. Result

We showed in our article how an existing open source water network model (QWAT model) can be changed in order to accommodate new requirements, but it was only one of the steps we've done to improve the QWAT model.

Our way of extending the open source model, namely QWAT, it's not the only way, and other persons embraced our ideas and extended QWAT model in a slightly different way, which brought us joy to see that our work has been appreciated [7].

Lately, another idea came to our attention, which is the possibility to use graph databases for our processes [11] [12]. We know that graph databases are suitable for recommendation engines and those can be used in our environment, namely QWAT. Before presenting our envisioned workflow, we have to outline that our relational database data is already in a friendly graph format and already uses a graph extension called pgRouting. All these will probably allow us in the future, to export our data to graph databases and to extract more information out of it. At this point and this time, we formulated the following algorithm to be used to export data to a graph database [13]:

- choose a graph database – only once.
- define case scenarios.
- specify relations or define new views to be exported.
- export the data to graph databases.
- run case scenarios to find out results.
- import results into the relational database and make use of them.

By doing the above steps in an automated fashion we will allow users to focus onto the results and thus maximizing the amount of information extracted from a relational database. We plan to test our proposed use of graph databases in the nearest future and see how much we can benefit out of it.

The work presented in the current paper shows how to find the water path in a water network, modeled in an open source database (QWAT), but there are commercial databases that also do that. One of those commercial databases is proposed by ESRI (Environmental Systems Research Institute). Regarding the performance of our model compared to ESRI's model we can't tell much because of the costs involved in installing the ESRI application.

We used our model for identifying the customers in a Romanian city called Sighetu Marmatiei located in the northern part of Romania. The city of Sighetu Marmatiei has about 20000 customers and from those customers only about 9000 are placed on the map and linked to private branches. The time to extract those city customers using our model is around 2-3 minutes which is a reasonable time.

VI. Conclusion

The current paper shows that an open source database model of a water network can be extended to accommodate new functions and those are similar to the functions from a commercial database. We achieved that purpose by adding tables, functions to an existing relational database, namely QWAT. The new tables and functions allowed us to identify the basic water flow of a water network but that flow did not take in consideration pressure zones or pumps [14]. On other hand our paper didn't go into the hydraulic analysis of the water network.

An improvement that easily can be done by any water supplying company, is to add electric valve actuators, either to every consumer or to valves within the water network and to each actuator add a Wi-Fi circuit breaker. Connecting those circuit breakers to the Internet and further to QWAT model, the water supplying companies will be able to shut on or off water to its clients, remotely [15].

In conclusion our paper presented a way of solving a problem for a water supplying company by using open source databases and their features.

***Abstract*—In olden days it is difficult to identify the unsusceptible forces happening in the society but with the advancement of smart devices, government has started constructing smart cities with the help of IoT devices, to capture the susceptible events happening in and around the surroundings to reduce the crime rate. But, unfortunately hackers or criminals are accessing these devices to protect themselves by remotely stopping these devices. So, the society need strong security environment, this can be achieved with the usage of reinforcement algorithms, which can detect the anomaly activities. The main reason for choosing the reinforcement algorithms is it efficiently handles a sequence of decisions based on the input captured from the videos. In the proposed system, the major objective is defined as minimum identification time from each frame by defining if then decision rules. It is a sort of autonomous system, where the system tries to learn from the penalties posed on it during the training phase. The proposed system has obtained an accuracy of 98.34% and the time to encrypt the attributes is also less.**

***Keywords*—HybridFly; Advanced Encryption Standard (AES); reinforcement; anomaly detection; crime rate prediction; security attacks; RCNN**

I. Introduction

Anomalies always refer to the abnormalities or deviations that occur in regular flow. Since, all the devices in the IoT are arranged in the distributed network manner, the implementation of anomaly has its impact on the designed system in terms of root cause analysis detection, cost and threat reduction. The various kinds of mechanisms that can identify anomaly are discussed in Fig. 1.

The Visual Discovery is the trending approach for anomaly detection process, where IoT connected video surveillances is connected in network. During this process, huge amount of data are captured and it is difficult to work on those data streams with high and multi-dimensions. So, an anomaly marker system is developed, in which threshold is marked with the help of neighborhood estimation. So, an anomaly marker system is developed, in which threshold is marked with the help of neighborhood estimation.

In this existing system, the visualization process helps to form the segments which are occasional and peculiar and it also finds the correlation between different entities that are captured in the data streaming process with in the marked area of regions. The threshold values in this mechanism are dynamic in nature, which are automatically adjustable based on the application data in the marked region. But, the system suffers with unbalanced noisy data.

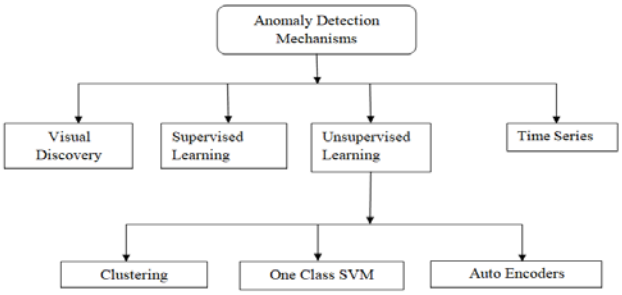

Fig. 1. AD Mechanisms for Crime Predictions.

II. Literature Survey

In [1] the primary goal of an abnormality vulnerable model is to classify the system's characteristics into usual and untruthful behaviors. To assess the tendency of occurrences, smart city managers must use anomaly observation engines to safeguard information from being compromised by flaws or breaches. This paper focused on conducting an analogy of various ML methodologies over DNN by performing a research study to identify the best method that can work with abnormalities in data. This study has chosen the issue of attack type by the rarity in IoT. This study was carried out on various attacks that may occur by the abnormalities and an entire study was made out. The researchers have also developed a grid structure that can determine the various types of interventions and foresee the possibility of happening an intrusion. This research helps in choosing the best methodology for others to perform with their own study from the proposed method depending on their issue as this study explains each method that was used layer by layer.

In [2] an innovative and expert motive that was developed to help in the growth of the resources or for the people using the advanced technologies that connects various electronic gadgets like sensors and work on together by generating a cumulative output is the development of smart cities. This amazing development was deployed in most of the places round the globe, but to make the devices derive better precise

values that helps in yielding best accurate outcomes and to make the developed machine more reliable, DL concepts were opted. This paper relies on various DL techniques and derives a cumulative study depending on the structural enhancement on the smart city information. Along with the usage of these preferred technologies, their usage, utilizations, and post enhancements were also explained.

The standard methodologies used to deploy the values that usually deviate out from the actual information, but it will be useful in some conditions, with mathematical strategies [3]. Such type of data also satisfies a few constraints so that ignoring this information paves data loss. This data can also be included to make the machine perfect. So, these papers focused on deploying a method that trains itself given a condition with all the possibilities available and learn from its experience. This method has shown better results in gaming, as stated and to promote it to next level, this model was applied in real time. This model was deployed and compared with those outcomes of ML techniques with various performance calculations and stated that their neural grid has derived more precise results with less issue and keep tracking of all the abnormalities.

With the increasing growth of intellectual areas and connecting the electronic devices the information is gathered and is shared among the united devices which lead in misleading of the information and exposure of risks is high [4]. So, rather than focusing on the raising technologies, advancing the growth of security devices or systems, analyzing them continuously and to eradicate the unnecessary conditions are also critical. For this issue, ML methods were opted to identify the rate of efficiency of the services provided within the intelligent city with security problems. The researchers have developed a self-learning system that learns from the given constraints or the past experiences from the information that supervises the overall activities that were organized. A neural grid examines the incoming activities and identifies the suspicious activities by breaking down them into chunks of parts since it reduces the difficulties and enhances the performance of the grid.

The problems that may rise due to the connectivity of electronic devices within an intellectual city are as similar as those that arise in an intelligent home rather on a smaller scale, but the risks that may occur to the associated accessories with security and for handling of the information [5]. The consequences of a security flaw are not restricted to online; it could also influence or be assisted in spatial context, for as by speech. Vulnerability assessment in this ecosystem should not rely only on estimation methods that retain the same throughout times and for all participants. The researchers have presented a system that automatically adjusts to is ecosystem whenever a new commodity is introduced that also distinguishes the necessary abnormalities. This method was induced in a reward technique to its attributes under its related ecosystem of untagged data and finds the anomalies.

With the rise in advanced technologies and their applications in real life have changed into a smarter life like form urban areas to intellectual cities [6]. This also helped in usage of various sources and services in hand to very common people as well. But even these advancements have challenges, one of which is power issue. These electronic devices needed to be associated with the commodities and should always be in a communication in share but have limited power storage devices along with the issues in networks and information protection. This paper deployed a statistical self - learning model that focuses on avoiding the DDos aggression on IoT accessories and their networks. These models were deployed based on the correlations of the various models within the layers of the network grids that also focuses on the security uncertainties.

Recently, advancements in connecting the intellectual accessories have improved with various type of grids and development [7]. One of such enhanced topologies with a harmonized structure was implemented in WMN which had derived several powerful attributes for development of the intelligent smart grids NAN with the advancing research on the devices that record the capabilities, working and usage of a smart system. With the raise of such systems, the uncertainties that may happen have dragged the scientist's attention with are related to ignorance of uncertainties. To find those abnormalities patterns, a model that finds out them locally on each site was established throughout the power distinguished model. A self-learning technology with block chain was developed to associate the local patterns of the outliers on a larger image.

The advancements in the connected system under a single ecosystem model were increased regularly and are in a great demand in multiple fields to its varied applications [8]. But increasing technologies also increases that risks with those related to various modules in between. The recent advancements in ML with named or tagged data for distinguishing the objects have helped in reaching out the problems. Detecting the attacker is one of the major problems when dealing with protection of devices in association. This paper has established a methodology focusing on this issue with a model that learns by itself based on the given attributes, constraints set and information of past. This method on working on the same data iteratively develops itself and can distinguish a risk or suspicious action when it is introduced. This research was applied to a live data with tagged names and stated that it has shown a better performance in contrasting with ML models.

The study of 19 unsupervised anomaly detection algorithms is with evaluation for multiple domains [9]. These evaluations focused on strengths and weakness of different approaches. This research is applied on 10 different datasets which is focused on global/local anomaly behaviour on real-world applications.

Prevention from cyber-attacks is very much needed for secure operation [10]. This research paper is about online anomaly detection problem which mentioned a solution for this using model free reinforcement learning. The results generated by this approach show the timely and accurate prevention by detecting the cyber-attacks which are targetting on smart grid.

III. Proposed Methodology

To reduce the crime rate in the smart cities, the proposed system has developed an anomaly detector integrated with reinforcement techniques especially in the remote places during the mid-night hours. The Fig. 2 represents different data frames associated with fire crime accident happened at a business location.

Fig. 2. Fire Accident Captured in Video Surveillance.

Proposed system works on the dataset known as "UCF-Crime Anomaly", which has multi cases video captured records of different crime incidents occurred in various locations in India. The major goal of this system is to identify the criminals and also sends notification to the nearest police station about the incident. The reinforcement technique helps the model in identifying the multiple objects simultaneously and generates a sequence of actions by generating the dynamic rules based on the captured entities. The overall experimental setup is illustrated in Fig. 3.

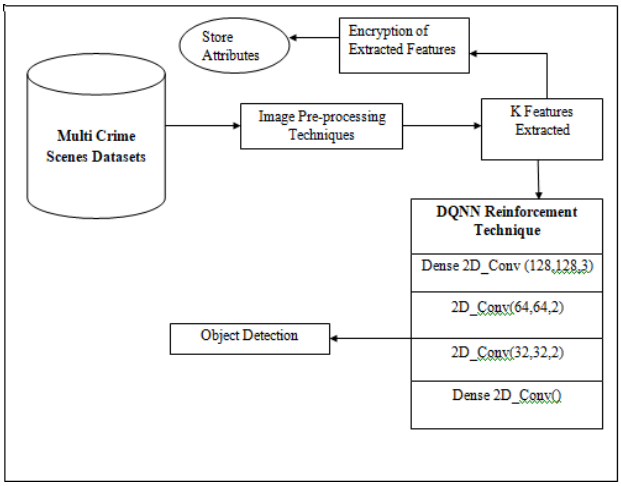

Fig. 3. Object Detection Process in Crime Anomaly Detection.

The proposed model, starts processing the objects and persons captured by the video by finding the facial land marks for the persons and RCNN for the objects. The proposed model uses traditional processing techniques like brightness and geometric transformation.

In brightness transformation, it implements histogram equalization to enhance the quality of the pixels it uses cumulative distributive frequency and produces normalized histogram. The reason for selecting histogram equalizer is it is efficient in dealing non-monotonic and non-linear structures. The crime scene contains more number of dissimilar and complex structured figures. So histogram equalizer is the apt brightness technique. In geometric transformations, the proposed algorithm majorly focuses on interpolation based on Grey scale factors. The change of direction or enhancements to the images produce new co-ordinates, these values may not be accommodated. The system needs interpolation mechanism to fit these new co-ordinates system. The proposed system implements linear interpolation technique, in which the neighboring pixel values are examined and considers the value with maximum brightness function as output.

Then for the person identified images are fine tuned to remove the noisy data during the capturing process and extract the important features. The proposed system uses the concept of dynamic fly to select the adaptive features and extract the needed features. The concept of genetic algorithm is opposite to the correlation because the attractiveness property states that distance have inverse impact on the attraction. The extracted features are encoded using Hybrid Fly algorithm to protect the information for further mishandling by the attackers or hackers.

Algorithm: Pseudocode for Attribute Encryption using Hybrid Fly Algorithm:

Begin

1. Define an objective function of K-extracted dimensions
2. Set up initial dimensions as firefly population, k
3. Determine the intensity for each firefly group based on the threshold
4. for each i 0 to k
5. for each j 0 to i

i. if (F[i]>F[j])

Then update the firefly to next fold

ii. Else

Calculate attractiveness distance based on the threshold

iii. best_feature[i] Update rank value for each feature by finding the best score

6. new_feature AES(best_feature[i],key=256)

End

In the proposed system, model free Deep Q-Learning Neural Network(DQNN) technique is implemented by defining an action value function in terms of current state and action to be performed on the current state by the agent based on the rules generated by the AO* algorithm. The major goal of this NN model is to maximize the rewards in every iteration

so that the time to detect the object decreases. The reward function is defined as shown in (1).

DQNN(S_New, A_New)←R(S_New,A_New)+α* max(S_old,A_New) (1)

In every iteration DQNN, updates the table associated with state and action. The states are passed as input to the neural network, which is designed as the auto encoder. All the Q-values are obtained as continuous output. The "tanh" activation helps the regressor in predicting the output variable. The output of the objection is represented in Fig. 4.

Fig. 4. Person Identification in Crime Scene.

For object detection, the CNN creates the feature map based on the selective search to create new regions of interests in the network. The visual attention mechanism helps the system to consider the weighted average mechanism, to obtain the new vectors.

IV. Result and Discussion

The proposed system to prove its efficiency, it has performed a comparative study on the different existing mechanisms and is illustrated in Fig. 5.

Fig. 5 represents different algorithms compared on the x-axis and accuracy percentages on the y-axis. There is a clear evidence that proposed model has exhibited best accuracy among all the others. The model has also obtained recall and precision values in terms of identifying the true positive and false negative labels. The model also discusses the comparison based on the encryption time of different security algorithms and the proposed algorithm and is illustrated in Table I.

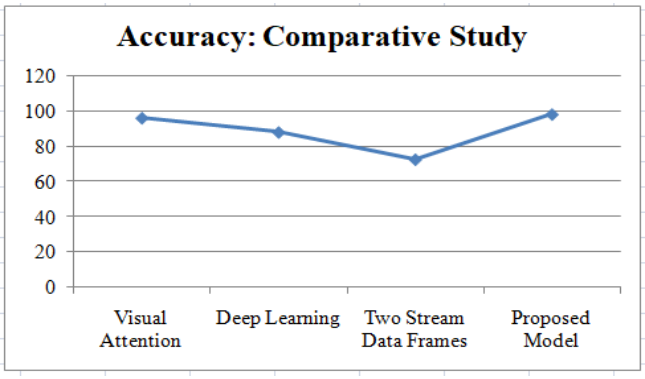

Fig. 5. Fire Comparative Study on Accuracy in Predicting the Object Detection.

TABLE I. File Encryption Time

S.No	Input Size in MB	RSA	DES	Proposed
1	25	0.485	0.41	0.334
2	50	0.535	0.443	0.352
3	75	0.563	0.499	0.431
4	100	0.625	0.542	0.46

In Fig. 6, X-axis represents size of the file in MB as mentioned in Table I and Y-axis represents time in nano seconds.

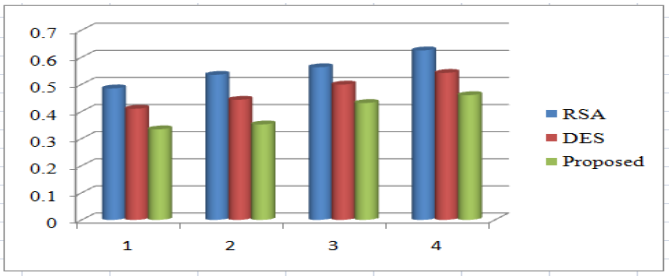

Fig. 6. Encryption Time- Comparative Study.

When compared to RSA and DES algorithms, proposed algorithm has got less time to encrypt the file and the encryption time increases when the file size increases. This description is illustrated in Fig. 6.

V. Conclusion

With the reinforcement technique it is observe that high precision and accuracy values are obtained with very short training of the system. One of the advantages of the proposed system is assigning ranks to the peculiar objects that has been captured and also reduces the ranking losses that incur due to the miss-classification of the objects. The background subtraction process helps the system to improve the quality of the software and integrated visual attention mechanism can also works fine in identification of moving objects. The involvement of the computer vision has enhanced the quality and training phase automatically without any human intervention. The proposed system has implemented model free technique because it consumes less space, since it does not involve any storage of states and actions but it applies brute forces techniques. So, the knowledge updation is time consuming task. In the future work, research can be extended based on the time lines and historical data that happened frequently in the span of time which involves model based techniques.

***Abstract*—Increasing agricultural productivity such as tomatoes needs to be increased, considering the consumption growth reaches 6.34% per year. Efforts to increase productivity can be made through several methods, such as counting and predicting the time of fruit to be harvested. This information is a a visual problem, so computer vision should solve it as an automation method in the industry world. With this information, the farmer can monitor the tomato fruit growth. The proposed method is a framework that has been implemented in real-time processing. To obtain growth information of tomatoes, the tomato area can be used as a region of interest (ROI) every week or another scheduled time. As the challenge of this research, this ROI can be extracted using segmentation analysis. The segmentation method used is Mask Region-Convolutional Network (R-CNN) with ResNet101 architecture. The accuracy of this method is obtained from the similarity value between the proposed method and the ground truth used, namely 97.34% using the Dice Coefficient and 94.83% using the Jaccard Coefficient. This result indicates that the method can extract the ROI information with high accuracy. So, the result can be used as a reference for the farmer to treat each tomato plant.**

***Keywords*—Deep learning; Mask R-CNN; segmentation; tomato; growth**

I. Introduction

Tomato consumption from 2016 - 2020 increased from 883.23 thousand tons to 1,084.99 thousand tons, or an increase of 6.34% from 2019 [1]. Despite an increase in production, tomato fruit has perishable properties and is classified as a climacteric fruit, where the peak of respiration and ethylene production occurs at the beginning of fruit ripening [2]. This can cause tomatoes to be easily damaged, causing a reduced supply of tomatoes at the consumer level and food insecurity. In addition, tomato production also faces future challenges in scarcity of water resources, soil salinization, and other abiotic stresses. The growth and development of tomato plants are influenced by several factors, including temperature, humidity, and altitude. If the environment does not support the growth and development of tomato plants, it will affect the productivity of tomato plants.

Increasing agricultural productivity through several methods, such as fruit counting and prediction of fruit to be harvested and early detection of environmental diseases and weeds, can be done at this time. Solutions for utilizing the latest technologies such as deep learning, the internet of things, and robotics are very effective and efficient for plant management [3]. Smart farming systems can reduce waste, increase productivity, and allow the management of more resources through remote sensing [4]. Remote monitoring through intelligent farming systems allows production yields to increase because farmers need a lot of time to solve pests, soil conditions, rain, or weeds, which can now be done through remote sensing and automation. A survey that has been conducted [5] has analyzed various articles related to deep learning technologies, and each work is compared with existing techniques. Deep learning methods have been widely used in various fields of agriculture, such as plant disease detection, crop classification, weed identification, fruit counting, land classification, obstacle detection, image translation, weather forecasting, yield prediction, and animal behavior classification [6].

Deep learning technology that has been applied to the horticultural domain for variety recognition, yield estimation, quality detection, growth, surveillance, and other detection, where this review aims to assist researchers and provide guidance to them in the use of deep learning. This guide is to understand the strengths and weaknesses that may occur when implementing deep learning. From the results of a review that has been carried out [7], there is a deep learning technique for object detection that is commonly used in horticultural crops, namely Convolutional Neural Network (CNN). There are three types of object-based detection with CNN; the first is object recognition such as LeNet, AlexNet, VGGNet, GoogLeNet, and ResNet, while the second is a combination of the first method with two-stage detection to achieve improved and accelerated detection. This method includes R-CNN, Faster R-CNN, and Mask R-CNN. As for the third type, detection is for one stage, which can immediately give the results of object boundaries according to their position. Using these models, fruit yields can be estimated automatically, and plant stress levels can be detected early. An agriculture science model with the help of deep learning techniques can be used to detect leaf diseases with images of corn, peaches, grapes, potatoes, tomatoes, and strawberries [8][9]. In this case, the image processing technique used is the CNN model for plant disease detection. The tests that have been carried out give an accuracy rate of 94.29%.

The Faster R-CNN method in the classification process of apple objects can give very accurate results [10]. A citrus fruit yield mapping system has been developed using a robotics platform [11]. The results of presenting the Fast R-CNN method used to detect citrus fruits that have been taken from different conditions (distance to fruit, camera angle, and slight

variation) with the implementation of this method give better results than the human process with an Average Precision score (AP)=0.76. The blueberry fruit calculation process has been automatically developed based on ripeness and maturity classification with deep learning methods. In this case, what is used for blueberry fruit segmentation is the R-CNN model by producing an average precision for validation and test datasets is 78.3% and 71.6% below the 0.5 intersections over union (IOU) threshold with an accuracy of 90.6% and 90.4%, respectively [12].

There is another framework, namely the YOLOv3 framework, which has been modified to YOLO-tomato, which can show better results than other advanced methods so that the YOLO-tomato method is better for detecting tomatoes in real-time with complex tomato environmental conditions [13]. The deep learning architecture used in general is a semantic segmentation architecture such as Deep Neural Network (DNN) in the field of Computer Vision (CV) [14]. The most popular DNN architectures are AlexNet, GoogleNet, VGGNet, and Resnet. Implementation of semantic segmentation techniques with DNN architecture has several problems, one of which is caused by the many parameters involved or overfitting. DNN requires high-quality labeled data and large-scale data. So, an effective solution is to build large, high-quality data sets that are difficult to achieve. Semantic detection in real-time is very important because it can be useful in autonomous systems and robotic interactions. Therefore, several new methods are adopted to increase computational efficiency, accuracy, and background noise. The semantic segmentation architecture is a fully convolutional network (FCN), ParseNet, deconvolution network, U-Net, feature pyramid network (FPN), and Mask R-CNN. The survey results show that there are many scopes of improvement in terms of accuracy, speed, complexity, and overfitting problems, so that new methods or combinations of semantic segmentation architecture are needed to increase efficiency and accuracy. In one extension of this model, [15] proposed a Mask R-CNN for object instance segmentation, which beats all previous benchmarks on many COCO challenges. This model efficiently detects objects in an image while simultaneously generating a high-quality segmentation mask for each instance. Mask R-CNN is essentially a Faster RCNN with three output branches. The first computes the bounding box coordinates, the second computes the associated classes, and the third computes the binary mask to segment the object. The Mask R-CNN loss function combines the losses of the bounding box coordinates, the predicted class, and the segmentation mask and trains jointly. In this research, Mask R-CNN is used to segment the tomato area. The segmentation is more challenging than object detection or classification because all subject areas should be identified, and the pixel that false detection would have become an error of the method. Mask R-CNN more comprehensively detecting the region rather than R-CNN with masking method.

II. METHODS

This research proposes a framework consisting of several stages, namely image data collection, image data labeling, data set separation for training and model validation, then continued by building a model and implementing segmentation using Mask R-CNN and ending with similarity testing between segmentation results using the deep learning method with manual segmentation results. In detail, the stages in the proposed framework can be seen in Fig. 1.

A. Data Collecting

All images were obtained from the primary data captured from tomatoes in a greenhouse. The data was collected from tomatoes is planted in the period from July to September 2021. The commercial tomato varieties planted and used as the data are Tora, Servo, and Tatyana. These varieties can live in the lowlands. The image was taken using a mobile phone camera and mobile robot camera with resolution 2592×1944 (5MP). The image contains multiple objects inside. The total dataset collected is about 600 images (includes 210 images Tora, 185 Servo, and 205 Tatyana). From these images, there are 2476 objects of tomato that can be identified visually. In this study, no preprocessing stage was applied to the image to be tested. Only train data needs to be labeled to support the Mask R-CNN method, and this is related to system development in actual conditions, where lighting and image transformation obtained are unavoidable. An example of an image data set can be seen in Fig. 2.

B. Image Labeling

Image segmentation aims to recognize and understand what's in the image at the pixel level. Every pixel in an image belongs to a single class, as opposed to object detection, where the bounding boxes of objects can overlap.

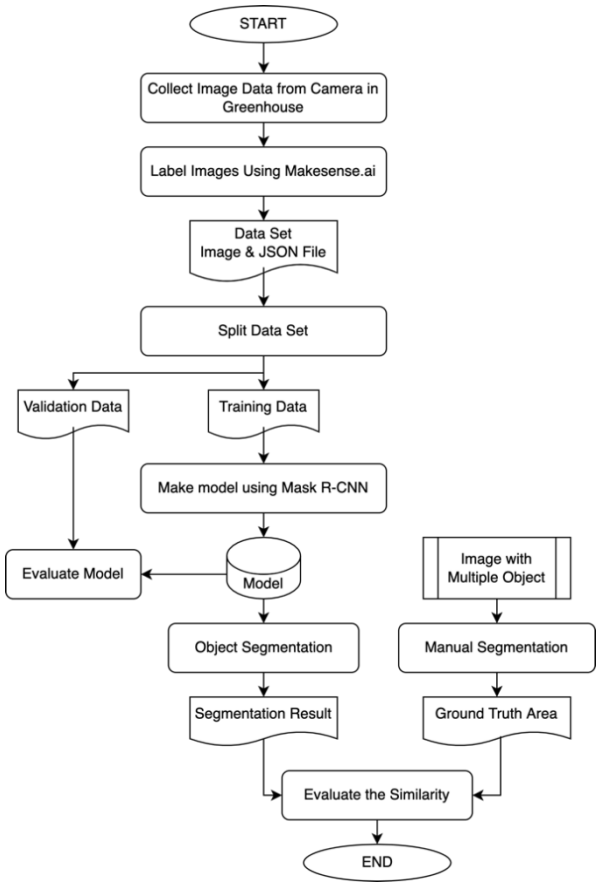

Fig. 1. Proposed Framework.

Fig. 2. Sample of Image Data Sets.

Fig. 3. Image Labeling Process using Maksense.ai.

Therefore, one preprocessing stage is needed in image segmentation, namely, image labeling. As shown in Fig. 3, an example image labeling, there are two tomatoes, so the model should be identifying all the pixels belonging to each tomato. That's where instance segmentation comes in. With instance segmentation, multiple disparate regions can belong to a single instance of a class. Each tomato in the example is annotated as an instance of the tomato class and is also given an ID such as "Tomato 1," "Tomato 2," and so forth. Therefore, the model can identify all the pixels belonging to an individual tomato even if the instance contains multiple regions.

The labeling process gives a point on the edge of the object. These points will be connected to form a polygon line. The coordinates of these points will be stored in a JSON file which must be called when executing the training model method.

C. Modelling and Testing using Mask R-CNN

Mask R-CNN is a deep learning framework that can detect objects in an image that generates a segmentation mask for each instance or commonly called instance segmentation [15]. This method runs on Faster R-CNN [16] (can be seen in Fig. 4), so that in performing mask detection, the R-CNN can be divided into three parts, namely: (i) feature extraction network, (ii) region-proposal network, and (iii) instance detection and segmentation networks.

1) Feature extraction: Mask R-CNN applies multiple backbone architecture. Some of the backbones used for Mask R-CNN are ResNet, ResNet, and FPN. In the Region Proposal Network (RPN) process, a Region of Interest (RoI) will be generated through an alignment process which will then be input for the instance detection and segmentation networks.

Mask R-CNN uses a combination of ResNet101 architecture and FPN (Feature Pyramid Network) to generate RoI features when feature extraction is performed. FPN is a basic component in the recognition system to detect objects at different scales using the same image.

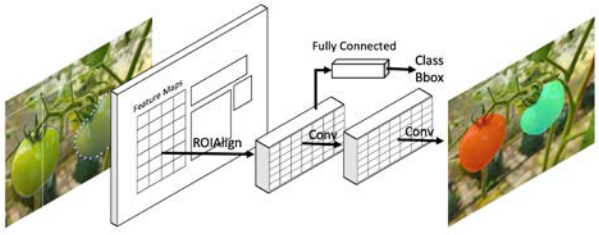

Fig. 4. Mask R-CNN Architecture.

FPN uses a variety of feature maps to produce higher-quality information. FPN is a feature extractor designed using the pyramid concept but is superior in speed and accuracy. FPN processes information in two ways, namely bottom-up (bottom-up) and top-down (top-down).

Bottom-up data processing extracts features using ResNet, in which the spatial dimension of each layer decreases while the semantic value increases. Top-down processing increases the resolution of the semantic layer, but the location of objects is not precise. FPN adds lateral connections between reconstructed layers and a corresponding feature map to help detectors better predict locations. Lateral connection is the convolution and addition operation between the two corresponding levels of the two pathways. FPN surpasses the single ConvNet because it retains semantic features at various resolutions.

From ResNet101 four feature maps were extracted (layer-1, layer-2, layer-3 and layer-4). An approach called the top-bottom pathway is used to produce the final feature map. The top-bottom pathway approach starts from the top feature map (x/32, y/32, 256) and starts down to a larger feature map by applying the up-sample operation. A 1 x 1 convolution was performed to reduce the number of channels to 256 before sampling and then added elements to the up-sample output from the previous iteration. All up-sample outputs were applied to a 3 x 3 convolution layer to produce the last four feature maps, while the fifth feature map was generated from the max-pooling operation.

2) Region proposal network: Each feature map generated in the feature extraction process will go through a 3 x 3 convolution layer. But before that, the feature map is scanned using anchor boxes with various scales and ratios. The resulting output is then forwarded to two branches, one relating to the objectivity or confidence score and the other to the bounding box regressor. A confidence score can be obtained by calculating the IoU (intersection over union) between the bounding box and the ground truth. IoU is obtained by dividing the overlapping area by the combined area of the ground truth and bounding box. The confidence score ranges from 0 to 1. The greater the Confidence score means, the higher the system confidence that the object contained in the bounding box is the object to be detected.

3) Instance detection and semantic segmentation: The segmentation instance process is carried out using a fully connected network that takes RoI as input to detect the presence of objects, bounding boxes, class labels, and confidence values. A fully Convolutional Network (FCN) is

used to perform semantic segmentation on the image by predicting the semantic class of each pixel in the bounding box. This causes each instance to display a different color according to its bounding box.

D. Manual Segmentation

A manual segmentation process is needed to generate Ground Truth data. This data is used to compare whether the segmentation process using the Mask R-CNN method is successful in approaching expert judgment. Manual segmentation is carried out using an image processing application to remove or change the background with black color or a value of 0 (see Fig. 5.b) and then convert to a binary image (see Fig. 5.c).

E. Similarity Evaluation using Dice and Jaccard Coefficient

Dice and Jaccard coefficient have been utilized to measure the segmentation accuracy. Rockefeller used these coefficients in the segmentation in cucumber seed [17]. The Jaccard coefficient measures similarity between sample sets. It is defined as the size of the intersection divided by the size of the union of the sample sets. Sample sets are obtained by mask (black, white) image on every region from segmentation result and ground truth image, to be detailed see Equation 1. Samples sets contain, i.e., the region of interest from algorithm segmentation result and manual segmentation by an expert judgment as ground truth data. The Jaccard coefficient also called Intersection over Union (IoU), is used in the Mask R-CNN evaluation model.

$$J(X,Y) = \frac{|X \cap Y|}{|X \cup Y|} \quad (1)$$

Where X is the set of every region from segmentation and Y is the set of every region from the ground truth image, which has a true value (1 in binary image).

Then, almost like Jaccard, Dice distance is also utilized to measure the similarity, but it has different properties, Equation 2. Dice are used as an optimist measurement which gives the double weighting value on the true positive value (intersection of two regions).

$$D(X,Y) = \frac{2|X \cap Y|}{|X| + |Y|} \quad (2)$$

Where 2 |X ∩ Y | is the double weighting of number value which is intersected on two data sets. While |X| and |Y | are the number of data sets which are having true value (1).

(a) (b) (c)

Fig. 5. Manual Segmentation Process. (a) Original Image, (b) Remove or Change Backgorund, (c) Convert to Binary Image.

III. Results

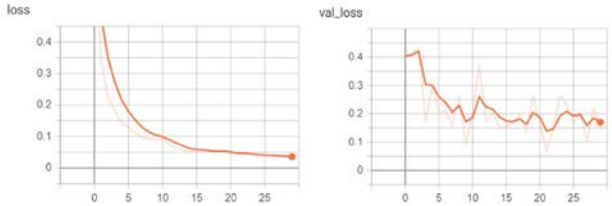
A. Model Evaluation

To conduct training and validation, 530 data sets were used consisting of various types of age and tomatoes. Of all the data sets, 70% are used as training data sets and 30% for testing data sets. The evaluation of the results of the model form can be seen in Fig. 6. Fig. 6.a shows the training loss, which goes towards 0 as the epoch value increases, while Fig. 6.b shows the validation loss, which is 0, although it is not as good as the training loss. However, these two graphs are convergent, showing that the model formed is fit, meaning that the model can predict the data set outside the training data.

B. Segmentation Result

After the model is formed and thorough evaluation, it is declared fit. Then the model is then used to perform image testing segmentation. Mask R-CNN can perform segmentation by providing a mask, and at the same time assigning class labels as class numbering "Tomato-1" and "Tomato-2" so that objects can be separated. In addition, this method can also provide a bounding box accompanied by a confident value from the results of the class classification. In Fig. 7.a can be seen the segmentation results, where the confident value can also be seen. Fig. 7.b and Fig. 7.c are the results of extracting fruit areas "Tomato-1" and "Tomato-2".

The next process is to calculate the number of pixels from the area of each tomato. The first process is to convert the image into a binary image or a value of 0 (black) and 1 (white). Furthermore, the total number 1 in the image can show the number of pixels of each object. Fig. 8 shows the result of converting an image into a binary image.



(a) (b)

(a) (b) (c)

Fig. 7. Segmentation Result. (a) Image Segmented with Mask, (b) Tomato-1 Area, (c) Tomato-2 Area.

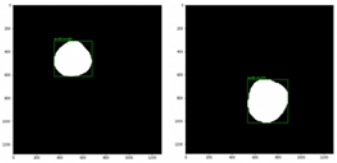

Fig. 8. The Result of Binary Conversion Process.

C. Segmentation Evaluation

Segmentation results are evaluated using the Dice and Jaccard coefficient. This method is used to assess the similarity between the proposed method result and the ground truth obtained through manual segmentation. In Fig. 9, the segmentation results using the proposed method do not have smooth or imperfect edges like manual segmentation results. Thus, this deviation makes the difference in the number of pixels between the two. The evaluation results show that the first image has a similarity value based on the Dice coefficient of 97.90. This value shows 97.90% of the pixels in the segmentation area with the proposed method are the same as the manual segmentation results, likewise, with the Jaccard coefficient, which shows a value of 95.90. Jaccard always gives less value than Dice.

In Fig. 10, the graph of the similarity evaluation results on 30 data sets used as testing data can be seen. The graph shows that the average evaluation result is above 90%. Only one image can be segmented with a similarity value of about 87%.

The average evaluation results for 30 images with the Dice coefficient is 97.34% and using the Jaccard Coefficient is 94.83%. These results indicate that the Mask R-CNN can segment well on the image of tomatoes from various types of tomatoes and tomato colors. Thus, the calculation results in the form of some pixels from the tomato area can be declared valid so that the research can be continued with analyzing the development of tomatoes.

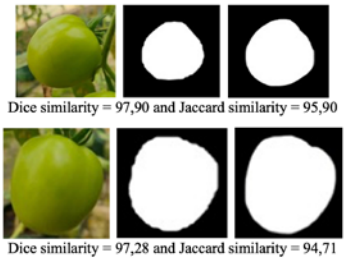

Fig. 9. Segmentation Evaluation. Left: Original Image, Center: Proposed Method Result, Right: Manual Segmentation Result.

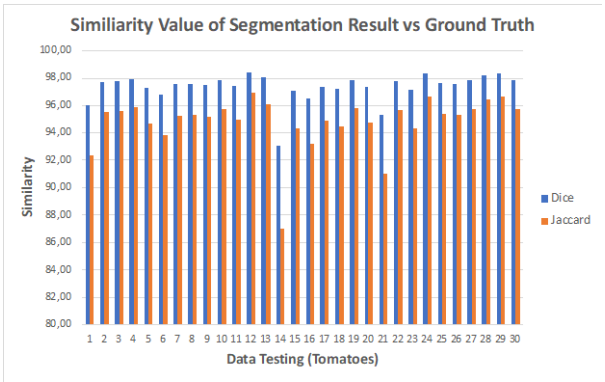

Fig. 10. Similarity Value of Segmentation Result vs Ground Truth.

IV. Discussion

One of the indicators related to the increase in tomato production is the growth of tomato fruit after flowering. The camera can capture fruits formed for a week as objects that have characteristics, namely round or oval or other shapes according to the type of plant. Tomato fruit growth can be seen from the area of the fruit. Although the picture of the fruit must be taken from a consistent direction, for example, in the first week after fruit formation is taken using a camera from an angle of 180 degree or straight from the top of the tree, then in the following week, it is taken from above as well. Likewise, if taken from the side of 90 degree.

In Fig. 11, you can see a graph of the increase in the ten observed fruits (not all of them are shown due to the clarity of the graph). Some fruits have different growth patterns. Knowing each fruit's growth pattern or average can be recommended regarding environmental engineering and proper fertigation. Thus, fruit growth can be evenly distributed, and harvest targets can be achieved.

Tomato fruit development during four weeks of the observation showed good development and was detected by increasing the number of pixels area. Tomato fruit develops every week marked by increasing fruit dimensions and fruit color that changes from light green to a red tinge and finally red. The time required by tomatoes from flowering to harvesting was 5-6 weeks [18]. In Fig. 12 can be seen the average of tomato fruit growth in a week, which shows how each tomato grows and require special handling for such fruit like tomato 5 and 6. According to [19], the weight of small vegetable tomatoes has an average weight of < 50 g per fruit, medium size with a weight range per fruit of 50 - 70 g, and large size with a weight per fruit of > 70 g. This size unit must be converted in some pixels by volume calibration, so the unit can match the image processing standard.

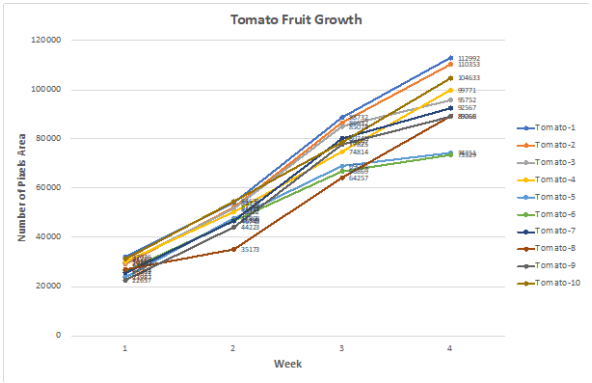

Fig. 11. Tomato Fruit Growth in 4 weeks after Fruit Formation

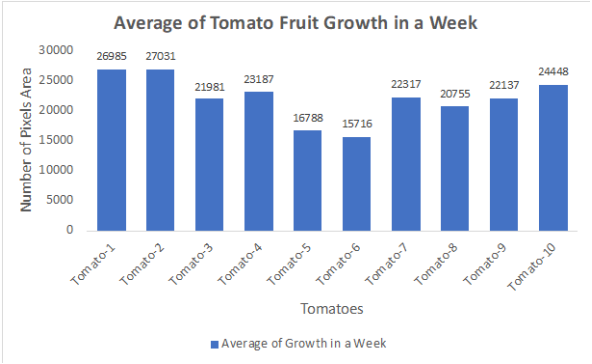

Fig. 12. Tomato Fruit Growth in 4 weeks after Fruit Formation.

V. Conclusion and Future Work

The Mask R-CNN method can perform properly and has accuracy as indicated by the similarity value measured by the Dice Coefficient and Jaccard Coefficient with an average value of 97.34% and 94.83%, respectively. This similarity value indicates that this method can be used to find the Region of Interest area of tomato objects so that it can be used to measure tomato growth. The entire system has worked in real-time with various problems such as lighting, morphology, and transforming fruit shapes and other objects. The real-time segmentation method is difficult to implement using K-Means, SVM, or Neural Network methods. For future work, it is necessary to calibrate the fruit weight unit (kg) into the volume, while in terms of the proposed method, a volume estimation process must be added. Thus, higher accuracy will be obtained regarding the analysis of tomato fruit growth based on the image.

Personalized Recommender System for Arabic News on Twitter

Bashaier Almotairi, Mayada Alrige, Salha Abdullah
Department of Information Systems
Faculty of Computing and Information Technology
King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—Reading online news is the most popular way to read articles from news sources worldwide. Nowadays, we have observed a mass increase of information that is shared through social media and specially news. Many researchers have proposed different techniques that focus on providing recommendations to news articles, but most of these researches focused on presenting solution for English text. This research aimed to develop a personalized news recommender system that can be used by Arabic newsreaders; to display news articles based on readers' interests instead of presenting them only in order of their occurrence. To develop the system we have created an Arabic dataset of tweets and a set of Arabic news articles to serve as the source of recommendations. Then we have used CAMeL tools for Arabic natural language processing to preprocess the collected data. After that, we have built a hybrid recommender system through combining two filtering approaches: First, using a content-based filtering approach to consider the user's profile to recommend news articles to the user. Second, using collaborative filtering approach to consider the article's popularity with the support of Twitter. The system's performance was evaluated using two evaluation metrics. We have conducted a user experimental study of 25 respondents to perform an assessment to get the users' feedbacks. Also, we have used Mean Absolute Error (MAE) metrics as another way to evaluate the system accuracy. Based on evaluation results we found that hybrid recommender systems would recommend more relevant articles to users compared to the other two types of recommender system.**

Keywords*—Hybrid recommender system; online social network; Arabic news recommendation

I. Introduction

The magnitude of data generated on the Internet by different business communities, administrations, industrial sectors, scientific research and general data has increased immeasurably [1]. The research of [2] has reported that the world produces about 2.5 quintillion bytes of internet data daily, and almost 90% of this data is unstructured. Similarly, on social media sites, there is a massive bulk of un-related data and other non-authentic news which cause the users several issues related to privacy, psychological problems and many more. Organizations and some users need different new methods to process the extensive, massive data, on social media, into meaningful comprehensions. A report by [3] stated that more than half of the world's population is presently using the Internet and more than 250 million population use Arabic.

Understanding Arabic words and their vowels and consonants is still lacking in machine learning and getting the proper theme of the words written in Arabic. This situation is due to the significant number of Arabic languages subcategories with different accents and meanings, which cause the listener to misconception the idea [4]. The text categorization to assign a category to Arabic language content on the Internet and in social media lags behind the actual outcomes, since there are no firm rules for Arabic language understanding by machine learning systems [5]. Part of these massive Arabic data on social media and other platforms is news. The relation between journalists and audience is shifting towards the use of new technologies and algorithms in digital news. Several platforms display your content in this digital world as YouTube, Instagram, Facebook and different news sites and journals. Different other platforms are being used in news field, but not all of these platforms are authentic and reliable for the news and data collected.

This research's motivation is the need for a valuable tool or system to help readers in such information overload situations. Thus, the news at any site can be displayed in an order based on the reader's interests, instead of using the same order of presentation for all readers based on a publisher's opinion. The motivation for the solution comes from [1], where the researcher has developed a news recommender system with the help of micro-blogging services. News articles are sorted based on the popularity of the article, which is identified using tweets from the public timeline of Twitter. The researcher has also built the user profile based on the user's interests, so the news articles are sorted by matching the user profile's characteristics. The research of [6] has developed a personalized recommender system for calculating the closeness between Twitter users in a social circle. The system suggests topics or interests that users may have to analyze social information. This solution and other similar propositions have already been presented English medium, but not in the Arabic language.

The research aims at developing an Arabic recommender system to display news or articles to each reader based on their interests instead of presenting them only in the order of their occurrence using Twitter.

The research is organized as follows. Section 2 gives a comprehensive overview of recommender systems and discusses other researchers' work in this field. Section 3 discusses the process of data gathering and preprocessing to move to Section 4, where it describes the design and implementation of our Arabic news recommender system.

Section 5 discusses the evaluation of the proposed system's result using one of recommendation systems evaluation metrics. Finally, Section 6 summarizes the research and suggests future works.

II. Literature Review

A. Recommendation Systems

The rapid increase in the amount of accessible digital data and the vast numbers of Internet users has generated a possible knowledge overload problem that sometimes hinders timely accessibility to online information or needed items. Data gathering systems, including Google, Altavista and DevilFinder, have slightly fixed the issue, but the personalization and prioritization of the information have been missing. It has generated a much higher demand for recommendation systems compared to older times. These systems are considered as knowledge retrieval systems used to tackle the issue of overloading information [7]. This is done via filtering essential fragments of information from a substantial amount of dynamically produced information as per user interest, actions or preferences noticed regarding specific items [8]. Using information from user profiles, recommendation systems possess the potential to predict if a user will choose something or not [9].

While several strategies have been established in the past, research is still ongoing as it is mainly used in many apps that configure suggestions and deal with overloading information [10]. These systems benefit both service providers and users [11], they substantially reduce transaction costs for detecting and choosing products in an online retail environment [12]. These systems have been shown to enhance the reliability of the decision-making process. When setting up e-commerce, the recommended systems boost sales since they successfully sell more products [11]. Throughout libraries science, these systems assist consumers by encouraging them to step past index searches. Recommending programs assist consumers of research libraries by encouraging them to pass beyond catalogue searches. Consequently, the need to utilize precise and effective recommendations strategies inside a program that can offer reliable and relevant advice to consumers could not be overemphasized [9].

B. Recommendation Systems' Approaches

Using systems of recommendation that are both reliable and efficient is necessary for a program that aims to offer excellent and practical guidance to its user, demonstrating the value of knowing the characteristics and potential of different domain approaches. Classifying recommendation system is usually based on the rating estimation [10]. Generally, there are three approaches to recommendation systems:

- Collaborative filtering approach.
- Content-Based filtering approach.
- Hybrid Filtering approach.

Collaborative filtering is a domain-independent predictive strategy where the information cannot be conveniently and accurately classified via metadata, e.g., music and movies. This approach operates by constructing a database with user preferences for specific items. Afterwards, it groups the users with related preferences and interests to make recommendations by calculating how similar their profiles are [13]. Content-based filtering technique uses an algorithm which is dependent on domain and relies primarily on evaluating the properties of objects for producing predictions. It is most suitable where documents such as publications, web pages and news, have to be recommended. Throughout this method, recommendations are provided using user identities formed by using features that have been derived from the contents of those items that previously have been reviewed by the particular user, so the system will recommend the user of items that are so related to the items he/she liked before [14,15].

To understand the difference, Content-Based filtering requires information about items' features, instead of using user's interactions and feedback. Good examples are movie attributes such as actor genre, year, director or textual articles content. On the other side, Collaborative filtering doesn't require anything else except the user's historical preference on a set of items to recommend from. So it assumes that user who has agreed in the past will also tend to agree in the future [14,15].

Traditional filtering techniques have distinct weaknesses and strengths. For instance, Collaborative filtering suffers from cold start and sparsity issues, whereas content-based suffers from need and narrowness explanation. Nevertheless, hybrid solution that uses one method to render recommendations where the other fails lead to a more reliable recommendation framework [16,17]. Hybrid filtering combines various recommendation techniques to optimize the system's optimization to avoid specific difficulties and challenges with the systems of recommendation [18]. By using more than one filtering technique, the limitations can be minimized and the recommendations will be more accurate in a hybrid model [19].

C. Current Researches in Recommendation Systems

Some researchers have proposed the hybrid recommendation system technique as an excellent solution to solve or enhance their research issue. The research [20] has discussed the impact of visual information, i.e., customers' photos and put on some blogs, to predict favourite restaurants for any given user. By considering the visual information as an intermediate, the researcher suggested integrating two common recommender system approaches, collaborative filtering and content-based filtering, to show the proposed hybrid system's effectiveness with considering visual information. Another research of [21] has described a recommendation system built on a probabilistic programming language and discussed the benefits and challenges of explaining the generated recommendations to users. Using an online user survey, the research evaluated the explanations for hybrid algorithms in a set of text, visual and graph formats, which are either new designs or derived from existing hybrid recommendation systems. Moreover, the research showed that hybrid systems demonstrate better accuracy than recommendation strategies that use a single source.

A study of [22] had focused on creating an engine for a product recommendation, which can be accessed by third-party software to obtain certain product recommendations using some input data. The study's overall aim was to make novel contributions on how the user events can be gathered and processed and how they can be used by the methods of data mining to make product recommendations. The study has solved product recommendations appropriate for big data by investigating methods to process user event data.

D. News Recommendation Systems

The relation between journalists and audiences is shifting towards new technologies and algorithms in digital news [23]. Several platforms display the digital world's content as YouTube, Instagram, Facebook and different news sites and journals. Different approaches are being used in the news field, but not all platforms are authentic and reliable for the news and data collected. These news fields serve the expanded eyes of the viewers or listeners. The study of [24] showed how the news topics could be used to recommend English news articles. The researcher used supervised learning methods such as Naive Bayes, linear regression and logistic regression. All of these machine learning models have a different nature to determine the user ratings for an article. The research of [25] has presented a robust system for providing English real-time news recommendations to the user based on the user's history of the last visits to the website, popularity of stories and current user's context.

E. Arabic Language and Recommendation Systems

Arabic language is one of the most widespread languages globally [26], spoken by more than 422 million people. Its speakers are distributed in the region known as the Arab world and many other neighboring regions such as Turkey, Chad, Mali, Senegal and Eritrea. Arabic language considered as one of the Semitic languages that are rich in syntax (words arrangement to make phrases and sentences) and its morphology (the structure of internal word) [27]. There are three forms of Arabic language: classical Arabic [28], which is the language of Islam's Holy Book (Qur'an) that is not used in daily life, modern standard Arabic (MSA) as well as dialect Arabic. MSA is the standard form that is used in official news, education and media.

Unfortunately, the Arabic language's Recommendation Systems did not acquire enough attention [29]. It happened due to the limited number of tools and other challenges related to the language's nature. According to [30], the Arabic language became a challenge for researchers and machine learning developers due to language richness, language complexity, ambiguous structure of Arabic, and available Arabic types dialects.

F. The Microblogging Service Twitter

Microblogging is a general term of any web service that allows the users to broadcast short messages to other users of the service quickly from mobile devices. One of the first microblogging services is Twitter.com [31]. Twitter is one of the digital platforms where users can read news. It is a microblogging or a social networking service on which users can post and interact with messages known as tweets [32]. Registered users can like, post and retweet any tweets, while unregistered users can read them only. Any user can access Twitter through the website interface, through short message service SMS or its mobile application.

Now-a-days, Twitter has become one of the most popular services with students, academics, politicians, policymakers and the general public. In the past, many users find some difficult in understanding what Twitter is and how they can use it. However, now it has becomes the social media platform of choice for many.

In collaboration with research company DB5, the American Press Institute with Twitter has created a new study that explores and examines the relationship between news use and the Twitter environment [33]. The study involved an online survey of more than 4,700 active social media users. It found that Twitter users tend to be heavier newsreaders than other social media users. The study also found that reading news is one of the main activities they engage in on the network.

While these users on the service in general, or sometimes do so just as a way of passing the time, they behave differently when following breaking news. They participate, comment, post and share at moments more when events are moving fastest. These signals can lead news publishers to make more effective use of social media in general and Twitter in more particular.

Due to the limitation discussed above, we propose a hybrid personalized Arabic news recommender system that recommends interesting articles or news to users using Twitter service. The proposed tool sorts the news in two ways: Firstly, using a content-based filtering algorithm to consider the user's profile to recommend news articles to the user. Secondly, using collaborative filtering algorithms to consider the article's popularity with tweets from Twitter's timeline. We propose this approach to help users find interesting news articles to read by combining the above two filtering techniques of sorting articles [34].

III. Data Gathering and Preprocessing

A. Data Collection

1) Obtaining news articles: In order to collect Arabic News articles, we accessed RSS (Really Simple Syndication) feeds of online Arabic news sites such as Alarabiya (https://www.alarabiya.net/) and CNNArabic (https://arabic.cnn.com/). RSS is an XML file format created by news website editors for distributing and sharing web content, such as news headlines and summaries. Using an RSS reader, users can view data feeds from many news sources [35]. Alarabiya and CNNArabic organize their news articles by categories, e.g., Politics, Economics, Sport, etc. Therefore we know the associated topic for every article in the collection. The article collection includes 150 different Arabic news articles collected from six different main categories (Sports, Economics, Technology, Entertainment, Health and Politics).

2) Obtaining tweets dataset: In order to obtain a dataset of tweets, a streaming API is set up to store incoming tweets as

soon as they are posted in the Twitter public timeline using Tweepy Library. The data returned from Twitter streaming API are formatted using JSON (JavaScript Object Notation). In this research we only need the text attribute that contains the actual tweet text, the other attributes in the tweet object were ignored. The dataset for this research is a collection of 100,000 of last published tweets which are collected along with the news articles dataset on the same day.

B. Data Preprocessing

To create all data preprocessing steps for Arabic text, we decide to use CAMeL tools [36]. It is an open-source toolkit for Arabic natural language processing in Python. CAMeL tools offer utilities for preprocessing, dialect identification, sentiment analysis, named entity recognition and morphological modelling. What makes CAMeL the most suitable tool for our proposed system is that it is implemented in Python which is our research programming language, whereas other available tools are only supporting Java. The tools also provide APIs and command line interfaces in order to cover CAMeL's utilities, where others provide only command-line tools. This can lead to overhead writing glue code that includes interfaces to different packages. Through using CAMeL tools, we have followed the steps below in order to preprocess the obtained data.

1) News articles cleaning: The RSS news articles need to be preprocessed before making them ready for implementation. We needed to remove unnecessary content such as numbers, special characters and HTML tags.

2) Tweets cleaning: On the other side the tweets dataset need to be cleaned as well to eliminate unwanted noise and preserve textual content only, this can be done be by addressing the issues of character replication, abbreviations, hashtag, URLs, usernames, whitespace and removing repeated tweets.

3) Tokenization: The first step after data cleaning is tokenization; this step consists of splitting the text into tokens or words separated by punctuation characters or whitespaces. The result of this phase is a set of words.

4) Normalization: It is the process to change all the forms of a word into a common form. To get texts common forms, the added normalizer removes the 'tatweel' character '_'such as changing the word "واســـع" which means "wide"to look like "واسع ",and tashkeel such as "هُدنَةٍ" which means "truce" to make it as "هدنة". There are also other steps include removing symbols and special characters such as ! ? (), numbers such as 6which is 6 in English , non-Arabic words such as طبعا "NO", and Al "ال التعريف" which is used as the definite article 'the' in English. We will also replace the letters "أ" and "إ" with the letter "ا" and the letter "ة" with the letter "ه".

5) Stop words removal: Stop words such as prepositions and pronouns are used frequently in tweets and news articles dataset. We decided to remove them since they are not significant in the research. For instance, these words have been removed: "من" of, "على" on, "انت" you and so on.

Fig. 1 shows the general dataset cleaning and preprocessing phases.

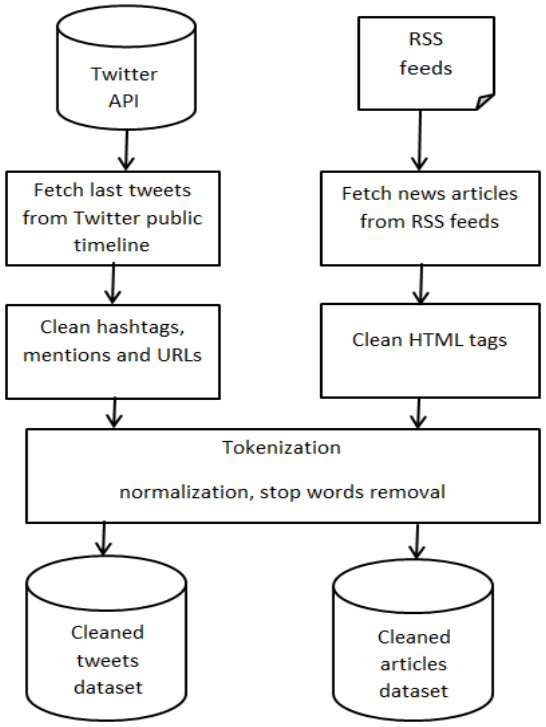

Fig. 1. Dataset Cleaning and Preprocessing.

IV. Design and Implementation

A. High-Level Design

Our proposed system consists of three parts: collaborative recommender system which is popularity-based, content-based recommender system which is profile-based and hybrid recommender system which is the combination of the two previous systems.

The first recommender selects news articles based on the popularity of the article. In this research, the article popularity is identified with the help of the Twitter service. So tweets are gathered from Twitter public timeline and preprocessed to identify the articles that users around the world are tweeting. The tweets are then compared to the news articles based on the co-occurring terms in the articles and the tweets. Articles that mentioned frequently in the tweets will be considered popular or hot.

The second recommender sorts the news articles based on their similarity to the user's profile. In this research, the users build their profiles by providing input about their level of interest in each of six news categories. The incoming news articles are classified into same set of categories using K Nearest Neighbors text classifier. This classifier works by finding the K nearest matches in the training data and then using the label of closest matches for predicting [37]. The articles are then sorted based on the similarity between the categories the user showed interest in his/her profile and the categories which the article belongs to.

Finally the hybrid recommender combines the results from the two recommenders to recommend news articles to the user. It sorts the new articles based on the combination of their popularity ranking and the similarity to the user's profile.

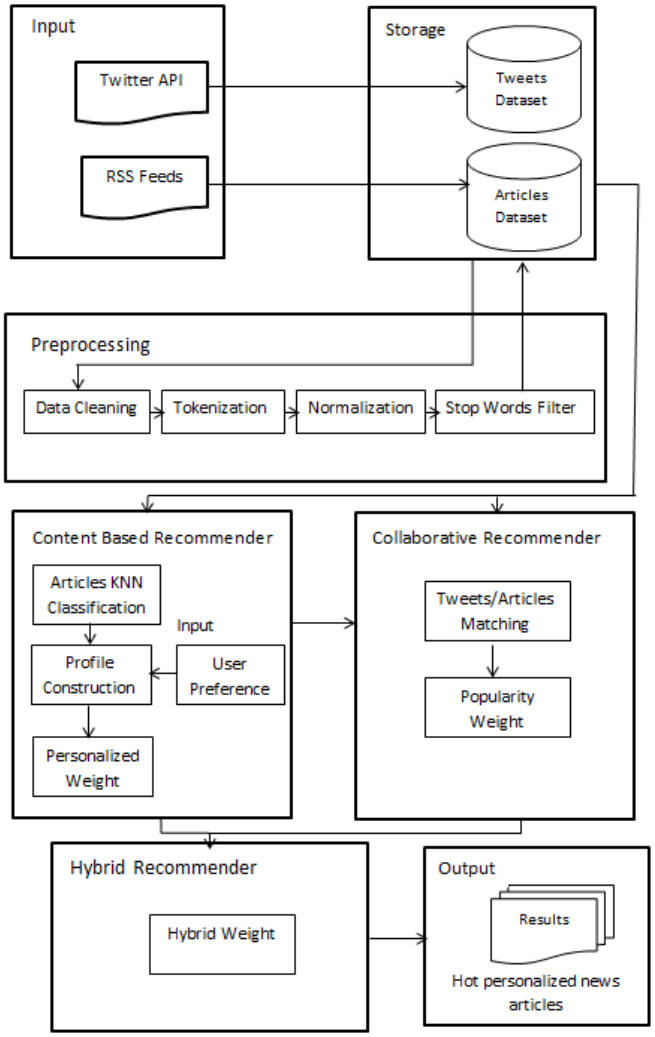

Fig. 2. General Architecture of the System Components.

Fig. 2 shows an architectural diagram of the proposed hybrid recommender system.

B. Collaborative News Recommendation

After the RSS news articles are gathered and preprocessed, the news articles are then indexed using ElasticSearch. ElasticSearch is a free open source search engine built on top of Apache Lucene [38]. It can index many types of content and can be used for several cases such as website search, application search, monitoring application performance, business analytics, etc. It is known for its simple REST APIs which make it flexible to use from any programming language. In addition, it supports 34 languages including Arabic and provides analyzers for every language.

To identify the most popular news articles, the processed tweets are passed as queries to ElasticSearch server. Every tweet is queried against the server to return the articles that correspond to the tweet content. The server returns the articles associated with the tweet content together with a weight that refers to the similarity between the tweet as query and the article. So the articles are sorted according to their accumulated weights across all tweets. The news articles will be ranked based on their popularity using cosine similarity measures between articles and tweets as shown in (1) [39].

$$\text{Popularity Weight} = \text{CosineSimilarity}(\text{Article}, \text{Tweet}) \quad (1)$$

C. Content-Based News Recommendation

This recommender uses the same news articles collection as in the collaborative recommender. Although, news articles are placed in just one category by the website editors, they actually might belong to more than one category. To allow for that in the recommender, each news article is classified into seven potential categories using K Nearest Neighbor classifier. With this algorithm we can classify the articles into categories based on the articles similarity to the training documents for each category.

K-Nearest Neighbors classification algorithm [37] identifies K most similar training documents to the article and then uses these similarity scores as a vote for the category that the training documents belong to. Thus the article similarity to each category is the sum of the scores of the article's similarity to the training documents in that category which placed in overall top K most similar documents. So then the categories are sorted through their accumulated score. Then we use ElasticSearch again to create a second index that maps from category IDs to documents IDs and weights. So this index stores news articles based on the category that they belong to instead of the keywords in the article.

Every user creates his profile based on his interest in different categories, every user has an interface to build his profile manually by scoring the categories. Fig. 3 shows the interface that allows the user to create his unique profile. Each user will enter scores in the range of (0-10) so that the total at the end will equal to 10.

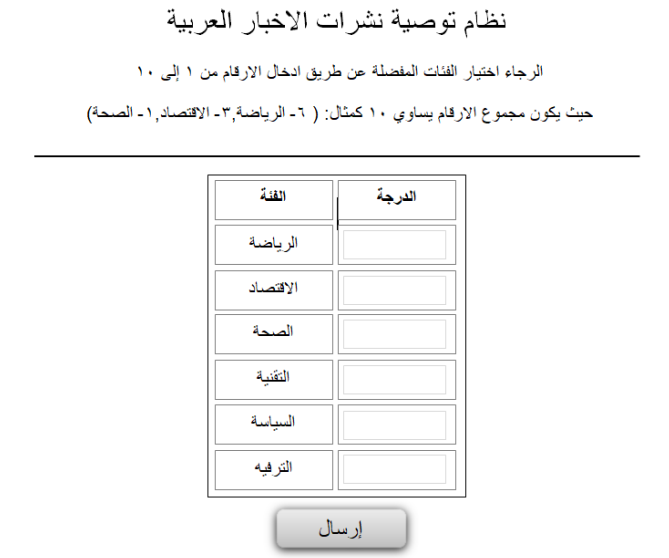

Fig. 3. User Profile Interface.

After that, this user profile is used to identify the documents which best match his profile. The articles and profiles can be considered as feature vectors where every category is a feature. In (2) we have used cosine similarity measure [39] to get the similarity of each article to the user's profile as shown below.

Personalized Weight = CosineSimilarity(Article, Profile) (2)

D. Hybrid News Recommendation

This system combines the scores result by each of the previous two recommenders to generate a new recommendation that integrates the news articles' match to the user's interest with the news articles popularity everywhere. It calculates the hybrid weight through multiplying popularity weight by personalized weight as shown in (3) [40].

HWeight= Popularity Weight* Personalized Weight (3)

V. Evaluation

One of the important phases in building any recommender system is evaluation. There are different metrics to evaluate the performance; the most common are accuracy and experimental studies [41]. Accuracy metrics are divided into decision support and statistical metrics. Decision support metrics show prediction procedure as a binary operation (0 and 1) to distinguish good items from the items that are not good while statistical metrics evaluate the accuracy through comparing the predicted rankings or ratings directly with actual rating.

Deciding about the suitable metric depends on the dataset features and the type of tasks that the recommendation system will do. Based on our research and collected dataset we have evaluated our system through the two metrics, calculating the statistical accuracy through using Mean Absolute Error (MAE). The other metrics is done through performing a user experimental study to measure user satisfaction.

A. Mean Absolute Error (MAE)

It is the most commonly used metric in recommender systems [42]. This metric provides measures and illustrates the difference between the actual and estimated prediction over many items and users. It is given in (4):

$$MAE = \frac{\sum_{i=1}^{d}|a_i - p_i|}{d} \quad (4)$$

Where a is actual observation and p is predicted value divided by d which is the total number of actual ratings or ranks in an item set, the smaller value of MAE the better accuracy we get.

To calculate MAE, we have divided the dataset into training and testing sets. 70% of the data has been used as training set and the rest 30% of data has been used as test set, so variable R in Table I represents the train/test ratio that illustrates the percentage of data used in training set. We have compared MAE results across the three filtering approaches as shown in Table I.

Fig. 4 shows the comparison results of the three filtering approaches, we can observe that the greater value of R is the Lower value of MAE. Besides the most important thing we can notice is that hybrid filtering has the best MAE results compared to the other two approaches.

B. User Experimental Study

We have created a random sample of 25 respondents (n=5) who are native Arabic Speakers from different educational levels. The respondents have created their user profiles manually by providing their interests in the six news categories to form the user profile. Every respondent has a web page to enter weights for every category and the weights must be sum to ten. We also have made three results sets from news collection for every respondent based on the three filtering approaches. The presentation order of news articles was random so the respondent could not realize which system recommended the articles. The respondent has asked to rate each article in a 3-point likert scale as it is relevant to his interest, somehow relevant or not relevant. When the respondent finishes, all information such as filtering approach, article's rank, article's weight, and respondent's rating are logged into a file. Fig. 5 shows a snapshot example of one of the respondents' response.

TABLE I. MAE Comparison Results

Training Ration	Content-Based filtering	Collaborative filtering	Hybrid filtering
R=0.1	0.646	0.618	0.520
R=0.2	0.634	0.597	0.502
R=0.3	0.619	0.569	0.497
R=0.4	0.602	0.547	0.471
R=0.5	0.578	0.524	0.454
R=0.6	0.554	0.502	0.422
R=0.7	0.521	0.478	0.387

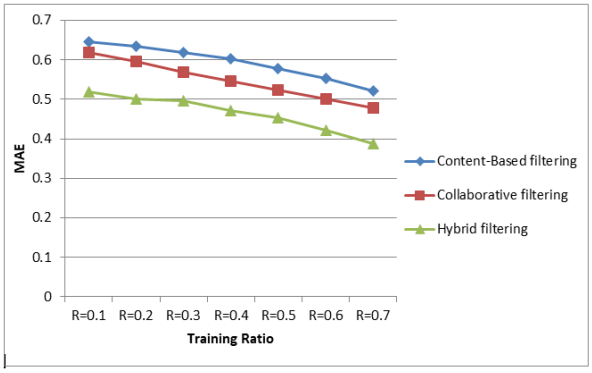

Fig. 4. MAE Comparison Result.

ID	S1 Rank	S1 WT	S2 Rank	S2 WT	S3 Rank	S3 WT	Resp Rating
122	70	0.16634	7	0.91926	20	0.15291	1
621	10	0.47541	138	0.00028	143	0.00013	0
540	25	0.37411	11	0.91634	6	0.34281	2
131	43	0.27787	6	0.92714	13	0.25763	1
618	3	0.68637	0	0	0	0	0
604	6	0.57957	33	0.69677	2	0.40383	2

Fig. 5. Example of Respondents' Response.

In Fig. 5, S1 Rank refer to where the article was ranked by the collaborative recommender and S1 WT indicate the normalized weight of that article, the same information is available for S2 (the content-based recommender) and S3 (the hybrid recommender). The Resp Rating column shows how the respondent rated each article, where 2 is for relevant, 1 is for somehow relevant and 0 for not relevant. To analyze the result we have calculated the average rank for all respondents over the three filtering approaches as shown in Table II.

TABLE II. AVERAGE RANK

	Not relevant	**Somehow relevant**	**Very relevant**
Collaborative	58.3	70.0	59.1
Content-Based	75.6	63.5	57.4
Hybrid	56.1	54.2	40.5

The table displays the average ranking of the top ten articles presented in each approach. For instance, the articles rated by the respondents as very relevant, the collaborative system ranked those articles on average as 59^{th}. The content-based system ranked the very relevant articles 57^{th} while the hybrid ranked them as 40^{th}. So it is shown clearly the hybrid system ranked the articles higher than the other systems. This study supports MAE results where we have seen that hybrid system get less MAE value than other two systems.

VI. DISCUSSION AND CONCLUSION

This research aims to develop an Arabic recommender system to display news or articles to each reader based on their interests instead of presenting them only in the order of their occurrence using Twitter. To achieve that, we started with collecting the news articles and the dataset of tweets from Twitter and preprocessing them to prepare them to be used in building the recommender system. Then we explained the design and implementation of all the components of the proposed recommender system. Lastly, we have evaluated the recommender system through the two metrics, calculating the statistical accuracy through using Mean Absolute Error (MAE). The other metrics is done through performing a user experimental study to measure the user satisfaction.

Based on the result of the evaluation we found that the hybrid system performs better than the collaborative and content-based recommendations. This means that news articles recommended by the hybrid recommender system are more relevant to the user compared to the other two systems.

Although this research has successfully achieved the goal of developing a personalized Arabic news recommender system, it has certain limitations that are inherent in most of the recommender system researches. First, the size of the created dataset was relatively small, which imposes the need to evaluate the robustness of proposed system against large datasets. Second, creating a new application for Twitter developer account was another challenge. Setting up a Twitter API wasn't easy as it used to be, we have tried several times with Twitter team until we got final application approval.

In future, we have many directions to enhance this research. The accuracy of the proposed news recommender system can be further improved through incorporating other features such as location. In this case the system can recommend news articles based on the user's geographical location. We can increase the efficiency of the system on a wider range of Arabic news articles in order to scale the system and enhance its algorithm so it can apply in different categories of news articles.

***Abstract*—The objective of this study is to analyze and discuss the metrics of the Machine Learning model through the Ensemble Bagged Trees algorithm, which will be applied to data on satisfaction with teaching performance in the virtual environment. Initially the classification analysis through the Matlab R2021a software, identified an Accuracy of 81.3%, for the Ensemble Bagged Trees algorithm. When performing the validation of the collected data, and proceeding with the obtaining of the predictive model, for the 4 classes (satisfaction levels), total precision values of 82.21%, Sensitivity of 73.40%, Specificity of 91.02% and of 90.63% Accuracy. In turn, the highest level of the area under the curve (AUC) by means of the Receiver operating characteristic (ROC) is 0.93, thus considering a sensitivity of the predictive model of 93%. The validation of these results will allow the directors of the higher institution to have a database, to be used in the process of improving the quality of the educational service in relation to teaching performance.**

Keywords*—Machine learning; ensemble; bagged trees; predictive analysis; teaching performance

I. Introduction

The information and communication technology (ICT) sector is currently a leader in the analysis of data from different media [1], [2], such as virtual platforms, survey administration software, among other technological tools [3], [4], which capture or acquire information to be processed and analyzed in descriptive statistical research or in research on predictive models applicable to various areas of knowledge [5].

The advantages that the introduction of ICT has generated in the education sector is based on the importance of technology to develop research that previously could not be carried out, [6], [7] as is the case of the identification of predictive models for the analysis or monitoring of university teaching performance, student performance, among other relevant factors for the education sector [8]-[10].

Worldwide, the education sector has undergone changes and transformations, due to the virtualization of the teaching-learning mode, [11], [12], [13], as a consequence of this scenario, universities face new challenges, to safeguard the quality of education that goes hand in hand with the advancement of technology [14]-[16].

Given this, in the education sector, an increasing amount of data has been generated with greater relevance, product of the iterations of the different actors of the educational process, these being the teacher, the students and the institution, through the application of tools technological, such as survey software, which generate a database [17], [18]. As indicated, the data that are stored, are used in order to improve the efficiency of the educational process through predictive models, among the factors to optimize are academic performance, student dropout, teaching performance, graduate follow-up [19].

There are various technologies used to obtain predictive models, which use data from virtual platforms and survey administration software, applied to students by universities [20]. Within these technologies is the branch of Artificial Intelligence that within its fields houses Machine Learning [21]-[23]. As indicated in [24], Machine Learning is a set of algorithms capable of learning to perform certain tasks from the generalization of examples. Machine Learning has been successfully applied to a variety of areas of human endeavor, and has recently been applied to the educational sector, whose purpose is oriented towards the design of algorithms, methods and models, which will allow the exploration of data from teaching-learning environments [25], [26].

Among the multiple algorithms of Machine Learning, there is Ensemble Bagged Trees, which is an algorithm that is used in joint learning [27]. This can combine training and base

classifiers to produce ensemble models or use an algorithm with multiple test data sets as the basis [28]. In this regard, in [29] it is pointed out that the Bagged Trees algorithm forms different trees when there is a change in the starting point of the training data that results in a decrease in stability. This technique or algorithm is also suitable to be used in the search for optimal models for large data, since the classification becomes easier [30], [31].

In this sense, the main objective of this article is to determine the predictive model using Machine Learning through the Ensemble Bagged Trees algorithm, for the predictive analysis of university teaching performance, in order to use it as part of the procedure to improve the quality of the educational process. Initially, the methodology used will be detailed, then the validation of the algorithm will be determined, by means of the accuracy and the confusion matrix, to finally analyze the total performance metrics (Accuracy (A), Precision (P), Sensitivity (S) and Specificity (R)) of the selected algorithm, from obtaining the receiver operating characteristic curve (ROC).

The contribution of the research focuses on applying a novel technique for the higher institution, through machine learning making use of the data and information collected, which allows making preventive and corrective decisions based on reliable results, obtained through a methodology not so complex.

II. Research Methodology

A. Type and Level of Research

The type of research is applied, since it starts from the identification of a problem, related to the improvement of university teaching performance, for which use is made of methods or tools already defined such as predictive models through Machine Learning, which employs the Ensemble Bagged Trees algorithm. Likewise, the research level is descriptive, since it focuses on analyzing and discussing the metrics of the predictive model obtained through the Ensemble Bagged Trees algorithm, applied to the perception data of engineering university students.

This research also seeks to design a predictive multidimensional model that can be used to create and store new data for the higher institution. Based on this technological tool, it determines patterns and calculates association rules, providing support and reliability to the results obtained. Performance metrics such as Accuracy, Precision, Sensitivity and Specificity show improved performance over the manual method of the same procedure commonly performed in research [28].

B. Participants

The participants in this research are made up of students from the sixth to the tenth cycle of professional engineering schools, with a total of 581 students, this selection criterion is part of a regulation established and approved by the higher institution. It should be noted that it was possible to collect data from the entire population, for this reason, it can be noted that the sample coincides with the population.

C. Data Collection Technique and Instrument

The data collection technique is the survey, and the instrument used to collect data regarding university teaching performance is the questionnaire, which was carried out virtually, due to the context of the health emergency declared by the Covid -19. The virtual platform of the higher institution was used, which gave access to the data collection instrument through the code of each student, which guaranteed the security and reliability of the information. The questionnaire consisted of responses on a Likert scale ranging in levels from 1 to 4 (from dissatisfied to very satisfied). These levels of satisfaction in the analysis will be represented as the classes of the predictive model. In Fig. 1, the indicators considered as predictive elements in the perception of university teaching performance are shown.

D. Reliability of the Collected Data

As part of the methodology, the validation of the collected data is carried out, through Cronbach's Alpha coefficient using the SPSS software, this analysis carried out, it is observed in Table I that the consistency coefficient is equal to 0.932. As indicated in [12], values greater than 0.9 indicate great consistency that is, high homogeneity and equivalence of the response of all indicators. Once this result is obtained, the following section shows the results.

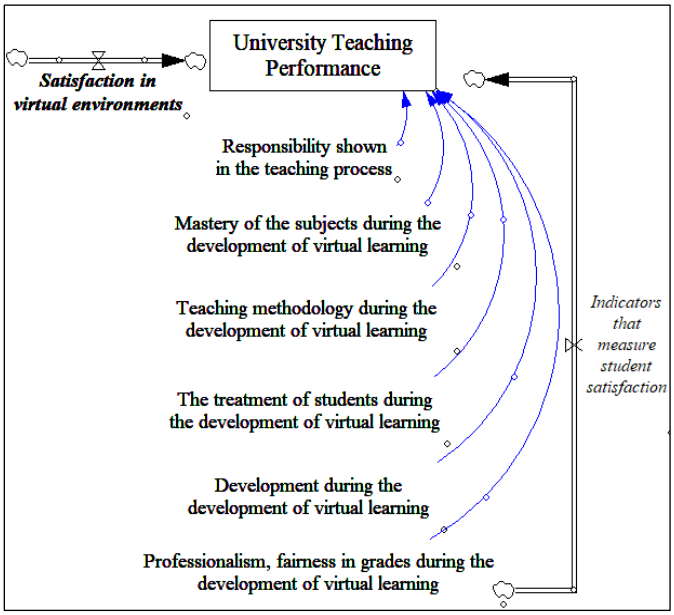

Fig. 1. Indicators that Measure Student Satisfaction with Teaching Performance.

TABLE I. Cronbach's Alpha Test

Reliability statistics	
Cronbach's alpha	***No. of elements***
0.932	6

E. Data Processing Design

The data processing design responded to a non-experimental transactional process, in which data was collected through a virtual questionnaire. In Fig. 2, the methodology of the research process is shown, which begins with the collection of data on the perception of engineering students from a public university in Peru. These data are related to the 6 indicators that are visualized in Fig. 1, whose appreciation regarding teaching performance is of an ordinal qualitative type, thus establishing 4 classes (very satisfied: 4, satisfied: 3, not very satisfied: 2 and dissatisfied :1).

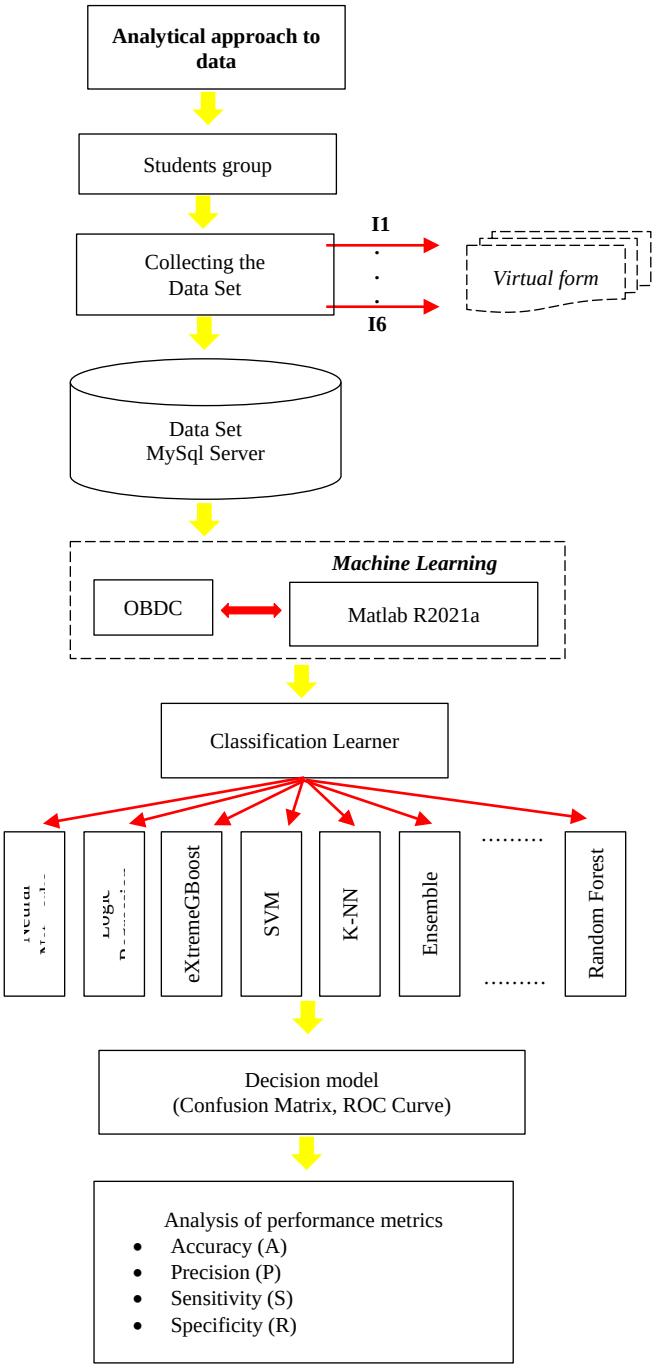

Fig. 2. Methodology of the Research Process through Machine Learning.

Likewise, the information collected was stored in a database in Microsoft SQL Server, associated through the Open Data Base Connectivity (OBDC) driver and the Matlab R2021a software. Using the Matlab software, we proceeded to use the "Classification Learner" tool, in order to identify the best Machine Learning algorithm, through its metrics. This algorithm allows the classification of students from the results obtained from the indicators specified in Fig. 1.

III. Results and Discussion

A. Determination of the Predictive Model

Using the Matlab R2021a software, and using the Classification Learner and Statistics and Machine Learning Toolbox 12.1 application, the best predictive model determined by the validation of the accuracy is identified, in Fig. 3, the results generated by the software are shown. Matlab R2021a.

As shown in Fig. 3, the Machine Learning algorithm that presents the best accuracy, for classifying the level of satisfaction with respect to university teaching performance, is the Ensemble Bagged Trees algorithm with an accuracy of 81.3%.

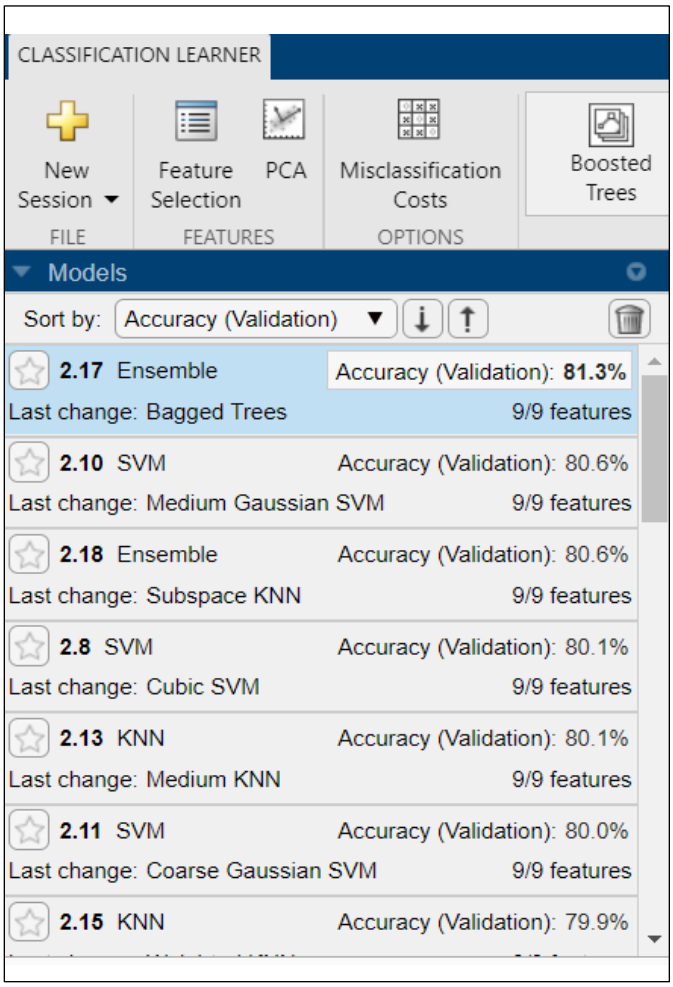

Fig. 3. Validation of the Prediction Algorithms Ordered by their Accuracy.

B. Results of the Predictive Model Metrics

When using the predictive model through Machine Learning through Ensemble Bagged Trees, to determine satisfaction with university teaching performance, confusion matrices are obtained, which represent elements of validation or performance measurement of the predictive model.

In Fig. 4, the confusion matrix is shown, with respect to the sensitivity metric, in it you can visualize the number of observations made by the classification system, and it reports the number of false negatives (FNR), which is the number of positive examples wrongly classified as negative and true positives (TPR) that define the number of positive samples correctly classified as positive, which shows the closeness between the levels of satisfaction predicted (Predicted class) by the model with respect to its true value (True class).

As can be seen in Fig. 4, of the 4 classes on which the predictive model acts through Ensemble Bagged Trees, class 3 shows the highest percentage of sensitivity, this means that the predictive model has the ability to discriminate between a true positive (TP) of a false negative (FN) in this class (satisfied), in this case it is 89.9%, as observed in this class the model was only confused by 10.1%. While the lowest level of sensitivity of the predictive model is shown in class 1 (satisfaction level: dissatisfied), whose value is 63.9%.

In Fig. 5, the confusion matrix is shown with respect to the precision metric, since the values of the main diagonal indicate the precision of the predictive model for each class.

In Fig. 5, the confusion matrix is shown regarding the precision metric of the predictive model for each class, in which it is observed that the predictive model for class 1 (satisfaction level: dissatisfied) shows the highest precision rate, in this case it is 88.5%. This result indicates that the level of dispersion of the data for this class is very low.

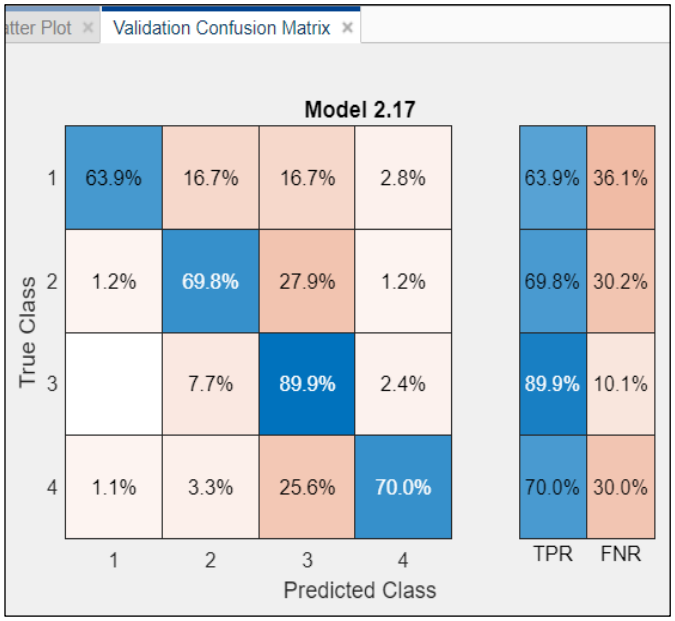

Fig. 4. Confusion Matrix based on TPR and FNR rates.

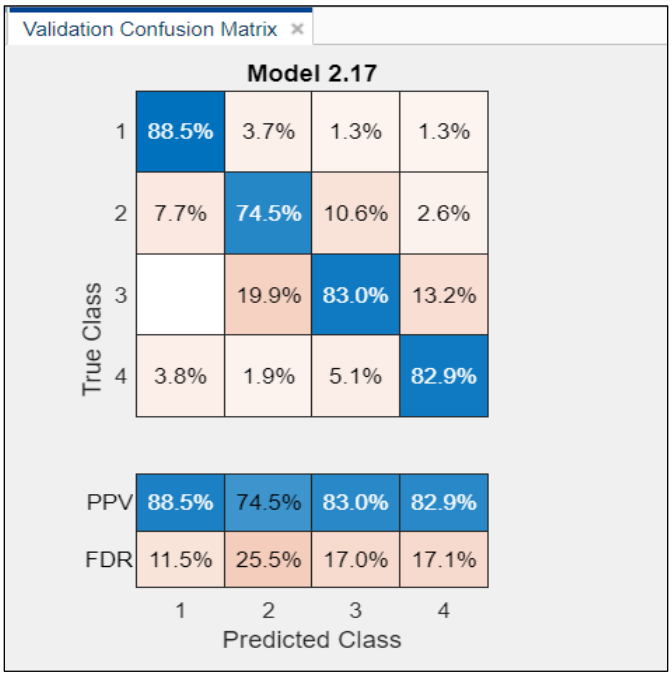

Fig. 5. Confusion Matrix based on PPV and FDR rates.

Table II shows the metrics of the predictive model through Ensemble Bagged Trees, for each class, in which it is evidenced that the total Precision is 82.21%, the total Sensitivity is 73.40% and the total Specificity is 91.02%, and the Accuracy presents a total value of 90.63%.

As part of the predictive model through the Ensemble Bagged Trees algorithm, the response that Matlab provides for each class under study is evidenced, its corresponding Receiver operating characteristic (ROC) graph and considering that the ROC graph describes the Sensitivity and Specificity of the algorithm classifier, the findings in Fig. 6, allow us to establish that for class 1 (dissatisfied), a sensitivity of 93% is shown.

In addition, the discrimination threshold is 0.64 for the rate of true positives and 0.00 for the rate of false positives, showing an area value on the curve (AUC) of 0.93, this value being close to 1, it is noted that the model for class 1 is optimal.

In Fig. 7, the ROC graph for class 2 (not very satisfied) is shown, where a sensitivity of 91% is displayed. In addition, the discrimination threshold is 0.70 for the rate of true positives and 0.08 for the rate of false positives, showing an area value on the curve (AUC) of 0.91, this value being close to 1, it is noted that the model for class 2 is optimal.

TABLE II. CLASSIFICATION PREDICTIVE ALGORITHM METRICS

Class	Metrics			
	Sensitivity	***Specificity***	***Accuracy***	***Precision***
1	63.89%	99.56%	97.76%	88.46%
2	69.77%	92.45%	86.99%	74.53%
3	89.93%	74.16%	83.36%	82.96%
4	70.00%	97.92%	94.41%	82.89%

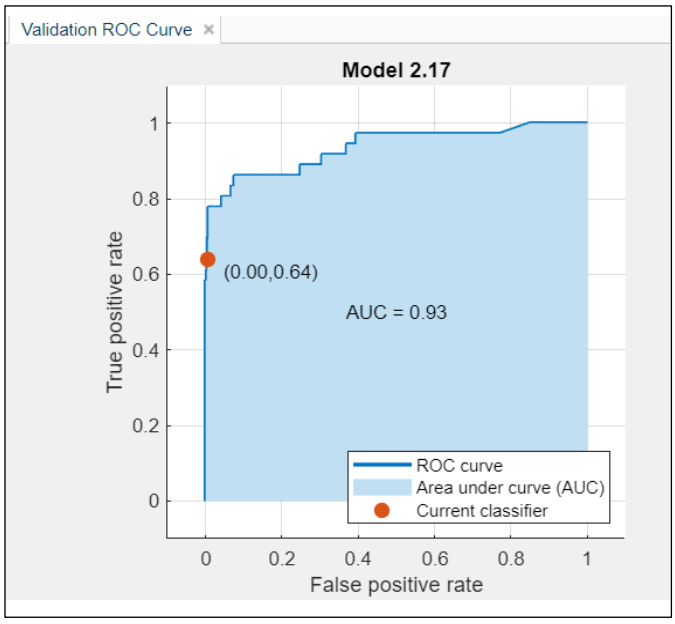

Fig. 6. ROC Charts for Class 1.

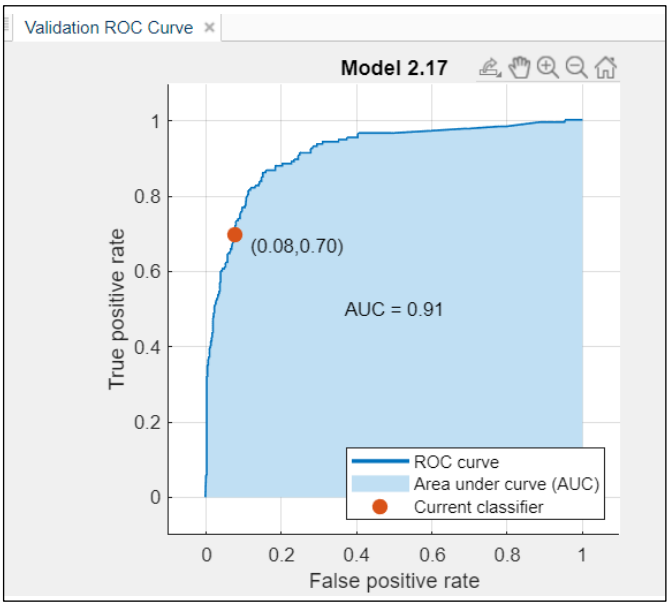

Fig. 7. ROC Charts for Class 2.

In Fig. 8, the ROC plot for class 3 (satisfied) is shown, where a sensitivity of 91% is displayed. In addition, the discrimination threshold is 0.90 for the rate of true positives and 0.26 for the rate of false positives, showing an area value on the curve (AUC) of 0.91, this value being close to 1, it is noted that the model for class 3 is optimal.

Finally, in Fig. 9, the ROC graph for class 4 (very satisfied) is shown, where a sensitivity of 92% is displayed. In addition, the discrimination threshold is 0.70 for the rate of true positives and 0.02 for the rate of false positives, showing an area value on the curve (AUC) of 0.92, this value being close to 1, it is noted that the model for class 4 is optimal.

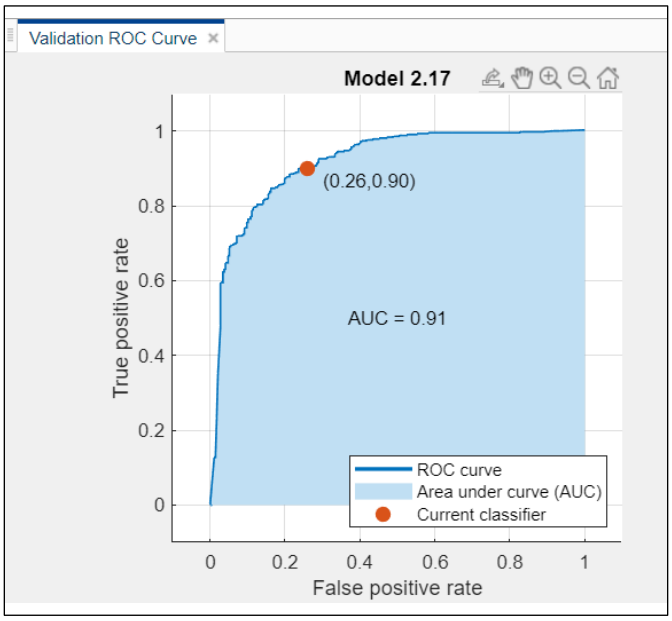

Fig. 8. ROC Charts for Class 3.

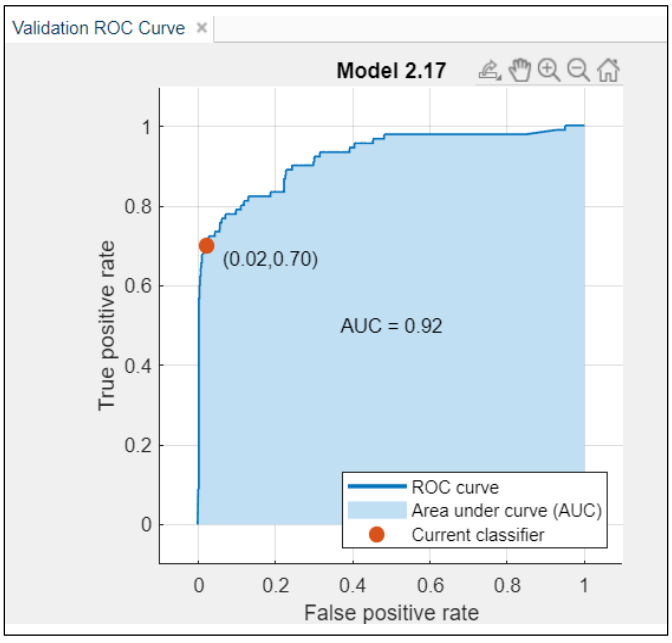

Fig. 9. ROC Charts for Class 4.

C. Discussion

In relation to the results obtained, it is evidenced that the predictive model, based on the Ensemble Bagged Trees algorithm, presents acceptable metrics of precision, sensitivity, specificity and accuracy, in its 4 classes each of its classes, in this way the predictive model obtained provides security and reliability, contributing to decision making to improve the quality of the course content and the pedagogical methodology. In this regard, in [16] it is pointed out that preventive and corrective decision-making in higher education institutions involves building predictive models based on intelligent systems.

As indicated in [6], researchers have been concerned in recent years to work on the development of models that allow understanding aspects of the academic life of the student, teachers and institutions that allow the preparation and making of correct decisions, for the improvement continuity of educational quality. Likewise, in [19] it is indicated that the results obtained and validations show a precision of 82%, therefore, it can be pointed out that the process describes an optimal performance of the algorithms, so its incorporation would be satisfactory to be incorporated to the management of virtual educational knowledge.

In relation to the metrics of the predictive model, the model obtained through Matlab R2021a presents a general precision of 82.21% and an accuracy of 90.63%, being considered an optimal model, in this regard in [20], the author states that his predictive model was good since its general precision was 75.42% and an area under the ROC curve of 0.805. Likewise, in the investigation of [27] it is pointed out that the general result shows that each of the techniques used shows a good result in the classification and prediction performance, obtaining a greater precision of 86.9%.

On the other hand, the results of [26] showed a precision rate of 89.31% and a specificity rate of 91.25%, these measures are substantial to select classifiers since the researcher intends to minimize false negatives.

Regarding the term optimal model, in [4] it is pointed out that the so-called optimal models are combined with the dominant sets, which significantly improve the performance of prediction models and are highly influential in academic performance factors. Likewise, regarding the area on the curve, whose highest value in this research was 0.93 or 93%, in [4] it is indicated that an AUC of 50% of 91% or 99%, which was obtained in the research represents a better Classifier algorithm performance, favorable results for research.

The results of this study, from the perspective of innovation, will make it possible to achieve great changes, delegating functions, promoting competencies and fostering the continuous updating of higher institutions, all from the perspective of visionary leadership. In [10] it is pointed out that the proposed model accurately predicts the completion of the course and the performance of students in the university, thus allowing the organization to provide a better quality of service, since the satisfaction of the student depends on it student.

IV. Conclusion

The use of technological tools such as Machine Learning and its algorithms are supporting and strengthening decision-making from an administrative and academic point of view and in the educational sector. According to the results obtained, it is concluded that the metrics of the Machine Learning model through Ensemble Bagged Trees, applied to the predictive analysis of university teaching performance, present on average optimal values in their validation metrics such in their 4 classes, with a precision of 82.21%, a Sensitivity of 73.40%, a Specificity of 91.02% and an Accuracy of 90.63%. From the validation of the Machine Learning algorithm metrics, its implementation is viable and reliable in improving the performance of university teachers. Finding the 4 classes of the predictive model with relatively high values, the results allow establishing the grouping of engineering students who can achieve a level of satisfaction based on the indicators called predictors (indicators), through which the authorities of the higher institution can make timely decisions to improve the percentage of satisfied students in relation to university teaching performance.

Once the conclusions are presented, it can be noted that the present study achieved its purpose of determining the best performance model for the predictive analysis of university teaching performance, which is why it can be used as part of the procedure to improve the quality of the educational process. Because these results allow to have a relevant, reliable database that is obtained in less time compared to manual processes.

***Abstract*—The cancer reports of the past few years in India says that 30% cases have breast cancer and moreover it may increase in near future. It is added that in every two minutes, one woman is diagnosed and one expires in every nine minutes. Early diagnosis of cancer saves the lives of the individuals affected. To detect breast cancer in early stages, micro calcifications is considered as one key symptom. Several scientific investigations were performed to fight against this disease for which machine learning techniques can be extensively used. Particle swarm optimization (PSO) is recognized as one among several efficient and promising approach for diagnosing breast cancer by assisting medical experts for timely and apt treatment. This paper uses weighted particle swarm optimization (WPSO) approach for extracting textural features from the segmented mammogram image for classifying micro calcifications as normal, benign or malignant thereby improving the accuracy. In the breast region, tumour part is extracted using optimization methods. Here, Convolutional Neural Networks (CNNs) is proposed for detecting breast cancer which reduces the manual overheads. CNN framework is constructed for extracting features efficiently. This designed model detects the cancer regions in mammogram (MG) images and rapidly classifies those regions as normal or abnormal. This model uses MG images which were obtained from various local hospitals.**

***Keywords*—Breast cancer; microcalcifications; weighted particle swarm optimization (WPSO); Convolutional Neural Networks (CNNs) mammogram**

I. Introduction

Breast cancer is the most commonly found in women which causes deaths who are aged from 20 to 59. According to the Ministry of Health and Medical Education, it has become the most common disease in recent years in Iran [1]. Today, 88% of women diagnosed with breast cancer have a life expectancy of 10 years. In the United States, it has been reported that about 12% of women were identified during their lifetime, and were referred to as the second cause of women's death [2]. Diagnosing the disease at the earlier stages is important because in the early stages, cancer masses are restricted to the breast and the chance of surgical treatment in a less invasive manner is increased. The mortality rate is also decreased in the early stage [3]. Also, the use of classifiers such as artificial neural networks in various fields of engineering sciences is increasing to analyze the time series and various issues of classification. Due to the invention of techniques in the recent era for early diagnosis of breast cancer, the survival rate of the patients is improved. Now-a-days, X-ray mammography and MRI (Magnetic Resonant Imaging) techniques are widely utilized with few implications and limitations. X-ray is very harm due to the ionizing radiation and thus its contact with patients has to be only for very short duration. Conversely, MRI technique is expensive while mammography is of less cost, but hard to provide consistency and accuracy in analysing breast cancer [4]. Moreover, errors occur while analysis. To increase the rate of accuracy and reduce the occurrence of errors, supervised machine learning approaches like KNN, SVM, LSSVM are developed. These models efficiently classify the features as normal or abnormal classes. These methods are complex and even tedious with low CR. Therefore, to provide a solution for all the drawbacks of breast cancer, an optimal classification model is required for which machine learning approaches based on image processing are developed to classify cancer and non-cancer images which involved mammogram images. As the features are essential to discriminate breast cancer as benign or malignant, feature extraction process is of most important. Once the features are extracted, properties of the image like depth, coarseness, smoothness, and regularity are obtained with the help of segmentation process [5]. Scientifically, with breast cancer, division of tumor cells is uncontrolled and abnormal tumor cells need more nutrients for growing continuously and to reproduce. The cancer cells penetrate into the surrounding for gain in nutrients. There is a heterogeneous variation in the circulation of blood with various tumors and hence lesion morphology characteristics and ambiguity with edges in diagnosing images are significant in dicators for evaluation. The paramagnetic contrast agent spreads in blood which enters into the blood vessel and passes in the intercellular space as well as cells easily via penetrable capillary wall; hence the sputum concentration is high in the tumor rich region. This abnormality can be found using TIC when DCE-MRI is utilized for several imaging of the same tissue in various stages. Thus, edge, shape, etc. which are static characteristics and initial increase and change in signal which are dynamic characteristics of the lesion plays a major role in identifying the tumor as benign or malignant. MRI images are usually clear and complete with multi-angle, multi-faceted imaging. With the breast, surface coil has been used for clinical purpose, and MRI technology is improved to be much clear. However, the true positive rate and the true negative rate obtained while diagnosing breast cancer are also improved simultaneously [6].

Here this paper contributes weighted particle swarm optimization (WPSO) approach for extracting textural features from the segmented mammogram image for classifying microcalcifications as normal, benign or malignant thereby improving the accuracy. In the breast region, tumor part is extracted using optimization methods. Here, Convolutional Neural Networks (CNNs) is proposed for detecting breast cancer which reduces the manual overheads. CNN framework is constructed for extracting features efficiently. This designed model detects the cancer regions in mammogram (MG) images and rapidly classifies those regions as normal or abnormal.

The remaining part of this work is presented as follows. An outline of relating works is discussed in Section 2; Section 3 elaborates the proposed methodology while Section 4describes the experiments and discusses the obtained results. Finally, Section 5 concludes the work with future improvements.

II. Related Work

This section discusses few related works carried out for diagnosing breast cancer which involved various optimization techniques. It is well known that breast cancer is one serious and dangerous cancers among women and hence diagnosing at the earlier stages is more effective to provide treatment and protect the lives of patients. Till now, several approaches are coined for detecting breast cancer which addresses different sorts of challenges and few of them are reviewed here. Asri et al. [7], in 2016, employed machine learning methods for the prediction and classification of WBC actual dataset. Various classifiers were used which includes SVM, Naive Bayes, KNN and decision tree C4. SVM produced an accuracy with Weka tool. In [8], Chowdhary et al. utilized mammography images for the detection of breast cancer using intuitive fuzzy histogram magnification approach there by data was processed and image quality was improved. Then, probabilistic Fuzzy Clustering approach was employed for segmenting and separating the cancer tissues. Hence, this model was suitable for processing larger cancer datasets with the objective to offer better accuracy. Next, with the methods like grey area coefficient and linear binary pattern, textural properties were extracted. The accuracy obtained was 94% but hard while dealing with larger datasets and extends the processing time. Aalaei et al. [9] employed genetic meta-specificity reduction for classifying breast cancer. Three datasets namely WBC, WDBC and WPBC were used for evaluating which used Artificial Neural Network (ANN) cluster. The accuracy estimated for the method used with WBC, WDBC and WPBC datasets were 96, 96.1 and 76.3, respectively. Even though feature set was reduced, accuracy could be improved. Nilashi et al. [10], in 2017, designed a knowledge-based system which involved fuzzy logic. The process was carried out in three steps: initially Wisconsin Breast Cancer data was processed. Then, data with similar groups was clustered by the use of Expectation Maximization (EM) clustering technique. Finally, once the features were reduced by PCA, fuzzy rule set was categorized as data by means of regression tree. The accuracy obtained was 93.2%. Sometimes when learning rules are applied on datasets, the classification task is complicated. In [11], the use of Bat algorithm selected optimal features for diagnosing breast cancer. 286 samples were selected from WDBC dataset for which simple random sampling approach was involved for feature selection. After selecting the features, according to the classification similarity which involved Random Forest (RF), overall ranking was performed and obtained an accuracy. As samples are selected at random, selection of features was sometimes difficult. In [12], Dore swamy et al. improved Bat algorithm to classify breast cancer images. 569 samples of UCI data were involved in experimenting this method. The accuracy for training set was 92.61 while that of the testing was 89.95. In [13], an approach using PSO was utilized for reducing the specificity in diagnosing breast cancer. The objective was to estimate the level of breast cancer. 699 pre-processed samples of UCI data after reducing the specificity were used by PSO algorithm along with decision tree C4.5 to classify the samples into two classes namely malignant and benign. The accuracy achieved was 95.61%. Sahu et al. [14] used a hybrid approach for classifying and diagnosing breast cancer. With PCA feature reduction and various clusters, it was found that ANN classification produced 97% of performance than other clusters. 699 samples with 9 features were used in the experiment to label them as benign and malignant. Even though results achieved are better, every method has few weaknesses and limitations. In [15], Gao et al. integrated shallow CNN with deep CNN and formulated SD-CNN. Shallow CNN was used with the intention to extract “virtual” recombination of images which has lower energy, while deep CNN extracted the novel features related to LE. Additionally, knowledge of nonlinear mapping was gathered from LE for recombining images; shallow CNN and deep-CNN was created with 49 CEDM each. The performance was enhanced in terms of AUC and was accurate than the methods existing. In [16], Ting et al. developed CNNI-BCC which helped medical experts in diagnosing breast cancer at the earlier stage. This model enhanced the classification using CNN and the breast cancer images were classified as various types like benign, malignant, and healthy. From the numerous experiments conducted, this model enhances accuracy, sensitivity as well as AUC.

Diagnosing and classifying approaches involved for breast cancer were not tested and evaluated with three various data sets of breast cancer. In [17], Araujo et al. proposed a method for the classification of hematoxylin and eosin stained breast biopsy images using CNNs. High Sensitivity for Carcinoma cases are obtained from this classification scheme. In [18], Belsare et al. Classification of image is performed on different classes using LDA. This proposed approach is helpful for Pathologist. In [19], Tan et al. Developed a new version of breast cancer detection by using CNN, tested on mammogram images. This shows the improved accuracy results. In [20], Henry et al. Effectiveness of CNN was analyzed based on the existence of breast abnormalities in mammograms. In [21], Khan et al. developed a method of cancers classification for relevant genes using ANNs. In [22], Dhungel et al. introduce a novel automated CAD system with minimal user. Deep learning and structured output models are explored, proposed CAD system results for INbreast data set. In [23], Al-antari et al. proposed CAD system based deep learning, deep convolutional network (CNN) is used to recognize the mass

and classify it as either benign or malignant. In [24], Al-antari et al. proposed an integrated CAD system of deep learning detection and classification, develop a Cad system for practical breast cancer diagnosis. In [25], Fang et al. constructed CNN to utilize three dimensional spatial correlations information of breast tumors very effectively. In [26], Aya et al. introduce a new automatic segmentation Method (SM) for identifying the ROI from breast thermograms. In [27], Hu et al. provide an overview on deep learning and hope on the survey for cancer detection and diagnosis. The specialties of the present investigation are reduction is detecting costs, using better classifier with no adverse effects of aggressive approaches, higher accuracy of detection than the paper cited, choosing titles appropriate with the data available and comprehensive comparison with the researches made so far.

III. Proposed Methodology

The work flow of the methodology developed is illustrated in Fig. 1. The phases like pre-processing, segmentation and feature extraction are discussed below. CNN classifier is involved to obtain the accuracy of classification.

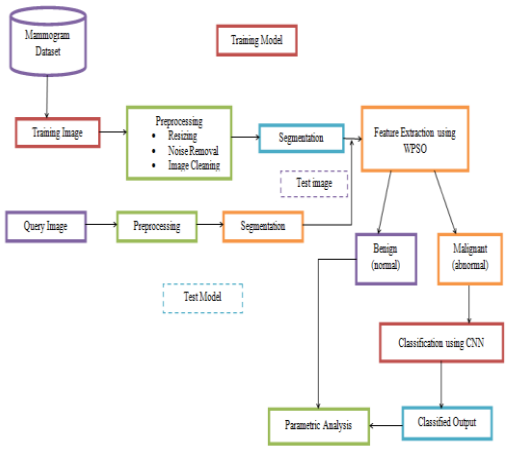

Fig. 1. Architecture of the Proposed Technique.

A. Pre-processing Steps

Step 1: Looking for an input Breast Image.

Step 2: The raw image provided as input raw undergoes resizing to 256 x 256.

Step 3: When 3-dimensional (3D) images are provided as input, they are converted to 2D, since mostly image processing is carried out only with 2D images i.e, RGB image is converted into gray scale image.

Step 4: Two filtering techniques are applied for de-noising as described below:

Step 4.1: Out_1 = Laplacian filter is applied on the gray scale image .

Step 4.2: Out_2 = Then mean filter is applied on the gray scale image.

Step 4.3: Out_3 = Out_1 – Out_3.

Step 4.4: The final output of the pre-processing stage is the pre-processed breast imageOut_3.

Step 5: Out_3.

B. Segmentation Steps

Input: Out_3 Pre-processed Image.

Step 1: Gradient is obtained along X and Y axis in variables Out X and Out Y.

Step 2: Gradient values are combined to obtain gradient vector G val which is given by.

G val=[1/(1+(Out X+ Out Y))]

Step 3: G val obtained in radians is converted to degrees so that orientation information of image pixels can be attained.

Step 4: Out_3 image is partitioned to grids GRi.

Step 5: Threshold values are defined for intensity Ti and orientation To.

Step 6: for every grid GRido.

1) Histogram Hi for every pixel Pjis computed over grid GRi.

2) 6.2. Most frequent histogram of grid GRiis found which is represented by Freq H.

3) 6.3. Any arbitrary pixel Pjis selected which is related to Freq H which is then assigned to pixel information seed point (SP) with Intensity Ip and Orientation Op.

4) 6.4. Intensity along with orientation constraints for adjacent pixel is verified.

5) 6.5. When both constraints are fulfilled, then decided that region is grown, or else.

Next grid is considered for further process.

Step 7: Output: Segmented Image

C. Weighted PSO based Feature Extraction

A heuristic global optimization technique namedWeighted Particle Swarm Optimization (WPSO) algorithm simulates the social behaviour of flock in g bird towards a position for attaining the exact objective in a multidimensional space. This approach involves a population of particles (called swarm) in the search space. For every particle, the status is categorized based on its location $\vec{x}_i = \{x_{i1}, x_{i2}, \ldots . x_{id}\}$and the velocity of particle i is given by $\vec{v}_i = \{v_{i1}, v_{i2}, \ldots . v_{id}\}$.To find the optimal solution, every particle deviates from its actual searching direction to a new direction based on two concepts namely the best location of the given particle (pbest) and the one obtained so far by swarm (gbest). WPSO identifies the optimal solution after velocity and position of every particle are updated in relation with the equations,

$$v_{id}^{(t+1)} = wv_{id}^{t} + c_1 r_1 (p_{id} - x_{id}^{t}) + c_2 r_2 (p_{gd} - x_{id}^{t}) \quad (1)$$

$$x_{id}^{(t+1)} = x_{id}^{t} + v_{id}^{(t+1)} \quad (2)$$

where t and d represent the iteration in the evolutionary space and dimension in search space respectively. W denotes the weight of inertia. c1 and c2 represent the personal and

social learning factors. r1 and r2 are uniformly distributed random values ranging between 0 to 1. pid and pgd denotes pbest and gbest in the dimension d.

The basic steps performed in WPSO algorithm are as described below:

- Initialization: Random positions and velocities are used to initialize the particles.
- Evaluation: For every particle, value of the objective function is estimated.
- Finding pbest: When the value obtained with the objective function is better than the p best for particle i, then the current value is assigned as the new p best.
- Finding gbest: When p best is better than gbest, then gbest is assigned to the current value.
- Updating the position and velocity: For every particle, velocity is updated using Equation 1, and the particle is moved to the next position based on Equation 2.
- Terminating Criteria: When the required number of iterations are reached, the process ends or else repeated from step 2.

For the search space, exploration and exploitation are controlled by weight as velocity is adjusted dynamically. Moreover, weight controls the impact of the previous velocities on the current one. Thus, the exploration capabilities are compromised between global and local swarm. Larger weight simplifies global search for new areas while the smaller weight simplifies local search. When the weight is chosen properly, global and local exploration of swarm is balanced providing better solution. Hence, weight can basically set to a larger value for better global exploration of the search space and then decrease it gradually to obtain refined solution. When the weight decreases linearly, exploration from global to local change linearly. Search algorithm are required to have non-linear searching ability. With few statistical features obtained, PSO search is easily understood and the suitable weight is calculated for the next iteration. Here, when there is an increase in total generation, there is a linear decrease in weight w while optimization in relation to

$$W = w_{max} - \left(\frac{w_{max} - w_{min}}{iter_{max}}\right) * iter \quad (3)$$

Where w_{max} andw_{min}denote the maximum and minimum inertia weight respectively, $iter$and $iter_{max}$are the current iteration and maximum number of iterations respectively. For particle i, the best position is position that the particle visited (past value of Xi), which provides highest fitness value. For minimization, a position with small function value is considered to have fitness. f(X) denotes the minimized objective function for which the updated equation is

$$P_{bestid}^{(t+1)} = \{x_{id} t \; if \; f(x_{id}(t+1) \geq P_{bestid}^{t} \text{or} P_{bestid}^{(t+1)} = \{x_{id}(t+1) \; if \; f(x_{id}(t+1) \geq P_{bestid}^{t} \quad (4)$$

A faster rate convergence is provided by the g best with the expense of robustness and only a single best solution is maintained termed as global best particle. The role of this particle is to act as an attractor and hence pulls every particle towards it. Ultimately, every particle converges at this position and thus has to be regularly updated if not swarm converges prematurely. For every particle in the swarm, fitness value is computed using the objective function. Then, Pid and Pgd values are evaluated and updated with the global best position or better particle best position if obtained.

Steps for WPSO:

Initialize the function.

Create objective function.

Objective function is based on intensity of pixel.

Set iteration count = 1000.

Calculate pixel intensity of images.

Optimize the cancer image pixel intensity.

Calculate optimal value for input image pixel.

Extract tumor part with maximum pixel intensity.

Calculate accuracy.

D. Classification using Convolution Neural Networks

CNN takes the breast cancer image dataset an input for classification. Then, deep convolutional kernels are trained using the introduced CNN architecture. RELU nonlinearity is used in convolution layers and are defined as:

$$f(x) = \begin{cases} x, if \; x > 0 \\ ax, otherwise \end{cases} \quad (5)$$

Generally, convolution layer is stated as:

$$y^j = fb^j + \sum_i k^{ij} + x^i \quad (6)$$

Here, xi represents the ith input map and yi denotes the j^{t} ^{h}output map. bjis the bias parameter of jth map, convolution process between two functions is given by *, and convolutional kernel involved between i and j maps is bij. Max-pooling layer was the next layer following the convolutional layer. In max-pooling layer, every neuron provides yi pools in the output map yi pools against s * s non-overlapping areas of xi. In general, max-pooling layer is defined as:

$$y_j^i = max_{0 \leq m \leq s}\{x_{j.s+m}^i\} \quad (7)$$

Convolutional as well as max-pooling layers are fully connected which is followed by Softmax classifier containing output classes which equals the number of outputs. In the architecture introduced, tan h is used as a non-linear protocol in connecting one layer with another. The function of Softmax function equals squashing, and dataset with k-dimension is re-normalized producing real values ranging from 1 to 2. This is represented mathematically as:

$$\sigma(z)_j = \frac{e^{zj}}{\sum_{k=1}^{k} e^{zk}}, for \; j = 1, \ldots k \quad (8)$$

Error obtained while developing ML approaches are training and generalization errors. The former is observed

while training the neural network, where the latter is produced while testing the proposed classifier. In the process of deep learning, training is frequently affected with the process of overfit and under-fit. To surpass these issues, after every layer, batch normalization is applied in the proposed architecture for BCC. Dropout layer was added next to the first fully connected layer. The entire architecture developed for breast cancer classification is illustrated in Fig. 2.

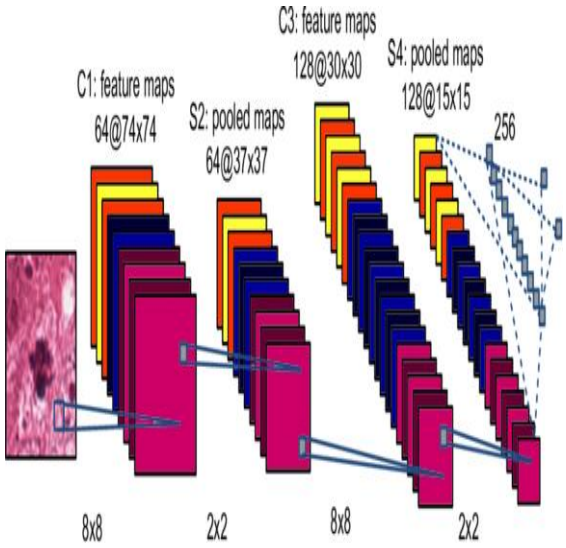

Fig. 2. Proposed CNN Architecture for Breast Cancer Classification.

E. Training of CNN

The proposed CNN architecture has two classes namely benign and malignant. Weighted loss function was employed for training the proposed CNN classifier.

$$\xi(w, x_n, y_n) = -\frac{1}{N}\sum_{n=1}^{N} \alpha_n \sum_{k=1}^{k} t_{kn} ln y_{kn} \quad (9)$$

Here xn represents input vector, yn the prediction obtained from classifier for n^{th} clinical input, and tn its actual response. K and N are the number of classes total clinical samples.

For recognizing, patch results of the entire image are combined. As the model is trained with image patches, strategy is necessary for partitioning the actual testing images into patches, then executing and combining the results obtained to get optimal result but is computationally too complex. Rather, grid patches are obtained from the images which provide the set of non-overlapping patches, and this was reasonable and balanced the performance of classification as well as computational cost. By implementing this model, every patch produced the probability of every possible class for the given patch of the image. For combining the results produced by the patches for the test image, three various fusion rules were involved and found that Sum rule produced better results.

IV. Performance Analysis

Detection of breast cancer in the earlier stages is critical for treatment and managing its condition. This study presented a detailed derivation methods and processes along with way it is applied in detecting tumor. According to the tissue segmenting method, the effects of the obtained number of glandular tissues is analysed. It is observed that presence of numerous glandular tissues worsen the imaging effect later. Simultaneously, a progressive approach to detect multiple tumors is also introduced. Imaging is done in three steps: preliminary examination, refocusing, and image optimization by which every tumor is detected successfully. Here, WPSO-CNN is used for extraction of features and classification of tumor, and this has obtained enhanced accuracy. Features were obtained and classified the image of histopathology. The below Fig. 3 shows extracted feature of histopathology image using WPSO-CNN. The Fig. 4 shows classified image with malignancy.

The accuracy, precision, recall and F-1 score graph has been shown below in Fig. 5,6,7,8. The below graphs show comparison of parameters between existing and proposed techniques.

From analysis of results obtained for proposed technique, it is observed that performance is significantly improved. The analysis of results expressed that proposed technique exhibits its significant performance in Classification.

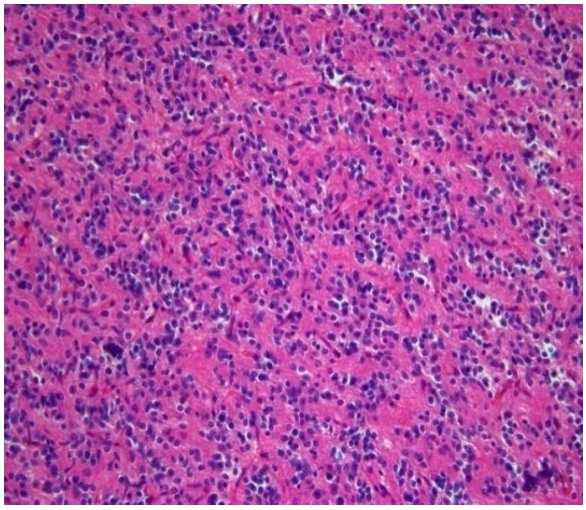

Fig. 3. Feature Extracted Tumor Image of Histopathological Image.

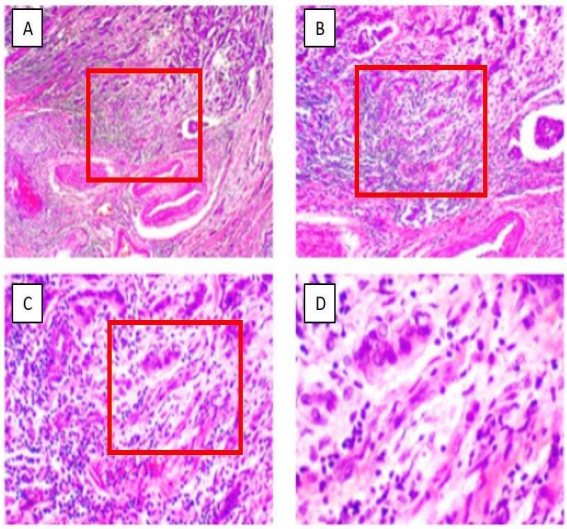

Fig. 4. Classified Image of Histopathology Detecting Malignancy.

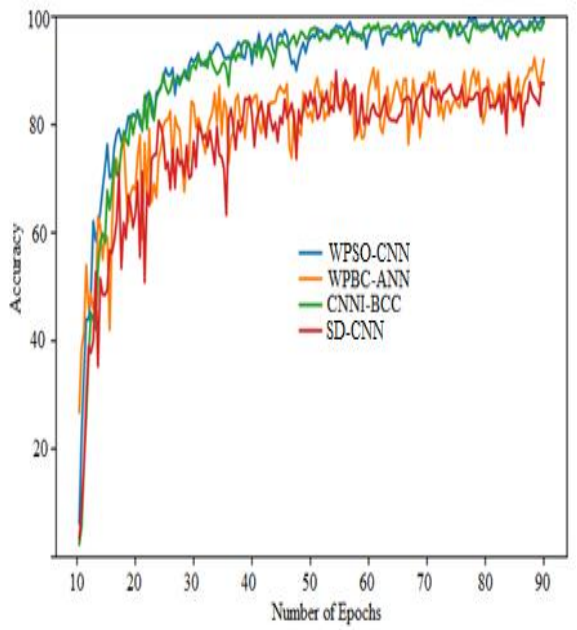

Fig. 5. Comparison of Accuracy.

In Fig. 5, shows the classification of accuracy analysis for proposed technique. The accuracy measured for proposed technique is measured significantly higher than the existing techniques.

In Fig. 6, shows the classification of precision analysis for proposed technique. From overall comparison of proposed technique with existing classifiers is presented. The measurement of precision provides the analysis is expressed that the proposed technique provides improved performance rather than existing techniques.

In Fig. 7, shows the classification of Recall analysis for proposed technique. The Recall measurement provides the analysis and the comparative analysis expressed that the proposed technique provides improved performance than the existing classification techniques.

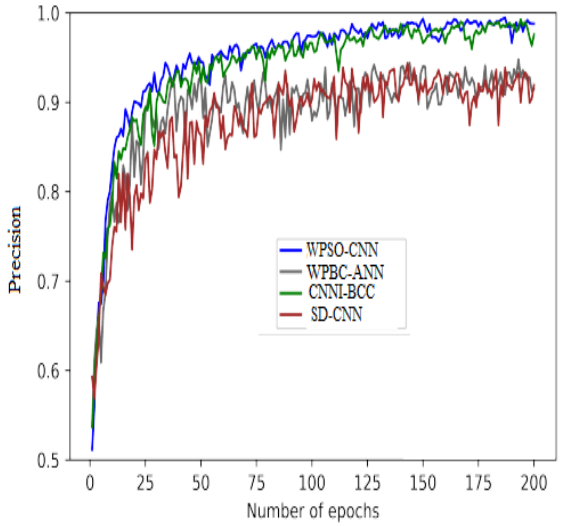

Fig. 6. Comparison of Precision.

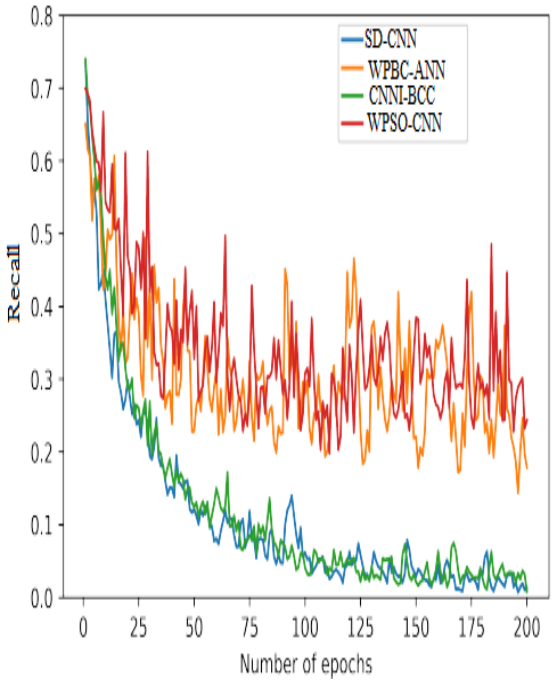

Fig. 7. Comparison of Recall.

In Fig. 8, shows the classification of F1-Score analysis for proposed technique. The F1-Score is measured and provides the analysis and through analysis, it is concluded that the proposed technique exhibits improved performance rather than the existing classification technique.

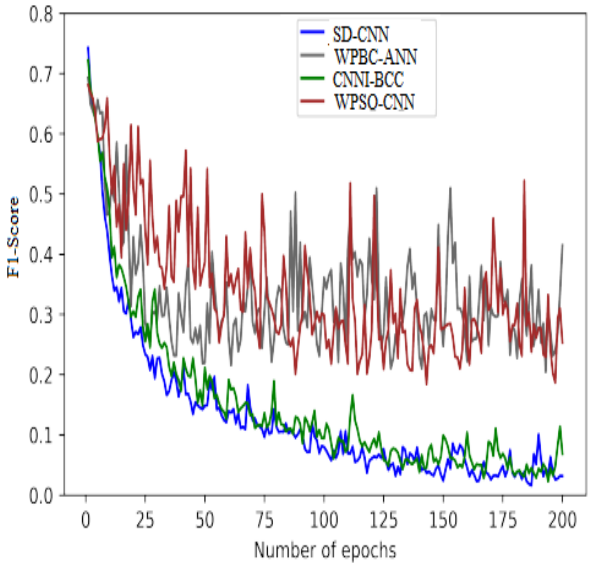

Fig. 8. Comparison of F-1 Score.

Limitations of the proposed WPSO-CNN:

- WPSO-CNN is best suitable for image-classification, dealing with high-dimensional Data (images).
- WPSO-CNN is not best suitable for smaller data sets.
- WPSO-CNN becomes slower, if there are more layers.

V. CONCLUSION

The objective to carry out this research is to improve accuracy of detection using CAD technique for detecting breast cancer. With this objective, a framework was contributed along with its flow and parameters used for simulation. Publicly available dataset is involved for analysing the effectiveness of the method for classifying normal and abnormal breast images of several individuals. Here, weighted particle swarm optimization (WPSO) with CNN (Convolutional Neural Networks) is employed named as WPSO-CNN with the objective to extract the features and estimate the error between the estimated and true density using kernel density estimation based classifier for diagnosing breast cancer. From the results it is observed that the performance of WPSO-CNN is remarkable than existing approaches. The future work is to possibly develop an online breast cancer detection system since the detecting systems used currently are offline.

Real-Time Emotional Expression Generation by Humanoid Robot

Master Prince
Assistant Professor, Department of Computer Science
College of Computer, Qassim University, Buraidah, 51452, Al Qasim, Saudi Arabia

***Abstract*—Emotion integrates different aspects of a person, including mood (current emotional state), personality, voice or speech, color around the eyes, and facial organs' movement. We are considering the mood because a person's current emotional state must always affect upcoming emotions. So behind an emotion, all these parameters are involved, and a human being can easily recognize it by seeing that face even if more than one person is there, so for the robot to make human-like emotion, all these parameters have to be considered to imitate artificial facial expression against that emotion. Most researchers working in this area still find difficulties in determining exact emotion by the robot because facial information is not always available, especially when interacting with a group of people and mimicking exact emotion that the user can effectively recognise. In our study, the loud most speeches among the people sensed by the robot and color around eyes are considered to cope with these issues. Another issue is the rise time and fall time of emotional intensity. In other words, how long should the robot keep an emotion here? An experimental approach is applied to get these values. The proposed method used an emotional speech database to recognize the human emotion using convunational neural network (CNN) and RGB patterns to mimic the emotion, which simulates an improved humanoid robot that can express emotion like human beings and give real-time responses to the user or group of users that can make more effective Human-Robot Interaction (HRI).**

Keywords*—*Artificial facial expression; emotional speech database; convunational neural network; RGB pattern; humanoid robot; human-robot interaction

I. Introduction

The human face is very special in different aspects; one of those aspects is expressing emotion. By expressing emotion, human beings express their feelings, and others can easily understand the feeling and respond as well [Y. Yang et al., (2007)]. However, when we talk about HRI, it becomes challenging for the humanoid robot to determine the exact emotion expressed by the person (human) who is interacting at a particular moment, especially when interacting with a group of people and when emotion is not evident with the face because according to psychologist numerous types of expression can be produced by a human. Moreover, we have only seven recognized expressions: Natural, Happy, Sad, Anger, Surprise, Fear and Disgust.

Robotics has become a very emerging area in today's world; it plays a significant role in various fields like medical science, military applications, home appliances, education, and many more. In recent years, a popular research area in robotics has been developing intelligent robots that can interact with people as companions rather than machines. To interact with a humanoid robot, HRI is very important; studies of human-robot interaction will be improved by automated emotion interpretation. A humanoid robot must be able to understand the person's actual emotional state at a particular instance.

Here the proposed method used our previous emotion recognition method that represents the intensities of the emotions instead of emotion. Once the intensity of the emotion was known, the main goal was to determine fusion weight for each primary emotion based on all those parameters, which include mood, personality, and intensities of the recognized emotional states employing fuzzy Kohonen clustering network (FKCN), which give us a smooth variation of facial expressions. Finally, the control point's vector is used to mimic the artificial face simulator [Prince. M. (2017)].

The parameter is determined as; for the mood previous emotional state has been buffered, for personality Big Five model of personality has been considered [Power R. A. et al. (2015)], for Euclidean intensity distances between the feature vector of standard and user emotion are proposed being used, for speech the training data set of data statistic and machine learning based on Ultra-large-scale database of natural language are used [McGilloway et al. (2000); Greasley (2000); Mohamad Nezami et al. (2019)], and for the colour around eyes RGB color patterns for different emotions have been used [Johnson et al. (2013)].

One of the objectives of most of the research is to improve the life of human beings. So in this regard studying human-machine behaviour becomes essential. Moreover, Human-Computer Interaction (HCI) is one of the areas under which humans and machines should have better communication skills. Ultimately, when we communicate with the humanoid robot, we want to communicate as a companion rather than as a machine closer to human nature.

Here, we are proposing a humanoid robot model that can emotionally respond and a human being. The robot can recognize the user emotional state and would respond accordingly. That could mean that if the user is happy, then the robot should behave like if it is also happy, which would improve the interaction between a human and a machine. The problem arises for the robot to communicate with a user whose expression is not clear on his face, especially when people are involved.

The rest of the paper organized as the related work section is following this section then the complete methodology is presented, the result and discussion section is presented following the methodology and finally the work was concluded.

II. Literature Review

Most research on robotics heads mimicking human facial expression is done in some universities and research institutions of the United States, Japan, and the European Union. A robot called Kismat is one of the examples of it, developed by Cynthia Breazeal at the Massachusetts Institute of Technology. Waseda University, Japan, has developed a series of robots named WE-R since 1996 [Hiroyaus Miwa, (2001)].

In the recent decade, many researchers have been trying to recognise human beings' facial expressions automatically. Various pattern recognition methods have been used in order to recognize facial expressions. As in our previous works [Master Prince, (2013a); Master Prince (2013b)], the novel approach has been introduced to recognize facial expressions. As discussed in [Young. A. W. et al., (1989); Padgett. C. et al. (1997)] reported that approaches to emotional robot design often adopted results from psychology to design robot behaviours to mimic human beings. Miwa et al. proposed a mental model to build the robotic emotional state from external sensory inputs [Miwa. H.et al., (2003), Miwa. H.et al. (2004)]. Duhaut presented a computational model which includes emotion and personality in robotic behaviours [Duhaut. D. (2008)]. Moshkina et al. give a model of time-varying effective response for humanoid robots based on the Traits, Attributes, Moods and Emotions [Moshkina et al. (2011)]. One of the most important aspects is the robot mood transition from the current to the next mood state, which influences the robot's interaction behaviour and a user's feeling. Meng-Ju Han et al. introduced an effective model to make transition among mood states would become smoother and thus might enable a robot to respond with more natural emotional expressions [Meng-Ju Han et al. (2013)]. Imitating emotions with RGB patterns has previously been proposed with other types of robots. For example, Kanoh et al. asked 50 people to identify which of Ekman and Friesen's six basic emotions the Ifbot was imitating with its 29 pre-programmed facial expressions [Ekman P. et al. (1969), Kanoh. M. et al. (2005)]. Angelica Lim and Hiroshi G. Okuno proposed speech and gait analysis to recognize human emotion [Angelica Lim et al. (2012)].

Previous researches have shown powerful tools for designing emotional robots. It is observed that exact emotion recognition and exact mimicking the artificial emotion plays a vital role in effective HRI. These representations lack a theoretical basis to support the assumptions in their emotion recognition design and simulation of the artificial face. That motivates me to investigate an effective emotion recognition system and an excellent artificial face simulator. Emotion recognition system by recognizing the pattern of the facial muscles is not enough. The speech recognition and speech synthesis function modules are embedded as emotion recognition procedures [Jianfeng *et al*. (2019); Mehmet *et al.* (2020)]. The combination of control point vectors and RGB patterns is used to imitate the artificial emotion with a smooth mood transition and get back to its normal intensity state of the current emotion after showing its actual intensity. Questionnaire surveys were conducted to evaluate the effectiveness of the proposed method.

III. Proposed Work

Our previous work proposed a model artificial brain emotion recognition and generation system (ABERGS) [Prince. M. (2017)]. This work is an extension of ABERGS, where facial expression is fused with the voice to simulate artificial expression. In our proposed work, the loud voice recognized by the robot were classified as recognized emotion using the trained CNN model [Jianfeng et al. (2019)] and RGB patterns were used to enhance artificial expression [Johnson et al. (2013)]. The purpose of the RGB pattern is to use it around the robot's eyes to express exact emotion.

In order to find out RGB color patterns against each specific emotion, an experiment was set up.

A. Speech Emotion Recognition

Fig. 1 illustrates the layers which are substituted to the CNN (feature learning block (FLB) and LSTM (Long short-term memory). Four FLBs extract the low-level features of speech, such as emotional features, and LSTM can learn the high-level features, which contain both the local information and the long-term contextual dependencies.

The pretrained model [Jianfeng *et al*. (2019)] was used as transfer learning to get trained with emotional speech dataset [McGilloway *et al.* (2000)], and the accuracy was outstanding, as shown through the confusion matrix in Fig. 2. The idea was to verify the accuracy of the model.

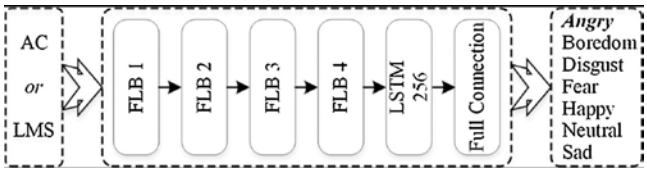

Fig. 1. Block Diagram of the Overall Architecture of the CNN [Jianfeng et al. (2019)].

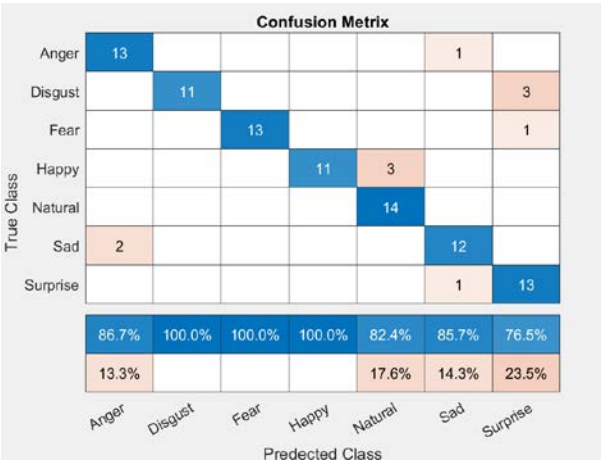

Fig. 2. Confusion Matrix Post-Training Model [Jianfeng *et al*. (2019)] with 98 Samples of [McGilloway *et al.* (2000)] Emotional Speech Dataset.

B. RGB Pattern Recognition

A movie clip against each major emotion (Natural, Happy, Sad, Anger, Surprise, Fear, and Disgust) has been selected. In a small theatre room, 20 participants are invited to watch the movies. A video (pointing to eyes) of each participant has been made against each movie clip. Now we have 7*20 videos (20 videos for each emotion). Now, each video is analyzed as below:

Measurements of the following attributes of each color (R, G and B) for each emotion.

- Intensities: An intensity of emotion.
- Duration: How long does emotion exist?

Intensity calculation: Here, the intensity is measured in terms of the RGB scheme. Each frame of the video is converted into a grayscale color scheme. Each color's intensities (R, G and B) can range between 0-255.

$$^{H}I_r = \sum_{f=1}^{20} r/20 \quad (1)$$

$$^{H}I_g = \sum_{f=1}^{20} g/20 \quad (2)$$

$$^{H}I_b = \sum_{f=1}^{20} b/20 \quad (3)$$

The above equations show the average intensity of each color pattern (R, G and B) against happy emotion. Here R, G and B value ranges from 0 to 255. The same intensities of each color pattern (R, G and B) for all other emotions can be calculated.

Duration calculation: The time duration between emotions initiated and coming back to the normal state. The RGB value for normal emotion has got 150, 150, and 0, respectively. It consists of two things;

- Rise time: Time is taken to rise from normal to peak value.
- Fall time: Time is taken to return to the normal from the peak value.

$$D_H = D_r + D_f \quad (4)$$

where D_H is the total duration of an emotion existing on the face, D_r is the time taken to rise from normal to peak, and D_f is the time taken to return to the normal from the peak value. Same as intensity, duration is also calculated on average.

After analysis, all the videos, follow Table I is obtained. Which shows duration, color (RGB), rise and fall time for all recognized emotions. Table I: RGB color pattern's Intensities, Duration, Rise time and Fall time.

C. RGB Pattern Evaluation

Table I from the previous experiment determined which pattern of color intensity and duration of the RGBs that humans associate with specific emotions. The purpose of this experiment is to examine whether humans recognize these RGB patterns as emotions or not. Two RGB patterns for each emotion are based on Table I and glow through the computer screen, as shown in Fig. 3.

TABLE I. RGB COLOR PATTERN'S INTENSITIES, DURATION, RISE TIME AND FALL TIME

Emotion	Duration (Sec)	Color(RGB)	Rise time (%)	Fall time (%)
Normal 0 150, 150, 0 0 0 Anger 1.7 255, 0, 0 83 17 Surprise 4.0 255, 255, 0 83 17 Disgust 2.3 0, 75, 0 83 17 Sadness 4.3 0, 100, 225 20 80 Happiness 2.1 200, 120, 0 80 20 Fear 4.0 0, 20, 80 20 80				

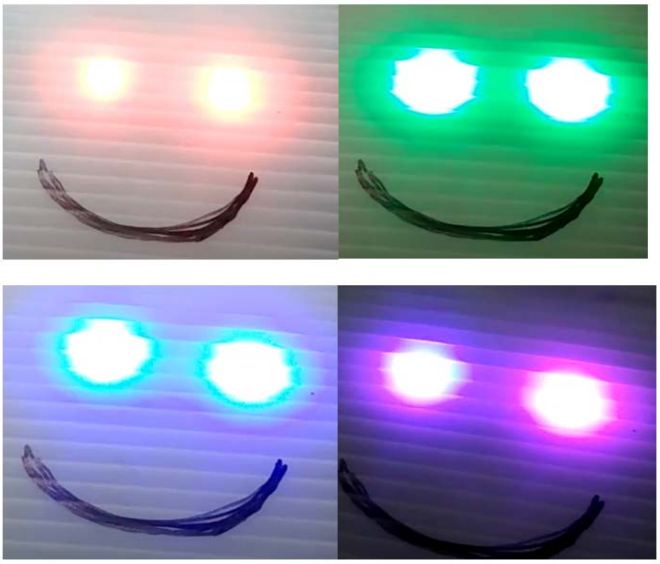

Fig. 3. RGB Patterns shown on the Computer Screen to Recognize Emotion for RGB Pattern Evaluation.

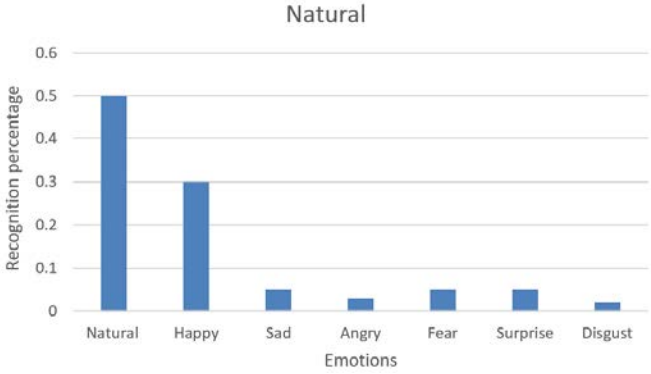
For this, fifty participants were invited, and a survey was conducted. They were asked to check on the recognized emotion after seeing the RGB pattern on the computer screen into robot eyes, and the patterns were shown in random order to avoid ambiguity.

The responses of the participants are interpreted into a bar chart, as shown in Fig. 4. The result was significant as all the emotions were recognized. Moreover, some ambiguity was witnessed between Natural and Happy, Sad and Angry, and Fear and Surprise.

Finally, the data has been collected and analyzed.



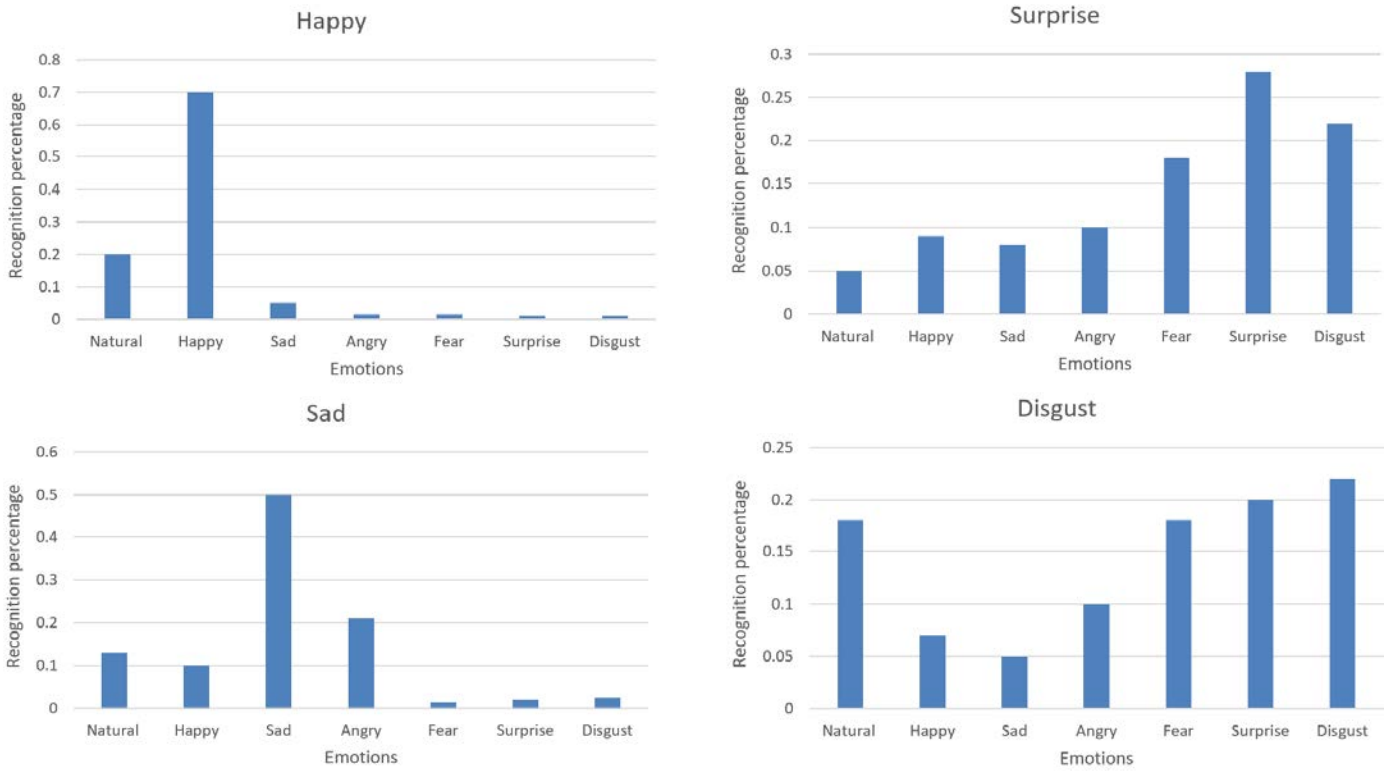


Fig. 4. Average Degree of Recognition for RGB Patterns against each Emotion.

IV. Result and Discussion

The result shows a moderate degree of recognition against each emotion. As a result, it was a bit ambiguous, but when it combined with ABERGS [Prince. M. (2017)], the result was very effective. Fig. 5 illustrates the simulated image.

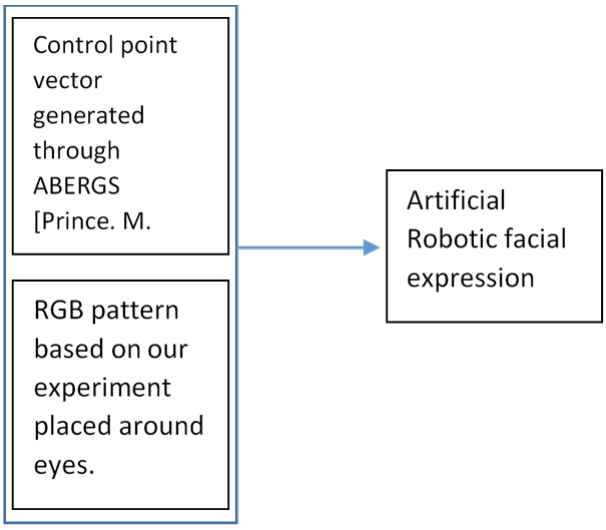

Fig. 5. ABERGS [Prince. M. (2017)] and the RGB Pattern used simultaneously to Mimic Robotic Facial Expression.

TABLE II. COMPARATIVE SATISFACTION LEVEL OF ABERGS [PRINCE. M. (2017)] VS ABERGS [PRINCE. M. (2017)] WITH RGB

Emotions	Satisfaction Level (without voice)	Satisfaction Level (With voice fusion)	Satisfaction Level (With RGB Pattern)
Natural	96.5%	98%	98.7%
Happiness	97%	98%	99%
Surprise	96.5%	97.5%	98%
Fear	97.5%	99%	99.2%
Sadness	96%	98%	98.3%
Disgust	97.5%	98.5%	99%
Anger	95.0%	98%	99.8%

Table II illustrates the effectiveness of the RGB pattern with ABERGS [15].

V. CONCLUSION AND FUTURE WORK

The proposed model uses facial image, voice and simulate artificial emotion on a robotic face with an RGB pattern in the eyes. With the first experiment and RGB patterns were determined, and with the second experiment, the model's effectiveness was tested. The results were very effective. For future work, human gait can also be considered in order to recognize the emotion of the human being. Second, we will focus more on processing speed by using GPU with an efficient algorithm.

ACKNOWLEDGMENT

Abstract*—Stroke is the second leading cause of death globally. Computed Tomography plays a significant role in the initial diagnosis of suspected stroke patients. Currently, stroke is subjectively interpreted on CT scans by domain experts, and significant inter- and intra-observer variation has been documented. Several methods have been proposed to detect ischemic brain stroke automatically on CT scans using machine learning and deep learning, but they are not robust and their performance is not ready for clinical practice. We propose a fully automatic method for acute ischemic stroke detection on brain CT scans. The system's first component is a brain slice classification module that eliminates the CT scan's upper and lower slices, which do not usually include brain tissue. In turn, a brain tissue segmentation module segments brain tissue from CT slices, followed by tissue contrast enhancement using the Extreme-Level Eliminating Histogram Equalization technique. Finally, the processed brain tissue is classified as either normal or ischemic stroke using a classification module, to determine whether the patient is suffering from an ischemic stroke. We leveraged the use of the pre-trained ResNet50 model for slice classification and tissue segmentation, while we propose an efficient lightweight multi-scale CNN model (5S-CNN), which outperformed state-of-the-art models for brain tissue classification. Evaluation included the use of more than 130 patient brain CT scans curated from King Fahad Medical City (KFMC). The proposed method, using 5-fold cross-validation to validate generalization and susceptibility to overfitting, achieved accuracies of 99.21% in brain slice classification, 99.70% in brain tissue segmentation, 87.20% in patient-wise brain tissue classification, and 90.51% in slice-wise brain tissue classification. The system can assist both expert and non-expert radiologists in the early identification of ischemic stroke on brain CT scans.

I. Introduction

Globally, stroke is a leading cause of death, accounting for around 15 million deaths annually [1], [2]. Even in low-income and middle-income countries, stroke is a major cause of mortality, and in the Kingdom of Saudi Arabia (KSA), annual stroke incidence has increased to 29.8 per 100,000 [3]. Notably, 87% of all stroke incidents result from ischemic stroke, whereas the remaining 13% are hemorrhagic [4]. Andersen et al. [5] investigated 39,484 stroke patients, reporting that 35,491 (89.9%) suffered from ischemic stroke and 3,993 (10.1%) experienced hemorrhage stroke. Generally, stroke arises from the sudden interruption of blood flow to neuronal tissue; a blockage within blood vessels leads to ischemic stroke, while blood vessel rapture causes hemorrhagic stroke [2]. To manage ischemic stroke, anti-thrombolytic therapy (removing the blockage by clot breaking) and thrombectomy (removing the clot mechanically) are used, while decompression and blood pressure reduction are used for hemorrhagic stroke [2].

Diagnostic imaging is essential in routine clinical practice to confirm early-stage ischemic stroke. Computed Tomography (CT) is regarded as the front-line modality to evaluate patients with suspected stroke due to its accessibility and cost-effectiveness, which is not the case with Magnetic Resonance Imaging (MRI) [6], [7]. Typically, suspected stroke patients are handled by emergency room physicians, and the condition is often misdiagnosed or diagnosed late due to difficulties in arranging urgent assessments with experienced neuro-radiologists. This often negatively influences stroke management [8].

State-of-the-art methods in computer science are assisting clinicians and neurologists, including for the application of image processing techniques to digital medical images [9], [10], [11]. For example, Chung et al. [12] developed a system to detect hyperacute ischemic stroke in CT images, achieving an accuracy of 81% in classifying stroke and non-stroke images. Methodologically, the authors extracted ranklet features from pre-processed CT images and identified 23 important features for stroke detection, 8 of which were used to establish the prediction model. Guoqing et al. [13] developed a system based on asymmetric image patch classification to detect ischemic stroke signs on non-contrast CT images, achieving an accuracy of 76.84% on 108 stroke cases that trained radiologists did not detect.

Chin et al. [14] developed a CNN model for automatic ischemic stroke diagnosis. Model training and testing involved 256 patch images of size 32×32 extracted manually from CT images. Their system achieved testing and training accuracies of 92% and 97%, respectively. Pereira et al. [15] used two CNNs, one with a 50/50 protocol and another with 75/25, for training and testing with 300 CT images (100 healthy, 100 ischemic, 100 hemorrhagic). Contrasting architectures were used, with the most effective results being 97.5%, 100%, and 99.1% classification accuracies for hemorrhagic, ischemic, and healthy images, respectively, using the 75/25 protocol on their second model. Anis et al. [16] applied deep transfer learning for ischemic stroke detection on CT images, using 400 images with data augmentation (specifically, horizontal flipping) to compare the results to ResNet50, GoogleNet, and VGG-16 pre-

trained CNNs. Using 5-fold cross-validation, they reported that ResNet50, GoogleNet, and VGG-16 achieved 100%, 99.4%, and 92.2% accuracies, respectively, on their training set, while accuracies of 100%, 98.8%, and 90% were reported on the validation set.

Gautam and Raman [17] developed a 13-layer CNN model to classify ischemic and hemorrhagic stroke. Their CT image dataset (300 healthy, 300 ischemic, 300 hemorrhagic) was pre-processed using quadtree-based multi-focus image fusion [18]. Two copies were created for each image, after which contrast adjustment was applied to the first and filtering to the second using a 3×3 averaging filter. The copies were fused and passed to the CNN model, which consisted of an input layer (512×512×1) and two convolutional layers, each followed by a Rectified Linear Unit (ReLU) activation and max-pooling layer, two fully connected layers with a ReLU activation and dropout layer after the first fully connected layer, and a softmax classification layer. Two datasets were established, one containing stroke images only and another containing both stroke and healthy images, and an 80/20 data split protocol with 10-fold cross-validation was applied in each case. They achieved 98.33% and 98.77% classification accuracies on the first dataset, respectively, whereas 92.22% and 93.33% were achieved for the second dataset. The model significantly outperformed fine-tuned AlexNet and ResNet50.

These results highlight the clinical value of computational techniques in stroke detection [19], [20]. However, there is room for improvement, which has caused researchers to leverage Deep Learning (DL) techniques. DL is a subfield of artificial intelligence wherein algorithms learn to make accurate predictions without explicit programming [9], [11], [19]. Convolutional Neural Network (CNN) is a biologically inspired DL paradigm that holds promise in diagnostic medicine due to its ability to outperform humans in image and speech recognition/translation tasks [21].

This research proposes a DL system for acute ischemic stroke classification on brain CT scans. The system determines whether a brain CT slice contains brain tissue, segments the brain tissue, enhances the contrast of the segmented brain tissue, and identifies signs of acute ischemic to determine stroke incidence. CNN-based techniques are adopted in the first two tasks, whereas an efficient multi-scale CNN model – the 5-Scale CNN model (5S-CNN) – is proposed to resolve difficulties associated with distinguishing between normal/abnormal brain regions. A dataset from King Fahad Medical City (KFMC) containing over 130 annotated patient records is used to design, develop, and validate the system, and cross-validation is performed to evaluate the CNN models.

II. Proposed Method

The main technical objective of this research is to develop a robust and intelligent method for the diagnosis of ischemic stroke on brain CT scans, which will assist the clinical decision-making of neurologists. In routine clinical practice, brain CT scans are manually interpreted by professionals, expert operators, or both. This process involves the manual scanning of each slice of the patient's brain CT scan for the presence of stroke. Each patient's CT scan contains 35 to 45 CT slices on average (based on the collected dataset). Manual scanning also includes manual adjustment and enhancement of the contrast of the scanned slice for better visualization.

To formulate such a process, let $C = \{S_i\}_{i=1}^{n}$ represent a patient's CT scan, which consists of n slices S_i of size 512×512×1, as shown in Fig. 1.

Ischemic stroke can appear in any slice within a patient's CT scan; it can also appear at any location in the brain tissue within a slice. Ischemic stroke changes the texture of the affected region of brain tissue, as indicated by comparing the left panel of Fig. 2, which shows a normal brain CT slice, to the right panel, which shows an example of acute ischemic stroke.

Fig. 2 reflects the fact that ischemic stroke can affect any region of the brain tissue. Additionally, the affected area can have any regional size. The affected area becomes darker in texture as the time from its occurrence increases [22].

To determine whether a patient is experiencing an ischemic stroke, it is necessary for a sign of the ischemic stroke to appear on at least one slice of the patient's CT scan. Therefore, each slice must be processed individually, which can be categorized as a classification problem. In any given brain CT slice, there are usually parts that are irrelevant (e.g., scalp, skull, and unrelated background objects) because they do not contribute to the diagnosis. Such parts must be removed, enabling only the brain tissue region to be segmented and separated, which can be categorized as a segmentation problem. Additionally, certain slices in the upper and lower parts of the CT scan do not include brain tissue, and so these slices must be excluded before any processing occurs. This also is categorized as a classification problem, the objective of which is to identify whether a given CT slice contains brain tissue.

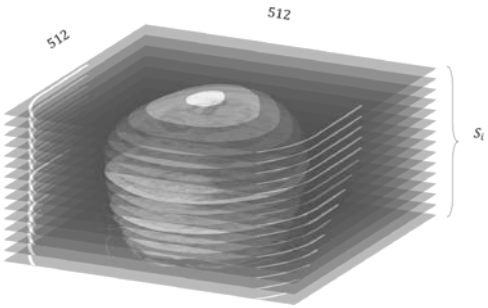

Fig. 1. Brain CT Scan of a Patient.

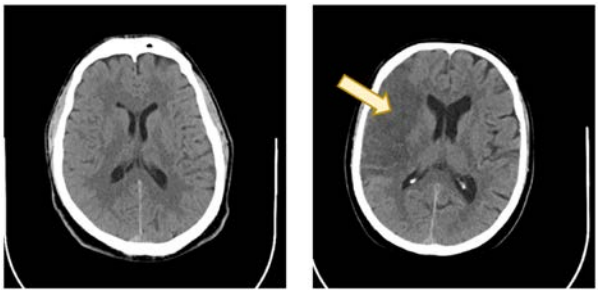

Fig. 2. Normal Brain CT Slice (Left) and Acute Tschemic Stroke (Right).

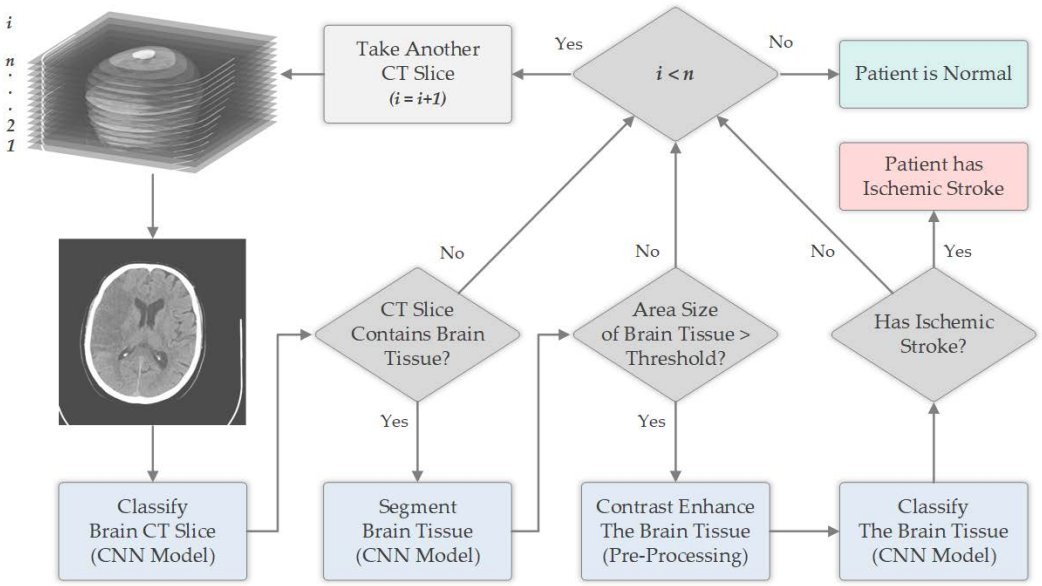

Fig. 3. The Architecture of the Proposed Method.

Given the above discussion, the development of an intelligent method for the automated diagnosis of a patient's brain CT scan involves four main components, which collectively process each slice of a given brain CT scan and systematically determine whether the patient is experiencing an ischemic stroke. As shown in Fig. 3, these components are the Brain CT Slice Classification Model, Brain Tissue Segmentation Model, Brain Tissue Contrast Enhancement Component, and Brain Tissue Classification Model.

The proposed method begins by reading an input CT slice to determine whether the slice should be considered for processing. In any brain CT scan, it is common for the first and last few slices not to contain brain tissue; these slices must be removed prior to any further processing. Also, since some of these CT slices do not contain brain tissue, despite having textural similarities to slices with brain tissue (see Fig. 4), it is necessary to leverage a classification model to determine whether a given slice contains brain tissue.

Before developing this model, a dataset was prepared containing labeled images of CT scan slices with and without brain tissue. Fine-tuning, training, and evaluation of the pre-trained networks were performed. Fine-tuning involves updating each model's input layer to match the size of brain CT slices, which are fixed at 512×512×1. Also, the first convolutional layer's kernels, which are 3-dimensional (spatial × depth) kernels $k(x, y, 3)$, are updated to 2-dimensional kernels $k'(x, y)$ using the mapping $K: k(x, y, 3) \rightarrow k'(x, y)$ such that

$$k'(x, y) = K(k(x, y, 3)) = \frac{1}{3}\sum_{d=1}^{3} k(x, y, d) \quad (1)$$

The final classification layer was also replaced with a new classification layer consisting of two neurons. This is because CT slice classification is a two-class problem (i.e., slice with/without brain tissue). Fig. 5 shows the concept of updating a pre-trained network to be re-trained for brain CT image classification. Training and evaluation included the use of K-fold cross-validation, which increased reliability and generalization and enabled the selection of the model with the best results.

After confirming the existence of brain tissue within the input CT slice, the brain tissue segmentation component detects and segments the brain tissue. In this process, irrelevant parts are removed and only the brain tissue is retained. It begins with an original input slice, as shown in Fig. 6(a). A trained semantic segmentation model is then applied, resulting in an image segmented by class, as in Fig. 6(b). Finally, morphological image analysis is implemented by maintaining the largest segmented group of pixels and filling its holes to obtain the segmented brain tissue [25], as shown in Fig. 6(c).

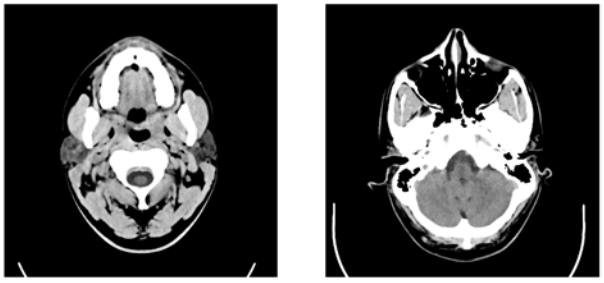

Fig. 4. CT Image with No Brain Tissue (Left) and CT Image with Brain Tissue (Right).

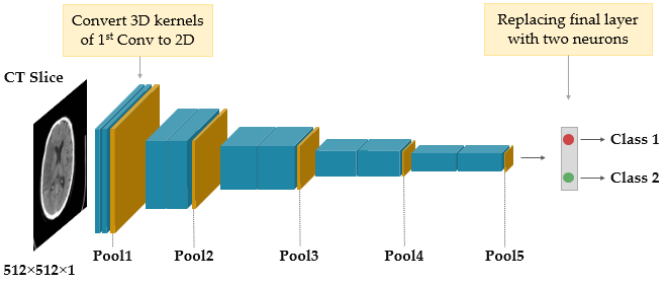

Fig. 5. Adopting a Pre-trained CNN Model for CT Slice Classification.

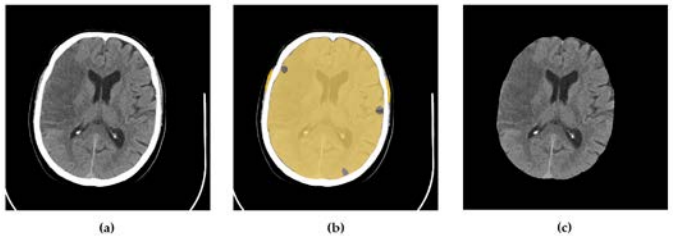

Fig. 6. Brain Tissue Segmentation: (a) Original Image, (b) Applying Semantic Segmentation Model, and (c) Maintaining the Largest Segmented Group of Pixels and Filling its Holes.

DL-based segmentation methods have shown promising results for the segmentation of medical images [26], [27], [28]. The state-of-the-art DL-based framework, namely Fully Convolutional Networks (FCNs) [29], has been used for brain tissue segmentation. FCNs implement a pixel-wise classification process using a CNN model as a classification backbone, which classifies each pixel within an image and assigns it to a particular class, thereby resulting in an image segmented by class. We employed the FCN-8 architecture and tested the four widely-used state-of-the-art pre-trained CNN models as a classification backbone: AlexNet, GoogleNet, ResNet18, and ResNet50. As in brain CT slice classification, ResNet50 yielded the best segmentation results compared to the other models.

Before developing this model, an annotated dataset was prepared by manually annotating the pixels of each CT slice. Each pixel value in every image of this dataset represents a categorical label (either a brain tissue pixel or not). Fine-tuning involved updating the backbone model's input layer to take a CT slice of size 512×512×1 as input and, in turn, updating the first layer's kernels from 3D to 2D, as implemented for slice classification. In addition to this update, all pre-trained models were modified according to the FCN-8 up-sampling structure of the FCNs approach [29]. For training and evaluation, K-fold cross-validation was also used to select the most reliable and generalized segmentation model. Fig. 7 illustrates the concept of updating a pre-trained network according to the FCN-8 architecture to be re-trained for brain tissue segmentation.

Although the optimal segmentation model may lead to high segmentation accuracy, it is common for certain pixels or groups of pixels to be misclassified. This is shown in Fig. 6(b), where some pixels are classified as brain tissue while they are not, and vice versa. Therefore, post-processing is needed, which involves removing small connected components of pixels, and retaining the largest connected group of pixels (which usually represents brain tissue). This is followed by filling in the holes [30], [25] if there is a sufficient ischemic stroke identification area size. Based on recommendations from a medical team, the final segmented brain tissue must be sufficiently large in terms of its area to contribute to the identification of an ischemic stroke. Thus, to make decisions about whether to include or exclude the segmented brain tissue for further processing, the area of the segmented brain tissue (in pixels) is compared to a fixed threshold recommended by the medical team. This comparison excludes any insufficient and small, segmented brain tissue that has an area smaller than the fixed threshold.

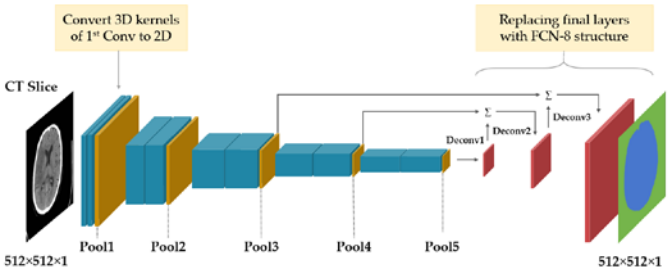

Fig. 7. Adjusting a Pre-Trained Network for Brain CT Image Ssegmentation using FCN-8 Structure.

Due to the low contrast of brain CT slices, multiple image contrast enhancement techniques have been proposed, particularly for medical images [31], [32], [33], [34]. These techniques are used to boost the interior details within brain tissues for visibility, classification, and ultimately interpretation. The Extreme-Level-Eliminating Histogram Equalization (ELEHE) method, proposed by Tan et al. [35], was developed mainly to improve ischemic stroke detection on brain CT images. ELEHE ensures that substantial differences in the distribution of the input CT image histogram are eliminated, resulting in a stretched histogram containing every intensity level value other than the unnecessary two extreme levels that result from regular Histogram Equalization (HE) [30].

Before enhancement, each slice is normalized by stretching the grey-level values within the range of 0 to 216. To enhance a CT slice using ELEHE, the first step calculates the Probability Density Function (PDF) of the slice's grey-level values. The next step involves eliminating the two extreme levels of the resulting PDF, thereby ensuring the maintainability of those levels while stretching the remaining grey levels. Following this, the Cumulative Density Function (CDF) is computed, after which a Transfer Function (TF) is applied to the values of the resulting CDF. Fig. 8 shows a brain CT image enhanced with ELEHE contrast enhancement.

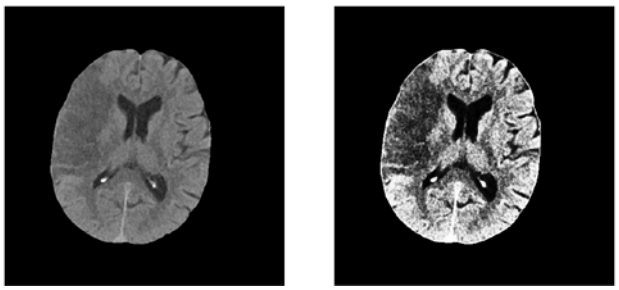

Fig. 8. Brain CT Image (Left) and Brain CT Image after applying ELEHE (Right).

After segmenting the brain region and applying contrast enhancement, the resulting brain tissue is classified to determine whether the CT slice is a case of normal or ischemic stroke, the latter of which indicates that the patient is suffering from ischemic stroke. If the classification of every processed slice of the CT scan is normal, then the patient is regarded as not suffering from ischemic stroke. Since there are two classes to consider (i.e., ischemic stroke or normal), the dataset preparation for this classification included labeled CT slices

indicating an incidence of ischemic stroke or not. All slices with ischemic stroke incidence were labeled as acute, while slices with no stroke incidence were labeled as normal.

Ischemic stroke can manifest with any regional size and it can appear at any location within the brain tissue visualized by CT. Given this, a multi-scale analysis of brain tissue is needed to determine whether there is an instance of ischemic stroke. State-of-the-art pre-trained CNN models such as AlexNet, GoogleNet, ResNet18, and ResNet50 deal with only one scale, therefore the performance of these models is unsatisfactory. To overcome this issue, a lightweight multi-scale CNN model named the 5-Scale CNN model (5S-CNN) is proposed. After segmentation and contrast enhancement of the input CT brain tissue image, 5S-CNN uses a 5-branch architecture wherein each branch applies a different filter size to learn features at different scales.

5S-CNN consists of 77 layers, as shown in Fig. 9. Within this model, a total of 16 convolutional (Conv) blocks are used, where each block starts with a Conv layer followed by Batch Normalization (BN) and Rectified Linear Unit (ReLU) layers. The ReLU layers introduce non-linearity into the model in a very simple way of applying a thresholding operation to the pixels resulting from the BN layers, in which positive pixels are retained, and negative ones are assigned to zero. A max-pooling layer is positioned after each Conv block, resulting in a total of 16 pooling layers in the proposed model. The use of max-pooling layers enables the selection of only one pixel whose value is the highest compared to the other pixels within the pooling receptive field. This leads to the extraction of relevant features as well as a reduction in image size.

Within the first Conv layer of the proposed model, 16 filters with a size of 4×4 and stride of 2×2 are used, which down-samples the CT input image from 512×512×1 to 255×255×16. Thereafter, max-pooling with a size of 3×3 and stride of 2×2 is applied, which reduces the first Conv output size to 127×127×16. It is then passed to 5 branches having three consecutive Conv blocks in each branch. The first Conv blocks in these branches contain 32 filters in each branch with sizes of 11×11, 9×9, 7×7, 5×5, and 3×3 in order to extract and learn features at different scales. After the first Conv block of each branch, two Conv blocks are used with 64 and 128 filters, respectively, of size 3×3 and stride 1×1; in these Conv blocks, a 3×3 filter size is used to reduce the number of learnable parameters as well as the model's computational cost. Additionally, each Conv block within each branch is followed by a max-pooling layer with a receptive field size of either 3×3 or 2×2 depends on whether the previous output feature map is odd or even in terms of its width and height.

At the end of each branch, a Global Average Pooling (GAP) layer is used to generate a channel descriptor for that branch. The resulting 5 GAP descriptors are combined using a concatenation layer and, in turn, for fusion, the output is used as an input to a Fully Connected (FC) block that has an FC layer with 256 filters, followed by a BN layer and ReLU layer, respectively. In the end, a single FC layer with two neurons and a softmax are used as a classifier. The number of neurons in this FC layer is targeted at the number of classes of interest (i.e., ischemic stroke or normal).

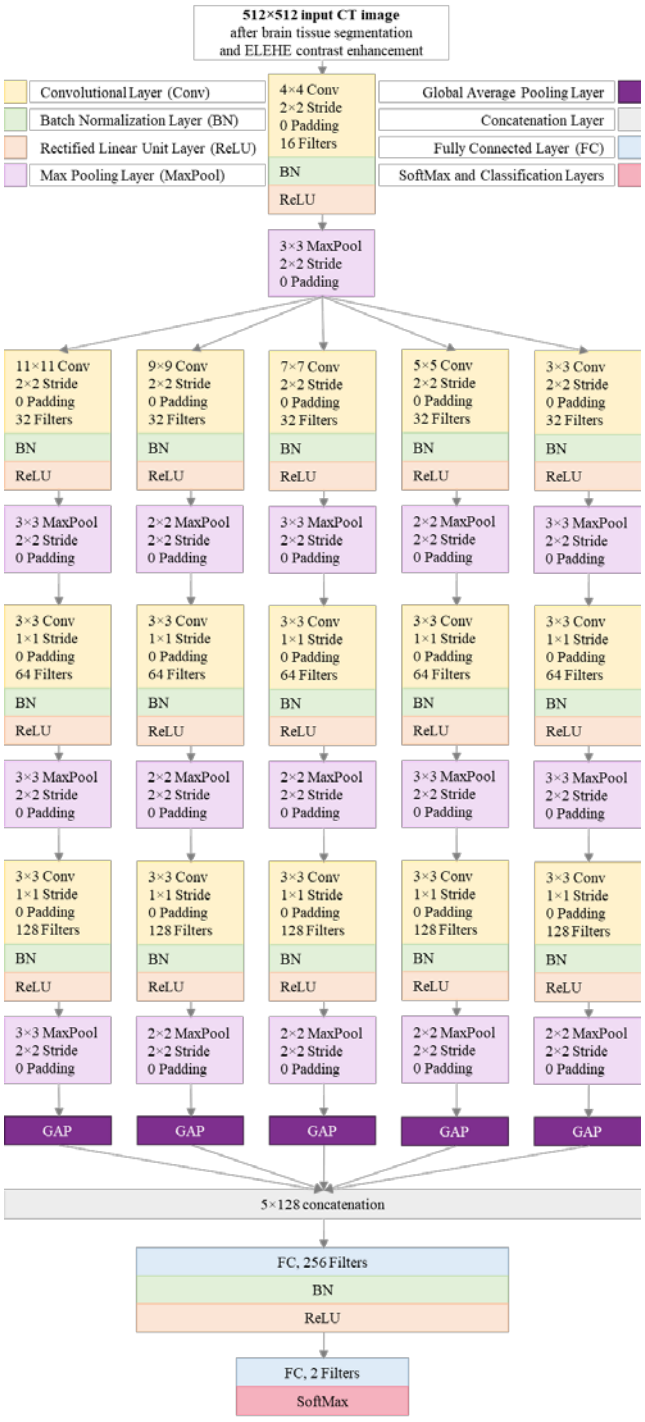

Fig. 9. The Proposed 5-Scale CNN Model (5S-CNN) Architecture for Ischemic Stroke Classification.

For comparison, the pre-trained models for tissue classification were fine-tuned using the approach adopted in the first and second components (i.e., CT slice classification and brain tissue segmentation). Specifically, the input layer of each pre-trained model was updated to match the DICOM brain CT image size of 512×512×1. Additionally, the filters' weights for the first convolutional layer were updated from 3-dimensional kernels to 2-dimensional kernels, which was achieved by taking the mean of each filter value across the

depth dimension, as in (1). The final classification layer was replaced with new classification layers targeted at brain tissue classification.

The same training and evaluation procedures were performed on each model, including the 5S-CNN, and each segmented CT slice was contrast-enhanced using ELEHE before being passed as an input to any model. As in the first and second components, K-fold cross-validation was used to validate the reliability and generalization of each model.

III. Dataset Collection, Annotation, and Preparation

The dataset used to develop and validate the proposed method was collected from King Fahad Medical City (KFMC) under Institutional Review Board (IRB) approval with log number (17-031). The dataset contains brain CT scans from more than 130 patients, consisting of proven cases of both normal and acute ischemic stroke scans. The collection process involved compiling a shortlist from clinical and radiologic databases of patients who presented at emergency rooms or clinics between January 2015 and January 2018 with symptoms and signs of stroke. Revision for inclusion and exclusion of the selected patients was performed, in which scans with artifacts (e.g., motion and metal) and findings of hemorrhagic stroke were excluded. The remaining scans were included for analysis and modeling. During the medical team's annotation process, records of included patients were annotated and categorized into either normal or acute based on review findings. Each scanned record was further annotated by specifying the slices of the patient's CT scan that were affected by the ischemic stroke.

Dataset preparation for the Brain CT Slice Classification Model included a subset of 1,130 CT images selected randomly from 100 patients. The dataset contained 570 images labeled as Brain CT Slice from 50 patients, and 560 images labeled as Not Brain CT Slice from 50 patients. For the Brain Tissue Segmentation Model, another subset of the collected dataset was prepared that included 365 CT images from 18 randomly selected patients. This subset was manually labeled using MATLAB Image Labeler under the supervision of the medical team. Pixel-wise labeling was used to label each selected image, wherein each pixel in every image was labeled as either Brain Tissue or Not Brain Tissue. In the Brain Tissue Classification Model, the collected dataset included 63 patients with an acute diagnosis, having 300 CT images labeled as Acute. For data balancing and cross-validation, 62 patients with a normal diagnosis were selected, having 300 CT images labeled as Normal.

IV. Data Augmentation

A large number of training images is required to train deep learning models, especially for image classification tasks. When only a small number of training images is available, model overfitting to the training images arises, which weakens the model's ability to adapt to new data. Different image augmentation techniques exist that can be used to improve the performance and generalization of deep learning models. These techniques rely on the creation of different forms of the original images used for training [36].

In our case, five augmentation techniques were used in the training of all models, including random reflection in both horizontal and vertical axes. The horizontal reflection applies the random reflection in the left-right direction of the image, while the vertical reflection applies the random reflection in the top-bottom direction. The other two techniques used were image translation on both directions of the input image, including the x-axis direction (horizontally) and the y-axis direction (vertically). It is necessary to specify a pixel range for this translation technique, which was set at 10 pixels for both translation directions. The fifth augmentation technique was random rotation, which was set in the range of 10º image rotation clockwise and anticlockwise.

V. Experiments and Results

All experiments were performed on a machine running the 64-bit Windows 10 operating system. The machine had an Intel® Core™ i7-8750H CPU @ 2.20GHz and 32GB of RAM, and it was equipped with an NVIDIA GeForce 1070 with 8GB of GPU memory. Model training and testing were implemented and evaluated using the 64-bit version of MATLAB R2020b.

To increase the generalization and reliability of the results, as well as due to data limitations, 5-fold cross-validation was used to validate the trained models. Depending on the type of model and its dataset, as in Table I, each model was trained and tested five times; every time, one-fold was used for testing, while the other four folds were used for training and validation. The data splitting approach was 70%, 10%, and 20% for training, validation, and testing, respectively.

TABLE I. Dataset Preparation for each Model

Model	Labeling Type	Labeling As	No. Images	No. Patients
Brain CT Slice Classification	Image as a class	Brain CT Slice	570	50
		Not Brain CT Slice	560	50
Brain Tissue Segmentation	Pixel as a class	Brain Tissue	365	18
		Not Brain Tissue		
Brain Tissue Classification	Image as a class	Acute	300	63
		Normal	300	62

In the Brain CT Slice Classification Model, 5-fold cross-validation was used to evaluate each of the fine-tuned pre-trained models (i.e., AlexNet, GoogleNet, ResNet18, and ResNet50). In each run of this approach, 226 images were used as a testing fold, while from the remaining images, 814 and 90 images were used for training and validation, respectively. For the Brain Tissue Segmentation Model, the adjustments to the pre-trained models, which included updating their structures to match the FCN-8 structure, were also evaluated using 5-fold cross-validation. In this case, each fold included 263, 29, and 73 images for training, validation, and testing, respectively.

Evaluation of the Brain Tissue Classification Model included evaluating the classification performance of the fine-tuned pre-trained models as well as the proposed 5S-CNN model in slice-level and patient-level classifications. Slice-level evaluation, considering that the same patient's slices are in only the training, validation, or testing dataset, demonstrates the slice-wise classification performance. However, patient-

level classification analyzes the performance for every slice of a patient and reports a single resulting class for that patient. Although patient-wise evaluation is the standard approach in the medical field [37], slice-level evaluation was also performed because a patient should be diagnosed with ischemic stroke if at least one slice of the patient's CT scan shows a sign of the ischemic stroke. The slice-level dataset splitting approach does not strictly comply with the 70%, 10%, and 20% method, especially when considering the use of cross-validation. The reason is that every patient will have a different number of CT slices that are affected by ischemic stroke. The patient-level acute vs. normal classification included 125 patients, and it was validated using 5-fold cross-validation. In each run of this approach, 25 patients were used as a testing fold, while from the remaining 100 patients, 90 were used for training and 10 for validation. ELEHE contrast enhancement was applied to each input image prior to Brain Tissue Classification.

Among the available optimization algorithms, the Adam optimization algorithm has been shown to outperform its counterparts. Therefore, all trained models were trained using the Adam optimization algorithm with a gradient decay factor of 0.9. The initial learning rate was set to 0.001 while the regularization factor was set to 0.0001. Each model was trained for 100 epochs with a minibatch size of 16 due to memory limitations.

For evaluation, the commonly employed performance measurements of accuracy, sensitivity, specificity, precision, and F1 score are used. However, the performance of segmentation models was evaluated in terms of pixel global accuracy, mean recall, mean Intersection over Union (IoU), Weighted Intersection Over Union (wIoU), and mean Boundary F1 (BF) score. Using 5-fold cross-validation, the mean and standard deviation of the resulting measurements over the five testing folds were reported. Performance measurements of the classification models were derived based on the concepts of True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN), as in (2–7).

For the evaluation of segmentation models, the pixel global accuracy measurement indicates the percentage of correctly identified pixels corresponding to the total number of pixels, regardless of the class type, as in (2). Mean recall measures the ratio of accurately classified pixels to the total number of pixels based on class type, which is averaged across both classes (see (3)). IoU computes the ratio of accurately classified pixels to the total number of ground truth and predicted pixels based on class type, as shown in (7). By averaging the resulting IoU over classes, the mean IoU can be obtained. In wIoU, the average IoU of each class is weighted by the total number of pixels in its corresponding class. The BF score calculates the predicted boundary of each class relative to its true boundary, as shown in (6). The mean BF score can then be obtained by averaging the resulting BF scores over classes.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN}(\times 100\%) \quad (2)$$

$$Sensitivity = \frac{FP+FN}{TP+TN+FP+FN}(\times 100\%) \quad (3)$$

$$Specificity = \frac{TP}{TP+FN}(\times 100\%) \quad (4)$$

$$Precision = \frac{TN}{FP+TN}(\times 100\%) \quad (5)$$

$$F1\ Score = \frac{TP}{TP+FP}(\times 100\%) \quad (6)$$

$$\text{IoU} = \frac{2TP}{2TP+FP+FN}(\times 100\%) \quad (7)$$

A. Experimental Results for Brain CT Slice Classification

The experimental results for the brain CT slice classification task, which is the first step of the proposed methodology (as shown in Fig. 3), are given in Table II. Each in Table II presents the evaluation results for each of the fine-tuned pre-trained CNN models (i.e., AlexNet, GoogleNet, ResNet18, and ResNet50). For each evaluated model, the mean and standard deviation of the resulting measurements are computed using 5-fold cross-validation.

Based on the obtained results (see Table II), the selected model for the brain CT slice classification task was the fine-tuned ResNet50. This decision was made because ResNet50outperformed other models on each metric except sensitivity which was equal to ResNet18 but better in terms of standard deviation.

B. Experimental Results for Brain Tissue Segmentation

The brain tissue segmentation results, using FCN-8 with different fine-tuned backbone models, are shown in Table III. In this experiment, 365 images were used, in which every pixel within each image was labeled as either a brain tissue pixel or not a brain tissue pixel. The results of Table III show that both ResNet18 and ResNet50 produced similar results, but both outperformed other models.

FCN-8 with fine-tuned ResNet50 performed excellently in segmenting brain tissue pixels, achieving 99.70% global accuracy with a standard deviation of 0.04% (see Table III). However, certain pixels were misclassified. Therefore, as explained in section II, post-processing was applied after brain tissue segmentation; the area of the largest segmented connected group of pixels in the CT slice (which usually represents brain tissue) was compared to a threshold fixed at 1,000 pixels to either include or exclude the brain CT slice for further processing. The threshold was fixed based on the recommendations of the medical team. This comparison ensures that the area of the segmented brain tissue is sufficiently large for the subsequent brain tissue classification task. After this, it is necessary to fill the holes within the segmented brain tissue to ensure that misclassified brain tissue pixels are included in the largest segmented connected group of pixels. Fig. 10 shows experimental examples of segmented brain tissues using FCN-8 with fine-tuned ResNet50 followed by post-processing.

C. Experimental Results for Brain Tissue Classification

After brain tissue segmentation, the final task is to classify the segmented brain tissue as ischemic stroke or normal. Patient-wise and slice-wise classification experiments were performed for validation in this experiment. Each input image was enhanced using the ELEHE contrast enhancement technique prior to the training and testing of the fine-tuned pre-trained models and the 5S-CNN. As shown in Table IV, the 5S-CNN model with ELEHE contrast enhancement

outperformed the other models for every scenario, reflecting its power in terms of multi-scale feature learning. In addition, the decision made regarding the number of branches used in the proposed multi-scale CNN model (5S-CNN) was based on experimenting with the multi-scales of 2, 3, 4, and 5 branches. Five branches were found to yield the best results in all scenarios (patient-wise and slice-wise classification), as shown in Table V.

TABLE II. BRAIN CT SLICE CLASSIFICATION RESULTS (MEAN ± STANDARD DEVIATION) AVERAGE OVER THE FIVE FOLDS OF EACH MODEL

VI. DISCUSSION

The first two tasks (i.e., CT slice classification and brain region segmentation) are relatively easy problems; ResNet50 and FCN-8 based on ResNet50 work adequately in both cases. However, the third task (i.e., classification of brain tissue as normal or ischemic stroke) is comparatively difficult due to the textural similarity between the normal region and the region affected by ischemic stroke. For this purpose, the 5S-CNN model is proposed. In this section, we discuss the classification results for fine-tuned pre-trained networks as well as the proposed 5S-CNN regarding the task of classifying ischemic stroke against normal cases in patient-wise and slice-wise classifications, the results for which are given in Table IV.

In brain tissue classification, AlexNet and GoogleNet achieved the lowest performance in both patient-wise and slice-wise classifications. Mean accuracies of 74.40% and 75.20% and standard deviations of 8.29% and 7.16% resulted from both fine-tuned models in patient-wise classification, while slice-wise classification achieved mean accuracies of 76.61% and 79.30% and standard deviations of 6.34% and 6.84%. For patient-wise classification using AlexNet, the values for average sensitivity, specificity, precision, and F1 score were 84.57%, 70.27%, 56.67%, and 66.95%, respectively, while GoogleNet achieved 81.95%, 74.36%, 65%, and 69.80% for these metrics. However, slice-wise classification resulted in an average sensitivity of 78.11%, specificity of 76.43%, precision of 70.73%, and F1-score of 73.39%, while GoogleNet achieved 80.37%, 79.09%, 77.82%, and 78.57% for these metrics, respectively. The standard deviation of sensitivity for AlexNet was 4.95% in the patient-wise scenario and 7.66% in the slice-wise scenario, while for GoogleNet, the values were 11.07% and 8.35%, respectively. Notably, the accuracy difference of 2.69% in the patient-wise scenario and 0.8% in the slice-wise scenario indicates the favorable generalization performance of GoogleNet. Compared to GoogleNet, ResNet18 and ResNet50 were associated with better performance, achieving mean accuracies of 79.20% and 81.60% in patient-wise classification and 82.61% and 84.14% in slice-wise classification, respectively.

For ResNet18, the average values for sensitivity, specificity, precision, and F1 score were 82.98%, 77.59%, 71.67%, and 76.30%, respectively in the patient-wise scenario, while the values for the same metrics were 80.44%, 85.50%, 84.35%, and 81.40% in the slice-wise scenario. ResNet50 yielded better performance values with an average sensitivity of 86.79%, specificity of 79.35%, precision of 73.33%, and F1 score of 78.68% in the patient-wise scenario, while the slice-wise scenario resulted in 83.18%, 85.34%, 85.08%, and 83.69%, respectively. Only in the slice-wise scenario, ResNet50 outperformed ResNet18 in all performance metrics except specificity, where the results indicated a specificity difference of 0.16% for ResNet18.

The proposed model, 5S-CNN, outperformed the other models on every metric in both patient-level and slice-level classification. Values of 87.20%, 88.95%, 87.44%, 85.00%, and 86.19% were achieved in the patient-wise scenario with respect to sensitivity, specificity, precision, and F1 score, while values of 90.51%, 90.72%, 91.38%, 91.15%, and 90.11% were achieved for slice-wise classification. Also, the standard deviation of the proposed model outperformed the other models on all metrics except specificity and precision, only in the slice-wise scenario. In this case, the standard deviation of 5S-CNN was 5.71% and 7.77% in these two metrics, whereas the specificity and precision of ResNet50 were 5.39% and 5.04%, respectively. Acute stroke is an early sign of ischemic stroke, and it is very difficult to identify due to the subtle differences that exist between normal brain regions and those affected by acute ischemic stroke. However, in this case, 5S-CNN yielded an excellent performance overall.

Table VI shows a comparison of model complexity for the ischemic stroke classification models based on the number of parameters and Floating-Point Operations (FLOPs). The number of parameters is the sum of all learnable weights and biases of all Conv and FC layers within a CNN model. By contrast, the number of FLOPs reflects the computations required for a single forward pass within the model. After adopting the pre-trained networks for brain CT images, AlexNet had the greatest number of parameters (approximately 57.7 million) and around 7.6 billion FLOPs. GoogleNet consisted of approximately 5.1 million parameters and 7.7 billion FLOPs. Notably, despite the substantial difference in the number of parameters, AlexNet and GoogleNet had almost the same number of FLOPs. This is attributable to the small kernel sizes and feature maps of GoogleNet, which contributed to the similar computational cost of AlexNet and GoogleNet. ResNet18 had approximately 11.2 million parameters and 9.1 billion FLOPs, meaning that its computational cost exceeds AlexNet and GoogleNet. ResNet50 had the largest number of FLOPs compared to the other models, amounting to

approximately 19.8 billion FLOPs, along with 23.2 million parameters. The significant number of FLOPs means that ResNet50 is substantially more computationally expensive and consumes more training time compared to its counterparts. The proposed model, 5S-CNN, has the lowest number of parameters (approximately 0.8 million) and FLOPs (approximately 0.6 billion). Therefore, in addition to outperforming the other models in terms of classification results, 5S-CNN is also more computationally efficient.

TABLE VI. COMPLEXITY OF MODELS USED FOR STROKE CLASSIFICATION

Model	Parameters (Millions)	FLOPs (Billions)
AlexNet	57.5	7.6
GoogleNet	5.1	7.7
ResNet18	11.2	9.1
ResNet50	23.5	19.8
5S-CNN	**0.8**	**0.6**

It is worth comparing the proposed method to those of Pereira et al. [15], Anis et al. [16], and Gautam et al. [17]. Each of these researchers also leveraged DL methods for ischemic stroke detection using brain CT images. The performance of these methods, as reported in the introduction, was determined based on each research group's private datasets. Therefore, to facilitate a fair comparison, we implemented these methods and trained them on the collected dataset based on the authors' recommendations. Both patient-wise and slice-wise brain tissue classification experiments were performed. The results and confusion matrices are shown in Table VII, as well as Fig. 11.

For the classification of acute ischemic stroke against normal cases, the results in Table VII show that 5S-CNN outperformed the other three methods on all performance metrics in both the patient-wise and slice-wise scenarios. Furthermore, the confusion matrices in Fig. 11(a) show the decisions that each method made regarding the optimal testing fold across the five cross-validated folds. In this fold, a total of 25 patients with 136 CT images were used for testing. Among those, 13 patients with 73 images had acute ischemic stroke, while 63 images were normal from the remaining normal patients.

In the patient-wise scenario, 5S-CNN correctly classified all acute patients as having acute ischemic stroke, whereas the other methods misclassified at least one acute patient as a normal patient. In this case, the classifier determines that a patient has acute ischemic stroke if one of the patient's CT slices is classified as having acute stroke. Due to this, the methods of Pereira et al. [15] and Anis et al. [16] were able to correctly classify 4 normal patients, while 8 were misclassified as having acute ischemic stroke. Also, the method proposed by Gautam et al. [17] misclassified 9 normal patients as having acute ischemic stroke. In the case of 5S-CNN, only 2 normal patients were misclassified as having acute ischemic stroke. As such, 5S-CNN outperformed all other models in this area.

A similar trend is seen in the scenario of slice-wise classification, as shown in Fig. 11(b). 5S-CNN correctly classified 69 acute stroke slices out of 73 images, while 21, 11, and 38 images were misclassified in Pereira et al. [15], Anis et al. [16], and Gautam et al. [17], respectively. In the classification of normal images, the compared methods misclassified more than 14 normal images as acute ischemic stroke, while 5S-CNN misclassified only 6 images out of the 63 normal tested images. Although our model misclassified 4 images as normal from the acute patients in slice-wise classification, it correctly classified all patients as suffering from acute ischemic stroke in the patient-wise scenario. The encoding of multi-scale information from the CT scans proves the potential of the 5S-CNN model to improve clinical decision-making.

Compared to state-of-the-art models, as well as similar works, the proposed method uses a fully automated approach to analyze brain CT images and determine whether it includes brain tissue or not. In turn, through the segmentation of brain tissue within the CT image, the method enables irrelevant objects and background to be eliminated, as well as ensuring the accurate segmentation of all brain tissue pixels using morphological operations. Following this, the method applies the ELEHE contrast enhancement technique to boost the interior details of the segmented brain tissue, thereby facilitating more effective classification. Finally, classification of the resulting brain tissue using the proposed model outperformed state-of-the-art CNN models, as well as models proposed in similar previous methods. All CT slices in the collected dataset were used without altering their original 16-bit greyscale range, thereby ensuring the stability of the original pixel values. Additionally, rather than resizing original images to fit the pre-trained networks, the pre-trained networks were fine-tuned to fit the original size of CT brain images. Taken together, the use of 5-fold cross-validation shows the generalization of the proposed 5S-CNN model, as well as its low susceptibility to overfitting.

Nevertheless, the 5S-CNN model is limited to deciding whether a brain tissue shows any signs of ischemic stroke without any localization of the stroke lesion within the brain CT slice. Another limitation of the proposed model is the possibility of misdiagnosing ischemic stroke in slices with three brain tissue areas separated by bones, which usually occur at the lower part of a brain CT scan. The developed segmentation module preserves the largest brain tissue area for further analysis and removes the rest. This decision was taken based on the medical team's recommendation for the current study, and it is a potential area for investigation in future works.

VII. CONCLUSION

This paper proposed a novel, automated approach for acute ischemic stroke classification in brain CT images. A pre-processing technique that can be applied to the CT scans of patients with suspected ischemic stroke was presented, including the removal of CT slices that do not contain brain tissue, segmentation of brain tissue within the remaining slices, ELEHE contrast enhancement of the segmented brain tissue, and classification of brain tissue as an ischemic stroke or normal. A lightweight multi-scale CNN model (5S-CNN) was proposed for brain tissue classification on CT slices, to determine whether the patient is experiencing an ischemic stroke. Notably, this novel model outperformed state-of-the-art models. The model uses a 5-branch architecture, with different filter sizes for each branch, to learn features at different scales, which is crucial because ischemic stroke can have any regional size and appear at any location within brain tissue. A comparison with similar methods revealed that the proposed method outperforms the best-known current methods. The main focus of this research is to identify the presence of acute ischemic stroke on CT slices automatically. However, stroke lesion segmentation is essential for treatment decisions and management. We intend to investigate this area further in the future, ideally exploiting an expansion in the size of the existing collected datasets and samples.

ACKNOWLEDGMENT

The authors are thankful to the Deanship of Scientific Research at King Saud University, Riyadh, Saudi Arabia for funding this work through the research group no. RGP-1439-067. We would also like to thank Dr. Shanker Raja from King Fahad Medical City (KFMC) for his support during this research, as well as Dr. Abdulaziz AlSaad, Dr. Juman AlGhamdi, and Dr. Abeer AlDhawi from the Neurology Department at KFMC.

***Abstract*—The traditional classroom-based teaching and learning of the History subject are ineffective and less interactive, influencing the students' interest and motivation to learn history. Therefore, museum-based learning was proposed to supplement classroom-based learning for effective teaching and learning of the History subject. However, the excursions to the museum are often hindered by issues caused by the geographical location, the museum's policies, and student commitments. The hindrances motivated the researchers to design and develop a role-playing game (RPG) in Muzium Negara (National Museum of Malaysia) known as 'Waktu Silam' to enhance students' interest, motivation, and knowledge on the cultural and historical heritage of Malaysia. A survey questionnaire was distributed to assess the enjoyment level provided by the game. The results showed that 84.8% of participants had experienced the element of enjoyment in this game. This study anticipated enhancing the student interest and knowledge in history, enhancing visitors' experience, and promoting tourism to Muzium Negara. Additionally, the project is expected to include multiplayer functionality to add more interactivity to the game in future works.**

***Keywords*—Muzium Negara; history; role-playing games; gamification; museum-based learning; enjoyable**

I. Introduction

The History subject was made compulsory and a core subject for students by the Malaysian Ministry of Education in 1989 [1]. The subject has become a compulsory-pass subject for secondary school students sitting for the Malaysian Certificate of Education examination (Sijil Peperiksaan Malaysia/SPM) since 2013 [2][3][4]. This step proved that the History subject is vital for several academic reasons. The History subject's main objective is to foster patriotism spirit towards the nation, creating the spirit of unity among people of different races and embedding a sense of pride to be Malaysians among students [1][2][3][4]. The content of the curriculum has undergone rapid changes since the colonial era until Malaysia achieved independence, and the entire chronology has been recorded in the syllabus.

The syllabus of the History subject in the textbook comprises many facts and figures. Students need to memorize the facts to establish the connection between the chronology and to understand the concept of history [2][5]. As a result, the learners feel disinterested and unenjoyable in learning history as they cannot sense or comprehend the significance of such historical events [6]. Furthermore, the traditional classroom-based learning when teaching history is a teacher-centred approach that is proven ineffective and less interactive in enhancing students' interest, motivation, and knowledge [7]. Traditional storytelling when teaching history can cause boredom among the students.

Additionally, a study by Jaafar and Mohd Noor [7], and Napiah, Awang, Ahmad and Che Dahalan [2] stated that learning history is abstract in nature compared to visiting museums or historical places that are more realistic [2][8]. Students will find it more meaningful and practical to understand the history if they gain the experience and engage with the artefacts in the museum. Napiah et al. [2] showed that learning history in a real museum setting contributes a positive effect and helps students understand history better than in the classroom setting [2]. This scenario is an effective way to assist students in remembering chronological history without solely memorizing the facts.

Museum-based learning was proposed to supplement classroom-based learning for effective teaching and learning in history [2][9]. Students are exposed to the genuine historical artefacts exhibited in the museum through this approach. They will gain new learning experiences by seeing, touching, and interacting with historical materials that are not available in classroom settings. Hands-on history learning will also be more fun and interesting. Furthermore, learning history in a museum setting also enhances the students' understanding of the historical concepts taught in the classroom [8][10]. However, the excursions to the museum are often hindered by several issues due to the geographical location, the museum's policies, and student commitments. Therefore, not every student will obtain the opportunity to visit the museum to explore and experience the exhibition.

The issue has motivated the current study's researchers to develop an RPG known as 'Waktu Silam' to give the targeted users the sense and enjoyment of virtually learning the historical content in the national museum of Malaysia, Muzium Negara. 'Waktu Silam' is in the Malay language, which means "the old days". The researchers implemented game-based learning through the RPG genre to learn historical contents in

This study is sponsored by the Indonesian Ministry of Research and Technology and Universitas Pendidikan Indonesia.

Muzium Negara. Game-based learning is deemed an exciting and effective way of learning when adequately constructed using learning principles as a goal. Besides, the proposed games can enhance students' motivation, encourage engagement, and promote learning [11]. The nature of history as a subject makes it essential for current and emerging instruments established to support the main delivery of instruction [5]. Players with or without the intention to learn history may find history easy and be excited to learn with this game.

The upcoming sections of this paper begin with Section 2 that outlines the study's background that focuses on Muzium Negara's overview, the introduction of game-based learning and RPG, and related works. Subsequently, Section 3 presents the study's design and development, Section 4 elaborates on the results and discussions, while Section 5 concludes the paper.

II. Background of Study

A. Muzium Negara

Muzium Negara is the national museum of Malaysia, strategically situated in the heart of the capital city of Kuala Lumpur. The museum was built resembling the Malay palace-style as a symbol of the guardian of the nation's history. The structure is three-storeys high with 109.7 metres long, 15.1 metres wide, and 37.6 metres at the central point. The building was officially opened on 31st August 1963. The galleries in the museum have been upgraded to represent an exhilarating and state-of-the-art approach to exploring Malaysia's history from the pre-historical era to the present time.

The museum houses four main exhibition galleries, as shown in Fig. 1, namely, the Prehistoric Era, Malay Kingdoms, Colonial Era, and Malaysia Today galleries [12][13]. The Prehistoric Era gallery showcases the evolution of the earth's surface until the origin of Malaysia's earliest inhabitant. Additionally, the gallery outlines the discovery of the Palaeolithic age (200000 years ago) stone tools to the Hindu-Buddhist temple and relics found in Lembah Bujang. The Malay Kingdom gallery traces the historical timeline of the first Malay Kingdoms in the archipelago, specifically the Malay Peninsula. The gallery also highlighted the glorifying days of the Malacca Malay Kingdom in the 15th century.

Conversely, the exhibition presents the historical chronicles of the control and administration of foreign powers: the Portuguese, Dutch, British, and Japanese, and the subsequent effects on the nation's political, social, and economic situations in the Colonial Era gallery. Finally, the Malaysia Today gallery walks the visitors through the arduous path trodden by the peoples' relentless struggle for independence and the formation of a new nation. The gallery demonstrates the transformation process and achievement gained since Malaya's independence in 1957.

Muzium Negara welcomes many tourists daily, including foreigners and Malaysian students. The museum inspires a more comprehensive understanding of Malaysia and its multiracial composition through collections, exhibitions, research, publications, educational and public programmes. Muzium Negara also bears the responsibility of nurturing, protecting, and publishing information on cultural history and natural heritage. Thus, Muzium Negara plays a crucial role in history authentication and preservation.

B. Game-based Learning and Role-Playing Game

Game-based learning (RPG) is considered an effective approach for teaching and learning purposes. The application of digital games in education helps to develop interest and motivate learners [14]. It can motivate students to focus their attention on education in an enjoyable and engaging way. In addition, game-based learning also provides an opportunity for students to experience a new learning method where students can be more active in learning sessions. Students gain a chance to experience, take risks, and learn without fear of failure from real-life consequences [11]. Some studies established that games could produce positive learning outcomes, efficient in promoting learning and retention, as well as provide an engaging experience compared to traditional instructional methods [15][16]. For example, a study by Wan Fatimah, Afza, and Mohd Hezri Amir [17] have developed an RPG prototype named Maths Quest to engage and assist children in learning mathematics. The heuristic evaluation in terms of learnability, satisfaction, screen design and performance effectiveness has been conducted and received positive feedback from the participants. A different study by Sung and Hwang [18] also proposed a game-based learning approach to guide students in science courses. The result from the experiment shows that the game helps in promoting students' learning attitudes and motivation as well as improving their learning achievement and self-efficacy.

The RPG is among game genres where the player controls a fictional character (or characters) that embarks on a pursuit in a fantasy world. The RPGs varied range share a parallel emphasis by providing the player with a role that advances and progresses via playing and storytelling experience. However, a robust variation exists across and within the format. The RPG also offers a remarkable opportunity to assess most of the crucial questions in-game studies [14]. Besides, RPGs involve a good storyline and interactions with other objects or characters. The storylines and interactions will provide users with the intended experience made by the developer. RPGs can also be used to develop educational games with such features.

The RPGs provide learning environments that engage collaborative problem solving and distribute apprenticeship when playing and influence digital and print literacy advancement, besides science, math, and computational literacy. Hammer, Schrier, Bowman, and Kaufman [19] highlighted that the RPGs are deeply related to constructivism and sociocultural learning theory. The learning in constructivism happens through hands-on experimentation with a new situation, whereas the learning in sociocultural takes place through the adoption of new social roles. The underlying educational theories for each feature makes it appropriate for learning and explain how it is employed in education [19]. These reasons denote that RPGs can be considered a good educational platform although underrated.

III. Related Work

Devising simulated worlds generates an illustrious, sophisticated approach to the design concepts behind virtual worlds. A virtual environment is denoted as the most frequently utilized alternate phrase for platforms otherwise acknowledged as virtual worlds [20]. An avatar or character that mimics the user in the virtual environment can facilitate the user to observe the virtual three-dimensional (3D) environment and induce immersion towards the user. The use of avatar is the medium that allows users to manoeuvre objects in the virtual environment [21]. The virtual environment can be categorized into two general types: multi-user virtual environment (MUVE) and Massively Multiplayer Online Role-Playing Game (MMORPG). According to Döpker, Brockmann and Stieglitz [22], the significant dissimilarity in MUVEs is that the users do not have a specific goal to attain or a start-finish character as in MMORPGs. Thus, integrating RPG elements into a virtual museum can generate users' interest in learning cultural heritage in engaging ways.

The museum's virtualization includes tasks mapping that must be undertaken in a virtual reality museum context for individual tasks in a 3D game [23]. A study by Prasetyo and Suyoto [24] found that implementing the gamification methods at museums can encourage the community to be motivated to visit the museum. Similarly, a study by Araujo, Koenigschulte, and Erb [25] also revealed that implementing interactive games for museum environments can enhance visitor experiences. Another research from López-Martínez, Carrera, and Iglesias [26] found that applying game concepts to museums can contribute to higher levels of cognitive engagement among users. A study by Cosovi´c & Brki´c [27] also shows that game-based learning is a resolution to transform a traditional museum into a virtual museum and encourage active learning where game-based learning can assist in preserving the cultural heritage. All these approaches integrate game elements into virtual reality museums.

Lepouras and Vassilakis [23] pointed out that education through entertainment is crucial to enhancing user engagement in learning. Approaches utilizing game-integrated entertainment aspects can enhance the user's learning process. Apart from that, digital games can also be used as a persuasive tool to persuade people to learn or improve their knowledge [28]. Therefore, game elements have been applied in various subjects such as Islamic teaching [28], programming [29], and history [30]. In term of History subject, a study by Lee, Talib, Zainon, and Lim [30] have designed and implemented a framework using RPG on the mobile application. The implementation is based on the narrative story of Merong Mahawangsa, a legendary Malaysian warrior. In contrast, our work allows the player to learn historical knowledge from Malaysia's national museum virtually.

IV. Methodology

The researchers implemented the Agile Development Methodology for the development of this project. The phases of the agile development model involved Plan, Design, Develop, Test, Release, and Feedback. Although relatively new, the methodology helps create the project based on thorough evaluation and understanding. The methodology is

based on implementation over the documentation with consumer involvement and can solve both problems and agility adjustments. Besides, the methodology uses and works through an iterative development framework known as Scrum. Scrum functions in the game development methodology by breaking down game development into a series of tasks named "sprints". The game developers split the game into clusters of associated jobs or features to ease the work with sprints. Additionally, the model stresses small phases with minimal planning and gives moderate access to frequent change requirements in the processes.

The following is the brief explanations of each phase on the Agile Development Methodology Fig. 2:

- Plan: At this stage, the researchers go through the brainstorming session to idealize the game concept, scope and goal. The initial user requirements were also analyzed and documented. The researchers also identified the software and hardware requirements for the development of the project.
- Design: The researchers focused on the plot and storyboard design as defined in the planning stage at the design stage. The details of the design phase are discussed in the next sub-section.
- Develop: The project's development was started once the plot and storyboard designs were agreed upon and confirmed.
- Test: In the testing stage, the verification and validation of the developed project were conducted. The testing ensured that the project had fulfilled the requirements and eliminated any errors or bugs. It is to prevent any undesirable issues from occurring.
- Release: The project was released into production once the testing phase was cleared.
- Feedback: At this stage, the researcher used the convenience sampling method to collect the users' feedback about the developed project. The researchers have distributed survey questionnaires to young adults aged between 17 and 25 years old. The questions were adapted from the eGameFlow model [31]. There are eight dimensions of scale in this model which are the Concentration, Clear Goal, Feedback, Challenge, Autonomy, Immersion, Social Interaction and Knowledge Improvement. Table I shows the description of each dimension.

A. Design Phase

The design phase focused on the plot and storyboard design. The researchers applied the narrative structure mechanism guided by Freytag's pyramid to design the game's plotline. Freytag's pyramid was initially identified from a successful theatrical tragedy and has been widely applied by game designers [32]. The narratives mechanism is extensively utilized in RPG and plays a crucial role in developing an engaging and meaningful game [33]. Based on Freytag's pyramid, the stories can be segregated into five acts: Exposition, Rising Action, Climax, Falling Action, and Conclusion. Table II describes the details of each act's narrative purpose in Freytag's pyramid. The researchers adopted Freytag's pyramid to design the narrative structure of the game plot as in Fig. 3.

The game's overall acts are displayed in Fig. 4. First, the player can choose to start the game from the main menu. Then, a cut-scene that introduces the main character and the mission to be accomplished is shown. Next, the player will be prompted to begin the journey to Muzium Negara and explore the exhibition galleries. The player can explore any gallery in the Muzium Negara and interact with the exhibited artefacts. Detailed history information is displayed for each artefact. The game's climax starts when the player is suddenly knocked out and enters a new world, the Prehistoric Era. A non-player character in this new imaginary world will explain the mission to be accomplished to exit the world. Pop-up details are available along the mission mentioning the world's history and the artefacts found. The players can choose to proceed to the next level or end the game once the mission is completed. The following levels include the imaginary world related to the galleries in Muzium Negara, namely, the Malay Kingdom, Colonial Era, and Malaysia Today.

TABLE I. THE DESCRIPTION OF SCALE DIMENSION IN THE EGAMEFLOW MODEL

Scale Dimension	Description
Concentration	The game must include activities that stimulate the player's concentration while avoiding the stress associated with learning overload, which might cause the player to lose focus on the game.
Clear Goal	The game's objectives and tasks should be clearly stated at the beginning.
Feedback	Feedback enables a player to evaluate the knowledge gap between their present level of understanding and the knowledge required to complete the game's task.
Challenge	The game should include challenges that are appropriate for the player's skill level, with the difficulty of these challenges increasing as the player's skill level improves.
Autonomy	The learner should enjoy taking the lead in game play and having complete control over his or her decisions.
Immersion	The game should lead the player into a state of immersion.
Social Interaction	The game's tasks should become a way for users to socialise.
Knowledge improvement	The game should improve the player's level of knowledge and skills while meeting the goal of the curriculum.

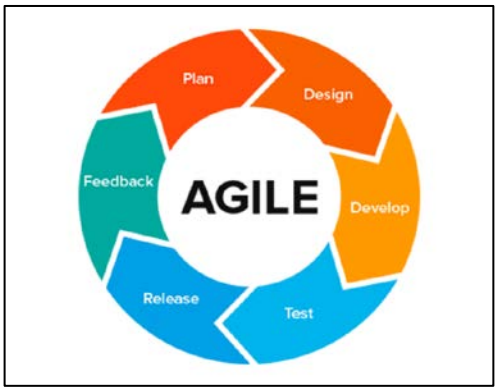

Fig. 2. Agile Development Methodology.

TABLE II. THE NARRATIVE PURPOSE OF EACH ACT IN FREYTAG'S PYRAMID

Act	**Narrative Purpose**
Exposition	Describes the setting, protagonist, and primary conflict. Ends with the inciting moment that drives the story forward.
Rising Action	Develops the primary conflict and relates with secondary conflicts. The protagonist overcomes minor obstacles.
Climax	The story's turning point. The exact nature of the primary conflict crystallizes, the antagonist is revealed, and the path ahead is made clear.
Falling Action	Resolves the primary conflict. Leads to a moment of final suspense, where the outcome is in doubt.
Conclusion	The story returns to a state of normality. Ties up loose ends.

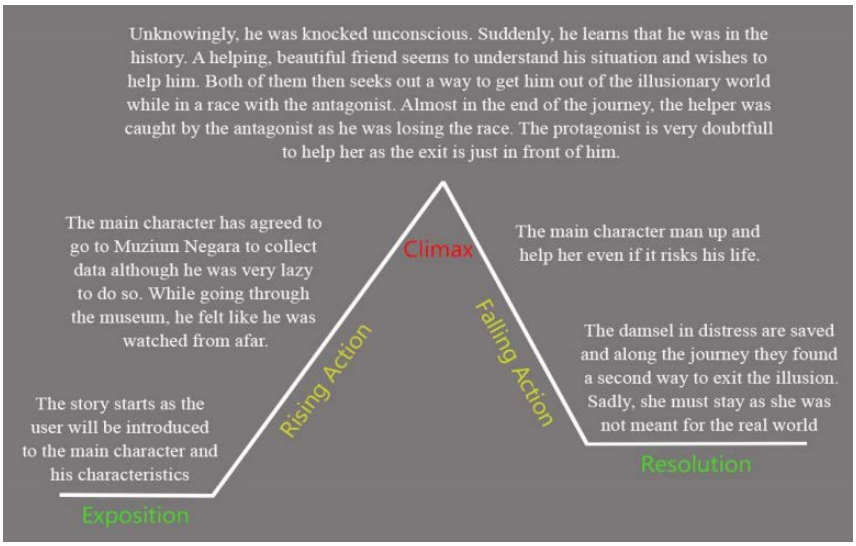

Fig. 3. The Plot Design.

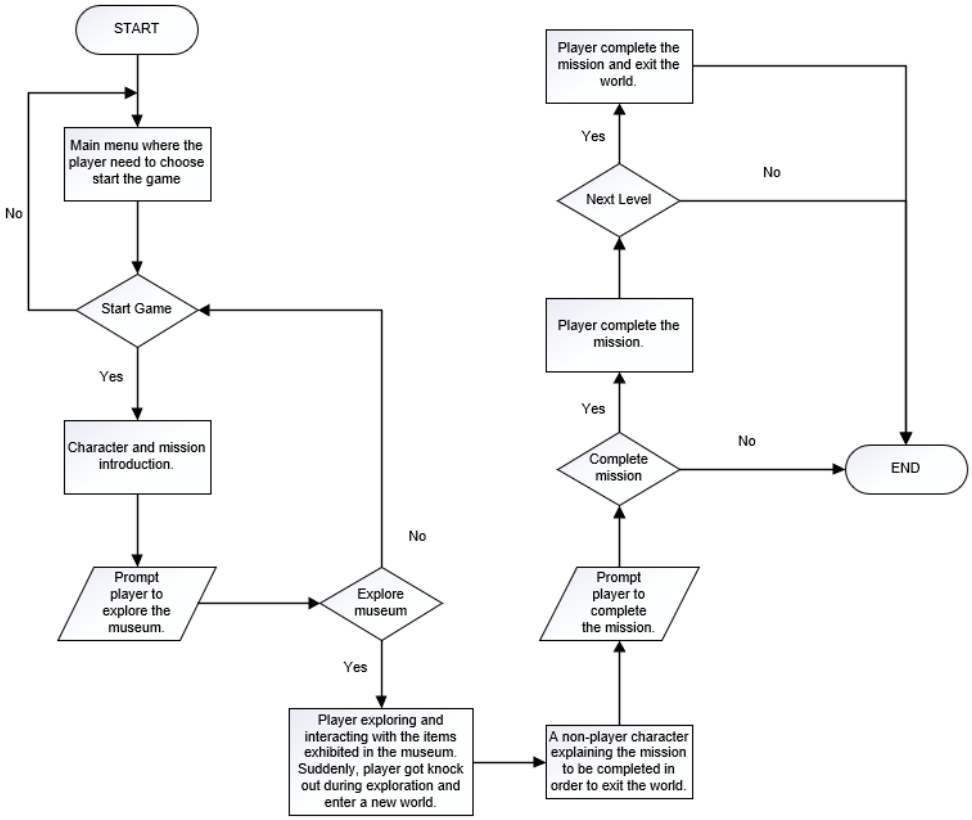

Fig. 4. The Overall Flow of the Game.

B. Development Phase

The project's development started with the plot's completion and storyboard design. All the project's models, including the museum and artefacts, were developed using Blender, an open-source 3D creation suite. Fig. 5 shows the museum's exterior design development and its artefacts modelled using Blender. Conversely, the environment scene for the game was developed using Unity, a cross-platform game engine developed by Unity Technologies. Fig. 6 shows the glimpses of the scene produced during the design and development phase.

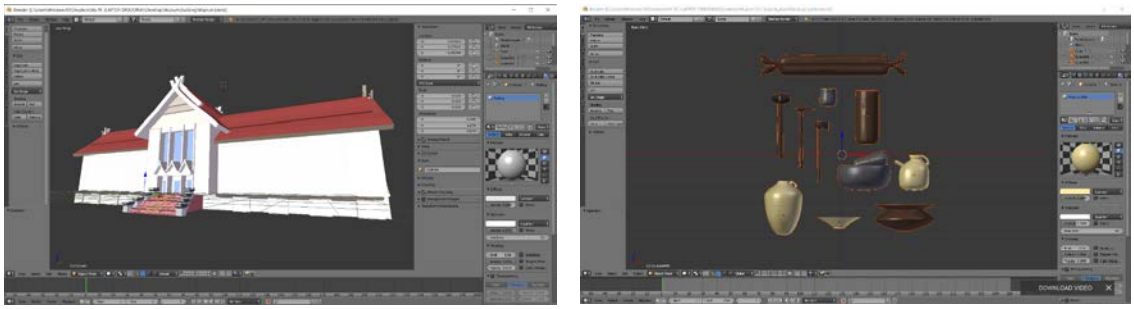

Fig. 5. The Development of 3D Models using Blender.

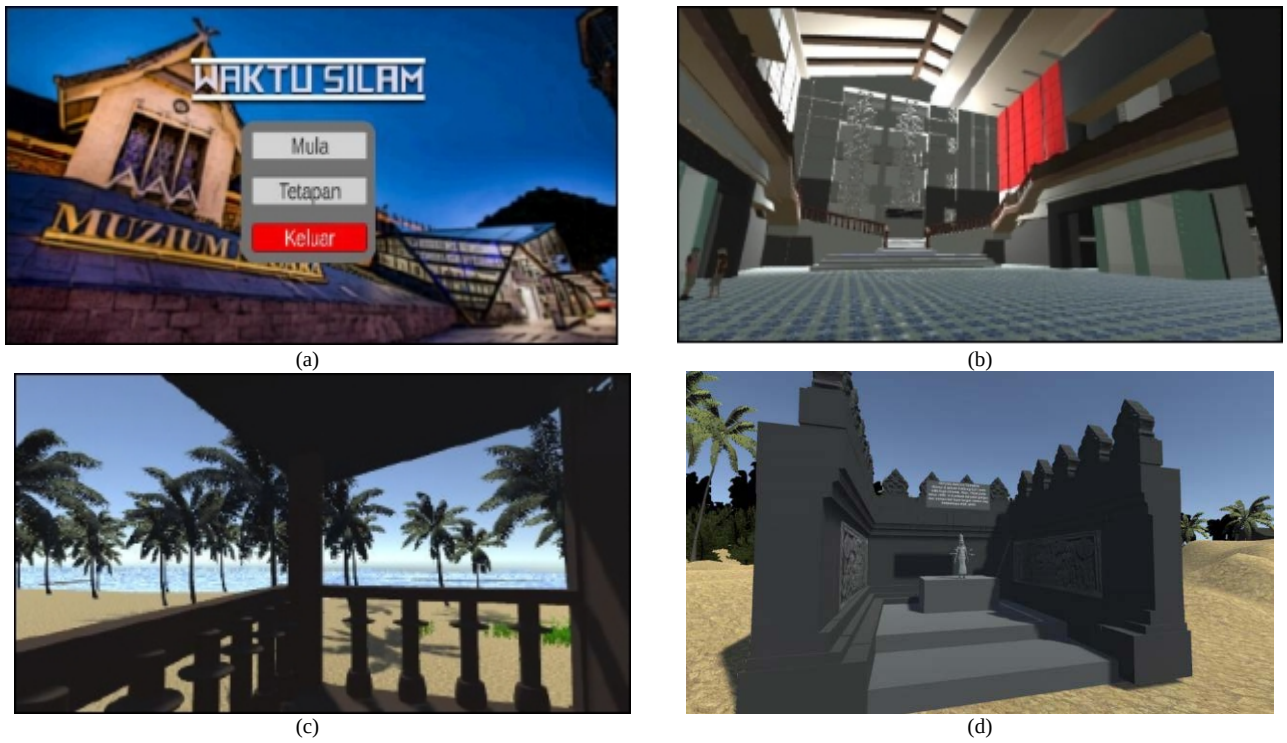

(a) (b)

(c) (d)

Fig. 6. The Scene Environment Developed using Unity – (a) The Exterior Design of Muzium Negara, (b) The Interior Lobby of the Museum, (c) The Malay Kingdom Scene and (d) The Artefacts and Monument.

V. Result and Discussion

The researchers adapted the eGameFlow model to evaluate the performance of the developed game. eGameFlow model acts as a scale to measure the respondents' enjoyment experience through its enjoyment factors. The factors adapted incorporate concentration, goal clarity, feedback, challenge, control, immersion, social interaction, and knowledge improvement. Nevertheless, social interaction was not included as the evaluation element because the games were neither developed nor created for multiplayer.

According to the survey results, 32 respondents took part in the evaluation. The majority of respondents were aged 21 to 25 years old, whereas 23 out of 32 respondents (71.9%) were male. Table II presents the average mean for each element when the descriptive analysis was performed. Next, the analysis calculated the average mean of each element into a total average to determine the evaluation's outcome. The total mean is 4.24, or 84.8% of the respondent's enjoyment while playing the game. The analysis results from the survey demonstrate that most respondents agreed that the '*Waktu Silam'* game is enjoyable to be played. In addition, the '*Waktu Silam'* game was identified to efficiently increase the knowledge on knowing and memorizing history content in the museum. Furthermore, this game can enhance the player's knowledge about Malaysia's history.

TABLE III. RESULT OF THE AVERAGE MEAN FOR EACH EGAMEFLOW ELEMENTS

Elements	Item	Questions	Mean	Average Mean
Concentration	C1	The game grabs my attention	4.21	4.13
	C2	The game provides content that stimulates my attention	4.21	
	C3	Most of the gaming activities are related to the learning task	4.28	
	C4	No distraction from the task is highlighted	3.93	
	C5	Generally speaking, I can remain concentrated in the game	4.06	
	C6	I am not distracted from tasks that the player should concentrate on	4.19	
	C7	I am not burdened with tasks that seem unrelated	4.09	
	C8	Workload in the game is adequate	4.06	
Goal Clarity	G1	Overall game goals were presented in the beginning of the game	4.09	4.16
	G2	Overall game goals were presented clearly	4.16	
	G3	Intermediate goals were presented in the beginning of each scene	4.03	
	G4	Intermediate goals were presented clearly	4.28	
	G5	I understand the learning goals through the game	4.22	
Feedback	F1	I receive feedback on my progress in the game	4.19	4.10
	F2	I receive immediate feedback on my actions	3.81	
	F3	I am notified of new tasks immediately	4.09	
	F4	I am notified of new events immediately	4.06	
	F5	I receive information on my success (or failure) of intermediate goals immediately	4.25	
	F6	I receive information on my status, such as score or level	4.19	
Challenge	H1	I enjoy the game without feeling bored or anxious	4.38	4.12
	H2	The challenge is adequate, neither too difficult nor too easy	4.09	
	H3	The game provides ‘hints’ in text that help me overcome the challenges	4.06	
	H4	The game provides ‘online support’ that helps me overcome the challenges	3.67	
	H5	The game provides video or audio auxiliaries that help me overcome the challenges	4.19	
	H6	My skill gradually improves through the course of overcoming the challenges	4.19	
	H7	I am encouraged by the improvement of my skills	4.16	
	H8	The difficulty of challenges increases as my skills improved	3.94	
	H9	The game provides new challenges with an appropriate pacing	4.19	
	H10	The game provides different levels of challenges that tailor to different players	4.28	
Autonomy	A1	I feel a sense of control the menu (such as start, stop, save, etc.)	4.84	4.63
	A2	I feel a sense of control over actions of roles or objects	4.34	
	A3	I feel a sense of control over interactions between roles or objects	4.69	
	A4	The game does not allow players to make errors to a degree that they cannot progress in the game	4.59	
	A5	The game supports my recovery from errors	4.15	
	A6	I feel that I can use strategies freely	4.69	
	A7	I feel a sense of control and impact over the game	4.69	
	A8	I know next step in the game	4.84	
	A9	I feel a sense of control over the game	4.84	
Immersion	I1	I forget about time passing while playing the game	4.09	4.23
	I2	I become unaware of my surroundings while playing the game	4.38	
	I3	I temporarily forget worries about everyday life while playing the game	4.34	
	I4	I experience an altered sense of time	4.15	
	I5	I can become involved in the game	4.22	
	I6	I feel emotionally involved in the game	4.38	
	I7	I feel viscerally involved in the game	4.06	
Knowledge Improvement	K1	The game increases my knowledge	4.06	4.31
	K2	I catch the basic ideas of the knowledge taught	4.06	
	K3	I try to apply the knowledge in the game	4.38	
	K4	The game motivates the player to integrate the knowledge taught	4.69	
	K5	I want to know more about the knowledge taught	4.38	
		Average Mean		**4.24 (84.8%)**

VI. Conclusion

The researchers designed and developed an RPG named '*Waktu Silam'* as an educational game where the player can virtually learn the historical content in Muzium Negara. The main objective for the game's development is to enhance students' interest, motivation, and knowledge of the Malaysian cultural and historical heritage. Unlike previous research, this initiative allows the player to virtually engage with the artefact in the Muzium Negara and immerse themselves in the virtual world to learn about the past. The evaluation of the game's enjoyment by adapting the eGameFlow model has been conducted. The results showed that the participants experienced about 84.8% enjoyment while playing the game.

For future work, we plan to include the game's console version and add multiplayer functionality to improve the game's interactivity. Additionally, the researchers also plan to collaborate with Muzium Negara to obtain more information for the game. The collaboration will increase the quality of details and information on the history and enhance the game's quality. The researchers envision that the collaboration will indirectly help boost tourism to Muzium Negara.

***Abstract*—Paddy is one of the largest consumed staple foods across the globe, especially in Asian countries. With the population growing larger and the agricultural land shrinking, there is a need to increase the yield of the crop to meet the ever-growing food demand. The yield of paddy largely depends on the irrigation of the paddy field, that is maintaining the optimum water level in the paddy field. The solution to this irrigation problem has been proposed in this paper, by addressing various challenges in implementing the Unmanned Ground Vehicle (UGV) and Internet of Things (IoT) system in paddy cultivation. A UGV which carries the sensors were used to collect the sensor data (water level, rainwater, humidity, temperature, light intensity) from the paddy field, which is controlled by cloud-based solution and by the mobile application-based solution. The data was then processed and used to control the water valves which can again be controlled by using cloud and mobile application. Water level maintained by using the mobile application-based solution, cloud-based solution and by following the traditional method of irrigation was compared and the cloud-based solution was found to be more efficient. Thereby providing a solution which reduces the manpower required for the process of irrigation when compared to the traditional irrigation method, also reducing the water wastage, therefore conserving water.**

Keywords*—Sensor; cloud; mobile application; agriculture; water valve

I. Introduction

The Internet of Things (IoT) has entered almost all the areas in today's world. The concept of one thing being connected to other things. The ability to work with coordination, by communicating with one another over the Internet, has found a lot of application in fields like industry [1], smart city [2], connected building and campuses [3], smart home [4], health care [5], logistics [6], connected car [7]. Many research works are being done in various fields and domains [8], one of the fields where extensive research is being done is in agriculture [9].

The ever-growing population of the world, the diminishing natural resources, the depleting water resources has made food security a global concern. With only 11% of the earth surface [10] available for feeding 7.7 billion people across the globe [11], there is a need to implement new technologies in the field of agriculture. The leading food crops in terms of global consumption are paddy, wheat, and corn. Paddy is the most consumed, about an average of 50% of the daily caloric supply in Asian countries such as India, China, Indonesia, Japan, Philippines, Thailand etc. [12]. With urbanization, there is a competition for water sharing between cities, industries, and agriculture. It is estimated by [13] that the production of paddy must be increased by 50 to 60 per cent without increasing the land and water usage for paddy for the next 30 years. With many of the country economy depending mainly on paddy production, there is a need to implement innovations in the field of agriculture to cope up with all these challenges. The business data platform Statistica [14] estimates that about 3.8 billion people across the globe will have access to mobile phones and Internet by 2021, the use of Internet of thing can be the game-changer to boost the paddy production for all the developing nations.

Robots are machines that perform certain tasks and are usually controlled by a computer program. There are various kinds of robots such as autonomous robots (Robots which have central processing unit and can perform set of tasks on their own) and remote-controlled robots (Robots which are instructed by humans using a remote to perform tasks). Robots can also be classified into Unmanned Ariel Vehicle (UAV) and Unmanned Ground Vehicle (UGV) based on whether the unmanned robot moves in the air and moves on land respectively. Robots have entered agriculture to help farmers in various repetitive tasks or tasks that are difficult to be performed by humans. They are already being tested on applications such as spraying fungicides [15], pesticides [16], they are also used in mushroom picking [17]. There has been widespread research across the globe on robotics, with rapid research and development of robots, the markets will exhibit rapid growth during the coming decades [18].

II. Literature Review

The major factor influencing the yield of any crop is irrigation. In the paddy field, to increase the yield it is required to maintain standing water throughout the growth period, so the main aspect of irrigation system is maintaining the water level in the paddy field to the optimal level at all times [19]. Lots of IoT solutions has been developed by researchers across the globe for smart irrigation systems. One of them being the Wireless Sensor Networks (WSN) used in [20] where several sensor nodes are placed in various locations of the agricultural

land and the soil moisture, temperature, humidity, and various other parameters are being measured. The Same concept of WSN was used in [21] to obtain temperature, humidity, phosphorous, nitrogen, calcium, soil temperature, moisture, and PH data in the sugarcane field. In [22] two different types of wireless sensor network were used to obtain real-time data for irrigation in nurseries, the wireless sensor network can be used in all the above-mentioned field. It can also be used in paddy cultivation as in [23] where wireless sensor network was utilized to monitor and irrigate the paddy field. This may lead to additional work thereby increasing the cost of production as the wireless sensors have to be removed from its place each time when heavy machinery is used for various activities in the paddy field.
