Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

CONTENTS

Rain Attenuation in 5G Wireless Broadband Backhaul Link and Develop (IoT) Rainfall Monitoring System

Konstantinos Zarkadas[1],George Dimitrakopoulos[2]
Department of Informatics and Telematics, Harokopio University, Athens, Greece

***Abstract*—Climate change is the cause of more frequent and intense rainfall where they affect wireless communications because they cause severe weakening of the power of the emitted signal. These losses reduce network coverage and, therefore, system availability. The proposed solution is to integrate an Internet of Things (IoT) rainfall monitoring system where it will be able to collect real-time data on the height of rain that erupts in a particular place. This data will help areas where base stations install and the distance of the link that may need to be changed to reduce rainfall's harmful effects. So, the prediction of attenuation due to rain is an essential parameter in both terrestrial and satellite connections. The present study uses the ITU-R P 838 and ITU-R P 530 models to theoretically calculate losses in a 5G wireless broadband link with 99.9% link availability. This study conducts three frequency bands, 24 GHz, 28 GHz, and 38GHz, in Palo Alto, California. The travel distance is 5km, while the rainfall rate for the analyzed area is in zone D. The results show that the attenuations are proportional to the frequency, polarization, and rainfall rate.**

Keywords*—*Rain attenuation; Internet of Things; wireless broadband

I. Introduction

Heavy rains occur more frequently, one of the many global warming [1], [2]. It is no longer a scenario that was to show its effects in the distant future. The situation is now difficult, and its first consequences are appearing. Studies have shown that global warming has a significant effect on precipitation. As early as 2011, the atmosphere's ability to retain water from water vapor increased by 7% for every 1 ° C of heating [3]. An essential factor in landslides in a geographical area is the seasonal period where the percentage of water is different, as revealed by research that has been studied [4]. More specifically, for the North American region, the rains during the summer months are more in the summer than in the winter. It also noted that energetic precipitation has been increasing both in frequency and rhythm since 1901.

Rainfall varies from year to year and is distinguished by the rate, duration, and amount of water that sometimes negatively impact crops, telecommunications, energy, and many other human activities and infrastructure. There are losses generated by electromagnetic waves transmitted during wireless communication in the telecommunications sector due to the absorption and scattering [5]. As a result, the coverage area and the efficiency of the wireless communication network are limited. The high frequencies in the microwave zone, millimeter-wave already used for 5G technology, are significantly affected by signal attenuation due to rain [6]. It studies that frequencies above 10 GHz are significantly affected [7]. It is evident that climatic conditions significantly affect systems exposed or affected under the right weather conditions and cause malfunctions in the network. From the research so far, it cannot be accurately calculated that the amount of water will evolve on a rainy day. Even meteorological stations with their technological advancement in mathematical models may not have accurate data on the intensity or duration of rainfall or a storm. In recent years, smart meteorological stations have been created that calculates the intensity of the rain but not its height. So, the primary goal of the document is to design and implement a rainfall monitoring system. This solution promotes an IoT system that detects rainfall in real-time and provides information through a cloud service called Adafruit IO. This measured inferred whether the rate of rain would increase or not—this communication base on the MQTT protocol and the development of interfaces from the platform.

This article is structured as follows. Section 2 refers to the related work done so far and the theoretical background of rain attenuation. Section 3 shows the measurement setup and the theoretical measurements of the microwave link. In Section 4 present the experimental setup and analyze the IoT system of rain. The results will provide and discussed in Section 5. Finally, Section 6 contains concluding remarks and an outlook on future work potentials.

II. Theoretical Background

A. Related Work

All Scientists and engineers are concerned about limiting or controlling the damage caused by heavy rainfall. They are developing search and alert applications for years with the help sensors and microcontrollers connect on the internet and transfer information to and from the user. In [8], an application is developed, which is essentially a meteorological station that informs about the meteorological changes such as the measurement of temperature, humidity, rainfall, carbon monoxide, altitude, and LPG in the environment. It consists of a microcontroller Arduino Mega where it connects to the individual sensors that, when stimulated, will give the message on the LCD screen. Besides, the device sends SMS to the user and informs them about the prices collected with a GSM module's help. In the end, the results compared with the data of the national meteorological company.

In [9], a system creates to control the rate of rainfall. It is a system that has the structural features of a rain gauge. It consists of a funnel that collects the water where it falls into a sensor—also connected to the EZ430-RF2500 where it contains the MSP430F2274 microcontroller and a CC2500 transceiver for data transmission, which, in turn, is sent to another transceiver which is the central station connected to a laptop (Laptop computer unit) in C language in GUI graphical interface.

Even in [10], a system works as a rain gauge created; it consists of the detection unit with a sensor that works as a rain gauge. It consists of two parts, a funnel and a container that collects water. There is an Arduino Uno microcontroller that recovers data from the sensors. This system is even environmentally friendly as solar collector power it, and on days when there is no sunshine, the battery that has already charged use. There are three ways to communicate with the server: The station communicates through the 3G network with an Arduino Ethernet card and a 3G modem. The second through a 433 MHz free band, which use for industrial or scientific purposes. Finally, it will be easier to use the GSM network with a GSM shield with an Arduino card.

Increasingly, the technological advancement of sensors in both field of application, cost, the size has contributed to the development of many constructions at both research and mechanical level. In particular, projects to detect floods or weather conditions in areas such as crops, livestock units, renewable energy units (e.g., solar parks), and even smart cities. Also, 3G and 4G technologies have further promoted the implementation of many such applications. Today, Internet of Things (IoT) technology is making its presence felt, which is greatly aided by the infrastructure, efficiency, and flexibility offered by 5G technology, equipped with high speeds, capacity, low latency, which offers reliability in telecommunications systems. Therefore, due to this technological boom and the reliability of wireless systems that should provide uninterruptedly, this article gives weight to studying the effects of rain on a point-to-point microwave connection. This connection has fifth technology features, and the data collected by calculations is from three different frequencies with an ordinary rainfall rate (mm / h). The difference with the research so far is that the rain detection systems have to do with developing a meteorological station or the creation exclusively of a rain meter where the rain rate calculates directly. This need in the present study was by developing an IoT system for calculating the amount of rain (mm) that cleans itself every 1 second and informs in real-time about the rainfall course. Besides, a microcontroller uses where it collects information. The rain sensor and the help of a servo motor clean the flat surface to receive the next measurement. Finally, this system can interconnect the hardware through a cloud platform, accessible to the user. It will distinguish the sensor output and act immediately for any failures in terms of signal coverage or, in general, to analyze data on the availability of the broadband network.

B. Background

The signal attenuation calculates with appropriate models that help to calculate in theoretical attenuations [11]. The International Telecommunication Union (ITU) has helped facilitate international interconnection, spectrum sharing, and technical standards to ensure networks and technologies' smooth operation. Based on international recommendations (ITU-R P.838-3) [12], the specific attenuation of the γR (dB / km) signal obtained by the rainfall rate R (mm / h) from the following formula:

$$\gamma R \ = \ KRa \ (dB/km) \qquad (1)$$

The values k and a are coefficients that set depending on the operating frequency and the field polarization, defined by ITU-R P. 838 -3 in Table I.

The rate of rainfall comes in two ways, either from meteorological stations through individual measurements that calculate the average intensity per year, or from the categorization made by ITU - R. 837.1 [13] in acceptable climate zones in Table II.

In more detail, if a radio cluster with 99.99% availability is studied, it should be ensured that the connection will be available even at high rainfall rates that cause attenuation, with a probability of occurrence exceeding 0.01% of the time.

Therefore, after calculating the specific attenuation of the γR (dB / km) signal for horizontal and vertical polarization with the help of Table I, the ground rate r factor is defined by the standard (ITU-R P 530.), should be calculated [14] and given by the following formula:

$$r = \frac{1}{1+\frac{d}{d_0}} \qquad (2)$$

TABLE I. FACTORS K AND ACCORDING TO THE ITU-R P.838-3 STANDARD

Frequency (GHz)	K_H	a_H	K_V	a_V
20	0.09164	1.0568	0.09611	0.9847

TABLE II. THE RATE OF RAINFALL IN (MM /H) DEEPENING ON THE PERCENTAGE OF TIME PER ZONE

Percentage of time (%)	B	C	D	E	F	G	H	J	K	L
1.0	0.5	0.7	2.1	0.6	1.7	3	2	8	15	2
0.3	2	2.8	4.5	24	45	7	4	13	42	7
0.1	3	5	8	6	8	12	10	20	12	15
0.03	6	9	13	12	15	20	18	28	23	33
0.01	12	15	19	22	28	30	32	35	42	60
0.003	21	26	29	41	54	45	55	45	70	105

where d (km), the actual length of the path, while d0 is defined as follows:

$$\begin{cases} 35e^{-0.015R_{0.01}}\, R_{0.01<100mm/h} \\ \quad 35^{-1.5}R_{0.01\geq 100mm/h} \end{cases} \psi \qquad (3)$$

If R0.01> 100 mm / h, place the value 100 mm / h in place of R0.01 The length of the current path calculated:

$$d_{eff} = r * d\ (km) \qquad (4)$$

Thus, the total value of the losses is calculated as follows:

Horizontal polarization

$$L^H = \gamma^H_{R0.01} * d_{eff}\ (dB) \qquad (5)$$

Vertical polarization

$$L^V = \gamma^V_{R0.01} * d_{eff}(dB) \qquad (6)$$

C. Measurement Setup

1) Description of area: The selected area is Palo Alto (37 26 13 N - 122 07 48W), located northwest of Santa Clara County, California, USA. It locates in the center of Northern California, and the choice of this location is not accidental. Heavy rains in northern California expect to increase in the coming years [15]. Also, the geographical area belongs to zone D, according to the ITU - R. standard 837.1.

2) Experimental data: The scenario concerns a wireless broadband link with Line of Sight (LOS), where the route length is 5 km. Both the transmitter and the receiver operate at 24, 28, and 38 GHz. These frequencies are ideal. After all, they work in the 5G spectrum because they have lower oxygen uptake rates [16]. The equipment is iPASOLINK NEC VR4 based on fifth-generation (5G) technical specifications Fig. 1. This equipment is already used by telecommunications providers as a reliable wireless backhaul solution to support a fifth-generation (5G) network. It consists of an external ODU type IAG unit with channel bandwidth up to 112MHz, low power consumption - 13 ~ 38GHz: 42 dBm (30% lower than the current version), modulation 2048 QAM, with a capacity of 1Gbps and a bandwidth of 112 MHz, elements that are equally compatible with NR 5G Fig. 2.

Fig. 1. Location of Wireless Broadband Backhaul Link.

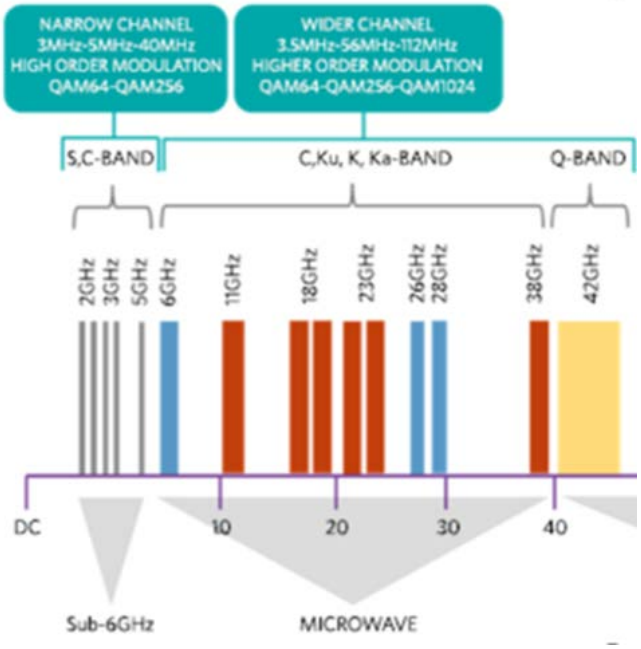

Fig. 2. Characteristics of Microwave Wireless Backhaul [17].

D. Theoretical Measurements

At this point, rainfall attenuation with coupling availability of 99.99% is calculated, with a distance of 5km for each of three operating frequencies:

- 38 GHz

Horizontal polarization

According to Table II, the coefficients K and α at 38GHz receive the following values.

KH = 0.4001, α = 0.8816

With the help of relation (1) the losses per km are:

$$\gamma^H_{R0.01} = K_H * R^{\alpha}_{0.01} = 0{,}4001 * 19^{0{,}8816} = 5{,}36\ (\frac{dB}{km})$$

Vertical polarization

Similarly, as before, the losses for vertical polarization are calculated

$$\gamma^V_{R0.01} = K_V * R^{\alpha}_{0.01} = 0{,}3844 * 19^{0{,}8552} = 4{,}76(\frac{dB}{km})$$

To calculate the total losses of horizontal and vertical polarization, the losses per km (as done earlier) and the current deff path's length must be measured. It is useful because it shows that along with the link, there is heterogeneity of meteorological conditions (e.g., more torrential rain elsewhere, not elsewhere), it is always less than the actual length. The current deff path calculate by multiplying the factor r by the actual length d.

After first calculating the sufficient path length through rain, for $R_{0.01}$<100mm/h:

$$d_0 = 35e^{-0{,}015*R0{,}01} = 35e^{-0{,}015*19} = 26{,}32$$

Thus, the reduction factor r:

$$r = \frac{1}{1+\frac{d}{d_0}} = \frac{1}{1+\frac{5}{26{,}32}} = 0{,}84$$

Therefore, the length of the active path can now set:

$$d_{eff} = r * d = 0{,}84 * 5 = 4{,}2km$$

So the total losses for each polarization are calculated separately:

Horizontal polarization

$$L^H_{R0,01} = \gamma^H_{R0,01} * d_{eff} = 5{,}36\left(\frac{dB}{km}\right) * 4{,}2(km) = 22{,}51dB$$

Vertical polarization

$$L^V_{R0,01} = \gamma^V_{R0,01} * d_{eff} = 4{,}76\left(\frac{dB}{km}\right) * 4{,}2(km) = 20dB$$

- 24 GHz

Horizontal polarization

According to Table II, the coefficients K and α at 24GHz take the following values. With the help of relation (1) the losses per km are:

$$\gamma^H_{R0.01} = K_H * R^a_{0.01} = 0{,}142 * 19^{1{,}01} = 2{,}77\ (\frac{dB}{km})$$

Vertical polarization

Similarly, as before, the losses for vertical polarization are calculated

$$\gamma^V_{R0.01} = K_V * R^a_{0.01} = 0{,}140 * 19^{0{,}95} = 2{,}29(\frac{dB}{km})$$

To calculate the total losses of horizontal and vertical polarization, the losses per km (as was done earlier) and the current deff path's length must be measured—the current deff path calculated by multiplying the factor r by the actual length d.

After first calculating the sufficient path length through rain, for $R_{0.01}$<100mm/h:

$$d_0 = 35e^{-0{,}015*R0{,}01} = 35e^{-0{,}015*19} = 26{,}32$$

Thus, the reduction factor r:

$$r = \frac{1}{1+\frac{d}{d_0}} = \frac{1}{1+\frac{5}{26{,}32}} = 0{,}84$$

Therefore, the length of the active path can now set:

$$d_{eff} = r * d = 0{,}84 * 5 = 4{,}2km$$

So, the total losses for each polarization are calculated separately:

Horizontal polarization

$$L^H_{R0,01} = \gamma^H_{R0,01} * d_{eff} = 2{,}77\left(\frac{dB}{km}\right) * 4{,}2(km) = 11{,}63dB$$

Vertical polarization

$$L^V_{R0,01} = \gamma^V_{R0,01} * d_{eff} = 2{,}29\left(\frac{dB}{km}\right) * 4{,}2(km) = 9{,}61dB$$

- 28GHz

Horizontal polarization

According to Table II, the coefficients K and α at 28GHz take the following values.

With the help of relation (1) the losses per km are:

$$\gamma^H_{R0.01} = K_H * R^a_{0.01} = 0{,}20 * 19^{0{,}96} = 3{,}37\ (\frac{dB}{km})$$

Vertical polarization

Similarly, as before, the losses for vertical polarization are calculated

$$\gamma^V_{R0.01} = K_V * R^a_{0.01} = 0{,}19 * 19^{0{,}92} = 2{,}86(\frac{dB}{km})$$

To calculate the total losses of horizontal and vertical polarization, the losses per km (as was done earlier) and the current deff path's length must be measured. The current deff path calculate by multiplying the factor r by the actual length d.

After first calculating the sufficient path length through rain, for $R_{0.01}$<100mm/h:

$$d_0 = 35e^{-0{,}015*R0{,}01} = 35e^{-0{,}015*19} = 26{,}32$$

Thus the reduction factor r:

$$r = \frac{1}{1+\frac{d}{d_0}} = \frac{1}{1+\frac{5}{26{,}32}} = 0{,}84$$

Therefore, the length of the active path can now set:

$$d_{eff} = r * d = 0{,}84 * 5 = 4{,}2km$$

So the total losses for each polarization are calculated separately:

Horizontal polarization

$$L^H_{R0,01} = \gamma^H_{R0,01} * d_{eff} = 3{,}37\left(\frac{dB}{km}\right) * 4{,}2(km) = 14{,}15dB$$

Vertical polarization

$$L^V_{R0,01} = \gamma^V_{R0,01} * d_{eff} = 2{,}86\left(\frac{dB}{km}\right) * 4{,}2(km) = 12{,}01dB$$

III. Experimental Setup

A. System Architecture

IoT is a device system that interconnects via the Internet. It does with the help of many platforms and protocols on the market. The development of this rainfall detection system (IoT) aims to inform the user about the course of the precipitation, as it is an essential factor for the degree of intensity with which the rain erupts in a certain period (per hour or minute) [18]. The system analyzed consists of a low-cost microcontroller (ESP32) with integrated Wifi and dual-function Bluetooth

(Fig. 3). This connection to all the sensors and many parts of circuits such as (power supplies, analog inputs-outputs, digital outputs, and breadboard). Its primary function is to collect the sensors' data, process them, and inform about its condition through the Adafruit IO service with the internet unit's help. Also used is a SUNKEN rain sensor with dimensions of 13 x 8.4 x 1.3 inches and a Miuzei SG90 9G micro servo motor (Fig. 4).

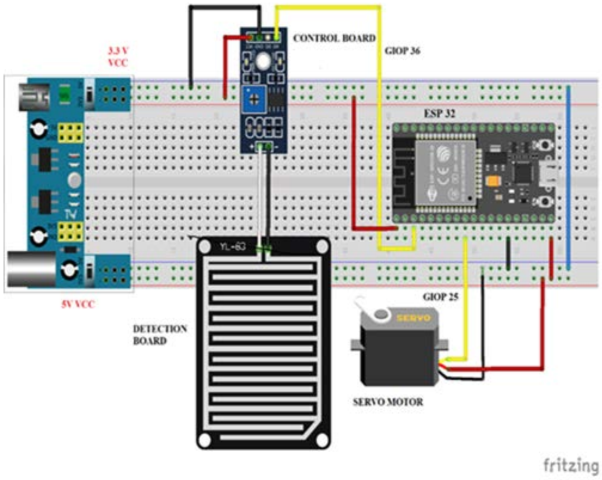

Fig. 3. Simulation of Project.

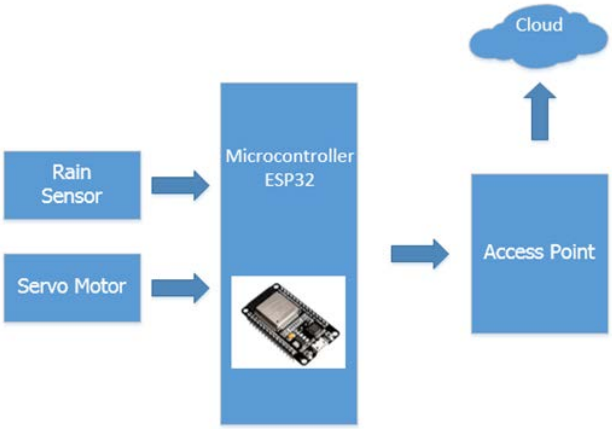

Fig. 4. Block Diagram of Projects.

B. Input System

This system works by receiving data from a rain sensor, where the engine activates after a specific range of values. The output data obtained through ESP 32, where analyzed below:

- Input Data of Rain Sensor

This device uses to control rain or flood in various applications. It included a detection board, a control board where the sensor's sensitivity is regulated—his logic based on a variable resistance. The sensor is a resistor that shows less resistance when wet and more resistant when dry. When there is no water drop on the surface, then the resistance increases, and so at the output, there is a high voltage according to V = IR (Ohm's Law). Correctly, the rain sensor can be used both as a digital input, i.e., distinct values of 0 or 1 can characterize it. (e.g., a switch that can be on (Off / Off) or it can use as an analog input, i.e., it can be characterized as from a price range (e.g., a potentiometer where it can get a price range depending on where it turned). So when there is an analog device, the reading of an analog value with ESP 32 allows us to measure different voltage levels between 0 V and 3.3 V, where this can translate into 0 to 1023 integers. The range is determined by the built-in ADC, which in the case of ESP 32, is ADC 10 bit (2 ^ 10 = 1024). The specifications of rain sensor set out in the Table III.

- Servo motor

Servo motors are small devices that have a shaft protruding on their outer casing. It is a device that can rotate an axis from 0 to 180 or 360 degrees. He could change the angle (move) if a coded signal sents. As long as this signal is present on the Servo input line, it will keep its axis in a specific position. When the signal changes, it causes the servo to change the angle of the shaft. This device is used for many projects, such as controlled aircraft, cars, and robotics. In this case, the engine uses as an analog output.

- Process System

Make clear to the real-time user that the values collected by the microcontroller have set up, a scale showing the total value of the analog value range set by Table IV is displayed, depending on the amount of water falling on the panel. This table has created with the help of a cylindrical tube graded in millimeters [9]. Finally, it should note that the panel place at a slope of 40, which results in the expulsion of a large amount of water more significant than 50 mm.

- Micro controller esp 32

The ESP32-DEVKIT V1 is an MCU Wi-Fi + BT + BLE unit with a wide range of applications, from low-power network sensors to the most demanding tasks such as voice coding, music streaming, and MP3 decoding. Two CPU cores can control individually, and the CPU clock frequency is adjustable from 80 MHz to 240 MHz. The controller has a data rate of up to 150 Mbps and an output power of 20.5 dBm on the antenna to ensure wireless transmission. Its integration with Bluetooth and WIFI makes it flexible for many applications. The controller can connect digital input/output units and analog inputs/outputs, useful for many applications. These units are nothing more than electronic data that, when excited, send a signal to the controller, then it gives the corresponding command with which the user programs it. At this stage, the program code writes in MicroPython language.

TABLE III. SPECIFICATIONS OF THE RAIN SENSOR

Pin	Description
Voltage Rating	5V
GND	Negative power source.
Power supply voltage	3.3-5V
Sensor Board Size	54mm x 40mm
Shield PCB Size	30mm x 16mm
Sensitivity Adjustment	Clockwise is more sensitive.

TABLE IV. RULE BASE SYSTEM

Analog value	Direct reading gauge (mm)
980 - 890	5
890 - 780	10
780 - 670	20
670 - 580	30
580 - 450	40
450 - 400	50

- Software IDE

In this study, use Thonny, where is the Python Integrated Development Environment (IDE) used. It is especially useful for code entry. It has a built-in error detection program. This editor also allows to program the ESP32 and ESP8266 boards with MicroPython and is compatible with Windows, Mac OS X, and Linux. MicroPython came from the Python 3 language and developed to program microcontrollers and electronic devices connected to it. While MicroPython is not yet as well-known as C and C ++ for electronic device scheduling, it is slowly becoming popular with more and more microcontrollers and IDE. It is also effortless to use, and its interface makes it very easy for a novice user. It also features a read-evaluate-print (REPL). This feature helps the user connect to the board and execute it directly without compiling it. In the present phase, the interpreter, MicroPython (ESP32), and the corresponding USB prey that the board has connected to select the code to load on it select.

- Adafriut IO

Adafruit.IO is a cloud service - this means that it does not need to be managed by the user. This platform uses to connect to the Internet. To store and retrieve data, but can do much more than that. Adafruit.Io can handle and visualize many data streams. The platform environment is quite user-friendly (Fig. 5). Also, the Adafruit online platform works with many microcontrollers (including ESP32) and, with the support of the MQTT protocol, allows easy and secure management of IoT systems.

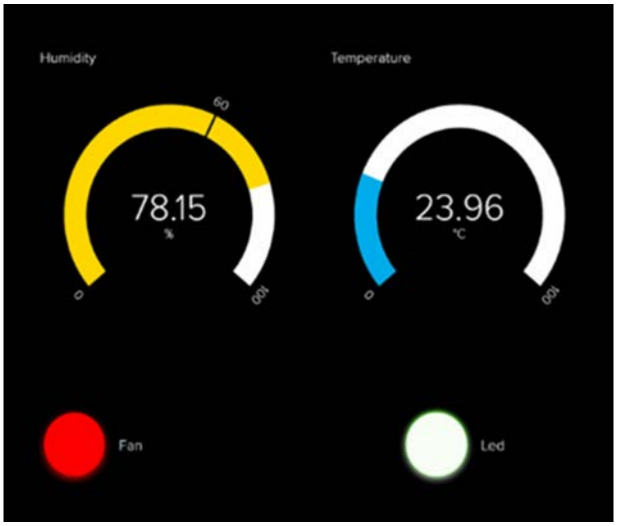

Fig. 5. Interface Adafruit IO.

C. Working of IoT based Rainfall Monitoring System

The construction shows that the rain height's size can place in a base station, a residential complex, lighting columns, and different environments (urban or rural areas) (Fig. 6). The basic idea is to inform the user in real-time via a local network from the platform. An ESP32 device can play the role of an Access Point or a Station. The data output thus passes to the Adafruit IO platform via the MQTT protocol.

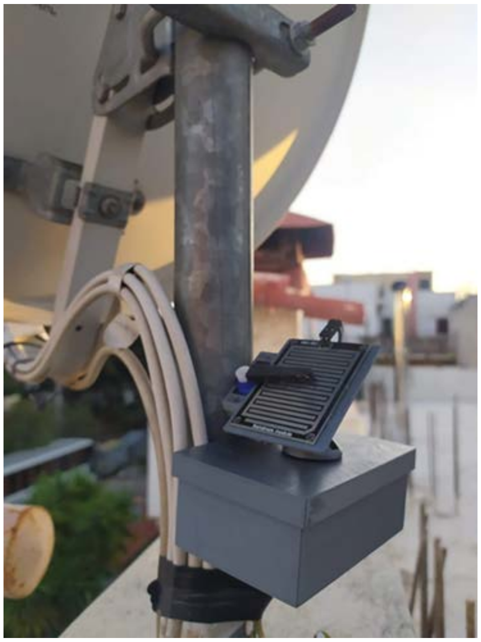

Fig. 6. IoT based Rainfall Monitoring System with 3D Case.

The sender is the (publisher), and the recipient is the (subscriber). Both do not come into direct contact with each other. However, a third party (MQTT broker) directs the publisher's messages to any endpoint, that is, the subscriber. The following Fig. 7 shows the IoT system architecture, where the sensor is located on the transmitter and through the MQTT broker sends the appropriate messages to the monitor that controls them in real-time.

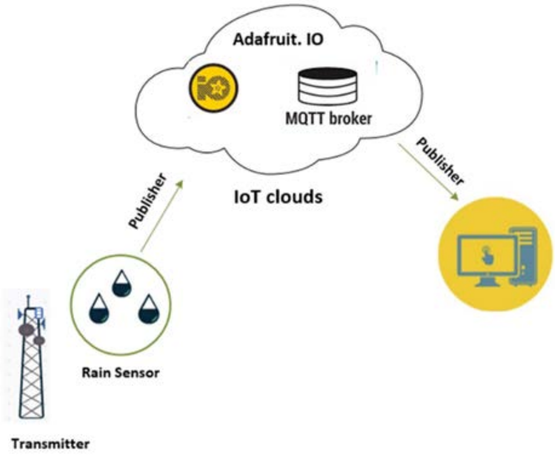

Fig. 7. MQTT Broker Network Architecture in Wireless Broadband.

The board has programmed so that the dry surface indicates the value of 1023. The values that can be displayed come from many experimental tests with a cylindrical tube graded in millimeters. There are no other values from one point onward because the rain panel is placed at a slope of 40°, resulting in not enough water to remain when it falls on it due to gravity.

IV. Results and Discussion

A. *Theoretical Measurement Results*

Theoretical weather calculations on wireless communication systems would be more straightforward if there were no rain or humidity effects. As it is known from the bibliography so far, the rain can weaken the radio waves' power depending on its rhythm and operation frequency. The present study presents the scenarios presented at Palo Alto-based on three different frequencies of 24 GHz, 28 GHz, and 38 GHz, where they are ideal for 5G wireless broadband connections.

From the theoretical measurements made, the rainfall attenuation calculates with a coupling availability of 99.9%, with a distance of 5km for each of the three operating frequencies (Fig. 8). It found that the lower the operating frequency, the lower the radio signal's attenuation, and that different loss values are presented based on polarization. Horizontal polarization is more prone to damping than vertical polarization. As raindrops increase in size, they get more extended in the horizontal direction. They, therefore, will attenuate horizontal polarization more than vertical polarization. The shape of the drops explains this as they fall from the atmosphere. In particular, during the fall, they change shape showing the tendency to distribute their volume, mainly along the horizontally polarized electric field. In this regard, the field interaction with the droplet is more critical in horizontal polarization than in vertical. Therefore, the scenario where it is less affected by rainfall is the operation at 24 GHz. The frequency range from 24 GHz and above offers low latency and high data rate [19]. Such a wireless connection will continue to provide high-quality services to users, even in severe weather conditions.

The specific attenuation depends on the value of the frequency. As the frequency increases, so do the specific attenuation based on the international recommendations (ITU-R P.838-3) [12].

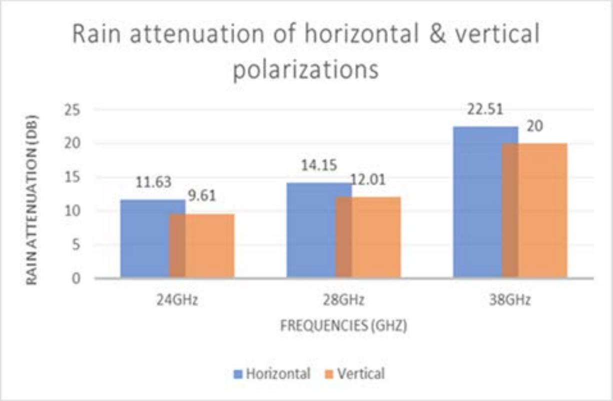

Fig. 8. Rain Attenuation of Horizontal and Vertical Polarizations.

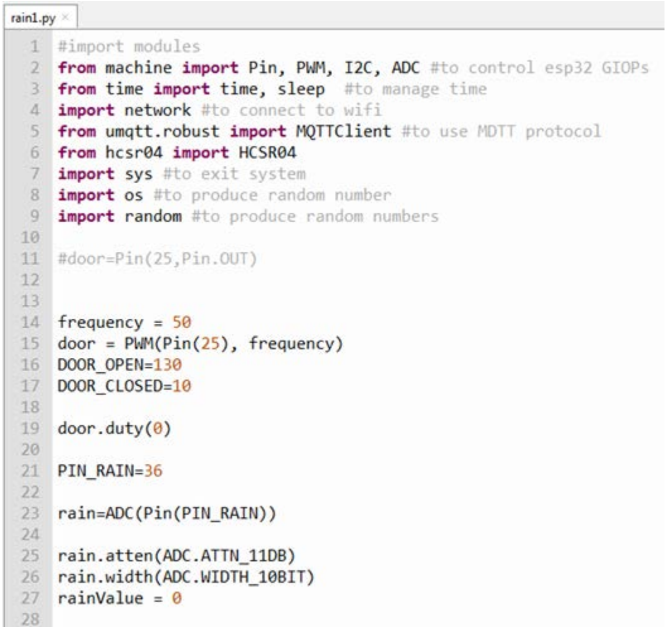
B. *Esp 32 Thonny IDE Output*

As studied in the scenario that took place, the parameter of the rate of the rainfall R (mm / hr) is critical because the original size that characterizes it is the height of the rain, where it measures in millimeters. In the theoretical measurements that followed, the rate was the same due to its geographical location. At present paper, an IoT system develops, which will present in real-time the rainfall in the standards of a scale that create for the display of the sizes. The planning divided into three sections:

In the first one, the required libraries have defined, the calls of the Pin, PWM, I2C, ADC classes, and the initializations of the analog input for the rain sensor and the initializations for the analog output, which is the servo motor (Fig. 9).



```
 1  #import modules
 2  from machine import Pin, PWM, I2C, ADC #to control esp32 GIOPs
 3  from time import time, sleep  #to manage time
 4  import network #to connect to wifi
 5  from umqtt.robust import MQTTClient #to use MDTT protocol
 6  from hcsr04 import HCSR04
 7  import sys #to exit system
 8  import os #to produce random number
 9  import random #to produce random numbers
10
11  #door=Pin(25,Pin.OUT)
12
13
14  frequency = 50
15  door = PWM(Pin(25), frequency)
16  DOOR_OPEN=130

```

Fig. 9. Libraries and Initialization of Variables.

In the second part of the code is defined as the communication MQTT client publisher, with the MQTT broker (server), where this, in turn, communicates with client subscribers. A Client can be both a publisher and a subscriber. The sensor's measurement is in line 119, and the value of the measurement is sent with the Send_Data () function on line 122. Essentially the line of code that sends the measurement to the interface is line 86. The above line sends the information str (rainValue) through the client created above (line 48), “mqtt_feedname1”. Specifically, the path, “io.adafruit.com/kostaszar/feeds/rain”. Rain is the name of the feed on the interface side, i.e., the value rainValue will send to the interface block connected to the feed rain.

The third and last show all those commands that are the program's central structure and are the ones that have the central role. It is essentially a repetition where it is checked every 10 seconds for the values it takeç. If the values listed in the platform interface are below 800, then the most significant amount of water is collected in the panel, so there is a need to clean where after two seconds, the rain sensor is ready to receive water again for the next recording. Within these two seconds, the engine has made two 180° turns. With a drop of 5 mm, the water drop, the program settings so that the range of values it can get is between 980 and 890. Then the 10 mm of water corresponds to 890 - 780 and the 20 mm of water in 780 - 670. The next Price range is 670 - 580 were with 30 mm of water. Finally, with 40 mm of water space, precipitation is 580 - 450, and with 50 mm of water, a value appears between 450 – 400.

Every element presents a size or an output to a feed. Each feed is a communication channel between ESP 32 (client) and Adafruit (broker). Dashboards can place the icons (blocks) by the developer. In this analysis, a rain gauge defines, from which the value displayed appears at a specific time, and the user can easily see it.

V. Conclusion

As studied for the 24 GHz, 28 GHz, and 38 GHz frequency bands, damping due to rain may seem vital because they create network coverage problems. Especially at 38 GHz, the damping for horizontal polarization is 22.51 dB. At 28 GHz, the damping is less by 8.36 dB, while at 24 GHz, the losses are smaller than the other two frequencies where they reach 11.63 dB for horizontal polarization.

In the era of the fifth generation of wireless broadband networks in urban areas due to the increased coverage and capacity requirements, the mobile communication networks distributed in cells. Where within a macro cell, there may be many smaller ones to serve more broadband services. The phenomenon of attenuation will be more evident in rural areas because, in addition to the prevailing weather conditions, the distance that the electromagnetic wave must travel as it travels taken into account. In contrast to urban areas where the distances are short, it seems that the 24 GHz frequency is ideal from the other two, although they are suitable for the development of fifth-generation networks.

Thus, mobile companies' ultimate solution will be to continually update the weather conditions prevailing in a base station or a wireless broadband backhaul installation—ideal for the places where the climate is changing rapidly and is affected by heavy rainfall. According to this document, sensor systems will be useful because they can interconnect with the World Wide Web and other devices that will allow them to exchange data and provide the required information.

Abstract—**In recent years, the mortality rate of cardiovascular diseases and the younger generation have attracted people's attention. At the same time, there is an increasing demand for devices that can monitor the physiological parameters of the heart. In this research, a wearable devices was designed and developed for heart sound collection. Microphones wrapped in urethane resin holders were directly fixed on the vest for heart sound collection. The device has received many positive reviews in terms of comfort. The cumulative contribution rate of the two common factors (material factor and clothing design factor) obtained through factor analysis was 75.371%, which was the main factor affecting the experience of using the device. Finally, the heart sounds of 11 healthy young people were collected and input into the completed convolutional neural network for detection, and an accuracy rate of 71.3% was obtained. Therefore, it can be concluded that the device improves the user experience and has a good effect on heart sound collection and detection.**

Keywords—Cardiovascular diseases; wearable devices; heart sound collection; convolutional neural network

I. Introduction

The number of people dying from cardiovascular disease (CVD) is steadily rising, including one-third of all deaths globally in 2019, according to a paper in the Journal of the American College of Cardiology that reviewed the total magnitude of CVD burden and trends over 30 years around the world [1]. With the current aging of the world, the mortality rate of cardiovascular diseases will continue to increase. At the same time, cardiovascular disease is no longer a patent for the elderly. Among the sick people, the ratio of middle-aged and young people is also rising, and cardiovascular diseases are getting younger. The main reason for this trend is the bad lifestyle habits of young people, such as long-term smoking, lack of sleep, unhealthy eating habits, lack of exercise, etc. [2-3].

As the rejuvenation of cardiovascular disease becomes more and more obvious, it has attracted widespread attention, and people's health awareness is gradually improving. At the same time, it means that the demand for medical equipment is constantly expanding, not only for medical equipment in hospitals, but also for equipment that can monitor human physiological parameters in daily life. This kind of equipment does not require the patient to stay in the hospital all the time, but it can monitor various physiological parameters of the human body in real time, reflect the health of the human body, and provide accurate basis for clinical diagnosis [4-7] for doctors to make timely diagnosis and treatment, to improve the efficiency of the hospital's diagnosis of the patient's condition. For elderly people and young people with great work pressure, getting 24 hours uninterrupted supervision in their daily life, can make them gain a sense of security to a large extent. The remote monitoring of physiological parameters has become a research hotspot in the field of biomedical engineering [8-9].

At present the type of physiological parameter monitoring equipment range on the market, divided by monitoring the way, there are wearable, portable, desktop detection equipment etc.; divided by function, there are heart sound and electrocardiogram (ECG) monitoring, defibrillation monitoring, sleep monitoring equipment etc. [10-11]. With the continuous advancement of technology and the increase of market demand, wearable monitoring equipment has become the future research direction. The most representative equipment at present is the wearable vest-type physiological parameter monitoring equipment Life Shirt developed by Vivo Metrics company in the United States. As shown in Fig. 1. The device can monitor different physiological parameters of the human body through multiple biosensors, such as ECG, blood pressure, heart rhythm, body temperature, etc. [12-14]. It has been used as a clinical medical instrument by many hospitals, but the data collected by the device cannot be transmitted in real time, so remote real-time monitoring cannot be realized.

In view of the high mortality rate of cardiovascular diseases, monitoring equipment specifically for heart sounds and ECG is also emerging in endlessly. Since heart sound auscultation is one of the most basic diagnostic methods for cardiovascular diseases, it is an important basis for the initial diagnosis [15-16], so the monitoring of heart sounds can reflect the human heart condition in a timely manner. This helps doctors find abnormalities in the heart as soon as possible so as to improve the diagnosis efficiency of the disease and enable patients to receive timely treatment. In the current research on heart sound monitoring equipment, it can be roughly divided into two categories: electronic stethoscope collecting heart sounds and microphone collecting heart sounds. Among them, the development of electronic stethoscope collection of heart sounds is relatively mature. For example, Beck C et al. [17] designed and developed a multi-mode physiological parameter collection wearable device including heart sound auscultation, which can be used with MATLAB software to obtain real-time data or store data in software; Tiwari, Hemant Kumar et al. [18] have designed an embedded stethoscope served as a platform for the computer aided diagnosis of cardiac sound for the detection of cardiac murmur, the device can display heart sounds on the TFT LCD display in real time, and stored on the micro SD card. However, these devices are inconvenient for daily carrying due to their large size. In terms of microphone collection of heart sounds, Kirchner J et al. [19] proposed a wearable system for long-term capture of chest sound, including four microphones for receiving physiological signals and one microphone for receiving ambient noise. The performance of the device was evaluated in different environments, and the use of combined microphones improved the noise cancellation; Aguilera-Astudillo C et al. [20] demonstrate a chest piece which consists of an electret microphone embedded into the drum of a 3D printed chest piece. And use the electronic dongle to amplify the microphone signal and reduce external noise, while the mobile phone can display the heart sound signal. From the above studies, we can find that the use of electronic stethoscopes to collect heart sounds is not convenient for daily wear due to the size of electronic stethoscopes, and the use of microphones to collect heart sounds did not investigate the comfort of the device and the wearing experience, so we believe that there is still more room for research in the wearing comfort of heart sound monitoring devices.

Fig. 1. Life Shirt Wearable Physiological Parameter Monitoring System.

In view of previous research, this paper is devoted to the design and development of an easy-to-wear heart sound collection device, to discuss and study the comfort of the device, and to analyze the collected heart sounds using convolutional neural networks (CNN). The organization structure of this article is as follows: Section II explains the design of the heart sound collection vest in detail; Section III introduces the heart sound collection experiment and heart sound data analysis; Section IV analyzes the results and discusses them; Section V draws conclusions and Section VI summarizes the shortcomings and makes suggestions for future work.

II. Design of the Heart Sound Collection Vest

This part introduces the design and development of the heart sound collection vest. First, a 3D printing mold was designed and printed according to the size of the microphone. After that, urethane resin was used to make a super soft microphone holder. Finally, according to the 4 positions of the heart sound auscultation, the microphone was fixed on the vest to make a wearable heart sound collection vest.

A. The Design of the Microphone Holder

1) 3D printing mold design: The microphone used in this design is the Uni-directional Electret Condenser Microphone produced by Primo Company, the model is EM297, as shown in Fig. 2, the diameter is 10mm, and the thickness is 4.5mm. According to the instructions of the microphone, the sound hole on the back of the microphone cannot be blocked in order to receive the sound. At the same time, in order to ensure that the microphone can accurately receive the sound, the microphone needs to be close to the skin, which requires the microphone to withstand a certain amount of pressure, so it is necessary to make a suitable holder to ensure that the microphone can receive normally and accurately.

According to [21], when the diameter of the holder is 17mm, and there is a 1.5mm thick silicone layer between the microphone and the skin, the microphone has the best sound reception. Therefore, according to the shape and size of the microphone, the 3D printing mold of the holder has shown in Fig. 3 was designed. The mold is a cylinder and adopts a fully-wrapped type except for the sound hole on the back. At the same time, a dedicated space is reserved for the microphone wire.

2) Development of soft skin-friendly holder: In view of the fact that the microphone holder needs to be in direct contact with the skin, the urethane resin with a hardness of 0 produced by EXSEAL company was selected to make the holder in consideration of skin affinity when selecting the material. This urethane resin has excellent softness, sufficient molding strength even if the hardness is 0, and this urethane resin has a softness like a human skin.

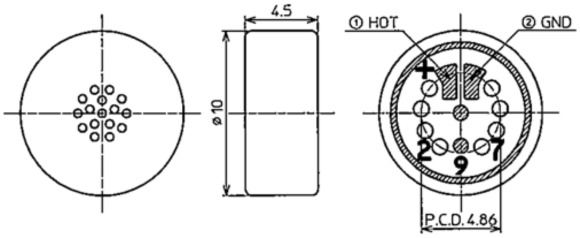

Fig. 2. Schematic Diagram of Microphone.

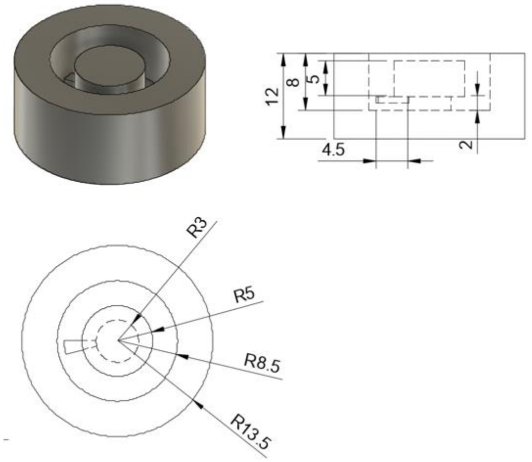

Fig. 3. Schematic Diagram of the 3D Printing Model of the Microphone Holder (unit: mm) (a) Holder Molding Model (b) Model Front view (c) Model Top View.

According to the product's instructions, first calculate the volume of the mold before preparing the gel, and spray the mold with a special release agent for urethane resin in advance to facilitate the release of the holder afterwards; then mix the two liquids (the weight ratio of main agent and curing agent is 3:1) and pour them into the 3D printing mold; finally, after 24 hours, take out the molded holder from the mold. Fig. 4 shows the process of manufacturing the microphone holder. The holder wraps the microphone well and protects the relatively fragile and breakable wires of the microphone. Fig. 5 is a schematic diagram after the microphone is installed in the holder.

B. The Design of the Heart Sound Collection Vest

1) Location of heart sound auscultation: According to [22], there are 4 commonly used positions for heart sound auscultation. As shown in Fig. 6, the mitral valve is located at the strongest point of the apical beat, and is normally located at the fifth intercostal space on the inner side of the left midclavicular line; the pulmonary valve is in the second intercostal space on the left edge of the sternum; the aortic valve is in the second intercostal space on the right edge of the sternum; the tricuspid valve is on the left edge of the lower end of the sternum, that is, the 4-5th intercostal space on the left edge of the sternum. The general auscultation sequence is the beginning of the mitral valve - the pulmonary valve - the aortic valve - the tricuspid valve.

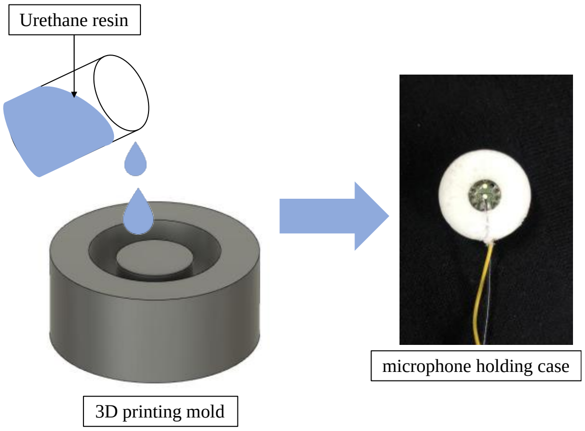

Fig. 4. Schematic Diagram of Making Microphone Holder.

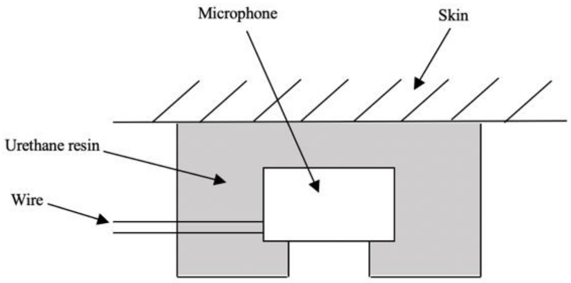

Fig. 5. Schematic Diagram of the Microphone Placed in the Holder.

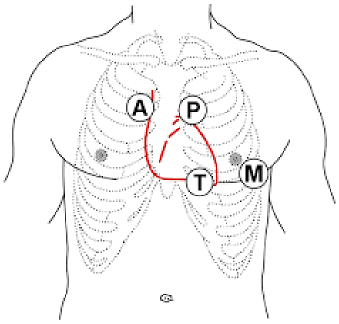

Fig. 6. Position of Heart Sound Auscultation. A = Aortic Valve; P = Pulmonic Valve; M = Mitral Valve; T = Tricuspid Valve.

2) Making of heart sound collection vest: A wearable vest for heart sound acquisition was proposed as the main object of this study based on the location of heart sound auscultation and taking into account the comfort, fit and appearance of the device.

A fabric made of Polyester 90% and Lycra 10% was used as the base fabric, and a suitable vest was made according to the m size of men's and women's clothing size. The vest was designed with two layers of fabric, which could facilitate the fixation of the microphone and make the vest neat in appearance. After that, according to the four positions of heart sound auscultation, the fixing sleeve with microphone is fixed on the corresponding position on the inside of the vest: firstly, the position of the microphone is determined, then it is wrapped with cloth and sewn on the vest, then holes are made at the suitable position nearby for the wire to pass through, and finally the wire is fixed on the vest with needle and thread and passed out from the side of the vest. As shown in Fig. 7, (a) is a diagram of the microphone device inside the vest, and (b) is a diagram of the exterior of the vest.

Fig. 7. Physical Diagram of the Heart Sound Acquisition Vest (a) Microphone Device on the Inside of the Vest (b) Diagram of the Outside of the Vest.

III. Experiments and Methods

This section describes the experiments used to evaluate the acquisition effectiveness of the designed heart sound collection vest and the comfort of wearing it.

A. *Heart Sound Collection Experiment*

A heart sound collection experiment was conducted on healthy young people to evaluate the collection effect and wearing comfort of the heart sound collection vest. 11 students (5 females and 6 males) participated in the experiment. Ages ranged from 21 to 29. Height, weight and chest circumference of the participants were measured before the experiment: height ranged from 1.61-1.7m, weight ranged from 54-56 kg and chest circumference ranged from 80-93 cm for females, and height ranged from 1.58-1.75m, weight ranged from 55-68 kg and chest circumference ranged from 81-98 cm for males.

The heart sound collection experiment was carried out in an indoor experimental environment with a temperature of 20 degrees Celsius, a humidity of 45%, and a surrounding environment with a decibel number of 15dB. The participants wore a vest of appropriate size, and the heart sounds were collected and stored in the following order of auscultation: mitral valve area - pulmonary valve area - aortic valve area - tricuspid valve area, with 3-5 heart sounds randomly collected for 30-180 seconds at each location, as shown in Fig. 8..

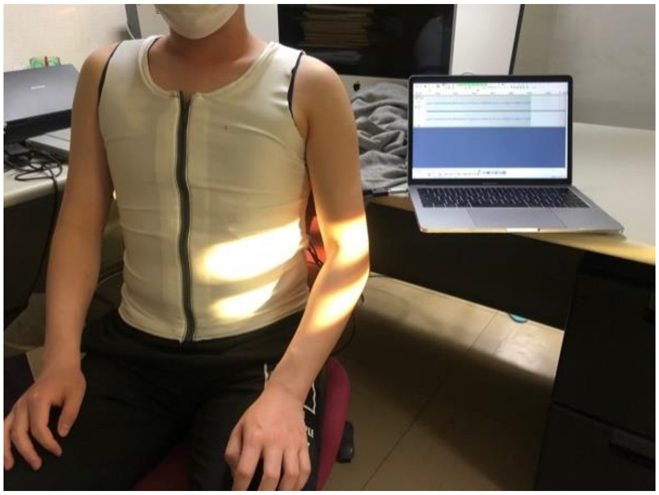

Fig. 8. Experimenter in Heart Sound Collection Experiment.

B. *Investigation of Device Comfort*

After the completion of the heart sound collection experiment, the experimental participants were asked to complete an assessment questionnaire for the heart sound collection vest. The questionnaire was set up with reference to the Semantic Difference [23], which is a measure of semantic differentiation. It was developed by the social psychologist Osgood et al. in the 1950s. Such scales consist of a series of bipolar adjective word pairs that are generally divided into seven equal rating scales. They have the quality of showing the semantic space in which any concept has meaning, and can be used accordingly to describe the underlying meaning of any concept and its associated problematic nature or property aspects. In the present study for the wearable device, considering the user-friendly characteristics that the device needs to have, seven contrasting adjectives and a 7-point rating scale from -3 to +3 were proposed in terms of material, prolonged wear, and appearance for the experimental participants to rate this heart sound collection vest. The seven adjectives were 1) tight/loose, 2). Strong/weak, 3) heavy/light, 4) hard/soft, 5) unattractive/nice, 6) inconvenient/convenient, 7) dislike/like. Each adjective group corresponds to an explanatory question: 1) Do you think the pressure exerted by this device on the skin is tight or loose? 2) Do you think the stimulation of this device on the skin is strong or weak? 3) Do you think this device is heavy? 4) Do you think the touch of this device is hard or soft? 5) Do you think the design of this device is good-looking? 6) Do you think this device is convenient to put on and take off? 7) Do you like to use this device for a long time?

IV. Results and Discussion

A. *Heart Sound Data Denoising*

There are many noises generated during heart sound collection, for example: ambient noise; vibration of the microphone caused by chest vibration and the zipper of the vest is located in the middle of the chest causing the microphone in the pulmonary valve area and aortic valve area to not fit well to the skin, generating a lot of noise, etc. Therefore, filtering and denoising are needed before heart sound data detection. In this study, an algorithm written in python is used to remove the noise. The steps of the algorithm are: 1) calculate Fast Fourier Transform (FFT) on the noisy audio fragment, 2) calculate statistics from the FFT of the noise, 3) calculate a threshold based on the statistics of the noise (and the desired sensitivity of the algorithm), 4) calculate FFT from the signal, 5) determine the mask by comparing the signal FFT with the threshold, 6) the mask is smoothed in frequency and time using a filter, 7) the mask is applied to the FFT of the signal and is inverted. After processing the heart tone data using this algorithm, the spectrograms of the heart tone data before and after denoising are obtained as shown in Fig. 9. The upper panel is before denoising and the lower panel is after denoising, and it can be clearly seen that most of the noise is removed.

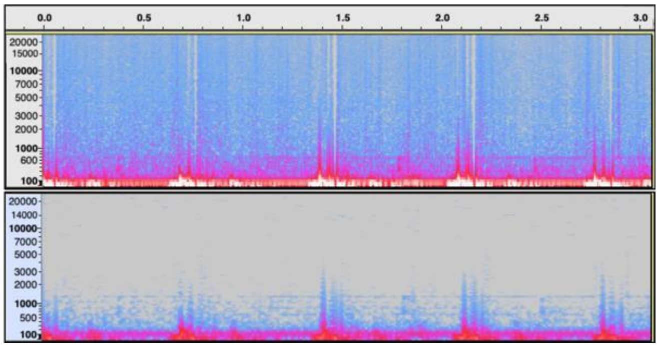

Fig. 9. Spectrograms of Heart Sounds before and after Denoising.

B. *Heart Sound Data Detection Results*

To test the denoising effect, the heart sound data before and after denoising were fed into the convolutional neural network (CNN) [24] that had been built to obtain the accuracy of heart sound data detection. Firstly, the heart sound data were divided in 5-second intervals, and then the sample heart sounds were converted into grayscale spectrograms by an automatic procedure using the librosa library, and finally fed into the CNN. This CNN consists of 5 layers, including 3 convolutional layers, 1 fully connected layer and 1 normalized exponential function softmax classification layer. The network parameters for each layer are as follows: for the first convolutional layer, we used 32 filters with a convolutional kernel size of 3 × 3 and a step size of 1 × 1, and the pooling (using the max-pooling method) size was 2 × 2 and a step size of 1 × 1. We used a modified linear unit (ReLU) activation function with a random deactivation (loss) rate of 0.1. For the second and third convolutional layers, we used 64, 128 filters. The convolution kernel size is 3 × 3 and the step size is 1 × 1. The pooling operation, activation function and dropout probability were the same as in the previous layer. For the fourth layer, we use a fully connected dense layer with an output size of 500, a ReLU activation function and a dropout function (probability 0.25). In the last classification layer, we used a Softmax classifier.

The detection of the convolutional neural network shows that the accuracy of the un-denoised heart sound data is 34.89% and the accuracy of the denoised heart sound data is 71.30%. In order to investigate the detection accuracy of the heart sound collection vest under the wearing of different gender groups, the detection results of the heart sound data were analyzed according to male and female as well as each person, as shown in Tables I, II, and III.

From Table I, it can be seen that although the accuracy of heart sound data for males before denoising was lower than that of heart sound data for females, after denoising, the accuracy of heart sound data for both males and females exceeded 70%, which indicates that the denoising procedure was effective and was able to remove most of the noise and improve the accuracy of heart sound detection.

Table II shows the comparison of the accuracy of heart sound data before and after denoising for males, from which it can be found that the accuracy of the heart sound data obtained in the state of collecting heart sounds while wearing the same vest varies due to the different height, weight and chest circumference of each experimental participant. The reason for this is that the tighter the vest fits to the skin, the clearer the heart sound data is and the higher the accuracy rate is after denoising. Therefore, the better the fit of the vest to the skin, the better the collection results.

Table III shows the comparison of the accuracy of heart sound data before and after denoising in women, from which it can be found that the heart sound data of experimental participants No. 1 and No. 2 obtained more than 91% accuracy after denoising, and the other three also obtained more than 64% accuracy, indicating that the heart sound acquisition vest can acquire heart sounds well. However, the detection accuracy of individual heart sound data varied widely due to the difference in body size of each individual and the fact that the vest for women was designed without the inclusion of a bra part.

C. Factor Analysis of Heart Sound Collection Vest

Fig. 10 visualizes the semantic difference (SD) evaluation scores of men and women on wearable heart sound collection devices. It can be seen from the figure that men and women have roughly the same evaluation of the device, but women have given more positive feedback. Among them, both men and women think that the device has weak skin irritation, not heavy, soft, convenient to wear, and suitable for long-term use. These positive feedbacks may be attributed to the following factors: 1) Polyester and lycra used in the fabric of the vest are soft and stretchable, suitable for personal wear; 2) The microphone holder is made of urethane resin with a hardness of 0, it has a softness like a human skin; 3) The vest is designed with a zipper to facilitate putting on and taking off. At the same time, women think that the device has little pressure on the skin and the appearance is attractive, but men think that the device has a certain amount of pressure on the skin and the appearance is not very attractive. This is because there are certain differences in the design of the male and female vests, and it is also the direction of improvement in the future.

TABLE I. COMPARISON OF THE ACCURACY OF HEART SOUND DATA DETECTION BEFORE AND AFTER DENOISING

	Accuracy of data without denoising	Accuracy of data after denoising
Male	27.36%	70.01%
Female	40.16%	72.20%

TABLE II. COMPARISON OF THE ACCURACY OF HEART SOUND DATA DETECTION BEFORE AND AFTER DENOISING FOR MALES

	Height (cm)	Weight (kg)	Chest circumference (cm)	Accuracy of data without denoising	Accuracy of denoised data
M-1	168	68	95	42.54%	85.39%
M-2	173	67.5	98	43.51%	83.76%
M-3	175	65	87	11.28%	72.16%
M-4	175	60	89	12.96%	70.15%
M-5	167	55	81	12.16%	55.32%

F -5	169	56	82	64.73%	64.87%

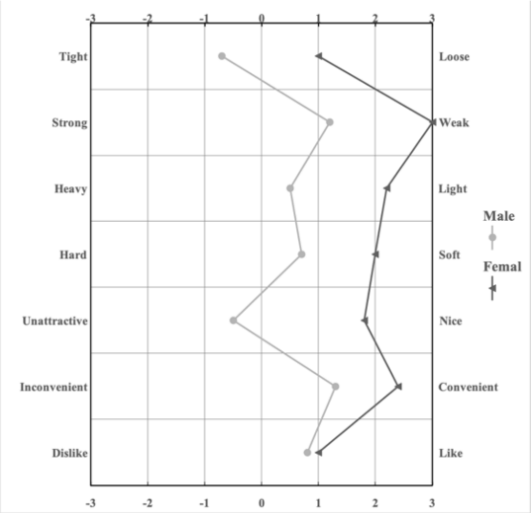

Fig. 10. Image Scale of SD Evaluation Score (Average Value) of Male and Female Wearable Heart Sound Acquisition Devices.

Factor analysis was conducted on the SD scores of 11 experimental participants on the wearable heart sound collection vest [25]. Factor analysis is the conversion of multiple measured variables into a small number of composite indicators (or latent variables), and it reflects an idea of dimensionality reduction. The variables with high correlation are clustered together through dimensionality reduction, thus reducing the number of variables that need to be analyzed while reducing the complexity of the problem analysis. Thus, the use of factor analysis provides insight into the potential factors affecting wearable heart sound collection devices.

Factor analysis was conducted using python. First, to confirm the suitability of the data for factor analysis, Kaiser-Meyer-Olkin (KMO) and Bartlett tests were performed with: KMO test is used to examine the bias correlation between variables, taking values between 0 and 1; the closer the KMO statistic is to 1, the stronger the bias correlation between variables and the better the factor analysis. Generally the statistic is above 0. 6 is adapted to do factor analysis [26]; and the smaller the value of P-Value indicates the more significant data differences. The results obtained through the test are shown in Table IV, the KMO of this experimental data = 0.617> 0.6,P-Value = 0.001, so it is suitable for factor analysis.

Then, the scree plot was drawn according to the number of factors and the corresponding eigenvalues of each factor, as shown in Fig. 11; Table V shows the total variance explained for each component of the factor analysis of the heart sound collection vest. From Fig. 11 and Table V, it can be obtained that the eigenvalues of the first 2 factors are greater than 1, while the variance contribution of these 2 common factors accounts for 75.371%, indicating that the extraction of these 2 common factors can explain the majority of the information of the original data. From Fig. 11 and Table V, it can be obtained that the eigenvalues of the first 2 factors are greater than 1, while the variance contribution of these 2 common factors accounts for 75.371%, indicating that the extraction of these 2 common factors can explain the majority of the information of the original data. Therefore, the number of common factors was determined as 2 to perform the required factor extraction.

TABLE IV. THE KMO AND BARLETT'S TEST OF THE FACTOR ANALYSIS OF THE WEARABLE DEVICES

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		0.617
Bartlett's Test of Sphericity	Approx. Chi-Square	41.853
	Sig.(P-Value)	0.001

TABLE V. TOTAL VARIANCE EXPLAINED OF EACH COMPONENT OF THE FACTOR ANALYSIS OF THE HEART SOUND COLLECTION VEST

	Initial Eigenvalues			**Rotation Sums of Square Loadings**		
Component	***Total***	***of Variance %***	***Cumulative %***	***Total***	***of Variance %***	***Cumulative %***
1	3,751	53.578	53.578	3.499	49.983	49.983
2	1.525	21.783	75.361	1.777	25.388	75.371
3	0.691	9.870	85.231			
4	0.513	7.328	92.559			
5	0.315	4.499	97.058			
6	0.165	2.357	99.415			
7	0.041	0.586	100.000			

TABLE VI. THE ROTATED COMPONENT MATRIX OF THE FACTOR ANALYSIS

	Factor1	Factor2
Heavy - Light	0.932	0.151
Unattractive - Nice	0.888	0.418
Strong - Week	0.811	0.011
Tight - Loose	0.795	0.271
Hard - Soft	0.733	-0.222
Inconvenient - Conveniente	0.053	0.864
Dislike - Like	0.102	0.843

Finally, the results shown in Table VI were obtained after rotating the factor loading matrix according to the method of great variance. Through Table VI, it can be found that common factor 1 has larger loadings on factors 1-5 (light pressure; weak skin irritation; lightweight; soft; good-looking), and common factor 2 has larger loadings on factors 6 and 7(easy to put on and take off, preferring long-term use), indicating that these 7 variables can be reduced to 2 male factors: material factor and garment design factor.

Compared with previous studies [17-20], this research designed and developed a complete wearable device instead of a single heart sound collector, and explored the wearing experience of the heart sound collection device, and the experimental participants gave a positive evaluation, all of whom found that the device is suitable for daily wear. In consistent with them the denoised heart sounds were clear, and additionally heart sound detection was added, using a convolutional neural network system to detect the pairs of collected heart sounds and obtain better results.

V. CONCLUSION

In this paper, a comfortable wearable heart sound acquisition device is presented. First, a urethane resin holder was fabricated according to the size and characteristics of the microphone. Then, suitable materials were selected and vests were made according to the physical characteristics of men and women respectively. Then, the microphone wrapped with holder was fixed on the corresponding position of the vest with reference to the heart sound auscultation position. Subsequently, 11 healthy young people (6 males and 5 females) were subjected to heart sound collection, and the collected heart sounds were input into the constructed CNN for testing to evaluate the performance of the device, and the highest accuracy rate of 85.39% for a single male, the highest accuracy rate of 91.59% for a single female and an average accuracy rate of 71.3% were obtained. Finally, the evaluation of the device by the experimental participants was analyzed and 2 common factors were extracted: material factor and garment design factor, indicating that these two factors can be focused on for future updates of the device. This study demonstrates that the wearable heart sound collection device is effective in heart sound collection and has been well evaluated in terms of product design.

VI. FUTURE WORK

The wearable heart sound collection device developed in this study can be used well for heart sound collection, but there are still many shortcomings. First, the design of the zipper in the middle of the chest causes a lot of noise during heartbeat collection, and the position of the zipper needs to be reconsidered and adjusted; second, the position of the microphone cannot be adjusted according to the size of each person and needs to be redesigned; third, a more skin-friendly material could be selected; and finally, the data transmission of the device should be updated to wireless transmission. It is hoped that in the future, a real-time heartbeat detection device can be made that can be worn daily for a long time.

ACKNOWLEDGMENT

This research was supported by JSPS KAKENHI Grant Number 19H04154. We would also like to thank the China Scholarship Council (CSC) for supporting the research of PhD student Huai Ximing, and to teachers and experiment participants who assisted in completing this research.

***Abstract*—The article is devoted to solving the scientific problem of accumulating and systematizing models and machine learning algorithms by developing a repository of deep neural network models for analyzing and predicting of spatial processes in order to support the process of making managerial decisions in the field of ensuring conditions for sustainable development of regions. The issues of architecture development and software implementation of a repository of deep neural network models for spatial data analysis are considered, based on a new ontological model, which makes it possible to systematize models in terms of their application for solving design problems. An ontological model of a deep neural network repository for spatial data analysis is decomposed into the domain of deep machine learning models, problems being solved and data. Special attention is paid to the problems of storing data in the repository and the development of a subsystem for visualizing neural networks using a graph model. The authors have shown that for organizing a repository of deep neural network models, it is advisable to use a scientifically grounded set of database management systems integrated into a multi-model storage, characterizing the domains of using relational and NoSQL storages.**

Keywords—Repository; deep learning; artificial neural network; spatial data; visual programming

I. Introduction

A significant role in solving the problem of strengthening the connectivity of territories of countries and regions is played by the introduction of effective digital infrastructures of spatial data (SDI), aimed at operational diagnostics of natural-social-production systems (NSPS) and high-precision forecasting of the development of natural processes and phenomena [1]. The core of systems of this class is represented by methods and algorithms for machine analysis of spatial data, which allow solving a whole range of applied problems – anomaly detection, data classification, data fusion. The subject of analysis can be space imagery data, aerial photography, information arrays about natural, social and economic objects with a distributed geospatial organization [2]. The areas of application of the results of the analysis in the national economy are extremely wide - from increasing the efficiency of agriculture to assessing the consequences of natural processes [3, 4].

SDI as a system can be decomposed into subsystems for storing, analyzing and distributing geospatial data. The development of the federal spatial data infrastructure is necessary in order to effectively solve the problem of remote monitoring of mobile objects and geographically distributed resources in order to ensure information connectivity of countries and create conditions for sustainable development of the country [5]. At present, the functioning of spatial data infrastructures should be based on and application of new effective methods, approaches and algorithms for the analysis of spatio-temporal data, which can function both on the basis of classical hard and soft computations based on the complex application of fuzzy logic, neural network models, evolutionary modeling [6].

With the development of the scientific and engineering basis and computing power, the direction of deep machine learning has recently been strengthened, based on the systematic use of many levels of nonlinear information processing for the extraction and transformation of hierarchical features, analysis and classification of patterns. Despite the growing interest in the topic of deep machine learning, this problem area requires serious study in the direction of strengthening the project orientation of the process of using deep neural network models for analyzing large spatial data [7]. This statement is based on the assumption that the processes of designing complex neural networks, determining their hyperparameters, the format of input and output data, and integrating training data arrays should be determined by the features of real problems to be solved [8]. In other words, the use of deep neural network models for solving practical design problems can be effective if the conditions for the consolidation of accumulated knowledge are met, heuristics and rules are collected into a single system, for interaction with which convenient graphical and application program interfaces are organized. Quality documentation on the use and flexible customization of pretrained models is of key importance. The indicated provisions determine the feasibility of forming a repository of deep neural network models in the digital SDI system, which provides system access to the storage of neural network models, as well as tools for choosing the optimal solution in a specific problem area and disclosing the features of its use.

The purpose of this article is to discuss problematic issues devoted to solving the problem of machine learning models systematizing by developing a repository of deep neural network models for analyzing and predicting of spatial processes. The matters of architecture development and software implementation of deep neural network models repository are considered.

II. Related Works

The task of designing and training effective deep neural network models for analyzing large arrays of spatial data encounters many problematic moments that require finding solutions. This article is devoted to solving the scientific problem of accumulating and systematizing models and machine learning algorithms by developing a repository of deep neural network models for analyzing and predicting the development of spatial processes in order to support the process of making managerial decisions in the field of ensuring conditions for sustainable development of regions. The purpose of the study is to provide support for the process of making management decisions in the field of forming conditions for sustainable development of regions through the development and development of a repository of deep neural network models for the analysis of spatial data [9]. The solution to the problem of forming the architecture and software implementation of a repository of deep neural network models should be based on a new ontological model that defines a formalized description of the topologies of deep models, tasks to be solved, a set of analyzed data, learning algorithms, as well as relationships between these entities [10].

The development of information systems based on machine learning algorithms is very different from the development of traditional software applications based on specifications and repeatedly tested algorithms. In addition, the process of training machine learning models can be expensive and computationally intensive. This fact determines the feasibility of creating a tool that provides the ability to reuse pre-trained machine learning models for the development of applied applications. The use of pretrained machine learning models deployed as web services is one of the top technology trends. Popular frameworks such as Tensorflow [11] and PyTorch [12] provide high-level API support for using machine learning model components.

Since deploying and maintaining machine learning models is still a non-trivial task that requires in-depth knowledge of machine learning and systems administration, organizations are building repositories of machine learning models in order to simplify the use of models within their business processes. Other companies form repositories that can be accessed by third parties. The Wolfram Neural Net Repository (launched in June 2018) [13] and the AWS marketplace (launched in November 2018) [14] are useful examples. Each model repository has a different structure and uses different heuristics to group the models. For example, AWS labels each model using a set of criteria (including the analyzed data), and each model can meet several criteria. Machine learning model repositories promise to close the operational gap between data scientists and software developers. In the field of spatial data analysis, the task of developing a repository of neural network models has its own specifics.

III. Methodology and Methods of Research

Analysis of the strengths and weaknesses of the currently existing repositories of deep neural network models of general purpose (AWS Marketplace, Open Neural Network Exchange, Wolfram Neural Net Repository and others) [15] made it possible to form a list of specific problems, the solution of which will ensure the creation of an effective system suitable for solving specific practical oriented tasks in the field of spatial data analysis.

1) Designing an ontological model for the storage of deep neural networks.

2) Development of a storage scheme for models of deep machine analysis of spatial data in the form of a meta-language.

3) Implementation of the function of converting repository models into representations used by modern software systems for machine learning.

4) Development of graphical web interfaces for a repository of deep neural network models with navigation functions.

5) Creation of a user authentication subsystem in order to differentiate access rights to deep neural network models.

6) Development of interfaces for obtaining structured information about specific neural network models.

7) Development of a subsystem for visualizing deep machine learning models in the form of graph-schemes within the framework of adaptive web interfaces.

8) Development of an application programming interface based on the architectural style of REST, to provide a unified program exchange.

9) Updating the repository of deep neural network models in the process of solving practice-oriented tasks in the field of ensuring conditions for sustainable development of Russian regions.

10) Development of a recommendation system for the selection and configuration of deep neural network models.

Work on the design, development and implementation of a repository of deep neural network models involves obtaining results characterized by scientific novelty. So, the ontological model of the storage of deep neural networks should be distinguished by the achievement of a detailed and comprehensive systematization of deep machine learning models used to analyze large spatial data by classes of design problems to be solved, types of analyzed data, architecture, objective (numerical) and subjective (expert) performance metrics [16]. On the basis of the ontological model, a conceptual storage scheme for deep machine analysis models can be created in the form of a meta-language, which allows them to be converted into representations used by modern machine learning frameworks [17].

Graphical web interfaces of the repository of deep neural network models should be justified from the standpoint of system analysis of user experience, allowing the selection of a relevant machine learning model for solving specific problems of spatial data analysis, obtaining systematized information about the required deep neural network model. It is also supposed to justify and deploy a subsystem for visualizing deep learning models through web interfaces in the form of a graph diagram, with the function of online editing of the model topology within the capabilities of a thin web client, as well as organizing an application programming interface based on REST architectural style to provide unified programmatic interaction with the repository. Of particular importance is the design and development of a new recommender system for the selection and configuration of deep neural network models, which allows for a relevant search for an effective architectural solution and its fine tuning for solving design problems through a graphical web interface of the neural network repository [18]. The repository of deep neural network models acquires practical value if the database is updated with new models for the analysis of spatial data, including remote sensing data. Each deep neural network should be tested on test sites in order to determine estimates of its effectiveness in solving practical problems: classification of remote sensing data, forecasting the development of natural processes.

IV. Results and Discussion

A. Development of an Ontological Model of a Repository

The development of a deep neural network repository should be based on an ontology that provides a formalized description of entities (ANN topologies, learning processes and accuracy assessment), as well as the relationships between them [19]. The relevance of this provision is determined by the hypothesis that the process of using deep learning to solve design problems can be supported only if the acquired knowledge, heuristics and rules are collected in a system for which convenient means of interaction are organized.

An ontological model of a deep neural network repository for spatial data analysis can be decomposed into domains of deep machine learning models, tasks to be solved, and data (Fig. 1). This allows you to give a comprehensive definition of the formalized area of knowledge: each stored model must be compared with a set of specific tasks and data sets (tensor, raster, vector, attributive). The domain of machine learning models is defined by concepts and relationships that describe various topologies (branching and chain structures of layers of various types (including fully connected, convolutional, recurrent) with various activation and regularization functions), as well as learning methods and algorithms.

The deep model is characterized by the format of the data received for analysis and the type of the output signal, the loss function, the initialization algorithm, the learning strategy (with a teacher, without a teacher, with partial involvement of a teacher, with reinforcement). Each deep model is associated with a meta description containing its category, characteristics of the project-oriented tasks to be solved, and guidelines for applied use. The design solution must store pre-trained copies, ready for solving design problems after fine-tuning. The software implementation of the repository was carried out on the basis of the artifacts of the object-oriented design stage, including the determination of the use cases of the system, the construction of structural and behavioral UML diagrams. The development of graphical interfaces of the repository must be carried out using UI / UX design methodologies using a software stack of web technologies, which will allow you to use the repository from anywhere in the world connected to the Internet. The API for interacting with external systems is based on the REST architectural style.

Thus, the process of forming a repository of deep neural networks in a digital SDI system should be based on a project-oriented approach, based on which each stored deep ANN should be compared with the range of design tasks within which it can be used.

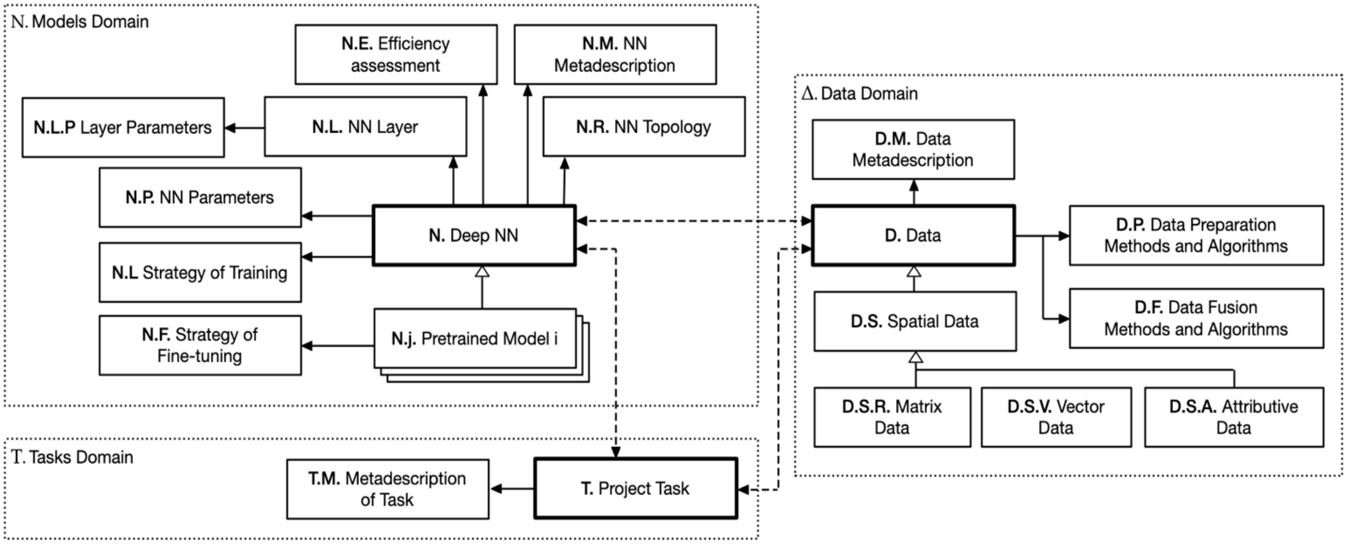

Fig. 1. Ontological Model of the Repository.

B. Designing the Storage Subsystem of Repository

To organize a data warehouse of a repository of neural networks, it is advisable to use a comprehensive science-based set of database management systems (DBMS). So, in relational storages, the organization of the data integration process is based on entities and relationships established between them. The highly organized structure and flexibility makes relational storage powerful and adaptable to different types of data domains, tasks, and models. To store spatial data, it is advisable to use a relational DBMS with support for spatial operations: PostgreSQL MySQL. Alternative advantages to the process of integrating spatial data can be provided by NoSQL storages, which should be classified into the following categories: a) resident databases - Redis (preferred for the development of data caching systems, buffers of high-speed exchange with the repository through software interfaces); b) document databases - MongoDB, RethinkDB (relevant for systematization of semi-structured data analyzed by neural networks, such as information for monitoring spatial processes, storage and registration of events); c) graph databases - Neo4j, JanusGraph (useful for storing information about the structure of neural network models); d) columnar databases - ClickHouse, Cassandra (represent an uncontested solution for organizing interactive analytical data processing modules (OLAP components) in a neural network repository); e) time series databases - InfluxDB, TimescaleDB (implemented to collect and manage spatial data that change over time, including indicators of the development of natural processes and transactions of the Internet of Things). Thus, for organizing a repository of deep neural network models, it is advisable to use a scientifically grounded set of database management systems integrated into a multi-model storage.

C. Development of Interfaces for Interacting with the Repository

The software implementation of the repository was carried out on the basis of artifacts of the object-oriented design stage, including the definition of the use cases of the system, the construction of structural and behavioral UML diagrams with the optimization of the object-oriented metrics of the system. The development of graphical interfaces of the repository was carried out using UI / UX design methodologies using a software stack of web technologies, which will allow you to use the repository from anywhere in the world connected to the Internet. The API is implemented using the REST architectural style. The graphical web interfaces of the deep neural network model repository should be equipped with navigation functions that allow the selection of a relevant machine learning model for solving specific problems of spatial data analysis from any device connected to the Internet (via a web browser). Subsystems for user authentication in the repository system have the task of differentiating the rights to select, use and edit models.

The developed web interfaces solve the problem of providing information about a specific neural network model (including a systematized description, architecture class, format of analyzed and output data, information about topology, subjective and objective performance indicators, recommendations for fine-tuning the model, examples of practice-oriented use). To improve the convenience of interacting with the repository, a subsystem for dynamic visualization of learning models was developed based on adaptive web interfaces in the form of dynamically aligned graphs, with an interactive ability to directly edit the architecture and topology of the neural network model through a thin web client (web browser) (Fig. 2).

Fig. 2. Graphical Interfaces for Editing a Deep Neural Network Model.

In the field of neural networks, there are a huge number of libraries, modules and patterns that can be implemented, combined and used for a wide range of tasks. For a visual display of the developed blocks with the aim of their effective use, you can turn to the visual design paradigm. Visual programming is the process of graphically representing a program using a standard set of graphical elements. With visual development, the number of forced control errors in the program is significantly reduced, therefore, the quality of the result obtained is increased.

When developing visual programming languages, drawing of graphs is used as the main approach, that is, in the form of a set of vertices (nodes) connected by arcs (edges). Unlike the textual form of notation, in which objects (symbols and words) form a sequence, and each object is associated only with the left and right "neighbors", the graph form allows you to visually depict more complex relationships, since in it each object can be connected to several others objects. In this sense, the text form is one-dimensional, while the graph form is two-dimensional. The ability to vary the geometric dimensions, shape and color of vertices, the appearance and thickness of arcs, change the relative position of the vertices without changing the topology of the graph significantly increases the expressive capabilities of the graph form of the program algorithm.

The creation of a visual (figurative) style of software development is the main motive for the development of graph-symbolic programming (GSP) technology. GSP technology is a technology for designing and coding algorithms and models based on a graphical way of representing programs, with the goal of fully or partially automating the design, coding and testing of software. This programming technology adheres to two fundamental principles: a) visual, graphical form of presentation of program algorithms and other components of their specifications; b) the principle of structured procedural programming. The implementation of this concept is excellent for solving the problem of visual programming of neural networks. Visual programming increases the clarity of the presented codes, significantly reduces the number of errors made at the design and coding stage of programs, and thereby speeds up the development process and increases the reliability of codes of developed programs. Together with the use of the block approach, visual programming methods will not only speed up development due to simple graphical interchangeability of logical blocks, but also provide simple portability of such programs. An application programming interface (API) based on the REST architectural pattern provides a unified interaction with the system for programmatic data exchange, including deep model export, editing, structured data retrieval, and other use cases.

The main directions for the further use of the expected results:

1) Implementation of intelligent systems for forecasting the development of natural and man-made emergency processes based on new technologies of integration, intellectual analysis and dissemination of large geospatial data into the activities of industrial enterprises and executive authorities of the region.

2) Provision of services for the use of a repository of deep neural network models according to the SaaS (Software as a Service) model with the possibility of flexible configuration of the provided solution.

3) Design, development and implementation of geoportal solutions aimed at creating information support for sustainable development of ecological, socio-economic systems of regions, effectively modified for specific corporate customers on the basis of a project-oriented approach. Development and development of socially-oriented geoportal solutions that ensure the effective dissemination of spatial data about nature, economy, social life, history and culture of the regions of the world.

4) Development and implementation of practice-oriented educational programs in the field of sustainable development of regional and global ecological-socio-economic systems with annual bilateral internships and practices to form competencies in the field of information support for sustainable development of world regions and global ecological-socio-economic systems.

The repository of neural networks gains practical value provided that the deep model storage is constantly updated. In the course of further work on the project under a grant from the President of the Russian Federation, it is planned to create and test new models of deep machine analysis, which will be tested in solving specific scientific and practical problems in the field of analyzing the state of natural geosystems, predicting the development and assessing the consequences of emergency situations.

V. Conclusions

The conducted research allows us to determine the reference points for the design, development and implementation of a repository of deep neural network models:

1) Ontological model of the repository, which determines the principles of systematization of deep models for the analysis of spatial data according to the classes of problems to be solved, the nature and dimension of the analyzed data, architecture and topology, properties of efficiency.

2) A formalized storage scheme for deep machine analysis models of spatial data in the form of a meta-language that allows them to be converted into representations used by modern machine learning software systems (Caffe, Torch, MXNet, TensorFlow, Keras).

3) Adaptive graphical web interfaces of the repository with navigation functions that allow you to select the relevant machine learning model for solving specific problems of spatial data analysis.

4) Subsystem for user authentication in the repository in order to restrict the rights to read, use and edit neural network models.

5) Adaptive web interfaces for obtaining systematized information about the required deep neural network model, including a systematized description, objective and subjective performance indicators, type of architecture and topological scheme (branching and chain structures of layers of various types: fully connected, convolutional, recurrent), practical recommendations for flexible setting hyper-parameters of the model, examples of applied use.

6) Subsystem for visualization of the neural network model of deep learning in the form of a graph diagram, with the possibility of interactive online editing of the topology and architecture of the model through a web browser, a thin client.

7) Recommended web system for the selection and configuration of deep neural network models, which allows to provide relevant search and fine-tuning for solving specific design problems in the field of spatial data analysis.

8) An application programming interface based on the REST architectural style, which allows for a unified interaction for programmatic data exchange with the repository (including import and export of deep models, obtaining information about them).

9) Database of deep neural network models repository, which includes pretrained models based on convolutional and recurrent layers, regularization, normalization and subdescritization modules with the possibility of their direct use for solving applied problems or further fine tuning.

The implementation of the project will make it possible to form a platform solution for solving urgent scientific problems of consolidation, storage, selection and effective use of deep models for solving project-oriented problems in the field of analyzing large arrays of spatial data. Integration of neural network models into the repository will allow starting the formation of a bank of intelligent algorithms designed to solve specific problems in the field of spatial data analysis to ensure sustainable development of regions, but also to solve the problem of interactive search for an effective model by forming a system of recommendations and developing expert tools that optimize the choice of algorithms.

***Abstract*—Indoor Positioning System (IPS) in generally perform as a network of devices that always located the objects or people inside a building wirelessly. An IPS has direction relies nearby anchors and also can be entirely local to your smartphone. With the rapid growth and sharp increase in Indoor Positioning System (IPS) demand in the world, there are a lot of researchers trying to invent new algorithm to develop IPS. This paper proposed the Bluetooth-Base Indoor Positioning Algorithm. The RF characteristics such as RSSI and WLAN RSSI fingerprinting system normally formed by two phases, fist is offline phase and second is online phase. Fingerprinting system handling both off-line and online data and estimate the user's location. Our algorithm design is a collection of Weighted K-Nearest Neighbors (WKNN) and Filtering algorithms by KALMAN Filter. Finally, to avoid the problems of IPS and get a better accurate we proposed two algorithms: Weighted K-Nearest Neighbors Particle Filter (WKNNPF) and Weighted K-Nearest Neighbors Extended Kalman Filter (WKNNEKF) compare to KNN and WKNN result. After comparing we found that the result of WKNNPF and WKNNEKF is better result than KNN and WKNN. The Probability in 3M of WKNN is about 79%, WKNNEKF is about 89%, and WKNNPF is about 95.1%. Among one of the proposed algorithms WKNNPF is better than WKNNEKF on accuracy 1.7-2 meters with 42.2m/s response time.**

I. Introduction

In present, indoor positioning system became more interested and more advantages for the people in the world. Many applications that we have seen some papers introduced in field of m-commerce that based on the principle of the well-estimated location of the various customer as well as in wireless network sector. For example here, it is talking about advertising in large stores or guides in museums which using modern portable devices is possible, in case if we estimate the exact location of a mobile terminal in every single time. Moreover, an automated delivery developed procedure, which is the method based on the user location is also necessary in term of to provide quality service in the area of wireless network, especially in condition of overweight shipments [1].

Bluetooth certification which is developed and manufacturing by the Special Interest Group (SIG) has widely point the technology that suitable for future use in the home or any indoor environment [2][3]. Hence, the totally proposed ideas of this paper was notice about the challenge with all of the issues faced in location estimation plus with the general evaluation criteria which focus on a Bluetooth-based indoor positioning system as well. Although, we can realized that the Location estimation take place in a mobile terminal without any changes of the values in the geometry network zone. The system developed as usual and it's based on a well-known and well-publicized of the triangular method by using the theoretical of received signal strength of the surrounding environment of the Bluetooth access point we have.

Anyways, to obtain precise position estimation, we must determine the dependence between distance and the received signal strength by specific condition carefully. Especially in indoor areas, some relevant boundary conditions, like make use of equations reflection and the wall drying for free as well as propagation impossible. Then, the necessary distance is mainly focus and calculated as well as by an approximate estimate of the received signal strength indicator (RSSI) in simple ways [4][5]. As we known that, the Bluetooth devices of retrieving the actual received signal strength do not provide any interface as well as we want, so our research developed based on this positioning system focus on the point which using the RSSI values that provided as mentioned as in the standard technic to obtain a range estimate between the access point and the mobile terminal as well. Although, this research demonstrated the theory of mathematical system and introduced the mathematical approach by positioning system is based. Our steps start from the beginning with position estimating which mainly based on signal strength using the Least Square

[*] Corresponding Author

Estimation (LSE), and then we have converted the RSSI measurement to the distance. After that, the implementation results of the actual test are presented.

II. Related Work

A. The Position Estimation based on Signal Strength

In this part we proposed the related technic which is a part of achieving the result. As shown in below equation, a position estimation method based on signal strength by using LSE is introduced and explain in detail as well.

In the mobile network we assumed N≥2 as the number of a base station and the position of a base station k is defined

by: $\overrightarrow{p_k} = (x_k, y_k)^T, k \in 1..N.$

Hence, the distances $r_i(\vec{x}), r_j(\vec{x})$ between stations i, j and a point in the x-y zone, has given as well as by

$\vec{x} = (x, y)^T$:

$$\begin{cases} r_i(\vec{x}) = \sqrt{(x-x_i)^2 + (y-y_i)^2} \\ r_j(\overrightarrow{x}) = \sqrt{(x-x_j)^2 + (y-y_j)^2} \end{cases} \quad (1)$$

The solution of the system of equation (1) as shown in above section, it causes two possible intersections of the corresponding circles. So, to get a perfect solution to solve this problem, it's importantly to calculate and set the location of the mobile device which based on the distance between the terminal and at least three different base stations among them is included [6]-[9]. Other thing, the single distances also can be obtained as well as by measuring the functional correlation to the signal strength. If the value of the distance between both points, the base station N>2 and the mobile terminal is already known. Otherwise, the location estimate also can be effectively as well by calculated using the LSE method. In numerical operations, this method calculates that point correctly in the x-y field, where the position that provides the least squared sum of the distance to the boundary of all possible parts given by Equation (2) as describe as below.

$$\begin{cases} r_i = \sqrt{(x-x_i)^2 + (y-y_i)^2} \\ r_j = \sqrt{(x-x_j)^2 + (y-y_j)^2} \end{cases}, i, j \in 1..N \quad (2)$$

Boundaries are directly calculated from Equation (3)

$$r_i^2 - r_j^2 = (x-x_i)^2 + (y-y_i)^2 - (x-x_j)^2 - (y-y_i)^2 \quad (3)$$

The position estimation is defined by $\overrightarrow{m} = (\hat{x}, \hat{y})^T$.

$$H \cdot \overrightarrow{m} = C \quad (4)$$

With

$$H = \begin{bmatrix} h_{x(2,1)} & h_{y(2,1)} \\ h_{x(N,1)} & h_{y(N,1)} \\ h_{x(N,N-1)} & h_{y(N,N-1)} \end{bmatrix}_{\binom{N}{2}\times 2}, \overrightarrow{m} = \begin{bmatrix} \hat{x} \\ \hat{y} \end{bmatrix}, C = \begin{bmatrix} C_{2,1} \\ C_{N,1} \\ C_{N,N-1} \end{bmatrix}_{\binom{N}{2}\times 1}$$

And $\begin{cases} h_{x(i,j)} = 2(x_j - x_i) \\ h_{y(i,j)} = 2(y_j - y_i) \\ C_{i,j} = r_i^2 - r_j^2 + x_j^2 - x_i^2 + y_j^2 - y_i^2 \end{cases}$

Hence, below is the formula of location estimation of the terminal:

$$\overrightarrow{m}^T = (H^T H)^{-1} H^T C \quad (5)$$

B. The Approximation of RSSI Measurements

This section talked about the way of converting the signal strength measurement into distances between shape of a sender and receiver in the free fields. Below is the equation (6) [10]:

$$s(\vec{x}) = c(d(\vec{x}))^{-\alpha} \quad (6)$$

Variations of signal propagation in indoor areas normally caused by dimming and reflection are strongly considered in easy way as well as by equation (6). Because there is no line of reflection and attention, this happened because those holding Bluetooth device obtain signal propagation in the empty which not suitable for indoor area. Hence, according to reason above we chose to estimate the correlation between signal strength and distance by focusing on on the measurement to improve our estimation as well. Bluetooth specification at that moment didn't release the possibility to extract signal directly. Consequently, after go through reason above we are using the RSSI values set by the Bluetooth protocol to connect the communication between the sender and the receiver in the network as well as we have shown below [11]-[14]. The RSSI value role as important paly that it is giving the distance between the received signal strength and the optimal receiver power rating, called the gold receiver power status. The definition of a golden power receiver has explained and shown in Fig. 1 below.

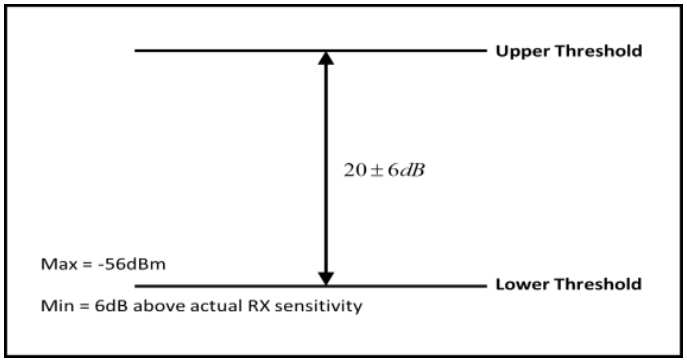

Fig. 1. Golden Receiver Power Rank of the RSSI.

Here, we explain the Fig. 1 above about the golden receiver power status about it working principle. It is determined by two levels which describe below [15][16]. First is the low level that noted by the 6dB to the actual the receiver and maximum of this value mentioned by -56dBm. Second is the high level is 20dB on the low one. It provided accuracy of the upper threshold and the noted with the value is about ±6dB. Hence, we can assume S assigned the received signal strength and the value of S is noted by:

$$S = RSSI + T_0, for RSSI > 0$$
$$S = RSSI - T_{u,} for RSSI < 0$$
$$T_0 = T_u + 20dB \qquad (7)$$

Where: T_0 : Upper Threshold

T_u : Lower Threshold

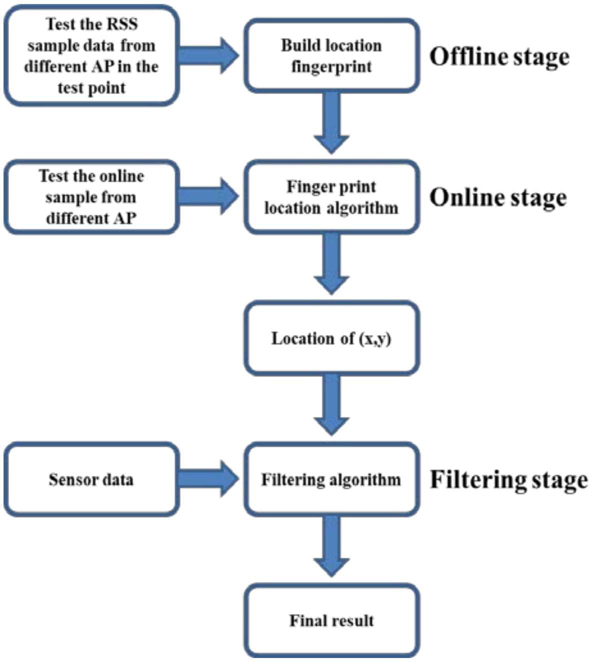
Normally, pursuant to the definition of a gold recipient rating determines the RSSI to distance conversion. Although, if the value of RSSI is within the range of the golden receiver defined by zero, it’s mean that, there is no special function can be estimated as well as we can [17]. Therefore, only measurements that provide result in a positive range of RSSI could be considered and granted by functional estimation. Then we can achieve the estimate result by the parameterization in suitable function we chose:

$$y = c \ln x + b,$$
$$y = c_0 + c_1 x + c_2 x^2$$
$$y = c_0 + c_1 x + c_2 x^2 + c_3 x^3 \qquad (8)$$

III. Methodology

Our research methodology used the Bluetooth positioning system model to provide a user interface as well as separated into three levels. The indoor area under consideration is covered by the x-y is the first stage of preparation phase, then RSSI function is covering to the environmental conditions which can estimated as well. Hence, the last part of our solution we used the location method to determine the mobile terminal location by dealing based on the RSSI estimation measurement. In this relation, we are mainly focus on the triangular method in term of mathematical calculations in above section by calculation RSSI values of three entry points. Below is the flowchart of the matching process which mentioned as Fig. 2, it is detail and overview of the operational analysis.

In addition to improve the fingerprint method (RSSI), our algorithm design is a collection of Weighted K-Nearest Neighbors (WKNN) and Filtering algorithms (KALMAN Filter). Other thing, to avoid the problems of IPS and get a better accurate we proposed two algorithms are WKNNEKF and WKNNPF.



Test the RSS sample data from different AP in the test point
Build location fingerprint
Offline stage
Test the online sample from different AP
Finger print location algorithm
Online stage
Location of (x,y)
Sensor data
Filtering algorithm
Filtering stage
Final result

Fig. 2. Flowchart of the Matching Process.

The access points have been assigned and share in a laboratory room of school of information and communication engineering, Guilin University of Electronic Technology. That room is a computer room with a size of 12 x 21m which is shown in Fig. 3.

In this experiment we have done carefully. We were recorded several times of the distances of the randomly selected sections to archive a good approximation function between the RSSI and the single access point as well as we can. The average results among of all measurements which belonging to a segment and access point may generate the RSSI reference value per segment. In our scenario, we can realize from Fig. 2 and 3 and we can explain that the RSSI values of all access points are best equipped with the polynomial function of the order 3. The positioning algorithm has been implemented in MATLAB.

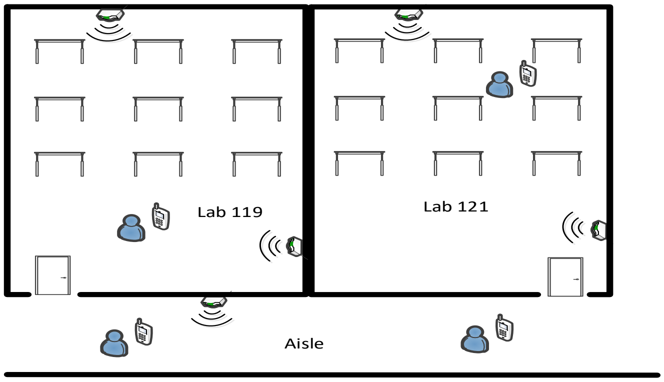


Fig. 3. Indoor Environments Experimental.

IV. Results and Analysis

According to the experiment methodology, we separated results with 3 different algorithms are WKNN Algorithm in Fig. 4, WKNNEKF Algorithm in Fig. 5, WKNNPF Algorithm in Fig. 6.

After we got the results in each algorithm of Fig. 4, 5, 6. We found that the accurate point of WKNN algorithm is bigger than WKNNEKF and WKNNPF algorithm, and the accurate point of WKNNEKF algorithm is smaller than WKNN and bigger than WKNNPF. And the last one is the accurate point of WKNNPF algorithm is smaller than WKNNEKF and much smaller than WKNN so far. Moreover, we have compared the cumulative probability of the positioning error to find the best performance of each algorithm in Fig. 7. Those algorithms mentioned in three difference colors. Red stand for WKNN algorithm, green stand for WKNNEKF algorithm and blue stand for WKNNPF.

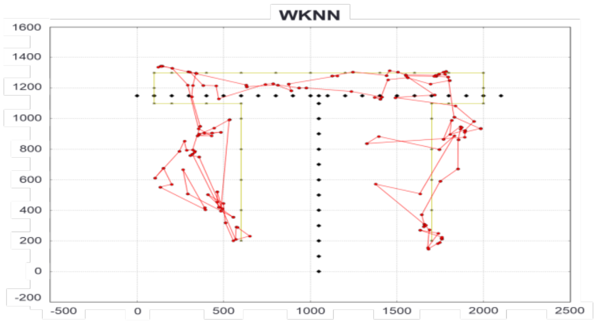

Fig. 4. WKNN Algorithm Result.

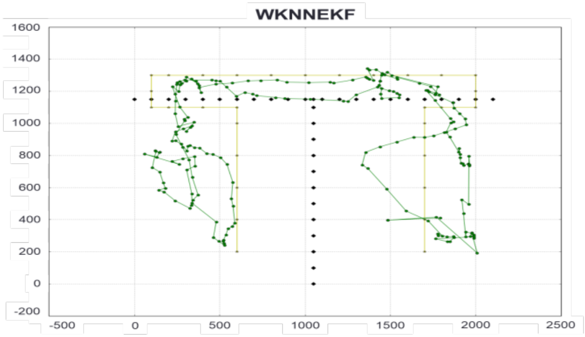

Fig. 5. WKNNEKF Algorithm Result.

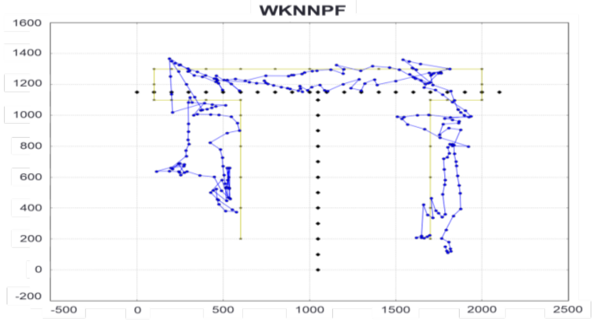

Fig. 6. WKNNPF Algorithm Result.

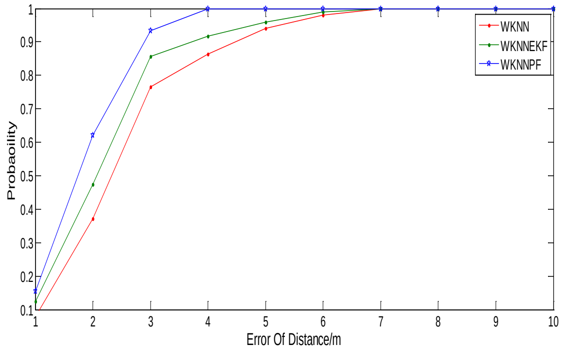

Fig. 7. Errored of Distance/m.

TABLE I. The Probability in 3M

Algorithm	*Mean derivation*	*Minimum derivation*	*Maximum derivation*	*The probability in 3M*
WKNN	3.2m	1.2m	3.8m	79.0%
WKNNEKF	2.5m	0.92m	3.0m	89.0%
WKNNPF	2.0m	0.22m	3.0m	95.1%

The result in Fig. 7 and Table I shows that the probability in 3M of WKNN is about 79.0%, the probability in 3M of WKNNEKF is about 89.0% which is better than WKNN about 10%, and the probability in 3M of WKNNPF is about 95.1% which is better than WKNN about 16.1% and WKNNEKF about 6.1%. It's mean that the proposed algorithm WKNNEKF is better than WKNN and the proposed algorithm WKNNPF is better than WKNNEKF. After we found that WKNNPF algorithm is the best algorithm among the proposed algorithm in this paper, we try to find the algorithm response time of WKNNPF algorithm performance. Then we found that WKNNPF response time is 42.2m/s as shown in Fig. 8 below.

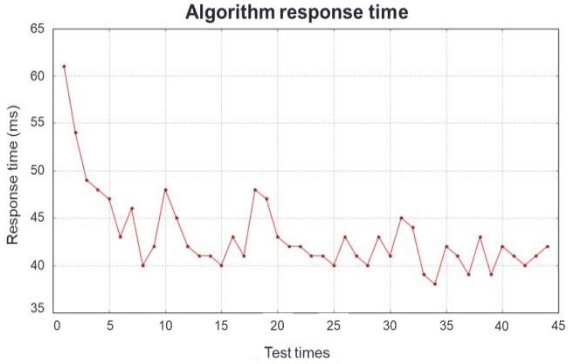

Fig. 8. WKNNPF Performance.

V. Conclusions

In this paper, we carefully experimented with both theory and practice to apply indoor location algorithms. As we all know, there are many previous documents describing IPS with different ways and solutions. Most of them focus on wireless sensors to develop their new algorithms. In a similar way, this paper proposes to study of the Bluetooth-based Indoor Positioning Algorithm. Based on RF characteristics such as RSSI and WLAN RSSI fingerprinting system normally consists of two phases, offline phase and online phase. Fingerprinting system handling both off-line and online data and estimate the user's location. Our algorithm design is a collection of Weighted K-Nearest Neighbors (WKNN) and Filtering algorithms by KALMAN Filter. Finally, to avoid the problems of IPS and get a better accurate we proposed two algorithms: WKNNPF and WKNNEKF which get the better result than KNN and WKNN, and one of the proposed algorithms WKNNPF is better than WKNNEKF on accuracy 1.7-2 meters with 42.2m/s response time.

Acknowledgment

First of all, I would like to thanks to supporter including resources and experiment place. This research can't complete without their support. This work was fully supported by three departments, first is school of information and Communication Engineering of Guilin University of Electronic Technology offered funds and place for experiment and second is the National Natural Science Foundation of China (Nos. 61562016, 61702129, 61772149, and 61320106008) provided software and technic, and third is Guangxi Key Laboratory of Intelligent Processing of Computer Images and Graphics (No. GIIP201703) offered funds and the ideas of algorithm.

Exploring Machine Learning Techniques for Coronary Heart Disease Prediction

Hisham Khdair[1], Naga M Dasari[2]
International Institute of Business and Information Technology,
Federation University Associate
Adelaide, Australia

***Abstract*—Coronary Heart Disease (CHD) is one of the leading causes of death nowadays. Prediction of the disease at an early stage is crucial for many health care providers to protect their patients and save lives and costly hospitalization resources. The use of machine learning in the prediction of serious disease events using routine medical records has been successful in recent years. In this paper, a comparative analysis of different machine learning techniques that can accurately predict the occurrence of CHD events from clinical data was performed. Four machine learning classifiers, namely Logistic Regression, Support Vector Machine (SVM), K- Nearest Neighbor (KNN), and Multi-Layer Perceptron (MLP) Neural Networks were identified and applied to a dataset of 462 medical instances and 9 features as well as the class feature from the South African Heart Disease data retrieved from the KEEL repository. The dataset consists of 302 records of healthy patients and 160 records of patients who suffer from CHD. In order to handle the imbalanced classification problem, the K-means algorithm along with Synthetic Minority Oversampling TEchnique (SMOTE) was used in this study. The empirical results of applying the four machine learning classifiers on the oversampled dataset have been very promising. The results reported using different evaluation metrics showed that SVM has achieved the highest overall prediction performance.**

Keywords*—*Coronary heart disease; machine learning; prediction; classification

I. Introduction

Heart disease refers to a wide range of conditions that affect the structure and function of the heart. CHD is one of the most common types of heart disease, and it is one of the leading causes of death around the world. CHD occurs when plaque builds up in the walls of the coronary arteries, it restricts blood flow to the heart muscle, and will eventually result in a heart attack. According to the Australian Institute of Health and Welfare (AIHW), CHD was Australia's leading cause of death in 2018, accounting for 17,500 deaths. This accounts for 11% of all deaths in Australia and 42% of all cardiovascular deaths [1].

Traditional risk factors for CHD are thought to be High-LDL cholesterol, low-HDL cholesterol, high blood pressure, diabetes mellitus, smoking, a family history of CHD, age, obesity, and an unhealthy lifestyle [2]. The estimated cost of CHD in 2015–16 in Australia was more than $2.2 billion. Private hospital services and public hospital admitted patient services accounted for a minimum cost of $813 million and $693 million, respectively. The burden on the Pharmaceutical Benefits Scheme (an Australian Government subsidy on medicine) for CHD was estimated to be around $218 million [1].

CHD can however be effectively managed with a change in lifestyle and adopting healthy habits, and hence save the high cost of medical treatment and hospitalization if early detected. With early detection of CHD, patients can have a range of treatments advised by doctors to reduce the risk of future heart problems and relieve or manage symptoms. In this context, electronic health records (EHRs, also called medical records (EMRs)) can be considered a useful resource of information to help medical practitioners in the detection or the prediction of CHD [3-6].

Advances in machine learning and artificial intelligence have motivated many scientists to use such technologies in the early detection of high-risk diseases such as heart diseases, diabetes, various types of cancer [7-9]. Machine learning applied to EHR can be a useful tool for predicting the CHD event with heart disease symptoms [10-12] as well as exploring the most significant clinical features and risk factors that may lead to heart attack and deaths. Clinicians and physicians can take advantage of machine learning for clinical feature ranking and unveil hidden and non-obvious correlations and relationships between patients' data. Several supervised machine learning classifiers were used for this purpose and have achieved success in this regard such as logistic regression, SVM, deep learning, KNN, decision tree [3, 13-15].

However, most of the machine learning models designed for the prediction of CHD have achieved modest accuracy [16], More recent models show some improvements but only in the prediction accuracy though [17, 18]. Moreover, the predicting variables of these models have limited interpretability [5, 12]. Even though scientists have identified a large number of predictors and indicators, there is still no consensus on such clinical features and their roles in affecting the occurrence of CHD [2, 19].

In this paper, we study a dataset of 462 medical records obtained from South African Heart Disease. The dataset is a quantitative sample of males in a heart-disease high-risk region of the Western Cape in South Africa-KEEL[20]. The objectives of this study are:

- To investigate machine learning techniques that achieve a high prediction performance in predicting CHD.
- To identify the most effective machine learning models that achieve the best prediction performance on the given dataset.
- And, to identify the best features that help in achieving

the best performance on the given dataset.

In this study, the machine learning classifiers that have been identified and utilized are Logistic Regression, SVM classifier, KNN, and MLP Neural Network. They were identified based on the literature as well as their performance on the given dataset and the suitability of the nature of the available data. The structure of the paper is as follows, we first discuss the related work in section 2, then we discuss the methodology in section 3, where we describe in detail the dataset, the exploratory data analysis, and the feature selection methods. The experimental framework is presented in section 4, results, discussion, and conclusion are discussed in sections 5 and 6 respectively.

II. Related Work

Several researchers have performed studies on routine clinical data (or EHR) obtained from primary health care centers or family practices to predict the occurrence of heart disease [3, 21-24, 46]. Electronic health records have been used or in combination with several machine learning algorithms to predict CHD [25, 26]. Machine learning algorithms have proved to be efficient techniques in predicting heart diseases [3, 18, 27, 47].

In a study performed on 378,256 instances of patient data obtained from UK family practices, the authors in [3] have used the machine learning algorithms logistic regression, random forest, gradient boosting machine, and neural networks. The authors have established that the algorithms have improved the prediction of heart disease, CHD. Improvements in accuracy according to AUC c-statistic are random forest +1.7%, logistic regression +3.2%, gradient boosting +3.3%, neural networks +3.6% when compared to baseline American Association of Cardiology (ACA) and American Heart Association method. In another study, the researchers in an experimental analysis [22] have applied several machine learning algorithms; Decision Tree, Naïve Bayes, K-nearest neighbors, SVM, Multi-Layer perceptron, radial basis function, and Single Conjunctive Rule Learner individually and in combination on the Cleveland dataset [28] which is available at University of California Irvine (UCI) machine learning repository. The authors have compared the algorithms using Precision, Recall, F-Measure, ROC, and accuracy. Support vector machine has provided the best results in the experiment with 84.15% accuracy and 0.897 F-measure. They have applied bagging, boosting and stacking methods to improve the results.

In recent work, the Cleveland and Statlog [29] datasets are further experimented with, by another set of researchers with impressive results [17]. Statlog dataset contains 270 samples with 150 absence of heart disease and 120 presence of it. Cleveland database contains 303 instances with 164 without heart disease and 139 positive cases. The algorithms used in this work were support vector machine, Logistic Regression, Naïve Bayes, deep neural networks, random forest, decision tree, and k-nearest neighbor. Their experiment results have shown that deep neural networks work better for Statlog database whereas SVM works better for the Cleveland database. However, the accuracy in both cases is very high, a fraction above 97%, which is signficantly high when compared to any other study. While the reported accuracy was very high at 97%, the other metrics such as precision, recall and specificity were not investigated which are important to measure the efficiency of a machine learning algorithm.

In experimenting with ensemble machine learning algorithms the authors in [27] have used 4 different datasets obtained from Cleveland Clinic Foundation (CCF), Hungarian Institute of Cardiology (HIC), Long Beach Medical Center (LBMC), and Switzerland University Hospital (SUH) to predict CHD. The datasets contain 303, 294, 200, and 123 instances, respectively. All the patient instances were formatted uniformly with 76 attributes each out of which only 29 were used due to missing values. Adaptive boosting algorithm has been used for training and prediction. The experimental results produced accuracy and F-score for the different datasets in the order CCF – 80.14, 0.76; HIC- 89.12, 0.83; LBMC-77.78, 0.87; and SUH-96.72, 0.98.

In an experiment on deep learning, Baccouche et al. [30] have worked on heart disease data consisting of 900 samples with 149 attributes each, out of which 16% are related CHD instances. The data was obtained from Medica Norte Hospital, a Mexican hospital in Mexico. The authors have proposed an ensemble neural network framework with Bidirectional Long-Short Term Memory (BiLSTM) or Bidirectional Gated Recurrent Unit (BiGRU) with a CNN model with an accuracy rate of 91%.

Working on the dataset we are working on, Gonsalves et al. [16] performed experimental analysis using Decision Tree, Naïve Bayes, and support vector machine algorithms on WEKA tool. The accuracies obtained for all the three algorithms are above 70% with Naïve Bayes showing the highest with 71.5%. They have attributed the low accuracy to the small size of the dataset and the class imbalance problem in the dataset.

Based on the literature it is noticed that machine learning techniques such SVM, KNN, MLP Neural Networks, decision tree and boosting algorithms are widely used for predicting coronoary heart disease.

III. Methodology

We present the dataset we used for the experiment, exploratory data analysis, and feature selection methods used in this section.

A. Dataset

The dataset for this study has been retrieved from South African Heart Disease [20], which is a subset of a wider dataset. It has a total of 462 medical observations (instances) and 10 features, 9 as independent clinical features, and 1 is the target variable, a labeled binary class as 0 or 1, i.e., CHD event has been detected for the medical observations as positive or negative. The data is for a group of men from a high-risk area for heart disease in South Africa.

Each high-risk patient was monitored in the dataset and the features retrieved were as follows: systolic blood pressure (Sbp), cumulative tobacco in kg (Tobacco), bad cholesterol also known as low-density lipoprotein cholesterol (Ldl), adiposity, family history of heart disease (Famhist), type-A behavior (TypeA), Obesity, current alcohol consumption (Alcohol),

TABLE I. Description of Features in the Dataset

Feature	Explanation	Type and Range	Null Values
Systolic Blood Pressure	Blood pressure measure against the artery walls as the heart beats	Numerical [101, 218]	no
Tobacco	Accumulative tobacco in the body in (kg)	Numerical [0.0, 31.2]	no
LDL Choles-terol	low-density lipoprotein, also called bad cholesterol	Numerical [0.98, 15.33]	no
Adiposity	Adiposity is a measure of percentage of body fat	Numerical [6.74, 42.49]	no
Family History	Family history of heart disease	Binary [0, 1]	no
Type A Behavior	Type A behavior and personality	Numerical [13, 78]	no
Obesity	Weight-to-height ration measure (body mass index, bmi)	Numerical [0.0, 147.19]	no
Alcohol	Current alcohol consumption	Numerical [15, 64]	no
Age	Age of the patient	Numerical [15, 64]	no
CHD Event target	If Coronary heart disease was detected	Binary 0, 1	no

age at onset (Age), and coronary heart disease (Chd) (yes=1 or no=0).

B. Data pre-processing

The original dataset was in .dat format, we have converted it to .csv, and we edited the name of the columns to be more expressive. We have encoded the existing categorical text values in the original dataset into numerical values to be able to be fitted into machine learning models. The description of the features is shown in Table I.

C. Exploratory Data Analysis

The statistical quantitative characteristics of the dataset for numerical features are described in Table II. It can be noticed that the measurements for LDL Cholesterol, Obesity, and also Type A Behavior has slight differences in the mean value for patients with positive CHD event and negative event. The visualization of the counts of observations of the Family History binary class with respect to the negative CHD events and positive CHD events, as well as frequency of the target class CHD Event in the dataset, are shown in Fig. 1 and Fig.2 respectively. Out of 302 subjects without heart disease, 206 of them do not have CHD in the family history whereas 96 have the family history. For positive cases, 64 of them do not have CHD in the family history and 96 have CHD in the family history.

Fig. 3 presents the distribution of each feature's data based on CHD events with the minimum value, first quartile (Q1), median, third quartile (Q3), and the maximum value. The classes in many features seem overlapping, and several features record many outliers in the dataset. The distribution of the data is also skewed.

TABLE II. Statistical Characteristics of the Dataset

Feature	Full Sample		Full Sample		Full Sample	
	mean	std	mean	std	mean	std
Systolic Blood Pressure	138.33	20.5	143.74	23.68	135.46	17.98
Tobacco	3.64	4.59	5.52	5.57	2.63	3.61
LDL Choles-terol	4.74	2.07	5.49*	2.23	4.34*	1.87
Adiposity	25.41	9.82	54.49*	10.25	52.37*	9.52
Type A Behavior	53.1	9.82	54.49*	10.25	52.37*	9.52
Obesity	26.04	4.21	26.62*	4.39	25.74*	4.09
Alcohol	17.04	24.48	19.15	26.18	15.93	23.5
Age	42.82	14.61	50.29	10.65	38.85	14.88

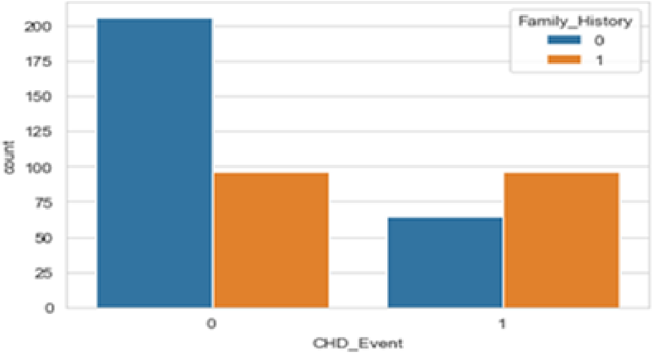

Fig. 1. Family History vs CHD_Event.

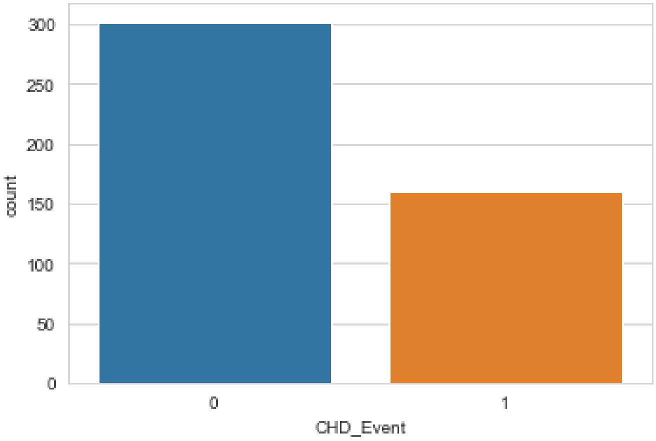

Fig. 2. Frequency of Positive and Negative CHD Events in the Dataset.

D. Feature Selection

The dataset includes many of the widely known risk factors or features that cause CHD, but we aim to rank which features are the most relevant to the target in predicting CHD and which features are the least relevant. This allows it to be further analyzed and interpreted by experts in the domain and could be used as the basis for gathering more or different data.

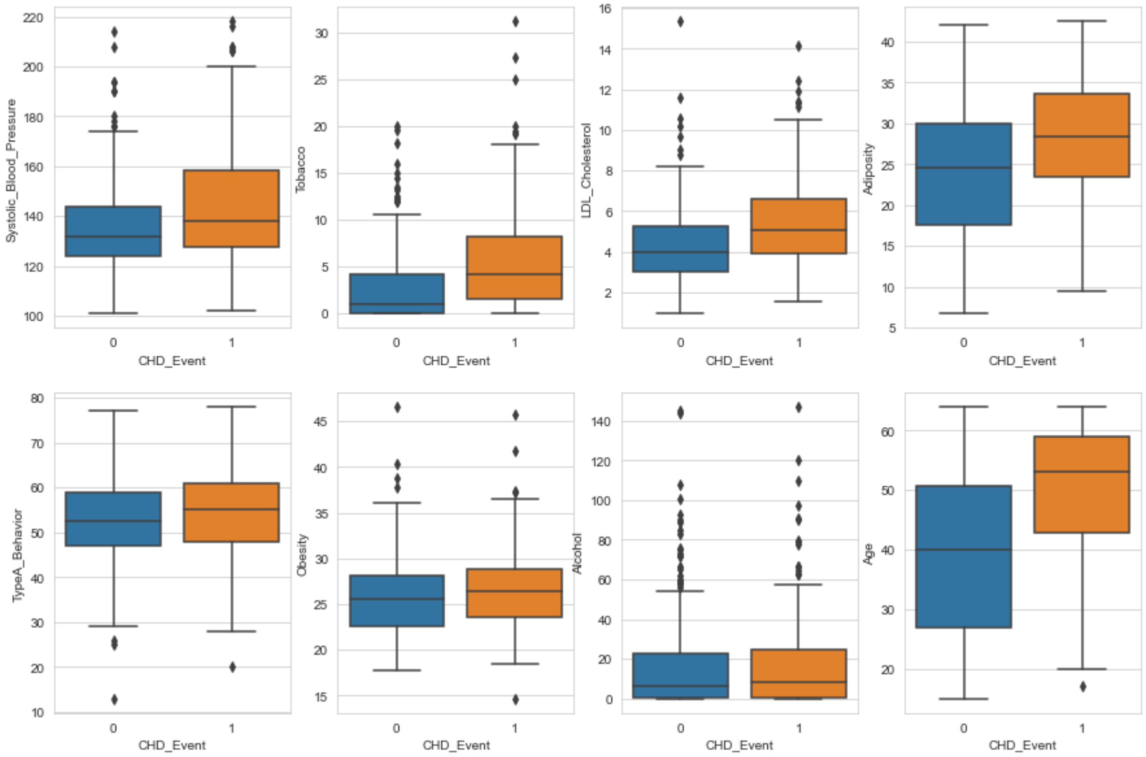

Fig. 3. Boxplot Representing the Distribution of Data Features with respect to CHD_Event.

1) ANOVA method: ANOVA stands for änalysis of variance änd it is a parametric statistical hypothesis test that determines whether the means of two or more samples of data (usually three or more) come from the same distribution or not [31]. An F-statistic, also known as an F-test, is a class of statistical tests that use a statistical test like ANOVA to measure the ratio between variance values. An ANOVA f-test is a type of F-statistic that uses the ANOVA method [32].

We used an implementation of the ANOVA f-test function from the scikit-learn machine learning library, which suits our classification problem task. Table III shows the scores of ANOVA f-test ranking of the features, i.e., the scores calculated for each input feature and the target variable (CHD Event) in descending order, the higher the score, the more important the feature.

2) Feature Importance: Statistical methods calculate the score of the feature ranking with relation to the features and the target variable, however, the importance and ranking of the features might be different when working together to predict the target variable. However, using machine learning methods for feature ranking provides insight into prediction models and which features are the most important and least important to the models when making a prediction.

Another method we used to compute a set of feature importance scores for our dataset is the permutation feature importance. The concept of Permutation Feature Importance was first introduced by Breiman [33] and applied to a random forest model. Permutation Feature Importance works by randomly changing the values of each feature column, one column at a time. It then evaluates the model.

TABLE III. ANOVA F-TEST RANKING

Feature	Score
Age	74.330
Tobacco	45.400
Family History	36.861
LDL Cholesteroal	34.197
Adiposity	31.756
Systolic Blood Pressure	17.674
Type A Behavior	4.948
Obesity	4.655
Alcohol	1.806

We have used the permutation_importance function from scikit-learn library with Random Forest as the fit model. We chose accuracy as the standard metric to measure performance in this context because this a classification problem. The ranking of the features is shown in Fig. 4.

The different methods of feature ranking showed that several features are most common as the most important features such as Age, Tobacco, LDL Cholesterol, Systolic Blood Pressure, Adiposity, and Family History. However, in our machine learning modeling experiments we used almost all the features and dropped Obesity as it has a high correlation with Adiposity, we used Pearson's correlation to calculate the

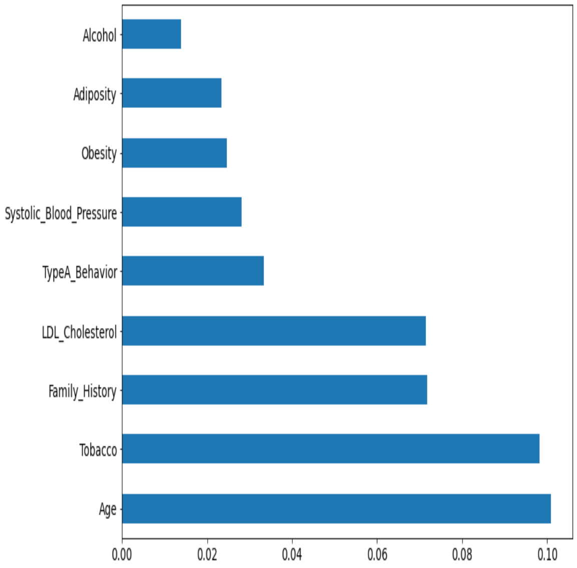

Fig. 4. Feature Importance using Random Forest.

score of the correlation between features and to drop the most correlated ones.

3) Pearson’s Correlation Coefficient: Pearson’s Correlation method is used for finding the feature correlation to remove the redundant features. As shown in Fig. 5, the correlation is represented as a number between -1 and 1, which indicates the extent to which two variables are related.

A correlation coefficient higher than 0.7 is considered strong and therefore one of the features can be dropped because this will affect the prediction accuracy. Given this, the obesity feature was dropped from the training dataset.

IV. Experimental Framework

In this study, we used scikit-learn Python library to conduct the experiments, the selected models, namely, Logistic Regression, SVM, KNN, and MLP Neural Network were applied on the dataset described in the last section, with 462 samples, 8 predictors (dropping Obesity feature) and 1 target variable.

Ten-fold stratified cross-validations were used for model training and testing. The stratified folds were used in these experiments because the dataset is imbalanced with evident imbalanced class distributions, as discussed earlier.

The machine learning techniques utilized for the prediction of CHD are set up as follows:

A. Logistic Regression

The logistic regression technique uses the logistic function [34] to model a binary dependent variable. The technique is capable of solving linear separable classes as well as complex problems. We have used the GridSearchCV function from scikit-learn library to find the optimal parameters, and the logistic regression was configured with ‘lpfgs’ solver, ‘l2’ penalty, and we set up ‘C’ to 0.25.

B. SVC

Based on the Support Vector Machine algorithm [35], this technique separates data points that belong to different classes with a decision boundary (hyperplane). The main parameter here is the kernel, it maps the observations into some feature space. With the help of GrisdSearchCV function, the kernel was set up to ’rbf’, ‘C’ to 10 and we configured ‘gamma’ to auto.

C. KNN

KNN does not try to build an internal model, the computations are not done until the classification time. KNN stores instances of the training data in the features space and the class of an instance are determined based on the distance measure from its neighbors, Therefore, the most important parameter is the number of neighbors to be considered, here we set it up to 17. We used the elbow method [36] to calculate the optimal number of neighbors. And we set up ‘minkowski’ as the metric for the distance measure.

D. MLP Neural Networks

MLP is a neural network that consists of more than two layers with a number of neurons in each layer. We set up 3 layers with 50, 20, and 10 neurons consecutively. The activation function was set up to ‘tanh’ and the learning rate to ‘0.01’.

E. Classification of Evaluation Metrics

Accuracy, Precision (Positive predictive value), Recall (Sensitivity or True Positive rate), F1 score, in addition to Specificity (True Negative rate) were mainly used to evaluate the performance of the prediction models.

To calculate these, the confusion matrix is used to describe the performance of each predicted negative and positive class, as in Fig. 6.

Where:

- TN: is the total number of patients who correctly identified that they have no CHD.
- FN: is the total number of patients incorrectly identified that they have no CHD.
- TP: is the total number of patients correctly identified that they have CHD.
- FP: is the total number of patients incorrectly identified that they have CHD.

In imbalanced datasets precision, recall, and F1 score are often more important measures than accuracy. In this problem, even the accurate prediction of the CHD patients matters the most, i.e., high precision or high recall [37]. However, there is always a precision/recall trade-off, and in CHD prediction, high recall might be even preferred over high precision.

The aforementioned metrics can be calculated from the confusion matrix as follows:

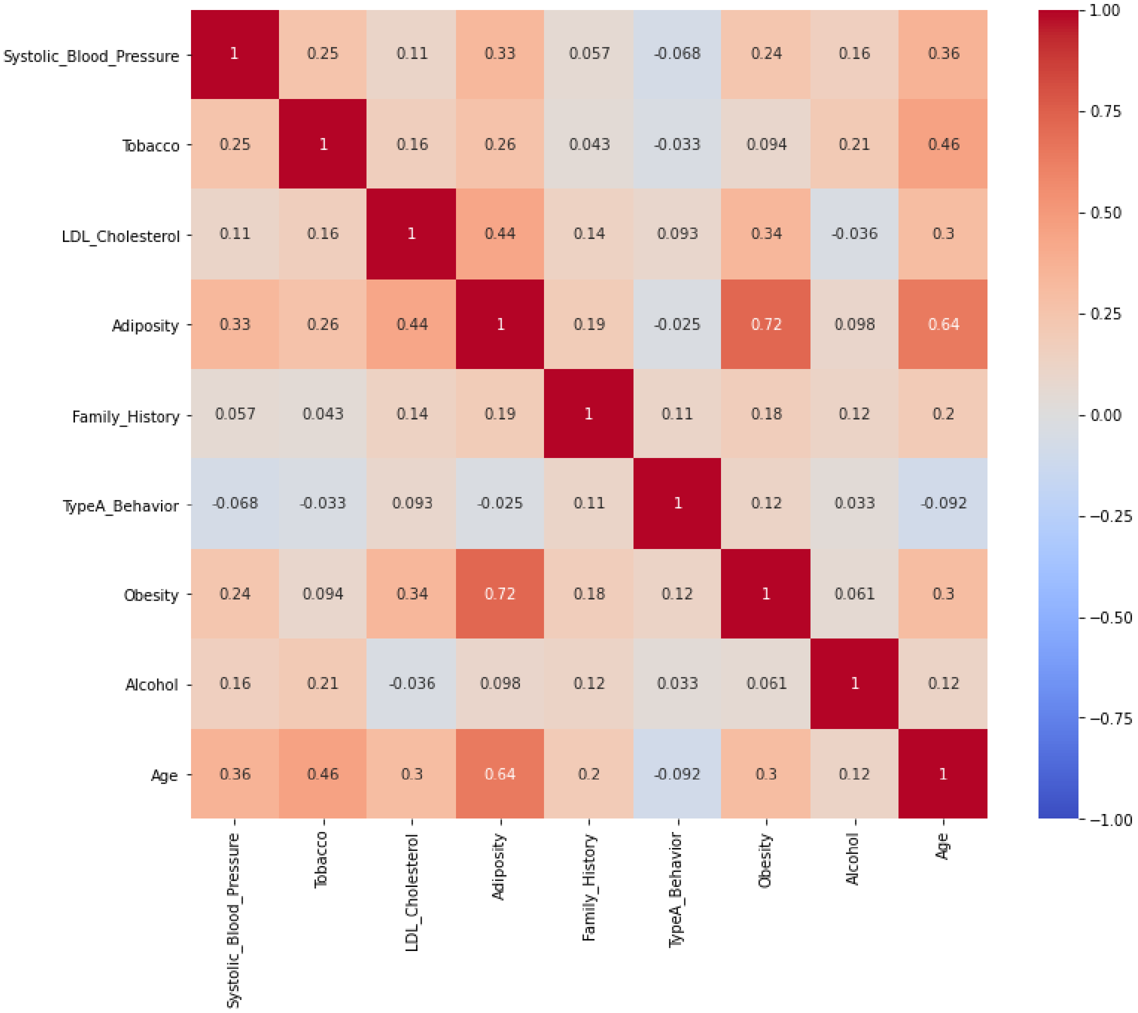

Fig. 5. Pearson's Correlation Matrix.

True			
0	TN	FP	
1	FN	TP	
	0	1	Predicted

Fig. 6. Confusion Matrix.

- Precision (Positive predictive value)

$$TP = \frac{TP}{TP + FP} \quad (1)$$

- Recall (Sensitivity or True positive rate)

$$recall = \frac{TP}{TP + FN} \quad (2)$$

- Specificity (True negative rate)

$$specificity = \frac{TN}{TN + FP} \quad (3)$$

- F-score

$$F1 = \frac{2}{\frac{1}{precision} + \frac{1}{recall}} \quad (4)$$

- Accuracy

$$accuracy = \frac{TP + TN}{TP + FP + FN + TN} \quad (5)$$

F. Data Oversampling

In general, many medical datasets show signs of imbalanced class distribution which greatly hampers the detection of rare events, as most classification methods implicitly assume an equal occurrence of classes [38, 39]. The dataset of this study is a very small size with a total of 462 instances, distributed into 302 negative CHD instances and 160 positive CHD instances.

In an imbalanced class distribution problem, the sample size is critical in evaluating the classification model, and the high error rate caused by the imbalanced class distribution decreases as the size of the training dataset increases [39]. Furthermore, in the dataset at hand, many variables are not linearly correlated, not linearly separable, and are complexly

TABLE IV. PREDICTION RESULTS - MEAN OF 10 FOLD CROSS-VALIDATION

Classifier	Accuracy	F1 Score	Precision	Recall	Specificity
SVM	**0.738***	0.550	0.679	0.463	0.884
MLP Neural Network	0.734	0.553	0.661	0.475	0.871
KNN	0.732	0.504	**0.7***	0.394	**0.911***
Logistic Regression	0.727	**0.563***	0.633	**0.506***	0.844

overlapping, as discussed earlier. The authors in [40] have stated that not the imbalanced distribution of classes is the main problem in the classification with imbalanced data classification, but many characteristics, among them “the presence of small disjuncts, the lack of density in the training data, the overlapping between classes, the identification of noisy data”.

Several techniques have been introduced and used for handling the imbalanced datasets and improving the prediction [41-43]. In this study we have used Synthetic Minority Oversampling TEchnique (SMOTE) for short, this technique was first described by [41]. In particular, we have used the K-means SMOTE method [44, 45].

1) K-means SMOTE: SMOTE with the K-means method improves classification by producing minority class samples in safe areas of the input space. The method reduces noise while effectively addressing imbalances within and within samples. We used the KMeans SMOTE class from the imbalanced-learn Python library.

V. RESULTS

The mean accuracy results of applying the 10-fold stratified cross-validation on the dataset were obtained show that SVM slightly outperformed MLP neural network classifier, KNN, and Logistic Regression. The results were 73.8%, 73.4%, 73.2% and 72.7% respectively. However, as discussed before, accuracy alone is not the main concern here because this is an imbalanced dataset, the distribution of the labeled target class is unequal. The mean scores of applying 10-fold stratified cross-validation with F1 score, Precision, Recall, Specificity of the 4 classifiers are summarized in Table IV. The results show improvements in the accuracy compared to previous research results on the same dataset.

A. Results on the Oversampled Dataset

The dataset now has 604 samples with 302 instances with negative CHD events and 302 instances with positive CHD events. The mean scores of applying the classifiers 10-fold stratified cross-validation on the dataset after oversampling are summarized in Table 5. The classifiers are ordered based on the accuracy we also calculated the Matthews Correlation Coefficient (MCC) score, to highlight which classifier achieved good results in all 4 categories of the confusion matrix.

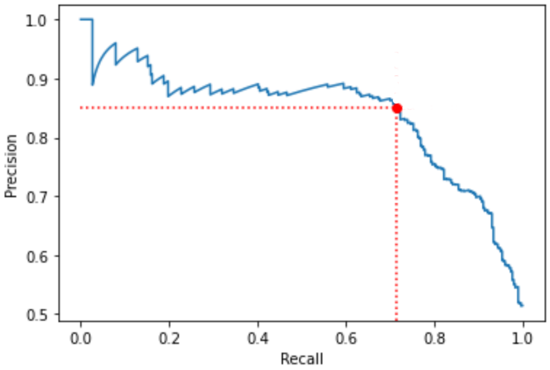

Fig. 7. Precision vs Recall in SVM.

The results show major improvement on the recall score with an average of 32% for all classifiers. From 10 fold cross-validation, MLP neural network has recorded an average 80.3% of Recall score, while KNN has achieved an average 80% of Precision score and an average 85.8% of Specificity score. The overall accuracy for all classifiers has also been improved, SVM has achieved the highest overall accuracy and good results in all scores combined.

Fig. 7 shows the plot of the precision vs recall for SVM classifier, as it can be noticed the precision has dropped at around 78% of recall, so we can even create an SVM model with let’s say over 85% of Precision score with over 71% of recall by tunning the threshold of precision.

VI. DISCUSSION AND CONCLUSION

Our results show that, given sufficient data and proper selected clinical features, machine learning techniques are capable of predicting the occurrence of CHD events with high accuracy. The application of the four machine learning techniques SVM, KNN, MLP neural networks, and logistic regression using the South African Heart Disease dataset with the selected features reported roughly as high as 74% accuracy. While this shows a noticeable improvement in the prediction performance compared to previous researches on the same data, the main issue in this study was to resolve the imbalanced classification problem in the dataset and achieve even higher scores in Precision and Recall in particular, in addition to improving the overall prediction accuracy. Such a problem in the dataset was tackled by applying K-means SMOTE oversampling techniques, and as a result, the prediction performance of all prediction models has significantly enhanced, with an average improvement of 32% on the Recall score and an average improvement of 11% on the Precision score.

Among the four prediction techniques applied on the oversampled dataset in this study, SVM has obtained the best results in all the four confusion matrix categories, marginally followed by KNN, MLP neural network, and logistic regression respectively. However, from the usability standpoint, one might choose to use KNN as a prediction model for this problem, since KNN has obtained an 80% Precision score and around 86% Specificity score. Whereas MLP neural network has reported an 80% Recall score. Recent trends in prediction and classification are going toward using a combination of

TABLE V. Prediction Results on the Oversampled Dataset- Mean of 10 Fold Cross Validation

Classifier	MCC	Accuracy	F1 Score	Precision	Recall	Specificity
SVM	**+0.561**	**0.781***	0.780	0.784	0.776	0.785
MLP Neural Network	+0.549	0.774	0.781	0.760	**0.803***	0.745
KNN	+ 0.553	0.776	0.767	**0.8***	0.737	**0.858***
Logistic Regression	+0.538	0.769	0.775	0.755	0.795	0.742

prediction techniques for more accurate and more reliable outcomes. That is, it is a good idea in practice to use the SVM, KNN, MLP neural network classification models together for predicting the positive and negative CHD cases, as they strengthen and complement each other.

Our feature selection techniques have showed and confirmed that clinical features and risk factors such as, Tobacco, LDL Cholesterol, Systolic Blood Pressure, Adiposity, and Family History are among the most important features that help in the early detection and the prediction of the presence of CHD events from medical records. Medical practitioners can take advantage of the exploratory data analysis conducted on the dataset to show correlations and relationships between patients' data.

The success of machine learning relies heavily on the richness of the data representing the phenomenon under consideration. Even though the selected dataset has the most widely known features and risk factors for predicting CHD, with a rather rich set of features, more data and more variables can potentially help improve the prediction results. If additional external datasets with the same features from different regions had been available, we would have used it as a validation of our findings.

As future work, we are planning to apply our machine learning approach on other datasets of cardiovascular diseases, cancer, and infectious diseases. We are also preparing to deploy the models as a web service and integrate it in a web application to allow medical practitioners assess its usability in the real world.

Gjøvik, Norway

***Abstract*—Cyber-physical systems (CPS) integrate computation and communication capabilities to monitor and control physical systems. Even though this integration improves the performance of the overall system and facilitates the application of CPS in several domains, it also introduces security challenges. Over the years, intrusion detection systems (IDS) have been deployed as one of the security controls for addressing these security challenges. Traditionally, there are three main approaches to IDS, namely: anomaly detection, misuse detection and specification-based detection. However, due to the unique attributes of CPS, the traditional IDS need to be modified or completely replaced before it can be deployed for CPS. In this paper, we present a survey of specification-based intrusion detection techniques for CPS. We classify the existing specification-based intrusion detection techniques in the literature according to the following attributes: specification source, specification extraction, specification modelling, detection mechanism, detector placement and validation strategy. We also discuss the details of each attribute and describe our observations, concerns and future research directions. We argue that reducing the efforts and time needed to extract the system specification of specification-based intrusion detection techniques for CPS and verifying the correctness of the extracted system specification are open issues that must be addressed in the future.**

***Keywords*—Cyber-physical systems; intrusion detection systems; specification-based intrusion detection mechanism; security**

I. Introduction

The recent years have witnessed an increasing growth in the development and deployment of different types of cyber-physical systems (CPS). CPS have shaped every aspect of our lives as their applications span through several domains including electrical power grids, water and wastewater management, oil and gas sector, traffic systems and many other domains. Considering the nature of CPS, security incidents could lead to physical harm to people, destruction of property or environmental disasters. For this reason, the secured operation of CPS is a major concern for all stakeholders.

According to Gartner analysts [1], CPS security incidents are expected to rise in the coming years due to a lack of security focus and spending that are aligned to CPS. They also observe that the liability for CPS security incidents will not only affect the corporate entity but will also lead to a personal liability for 75% of CEOs by 2024. This is a wakeup call for all those charged with the responsibility for the secured operation of CPS and for greater attention to the development and deployment of appropriate security controls for CPS.

One of the security controls for CPS involves the use of intrusion detection systems (IDS). Traditionally, there are three main approaches to IDS, namely: anomaly detection, misuse detection and specification-based detection. However, due to the unique attributes of CPS, the traditional IDS need to be modified or completely replaced before it can be deployed for CPS. A discussion of the techniques and challenges on the use of IDS in CPS have been provided by Han et al. in [2] . Our interest in this paper is to survey the use of specification-based intrusion detection techniques for CPS.

Some works in the literature have conducted surveys related to the use of IDS for CPS [3], [4], [5]. Mitchell and Chen [3] presents a survey of IDS design principles and techniques for CPS. They categorize the existing CPS IDS techniques in the literature, describe their advantages and disadvantages and suggest future research areas. Zarpelão et al. [4] also conducted a survey of IDS in Internet of Things (IoT). They classify the IDS proposed in the literature according to the following attributes: detection method, IDS placement strategy, security threat and validation strategy. A much recent survey related to the use of IDS for CPS is presented by Wu et al. [5]. They conducted a survey of the proposed IDS designs for in-vehicle networks. However, to the best of our knowledge, none of the existing surveys have considered the use of specification-based IDS for CPS.

In this paper, we present a survey of specification-based intrusion detection techniques for CPS. In particular, we classify the existing specification-based intrusion detection techniques in the literature according to the following attributes: specification source, specification extraction, specification modelling, detection mechanism, detector placement and validation strategy. We also discuss the details of each attribute and describe our observations, concerns and future research directions. We argue that reducing the efforts and time needed to extract system specification of specification-based intrusion techniques for CPS and verifying the correctness of the extracted specification are open issues that must be addressed in the future.

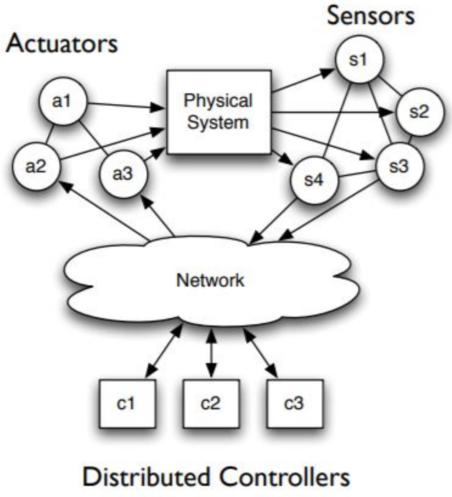
The rest of this paper is organised as follows. Section II presents a discussion on CPS and specification-based intrusion detection, which provides an understanding for describing the suitability of specification-based intrusion detection techniques for CPS. Section III provides a survey of specification-based intrusion detection techniques for CPS and the proposed taxonomy. Section IV describes our observations, concerns and future research directions, which is one of the most relevant contributions of this work. Section V concludes the paper.

II. Background

A. Cyber-Physical Systems

CPS facilitate the integration of computation and communication capabilities to monitor and control physical systems. This enables the accomplishment of time-sensitive functions with different degrees of interaction with the environment, including human interaction [6]. As a result of this, CPS are called time-sensitive systems which makes timing a central theme in their design and implementation. CPS are also referred to as safety-critical systems because the failure of the system due to faults or other external influences, could endanger the lives of humans operating the physical systems, those embedded with the CPS (medical devices) or those within the radius of their operation (nuclear plants). The application of CPS span through several domains and they include modern vehicles, medical devices, industrial systems, etc., all with different standards, requirements, communication technologies, and time constraints.

The general architecture of CPS is depicted in Figure 1. CPS as showed in the diagram, typically have a physical system that is being monitored and controlled, a set of sensors that report the state of the physical system, a set of actuators that are used by the controllers to maintain the system in the desired state, and a set of controllers (or a controller) that monitors and controls the physical system using the sensors and actuators, and via a communication channel [7]. The interaction between these components of CPS is known to be vulnerable to cyber attacks. For example, a power station located north of the city of Kiev, Ukraine, suffered a cyber attack which blacked out a portion of the Ukrainian capital equivalent to a fifth of its total power capacity [8]. This calls for increased efforts towards addressing the security issues of CPS.



[7]

Fig. 1. The General Architecture of CPS.

There are several security challenges in the operation of CPS. These challenges can be attributed to the unique features of CPS which makes the traditional security solutions ineffective in addressing the security challenges of CPS. For example, CPS have time constraints because the physical processes are generally time-aware and deadline sensitive [9]. Also, the complexities in the analysis and design of security solutions for CPS are further exacerbated by the need to understand and address the upstream and downstream dependencies of the component systems [6]. Therefore, the current information technology (IT) security controls would have to be modified significantly or to be completely replaced because they are unable to address the security challenges of CPS.

One of the security solutions for CPS involves the use of intrusion detection systems (IDS). There are three main approaches to IDS, namely: anomaly detection, which relies on comparing current behaviour with the pre-established normal behaviour to detect an intrusion; misuse detection, which use intrusion signatures to detect an intrusion; and specification-based detection, which depends on the monitoring of the specified system behaviour to detect an intrusion [10]. A review of the existing intrusion detection techniques for CPS has been provided by Mitchell and Chen in [3] and Han et al. in [2] discuss the techniques and challenges of intrusion detection in CPS. We are interested in the use of specification-based IDS for CPS in this paper. The following subsections provide an in-depth discussion on specification-based IDS and its suitability for CPS, so as to motivate our survey of the existing specification-based intrusion detection techniques for CPS.

B. Specification-based Intrusion Detection

The notion of specification-based intrusion detection was first introduced by Ko et al. in [10]. It leverages the specification of a system, which describes the expected behaviour of the system. Any deviation of the system operations from the defined correct behaviour is flagged as a security violation. In general, the specification-based intrusion detection process involves the use of a specification source to extract the expected behaviour of a system, which in turn is modelled. A detection mechanism is then applied to the modelled specification for monitoring the system behaviour for any deviation. Figure 2 provides a diagrammatic illustration of the specification-based intrusion detection process.

Specification-based intrusion detection has shown to be a better approach to IDS than anomaly detection and misuse detection [11]. Even though anomaly detection is able to detect novel attacks, it suffers from a high rate of false alarm because unseen legitimate system behaviours are classified as anomalies. Misuse detection, on the other hand, does not generate false alarms but it is unable to detect novel attacks. Hence, specification-based appears to be the mean between misuse detection and anomaly detection because it combines the advantages of both approaches. Its false positive rate is similar to misuse detection as it does not generate false alarms when unusual system behaviours are discovered. Similar to anomaly detection, specification-based intrusion detection is able to detect novel attacks because it detects attacks as deviations from the defined correct system behaviours.

The use of specification-based intrusion detection spans through several domains. Initially, it was intended for execution

Fig. 2. Specification-based IDS Process.

monitoring of security-critical programs in distributed system [10]. However, it has been applied to routing protocols such AODV [12], [13], [14] or OSLR [15], DNP3 protocol [16], [17], [18] Voice over IP [19], [20], [21] and other areas of CPS as discussed in section III. A practical experience in the use of specification-based intrusion is presented by Uppuluri and Sekar in [11]. In this work, the experiments conducted show that specification-based intrusion detection is able to detect 80% of the attacks without knowledge about the attacks or the attacker behaviour. They observe that the combination of specification-based intrusion detection with some misuse specification increases the detection ability to 100% with 0% false positive rates.

Specification-based intrusion detection can also be combined with anomaly detection. This is the method adopted by Sekar et al. in [22] and Stakhanova et al. in [23]. Sekar et al. [22] use state-machine specification in combination with information about statistics that need to be maintained to detect anomalies. They evaluate effectiveness of the approach is using 1999 Lincoln Labs intrusion detection evaluation data and the results show that the proposed intrusion detection approach detects all of the probing and denial of service attacks with a low rate false alarm. In the case of Stakhanova et al. [23] the proposed technique facilitates the automatic development of the normal and abnormal behaviour specification in a form of variable-length pattern classified using anomaly-based method. They assess the proposed technique via simulations using publicly available synthetic data and the results show that the approach can detect unknown anomalous behaviour and known anomalous behaviour with a low rate false alarm.

C. Suitability of Specification-based Intrusion Detection for Cyber-Physical Systems

There are several characteristics of CPS that makes specification-based intrusion detection the most suitable type of intrusion detection approach for CPS. One of these characteristics is the laws of physics that govern the physical systems in CPS. The IDS deployed in CPS are expected to monitor physical processes for intrusion. These physical processes are governed by the laws of physics, which makes certain behaviours of the physical systems more likely to be seen than others [3]. Thus, specification-based intrusion detection technique can be used to define these behaviours and to monitor the physical systems for any deviation from these expected behaviours.

Another feature of CPS environment is that activities are usually automated and time driven in a closed-loop settings [3]. This provides some regularity and predictability in the CPS environment which can be used for monitoring. It is different from the IT environment where activities are user triggered and users' behaviours can be very unpredictable. Consequently, the regularity and predictability of CPS environment can be exploited by specification-based intrusion detection to define the correct behaviours of the system, which is subsequently used to monitor behaviours outside the defined behaviours.

Moreover, the protocols deployed in CPS are well-known and widely used which makes it easy to extract the correct behaviour of the system. As a result of this, it is attractive to use specification-based intrusion technique for CPS. This is because the protocol specifications which are readily available can be used as specification source to extract the expected behaviour of the system. Also, specification modelling and detection mechanism can then be employed to complete the specification-based intrusion detection process.

III. Specification-based Intrusion Detection Techniques for Cyber-Physical Systems

In this section, we present a survey of specification-based intrusion detection techniques for CPS. We observe that a common feature of the specification-based intrusion detection techniques for CPS is as follows: a set of properties, which indicates the correct system behaviour is sourced, extracted and modelled; and then, a detection mechanism is used to monitor for any deviation from the defined system specification. Using this understanding, we classify the existing literature according to the following attributes: specification source, specification extraction, specification modelling, detection mechanism, detector placement and validation strategy. The proposed taxonomy of specification-based intrusion detection techniques for CPS is depicted in Figure 3 and Table I summarizes the existing works on specification-based intrusion detection techniques for CPS.

A. Specification Source

Specification source refers to how the set of properties that indicates the correct system behaviour is obtained. There are three major specification sources of specification-based intrusion detection techniques for CPS, namely: protocol specification, reference model and observed behaviour.

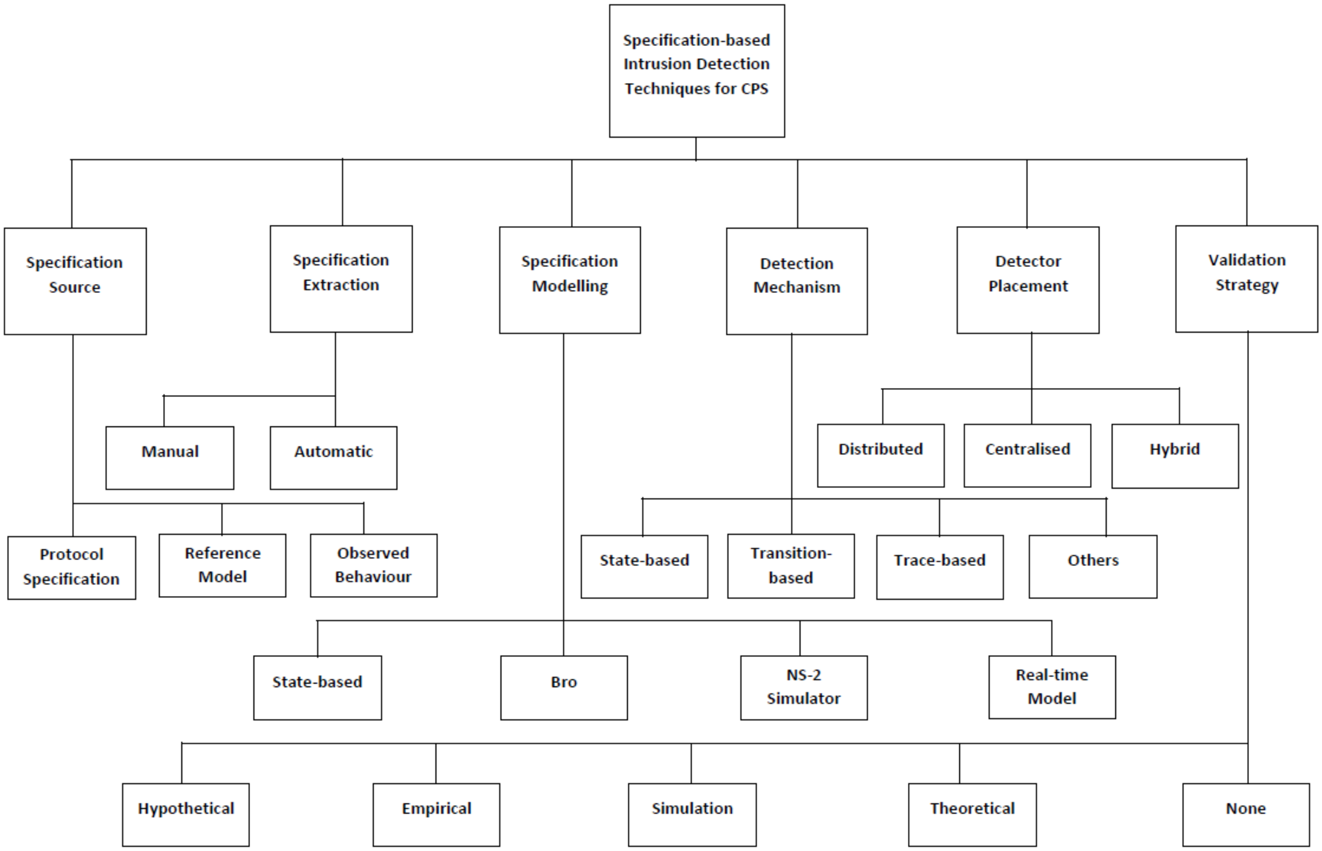

Fig. 3. Taxonomy of Specification-based Intrusion Detection Techniques for CPS.

1) Protocol Specification: Protocol specification is a formal document that defines the expected behaviour of a system. Given the well-defined behaviour of CPS, several protocol specifications have been deployed as the specification source to describe its correct behaviour in many studies. For example, Tseng et al. in [12] utilise the Ad hoc distance Vector (AODV) routing protocol specification as specification source. Other works that have employed AODV routing protocol specification as specification source include Hansson et al. in [13] and Hassan et al. in [14].

Gil et al. in [24] have used IEEE 802.11 protocol and the extensible authentication protocol (EAP) specifications as specification source to define the desired behaviour of wireless local area network. Song et al. in [25] combine both informal protocol specification and other documents from dynamic registration and configuration protocol as specification source. The spanning tree protocol (STP) specification has been leveraged as specification source by Jieke et al. in [26] to describe the expected behaviour for carrier Ethernet network infrastructure. And Tseng et al. in [15] use H.323 protocol specification as specification source.

McParland et al. in [18] deploy protocol guidelines for both ModBus TCP and DNP3 as specification source. They abstract the specific details away of the protocols to focus on the physics models of the system. Unlike them, Lin et al. in [16] and [17] employ only DNP3 as specification source to extract the normal behaviour of the system. Further, Berthier and Sanders in [27] use C12.22 standard protocol specification as specification source to ensure that all violations of the specified security policy of the system will be captured.

The controller area network (CAN) protocol specification has been utilised by Olufowobi et al. in [28] as specification source. Larson et al. in [29] employ the CAN protocol version 2 and the CANOpen application layer draft standard 3.01 as specification source to extract the expected behaviour of electronic control unit of an in-vehicle network. Also, Esquivel-Vargas et al. in [30] exploit the Building Automation and Control Networks (BACnet) protocol as specification source to depict the normal behaviour of each device in the BACnet network.

2) Reference Model: The reference model of the system under consideration has also been employed in several studies as specification source, to obtain the correct system behaviour [31], [32], [33], [34]. Mitchell and Chen in [31] employ the reference model of a modern electrical grid CPS embedding physical components as specification source. They also use the reference model of unmanned air vehicles and reference model of medical CPS in [32] and [33] respectively as specification sources. Also, Sharma et al. in [34] utilize the reference model of unmanned air vehicles CPS as specification source.

3) Observed Behaviour: Observed behaviour of the system under consideration is another method that can be employed as specification source, to define the correct behaviour of a system. It involves the monitoring of a system during its

TABLE I. Summary of the Existing Works on Specification-based Intrusion Detection Techniques for CPS

normal operation and then using the knowledge obtained as specification source, to specify the correct behaviour of the system. For example, Pan et al. in [35] use time-synchronized data from synchrophasor and observable events from audit logs as specification source to define the correct behaviour for the cyber-physical environment in electric power system. Also, the specification source utilized by Carcono et al. in [36] is based on monitoring the evolution of the target system states.

B. *Specification Extraction*

Specification extraction is the method that can be deployed to extract the correct behaviour of the system using the specification source. This can either be accomplished manually or automatically.

1) Manual: Most of the specification extraction methods adopt a manual approach for the extraction of the correct system behaviour from the specification source [18], [27], [16], [12], [17], [24], [25], [26], [13], [14], [15], [35], [36], [33], [32], [31]. This method has been shown to be an expensive and very tedious process [27]. As a result of this limitation, there have been attempts in the past few years towards the automatic extraction of the correct system behaviour from specification sources.

2) Automatic: Efforts have been made in recent years to extract the correct system behaviour from the specification source automatically [30], [34], [28]. Esquivel-Vargas et al. in [30] made the first attempt to extract specification automatically. In this work, they implement automated specification extraction in two steps: a subset of the devices capabilities is observed in the network traffic; and based on this observation, an algorithm is used to extract all the devices capabilities from the specification source. Automated specification extraction has also been employed by Sharma et al. in [34] to derive the behaviour rules of IoT device using the operational profile as specification source. And most recently, Olufowobi et al. in [28] exploit real-time schedulability analysis of messages to automate specification extraction.

C. *Specification Modelling*

Specification modelling describes the modelling approach that is adopted to model the specification extracted from a specification source, to describe the correct system behaviour. This subsection presents the different methods that are currently being used for specification modelling.

1) Specification Modelling Using State-based Approach: State-based approach is the most common method for specification modelling. There are several variants of the state-based approach currently in use. The standard state machine has been used by Mitchell et al. in [31], [32], [33] for specification modelling where the extracted specification is transformed into state machines. Jeike et al. in [26] employ state machine for specification modelling. In this work, the states of the machine are states of the protocol, and the state transitions are caused by the receptions of BPDUs or expiration of timeouts. Standard state machines have also been deployed by Berthier and Sanders in [27] to capture the expected system behaviour. And Sharma et al. in [34] have converted the extracted specification into state machines for specification modelling.

Another variant of the state-based approach that has been adopted for specification modelling is the finite state machine. Tseng et al. in [12], [15] use finite state machine for specification modelling. They specify the correct AODV routing protocol behaviour using the finite state machine in [12] and describe the valid routing behaviour of a network node based on Optimised Link State Routing (OLSR) protocol in [15]. The extended finite state machine has been applied by Hansson et al. in [13] and by Song et al. in [25] for specification modelling. Gill et al. in [24] utilise state transition model to describe the extracted specification and state transition patterns are employed by Pan et al. in [35] for specification modelling. Also, a sector specific state modelling language referred to as Industrial State Modelling Language (ISML) has been employed in [36] for specification modelling.

2) Specification Modelling Using Bro: Another tool that can be used for specification modelling is the open source Bro network security monitor (now known as Zeek) [37]. McParland et al. in [18] use Bro scripts for specification modelling but the specific details of the communication protocols and technologies are removed to concentrate on the physics models of the devices being investigated. Similarly, the security specifications of DNP3 protocol have been modelled as a parser and integrated into Bro by Lin et al. in [16], [17]. And Esquivel-

Vargas et al. in [30] use Bro for specification modelling of the automatically extracted correct system behaviour.

3) Specification Modelling Using NS-2 Simulator: NS-2 stands for Network Simulator Version 2 and it is an open-source event-driven simulator for modelling the dynamic nature of communication networks [38]. Hassan et al. in [14] employ NS-2 simulator for specification modelling. In this work, the extracted specification for the runtime behaviour of AODV protocol is implemented using the NS-2 simulator, which allows the detection of any violations from the correct system behaviour.

4) Specification Modelling Using Real-time Model: A recent work by Olufowobi et al. in [28] has proposed the use of a real-time model for specification modelling. In this work, CAN traces that describe the normal behaviour of the network is used to extract real-time parameters as the features which represent the desired specification. Then, the real-time model of the CAN is deployed to specify the expected system behaviour and to flag the violations of the model as indications of a compromised network.

D. Detection Mechanism

Detection mechanism refers to the method that can be adopted to ascertain if there is any deviation from the expected system behaviour. Such deviations are flagged as malicious and since it only relies on the defined specification, this approach is able to detect zero-day attacks. We classify the detection mechanism based on the taxonomy suggested in [39] and the recent developments in the field.

1) State-based Detection Mechanism: Most of the detection mechanism deployed by specification-based intrusion detection techniques for CPS are based on states. The desired state of the system is defined using the specification source that have been extracted and modelled. The goal of the detection mechanism is to detect any deviation from the desired state. For example, Tseng et al. in [12], [15] use a finite state machine for detecting incorrect route request and route reply messages of the AODV routing protocol. They employ predefined finite state machine constraints in [12] which are based on the sourced, extracted, and modelled correct specification; any deviation from these constraints are flagged as malicious. And in [15] the detection mechanism involves checking whether the network node violates the constraints based on the finite state machine.

Mitchell et al. have also used state-based method as detection mechanism in [31], [32], [33]. In these works, they transform the behaviour rules into state machines, which are then used to monitor the system for deviations from the specified system behaviour. Similarly, Berthier and Sanders in [27] use a state machine module to keep track of the state of each device for which traffic is capture, to ensure that stateful constraints are not violated. And Sharma et al. in [34] transforms behaviour rules into a C-language state machine labelled with safe and unsafe states; against which normal and malicious behaviours of the IoT device can be statistically described.

The DNP3 analyser used by Lin et al. in [17], [16] as detection mechanism is based on states. They observed that the DNP3 analyser can maintain states from the parsed network packets and using this states, the incoming packets can be corrected and analysed to ensure there are no violations. Also, Carcano et al. in [36] propose the concept of critical state analysis and state proximity as detection mechanism. They argue that the critical states of a CPS are well documented and that by monitoring the evolution of the physical process states and keeping track of when the CPS enter into a critical state, it is possible to detect attack patterns (known or unknown) likely to drive the CPS into a critical state.

2) Transition-based Detection Mechanism: The detection of malicious behaviour can also be accomplished by monitoring the transition between states. McParland et al. in [18] describes operational protocols using pre- and post- conditions of physical state transitions and any transition that does not lead to a good state is flagged as a potential failure or attack on sensors or actuators. The detection mechanism presented by Gill et al. in [24] used as state transition modelling. In this work, the detection mechanism is achieved by monitoring any anomalous transition in the observed state transition model. And temporal-state transitions are used by Pan et al. in [35] as the detection mechanism. The method adopted in this work involves the monitoring of transition from state to state to detect patterns that are likely to interrupt the protection scheme.

3) Trace-based Mechanism: Trace-based method is another detection mechanism that can be used to monitor deviations from the specified system behaviour. For example, Song et al. in [25] define a set of valid network traces that indicates all finite traces of a network accepted by the specification. They then employ these traces as detection mechanism by monitoring for any trace violating the specification. Olufowobi et al. in [28] use CAN traces as detection mechanism. The CAN traces used in this work depict the normal behaviour of the network, and the detection mechanism involves checking to see if the CAN traces conform with the specification.

4) Other Methods: There are other methods that can be used as detection mechanism which is neither state-based, transition-based, nor trace-based. One of such method presented by Jieke and Redol in [26] and Hansson in [13] combines the attributes of state-based method and transition-based method. In this works, the detection mechanism depends not only on the state of the system but also on the transition between states. Another method is the detection mechanism that has been described by Hassan et al. in [14] which involves identifying misuses to routing messages based on the derived specification. Also, Larson et al. in [29] employ a detection mechanism that checks protocol violations by monitoring the ECU object directory for illegal modifications.

E. Detector Placement

In the use of specification-based intrusion detection techniques for CPS, the detector placement strategies can be distributed, centralised, or hybrid (a combination of both the distributed and the centralised detector placement). This type of classification has been used by Zarpelão et al. in [4] to describe the possible placement strategies for intrusion detection systems in Internet of Things. Hence, this subsection presents the three types of detector placement methods that can be used in specification-based intrusion detection techniques for CPS.

1) Distributed Detector Placement: The use of distributed detector placement is the most desired placement strategy of specification-based intrusion detection for CPS. This is because of the distributed nature of CPS and the need for an IDS which allows every device to be monitored by other devices and ensures there is no single point of failure. For this reason, the use of distributed detector placement in specification-based intrusion detection for CPS has been proposed in [33], [12], [26], [15], [31], [32], [26], [13], [14], [15], [34].

2) Centralised Detector Placement: Centralised detector placement refers to the detector placement where the detector is located at a centralised component, for example, a dedicated host or a network router. This is the strategy employed by most of the survey works [18], [27], [16], [30], [28], [35], [17], [24], [25], [36]. Even though the use of centralised detector placement creates a single point of failure, the ease of its implementation is responsible for its prevalence.

3) Hybrid Detector Placement: Hybrid detector placement is an approach that attempts to combine the benefits of distributed detector placement and centralised detector placement. This approach has been deployed by Larson et al. in [29]. They observe that placing a detector in the network device would make the use of specification-based intrusion detection impossible in CAN environment because it cannot ascertain if the source of the message is allowed to transmit, or if the destination is allowed to receive. As of result of this, they combine distributed detector placement and centralised detector placement to remedy the limitation of centralised detector placement.

F. Validation Strategy

This subsection aims to present the validation strategy that have been employed in the use of specification-based intrusion detection techniques for CPS. Validation is the process of ascertaining if the developed model behaves with acceptable accuracy according to the objectives of the study [40]. To classify the existing validation strategy in the use of specification-based intrusion techniques for CPS, we use the classification of validation methods proposed by Verendel in [41] namely: hypothetical, empirical, simulation, theoretical, and none.

1) Hypothetical: Here, hypothetical examples are used for the validation of the proposed techniques. This is the approach that is adopted by Larson et al. in [29] and Tseng et al. in [12]. Larson et al. [29] use hypothetical example where assumption about the capability of an attacker is made. They apply this to a conceptual network model connecting two networks through a common Gateway to validate their proposed specification-based intrusion detection technique. Similarly, Tseng et al. [12] employ a hypothetical example of how the network monitors trace AODV packets based on the AODV scenario they described to validate their proposed specification-based intrusion detection method.

2) Empirical: Empirical methods have also been used as validation strategy of specification-based intrusion detection for CPS. Berthier and Sanders [27] utilise empirical evaluation and observe that the objectives of such verification are two folds: verifying that the implementation is correct, and measuring the performance of the implementation under various conditions.

3) Simulation: Simulation is the most popular validation strategy used by the existing literature surveyed in this paper [18], [33], [16], [30], [28], [34], [35], [17], [24], [13], [14], [15], [36], [31], [32]. For example, McParland et al. [18] in the validation of their proposed approach use a collection of Modbus master and salve simulation tools and DNP3 simulation tools. Mitchell and Chen in [31], [32], [33] use Monte Carlo simulation for the validation of their proposed techniques. Lin et al. [16] employ a test-bed to simulate SCADA-specific attack scenarios in the bid to validate their proposed method. And Carcano et al. [36] simulated a prototype of the approach they described as validation strategy.

Moreover, the validation strategy using simulation may require the development of a specialised tool. This is the approach adopted by Hansson et al. in [13]. They develop a simulation environment in C++ called Aquarius, which is then deployed for the validation of their proposed technique. Well-known tools have also been deployed as validation strategy. For example, Hassan et al. [14] use NS-2 network simulator, Tseng et al. [15] use GloMoSim simulation platform and Gill et al. [24] use a custom Snort-Wireless preprocessor.

Pan et al. [35] implemented a test-bed to simulate an electric transmission system which they used to validate the specification-based intrusion detection framework proposed in their work. Esquivel-Vargas [30] also simulate a prototype which is implemented using third-party software tools and custom scripts to validate their proposed approach. The validation of the method proposed by Sharma [34] is accomplished using UAV-CPS simulated in MATLAB. And the validation strategy employed by Olufowobi [28] involves the simulation of their proposed method with real CAN logs collected from two passenger cars and on an open-source CAN dataset collected from real-world scenarios.

4) Theoretical: Theoretical methods as validation strategies involve the use of formal or precise theoretical arguments to support the obtained results. This method has been used by Song et al. in [25] to validate specification-based intrusion detection technique. They utilise ACL2 theorem prover [42] and the enforcement of security requirements is defined and proved as theorems in ACL2.

5) None: None refers to the papers where no validation methods are deployed. Among the works we surveyed in this paper, only the work by Jieke and Pan [26] falls in this category.

IV. Observations, Concerns and Future Research Directions

We observe from this study that specification-based intrusion detection technique has been applied in several domains of CPS. For example, it has been employed by McParland [18] for monitoring security of networked control systems. Mitchell and Chen [33] have proposed the use of specification-based intrusion detection for safety critical medical cyber physical systems. Also, specification-based intrusion detection has been proposed for monitoring in-vehicle networks by Larson et al.

[29] and Oluwofobi et al. [28]. Bertheir and Sanders [27] propose the use of specification-based intrusion detection to monitor traffic at the edge of an advanced metering infrastructure. Other applications of specification-based intrusion detection techniques for CPS include SCADA systems [16], [17], [36], building automation systems [30], mobile ad hoc networks [12], [25], [13], [14], [15], IoT devices [34], power system [31], [35], unmanned air vehicles [32] and wireless local area networks [24].

There are several protocols that have been deployed in the operation of CPS. For this reason, it is natural to see that many of the existing literature of specification-based intrusion detection techniques for CPS involve the monitoring of protocols used in CPS. For instance, CAN protocol which is used for in-vehicle networks has been studied by Larson et al. in [29] and Oluwofobi et al. in [28]. Also, specification-based intrusion detection has been proposed for monitoring DNP3 protocol [16], [17], [18]. Other protocols that have been considered by the surveyed papers include C12.22 standard protocol [27], BACnet protocol [30], IEEE 801.11 protocol [24], spanning tree protocol [26], OLSR protocol [15], dynamic auto-configurations protocol [25], and AODV protocol [12], [13], [14].

We also note that only the works by Berthier and Sanders [27], Sharma et al. [34] and Song et al. [25] employed formal modelling for the verification of the specified behaviour. The use of formal modelling is an important aspect of specification-based intrusion detection technique as it enables the verification of the extracted specification. Since specification-based intrusion detection techniques depend on the specified system behaviours, it is imperative that these behaviours represents the correct behaviour of the system and formal modelling provides a tool for such verification. Unfortunately, only a few of the existing literature on specification-based intrusion detection for CPS attempted to verify the derived system specification.

Moreover, we notice that the traditional IDS performance metrics have been used in some of the existing works on specification-based intrusion detection techniques for the evaluation of their proposed technique. Performance metrics are used to measure the performance of IDS. For example, false positive rate has been used in [27], [24], [13], [36], [15] and the combination of false positive rate and false negative rate have been used in [33], [30], [28], [31], [34], [32]. In addition, Lin et al. in [17], [16] use throughput as the performance metric.

One of the biggest concerns in the use of specification-based intrusion detection techniques for CPS is the efforts and time required for specification extraction. As we have already observed, most of the existing works in the use of specification-based intrusion detection techniques for CPS employed the manual approach for specification extraction. This method is prone to errors and could jeopardize the intrusion detection ability of the specification-based IDS. Although efforts have been made by Esquivel-Vargas et al. in [30], Olufowobi et al. in [28], and Sharma et al. in [34] to address the problem through the use of automatic specification extraction, it still remains an open research issue.

Another concern when deploying specification-based intrusion detection techniques for CPS is verifying the correctness of the extracted specification. The ability of a specification-based IDS to detect anomalous behaviour depends on how correct the extracted specification represents the normal system behaviour. One of the ways to verify the correctness of the extracted specification is through the use of formal modelling. Out of the 20 works we surveyed, only Berthier and Sanders [27], Sharma et al. [34] and Song et al. [25] have deployed formal modelling for the verification of the correctness of the extracted specification. Thus, future research works need to consider the best methods for verifying the correctness of the extracted specification so as to encourage the practical application of specification-based IDS for CPS.

V. Conclusion

In this paper, we presented a survey of specification-based intrusion detection techniques for CPS. We selected 20 papers in the literature that proposed the use of specification-based intrusion detection mechanism for CPS. These papers were published between 2005 and 2020. We proposed a taxonomy to classify these papers, which is based on the following attributes: specification source, specification extraction, specification modelling, detection mechanism, detector placement and validation strategy. We observed that to fully realize the potentials of specification-based intrusion detection techniques for CPS, more work needs to be done in the future to reducing the efforts and time required to extract the system specification and to verifying the correctness of the extracted system specification.

Exploring Factors Associated with Subjective Health of Older-Old using ReLU Deep Neural Network and Machine Learning

Haewon Byeon
Department of Medical Big Data, College of AI Convergence
Inje University, Gimhae 50834, Republic of Korea

***Abstract*—Resolving the health issues of the elderly has emerged as an important task in the current society. This study developed models that could predict the subjective health of the older-old based on gradient boosting machine (GBM), naive Bayes model, classification and regression trees (CART), deep neural network, and random forest by using the health survey data of the elderly and compared their prediction performance (i.e., accuracy, sensitivity, specificity) the models. This study analyzed 851 older-old people (≥75 years old) who resided in the community. This study compared the accuracy, sensitivity, and specificity of the developed models to evaluate their prediction performance. This study conducted 5-fold cross-validation to validate the developed models. The results of this study showed that the deep neural network with an accuracy of 0.75, a sensitivity of 0.73, and a specificity of 0.81 was the model with the best prediction performance. The normalized importance of variables derived from deep neural network analysis showed that depression, subjective stress recognition, the number of accompanying chronic diseases, subjective oral conditions, and the number of days walking more than 30 minutes were major predictors for the subjective health of the older-old. Further studies are needed to identify factors associated with the subjective health of the older-old with considering the age-period-cohort effects.**

Keywords—Gradient boosting machine; classification and regression trees; Naive Bayes model; deep learning; subjective health

I. Introduction

The elderly population is increasing rapidly in South Korea. As of 2018, South Korea has entered the aging society because the elderly population (≥65 years old) exceeded 14% of the total population [1,2]. Moreover, it is expected that South Korea will become a super-aged society, where the elderly population is at least 20% of the total population [1,2]. If this trend continues, it is estimated that the elderly population will be 16.16 million people, 3.7 folds of that in 2005 [1]. In particular, as the average life expectancy is extended, the older-old (75 years or older) is also expected to increase by 8.6 times compared to 2005 [1].

The increased elderly population due to aging caused health problems such as an increase in geriatric diseases and social problems such as an increase in the burden of medical expenses [3,4]. Resolving the health issues of the elderly has emerged as an important task in the current society [5]. In particular, as the baby boomer generation is rapidly turning into an elderly population, South Korean society needs to prepare measures for faces more serious and complex elderly issues to be resolved [6,7,8]. Consequently, the subjective health of the elderly has been studied extensively [6,7,8]. However, these previous studies have limitations. First, most previous studies [9, 10] that identified factors affecting the subjective health status of the elderly usually treated the elderly, ⩾65 years old, as a homogeneous group and developed a model for predicting a subjective health condition without categorizing them into different age groups. Second, it is difficult to generalize and extrapolate the results of previous studies [11] to the whole elderly population in South Korea because they mostly targeted a small elderly group in a specific area. Third, previous studies [12] targeting the elderly in South Korea mainly used tools that were developed in South Korea to measure subjective health or quality of life, and as a result, it is difficult to compare the results of these studies with those published in other countries that do not speak Korean. In particular, as researchers began to recognize issues associated with defining the elderly, ⩾65 years old, as a homogenous group [13], some studies [14,15] subdivided the elderly into the young-old (<75 years old) and the older-old (⩾75 years old).

As South Korea entered the aging society in 2017, it is necessary to explicitly identify the subjective health-related factors of the older-old whose daily living ability has declined. Previous studies [16,17,18,19,20,21,22] evaluated factors related to the subjective health of the older-old and reported that the number of accompanying chronic diseases, depression, socioeconomic status, gender, and social network with friends and relatives as the predictors of subjective health. However, since these previous studies used regression analysis to develop a prediction model, it was efficient to identify individual risk factors but the model is limited in identifying multiple risk factors such as lifestyle and socioeconomic level [23]. In addition, the regression model assumes independence, normality, and homoscedasticity [24]. If the model is developed using data that violate the normality assumption, it may produce biased results [24].

Recently, machine learning has been widely used in various fields as a way to solve the limitations of this regression model. Machine learning can accurately analyze even data that somewhat violate the normality assumption and nonlinear data in the estimation process, which are advantages of machine learning [25]. This study developed models that could predict the subjective health of the older-old based on gradient boosting machine (GBM), naive Bayes model, classification and regression trees (CART), deep neural network, and random forest by using the health survey data of the elderly and compared their prediction performance (i.e., accuracy, sensitivity, specificity) the models.

II. Methods and Materials

A. Study Subjects

This study analyzed the raw data of the 2016 Seoul Panel Study Data (SPS-data). The SPS-data was carried out from June 1 to August 31, 2016, for understanding the status of the welfare vulnerable class living in Seoul and estimating the welfare level of citizens. The population was the households living in Seoul at the time of the 2005 Population and Housing Census, a complete enumeration census. The sample was extracted from the census data using the randomized stratified sampling method for 25 districts in Seoul. This study excluded those who were imprisoned, were admitted to a nursing hospital, or moved to a silver town, and foreigners. As for the survey method, the interviewer visited the target household and conducted a computer-aided personal interview. This study analyzed 851 older-old people who resided in the community and completed the survey.

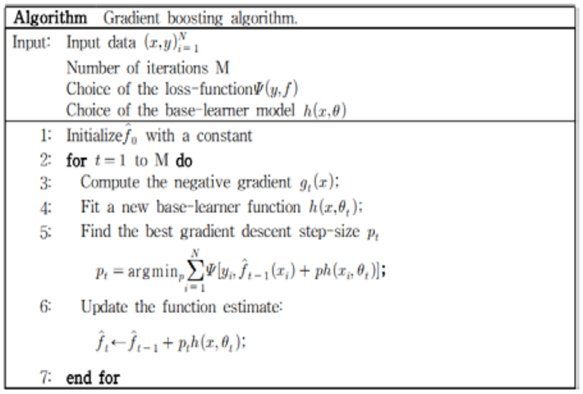
B. Measurements and Definitions of Variables

Subjective health status, outcome variable, was measured on a 5-point Likert scale (very good, good, moderate, bad, and very bad). Explanatory variables included age, sex, smoking (smoker or non-smoker), drinking (once a week or less or more than twice a week), economic activity (yes or no), mean monthly household income (less than KRW 1.5 million, KRW 1.5-3 million, or KRW 3 million or more), educational level (elementary school graduation and below, middle school graduation, high school graduation, or college graduation or above), social activities in the past month (yes or no), living with a spouse (living together, bereavement/separation, or single), disease/accident/addition experience in the past two weeks (yes or no), subjective stress recognition (yes or no), number of accompanying chronic diseases, body mass index, number of days walking for 30 minutes or more (1 or less than day per week or 2 days per week or more), depression, subjective oral conditions, self-perceived diet, frequency of meeting with neighbors (once a month or less or more than twice a month), and meeting frequency with relatives (once a month or less or more than twice a month).

The number of chronic diseases (e.g., diabetes, hypertension, and hyperlipidemia) was classified into none, 1, 2, and 3 or more. The body mass index (BMI) was classified as "underweight" when it was less than 18.5, "normal" when it was 18.5 or more and less than 25, "overweight" when it was 25 or more and less than 30, and "obesity" when it was 30 or more. Subjective stress was defined as a "high-stress group" when the respondents said they felt a lot of stress and a "low-stress group" when they answered that they felt a little stress. Depressive symptoms were classified as "depressed" when feeling depressed for more than two weeks in a row and "not depressed" when not feeling depressed for two weeks or more in a row. Subjective oral conditions were defined as "good", "normal", and "bad". The self-perceived dietary life was classified into "sufficient diet life" when the respondents answered "ate enough quantity of food and a variety of foods in the last year" or "ate enough quantity of food and not various foods" and "insufficient diet life" when they answered "insufficient food from time to time due to economic difficulties" or "frequently insufficient food due to economic difficulties".

C. Development of Prediction Models: GBM

GBM is a machine learning algorithm that creates a strong learner by combining weak learners of a decision tree by using an ensemble technique [26]. This model generalizes the model by generating a model for each step like other boosting methods and optimizing a loss function that can be arbitrarily differentiated. A model is created, even if the accuracy is low, and the errors of the generated model are compensated by the following model. Through this process, the accuracy of the current model becomes better than that of the previous model: a more accurate model (or a stronger learner). The basic principle is to increase accuracy by repeating this process. GBM's algorithm is presented in Fig. 1.



```
Algorithm  Gradient boosting algorithm.
Input:  Input data $(x,y)_{i=1}^{N}$
        Number of iterations M
        Choice of the loss-function$\Psi(y,f)$
        Choice of the base-learner model $h(x,\theta)$
Initialize$\hat{f}_0$ with a constant
for $t=1$ to M do
    Compute the negative gradient $g_t(x)$;
    Fit a new base-learner function $h(x,\theta_t)$;
    Find the best gradient descent step-size $p_t$
        $p_t = \arg\min_p \sum_{i=1}^{N} \Psi[y_i, \hat{f}_{t-1}(x_i) + ph(x_i,\theta_t)]$;
    Update the function estimate:
        $\hat{f}_t \leftarrow \hat{f}_{t-1} + p_t h(x,\theta_t)$;
end for
```

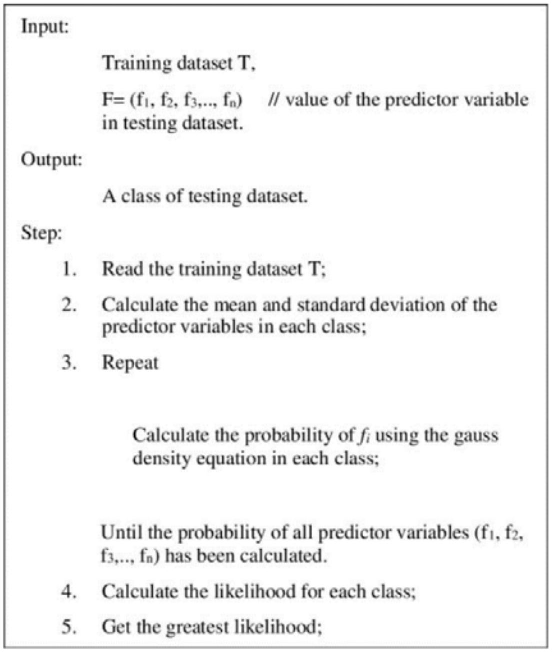
Fig. 1. Algorithm of GBM [26].

D. Naïve Bayes Classification

Naïve Bayes classification is a method of classifying observations into different groups using Bayes theory (Fig. 2)[27]. Bayes theory refers to a way of calculating the posterior probability by using an observation when there is a prior probability.

E. CART

CART is one of the analysis algorithms of the statistical decision classification model, which measures impurity using the Gini Index [28]. It is an algorithm based on a binary split, which generates only two child nodes from a parent node [28]. The advantages of CART are that it is easy to interpret the generated rules and can analyze both continuous and categorical variables. For continuous variables, a separation rule is created in the form of "$X \leqslant C$?" or "$X \geqslant C$?" [28]. For categorical variables, a rule of binary separation is created in the form of "$X \in \{A, B\}$" [28]. In the model of this study, the criterion for separating and merging decision rules for CART was set to 0.05. The number of child nodes was limited to 100, the number of parent nodes was limited to 200, and the number of branch branches was limited to 5.



```
Input:
        Training dataset T,
        F= (f1, f2, f3,.., fn)    // value of the predictor variable
        in testing dataset.
Output:
        A class of testing dataset.
Step:
    1.  Read the training dataset T;
    2.  Calculate the mean and standard deviation of the
        predictor variables in each class;
    3.  Repeat

            Calculate the probability of $f_i$ using the gauss
            density equation in each class;

        Until the probability of all predictor variables (f1, f2,
        f3,.., fn) has been calculated.
    4.  Calculate the likelihood for each class;
    5.  Get the greatest likelihood;
```

F. Deep Neural Network

Deep neural network is an algorithm made up of an input layer composed of independent variables, an output layer composed of dependent variables, and two or more hidden layers between the input and output layers [29]. Each layer has independent nodes and a node is connected to other nodes in other layers by weighted neurons (connecting lines) (Fig. 3).

This study used H2O Deep Learning among various deep learning types. H2O's Deep Learning is based on a multi-layer feedforward artificial neural network that is trained with stochastic gradient descent using back-propagation.

In this study, the number of hidden layers was set to 2, nodes of each layer were set to 10 (total of 20), and epochs (number of repetitions) were set to 5. In this study, a model was developed using the Rectifier Linear Unit (ReLU) designated as a default as the active function of deep learning (Fig. 4).

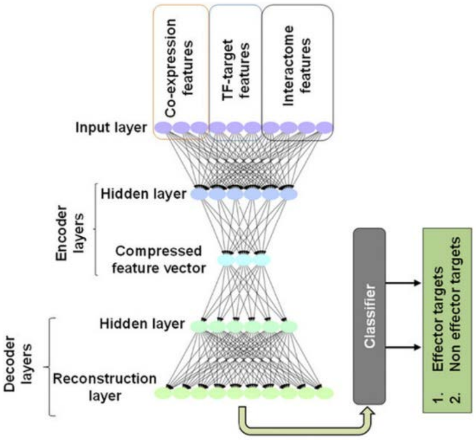

Fig. 3. The Concept of Deep Neural Network [30].

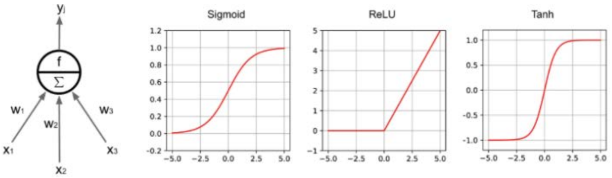

Fig. 4. The Widely used Nonlinear Activation Function of Deep Neural Networks [31].

G. Random Forest

Random Forest is an ensemble method that learns an independent decision tree for each sample after generating a large number of random samples from training data using bootstrap (conduct random restoration sampling of the same sample size from a given data) and decides a final model by synthesizing the results (Fig. 5).

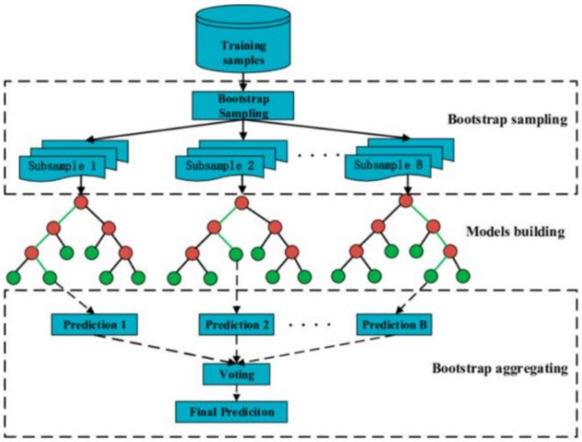

Fig. 5. The Concept of the Random Forest Model [32].

H. Validation of the Prediction Models

This study developed models for predicting the subjective health of the older-old using GBM, naive Bayes model, cart, deep neural network, and random forest. This study compared the accuracy, sensitivity, and specificity of the developed models to evaluate their prediction performance. This study conducted 5-fold cross-validation to validate the developed models.

In the analysis stage, models containing randomness, such as a random forest, were developed while fixing the seed number to "9876543". This study defined the model with the highest accuracy as the best prediction model (best prediction performance) after comparing prediction performance. If two models had the same accuracy, a model with a higher sensitivity was defined as a better prediction model. All analyzes were performed using R version 3.6.2 (Foundation for Statistical Computing, Vienna, Austria).

III. Results

The accuracy of five models (GBM, naive Bayes model, cart, deep neural network, and random forest) for predicting the subjective health of the older-old is presented in Fig. 6. The results of this study showed that the deep neural network with an accuracy of 0.75, a sensitivity of 0.73, and a specificity of 0.81 was the model with the best prediction performance.

The normalized importance of variables derived from deep neural network analysis showed that depression, subjective stress recognition, the number of accompanying chronic diseases, subjective oral conditions, and the number of days walking more than 30 minutes were major predictors for the subjective health of the older-old (Fig. 7). Among them, depression had the highest importance (Fig. 7).

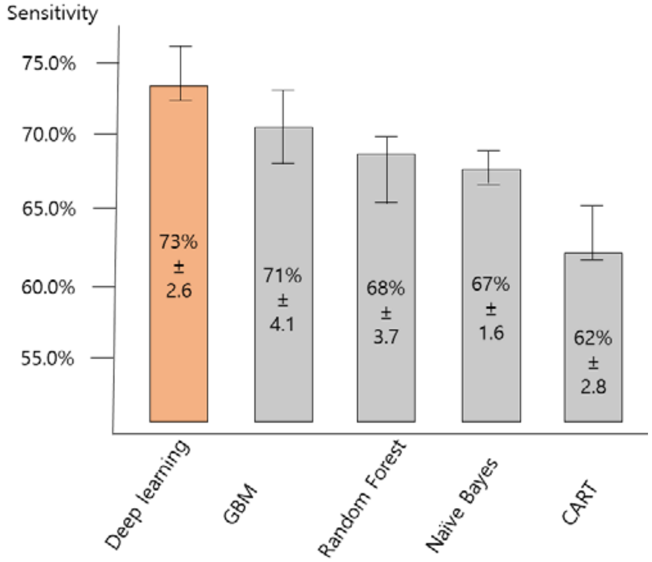

Fig. 6. Comparing the Sensitivity of a Machine Learning Model and a Deep Learning Model for Predicting the Subjective Health of the Older-Old.

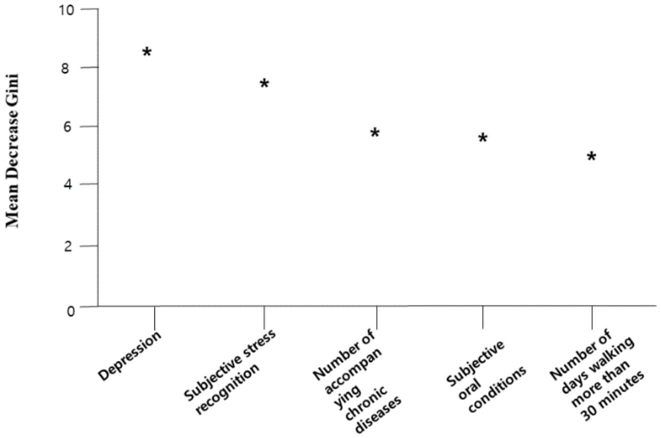

Fig. 7. The Importance of Variables in the Prediction Model for the Subjective Health of the Older-Old (Only the Top 5 Variables are Presented) Conclusions.

IV. Conclusions

This study compared the accuracy of prediction models for the subjective health of the older-old in South Korea and confirmed that the deep neural network-based prediction model had the best prediction performance among GBM, naive Bayes model, cart, deep neural network, and random forest. These results are consistent with the results of da Silva et al. [33], which predicted the health condition of the elderly and showed that the performance of deep learning was superior to that of machine learning methods such as naive Bayes, J48 Decision Tree, and SVM.

Another finding of this study is that depression, subjective stress recognition, number of accompanying chronic diseases, subjective oral conditions, and the number of days of walking more than 30 minutes were identified as the main predictors for the subjective health of the older-old. The result was different from the previous studies [34,35,36] that identified the subjective health of the elderly using regression analysis and reported that social network (e.g., the presence of a spouse), education level, job status, and household income level were the main factors for subjective health. It is believed that these results reflected the interactions of the aging effect, period effect, and cohort effect, indicating the similar socioeconomic level of the older-old in South Korea, where unhealthy elderly people have already passed away. However, Kim et al. [37] evaluated the subjective health of the elderly and reported that the higher the household income level improved the satisfaction of subjective health. Further studies are needed to identify factors associated with the subjective health of the older-old with considering the age-period-cohort effects. Furthermore, additional studies are needed to compare prediction performance such as accuracy, sensitivity, and specificity using data of various diseases in order to prove the effectiveness of deep learning in epidemiological data.

Propose Vulnerability Metrics to Measure Network Secure using Attack Graph

Zaid. J. Al-Araji[1], Sharifah Sakinah Syed Ahmad[2], Raihana Syahirah Abdullah[3]
Faculty of Information Communication Technology
Universiti Teknikal Malaysia, Melaka
Melaka, Malaysia

***Abstract*—With the increase in using computer networking, the security risk has also increased. To protect the network from attacks, attack graph has been used to analyze the vulnerabilies of the network. However, properly securing networks requires quantifying the level of security offered by these actions, as you cannot enhance what you cannot measure. Security metrics provide a qualitative and quantitative representation of a system's or network's security level. However, using existing security metrics can lead to misleading results. This work proposed three metrics, which is the Number of Vulnerabilities (NV), Mean Vulnerabilities on Path (MVoP), and the Weakest Path (WP). The experiment of this work used two networks to test the metrics. The results show the effect of these metrics on finding the weaknesses of the network that the attacker may use.**

Keywords—Attack graph; security metrics; attack path; path analysis; attack graph uses

I. Introduction

Nowadays, the use of network technology has increased [1], [2]. Nonetheless, since the network is advantageous for people to live and work in, it also carries security problems that must not be overlooked [2]. In many key computer systems and applications, security has been and will remain a major concern. A comprehensive cybersecurity attack will significantly harm the target system as well as the credibility of the businesses or organizations that use it [3]. An attacker may use such attacks to get access to private data, degrade network performance, and eventually take complete control of the targeted system. To detect or protect the network from attacks, the researchers have used many methods [4]. One of these methods in vulnerabilities analysis is an attack graph.

Attack graph has been used for the first time by Philips and Swiler [5], [6]. Since then, researchers have suggested many methods to produce an attack graph. For example, Ammann et al. (2002) proposed the generation method based on monotonicity [7], while Vaibhav Mehta et al. (2006) proposed a ranking attack graph relying on graph neural network (GNN) [8]. Furthermore, Apart from that, Yun Chen et al. (2017) proposed an attack graph generation algorithm relying on a supervised Kohonen neural network [9], while HengLi et al. (2017) introduced a searching forward complete attack graph generation algorithm depending on hypergraph partitioning [10]. Also, Bintao Yuan et al. (2020) introduced the network vulnerability assessment method depending on the graph database and elaborated its efficacy in solving state explosion and other methods [11].

An attack graph may be utilized for many reasons, with positive or negative consequences [13]. Typically, attack graphs are used by researchers to improve the network's security. One of these applications is the computation of network security metrics. Attack graphs may be employed to generate network security metrics to analyze the target network's overall security. These metrics may be utilized to assess the target network's security risk. National Institute of Standards and Technology (NIST) describes security metrics as techniques that gather, analyze, and report pertinent performance-related data to aid decision-making, maximize performance, and increase transparency [12].

There are many security metrics proposed by researchers, such as Shortest Path (SP) Metric, Mean of Paths Length (MoPL) Metric, Number of Paths (NP) Metrics, etc. Some are combined to get new metric with new features and better results, like combining NP and MoPL to get Standard Deviation of Path Lengths (SDPL) Metric proposed by [13].

In[14], the authors divided the attack graph-based security metrics into two types, which are host and network-based metrics. Host-based security measures the level of security of individual hosts in a network. The host-based is divided into two types, which are with and without probability. Meanwhile, the network-based uses the structure of a network to aggregate the network's security property. This type of metrics is classified into two categories, which is path and non-path metrics.

However, using these metrics sometimes gives misleading results, failing to sufficiently account for the number of ways an attacker violates a security policy. In this case, not only the number of the ways but the accuracy is also responsible. For example, the shortest path is not necessary to be the path used by the attacker. It also does not take into account the attack effort connected to the attack paths.

In this paper, three metrics are proposed, which are Number of Vulnerability (NV) Metric, Mean Vulnerabilities on Path (MVoP) Metric, and Weakest Path (WP) Metric to reduce the misleading of the security metrics. The NV and MVoP will view how strong the network is and indicate how much effort the attacker needs to breach network security. On the other hand, it will also measure how much effort is required by the administrator to guard the network from any attacker. Meanwhile, the WP metric views the network's weakest path, which allows the attacker to breach the network policy with minimum effort.

The remainder of the paper is laid out as follows. Section 2 presents the attack graph overview, while Section 3 gives the security metrics related work, Section 4 proposes the security metrics, Section 5 is the experiment performed and results, while Section 6 gives the conclusion.

II. Attack Graph Background

The concept of attack graph has been proposed by Philips and Swiler [15], As shown in Fig. 1. Since then, many researchers have generated attack graphs differently using different methods to improve the attack graph. It is a security model denoting the chains of vulnerabilities, where exploits in the network can be in various forms. The attack graph representation can be organized [16] as a state-oriented, exploit-oriented, or state-exploit-oriented attack graphs [17]. Attack graph generation helps merge low-level vulnerabilities to display all attack paths from source to network goals. By examining the exploited attack paths, security experts should concentrate on patches or configuration bugs that present greater risks. The probabilistic attack graph's risk assessments support such decisions even more [18].

Attack graph generation has three steps which are reachability, attack model, and core building. The attack graph reachability explores the conditions of accessibility in the network, defining whether two given devices could reach one another. The most common representation of network reachability data is a reachability matrix, in which the rows and columns represent the network's hosts. Moreover, each entry indicates the reachability condition between the hosts on the corresponding row and column, respectively [20]. Various connections between the hosts may be represented by a reachability matrix, including transport, network, physical, and application-level connections. Its spatial complexity is on the order of the square of the network's number of hosts [20].

The second phase is the attack model. Attack graph modelling deals with the modelling of attack templates, determining attack graph structure, and modeling networks. The attack template modelling comprises the representation of pre- and post-conditions for the vulnerability. It also provides a process by which information in public vulnerability and weakness databases can be extracted from these conditions for particular vulnerabilities [20].

The attack graph structure's determination involves determining which node and edge types could be contained in the attack graph. Network modelling aims to define a suitable representation of network information [6]. The third phase is the attack graph core building, which denotes the main algorithm employed to develop the attack graphs. Many paths will be pruned in this stage during creating the resulting attack graph in this process [20]. From two different viewpoints, an attack graph core building mechanism could be taken into account. One is the method of evaluating the attack paths, and the other is the method of pruning the attack paths [20].

Generating an attack graph may be utilized for various reasons comprising negative or positive impacts. According to [20], attack graph can be used in four prespectives as in Fig. 2.

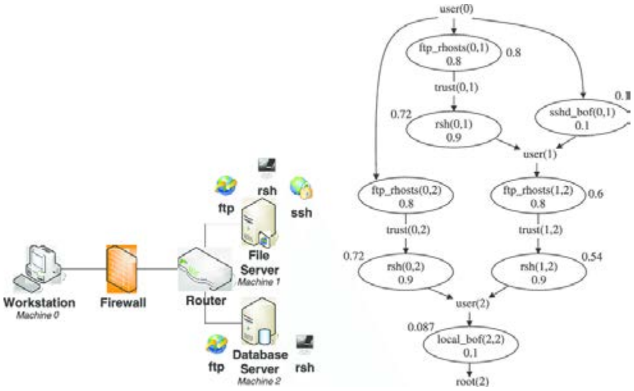

Fig. 1. An Attack Graph Sample [19].

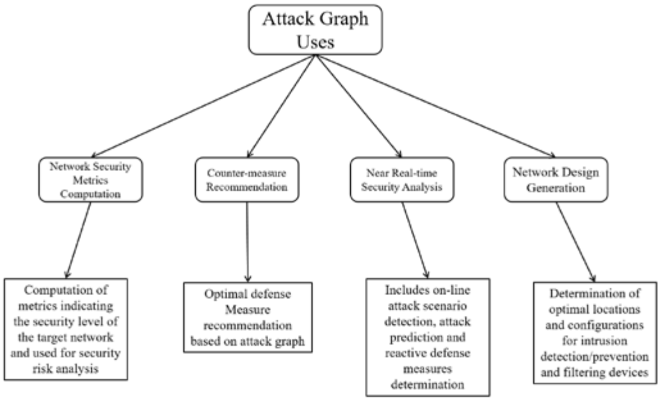

Attack Graph Uses
Network Security Metrics Computation
Counter-measure Recommendation
Near Real-time Security Analysis
Network Design Generation
Computation of metrics indicating the security level of the target network and used for security risk analysis
Optimal defense Measure recommendation based on attack graph
Includes on-line attack scenario detection, attack prediction and reactive defense measures determination
Determination of optimal locations and configurations for intrusion detection/prevention and filtering devices

Fig. 2. Attack Graph uses [20].

Attack graphs can be used for recommending near optimal security defense counter-measures. Optimal counter-measure recommendation can also find practical usage for determining proactive defense recommendations. It can also use the attack graphs generated by accounting for the goal privileges pointing to critical network resources [21].

Another use for the attack graph is network design generation can find practical use in locating the intrusion detection/prevention systems and firewalls optimally in the target network. It can also be used to determine firewall and access control rules, if necessary support for resolving conflicting rules and processing different custom rule formats is provided [17].

Attack graphs can be used for on-line security situational assessment (monitoring) and detecting ongoing attack scenarios by performing highlevel correlation and aggregation of the intrusion alerts and system logs collected throughout the target network. The detected attack scenarios can be used to perform future attack predictions and determine reactive defense measures [17].

Attack graphs also can be used to derive network security metrics used for global security assessment of the target network. These metrics can be used to perform security risk analysis for the target network. Each node (generally indicating a network state) and each edge (generally indicating a vulnerability exploit) on the attack graph can be assigned a probability of occurrence. A node can also be assigned a possible damage value, if the corresponding network state for the node indicates the compromise of some information source for a network host. From these probability and damage values, the cumulative risk values are computed for each network state on the attack graph [17]. In this paper, we will use the attack graph to derive the security metrics.

III. Security Metrics

Metrics, as defined by the NIST, are instruments that gather, analyze, and report applicable performance-related data to aid decision-making and increase performance and transparency. Comprehensive network security and CSA management necessitate the use of security metrics [12].

Security metrics have different categories. Based on Nwokedi C. Idika [22], security metric can be classified into two main classes, which are primary and secondary as in Fig. 3. The primary security metric classes are architectural-based security metrics and performance-based security metrics. The difference in the two classes stems from the type of attributes they measure. Architectural-based metrics measure internal attributes. Performance-based metrics measures external attributes. The secondary security metric classes are security metrics, complexity-based security metrics and time-based security metrics. These metrics can be applied to internal and external attributes of a network. Most of the primary class belong to secondary class as well but not all metrics belong to a primary class but not necessarily a secondary class.

Attack graph-based security metrics is a type of architectural metric [22]. It is a value produced from measuring the internal attributes of a network that affect IT security or operational security. The values are derived from generating an attack graph and subsequently deploying an analysis over the attack graph. This analysis is the measurement that produces the attack graph-based security metric [22].

According to Enoch et al. (2017) attack graph security metrics can be divided to two categories depending on the network reachability which are Host-based and Network-based as in Fig. 4 [23].

The host-level metrics are used to quantify the security level of individual hosts in a network. The host based metrics are classified to two categories which are security metrics with probability and security metrics without probability [24]. The classification had been done because sometimes it is infeasible to find a probability value for an attack, and some analysis and optimisation can be done with or without probability assignments [20].

The network-level metrics are used the structure of a network to aggregate the security property of the network. The network-based security can be classified to two categories which are security metrics path-based and security metrics non path-based. Path based metrics use the reachability information of a network to quantify the security level of the network. While in non path-based metrics, the structure and attributes of a network are not considered; instead, the security of a network is quantified regardless of the network structure [22]. Researchers had proposed many metrics. In this section, some of the previous works will be explained.

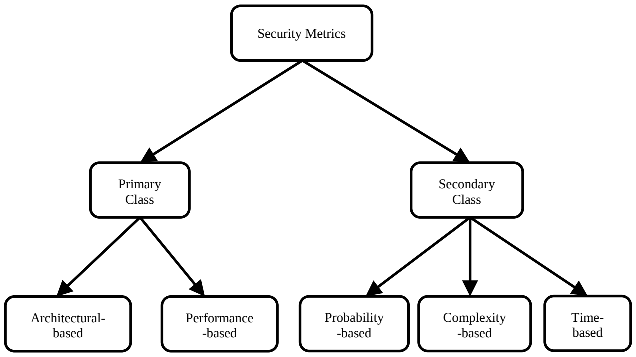

Fig. 3. Security Metrics Classification [22].

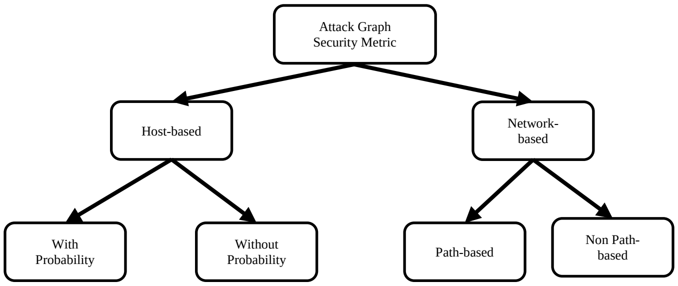

Fig. 4. Attack Graph Security Metrics Classification [23].

Phillips and Swiler (1998) proposed the Shortest Path (SP) Metric. The shortest attack path is the one that takes an attacker from his initial state to his desired goal state using the shortest distance. The length function used to calculate the distance is determined by the security engineer who conducts the attack graph analysis. Nonetheless, this metric does not signify the number of shortest paths in a network. Also, there is no guarantee that the short path is the path used by the attacker [5]. Because of the metric is depending of the length of the path, this metric is path-based metric.

Moreover, Ortalo (1999) suggested the Number of Paths metric (NP). The number of attack paths in a given attack graph is expressed by this security metric. It measures how vulnerable a network is to be attacked. A larger Number of Paths metric suggests a more exposed network. This metric, however, does not account for attack effort, implying that two networks with the same number of attack paths are considered to be of equal security [25]. This metric is path metric because it counts the network paths.

Furthermore, Idika details the Mean of Path Lengths metric (MPL), first introduced by Wei Li (2006) as the Average Path Length metric [26]. It calculates the arithmetic mean of all path lengths to reflect the typical path length. It also estimates how much effort an attacker would impose to break a network security policy. Since an attacker may not have the same perspective of known vulnerabilities as a security engineer, this metric is important. Because of this lack of experience, the attacker may pick a path that is not the shortest. Alternatively, an attacker may choose the other path because the attacker believes the security engineer is using the shortest path analysis. However, this metric cannot be applied alone because it depends on the NP metric [13]. This metric is considered as path metric because it calculate the average of the path length of the network.

These security metrics can be used to retrieve security-relevant data, but they can also produce false results. The Shortest Path and Mean of Path Lengths metrics do not account for all the possible ways an attacker would break a security policy. The attack effort related to the attack paths is not fully accounted for by the Number of Paths metric. To overcome these problems, this work proposes three metrics, which is NV, MVoP, and WP explained in the next section.

IV. Proposed Metrics

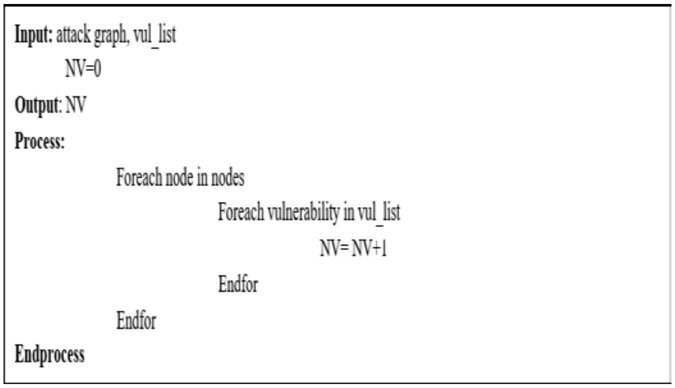
In this section, three attack graph-based security metrics will be proposed: Number of Vulnerabilities Metric (NV), Mean of Vulnerabilities on Path Metric (MVoP), and Weakest Path Metric (WP).

A. Number of Vulnerabilities (NV) Metric

The Number of Vulnerabilities (NV) Metric represents the number of weakness in each node of the network that an attacker can use to cross privilege boundaries in the network. This metric aims to understand the number of disadvantages in the network and allow the administrator to fix it and compare the security of two networks with different size and topology. The formalization of the NV metric is presented in equation 1:

$$NV = \sum V(p_1, p_2, \dots, p_n) \tag{1}$$

Here, V represents the vulnerabilities, p represents the path, and n denotes the number of nodes. Thus, the metrics will calculate the vulnerabilities for each path starting from p_1 to p_n. The pseudocode of NV metric calculation is in Fig. 5. Basically the input in the pseudocode is the attack graph to select all the nodes and the vul_list which represent the vulnerabilities list. The process is so simple is to select a node from all the nodes in the attack graph and calculate the number of vulnerabilities in that node and add them to the counter. This metric is host-based and without probability metric because this metric calculate the vulnerabilities from the host.



```
Input: attack graph, vul_list
      NV=0
Output: NV
Process:
            Foreach node in nodes
                        Foreach vulnerability in vul_list
                                    NV= NV+1
                        Endfor
            Endfor
Endprocess
```

Fig. 5. NV Metric Calculation.

B. Mean Vulnerabilities on Path (MVoP) Metrics

The Mean Vulnerabilities on Path (MVoP) metric represents the average number of the path's vulnerabilities. This metric indicates how much effort an attacker would have to put in to break a network security policy. It also provides a view for the defender to expect the attacker's move. The formalization of the NV metric is presented in equation 2:

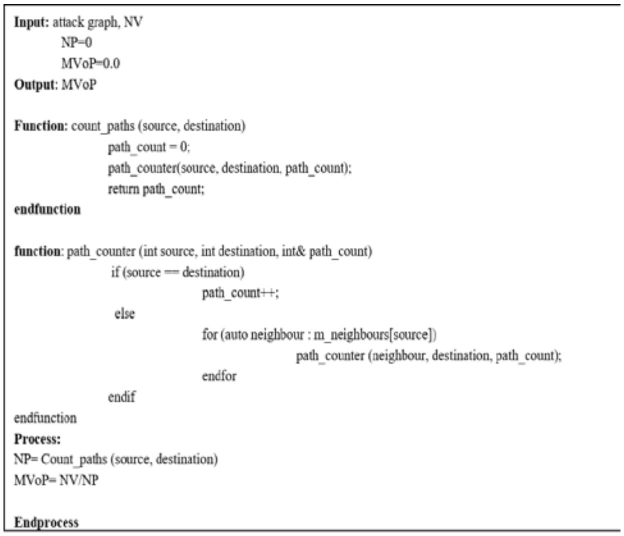
$$MVoP = \frac{NV}{NP} \tag{2}$$

where NV implies the number of vulnerabilities on the network, while NP is the number of the network paths. The formalization of NP is presented in equation 3:

$$NP = |p_1, p_2, \dots ., p_k| \tag{3}$$

where p represents the path and k represents the number of the path. Fig. 6 shows the NP and MVoP metrics calculation. To calculate MVoP metric, we need to calculate NV and NP metrics. The NV metric has been calculated above (see Section 4.1). In this section, we will calculate the NP metric.

The calculation of NP metric is depending on the edges between the nodes, basically each node has many edges with other nodes, to calculate this edges, we used edges list for each node, the we start counting the path from the source to destination using edge list. During the calculation the source change depending on the edge list until the source equal the destination which is mean it is a path. After calculating the numbe of the path, we calculate the MVoP by dividing NV on NP. This metric is considered as path-based and without probability metric because it calculate the vulnerabilies number from the host and calculate the path number from the network.



```
Input: attack graph, NV
      NP=0
      MVoP=0.0
Output: MVoP

Function: count_paths (source, destination)
            path_count = 0;
            path_counter(source, destination, path_count);
            return path_count;
endfunction

function: path_counter (int source, int destination, int& path_count)
            if (source == destination)
                        path_count++;
            else
                        for (auto neighbour : m_neighbours[source])
                                    path_counter (neighbour, destination, path_count);
                        endfor
            endif
endfunction
Process:
NP= Count_paths (source, destination)
MVoP= NV/NP

Endprocess
```

Fig. 6. MVoP Metric Calculation.

C. Weakest Path (WP) Metric

The Weakest Path (WP) Metric is similar to the shortest path metric but in another term, which is the network's strength. The path's strength does not depend on the NV only but also on the score of vulnerability itself. The vulnerability score can use the CVSS that NIST had invented. The formalization of calculating the path score using CVSS is presented in equation 4:

$$V(p) = \frac{\sum_{k=1}^{k=n} CVSS(v(a,b))}{n}, \tag{4}$$

where p represents the path, v represents the vulnerability between node a and b, k denotes the number of the nodes in the path, and n refers to the number of the nodes. Basically, the equation calculates the average score of each vulnerability in the path.

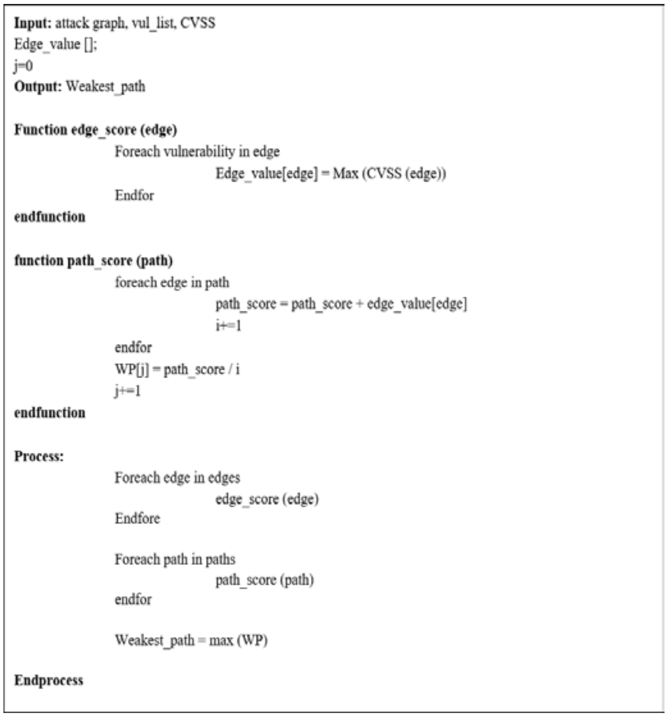
After calculating the path vulnerability score, the score results are compared between all paths in the network to represent the weakest path. The formalization of the WP metric is defined in equation 5:

$$WP = \max\big(V(p_1), V(p_2), \ldots, V(p_k)\big) \qquad (5)$$

where p represents the path, k represents the path number, and $V(p_k)$ represents the summation of the path vulnerabilities score. The calculation of the WP metric in Fig. 7.

The calculation of the weakest path is depending on the value of each edge in the path. To calculate the edge value, we need to find the vulnerabilities score of the edge, so the input will be the attack graph, vulnerabilities list and vulnerability score (CVSS). Then we calculate the edge score by finding the maximum vulnerability score in edge.

After calculating the edge value, the path score will be calculated. Basically, the value of the path will be the average number of edge value in the path. The path score will be saved to compare it with other paths score to find the weakest. The highest path score in the paths will be the weakest path in the network. This metric is considered as path-based metric because it calculate the path score.



```
Input: attack graph, vul_list, CVSS
Edge_value [];
j=0
Output: Weakest_path

Function edge_score (edge)
        Foreach vulnerability in edge
                Edge_value[edge] = Max (CVSS (edge))
        Endfor
endfunction

function path_score (path)
        foreach edge in path
                path_score = path_score + edge_value[edge]
                i+=1
        endfor
        WP[j] = path_score / i
        j+=1
endfunction

Process:
        Foreach edge in edges
                edge_score (edge)
        Endfore

        Foreach path in paths
                path_score (path)
        endfor

        Weakest_path = max (WP)

Endprocess
```

Fig. 7. WP Metric Calculation.

V. Experiment and Results

In this section, the experiment of the three metrics had been done. The experiment used two attack graphs generated with two different networks. In the following, the network's topology will be explained. Then, the results of applying the metrics will be discussed.

A. Network Design

In this experiment, we chose two networks to test the effect of our proposed metrics. The network A has two workstations, three servers, a firewall and an external attacker, as in Fig. 8. The network connectivity in this network topology depends on firewall rules given as follows:

- There is bidirectional connectivity between the webserver and other machines in the network.
- The external host is the attacker located on the internet and has access to the webserver through HTTP protocol and HTTP port.
- The two workstations and fileserver have access to each other through NFS protocol and NFS port.
- The two workstations and fileserver have access to the internet through HTTP protocol and HTTP port.
- The two workstations have access to the database server.

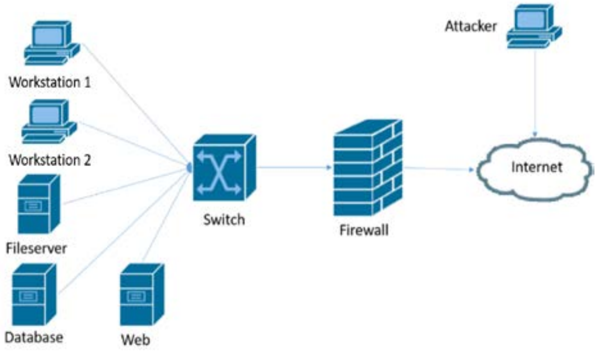


Fig. 8. Network a Topology.

Meanwhile, the network B has two workstations: a web server and database server and an attacker, as in Fig. 9. The network connectivity in this network topology depends on firewall rules listed as follows:

- There is bidirectional connectivity between the webserver and other machines in the network.
- The external host is the attacker located on the internet and has access to the webserver through HTTP protocol and HTTP port.
- Workstation 4 has access to the database server.
- All workstations have access to the internet through HTTP protocol and HTTP port.
- All workstation has a connection with each other.

The experiments evaluated the generating attack graph in the following environment. The CPU is core i5 2.0 GHz with 8 GB of RAM, the operating system is windows 10, and the coding was performed using Microsoft Visual Studio C# 2012. Also, the Common Vulnerabilities and Exposures (CVE) and National Vulnerability Database (NVD) lists were employed, which were provided by NIST to load the vulnerabilities to the attack graph.

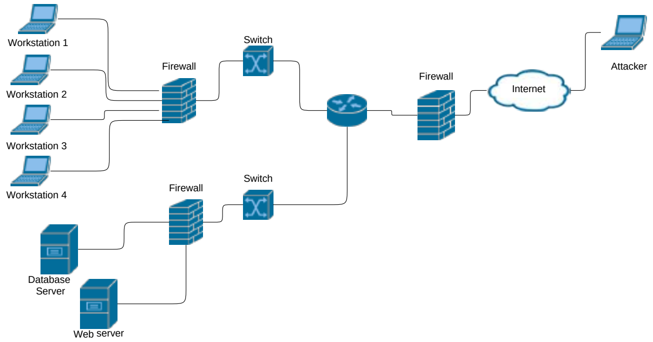

Fig. 9. Network B Topology.

B. Results

In this section, the findings of the experiment will be discussed. Before explaining the results, the paths from the started node (the attacker) to the targeted node (database server) in both networks and list of vulnerabilities must be identified.

The number of the paths in network A is four (4) paths, while the network B has 14 paths, as illustrated in Table I. The paths extracted from the networks based on the topology of the networks.

Here, A represents the word Attacker, W represents the word webserver, D represents the word database, and the numbers represent the workstations. The Attacker can reach the workstations through the webserver only. In this case the next step for the Attacker is webserver. While the webserver has bidirectional connection to the workstations, but the webserver cannot reach directly to the database server which only can be reached by both workstations in network A and workstation 4 in network B, in this case the Attacker need to conquest the workstations before can conquest the database server by exploit the vulnerabilities in the network.

A vulnerability is identified by CVE as a weakness in the computational logic (e.g., code) found in software and hardware components. Usually, the node can have more than one vulnerability because it depends on the applications that installed and the hardware is used. This section will explain some of these vulnerabilities that found in network A and network B as in Table II.

The first vulnerability that discovered is CVE-2010-0490, this weakness in Internet Explorer 6, 7 and 8 with the possibility that remote intruder can execute arbitrary code on the target machine. While CVE-2014-2510 in the outlook, this vulnerability remote authenticated users to read arbitrary files via an external entity declaration in conjunction with an entity reference. The next vulnerability is CVE-2018-15983 in adobe flash player, this vulnerability has an insecure library loading (dll hijacking) vulnerability. Successful exploitation could lead to privilege escalation. The CVE-2010-0483 vulnerability discovered in VBScript, this vulnerability might allow user-assisted remote attackers to execute arbitrary code via a long string in the fourth argument (aka helpfile argument) to the MsgBox function.

1) *NV and MVoP:*

Upon implementing the NV metric on both graphs, the results show that the network A has more vulnerabilities than the network B, as displayed in Table IV. Even the network B has more nodes than the network A, but it has fewer vulnerabilities than the network A. The reason is that the nodes can have more than one vulnerabilities at the same time. Depending in this metric network B is more secure than network A, unlike NP metric which shows than network A is more secure than network B. The reason of the different between two metrics which is the NV metric is depending on the weaknesses of the network not like NP metric which depend on the paths only.

Also, for the MVoP metric, the network A has more vulnerabilities in each path than the network B. The reason for that is the network A has few paths and more vulnerabilities than the network B, as displayed in Table III. The result of MVoP metric shows that network B is more secure than network A, unlike MPL metric which shows network A is more secure. The reason is MVoP depends on the average number of the weaknesses in the path, while MPL depends on the average length of the paths.

TABLE I. PATHS OF THE NETWORKS

No	Network A paths	Network B paths
1	A-W-1-D	A-W-4-D
2	A-W-2-D	A-W-1-4-D
3	A-w-1-2-D	A-W-2-4-D
4	A-W-2-1-D	A-W-3-4-D
5	-	A-W-1-2-4-D
6	-	A-W-1-3-4-D
7	-	A-W-2-1-4-D
8	-	A-W-2-3-4-D
9	-	A-W-3-1-4-D
10	-	A-W-3-2-4-D
11	-	A-W-1-2-3-4-D
12	-	A-W-1-3-2-4-D
13	-	A-W-2-1-3-4-D
14	-	A-W-2-3-1-4-D
15	-	A-W-3-1-2-4-D
16	-	A-W-3-2-1-4-D

TABLE II. EXAMPLE VULNERABILITIES

No	Vulnerability	CVSS Score
1	CVE-2010-0490	9.3
2	CVE-2014-2510	6.8
3	CVE-2018-15983	7.8
4	CVE-2010-0483	7.6

TABLE III. METRICS IMPLEMENTATION RESULTS

Metrics	Network A	Network B
NV	18	15
MVoP	4.5	1.07
NP	4	16
MPL	3.5	5.06

The result of NP metric and MPL metric are not accurate enough of measuring the strength of the network because they do not see the detail of the network, while NV and MVoP metrics are more accurate because of calculating the weaknesses of the network.

2) WP metric: For the third metric, WP metric, the experiment compares the path's strength between the same network paths. To calculate the path strength, the metric takes the highest score vulnerability in the link between two nodes to determine the path's score. Table IV shows the score between all links in both networks.

The results of the edges strength had been calculating depends on the highest vulnerability score in the edges. There are many vulnerabilities had been dropped in the calculation because the score of these vulnerabilities is smaller than the vulnerabilities that been calculated because we assumed that the vulnerabilities that have higher score are more danger and have a high chance to be exploit by the attacker. Based on these edges scores, the weakest path had been calculated as in Table V.

Table VI shows that path number 2 in the network A and path number 8 in the network B has the highest number of WP metric calculation, implying the weakest path in the network.

Comparing with SP metric, the results show that WP metric are more specific, accurate and effective, as in Table VI.

TABLE IV. EDGE VULNERABILITY SCORE

No	Network A links score	Link Score	Network B links score	Link score
1	A-W, W-A	9.8	A-W, W-A	9.2
2	1-2, 2-1	7.8	1-2, 2-1	5.4
3	W-1, 1-W	6.2	1-3, 3-1	8.1
4	W-2, 2-W	8.1	1-4, 4-1	7.2
5	1-D, D-1	6.8	2-3, 3-2	8.1
6	2-D, D-2	8.8	2-4, 4-2	6.4
7			3-4, 4-3	7.8
8			W-1, 1-W	7.3
9			W-2, 2-W	7.8
10			W-3, 3-W	6.1
11			W-4, 4-W	6.4
12			D-4, 4-D	8.1

TABLE V. WP METRIC SCORE FOR BOTH NETWORKS

Number	Network A path	WP metric	Network B path	WP metric
1	A-W-1-D	7.6	A-W-4-D	7.9
2	A-W-2-D	8.9	A-W-1-4-D	7.95
3	A-W-1-2-D	8.15	A-W-2-4-D	7.87
4	A-W-2-1-D	8.12	A-W-3-4-D	7.8
5	-		A-W-1-2-4-D	7.28
6	-		A-W-1-3-4-D	8.1
7	-		A-W-2-1-4-D	7.5
8	-		A-W-2-3-4-D	8.2
9	-		A-W-3-1-4-D	7.74
10	-		A-W-3-2-4-D	7.58
11	-		A-W-1-2-3-4-D	7.65
12	-		A-W-1-3-2-4-D	7.86
13	-		A-W-2-1-3-4-D	7.73
14	-		A-W-2-3-1-4-D	8.08
15	-		A-W-3-1-2-4-D	7.21
16	-		A-W-3-2-1-4-D	7.35

TABLE VI. METRICS COMPARISON

Metric	Network A	Network B
WP	- A-W-2-D	A-W-2-3-4-D
SP	- A-W-1-D - A-W-2-D	A-W-4-D

The SP metric has two paths in the network A, causing misleading results, while the WP metric has been more specific and gets one path only. In the network B, the SP and WP metrics get different paths because the SP metric counts the node number between the started and targeted node. Simultaneously, the WP is more specific and calculates the vulnerability score in each link, giving the easiest path for the attacker to reach the target.

VI. CONCLUSION

In this paper, three metrics had been proposed, which is NV, MVoP, WP metrics. These three metrics depend on vulnerabilities as a major factor to measure the security of the network. The experiment had been performed in two attack graphs generated using two different networks. The results show that the network A has more vulnerabilities, while the MVoP is higher than the network B, even though it has more nodes and paths. For the last metric, the WP metric, the network's A result shows that the shortest path is the weakest path of the network while it was not the shortest path in the network B.

VII. Future Work

Further investigation and research are still required, especially in the flowing fields:

- The work developed using the metrics and the experiments will be performed for larger graphs.
- Also, we will attempt to combine the metrics to obtain better results.

***Abstract*—The popularity of digital games is increasing with a global market value of RM197.6 billion. However, the game produced locally still has no impact. One reason is that there is no emphasis on the game design process in the game development education program. Games designed have a problem in terms of creativity, and there is still no specific method of training creative thinking. This study aims to identify and validate game design's creativity components and develop a Creativity Training Model for Game Design (LK2RBPD Model) verified through the Game Design Document Tool (GDD Tool) prototype. This research has four main phases: the requirements planning, design, development, implementation, and testing phases. In the requirements analysis phase, the component of LK2RBPD Model was identified. The LK2RBPD Model contains elements from industry practices of game designing, creative and innovative thinking skills, creativity dimensions, Sternberg Creativity, and Cultural Activity theories. The GDD Tool prototype implementing the model was developed and tested. The LK2RBPD Model was evaluated using questionnaire survey, SWOT (Strengths, Weaknesses, Opportunities, and Threats) analysis, and verification of ideas in the GDD Tool prototype. Evaluation using a five-point Likert scale shows that GDD Tool prototype is effective in implementing 19 components. Expert verification on the results of game design ideas and creativity building using Cohen Kappa calculations is 0.94, indicating an excellent agreement. The results show that the LK2RBPD Model can be effectively used to train creativity in game design. This research's contributions are LK2RBPD Model, creative game design ideation process guideline, and GDD Tool prototype design.**

***Keywords*—Creativity training; game design; creative ideas; creative thinking**

I. Introduction

Technological change is very significant, especially in information and communication technology (ICT), which has led to rapid development in various fields and aspects of life [1]. Changes in ICT have been particularly noticeable when the explosion of electronic and digital devices has dominated today’s technology market. Digital games have also become a large industry, generating billion dollars worldwide. Despite the expansion, this industry is facing a number of problems [2]. The popularity of digital games is increasing, with a global market value of RM197.6 billion. However, the game produced locally still has no considerable impact. One reason is that there is no emphasis on the game design process in the game development education program.

Many digital games on various platforms have been created, either for entertainment or for other purposes. Various studies have shown the potential and effectiveness of computer games for education, they are found to be more efficient, beneficial, and of quality [3] [4] [5]. Regardless of the purpose of the computer games, the fundamental emphasis should be on the game design and the design process's creative aspect.

The game design process plays a crucial role in producing a good and creative game. According to [6], the process of game design is divided into two main phases that need to be emphasized, namely ideation and conceptualization. Ideation refers to the process of generating creative and innovative game design ideas, while conceptualization is to outline the concept in the form of game prototypes that involve programming, architecture, sound, and interface. According to [6], creating an interactive and effective computer game is a huge issue and challenge because various assumptions in the creating of a computer game can have a significant impact on users. This is further reinforced by [7] [8] in their studies, that three important elements are emphasized in the construction of computer games, namely, a creative resource involving graphics and sound, files involving creative graphic rules, and a game engine involving the control of every graphic and sound. According to [9], the game design process needs to have certain creativity based on the practice of human game designers and an advanced analogy with creativity in science, acceptable to computational achievements in the form of discovery systems. In addition, [10] [11] [12] also agreed on the need to generate game ideas that require creative strategies in game designing. According to a recent study by [13], an effort to create or adopt tools that increases team communication is necessary to maintain designers and programmers’ working in a strong collaborative atmosphere to produce creative game designs. Thus, it can be concluded that the computer games design needs to be emphasized in the game development education.

Creativity is defined as a process that occurs to a human being and a quality that is natural and learned. According to [14] [15], creativity is the ability of those who excel in creative endeavors, reflecting the idea of the human imagination as an intuitive notion of skill. The author in [5] considered creation as the process of finding sufficient facts, problems, ideas, and solutions, with cognition, imagination, and judgment, i.e. creative problem-solving. The author in [14] deemed creativity as the creation for particular needs or purposes by incorporating elements connected to form new relationships. Issues in a game product involve issues of creative thinking in game design and development. Creativity and skills are among the most important aspects for a digital game developer and designer. Eighty percent of games are expected to fail in meeting their business objectives due to poor designs and lack of creativity [16]. Creativity is an essential constituent in the game design process, which requires creative ideas, storytelling, character design, interface design, environmental design, and animation [17]. Also, game design demands a continuous process which incorporates many important aspects, including discipline and creativity [18] [19].

Game designers still face difficulty determining players' needs; therefore, the game design process desperately needs a model to help solve innovation and creativity problems [20] [18] [21]. This indicates that the gaming industry can use a model that will help improve the game's quality. According to [22], a software product's design requires a good planning process and a systematic methodological guide to software development. According to [23], innovative and creative processes are among the essential elements of the game business model. Furthermore, the most effective activities toward achieving business success are innovative and creative processes [24].

Meanwhile, the game design process requires more quality resources for the gaming industry's creative development. According to the Official Portal of the Multimedia Development Corporation (MDEC 2019), despite sufficient resources to meet demands, existing talent sources indicate serious problems with quality and skills. Thus, a creative thinking learning model is needed to address the talent gap inherent in the country's creative industry and show that everyone needs to practice creative skills.

II. Research Methodology

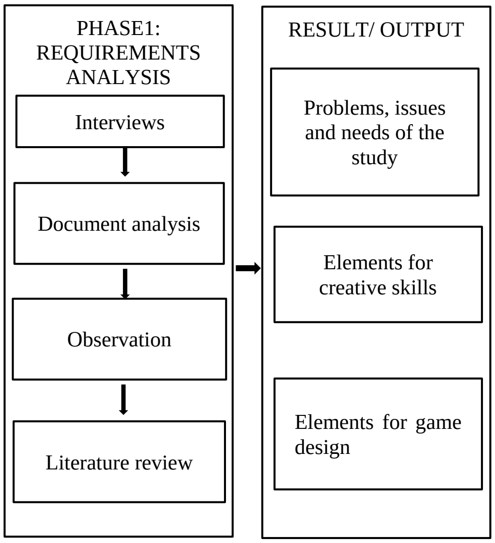
This study uses a mixed-method design approach that combines qualitative and quantitative study design to collect systematic data [25] [26]. Data collection includes course document analysis, interviews, questionnaire surveys, SWOT analysis, and analysis of game design documents. This research used Rapid Application Development (RAD) methodology, which includes requirements planning, design, development, implementation, and testing phases. The data collected were from the activities of each phase.

A. *Requirements Planning Phase*

The requirements planning phase involved the collection of the required information at the beginning of the study. In this phase, issues and problems together with elements of the model were identified. The phase activities include unstructured interviews for game design practices from six game designers and three game design lecturers, analysis of game development course documents and program structure, students' final project evaluation reports, students' observations on the game design process, and the literature review. Fig. 1 shows a summary of the activities performed in this phase.

B. *Design Phase*

In the design phase, the elements identified are grouped and mapped into different components of the LK2RBPD Model. The four phases of design activities are (i) excluding/removing elements not suitable for use in creative skills training for game design, (ii) grouping of similar elements by categorizing them into four components categories of designer, knowledge, skills, and technology support, which are essential to the model based on the four dimensions of creativity (person, environment, process, and product) [27][28], (iii) mapping of components by determining their relationship and visualizing via diagrams, based on the Input, Process, and Output model [29][30]; (iv) Expert verification to validate the components in the model using the Inter Rater Reliability (IRR) technique by four experts from the gaming industry and academia [31][32]. Fig. 2 summaries the activities performed in the design phase.



PHASE1: REQUIREMENTS ANALYSIS
Interviews
Document analysis
Observation
Literature review
RESULT/ OUTPUT
Problems, issues and needs of the study
Elements for creative skills
Elements for game design

Fig. 1. Requirement Planning Phase.

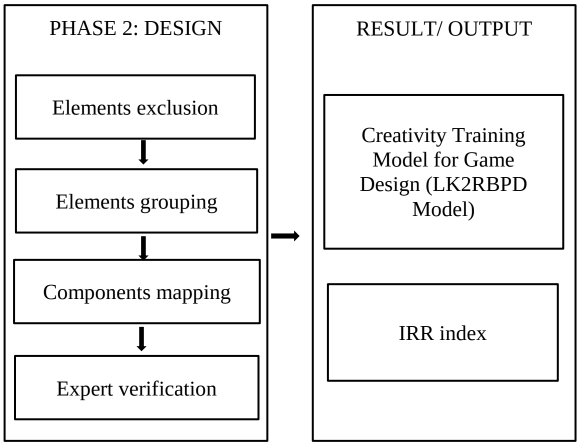


Fig. 2. Design Phase.

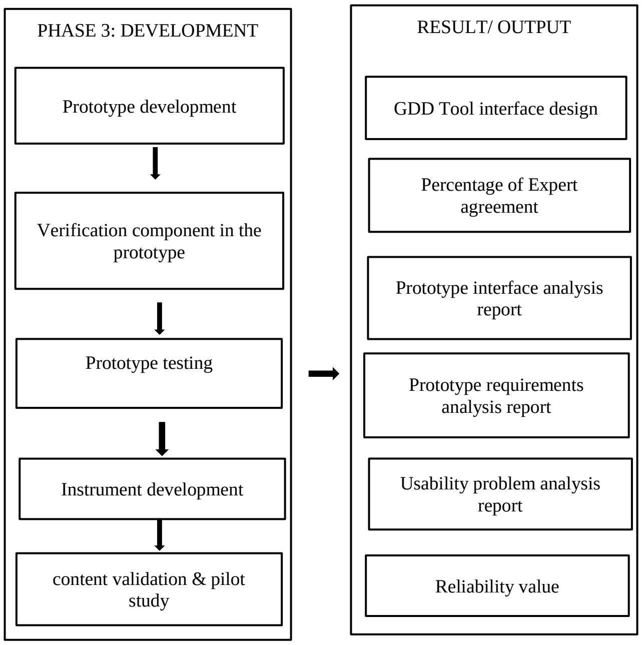
C. *Development Phase*

The development phase involves five activities. The first activity is prototype development with implementation of the LK2RBPD Model - the GDD Tool. Second activity is verification of the LK2RBPD Model component in the GDD Tool prototype, conducted by five (5) experts (Numbers (N) = 5: Male (M) = 1; Female (F) = 4) comprising of two game industry experts and three academic specialists / lecturers of game design and development. Semi-structured interview method using a checklist and a low fidelity prototype were used. The third activity is the prototype test, conducted using Thinking Aloud Testing [33] with five students majoring in game design. In the test's procedure, testers would be logged in as system users, and they would follow the instructions given to test the GDD Tool's features: choosing roles, generating ideas, brainstorming, and downloading game design documents. Additionally, respondents would need to provide feedback on the low prototype design of the GDD Tool in the checklist provided. The fourth activity is the questionnaire (instrument) development for content validation on the implementation of the LK2RBPD Model component. A 5-point Likert's Scale (1 = strongly disagree, 2 = strongly disagree, 3 = neutral, 4 = agree, 5 = strongly agree) questionnaire consisted of 83 questions has three main sections: part A (student information), part B (question items according to the LK2RBPD Model component), and part C (SWOT Analysis). Five experts (N = 5: M= 1; F = 4) from various fields of expertise validated the questionnaire. Finally, a pilot study was conducted with 15 students for reliability testing of the instrument. Fig. 3 summarizes the activities in the development phase.

D. Implementation and Testing Phase

In this phase, the GDD Tool prototype was evaluated through 45 students-perception questionnaire survey. Descriptive mean score used three-level indicators: 0.00 - 1.67 = low, 1.68 - 3.34 = medium, and 3.35 - 5.00 = high [34] [35]. Finally, creativity and innovation was evaluated based on observations on ideation process and the game design documents (GDD) produced through GDD Tool. GDD were assessed by five experts, who are game designers. The evaluation was carried out in two sessions. The first session was conducted without using the GDD Tool, in the form of a regular discussion. The researcher provided the students with instructions on the production of game design documents and gave them some ideas on game design. The second session required the GDD Tool, so the testing procedure was initiated with a demonstration that provided the respondents with instructions on how to use the GDD Tool. Fig. 4 shows a summary of the activities in this phase.



PHASE 3: DEVELOPMENT
Prototype development

III. Results and Discussion

Results identified from requirements analysis were 19 elements essential for training creative skills in game design, consisting of industry practices, creative and innovative thinking skills, creativity dimensions, Sternberg's theory of creativity, and cultural activity theory. These elements were grouped into four components: (1) the designer component consists of elements (intelligence, thinking style, motivation and personality) while (2) the knowledge component consists of the elements (experience, game genre, environment and storyline) next (3) the skills component consists of the elements (linking, synthesizing, imitation, game analysis, generating ideas, inventing and play centric) and last (4) the technology support component that consists of elements (goals, rules, community, and distribution of tasks), forming the LK2RBPD Model.

The IRR approval rate for expert validation of the model is 94 percent, an acceptable level of trust agreement. IRR values from 75 percent to 90 percent indicate acceptable levels of agreement when using a percentage of consent [31] [32] [35]. Fig. 5 shows the LK2RBPD Model with 19 components (intelligence, thinking style, motivation, personality, experience, game genre, environment, storyline, correlate, synthesis, imitation, game analysis, generate idea, invent, play centric, goals, rules, community and task distribution. Model construction and validation has been discussed in detail in [36].

The model evaluation is done via the GDD Tool low fidelity prototype. Results of the experts' agreement on the implementation of the LK2RBPD Model components in the GDD Tool's low-fidelity prototype is good (Cohen Kappa coefficient = 0.84) [37]. However, only 17 components of the model were identified and agreed upon by all the experts (Table I). Table II shows the experts' feedback on GDD Tool prototype interface. Experts' feedback using the provided checklist was then used to develop the final prototype, based on the system requirements (Table III).

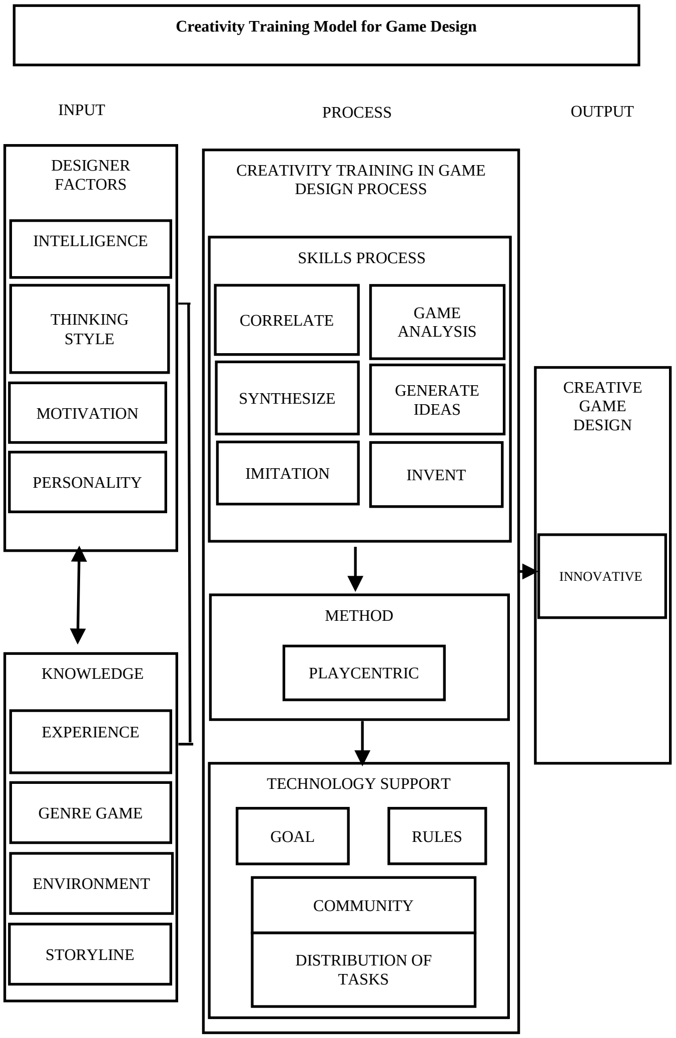

Fig. 5. LK2RBPD Model.

TABLE I. EXPERTS' AGREEMENT ON THE IMPLEMENTATION THE LK2RBPD MODEL COMPONENTS

No	Components	Expert1	Expert 2	Expert 3	Expert 4	Expert 5
1.	Intelligence	/	/	/	/	/

TABLE II. EXPERT FEEDBACK ON GDD TOOL PROTOTYPE INTERFACE

No	Elements of Prototype interface	Suggestion for improvement
1.	Colour usage	• Change the background colour to make it a more vibrant, engaging and effective design. • Ensure appropriate and consistent use of colours and combinations on each interface. • Consistent use of colour for each menu button on the interface.
2.	Text/Fonts style and size	• Change text style and size for communicating purposes, communicating ideas and facts. • Sensitive font: for computer display. • Sans serif font types are more commonly used because it's more accurate for inside use of computer resolution. • The choice of style and text size should be more appropriate to explain how the generated application works, to guide the user to browse the application, and to send information to the designed application. • Consistent use of text size for page title, description of words in words or paragraphs and instructions for operating the application. • Use of the title of each interface in accordance with the functions and processes that will be used by the GDD Tool user. • Consistent use of English.
3.	Menus	• Add menu buttons to the Comment Page and Best Ideas interface for the purpose of providing the client with a flow of games in the diagram (for better understanding). • Add a critic menu button to the Client's Idea interface. • Add an Edit button to the Game Design Document interface. • Use a consistent and appropriate menu button design to ensure that users are aware of the existence of buttons and functions. • The menu button position is placed in the centre of the interface. • The position of the client name is arranged in a more organised manner on the Client Name interface.
4.	Sequence of Action	• The Rules interface is placed on the first interface of the GDD Tool application so that users can better understand the rules when using the GDD Tool.

TABLE III. GDD TOOL PROTOTYPE REQUIREMENTS

No	Prototype Requirements	Suggestion and improvement
1.	Input	• The instructions should be clear for each interface that requires text input from the user. • Suggest options for emoticons or Likes on the Comment Page interface. • The Best Ideas interface reward/likes function to enhance user motivation.
2.	Process	• Functional enhancements to the Role Select interface according to the MDA Framework game design framework which is Mechanics designer, Dynamics designer and Aesthetics designer. • Enhanced chat between clients.
3.	Output	• Need to display instructions or information about the GDD Tool on the first interface that is represented by the Help/About/Rules button. • Replace the rule sentence with the illustration/flow chart/video/animation in the Rules interface. • Need statement or instructions for user to download document in doc/pdf format.
4.	Data source	• Must have a stable domain for easy access to developed applications.
5.	Control	• Functions added to the Game Design Document interface - only hosts are given the functionality to edit, update, and submit. • Extension of time given to client on Comment Page interface according to eureka concept.

System requirements analysis is part of the initial study to identify system-specific problems and requirements, including input requirements, process requirements, output requirements, data handling, and system control resources. System-specific requirements are specifications of what the system will do when implemented [38]. Table III shows an analysis of the GDD Tool prototype requirements.

Usability Testing allows users to try using a real prototype or an application of a particular task. The goal is to find out how well the designed application or service can be used, so that any arising problem can be highlighted or discovered during testing [33]. For usability testing (pilot test) of the GDD tool prototype, five tasks were assigned to 5 users, and 8 problems were identified. The list of usability issues is shown in Table IV.

The agreement on the prototype usability problems, the Cohen Kappa coefficient is 0.54, which indicates a medium-scale level usability problem for the GDD Tool. This value implied that although improvements to the usability problems or issues should still be made, the GDD Tool prototype can be used by the user without major complications. Many of the problems encountered in the test were related to the respondents' misunderstanding the purpose of the GDD Tool application or their inability to identify the next steps in the application process, similar to the problems found by [39] [40] [41] in studies done with more experienced users. Additionally, the reliability value of the Cronbach's alpha was 0.84, indicating that the questionnaire items had reliability [37], so can be used for final evaluation.

TABLE IV. USABILITY PROBLEMS OF GDD TOOL PROTOTYPE

No	Tasks (T)	Code Problen (P)	Problems	User (U)
1.	Task 1: User needs to join the idea brainstorming session (T1)	P1	Users do not know how to start the application.	U1, U2, U3, U4, U5
2.	Task 2: User needs to select a role in the GDD Tool. (T2)	P2 P3	Users are not clear about their role in the selection process. Host is not clear about the role of the GDD Tool.	U1, U2, U4 U5
3.	Task 3: Users need to generate ideas in game design (T3)	P4	Users require more time beyond the allocated 15 minutes to generate ideas.	U1, U2, U3, U4, U5
4.	Task 4: Users need to brainstorm and choose creative game design ideas (T4)	P5 P6 P7 P8	Users do not understand the instructions provided. User shows or expresses impatience by clicking on the objects that respond slowly. Users show a tendency to take actions randomly (intentionally or otherwise). Button disappears when clicked.	U1, U2, U4 U1 U1, U2 U4, U5
5.	Task 5: Users need to create and download Game Design Document GDDD (T5)		No issue	U1, U2, U3, U4, U5

The final results from questionnaire survey show that all the components of the LK2RBPD Model have high ratings. Overall, the analysis showed that 19 components of the LK2RBPD Model have high mean reading scores of 4.11 to 4.30, as shown in Table V.

Results of SWOT analysis of the GDD Tool prototype is shown in Table VI. Theme analysis was used to sort out answers based on themes of strengths, weaknesses, opportunities, and threats.

The results of the SWOT analysis show that the prototype has strengths and opportunities. However, some threats and weaknesses in the areas of technology need to be improved, such as internet accessibility, poor information sharing, misuse of application features, and competition from social applications.

Finally, the result of creativity and innovation evaluation based on the ideation session process is presented in Table VII while experts' evaluation of the game design documents using the GDD Tool prototype is in Table VIII.

TABLE V. MIN SCORES AND STANDARD DEVIATIONS FROM SURVEY QUESTIONNAIRE IMPLEMENTATION MODEL LK2RBPD

No	Construct	Min Scores	Standard Deviations
1	Intelligence	4.21	0.63
2	Thinking style	4.30	0.59
3	Motivation	4.20	0.57
4	Personality	4.16	0.71
5	Experience	4.11	0.67
6	Game Genre	4.20	0.64
7	Environment	4.28	0.58
8	Storyline	4.25	0.63
9	Correlate	4.28	0.59
10	Synthesise	4.30	0.59
11	Imitation	4.23	0.67
12	Game analysis	4.33	0.58
13	Generate ideas	4.26	0.62
14	Invent	4.21	0.59
15	Play-centric	4.24	0.55
16	Goal	4.23	0.61
17	Rules	4.23	0.57
18	Community	4.23	0.65
19	Distribution of tasks	4.32	0.54

TABLE VI. SWOT ANALYSIS

Team	Answer
Strengths	"Can play more than once anywhere" “Able to come up with ideas and create stories quickly” “It really helps to come up with ideas” “Can improve a lot of ideas” “Lots of creative ideas” “Being able to talk online with a group of friends to build the best game design” “GDD tool helps me to know more about the process of creating game designs, game design documents” “Being able to share ideas and stimulate creative ideas” “GDD Tool can improve creative thinking skills” "I can think a lot" “Being able to connect with friends and talk about game design ideas” “Each user can play their own role” “Get lots of creative ideas” “Developing ideas for the better
Weaknesses	“The interface can be improved to make it more interesting” “Needs strong internet access” "Host role may expand" “No rules on the voting site need complete instructions” “Add community members for more ideas” “No images led to the development of game ideas”
Opportunities	"It's accessible everywhere but it's still a one-on-one session for developing creative ideas in game design" "Be able to train yourself to think creatively" “Can be used many times” “Can easily create GDD” “Can add other functions like audio and other” “Allows sharing of ideas anywhere” "Can be used by everyone" "Students get ideas for game design" “Final semester students will gain more and more knowledge in game design when using the GDD Tool “ “Can expand the use of the GDD Tool to other students / institutions” “Can introduce this GDD Tool to other colleges that have gaming programs” "Can be a training tool for train creative thinking" "Allows many people to use it well"
Threats	"Too easy to disconnect" "Requires a strong internet connection" “Theft of ideas can happen”

TABLE VII. IDEATION SESSION REPORT

Discussions without using the GDD Tool:	Discussions using the GDD Tool:
• There is no fixed time on when to start the discussion.	•The discussion session is conducted at a time that is set and controlled by a Host.
• Discussions take long time and waste of time without any brainstorming activity.	• The discussion is clearly set out in accordance with the goals and rules set in the GDD Tool.
• Does not achieve the actual goal of the discussion.	• Community members have the time and platform to generate ideas.
• All members of the community want to talk at the same time.	• Ideas are generated based on the keywords provided in the GDD Tool.
• There is no platform for channelling ideas.	• Ideas can be created creatively.
• Ideas are written on paper and difficult to keep.	• Each member’s ideas can be shared with other community.
• The discussion took a long time because there was no proper monitoring and distribution of tasks among the members	• Using the GDD Tool can train creative thinking for game ideas, while game designers can develop their imagination and introduce new game ideas that can be produced.
• Difficult to generate ideas. • The situation cannot be controlled and it is difficult to obtain conclusion on the game design.	• Generate formal ideas by developing mechanics, dynamics and aesthetics elements in game design.
• Ideas can be produced, but not made in a complete game design document, instead just drawings and notes that cannot be referenced.	• Ideas are improved as they are generated based on game objectives, user targets, game levels, and game names.
• Each member’s ideas cannot be shared with other community partners.	• A complete and creative game design document can be created as soon as the GDD Tool usage session ends.
	• Game design documents can use as a reference for the game development phase.

A total of nine (9) game design documents were produced from the use of the GDD Tool session by 45 respondent focus groups of students majoring in game design and development. GDDs analysis produced a total of 72 data (ideas). The experts' agreement on the creative game design ideas is 97 per cent. For comparison, the level of expert agreement is calculated using Cohen Kappa formula, K: 0.94 (94%), which signifies excellent agreement [42]. The evaluation results confirm that the LK2RBPD Model could be used effectively to develop and train creativity in game design. Table VIII and Table IX show the experts agreement on game design ideas derived from the final test of the GDD Tool prototype.

IV. CONCLUSION AND IMPLICATIONS

This study successfully identified 19 components of the LK2RBPD Model and implemented them in the GDD Tool prototype. Evaluation results of the LK2RBPD Model components in the GDD Tool prototype, and the assessment of creativity and innovation in the game design confirmed that the LK2RBPD Model could be used for training the creative skills of game design to produce game. The results of this study successfully identified 19 components of the LK2RBPD Model and implemented them in the GDD Tool prototype. Evaluation result of the LK2RBPD Model components in the GDD Tool prototype, and the assessment of creativity and innovation in the game design confirmed that the LK2RBPD Model could be used for training the creative skills of game design to produce game design documents. Evaluation result of the LK2RBPD Model components through the use of the GDD Tool prototype indicated a rating higher than 4.0, which means that the GDD Tool prototype can be used to train creative skills in game design. As for the results of experts' agreement on creativity and innovation in game design, creative game design documents showed an excellent agreement of 97 per cent or K: 0.94. This shows that creative skills can be trained by involving the important and necessary components of the LK2RBPD model in producing a creative game design. Apart from that, technological aids/tools also help train creative skills in game design. The results of this study have identified three (3) guidelines that need to be in place to generate a creative idea and can be used as a reference for game designers in the process of generating creative game design ideas. This study found that creative thinking can be trained on each individual in particular, to produce a creative game design document by following these three guidelines: (i) ideas are generated through a selection process of some of the best ideas, ii) the ideas produced need to be targeted such as the target user, game name, game objectives and game level and iii) idea generation needs to be more formal that is according to the rules of form, characteristics and certain ways that are acceptable and considered appropriate according to the rules or steps necessary in a game design. The five experts in the field of game design agreed that creative skills training is effective in developing creativity and innovation in the ideation phase of game design. Individuals could be trained successfully in creative thinking, as well as to develop creative ideas by implementing the 19 components of the LK2RBPD Model. The results demonstrate that the objectives of the study have been achieved and the LK2RBPD Model can help solve some problems in this research area. However, further research can be carried out with the use of elements involving creativity and innovation as well as other appropriate training and learning theories according the needs to train creative skills in game design. In addition, the improvement of GDD tools in various platforms with the use of more interactive elements such as chat rooms, image uploads, videos, animations and software functions according to the latest trends that can be used as a communication platform to game designers in producing a creative game design.

ACKNOWLEDGMENT

We acknowledge the assistance from Metro Polytechnic Kuala Lumpur and the Polytechnic and Community College Department, University Kebangsaan Malaysia (UKM) for supporting the research under grant GUP-2019-059 and HLP Federal Training Specialist, Ministry of Higher Education Malaysia for funding the study.

Abstract*—The increasing number of aging populations worldwide versus vast developments in mobile technology creates questions on how older adults adapt and apply mobile technology in their daily life. This research focused on spiritual user experience for older adult users because older adults are claimed to be more spiritually inclined as they aged. Despite high profile calls for research in the area of spirituality, the research pertaining spirituality in HCI is still in infancy state. Recent literatures discover most studies focus on design for spiritual user experience and evaluation of spiritual application for adult users, but fundamental of spirituality and its elements from the view of user experience is limited. Therefore, this study employs qualitative method approach within an interpretive paradigm to propose a model for Spiritual User Experience from the perspective of Islamic older adult users. The Geneva Emotional Musical Scale (GEMS) was adopted as a theoretical lens in order to gain deeper insights on the spirituality elements. A single case study was conducted with the total of 11 participants to research on the spirituality user experience elements among older adults. The triangulation of qualitative data collection through 3E diary, interviews and observations was conducted. All data were analyzed verbatimly using thematic analysis. Six themes emerged from the analysis which are effectiveness, efficiency, learnability, satisfaction, sublimity and vitality. These themes are further categorized into 10 attributes; effectiveness (accessibility features), efficiency (simplicity and portability), learnability, satisfaction (attractiveness and reliability), sublimity (transcendence and peacefulness) and vitality (energy and joyful activation). These are embedded into a model known as Spiritual User Experience (iSUX) which are evaluated by the Islamic religious experts, user experience expert and older adult's representatives. This model could be a reference for spiritual model development apps among developers and provide understanding for researchers in the HCI domain. In conclusion, the Spiritual User Experience (iSUX) is hope to increase the understanding of spirituality from the domain of user experience.

Keywords*—*Techno-spiritual; user experience; human computer interaction; Geneva emotional musical scale; 3e diary; older people

I. Introduction

Spirituality is the most important part of life for every people. Spirituality is the feeling of connectedness to the higher power or consciousness and it also develop individual beliefs, practices and rituals [1]. Nowadays, people start to use technology in many ways to support spirituality. There are a lot of technological applications including the ICT tools such as email, SMS, computer software, websites and mobile applications for supporting spirituality practices. The use of technology in spirituality is also high, for instance, [2] reported that there are almost 6,000 iPhone and iPad applications exist in the market to assist human spirituality from various perspectives. Additionally, [3] highlighted that there is an increasing number of Islamic websites created daily on the internet to spread teachings and services related to spirituality. Apparently, people are searching for spiritual technologies to support for their spiritual experiences with the help from the technology.

Spiritual experience is a type of user experience. Spiritual experience is a rich body of work that addresses user experiences related to the feeling of transcendent, connectedness to God and consciousness toward higher power [4]. The activity of using the spiritual technology can evoke various kind of affect and emotions. These emotions are evoked by the interaction while engaging with spiritual technology. Individuals will respond emotionally to these activities because of their personal spirituality values. For example; a user feels happy when reciting Quran using mobile Quran application; or a user feel satisfied with achievement of dzikir since personal dzikir informatics can keep track of their dzikir counter. Since then, HCI has expanded in scope to move beyond usability and focusing on this subjective spiritual experience. There is, for example, a little work being done in HCI on affect and emotion for spirituality [2]. Most of other HCI studies focusing on the design element that can trigger the spirituality feelings and emotions but did not mention specifically the spirituality elements from the perspectives of

*Corresponding Author

user experience. Moreover, the statistics reveals that researchers are more interested in focusing on the adults as a target user whereas the study on older people study is way behind [5]. Apparently, research for older people in spirituality domain is important since a theory proves that people will become more spiritualized as they age [6]. Therefore, this research aims to answer the following research questions:

1) What are the spirituality elements from the context of user experience?

2) How can the identified spirituality elements be used as a guideline in spiritual user experience application development?

II. Research Background

Numerous models and frameworks have been found in the literature to explain about UX. Apparently, UX has been used widely across many research fields such as business, social science, medical, design and also information technology [7],[8]. In consequence, it shows that UX is an important element especially when it comes to product, system or services delivery towards users. In spite of various UX model there is one comprehensive UX model proposed by [9] which specifies three UX core components and the relationship among it known as Component Model of User Experience (CUE-Model). In 2008, the model has been justified by [10] and the enhancement of the model lead towards the new model. The model addresses instrumental and non-instrumental quality as well as emotions responses by user towards technology. The instrumental quality in the model refers to usability which is the effectiveness of a system [9] and non-instrumental quality involves the hedonic [11] elements such as visual aesthetics and haptic quality [9].

Music plays a great role in human everyday lives. Obviously by listening to music could evoke human positive and negative emotions such as happy, sad, amaze, motivated and energetic. Many research has been done to explore on the links between emotive states evoked by music. A study by [12] proposes the Geneva Emotional Music Scale or GEMS which is widely used. The GEMS scale taken from [12] can be categorized into three major emotion components which are the vitality, unease and sublimity. The first component which is vitality is a positive emotions and includes emotions such as power and joyful activation. The second component is unease that is negative emotions which include tension and sadness elements. And the last emotion component is sublimity which is a positive component and includes elements such as wonder, transcendence, tenderness, nostalgia and peacefulness.

III. Methods

A. The Participants

Kompleks Warga Emas Seksyen 24 (Golden Citizen Complex) located in Shah Alam, Selangor, Malaysia is being selected as a case study of this research. This complex is a center which gathered older adult members from within Shah Alam city to promote beneficial programs or community activities in addition to reduce gap between young and old generations. This complex was chosen as the research area because Shah Alam is the state capital of Selangor in which Selangor has the highest population density among all states in Malaysia [13]. Muslim older adults were chosen in this research since Malay is the highest race composition in Malaysia and majority of Malay is Muslims. Total of 11 Muslim older adult participants were selected based on purposive sampling from among the participants who volunteered to participate in the Learning Quran Bahasa Melayu mobile application workshop using Tablet PC conducted by researchers.

B. Model Development Process

This research comprises of five processes as depicted in Fig. 1 which are research planning, pilot study, UX evaluation, UX model development and expert evaluation. Detail explanation for each processes were discussed further in the following section.

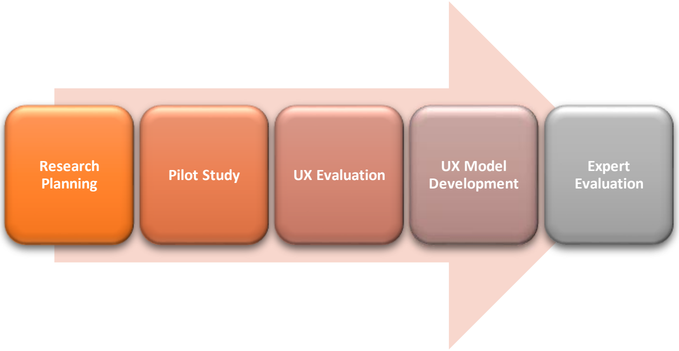

Fig. 1. Research Design.

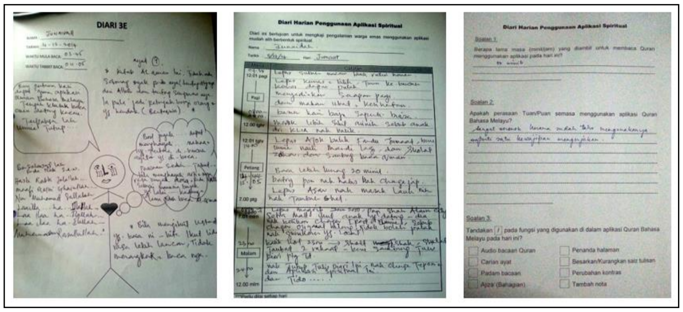
1) Research planning: Research planning involves steps such as initiation of the research and also development of the research plan. It is important in this study to first understand the concept of spirituality in the context of user experience. Systematic literature review involves selected journals and proceedings from top listed HCI indexed papers listed by google scholar metric raking is used. Review from previous prominent scholars provides guidance to obtain definition and identify the spirituality elements.

2) Pilot study: This pilot study aims to identify data collection procedure and to test diary and interview instruments to be used for the older adults.

Three types of diary design as shown in Fig. 2 were tested with older adult participants which are daily dairy, 3E diary and structured diary. Two older adults' participants which is a male, 62 years old and a female, 60 years old were selected using snowball sampling to be interviewed and involved in a diary study for seven consecutive days. The selected case study is within Selangor state. From the pilot study reveals that 3E diary design is the most suitable diary tool to explore spirituality experience compared to the other two diaries since 3E diary allows older adults to draw facial expressions to express emotional status furthermore encourage older adults to explain it in their writing. For instance, in spirituality context, the older adults may draw crying face to express the feeling of sadness and repentance when the older adult users feel the connection with God. Further explanation on pilot study is as discussed in previous paper [14]. The selected tool will next be used in the next process which is UX evaluation.



DIARI 3E
Diari Harian Penggunaan Aplikasi Spiritual
Diari Harian Penggunaan Aplikasi Spiritual

Fig. 2. Three Types of Diary Design Tested with Participants.

3) UX evaluation: This research implemented single case study research strategy to obtain spiritual user experience data from the older adult users. Fig. 3 shows the procedures involved in user experience evaluation. The following brief explanation is for the procedures implemented in user experience evaluation with older adult users.

- Set appointment and asking for participant's approval. Relationship between researchers and complex manager is good since researchers have joined several community activities with older adults in the past. Researchers went to the complex to meet the management committee two weeks before the workshop day to book for workshop room and to set the workshop date. To create rapport, researchers also participate in the series of Al-Quran recitation classes at the complex.

- Workshop I & II. During the workshops, ll participants were seated according to their preferences. Program started with speech from the Program Director explaining about the objectives of the workshop. Next, a montage and tutorial video on how to use Tablet PC and Quran Bahasa Melayu application were presented to all audiences. Older adult participants were then divided into three small groups by researchers and the division of group is made according to their gender either male group or female group. Each group consists of either 2 or 3 persons. Firstly, the facilitator demonstrates the method to use the Tablet PC to participant 1. Next, participant 1 need to teach the other team members alternately in a small teaching team. Teaching process is finish when every member in the group understands all features and functions in the Quran Bahasa Melayu application. Teaching team procedures is as shown in Fig. 4. The following Table I and Table II presented the demographic profile of participants in workshop I and workshop II.

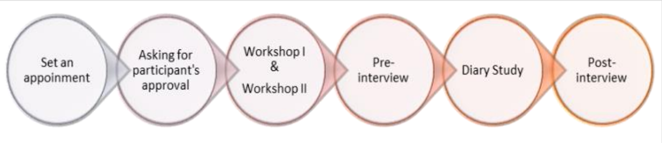


Fig. 3. User Experience Evaluation Procedures.

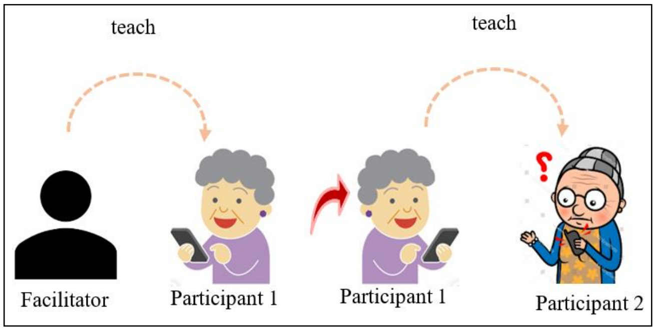

Fig. 4. User Experience Evaluation Procedures

TABLE I. LIST OF PARTICIPANTS FOR WORKSHOP I

Participant ID	Age	Gender	Employment Background
P1	68	Male	Retiree
P2	61	Female	Retiree
P3	68	Female	House wife
P4	71	Female	Retiree
P5	74	Male	Retiree
P6	61	Male	Working (part time)

TABLE II. LIST OF PARTICIPANTS FOR WORKSHOP II

Participant ID	Age	Gender	Employment Background
P7	65	Male	Working
P8	68	Female	Retiree
P9	61	Female	Retiree
P10	63	Male	Retiree
P11	67	Female	House wife

User experience evaluation workshop has been executed twice. The reason for conducting the workshop twice is due to the lack of participant's number in workshop I. Since the workshop was held on weekend, there were fewer participants present because they had to attend the wedding feast, visit children's house and taking care of daughter in confinement period. Moreover, the workshop is tentatively done in small scale number of participants (around 10 to 15 participants only), so that participants can learn in a conducive pace. The second series of workshops were also conducted using the same procedure.

- Pre-interview. After completing the teaching session, five participants were randomly selected to be interviewed. Interview sessions were conducted in the workshops one by one by three facilitators. Each interview session lasted about 30 to 40 minutes for each participant and the conversation was audio and video recorded for reporting purposes. The aim of this pre-interview is to obtain participant's background information, participant experience in using mobile phones and also their experiences in using any spiritual mobile applications. This information is essential, especially to know the level of exposure towards spiritual mobile applications usage among older adults in their daily lives.

- Diary Study. The diary study was conducted based on the method solicited from [15] which previously studied about older adults and hospitalization experience. After pre-interview session has completed, all participants from the workshop session was asked for their willingness to participate in the diary study. Each participant was asked in advanced for their willingness to participate in the study to prevent them from being burdened and this is to ensure that the collected data is reliable. Each of the older adult participants was provided with Tablet PC set with charger, a set of 3E diary, a pen, a user manual and a paper bag. The Tablet PC was equipped with Quran Bahasa Melayu application installed in it, meanwhile, the diary set consist of seven pieces of printed 3E diary template. User manual contains the guidance to the participants on how to start the Tablet PC until how to use Quran Bahasa Melayu application. The paper bag is also provided to keep all the probe kits and bring home for a week. Each participant's was asked to report their spiritual feelings in 3E dairy after each application's usage to capture their emotions. To keep encourage and remind the participant about writing the diary, researchers will contact the participants through phone call and short message service (SMS) at about 2 to 3 times a week as suggested by [15], [16]. The diary was collected back by researchers after a week through collecting them at participant' house or in complex. Each of the diary was interpreted by researchers before the post-interview session.

- Post-interview. Once the interpretation has completed in approximately two weeks to a month, a post-interview question was set up with each of the participant's. Post-interview objectives are to clarify the data gathered from the 3E diary and to explore participant's experience after using the application. This method is also done to avoid misunderstandings of the interpreted data by researchers. Each interview lasted in about 1 to 2 hours where the interview was done at participant's house or in complex. Further explanation on the UX evaluation tools used in this research is as discussed in previous paper [18].

4) UX model development. Once the data from pre-interview, diary, post-interview and observation were collected from the participants, thematic analysis is used to analyze all the data's. Seven steps adopted from [17] were used to analyze all data. Data were thoroughly processed step by step starting from familiarizing with the data, generating initial codes, searching for themes, reviewing themes, defining and naming themes and lastly producing the report. Triangulation which involves multiple sources of data is used to ensure the credibility of output.

Expert evaluation session with three different roles of informants which are the Islamic religious experts, the UX expert and the older adult users were implemented. All three Islamic religious experts have at least five years of experience in the field and has minimum Master's level of Islamic religious education. For UX expert, a senior researcher who currently engaging project pertaining user experience in the field of elderly and cultural was selected. Meanwhile, all three older adult users who have been recruited have at least five years' experience of using spiritual mobile applications. All experts were either emailed or face to face interviewed to review each of the themes and categories in the iSUX Model. Each of the expert panels were provided a list of operational definition for each elements in the iSUX model to understand further on the model. Panels then interviewed to give their opinion on each of the elements. Finally, all opinions and comments from expert panel were evaluated thematically and the iSUX model where then amended.

IV. Results and Discussion

A. Participants Feedbacks

All 11 participant's responses through pre-interview, diary study, post-interview and observation were analyzed using thematic analysis. The results were grouped into themes and categories (sub-theme) as following:

1) Effectiveness. Effectiveness theme consist of one category which is simplicity.

- Simplicity: is being defined as the quality or condition of system, product or services of being easy to use or understand. The simplicity element in HCI is widely known especially in evaluation and cannot be disregarded especially when designing with older adult users [7],[8]. Quran application was reported by participants to have simplicity element in terms of its function, presentation, content and appearance. Using Quran mobile application perceives as difficult at first, however, the perception was changed after usage.

2) Efficiency. Efficiency theme consists of two categories which are accessibility features and portability.

- Accessibility features: it provides evidence for reporting that one of the Quran mobile application's strength is on the application's function. Majority of older adults' participants reported in interview and 3E diary on the advantage of using Quran application such as the recitation audio. The audio recitation function allows elderly users to keep listening to Quran recitation despite doing other tasks such as doing house chores and while in vehicle.

- Portability: Portability can be defined as the ability of the application to be easily moved from one environment to another environment. The result shows that Quran spiritual mobile application is easy to be used and carry everywhere makes it easier to recite Quran even in car or airplane as well as in other places such as in hospital.

3) Learnability. Learnability could be defined as of how competent older adults' user may use Quran mobile application without too much effort. Result shows that some elderly users rely on Quran mobile application to learn Quran especially on the correct way to pronounce each of the verses. Furthermore, Quran recitation audio is very much helpful for Quran novice in learning Quran recitation.

4) Satisfaction. Satisfaction theme consists of two categories which are reliability and attractiveness.

- Reliability: The interviews and 3E diary proves that elderly users are aware and very cautious about Quran mobile application. Among aspect emphasized by participants including the accuracy of Quran application content especially on the spelling and punctuation. It shows that the participants are very cautious upon choosing the correct version of Quran applications from application store.

- Attractiveness: Cognitive and vision impairment caused elderly to hardly focusing on devices for long duration. Cognitive ability to focus in longer duration decreased whereas vision ability like eyes sensitivity becomes less. All these changes should be taken into account while delivering an application for older adult users. For instance, in the interview session, an elderly participant did address on the importance of using colourful text for the Quran application to avoid from feeling boredom.

5) Sublimity. Sublimity theme consists of two categories which are transcendence and peacefulness.

- Transcendence: Majority of participants addressed on the subjective experience related to Islamic spirituality that meet the criteria of transcendence. Codes which are identified as the feeling of transcendence are centered on a sense of divine. Transcendence in this study relates to the context of the relationship with God or transcendent being, individual transcendence as well as relationship with others including the nature. Participants shared the inner feeling of connection to God while engaging Quran Bahasa Melayu application by addressing the servitude and remorse feelings, being guided, feel fear of God through diary and interview.

- Peacefulness: The definition of peacefulness as according to [12] is when there happen to be a separation of threats either in physical or psychology with the real world. The emotional states of calmness and feeling relaxed were reported frequently in respond to engage Quran mobile application among elderly participants. Reciting Quran using Quran application offers positive emotional effect as reported by participants in the diary where it is able to soothe their mind while releasing stress.

6) Vitality. Vitality theme consists of two categories which are energy and joyful activation.

- Energy: Reciting Quran application is found to be uplifting while boosting participants' energy. Specifically, participants spoke about their eagerness to use Tablet PC, which eventually motivated participants to recite Quran often using mobile application. In fact, one participant indicated in the diary that with reciting Quran using application is capable to eliminate the unwilling and laziness feeling to recite Quran.

- Joyful Activation: Several participants who shared similar positive experiences noted that the Tablet PC encourages their curiosity to recite Quran up to long duration. In addition, one participant stressed that it is very happy to recite using application for it has many good features for instance, the tajweed marker and the translation which resulting in a better understanding of the Quran meaning.

The following Table III shows several older adult users feedbacks from the collected data. All users' feedbacks were analyzed thoroughly to produce meaning.

TABLE III. PARTICIPANT'S FEEDBACKS

Participant's ID	**Feedback**	**Category**	**Theme**
P7	It is a good and **simple application**. Easy to use and like to use it.	Simplicity	Effectiveness
P11	I never used a tablet and IT. At first I thought it is very hard, but **it is OK**.		
P2	It is fun to use the tablet, we just listen to it when we switched it ON. It will play and we just listen to it… **if we switched it ON we can do other work**.	Accessibility features	Efficiency
P4	After *Isyak* prayer, ON the tablet and listen to *surah Al-Maidah*. I often **use a tablet while I am in a vehicle**, while appreciating its translations.		
P4	For myself, I like to **use the table when I am outside of the house** - for example **in a car** while travelling. Also while relaxing. Can be use **while cooking** also.	Portability	
P9	With tablet, if we do not know, we just **turn ON the sound and follow**; with the book, right or wrong, nobody can correct it. Those who do not know how to read can also learn	Learnability	
P11	Yes, sometimes I think that the **Quran need to be checked**. For example, when it has been printed, there might be a missed mark.	Reliability	Satisfaction
P11	The **letters have colours**…because we are old and it catches our interest. If black and white, its look normal...older people can be that long.	Attractiveness	
P2	If I switched it ON, it feels sad because we are listening to people reading, feel enjoyable… feel "high". Feels like we are interacting with Allah. **Like we are talking to Allah. The message is absorbed into the soul.**	Transcendence	Sublimity
P5	A deep feeling. More focused, more concentrate. By using the tablet, it **feels more close to Allah**… **Feel the fear to Allah, horrified**.		
P4	After listening to the Quran – **the heart and soul feel calm.** No negative thoughts. Only good thinking.	Peacefulness	

P6	**Does not get bored** using the tablet even though already read many verses.	Energy	Vitality
P2	**Enjoy reading** until I realize it has been quite some time and feel tired.	Joyful Activation	
P9	**Fun to use**, just switch it ON.		

Findings from the research presents ten spiritual user experience categories identified for older adults as shown in Fig. 5.

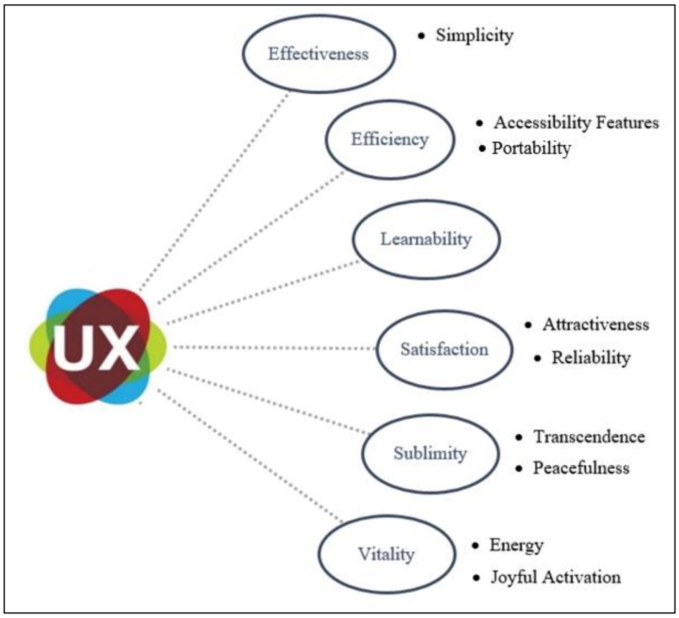

Fig. 5. List of Identified Categories and Themes.

The lists of the categories are simplicity, portability, accessibility features, learnability, reliability, attractiveness, transcendence, peacefulness, energy and joyful activation. These ten categories were grouped into six spiritual user experiences themes for older adults namely; efficiency, effectiveness, learnability, satisfaction, sublimity and vitality.

B. Spiritual User Experience (iSUX) Model

iSUX Model can be categorized into three central user experience (UX) components as highlighted by [9] which are the instrumental qualities, non-instrumental qualities and the emotional reactions. The first component, which is the instrumental qualities focused on user experience towards the ease of use and functionality of the application. This component is related to the usability aspects of using spiritual applications. The second component, which is non-instrumental qualities, focus on the look and feel of the application in which this component is related to the subjective user experience of the applications. Non-instrumental qualities concerns are on the affect and emotional aspects, where it talks around the evocation of emotions while using the spiritual applications. Finally, the third component, which is the emotional user reactions is actually the emotional responses from users while using the spiritual applications. Based on the research findings, it can be concluded that spirituality elements exist in both instrumental qualities and non-instrumental qualities components as depicted in Fig. 5. The older adults use spiritual mobile application with the purpose to fulfill their spirituality needs. From the non-instrumental qualities aspect, the activity of using the spiritual mobile applications observably can evoke the spiritual emotions. One can experience joy when the application is unexpectedly easy to use or when the older adult's successfully operating the application. Older adults will respond emotionally especially when they have personal spirituality values such as crying when they listen to the verses translation pertaining the day of judgment, heaven and hell. While from the instrumental qualities aspect, it shows that the accessibility features of spiritual application helps the older adults a lot in using the technology. The portability of spiritual mobile application makes older adults easy to recite Quran everywhere even at the public places or while in the vehicles.

The perception of both qualities influences the third component of UX which is the emotional user reactions. For example, the audio recitation and text resizing function in spiritual mobile application may affect perceived effectiveness and lead to motivation to use the application in future. In addition, a similarity of mobile Quran design with the original Al-Quran may impact on transcendental and cause emotional responses such as fear to God, calm and sense of conviction. In conclusion, the ability of designing and developing spirituality applications that could evokes positive experiences can be increased by formulating spiritual value profiles in the early stage. Therefore, the iSUX Model is proposed to discover spiritual elements to help pave the way for a study of spirituality in the domain of user experience in future.

V. Conclusion

This research is hoped to provide significance understanding to the body of knowledge by amplifying the relatively limited research studies done on spiritual mobile applications towards the researchers in the field of HCI. In this research, the model for spiritual user experience was presented. This research identifies key elements of spirituality for user experience with based on the data gathered from the older adults. The model namely iSUX was then developed based on the data findings supported with expert evaluation as well as theoretical views from the field of musical and theological. Even though spirituality elements fall under both qualities in iSUX model, however, the non-instrumental quality is more prominent where it discusses more about the derivation of emotions to the Creator. Emotional responses can result through physical outwardities such as crying, happy, calm and scared. Further investigation on subjective spiritual user experience is very interesting to explore more. This iSUX model is useful to practitioners and researchers as it provides spiritual user experience elements that may be considered in developing spirituality application for older adult users. Designing the needs of older adult users is perceived designing for all.

Indeed, this research was conducted in an emerging and important domain, within the area that is still in infant state and need attention from numerous HCI scholars to embark research on spirituality. In conclusion, it is hoped that this research could provide significance contribution to the body of knowledge and can act as a sound basis for further research in spiritual user experience. Finally, it is also researcher's hope that this study could inspire new ideas that in turn create a spark of more research in spirituality domain in future.

ACKNOWLEDGMENT

This work was supported by Universiti Teknologi MARA (UiTM), and also funded by the Research and Innovation, Universiti Kuala Lumpur. Special thanks to all older adult participants from Kompleks Warga Emas, Seksyen 24, Shah Alam for their willingness and cooperation in this study.

Reversible Data Hiding using Block-wise Histogram Shifting and Run-length Encoding

Kandala Sree Rama Murthy[1], V. M. Manikandan[2]
Department of Computer Science and Engineering
SRM University-AP, Andhra Pradesh, India

***Abstract*—Histogram shifting-based Reversible Data Hiding (RDH) is a well-explored information security domain for secure message transmission. In this paper, we propose a novel RDH scheme that considers the block-wise histograms of the image. Most of the existing histogram shifting techniques will have additional overhead information to recover the overflow and/or the underflow pixels. In the new scheme, the meta-data that is required for a block is embedded within the same block in such a way that the receiver can perform image recovery and data extraction. As per the proposed data hiding process, all the blocks need not be used for data hiding, so we have used marker information to distinguish between the blocks which are used to hide data and the blocks which are not used for data hiding. Since the marker information needs to be embedded within the image, we have compressed the marker information using run-length encoding. The run-length encoded sequence is represented by an Elias gamma encoding procedure. The compression on the marker information ensures a better Embedding Rate (ER) for the proposed scheme. The proposed RDH scheme will be useful for secure message transmission also where we are also concerned about the restoration of the cover image. The proposed scheme's experimental analysis is conducted on the USC-SIPI image dataset maintained by the University of Southern California, and the results show that the proposed scheme performs better than the existing schemes.**

Keywords—Histogram shifting; run-length encoding; secure message transmission; overflow; Elias gamma

I. Introduction

Data hiding is a well-explored information security area in which a hidden message can be safely transmitted by embedding it in a digital media mask [1, 2]. Digital images are often used as a cover medium for data hiding purposes. The conventional data hiding scheme makes permanent changes to the cover image pixel values during data hiding process and at the receiver side, only the hidden message will be extracted and not concerned about the cover image. The image obtained after data hiding is termed as stego image. The sender embeds the secret message into the cover image and communicates the stego image and a key for extraction to the sender. If the receiver can extract the hidden message and recover the original image completely then the scheme is called Reversible Data Hiding (RDH) [3]. For the past two decades, RDH schemes are widely studied and a number of algorithms are proposed in this domain. The overview of a RDH scheme is graphically shown in Fig. 1.

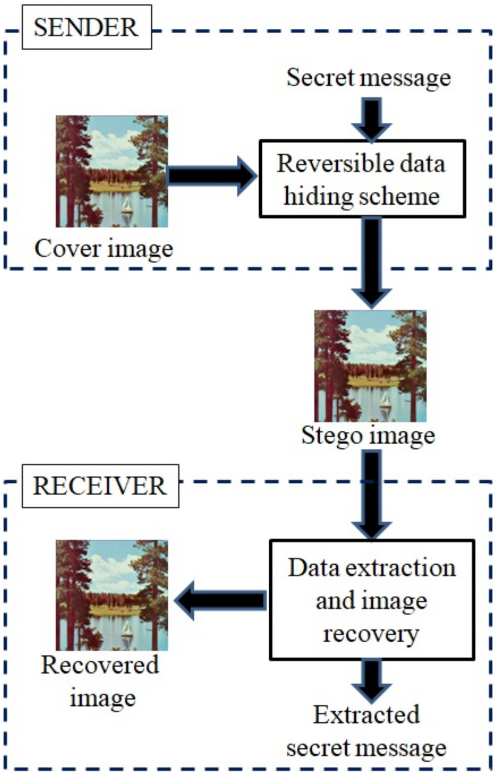

Fig. 1. Overview of RDH.

II. Literature Review

Most of the existing RDH schemes are centered around the idea of compressing a bit plane of image to create extra space for the secret message [3-5]. Difference expansion techniques [6-8] and histogram shifting based approach is discussed in [9-13]. There are a number of algorithms that use entirely different approaches for data hiding are also available in the literature [14-16].

In medical image transmission, patient records can be securely sent along with medical images using RDH methods which enable us to recover both the image and message without any loss of data. The reversible watermarking schemes are widely used for authenticating medical images in which a watermark will be embedded in the medical image instead of a secret message. The cloud service providers commonly use RDH schemes to hide some additional metadata on the images uploaded by the clients.

In this research, we explored a histogram shifting based RDH scheme and introduced a block-wise histogram shifting based RDH scheme with a better embedding rate by compressing the marker information using run-length encoding. The marker information is additional information that helps to distinguish the blocks which are used for data hiding and the blocks which are not used for data hiding.

For a better understanding of the proposed scheme, the basic histogram shifting based RDH scheme is detailed in Section III. The proposed scheme is detailed in Section IV. The experimental study and result analysis is detailed in Section V. A few other alternatives that we tried along with the proposed scheme are briefed in Section VI. The conclusion and a few insights to future work are given in Section VII.

III. Preliminaries

In this section, we briefly discuss the basic histogram shifting based RDH scheme [9] since we extended the same in this manuscript. An overview of the block-wise histogram shifting based RDH scheme introduced in [13] is also discussed in this section for better understanding of the proposed scheme.

```
Algorithm I: Basic histogram shifting based RDH algorithm

Input   :  Cover image $I$ and the secret message $D$
Output  :  Stego image $S$
Step 1  :  Find the histogram $H$ of the cover image I
Step 2  :  Identify the peak pixel value $P$ from the histogram $H$
Step 3  :  Increment all the pixels which are greater than $P$ by one to get the new image $S$. No need to do any changes on the pixels having intensity value P or less than $P$.
Step 4  :  Read the pixels in $S$ in a predefined order (either row-wise linear order or in a pseudo-random order based on a data hiding key) and if we find a pixel at location ($X$, $Y$) with the pixel value $P$ in which we can hide one bit $Q$ from the secret message $D$. Add the $Q$ value with the pixel at location ($X$, $Y$) to perform data hiding. Note that the new pixel value will be ($P$+1) if we hide the secret bit 1 and the pixel will be unchanged if we embed secret bit 1. Do this process to embed all the bits from secret message to get the final stego image $S$.
Step 5  :  Return the stego image $S$
```

The data extraction and image recovery process in histogram shifting based RDH process is given in Algorithm II.

The major challenges with the basic histogram shifting based RDH scheme are listed below:

- Embedding Rate (ER) (the number of bits that can be embedded per pixel) is very low. For more information please refer to section IV. a.
- Overflow is quite common when the original cover image contains some pixel value 255.

```
Algorithm II: Data extraction and image recovery process

Input   :  Stego image $S$, the pixel value $P$ used for data hiding
Output  :  Recovered image $I$ and the extracted message $D$
Step 1  :  Read one pixel $K$ from $S$ in a predefined order. Do the following to extract the hidden message $D$ and recover the original image I:
           Case 1: $K<P$
                   Just keep $K$ as it is in the recovered image $I$.
           Case 2: $K==P$
                   Extract a bit 0 and append it with the secret message $D$ and no need to do any change for the pixel value keep as it is in the recovered image $I$.
           Case 3: $K==P+1$
                   Extract a bit 1 and append it with the secret message $D$ and to get the recovered pixel value, decrement the pixel value by one and keep it in recovered image $I$.
           Case 4:$K>P+1$
                   Decrement the pixel value by one and keep it in $I$ to recover the original pixel value and do not extract any secret message bit.
Step 2  :  Return the recovered image $I$ and extracted secret message $D$
```

A scheme is introduced in [17] to handle the overflow in the histogram shifting based on RDH. A block-wise histogram shifting based scheme is introduced by us [13] in which the overflow handling technique is used. In addition to that, block-wise histogram shifting based approach is used to improve the ER. The main idea is that instead of generating the histogram of the whole image, we divided the image into fixed size blocks and applied the histogram shifting algorithm on each block. The embedding rate in the histogram shifting algorithm is proportional to the peak value of a pixel, and by dividing the image into blocks, the overall embedding rate is increased significantly without affecting the visual quality of the stego image. We also eliminated the need of sending a key separately to the receiver by embedding the key, which is the peak pixel value, within the first a few pixels of each block using the least significant bit substitution.

A major hurdle in histogram shifting is the problem of overflow bits. When we are shifting the pixels by one position, the end pixel value can't be shifted ahead. The solution we provided is to make a marker list of all the end pixel values before and after shifting and store this information within each block by embedding it along with the message. On the retrieval of the message, this marker information can be utilized to distinguish the overflow bits and deal with them separately. To store this marker information within a block along with a portion of the secret message, each block's peak value must be greater than the number of overflow bits plus the binary size of the key. This condition disqualifies a few blocks to be used for data embedding. The marker information is embedded in the first block of the image and thus the entire first block is omitted in the rest of the algorithm.

The scheme discussed in [13] divides the original image into blocks of size *B*×*B* and we need to find the histogram of each block. If the peak in the histogram of the selected block is capable to provide a sufficient embedding rate to hide the peak pixel value, overflow information, and at least one secret message bit then it will be treated as a block suited for data hiding. All the blocks will be verified at the beginning itself to generate marker information in which 0 corresponded to a block indicates that the block is not usable for data hiding and 1 indicates that the block can be used for data hiding.

Let us assume that the original image is of the size *R*×*C* pixels then the original image will have *N* non-overlapping blocks of size *B*×*B* where *N* is defined as follows:

$$N = \left\lfloor \frac{R}{B} \right\rfloor \times \left\lfloor \frac{C}{B} \right\rfloor \tag{1}$$

All remaining (N-1) blocks have been used for data hiding in the current scheme except for the first block, and the size of marker information M will be N-1. The marker bits are embedded in the first block of the cover image by replacing the N-1 least significant bits (LSB) from the first N-1 pixels in the first block of the cover image. It may be noted that at the receiver side, we must recover the original image as it is. For this purpose, the LSBs of the first *N*-1 pixels are embedded in the image itself while hiding the secret message. If there is a possibility to reduce the number of bits in the marker information then it will help to improve the actual embedding rate. It should be noted that the actual embedding rate is defined based on the number of secret message bits that we can embed in the image without considering all the other overhead such as embedding marker information, the embedding of overflow information, etc.

The proposed scheme explored the possibility of reducing the number of bits required for marker information. During the existing scheme's experimental study, it is observed that in most of the images most of the blocks are used for data hiding. In such cases, the marker information will be a sequence of bits in which very rarely a bit 0 will be present. Note that if the J^{th} bit is 0 in the marker information, it indicates that the J^{th} block is not used to hide data.

In this manuscript, we propose an RDH scheme that compresses the marker information using run-length encoding. The run-length encoded sequence is encoded using a variable length encoding scheme called Elias gamma. The run-length encoding sequence is popularly used to compress the data when it contains redundant information. We observed that the marker information is always having a high amount of redundancy (1's are coming consequently as most of the blocks are used for data hiding) which motivated us to use run-length encoding to compress the marker information. The run-length sequence should be converted into a sequence of bits and we have used Elias gamma encoding process in the proposed scheme. The Elias gamma is a well-known variable length encoding scheme. For better understanding, the run-length encoding process is briefly described here with an example. Let us assume *C* is a bit sequence as follows:

C: 1000000000000000111111100000000000000000

The corresponding run-length sequence *L* will be

L: 1, 1, 15, 7, 17

In run-length sequence we will keep the starting bit of the *C* as it is. In the above example the first bit is 1, so we kept it as it is in the run-length sequence. The second value 1 indicates that 1 is repeating 1 time in *C*. The third value 15 indicates that 0 is repeating 15 times in *C*. The next value 7 indicates that 1 repeats 7 times in *C* and so on.

The run-length encoded sequence *L* can be converted into sequence of bits *E* by using Elias gamma encoding scheme. The Elias gamma encoding scheme is given Algorithm III. The input will be run-length sequence and the output will be *E*.

```
Algorithm III: Elias gamma encoding on run-length sequence
Input    :  Run-length sequence $L$ which consists of $N$ values
Output   :  Elias gamma encoded sequence $E$
Step 1   :  Take the starting bit value (first value from $L$) and
            keep it in $E$
Step 2   :  $X$=1
Step 3   :  While $X<N$
Step 4   :  $D=L_X$ //$X^{th}$ value from $L$
Step 5   :  Convert $D$ into binary, say $B$
Step 6      Find the number of bits $K$ in $B$
Step 7   :  Append ($K$-1) 0's to E then append $B$ to $E$.
Step 8   :  $X=X+1$
Step 9   :  EndWhile
Step 10  :  Return the Elias gamma encoded sequence $E$
```

If we apply the run-length encoding procedure on the run-length sequence that we have obtained in the previous step, the corresponding binary sequence *E* will be the following:

E: 11000111100111000010001

The total number of compressed data bits is 23 and we achieved a compression ratio of 30/23=1.30.

We have used run-length encoding with Elias gamma to compress the marker information. Run-length encoding is a lossless compression scheme that will help us to decompress the information without any loss.

In the next section, the proposed algorithms are given where we have used all the basic concepts we have discussed here.

IV. Proposed Scheme

This segment addresses the proposed scheme. The sequence of operations using the run-length encoding scheme in the proposed block-wise histogram-shifting based RDH is defined:

Algorithm IV: Proposed histogram shifting based RDH using run-length encoding

```
Input   : The cover image $I$ and the secret message $D$
Output  : The stego image $S$
Step 1  : Divide the cover image into blocks (non-overlapping) of size $B×B$ pixels.
Step 2  : Access one block at a time and check whether or not the block is suitable for hiding data. To check this for the $K^{th}$ block, compute the histogram of the block and find the peak intensity $P_K$ value and its corresponding count $C_K$.
          If $C_K>F+8$
                $M_K=1$ //$K^{th}$ marker bit
          Else
                $M_K=0$
          Where $K=1, 2,…N-1$ and $F$ is the number of 255's or 254's in the $K^{th}$ block which indicates the overflow information required. 8 bits are needed to keep the LSB's of the first 8 pixels which will used to store the peak intensity value.
Step 3  : Apply the run-length encoding process on the marker information $M$ to get the run-length run-length sequence $L$
Step 4  : Apply Elias gamma encoding procedure on $L$ to get compressed binary sequence $E$
Step 5  : Find the length of $E$, say $Z$
Step 6  : Access the first block and extract Z LSB's from the first Z pixels, say T is the list of Z LSB's.
Step 7  : Replace the LSB's of first $Z$ pixels by the bits in $E$ and keep the modified block as the first block of the stego image $S$.
Step 8  : The secret message $D$ should be appended at the end of $T$
Step 9  : Access the $K^{th}$ block $G_K$ for data hiding purpose in the predefined order. Find the peak pixel value from the block $G_K$ by considering the histogram of the image block and store the 8-bit peak pixel binary value at the LSB position of the first 8 pixels of the block, if and only if the block is suitable for hiding the data. The LSBs of the first 8 pixels W, along with the overflow information, should be embedded in the same block itself. The overflow handling bits $O$ are computed by traversing the whole block one by one and the 0 bit will be used to mark the pixels originally with 254 and 1's will be used to mark the pixels with overflow (originally 255).
          The same process that is described in Algorithm I is used for data hiding but the only difference is that we will be applying the same thing on a block (except the first 8 pixels) and the bits that are going to hide consists of LSB information of the first 8 pixels, the overflow information and some bits from actual secret message. The altered GK blocks will be positioned at the corresponding position in I.
Step 10 : Step 9 should be repeated for all the blocks in the image $I$ to get final stego image $S$
Step 11 : Return the stego image $S$.
```

The sender just needs to send the stego image S to the receiver for data retrieval and image recovery during the data hiding. The marker information about the order followed during data hiding is embedded in stego image. In our experimental study, we have followed row-wise linear order during data hiding phase. The image recovery and data extraction is possible from the stego image S. The process is described in Algorithm V.

Algorithm V: Image recovery and data extraction from the proposed scheme

```
Input   : The stego image $S$
Output  : The extracted message $D$ and the recovered image $I$.
Step 1  : Divide the stego image $S$ into blocks (non-overlapping) of size $B×B$ pixels.
Step 2  : Find the number of non-overlapping blocks $N$ in the image $S$.
Step 3  : Keep on extracting the LSB's of the pixels from the first block and apply the Elias gamma decoding and run-length decoding procedure on the fly. Continue this process until we are getting a bit sequence $M$ having size ($N$-1). This will be the actual marker information which is used identify the blocks used for data hiding. Let us assume that we have accessed $V$ number of pixels to get a bit sequence $M$ of $N$-1 bits.
Step 4  : Access the $K^{th}$ block $G_K$ from stego image S and process it if $M_K$ is 1. Otherwise just ignore it.
Step 5  : If the $G_K$ is used during data hiding then extract the first 8 bits from the first 8 pixels and convert into corresponding binary $P_K$. Apply data extraction and image recovery process (almost same as Algorithm II) from the block $G_K$ (excluding first 8 pixels). The first 8 bits from the extracted message should be used to recover the first 8 pixels by replacing the LSBs. Next $W$ number of bits $O$ will be used to retrieve the pixels having value 255. The size of the $W$ will be nothing but number of 255's in the current block $G_K$. The bit 0 in $O$ says that the 255's should be decremented by one and the bit 1 in $O$ says that the 255 should keep as it in the recovered image. The remaining bits extracted from this will be keep on appending with a bit sequence $D$'. Repeat this process for all the blocks in the image and store the values in $I$.
Step 6  : Extract the first $V$ number of pixels from $D$' and replace it in the LSB's of first $V$ pixels to recover the first block and keep the block as the first block of $I$.
Step 7  : Remove the $V$ number of bits from $D$' to get $D$ which will be the actual extracted message.
Step 8  : Return extracted message $D$ and recovered image $I$.
```

V. Experimental Study and Result Analysis

The experimental research and analysis of outcomes is performed on every image from the USC-SIPI image dataset

[18] managed by the Southern California University. Since the dataset consists of both color images and grayscale images of various sizes, to attain uniformity we have converted all images into 8-bit grayscale images of size 512×512 pixels. Our algorithm can be implemented on color images as well without any preprocessing. In all the images we have embedded the maximum possible number of bits as secret message. A pseudo-random bit sequence is generated as the secret message. The USC-SIPI image dataset has four different categories of images: aerials, textures, sequences and miscellaneous (misc.). The optimum block size is empirically decided as 16×16 pixels and all the experimental study of the proposed scheme is performed by taking this block size. We have conducted an experimental with various block sizes such as 128×128, 64x64, 32x32, 16x16 and 8x8 and picked the block size which provides the maximum ER. We have analyzed the following efficiency parameters during the study:

1) Embedding rate
2) Peak signal to noise ratio (PSNR)
3) Structural similarity index (SSIM)
4) Natural image quality evaluator (NIQE)
5) Blind image spatial quality evaluator (BRIQUE)

A. Analysis of Embedding Rate

Embedding rate (*ER)* is defined as follows:

$$ER = \frac{K}{R \times C} \tag{2}$$

where K is the maximum number of bits in the message that can be embedded in a R×C size image. The embedding rate is usually denoted by bits per pixel (bpp). The embedding rate of the scheme proposed is purely dependent on the distribution of pixels in the image. In the proposed scheme we are utilizing some of the actual embedding possibilities to hide the pixel recovery information. So we basically considered the effective embedding rate by deducting all the overhead information. Table I provides the average embedding rate obtained from all four types of images from the proposed scheme.

If the image consists of too much smooth regions with less possibility of overflow then it will be capable to provide a high embedding rate. From Table I, it can be observed that the average ER from all four categories of images is better than the existing schemes. Some additional overhead bits are reduced in the proposed scheme through the use of run-length encoding process. The embedding rate from the four well-known images such as airplane, boat, baboon and peppers is given in Table II. It also shows the embedding rate from the existing schemes [9], [13].Table II shows that for all the four well-known images, the embedding rate of the proposed scheme is better than the embedding rate of the existing schemes mentioned in [9] and [13].

B. Analysis of PSNR and SSIM

Two image quality measurement tests are the PSNR and SSIM values, which help to analyze the image's quality deterioration based on a reference image. The low quality images maybe an indication of some hidden images and the attackers may try to do steganalysis on such images to extract the hidden messages. So the researchers are very much concerned about the stego image quality while proposing new RDH scheme. If the original image is exactly same as the stego image, then PSNR will be ∞ and SSIM will be 1. But this will not happen since we are supposed to do some alteration in the pixels to hide the secret message and such changes will lead to reduction in PSNR and SSIM measure. If the PSNR and SSIM measure are high it indicates that there is low quality degradation on the stego image due to data hiding process. Table III presents a comparison between the PSNR for well-known images from the existing schemes and the proposed scheme.

The average SSIM value for all four categories of images from the existing schemes and the proposed scheme is given in Table IV.

Table V contains the SSIM values from the existing schemes and the proposed scheme for well-known images.

TABLE I. COMPARISON OF AVERAGE ER FROM ALL CATEGORY OF IMAGES

Image category	**Scheme in [9]**	**Scheme in [13]**	**Proposed scheme**
Misc.	0.0388	0.1081	0.1089
Textures	0.0230	0.0521	0.0529
Sequences	0.0266	0.0765	0.0774
Aerials	0.0252	0.0588	0.0597

TABLE II. COMPARISON OF ER (BPP) FOR WELL-KNOWN IMAGES

Image category	**Scheme in [9]**	**Scheme in [13]**	**Proposed scheme**
Baboon	0.0105	0.0201	0.0210
Peppers	0.0105	0.0438	0.0447
Boat	0.0221	0.0442	0.0451
Airplane	0.0317	0.0903	0.0912

TABLE III. COMPARISON OF PSNR (IN DB)

Image name	**Scheme in [9]**	**Scheme in [13]**	**Proposed scheme**
Baboon	50.4139	50.9370	50.9405
Peppers	50.0807	51.0778	51.0815
Boat	51.9712	50.9220	50.9259
Airplane	53.9372	52.2065	52.2121

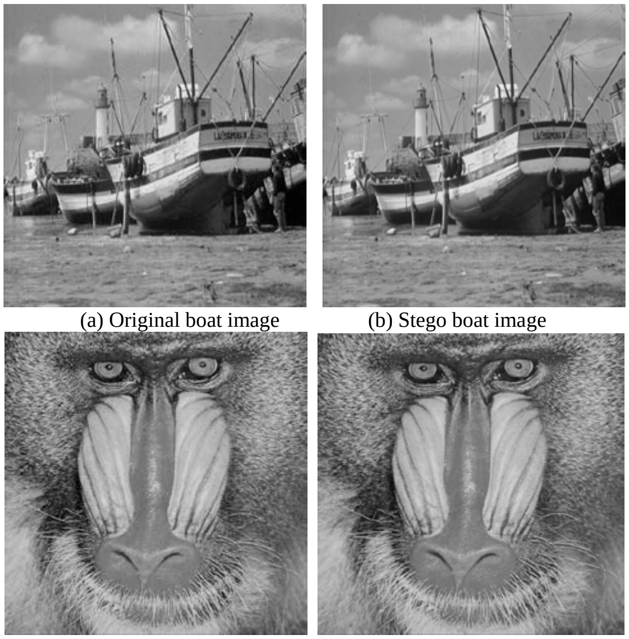
TABLE IV. COMPARISON OF AVERAGE SSIM FROM PROPOSED SCHEME AND EXISTING SCHEMES

Image category	**Scheme in [9]**	**Scheme in [13]**	**Proposed scheme**
Misc.	0.9993	0.9987	0.9987
Textures	0.9996	0.9994	0.9994
Sequences	0.9997	0.9989	0.9989
Aerials	0.9996	0.999	0.999

TABLE V. COMPARISON OF SSIM FROM PROPOSED SCHEME AND EXISTING SCHEMES FOR WELL-KNOWN IMAGES

Image category	Scheme in [9]	Scheme in [13]	Proposed scheme
Baboon	0.9998	0.9996	0.9996
Peppers	0.9998	0.9989	0.9989
Boat	0.9996	0.9991	0.9991
Airplane	0.9996	0.9987	0.9987

The results shown in Table III, Table IV and Table V indicate that from all the well-known images we are getting a very high PSNR and SSIM measure. In general, the data hiding schemes that can generate stego image with a PSNR of 50 dB or more is treated as a good scheme. The SSIM values are very close to 1 also. Two sample cover image and the corresponding stego image obtained after data hiding process is given in Fig. 2.



(a) Original boat image (b) Stego boat image

(c) Original baboon image (d) Stego baboon image

Fig. 2. Sample Results.

C. Analysis of NIQE and BRISQUE

The NIQE and BRISQUE are two well-known no-reference image quality measures [19, 20]. In addition to the reference based image quality assessment techniques such as PSNR and SSIM, we have analyzed the quality of the stego images using no-reference image quality assessment approaches such as NIQE and BRISQUE. .In Fig. 3 and Fig. 4, the NIQE and BRISQUE measures of well-known images obtained from the proposed scheme and the existing schemes are given.

In Fig. 3, NIQE-1 indicates the NIQE measure from the original image and NIQE-2 is the NIQE measure from the stego image. A high NIQE measure means that the image quality is good.

The data shown in Fig. 3 and Fig. 4 indicates that the stego image quality is not much deviated from the quality of the original image.

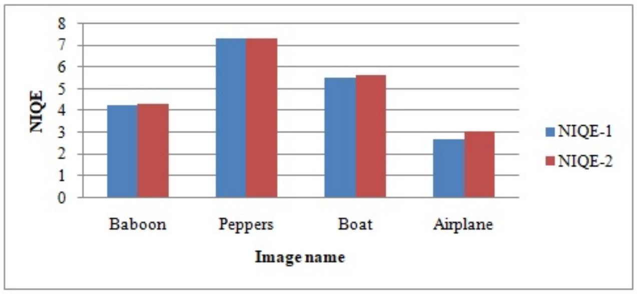


Fig. 3. NIQE Measure from Original Image and Stego Image.

The BRISQUE image quality measures of original image and stego image are given in Fig. 4. It may be noted that the low BRISQUE measure indicates high image quality. In Fig. 4, BRISQUE-1 is the BRISQUE measure from the original image and BRISQUE-2 is the stego image's BRISQUE measure.

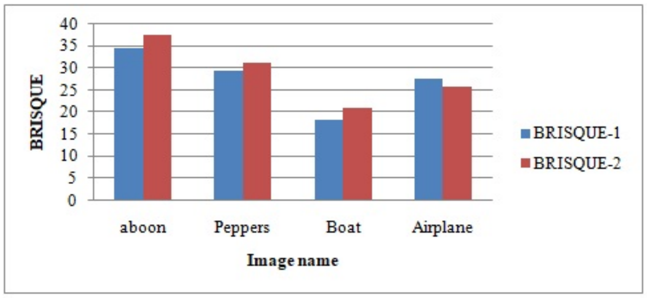

Fig. 4. BRISQUE Measure from Original Image and Stego Image.

VI. ALTERNATE APPROACHES FOR IMPROVEMENT

In addition to the Algorithms discussed in Section II, we have attempted a few other alternatives to improve the proposed scheme. The histogram of each block can also be left-shifted instead of the default right shift operation based on the following considerations:

1) The number of pixel values less than the peak pixel value is less than the number of pixels greater than the peak value. This demands us to change fewer pixel values and thus the stego image quality will be improved.

2) The number of underflow marker bits (0's and 1's) is less than the number of overflow marker bits (255's and 254's). This reduces the marker bits that need to be embedded along with the message and thus the embedding rate will increase.

In all the methods we have proposed so far, we have omitted the entire first block of the image for storing marker information. Since we have compressed the number of marker information that needs to be stored in the first block, we no more need nearly more than half of the first block for storing the marker bits. Hence we can also utilize the first block for data hiding which will marginally improve the embedding rate. We have implemented the above-mentioned techniques also but didn't incorporate them with the proposed algorithm as there were only marginal and mixed improvements in results.

VII. Conclusion

A block-wise histogram shifting based RDH scheme with a high embedding rate is proposed in this manuscript. In the proposed scheme, marker information is generated by checking the suitability of a block for data hiding and this information is compressed by using run-length encoding with Elias gamma encoding procedure. In order to facilitate the data extraction and image recovery process, the Elias gamma encoded marker information is embedded in the first block of the cover image. A better embedding rate without losing the visual quality of the stego image is attained in the experimental analysis of the proposed scheme. The visual quality of the stego images is measured using a metric of reference image quality, such as the peak signal to noise ratio and the structural similarity index. Most of the stego images gave a PSNR value greater than 50 dB and SSIM values close to 1. In addition, the visual accuracy of the stego image is measured using non-reference image quality tests such as natural image quality evaluator and blind image spatial quality evaluator, and the results show that the quality of the stego image does not differ significantly from the quality of the original image. The future works can be focused to apply histogram shifting on the histogram of regions generated through segmentation rather than on the non-overlapping blocks.

Acknowledgment

We kindly acknowledge the endless support received from the parent institute for successfully completing the project.

A Bird's Eye View of Natural Language Processing and Requirements Engineering

Assad Alzayed[1], Ahmed Al-Hunaiyyan[2]

Public Authority for Applied Education and Training, (PAAET), Kuwait

***Abstract*—Natural Language Processing (NLP) has demonstrated effectiveness in many application domains. NLP can assist software engineering by automating various activities. This paper examines the interaction between software requirements engineering (RE) and NLP. We reviewed the current literature to evaluate how NLP supports RE and to examine research developments. This literature review indicates that NLP is being employed in all the phases of the RE domain. This paper focuses on the phases of elicitation and the analysis of requirements. RE communication issues are primarily associated with the elicitation and analysis phases of the requirements. These issues include ambiguity, inconsistency, and incompleteness. Many of these problems stem from a lack of participation by the stakeholders in both phases. Thus, we address the application of NLP during the process of requirements elicitation and analysis. We discuss the limitations of NLP in these two phases. Potential future directions for the domain are examined. This paper asserts that human involvement with knowledge about the domain and the specific project is still needed in the RE process despite progress in the development of NLP systems.**

Keywords—Automated text understanding; natural language processing; requirements engineering; requirements elicitation

I. Introduction

Natural Language Processing (NLP) has a significant functional value in many application fields. NLP is especially useful in the requirements engineering (RE) domain. RE is a vital part of software engineering and considered as the first phase in the software development life cycle. It consists of several activities, including elicitation, analysis, documentation, validation, and management of requirements [1]. RE is a complicated process that is both time-consuming and error-prone, especially for large projects [2]. The RE process defines all of the requirements that a new system needs to complete to be successful. In addition, RE process collects the necessary and appropriate domain knowledge that comprises the requirements of the stakeholders (customers, end-users, domain experts). The requirements elicitation and requirements analysis tasks are performed incrementally and iteratively to accomplish this goal. These tasks use both informal natural language (NL) and formal modeling language. Using NL helps communicate with the stakeholders. It is the universal format language understood by end-users and stakeholders from all involved disciplines [3]. However, NL can be ambiguous and result in misunderstandings concerning the definition of requirements.

NLP can improve the communication between requirement engineers and domain experts (i.e., the users) by creating suitable RE specification documents [3]. NLP can also improve computer understanding of natural language text written by humans [4].

This paper presents a survey of how NLP supports current RE approaches. Specifically, the following research questions are addressed:

Q1: What is the current state of the practice for elicitation and analysis phases in RE using NLP as the platform?

Q2: What are the activities for the requirements elicitation and analysis in RE using NLP as the platform?

Q3: Are NLP systems improving the requirements elicitation and analysis for RE?

Q4: What are the current limitations of using NLP in requirements elicitation and analysis?

A literature review was conducted to address these research questions. This literature review summarized the research reporting use of NLP to support RE activities. The literature review was divided into data preparation, data collection, and data analysis stages. First, the literature search criteria were developed based on the research questions. Second, literature searches were conducted over a predefined collection of databases, including Springer Link, Scopus, IEEEXplore, Google Scholar, Science Direct, and ACM Digital Library. The literature search results were evaluated by title and abstract for all four study questions. This literature review was not an exhaustive review. Instead, this literature review provides a snapshot of the state-of-the-art practices based on the Kitchenham guidelines [5] for conducting systematic literature reviews.

This paper provides an overview of the current state of practices and challenges associated with the elicitation and analysis phases of RE employing NLP techniques. This study focused on three important aspects:

- Providing an overview of the challenges facing the requirements elicitation and the requirements analysis (i.e., ambiguity, inconsistency, incompleteness, and requirements classification).

- Providing an overview of the state-of-the-art approaches to NLP support of current RE operations. Precisely, this study focused on how the available NLP tools and techniques support requirements elicitation and requirements analysis.
- Providing an overview of the limitations of NLP use in requirements elicitation and requirements analysis.

This paper is organized as follows. Sections II and III provide background discussion about NLP and RE. Section IV provides an overview of RE activities where NLP was used to support the requirements elicitation and analysis processes. Section V discusses current requirements elicitation and analysis practices in NLP. Section VI discusses the current limitations of using NLP in requirements elicitation and analysis. Section VII provides general discussions. Finally, Section VIII concludes the paper.

II. Requirements Engineering

The elicitation, analysis, and management of requirements on the basis of semantics during the system development process are difficult due to a large number of requirements for large system engineering projects. Experts normally face numerous constraints during the processes of elicitation and analysis. These constraints include time restraints, insufficient human cognitive capacity to understand the full scope of the processes, and the volume of data to be processed [6]. These considerations make it difficult to manage and maintain the quality of the software requirements specification (SRS) document.

Requirements elicitation involves understanding the objectives and motivation for proposed system software. This phase usually begins with fundamentally informal knowledge and involves unfamiliar people with the processes for developing a software system. Thus, data interpretation is influenced by misunderstandings between the analysts and the consumers [7]. In RE, it is essential to have an excellent semantic understanding of the situation before beginning the process of requirements elicitation [8]. Traditionally, requirements were communicated to the elicitation team using NL text to prevent misunderstandings related to variations in terminology. However, ambiguity is a problem related to NL [9]. The elicitation team may misinterpret or misunderstand the stated requirements specified using NL due to the method used to communicate these requirements. Additionally, problems can occur that are associated with the elicitation of functional requirements (FRs) and the numerous sub-categories of the non-functional requirements (NFRs) [10]. These problems stem from differences in computer jargon and terminology to describe the requirements between the stakeholders and the requirements engineers [11]. The lack of consistency in the requirements documentation process makes the requirements classification process difficult and prone to error [12]. Cordes and Carver (1989) [13] stated that requirements are not created by a single human individual but are the result of common needs from multiple communities. These requirements can introduce uncertainty and inconsistencies. They further state that different participants in the requirements elicitation process have different interpretations of the meaning of the requirements. The participants have different opinions about the design of the new system based on their interpretation of the requirements. The resulting requirements will be ambiguous, contradictory, and incomplete if the participants in an elicitation process do not have a common semantic understanding of the requirements.

Requirements analysis involves understanding and assessing the documented requirements. This phase is concerned with checking the set of elicited requirements for qualifying conflict, omission, duplication, ambiguity, and inconsistency criteria. Common requirements analysis practices involve using checklists for analysis, prioritization, and sorting of requirements, using interaction matrixes to define differences and overlaps, and developing a risk evaluation of the requirements [14].

Requirements elicitation and requirements analysis are usually interlinked processes. Requirements are identified during elicitation, and then analyses are performed. If issues are identified, they are addressed and solved using the source of the requirements [14]. Once a requirement has been elicited, modeled, and analyzed, the SRS document should be clearly and unambiguously documented [15]. The SRS is part of a contract and must simply, accurately, and unambiguously define the requirements of the user and the system. An SRS that is inconsistent, unmanaged, vague, incorrect, or unclear inevitably leads to cost overruns and missed deadlines [16], [17] and [18]. A noteworthy research issue in RE is ambiguity which is described as “a statement having more than one meaning.” Ambiguities may be lexical, syntactic, semantic, pragmatic, vague, generic, or linguistic [19].

The use of NLP in RE is critical because requirement specifications are developed in collaboration between the software analysts and the end users. End users, consumers, and customers will not sign a contract if the requirements are written in the formal language. [20].

Several projects have demonstrated that the RE process can be automated or semi-automated by using NLP [21], [22], and [23]. Furthermore, NLP can support requirements elicitation and requirements analysis by automatically eliminating the ambiguity barrier.

III. Natural Language Processing

NLP is technically one of the sub-fields of artificial intelligence. NLP implements computational and linguistics techniques to assist computer understanding. Additionally, NLP can create human language in the form of texts and speech/voice [24]. The processing of NL is difficult and involves different techniques from those used in artificial languages [25]. NLP approaches are usually based on machine learning (ML). For NLP, the ML process is composed of two tasks: natural language understanding (which is the task of understanding the text) and natural language generation (NLG) (which is the task of generating text with a syntax that is widely used by humans) [26] and [27]. Another study [28] identified three types of NLP technologies: NLP techniques, NLP tools, and NLP resources. An NLP technique is a functional method, approach, process, or procedure for conducting a specific NLP task. NLP techniques include part-of-speech (PoS) tagging, parsing, and tokenization. An NLP tool is a software system or software library that continues to support one or more NLP techniques. Examples of NLP tools include Stanford CoreNLP7, NLTK8, and OpenNLP9. An NLP resource is a linguistic data resource that assists NLP techniques or tools. An NLP resource can be a language lexicon (i.e., dictionary) or a corpus (i.e., a collection of texts).

A lexical analysis can be included in a requirements document to specify pre-built dictionaries, databases, and rules. The goal of lexical analysis is to analyze the meaning of specific words. Five key techniques can be used in a lexical analysis: sentence splitting, PoS tagging, tokenization, morphological analysis, and parsing. Sentence splitting involves separating the text into different sentences. During this process, the NL text is evaluated to determine sentence boundaries.

Tokenization involves dividing a sentence into meaningful components, called tokens. Depending on the form of the text, which is partially determined by the sentence splitting, the tokens are assigned to a category, including punctuation marks, numbers, symbols, and words. The PoS tagging method involves tagging each token with its grammatical group, depending on its meaning and context. Each token is designated with a tag, including noun, verb, adjective, or determinant [29].

The morphological analysis is the initial stage in syntactic analysis. The goal of syntactic analysis is to define the origin of a compound word. Compound words are quickly stemmed and lemmatized. Stemming is the process that reduces a compound word into its ground form or origin. Lemmatization is the process that searches for the ground form of a word [29].

Parsing is a process that analyzes a sentence by taking each word and determining its structure based on its constituent sections. Two components are required to parse a piece of text: a parser and a grammar. Ambiguous sentences may require several different types of analyses in the grammar of NLs [30]. There are two main parsing approaches: dependency parsing and phrase structure parsing. Dependency parsing focuses on the connections between the words in a sentence. Phrase structure parsing involves construction of a parse tree using probabilistic context-free grammar.

The output of a lexical analysis serves as the input for a syntactic analysis. This method performs a sentence analysis of the words to determine the grammatical structure of the sentence. It requires both grammar and a parser. This level of processing results in a representation of the sentence that shows the structural relationship of the dependence between words [4].

Semantic processing defines the potential meaning of a sentence by focusing on associations between word-level meanings in a sentence [4]. Semantic processing builds a description of the objects and actions identified in a sentence and include the details given by the adjectives, adverbs, and prepositions [31].

The goal of categorization is to automatically assign new documents to categories that are already defined [32]. In RE, the NLP method is used to collect requirements from a text; analyze the consistency, linkages, similarities, and ambiguities in the text; and automatically group the text. It also classifies requirements for specific purposes that may be useful during software development. Work associated with the classified requirements may be split between different software development teams, with each team assigned a different class of requirements [33].

IV. NLP for Requirements Elicitation and Analysis

Traditionally, requirements elicitation and requirements analysis are manually processed, expensive, time-consuming, and resource-demanding [17]. Researchers have applied NLP techniques and tools to support a range of linguistic analysis tasks performed at various phases to produce complete requirements documents without ambiguity and inconsistency [34]. The requirements can be illustrated for the stakeholders in a semi-automated or automated way [35], [36], and [37]. Requirements may appear in different forms, including lists of single words, phrases, paragraphs, short texts, and special characters.

Generally, requirement engineering problems are primarily caused by heavy dependence on humans use of NL [38]. NL is syntactically ambiguous and semantically inconsistent. A systematic analysis of literature from 1995 to 2016 indicates that assembly of ambiguous requirements remains one of the most critical problems in software engineering [39]. In response, researchers have attempted to use NLP systems to solve the ambiguity challenges of NL. NLP systems have also been used to support the communication process between system users and stakeholders during the development stages of a system [15]. Communication techniques may focus on pre-selected tools (e.g., Stanford Parser), preferred methods (e.g., rule-based and ontological-based), or degree of automation. The work of [40] provides a detailed discussion about the current approaches to ambiguity in the field of requirements. This paper evaluates empirical work on NLP tools and techniques for dealing with different types of requirement ambiguity [40]. These studies indicate that a significant number of current software implementations solely rely on ambiguity recognition. However, compensation is the responsibility of the stakeholders.

An interesting research area is using NLP for eliciting and analyzing domain requirements based on developed domain ontologies. Ontologies provide a standardized means of organizing information among stakeholders in RE. Thus, ontologies may significantly enhance the quality of the elicited requirements [41]. For example, [42] used a domain ontology and meta-model requirements to generate and elicit requirements. Similarly, [43] describes three core features of domain ontologies ideal for elicitation requirements: explicit relational expression, competent relationship recognition, and explicit temporal and spatial expressions. For the creation of certain domain ontologies, A rule-based approach is recommended for the creation of certain domain ontologies from NL technical documents [44]. The research [45] used NLP to derive formal representations of the requirements based on object-oriented designs using intermediate models.

NLP is recognized as general assistance in analyzing requirements for ambiguity defection [46]. NLP techniques were used to retrieve information and synthesize models. For example, [47] produced unified modeling language (UML) templates (e.g., use-case, analysis class, collaboration, and design class diagrams) from the requirements of natural language using a collection of syntactic reconstruction rules. In addition, [48] proposed a tool-supported approach to promote the process of requirements analysis and the retrieval of class diagrams from textual requirements that support NLP and domain ontology techniques.

Emerging software paradigms, including social networks, mobile computing, and cloud computing, has expressed a growing interest in using NLP techniques. Additionally, NLP techniques are being explored for extensive data analysis to enable data-driven RE [49] and crowd-based RE [50]. Requirements articulated in user stories have been presented as an interesting application of NLP to support agile methodology [51].

V. Current State of Practice of NLP in RE

Applying NLP to RE is an area of research and development that implements NLP tools, techniques, and resources to a range of requirements documentation to facilitate various linguistic analysis activities performed at different RE phases. These tasks include detecting language problems, defining core domain terms, and creating traceability links between requirements [28].

Currently, most NLP tools are used for solving problems in the elicitation phase. NLP tools are also used to extract NL text by the process model, based on parsers and tagging [52]. For example, [53] used 2PoS tagging for preprocessing during the development of conceptual models. This paper proposed an automated solution called Visual Narrator based on NLP. Visual Narrator derives a conceptual model based on user story requirements. In this process, the PoS tagging is used to define the linguistic pattern of the sentence. If the PoS tagging is determined to be a requirement, it is collected from the text corpus and gathered for the next steps in the methodology. The automated approach enables identifying dependencies, redundancies, and inconsistencies between requirements based on a comprehensive and understandable view created from long textual requirements.

The latest trend in requirements elicitation uses NLP is to mine accessible databases (e.g., social media, requirement documents, or Apple Store feedback). The mining process is carried out with the help of ML techniques, NLP, and text mining [54]. Recently, a growing body of research has assessed the use of NLP techniques to extract requirements based on different types of user feedback for the requirements elicitation process [55]. For example, [56] created a tool for detecting ambiguous words in translated SRS.

Currently, an approach has been used to automate requirements elicitation and classification criteria which utilizes an intelligent conversational chatbot. For example, [57] used ML and artificial intelligence to develop a chatbot that interacts with stakeholders using NL and creates formal system requirements based on conversation. This chatbot then classifies the elicited requirements into functional and non-functional system requirements. Additionally, chatbots are widely used in web applications to provide help or information requested by users. For example, CORDULA is a framework that uses chatbot technology to establish contact with end-users for requirements elicitation and understand users' needs. CORDULA guides the users to their desired outcome with minimal effort required by the end-user [58].

Domain ontology has been widely used to improve the elicitation and analysis of functional and NFRs. For example, [59] used NLP to extract NFRs for natural language documents. Furthermore, [60] used an ontology-based approach to support the collection of knowledge to identify possible solutions for eliciting NFRs. Additionally, NLP has been used in similarity analyses to identify functional and NFRs from user app reviews [61] and [62]. The study of [63] proposed an ontology-based approach to support software requirements traceability, which makes it possible for a development team to effectively manage the evolution of the requirements for a software product.

New requirements analysis tools based on NLP are emerging. These tools should significantly reduce the cost of fixing requirement errors by faster identification, thus freeing domain experts from tedious, time-consuming tasks. For example, QuARS (Quality Analyzer for Requirements Specifications) is a tool that analyzes NL requirements in a comprehensive and automated manner using NLP techniques. QuARS emphasizes detecting potential linguistic weaknesses (i.e., ambiguity) that can create issues with interpretation at the next stage of software development [64]. This tool partially assists with the analysis of accuracy and completeness by grouping requirements based on specific concerns. However, user interaction is recognized as a crucial factor adversely affecting the performance and approval of the entire processing. The study of [65] proposed an NLP technique that uses a classification method to automatically handle redundancy and inconsistency problems in a requirement document.

An annual workshop called the NLP4RE (Natural Language Processing for Requirements Engineering) was established to explore interests in NLP applications related to RE issues [66]. The goal of NLP4RE is to help requirements analysts perform multiple linguistic analysis activities for RE phases. This workshop has produced numerous publications and gained broad interest from diverse cultures. About 42.7% of NLP4RE studies focused on the analysis phase. These analysis phase studies used detection as the core linguistic analysis activity and requirements specifications as the processed document type [28].

In the industrial sector, many companies have begun developing NLP tools for RE. For example, Qualicen developed Requirements Scout, a tool that analyses requirement specifications, detects requirement ambiguity, and requirement “smells.” The ThingsThinking system offers several tools under the brand name, Semantha®. This system includes a tool that classifies requirements and identifies the associated risks. It also has a tool that performs document comparison on a semantic level, which can be used for analysis of requirements documents created by multiple stakeholders. QRA Corp developed QVscribe, a tool that checks the quality and consistency of requirements documents. OSSENO Software developed ReqSuite, which is a tool to support the writing and review of specifications. IBM recently developed the IBM Engineering Requirements Quality Assistant, which is an application that leverages the advanced NLP capabilities of IBM Watson for automated requirements analysis and management.

VI. Current Limitations of NLP in Requirements Elicitation and Requirements Analysis

An automated means of enabling software engineers and project managers to develop and refine their NL requirements is needed in RE. NLP can reduce the human effort in making NL requirements clear, consistent, unambiguous, and easy to understand by all stakeholders before moving into modeling and design phases. There are still numerous limitations on the capabilities and rationales for using NLP techniques, despite research developments on NLP for RE. Various challenges for NLP use within requirements elicitation and analysis still exist, including the followings:

- Coreference resolution: Coreference resolution is the task of extracting several expressions in a sentence or text that refer to the same entity/actor in a requirements document. It is especially employed at the semantic/pragmatic level when two nouns are treated the same [67]. Coreference resolution is a key challenge of NLP, not only in English but also for all other languages [68].

- Emotion Detection (ED): While the use of NLP system in requirements elicitation and feedback techniques are well defined, there are no current state-of-the-art techniques that combine emotionally driven features and the capture of user feedback on these features [69]. Emotion recognition may also be used to evaluate social media data or to spot fake news [70]. A major challenge in ED is that the cultural affiliations of an individual may significantly impact their expressed feelings in a situation [69]. However, progress is being made as several methods have been developed to solve this problem. These methods include the use of a knowledge-enriched transformer [71], focusing on latent representation [72], and building new datasets that focus on emotions [73] and [74].

- Unimodal LNP: Current NLP systems are primarily unimodal. Thus, they are limited to process and analysis of linguistic inputs [75]. However, humans are multimodal. They use diverse combinations of visual, auditory, tactile, and other inputs. Humans do not handle each sensory model in isolation but rather simultaneously. This process incorporates each sensory model to enhance the quality of awareness and understanding [76]. Therefore, from a computational point of view, NLP needs to have these same abilities to achieve human-level ground and understanding in a variety of AI tasks. NLP must be assisted by multimodal control interfaces, identification and understanding of human behavior, and collaborative decision-making between the system and individuals or groups to understand the requirements of the customer and other stakeholders [77]. Visual question answering is a method that addresses the challenging unimodal aspect of NLP systems [78]. Many other methods are used to integrate multimodality into NLP structures, including declarative learning-based programming [79], multimodal datasets [80], procedural reasoning networks [81], and unified attention networks [82].

- Ability to recognize requirement sentences that contain contextual information rather than merely describing the process steps [28]. The inherent ambiguity of NL can lead to differing interpretations of the same sentence [83].

- Domain ontologies approach: [43] found that requirement analysts were more likely to misidentify concepts and relationships when using a domain ontologies approach. Thus, domain ontologies need to be investigated to develop a deeper understanding of the requirements and their respective relationships [84].

- NLP accuracy in extracting the correct requirements must be improved. NLP must be enhanced by other methods (e.g., ML) to eliminate errors. Accuracy must be substantially improved if NLP to be seriously considered for use with RE [85].

- The algorithms for detecting ambiguity need improvement and fine-tuning while simultaneously avoiding over-fitting. These improvements are needed to evaluate whether the use of domain ontologies can lead to a deeper understanding of the requirements and their relationships [86].

- PoS detection is generally considered a challenge that has been resolved. However, there are still issues with incorrect POS tags [87].

Attempting to resolve all ambiguities in a requirements specification is a time-consuming process that cannot be fully automated. Human interaction is needed to overcome dynamic ambiguities that are dependent on domain knowledge. Controlled language is helpful in identifying or avoiding ambiguities in SRS. However, the input must be written in the constraint language, and lexical and syntactic ambiguities must be addressed. Furthermore, methods that use knowledge-based, ML, and ontology techniques may produce precise outcomes by detecting semantic ambiguities in the requirements specifications [88], [89], [90].

VII. Discussion

Our research focused on a specific field and evaluated a range of trends explained and summarized in this section. The objective of this research was to provide a state-of-the-art summary of NLP performed in various RE activities. This research is intended to be an overview for domain experts and serve as an entry point for researchers in this area. We present results based on the conducted literature review. As previously discussed, the literature review was not entirely systematic.

Thus, our findings may be revised and/or expanded by future studies within this domain.

Table I and Section IV provide answers to RQ1 (“What is the current state of the practice for elicitation and analysis phases in RE using NLP as the platform?”) and RQ2 (“What are the activities for the requirements elicitation and analysis in RE using NLP as the platform?”). Twenty-five articles (i.e., the “Contributions” column in Table I) were closely analyzed to assess the state-of-the-art of NLP the use NLP in RE activities. We assume that most studies are preliminary proposals because there are more academic research papers than actual software projects for industrial applications. As listed in Table I, the “NLP Tasks” and “RE Support.

TABLE I. CONTRIBUTIONS AND RE ACTIVITIES SUPPORTED BY NLP

N	Contribution	Publication Year	Objective/Purpose	NLP Tasks	RE Activities Support	Tools +Techniques + Resources	User interaction
1	Shah (+)	2015	Compare NLP approaches to resolve ambiguity	Detection	Elicitation + Analysis	-	-
2	Omoronyia et al., (-)	2010	Reducing the effort of building a domain ontology for requirements elicitation by analyzing NL text from technical standard	Extracting semantic graphs	Elicitation	POS tags Sentence parser	Medium
3	Ibrahim et al., (*)	2010	Using NLP and domain ontology to extract UML class diagram from informal NLP by using the RACE tool to produce class diagram from requirements	Extracting	Analysis	PoS tags, Open NLP parser	Medium
4	Maalej et al., (*)	2015	The authors discussed how software development organizations can employ user feedback to identify, prioritize, and manage requirements	Classification	Elicitation + Prioritization	-	-
5	Bano (+)	2015	The findings of a mapping analysis are discussed in a collection of empirical work from the last two decades that discuss the concept of complexity in RE using NLP methods and techniques	Ambiguity Detection	-	-	-
6	Robeer et al., (+)	2016	Extracting conceptual modules from user stories requirements using NLP	Modeling	Analysis	spaCy tagger	Low

25	Mezghani, et, al., (-)	2018	Proposes an approach using NLP to detect technical business terms associated with the requirements documents	Classification + Clustering	Analysis	PoS tagging + Noun chunking	

Legends: (+) improves state of the art; (*) no information related to state of the art; (-) comparable with state of the art

Activities” columns address RQ2 and describe the various RE tasks that can be assisted by NLP techniques. These RE tasks include traceability, ambiguity detection, and requirements classification. The available techniques and tools developed to support each RE task are presented (e.g., PoS, tagging, and tokenization). The “Contributions” column in Table I also includes a partial response to RQ 3 (“Are NLP systems improving the requirements elicitation and analysis for RE?”). The answer to RQ3 appears to be preliminary; as indicated by the lack of comparison with state of the art in Table I. Table I also include information related to the quantity the NLP data and user expectations, emotions, and experiences. This rich data set may be used by software developers to assess better their product users' needs, experiences, and sentiments. Mining NLP, especially user opinions, can yield valuable information for product upgrades by software development organizations. However, it is often difficult to extract user requirements from massive amounts of data. Opinions are often shared without regard to grammar or style. This issue has recently caused problems with corpus processing. As a result, we assume that the collected data are unstructured. Software developers focus on user feedback for requirements elicitation and analysis. However, the trustworthiness of comments, tweets, or feedback remains a major problem for the software development community. In section VI, we discussed a variety of limitations in this domain. Other challenges or limitations that the RE community faces by using NLP as the source for eliciting user requirements include user privacy and personalization [55]. These findings address RQ4 (“What are the current limitations of using NLP in requirements elicitation and analysis?”).

Table I lists the NLP methods used in the articles reviewed in this paper. Most researchers use NLP techniques for the identification of ambiguity in RE. Furthermore, due to its wide role in RE, the analysis process was the phase with the most attention in the research. We observed that NLP was primarily used in the preprocessing phase to convert data into a format that was consumable by all stakeholders. Most of the papers in our survey claim that the vast amount of imprecise data generated by NL users may provide tremendous benefits to software development organizations if processed with an NLP system. Most of the articles also indicate that NLP use with RE is still in its early stage; however, this research topic is rapidly expanding. Although NLP can compensate for many of the requirements’ ambiguity, inconsistency, and incompleteness, there are still circumstances where interaction with end-users is required for clarification [58]. This finding is supported by entries in the “User Interaction” column in Table I. Most of the papers about the use of NLP in requirements elicitation and analysis indicate that parsing requirement texts and classifying the information stored in them are difficult for humans. Thus, these activities should be automated as much as possible.

Furthermore, we discovered that most of the analyzed studies obtained their requirement datasets from external sources (e.g., Twitter, or an app store) rather than from existing documents for requirement elicitation. We found that the current state of the art in this area indicates that the first two phases prioritize researchers and practitioners. Table I shows most of the NLP techniques employed parsers and taggers to explain the tools used in text processing. This finding is supported by the results from [53]. In that study, NLP techniques are applied to sentence segmentation, tokenization, PoS tagging, shallow parsing, dependency parsing, word stemming, lemmatization, and role labeling.

Within the RE field, NLP is primarily used to analyze requirements and schedule them for further processing. This is primarily focused on developing models from elicited requirements and improving the consistency of the SRS. Both SRS and NLP share three common tasks: PoS tagging, rule-based analysis, and syntactic parsing. Two areas that lag behind the other RE (sub-)phases in the scope are requirements documentation (e.g., drafting of the SRS) and requirement prioritization. We assume that the writing requirements are supported by the NLP, including implementation of a specific template, spell checking, and explicitly resolving any possible ambiguities. These writing requirements may be beneficial to requirements engineers. However, since these tools necessitate live contact with requirement engineers, this research is not regularly performed than less advanced tools (e.g., solely for ambiguity checking).

Classification, model extraction, and detection seem to have more advancement than other areas of research, based on the number of publications and reported NLP tasks. This assumption is also valid for ambiguity detection.

VIII. Conclusion

This paper reviewed the current status of using NLP and its limitations in requirements elicitation and analysis processes. With the need for faster speed, lower cost, and higher quality in software engineering, there is an increasing need for automated support for all processing requirements of elicitation and analysis in the RE artifacts. While the pressure from industrial customers is obvious, extensive work is still needed to create automated NLP-based processes in RE. NLP tools and techniques have been proposed to automatically or semi-automatically detect syntactic, semantic, and pragmatic ambiguities in the requirements. Many solutions have been proposed from academia and industry to evolve the use of NLP in RE. Despite progress in NLP, there are still limitations to the NLP system. There is extreme pressure from the industry to improve the accuracy of NLP used to extract system requirements. Therefore, NLP must be enhanced for the elimination of residual errors. The accuracy must be substantially increased if it is to be seriously considered for use in RE. Based on the results from this paper’s review and due to its limitations, NLP systems cannot be considered as a solution that can fix all RE issues. Nevertheless, NLP can be used to assist RE analysts. Findings from this study indicate that NLP can be used in real-world applications. Future research may produce more specialized NLP tools that can help consolidate the domain model and serve as translators between different RE documents and structured models.

These findings provide an understanding of the state of the art in this field of study and are useful for developing an analytical framework for complete systematic literature reviews. From the standpoint of RE, it may be important to investigate how NLP task combinations can be streamlined to fully perform additional tasks. The same is true for NLP in requirements management where requirements are managed within a software system, from elicitation to implementation to reuse. The NLP tasks described in this paper is not a comprehensive list. A possible extension of this research may examine NLP activities that have not yet been used in the field and how they may be used in the future applications.

Acknowledgment

The authors wish to thank the Public Authority for Applied Education and Training for providing the resources needed to conduct this research.

***Abstract*—Digital news platforms and online newspapers have multiplied at an unprecedented speed, making it difficult for users to read and follow all news articles on important, relevant topics. Numerous automatic text summarization systems have thus been developed to address the increasing needs of users around the world for summaries that reduce reading and processing time. Various automatic summarization systems have been developed and/or adapted in Arabic. The evaluation of automatic summarization performance is as important as the summarization process itself. Despite the importance of assessing summarization systems to identify potential limitations and improve their performance, very little has been done in this respect on systems in Arabic. Therefore, this study evaluated three text summarizers AlSummarizer, LAKHASLY, and RESOOMER using a corpus built of 40 news articles. Only articles written in Modern Standard Arabic (MSA) were selected as this is the formal and working language of Arab newspapers and news networks. Three expert examiners generated manual summaries and examined the linguistic consistency and relevance of the automatic summaries to the original news articles by comparing the automatic summaries to the manual (human) summaries. The scores for the three automatic summarizers were very similar and indicated that their performance was not satisfactory. In particular, the automatic summaries had serious problems with sentence relevance, which has negative implications for the reliability of such systems. The poor performance of Arabic summarizers can mainly be attributed to the unique morphological and syntactic characteristics of Arabic, which differ in many ways from English and other Western languages (the original language/s of automatic summarizers), and are critical in building sentence relevance and coherence in Arabic. Thus, summarization systems should be trained to identify discourse markers within the texts and use these in the generation of automatic summaries. This will have a positive impact on the quality and reliability of text summarization systems. Arabic summarization systems need to incorporate semantic approaches to improve performance and construct more coherent and meaningful summaries. This study was limited to news articles in MSA. However, the findings of the study and their implications can be extended to other genres, including academic articles.**

Keywords*—AlSummarizer; Arabic; automatic summarization; discourse markers; extraction; LAKHASLY; news articles; RESOOMER; sentence relevance

I. Introduction

The recent unprecedented growth of digital news platforms and online newspapers has resulted in considerable changes in terms of news production and audience reception. Compared to traditional newspapers, digital news networks and online newspapers are extremely fast and easily accessible. Different reports indicate that online newspapers replaced traditional newspapers causing them to lose much of their audience [1]. That is why, almost all daily and weekly newspapers in the West and in the Arab world run their own websites and publish electronic editions [2-4]. Furthermore, news websites have now proliferated in an unprecedented manner, and without any of the traditional restrictions. There is no need for licenses, offices or even employees and correspondents. Anyone can create a news website in the same way used to create a personal website. This has the effect of producing fast and prolific news in an unprecedented manner.

The extensive number and popularity of online newspapers have changed the way people consume newspapers and magazines in many ways. According to Watson [5], by 2020, more than two-thirds of people in the United Kingdom were reading or downloading online news, newspapers, or magazines. In comparison to 2007, the number of online readers had tripled. As of February 2019, the Guardian and Mail Online were the second and third most popular websites in the UK, respectively, as shown in Fig. 1.

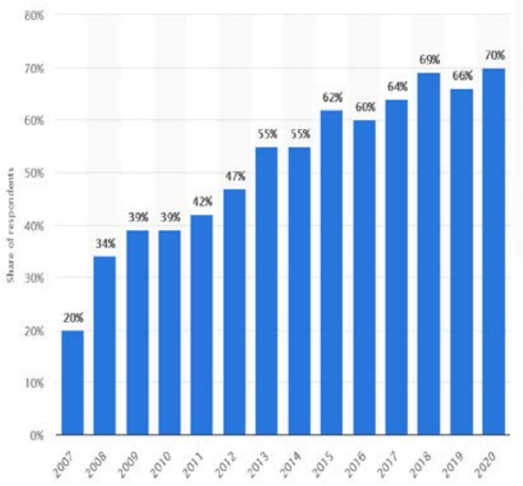

Fig. 1. Share of Individuals Reading or Downloading Online News, Newspapers or Magazines in Great Britain from 2007 to 2020 (Statista.com).

In the same study, Thurman [6] asserts that over recent years online newspapers and news websites have been gaining massive popularity and increasing in an unprecedented manner. In the face of these developments, it is impossible for a normal audience to follow all that is written on important and relevant topics. It is a challenging task for individuals to read this huge content in a limited time span, as the news changes daily if not hourly.

In response, numerous automatic summarization systems have been developed over recent years to generate meaningful summaries that can reduce reading and processing times. Researchers have developed summarization tools and methods that automatically summarize the content of news articles in effective ways. It is even argued that summarization has become an integral part of everyday life [7]. This can be seen in the rapid developments of numerous applications and websites including Summarize Bot, Resoomer, SMMRY, Inshorts, and Text Summarization API (Rapid API) that provide summarization services to news articles to millions of users around the world.

Despite the availability of text summarizers in different languages including Chinese, English, French, and Spanish that provide good summarization services for millions of global users, automatic summarization in Arabic is still very limited. This can be attributed to the unique linguistic system of Arabic where multilingual text summarizers cannot be used with Arabic texts. It is also true that the morphological and syntactic properties of Arabic still pose serious challenges for different Natural Language Processing (NLP) applications, including information retrieval, localization, machine translation, and automatic text summarization [8, 9].

Another reason for this limitation is the lack of evaluation studies of automatic Arabic text summarization. Evaluation is an integral part in the automatic summarization process [10-16]. According to Al Qassem, et al. [17], the evaluation process is one of the main challenges that have adverse impacts on the availability and reliability of automatic Arabic text summarization systems. This can be attributed to the lack of gold standard summaries for Arabic. They add that automatic evaluation of Arabic summarization is more complicated due to the lack of Arabic benchmark corpora, lexica, and machine-readable dictionaries.

To address this limitation, an evaluation of three text summarizers AlSummarizer, LAKHASLY, and RESOOMER is carried out hereunder. A corpus of 40 news articles was built. The articles were randomly selected from the most popular and digital news networks and online newspapers in the Arab world. It was, however, considered that the selected news articles cover different themes and subjects including politics, business, sports, and entertainment. Only articles written in Modern Standard Arabic were selected. The rationale being that MSA is still the formal and working language of the Arab newspapers and news networks.

The remainder of this article is organized as follows. Section 2 is a brief survey of automatic summarization literature in general and automatic Arabic text summarization systems in particular. Section 3 defines the research methods and procedures. In this part, the selected summarizers and articles are defined. Procedures of carrying out the study are also defined and established. Section 4 reports the results. It evaluates the performance of the selected summarizers regarding the news articles. Section 5 concludes the study.

II. Previous Work

Previously, text summarizations were carried out using non-computational methods, using philological methods where experts and professionals produced their summaries based on their own evaluation of the most important concepts in the texts under investigation. With the development of digital technologies, computational approaches have been integrated into text summarization for generating automatic summaries of different text genres. It can be obviously seen that the recent years have witnessed an increasing rate in the development of automatic text summarizers. These have been essentially developed to address the increasing needs of users all over the world. Gambhir and Gupta [18] assert that it has now become impossible for traditional or non-computational classification methods to deal with the large amounts of data available today. They indicate that conventional or non-computational summarization methods are no longer effective or reliable to deal with the prolific size of digital texts and archives available on the internet. According to Cheng and Lapata [19], the need to access and digest large amounts of textual data has provided strong impetus to develop automatic summarization systems, aiming to create shorter versions of one or more documents, whilst preserving their information content. Much effort in automatic summarization has been devoted to sentence extraction, where a summary is created by identifying and subsequently concatenating the most salient text units in a document.

Soni, et al. [20] agree that due to massive rate of rising data at a on the Internet, automatic text summarization tools have a powerful effect on today's world. The entire material is very difficult for a person to describe and ingest. It is a very difficult task to manually convert or summarize, hence, automation is required. Using artificial intelligence methods, automatic text summarization can be accomplished.

Nenkova and McKeown [21] add that objectivity and consistency have always been main considerations in automatic summarizations. The argument is that automatic summarization is imperative for addressing the inconsistencies and lack of objectivity that were associated with conventional or non-computational methods of text summarization.

The first attempt of computer-based text summarization is attributed to Hans Peter Luhn in 1958 [22-25]. In his article 'The Automatic Creation of Literature Abstracts', Luhn [26] proposed an algorithm to facilitate quick and accurate identification of the topic of published papers in a way that saves prospective readers time and effort in finding useful information in a given article or report. The underlying principle of Luhn's approach was that the salient points of an author's argument can be identified through the statistical analysis of the most frequent words and phrases occurring in texts. The hypothesis was that authors generally use important words more frequently throughout a paper and this can be conveniently used as a predictor for selecting the sentences with more repetition of the keywords and extracting them to generate an automatic summary [27-29].

Despite the development of different approaches to automatic text summarization, extractive methods remain the most popular summarization methods. In such methods, automatic summarizers are trained to identify the most important phrases and sentences, usually using statistical methods, and generate automatic summaries based on the extraction process of these sentences and phrases. Extractive-based summarization approaches are based on identifying and selecting only the most important phrases and sentences in texts under consideration. To generate an automatic summary, automatic summarizers then incorporate all the important phrases and sentences. In this case, therefore, every line and word of the summary actually belongs to the original summarized text [30].

In Arabic, over recent years, a very limited number of automatic text summarization systems have been developed, compared to other languages including English, Spanish, and Chinese [16, 17, 31]. Al-Saleh and Menai [10] comment that despite the long history of text summarization, studies of the Arabic language in this area have only recently emerged, and they have been negatively influenced by the lack of Arabic gold standard summaries.

The literature indicates that automatic text summarization systems have been largely based on extractive methods. These extractive summarization systems are mainly based on numerical and statistical measures [32-36]. The main hypothesis in these approaches is the ability of training the machine to identify the most important sentences and phrases for building the summaries. This is usually carried out through using different statistical measures including Principal Components Analysis (PCA) and Term-Frequency Adverse Document-Frequency (TD-IDF). To simplify, these weighting methods are used as indicators for retaining only the important information within texts and discarding information of secondary or minor importance. Successful implementation of these mechanisms is thus a critical factor for the success of summarization systems [37].

Weighting methods are usually combined with other methods that support the identification of the most important sentences, clauses, and phrases in the texts. One popular method is the position or location of sentences. The premise is that the location of a sentence in a document is related to the amount of information it contains. Other techniques involve grouping and summarizing related texts in a process known as multi-document summarization.

The argument is that the majority of automatic Arabic summarization systems are based on statistical methods. One limitation with these techniques is that automatic summaries are based only on those sentences with the highest scores based on statistical measures and techniques. In response, symbolic approaches have been adopted [38-41]. Unlike the numerical and statistical approaches, symbolic-based extractive summarization systems are based solely on linguistic information and indicators for identifying the most important sentences and expressions within texts. The premise of such approaches is that summaries should be built on a rhetorical structure that considers the rhetorical relations within texts. Work on symbolic-based extractive summarization systems is still very limited.

Over recent years, work on/with automatic Arabic summarization systems has reflected on the development of online summarizers that provide summarization services for users in an easy and accessible way. These summarizers are based on the developments in automatic Arabic summarization research and industry. One major problem, however, is the lack of evaluation studies that can determine the readability and reliability of these summarizers. This study addresses this gap in the literature through an evaluation of three Arabic summarizers, namely AlSummarizer, LAKHASLY, and RESOOMER.

III. Methods and Results

This study is based on a corpus of 40 newspaper articles. The articles were selected from nine newspapers issued published in different Arab countries, as shown in Table 1.

The selected articles and opinions represent different topics including politics, business, and sports as shown in Table 2.

TABLE I. THE SELECTED NEWSPAPERS

Selected newspapers		
Newspaper Title	***Country***	***Number of articles***
Al-Ahram	Egypt	8
Al-Bayan	Emirates	4
Al-Itihad	Emirates	3
Alrai	Jordan	3
Al-Watan	Kuwait	4
Annahar	Lebanon	4
Assabah	Morocco	4
Al-Jazeera	Saudi Arabia	5
Asharq Al-Awsat	Saudi Arabia	5

TABLE II. TOPICS OF THE SELECTED ARTICLES

Articles topics	
Category	***Number of articles***
Politics	8
Business	8
Sports	8
Entertainment/Culture/ Family (ETF)	8
Science/Technology	8

For convenience, the selected articles were coded 01-40, as shown in Table 3. The full information pertaining to the selected articles, including transliteration and English translations of the headlines of the selected articles is given in Appendix No. 1.

The selected articles were summarized using three Arabic summarizers: AlSummarizer, LAKHASLY, and RESOOMER. These are currently the most popular Arabic summarizers. All three summarizers are based on extractive summarization methods. AlSummarizer is multilingual software that provides summarization solutions in different languages including Arabic, Dutch, English, Farsi, and Turkish. LAKHASLY is an Online Summarization tool. It provides automatic summaries for Arabic and English texts. It is widely used all over the world for users interested in Arabic summaries. Finally, RESOOMER is online summarizers which provide summarization services in different languages including Arabic, English, French, German, Italian, Polish, and Spanish.

For evaluating the performance of the selected summarizers, manual (human) evaluation methods were used. Three examiners were selected to generate manual summaries and to examine the linguistic consistency and relevance of the automatic summaries to the original news articles.

IV. ANALYSIS AND DISCUSSIONS

To evaluate the performance of the three selected Arabic summarizers, the automatic summaries were compared to the manual (human) summaries produced by the experts who participated in the study. Results are shown in Table 4, Table 5, and Table 6.

Comparisons to the manual summaries indicate that the scores of the three summarizers are very similar. The scores also indicate that the performance of the three summarizers is not satisfactory. This has negative impacts on the reliability of these summarizers. Another problem with the three summarizers is the lack of sentence relevance and coherence.

This can be seen in the following example taken from LAKHASLY. There is a problem with the sentence relevance. Sentences are not well connected to one another, which has adverse impacts on the readability and understanding what the original text about, as shown in Box 1.

TABLE IV. SENTENCE OVERLAP IN THE AUTOMATIC SUMMARIES GENERATED BY ALSUMMARIZER

TABLE VII. BOX NO. 1. AN AUTOMATIC SUMMARY GENERATED BY LAKHASLY

Original Text
أعربت المملكة أمس عن القلق الشديد من تنامي وتيرة خطاب الكراهية والتعصب ضد المسلمين حول العالم، حيث أصبح التعصب والإسلاموفوبيا خطرًا واضحًا يهدد أمن المجتمعات المستقرة. وقال مندوب المملكة الدائم لدى الأمم المتحدة في جنيف الدكتور عبدالعزيز الواصل في كلمة المملكة أمام مجلس حقوق الإنسان المنعقد في جنيف: إن المملكة العربية السعودية تعرب عن القلق من استهداف الأقليات الدينية بصورة متزايدة بسبب معتقداتهم ومن تنامي خطاب الكراهية داخل الأطياف السياسية التي تستخدم مصطلحات الإقصاء والتهميش وغيرها في ظل وجود منصات التواصل الاجتماعي التي سهلت بث التطرف والكراهية وتعزيز الصور النمطية السلبية ووصم المسلمين عبر وسائل عابرة للحدود. وأكد الواصل خلال الحوار التفاعلي مع المقرر الأممي المعني بحرية الدين والمعتقد، أهمية ترسيخ قيم التفاهم والتسامح والحوار والتعددية والتعارف بين الشعوب والتقارب بين الثقافات ومحاربة كل أيدلوجية تدعو للكراهية وتحرض على العنف وتسوّغ الجرائم الإرهابية التي لا يمكن قبولها في أي دين أو قانون، داعيًا إلى أهمية وجود إرادة دولية وشاملة وذلك من خلال مكافحة الخطاب المتطرف وخطاب الكراهية وعدّ الدين جزءًا من الحل وليس سبب المشكلة. ولفت الانتباه إلى أن المملكة تولي اهتماماً خاصًا بهذا الموضوع حيث أسست مركز الملك عبدالله بن عبدالعزيز العالمي للحوار بين أتباع الأديان والثقافات، وتبنَّت عدة مبادرات للاعتدال ومكافحة التطرف، منها تأسيس مركز اعتدال في المملكة العربية السعودية الذي أطلق مؤخرًا مشروعًا جديدًا تحت عنوان «تفنيد «للتصدي للأفكار المتطرّفة عبر فضاءات «الإنترنت» ومواقع التواصل الاجتماعي، كما استضافت المملكة مؤتمر رابطة العالم الإسلامي الذي عقد في مكة المكرمة في 2019 حيث أقر 1200 شخصية إسلامية من 139 دولة يمثلون 27 مكونًا إسلاميًا من مختلف المذاهب والطوائف، «وثيقة مكة المكرمة» التي تتضمن 29 بندًا لإرساء قيم التعايش بين أتباع الأديان والثقافات والأعراق والمذاهب في البلدان الإسلامية وتحقيق السلم والوئام بين مكونات المجتمع الإنساني كافة.
Summary
وقال مندوب المملكة الدائم لدى الأمم المتحدة في جنيف الدكتور عبدالعزيز الواصل في كلمة المملكة أمام مجلس حقوق الإنسان المنعقد في جنيف: إن المملكة العربية السعودية تعرب عن القلق من استهداف الأقليات الدينية بصورة متزايدة بسبب معتقداتهم ومن تنامي خطاب الكراهية داخل الأطياف السياسية التي تستخدم مصطلحات الإقصاء والتهميش وغيرها في ظل وجود منصات التواصل الاجتماعي التي سهلت بث التطرف والكراهية وتعزيز الصور النمطية السلبية ووصم المسلمين عبر وسائل عابرة للحدود .أهمية ترسيخ قيم التفاهم والتسامح والحوار والتعددية والتعارف بين الشعوب والتقارب بين الثقافات ومحاربة كل أيدلوجية تدعو للكراهية وتحرض على العنف وتسوّغ الجرائم الإرهابية التي لا يمكن قبولها في أي دين أو قانون، وتبنَّت عدة مبادرات للاعتدال ومكافحة التطرف،

Omar [42] explains that if sentences and clauses in the automatic summaries are not connected, the overall argumentative structure of the text is not supported and the thematic significance of the original texts is lost. He adds that in many cases automatic summaries generated in this fashion are misleading for readers and users. Alami, et al. [43] agree that one main reason for the low performance of text summarizers in Arabic is that sentences in the extracted or generated summaries are not relevant; therefore, the main point of the original texts is not clear. The lack of sentence relevance thus has negative impacts on the user’s ability to grasp the meaning of original texts. In such a case, automatic summaries do not provide the users with concise and relevant information that helps them determine and assess the importance of texts without having to read all of the texts.

The lack of sentence relevance and coherence in automatic summarization in Arabic can be attributed to the multilingual nature of automatic text summarizers. Many of the summarizers are usually offered in different languages without considering language- specificity. It is almost agreed upon, that the unique linguistic properties of Arabic are always associated with the low performance in different natural language processing (NLP) applications including automatic summarization [10, 17, 44-46]. To put it into context, the morpho-syntactic system of Arabic is different in many ways from English and other Western languages (the original language/s of automatic summarizers). The morphological and syntactic properties of Arabic are indispensable in building sentence relevance and coherence in Arabic. According to Al Qassem, et al. [17], the main challenge in Arabic text summarization is in the complexity of the Arabic language itself: 1) the meaning of a text is highly dependent on the context; 2) there are more inherent variations within Arabic than any other language; 3) the diacritics are usually absent in the texts of news articles and any online content.

To improve the sentence relevance in the automatic summarization of news articles in Arabic, this study proposes that summarization systems should be trained to identify the discourse markers within the texts and furthermore to use these discourse markers in the generation of automatic summaries. The hypothesis is that discourse markers can be gainfully used to create cohesive texts with sentences that are linked together and relevant to one another. In other words, discourse markers can be used to build cohesive and coherent texts through interrelated sentences which will have positive impacts on the quality and reliability of text summarization systems. Arabic summarization systems need to integrate semantic-based methods for improving the quality of summarization performance and generating more coherent and meaningful summaries.

V. Conclusion

Digital news platforms and online newspapers have multiplied today at an unprecedented speed, making it difficult for users to read and follow all news articles on important relevant topics. Numerous automatic text summarization systems have thus been developed to address the increasing needs of users around the world to access summaries that reduce reading and processing time. In Arabic, different automatic summarization systems have been developed and/or adapted in order to address the increasing need for automatic Arabic summaries. Evaluation of automatic summarization performance is as important as automatic summarization itself.

Despite the importance of the evaluation and assessment of automatic summarization systems for identifying the limitations and for improving the summarization performance, very little has been done on the evaluation systems of automatic text summarization in Arabic. Therefore, an evaluation of three text summarizers AlSummarizer, LAKHASLY, and RESOOMER was carried out. A corpus of forty news articles was built. Only articles written in Modern Standard Arabic (MSA) were selected. The rationale being that MSA is still the formal and working language of Arab newspapers and news networks. For evaluating the performance of the selected summarizers, manual (human) evaluation methods were used. Three examiners were selected to generate manual summaries and to examine the linguistic consistency and relevance of the automatic summaries to the original news articles. To evaluate the performance of the three selected Arabic summarizers, the automatic summaries were compared to the manual (human) summaries produced by the experts who participated in the study. Results indicated that the scores of the three summarizers were very similar. The scores also indicate that the performance of the three summarizers is not satisfactory. Furthermore, the automatic summaries have a serious problem with sentence relevance that has adverse impacts on the reliability of such systems.

It can be concluded that the poor performance of Arabic summarizers can be mainly attributed to the unique morphological and syntactic characteristics of Arabic. The morphological-syntactic system of Arabic is different in many ways from English and other Western languages (the original language/s of automatic summarizers). The morphological and syntactic properties of Arabic are indispensable in building sentence relevance and coherence in Arabic. Thus, this study proposes that summarization systems should be trained to identify the discourse markers within the texts and furthermore to use these discourse markers in the generation of automatic summaries. This will have positive impacts on the quality and reliability of text summarization systems. Arabic summarization systems need to incorporate semantic approaches for improving the quality of summarization performance and building more coherent and meaningful summaries.

This study was limited to the news articles in MSA. However, the findings of the study and their implications can be extended to other genres including academic articles. Further research, however, is recommended to address the performance of automatic Arabic text summarization in social media language and colloquial dialects in Arabic.

AUTHORS' PROFILE

Fahad Alliheibi is a Full Professor of Arabic Language and Linguistics in the Department of Arabic Language, College of Arts, King Abdulaziz University (KSA). Prof. Alliheibi received his PhD degree in Linguistics in 1999 from Durham University, UK. His research interests include Arabic Linguistics, Pragmatics, Text Linguistics, and Translation.

ORCID: 0000-0002-2233-5165

Abdulfattah Omar is an Associate Professor of English Language and Linguistics in the Department of English, College of Science & Humanities, Prince Sattam Bin Abdulaziz University (KSA). Also, he is a standing lecturer of English Language and Linguistics in the Department of English, Faculty of Arts, Port Said University, Egypt. Dr Omar received his PhD degree in computational linguistics in 2010 from Newcastle University, UK. His research interests include computational linguistics, digital humanities, discourse analysis, and translation studies.

ORCID: 0000-0002-3618-1750

Nasser Al-Horais is a Full Professor of Arabic Language and Linguistics in the Department of Arabic Language and its Arts, College of Arabic Language & Social Studies, Qassim University (KSA). Prof. Al-Horais received his PhD degree in Linguistics in 2009 from Newcastle University, UK. His research interests include Arabic Syntax, Generative Linguistics (Minimalist Program), Discourse Analysis, and Comparative Syntax.

***Abstract*—System identification is a very powerful tool for determining the system model and parameters from sets of observable input and output data. Once the system parameters are obtained, the system dynamic behavior, including all the system characteristics (time constant, overshoot, settling time, etc.) can be accessed and evaluated. Despite the difficulty and communication channel lag, online parameter estimation outperforms offline system identification due to the ability to remotely monitor and control the system as well as improve the system's controller, making it more accurate and reliable. With the extreme development in technology, the importance of combining wireless networks with closed automatic control systems has emerged. This connection facilitates communication processes between the different units in the control for remotely controlled of the output. However, there are some errors affecting such system resulted from communication channel, A/D and D/A conversion process, identification process, or the existence of adaptive weight Gaussian noise. In this paper, the errors were investigated using real system, and then a suitable controller was tuned and optimized in order to reduce and eliminate various errors. The results show excellent dynamic behavior of the system under transmitting and receiving process.**

***Keywords*—Online parameters estimation; Open Platform Communication; OPC; communication channel; ARMAX model (autoregressive-moving average with exogenous terms); DC-DC Converter; chopper circuit**

I. Introduction

Since online system identification has a number of benefits, such as estimating parameters in real time while the system is operating as well as gaining the ability to monitor and operate the system remotely, it also has a number of challenges. These challenges include (1) analog system discretization with the proper sampling time depending on the system dynamics (2) use a communication channel to send and receive data (3) using the regression method to find the new approximate parameters based on the nature of the measured data (4) deploying the identification process algorithm to determine the new estimated parameters (5) fine-tune an appropriate controller to reduce or remove all identification process errors, this paper focuses on the online parameters estimation for a DC-DC chopper circuit by applying the measured input and output data to the identification algorithm via OPC (Open Platform Communication) after being modeled in the form of ARMAX model(autoregressive-moving average with exogenous terms).

II. DC-DC Chopper Circuit Models

The buck-boost type of the DC-DC Converter will be modeled in both continues and discrete domains.

Fig. 1 shows Buck/Boost converter circuit diagram.

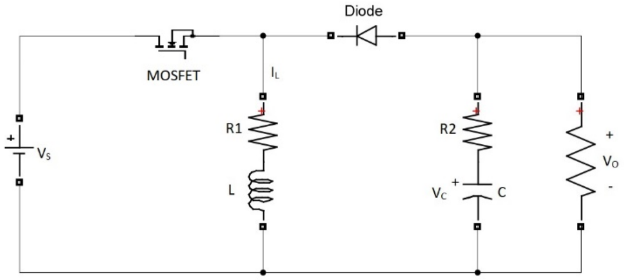

Fig. 1. Buck-Boost Converter Circuit.

Equation 1 describes the relation between input and output voltages which depends on the duty cycle d.

$$V_O = \frac{d}{1-d} * V_S$$

Mode 1: the switch is short circuit, and the diode is open circuit.

Mode 2: the switch is open circuit, and the diode is short circuit. Assume that the switch and the diode are ideal devices without delay [1, 2]. The state space representation matrices for mode 1 and 2 are:

- Mode 1

$\dot{x} = A_1 x + B_1 u$ and $y = C_1 x + D_1$

$$\mathbf{A_1} = \begin{bmatrix} -\frac{R_a}{L} & 0 \\ 0 & -\frac{1}{C} * \left(\frac{1}{R_O + R_b}\right) \end{bmatrix} \qquad \mathbf{B_1} = \begin{bmatrix} 1/L \\ 0 \end{bmatrix}$$

$$\mathbf{C_1} = \begin{bmatrix} 0 & 1 - \frac{R_b}{R_O + R_b} \end{bmatrix} \qquad \mathbf{D_1} = \mathbf{0}$$

- Mode 2

$\dot{x} = A_2 x + B_2 u$ and $y = C_2 x + D_2 u$

$$\mathbf{A_2} = \begin{bmatrix} -(\frac{R_a}{L} + \frac{R_O * R_b}{L*(R_O+R_b)}) & -\frac{R_b}{L*(R_O+R_b)} + \frac{1}{L} \\ -\frac{1}{C} * (\frac{R_O}{R_O+R_b}) & -\frac{1}{C} * (\frac{1}{R_O+R_b}) \end{bmatrix} \qquad \mathbf{B_2} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\mathbf{C_2} = [-\frac{(R_O * R_b)}{R_O+R_b} \quad 1 - \frac{R_b}{R_O+R_b}] \qquad \mathbf{D_2 = 0}$$

Mode 1 for Buck/Boost converter is valid for dT_S and mode 2 is valid for $(1-d)T_S$, where T_s is the sampling period. After combining both modes equations using averaging technique and divide them by sampling period T_S, the system block diagram for the Buck/Boost circuit is shown in Fig. 2 [3,4].

In order to study the effect of disturbance on the system output, then MISO (Multi-input single output) system can be presented as two transfer functions, first one describes the relation between first input which is the disturbance and the output voltage, and the other transfer function describes the relation between the second input which is the reference voltage, and the output voltage [5-14]. Fig. 3 shows the MISO block diagram.

Laplace Transform is a useful tool for solving differential equations and analyzing analog systems. It enables us to examine stability through the use of simple pole-zero plots and to describe frequency response of systems through factorization. The Z Transform is a similar tool that can be used with digital signals. It saves us a lot of time manipulating difference equations. It will assist you in understanding the behavior and stability of a digital system.

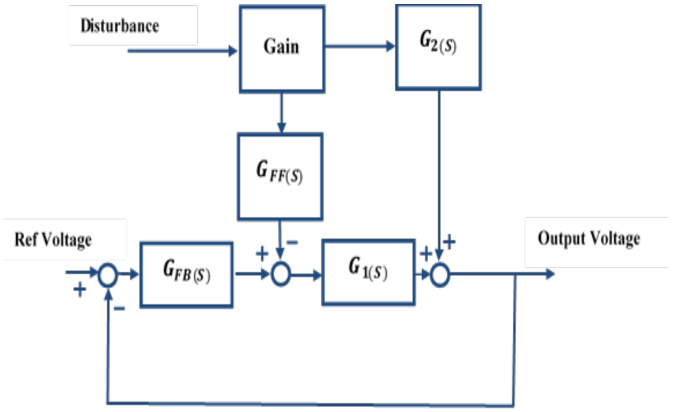

Fig. 2. Buck/Boost Circuit Block Diagram.

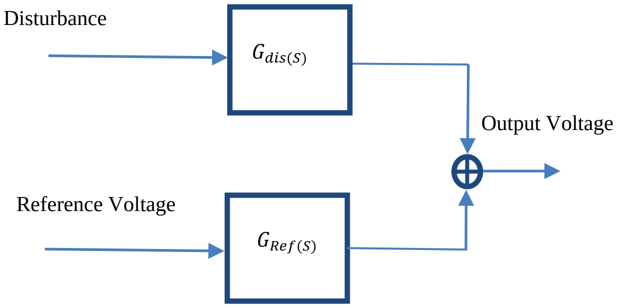

Fig. 3. MISO Block Diagram.

The unilateral Z-Transform of a digital sequence xn is given by.

$$Z(x_n) = X(z) = \sum_{n=0}^{\infty} x_n z^{-n}$$

The discrete state space model is:

$$x(k+1) = Gx(k) + Hu(k)$$

$$y(k) = Cx(k) + Du(k)$$

Table I shows the transformation from continuous to discrete.

TABLE I. TRANSFORMATION FROM CONTINUOUS TO DISCRETE

Continuous	discrete
$Ax(t)$	$Gx(k)$
$Bu(t)$	$Hu(k)$
C	C
D	D

The pulse transfer function will be obtained as following:

$$\frac{\mathrm{Y(z)}}{\mathrm{U(z)}} = \mathrm{C(zI-G)^{-1}H + D}$$

The structure of the Auto Regression Exogenous ARX model can be written as follows:

$$A(q)y(t) = B(q)u(t-nk) + e(t)$$

Where A(q) and B(q) are defined by:

$$A(q) = 1 + a_1 q^{-1} + \cdots + a_{nq} q^{-na}$$

$$B(q) = b_1 + b_2 q^{-1} + \cdots + b_{nb} q^{-nb+1}$$

where, $u(t)$ and $y(t)$ are respectively, the input and the output of the system, "t" is time unit, and q-1 represent the delay operator, $[qu(k) = u(k-1)]$.

III. Hardware and Software Configuration through OPC Communication Channels

This section illustrates experiment and hardware as well as the software configuration, the components of the real experiment are: Tow computers with network interface card (NIC), Ethernet cable cat5 with Rj45 connecters in both side And an Ethernet switch. Tow computers have been used here to make the identification process more realistic, the data are being transferred from one to the other and then received again.

OPC is a compatibility framework for transferring data securely and reliably in the industrial automation and other industries. It is platform that irrelevant and ensures a smooth flow of data between devices from various manufacturers, and OPC; it is based on the client server model as shown in Fig. 4. [15-18].

The OPC software used in this paper is KEPSERVER, this platform's design enables users to connect, manage, monitor, and control various automation devices and software applications via a single user interface [19].

OPC Client
OPC Server

Fig. 4. OPC Client and Server.

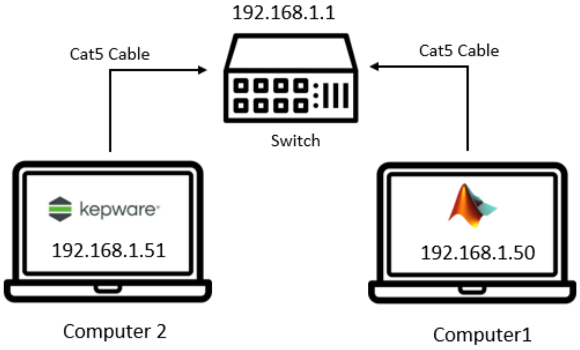

Fig. 5. Software and Hardware Topology.

Each one of the computers must be given a specific IP address through the Ethernet switch, one of the computers will be the OPC server "KRPSERVER" [20] and the other computer will be the OPC client "MATLAB" Fig. 5 shows the hardware and software topology [21].

As you can see from Fig. 5, both computers must be in same subnet mask OPC Client - computer 1 is configured with "192.168.1.50" IP address and OPC Server – computer 2 is configured with "192.168.1.51" IP address.

IV. Results and Discussion

The effect of each identification factor, including sampling time T_s, regression model type, number of parameters in A(q) and B(q), OPC communication channel effect, and the effect of adding noise to the input disturbance signal, will be investigated. The values of the DC-DC Buck/Boost converter circuit parameters are shown in the Table II.

The continuous transfer functions of the block diagram shown in Fig. 2 become:

G_1(s) between disturbance and Output voltage.

$$G_1(s) = \frac{0.74527\ (s + 7.5e04)(s - 1616)}{(s^2\ +\ 227.2s\ +\ 2.085e05)}$$

G_2(s) between $\hat{u}$ and $\hat{y}$

$$G_2(s) = \frac{-6.995\ (s + 5.757e04)}{(s^2\ +\ 227.2s\ +\ 2.085e05)}$$

The feedback controller G_{FB}(s):

$$G_{FB}(s) = \frac{S + 1789}{S + 7.757e04}$$

The feedforward controller G_{FF}(s):

$$G_{FF}(s) = \frac{-0.33}{S}$$

TABLE II. Buck-Boost Circuit Parameters

The parameter	The value
$\overline{V_{IN}}$	40 V
L	2.85*10^{-3} H
C	193*10^{-6} F
R_1	0.09 ohm
R_2	0.09 ohm
R_O	27.9 ohm
$\bar{d}$	2/3
Fs	60 HZ

All transfer functions will be converted to discrete form depending on the sampling time Ts. Each value of Ts gives a specific pulse transfer function, assuming Ts = 0.001second such that:

G_1(z) between $\hat{d}$ as input and $\hat{y}$ as the output in Z domain:

$$G_1(z) = \frac{0.74527(z + 11.52)(z - 7.534)}{(z\verb|^|2\ +\ 1.613z\ +\ 0.7968)}$$

G_2(z) between $\hat{u}$ as input and $\hat{y}$ as the output in Z domain:

$$G_2(z) = \frac{-0.1898(z + 0.8653)}{(z\verb|^|2\ +\ 1.613z\ +\ 0.7968)}$$

The feedback controller pulse transfer function G_{FB}(z):

$$G_{FB}(z) = \frac{Z - 0.9689}{z\ -\ 9.941e - 26}$$

The feedforward controller pulse transfer function G_{FF}(z):

$$G_{FF}(z) = \frac{-0.00033}{z - 1}$$

Fig. 6 shows the online identification process with all its steps, the blue dashed line is the OPC communication channel, while the black line indicates the MATLB system signal.

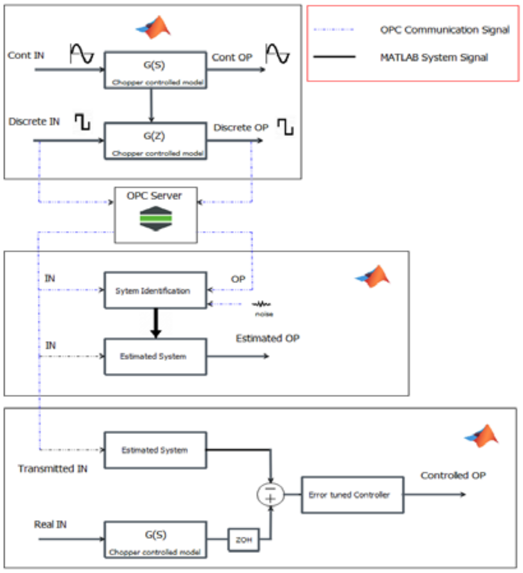

Fig. 6. Identification Process System Block Diagram.

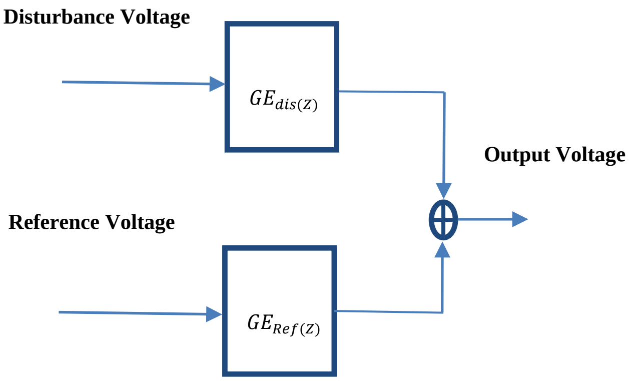

Fig. 7. Estemated Transfer Functions.

After the parameter's estimation of $G_{dis(S)}$ and $G_{Ref(S)}$ new estimated transfer functions are obtained $GE_{dis(Z)}$ and $GE_{Ref(Z)}$ as shown in Fig. 7. Where, $GE_{dis(Z)}$ describe the relation between first input (disturbance) and output, and $GE_{Ref(Z)}$, describe the relation between second input (disturbance) and output.

A. Sampling Time Ts

In this section, sampling time will be investigated, and the effect of changing Ts on the identification process will be determined, the parameters value for the DC-DC Converter will be as in the Table II. The identification parameters are shown in Table III.

TABLE III. CONSTANT IDENTIFICATION FACTOR RELATED TO VARYING TS

The parameter	The value
Regression type	ARMAX
Regression parameter	A(q)=3 B(q) = 3
OPC	Scan Rate = same as Ts Communication remotely via ethernet cable
Noise	No noise

But sampling time Ts will be varying, the examples below will explain this methodology.

a) Example 1

In this example the sampling time will assumed to be 0.1 second, Fig. 8 shows the continues OP (output) and Discrete OP (output).

The estimated parameters for both transfer function $GE_{dis(Z)}$ and $GE_{Ref(Z)}$ are shown in Table IV.

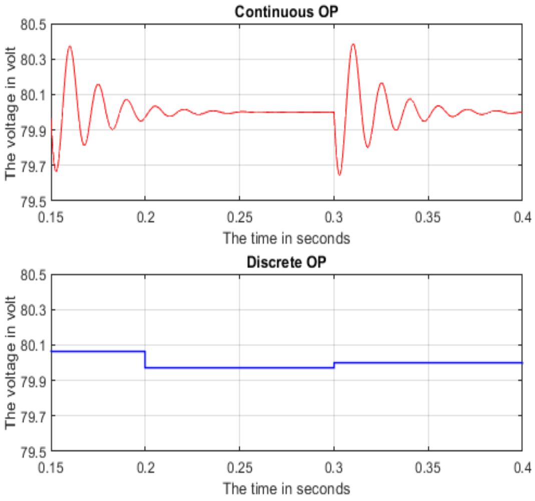

Fig. 8. Continuous and Discrete Outputs related to 0.1 Second Sampling Time.

Fig. 9 shows the Estimated OP(Output).

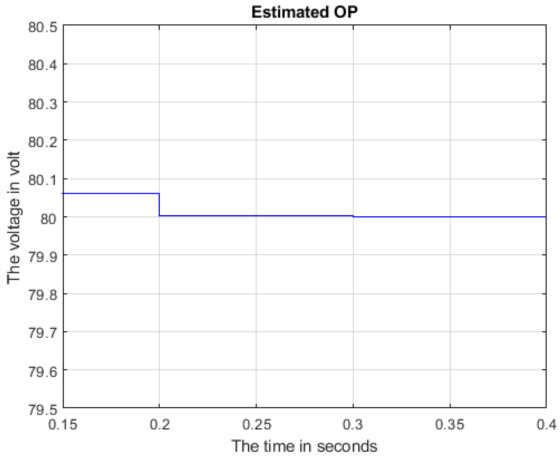

Fig. 9. Estimated Output related to 0.1 Second Sampling Time.

TABLE IV. ESTIMATED PARAMETERS RELATED TO 0.1 SECOND SAMPLING TIME

q-operator	Estimated parameters in both transfer functions			
	$GE_{dis(q)}$		$GE_{Ref(q)}$	
	$A(q)$	$B(q)$	$A(q)$	$B(q)$
q^0	1	0	1	0
q^{-1}	-9.64E-08	-2.37E-05	3.6E-04	1.001
q^{-2}	2.2E-016	2.2E-016	2.6E-05	-3.6E-4
q^{-3}	2.2E-016	2.2E-016	2.2E-16	-2.6E-05

b) Example 2

In this example the sampling time will assumed to be 0.01 second, Fig. 10 shows the continues OP and Discrete OP.

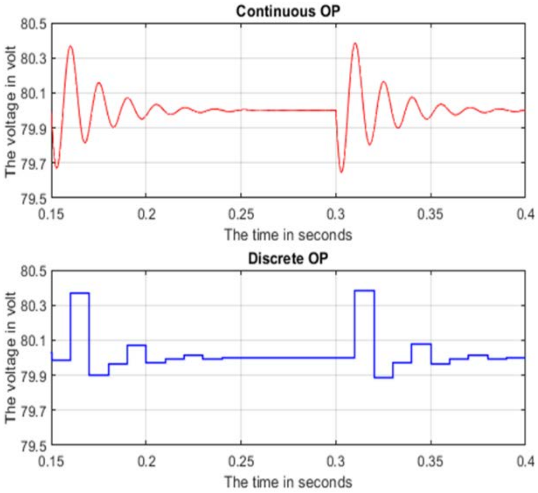

Fig. 10. Continuous and Discrete Outputs related to 0.01 second Sampling Time.

Fig. 11 shows the Estimated OP.

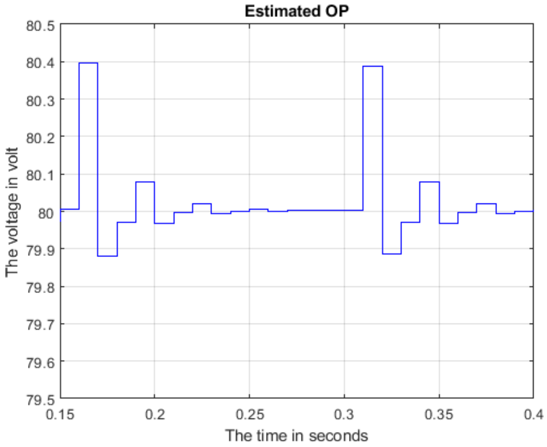

Fig. 11. Estimated Output related to 0.01 Second Sampling Time.

The estimated parameters for both transfer function $GE_{dis(Z)}$ and $GE_{Ref(Z)}$ are shown in Table V.

TABLE V. ESTIMATED PARAMETERS RELATED TO 0.01 SECOND SAMPLING TIME

q-operator	Estimated parameters in both transfer functions.			
	$GE_{dis(q)}$		$GE_{Ref(q)}$	
	$A(q)$	$B(q)$	$A(q)$	$B(q)$
q^0	1	0	1	0
q^{-1}	0.3443	0.048189	0.3356	0.8474
q^{-2}	0.1861	-0.04588	0.2025	0.2453
q^{-3}	-0.1129	-0.002297	-0.1114	0.334

c) Example 3

In this example the sampling time will assumed to be .001 second Fig. 12 shows the continues OP and Discrete OP:

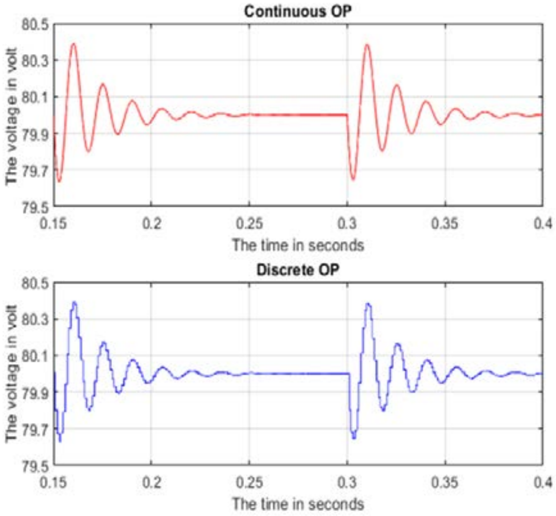

Fig. 12. Continuous and Discrete Outputs related to 0.001 Second Sampling Time.

Fig.13 shows the Estimated OP.

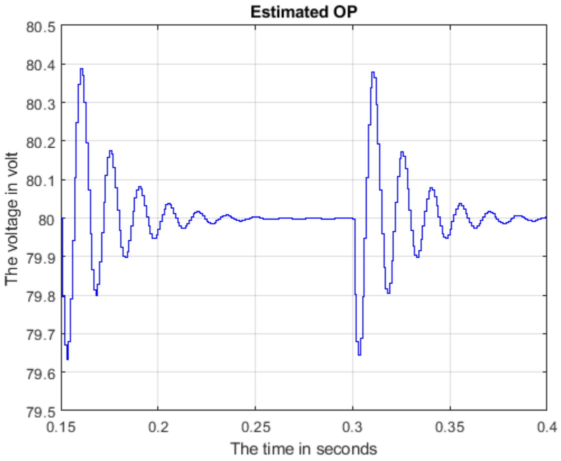

Fig. 13. Estimated Output related to 0.001 second sampling Time.

The estimated parameters for both transfer function $GE_{dis(Z)}$ and $GE_{Ref(Z)}$ are shown in Table VI.

TABLE VI. ESTIMATED PARAMETERS RELATED TO 0.001 SECOND SAMPLING TIME

q-operator	Estimated parameters in both transfer functions.			
	$GE_{dis(q)}$		$GE_{Ref(q)}$	
	$A(q)$	$B(q)$	$A(q)$	$B(q)$
q^0	1	0	1	0
q^{-1}	-2.657	-0.0244	-2.617	-0.0029
q^{-2}	2.505	0.04952	2.434	0.01425
q^{-3}	-0.8339	-0.02513	-0.7972	0.00864

- Discussion

The conclusion is that as the sampling time increases, the identification error decreases and the identification process becomes more accurate, because as the sample time increases, more data from the system is analyzed and the identification loop has more data to estimate the parameter. In the case of Ts =0.001, we have 401 sets of values, which is sufficient to accurately estimate the parameter, whereas when Ts =0.01, we only have 41 sets of values, which is insufficient to estimate the parameters. On the other hand, choosing Ts to be very low will take a long time to complete the identification process, In the worst-case scenario, Ts=0.1 second leads to poor identification because the system completes its dynamic behavior and reaches steady state in 0.15 second, because when Ts=0.1 second, only two values are generated to describe the complete system's behavior, which is insufficient. Assuming Ts = 0.001, we have two advantages.

1) 1. provides a sufficient set of data to enable accurate identification.

2) It takes an acceptable amount of time, not too long but also not too fast.

Conclusion is that assuming Ts =.001 is better for this system, considering the response time and dynamic behavior for our system (DC Converter circuit), Table VII compares the sampling time with the system characteristic (overshoot, response time... etc.), delay time, and the identification error in general, also the ability to tune a controller to overcome the identification error.

Table VIII shows that as much as the sampling time increase high delay is added, extremely high identification error and the system characteristic and be measured or obtained.

B. *Number of Parameters*

The effect of changing the number of parameters will be investigated in this section, and thus the effect of changing the number of parameters on the identification process will be determined; the parameters value for the DC-DC Converter will be as shown in Table II.

TABLE VII. SAMPLING TIME EFFECT TO THE IDENTIFICATION PROCESS

TS(Second)	System characteristics	Identification error	Controller tuning	Delay time
0.1	Cannot be obtained	Extremely high	No controller	Very Hight more than 0.2 second
0.01	Can be obtained with high error	Hight	Controller can be tuned but error will still high	Hight around 0.02 second
0.001	Can be obtained highly accurate	Low	Controller can be tuned, and the error will be reduced	Low around 0.002 second

TABLE VIII. CONSTANT IDENTIFICATION FACTOR RELATED TO VARYING PARAMETERS NUMBER

The parameter	The value
Regression type	ARMAX
Sampling Time	Ts = 0.001
OPC	Scan Rate = same as Ts Communication remotely via ethernet cable
Noise	No noise

The identification parameters are shown in Table VIII.

But the parameters number will be varying, the examples below will explain this methodology.

a) Example 4

In this example the parameters number will assumed to be two in both A(q) and B(q), referring to Fig. 12 the continues OP and Discrete OP are shown.

Fig. 14 shows the Estimated OP.

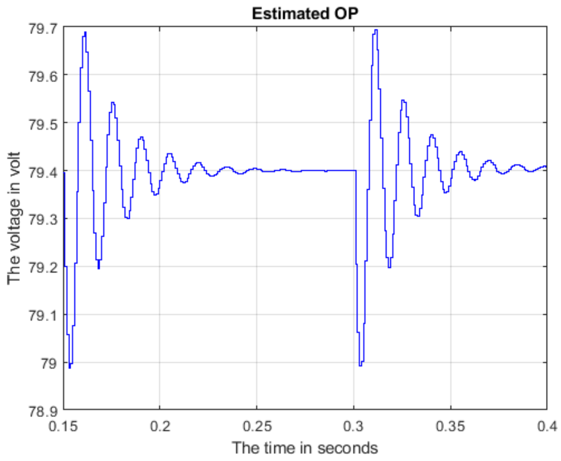

Fig. 14. Estimated OP related to Two Parameters.

The estimated parameters for both transfer function $GE_{dis(Z)}$ and $GE_{Ref(Z)}$ are shown in Table IX.

TABLE IX. ESTIMATED PARAMETERS RELATED TO TWO PARAMETERS

q-operator	Estimated parameters in both transfer functions.			
	$GE_{dis(q)}$		$GE_{Ref(q)}$	
	$A(q)$	$B(q)$	$A(q)$	$B(q)$
q^0	1	0	1	0
q^{-1}	-1.732	-0.02445	-1.786	-0.0029
q^{-2}	0.9079	0.02445	0.8227	0.03975

b) Example 5

In this example the parameters number will assumed to be three in both A(q) and B(q), referring to Fig. 12 the continues OP and Discrete OP are shown.

Fig. 15 shows the Estimated OP.

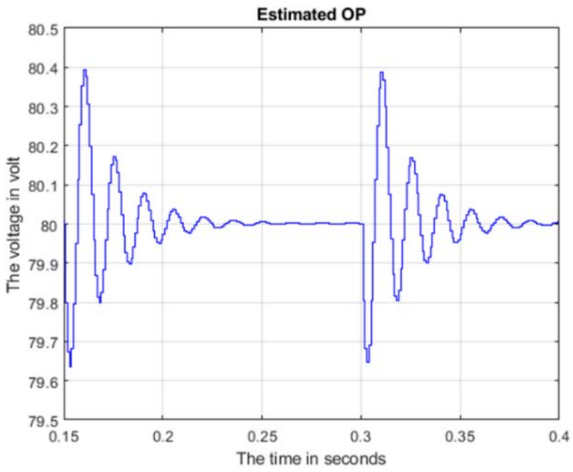

Fig. 15. Estimated OP related to Three Parameters.

Table X shows the estimated parameters in both transfer functions.

TABLE X. ESTIMATED PARAMETERS RELATED TO THREE PARAMETERS

q-operator	Estimated parameters in both transfer functions.			
	$GE_{dis(q)}$		$GE_{Ref(q)}$	
	$A(q)$	$B(q)$	$A(q)$	$B(q)$
q^0	1	0	1	0
q^{-1}	-2.657	-0.0244	-2.617	-0.0029
q^{-2}	2.505	0.04952	2.434	0.01425
q^{-3}	-0.8339	-0.02513	-0.7972	0.00864

- Discussion

A conclusion is reached, which is that as the number of parameters increases, the identification error decreases and the identification process becomes more accurate, because as the number of parameters increases, more of the system's properties and characteristics can be measured. When the number of parameters is assumed to be two, thigh error is introduced into the system, and these two parameters cannot describe the system dynamic. However, when the number of parameters is three, the induced error is very low and can be ignored, resulting in good identification with all the original system properties being obtained well. On the other hand, as the number of parameters increases, more complexity is added to the system, making tuning a controller to reduce identification errors more difficult, in this case, selecting three parameters is sufficient, and the induced error is very low. Conclusion is that assuming number of parameters to be three is the better choice as it leads to good identification and low complexity.

Table XI compares the number of parameters with the system characteristic (overshoot, response time … etc.), Degree of complexity, the identification error in general and the ability to tune a controller to reduce or eliminate the identification errors.

TABLE XI. NUMBER OF PARAMETERS EFFECT TO THE IDENTIFICATION PROCESS

Number of parameters	System characteristics	Identification error	Controller tuning	Degree of complexity
2	Can be obtained with high error	high	No controller	Low complexity
3	Can be obtained with low error	Low	Controller can be tuned, and the error will be reduced	Low complexity

Table XI shows that as the number of parameters increases, good identification is obtained, but the system becomes very complex, so choosing three parameters results in an acceptable error and a low degree of complexity. Making a system with a low degree of complexity is preferable to making a system with a high degree of complexity as long as the error remains within acceptable limits.

C. Regression Model Type

In this section, the effect of changing the regression model will be investigated, and the effect of changing the model type either ARMAX or ARX to the identification process will be determined, the parameters value for the DC-DC Converter will be as in the Table II, the identification parameters is shown in Table XII.

TABLE XII. CONSTANT IDENTIFICATION FACTOR RELATED TO VARYING PARAMETERS NUMBER

The parameter	The value
Regression parameter	A(q)=3 B(q) = 3
Sampling Time	Ts = 0.001
OPC	Scan Rate = same as Ts Communication remotely via ethernet cable
Noise	No noise

But the regression model type will be varying, the examples below will explain this methodology.

a) Example 6

This example will compare the effect of both regression models ARMAX and ARX and the other factors as shown in Table XIV will be constant, Fig. 12 shows the continues OP and Discrete OP:

Fig. 16 shows the Estimated OP for ARMAX & ARX.

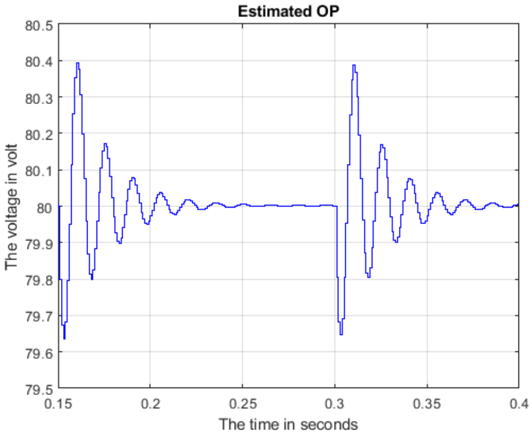

Fig. 16. Estimated OP for Both ARX and ARMAX.

After applying the identification algorithm for ARMAX and ARX, both models give the same parameters in both transfer functions $GE_{dis(Z)}$ and $GE_{Ref(Z)}$ as shown in Table XIII.

TABLE XIII. ESTIMATED PARAMETERS IN BOTH ARX AND ARMAX

q-operator	Estimated parameters in both transfer functions			
	$GE_{dis(q)}$		$GE_{Ref(q)}$	
	$A(q)$	$B(q)$	$A(q)$	$B(q)$
q^0	1	0	1	0
q^{-1}	-2.657	-0.0244	-2.617	-0.0029
q^{-2}	2.505	0.04952	2.434	0.01425
q^{-3}	-0.8339	-0.02513	-0.7972	0.00864

- Discussion

After comparing the results of ARX and ARMAX, the results were similar; both models give the same estimated OP as well as the same value of the estimated parameters as shown in Table XIII.

Results above show that either ARX or ARMAX can work properly with low identification error, so choosing either of them has no effect on the identification process; however, from ARMAX concept it would work more efficiently if the system became more complex with a large variation in the input or output signals because it combines the advantages of both MA (moving average) and AR (autoregressive).

D. *OPC Communication Channel*

In this section, the effect of the OPC communication channel will be investigated, the identification process will be working in two modes:

1) Local mode, where no communication channel is used and all the data analyzing will be locally in the same computer and in the same environment which is MATLAB 2020.

2) Remote mode, where the data is transferred and received from one computer to the other in the private network through the OPC communication channel via ethernet cable cat5.

The parameters value for the DC-DC Converter will be as in the Table II, the identification parameters are shown in Table XIV.

TABLE XIV. CONSTANT IDENTIFICATION FACTOR RELATED TO LOCAL AND REMOTE MODES

The parameter	The value
Regression parameter	A(q)=3 B(q) = 3
Sampling Time	Ts = 0.001
Regression Model	ARMAX
Noise	No noise

The identification error will be studied in both remote and local mode; also the communication channel effect will be obtained.

a) Example 7

The local mode identification process will be studied, Fig. 12 shows the continues OP and Discrete OP, Fig. 17 shows the comparison between the Discrete OP and Estimated OP in local mode.

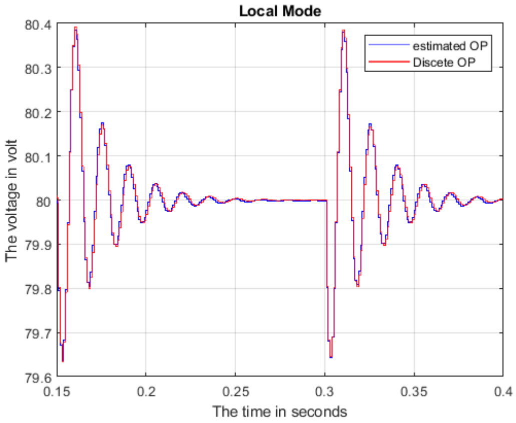

Fig. 17. Estimated OP in Local Mode.

As shown in Fig. 17, the estimated OP is very close to the discrete OP with a very low amount of error and an efficient identification, which is caused by processing the data very quickly with no delays because the local mode does not require sending or receiving data from one computer to another, and no hardwires (Ethernet cable cat5) are used.

The estimated parameters for both transfer function $GE_{dis(Z)}$ and $GE_{Ref(Z)}$ are shown in Table XV.

TABLE XV. ESTIMATED PARAMETERS RELATED TO LOCAL MODE

q-operator	Estimated parameters in both transfer functions			
	$GE_{dis(q)}$		$GE_{Ref(q)}$	
	$A(q)$	$B(q)$	$A(q)$	$B(q)$
q^0	1	0	1	0
q^{-1}	-2.65837542	-0.0244	-2.6151791	-0.0029257
q^{-2}	2.508143613	0.0495739	2.43228732	0.01426002
q^{-3}	-0.8365384	-0.025169	-0.7969769	0.008797002

b) Example2

The remote identification process will be studied, Fig. 12 shows the continues OP and Discrete OP, Fig. 18 shows the comparison between the Discrete OP and Estimated OP in remote mode.

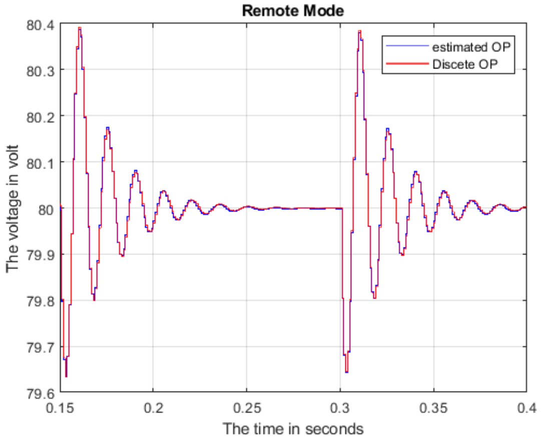

Fig. 18. Estimated OP in Remote Mode.

As shown in Fig. 18, the estimated OP is very close to the discrete OP with very amount error and an efficient identification. Using an OPC communication channel has no effect on the identification process because of the low error, and the communication channel was very fast and accurate due to the Ethernet cat5 high speed rate, high accuracy of the OPC communication channel and high-speed processing units.

The OPC communication channel error is caused by the delay time, as the OPC communication channel transmits the data as a query, it collects the data and convert it to a query then it sends it as packets over the Ethernet Cat5 cable, Due to high processing units and using cable with very high transition speed rate the communication channel does not add high error but rather a very small amount of error caused by the delay time.

Comparing the Discrete output with the received output is the key to determining the communication channel delay error. Fig. 19 shows MATLAB block for this comparison.

Fig. 19 shows MATLAB blocks for the comparing between received OP and Discrete OP, Fig. 20 shows the comparing results.

Fig. 20 shows the communication error, it clears from this figure that there is an error caused by the OPC communication channel.

Because the communication channel error is a delay time error, the best way to test the communication channel's performance is to add the same amount of delay to the discrete OP and then compare these signals again, as shown in Fig. 21.

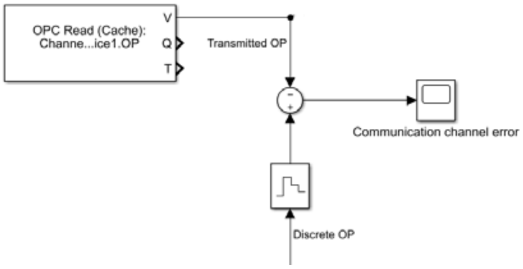

Fig. 19. Discrete and Received Outputs Comparison.

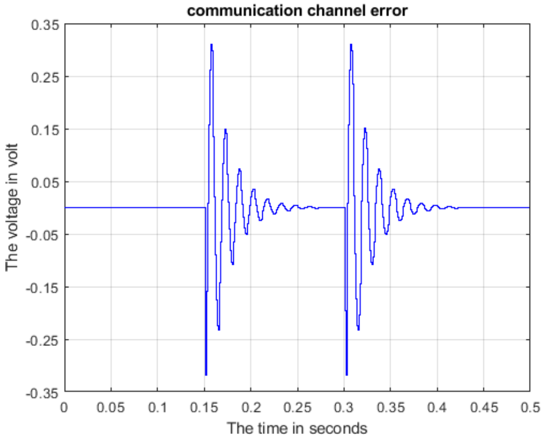

Fig. 20. Communication Error.

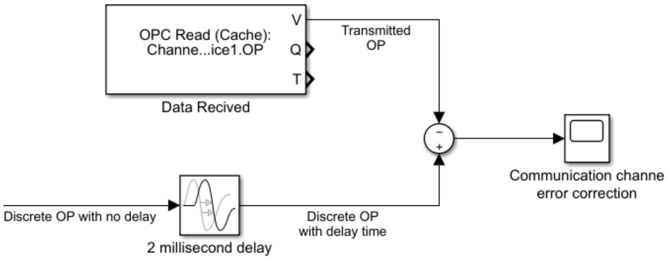

Fig. 21. Example of a Figure Caption.

Fig. 21 shows the MATLAB block ordering to compare the delayed Discrete OP signal with the received OP, Fig. 22 below shows the comparison result.

Fig. 22 shows that the communication channel error has been eliminated by adding 2 millisecond delay time to the discrete OP, as a result of this comparison, the OPC communication channel error is just 2 millisecond delay with neglectable noise, the noise as shown in the figure above are two pulses with very low amplitude the value of the noise amplitude is a power of -4 ($\times 10^{-4}$) which makes it neglectable and does not affect the identification process, the hardwire cable is the main cause for this noise.

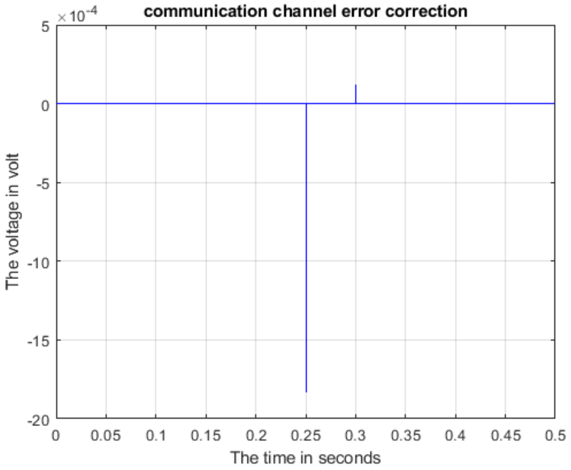

Fig. 22. Delay Time Error Cancellation.

TABLE XVI. ESTIMATED PARAMETERS RELATED TO REMOTE MODE

q-operator	Estimated parameters in both transfer functions			
	$GE_{dis(q)}$		$GE_{Ref(q)}$	
	$A(q)$	$B(q)$	$A(q)$	$B(q)$
q^0	1	0	1	0
q^{-1}	-2.6572643	-0.024396	-2.616792	-0.0029133
q^{-2}	2.50481665	0.0495228	2.4338879	0.01424647
q^{-3}	-0.833855	-0.025127	-0.7971178	0.0086445

The estimated parameters for both transfer function $GE_{dis(Z)}$ and $GE_{Ref(Z)}$ are shown in Table XVI.

- Discussion

The remote mode, which uses an OPC communication channel via a hardwire Ethernet cable cat5, results in a good identification process with very low error, as long as the transmitted signal has a short delay time, as a result of using a high-speed rate cable with a high computer processing unit performance, the communication channel error will be very small, and in some cases can be ignored.

Because the remote mode provides low communication channel error, the advantage of using it instead of the local mode is high, due to the remote-control ability that does not exist in the local mode. The conclusion is that using remote mode is better than using the local mode because of the low error presence as well as the ability to remotely control and observe the system via the network.

E. *Noisy Input Disturbance Signal*

The effect of changing the noise amplitude and frequency at the input disturbance signal will be investigated in this section, the output signal will be noise free, as will the reference input signal, and thus the effect of changing the noise configuration to the identification process will be determined, The DC-DC Converter parameters will be as shown in Table II.

The identification parameters are shown in Table XVII.

TABLE XVII. CONSTANT IDENTIFICATION FACTOR RELATED NOISY INPUT SIGNAL

The parameter	The value
Regression parameter	A(q)=3 B(q) = 3
Sampling Time	Ts = 0.001
OPC	Scan Rate = same as Ts Communication remotely via ethernet cable
Regression model type	ARMAX

Fig. 23 shows the MATLAB blocks for the noisy input signal.

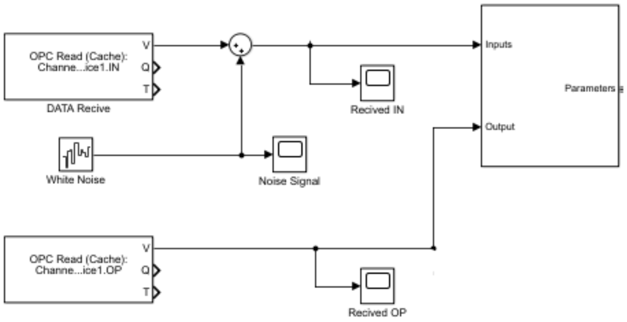

Fig. 23. MATLAB Ordering Blocks for Noisy Input Signal.

As illustrated in Fig. 23 the input signal with adding noise is applied to the identification algorithm, on the other hand the output signal and the reference input signal still noise free signals.

But the noise configuration will be varying, the examples below will explain this methodology.

a) Example 8

In this example noise will assumed to be 0.01 Power spectral density with 100 Hz, the following Fig. 24 shows the Received communicated noise input signal with 0.01 PSD and 100 HZ frequency compared with the (not communicated signal) MATLAB input signal, the input signal here is the disturbance signal to the converter circuit and the other input which is the reference signal will be noise free.

Fig. 25 shows the Estimated OP and the Discrete OP.

It is clear from Fig. 25 that the estimated OP deviates greatly from the discrete OP, so that as the noise PSD and frequency increase, the identification process efficiency decreases, and high error is added to the system. From Fig. 25, the system characteristics (settling time, overshoot, oscillations number.... etc.) can be measured but with high error.

The estimated parameters for both transfer function $GE_{dis(Z)}$ and $GE_{Ref(Z)}$ are shown in Table XVIII.

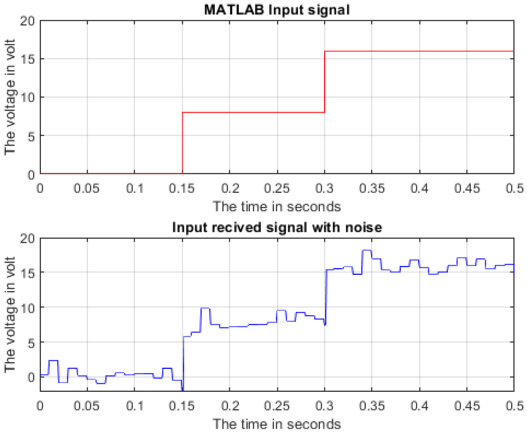

Fig. 24. Noisy Input related to 0.01 PSD and 100 HZ Frequncy.

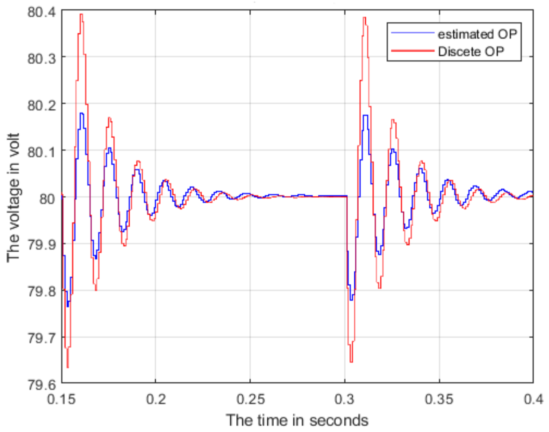

Fig. 25. Estimated and Discrete OP related to 0.01 PSD and 100 HZ Frequncy.

TABLE XVIII. ESTIMATED PARAMETERS RELATED TO 0.01 PSD AND 100HZ FREQUENCY

q-operator	Estimated parameters in both transfer functions			
	$GE_{dis(q)}$		$GE_{Ref(q)}$	
	$A(q)$	$B(q)$	$A(q)$	$B(q)$
q^0	1	0	1	0
q^{-1}	-1.80	-0.014765	-2.6169	-0.0029
q^{-2}	1.0196	0.0173581	2.4341	0.0142
q^{-3}	-0.0501	-0.00252	-0.7972	0.0086

b) Example 9

In this example noise will assumed to be 0.03 Power spectral density with 200 Hz, the flowing Fig. 26 shows the Received communicated noise input signal with 0.03 PSD and 200 HZ frequency compared with the (not communicated signal) MATLAB input signal, the input signal here is the disturbance signal to the converter circuit and the other input which is the reference signal will be noise free.

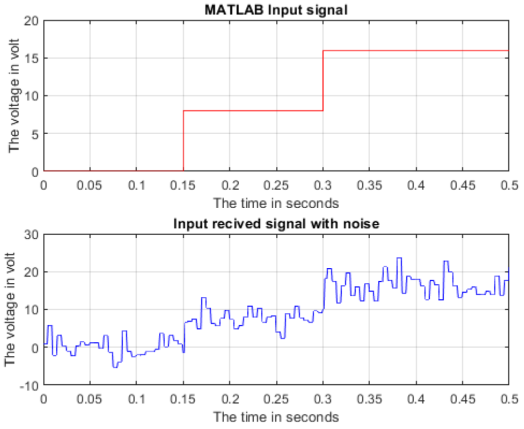

Fig. 26. Noisy Input related to 0.03 PSD and 200 HZ Frequncy.

Fig. 27 shows the Estimated OP and the Discrete OP.

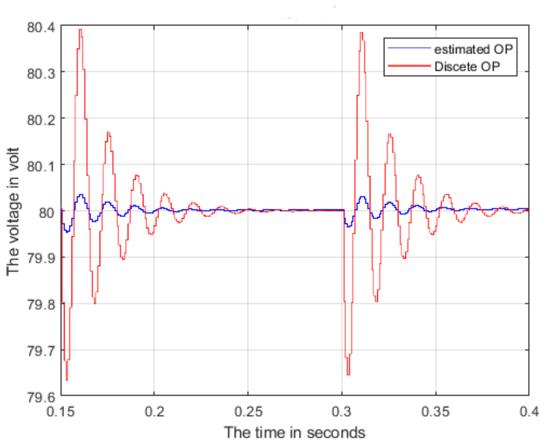

Fig. 27. Estimated and Discrete OP related to 0.03 PSD and 200 HZ Frequncy.

It is clear from Fig. 27 that the estimated OP deviates greatly from the discrete OP, so that as the noise PSD and frequency increase, the identification process efficiency decreases, and high error is added to the system. From Fig. 36, the system characteristics (settling time, overshoot, oscillations number, etc.) can be measured but with even higher error from previous example.

The estimated parameters for both transfer function $GE_{dis(Z)}$ and $GE_{Ref(Z)}$ are shown in Table XIX.

TABLE XIX. ESTIMATED PARAMETERS RELATED TO 0.03 PSD AND 200HZ FREQUENCY

q-operator	Estimated parameters in both transfer functions			
	$GE_{dis(q)}$		$GE_{Ref(q)}$	
	$A(q)$	$B(q)$	$A(q)$	$B(q)$
q^0	1	0	1	0
q^{-1}	-1.7041	-0.0023	-2.6169	-0.0029
q^{-2}	0.8616	0.0024	2.4341	0.0142
q^{-3}	0.02905	-8.1281e05	-0.7972	0.0086

- Discussion

From the previous examples, it is clear that as the noise amplitude and frequency increase, so does the identification error, the identification error caused by noise can be seen as compression in the Y-axis; as the noise amplitude and frequency increase, the response will compress more; however, the system dynamic remains unchanged, so this error can be reduced or eliminated by tuning a proper controller that makes the identification process efficient.

Also, as shown in the Table XIX it clears that the parameters in both A(q)&B(q) change only in $GE_{dis(q)}$ but the $GE_{Ref(q)}$ remains the same in all example, the reasons of that is coming from adding the noise to the disturbance signal only making only the transfer $GE_{dis(q)}$ changes as this transfer function describe the relation between the disturbance and the output, so that it is logical to change every time the disturbance noisy signal changes.

On the other hand, $GE_{Ref(q)}$ which describe the relation between the reference input signal and the output voltage does not change as the input reference signal still the same in all examples with no noise added.

Future work can be conducted in many directions and applications. The use of OPC communication channel would have interesting future directions in many applications such as power [22-25], health [26-31], communication [32-37], AI applications [38-43], and optimization [44,45].

V. Conclusion

The identification process is highly dependent on the error associated with each factor. To determine whether the identification process is efficient or not, the effects or error associated with each factor are investigated to determine whether the identification process can truly provide a good estimate or not. As a result, before proceeding to the online detection, these factors must be optimized to produce the least amount of error possible, ensuring that the best parameters have been estimated.

***Abstract*—Global image enhancement techniques are used to enhance contrast in images but these techniques are found to be under-enhanced or over-enhanced in differently illuminated regions of the image. Local color correction methods work on local pixel regions to optimize the color contrast enhancement but they also have been found to show a lag while covering pixel regions which are overexposed, compared to those which are underexposed causing local artifacts. In this work, we overcome the shortcomings of both the local color correction and global color correction. This method uses local color correction in the Hue Saturation Luminance (HSL) domain, and fuzzy intensification operators are used to control the color fidelity of the local color corrected images. Thus, is able to sort out the problem of overexposed and underexposed regions and provide optimized contrast enhancement in colored images. Several experiments have been performed to analyze the performance of the proposed method and feasibility as compared to existing techniques. Performance parameters such as Mean Square Error (MSE), Peak Signal to Noise Ratio (PSNR), Structural Similarity Index Measurement (SSIM) and Naturalness Image Quality Evaluator (NIQE) is evaluated and the comparison with some existing techniques of contrast enhancement of color images is performed. The obtained result have good contrast and approve the better performance of the proposed method in support of the quantitative measure of perceptual appearance of the processed images and low computational time.**

Keywords—Contrast enhancement; local color correction; fuzzy operators; optimization

I. Introduction

Image enhancement is one of the most important steps in any image processing algorithm whether it is pattern detection, image classification or biometric recognition. Most of the computer vision based algorithms consist of image quality enhancement steps at some stages. The image quality is also strongly affected by the image acquisition device's quality. A higher-resolution camera is needed for better image quality, which can significantly increase the system's cost. Several methods of image enhancement exist which can improve the characteristics of the images to acceptable level even if they have been acquired with low quality cameras. Considering the factors like domain, environment, quality of images etc. different mathematical arbitrations can be applied on the images to improve their characteristics. Image correction may include various steps such as saturation, sharpness, denotation, tonal shift, tonal equilibrium and contrast correction. Even from the perspective of humans, the perceptibility of images is dependent on the contrast of the images. Contrast generally refers to the difference between different pixel levels based on their intensity. Compared to the other objects and the context, the difference between visual properties makes the parts of images distinctive. The sensitivity to human contrast depends on the spatial frequency; thus, when determining the contrast the spatial content of the picture should be considered. Local contrast is defined in accordance with the local luminance and background lights as a function of every point in the image as well as in every frequency band [1]. The variation in color and brightness of the element and other items within the same field of view is calculated to provide the visual perception of the real world.

The techniques of contrast enhancement can usually be divided into two categories: direct and indirect. Direct methods define a function based on the contrast whereas indirect methods don’t define a specific contrast function. The direct and indirect methods are categorized further as spatial methods in which pixel level operations are performed and frequency domain methods operating in transformation of images [1]. Color image enhancement poses more challenges as compared to a grayscale image enhancement because of the presence of three color intensity levels viz. red, green and blue as compared to a single intensity level in case of grayscale images. Thus techniques like histogram equalization (HE) which gives a fast image enhancement with a grayscale image cannot be directly used for color image enhancement. Histogram Equalization, however, is not widely used in consumer electronics because it can lead to irregularities such as changes in excessive brightness, vibration and saturation of light [2]. One of the popular techniques from the family of general histogram modification techniques are gamma correction techniques accomplished by using a particular adaptive parameter “γ”, defined as below [3]:

$$T(l) = l_{max}(l/l_{max})^{\gamma} \tag{1}$$

where “l_{max}” is the maximum intensity of the input.

The gamma curves illustrated in Fig. 1 show that “ γ >1” has exactly the opposite effect as those generated with “γ < 1”. Global correction methods like gamma correction suffer from this problem of uneven distribution of pixel color intensity.

Many algorithms concentrate on improving the image quality, but usually lead to an unnatural appearance such as confusion and objects with light sources. Many others therefore seek to reduce over-improvement at the cost of accuracy [4]. Since traditional histogram algorithms can result in over-enhancement, several algorithms have been suggested, including limitation of brightness and contrast. Maintaining efficiency in applications requires the preservation of light. The preservation of luminosity in areas of diminished intensity, such as dark regions, is disadvantageous to detailed enhancement in uniform illumination images [4]. An improvement over the traditional HE is the brightness preserving dynamic histogram equalization (BPDHE) algorithm, which maintains mean brightness of the image by taking the same mean brightness of the output image as that of the input image [5].

In local enhancement techniques, transformation of image pixels is dependent on neighboring pixel information. A small window is moved over every pixel of the image and only those blocks of images are enhanced, whose pixel falls under the window. Local information is preserved and brightness is improved for future use. Therefore contrast ratio can be smoothly improved in all parts of the image. Global knowledge about luminosity is missing and local objects can be created. Compared to the global enhancement methods, code complexities of these methods are high. Hybrid strategies provide global and local strategies for development. Here, adjacent pixels and global image information are taken into account during the transformation [6].

The need to improve the image visual quality that is produced under intense lighting conditions resulted in the development of an overexposure and underexposure fusion of blurred enhanced images. This can be done with the Gaussian membership function by means of a smooth image creation process. For further optimization, Discrete Wavelet Transform (DWT) based fusion of these fuzzy enhanced images is possible. The improved Fuzzy algorithm reduces noise, preserves information and improves image contrast [7]. Nonlinear and knowledge-based fuzzy techniques are feasible, creating a new technique for the enhancement of contrast.

In a dehazing based enhancement model suggested by Dong et. al [8], a photometric negative of the input image resembling hazy image has been obtained. The enhancement is then achieved by dehazing the hazy image effects, but this approach had issues with blocking artefacts, and the images produced seemed artificial or sketchy.

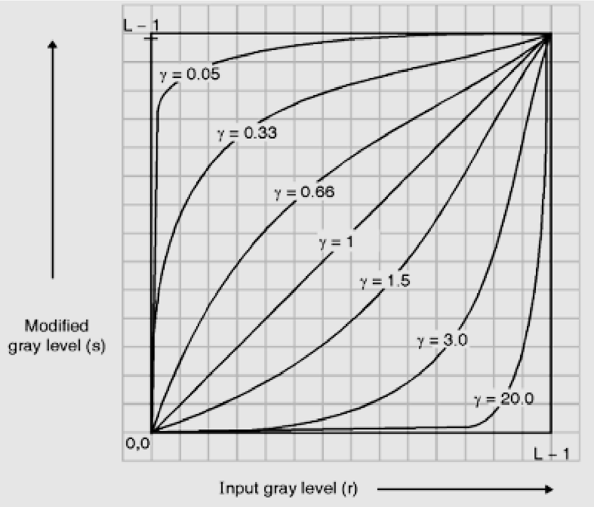

Fig. 1. Gamma Variation.

Retinex based methods have been developed which model human vision of color and luminance. Adaptive Multi Scale Retinex (AMSR) achieves better illumination and tone fluency by adding weights on the single scale retinex of the input image [9] over the various retinex methods such as Single Scale Retinex and, multi scale retinex.

Differential grey level histogram for Color images (DHECI) [10], generates two differential grey level histograms one for the intensity and the other for saturation level. The enhanced image is obtained as a weighted sum of these two levels controlled by a human color perception parameter.

Retinex based methods do not consider the noise factor while increasing the luminosity of the images. The joint denoising and enhancement(JED) technique [11], is an integrated approach providing both enhancement and denoising by combining both the luminance map estimation and the reflectance map in sequential steps, thus able to remove noise and obtain better enhancement.

In this work, a novel framework for an optimized image enhancement has been presented, which is modeled to include both the properties of local enhancement as well as global enhancement. Local color correction provides the local contrast enhancement and then fuzzy intensification operators are used to provide global color enhancement. The upcoming sections consist of literature review of previous work done in the field of color image enhancement in Section 2, description of proposed methodology and algorithms is presented in Section 3, results and discussion is presented in Section 4 and conclusion is presented in Section 5.

II. Literature Review

Chun-Tsai et al. [12] suggested to use the fuzzy logic concept and illumination analysis to correct color images of face. The images are divided by a fuzzy logic classification scheme into back lit, normal lit and front lit images. Lighting has been evaluated for the distributions of image illumination, over the input image. There are a growing array of peaks and valleys. The properties of this piecewise linear transformation are these peaks and valleys. The results showed that in comparison with other available methods, the method is efficient and effective.

The automated self-contained method for determining contrast gain function for automatic contrast improvement was suggested by Iyad F. Jafar et al. [13]. Contrast gain functions abbreviated by FACE(fuzzy adaptive contrast enhancement) adapted and modified smoothly in conjunction with the neighbourhood characteristics of the pixels, resulting into low, medium, and high activity gain. The Gain Function is defined by local image statistics, Fuzzy C-means (FCM) clustering and a Fuzzy Inference System (FIS) based on rule-based processing on a wide spectrum of pictures. In comparison with other methods, the process produced significantly improved contrast images and less artifacts.

A novel fusion-based technique was introduced by Amina Saleem et al. [14], to improve both grayscale and color images. The results show that the proposed algorithm is effective in strengthening local and global contrasts, reducing saturation and over-improvement while retaining the original imagery. The fusion-based enhancement method is ideal for non-real - time image processing applications that require high-quality images.

Mohan Liu et al [15] introduced a new conceptual contrast metric which follows the traditional background and foreground energy model and the energy used to calculate the technological luminance contrast instead of the maximum, minimum, and average luminance intensities. The authors also demonstrate that the chrominance information can also be used to assess the contrast quality of images. The technical measure of the luminance contrast is mapped onto a perceptual-based measure using a human attention model. This method yields massive enhancements relative to the state-of-the art, but at the expense of increased complexity.

A new improvement approach to both images and videos was introduced by Shih-Chia Huang et al [16]. In addition to probability and statistical inferences, the histogram analysis gives the special knowledge of a single image. The weighting distribution in the second step is used to smooth the fluctuating tendency and thereby avoid the creation of objects which are unfavorable. The picture contrast automatically improved by a smoothing curve in the third step. For multiple frames in a video set, writers used temporal information to reduce the computation time. The entropy model was used to decide if the transformation curve would be modified or not depending on the variation in the information material.

V. Magudeeswaran et al. [17] proposed the Fuzzy logical histogram equalization method which provided, the enhanced image contrast with the inaccuracy of gray-level values by the use of numerically produced fuzzy data. It is an efficient way to improve performance in comparison with classic flat histograms. The color quality, brightness and image contrast can also be enhanced automated. The approach suggested, efficiently removes the washed-out and adverse objects caused by many current approaches.

Jeyong Shin et al. [18] proposed a new histogram-based approach of enhancing contrast, to maintain the position of the initial histogram and to improve global contrast. The question of optimization is introduced where the histogram incorporates possible local conditions in order to increase the contrast to the location. The method makes a smooth change in comparison to different histogram profile images by creating clearer comparing images of local histograms.

Chin Yeow Wong et al. [19] used optimized chosen hyperbolic tangent profiles to eliminate unnecessary artifacts. A series of experiments were conducted to improve color image quality using qualitative evaluations and quantifiable measures such as entropy, gradients, colorfulness and saturation. The pipeline approach has been stressed as increasing image quality, enhancing contrast and sharpening color images, without losing color and saturation. The method is easy to use and sufficient for systematic color image preprocessing.

Zohair Al Ameen [20] developed a system using tuned blurred intensification operators to rapidly filter bad photographs taken in a dusty weather. The processing of images was effective in producing appropriate colors and fine details, as has been showed by tests on different images.

A new method to enhance image contrast based on local histogram equalization was implemented by M. Shakeri et al [21]. Originally, the image was divided into several sub-images with a clustering of the brightness values, where clusters are calculated using an automatic method based on histogram analysis of the two images. Every cluster of the image brilliance levels represented a spectrum in the histogram which was added to each histogram segment with the transfer feature introduced; the improved image obtained across the segments.

Zohair Al-Ameen [22] introduced a new, flexible stretching technique based on the concept of linear contrast to increase the color image contrast with few calculations. The method is tested with a variety of real low-contrast color images compared to four technical improvement techniques and three prominent IQA (Image quality Analysis) measures, measure the quality of the results collected. Technique received satisfactory results by obtaining results, as it produced natural contrasting pictures without visible features and by rating the highest precision, it outperformed comparative techniques.

The perceptively controlled enhancement of contrast and color in photographs using JND transform and color continuity was proposed by Long Yu et al. [23]. The JND (Just Noticeable Difference) transformation was done to obtain a JND map representing HVS response. Perceptual GEMs have been paired with JND transform to enhance contrast, color reproduction and images. Experimental results showed that the method effectively improves color and dark-tone low-contrast images.

The new technique of fugitive contrast enhancement, which A. A. Salih et al. [24] suggested, is designed to improve individual regions that use the Gaussian membership function (GMF) as their main tool in their fluxation processes. Their method has successfully improved low-contrast and uniform picture lighting with the highest performing and quantitative picture analysis.

Magudeeswaran Veluchamy et al. [25] used improved adaptive gamma correction and histogram equalization based image enhancement on benchmark test images with subjective and objective measures. The method represents natural colors more accurately and outperformed the other existing enhancement methods in terms of entropy, colorfulness and histogram utilization efficiency and having least annoying artefacts.

Syed Zaheeruddin et al. [26] proposed an improvement in contrast in uniform illumination images by the means of homographic decomposition. The proposed method results in better luminosity, contrast and detail, compared to other common methods.

To reduce over enhancement and detail preservation, Subramani, B., et al. [27] proposed quadrant dynamic clipped

HE method with gamma correction. Author partitioned the histogram of the input image into four sections using its mean value and applied histogram clipping and gamma correction to control the color enhancement rate. All clipped sub histogram is equalized independently and then combined together which produces an enhanced image. Experimental results shows that proposed method performed well in terms of preserving entropy, colorfulness, saturation, and obtaining uniform degree enhancement.

In order to improve the lightness and contrast in colored images G., Hazim et al. [28] introduced the Fuzzy Logic Based-on Sigmoid Membership Function (FLBSMF). The lightness component was covered by the algorithm only using the YIQ color space without changing colors. The results of the experiment showed a better color image and good average entropy value, mean square saturation error, and lightness order error.

Magudeeswaran Veluchamy et. al. [29] presented a Fuzzy Dissimilarity Adaptive Histogram Equalization with Gamma Correction (FDAHE-GC) algorithm in which a Fuzzy Dissimilarity Histogram (FDH) is obtained from the neighbourhood characteristics forming intensity mapping function. Different methods for evaluating the performance of the presented method include entropy, Colorfulness, Hue Deviation Index, Saturating, Contrast Enhancement Factor, and Gradient which show improved color enhancement.

Another intensity based enhancement was presented by Krishnamurthy Mayathevar et al. [30], using fuzzy histogram constructed using intensity of neighbourhood regions and further improved by gamma correction in dark regions. Fading effect is mitigated by limiting maximum saturation range as well.

We find that contrast stretching loses some of the detail information of the images during enhancement, Histogram Equalization and its variations gives better results but it cannot preserve the brightness of the original image. Homomorphic filtering techniques have better response but suffers from bleaching effects and multiplicative noise. Retinex is the advance technique for the color image but it still suffers from Gray level violation problem, washed out appearances and unnatural color rendition.

Proposed model is simple, effective and solve the key shortcomings of current models. The main concept behind the proposed method is local color correction in the Hue Saturation Luminance (HSL) domain and fuzzy intensification. The RGB colorspace is first converted to the Hue, Saturation and Luminance colorspace. Local color correction is applied to the luminance component to optimize the color enhancement based on neighboring pixel. Fuzzy intensification operators are used to control the color fidelity of the local color corrected images and thus is able to sort out the problem of overexposed and underexposed regions and provide optimized contrast enhancement in colored images. Several experiments have been performed to analyze the performance of the proposed method and feasibility as compared to existing techniques.

III. Proposed Method

The proposed framework has been shown in the block diagram in Fig. 2.

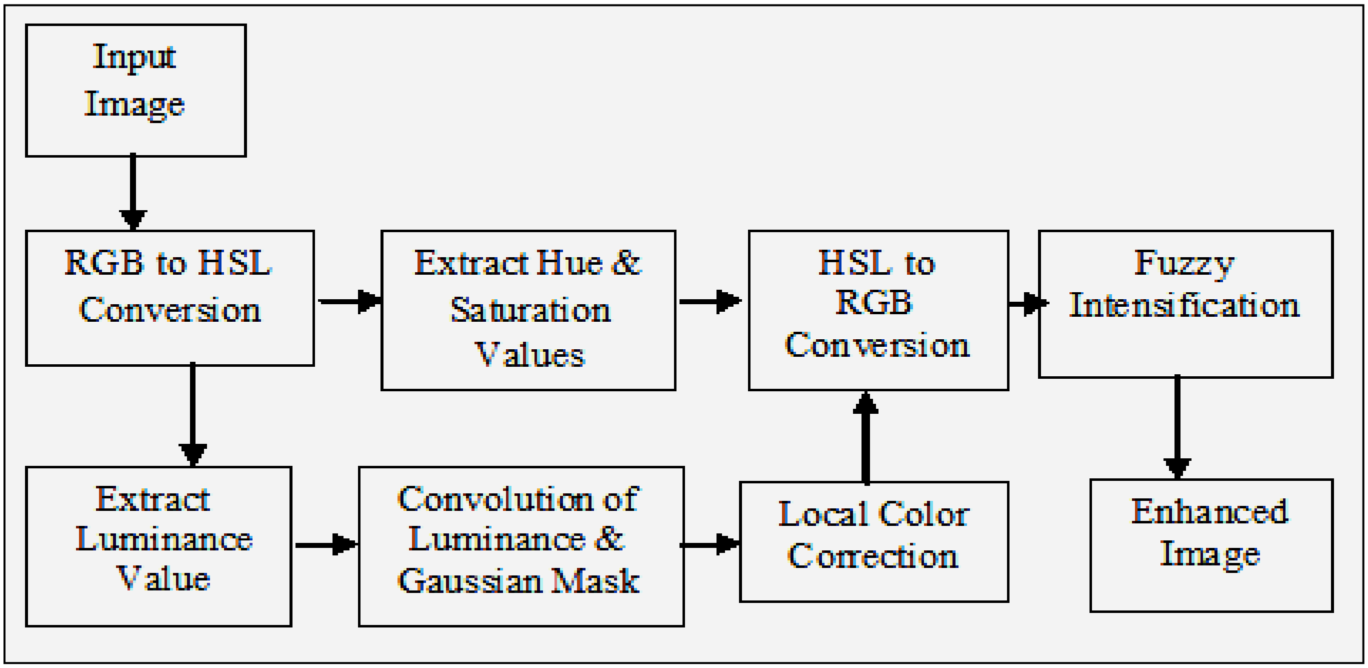

Fig. 2. Block Diagram of Proposed Framework.

Algorithm 1: Color Space Conversion

Step 1: RGB image values is converted to the range 0-1.

Step 2: Obtain the maximum and minimum values from the R,G,B values.

Step 3: Calculate the Luminance (L) value by adding the max and min values and divide by 2.

Step 4: Calculate Saturation(S)

If L< 0.5,

S = $(I_{max}-I_{min})/(I_{max}+I_{min})$

If L>0.5

$$S = (I_{max}-I_{min})/(2.0-I_{max}-I_{min}) \quad (2)$$

where I_{max} & I_{min} are respectively maximum and minimum image pixel value.

Step 5: The Hue(H) formula is depending on what RGB color channel is the max value.

If Red is max, then

H = $(G-B)/(I_{max}-I_{min})$

If Green is max, then

H = $2.0 + (B-R)/(I_{max}-I_{min})$

If Blue is max, then

$$H = 4.0 + (R-G)/(I_{max}-I_{min}) \quad (3)$$

Where *R,G,B* represents the respective color intensity value in the RGB space.

The Hue values are converted to degree values.

The next step is to apply Local Color Correction on the Luminance component. A mask of luminance metric is computed from the original luminance and a Gaussian kernel, which guarantees that image contrast, will not be excessively reduced along the edges is calculated. The resulting mask indicates the corresponding regions of the image which will become dark or light than the original image. The algorithm for color correction is as shown below.

Algorithm 2: Local Color Correction

Step 1: Extract Luminance Component, L $L \leftarrow HSL$

Step 2: Apply Fast Fourier Transform(FFT) on Luminance component, $L_{dft} \leftarrow L$

Step 3: Calculate Gaussian Mask on L, $G_L \leftarrow L$

Gaussian Mask can be defined as:

$$G_L = e^{-2\pi^2\sigma^2(\varepsilon_1^2 + \varepsilon_2^2)} \quad (4)$$

where "ξ" is the frequency of the k^{th} sample given by, $\xi = k/N$, for $k = -N/2,.. N/2-1$, where *N* is the total number of samples and σ is the standard deviation.

Step 4: Apply Discrete Fourier Transform (DFT) on Gaussian Mask (calculated using equation 5) of Luminance, $G_{LDFT} \leftarrow G_L$

$$M'(x,y) = (G_L \text{ x } I)(x,y) \quad (5)$$

Step 5: Perform Convolution of L_{dft}&G_{LDFT}, L_{conv}

Step 6: Apply Inverse Fast Fourier Transform (IFFT) on luminance convolution value L_{conv} and calculate output color corrected luminance, as per equation 6:

$$L_{out}(x,y) = (L_{conv}(x,y))2^{(2M'(x,y)-1)} \quad (6)$$

Equation (6) represents the Output Luminance L_{out} where *x and y* indicate the coordinates.

The color corrected luminance is combined with the original hue and saturation to obtain the color corrected image matrix. The fuzzy intensification operators are then applied on this image to obtain an optimized enhancement.

In order to measure fuzzy intensification operators, two variables are necessary. Firstly, tau(τ) is a parameter that describes the operators threshold limits. The second parameter is a membership function, which is necessary since the default range between zero and one is fixed by pixels of a given channel. Using "τ" allows the operators to filter image pixels.

$$fIr = \frac{[Ir - \min(Ir)]}{\max(Ir) - \min(Ir)} \quad (7)$$

$$fIg = \frac{[Ig - \min(Ig)]}{\max(g) - \min(g)} \quad (8)$$

$$fIb = \frac{[Ib - \min(Ib)]}{\max(Ib) - \min(Ib)} \quad (9)$$

where, *fIr*, *fIg&* *fIb* represent membership function value for each channel respectively.

$kI_R = 2 * (fIr(x,y))^2 \ if \ fIr(x,y) < \tau R$

$$1\text{-}2 * (fIr(x,y))^2 \ otherwise \quad (10)$$

$kI_G = 2 * (fIg(x,y))^2 \ if \ fIg(x,y) < \tau G$

$$1\text{-}2 * (fIg(x,y))^2 \ otherwise \quad (11)$$

$kI_B = 2 * (fIb(x,y))^2 \ if \ fIb(x,y) < \tau B$

$$1\text{-}2 * (fIb(x,y))^2 \ otherwise \quad (12)$$

where, {τR, τG, τB} are scalars. "kIR, kIG, kIB" are the processed channels by intensification operators. To obtain pixels of the output following functions are utilized.

$$u_R = (kIr)^{\tau R + \xi} \quad (13)$$

$$u_G = (kIg)^{\tau G + \xi} \quad (14)$$

$$u_B = (kIb)^{\tau B + \xi} \quad (15)$$

where "ξ" is the intensification tuning parameter which controls the trueness of colors in the image. The complete RGB image is obrtained by combining outputs.

IV. RESULTS AND DISCUSSION

The proposed framework has been tested on CEED dataset for contrast enhancement. The archive consists of 30 images, which consists of collected images and other popular images used by the other experts[31]. All images in the database are truecolor RGB images with pixel size 512x512 height and width respectively. The images contain various scenes of different illuminations, taken both inside and outside as well several benchmark images like peppers, barbara. Thus this dataset covers an exhaustive range of different image types and the proposed frameworks evaluation is carried on this dataset to cover different image types. For comparison, various existing methods have been selected viz. Histogram Equalization [4], BPDHE [5] DHECI [10], Dong [8], AMSR [9], and JED [11] algorithms. The visual appearnce of the enhanced images gives a qualitative approximation of the proposed framework. For an objective analysis of any image processing technique, quantitative parameters have been used in majority of research works. Some of the common performance measures which give a quantitaive approximation of any image processing methods are Mean Square Error(MSE), Peak Signal Noise Ratio(PSNR), Structural Similarity Index Measurement(SSIM) and Natural Image Quality Evaluation(NIQE).

MSE can be defined as difference between the original image and the output image. This difference must be very low for a better performance.

$$\text{MSE} =\sum_{i=1}^{N}((I(x,y)-I'(x,y))^2 \quad (16)$$

Where *I(x,y) and I'(x,y)* represent input and output image pixels respectively.

PSNR can be defined as the ratio between peak signal power and noise power. The PSNR gives a measure of the quality of reconstruction in the final image with respect to the original image.

$$\text{PSNR}=10\log_{10}\left[\frac{255^2}{MSE}\right] \quad (17)$$

Another parameter to measure perceived quality is SSIM, which considers image degradation as perceived change in "structural information" in contrast to MSE and PSNR which estimate the absolute errors only ehich is an important perceptual phenomena which include both contrast and luminance masking terms.

$$\text{SSIM}=\frac{(2\mu_x\mu_y+c1)((2\sigma_{xy}+c2)}{(\mu_x2+\mu_y2+c1)+(\sigma_x2+\sigma_y2+c2)} \quad (18)$$

where "μ_x" is mean of x," μ_y" is average of y, σ_x2 are respective variance &σ_y2 ,$\sigma_{xy}$is covariance. "c1" & "c2", two variables to stabilize the division with weak denominator.

NIQE is an image quality assessment method which uses measurable deviations from statistical regularities observed in natural images.

The experiment were carried out in MATLAB R2018a on original images dataset obtained form CEED 2016 databse of of images. Fig. 3 shows the result images which have obtained by implementing the various existing methods and proposed method for 'img1' image of CEED dataset.

Table 1 shows the experimental results of comparision of different techniques on the basis of MSE, PSNR, SSIM and NIQE parameter and the related graphs in Fig. 4(a), 4(b), 4(c) and 4(c), respectively.

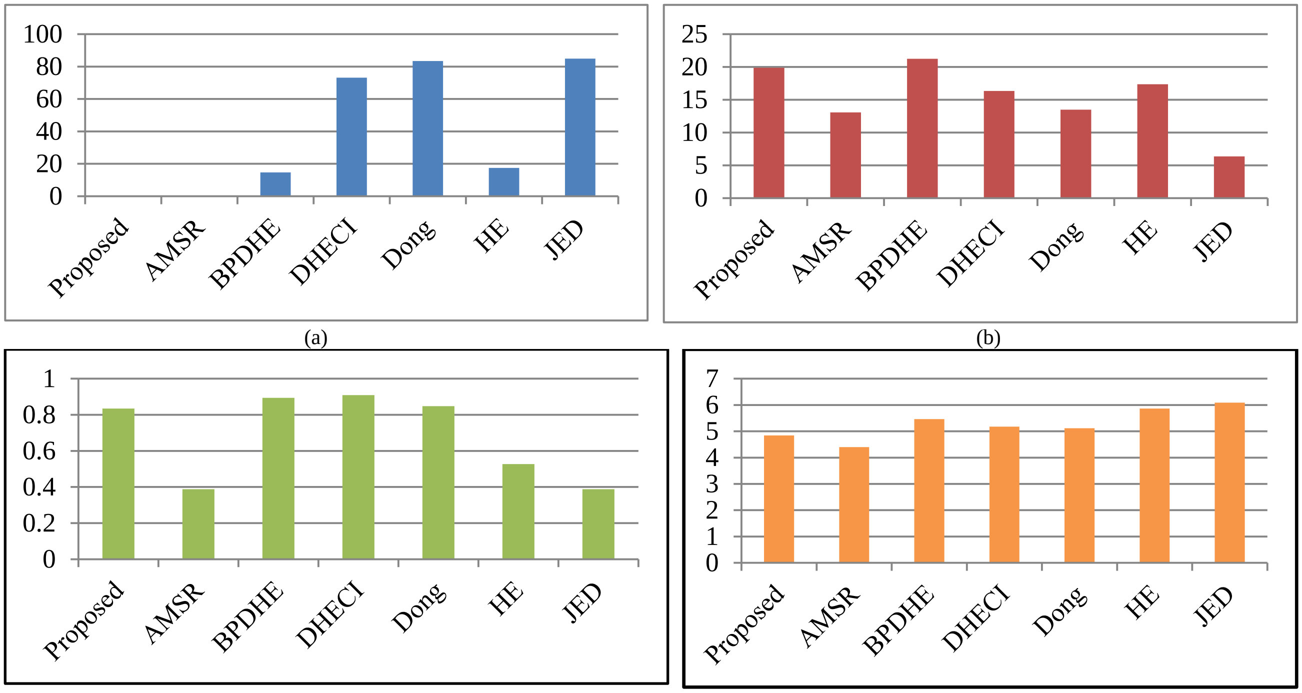
TABLE I. COMPARISON OF DIFFERENT TECHNIQUES WITH PROPOSED METHOD

Method	**MSE**	**PSNR**	**SSIM**	**NIQE**
Proposed	0.0034	19.8736	0.8349	4.8460
AMSR	0.0165	13.0662	0.3880	4.3994
BPDHE	14.7533	21.2600	0.8938	5.4617
DHECI	73.1251	16.3550	0.9094	5.1752
Dong	83.4262	13.4936	0.8479	5.1147
HE	17.4953	17.3790	0.5273	5.8644
JED	84.9617	6.3707	0.3880	6.0888



(a)

(b)

(c)

(d)

Fig. 4. Graphical Representation of Comparative Values of (a) MSE (b) PSNR (c) SSIM (d) NIQE.

The proposed method has been compared with the existing techniques in terms of various quality metrics as shown in Table I. The Mean Square Error values for the proposed technique is lowest indicating higher correlation with the original image. PSNR values for the img1 is also better as compared to all other methods except the BPDHE [5], which gives better PSNR value than the proposed method. SSIM values obtained for the proposed method is better than AMSR [9], HE [4] and JED [11], while lower than BPDHE [5], DHECI [10], Dong [8] and JED [11]. NIQE values obtained are better than all other methods except the AMSR [9]. Though, if we analyze the visual perceptibility as a qualitative measure, we can see that the methods having better quantitative values i.e. PSNR, SSIM or NIQE doesn't have a good visual perceptibility as compared to the proposed method. Thus, it can be said that there is a tradeoff between the performance measures and qualitative visual perceptibility as well, as is evident from this research. Thus, based on this, it can be said that the proposed technique achieves better performance in terms of both qualitative measures and quantitative metrics. Fig. 5 to Fig. 7 shows some more results for different images.

Table II shows the computational cost by proposed and existing methods, in terms of execution time. The execution time of the proposed method is slightly more as compared to AMSE, Dong and BPDHE but it is many times lower than DHECI and ZED methods. Although HE takes much less time to execute but its many drawbacks force to ignore the method. The proposed algorithm thus gives an acceptable performance in contrast optimization and performs well in terms of execution time as well.

	1.2339	0.6893	0.5416	14.5583	0.4748	0.0113	11.4457

V. CONCLUSION

In this research, a technique is proposed which takes into account both the local minima and global maxima problems. To overcome the problems and to present an optimal enancment approach, the RGB colorspace is first converted to the Hue, Saturation and Luminance colorspace. Local color correction is applied to the HSL colorspace to optimize the contrast of image based on neighboring pixel. Fuzzy intensification methods is used to control the color fidelity of the local color corrected pixels and thus the overexposed and underexposed regions have been optimally illuminated and obtained images are having good contrast. The methods were implemented and tested on CEED database images, along with the existing techniques. Proposed method provides satisfactory results as it produced natural contrast images with no artifacts and outperformed the other existing contrast enhancement methods in terms of MSE, PSNR, SSIM and NIQE image evaluation parameters.

ACKNOWLEDGMENT

I express my sincere gratitude towards Dr. Rakesh Kumar Yadav, Assistant Prof., Department of Computer Science and Engineering IFTM University Moradabad and Professor Ramapati Mishra, Department of Electronics and Communication Engineering, Dr. RML Avadh University Ayodhya for his valuable suggestions and guidance. I also pay thanks to Head of Department of Computer Science and Engineering IFTM University, Moradabad for providing us necessary facilities for the implementation of this research work.

Exploring Factors Associated with the Social Discrimination Experience of Children from Multicultural Families in South Korea by using Stacking with Non-linear Algorithm

Haewon Byeon
Department of Medical Big Data, College of AI Convergence
Inje University, Gimhae 50834, Republic of Korea

***Abstract*—The number of children from multicultural families is increasing rapidly along with quickly increasing multicultural families. However, there are not enough surveys and basic researches for understanding the characteristics of multicultural children and issues such as social discrimination. This study discovered the machine learning model with the best performance for predicting the social discrimination experience of children from multicultural families by comparing the prediction performance (accuracy) of individual prediction models and stacking ensemble models. This study analyzed 19,431 adolescents (between 19 and 24 years old: 9,835 males and 9,596 females) among the children of marriage immigrants. This study used random forest (RF), rotation forest, artificial neural network (ANN), and support vector machine (SVM) for the base model. Logistic regression algorithm was applied for the meta model. Each machine learning model was built through 5-fold cross-validation. Root-mean-square-error (RMSE), index of agreement (IA), and variance of errors (Ev) were used to evaluate the prediction performance of the developed models. The results of this study indicated that the prediction performance of the rotation forest-logistic regression model had the best performance. The future studies need to explore stacking ensemble models with the best performance through combining a base model and a meta model by using various machine learning algorithms such as clustering and boosting.**

***Keywords*—Stacking ensemble; meta model; root-mean-square-error; index of agreement; rotation forest**

I. Introduction

The number of foreigners residing in South Korea exceeded 2 million as of 2019. This accounts for 3.69% of the South Korean population, which is not a high percentage. However, it is recognized as a noticeable phenomenon in Korean society because the number of immigrants has increased rapidly over the past decade and immigrants are easily distinguishable due to differences in appearance and language [1]. In particular, as this issue has become linked to the marriage to men living in rural areas or men with low-income in urban areas since 2002, the number of multicultural families has reached 900,000 as of 2016 [2]. The number of immigrants will increase more as the population of South Korea will decrease due to the aging and low birth rate [3]. It has drawn more attention because the population composition will be diversified further due to this [3].

The multicultural family means a family made by uniting people with different nationalities or races through international marriage and other methods. South Korea prepared the “Measures to Support the Social Integration for Female Marriage Immigrant Families, Multi-racial People, and Immigrants” in 2006 to help multicultural families settle in South Korea stably. As the Multicultural Families Support Act was enacted in 2008, she strengthened the support for multicultural families at the policy level. As a result, social security and legal status were guaranteed for marriage immigrants.

As the number of foreigners residing in South Korea rapidly increases, the number of children from multicultural families (e.g., international marriage families and foreign workers’ families) is also increasing. Furthermore, as they attend schools, the possibility of conflict due to cultural differences has increased according to the increased personal and cultural contacts.

Nevertheless, in South Korea, social policies for multicultural families have mainly focused on employment or welfare for marriage immigrants and foreign workers [4,5]. Moreover, previous studies on multicultural families [4,6] have been conducted to examine only limited individual aspects such as socioeconomic characteristics, welfare level, human rights discrimination, employment status, and policy analysis. However, there are still not enough studies on the overall social discrimination experiences of children from multicultural families. Children from multicultural families (international marriage families) can be divided into children born in South Korea and those who have entered South Korea after being born in other countries. Since it has been reported that children could not adapt to South Korea well due to the unique characteristics of multicultural families and various changes that they experience during adolescence [7], it is necessary to expand the social foundation that can help them adapt to South Korea well for social integration.

In summary, the number of children from multicultural families is increasing rapidly along with quickly increasing multicultural families. However, there are not enough surveys and basic researches for understanding the characteristics of multicultural children and issues such as social discrimination. Therefore, it is needed to identify the characteristics of multicultural children and seek new policies that reflect them to prepare policies that encompass various problems including the social adaptation of multicultural children in preparation for a rapidly changing multicultural society.

Previous studies [8,9,10,11,12] on the adolescents from multicultural families in South Korea reported the difficulties in peer relations, social support, family support, and language as factors related to discrimination experiences. Most of them used regression analysis for a prediction algorithm. Regression analysis is efficient for detecting individual risk factors, but it is limited in identifying multiple risk factors [13,14]. As a way to overcome this limitation, recent social science studies [15,16] have used predictive modeling based on big data-based machine learning. However, since these prediction studies are based on individual prediction algorithms, the bias existing in each algorithm may be reflected in the prediction results.

This study identified the predictors of social discrimination experiences of children from multicultural families in South Korea by using individual prediction models based on machine learning and reduced the potential bias risk of the models by combining them into a stacking ensemble learning model. Moreover, this study discovered the machine learning model with the best performance for predicting the social discrimination experience of children from multicultural families by comparing the prediction performance (accuracy) of individual prediction models and stacking ensemble models.

II. Methods and Materials

A. Data Source

The data source of this study was the “Study on the National Survey of Multicultural Families [17]” in 2012, which was jointly surveyed by the Ministry of Health, Welfare and Family Affairs, the Ministry of Justice, and the Ministry of Gender Equality and evaluated multicultural families residing in South Korea. The Study on the National Survey of Multicultural Families was conducted to develop policies customized for multicultural families by identifying their living conditions and welfare needs. The survey items consisted of the general characteristics, employment, economic level, marriage, health, and health care of multicultural families. The survey targets for the national survey of multicultural families were 154,333 families, all marriage immigrants. In addition to marriage immigrants, this survey also evaluated the spouses and children of marriage immigrants separately. The target subjects were sampled based on the status of alien residents living in 16 cities and provinces and the basic status of multicultural families collected by the Ministry of Public Administration and Security. Since this survey collected data from all target samples, a sample design was not needed and the survey was conducted from July 20 to October 31, 2012. The multicultural families used for this study were (1) families composed of marriage immigrants and South Korean who obtained South Korean nationality by birth, acknowledgment, or naturalization and (2) families composed of foreigners who obtained South Korean nationality by acknowledgment or naturalization and South Koreans who obtained South Korean nationality by birth, acknowledgment, or naturalization in accordance with the Multicultural Families Support Act. This study analyzed 19,431 adolescents (between 19 and 24 years old: 9,835 males and 9,596 females) among the children of marriage immigrants.

B. Measurements and Definitions of Variables

The target variable (label) was defined as social discrimination experience (yes or no). Features were gender, age, residence (countryside or city), highest level of education (elementary school graduation and below, middle school graduation, high school graduation, or college graduation or higher), Korean reading level (good, average, or poor), Korean speaking level (good, average, or poor), Korean writing level (good, average, or poor), Korean listening level (good, average, or poor), learning support experience (yes or no), economic activity (yes or no), the experience of using a support center for multi-cultural families (yes or no), learning Korean (yes or no), Korean society adaptation training (yes or no), career counseling (yes or no), and social welfare center use (yes or no).

C. Single Machine Learning Algorithm (base model): Support Vector Machine (SVM)

SVM is a machine learning algorithm that finds an optimal decision boundary, which is a linear separation that optimally separates a hyperplane by transforming training data into a high dimension through nonlinear mapping [18]. For example, when A=[a,d] and B=[b,c] are non-linearly separable in 2D, it becomes linearly separable when they are mapped in 3D. Therefore, if an appropriate nonlinear mapping is applied to a sufficiently large dimension, data with two classes can always be separated in a hyperplane. The concept of SVM is presented in Fig. 1.

D. Random Forest

Random forest is an algorithm that randomly learns a number of decision trees. It uses a number of bootstrap samples. After generating a decision tree for each sample, the output value is predicted using the decision tree most frequently used among the generated decision tree when new data is input [20]. The concept of random forest is presented in Fig. 2.

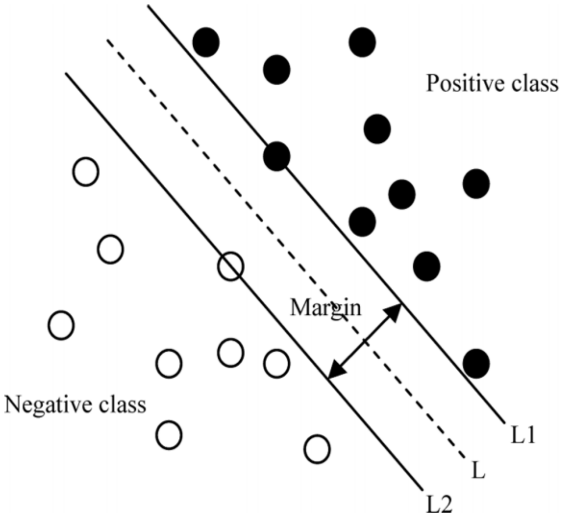

Fig. 1. Concept of SVM [19].

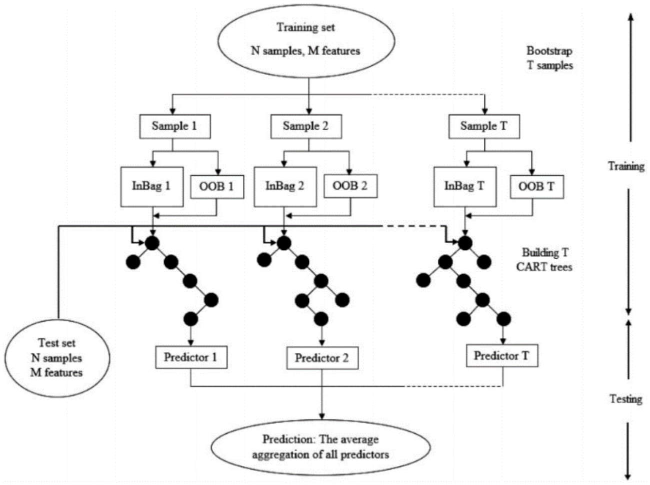

Fig. 2. Structure of Random Forest Algorithm [21].

E. Rotation Forest

Rotation forest is one of the random forest algorithms that performs learning while rotating the data axis by applying principal component analysis (PCA) to the training data. Rotation forest generates classifier ensembles based on feature extraction after excluding random features from the previous feature set used for learning. Principal component analysis (PCA) is performed on randomly divided subsets and training is conducted by rotating the data dimension [22]. Through this process, robust characteristics can be obtained for the input data showing complex distribution [23]. The performance procedure of the rotation forest is presented in Fig. 3.

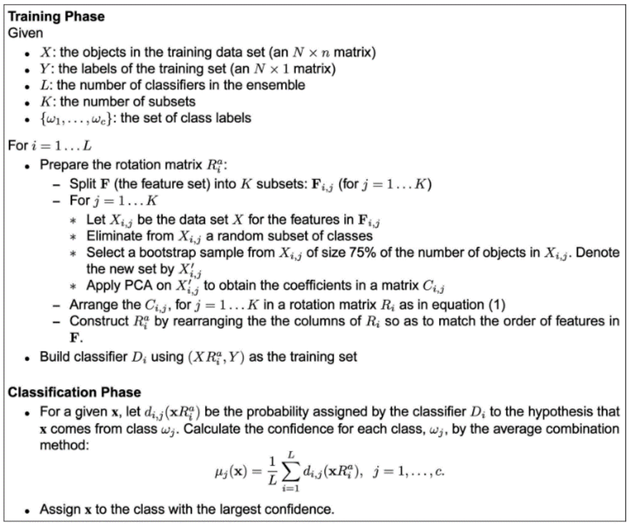
F. ANN (Artificial Neural Network)

ANN is an algorithm created based on the neural network structure of the human brain. It is composed of an input layer that inputs the target data, a hidden layer (or hidden layers) that is an intermediate step, and an output layer that shows the result. Every layer consists of a number of nodes, and only information that exceeds the threshold is passed to the next layer through the activation function. It is possible to predict the result in the output layer after deriving only the necessary information through this. The concept of ANN is presented in Fig. 4.

G. Stacking Ensemble (Meta Model)

This study predicted social discrimination experiences by using stacking ensemble techniques. Stacking ensemble techniques are superior in generalization and robustness to single machine learning models and have been used for classification and prediction in various fields [26,27,28,29]. It is a method of creating a new model by combining different models as if stacking them [30]. It improves the performance of the final model by taking advantage of each model and supplementing its weaknesses while going through the two stages (base and meta) [30].

This study used random forest (RF), rotation forest, ANN, and SVM for the base model. Logistic regression algorithm was applied for the meta model. The regression algorithm is the simplest method to increase the reliability of the base model while maximizing the generality and stability of the model. Feng et al., (2020) [31] reported that it would overfit the training data less probably. Due to this reason, the regression algorithm has been used as a meta model of the stacking ensemble algorithm in many recent publications [31,32], and this study also used it as a meta model for the same reason. The structure of the finally constructed stacking ensemble model is presented in Fig. 5.



```
Training Phase
Given
  • $X$: the objects in the training data set (an $N \times n$ matrix)
  • $Y$: the labels of the training set (an $N \times 1$ matrix)
  • $L$: the number of classifiers in the ensemble
  • $K$: the number of subsets
  • $\{\omega_1, \ldots, \omega_c\}$: the set of class labels

For $i = 1 \ldots L$
  • Prepare the rotation matrix $R_i^a$:
      – Split $\mathbf{F}$ (the feature set) into $K$ subsets: $\mathbf{F}_{i,j}$ (for $j = 1 \ldots K$)
      – For $j = 1 \ldots K$
          * Let $X_{i,j}$ be the data set $X$ for the features in $\mathbf{F}_{i,j}$
          * Eliminate from $X_{i,j}$ a random subset of classes
          * Select a bootstrap sample from $X_{i,j}$ of size 75% of the number of objects in $X_{i,j}$. Denote
            the new set by $X'_{i,j}$
          * Apply PCA on $X'_{i,j}$ to obtain the coefficients in a matrix $C_{i,j}$
      – Arrange the $C_{i,j}$, for $j = 1 \ldots K$ in a rotation matrix $R_i$ as in equation (1)
      – Construct $R_i^a$ by rearranging the the columns of $R_i$ so as to match the order of features in
        $\mathbf{F}$.
  • Build classifier $D_i$ using $(XR_i^a, Y)$ as the training set

Classification Phase
  • For a given $\mathbf{x}$, let $d_{i,j}(\mathbf{x}R_i^a)$ be the probability assigned by the classifier $D_i$ to the hypothesis that
    $\mathbf{x}$ comes from class $\omega_j$. Calculate the confidence for each class, $\omega_j$, by the average combination
    method:
        $\mu_j(\mathbf{x}) = \frac{1}{L}\sum_{i=1}^{L} d_{i,j}(\mathbf{x}R_i^a), \;\; j = 1, \ldots, c.$
  • Assign $\mathbf{x}$ to the class with the largest confidence.
```

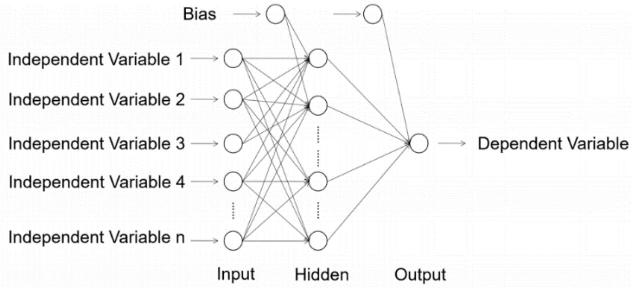

Fig. 4. Algorithmic Structure of a Typical ANN [25].

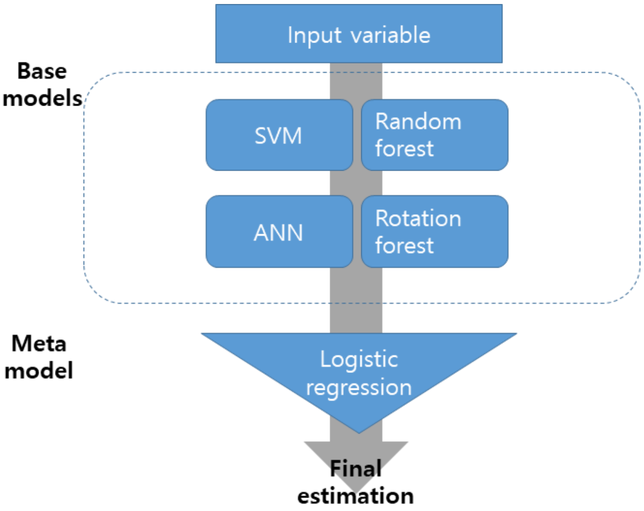

Fig. 5. The Structure of the Stacking Ensemble.

H. Validation of the Models

Each machine learning model was built through 5-fold cross-validation. This method validates the validity of learning by randomly dividing the entire sample into equal-sized five groups, validating it by using one of the groups as a validation dataset and the other groups as training datasets, and repeating this procedure five times. Root-mean-square-error (RMSE), index of agreement (IA), and variance of errors (Ev) were used to evaluate the prediction performance of the developed models. A lower RMSE indicates the higher accuracy of a prediction model. When IA is closer to 1 and Ev is lower, a model is more stable.

III. Results

Table I shows the general characteristics of adolescents from multicultural families in South Korea according to the presence of social discrimination experience. Among the all subjects (19,431 adolescents), 15.6% (3,035 adolescents) experienced social discrimination. The result of chi-square test revealed that residence, gender, highest level of education, the experience of using a support center for multi-cultural families, Korean speaking level, Korean listening level, Korean reading level, Korean writing level, career counseling, learning Korean, and Korean society adaptation training were significantly (p<0.05) different between adolescents from multicultural families with social discrimination experience and those without social discrimination experience.

TABLE I. General Characteristics of Adolescents from Multicultural Families in South Korea, n (%)

Variables	**Social discrimination experience**		**p**
	Yes (n=3,035)	**No (n=16,396)**	
Residence			<0.001
City	2,659 (16.2)	13,802 (83.8)	
Countryside	375 (12.6)	2,594 (87.4)	
Highest level of education			
Elementary school graduation and below	26 (12.9)	176 (87.1)	
Middle school graduation	394 (15.9)	2,084 (84.1)	
High school graduation	2,164 (15.3)	12,024 (84.7)	
College graduation or higher	451 (17.6)	2,112 (82.4)	
Gender			<0.001
Male	1,898 (19.3)	7,938 (80.7)	
Female	1,137 (11.8)	8,459 (88.2)	
Korean speaking level			<0.001
Good	2,176 (14.4)	12,939 (85.6)	
Average	635 (21.4)	2,330 (78.6)	
Poor	224 (16.6)	1,128 (83.4)	
Korean reading level			<0.001
Good	2,117 (14.0)	13,016 (86.0)	
Average	496 (19.6)	2,033 (80.4)	
Poor	422 (23.8)	1,348 (76.2)	
Korean writing level			<0.001
Good	2,033 (13.8)	12,731 (86.2)	
Average	506 (18.7)	2,196 (81.3)	
Poor	496 (25.2)	1,470 (74.8)	
Korean listening level			<0.001
Good	2,220 (14.4)	13,165 (85.6)	
Average	677 (24.1)	2,127 (75.9)	
Poor	137 (11.0)	1,105 (89.0)	
Economic activity			0.659
No	1,790 (15.7)	9,598 (84.3)	
Yes	1,245 (15.5)	6,798 (84.5)	
Korean society adaptation training			
No	2,888 (15.2)	16,104 (84.8)	
Yes	146 (33.3)	292 (66.7)	
Experience of career counseling			<0.001
No	2,611 (14.3)	15,602 (85.7)	
Yes	424 (34.8)	794 (65.2)	
Learning support experience			<0.001
No	2,526 (14.1)	15,336 (85.9)	
Yes	509 (32.4)	1,060 (67.6)	
Experience of using a support center for multi-cultural families			<0.001
Do not even know that such center exists	1,692 (18.8)	7,332 (81.3)	
Know the center but never used it before	1,125 (12.1)	8,198 (87.9)	
Not only know the center but also have used it before	218 (20.1)	867 (79.9)	

The prediction performance (i.e., RMSE, IA, and Ev) of the eight machine learning models for predicting social discrimination experience is presented in Fig. 6, 7, and 8, respectively. The analysis results of this study indicated that the prediction performance of the rotation Forst-logit regression model (RMSE = 0.15, IA = 0.72, and Ev =0.41) had the best performance.

The normalized importance of each variable of the rotation forest-logit regression model is presented in Fig. 9. The model confirmed that Korean society adaptation training, learning Korean, gender, the experience of using a multicultural family support center, and career counseling were major variables with high weight in the social discrimination experience of children from multicultural families in South Korea. Especially, Korean society adaptation training was the most important factor in the final model.

IV. Conclusion

This study compared the accuracy of models for predicting the social discrimination experience of children from multicultural families in South Korea by using eight machine learning algorithms, and confirmed that the rotation forest-logit regression model based on the stacking ensemble algorithm had the best prediction performance. In particular, the prediction model based on the stacking ensemble had improved accuracy (RMSE = 0.04-0.05) than other models and more stable (IA= 0.02-0.03) than other models. The results of this study support the possibility that the meta-model's prediction performance can be superior to the single prediction model for not only unstructured data such as videos and images but also structured data such as social science data. However, Lee & Kim (2020) [33] also reported that stacking ensemble algorithms had a longer execution time (runtime) than single machine learning algorithms, a limitation. Therefore, future studies using stacking ensembles need to evaluate the prediction performance comprehensively by comparing execution time (runtime) as well as accuracy. It is also needed to explore stacking ensemble models with the best performance through combining a base model and a meta model by using various machine learning algorithms such as clustering and boosting.

***Abstract*—Now-a-days, Cybersecurity attacks are becoming increasingly sophisticated and presenting a growing threat to individuals, private and public sectors, especially the Denial Of Service attack (DOS) and its variant Distributed Denial Of Service (DDOS). Dealing with these dangerous threats by using traditional mitigation solutions suffers from several limits and performance issues. To overcome these limitations, Machine Learning (ML) has become one of the key techniques to enrich, complement and enhance the traditional security experiences. In this context, we focus on one of the key processes that improve and optimize Machine Learning DOS-DDOS predicting models: DOS-DDOS feature selection process, particularly the wrapper process. By studying different DOS-DDOS datasets, algorithms and results of several research projects, we have reviewed and evaluated the impact on used wrapper strategies, number of DOS-DDOS features, and many commonly used metrics to evaluate DOS-DDOS prediction models based on the optimized DOS-DDOS features. In this paper, we present three important dashboards that are essential to understand the performance of three wrapper strategies commonly used in DOS-DDOS ML systems: heuristic search algorithms, meta-heuristic search and random search methods. Based on this review and evaluation study, we can observe some of wrapper strategies, algorithms, DOS-DDOS features with a relevant impact can be selected to improve the DOS-DDOS ML existing solutions.**

Keywords*—DOS-DDOS attacks; feature selection; wrapper process; machine learning

I. INTRODUCTION

With the exponential proliferation of Internet users, the network traffic has known a massive generation of data. These data are coming from individuals, private and public organizations. Moreover, the hard complexity of the Internet architecture and its interdependent suffers from different vulnerabilities, threats and risks ([1], [2]). Consequently, the attackers find an impressive amount of vulnerable systems [3].

Nowadays, cybersecurity attacks are becoming increasingly sophisticated, particularly the infrastructure attacks that make security analysis systems more vulnerable to several failures [1]. One of these most famous threats is Denial Of Service attack (DOS) and its variant Distributed Denial Of Service (DDOS) ([4],[5]). These serious and dangerous attacks violate the availability of information systems, which is a pillar of information security ([6],[5]**)**. The attackers seek to target computer systems, network devices, services and web applications to consume their CPU power, bandwidth, memory and processing time ([7], [3]).

The DDOS attack has the same purpose but with the difference of using intermediate of multiple networks between the attacker and its target ([7],[8]). This technique allows the attacker to amplify its attack with orchestrating a simultaneous sending of an excessive number of unwanted computing requests to its victim to overload its computing capacity.

To deal with these DOS-DDOS attacks, some traditional mechanisms are deployed such as firewalls, software updates, antivirus, Intrusion Detection Systems (IDS), etc.

However, many challenges and limits hinder these traditional techniques [6]. To overcome these limitations and drawbacks, Machine Learning (ML) techniques can be used as artificial intelligence systems to enrich, complement and enhance the traditional security experiences.

One of the key and critical pre-processing phases to success these DOS-DDOS ML models is feature selection. This process selects the most representatives DOS-DDOS characteristics from the initially DOS-DDOS dataset by eradicating those that are redundant and insignificant. Consequently, the obtained features subset improves the execution time, the detection rate and the accuracy of the used DOS-DDOS models.

In this context, this investigation presents a review and evaluation study related to DOS-DDOS attacks prediction based on one of the effective methods to select relevant DOS-DDOS features: Wrapper process.

This paper is organized as follows: In Section 2 we study some traditional mitigation solutions and their limits. Section 3 describes the interest of using machine learning (ML) in DOS- DDOS attacks prevention. Section 4 exposes the impact of feature selection on DOS-DDOS machine learning projects. In Section 5 we review and we evaluate recent and relevant feature selection results obtained by using three commonly used wrapper strategies: heuristic search algorithms, meta-heuristic search and random search methods. Finally, Section 6 presents our conclusions.

II. Dealing with DOS and DDOS: Traditional Mitigation and Solutions

DOS-DDOS attacks can take many forms such as SYN flood, SYN-ACK-ACK flood, UDP flood, ICMP flood, and so on. To deal with these forms of threats, many traditional, external and internal DOS-DDOS mitigation solutions are developed such as bandwidth provisioning, software updates, firewalls, antivirus software and Intrusion Detection Systems (IDS), etc. In the paragraph below, we discuss briefly these traditional solutions and their limits.

Generally, the use of firewall solution provides many mitigation solutions such as filter-based forwarding at logical interfaces, blocking of certain types of packets to reach a routing engine and packet counter and protection of a routing engine from DOS-DDOS attacks ([9],[10]). However, firewall solutions suffer from many lacks of security. As an example, the attacker can modify his DOS-DDOS attacks and make it legitimate.

The software updates keep the software up to date to avoid DOS-DDOS attacks on the application layer (the highest abstraction layer of the TCP/IP model) [11]. However, the irregularity of these updates creates a gateway to the attackers to modify the contents of memories (buffer overflow).

The Intrusion Detection System IDS (Hardware/Software solutions) is a complemented security for the firewall solutions. This solution is a common way often used to analyze and detect DOS-DDOS attacks [12]. IDS techniques are used in the aims to detect, classify and respond to DOS-DDOS actions that affect the integrity, the confidentiality or the availability of any network resources [13]. These systems are mainly based on two detection methods [14]: Misuse Detection (MD) and Anomaly Detection (AD).

The Misuse Detection is also known as Signature Detection, Pattern Detection, Knowledge-Based or Rule-based detection. This technique is one of the most common methods of Antivirus. It filters malicious packet of the known attacks thanks to its signature database of known attacks. It detects efficiently known attacks with low false positive. Nevertheless, it shows limits on detecting new forms of threats and many variants of known attacks.

The Anomaly Detection supervises the behavior of network traffic. It alerts the system at the slightest changes compared to the normal behavior. This method can detect new forms of attacks but generates high false positives and doesn't give clear information about the malicious events in some forms of attacks. Moreover, it is not feasible to IDS to manipulate high dimensional variables. Consequently, this technique can affect the efficiency and the velocity in detecting intrusions ([15],[16], [17]).

In addition to the limitations and drawbacks mentioned above, traditional techniques are hindered by many others challenges [6]. As an example, many traditional strategies of security are not sufficient to protect information systems against the new forms of DOS-DDOS attacks, need extra-storage and computational resources due to the high level of network traffic, suffer from a lack of source attacks information and are unable to detect and prevent many DOS-DDOS attacks in real-time.

To overcome these drawbacks, Machine Learning has become one of the key techniques to enrich and complement these traditional security experiences. In the paragraph below we discuss briefly the benefits that can be attained by using ML- techniques in DOS-DDOS attacks prevention.

III. The Use of Machine Learning in DOS-DDOS Attacks Prevention

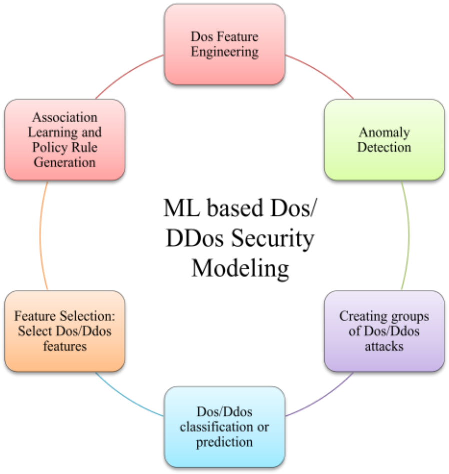
Machine Learning (ML) is an evolutionary field of Artificial Intelligence (AI) composed of a set of rules, methods and functions [18]. Applied to deal with many challenges in DOS-DDOS attacks, ML algorithms can learn from DOS-DDOS datasets and discover hidden knowledge from them [19].

By finding interesting DOS-DDOS patterns from training DOS-DDOS data, ML algorithms allow preventing and predicting many recent forms of DOS-DDOS behaviors.

Contrary to the traditional security solutions, ML models are powerful tools that can analyze in real time high dimensional DOS-DDOS traffic [20], classify the behavior of the DOS-DDOS traffic to determine the normal one from the abnormal and predict with high accuracy DOS-DDOS attacks before they happen.

Based on DOS-DDOS security modeling process (Fig. 1) and many common algorithms like K-Nearest Neighbors Algorithm (KNN), Support Vector Machines (SVM), Random Forest (RF) as well as Naïve Bayes (NB), etc. many recent research projects have shown other important preventing benefits of ML algorithms compared to the existing traditional solutions ([1], [12], [21]).

Feature selection is one of the critical pre-processing process to succeed and to improve the benefits mentioned above. In the paragraph below, we summarize the benefits of this process.



Dos Feature Engineering
Anomaly Detection
Creating groups of Dos/Ddos attacks
Dos/Ddos classification or prediction
Feature Selection: Select Dos/Ddos features
Association Learning and Policy Rule Generation
ML based Dos/ DDos Security Modeling

Fig. 1. Machine Learning DOS-DDOS Security Modeling Process

IV. Impact of Feature Selection Process DOS-DDOS Machine Learning Projects

Feature selection is one of the most critical pre-processing process in building DOS-DDOS Machine Learning (ML) models. This process is the first and crucial phase to improve the prediction accuracy, the detection rate and to reduce the execution time of DOS-DDOS models [22].

According to Bindra et al. [23], feature selection methods allow the DOS-DDOS security systems to distinguish DOS-DDOS attacks by using a minimum number of the most important features from network streams.

Applied to DOS-DDOS ML algorithms, feature selection is focused on selecting small and concise DOS-DDOS sets of characteristics describing the ML models [24]. It avoids the used features to contain redundant (correlation with other features) and noisier information of DOS-DDOS attacks without losing any piece of information. Consequently, it reduces the high memory requirements of security systems based on ML models ([25], [26], [27]).

Generally, the existing DOS-DDOS ML security systems use three commonly main categories of feature selection approaches: Filter, Wrapper and Hybrid methods [28].

The Filter methods are based on statistical methods which evaluate the relevance of DOS-DDOS features independently of any machine learning algorithms [27]. As a faster solution that computationally costs less, these methods are often used in high dimensional DOS-DDOS traffic ([29],[30]). However, the evaluation of individual information cannot take into consideration the correlation between the DOS-DDOS features. Consequently, the final DOS-DDOS subset can contain redundancy because some DOS-DDOS features can have the same ranking.

The wrapper strategies use a predetermined algorithm and its performance to assess the optimal DOS-DDOS subset features [31]. It executed in an iterative process, and at each iteration a new subset of DOS-DDOS features is generated to be evaluated by the classification algorithm [32]. The criterion of selection is principally based on the cross-validation accuracy during the DOS-DDOS training data [33].

The Hybrid method is a combination between filter method followed by wrapper approach, which offers the advantages of the two previous methods. It exploits their different criteria in different search stages [34].

V. Related Work

A. Objective of the Study

To detect and prevent DOS-DDOS attacks accurately, wrapper methods one of the *most effective* strategies to identify informative DOS-DDOS feature subsets from many high-dimensional DOS-DDOS network streams. This approach of feature selection is often addressed in many security solutions based on ML tasks. Indeed, increasing number of research projects have shown that many wrapper strategies can have an important impact on Accuracy, Detection Rate and time execution of existing DOS-DDOS ML systems.

In this context, we decided to focus our attention on the assessment of the performance of many DOS-DDOS experiments based on wrapper strategies and machine learning algorithms.

By studying different DOS-DDOS datasets, algorithms and recent results of several research projects, we review and we assess the impact of many recent wrapper strategies applied to predicting DOS-DDOS attacks. We have taken a more focused look at the impact of these strategies on number of DOS-DDOS features, detection rates, execution times and accuracies of DOS-DDOS attacks prediction.

We present four dashboards that are essential to understand the performances of three wrapper strategies commonly used in DOS-DDOS ML systems: heuristic search algorithms, meta-heuristic search and random search methods.

B. Review and Evaluation Study of Feature Selection Methods based on Wrapper Process

1) Used Datasets: To evaluate the performance of the wrapper strategies used in DOS-DDOS machine learning models, we start our review by studying relevant DOS-DDOS datasets commonly used by several DOS-DDOS research projects. These datasets are cited below:

The Knowledge Discovery and Data Mining (KDD'99) dataset was built based on the synthetic data captured in DARPA'98. This dataset is mainly composed of redundant records. Moreover, this configuration forces ML algorithms to learn less about infrequent records than the redundant ones. The inequality of attacks distribution between training and testing phase made the cross-validation more complicated.

This dataset is composed of four main families of attacks and forty one features.

The NSL_KDD was created to overcome the limits of the KDD'99 [35]. However, the main disadvantage of the NSL_KDD dataset, it does not include the modern low footprint attacks scenarios like the KDD'99.

The UNSW_NB15 is composed of nine family attacks and forty nine features. It includes a hybrid of the real modern normal behaviors and the synthetic attack activities [35].

Cyber Range Lab of the Australian Centre for Cyber Security (ACCS) is a dataset mainly composed of hybrid modern normal activities and attacks behaviors. It is composed of forty-seven features[36].

2) Use model evaluation metrics: To evaluate the reviewed DOS-DDOS Wrapper strategies, we have selected different metrics [37]. These metrics namely are: Classification Accuracy (Acc), Detection Rate (DR), Recall (Re), Precision (Pr), Specificity (Sp), Sensitivity (Sen), F-Measure (FM), False Alert Rate (FAR), False Negative (FN) and Time model execution (T).

The formulas associated with these metrics are listed above:

$$\mathrm{Acc} = \frac{\mathrm{TP+TN}}{\mathrm{TP+TN+FP+FN}} \quad (1)$$

$$\mathrm{DR} = \frac{\mathrm{TP}}{\mathrm{TP+FN}} \tag{2}$$

$$\mathrm{Re} = \frac{\mathrm{TP}}{\mathrm{TP+FN}} \tag{3}$$

$$\mathrm{Pr} = \frac{\mathrm{TP}}{\mathrm{TP+FP}} \tag{4}$$

$$\mathrm{Sp} = \frac{\mathrm{TN}}{(\mathrm{TN+FP})} \tag{5}$$

$$\mathrm{Sen} = \frac{\mathrm{TP}}{(\mathrm{TP+FN})} \tag{6}$$

$$\mathrm{FM} = \frac{2\times\mathrm{Re}\times\mathrm{Pr}}{(\mathrm{Re+Pr})} \tag{7}$$

$$\mathrm{FAR} = \frac{\mathrm{FP}}{\mathrm{FP+TN}} \tag{8}$$

Where: TP is True Positive: correct positive prediction. TN is True Negative: correct negative prediction. FN is False Negative: incorrect negative prediction and FP is False Positive: incorrect positive prediction.

3) Impact of used DOS-DDOS datasets and algorithms on the wrapper process: Generally, the performance of DOS-DDOS prediction models based on the Wrapper process depends strongly on the used ML algorithms and datasets. As shown in Table I, many algorithms performed well in detecting DOS-DDOS attacks compared to others. The accuracy can range from Acc=62.5% by using KDD'99 dataset and SVM algorithm to Acc=99.92% with Decision Tree J.48 algorithm and KDD'99 dataset. Indeed, according to the experiment of Jalill et al. (2010) [38] based on the KDD'99 dataset, the Support Vector Machine (SVM) algorithm has a serious problem in accurately detecting DOS-DDOS attacks compared to the Decision Tree J.48 algorithm which shows high prediction accuracy that exceed 99%.

TABLE I. IMPACT OF USED DOS-DDOS DATASETS AND ALGORITHMS ON THE WRAPPER PROCESS

Reference	**Dataset**	**Algorithm**	**Accuracy(%)**
Jalill et al. [38]	KDD'99	SVM	62.5
		J.48	99.7
Katkar and Kulkarni. [40]	KDD'99	J.48	99.92
		REPTree	99.56
		NB	87.50
		BN	99.68
		Sequential Minimal Optimization (SMO)	99.72
		REPTree + J48 +BN	99.94
Bellouch et al. [39]	UNSW_NB15	SVM	92.28
		NB	74.19
		C4.5	95.82
		RF	97.49

The experiments based on the NB, C4.5, RF algorithms and UNSW_NB15 dataset realized by Bellouch et al. (2018) [39], has shown that the prediction accuracy obtained by RF (Acc__{RF} = 99.94%) is better than C4.5 ($\text{Acc\_}_{C4..5}$ = 95.82%) and SVM (Acc__{SVM} = 92.28%). The NB algorithm shows less accuracy (Acc__{NB} = 74. 19 %) compared to RF, C4.5 and SVM.

The Bayesian Network (BN) algorithm used in the experiment of Katkar and Kulkarni [40] achieved good accuracy (Acc__{BN} = 99.68%) in detecting DOS-DDOS attacks thanks to its capacity of detecting anomalies in a multi-class [41].

By comparing the experiments carried out by Jalill et al.[38] and Katkar and Kulkarni [40], we have observed that SVM algorithm predict DOS-DDOS more accurately on the dataset UNSW_NB15 compared to the KDD'99 dataset ($\text{Acc\_}_{SVM\_UNSW\_NB}$ = 92.28% > Acc__{SVM_KDD} = 62.5 %). This important difference according to W. Xingzhu [42] is caused by the redundant records on the KDD'99 dataset and SVM has slower training on high dimensional datasets.

4) DOS-DDOS feature selection based on wrapper process and heuristic search algorithms: Based on heuristic functions or cost measures, wrapper strategies using heuristic search algorithms optimize and iteratively improve the process of DOS-DDOS feature selection [43].

Many heuristic searches such as SFS (Sequential Forward search), SBS (Sequential Backward search), LRS (Plus L Minus R Selection), RELR (Random Effect Logistic Regression), and GFR (Gradually feature removal method) have been used by many recent important research projects to solve accurately the problem of DOS-DDOS feature selection.

We discuss these projects in the paragraph below. At the end of this subsection, we present our first dashboard (Tables IIA, IIB, IIC) to summarize and to compare the performances of these strategies.

As an example of wrapper strategies based on heuristic search algorithms, we can cite the important investigation of Kavitha and Chrita (2010) [44]. In this study, the authors used the Best First Search (BFS) method. They selected two subsets composed simultaneously of seven and fourteen DOS-DDOS features. They applied four classifying algorithms: ID3, J48, NB and One R. These experiments have shown that ID3 and J.48 using a subset composed of fourteen DOS-DDOS features has the highest accuracy (Acc = 99%). One R and NB performed well in execution time (T=0.5s) with only seven features. The NB classifier achieved the highest specificity with Sp__{NB} = 99% by using seven features and Sp__{NB} =100% by using fourteen features.

Mok et al. (2010) [45] used Random Effect Logistic Regression (RELR) with a fixed Logistic regression (LR). This method selected five DOS-DDOS features by using the Stepwise Variable Selection Search (SVSS) strategy based on the KDD'99 dataset. The method achieved an accuracy equal to 98.74%.

Ahmad et al. (2011) [46] used Principal Components Analysis (PCA) to reduce the features and to choose the highest eighteen values. Genetic Algorithm (GA) was applied as wrapper method to the reduce space. This method selected twelve DOS-DDOS features. By using the Multi Layer Perceptron (MLP) as classifier on the output of GA and the KDD'99 dataset, this model has shown high accuracy (Acc_$_{MLP}$ = 99%) by using a minimum of features equal to 12 and the time of execution equal to 72 h.

L. Yinhui et al. (2012) [47] applied Gradually Feature Removal method (GFR) which selected nineteen best DOS-DDOS features. This strategy was based on SBS as search strategy and SVM as classifier. The accuracy of this model has been slightly reduced (Acc_$_{(19\ features)}$ = 98.62% < Acc_$_{(42\ features)}$ = 98.67%) by using a wrapper step. The execution time has been reduced from T $_{\_(42\ features)}$ = 18.94s to T_$_{(19\ features)}$ = 3.73 s.

Zhang and Wang (2013) [48] adopted SBS-BN and Bayesian network approach as a wrapper strategy. This experiment selected three best DOS-DDOS features and achieved good accuracy (Acc_$_{(3\ features)}$ = 98.98% > Acc_$_{(42\ features)}$ = 95.7%) with an interesting time of execution (T_$_{(3\ features)}$ = 2.37s < T_$_{(42\ features)}$ = 3.97s).

Al-Jarrah et al. (2014) [49] proposed a set of RF algorithm with forward and backward elimination ranking features selection techniques. This experiment demonstrated that FSR-RF outperforms with fifteen best features, BER-RF with fourteen features and RF with all used DOS-DDOS features: (Acc_$_{(15\ features)}$ = 99.98% > Acc_$_{(14\ features)}$ = 99.88 %) and (Acc_$_{(15\ features)}$ = 99.98% > Acc_$_{(42\ features)}$ = 99.89%).

J. Lee et al. (2017) [50] proposed SFFS-RFC to generate DOS-DDOS features subset and to measure the performance of each subset. This experiment has shown that SFFS-RFS improved the performance of the accuracy and the detection rate of attacks classification with only ten DOS-DDOS (Acc_$_{(10\ features)}$ = 99.89% and DR_$_{(10\ features\ )}$ = 99.9%). It realized a fewer FAR (FAR$_{\_(10\ features)}$ = 0.1% < FAR_$_{(41\ features)}$ = 1.7%) compared to the existing methods using the classifier C4.5 and reduced the execution time (T_$_{(10\ features)}$ = 0.18 s).

Harish and Manju (2018) [51] combined the Fisher Ratio Discrimination (FRD) with three different search strategies: SFS, SBS and LRS. They concluded that FDR using LRS, KNN and twenty DOS-DDOS features outperformed other methods. Thanks to its capacity to remove non-performing DOS-DDOS features from the initial subset, this strategy achieved a better accuracy with twenty features (Acc_$_{(20\ features)}$ = 98.87% > Acc_$_{SFS\_(25\ features)}$ = 98.27%) compared to FDR-SFS which selected 25 features. However, the execution time of FDR-SFS is less than FDR-LRS (T_$_{SFS\_(25\ features)}$ = 17.74 s < T_$_{SFS\_(20\ features)}$ = 17.98 s). On the other side the FDR-LRS with forty features showed a good accuracy compared to the accuracy of FDR-SBS with the same number of features (Acc_$_{LRS\_(40\ features)}$ = 99.09% > Acc_$_{SBS\_(40\ features)}$ = 98.78%). However the execution time of FDR-SBS is better compared to FDR-LRS (T_$_{SBS\_(40\ features)}$ = 32.18s < T_$_{LRS\_(40\ features)}$ = 32.95s).

Soodeh and Mehrdad (2019) [52] proposed a new framework composed of a hybridization of different algorithms. The objective of this framework is to handle new types of attacks better than other existing frameworks based on Forward Feature Selection (FFS). By using NSL_KDD dataset, this framework has shown that RF outperformed other algorithms with only thirteen features in attack detection accuracy ($Acc_{\_(13\ features)} = 98.9\%$). In the case of DOS-DDOS attacks, the KNN classifier has achieved the highest precision with eleven features ($Pr_{\_(11\ features)}= 99.8\%$). The classifiers RF, DT and KNN achieved the highest Recall value (Re = 99.8 %), and the highest F-measure ($FM_{\_RF\_(14\ features)} = 99.7\%$, $FM_{\_DT\_(10\ features)} = 99.6\%$, and $FM_{\_KNN\_(11\ features)} = 99.8\%$). The classifier NB showed the lowest measured values of all these metrics: $Acc_{\_NB} = 93.10\%$, $Pr_{\_NB} = 93.6\%$, Re = 87.3%, $FM_{\_NB} = 92.7\%$.

Malhotra and Sharma (2019) [53] used CfsSubsetEval and Best First as wrapper method. Based on NSL_KDD dataset and RF Bagging, PART and J.48 algorithms, this strategy selected eight best DOS-DDOS features. It increased slightly the accuracy and decreased significantly the execution time for all the classifiers. The accuracy of J.48 is 99.78% by using 6 and 42 features. However, this strategy decreased the execution time ($T_{\_J.48\_(42\ features)} = 61.68s > T_{\_J.48\_(6\ features)} = 7.95s$). The RF model decreased slightly the accuracy ($Acc_{\_RF\_(6\ features)} = 99.41\% < Acc_{\_RF\_(42\ features)} = 99.91\%$), and decreased drastically the execution time ($T_{\_RF\_(6\ features)} = 66.82s < T_{\_RF\_(42\ features)} = 191.06\ s$).

M. Wang et al. (2020) [54] combined SBS with Multi Layer Perceptron (MLP) to select the optimal DOS-DDOS features by using NSL_KDD dataset. This experiment showed that SBS-MLP can find an optimal DOS-DDOS feature subset and performed better accuracy than the full DOS-DDOS feature set among all the MLP-based detection methods ($Acc_{\_(31\ features)} = 97.66\% > Acc_{\_(42\ features)}= 97.61\%$). It enhanced the detection rate ($DR_{\_(31\ features)} = 94.88\ \%> DR_{\_(42\ features)} = 94.78\%$). It decreased the FAR value ($FAR_{\_(31\ features)} = 0.62\% < FAR_{\_(42\ features)} = 0.63\%$).

Polat et al. (2020) [55] evaluated the classifiers SVM, KNN, ANN and NB on their dataset initially composed of twelve features. This experiment used SFFS as a wrapper approach. They evaluated the performance of this approach by calculating many metrics: accuracy, sensitivity, specificity, precision and F-measure. By using a wrapper step and only selected DOS-DDOS features instead of all features, these different models increased the accuracy ($Acc_{\_ANN\_(6\ features)} = 91.44\% > Acc_{\_ANN\_(42\ features)} = 91.07\%) < (Acc_{\_SVM\_(10\ features)} = 92.15\% > Acc_{\_SVM\_(42\ features)} = 92.11\%) < (Acc_{\_NB\_(8\ features)} = 94.87\% > Acc_{\_NB\_(42\ features)} = 94.48\%) < (Acc_{\_KNN\_(8\ features)}= 98.30\% > Acc_{\_KNN\_(42\ features)}= 95.67$. However, the precision of SVM and KNN is slightly decreased by integrating the feature selection process compared to the initial set with all features ($Pr_{\_SVM\_(10\ features)} = 90.23\% < Pr_{\_SVM\_(42\ features)} = 91.42\%$), ($Pr_{\_ANN\_(6\ features)} = 88.11\% < Pr_{\_ANN\_(42\ features)} = 89.89\%$). The specificity is enhanced for all the used models, particularly by using a KNN model ($Sp_{\_SVM\_(10\ features)} = 97.26\%$, $Sp_{\_ANN\_(6\ features)} = 97.31\%$, $Sp_{\_NB\_(8\ features)} = 98.43\%$, $Sp_{\_KNN\_(6\ features)} = 99.45\%$).

Alabdulwahab and Moon (2020) [31] used the NSL_KDD dataset to evaluate different algorithms based on CfsSubsetEval and Best First as wrapper strategy. They tested CfsSubsetEval with six supervised classifiers: Logiboost, RBF, BayesNet, SMO and RepTree. By using six most relevant DOS-DDOS features, this experiment has shown an important improvement of the execution time ($T_{\_NBTree\_(6\ features)} = 14.23s < T_{\_NBTree\_(42\ features)} = 213.18s$, $T_{\_Logiboost\_(6\ features)} = 9.96s < T_{\_Logiboost\_(42\ features)} = 18.3s$. However, the accuracy was better without using the wrapper process ($Acc_{\_NBTre\_(6\ features)} = 99.46\ \% < Acc_{\_NBTree\_(42\ features)} = 99.87\%$). However, the RepTree algorithm decreased the accuracy and increased the execution time ($Acc_{\_RepTree\_(6\ features)} = 99.44\% < Acc_{\_RepTree\_(42\ features)} = 99.83\%$, $T_{\_RepTree\_(6\ features)} = 5.76s > T_{\_RepTree\_(42\ features)} = 3.59\ s$).

Umar et al. (2020) [56] applied Best First Forward as search strategy and DT to evaluate the performance of their detecting attacks model. This strategy selected nineteen best features by using UNSW_NB15 dataset. The assessment of this experiment was based on five metrics: Acc, DR, FAR and T. This method has shown that the execution time has overall decreased for different used classifiers ($T_{\_ANN\_(19\ features)} = 240s < T_{\_ANN\_(42\ features)}=660s$, RF ($T_{\_RF\_(19\ features)} =37.8s < T_{\_RF\_(19\ features)}= 44.4s$), NB ($T_{\_NB\_(19\ features)} = 2.86\ s < T_{\_NB\_(42\ features)} = 4.64\ s$).

By using nineteen DOS-DDOS features, the five metrics values of ANN, RF and SVM models are slightly the same as the baseline model.

The NB model achieved the worst detection rate ($DR_{\_NB\_(19\ features)} = 19.38\%$) and the same FAR value as the baseline model ($FAR_{\_NB\_(19\ features)} = FAR_{\_NB\_(42\ features)} = 0.01\%$).

The same performance was observed by the RF model ($FAR_{\_RF\ (19\ features)} = 27.73\% = FAR_{\_RF\_(42\ features)}=27.74\%$).

However, the classifiers KNN, SVM, ANN and RF increased the FAR value ($FAR_{\_ANN\_(19\ features)} = 37.36\% > FAR_{\_ANN\_(42\ features)} = 29.45\%$,

$FAR_{\_SVM\_(19\ features)} = 45.64\% > FAR_{\_SVM\_(42\ features)} = 40.51\%$).

Umar and Chen (2020) [57] used Best First as search strategy and DT as evaluator of their wrapper process. Based on UNSW_NB15, NSL_KDD datasets and four classifiers (ANN, SVM, KNN and RF), this process has selected twenty best DOS-DDOS features. The authors used five metrics to evaluate their models: Acc, DR, FAR and T. As results of this experiment, the RF algorithm outperformed the other used classifiers. By using the NSL_KDD dataset, the used wrapper process enhanced the accuracy and reduced the execution time ($Acc_{\_RF\_(20\ features)} = 99.7\ \% > Acc_{\_RF\_(42\ features)} = 98.8\ \%$, $T_{\_RF\_(20\ features)} = 13.2s < T_{\_RF\_(42\ features)} = 15s$). The use of UNSW_NB15 dataset and the wrapper step enhanced the RF accuracy and slightly increased the execution time due to the unnormalized data ($Acc_{\_RF\_(20\ features)} = 98.51\% > Acc_{\_RF\_(42\ features)} = 95.74\%$, $T_{\_RF\_(20\ features)} = 33.6s > T_{\_RF\_(42\ features)} = 32.4s$).

The performances of KNN, SVM and ANN were slightly lower by using twenty features, UNSW_NB15 and NSL_KDD datasets.

However, the SVM model increased drastically the execution time ($T\_{\text{SVM\_(20 features)}}$ = 10236.6s > $T\_{\text{SVM\_(42 features)}}$ = 5213.4s) by using the UNSW_NB15 and NSL_KDD datasets. The KNN and RF classifiers decreased the FAR value on the UNSW_NB15 dataset: ($FAR\_{\text{KNN (20 features)}}$ = 7.36% < $FAR\_{\text{RF\_(42 features)}}$= 11.42 %, $FAR\_{\text{RF\_(20 features)}}$ = 2.89 % < $FAR\_{\text{RF\_(42 features)}}$ = 8.77%).

However, the SVM model increased drastically the execution time ($T\_{\text{SVM\_(20 features)}}$ = 10236.6s > $T\_{\text{SVM\_(42 features)}}$ = 5213.4s) by using the UNSW_NB15 and NSL_KDD datasets. The KNN and RF classifiers decreased the FAR value on the UNSW_NB15 dataset: ($FAR\_{\text{KNN\_(20 features)}}$ = 7.36% < $FAR\_{\text{RF\_(42 features)}}$= 11.42 %, $FAR\_{\text{RF\_(20 features)}}$ = 2.89 % < $FAR\_{\text{RF\_(42 features)}}$ = 8.77%).

5) DOS-DDOS based on wrapper process and meta-heuristics search: Meta-heuristics are new optimization methods used in DOS-DDOS feature selection problems to provide near-optimal solution [34]. These methods are based on two main search strategies [58]. The first strategy is used to guarantee a global and efficient search to find a solution of DOS-DDOS feature selection. The second strategy is used to improve feature selection solutions.

Important research projects have applied meta-heuristic strategies to solve the problem of DOS-DDOS feature selection. In the paragraph below we discuss the important results of these investigations. At the end of this subsection, we present our second dashboard (Tables IIIA, IIIB, IIIC) to summarize and to compare the performances of these strategies.

TABLE III. (A): WRAPPER METHODS BASED ON META-HEURISTIC SEARCH (MHS)

As an example of relevant research projects based on wrapper process and meta-heuristic search, we can cite the important investigation of Jun Wang et al. [59]. In this study, the ABC-SVM approach was adopted as wrapper feature selection process. This wrapper strategy selected five DOS-DDOS best features from the KDD’99 dataset and found the best parameter to the SVM classifier. This method achieved good accuracy ($\text{Acc\_}_{\text{SVM\_(5 features)}}$ = 99.92%) and improved the time of execution ($\text{T\_}_{\text{SVM\_(5 features)}}$ = 12.20 s).

Alomari and Ali Othman (2012) [60] used an approach based on the Bees Algorithm (BA) as a wrapper feature method by using the classifier SVM. This experiment selected six DOS-DDOS features collected from the KDD'99 data set. They compared BA-SVM with other methods and concluded that their method achieved high detection rate and accuracy ($DR\_{}_{SVM\_(6\ features)}$ = 90.22%, $Acc\_{}_{SVM\_(6\ features)}$ = 93.36%) on detecting attacks with a low FAR ($FAR\_{}_{SVM\_(6\ features)}$ = 4.56%).

De La Hoz et al. (2014) [61] used a multi-objective procedure based on NSGA-II algorithm as wrapper feature selection to reduce the complexity of Growing Hierarchical Self-Organising Maps (GHSOM) algorithm. This wrapper method selected twenty-five representative features. As one of the multiple-objective based on the NSGA-II, the Jaccard index is evaluated after training the GHSOM. Their proposition improved the accuracy compared to the baseline model ($Acc\_(_{25\ features)}$ = 99.5% > $Acc\_(_{42\ features)}$ = 96.02%).

Senthilnayaki et al. (2015) [62] combined Genetic Algorithm (GA) with SVM. This study achieved high accuracy ($Acc_{\_(10\ features)}$ = 99.15%) with only ten best DOS-DDOS features compared to the baseline model ($Acc\_(_{42\ features)}$ = 82.45%).

Gaikwad and Thool (2015) [63] used Genetic Algorithm as wrapper feature selection which selected fifteen features. The authors used two classifiers Partial Decision Tree (PART) and C4.5, and they employed the Bagging on the two previous classifiers. This experiment has shown that using PART with the bagged classifier enhanced the accuracy and increased the execution time ($Acc\_{}_{Bagging\_PART}$ = 99.71% > $Acc\_{}_{PART}$ = 77.79%, $T\_{}_{Bagging\_PART}$ = 1589s > $T\_{}_{PART}$ = 274s). On the other side, using C4.5 with Bagging decreased the accuracy and increased drastically the execution time ($Acc\_{}_{Bagging\_C4.5}$ =77.86% < $Acc\_{}_{C4.5}$ = 79.08%, $T\_{}_{Bagging\_C4.5}$ = 1795s > $T\_{}_{C4.5}$ = 176.05s).

Wang Xingzhu (2015) [42] combined ACO feature weighting SVM. This wrapper strategy selected ten most important DOS.

DDOS features which achieved high detection rate and reduced the execution time ($DR_{\_(10\ features)}$ = 97.09% > $DR_{\_(42\ features)\ features)}$ = 92.71 %, $T_{\_(42\ features)}$ = 23.51s > $T_{\_(10\ features)}$ = 17.99s).

Eesa et al. (2015) [64] modified the Cuttle Fish Algorithm (CFA) and used it as wrapper feature selection method. They applied the classifier ID3 to detect attacks by using the KDD'99 dataset with ten best features. The process showed a real improvement of accuracy and detection rate compared to all used features ($Acc_{\_(10\ features)}$ = 92.83% > $Acc\_{}_{(42\ features)}$ = 73.26%, $DR_{\_(10\ features)}$ = 92.05% > $DR_{\_(42\ features)}$ = 71.08%). Moreover, the FAR value decreased from $FAR_{\_(42\ features)}$ = 17.68% to $FAR_{\_(10\ features)}$ = 3.9 %.

Kang and Kim (2016) [65] employed Local Search Algorithm (LSA) and K-means to find the optimal DOS-DDOS subset features, to reduce the training time and to avoid the over-fitting problem. This experiment evaluated the performance of twenty five selected DOS-DDOS features. The result has shown that using LSA-K-means as wrapper feature step with MLP enhanced the accuracy, increased the detection rate and reduced the FAR value ($Acc_{\_(25\ features)}$ = 99.37% > $Acc\_(_{42\ features)}$ = 96.93%, $DR_{\_(25\ features)}$ = 99.42% > $DR_{\_(42\ features)}$ = 93.38 %, $FAR_{\_(25\ features)}$ = 0.66% < $FAR_{\_(42\ features)}$ = 0.96%).

Hosseinzadeh Aghdam and Kabiri (2016) [66] build an intrusion detection system based on ACO (Ant Colony Optimization) feature selection method. This method converges faster to the optimal DOS-DDOS subset composed of four DOS-DDOS features. This strategy has increased the Recall and the F-measure values ($Re_{\_(4\ features)}$ = 99.78% > $Re_{\_(42\ features)}$ = 80.02 %, $FM_{\_(4\ features)}$ = 89.82% > $FM_{\_(42\ features)}$ = 83.76%). However, the precision is slightly decreased compared to the baseline model ($Pr_{\_(4\ features)}$ = 81.66 % < $Pr_{\_(42\ features)}$ = 87.86 %).

Khammassi and Krichen (2017) [26] combined Genetic Algorithm with Logistic Regression (LR) as Wrapper feature selection method. This experiment based on different decision tree classifiers (C4.5, RF, and NBTree) has maximized the accuracy by using the KDD'99 and UNSW_NB15 datasets with eighteen and twenty DOS-DDOS best features. The LR-RF strategy has achieved a high precision and Recall values ($Pr_{\_(18\ features)}$ = 99.97%, $Re_{\_(18\ features\ )}$ = 99.98%).

By using UNSW_NB15 dataset with twenty DOS-DDOS features, the LR-C4.5 process has achieved the worst Recall and precision values ($Re_{\_(20\ features)}$ = 4.11 %, $Pr\_(_{20\ features)}$ = 36.09%).

Enache et al. (2017) [67] conducted their experiment on the NSL_KDD dataset with many wrapper approaches (Algorithm (BA) ad Particle Swarm Optimization (PSO)). To evaluate these strategies they used the classifiers C4.5, SVM and BN.

The PSO-SVM process outperformed the other classifiers with only twenty-one features. It enhanced the detection rate and decreased the FAR value ($DR_{\_(21features)}$ = 97.17 > $DR_{\_(42\ features)}$ = 89.64 %, $FAR_{\_(21\ features)}$ = 1.6 % < $FAR_{\_(42\ features)}$ = 6.88 %).

By using eighteens selected features, the process BA-C4.5 achieved an interesting detection rate and increased slightly the FAR value ($DR_{\_(18\ features)}$ = 96.01 % > $DR_{\_(42\ features)}$ = 95.67 %, $FAR_{\_(18\ features)}$ = 3.20 % > $FAR_{\_(42\ features)}$ = 3.02 %).

Yin Chunyong et al. (2017) [68] used an artificial immune system as wrapper method which improved the Clonal Selection Algorithm (ICSA). This method based on the theory of biological immune system learning process selected twenty-one features from the KDD'99 dataset.

This subset realized a good accuracy and low FAR value ($Acc_{\_(21\ features)}$ = 99.5%, $FAR_{\_(21\ features)}$ = 0.1%).

Khorram and Baykan (2018) [69] tested and compared the performances of three wrapper feature selection methods by using two classifiers: SVM and KNN. The used wrapper methods are Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO) and Artificial Bee Colony (ABC).

This experiment showed that ABC-KNN strategy with seven features outperformed the use of all features ($T\_{}_{ABC\text{-}KNN\_(7\ features)}$ = 53s < $T\_{}_{KNN\_(42\ features)}$ = 291s, $Acc\_{}_{ABC\text{-}KNN\_(7\ features)}$ = 98.9 % > $Acc\_{}_{KNN\_(42\ features)}$ = 93.9%,

$\text{DR\_}_{\text{ABC-KNN\_(7 features)}}$ =98.7 % > $\text{DR\_}_{\text{KNN\_(42 features)}}$ = 91.9 %).

Mazini et al. (2019) [70] employed ABC as wrapper process to optimize their IDS by using NSL_KDD dataset, the classifier AdaBoost and the parameters regulation method.

This strategy selected twenty-five DOS-DDOS features and achieved a high accuracy, detection rate and low FAR values ($\text{Acc}_{\text{\_(25 features)}}$ = 98.90%, $\text{DR}_{\text{\_(25 features)}}$ = 99.61%, $\text{FAR}_{\text{\_(25 features)}}$ = 0.01%).

Samadi Bonab et al. [58] proposed an improved version of IDS based on the hybrid method Fruit-Flu algorithm (FFA) and the Lion Optimizer algorithm (ALO) as wrapper approach. This strategy based on the datasets KDD'99, NSL_KDD and UNSW_NB15 reduced the used features from 41 to 12 on KDD'99, from 41 to 16 on NSL_KDD and from 48 to 15 on UNSW_NB15. It applied the DT algorithm as a classifier on these different datasets. The performances are evaluated by using five metrics: Acc, Sp, Sen and T. This experiment has shown an enhanced accuracy and reduced the execution time on KDD'99 and UNSW_NB15 datasets ($\text{Acc\_}_{\text{KDD'99\_(12 features)}}$ = 99.73% > $\text{Acc\_}_{\text{KDD'99\_(42 features)}}$ = 97.99%, $\text{Acc}_{\text{\_UNSW\_NB15\_(15 features)}}$ = 99.12% > $\text{Acc}_{\text{\_UNSW\_NB15\_(42 features)}}$ = 85.56%). On the NSL_KDD dataset the use of this wrapper process didn't change the accuracy ($\text{Acc}_{\text{\_NSL\_KDD\_(16 features)}}$ = $\text{Acc}_{\text{\_NSL\_KDD\_(42 features)}}$ =93%). However, the specificity was lower on UNSW_NB15 and NSL_KDD compared to KDD'99 ($\text{Sp\_}_{\text{UNSW\_NB}}$ = 91.76 % < $\text{Sp\_}_{\text{NSL\_KDD}}$ = 97.10% < Sp__{KDD}= 99.67%).

The Tables IIIA, IIIB, IIIC summarize and compare the performances of all wrapper process and meta-heuristic strategies discuss above.

6) DOS-DDOS feature selection based on wrapper process and Random search methods: Random search methods applied DOS-DDOS feature selection projects to evaluate the DOS-DDOS features on random sampling around the problem region. These stochastic methods are mainly used to solve the global problem optimizations [71].

To optimize the DOS-DDOS feature subsets, many important research projects have used wrapper process and random search methods to solve this problem. We discuss these projects in the paragraph below. At the end of this subsection, we present our third dashboard (Table IV) to summarize and to compare the performances of these strategies.

As an example of these important investigations, we can cite the important study of Lin et al. (2012) [72] which combined Simulated Annealing (SA) with SVM algorithm to get the best feature subset. This experiment selected twenty three best DOS-DDOS features which evaluated by SA as random search and C4.5 decision tree as classifier. Compared to the initial set of features, the selected subset achieved a high accuracy equal to 99.96%.

Chowdhury et al. (2016) [36] used a wrapper feature selection method based on SA as random search and the ACCS dataset. This strategy selected three best features to detect attacks.

By applying the SVM algorithm with SA, this experiment has showed better accuracy, low FAR and FN values compared to all used features ($\text{Acc\_}_{\text{SVM\_(3 features)}}$ = 98.76% > $\text{Acc\_}_{\text{SVM\_(42 features)}}$ = 88.03%, $\text{FAR\_}_{\text{SVM\_(3 features)}}$ = 0.09% < $\text{FAR\_}_{\text{SVM\_(42 features)}}$ = 4.2%, $\text{FN\_}_{\text{SVM\_(3 features)}}$ = 1.15% < $\text{FN\_}_{\text{SVM\_(42 features)}}$ = 7.77 %).

Hasan Md El Mehedi et al. (2016) [73] adapted the Random Forest algorithm (RF) to select twenty-five best features by using the KDD'99 dataset. The performances evaluation is based on 3 metrics: accuracy, precision and FAR. Compared to the initial used dataset with all features, this wrapper strategy increased the accuracy, the precision and decreased the FAR value ($\text{Acc}_{\text{\_(25 features)}}$ = 91.90% > $\text{Acc}_{\text{\_(42 features)}}$ = 91.41%, $\text{Pr}_{\text{\_(25 features)}}$ = 98.94% > $\text{Pr}_{\text{\_(42 features)}}$ = 98.91%, $\text{FAR}_{\text{\_(25 features)}}$ = 5.82% < $\text{FAR}_{\text{\_(42 features)}}$ = 7.52%).

TABLE IV. WRAPPER METHOD BASED ON RANDOM METHODS

DOS-DDOS feature selection projects based on wrapper methods	DOS- DDOS used dataset	Used wrapper strategies	Number of DOS -DDOS features	Used classifier	Used Metrics	Values metrics with FS	Values metrics without FS
Lin et al. [72]	KDD'99	SA-SVM	23	SA-DT	Accuracy	99.96%	NA
Chowdhury et al. [36]	ACCS	SA	3	SVM	Accuracy FAR FN	98.76% 0.09% 1.15%	88.03% 4.2% 7.77%
Hasan Md El Mehedi et al. [73]	KDD'99	RF	25	RF	Accuracy Precision FAR	91.90% 98.94% 5.82%	91.41% 98.91% 7.52%
Najeeb and Dhannoon (2018) [74]	NSL_KDD	BFA	15	NB	Accuracy	94.83%	89.9%
Almasoudy et al. (2019) [75]	NSL_KDD	DE	9	ELM	Detection Rate Precision F_measure	91.5% 81.18% 86.03%	79.55% 94.90% 80.44%

Najeeb and Dhannoon (2018) [74] proposed an IDS model that combined the Binary Firefly (BFA) method with the Naïve Bayes (NB) classifier by using the NSL_KDD dataset. The BFA is initialized by a binary sequence contrary to the Firefly (FA) algorithm. This model was iterated two hundred times with fifteen selected features and achieved better accuracy compared to all used features ($Acc\_{(25\ features)}$ = 94.83% > $Acc\_{(42\ features)}$ = 89.9%).

Almasoudy et al. (2019) [75] has realized an IDS experiment based on Differential Evolution (DE) as wrapper based approach by using the NSL_KDD dataset. Nine candidate features are randomly selected. The Extreme Learning Machine (ELM) is used as classifier to compute the accuracy of DOS-DDOS features until it achieved high accuracy. Applied to DOS-DDOS attacks predicting, this method achieved high detection rate, high F-measure and decreased slightly the precision ($DR\_{(9\ features)}$ = 91.5% > $DR\_{(42\ features)}$ = 79.55%, $FM\_{(9\ features)}$ = 86.03 % > $FM\_{(42\ features)}$ = 80.84%, $Pr\_{(42\ features)}$ = 94.90 % > $Pr\_{(9\ features)}$ = 81.18%).

VI. Conclusion

Nowadays, cybersecurity attacks grow over time, especially the Denial of Service attack (DOS) and its variant Distributed Denial of Service (DDOS). These famous attacks continue to threaten private and public activities everywhere.

Dealing with these threats by using Machine Learning (ML) models can hold a great promise in DOS-DDOS security systems. By learning from and identifying a large amount of network traffic, these predictive models can efficiently handle the DOS-DDOS threats and overcome several limits and performance issues of the traditional security solutions.

One of the key preprocessing phases to success and optimize these DOS-DDOS cybersecurity intelligence models is feature selection step, particularly the feature selection method based on the Wrapper strategies.

Using Wrapper techniques improved significantly the selection of the relevant DOS-DDOS features and enhanced the performance of many existing ML solutions.

In this paper, we have advanced the development of this previous work by studying different DOS-DDOS datasets, algorithms and the results of several research projects. We have reviewed and evaluated the impact of many important wrapper strategies used by many existing DOS-DDOS security systems.

We have summarized the findings in three dashboards that are essential to understand the performance of three wrapper strategies commonly used in DOS-DDOS ML models: heuristic search algorithms, meta-heuristic search and random search methods.

This study shows that many wrapper strategies, algorithms, DOS-DDOS features with a relevant impact can be selected to improve the DOS-DDOS ML existing solutions.

Acknowledgment

I would like to express my sincere gratitude to my Professors and my family for the continuous support of my study and related research, for their patience, motivation, and immense knowledge.

***Abstract*—Internet of Things (IoT) is a technology that can connect everything to the Internet. IoT can be used in a wide range of applications which includes remote applications like Underwater networks. Remote applications involve the deployment of several low-power, low-cost interconnected sensor nodes in the specific region. With a massive amount of devices connected to the IoT and the considerable amount of data associated with it, there remain concerns about data management. Also, the amount of data generated in an extensive IoT-based remote sensing network is usually enormous for the servers to process, and many times data generated are redundant. Hence there is a need for designing a framework that addresses both aggregations of data and security-related issues at various aggregation points. In this paper, we are proposing an intelligent data aggregation mechanism for IoT-based remote sensing networks. This method avoids redundant data transmission by adapting spatial aggregation techniques. The proposed method was tested through simulations, and the results prove the efficiency of the proposed work.**

Keywords—Wireless sensor networks; Internet of Things; intelligent boundary determination; sensor nodes; data aggregation

I. Introduction

Internet of Things refers to connecting various things to the internet. IoT can be used in a wide range of applications. IoT applications include remote applications also. Remote IoT applications include military applications such as surveillance, battlefield monitoring, underwater applications such as oil spill detection, analysis of aquatic animals lifecycle, smart farming, forest applications such as fire monitoring, etc. Remote IoT applications use resource-constrained networks. It includes deploying several low-cost and low-power sensor nodes that can sense, process, and communicate the data. Each sensor node has a limited transmission range, limited energy, limited processing capabilities, and limited memory.

As sensor nodes are resource-constrained devices, several sensor nodes will be deployed in a smaller region. This leads to the generation of redundant data. Transmitting redundant data will leads to the wastage of energy and other resources. Redundant data transmission can be controlled by data aggregation techniques. There are different data aggregation techniques such as In-network data aggregation, Tree-based data aggregation, cluster-based data aggregation, Grid-based data aggregation, and hybrid data aggregation. There can be single-level or multiple levels of data aggregation. Data aggregation can be performed in homogeneous networks or in heterogeneous networks. Homogeneous networks include nodes with similar configurations and capabilities in the entire network. Heterogeneous networks include nodes with different configurations and capabilities organized in the multiple levels of hierarchy [15][17].

Data aggregation involves just combining the data from multiple sources into a single packet and forwarding it to the next node or destination. Traditional approaches always aggregate the data based on the count, average, sum, etc. The reduction of redundant data is not that significant through normal data aggregation techniques. Hence there is a need for adding some intelligence to nodes to decide whether to transmit the data or not [16]. In the constrained remote IoT applications where we have limited resources, communication consumes more energy than compared to processing. In this paper, we are proposing an intelligent data aggregation technique, which aggregates the data as well as provides intelligence to nodes to detect whether to send the data or not. Also, our present work adds features to detect the boundary of certain event occurrences in event-driven networks.

The paper is organized as follows: Related work is given in Section 2, Section 3 describes proposed work, Section 4 describes the simulation and results, the conclusion is provided in Section5.

II. Related Work

There are different traditional data aggregation mechanisms; they are flat-based [1][2][3] and hierarchical-based techniques.

In a flat network, the base station transmits a query message requesting data from the sensor nodes within the network. The nodes which have data relevant to the query sent will respond with the requested data. In this method, the base station performs excessive communications and computations. Because of this, if the base station fails, then the network connection will be lost with the outer world.

Under hierarchical data aggregation, many approaches have been proposed for energy efficiency and scalability. There exist four different types of hierarchical data aggregation they are the cluster-based data aggregation [4][5], tree-based data aggregation [9], grid-based data aggregation [8]., and chain-based data aggregation [6][7].

These traditional data aggregation schemes will just combine the data from multiple sources and forward it to the next node. In the majority of applications, normal data aggregation is not sufficient. We need to add some intelligence to the data aggregation and data transmission process within the limits of constrained resources.

J. Chen, S. Kher, and A. Somani, et al. proposed a scheme in [9], which involves Majority Voting. This approach is a data outlier detection method based on spatial correlation. Here if a reading of the local sensor node is different from the majority of its neighboring nodes, then it will be classified as abnormal.

Y. Sun, H. Luo, and S. K. Das et al. Proposed a scheme in [10]. Here according to the trustworthiness ranked by comparison with historical data and neighbor data, Weight will be assigned to every sensor data. Then weighted mean value will be calculated at the aggregator. This will be considered as the aggregated data.

S. Din, A. Ahmad, et al. Proposed a scheme in [11], where the nodes closer to the sink node performs direct communication and remains unclustered; the nodes which are one-hop away from the sink node perform multi-hop communication and remains clustered.

Bo Yin et al. in [12] specified a Tree-based scheme that involves the construction of an aggregation tree for complex queries. This ensures minimum communication cost.

Xiong Li et al. proposed a scheme in [13] where there will be three participants, they are edge server, terminal device, and public cloud center. The data from the terminal devices is encrypted and communicated to the edge server, then the edge server performs data aggregation of the data from terminal devices and forwards the aggregated data to the public cloud center. The aggregated plaintext data can be recovered by public cloud center through its private key.

S. Kumar and V. K. Chaurasiya et al. in [14] proposes a scheme, where data mining techniques are used to generate more accurate, consistent, and useful information than that generated by any individual sensor node.

III. Proposed Work

A. Assumptions and Architectural Setup

Following are the assumptions made in deployment of nodes in the WSN test bench.

1) Grid based deployment of nodes: nodes are deployed on a crisscross grid, to specifically determine location of each individual node. This assumption is both safe and valid as, there is a commercially available underwater robot capable of deploying nodes at specific coordinates of latitude and longitude. Such a deployment is also helpful in making intelligent inferences based on which nodes are communicating sensed data.

2) Number of nodes per grid is fixed: this assumption helps us compute statistically significant results after data collection is done and analysis is to be performed.

3) Node density is uniform: non-uniform node deployment does not allow implementation of intelligence.

4) Each node in a grid represents a single unit of area: data collected is representative of a fixed area under surveillance.

5) Unit squares (Grids) form a Level -1 cell: this logical rule imposed on grid helps in aggregation of data across levels of nodal deployment.

6) Every level-1 cell has a level-1 cell aggregator node: this is an architectural requirement of WSNs. aggregator nodes act as data aggregator for sensed data before being forwarded to upper layers.

7) Four level-1 cells combine to form a level 2-cell: multiple layers in the architecture will always help in implementation of an additional second layer of intelligence and additional aggregation.

8) One of the unit cell's cell-sink also works as a sink for four adjacent level-2 cells: this is strictly based on energy levels of nodes, suitable cell-sink is elected as the sink of adjacent cells based solely on this criteria.

9) All level-2 cells combine to form the region under observation: this is the highest level of aggregation implemented under our framework.

B. Node Deployment Phase and Network Establishment

1) Four different levels of nodes are deployed.

a) Ground Level Sensor Nodes: They are low power sensor nodes with capability to sense and forward the data to next level.

b) Grid Head: They are high power nodes. They can aggregate the data and also sense the information.

c) Level -1 Aggregator: They act like second level grid head. They gather the data from multiple grids and transfer it to Level-2 Aggregator after processing.

d) Level-2 Aggregator: They are at the top level of hierarchy, they can provide minor conclusions about the sensed information.

2) These nodes are deployed at the required locations.

3) The area of interest is divided into equal sized grids. Ground level nodes and Grid heads are deployed at each grid. High power node will be the grid head of that particular grid.

4) Each High power node broadcast a beacon message to the ground level sensor node to indicate its presence in the grid.

5) Each ground level nodes respond back to their grid heads by sending the beacon response. Same Procedure is followed between grid heads and anchor nodes, Anchor nodes and surface buoyant nodes.

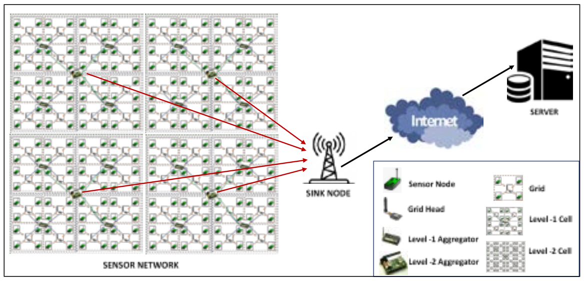

Fig. 1. Network Architecture.

Fig. 1 shows the proposed network architecture. The network is divided into smaller grid. Grids are combined to form level-1 Cell. Level-1 Cells are combined to form level -2 Cells. There will be sink node at the border of area of interest. Sink node forwards the data to server through internet connection.

C. *Data Aggregation*

Tier- 1Local aggregation (level 1):

Spatial aggregation: this primary level of aggregation is based on the percentage of area generating similar readings. Each grid has a designated grid head. The grid head communicates reading only if number of nodes reporting similar readings are greater than threshold percentage.

Spatial Aggregation is adapted in Grid as well as level-1 Cell by Grid head and Level-1 Aggregator.

Tier-2 Aggregation (level 2)

TABLE I. SYMBOLS USED IN THE ALGORITHM

Symbol	Description
S	Ground Level Sensor Node
G	Grid Head
L1	Level 1 Aggregator
L2	Level 2 Aggregator
SI	Sink Node
Ts	Threshold Percentage used by G for Level 1 Aggregation
Tg	Threshold Percentage used by L1 for Level 1 Aggregation
R1	Threshold Radius 1 for level 2 Aggregation
R2	Threshold Radius 2 for level 2 Aggregation
t_i	Time interval, i=1,2,3….
Ns	No. of Sensor Nodes which has sent similar readings
Ng	No. of Grid Heads which has sent similar readings
Ps	Packet sent by sensor node
Pg	Packet sent by Grid Head
PL1	Packet sent by Level-1 Aggregator
PL2	Packet sent by Level-2 Aggregator
D	Distance between L2 and L1
Dist	List of D computed in 1 time interval

Boundary value aggregation: region under observation has a Level -2 Aggregators that acts as a data aggregator. Radial survey is made periodically at three lengths of radii- minimum, nominal and maximum. Minimum is close to the Level -2 Aggregators, maximum is distance from Level -2 Aggregators to boundary of region under observation, and nominal is an intermediate distance.

Algorithm 1 shows how sensor senses and sends the data. Algorithm 2 and 3 depicts the level-1 aggregation techniques (Spatial aggregation). Level -2 aggregation is given in Algorithm 4. Table I describes the symbol used in the algorithm.

Algorithm 1: Sensing at Ground Level

```
1. For each ti i=1,2,3….
2.   S senses the data
3.   Prepare the packet Ps
4.   Send Ps to its G
5. End
```

Algorithm 2: Level-1 Aggregation at Grid Level

```
1. For each ti, i=1,2,3…..
2.   G: Compare the Ps received by all S under G and compute Ns
3.   If Ns >= Ts
4.       Aggregate the data
5.       Prepare the packet Pg
6.       Send Pg to L1
7.   Else
8.       Discard the data
9. End
```

Algorithm 3: Level-1 Aggregation at Level-1 Cell Level

```
1. For each ti, i=1,2,3…..
2.   L1: Compare the Pg received by all G under L1 and compute Ng
3.   If Ng >= Tg
4.       Aggregate the data
5.       Prepare the packet PL1
6.       Send PL1 to L2
7.   Else
8.       Discard the data
9. End
```

Algorithm 4: Level 2 Aggregation at Level-2 Cell level

```
Consider coordinates of L2: (XL2 , YL2) as centre point.
Let (XL1, YL2) be the coordinates of L1
For each L1 which has sent data to L2
    Find distance between the L1 and L2
    $D = Sqrt( (XL2 – XL1 )2 – (YL2 – YL1 )2 )$
    Add D to list Dist
End
Find largest D in Dist
If largest Di is within radius R1
    Radial_survey = minimum: Event spread in shorter region
    Prepare PL2 with a field Radial_survey
    Send PL2 to Sink
Else if Largest Di is between radius R1 and R2
    Radial_survey = nominal: Event spread in Moderate region
    Prepare PL2 with a field Radial_survey
    Send PL2 to Sink
Else if Largest Di is greater than R2
    Radial_survey = maximum: Event spread in longer region
    Prepare PL2 with a field Radial_survey
    Send PL2 to Sink
```

IV. Simulation and Results

In the proposed research work, we have used MATLAB as the simulation tool to check the efficiency of our proposed work. Initially, we considered the area of the application region with dimensions 800m (length) x 800m (breadth). Then the area under consideration is divided into equal-sized grids of size 100m each at ground level. Table II shows the various parameters used in the simulation. Fig. 2 depicts the topology created through simulation. Here blue color nodes represent sensor nodes deployed at ground level. Red color nodes represent the grid head; the magenta color nodes indicate nodes that are Level-1 Aggregators, Black color represents Level-2 Aggregators, and Green color indicates sink node.

Fig. 3 shows the amount of time required to detect the boundary of the event spread through Level-2 aggregation. In certain remote IoT applications detecting the spreading rate of a certain event is very important to take immediate measures. For Ex: the spread of fire in the forest, oil leakage in the ocean, etc.

Fig. 4 helps us to understand that the number of redundant transmissions in various techniques compared with our work. It is evident that redundant data transmission is significantly dropped compared to other traditional approaches. Our method requires a lesser number of packet transmissions compared to without aggregation deployment, traditional in-network architecture, and cluster-based approach. It is clear that the proposed work reduces redundant data transmission significantly.

TABLE II. Simulation Parameters

Parameter Type	**Parameter Value**
Area of application region	800 X 800 m^2
Grid range	100 m
Number of Ground level node in each grid	4
Number of High power nodes in each grids	2 (1Grid Head)
Number of Level-1 Aggregators in each group of Level-1 Cell	1
Number of Level-2 Aggregators in each group of Level-2 Cell	1
Simulation Time	150sec
Payload length	512 Bytes
Parameters of Ground level sensor node	
Initial Energy	4J
Transmission range	20m
Data rate	4kbps
Parameters of High power node/Grid Head	
Initial Energy	7J
Transmission range	25m
Data rate	6kbps
Parameters of Level-1 Aggregator	
Initial Energy	10J
Transmission range	30m
Data rate	8kbps
Parameters of Level-2 Aggregator	
Initial Energy	14J
Transmission range	35m
Data rate	12kbps

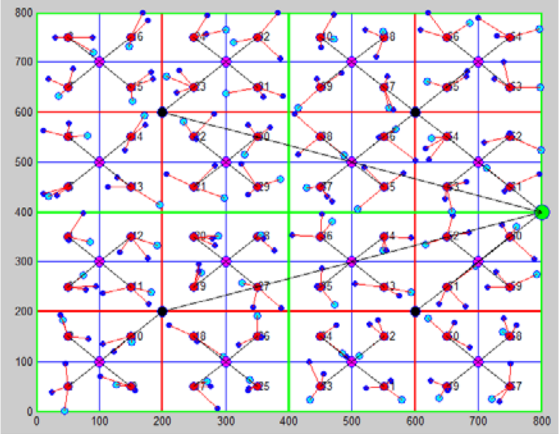

Fig. 2. Topology Setup.

Fig. 5 shows the number of the packet transmitted to sink. In this result also it is clear that our proposed method is better compared to others. The proposed method involves very little data transmission.

Fig. 6 shows the comparison of the proposed method with other traditional methods in terms of energy consumption. Result clearly shows that the proposed method consumes lesser energy compared to other techniques.

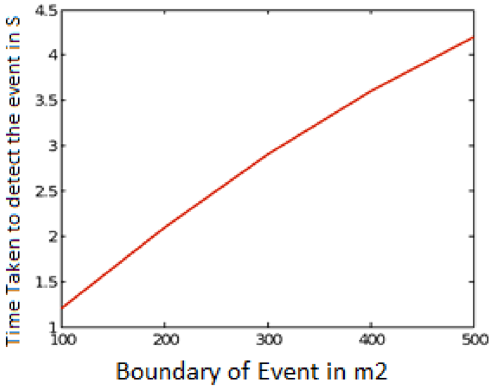

Fig. 3. Time Required for Detecting the Boundary of Event.

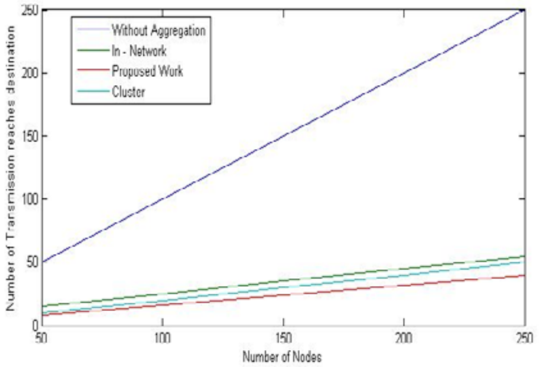

Fig. 4. Number of Redundant Transmission in Various Approaches.

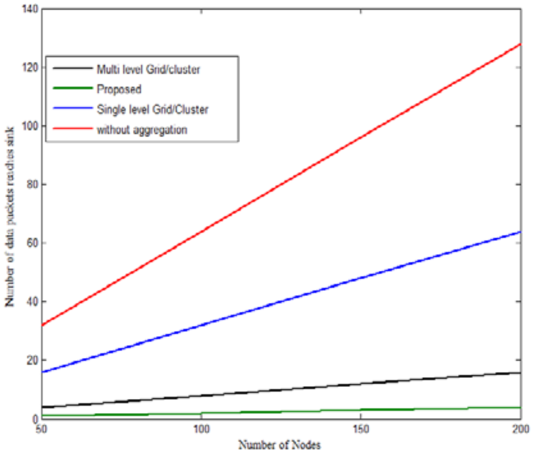

Fig. 5. Number of the Data Packets Transmitted to the Sink.

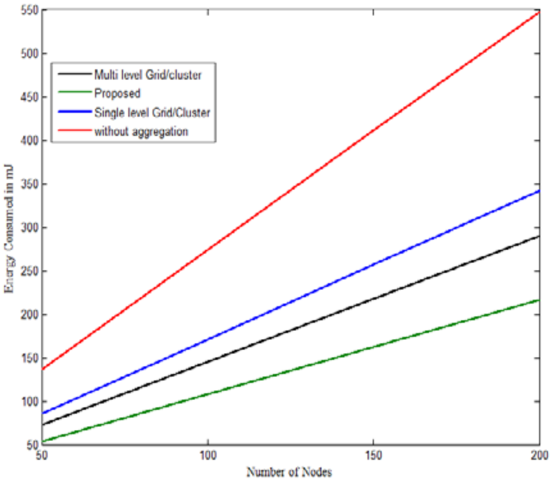

Fig. 6. Energy Consumed Per Round in Various Approaches.

V. Conclusions

Controlling redundant data transmission is a significant challenge in Constrained IoT Remote applications. In this proposed research work, Data Aggregation is addressed through spatial and boundary value aggregation, which is the novel scheme. The aggregation technique adapted reduces the number of redundant transmissions significantly. The efficiency of the proposed approach is compared with existing methods through simulation.

Abstract*—Deep learning is one of the most remarkable artificial intelligence trends. It remains behind numerous recent achievements in various domains, such as speech processing, and computer vision, to mention a few. Likewise, these achievements have sparked great attention in utilizing deep learning for dimension reduction. It is known that the deep learning algorithms built on neural networks contain number of hidden layers, activation function and optimizer, which make the computation of deep neural network challenging and, sometimes, complex. The reason for this complexity is that obtaining an outstanding and consistent result from such deep architecture requires identifying number of hidden layers and suitable activation function for dimension reduction. To investigate the aforementioned issues linear and non-linear activation functions are chosen for dimension reduction using Stacked Autoencoder (SAE) when applied to Network Intrusion Detection Systems (NIDS). To conduct experiments for this study various activation functions like linear, Leaky ReLU, ELU, Tanh, sigmoid and softplus have been identified for the hidden and output layers. Adam optimizer and Mean Square Error loss functions are adopted for optimizing the learning process. The SVM-RBF classifier is applied to assess the classification accuracies of these activation functions by using CICIDS2017 dataset because it contains contemporary attacks on cloud environment. The performance metrics such as accuracy, precision, recall and F-measure are evaluated along with theses classification time is being considered as an important metric. Finally it is concluded that ELU is performed with low computational overhead with negligible difference of accuracy that is 97.33% when compared to other activation functions.

Keywords—Auto-encoder; cloud computing; dimension reduction; intrusion detection system; machine leaning

I. Introduction

The Cloud services availability to the individuals, organizations, and Governments connected through web-enabled devices across the world on pay-as-you-go premise [1] have become very common. The security and privacy problems get magnified as new type of attacks when internet environment migrate to Cloud [2]. Among these types of malicious activities Distributed Denial of Service (DDoS) attacks are easily invoked by the attackers basically with malicious intent of denying the Cloud services.

This type of attacks causes the interruption of cloud services to legitimate users by inordinate resource consumption which would automatically results in Service Level Agreement (SLA) violation. Most of the Cloud services are inherently elastic so the DDoS attacks are damaging the cloud service provider (CSP) economically but not its physical system or server assets [3]. This phenomenon is known as Economic Denial of Sustainability (EDoS) EDoS attack.

Due to increase in migration to the cloud the security and privacy problems are also increased in cloud environment with new types of malicious activity penetrated by professionals with cutting edge technologies with malicious intent. Over the last three decades the problems related to security and privacy are major research problems and addressed by several researchers with the evaluation of Network Intrusion Detection Systems (NIDS). It is a necessity to improve the NIDS to mitigate the new type of attacks on cloud because several users are getting migrated to cloud environment. It is a necessary to improve the NIDS to mitigate the attacks on cloud environment and this problem is addressed by several researchers. They have identified significant measures to detect and mitigate such types of attacks using statistical, Machine Learning (ML) techniques and knowledge based approaches. The NIDS needs to be more robust to increase the users trust in adoption of cloud computing in future. Therefore Network traffic analysis of cloud is necessary to identify the patterns inorder to discriminate malicious users and legitimate users. ML approaches offer great strength and diversity in research for anomaly detection in NIDS using classification task [4].

Lot of significant research work is going on over the past two decades on dimension reduction using Wrapper methods, Filter based Approaches, etc. to address the curse of dimensionality [5]. One of the advantages of NIDS is the availability of huge collection of network data related to cloud environment on which machine learning algorithms can be applied to detect attacks. Such a complex and huge data may disgrace the performance metrics of classifiers [6]. Dimensionality reduction or feature learning is one of the stages in classification which helps to extract the relevant information from the original data to reduce the computational time without compromising the other performance metrics.

Recently Deep learning methods from the family of Machine Learning approaches are successfully applied to extract good feature representation automatically [7]. Due to its capability for extracting valuable and useful information from large data yields better classification process and lower complexity.

The chosen activation function plays an important role in deep learning models to improve the accuracy rate and reduce computational complexity [8]. Activation function is one of the principal factors which will affect the performance of the neural networks [9]. Activation functions are basically divided into linear or non-linear relying upon the function it represents. Activation functions are leveraged to transfer and control the outputs of neural networks, across various domains from object recognition and classification.

This research work proposes a comprehensive investigative study intended to identify suitable activation function of SAE. By implementing this activation function an attempt is made to extract an optimized feature subset. The SAE extracts key features from the CICDS2017 which is exposed to lot of vulnerabilities as it is on Internet. Then a SVM classifier stage is used to classify the attacks and distinguish between normal and anomalous traffic.

After examining the contemporary studies the SAE model is identified as one of the best model for dimension reduction of various types of bigdata analytical content like image, text and network intrusion detection. There is a need to identify the proper activation function that will be more effective in the process of dimension reduction using SAE by satisfying the criteria like high classification accuracy and minimum classification time.

In view of the above the problem is selected to identify suitable activation function of SAE for dimension reduction and evaluate the classification accuracies. To achieve this objective the study is carried out with following contributions.

- Sharp decisions are needed within a stipulated time which plays an important role for NIDS. So to suggest a novel framework for better NIDS with suitable activation function and classifier.
- To compare the different activation functions of SAE using SVM classifier with RBF kernel.
- To evaluate the performance metrics and computational time with adoption of CICIDS2017 dataset.
- Finally identified the effective activation function based on experimental results.

The rest of this paper is organized as follows: the related previous work is outlined in Section 2 and Section 3 is explains the description of the CICIDS2017 dataset. The methodology and experimental setup of the proposed model is depicted in Section 4. The results and discussions are presented in Section 5. Finally conclusions and future scope of this work are given in Section 6.

II. Literature Review

An IDS has been studied for the last two decades using various machine learning approaches. This section will discuss some of the approaches proposed by researchers to analyze the effect of activation functions for IDS as well as for feature selection.

In [10], Investigated the performance of different types of rectified activation functions using Convolutional neural network. The standard rectified activation functions of rectified linear unit (ReLU), leaky rectified linear unit (Leaky ReLU), parametric rectified linear unit (PReLU) and a new randomized leaky rectified linear unit (RReLU) are evaluated with three different dataset NDSB, CIFAR-10 and CIFAR-100. Observations are discussed based on the exploratory results. However, this study is limited to different types of rectified activation functions and not pertaining to large datasets.

In [11], studied the effect of Activation functions on classification accuracy using Deep Artificial Neural Networks (ANN). The ANN is used to classify real multi-spectral Landsat 7 satellite images and therefore the accuracy of the classification was evaluated with twelve different activation functions. The accuracy of classifier can be improved by selecting good activation function. However, the activation functions sigmoid and bipolar activation functions are recommended to specific field of remote sensing.

It is Observed and stated in [12] that activation functions play pivotal role in understanding neural network. “DBN suffers from vanishing gradient problem due to the saturation characteristic of activation function. Therefore, the selection of activation function in DBN is critical to reduce the network complexity and to improve the performance of pattern recognition”. DBN based classification with different types of activation functions like Sigmoid, Hyperbolic Tangent, MSAF, ReLU and LReLU can be used to examine their performance with MNIST dataset. Besides that, the randomization of training samples would significantly improve the performance of DBN. The experimental results showed that hyperbolic tangent activation function achieved the lowest error rate which is 1.99% on MNIST handwritten digit dataset.

Kunang, Y. N et al. in [13] presented a deep learning based dimension reduction approach in the first step using stacked autoencoder. The input neurons 120 were reduced to 8 neurons with seven activation functions i.e., linear, sigmoid, ReLU, SoftMax, Softplus, Softsign and tanh and couple of loss functions like Mean Squared error and cross entropy to seek out the suitable activation function. In the second step reduced data is fed as input to supervised classifier SVM with RBF kernel to evaluate the output of first step. Based on the results it’s shown that the ReLU and linear activation functions with cross entropy yields better results over the other combinations.

The authors in [14] compared non-linear activation functions alternative to sigmoid in deep neural networks on Image Dataset, and also different weight initialization methods Gaussian distribution, uniform distribution, learning rate from 0.01 to 0.2, batch size 50 and 100 epochs and effect of hidden layers were tested. Based on the experimental results it was noticed that the accuracies of ReLU and its variants are higher than the sigmoid activation function and the learning rate is faster in ELU and SELU compared to the ReLU and Leaky ReLU. However, this study did not pay attention to computational complexity.

In [15] fast activation function adaptive Linear Function (ALF) is proposed for anomaly detection to increase the speed and accuracy of the deep leaning structure for real-time applications. Deep Belief Network with new activation function ALF and Sigmoid, Tanh, and ReLU are used for classification on four datasets namely NSL KDD, Kyoto, KDDCUP'99 and CSIC 2010. The experiments were conducted with a combination of each dataset using all four activation functions. Exploratory results have shown that learning structure using the fast ALF activation function outperforms the state-of-the-art network Stacked Sparse AutoEncoder Based Extreme Learning Machine (SSAELM) in accuracy and convergence time. However, the proposed approach needs to be evaluated on contemporary datasets.

Another research work [16] built IDS model with a blend of two models, autoencoder and deep artificial neural network. In the first stage Stacked autoencoder based dimension reduction with sigmoid activation function in input/hidden layer/output layer using 4 hidden layers and reconstruction error is calculated with mean squared loss function performed. In the next stage deep artificial neural network model was built utilizing different activation functions like hard sigmoid, relu, sigmoid, softplus and tanh to further classify the network traffic. Conclusions are drawn based on F1-score which is best with relu activation function in comparison to other activation functions. However, this study is limited to binary classification and need to, be tested on multi-class classification.

Feng, J., & Lu, S in [9] studied the characteristics of linear and non-linear activation functions Sigmoid, Tanh, ReLU, LeakyReLU, PReLU, RReLU, and ELU are compared. Activation functions advantages and disadvantages in Artificial Neural Network are also discussed and concluded that choosing of suitable activation function depends on our aim and network structure.

A Novel method was proposed by [17] to test SVM classifier with different kernels and Deep Convolutional Neural Network (DCNN) method for classification with different activation functions ReLU, Sigmoid, SoftMax, and Tanh. Before performing the intrusion detection chi-square based feature selection was performed to lessen the size of NSL-KDD dataset. The experiments were conducted with different activation functions by fixing one function from the above said four activation functions in input and hidden layers .Then the remaining are used at output layer respectively for each experiment. DCNN yields better results with sigmoid as output layer activation function with any of the activation function in input/hidden layers. The performance of SVM and DCNN are analyzed and concluded that the DCNN performed well compared to SVM classifier in terms of accuracy. This study focused on binary classification.

Le, T. T. H. et al. explored six non-linear Activation functions i.e., Softplus, ReLU, Tanh, Sigmoid, ELU and Leaky ReLU in [18] and additionally the impact of those activation functions was analyzed with Recurrent Neural Network (RNN) model to find the best activation function for intrusion detection. The KDD cup dataset was employed to conduct experiments. Among the employed activation functions Leaky ReLU the best results in terms of performance metrics accuracy, precision, recall and False Alarm Rate (FAR). The study is associated with performance metrics but does not concentrate on time complexity.

Most of the above mentioned studies focused mainly on comparing the various activation functions in evaluation of classifying the performance of neural network models and dimension reduction carried out with autoencoders. They considered the image datasets. In my knowledge and opinion very few studies are carried out by the researchers on network intrusion detection as well as autoencoders being used for dimension reduction on outdated datasets like KDD Cup ' 99 and NSL-KDD etc. To fulfill these research gaps the present research is carried out with adoption of CICIDS2017 dataset as it contains modern type of attacks and generated on cloud environment.

III. Description of CICIDS2017 Dataset

The CICIDS2017 dataset generated by [19] is chosen to train the model, which contains benign and the up-to-date common attacks, which resembles the real world data. It includes the network traffic from 09:00 on Monday, July 3rd and continuously ran for an exact duration of 5 days, ending at 17:00 on Friday July 7th. Network data is extracted using CIC Flow Meter, 2017 with labeled flows based on the time stamp, source, and destination IPs, source and destination ports, protocols and attack (CSV files). The dataset is publicly available in PCAP files[1]. In the current study only Wednesday data is considered for intrusion detection. It consists of 6,92,703 instances and 85 feature columns including a label with 6 classes such as Benign, DoS GoldenEye, DoS Hulk, DoS Slowhttptest, DoS slowloris, Heartbleed. The distribution of records label wise is shown in below Table I.

The feature names and the Attacks distribution of the CICIDS2017 dataset are available in [20].

TABLE I. LABEL WISE DISTRIBUTION OF CICIDS2017 DATASET

Category	Class	Number of Records
Anomaly	DoS GoldenEye	10,293
	DoS Hulk	231,073
	DoS Slowhttptest	5,499
	DoS slowloris	5,796
	Heartbleed	11
Total Anomaly data	---	252,672
Normal	Benign	440,031
Total		692,703

IV. METHODOLOGY

A novel framework is developed for analyzing the performance of various activation functions of SAE for dimension reduction. For evaluation of the performance of these dimension reduction models SVM-RBF classifier is chosen. For this purpose CICIDS2017 dataset is used for conducting experiments. This methodology consists of three phases: A) Data pre-processing, B) Dimension Reduction, and C) SVM-RBF classification. The flow of the proposed framework is depicted in Fig. 1.

A. Data Preprocessings

In the first phase data cleaning and normalization operations are carried out.

Data cleaning: It involves finding the null records as Machine Learning algorithms cannot build a model or test them. Since the percentage of null records associated with each class is small so these records are deleted from the dataset.

Based on the statistical measures of the dataset given in Table II, such as maximum, minimum, standard deviation of each feature it is observed that all the values of attributes Bwd PSH Flags, Fwd URG Flags, Bwd URG Flags, CWE Flag Count, Fwd Avg Bytes, Fwd Avg Packets, Fwd Avg Bulk Rate, Bwd Avg Bytes, Bwd Avg Packets, Bwd Avg Bulk Rate are null in the dataset. These columns are also deleted from dataset because they potentially don't have any contribution towards classification.

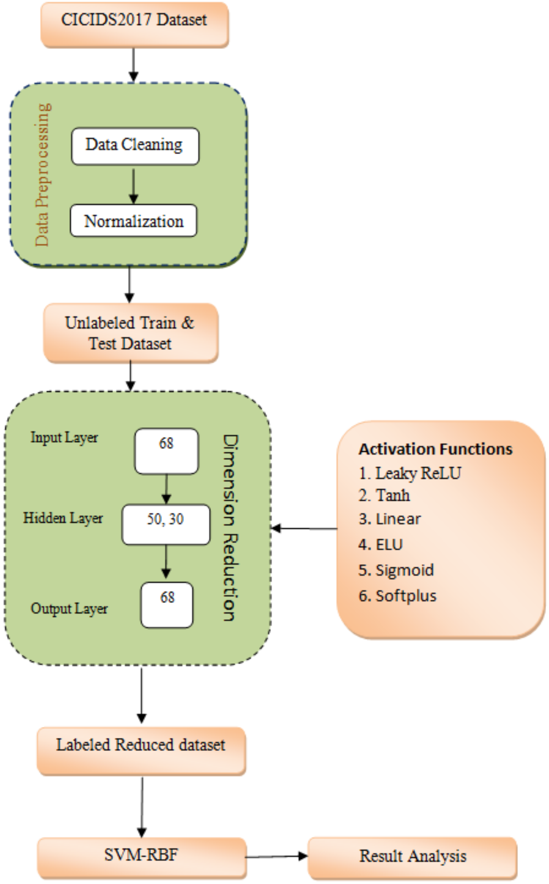

Fig. 1. Novel Framework for Comparison of Activation Functions for NIDS.

TABLE II. STATISTICAL MEASURES OF FEATURES WITH ZERO VALUES

	Bwd PSH Flags	Fwd URG Flags	Bwd URG Flags	CWE Flag Count	Fwd Avg Bytes/ Bulk	Fwd Avg Packets/Bulk	Fwd Avg Bulk Rate	Bwd Avg Bytes/Bulk	Bwd Avg Packets/Bulk	Bwd Avg Bulk Rate
count	692703	692703	692703	692703	692703	692703	692703	692703	692703	692703
mean	0	0	0	0	0	0	0	0	0	0
Std	0	0	0	0	0	0	0	0	0	0
min	0	0	0	0	0	0	0	0	0	0
25%	0	0	0	0	0	0	0	0	0	0
50%	0	0	0	0	0	0	0	0	0	0
75%	0	0	0	0	0	0	0	0	0	0
max	0	0	0	0	0	0	0	0	0	0

TABLE III. LABEL WISE DISTRIBUTION OF CICIDS2017 DATASET AFTER DATA CLEANING

Category	Class	Number of Records
Anomaly	DoS GoldenEye	10293
	DoS Hulk	2,30,124
	DoS Slowhttptest	5,499
	DoS slowloris	5,796
	Heartbleed	11
Total Anomaly data	---	2,51,723
Normal	Benign	4,39,972
Total	---	6,91,695

Additionally two features Byte/s and Flow Packet/s have infinity/NaN values in very few records which are replaced with zeros to avoid difficulties in applying the ML algorithms. After performing data cleaning operation the distribution of the remaining dataset is given Table III.

Normalization: [1]By nature the features of the dataset are quantitative. Several features of the dataset lie in a wide range mostly between the highest possible value and lowest possible value.

The features with higher values may dominate the features with low values. To avoid this, features to be normalized to eliminate such dominance before applying ML algorithms.

Normalization is a scaling technique in which values are transformed and rescaled so that they fall in specific range [0, 1]. In this paper features are scaled using min-max normalization. The feature f values with a range between fmin and fmax , then the normalization is defined by the equation of fnor= (fi - fmin)/(fmax-fmin), Where fnor is a normalized value of the ith value of feature f. An illustrative example of normalization for one record is given in Fig. 2.

B. Dimension Reduction using SAE

This section explores the impact of the different activation functions of SAE with specified hyper parameters as given below for feature dimensionality reduction.

The performance of NIDS using neural networks for dimension reduction as well as classification is dependent on three criteria. They are i) to identify suitable activation function, ii) the number of hidden layers to be used and iii) to adjust the proper weights for minimizing the loss between input and output. Using SAE for dimension reduction the chosen of activation function is a crucial problem.

Among the three the first one plays a crucial role for optimizing the feature subset. So this study considers to find the impact of the first criterion and the remaining are fixed at number of hidden layers are 3 and Mean Square Error as a loss function. The main focus of this study is to compare various prominent activation functions that are used in SAE for NIDS and evaluate them through the SVM classifier. Proper activation function also affects the classification time along with classification accuracy [11]. For this purpose six activation functions are chosen. The following Fig. 3 depicts the typical structure of the SAE which consists of input and output layers with three hidden layers, the same is being considered for conducting experiments.

0.352941, 0.000319,0, 3.67E-06, 4.90E-06, 9.57E-09, 0.000242, 0.002906, 0.001293, 0, 0.000307, 0.003026, 0.001373, 0, 0.005764, 0.40001, 0.000319,0, 0.000319, 0.000319,0,0,0,0, 6.67E-08,0,0,0,0,0,0, 7.23E-06, 3.67E-06, 8.70E-06, 1.31E-05, 0.004144, 0.000242, 0.002632,0,0,0,0,0,0,1,1,0, 0.023256, 0.003446, 0.001293, 0.001373, 7.23E-06,0, 4.90E-06, 3.67E-06, 9.57E-09, 0.003906, 0.01445,0, 0.344262,0,0,0,0,0,0,0,0,0

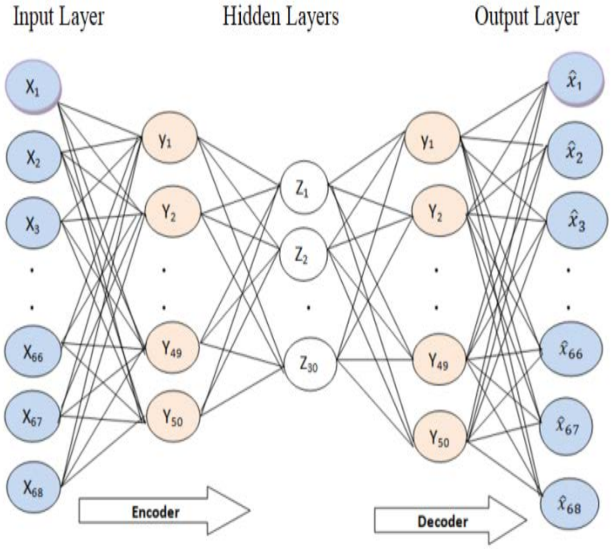

Fig. 3. Typical Structure of Stacked Autoencoder.

[1] http:[1]//www.unb.ca/cic/datasets/IDS2017.html.

The below SAE has 68 neurons in both input and output layers which are equal to the features of normalized train and test dataset. The numbers of neurons in three hidden layers are 50, 30 and 50 respectively. The role of activation function in neural network is to facilitate the transfer of data from input layer neurons to output layer neurons [18]. The chosen six activation functions are being applied.

Several different kinds of optimizers are used by different researchers even though their common purpose is minimizing the loss in learning process. Among those Adaptive Moment Estimation (Adam) is chosen for this study [21]. The following function is adopted for reconstruction error computation [22]. The mean square error function is calculated for the samples of $\mathrm{x_i}$ and reconstructed samples $\hat{\mathrm{x}}_\mathrm{i}$ as shown in equation 1. To find the optimal structure of SAE for dimension reduction with afore mentioned optimizer and loss function used. The unlabeled normalized train and test datasets of CICIDS2017 are taken as input datasets, because SAE is an unsupervised dimension reduction approach.

$$\mathrm{d}\,(x\ ,\hat{x}\ )=\frac{1}{N}\sum_{i=1}^{N}||x_i-\hat{x}_i||^2\ , \qquad (1)$$

where N is the number of input samples.

The following algorithms takes various hyper parameters weight vector W, bias vector, batch_size, epochs, number of layers (L), learning rate α and neurons_structure in each layer are assigned `to initial values. The training procedure of unsupervised SAE model for dimension reduction is given in Algorithm1 and Algorithm2. The input to Algorithm1 is number of SAE structures, number of hidden layers in each structure. Step3 inputs the number of neurons in each hidden layer. Followed by in step4 compute_MSE ( ) is invoked for each structure to setup the corresponding SAE architecture and iterated for all epochs with given activation function then returns the MSE error which is stored in loss. Input to Algorithm2 are train and test datasets {x1, x2… x68} where sample X∈R where, structures of SAE and the number of neurons in each structures. For each layer l the parameters are initialized to zero. In each iteration the hidden representation vector of layer l is computed based on the previous layer. After that the loss is calculated equation (4) in step 2.2.2, Next step is to update θ′ based on loss and completes all iterations similarly. Finally mean of all the epochs MSE loss is calculated and returned. Once the MSE losses of different structures are calculated then the minimum loss is identified and the corresponding structure is selected as optimized SAE structure for dimension reduction. All the above steps are repeated for each activation function.

Algorithm1: The training procedure to identify optimal SAE structure for dimension reduction is given in Algorithm1

```
Algorithm1: Optimized SAE model for dimension reduction

Input: S                        // number of SAE structures
       L                        // number of layers in structure
       neurons_structure [ ] [ ]  // array of SAE structures

Output: Optimized SAE structure

Step 1:  // Initialization
         S=0, neurons_structure [ ] [ ] <- 0, loss [ ]

Step 2: read S //Total Number of Structures

Step 3: for I in 1 to S do // for each structure I
    Step 3.1:  read L [I] // Number of Layers in the structure
    Step 3.2: for J in 1 to L [I] do
        Step 3.2.1:  read N // number of neurons in Layer J of structure I
        Step 3.2.2: store neurons_structure [I] [J] =N
    end for
end for
Step 4: for s in 1 to S do
    loss[s] = compute_MSE(s, neurons_structure [I], L [I], bias[I])
end for

Step 5: betsvalidation_loss= loss [1]
    Step 5.1 for k in 2 to S
        Step 5.1.1 if (bestvalidation_loss > loss[k])
            then
                bestvalidation_loss=loss[k]
                location = k
            end if
    end for

Step 6:  optimal structure= neurons_structure [location] [  ]
```

As a part of initiation towards optimization various structures of neural networks are used to reduce the MSE as per equation7. In the lines of [13] several experiments were conducted for the number of features and the corresponding MSEs are listed in Table IV. It is observed from the above table.

Algorithm2: The training procedure of unsupervised SAE model for dimension reduction is given in Algorithm2

```
Algorithm2: Compute_MSE (s, neurons_structure [ ], L) // Training SAE and calculate MSE

Input: Unlabeled normalized train dataset (UNTR) and test dataset (UNTS), UNTR & UNTS ⊆ R &
          UNTR ∩ UNTS=∅, data sample X ∈R where {$x_1$, $x_2$… $x_{68}$}
Output: Z      // Mean Square Error

Step 1:  /*Initialization

    h [ ][]<- 0 // output of each neurons of each hidden layer
    $\hat{x}_i$[ ][ ] <- 0 //reconstructed data
    batch_size =256 // number of samples per each iteration
    bias [ ] // bias vector of each hidden layer
    epoch=10 // number of passes to execute learning algorithm for entire dataset
    learning_rate =0.001 // weight adjusting control variable w.r.t gradient
    mse_sum=0, mean_loss=0
Step 2: create and configure the stacked autoencoder network with Adam optimizer
    Step 2.2: for e ∈ 1 to epoch do
        Step 2.2.1: for b ∈ 1 to b do
            n=neurons_structure [1]; // number of neurons for the first layer
            W = 0 // weight vector W= {$w_1$, $w_2$...,$w_n$}
            define h[1] [ ] = f (WX +bias) // First hidden layer
            for l in 2 to L do
                n=neurons_structure[l];
                W= 0 // weight vector W= {$w_1$, $w_2$...$w_n$}
                bias =1  // bias value
                h[l][ ]= f (W * $h_{l-1}$+bias)  // compute $h_l$ from $h_{l-1}$ of both
                                                     encoder and decoder
            end for
        end for
        Step 2.2.2 $\hat{x}_i$[ ][ ]=h[l][ ]
            for I in 1 to $\hat{x}_i$   do
            Z <-  $\frac{1}{N}\sum_{i=1}^{N} ||x_i - \hat{x}_i[\,][\,]||^2$
            sum = mse_sum + Z
            end for
        update layer parameters θ′l = (W, B) s. t Z is minimum
    end for

Step 4: mean_loss = $\frac{\text{mse\_sum}}{e}$

Step 5: return mean_loss
```

It is observed from the above table that the optimized MSE for majority of the activation functions is w.r.t to neurons structure 68-50-30-50-68. Hence this neurons structure is considered to reduce the dimensionality to 30.Once better optimized structure is identified then series of experiments are conducted for dimension reduction on training and testing data. The inner most hidden layer i.e. last layer of encoder provides the richer representation of CICIDS2017 i.e. 30 features with reduction of 44% of data. Evaluation of the classification efficiency of various activation functions used for dimension reduction are evaluated with SVM-RBF classification model. The next section explores the classification evaluation model.

C. SVM-RBF Classification Model

In this module SVM classifier with RBF kernel is used for multi–class classification. Initially SVM-RBF base model is trained and tested with default values of c and gamma. From the existing literature it has been found that the usage of SVM-RBF model in the context of multiclass classification is more suitable than any other existing classifier. Complete dataset which contains 68 features after due preprocessing has been given as an input to the python program with scikit library intended for dimension reduction. Later SVM-RBF classifier is trained with derived reduced datasets of six different SAE models using different activation functions which would serve as a thorough evaluation of the activation functions along with the corresponding confusion matrices. Further the standard performance metrics vis-a-vis accuracy, precision, recall and F-measure are calculated. These experiments were conducted on an experimental setup, Intel core i5 with 1.80 GHz processor with 8GB RAM, windows 10.

V. EXPERIMENTAL RESULTS AND DISCUSSION

This section discusses about the effect of six activation functions pertaining to SAE with the adoption of MSE as a loss function for dimension reduction. Further comparison of different classification metrics which are derived through SVM-RBF classifier is done. The experimental results w.r.t various performance metrics and computational time are given in below Tables V to VII as well as from Fig. 4 to 8.

TABLE V. VARIATION OF ACCURACY IN TRAINING AND TESTING FOR DIFFERENT ACTIVATION FUNCTIONS

Activation Function	**Training Accuracy**	**Testing Accuracy**	**Average of Training and Testing Accuracy**
Without Feature Selection	96.15	96.2	96.175
Leaky ReLU	96.89	96.96	96.925
tanh	96.98	97.05	97.015
Linear	97.19	97.26	97.225
ELU	97.26	97.33	97.295
Sigmoid	97.36	97.38	97.37
Softplus	97.33	97.4	97.365

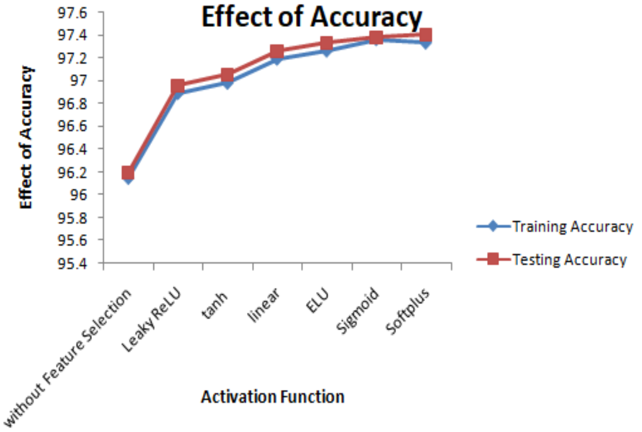

Fig. 4. Effect of the Accuracy of Training and Testing for different Activation Functions.

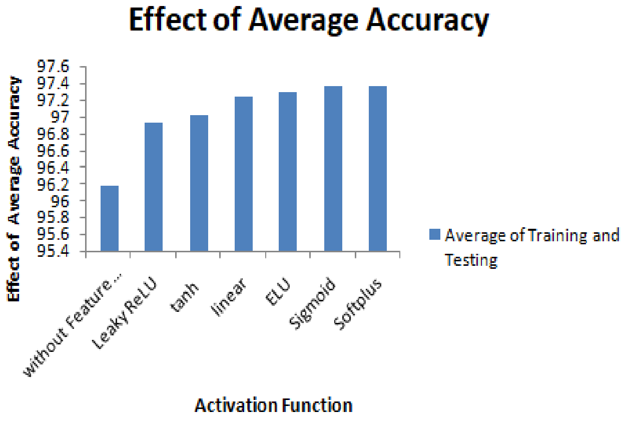

Fig. 5. Effect of Average Computational Time of Training and Testing Time for different Activation Functions.

It is observed that from Fig. 4 and 5:

- The six activation functions exhibits similar behavior for both training and testing.
- Amongst the six softplus gives better accuracy.
- Sigmoid and ELU follows softplus with a minor difference of 0.02 and 0.07, respectively.

TABLE VI. VARIATION OF COMPUTATIONAL TIME IN TRAINING AND TESTING FOR DIFFERENT ACTIVATION FUNCTIONS

Activation Function	**Training Time(Sec.)**	**Testing Time (Sec.)**	**Average of Training and Testing(Sec.)**
Without Feature Selection	24690.515	1123.724	12907.12
Leaky ReLU	4948.109	393.355	2670.732
tanh	7254.742	401.517	3828.1295
Linear	7587.699	302.599	3945.149
ELU	3115.355	306.596	1710.9755
Sigmoid	9128.278	364.093	4746.1855
Softplus	3837.29	338.254	2087.772

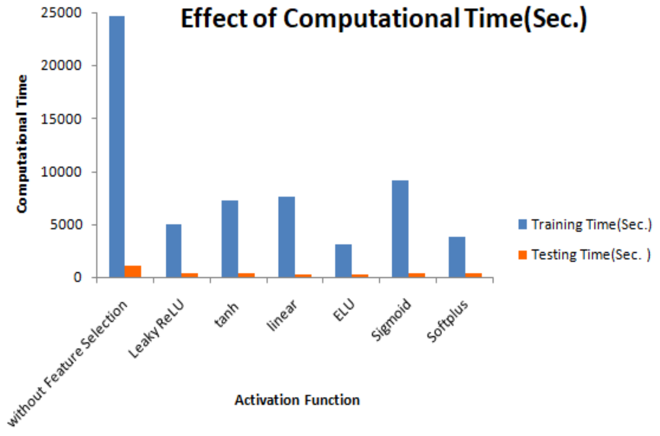

Fig. 6. Effect of the Computational Time of Training and Testing Time for different Activation Functions.

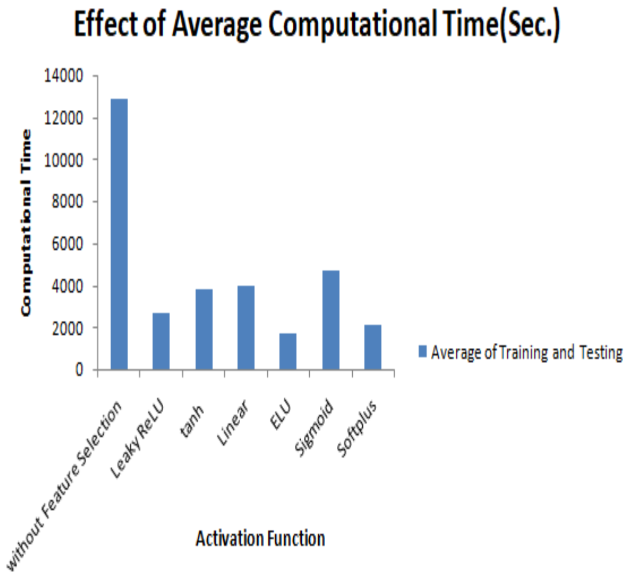

Fig. 7. Effect of Average Computational Time of Training and Testing Time for different Activation Functions.

The computational time of different methods of activation functions are presented in Table VI and Fig. 6 and 7. It is observed that the training and testing time of ELU activation function is minimum when compared to remaining activation functions. The activation function sigmoid takes highest total execution time. The other two activation functions tanh and linear exhibit more or less same computation time. Therefore ELU activation function must be the choice of researchers to reduce total training time and testing of SVM-RBF classifier using CICIDS2017 dataset.

The experimental results for metrics Precision, Recall, F-measure are presented in Table VII and Fig. 8. In case of precision linear and ELU activation functions exhibits highest performance with a value 0.97 and remaining all four activation function Leaky ReLU, tanh, Sigmoid and Softplus are on the lower side with a value of 0.96. The recall value of linear and ELU activation functions are higher and equal compared to other methods with a value of 0.95. The activation function linear shows next highest value with 0.95 followed by Sigmoid and Softplus which show with an equal value of 0.94. The activation functions linear and ELU obtained best measure results compared to other activation functions. It can be observed that the remaining activation functions are performing more or less equally with a minor difference ranging between 0.1 and 0.5.

TABLE VII. VARIATION OF PRECISION, RECALL AND F-MEASURE ACCURACY IN TRAINING AND TESTING FOR DIFFERENT ACTIVATION FUNCTIONS

Activation Function	**Precision**	**Recall**	**F-measure**
Without Feature Selection	0.79	0.68	0.72
Leaky ReLU	0.96	0.88	0.91
tanh	0.96	0.93	0.95
Linear	0.97	0.95	0.96
ELU	0.97	0.95	0.96
Sigmoid	0.96	0.94	0.95
Softplus	0.96	0.94	0.95

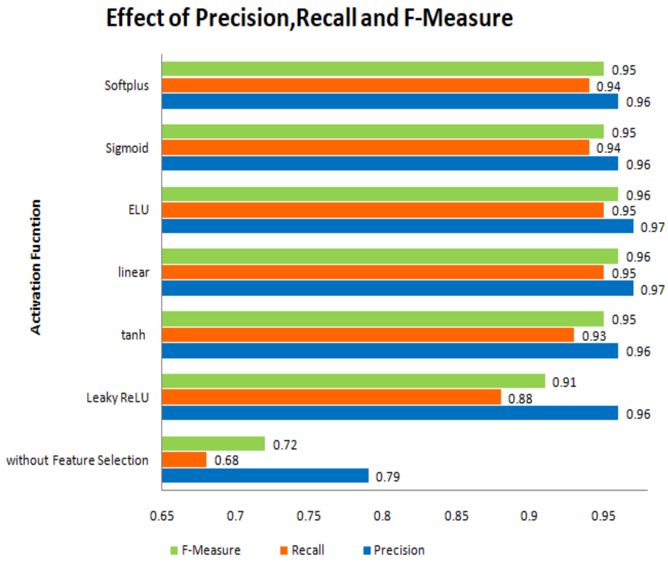

Fig. 8. Effect of Precision, Recall and F-Measure for different Activation Functions.

VI. Conclusion

This paper is intended to evaluate the SAE model for dimension reduction through six activation functions. The Experimental results exhibit that the activation function ELU gives better performance in terms of computational time. In the context of precision, recall and F-measure ELU and linear activation functions leads other functions. When classification accuracies are compared the Softplus yields marginal performance. From these experimental results it is observed that ELU is a better activation function with respect to computational time. Whereas ELU and linear provides better performance with respect to other performance metrics. To consider both computational time and classification performance the ELU is better with compromising of negligible difference of accuracy. Finally it is concluded that this comparative study will be of great help to the defenders to design suitable framework for NIDs on cloud environment to defend the intruders within a stipulated time. The extension for this study could be to compare the performance evaluation of different kernel functions of SVM with conducting of more experiments. As an enhancement of this study one can think about evaluating the performance metrics on a real time environment.

***Abstract*—Covid-19 pandemic has forced the teaching and learning activity into real time and real-world education meetings. The traditional physical and face-to-face meetings are avoided in accordance to reducing the close physical contacts among individuals. Thus, a new paradigm shift towards teaching and learning needs to be highly enforced. Teaching and learning on medical field especially require for real world anatomy against human or living things body. In response to providing the facility for medical teachers and learners, Gross Anatomy Augmented Reality (GAAR) is introduced. GAAR is an android mobile Augmented Reality (AR) learning tool to assist the educators and learners in internalizing 3D human anatomy with more fun and interactivity. The AR methodology is implied to attract the personal impacts and feelings towards operating of close to 'real' organ during anatomy practices. Traditional learning methods are changed with AR technology through small digital device. This application may be able to show the students the actual form of human gross anatomy and assist the teachers or educators' in explaining the sciences behind human body in more interactive and interesting. Furthermore, this application uses a 3-dimensional object, video and interactive info so that students are interested in using this application. The AR for education and learning is vital in bridging the digital divide among all generations through the conversion of static pictures into real-like 3D animation. The implementation results show that, through the real visualization, small to adult learners can imitate the real truth on human organ and how this can motivate them to take care of their bodies that would lead to a healthier living styles as well as easy memorizing of the subject contents.**

Keywords*—Augmented reality; gross anatomy; learning tool; android mobile application; 3D human anatomy

I. Introduction

Augmented reality (AR) is a technology of putting the static object into real and dynamic object. In AR, each object is enhanced to become a real physical world that is achieved through the use of digital visual elements, sound, or other sensory stimuli. The augmented technology aims to be an alternative method for educators and learners that offer for interactivity as compared to traditional methods. In response to Covid19 pandemic where the education and learning is conducted through virtual, the education sectors especially is facing greatest challenge in delivering the contents of any subject matters to all learners and key persons. Thus, some domain fields such as engineering, medical, pure sciences that requires total theory and practice are in demand for the technology that could build for a full interest among educators and learners.

Hence, Gross Anatomy Augmented Reality (GAAR) is developed as a touch-up and a complimentary tool as a combination of gross anatomy study into augmented reality (or close to reality) during early education level. This mobile AR application aims to enhance teacher's ability to educate students, drives their interest and help them to internalize through visual implicitly in the field of science and human anatomy. The environment of first, learning the theory, second make it visualize in real into their small and handy gadgets (i.e. smartphone device) could assist the implementation of GAAR to be run at all school.

The ultimate objective of this project is to design an application that include 3D models of anatomy such as liver, heart, kidney, stomach and skeleton system that have been developed during creation of mobile application environment combined with AR for the study of basic human anatomy. To achieve this objective, the following purpose hypothesis are tested: The development of GAAR mobile application specific purpose is for the field of human anatomy in three dimension (3D) in combination of AR is feasible and achievable, in order to be used as an educational tool for the student in primary and secondary schools. This acts as an alternative or replacement of a traditional teaching method and a description course on human anatomy.

Prior to the development of a good working prototype of the application, the next hypothesis is it usability. The developed GAAR serves as an alternative mechanism in teaching and learning human gross anatomy. The real implementation on the feasibility for the infrastructure and to evaluate errors in the model (human organ) and overall "look-and-feel" of the application is depending upon the feedback of future users of GAAR. This initiative aims to fulfill the successful run of operating scenarios of use as well as user satisfaction. The rest section of the study is organized as follows: Section 2 reviews on the related works and tools used for modeling and AR, Section 3 discusses on the methodology undertaken, Section 4 illustrates the experimentation of GAAR. Discussion is outlined in Section 5 and Section 6 summarizes the conclusion and future work of GAAR.

II. Related Works

A. Reviews of AR Apps

Teaching and learning demands for a best-fit approach for a sustainable long-life learning environment [1]. Especially in Medical Schools [2], medication practitioners practice the use of recorded videos [3] and podcasts [4] for virtual learning and during the online learning process [5]. The traditional method for an anatomy curriculum during 1980s demands for an improvements [6] and many technological advances in educational sectors has been proposed with the introduction of innovations such as virtual anatomy courses and dissections [7], three-dimensional (3D) atlas as initiated in [8] and "mARble" application that embeds augmented reality (AR) feature for iPhone users [9]. The use of AR applications in medical empower each user experiences and describes the appearance of a digital element generated with a computer [10]. The AR generates a fascinating output since the user can see in 360 angle degree from the human body until its anatomy [11]. Besides, an application that uses AR which called ROAR Augmented Reality created by Roar Interactive on 13 March 2016. *BARETA* [12] is an AR tool that combines AR and 3D modeling objects to provide simulation for touching as well as sighting.

As reported in School of Medicine of the Aristotle University of Thessaloniki, Greece, indicates the educational innovations in for teaching anatomy is being stigmatized with Andrea Vesalius paradigm [13]. This could be the facts towards dissection in anatomy. The actual intention of AR is not to replace anatomy dissection activity, but it tries to offer the alternative efforts to supplement the traditional curriculum [14-15]. Wikitude for instance, is coupled with its SDK7 that includes simultaneous localizing and mapping for recognition and tracking in 3D objects, image recognizing and tracking, cloud recognition, location-based services, smart glasses as well as external plugin integration in Unity [16].

B. Reviews of AR Platforms

1) Android OS: The Android Operating System is meant for the mobile device platform that underlies the Linux kernel. It was initiated by Open Handset Alliance on November 2007 using Java programming language [17]. Android is dedicated for open expansion platform where it offers upgrades across various versions. When Android starts releasing its source code, anyone can change it according to individual interests. The project uses the Android Software Developer Kit (SDK), that comes together with the tools and APIs. We integrate the SDK into a graphical user IDE (Integrated Development Environment). The novice can also use App Inventor application to develop an Android-based applications that can be browsed through online.

2) iOS: The iOS is Apple-mobile operating system (OS) for any Apple-manufactured devices includes Apple iPhone, Apple iPad, Apple iPod Touch and Apple TV. These products are popular with the niche style of identity recognition by gestures for instance the gestures to swipe, tap and also pinch. These gestures movement are performed on multi-touch capacities on screen touching displays that provides instant response actions and identify the fingers and pen that act as input.

C. Reviews of AR SDK

1) Vuforia: Vuforia is an augmented reality software development kit (SDK) that has been developed for mobile devices. It enables the creation of augmented reality applications. It uses computer vision technology to recognize and track planar images and 3D objects in real time. Vuforia acts as the first batch of AR environment for an AR application development that comes with a broad set of features. The Vuforia SDK for AR features comprises of a multi-objects recognition for objects like cylinders and boxes as well as the 3D objects like images, recognition for text of approximately 100,000 words in its vocabulary, the ability to customize the *VuMarks*, some form of high quality objects than any typical QR-code, feature for 3D geometric map of any environment using Smart terrain, feature to turn static image into full motion video, feature for Unity Plugin and lastly support for cloud and local storage. The Vuforia is supported in iOS, Android, Universal Window Pattern and Unity.

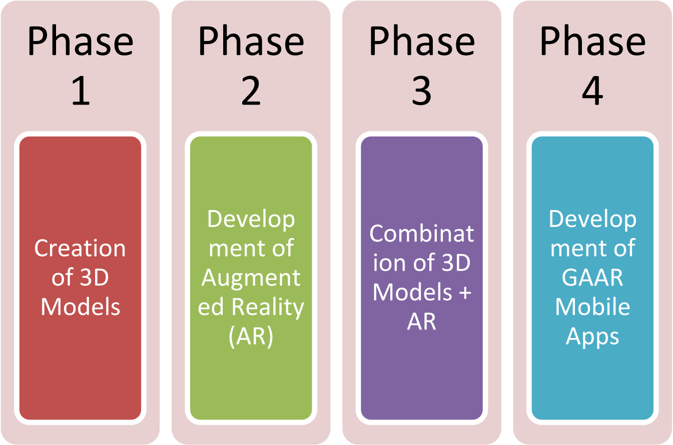
2) ARToolkit: An open-ended source tool for developing an AR application. Equipped with rich set of features for tracking, which include *Unity3D* and *OpenSceneGraph* that includes the facility for both single and dual camera, an apps with featuring object based on location such as GPS and compass support. Also added with the feature to create real-time AR Application, can be integrated with smart glasses, support for multiple language and automatic camera calibration. The ARToolkit supports for Android, iOS, Linux, Window, Mac OS and Smart Glasses and since it is an open source, it is free to use.

3) Wikitude: Wikitude and its SDK7 are included for parallel localizing and mapping. Offers for 3D image recognizing and tracking, recognized within cloud environment with location-based services and integrated with smart glasses and external plugins include Unity. The Wikitude is supported in Android, iOS and smart glasses platform.

The main scope of this article is to describe and demonstrate that development of a free educational mobile application that, with the use of AR, could also help teacher and students interact with each other and provide the user with basic anatomical knowledge for the human internal organs and skeleton system. The breakthrough aim of this application is to introduce the new technological techniques and tools that may reinforces and embarks Malaysia education processes when involving anatomy subject in primary or secondary schools.

III. Methodology

The research methodology is depicted in Fig. 1. There are four phases i.e. Phase 1: Creation of 3D Models, Phase 2: Development of Augmented Reality (AR), Phase 3: Combination of 3D Models and AR and final phase, Phase 4: Development of GAAR Mobile Apps.



Phase 1
Creation of 3D Models
Phase 2
Development of Augmented Reality (AR)
Phase 3
Combination of 3D Models + AR
Phase 4
Development of GAAR Mobile Apps

Fig. 1. GAAR Methodology.

To embark the teaching and learning approach with interactivity, the conceptual model of GAAR is outlined as in Fig. 2. The AR technology is to bridge the gap between the real-world surroundings (physical area) and the digital area. The teaching and learning activities are done with interactivities via a tool where there is only need to scan and doing anatomy exercises and see references from the resources provided in GAAR library. The specific content of GAAR is shown in Fig. 3. The traditional textbooks such as Nota Sains Sukan Tahap 1, Skim Persijilan Kejurulatihan Kebangsaan (SPKK) [18] and Augmented Reality for the Study of Human Heart Anatomy [19] are used to evaluate the 3D model of human anatomy such as heart, lung, kidney, human skeleton and liver to design for GAAR content structure.

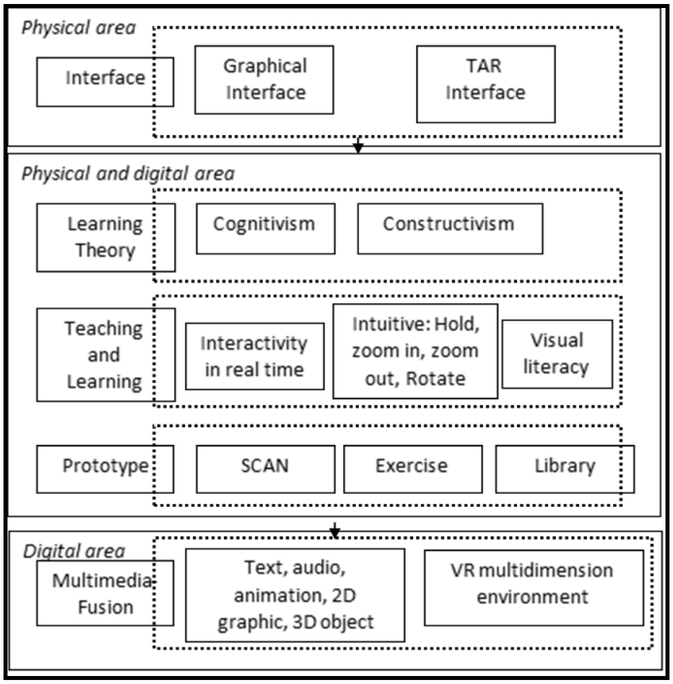


Fig. 2. GAAR Conceptual Model.

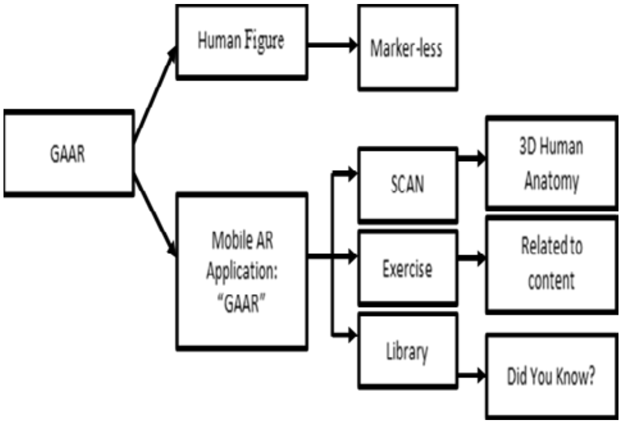

Fig. 3. GAAR Content Structure.

IV. Experimentation

A. Development

The interactive AR mobile application is only for Android mobile platform use only. Many external code libraries were used: Wikitude SDK, Android SDK, for the 3D models and the Autodesk Maya program for a 3D modelling and animation software. C# programming is used for creating mobile application using Unity3D. The GAAR mobile application used the concept of marker-less which mean that this mobile application does not required any medium or special paper to interact as marker. The only requirement for GAAR mobile application to work functionally need mobile phone with camera, android version 7.0 above and a flat surrounding to display the models. Using English language, the main menu of the mobile application is divided in seven categories i.e. Book Section, Quiz Game, Anatomy AR, About App, Option, Guide, Exit App. The main features which crucial for GAAR implementation which are anatomy AR, book anatomy and quiz game about anatomy to allow for better understanding about the structure of human skeleton and several main organs including their main function which suitable for young students to understands more about human science anatomy by providing 3D model which resemble to the actual organ and skeleton. Follows are the steps taken during development in Phase 1 of GAAR methodology.

Step 1: choose the correct marker-less Wikitude SDK for Unity as in Fig. 4.

Release Notes

Fig. 4. Choosing Marker-less Wikitude SDK.

Step 2: 3D modeling of human body using Autodesk Maya as in Fig. 5.

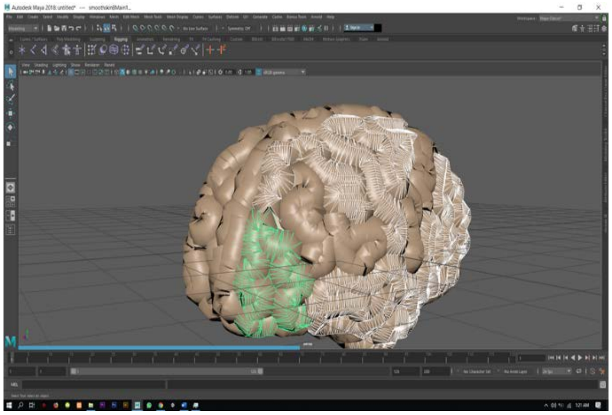

Fig. 5. Modelling in 3D.

Step 3: 3D model texturing in Autodesk Maya. Texturing is a process of making the surface model to look like real-world counterpart as in Fig. 6.

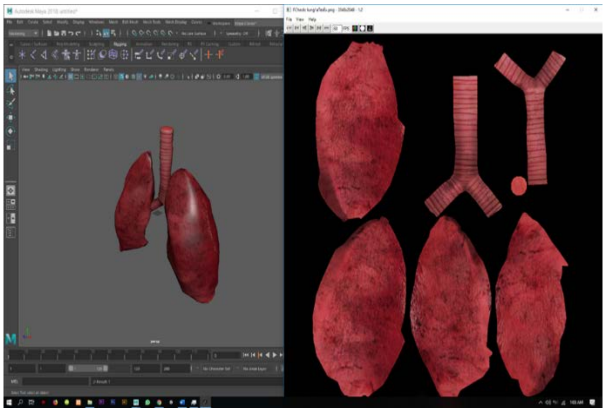

Fig. 6. Texturing.

Step 4: 3D model can be animated by rigging on a character as in Fig. 7. Rigging or skeletal animation means taking a static mesh to create an internal digital skeleton, and creating relationships between the mesh and the skeleton. This process also called as skinning, enveloping or binding process and adding a set of controls that the animator can use to push and pull the character around.

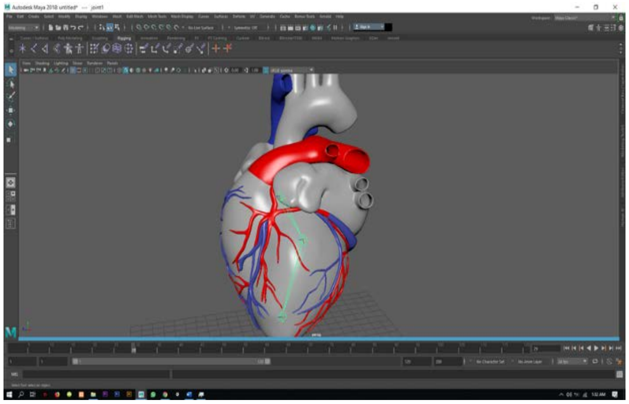

Fig. 7. Rigging.

Step 5: Building 3D model of human counterpart by importing into Unity3D software as in Fig. 8.

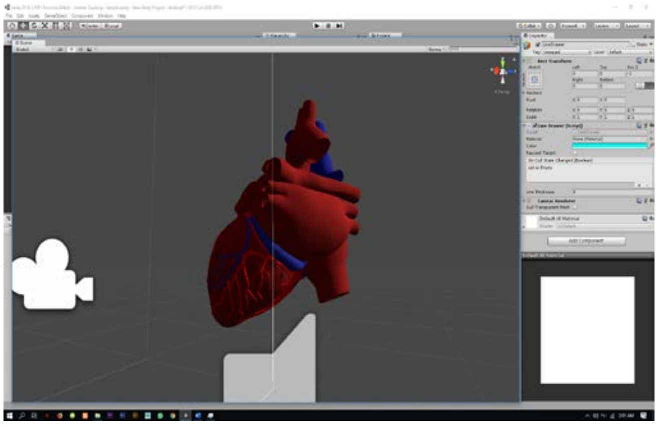

Fig. 8. Building 3D Model into Unity 3D.

Phase 2 is the programming or GAAR while Phase 3 is the combination of 3D models with AR where the *apk* files are created. Then in the last phase, the coding and programming are performed for GAAR mobile application.

B. *Interfaces*

Fig. 9 shows the home menu of the GAAR mobile application. When user first using the application, they will go to this home menu which consists seven buttons for user to explore. Fig. 10 shows the guide button feature. When user click on this button, they show the guide on what do each button state. As such, user can see which button that they need to know and be notify in early stage. These buttons guide with the symbol of boy reading manual, book section with the book symbol, quiz game with the symbol star. The middle button which is called Anatomy AR button which contain eight model of anatomy. The next three buttons is about application, option button and exit button.

Fig. 11 indicates the book section which contains seven buttons that indicated the several information about heart, lung, kidney, stomach, brain, liver and skeleton. Some model such as heart and lung have been provided with sound and animations. All the button give user the 3D model of anatomy and produce four main information about each button that suitable for young students and children. On the top, we have two button which are home button and Anatomy AR button. For the main part of GAAR mobile application is Anatomy AR button. Fig. 12 illustrates the interface of Anatomy AR. In this figure, the interface provides an information for start-up button which is used to explain the step that user needs to know before using Gross Anatomy AR. Then, once clicking on the initialize button, user will be directed with eight different icons which represent the 3D model organs. The GAAR contains eight different 3d models which are heart with animation, lung with animation, skeleton system, liver, kidney, brain, stomach and intestines (refer to Fig. 13). User also be notice with guides when using Anatomy AR as shown in Fig. 14. This small guide informs them on what user should do if user want to zoom, move, and rotate the 3d object. If the screen is full of 3d models, they can easily reset it all by pressing Reset button above go to Home page.

In Fig. 15, a 3D skeleton system model is displayed on the screen without any marker. The model also displays the name of bones and description about it. For each model, user have privileges to rotate using arrow provided or zoom by using two finger or move the model to another location. Next is Quiz game as stated in Fig. 16. The GAAR mobile apps provides simple questions which can test user memory based on the information that book section. Based on the figure above, there are nine multiple answer questions. Each question has its own countdown with test user capabilities to answer questions with at short timing. Next button act as submit answer after user pick an answer or not that allows user and audience know either the answer is true or false.

After finish answering those nine questions, the game shows the score and notify them the highest score of the previous challenge. If user want to try again, user can do this by pressing play again button or go to homepage at the home button below high score (see Fig. 17). Fig. 18 shows the graphic and game volume for GAAR mobile application. As for the graphic, it provided user low, medium and high resolution of pictures in the app. Game volume can be adjust either high or low depends on user. Hit apply button to set the options or hit back button to go to home menu. Lastly, the exit button used for user to check out from GAAR mobile application. In the button, it gives user the privilege for user to exit from using the app or stay using it (see Fig. 19).

V. Discussion

The advantage of a virtual human anatomy is that the gross appearance of the human anatomy drives user to explore for more since user can easily see the model in 360 degree from any angle and observe the shape and where it is located inside a human body. The color, shape, animation and sound give user a real-life experience that they explore human body in reality. Based on the results of our research an interactive mobile application can be created to supplement the traditional descriptive course. This form of application has the advantage that the student can access it from home. Factors such as the resolution of the camera, or the mobile phone have an impact on the in full color appearance but they do not cause deformation of the virtual object.

VI. Conclusion and Future Recommendations

With this application, the medical lectures, laboratory exercises and the anatomical models, the targets of medical curriculum are accomplished. Because anatomical models and academic lessons is tough to study by oneself, perhaps with GAAR, they are capable of using their own mobile device to interact with 3D model. This GAAR is a mechanism to build interest in human anatomy with immersion. There are a few suggestions that can be used to upgrade GAAR mobile application to be more efficient in future. Our recommendation is to use a paid license version of Wikitude SDK to get rid of the trial watermark in AR camera. Others would be to add more sound to give impact to user when using the application when studying, to improve with a consistent layout of each scene in GAAR mobile app to make it more appeal to user experience, to add more games or interesting activities that can increase user understanding and allow them to memorize the info through game and fun activity. Also, this GAAR could provide more unusual and unseen info but remains a crucial fact about human internal and external body.

The use of AR in education is regards to bridge the digital divide and to provide the static pictures into real-like 3D animation. Through the real visualization, small to adult learners can imitate the real truth on human organ and how this can motivate them to take care of their bodies that would lead to a healthier living styles as well as easy memorizing of the subject contents [20-21]. The GAAR is a mobile application that is useful for all generations of students as well as teachers which give more interactions to explore human body by using smartphone in real environment. Student does not need to understand something about human anatomy since they can now use the current textbook and explore it using GAAR. This not only help students to increase their knowledge but also help teacher explain more about human anatomy in their science subject. It is anticipated that by using GAAR, young student can achieve more knowledge and see much more than just using textbook only.

ACKNOWLEDGMENT

A special thanks to the financial support under UMT Grant with Vot: 53290 and UniSZA grant with code UniSZA/2018/PKP/01 (An intelligent mosquito home system). A sincere gratitude goes to the AMHS co-founder, One Team Network Sdn. Bhd. and Dr. Mos Healthcare Sdn. Bhd. for the idea creation and all faculty members in supporting our work.

GRASP Combined with ILS for the Vehicle Routing Problem with Time Windows, Precedence, Synchronization and Lunch Break Constraints

Ettazi Haitam[1], Rafalia Najat[2], Jaafar Abouchabaka[3]
LaRI Laboratory, Faculty of Sciences, University Ibn Tofail[1,2,3]
Kenitra, Morocco

***Abstract*—In this era of pandemic especially with COVID-19, many hospitals and care structures are at full capacity regarding availability of beds. This problem leads to ensure giving specific cares to people in need either in illness or disability in their own homes. Home Health Care (HHC) proposes this kind of services for patients demanding it. These services have to be done at the request of the patient which appears to be the client in a way that gives satisfaction to the requester of the service. Often, these demands are bound by a specific time that the workforce (caregivers) are obligated to respect in addition to the precedence (priority) constraint. The main purpose of the HHC structures is to provide a service that is good in term of quality, minimize the overall costs and shorten the losses. To reduce the costs of these HHC structures, it is mandatory to find comprehensible and logical ways to do it, for it is not permissible to touch the caregiver salary, HHC structures find themselves in the obligation to optimize by other means such as reducing the travel cost. Note that these structures give cares in one's home, which means that the travel aspect is important and is considered the core spending charges of the institution. Another fact is the satisfaction of the patients toward caregivers; this is an essential element to optimize in order to obtain a good quality service, to give a realistic aspect for the problem the lunch break of caregivers is introduced as a parameter. For those arguments, a conception of an efficient planning of caregivers involves using decision tools and optimization methods. A caregiver (vehicle) is attributed to a patient (customer) to do a number of cares with several options in accordance to the customer wishes like time windows requirement often specified by the client, the priority or precedence constraints are usually performed if a care have to be performed before another and could need the intervention of more than one caregiver and must have at least one lunch break a day and it is not always taken at a set time of the day and must be versatile to optimize customer demand satisfaction. To resolve this issue which is called VRPTW-SPLB, a mathematical model of the problem is proposed and explained as a Mixed Integer Linear Programming (MILP) and a greedy heuristic based on a Greedy Randomized Adaptive Procedure (GRASP) is proposed, two strategies based on local search and two metaheuristics, and a metaheuristic resultant of an hybridization of the two metaheuristics. At the end of the paper, results are shown on a benchmark extracted from the literature.**

Keywords—Optimization; VRP; home health care; ILS; tabu search; metaheuristics

I. Introduction

The world nowadays know a considerable increase in growing rate of population along with the several diseases that emerges day by day leading to a decrease in the number of beds in hospital per person. This situation arises many problems such offering adequate cares to needy people without delay. The Home Health Care services (HHC) becomes more complex and must adapt and evolve to cover all this variables by applying decisions in operational research context. To identify the source of the problem and its solution, defining the major actors is essential, these services are made essentially for disabled/elderly people that request many needs like medical care, hygienic care, assistance... In order to fulfill these demands, HHC structures offer the opportunity to perform such care in patient's homes along with the adequate and necessary equipment and resources may be caregivers or devices and gives the patient's the feeling that they are treated like if they receive treatment in a traditional hospital. This overall situation obligate to create a fine and good collaboration and coordination between human and material resources in order to establish a good and optimized planning that increases the quality of services offered by home health care with a controlled and reduced generated costs.

In this study, a generalization of the classical problem known as vehicle routing problem is proposed to deal with special and particular aspects linked to HHC. The problem studied in this paper consists of generating a set of routes executed by a group of vehicles (qualified caregivers) in order to visit a number of dispatched clients (patients) while satisfying a set of preferences aspired by the patients towards caregivers so that the operation is done in the most effective way. To enrich this study, the cares (2 or more) are of two categories according to the synchronization aspect, either simultaneously (at the same time) or in a given order(precedence), this case need the coordination of a high level of caregivers. To give the problem a realistic aspect that most of the studies neglect in their work is by considering the lunch break of caregivers which are operated only after the termination of a care by a caregiver.

To summarize what is being said, the problem studied is called the Vehicle Routing Problem with Time Windows, Synchronization, Precedence and Lunch Break constraints (VRPTW-SPLB). The constraints applied in this generalization of the VRP is appropriate to the maximum as it is in real life where most of patients have a preferred time to not precede or exceed, two or more cares can be done by more than one caregiver according to the skills of this latter, the cares can be one after another according to the priority of care and finally caregivers need the replenish their energy to continue the cares in the most efficient way thus the need to have a lunch break granted to the caregiver.

The next sections of this article are structured as follows: a section is devoted to the literature review of past works dealing with the vehicle routing problem in the home health care sector, the next section is dedicated to the problem definition, afterward a mathematical formulation is proposed in Section 4, next the explanation and components of the different metaheuristics used to solve the problem. Section 6 illustrates the computational results, while Section 7 is mainly for the discussion. Finally a conclusion and future perspectives are displayed.

II. Literature Review

The vehicle routing problem is regarded as an NP-Hard problem and considered within the field of Operational Research as one of the most studied in the last two decade. In order to assimilate a valid and explicit explanation of the vehicle routing problem as proposed by [1] is to build a route delivery with the least possible cost from a center (depot) to a series of distributed locations (customers) in accordance to a set of constraints that need to be respected. Both exact and approximate methods or approaches are considered as solution to the problem, only that metaheuristics methods are plainly approved to be effective as illustrated in [2] which is up to find a solution up to 26 variants of the VRP. The main body of this study is to plan and allocate several resources such as vehicles (caregivers), material... to a set of demanding requests made by a group of clients (patients) dispatched in a geographical region to achieve a predefined and specific services. From that perspective, the arousal of many constraints seem natural such as fixed time windows determined by the patient, preferences of patients toward caregivers, synchronization of services either simultaneously or not, lunch break of caregivers... Many approaches set by many authors such as [3-7] have realized and confirmed that the best methods to solve this problem is by using heuristics and metaheuristics. These authors experimented their approaches on qualified and known benchmark of the literature offered by [8,9]. Putting all this aside, it is obligatory to search and evaluate the most common objectives (cost, preferences, waiting time...) considered in those studies. Considering the HHC context, the vehicle routing problem offers as a problem many objectives to optimize; the total travelled distance by vehicles, the number of vehicles required, the total travelled time, patient's preferences toward caregivers are the most studied as objectives to optimize and frequently studied separately, thus these objectives can be considered on together but very rarely.

The idea supported in transportation in the home care as a logistical issue can be clustered into two broad categories, allocation and planning issues and pickup and delivery issues.

In this paper, the rest of the literature proposed in this study will be separated in three subsections, studies and works illustrated in the past talking on the subject of vehicle routing problem in home health care sector are shown in first, the second is an extension of contribution linked to the aspect synchronization and precedence in the vehicle routing problem and the last section is a highlights of the current contribution.

A. VRP in HHC

The logistics factor was first demonstrated in the field of Health Services by [10-12] on door-to-door transportation to support the elderly and/or disabled. The increasing rate of elderly people worldwide has prompted the authorities to introduce a scheme called DARP that translates to Dial-A-Ride in order to assist people with disabilities of any type. From this perspective, [13,14] have established a particular version of DARP that seeks to deploy a special team with appropriate and specific expertise to the home of the patient to assist them with any support they request (bath, dress, help to move...) until the resource that is responsible for transporting them to the hospital or a treatment structure arrives. This scenario has prompted researchers to integrate constraints such as synchronization constraints to ensure that priority between visits is respected, in order to ensure the effectiveness of this procedure, fine teamwork is expected by medical assistants and transporters. In the same category, a new constraint emerges for patient requirements that allow them to select a time window in which they are prepared to receive the care staff in their homes. The author in [15] suggests and incorporates this feature of time windows in the DARP for improved planning, but does not take into account the state of emergency and is instead concerned with minimizing the cost of transporting patients. The Dial-A-Ride problem has been expanded into the HHCP (Home Health Care Problem) conducted by a study well known in the literature [16] in which the key concept is to delegate caregiver staff to provide a certain amount of care needed by clients (patients) in their homes. The study shows two methods of resolution, the first of which was an exact method by suggesting a mathematical model with inter mixed variables (MILP) and the other one is a heuristic method. As for applying these methods on real instances, 10 patients and 4 nurses were considered to do the test, this will be the initial step to various and many papers addressing the same study but by using and testing various optimization resources and tools.

The optimization context in the home health care sector considers many aspects. The logistical aspect as concerned with this study contains two main categories that can be illuminated regarding other categories such as planning and allocation issues and pickup and delivery issues which are considered to be the most illustrated aspect on this field. For this study to be comprehensive and for the sake of simplification of the problem, generally a patient asking for a required care service is allocated a caregiver according to adequate skill and qualification for doing and fulfilling the service. Those skills and qualification are medical qualification, age, gender, language, specialty... The caregiver has a begin time and an end time throughout the day. As for the service required, it is characterized by a duration, skill and time window.

The dilemma of attributing visits to personal caregivers and the preparation of visits was studied in[17], where a MILP methodology and a Tabu search method were implemented to solve the problem and deliver fair and high quality solutions. In the same line, [18] proposed the same approach but considered as a partitioning problem which goal is to maximize the satisfaction of the patients and to minimize the transportation duration. There are studies in the literature that considers a single objective optimization such as [19] where the time windows constraint was introduced therefore the problem became VRPTW (Vehicle Routing Problem with Time Windows) and proposed a metaheuristics based on VNS and a mathematical formulation (MILP) in order to shorten the time that nurses consume in their movements and to maximize and increase the ratio nurses/patients of satisfaction. Another study [20] aims to solve the vehicle routing problem with time windows but this time with another approach and another implementation by introducing the Particle Swarm Optimization (PSO) so that the total travelled distance by nurses and caregivers is reduced with respect of constraints of time windows and vehicle's capacity. The multi-objective optimization is another variant of dealing with optimization in HHC, considering two functions to optimize at the same time leading to a high complexity of the problem.

The study in [21] deals with this multi-objective optimization by applying two metaheuristics based on ACO (Ant colony Optimization) which is an algorithm based on population, a mathematical formulation for the linear optimization and a multi-objective genetic approach.

Coordination of visits between nurses and/or caregivers is considered in the study of [22,23]. This coordination is either simultaneously or in a given order. The authors proposed a Branch and Bound method in order to reduce the travel cost of caregivers and to increase and maximize the satisfaction of patients toward nurses/caregivers. As for waiting time, which is a significant matter to consider was addressed by [24] for the sake of planning and scheduling visits to patients and giving tasks and mission to nurses/caregivers. First the mathematical formulation was established. Some authors tackled this problem by solving it in stages and not fully at once. This was done by [25,26] where a set of routes were generated initially before assigning routes to caregivers then enforce synchronization constraints in order to reach feasible and concrete solutions. A problem of node duplication was addressed by [27] where to run away from this duplication of nodes, an Iterated Local Search (ILS) was implemented and applied on relatively small instances of the literature. As for [28], maximizing the satisfaction of patients was prioritized along with the reduction of the cost of travel by using a Variable Neighborhood Search (VNS).

Synchronization constraints are really important to highlight the VRPTW problem in its totality where a set of request made by patients can have multiple visits and require the intervention of one or several caregivers either simultaneously or in a predefined order. In [7], work on this by formulating at first a mathematical skull of the problem, a GRASP and several metaheuristics for the sake of optimizing the total travel cost and increase the satisfaction of patients.

The pick-up and delivery aspect is studied and highlighted as well in many papers where a patient is to be picked up from a place or dropped off in a place. This was highlighted by [13]. This aspect of picking up and delivering is flexible to the points that authors in [4] proposed a system in order to deliver meals to patient's homes. To do so, patients were clustered and partitioned in zones according to the care structures policy. Meanwhile caregivers were also grouped in teams.

Before jumping on the constraints used in general, detailing synchronization constraints on the home health care sector is significant to the continuity of this study. As for our knowledge, the synchronization aspect dealing with the home care services are either considered in a simultaneous way likewise [27]. Other authors considered both simultaneous and precedence (in a given order) in separate, this is clearly shown in [23] and [14] where [7] and [29] illustrated the synchronization in the same model. In our study, we will consider both synchronization aspect in addition to a set of constraints that were not combined in the same study before.

Table II shows the overall constraints of paper found in literature meanwhile Table I expresses the constraints that are the most common.

As shown in Table II, the temporal aspect is what most of the authors are interested in for the aim to get a better quality of services. In the other hand, the constraints that give a realistic aspect to the problem are neglected in the most of the works such as lunch break of caregivers, precedence constraints and synchronization constraints.

B. *VRP with Synchronization Constraints in HHC*

When talking about timing and temporal constraints in the vehicle routing problem especially in the home health care sector, it is very needy to point at very important notion that enforce the realistic aspect of the problem overall. the study in [36] point in his classification that there is a dependence that takes place in the route taken by caregivers in order to get to patient's homes requesting cares, he defines it as synchronization. This starting point encourage other authors such as [27] to group and cluster this so-called synchronization into two main part, one for the simultaneous synchronization which is a two or more than one care is done at the same time, this type of synchronization require the intervention of more than one caregivers and is given a special attention (like transporting a patient from one place to another, bathing of a disabled patient...), the second type is more a synchronization that prioritize a care over another which means that two or more cares cannot be done simultaneously but need to be successive in a predefined order.

As for the literature and past works dealing with synchronization, we must cite [37] where he made the aircraft routing problem a simultaneous synchronization problem that ensure that a flight possessing an Id have to depart and take off in the same time at the same place. This resulted in an approach based on a decomposition called Dantzig-Wolfe decomposition.

Synchronization constraints proposed by [36] in the operation of collecting raw milk from farms consisted in a problem called Vehicle Routing Problem with Trailer and Transshipment (VRPTT). The problem is decomposed and constituted of two main vehicles trucks that can operate alone (autonomous) and trailers that can operate only with the help of a truck (non-autonomous). The authors conceived a mathematical formulation of the VRPTT and a simple heuristic. The synchronization used in this paper is a precedence one.

Precedence constraints in the home health care problems were addressed by multiple authors such as [38] where in the context of waste collection of a household the minimization of the overall travel duration is tackled. To ensure the fluidity of the work, vehicles were separated into two types, small ones called satellites that can drive on any type of road where the second one is large or compactors that have strict and known road to drive on. A local search procedure was used in order to find feasible solution of this problem.

C. *Contribution Highlights*

In this paper, the points addressed in the literature do not handle a majority of constraints in an efficient manner, where most of the authors push the search area of solutions to grow considerably by duplicating nodes. The second point that found its limitations as the instances grows is the use of models that are based on MILP (Mixed Integer Linear Programming) where only small instances give satisfactory solutions in the contrary of large instances. Authors decided then to use metaheuristic to work on larger instances, but fail in catching the optimal solutions and are trapped in local optimum because most of them don't use local search procedure in their work in order to avoid being trapped in a local optimum. For all these points, this paper aims to contribute in:

- Put a model that engage both simultaneous and precedence constraints, caregiver lunch breaks and time windows in the same design. Afterwards solve this model with a linear solver such as Cplex.
- Manage to work with multiples and several constraints such as time windows of patients, synchronization constraints with their two type (simultaneous/precedence), caregivers skills and qualification, caregivers lunch break and the preference of patients in regard of caregivers. It is very rare to find authors that handle more than three constraints at the same time in their work.
- Propose a hybrid algorithm in order to find feasible solutions of instances considered large on existing benchmark of literatures.

III. Problem Description and Mathematical Formulation

The vehicle routing problem is a problem that considers the determination of routes that must be taken by vehicles from a point i to a point j. The variant of the VRP considered in this study can be considered as a vehicle routing problem with time windows, synchronization, precedence and lunch break constraints (VRPTW-SPLB).

Consider G= (V, E) a graph where N = {1… n} is a set of clients (patients) and V= NUD a set of nodes. c is the initial depot and f the final one where D = {c, f}. Routes are linked by a set of points where m = [i, j] a margin, C_{ij} is the cost linked to the path ij and T_{ij} the duration travel. A health structure offers multiple services S = {1…s} to a set of patients where a patient i require a subset of services to the health structure $S_i = \{s \in S: e_{is} = 1\}$. A duration d_{is} is assigned to each service asked by a patient along with a time windows $[a_i, b_i]$ wherre a service cannot begin before a_i and cannot terminate afterb_i. The set of vehicles required to ensure the task of providing services to patients is denoted by K where each vehicle $k \in K$ have a time windows of availability specified by α_k, β_k. Prf_{ik} a number ensuring the preference of each vehicle k, this number defines the non-preferences of patient i in regard of the caregiver k.

P describes the lunch break of caregivers and nurses and L is the duration and $[w_p, z_p]$ is the time window as defined by [16]. g_{ik} is 1 if the caregiver consumes his/her break at patient i before service termination and 0 otherwise, g'_{ik} is 1 if the caregiver consumes his/her break at patient i after service termination, 0 otherwise. st_{ik} is the service start time of caregiver k at patient i and st_{pk} is the lunch break time start of the caregiver k. For the sake of simplicity, we write $k \in K_s$ if y_{ks}=1 and $s \in S_i$ if $e_{is} = 1$.

For the simplification and generalization of this study, we suppose that $k \in K$ accomplishes a unique service s. y_{ks} equals 1 if vehicle k offers the service s, 0 otherwise ($\forall\ k \in K, \forall\ s \in S$).

For customers (patients) whom are demanding more than one service either in a specific order or simultaneously, we define for each patient $i \in N$ a $slot_{isr}$ as the time separating the time start of service s and service r demanded by patient i where services s and r have to be provided in a given order (service s before service r).

Just to note that lunch breaks are not depending entirely on the time duration of the route, and a lunch break can be taken and utilized if the duration of the route outpaces and exceeds α_p. It is also permissible to take a lunch break at the end of a route even if the time window of the lunch break is not yet covered.

This problem formulation considers the minimization of the sum of non-preferences of patients towards caregivers and total travelling time by shortening to the maximum the total travelled distance overall.

To generalize the constraints of time in this formulation, we presume that all the requested services by patients are asked independently from the initial depot (center) c and their duration is 0 ($D_{cs} = 0$, $\forall\ s \in S$).

The Mixed Integer Linear Programming corresponding to our formulation is as follows:

$$\min \sum_{i \in V\setminus\{f\}} \sum_{j \in V\setminus\{c\}} \sum_{k \in K} C_{ij}\, x_{ijk} + \sum_{i \in N} \sum_{j \in V\setminus\{c\}} \sum_{k \in K} Prf_{ik}\, x_{ijk} \qquad (1)$$

Subject to:

$$\forall k \in K, \sum_{j \in N} x_{cjk} = 1 \qquad (2)$$

$$\forall k \in K, \sum_{j \in N} x_{ifk} = 1 \qquad (3)$$

$$\forall h \in N, \forall k \in K, \ \sum_{i \in V\setminus\{f\}} x_{ihk} = \sum_{j \in V\setminus\{c\}} x_{hjk} \qquad (4)$$

$$\forall i \in N, \forall s \in S, \ \sum_{j \in V\setminus\{c\}} \ \sum_{k \in K_s} x_{ijk} = e_{is} \qquad (5)$$

$$\forall i, j \in V, \forall s \in S: s \in S_i \cup S_j, \forall k \in K_s, st_{ik} + (T_{ij} + D_{is}) x_{ijk} \le st_{jk} + b_i (1 - x_{ijk}) \qquad (6)$$

$$\forall i \in N, \forall s \in S_i, \forall k \in K_s, a_i \sum_{j \in N} x_{ijk} \le st_{ik} \le b_i \sum_{j \in N} x_{ijk} \qquad (7)$$

$$\forall k \in K, \alpha_k \le st_{ck} \le \beta_k \qquad (8)$$

$$\forall k \in K, \alpha_k \le st_{fk} \le \beta_k \qquad (9)$$

$$\forall i, j \in V, \forall k \in K, x_{ijk} \in \{0,1\} \qquad (10)$$

$$\forall i \in V, \forall k \in K, \ g_{ik}, g'_{ik} \in \{0,1\} \qquad (11)$$

$$\forall i \in V, \forall k \in K, \ st_{ik} \in \{0,1\} \qquad (12)$$

The objective function (1) is to minimize the total travelling time and the sum of non-preferences. Constraints (2) and (3) ensure that each vehicle have to leave the initial depot and return to it. Constraint (4) guarantees the continuity and constancy of the routes while constraint (5) guarantees that the demands of customers (patients) are provided and executed. Scheduling and planning permitting the consistency between the durations of visits is maintained by constraint (6). Constraints (7), (8), (9) guarantee the respect of patients, caregivers time windows. Constraints (10), (11) and (12) define the nature of the decision variables.

Just to cite that the caregivers' lunch breaks are not entirely related to the time duration of the route taken, and a lunch break can be used on the condition that the duration of the route outpaces and exceeds α_p. It is also permitted to take a lunch break at the end of a route even if the time window of the lunch break is not yet covered.

IV. Resolution Approach

A metaheuristic is developed due to the challenge of solving large instances in an acceptable amount of time even though the proposed model decreases the graph size in comparison of prior formulations. The metaheuristic proposed is a hybridization of GRASP and ILS.

The GRASP method was firstly presented and dealt with by [39] for a covering set problem. The GRASP method was effective for construction routing problem, when [40] utilize it in order to solve a tour design problem with time windows to minimize the vehicle number used.

The GRASP method consists of iteration which produces in each iteration a new solution in two phases:

- Construct a feasible solution by the means of a greedy randomized heuristic.
- Improve the solution with the help a local search procedure by the iterative exploration of search space in order to improve the current solution.

The Iterated Local Search (ILS) belongs to a class of metaheuristic based on the exploration of a neighboring of near local optimum. The local optimum according to [41] is grouped in a cluster of search space. ILS initiates its search from a starting solution called initial solution of a good quality. This initial solution is created by the help of a greedy heuristic, and then improved by a local search to find a first local optimum. In the contrary of the GRASP, then a perturbation procedure is done on the current solution in each iteration in the hope to escape from the local optimum. When the solution is perturbed and improved by the local search, then this time the new solution becomes another local optimum. This cycle composed of perturbation and local search will not stop until a stopping criterion is met.

In the hybrid version, the ILS procedure replaces the local search of the GRASP method. The general structure of the GRASP combined with ILS is proposed to solve the VRPTW-SPLB is illustrated in the algorithm 1. Even tough, the algorithm is simple; its capacity to solve multiple combinatory problems is proven such as [42] for the localization routing in two echelon and [43] for the periodic vehicle routing problem with time windows.

The principle loop in the algorithm 1 (line 3-32) defines the hybrid method GRASP*ILS composed of a construction phase and an improvement phase done by the iterated local search (ILS). The first solution Sol_1 is generated by a parallel randomized constructive heuristic (PCH). In each iteration of the ILS algorithm (line10-25) calls the perturbation procedure (PP), then the random local search updates the last solution encountered (Sol_1) when this latter is improved. In order to stop the algorithm, stop conditions must be met such as the maximum number of iteration $\mathrm{Iter}_{\mathrm{MaxG}}$ is met. The second stop condition is when an inferior margin LM after a number of iteration $\max_{\mathrm{Failure}}$ counted by the variable NImp where there is no improvement of the current solution or just after a maximum number of iteration $\mathrm{Iter}_{\mathrm{MaxL}}$.

Algorithm: GRASP combined with ILS

```
1:  F* ← +∞
2:  $Iter_G$= 0
3:  **While** (($Iter_G$ < $Iter_{MaxG}$) and (F* > LM ) **Do**
4:      $Sol_1$← PCH($Sol_1$)
5:      **If** ($Sol_1$ $is\ feasible$) **Then**
6:          $Iter_G$ = $Iter_G$ + 1
7:          $Iter_L$= 0
8:          $NImp$ = 0
9:          $Sol_1$← LocalSearch($Sol_1$)
10:         **While** (($Iter_L$ < $Iter_{MaxL}$) and ($NImp$ < $max_{Failure}$) **Do**
11:             Sol ← $Sol_1$
12:             Sol ← PP(Sol)
13:             **If** (Sol is feasible) **Then**
14:                 $Iter_L$ = $Iter_L$ +1
15:                 Sol ← LocalSearch (Sol)
16:                 **If** (F(Sol) < F($Sol_1$)) **Then**
17:                     $Sol_1$← Sol
18:                     $Iter_L$ ← 0
19:                 **Else**
20:                     $NImp$ = $NImp$ + 1
21:                 **End If**
22:             **Else**
23:                 $NImp$ = $NImp$ + 1
24:             **End If**
25:         **End While**
26:         **If** (F($Sol_1$) < F*) **Then**
27:             S* ← $Sol_1$
28:             F* ← F($Sol_1$)
29:             $Iter_G$ ← 0
30:         **End If**
31: **End While**
32: **Return** Sol*
```

Just to note that F(Sol) corresponds to the cost of the solution Sol.

V. Numerical Evaluation

A. Instances and Implementation

The metaheuristics proposed in this paper were coded in Python3.8 and were executed and tested on a machine with a processor Core i7-5500 CPU with 8GB of RAM, functioning under Windows 10 Home as for the mathematical model, the test was done with CPLEX Studio version 12.10.

The benchmark used as instances are from [23], which is known for its features that includes all aspect studies in this paper such as: Time Windows, Synchronization and Preferences.

This benchmark contains three parameters; the number of customers is equivalent to patients in our case, the number of vehicles equivalent to caregivers and are grouped according to this scheme:

- 18 clients (patients) with the use of 4 vehicles (caregivers),
- 45 clients (patients) with the use of 10 vehicles (caregivers),
- 80 clients (patients) with the use of 16 vehicles (caregivers),

To incorporate the notion of synchronization, a range number linked to synchronization from two to four is determined, for the sake of generalization lunch break is always taken after performing successfully a service s. Time windows are grouped by small, medium and large. In this study, a limit was put to not exceed at most two requested services.

B. Algorithms Parameters

The main goal for setting parameters is to obtain the best performances by testing a limited number of parameters combination. For the sake of this study, the logical practice for choosing parameters is to parameter each algorithm used separately according to its suitability. For the hybrid method GRASP*ILS, parameters set to ensure the best testing possible are the number of restart $\mathrm{IterMax}_{\mathrm{G}}$, the iteration number without success $\mathrm{Max}_{\mathrm{fail}}$, the call number of ILS $\mathrm{IterMax}_{\mathrm{L}}$ and finally the perturbation procedure parameter $\mathrm{pert}_{\max}$ related to the number of patients to remove. The average number of local search executed in order to obtain the best solution for the hybrid version is restored and will be given as a stop condition for the hybrid method GRASP*ILS, all this is done by adding a counting variable that is incremented in each call of the local search procedure (AVD). The metaheuristics proposed in this paper are executed a number of 10 times and the best solution along with the average solution are given in comparison. The Table III states the parameters used for testing, each parameter is given a range value of testing and the best value is taken as a fixed parameter.

TABLE III. PARAMETERS FOR GRASP*ILS

Parameters	Notation	Test values Range	Value
Number of restart	$IterMax_G$	[10 .. 100]	45
Iteration number of ILS	$IterMax_L$	[10 .. 100]	45
Number of solution without improvement	Max_{fail},	[5 .. 50]	35
Perturbation level	$pert_{max}$	[1 .. 6]	3

C. Results and Interpretation

The results of experimentation of the 37 instances of each metaheuristic are found in the end of the paper, as for the summary results, they are given in Table IV and Table V. In order to have a better analysis of the obtained results, four comparisons are highlighted, one comparison for the metaheuristic GRASP*ILS with the CPLEX results, the second comparing the results of GRASP with the results of the ILS, the third comparing the GRASP with the CPLEX and finally the ILS with CPLEX. As for the representation of the results, the results are given for each group of instances (Gins_1 , Gins_2 , Gins_3). For CPLEX, instances that give feasible solution are denoted by (G_{cf}) and for all instances ($\mathrm{G}_{\mathrm{all}}$).

To understand the Table IV, the first part are the results obtained by the CPLEX solver, then the second part of the Table IV and the two parts of Table V highlight the results of the proposed methods. The performance indicators used to compare the different results are the average gap percentage of the best found solution of the GRASP*ILS method for the lower bound ($\mathrm{Ind}_{\mathrm{LB}}$), the upper bound ($\mathrm{Ind}_{\mathrm{UB}}$) along with each criteria separately ($\mathrm{Ind}_{\mathrm{Moving}}$) and ($\mathrm{Ind}_{\mathrm{Pref}}$). Afterwards, an exposition in seconds of the time required to obtain the best solution ($\mathrm{Tsec}_{\mathrm{min}}$). The average solution of the different executions are compared with the best solution of the results obtained by the GRASP*ILS method ($\mathrm{CObj}_{\mathrm{Ref}}$, $\mathrm{CMoving}_{\mathrm{Ref}}$) and $\mathrm{CPref}_{\mathrm{Ref}}$). Finally, the average computational time needed to obtain the average solutions is exposed in seconds denoted by ($\mathrm{Tsec}_{\mathrm{average}}$), as for the optimal solutions, we denote it ($\mathrm{Tsec}_{\mathrm{optimal}}$).

In the next tables, note that the results subject to the CPLEX solver which is there are no feasible solution are not included (Max time of execution is 1 hour).

Note that Ref=GRASP*ILS and X= Total cost of the objective function.

The CPLEX studio solver permitted to solve up to 23 optimal solution of the 37 instances tested. Meanwhile the hybrid method has solved all instances in a more reduced time (23,93 seconds for the GRASP*ILS compared to 609,53 for CPLEX).

In general, the overall results obtained show that the GRASP*ILS method is way better than CPLEX results with an average gain of 2,10%, That means that this method attain an average gap of 3,19% for the lower bound in 162,24 seconds. This gap is reduced more than 1% in comparison with the CPLEX results (4,47% of gap in 1414,51 seconds) in a computational time considerably small.

The efficiency of the hybrid method GRASP*ILS is confirmed by observing the results of the third instance group (Gins_3) where the hybrid method improve by 12,95% in 1186,43 seconds compared to the upper bounds of the CPLEX where the gap is nearly 23% in 3600 seconds.

Overall, the solutions presented by the hybrid method GRASP*ILS are better than the upper bound given by the CPLEX solver in 3600 seconds. In addition, the nature of the problem being NP-Hard make the CPLEX solver incapacity of producing feasible solution in a reasonable time nearly impossible for instances of more than 45 patients. In the other hand, GRASP*ILS work perfectly on larger instances.

After summarizing and analyzing the results given by the CPLEX solver and the hybrid method, an evaluation of the efficiency of the GRASP*ILS method is highlighted and compared to both the GRASP method and the ILS method.

TABLE IV. PERFORMANCE INDICATORS FOR THE 37 INSTANCES OF MILP AND GRASP*ILS

Indicators	**MILP**					**GRASP*ILS**				
	$Gins_1$	$Gins_2$	$Gins_3$	G_{cf}	G_{all}	$Gins_1$	$Gins_2$	$Gins_3$	G_{cf}	G_{all}

IndX_{Ref}	0,39	4,13	-2,39	1,44	0,95	0,00	2,93	6,17	2,51	2,72
$\text{IndMoving}_{\text{Ref}}$	0,23	0,33	-0,57	-0,95	0,00	0,00	1,68	2,73	-0,04	1,35
$\text{IndPref}_{\text{Ref}}$	-0,04	0,47	-0,06	0,82	0,15	0,00	-0,50	1,55	0,74	0,26
Tsec_{min}	0,18	64,33	465,32	106,94	148,98	0,21	260,49	1361,91	173,46	460,24
CX_{Ref}	19,78	14,27	2,17	14,93	13,08	0,97	8,73	8,30	5,76	5,68
$\text{CMoving}_{\text{Ref}}$	3,05	0,12	1,02	0,67	1,47	0,15	0,89	4,03	-0,07	1,46
$\text{CPref}_{\text{Ref}}$	1,76	2,38	7,22	4,39	3,45	0,45	1,15	1,62	1,60	1,01
$\text{Tsec}_{\text{optimal}}$	0,27	75,30	479,96	113,85	156,83	0,28	282,10	1331,94	181,53	459,76

By comparing the results of the two methods GRASP and ILS with the CPLEX results, it is clear that ILS is better than GRASP where ILS show a gap of 4,74% on the lower bound in merely 106,94 seconds where the GRASP is only 5,53% in 173,46 seconds. Thus, ILS improve the upper bound of the CPLEX by 0,65%, meanwhile GRASP only obtain a gap of 0,59%.

When comparing the best solutions obtained by the hybrid method GRASP*ILS (considered as references), the results show that the GRASP metaheuristic is less efficient with an approximate average gap of 2,51%. On the other hand, ILS seems more efficient than GRASP with an approximate average gap of 1,44% from the method of reference. By seeing the ILS results, the difference is not that much with the hybrid method considering the overall execution (0,85% of gap considering all instances).

To summarize, the results obtained lead us to say that the hybrid method is more efficient and stable than the standard version of ILS, where ILS is better than GRASP for a given number of local search calls. Finally, the last conclusion for this paper is that GRASP*ILS is better than ILS which is better than GRASP.

VI. CONCLUSION AND PERSPECTIVES

In this paper, three metaheuristics for the VRPTW-SPLB are proposed. A GRASP method and an ILS method which use a constructive heuristic inspired by the nearest neighbor method and a local search which explore in an organized manner all the neighboring in order to find feasible solution optimally. Firstly, an investigation and overview of the problem of the vehicle routing problem with time windows, synchronization, precedence and lunch break constraints in the sector of home health care is presented. Then a mathematical formulation of the problem is proposed by the aid of the mixed integer programming language (MILP). After introducing the algorithms used to solve the problem, a numerical results section along with its analysis is foreshadowed to know which algorithm gives the better solution. By the outcome, it is clear that the GRASP and ILS method gives better results for larger instances than the CPLEX solver, but compared to the lower bounds given by CPLEX, the GRASP method seems less efficient than ILS, this can be explained by the iterations independency realized by GRASP, for this reason the execution times are longer than ILS, but still reasonable for such a problem which is known to be NP-Hard. The combination of these two methods which result in GRASP*ILS method demonstrated that it is better in term of computational time and the quality of the results obtained. In order to complete this study as future research is to conduct statistical tests in order to establish which method is more stable and gives better results. The limitation found in this study are frequent in this problem such as ensuring the satisfaction of the patient by assigning to him a specific caregiver can lead to an increase in the overall cost which is very degrading in term of optimizing either resources and time. In order to escape from this, a multi-objective approach can aid to solve this matter. As a continuity of this study, a multi-objective approach of the same problem which is VRPTW-SPLB in home health care with genetic algorithms in order to optimize the overall movement costs and patient's satisfaction simultaneously will be conducted in a future paper.

***Abstract*—This study aims to develop a novel web-based decision support system for diabetic retinopathy screening and classification of eye fundus images for medical officers. The research delivers diabetic retinopathy information with a web-based environment according to the needs of the users. The proposed research also intends to evaluate the developed system usability to the target users. The complex characteristics of diabetic retinopathy signs contribute to the difficulty in detecting diabetic retinopathy. Therefore, professional and skilled retinal screeners are required to produce accurate diabetic retinopathy detection and diagnosis. The proposed system assists the communication and consultation among the medical experts in the hospital and the primary health cares located at the health clinics. The agile software development model is the methodology used for the development of this research project. The project collaborates with the Department of Ophthalmology, Hospital Melaka, Malaysia for the medical content expertise and testing. Representative medical officers from Hospital Melaka and all the public health clinics in Melaka were involved in the preliminary study and system testing. This research study consists of a web development producing an interactive web-based application of diabetic retinopathy consultation which comprises image processing and editing features as a core of the system. It is envisaged that this research project will contribute to the management of diabetic retinopathy screening among medical officers.**

***Keywords*—Consultation; diabetic retinopathy; eye screening; image editing; image processing; web development; testing**

I. Introduction

Diabetic retinopathy (DR) is a type of eye disease due to a diabetic condition that damages the retina, leading to blindness or vision loss. In Malaysia, diabetes in the eye is the most common cause of vision loss in working age adults. Therefore, screening of DR is important for early detection and early treatment. A precise retinal screening is required to help retinal screeners to distinguish the retinal images efficiently. This study aims to develop a web-based decision support system to screen and diagnose DR in eye fundus images. Furthermore, the study would examine the information on DR, including screening and diagnosis. This research also aims to determine the usability and needs demand by the target users of the developed system. The detection of DR is challenging due to the complex characteristics of the DR features as illustrated in Fig. 1 which emphasizes the need for highly qualified and experienced retinal screeners to ensure accurate detection and diagnosis of DR. Moreover, this system involves image processing and image editing features to enhance the visibility of fundus images captured by primary health cares. The built web-based system aims to create a new web application to provide online users with innovative services or solutions. Therefore, an enhancement web-based system based on online consultation to overcome the weaknesses of the current method such as many-to-many communication, image upload, image editing and image processing.

In this paper, basic information of DR and related works will be stated in the next section, a brief explanation on research materials and method used will be shown in the third section that includes the image processing and image editing features, while the fourth section will discuss the results of this research.

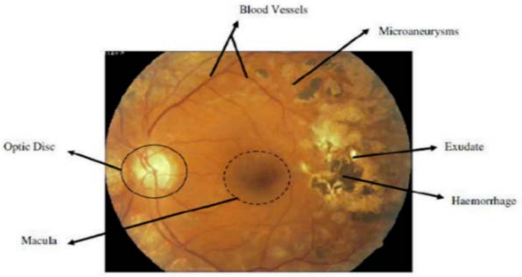

Fig. 1. Fundus Retinal Image with Lesions [1].

II. Literature Review

DR is a diabetic complication caused by elevated blood glucose levels. In order to diagnose DR symptoms, an eye screening is required. Microaneurysms, retinal haemorrhages, hard exudates, abnormal new vessels, cotton wool spots, and venous beadings are some of the signs that must be discovered throughout the DR screening process. Thus, it's essential to have a thorough consultation platform that allows primary health care to identify and classify the DR risk factors based on the patient's fundus image, since the vision impairment due to DR is increasing. Early detection and diagnosis of DR are vital for saving the vision of diabetic persons.

Globally, at least 2.2 billion people experience vision impairment, and of these, at least 1 billion people have vision impairment that could have been prevented or is yet to be addressed [2]. It is revealed that globally, 146 million (34.6%) were diagnosed as DR in 2014 for adults aged over 18 years with diabetes [2]. The largest number of blind and visually impaired people reside in the Asian region, namely, South Asia, followed by East Asia and Southeast Asia [3]. DR caused 1.1% of all cases of blindness and 1.3% of all visual impairment in 2015. The percentage of blindness caused by DR varied in the Asia-Pacific, ranging from less than 1% in South Asia (0.16%), Oceania (0.32%), East Asia (0.51%), and Southeast Asia (0.59%) to more than 3% in Central Asia (3.60%), high-income Asia-Pacific countries (3.87%), and Australasia (4.48%). Prevalence of blindness and visual impairment due to DR decreased between 1990 and 2015 in Oceania and Central and Eastern Europe, yet increased in high-income regions of Asia-Pacific, North America, Australasia, and Asian regions [3].

Malaysia also has the largest number of people with visual impairments, namely, from Kedah, Perlis, Johor, and Perak as studied by the Malaysian [4] as shown in Fig. 2 [5]. The result shows the prevalence of all states in Malaysia. Kedah demonstrates the highest percentage of people with diabetes with a difference of 4.8% in Perlis while a percentage difference of 0.8% in Johor. It is also shown that Johor has a difference of 0.4% of diabetic prevalence with Perak.

Fig. 3 shows the results by the [6] regarding the prevalence of diabetes mellitus in Malaysia with an age group above 30 years old. The percentage of diabetes mellitus in Malaysia is increasing from 1986 to 2011. It increased by about 2% from 1986 to 1996 within the range of 10 years. In 2006, it increased by 6.6% from 1996 which is also within 10 years. It shows that the prevalence between 1996 and 2006 increased by 4.3% higher than from 1986 to 1996. From 2006 to 2011, the percentage of the prevalence is increasing by 5.9% which is lower by 0.7% than between 1996 and 2006. Overall, it shows that the prevalence of this disease is gradually increasing.

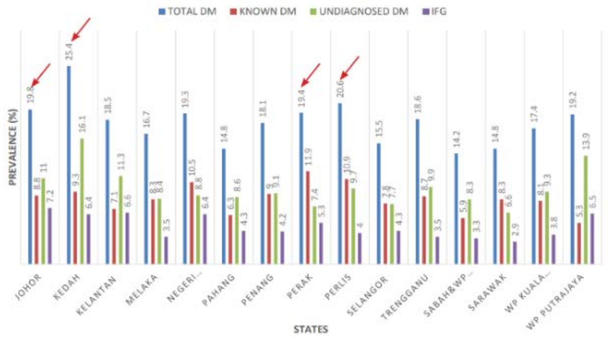

Fig. 2. Prevalence of Diabetes by States [5].

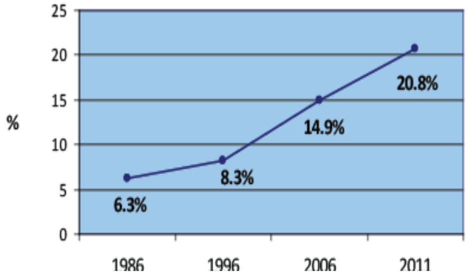

Fig. 3. Prevalence of Diabetes Mellitus in Malaysia (>30 Years Age Group) [6].

The proposed research project is a guideline in the development of a system. Several systems for detection and diagnosis of DR are reported in the literature which are development focused and proposed techniques for detecting certain features of DR. For instance, the existing system of automated DR screening detection as proposed by [7] and [8] that assist in diabetic retinopathy detection. Another existing related system is the teleophthalmology screening system developed by [9] which integrates multiple tools into ForusCare such as software platform where the system secures the image analysis module and stored and forwarded into the Amazon cloud. In addition, there are additional system features such as system installation and workflow that enhance communication and assures quality photos. [10] have developed a mobile system called mTEH that enables employees operating from different remote locations to be connected, securely stores all eye-screening participant data, and encourages improved decision-making of participants on eye health. An online teleophthalmology screening conferencing system was developed by [11] known as TeleOph as the virtual channel for DR screening. Telemedicine is a correlation between medicine and the technology available [12]. Recently, [13] proposed a telemedicine system that offers communication using 5G uRLLC and mMTC. Furthermore, another similar telemedicine that has made tremendous strides and successfully interacts with patients and doctors is HEMAN which is an IoT-based e-health care system for remote telemedicine [14].

III. Materials and Methods

The developed web-system is built using these programming languages and scripting; HTML5, PHP7, JavaScript, jQuery, CSS3, and SQL, with the CMS WordPress platform. These programming languages are chosen since these languages are able to perform responsively in any types of gadgets such as laptop, tab, and mobile [15]. This system also uses cPanel as the web hosting platform to publish the system online. Adobe Dreamweaver CC 2020 is another tool used in writing the codes and designing the interface and theme of the system. PHP7 performs many functions that need to connect to the database such as fundus image upload and retrieve. Other than that, jQuery language plays a big role in running the image editing and image processing plugin.

This section outlines the research process to accomplish the objectives of this research. Overall, the five phases cover in this research are analysis, design, development, testing, and evaluation; the methodology of this research to achieve the objectives of the research study. Fig. 4 presents the graphical illustration of the Agile model.

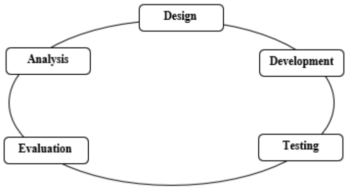

Fig. 4. Web Application Development Process.

A. Analysis

An online survey was created to collect data as the input for developing the system. The survey has been distributed to 202 primary health cares from Hospital Melaka and 32 health clinics around Melaka. This survey covered four main parts which are demographic, computer literacy/skills, current DR screening practice, and expected outcome. The details of the online survey are summarized in Table I. The online survey result clearly indicates that most of the respondents agreed to the development of the system. Moreover, this online survey helps analyze the problems, limitations, suggestions, and expected outcome of the system. Thus, it can be concluded that the proposed web-based consultation system is highly needed by primary health cares to conduct the DR screening process.

TABLE I. SUMMARY OF THE PRELIMINARY ONLINE STUDY

Date/Duration	23/6/2020 – 2/9/2020 (10 weeks)
Type of survey	Online questionnaire via Google Form
No. of respondents	202 respondents
No. of workplace	1 hospital, 32 health clinics
Type of respondents	Consultant, Specialist, Medical Officer and House Officer
No. of survey parts	4 sections - Demographic - Computer Literacy/Skills - Current DR Screening Practice - Expected Outcome

B. Design

In the design phase, considerations such as software needs, how the output of the system will look, what database will be used, and the timeline of development were identified. Fig. 5 shows the flow of the system process. The design phase for this system began with designing the web environment since the primary health cares required an online platform for the system. Therefore, this system needs to have a web domain and hosting for the system to be published and viewed on the web browser.

The next task was to design a database for the system. Designing a database requires the list of functions of the system and information needed to derive from the system to determine the possible tables and fields need to create in the database. Microsoft Visio software was used to design the Entity Relational Diagram and phpMyAdmin to create the database of the system. After the database was designed, creating web interactivity starts with the connection of the system to the database and triggering the buttons in the system. Ensuring that the connection of the database and trigger buttons are working fine will ease the next step which was designing the web-based interface with the bootstrap theme plugin. Once the system was completed with the design of web environment, database, interactivity and interface, the system proceeded to the development process.

C. Development

Once all the requirements and designs were documented, the development phase took place. There are four features that are the core function of the system. This system is able to be accessed through this link; http://drcs.com.my/ which has four types of users which are: Admin, Specialist, Primary Health Care, and Public. Admin is allowed to handle the user and hospital and health clinic data. The specialists can view the list of DR cases uploaded by the primary health cares and specialists can give feedback on the DR cases while using image processing and image editing features in the system. Primary health cares are allowed to fill up DR case form including uploading fundus images from both right and left eyes, view the list of DR cases uploaded by other primary health cares, and view the feedback from the specialists and reply to the feedback given. Besides that, the public type of user can gain information on the DR and DR screening, view an example of DR fundus images, and gain knowledge on the signs of DR from the fundus images. and gain knowledge on the signs of DR from the fundus images. Table II shows the list of the system users and their accessibility.

Fig. 6 depicts the flow of the development of the DRCS. The system development began with the basic functions which were Create, Read, Update, and Delete (CRUD) function for the user, hospital and health clinic, and diabetic retinopathy’s case details using PHP and MySQLi.

The image processing plugin which includes image color conversion and image filtering was developed. Subsequently, the development of image editing plugin that allows to crop, scale, and annotate the fundus image takes place. A forum area for specialists to review and comment on the DR cases with the primary health cares was provided in the system.

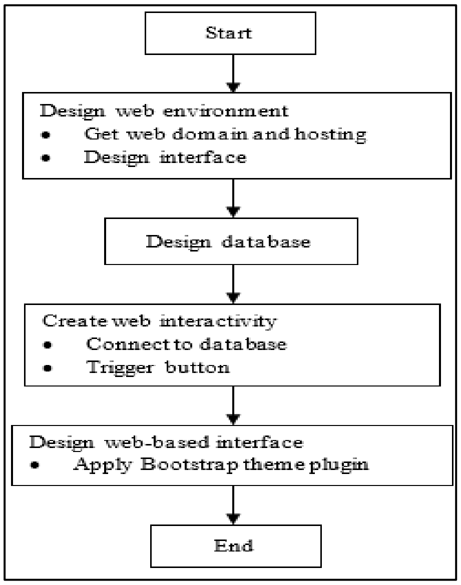

Fig. 5. Flow of the System Design Phase.

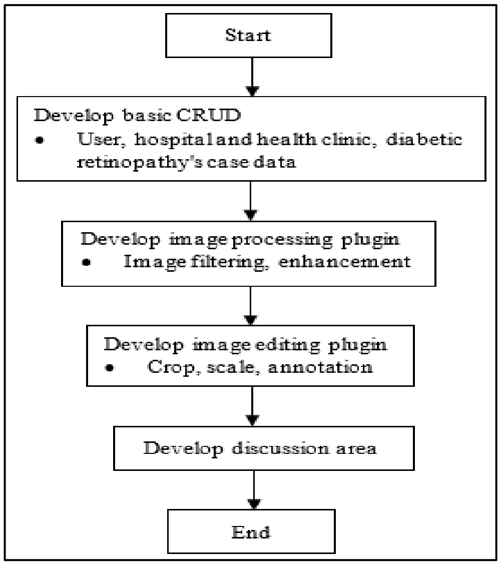
TABLE II. SUMMARY OF USER ACCESSIBILITY

Type of User	Accessibility
Admin	User and hospital/health clinic data
Specialist	DR case, discussion area
Primary Health Care	DR case, discussion area
Public	Information on DR and DR screening



Start
Develop basic CRUD
• User, hospital and health clinic, diabetic retinopathy's case data
Develop image processing plugin
• Image filtering, enhancement
Develop image editing plugin
• Crop, scale, annotation
Develop discussion area
End

Fig. 6. Flow of the System Development Phase.

1) Create, Read, Update, Delete: CRUD is the acronym for create, read, update, and delete which are the four basic types of functionality for constructing a web application. This system development includes inserting user, hospital or health clinic, and DR's case data. Create function will be called when new data need to be added into the database. The new entry is assigned a unique ID (identity document), which can be used to access the data later. Read or view function will view all the data currently exist in the database when it is called. The system will show the list of all the DR's data in a form as shown in Fig. 7. The update function will be called when no data need to be altered. Furthermore, the data will display all information from the selected row and users are able to edit data in each column at once. After the function is called, the corresponding data will be updated into new data. The delete function is also needed in this system to remove data that are no longer needed in the database.

The admin user is only allowed to handle user and hospital and health clinic details. In this system, only the admin can handle the registration of the new system user since the access and data are strictly confidential. Besides that, the admin is able to view the details of the users, such as username, password, email, full name, doctors' level, and workplace. As for hospital and health clinic details, the admin can add, view, edit and delete the details including the type of organization either hospitals or health clinics, name, address, region postcode, phone number, fax number, email, and status of the organization. Any changes in the details can be made by the admin only for security purposes. For instance, changes in phone and fax numbers can only be done by the admin of the system.

As for DR case form, primary health cares need to insert two fundus images from the right side and another two fundus images from the left side. Two views need to be captured for each side of the eye, which are macula center and optic disc center. These requirements for inserting fundus images area are based on the DR practice mentioned by the primary health cares during the preliminary study. Each DR case form includes the patient's detail consists of name, identification number, and age as shown in Fig. 7(a). It also has patient's eye details that include the Diabetes Mellitus (DM) Type, duration of DM, HbA1C, visual acuity, ocular complaint, provisional diagnosis, and types of co-morbids that are visualized in Fig. 7(b). Fig. 7(c) to Fig. 7(e) show the fundus image section required in the DR case form which needs to be uploaded by primary health cares containing both sides of fundus image uploading form and the date of the photo taken. In order to ensure the primary health cares insert the correct image format into the file form, the error function is created if the primary health cares inserted files other than the image file format listed such as .jpeg (or .jpg), .png or .tiff file format as shown in Fig. 7(c) and Fig. 7(d). This is to prevent primary health cares from inserting unnecessary file format such as .pdf, .gif or any other file formats.

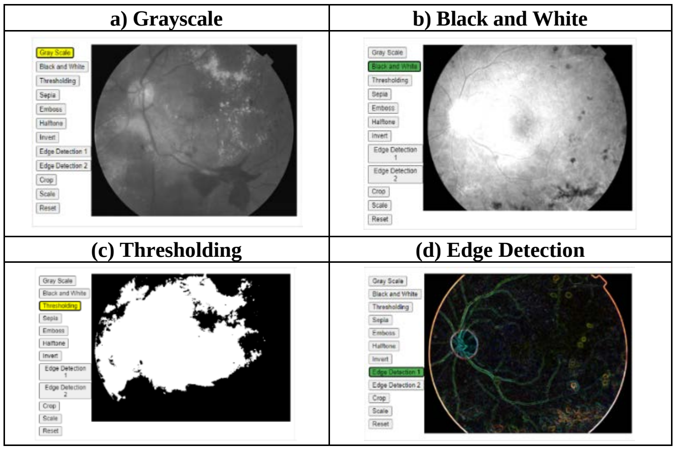
e) Date of fundus image taken

Date Photo Taken: : mm/dd/yyyy

Fig. 7. DR Case Form.

2) Image processing: Image processing performs some operations on an image to produce an enhanced image and is useful in extracting useful information from it. Image preprocessing techniques involved in the proposed work include color image conversion, contrast enhancement, filtering and segmentation among others. Current fundus images might not be so clear due to the noise during the image capture process. Therefore, this system includes image processing techniques which is important to help in processing the fundus image into a clearer version and able to help the primary health cares to detect the signs precisely. This plugin includes color image conversion such as grayscale, black and white as shown in Fig. 8(a) and Fig. 8(b), respectively. This plugin includes image filtering such as thresholding and edge detection as presented in Fig. 8(c) and Fig. 8(d). Thus, these image processing features help specialists view and locate the complex signs of DR such as microaneurysms and neovascularization.



a) Grayscale **b) Black and White** **(c) Thresholding** **(d) Edge Detection**

Fig. 8. Example of Image Processing Plugin.

3) Image editing: Image or photo editor plugin was implemented to support basic editing on the image uploaded such as adding text, crop, and scale. Fig. 9 shows an example of an image editing feature which is annotation of the eye image which could help the specialist to review or respond to the DR case submitted by the primary health cares effectively. This annotation feature is important to facilitate the specialist to label the signs of DR on the fundus image since the specialists are expert in detecting the critical signs of DR. Therefore, specialists are able to use any suitable tools of annotation listed in Table III by labelling or drawings on the fundus images that later can be viewed by the primary health cares. Several annotation styles were provided to the specialists to annotate the fundus image such as adding box, circle, adding text for notes, arrow, and draw. Each annotation tool is effective in labelling the signs of DR which ease the specialist to point out the critical signs for the primary health cares' view. At the same time, primary health cares are also able to see the label created by the specialist clearly. This annotation tool also provides the undo and redo button to erase the last change done to the fundus image.

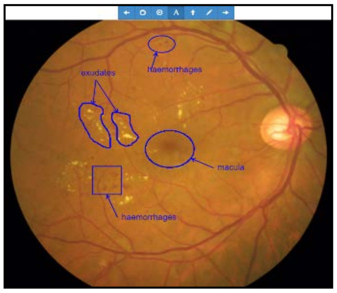


Fig. 9. Example of Applying Annotation Feature of Image Editing on the Fundus Images (Fundus Image Taken from the [4]).

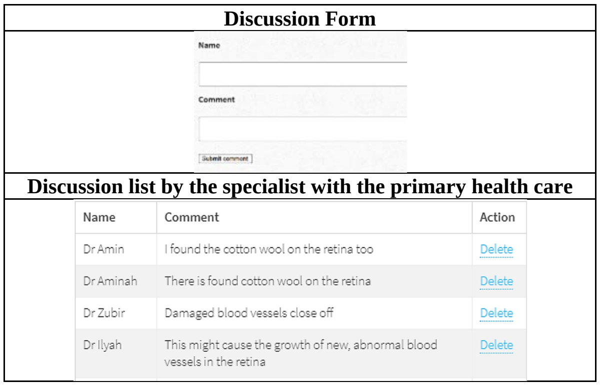
4) Forum: Based on the previous preliminary survey conducted, primary health cares mentioned that one-to-one conversation is a limitation in the current communication method. Therefore, developing a platform for discussion would be beneficial for primary health cares to share and learn by discussing with the specialist. In this system, the discussion area is mainly for the consultants and specialists to give their comments and verification to the data provided by the primary health cares in the DR case form. Fig. 10 shows an example of the discussion area of the case details where Fig. 10(a) is a form for the specialist or the primary health care to write the review and Fig. 10(b) is the listed review and comments done by the specialist.



Discussion Form

IV. RESULTS AND DISCUSSION

Alpha testing has been conducted to evaluate the usability of the system prototype. This testing was done by the consultants, specialists, and primary health cares from the Department of Ophthalmology, Hospital Melaka. The testing covers the functionality of the features available in the system. Table IV summarizes the alpha testing conducted. There are three different users in this system which are admin, specialist, and primary health care which give different perspectives for each user. Therefore, three different results are reported based on each type of user. Moreover, these results are important for this study to identify the effectiveness of the features for DR screening consultation. This section is divided into three types of user which are admin, specialist, and primary health care.

The first part of the questionnaire; demographic information of the respondents, aims to provide an overview of the general details of the respondents such as gender, age, level of work, current workplace, and years of work experience. These data are useful for strategic planning for consultation web-system. Based on the result summarized in Table V, the respondents are mostly female between 40 and 50 years old. The result also shows that the respondents are currently working in Hospital Melaka with more than 10 years of working experience in the medical sector.

A. Admin

1) Functionality of DRCS: The functionality of the system in the admin site covers the functions of CRUD in user, hospital, and health clinic details. The results of this functionality testing are detailed in Table XI. Based on the overall result for admin site, most of the respondents successfully used the functions in the system which are the basic CRUD functions for user details, hospital, and health clinic details.

TABLE IV. SUMMARY OF THE ALPHA TESTING CONDUCTED

Date/Duration	11/12/2020 (3 hours)
Type of survey	Online questionnaire via Google Forms
No. of respondents	10 respondents
No. of workplace	Hospital Melaka
Type of respondents	Consultant, Specialist, Primary Health Care
No. of survey parts	4 sections - Demographic - System Functionality - System Usability - Suggestion for Improvement

TABLE V. DEMOGRAPHIC

	Doctor's Level			***Total***
	Consultant	***Specialist***	***Primary Health Care***	
Gender • Male • Female	- 1 1	2 6 8	- 1 1	**2** **8** **10**
Age • Less than 20 years old • 20-30 years old • 30-40 years old • 40-50 years old • More than 50 years old	- - - - 1 1	- - 6 2 - 8	- - 1 - - 1	**0** **0** **7** **2** **1** **10**
Current Workplace • Hospital • Health Clinic	1 - 1	8 - 8	1 - 1	**10** **0** **10**
Working Years • Less than 3 year • 3-5 years • 6-8 years • 8-10 years • More than 10 years	- - - - 1 1	- - - 1 7 8	- - 1 - - 1	**0** **0** **1** **1** **8** **10**

2) Usability of DRCS: The usability of the system in admin site was evaluated based on how easy the system is used. From this section, respondents were able to find the design flaws in terms of error messages during the input of data, confirmation message before the data were deleted, and whether the functions applied in fundus images work as it supposed. Results of the system usability for admin are shown in Table VI. Overall, the results from this testing show that the respondents are satisfied and at ease with the design and performance of the system.

3) Suggestion for improvement: Based on the alpha testing with the doctors, the respondents suggested sending an auto-mail to the registered users including the username and password. They also suggested having a mobile-friendly view of the system for a compatible platform of the system.

B. Specialist

1) Functionality of DRCS: The functionality testing for the specialist site covers the functionality of the DR cases and image editing. Table VII shows the results of the testing. Based on the overall result for the specialist site, most of the respondents successfully use the functions in the system which are the DR cases view, functionality of the annotation tools, and image editing tools.

2) Usability of DRCS: In the specialist site, usability is evaluated based on the friendliness of the system to the users. The result of this usability testing is shown in Table VIII. Overall, the results from this testing show that most of the respondents agree with the friendliness of the system design except for information finding, where the result mostly shows disagreement due to the unavailability of the searching function.

3) Suggestion for improvement: Several suggestions were given by the respondents regarding the specialist site. For instance, it is suggested to provide a full scale for viewing the fundus image such as the zooming tool. Besides that, it is better to include the security function for patients and doctors' privacy. Regarding the case form of diabetic retinopathy, the respondents suggested a better arrangement of the data in the form containing the demographic information of the patients. For the discussion area, the respondents suggested that the specialist or primary health cares who are assigned to handle the case can only edit and delete the discussion. It is also suggested to disable the discussion area once the diabetic retinopathy case is completed to avoid any changes in the data.

C. Primary Health Care

1) Functionality of DRCS: In the Primary Health Care site, various parts are available in the system such as DR case details, fundus images processing, and discussion area for the primary health care, and specialist. This section provides the evaluation results on the functionality of the DR case details, fundus images, image processing, and image editing. Based on the overall result, most of the respondents have successfully used the functions, as presented in Table IX.

2) Usability of DRCS: The usability of the system for the primary health care's site was evaluated based on the easiness and efficiency of the system. Table X shows the result of the usability testing of the primary health care's site. Overall, the results from this testing show that the respondents mostly agree with the design and performance of the system, except for the information finding where respondents found it is difficult to search for the information of DR case or patients details when there are many DR cases listed in the system. This is due to the lack of searching feature in the system.

3) Suggestion for improvement: The alpha testing for primary health cares revealed that the respondents suggested more security for patients' details since the data are confidential. In addition, respondents suggested for the primary health cares' discussion area to be anonymous or semi-private.

V. DISCUSSION

In summary, a total of 10 respondents from Hospital Melaka have participated in the alpha testing of the system. The results of this testing enable a further review and evaluation of the functionality and usability of the developed system. Throughout the development of the system, it can be concluded that the system is able to overcome the problems and challenges of DR screening with the existence of the image processing and image editing plugins in the web-based environment. The image processing approach provides image filtering features and other image processing techniques which produce the image improvement and enhancement of several image characteristics or features for the next stage of processing. As for image editing, the annotation feature allows the primary health cares to draw or write on the fundus image, where the specialist is required to scribble some comments on the fundus image. Moreover, with the discussion area provided in the system, it allows the specialist to provide opinions and verify the content of the case details. This function also allows discussion and knowledge sharing of DR signs with other primary health cares through an online platform.

VI. CONCLUSION

The newly proposed system integrates image processing and image editing in a web-based method for DR screening. It improves the communication channel between the specialist and primary health cares. Furthermore, the proposed image processing and editing features reduce the burden in detecting the complex signs of DR in fundus image and create a sharing platform to discuss the DR cases among the users. This paper covers the analysis, design, development and testing phases of DRCS and place more details on the development part of the system. The project contributed to the medical and education fields. Furthermore, it sparks the users' awareness of computer technology that is useful through this application. The findings of this study will positively impact medical and education fields as it helps increase the efficiency among medical experts in treating eye diseases. This project would be a point of reference or benchmark for other eye disorders such as radiology, cornea, skin and hypertensive retinopathy.

ACKNOWLEDGMENT

This research is part of Master research currently being carried out at the Faculty of Information and Communication Technology, Universiti Teknik al Malaysia Melaka (UTeM) This research is fully funded by UTeM through Short Term High Impact Research Grant (PJP/2020/FTMK/HI17/S01715). We are grateful and would like to convey our sincerest gratitude to all primary health cares who have participated in the survey and testing phase.

***Abstract*—Internet of Things (IoT) is a leading technology which can interlink anything to Internet and makes everything to intelligent and smart. IoT is not just a single technology. IoT is a combination of various technologies like communication, data analytics, sensors and actuators, cloud computing, artificial intelligence, machine learning, etc. Applications of IoT are spread across various domains. IoT is most suitable for remote applications like underwater networks. One such application is oil spill detection in ocean. Oil spill in an ocean is a critical challenge that causes damages to marine ecosystem. Detection of oil spills in a real time manner helps to resolve the problem quickly to minimize the damage. IoT can be used to detect the oil spill by making use of sensors deployed at various locations of ocean. With a massive amount of sensors deployed and the huge amount of data associated with it, there remain concerns about the data management. Also amount of data generated in IoT based remote sensing network is usually enormous for the servers to process and many times data generated are redundant. Hence there is a need for designing a framework which addresses both aggregation of data and security related issues at various aggregation points. In this paper we are proposing a secure data transmission framework for detecting oil spill through IoT, which avoids redundant data transmission through data aggregation and ensures secure data transmission through authentication and light weight encryption.**

Keywords—Internet of things; wireless sensor networks; sensor nodes; data aggregation; authentication; light weight cryptography

I. INTRODUCTION

Internet of Things refers to connecting various things to the internet. IoT can be used in wide range of applications. IoT applications include remote applications also. Remote IoT applications include military applications such as surveillance, battle field monitoring etc. Underwater applications such as oil spill detection, analysis of aquatic animals lifecycle, etc. smart farming, forest applications such as fire monitoring etc.

The Application considered in this paper is oil spill detection. Oil spills are caused due to accidents in the ocean, leakage of oil, crude oil or gasoline pipelines. Oil spills are also caused due to negligence of offshore refineries or crude oil rigs. Irrespective of the cause of spill or slick, their effects are the same. Oil forms a separate film on the surface of water and stays there unless physically removed. The oil film causes harm to flora and fauna of the ocean. Detection of leakage in pipes or spillage of oil in accidents takes time and combating the pollution takes even longer time. The longer the film of oil stays on water surface, the greater is the damage caused to aquatic eco system. Due to the vastness of oceanic surface, application of Internet of Things to sense oil spills is a very practical technological solution. There are underwater robotic submarines available that can be used to deploy sensor nodes at specific locations. Buoyant nodes sense surface conditions and communicate observations to middle level nodes that in turn communicate to nodes on the bed. Levels of hierarchical node deployment allow us to implement intelligent communication of sensed data. Just knowing that oil spill has occurred is of little practical use. Instead if we also know the extent of damage, area of region polluted, some corrective combating tasks can be initialized.

Oil Spill detection is a remote IoT application, which uses resource constrained networks [22]. It includes deployment of many low cost, low power sensing nodes which has capabilities to sense, process and communicate the data. Each sensor nodes has limited transmission range, limited energy, limited processing capabilities and limited memory.

As Sensor nodes are resource constrained devices many nodes are deployed in shorter region. This leads to the sensing of redundant information. Transmitting redundant data will leads to the wastage of energy and other resources. Redundant data transmission can be controlled by data aggregation techniques. There are different data aggregation approaches: In-network data aggregation, Tree based data aggregation, cluster based data aggregation, Grid based data aggregation and hybrid data aggregation. There can be single level or multiple levels of data aggregation [21].

Along with data aggregation we need to consider the importance of secured data transmission. As Oil spill detection uses wireless communication, there remains concern about security. Fault alarm causes lot of damages as oil spill needs to be addressed in real time manner. There is need for simple and strong authentication scheme to identify the nodes identity. Also there is a need of light weight encryption algorithm to be used to secure the data transmission [19].

In this paper we are proposing a secure data transmission framework for oil spill detection applications which involves intelligent data aggregation technique and security mechanism. Proposed approach aggregates the data as well as provides intelligence to nodes to detect whether to send the data or not.

Also our present work add features to detect the boundary of oil spill which helps in identifying intensity of damage. In this paper we are adding simple ID based authentication mechanism to prove the nodes identity. We can use any of the existing lightweight cryptographic algorithm to secure the data communication.

The paper is organized as follows: Related work is given in Section 2, proposed approach is described in Section 3, Section 4 describes the simulation and results, conclusion is provided in Section 5.

II. Related Work

A lot of work has been carried out in detection of oil spills. Pangilinan et.al, have focused on determining the thickness of oil spill. Their hypothesis is that thicker the spill graver the effects of the pollution. They have determined the pixel intensity concerned with many competing parameters [1].

Reem Alattas has also worked on image analysis in oil spill detection. A threshold method is suggested to detect oil spill. SAR image processing is applied based on minimum cross-entropy with gamma distribution. A major drawback of the work is its intrinsic time lapse involved in data analysis. Oil spill like pollution must be combated as quickly as possible. Real time detection, if possible is most suitable for such problems. Additionally, the method proposed in [2] works with bi-modal images that have two classes of pixels only.

A.Gasul et.al [3] have proposed and tested a new method for SAR image analysis to detect oil spills. Their method works well with low resolution and distorted images as well. In spite of multi stages analysis algorithm implemented, ensuring error free end result is still difficult.

Kruti Vyas et.al in [4] have applied feature extraction of SAR images in oil spill detection. They have recognized three independent features for this purpose. They have performed a battery of experiments while considering types of images.

Mario Monteiro et.al, have made an extensive study of various aspects and challenges of detection of oil spills. Their work is particularly in connection with the seagull project. Their contribution is specifically in application of camera fitted unmanned aerial vehicles in combating water pollution. The author in [5] documents various challenges involved in detection of spills, with emphasis on time lapse between actual spill and its detection.

Unmanned surface vehicle is developed and analysed for performance in [6] by Deqing Liu et.al. Their work concentrates on frequent oil spills that happen at harbors, oil rigs and drilling platforms. They have designed a fluorosensor laser detector to achieve this aim. A feasibility analysis is also carried out by the authors.

Md. Shafi.K.T, et.al have developed a simple resonance based application to detect oil spill using planar microwave [7]. Proposed sensor is developed, deployed and tested in their work. The sensor designed is capable of detecting pollution beyond 5%.

There are different traditional data aggregation mechanisms, they are flat based [8][9][10] and hierarchical approaches.

In flat approach, the base station transmits a query requesting for a data from the sensing nodes within the area. The nodes which have relevant sensed information to the query sent will respond back. In this method base station performs excessive computations and communications. Because of this, if the base station fails, then network connection will be lost with the outer world.

Under hierarchical approach, many techniques have been proposed for energy efficiency and scalability. There are four types of hierarchical approach they are the cluster based data aggregation [11][12], tree based data aggregation [13], the grid based data aggregation [14]., and the chain based data aggregation [15][16].

These traditional data aggregation schemes will just combine the data from multiple sources and forward it to next node. In majority of applications normal data aggregation is not sufficient. We need to add some intelligence to the data aggregation and data transmission process within the limits of constrained resources.

J. Chen, S. Kher, and A. Somani, et al. proposed a scheme in [15] which involves Majority Voting. This approach is a data outlier detection method based on spatial correlation. Here if a reading of local sensor node is different from majority of its neighbouring nodes, then it will be classified as abnormal.

Y. Sun, H. Luo, and S. K. Das et al. proposed a scheme in [16]. Here according to the trustworthiness ranked by comparison with historical data and neighbour data, Weight will be assigned to every sensor data. Then weighted mean value will be calculated at the aggregator. This will be considered as the aggregated data.

S. Din, A. Ahmad, et al. proposed a scheme in [17], where the nodes closer to sink node performs direct communication and remains unclustered, the nodes which are one-hop away from the sink node perform multi-hop communication, and remains clustered.

Bo Yin et. al. in [18] specified a Tree based scheme which Involves construction of aggregation tree for complex queries. This ensures minimum communication cost.

S. Kumar and V. K. Chaurasiya et all in [20] proposes a scheme, where data Mining techniques are used to generate more accurate, consistent and useful information than that generated by any individual sensor node.

There exists different lightweight cryptographic techniques like AES [23], HEIGHT [24], PRESENT [25], DESLX [26], RSA [27] etc.

III. Proposed Work

A. Architectural Setup and Assumptions

Following are the assumptions made in deployment of nodes in the test bed.

1) Grid based deployment of nodes: to specifically determine location of each individual node. This assumption is safe and valid as, there is a commercially available underwater robot capable of deploying nodes at specific coordinates of latitude and longitude.

2) Number of nodes per grid is fixed: this assumption helps us compute statistically significant results after data collection are done and analysis is to be performed.

3) Node density is uniform: non-uniform node deployment does not allow implementation of intelligence.

4) Each node in a grid represents a single unit area: data collected is representative of a fixed area under surveillance.

5) 4 unit squares form a cell: helps in aggregation of data across levels of nodal deployment.

6) Every cell has a cell-sink node: this is an architectural requirement of WSN.

7) Four cells combine to form a level 2-cell: helps implement the second layer of intelligence and additional aggregation.

8) One of the unit cell's cell-sink also works as a sink for four adjacent level-2 cells: based on energy levels, s suitable cell-sink is elected as the sink of adjacent cells.

9) All level-2 cells combine to form the region under observation: highest level of aggregation implemented under our scheme.

*10)*Each node will communicate the observation only if the quantity observed is above a fixed threshold.

B. Node Deployment Phase and Network Establishment

1) Four different levels of nodes are deployed.

- Ground level sensor nodes: They are capable of sensing the oil density at the preliminary level and intensity of light.
- High power node at the ground level: They acts like grid head they can also sense the information.
- Anchor nodes at middle level: They act like second level grid head. They gather the data from multiple grids and transfer it to surface buoyant node.
- Surface buoyant node: They are at the surface level, they can sense the PH level of the water.

2) These nodes are deployed at the required locations using an underwater automatic vehicle (UWAV).

3) The area of interest is divided into equal sized grids. Ground level nodes and high power nodes are deployed at each grid. High power node will be the grid head of that particular grid.

4) Each High power node broadcast a beacon message to the ground level sensor node to indicate its presence in the grid.

5) Each ground level nodes respond back to their grid heads by sending the response beacon. Same Procedure is followed between grid heads and anchor nodes, Anchor nodes and surface buoyant nodes.

Fig. 1 shows the network architecture used in the proposed scheme.

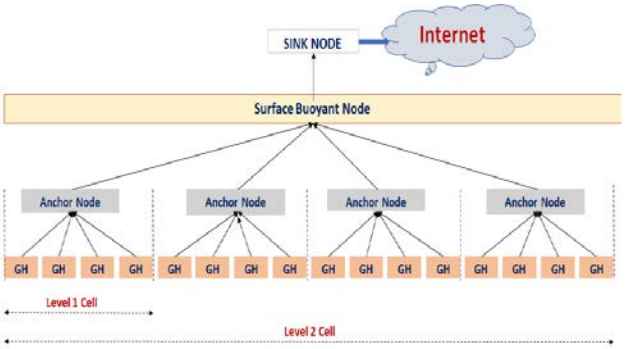

Fig. 1. Network Architecture.

C. Routing and Aggregation Phase

1) All the ground level sensor nodes sense the data and send the sensed data to its Grid head. Grid head aggregates the received data.

2) Grid Head adopts Spatial aggregation: based on the percentage of area generating similar readings. Each unit cell has a designated high power node acting as cell-sink. Communicate reading only if at least three out of four nodes report similar readings.

3) Grid Head sends data to Anchor node. Anchor node aggregates the data. Anchor node also adopts spatial Aggregation.

4) Anchor nodes send the aggregated data to surface buoyant node. Surface buoyant node aggregates and sends the data received as well as PH information to sink.

5) Surface buoyant node adopts Boundary value aggregation: region under observation has a sink node that acts as a data aggregator. Radial survey is made periodically at three lengths of radii- minimum, nominal and maximum. Minimum is close to the sink, maximum is distance from sink to boundary of region under observation, and nominal is an intermediate distance.

D. Boundary Detection

In the proposed system, a coordinate table is created. This table is a list data structure that stores coordinates of each node in the IOT infrastructure. Each entry consists of x, y and x coordinate values stored in an indexed linear linked list. An additional field stored data communicated from the sensor node.

Aggregation as well as intelligence is applied at middle level nodes and at bed nodes respectively. Boundary determination is implemented in the following steps:

1) Search the list of nodes and segregate nodes that have updated sensed data.

2) Perform a sequential search among the segregated nodes to determine nodes with maximum positive and negative coordinates of x, y and x.

3) Step 2 gives probable boundary nodes, compare their observed data with neighbor nodes to determine actual boundary nodes.

4) Communicate boundary coordinates.

5) Rate of spread is determined by calculating (a2-a1)/t, where a2 is the new area of oil spill after elapse of time unit t, a1 is the previously computed area of oil spread, i.e. before the elapse of time t.

E. Security

Assumptions

1) Grid Head, Anchor node, Surface buoyant nodes are considered as aggregator nodes.

2) Ground level sensor nodes are subordinate nodes for Grid heads, Grid heads are subordinate nodes for anchor node and anchor nodes are subordinate nodes for surface buoyant nodes.

3) Every ground level sensor node and other subordinate nodes maintains the following in its memory.

a) A pre shared Secret key shared with its aggregator node (Grid Head, Anchor node, Surface buoyant node).

b) A pre shared secret information (used for Authentication) shared with aggregator node.

4) Every aggregator node maintains the following in its memory.

a) Subordinate node ID.

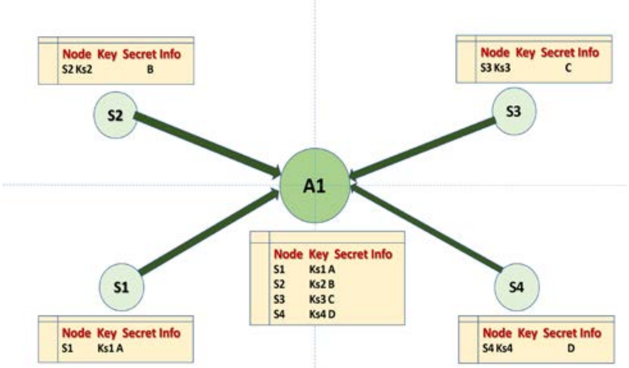
b) Pre Shared Secret Key for encryption and decryption.

c) Pre shared Secret Info for authentication.

Table I shows the Secret information repository format maintained by nodes. Fig. 2 shows the security architectural setup followed in the network.

TABLE I. SECRET INFORMATION REPOSITORY

Node ID	Key (Secret key shared with subordinate node)	Secret Info (Pre Shared Secret Information used for authentication)



Node	Key	Secret Info
S2	Ks2	B

Node	Key	Secret Info
S3	Ks3	C

Node	Key	Secret Info
S1	Ks1	A
S2	Ks2	B
S3	Ks3	C

IV. SIMULATION AND RESULTS

MATLAB is used as the simulation tool to check the efficiency of proposed work. Initially area of interest with dimensions 800m (length) x 800m (breadth) x 800m (depth) is considered. Then the volume under consideration is divided into equal sized grids of size 50m each at ground level. Table III shows the various parameters used in simulation. Fig. 5 depicts the 3 dimension test bed created through simulation and Fig. 6 shows Grid layout in 2 Dimension. Here blue color nodes represent nodes deployed at ground level. Red color nodes represent anchor nodes and the magenta color nodes indicate nodes that are buoyant on oceanic surface.

TABLE III. SIMULATION PARAMETERS

Parameter Type	Parameter Value
Area of application region	800 X 800 m^2
Sea Depth	800 m
Grid range	100 m
Number of Ground level node in each grid	4
Number of High power nodes in each grids	2
Number of Anchor node in each group of grids	1
Number of Surface buoyant nodes in each group of grids	1
Simulation Time	150sec
Payload length	512 Bytes

Initial Energy	14J
Transmission range	35m
Data rate	12kbps

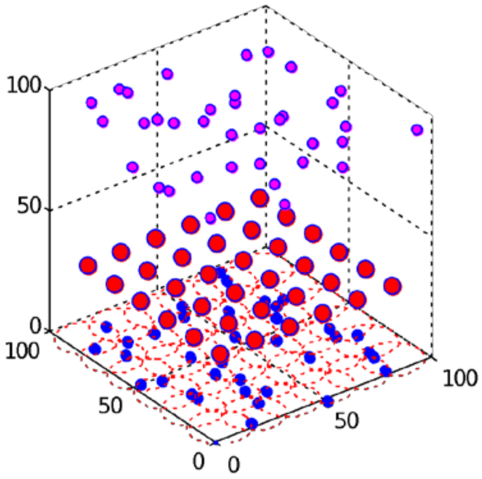

Fig. 5. 3-Dimension Test Bed.

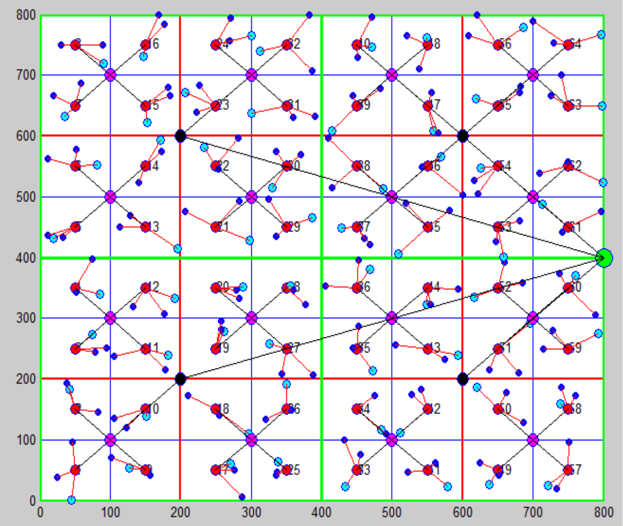

Fig. 6. Grid Layout.

Fig. 7 shows amount of time required to detect the oil spill versus the oil spread area. Time required to detect spills of larger area is evidently greater. From this we can analyse the spreading rate of oil in the water and intensity of oil leakage. As underwater communication is slower than normal environment redundant information transmission can be reduced to ensure the timely delivery of information and to avoid collision in the network Figure 8 helps us understand that the number of redundant transmission in various techniques compared with proposed work are much greater. Proposed method requires lesser number of packet transmissions compared to without aggregation deployment, in-network architecture and cluster based approach. It is clear that proposed work reduces redundant data transmission significantly.

The performance of various lightweight cryptographic techniques is shown in Table IV. Based on this suitable technique can be adopted [28].

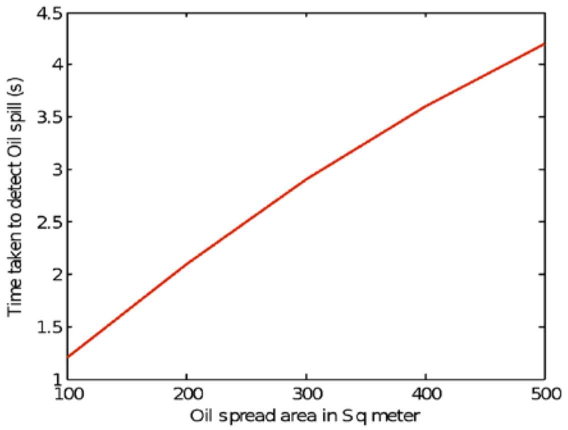

Fig. 7. Time Required for Detecting the Spreading of Oil Leakage.

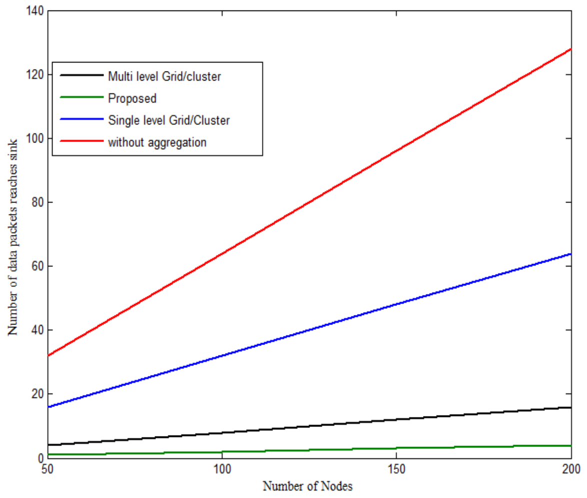

Fig. 8. Number of Redundant Transmission in Various Approaches.

TABLE IV. PERFORMANCE OF VARIOUS LIGHT WEIGHT CRYPTOGRAPHY TECHNIQUES

Light weight Cryptographic scheme	**Flash Memory (in Bytes)**	**Cycles (Encryption)**	**Cycles (Decryption)**
AES	3410	3766	4558
HEIGHT	5672	2449	2449
TEA	1140	6271	6299
DESL	3098	8365	7885

V. CONCLUSION

Adding intelligence to oil spill detection makes detection real-time and provides insight in to combating the pollution in the future. Collecting raw data triggered by an event gives minimal insight into crucial facts like thickness of oil film, expanse of oil spill and also reduces number of redundant transmissions. By detecting the boundary of oil spill we can easily predict the intensity of oil spread in the sea. This enables faster remedial actions. Also proposed methods eliminate the redundant data transmission through the spatial and boundary value aggregation. Proposed method secures the data transmission by adopting simple ID based authentication and existing light weight cryptography techniques. Adding intelligence to sensor nodes to make decision on oil spill can be considered for future enhancement.

***Abstract*—Aspect-based opinion mining is one among the thought-provoking research field which focuses on the extraction of vivacious aspects from opinionated texts and polarity value associated with these. The principal aim here is to identify user sentiments about specific features of a product or service rather than overall polarity. This fine-grained polarity identification about myriad aspects of an entity is highly beneficial for individuals or business organizations. Extricating these implicit or explicit aspects can be very challenging and this paper elaborates copious aspect extraction techniques, which is decisive for aspect-based sentiment analysis. This paper presents a novel idea of combining several approaches like Part of Speech tagging, dependency parsing, word embedding, and deep learning to enrich the aspect-based sentiment analysis specially designed for Twitter data. The results show that combining deep learning with traditional techniques can produce excellent results than lexicon-based methods.**

Keywords*—*Aspect-based sentiment analysis; dependency parsing; long short-term memory (LSTM); part of speech (POS) tagging; term frequency-inverse document frequency (TF-IDF)

I. Introduction

The past decade is undoubtedly dominated by data and its analytics. Now, anyone with an immense amount of data related to a domain and with the right tools to mine this colossal mountain of data is considered powerful. Surveys (either offline or online) are obsolete now as now more and more user is giving their opinions about myriad products and services on various social networking websites like Facebook, Instagram, LinkedIn, QQ, Telegram, Twitter, WhatsApp, WeChat, etc.[1]. All these social media platforms have been quite popular for exchanging opinions and sentiments and hence provide much-needed feedback about the specific products, services, vital events, organizations, or persons with the active participation of users. A lot of time, effort, and money has been put into analyzing user sentiments from a plethora of social sites especially Twitter due to the reason that tweets are limited to 140 characters[2]. This character limitation makes Twitter an easy and efficient tool for sentiment analysis, which can be pretty useful for organizations, who want to analyze related documents and make optimum changes to better suit their targeted customers. However, the sentiment analysis generally determines the overall opinion and hence may not be able to extract the precise essence needed to review that particular product or service.

This could be easily understood by the following example from a review about Cars: “Ford Mustang is awesome to drive, but the price is too high”. This particular sentence basically talks about two different features of the subject (Ford Mustang) here i.e., “Driving Comfort” and “Price”. Another notable point to comprehend is that a sentence may contain more than one aspect and the polarity of each aspect can be diverse. In the example shown above, “Driving comfort” is an undoubtedly positive polarity aspect while the “Price” aspect is declined more towards negative polarization. Hence to properly analyze the available data, a more detailed-level approach is needed, which is stated as the aspect-centered sentiment analysis. This methodology provides better insight for mining user opinions about the data under review. Overall, the sentiment analysis can be done at manifold stages that are document level, sentence phase, and aspect level[3]. Thus, in a nutshell, it can be stated that aspect-based sentiment analysis produces more fine-grained data analysis of user data.

In this research, an aspect-based sentiment mining problem is discussed on Twitter data and an efficient hybrid approach for the same has been proposed. The rest of this paper is organized as follows: Section II describes the numerous techniques used for aspect terms extraction. Section III gives an understanding of the projected framework. Section IV presents the outcomes of the proposed framework and evaluates them. Finally, Section V entails the conclusion and future work in the same direction.

II. Aspect Extraction Techniques

Sentiment analysis is usually defined as the computational study of a person’s opinions or emotions or views about a particular entity. Nevertheless, an entity has certain features associated with it, which must be considered with utmost precaution as these characteristics define opinions at the atomic level. Aspects can be briefly stated as the attributes or traits of a product or service [4]. An Aspect extraction is a primary process of identifying these significant attributes and a considerate argument here is that aspect extraction aiming at no particular aspect or target is of circumscribed usage [5]. Hence aspect extraction is the most imperative step for pulverized opinion mining. There are two sorts of aspects, namely: implicit and explicit aspects. The explicit aspects are mentioned overtly in the opinionated sentence whereas the implicit aspects are expressed indirectly and that is why more challenging to discover. For example: “Mustang is a classic car from Ford, renowned as being the muscle car”. In the above sentence, “Ford” as the “brand” of the car is an explicit aspect, while “muscle car” refers to the implicit aspect “performance”. The subsequent step to aspect extraction is finding the sentiment polarity of recognized features; like in the above example “brand” aspect is neutral and the “performance” aspect is positive.

Some of the key techniques employed for finding aspects are shown in Fig. 1.

1) Frequency-based approaches: Considered as the most traditional approach, it chiefly employees tracing out the most commonly occurring words. One such technique is Part-of-Speech (POS) tagging which basically finds out the classification of words based on the grammar within a text like a noun, pronoun, verb, adjective or adverb, etc. POS tagging is not only the simplified syntactically tagging taught in school education, but it also tries to find the relationship between the word under consideration and the adjacent words. Thus, POS tagging is not generic but depends upon the sentence to sentence and finally, it can be said that it tries to extract speech tags based on the sentence context. Also, an imperative point is that POS tagging does not actually do the Natural Language Processing (NLP), but it is the precondition to handle a lot of NLP tasks. The main characteristic of POS tagging is that it finds the recurrent noun and noun phrases from the reviews as they are usually the aspects [7]. POS tagging on a review is demonstrated in Fig. 2.

However, it must be understood that some of the aspects identified by this approach may not be the key aspects and must be rendered. Another frequency-based tactic is Pointwise Mutual Information (PMI), which is figured as the variance of the common information between the feature and the related word [8]. Last but not the least is Term Frequency-Inverse Document Frequency (TF-IDF) methodology which evaluates how significant a word is to a document in a group of the corpus by calculating two terms. The first term (TF) is the frequency of a word appearing in a document, divided by the overall words’ tally in that document. The second term (IDF) is computed as the logarithm of the whole documents in the corpus divided by the number of documents where the particular word appears [9]. In simple words, TF-IDF is the statistical tool that keenly discovers the most vital words in the articles. An important feature of TF-IDF is that some words seem noteworthy due to their huge frequency in the text, but actually, they are insignificant like the, this, that, etc. [8]. Hence, TF-IDF can be described as the amalgamation of two algorithms that diminishes the weight of stopwords and recognizes the high opinionated words, which actually influence the sentiments contained in the documents.

2) Relation-based approaches: These techniques are based on discovering relations between features and the opinion words to identify aspects clearly. One such approach is Dependency Parsing – which is based on extracting the grammatical (or syntactic) structure of a sentence and finding the relation between vital words and the words which modify these vital words [10]. The second practice is called Double Propagation, which disseminates information among opinion words and targets back and forth. This method comes under the semi-supervised category as it takes opinion word as the seed to start the process [11].

3) Supervised machine learning: The two most prominent aspect mining techniques Hidden Markov Model (HMM) and Conditional Random Fields (CRF) come under this category. HMM are a set of probabilistic visualization model that allows forecasting a sequence of hidden variables from a set of perceived variables. It is a great approach for tracing the aspects like it may predict the type of weather by observing the type of clothes worn by a person [12], as depicted in Fig. 3.

On the other hand, CRF is a discriminative model employed for predicting sequences where multiple variables are dependent on each other by imputing contextual information from previous labels [14]. Its main applications are in POS tagging and Named Entity Recognition (NER).

```

Fig. 2. POS Tagging Output.

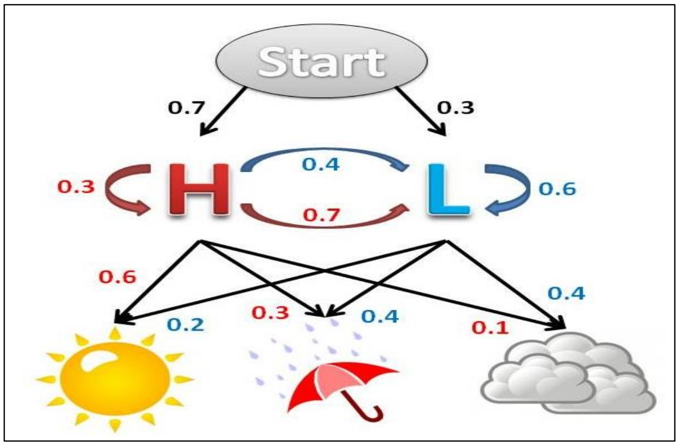

Fig. 3. Working of Hidden Markov Model [13].

4) Topic modeling: As the name suggests, it is a category of techniques used to automatically detect topics present in the text corpus. It comes under unsupervised learning for observing topics (a group of words) in a colossal amount of text clusters. Latent Dirichlet Allocation (LDA) is used to categorize text in a document to a certain topic by using Bag-of-Word (BOW) approach[15]. The prime objective of LDA is to match all the documents to the topics such that words in every document are customarily classified by those imagined topics. The next approach is Joint Sentiment Topic (JST) is the exquisite unsupervised technique that detects sentiments as well as the topics simultaneously from the text corpora by considering their mutual relations[16]. The next methodology categorized under topic modeling is the Aspect and Sentiment Unification (ASUM) model which automatically determines aspects and different sentiments towards these recognized aspects in one go. This model ascertains aspect-sentiment pair called 'senti-aspects' in an unsupervised way, explaining how much a particular word is related to aspect and sentiment [17].

III. Proposed Framework

The focal emphasis is to conduct an exploration of aspect-based sentiment analysis conducted on Twitter data. The planned work consists of the following steps:

1) Data collection from Twitter.

2) Data pre-processing and preparation.

3) Aspect extraction from the data.

4) Aspect selection & polarity detection.

5) Tweet level Sentiment classification & Performance evaluation.

The first and foremost step is collecting data from Twitter, which is a social media networking site. There are numerous ways to extract data from Twitter; among which the most popular one is Twitter API Search, which allows us to retrieve the latest tweets about any topic. For doing so, a Twitter development account must be created first. Earlier, this method had a limitation on the number of tweets and also on the number of requests received per hour from a particular IP address [18].

After the data collection process from Twitter, the next work is to prepare the data for analysis and this process involves cleaning and pre-processing of data. The data from Twitter is not in a particular format and it must be cleansed beforehand like removing the links, emoticons without clear sentiment, new lines, hashtags and symbols like @, punctuation marks, etc. For effective aspect discovery, tweets, users who tweeted them, followers of users, count of retweets, date of the tweet, etc. are chosen from the whole data. After data collection and pruning, the next step is to pre-process it. The data pre-processing starts with the removal of stopwords i.e. removing the commonly occurring words like a, an, the, and, or, is, etc. as these words do not convey meaningful opinions. Then, all the words in the corpus are changed to lowercase for enhanced understanding and investigation. Afterward, the corpus is subjected to stemming and lemmatization i.e., words are reduced to their basic or root form. It is a highly recommended part because it reduces derivationally related forms of a word. For example: "programmable" is changed to "program" and "running" is converted to "run". One example of text before and after pre-processing is shown in Fig. 4.

Fig. 4. The Output obtained after Applying Pre-processing on Data.

Now, the data is ready for opinion mining and the foremost thing to do is finding aspects in these tweets. It can also be done in myriad ways as discussed in the above section. The aspect-extraction followed here is a hybrid one as multiple methodologies are combined for doing so including POS tagging, Dependency, etc. POS tagging is used to find the frequent nouns and noun phrases which tend to be the explicit aspects, while depending on parsing is brilliant for finding the implicit tags. For bigrams and trigrams, tokens are identified by checking words on the left side for 'proper Nouns' identified earlier. If the dependency is a compound or adjective modifier, then it is regarded as the aspect term. If the token is an 'adjective' or 'verb', the words on both sides (left and right) are examined for adverbial modifiers, open-clausal components, and 'auxiliary' dependencies and if it happens, they are regarded as aspect terms. For negation modification, words to the left of verbs and words on both left and right are diagnosed for adjectives and auxiliaries and in this case, the polarity of aspect is changed. Thus an ensemble of techniques is employed here to give the best output and providing every key aspect from the text corpora obtained after data preprocessing. The aspects can be ranked in decreasing order of frequency and selected on this basis. The next phase is detecting the polarity of each aspect and there are three types of polarities: positive, negative, and neutral. Positive polarity refers to the constructive and affirmative comments about the aspect under consideration while negative polarity denotes the adverse and undesirable user views regarding that precise aspect and if the opinions do not fall under any of the above categories, it is considered as neutral polarity. Also, an imperative deliberation is that if an aspect has an equal number of positive and negative opinions, then it can be ignored. The algorithm for aspect-terms extraction can be described as the following:

1) Apply Tokenization first.

2) Prepare a list of stopwords, so that aspects, if identified on the stopword list, can be ignored.

3) Apply POS tagging for finding aspects.

4) The prime candidates for aspects are 'Nouns' or 'Proper Nouns' individually or in pair with Verbs/ Adverbs or Adjectives (explicit aspects).

5) For finding implicit aspects, dependency parsing is employed, along with bigrams and trigrams:

a) For a noun, check its dependency on its L.H.S. and if it is found to be 'compound', with an adjective or adjective modifier, then it should be an aspect-term.

b) For an adjective, check its dependency parsing on both L.H.S & R.H.S., if its dependency is auxiliary on L.H.S and 'negation modifier' on R.H.S, then is also identified as an aspect-term.

c) For a verb, if an adjective appears to its left or right and their dependency is 'adverbial modifier', then also it should be an aspect. Also, if an adjective appears on its L.H.S and dependency relation is negation modifier, the aspect is recognized.

Finally, the tweet level sentiments are analyzed using Vader Sentiment and Recurrent Neural Networks, and the results determined are verified in regard to state-of-art technologies. The overall process can be described by the Fig. 5 underneath.

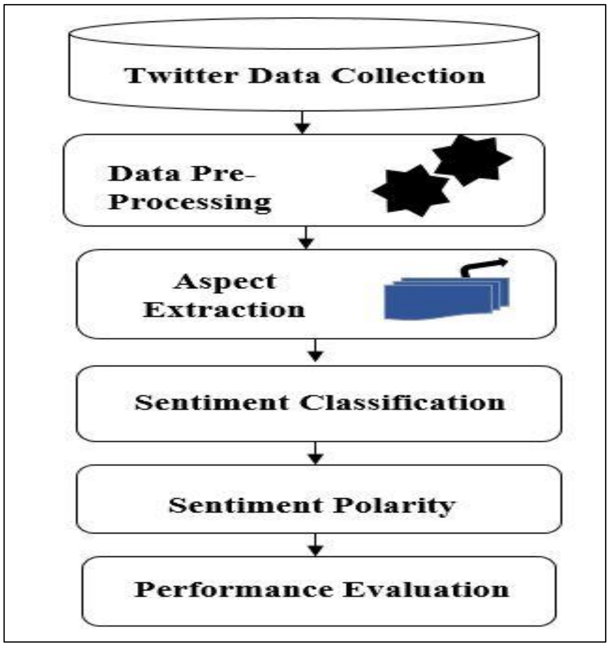

Fig. 5. Aspect-Based Sentiment Analysis Process.

IV. Results and Evaluation

The ensemble methodology for aspect-based sentiment analysis is a novel approach that does excellent work for up to 49493 tweets data corpus. However, more data means more training and better results. The new algorithm is also employed on 'Scraped_Car_Review_ford.csv', which can be downloaded from Kaggle for verification. This dataset has 49493 reviews about ford cars. Fig. 6 shows the first five tweets downloaded from the Twitter site.

The above image Fig. 7 shows the comparison between tweet frequency and the number of followers for verified Twitter users. The data downloaded from Twitter is pre-processed as discussed in the above section and sample output is shown in Fig. 4 above. After pre-processing of data including tokenization and stemming, POS tagging is applied. After obtaining POS tags for each token, some special words with peculiar tags are selected and these are Nouns, Noun Phrases (like NNP, NNS & NNPS), Adjectives, and Adverbs because these tags are extremely helpful while identifying aspects.

The wordcloud is primarily an innovative tool that generates an aesthetic amalgamation of frequently occurring words. It puts together recurrent textual data into a beguiling visual representation and shows them in bigger and bolder fonts according to their frequency [19]. Fig. 8 shows the potential aspects identified by POS tagging and frequency distribution:

Fig. 9 demonstrates the top 20 frequent words occurring in the tweets according to their frequencies arranged in descending order.

While Noun and Noun phrases are the potential aspects, adjectives and adverbs support their claim when the dependency is checked between them. This is identified by applying dependency parsing between them, as illustrated below in Fig. 10.

After all the aspects are extracted, their polarity needs to be checked and for that Sentiwordnet can be used to check the opinion sentiment for all the mined aspects according to the tweets they are appearing in. Finally, the overall sentiment classification can be calculated using Vader Sentiment, which is a proficient tool for mining the sentiments. Fig. 11 shows the overall sentiment distribution of the downloaded tweets.

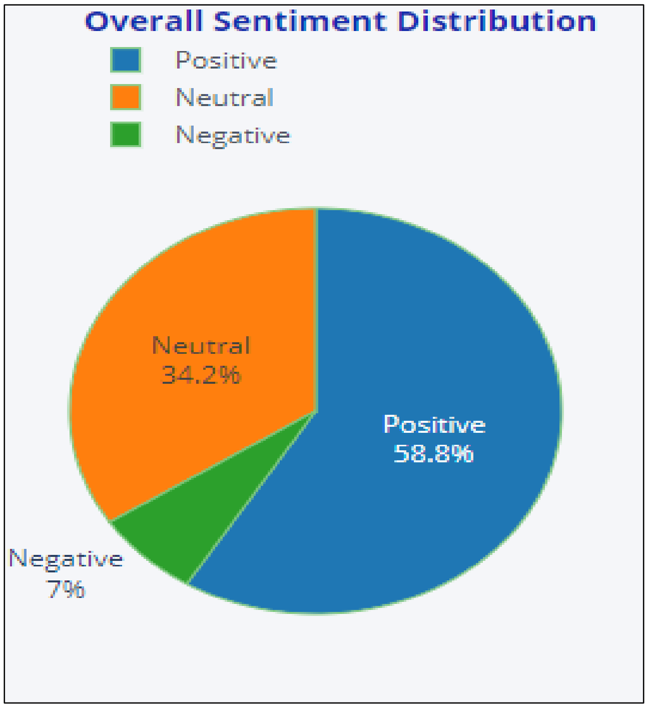

Fig. 11. Overall Sentiment Distribution.

An alternate sentiment categorization can be done using deep neural networks with the aid of TensorFlow and Keras. The model proposed in this paper is quite simple and contains three layers: embedding layer, a layer with LSTM functionality, and last but not least an output layer. The embedding layer will learn word embeddings for each, and every word contained in the corpus through pre-trained word embeddings provided by Google's word2vec. The second layer is of Long Short-Term Memory Networks (LSTM), which is an exceptional branch of Recurrent Neural Networks that are skilled in finding and learning relationships between features of an input sequence. An LSTM layer with 100 memory units is engaged in the model. Lastly, the dense layer provides uses a sigmoid activation function as it needs to classify the polarity of a tweet as either positive or negative. The summary of LSTM model used in this study is displayed in the Fig. 12.

The model once built, must be tested for accuracy to check if it is doing the intended work with efficacy or not. Table I lists the results of the proposed model, primarily the model score and its accuracy on the train and test data.

The validation loss and validation accuracy can also be identified for checking the model's performance. As evident from the Fig. 13, the model gave the best output till 5 epochs and then its performance decreases abruptly till 15 epochs. Hence, the epochs can be decreased to give a superior result.

As apparent from Fig. 14 beneath, the validation loss is quite high and hence the model overfits.

To conclude, the proposed model is evaluated for train and test data. The model shows 82% accuracy for training data but 99% for test data, which shows overfitting of the model.

V. Conclusion and Future Work

The opinion mining of user reviews about a specific product or service has been under the researcher's hammer for quite a long time now. Most of the work revolves around finding sentence-level sentiment analysis, which gives a bigger but not so clear picture of user's opinions. Hence a fine-grained approach that focuses more on the aspect-level sentiment classification is needed. This paper proposes an ensemble aspect extraction methodology based on POS tagging, dependency parsing, and dense neural networks which yields better outputs for sentiment analysis instead of using solo traditional methods. This research will be valuable for the individuals or commercial entities that may employ it for fine graining the existing users' opinion about specific features of their product or service and also targeting the potential customers. On the flip side, the model overfits the Twitter dataset under consideration. The future work of this research will be manifold.

Firstly, some parameters of the model must be modified to avoid overfitting. Secondly, several machine learning and deep learning classifiers can be employed for enhanced sentiment analysis. Finally, the most important prospect will be deploying it for more human languages like French, Spanish, Hindi or Tamil, etc.

***Abstract*—Recently, image encryption has taken an importance especially after the dramatic evolution of the internet and network communication. The importance of securing the images contents is due to the simplicity of capturing and transferring of digital images in various communication media. Although there are many approaches for image encryptions, chaos-based image encryption approach is considered one of the most appropriate approaches because of its simplicity, security, and sensitivity to the input parameter. This research paper presents a new technique for encrypting RGB image components using nonlinear chaotic function and DNA sequence. A new image with the same dimensions of the plain-image is used as a key for confusions and diffusion process for each RGB components of plain-image. Experimental results show the efficiency of the proposed technique, simplicity, and high level of resistant against several cryptanalyst.**

Keywords—Chaos-based; image encryption; confusion; diffusion; color image; RGB components; DNA sequence

I. Introduction

Images are the most common and popular multimedia data type now a days, due to the simple and easy way of capturing and transmitting [1]. The demand to transfer these images in a secure manner has also increased, and encryption is the preferred method to securely transfer image data. In addition, there are several drawbacks and weakness such as the requirement for powerful computing system and highly computational time, thus the implementation of these techniques cause low level of efficiency and it cannot guarantee data confidentiality and security [2]. Encrypting images that are sent over various communications channels has become one of the most important processes of most of the current applications and fields, such as military, educational, medical, industrial and social media [3], [4]. Image encryption can be defined as the use of set of process called algorithm to convert the plain image into a ciphered image in such a way that no one can recover it except for the sender and the intended recipient [2] [5]. A numerous image encryption techniques have been proposed, one of the most efficient techniques is the Chaos-based encryption [6]. Chaos-based encryption methods first introduced by Fridrich [7], [8], these methods are popular due to their randomness, unpredictability, sensitivity and topological transitivity. Fridrich suggested two processes for chaos-based image encryption: confusion and diffusion. The most important stages in image encryption is confusion which is considered about pixels position in plain image. Many efforts tried to kill the pixels neighbors' dependence by exchange the positions under certain condition to maintain the correlation of the pixels and the predictive of new pixels position [9]. We list in this section some of the related works starting with Choi et al. who proposed a framework by the using addition, rotation and XOR to achieve confusion and diffusion for the plain image. In the proposed framework the confusion-diffusion process is done by implement the rotation and XOR operation with chaotic sequences which are generated by the using of two logistic maps [10]. Another study by Bashir et al. proposed image encryption framework, this framework a 4-D chaotic image encryption technique based on a mechanism of dynamic state variables to increase the security and effectiveness of the chaos-based image encryption methods [11]. Kulsoom et al. proposed algorithm that is based on stream cryptography and it use DNA complementary rules in addition to one dimensional chaotic maps [12]. Kar et al. proposed bit-plane image encryption method chaotic, cubic, and quadratic maps. The proposed method is based on permutation, diffusion, and pixel randomization process, at first the proposed method generates chaotic two sequences by the using of the quadratic and the cubic map, then the generated two sequences will be used to shuffle the plain image. the shuffled image will decomposed into its bit-plain components to be encrypted later by the using of confusion and diffusion process [13]. Gu et al. proposed encryption algorithm for JPEG2000 images. The method suggested the use of bitwise XOR and cyclic rotation operation for 2-byte block encryption process also the repeating of encryption process is adopted to avoid an unwanted encryption marker code. The repeating of encryption process can neglect unnecessary computations [14]. Enayatifar et al. proposed a method for image encryption that is based on chaotic map and deoxyribonucleic acid (DNA). The process is started by convert two dimensional plain image into one dimensional array, then the process of pixel permutation is implemented by the using of chaotic map and deoxyribonucleic acid (DNA) while the diffusion is implemented by the using of DNA sequence and DNA operator both of permutation and diffusion of image pixels are done at the same time to reduce the sending time [15]. The remaining part of this article is structured as it follows: Section 2 introduces the background of image cryptography;

This project was funded by the Deanship of Scientific Research (DSR) under grant no. G- 526-611-1431.

The authors, therefore, acknowledge with thanks to DSR's technical and financial support representations Methodology

Section 3 introduces the proposed image encryption scheme with the key space. Section 4 describes the experimental results. Section 5 introduces the security resistance and the ultra key space of the proposed encryption scheme. Lastly, Section 6 draws the conclusion and future work.

II. Image Cryptography

Image encryption like the encryption of any other kind of digital data, it goes through the encryption process using specific encryption algorithm and a key [1]. Steganography is one of the encryptions methods that have been used in image cryptography in the last two (2) decades and in particular on watermarking [16]. The classical image encryption such as Data Encryption Standard (DES), RSA, and ADS are designed with good confusion and diffusion [17], but it has the weakness of low-level of efficiency because of the huge size and noticeable redundancy of image data [3],[18]. Due to the big size of image data, the implementation of images cryptosystems is carried out in spatial domain, frequency domain or hybrid domains of the plain images. Each of these domains has its own methodology. For example, in spatial domain, the pixel value and location in plain image can be directly encrypted using the general encryption function as shown in Equation 1.

$$E(x,y) = f[I(x,y)] \qquad (1)$$

Where *E(x,y)* is the output encrypted pixel C_i in the ciphered image, *I(x,y)* is the input plain pixel P_i in the plain image, and *f* is the encryption function. In frequency domain, image is analyzed mathematically to series of frequencies, each of these frequencies has two main components which are the amplitude and the phase shift [1]. Any changes in spatial domain image produce indirect change on its frequency domain representation. The information of frequency domain divided into two main components, and these components are high frequency components which represent sharp edges and noise of the plain image while the low frequency component corresponds to the smooth area [1]. In our proposed encryption scheme, we concentrate on spatial domain, frequency domain is out of the scope of our work. Classical and modern ciphers algorithms have all been developed for the simplest form of multimedia data. Chaos-based image encryption scheme is one of the encryption algorithms that works on spatial domain and that have suggested an efficient way to deal with fast and highly secure image encryption [18]. Encrypting images, using chaos-based image encryption scheme, considers the image as 2-dimensional array of pixels [5].

III. Proposed Image Encryption Scheme

The proposed image encryption algorithm in this research work is based on chaos-based image encryption scheme that has been proposed first by Fridrich [7], [8]. The scheme of the chaos-based image encryption is depicted in Fig. 1, as it is shown in Fig. 1 the plain image goes through two processes, namely, confusion process and diffusion process. At each stage there is a key input which is a single value starts with a seed value (easy to be predicted by cryptanalyst) and from this value the confusion key and key diffusion are created. In contrast, our proposed scheme follows Fridrich's scheme except the chosen key, in our proposed scheme the key is considered as another image (or on another say, a matrix of random values) with the same dimension (or bigger) the plain image.

The operations needed in encryption processes are confusion and diffusions as in. Both confusion and diffusion processes will be executed only one time for the purpose of reducing the computational time with the grantee of high level of security. Fig. 2 shows the general framework diagram of the proposed chaotic encryption algorithm. Stage (1), the plain-image and key image are gone through preparation process. The preparation process is responsible for analyse the chosen plain image and key image before passing them to the confusion process. The first check will be the size of plain image and key image, the key image should be equal or greater than the plain image, otherwise the process will fail. The second check will look for the plain image and key image, if they are in 8-bit grayscale the process will run and will deal with the images directly, while in 24-bits RGB images a new mechanism to extract the images (plain and key) RGB channels should be implemented to deal with each channel separately.

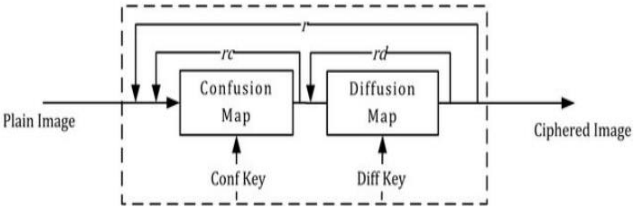

Fig. 1. Fridrich Image Encryption Scheme [8].

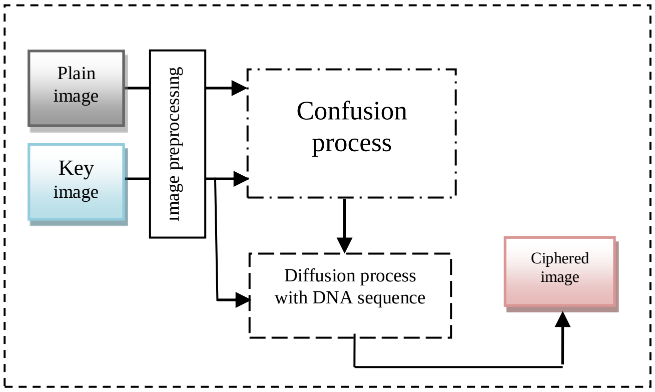

Fig. 2. Proposed Framework of Image Encryption Scheme.

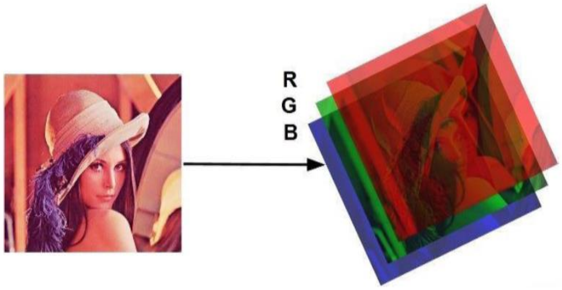

Fig. 3. 24-bit RGB Image Channels Extractions.

The extraction of the RGB channels of the plain and key images will store each image channel in a single 8-bits matrix with dimension equal to the dimension of the original image. Fig. 3 illustrate the extraction process that produces three channels image for plain and key image and each of these channels is 8-bit image. In the next subsections each process will be explained in detail.

A. Confusion Process

Confusion process goes through two processes, the RGB channels extraction (of both the plain image and the key image) and the confusion function that will be applied to each corresponding pixel in plain and key image as shown in Fig. 4. In confusion process, firstly, the chosen key image should be larger or of the same size of the plain image. Secondly, the confusion function which can be defined as any arithmetic, geometric, or bitwise function that will be performed on the corresponding pixels in RGB channels of the plain and key image as shown in Fig. 4. The chosen function should be strictly monotonically function (reversible function) [19], i.e., the encrypted pixel can be recovered back in the decryption process. For clarity, let RGB channels of the plain image represented by P_R, P_G, and P_B respectively. And for the key image, the RGB channels represented by K_R, K_G, and K_B respectively. For a plain image and key image with $n\,x\,m$ dimension, there are $n\,x\,m$ pixels, for simplicity we assume $n = m$, therefore number of pixels are n^2. In the confusion process, as explained previously, the corresponding pixels in plain and key images are operated by the confusion function (f) and result (an intermediate) new RGB channels with the same dimension of the original plain image.

Let us name these new channels as C_R, C_G, and C_B. The equations 2, 3, and 4 illustrate the operations for getting these channels (ciphered RGB), such that i and j are the indexes of the pixels and it ranges form $0 < i < n$ and $0 < j < n$. The function (*f*) is considered a bitwise XOR binary function in this study.

$$C_R(i,j) = f(P_R(i,j), K_R(i,j)) \quad (2)$$

$$C_G(i,j) = f(P_G(i,j), K_G(i,j)) \quad (3)$$

$$C_B(i,j) = f(P_B(i,j), K_B(i,j)) \quad (4)$$

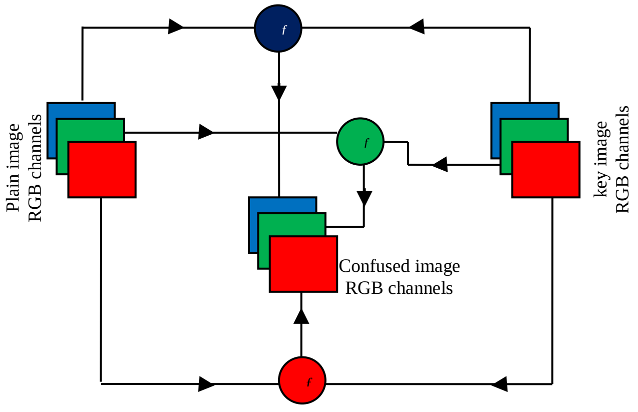

Fig. 4. Confusion Process for 24-Bit RGB Channels.

Confusion process is responsible for reducing the correlation between adjacent pixels by dissolving the pixels [9]. The method for dissolve this correlation is by applying confusion function of pixels in plain image and key image [3]. The output of this process is the RGB channels that will be input into the diffusion process.

B. Diffusion Process with DNA Sequence

Diffusion process starts at the end of confusion process and the output of confusion process will be the input of diffusion process. In this operation the output of confusion process will be encoded using DNA sequence computing as it will be explained in this section. DNA computing becomes important in many fields of research in the last four decades, in this research paper we employ DNA computing for the diffusion process. DNA sequence can be encoded and stored as a binary code of four pairs of two bits. The four chemical bases Adenine, Cytosine, Guanine, and Thymine are pair up with each other, A with T and C with G, each base-pair are the complement of each other. If we assume the binary coding of A is 00 therefore the binary coding of T is 11, and if the binary coding of C is 01 therefore the binary coding of G is 10. Therefore, for each pixel in the RGB channels (which come from confusion process) a new coding can be applied, for example, the pixel with binary 00101101 can be encoded using DNA sequence as AGTC as done in some related works [17], [20], [21]. The key image also will be encoded using the DNA sequence. The RGB channels which are the output of the confusion process will be operated with the RGB channels of the original key image using the logical addition and subtraction of the chemical bases as shown in Table I. The logical addition in this research work is employed for encryption process, the reverse operation which is the subtraction operation is employed in the decryption operation with the rules shown in in Table II.

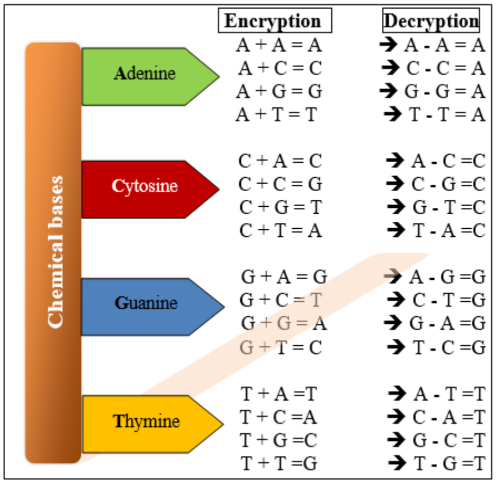
As shown in Table II below the subtraction operation is reverse function of the addition function, therefore using one logical operation for encryption process enforces us to use the other operation for decryption.

TABLE I. DNA LOGICAL ADDITION OPERATION

+	A	C	G	T
A	A	C	G	T
C	C	G	T	A
G	G	T	A	C
T	T	A	C	G

TABLE II. DNA LOGICAL SUBTRACTION OPERATION

-	A	C	G	T
A	A	T	G	C
C	C	A	T	G
G	G	C	A	T
T	T	G	C	A



Chemical bases	Encryption	Decryption
Adenine	A + A = A A + C = C A + G = G A + T = T	➔ A - A = A ➔ C - C = A ➔ G - G = A ➔ T - T = A
Cytosine	C + A = C C + C = G C + G = T C + T = A	➔ A - C =C ➔ C - G =C ➔ G - T =C ➔ T - A =C
Guanine	G + A = G G + C = T G + G = A G + T = C	➔ A - G =G ➔ C - T =G ➔ G - A =G ➔ T - C =G
Thymine	T + A =T T + C =A T + G =C T + T =G	➔ A - T =T ➔ C - A =T ➔ G - C =T ➔ T - G =T

Fig. 5. The Encryption and Decryption of the Chemical bases **A**denine, **C**ytosine, **G**uanine, and **T**hymine using Logical Addtion and Subtraction Operations.

he four chemical bases for DNA sequence that are using in the diffusion are operated using logical addition for encryption and logical subtraction for decryption. Fig. 5 depicts the 16 possible scenarios for additions and the 16 possible scenarios for subtractions [15].

Finally, the Encryption and Decryption techniques are reverse to each other, therefore the last operation in encryption will be the first operation in decryption.

IV. Result Analysis

In this section, the detailed results to verify the efficiency, robustness, and high level of security of the proposed encryption scheme are outlined. A standard Lena image with 256 x 256 gray scale and a key image of the same size was used to verify the proposed methods performance as shown in Fig. 6. The experiment has been performed using visual studio package and implemented in windows environment. The first step the key image in Fig. 6(b) is prepared using the same proposed encryption scheme, second step2, the prepared key image together with the plain image (Lena image) in Fig. 6(a) are input to the encryption process, the result ciphered image is shown in Fig. 6(c). The Lena image is loaded to the encryption software, the key image is prepared using the same encryption algorithm to add more noise to the key image (any image can be used as a key without encrypt it) and to improve the encryption of the original image and the pixels distributions of the encrypted image that returns noisy images as shown in Fig. 6(c). These aspects indicate high level of security against the attacks.

The second experiment has been performed for Firise's image (293x203) as shown in Fig. 7. The chosen encrypted key image is in the same dimension (293x203) as the plain image. The same experiment with this image is performed in the previous studies with the contradiction that in our study we have less computation time and high performance. The same process for encrypting Lena image is applied for Firise image, whereas Fig. 7(a) represent the plain image, Fig. 7(b) represents the encrypted key-image, and Fig. 7(c) represents the encrypted (ciphered) image.

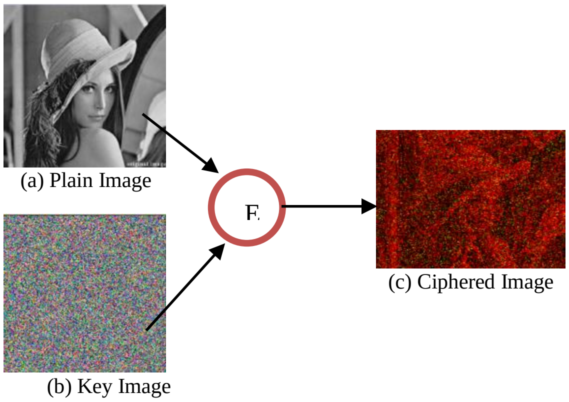


Fig. 6. Encryption Process for Lena Image (225x227), (a) Plian Image, (b) key Image, (c) the Encrypted Image.

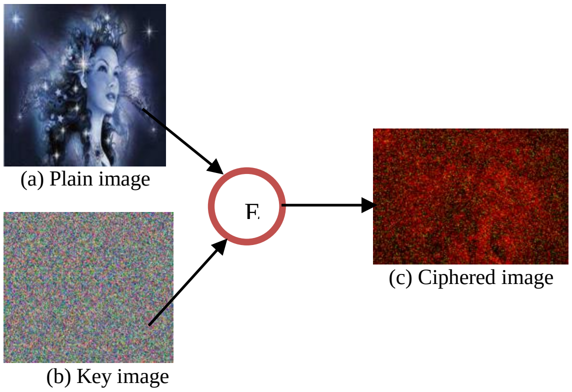

Fig. 7. Encryption Process for Firise Image (293x203), (a) Plian Image, (b) Key Image, (c) the Encrypteds Image.

The same methodology for image encryption using chaos-based approach has been conducted in our previous work [3]. Fig. 8 shows some of the experiments for encryption and decryption process for Lena image with 225x227 gray scale. The encryption process shown in Fig. 8 follows the same approach for conducting the proposed encryption scheme.

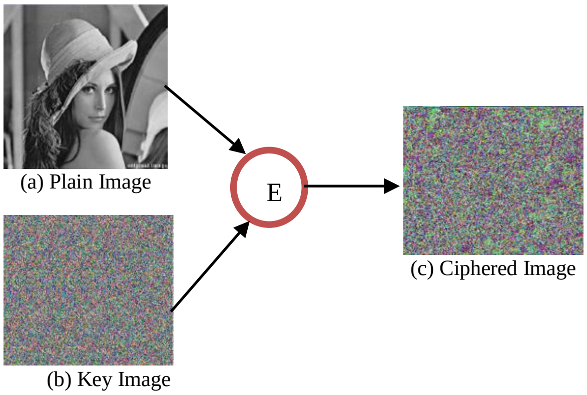

Fig. 8. Chaos-based Image Encryption Scheme[3], (a) Plian Image, (b) Key Image, (c) the Encrypted Image.

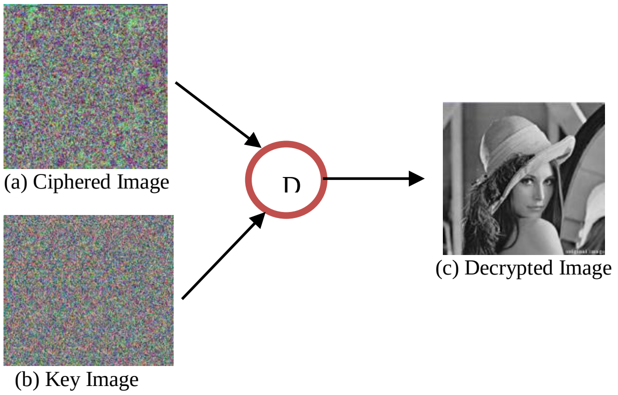

(a) Ciphered Image

(b) Key Image

(c) Decrypted Image

Fig. 9. Chaos-based Image Decryption Scheme [3], Lena Image (225x227), (a) Ciphered Image, (b) Key Image, (c) the Decrypted Image.

The reverse operation for image encryption is the decryption process. Fig. 9 shows the decrypted Lena image using the correct key image. Choosing wrong key image will not produce the correct plain image. For the key sensitivity and security analysis, next section investigates these issues.

V. Security Analysis

The proposed chaos-based image encryption scheme with DNA sequence coding has satisfied high-level of security, robustness, and efficiency, these features due to the high domain space of the key as well as the chaos features [22]. In this research work as well as our previous work, in [3], we use a key as an image for the encryption/decryption process in order to prevent the encrypted image against brute-force attack, statistical attack, known-plaintext attack and select plain text attack, these attacks are well known attacks listed in [3]. In the proposed cryptosystem, a confusion process is run, and the output goes to the diffusion process. If we assume we have $M \times N$-sized plain image, for simplicity put $M = N$ therefore the plain image will be N^2-sized image. For the encryption and based on the methodology of our encryption scheme the same key image dimension should be utilized i.e., we will need N^2-sized key image. Since the encryption process is working in bitwise therefore for gray scale image with 8 bits in each pixel, we will have $8*N^2$-sized key image with binary values 0 and 1. The possible combinations of a matrixes with $8*N^2$ binary values are in the domain 2^{8*N^2} , which increase exponentially as N increases. For the RGB channels the key space became ultra, since we will have 3 matrixes for R channel, G channel, and B channel, respectively and the key space become in $2^{8*N^2} * 2^{8*N^2} * 2^{8*N^2} = 2^{24*N^2}$. For example, a plain image of size 225x227 gray scale and key image with the same size, the brute-force attack needs to search the key in $2^{8*225*227} ==> 2^{51525}$ which is a very (ultra) large key space domain. This is the key point of our proposed algorithm, impossible for the key image to be predicated.

VI. Conclusion

The proposed study shows that the achieving of ideal secrecy system in cryptography can be performed with existence of confusion and diffusion processes. Despite the differential analysis is very interested attack but the proposed framework resolves this issue by the proposing of new technique for choosing key method. In general the proposed encryption framework consists of two processes (confusion and diffusion with DNA sequence) and one round of the two operations is grantee to produce high level of image security instead of having (n) rounds for confusion and (m) round in diffusion as in the conventional image encryption frameworks [7], [17], [23], [24]. This feature will reduce the computational time and the system complexity. The proposed confusion process (using confusion function) is responsible on the breach of high correlations of the adjacent pixels, while the diffusion process with DNA sequence logical operations increases withstanding against attack. Comparing to the several studies in literature our proposed algorithm's distinguished in terms of choosing the key as an image (instead of having single value) that contribute to high level of resistance of all kinds of attacks due to ultra-key space domain which is in the range of 2^{8*N^2} in the gray scale domain and 2^{24*N^2} in the RGB channels.

***Abstract*—This study has implemented a rule-based approach on grammar checkers by integrating a spell-checker with a morphological analyzer to improve the Afaan Oromo grammar checker. A corpus containing about 300,000 words has been prepared to be used for spell-checker. About 300 grammar rules are constructed to detect the grammar error within the Afaan Oromo text and to suggest the possible grammar correction. The developed frameworks have experimented on the document having pairs of 100 correct and incorrect sentences. The experimental result for checking the spelling errors has scored 73% of recall, 76% precision, and 75% of F-measure. The score for suggesting the correct spelling is 78% of recall, 62% precision, and 70% precision F-measure while the evaluation result for detecting the grammar errors has 47% recall, 90% precision and 68% f-measure score. For suggesting the possible correct grammar on the detected error, the system has scored 61% recall, 71% precision and 66% f-measure. The overall performance of the developed system has a good performance. However, there is still a need to conduct further research to improve the Afaan Oromo grammar checker.**

***Keywords*—Grammar checker; spell checker; part-of-speech tag; error detection; syntactic analysis; semantic analysis; morphological analyzer; NLP**

I. Introduction

For communication, a natural language is a language used by humans. Natural language processing (NLP) is a field of study mainly concerned with the communications between human languages and the computer. During a written communication, people may make an error which can be a spelling error and/or a grammar error. A spelling error is an error if the given the word does not exist in the language's vocabulary, whereas a grammatical error occurs when the written sentence is not as per the grammar rule of a given language [1].

With globalization, many individuals work on National and International languages for everyday communications. But it is difficult for many to write various contents using correct spelling and grammar, whether professional communication or a regular discussion, which makes grammar checking one important tool in the word processing software. Grammar checking has significance for having a good flow of ideas, exactness and quality of the expressed written content [1]. Grammar checking is one of the activities in the natural language's written communication and NLP application. Grammar checking checks the grammatical errors in text and suggests possible corrections in many cases. This is one of the most frequently used tools in language engineering.

One of the main challenges in the application of grammar checking for natural language is it is language-specific. Due to this, the grammar checker that works for one language may not work for another language. Therefore, it's necessary to design a grammar checker for each language as per the grammatical rule of a particular language.

Afaan Oromo is one of the most widely spoken languages in east Africa, which accounts for about 40 million speakers in Ethiopia; it is also spoken in neighboring Ethiopian countries like Kenya, Somalia, Djibouti and Egypt [2].

Today, Afaan Oromo is an official working language of Oromia national, regional, and educational languages for primary school (1-8) students in the Oromia region. As a result, many works for official and/or personal purposes use Afaan Oromo for interpersonal communication. Most of the time, while preparing various reports, peoples are vulnerable to make a grammatically wrong statement unintentionally or unknowingly. Some languages, such as English, French, etc., have a tool to catch and make corrections on these problems. However, Afaan Oromo is one of the under-resourced languages. Due to this, there are no tools that can assist the users in catching and making corrections on the grammatically wrong statements. Therefore, it is required to develop and implement the Afaan Oromo grammar checker to eliminate these problems. Developing a grammar checker for Afaan Oromo is significant for non-writers and nontechnical peoples to have accurate and quality written content. This study is intended to design and develop an integrated model to develop a grammar checker for Afaan Oromo using morphological analysis – A Rule-Based Approach.

II. Grammar Checker Approaches

There are three widely used approaches by various researchers like Syntax-based approach, statistical-based approach and rule-based checking [3].

- Syntax-based approach: In this approach, text parsing is used by assigning a tree structure to the sentence. If the text parsing mismatches, the statement is labeled as a grammatically wrong sentence; otherwise, it is considered correct.

*Corresponding Author

- Statistical-based approach: In this approach, a corpus annotated with its part of the speech tag is prepared and used to build a sequence of parts of the speech tag list. If the frequency of the tagged text is less than with the already trained model, this text is considered incorrect otherwise it's it is considered correct.

- A rule-based approach: In this approach, a set of grammar rules has been manually prepared to match against a text. If the text matches the crafted rules, it is considered a correct otherwise wrong sentence.

III. Related Works

Various studies have been conducted on natural language processing for the Afaan Oromo language. For instance, [4] have designed a spell checker for non-word Afaan Oromo spell checker. This work is focused on checking misspelled words and use the proposed algorithm to observe if the right word is generated under suggestion. But authors are not considering the context of the statement in their work.

The author in [5] attempted to design a grammar checker for Afaan Oromo using a rule-based approach. The author constructed about 123 rules for the detection of the Afaan Oromo grammar error. The rules are constructed depending on the language rule of affixation. However, false alarms in the developed framework lead the system to become challenged to catch the grammar error correctly. The author in [5] has mentioned some of the reasons for the problem that occurred. These are some words root and affix are identified wrongly by the stammer, a wrongly assigned part-of-speech tag and incompleteness of the rules. However, there are many reasons for the problems with [5] framework in addition to the reasons mentioned. Rules ranging from 81-86 were constructed to catch the error of past perfect tense. But this system may falsely alarm the correct grammar as wrong due to incorrect rules. Let's have a look at the following example, which tests his rule. One of the rules which are crafted by [5] says, "If the subject of the sentence is third-person singular masculine, so the verb must end with the suffix -ee, and the sentence must end with ture.”

Example: Callisee Bira dabruu yaalee ture. (He tried to pass in silence).

But the above rule may flag other correct statements as a grammatically wrong sentence. Because, in Afaan Oromo, if the subject of the sentence is third-person singular masculine, but the verb may end with the suffix other than -ee and also it's not necessary for the sentence to end with ‘ture’.”

Example: Callisee Bira dabruu yaalus hin milkoofne. (He tried to pass in silence, but he did not).

The author in [6] has developed the Afaan Oromo grammar checker by using a statistical approach. The author has implemented two statistical approaches: the token n-gram frequency whose probability of sequence is calculated and the tag n-gram frequency whose POS tag is assigned to all tokens, and the probability of the tag sequence is calculated for training and testing the checker. However, [6] didn't incorporate the checking of spelling errors in his work which is fundamental to the work of grammar checkers. The corpus used for training contains only 10000 words due to this POS tagger, and the Morphological analyzer has become inaccurate. Additionally, the article didn't highlight constructing a rule that will be used for training the model and improving the model performance. As a result of the factors mentioned, the work proposed in the paper has to be improved by incorporating spell checking along with a good morphological analyzer.

Even if few works have been done on grammar checkers for the Afaan Oromo language, there is still a gap in developing a good grammar corrector that can help to fix common spelling errors, instances of the passive voice, clunky and hard to understand language.

IV. Material and Methods

A. Material Used

Various development tools have been used to design the Afaan Oromo grammar checker. Python is one of the tools that were used to develop the prototype. Python is used because it's easy to work with, learn and adaptable scripting language, making it attractive for development [7]. HORN MORPHO 2.5 is used for POS tagging activity. It is a program that analyzes Amharic, AO, and Tigrinya words into their constituent morphemes (meaningful parts) and generates words, given a root or stem and a representation of the word's grammatical structure [8]. The proposed research has also used the Hunspell dictionary to store the required grammar correction rules and integrate the developed framework into Apache OpenOffice.

B. Design Approach

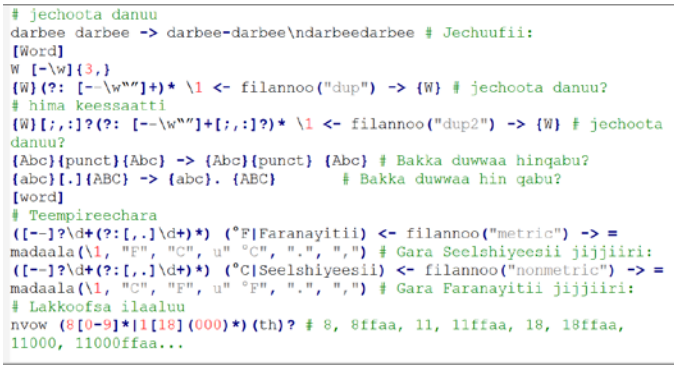
There are quite a lot of ways in which diverse approaches to grammar checking can be illustrated. This study intended to develop a grammar checker for Afaan Oromo using a rule-based approach by integrating with spell-checker and morphological analyzer. The dictionary containing about 300,000 unique words is constructed that can help to detect spelling errors. For grammar checking, a set of grammar rules has been constructed, which accounts for about 250 rules that check the errors in the grammar.

To perform the grammar checking, the developed system will find a word from the sentence. Then the tag of the word is checked against the developed grammar rules to detect various errors such as style problems, agreement in gender, number, word order, etc. If the sentence contains an error, the suggestion to the error will be displayed. The designed framework has two components, namely the spell-checker component and grammar checker component.

1) Spell-checker components: The spell-checker components have a set of words and affix rules of Afaan Oromo languages. This component helps to catch the spelling errors from the texts and suggests the possible correction to the wrong words depending on the morphological rules of the Afaan Oromo languages.

2) Grammar checker components: This module consists of a set of grammatical rules of the Afaan Oromo languages.

This component works by checking the arrangements of words in a given sentence. The crafted rules check the syntactic agreement features in the statement, i.e., the agreement in the gender (Masculine or Feminine), number (Singular or Plural), a person (1st/2nd/3rd person singular, 1st/2nd/3rd person plural) and proofreading (punctuation). In Fig. 1, some of the sample rules are constructed.



```
# jechoota danuu
darbee darbee -> darbee-darbee\ndarbeedarbee # Jechuufii:
[Word]
W [-\w]{3,}
{W}(?: [--\w"”]+)* \1 <- filannoo("dup") -> {W} # jechoota danuu?
# hima keessaatti
{W}[;,:]?(?: [--\w"”]+[;,:]?)* \1 <- filannoo("dup2") -> {W} # jechoota
danuu?
{Abc}{punct}{Abc} -> {Abc}{punct} {Abc} # Bakka duwwaa hinqabu?
{abc}[.]{ABC} -> {abc}. {ABC}        # Bakka duwwaa hin qabu?
[word]
# Teempireechara
([--]?\d+(?:[,.]\d+)*) (°F|Faranayitii) <- filannoo("metric") -> =
madaala(\1, "F", "C", u" °C", ".", ",") # Gara Seelshiyeesii jijjiiri:
([--]?\d+(?:[,.]\d+)*) (°C|Seelshiyeesii) <- filannoo("nonmetric") -> =
madaala(\1, "C", "F", u" °F", ".", ",") # Gara Faranayitii jijjiiri:
# Lakkoofsa ilaaluu
nvow (8[0-9]*|1[18](000)*)(th)? # 8, 8ffaa, 11, 11ffaa, 18, 18ffaa,
11000, 11000ffaa...
```

Fig. 1. Sample Rules.

V. Implementation and Evaluation

1) Implementation: The developed framework has been implemented using a Libreoffice text/document writer. LibreOffice is one of the document writer software supporting the integration of the Afaan Oromo spelling and grammar checker. Fig. 2 shows a list of extensions already in the Libreoffice software before installing the Afaan Oromo spelling and grammar checker.

As shown in Fig. 2, installing the developed framework as an extension of writing aids, there is no indicator of the Afaan Oromo language. However, after installing the Afaan Oromo spelling and grammar checker, the writer started to indicate an icon showing the language extension for grammar and spell-checking is installed. As shown in Fig. 3, the layout for the language extension is highlighted with a red color.

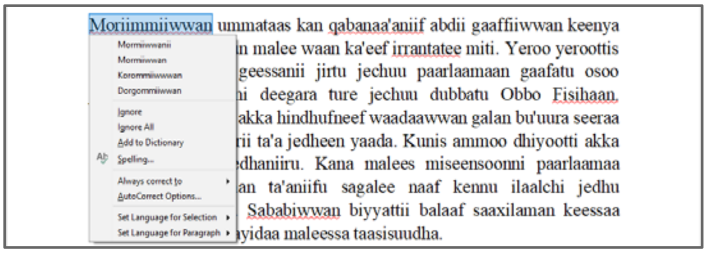
Fig. 3. Layout after Installing the Afaan Oromo Spelling and Grammar Checker.

The developed framework has been implemented to perform spelling checking, correction, grammar error detection and suggestion.

a) Spell-Checker Implementation: At this phase, the system is implemented to detect the wrongly spelled words and suggest possible corrections. Fig. 4 shows the implementation of the spell-checker.



Moriimmiiwwan ummataas kan qabanaa'aniif abdii gaaffiiwwan keenya
n malee waan ka'eef irrantatee miti. Yeroo yeroottis
geessanii jirtu jechuu paarlaamaan gaafatu osoo
hi deegara ture jechuu dubbatu Obbo Fisihaan.
akka hindhufneef waadaawwan galan bu'uura seeraa
rii ta'a jedheen yaada. Kunis ammoo dhiyootti akka
dhaniiru. Kana malees miseensoonni paarlaamaa
an ta'aniifu sagalee naaf kennu ilaalchi jedhu
Sababiwwan biyyattii balaaf saaxilaman keessaa
yidaa maleessa taasisuudha.

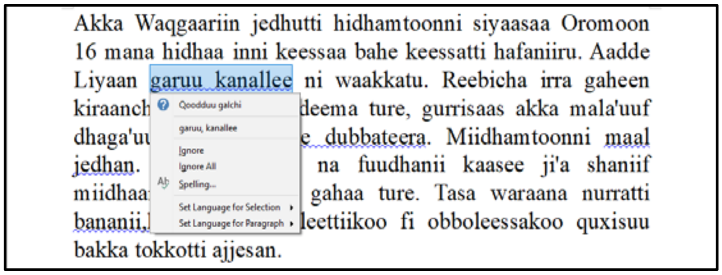
Fig. 4. Spell-Checker Implementation Sample Screenshot.

To indicate the wrongly spelled word in a sentence, all wrongly spelled words are underlined with a red flag. But if the word has no spelling error, no sign is displayed. As shown in Fig. 4, the wrongly written words are flagged with a red color underscore. When these wrongly written words are right-clicked, the possible suggestion is shown.

b) Grammar-Checker: This implementation was done to determine the wrongly written statements and extract the grammatically wrong statements within the text by the system. The prepared corpus (doc1 and doc2) is used alternatively for error detection and false alarm identification in this implementation. Fig. 5 is the screenshot of the implementation of detection and correction of the grammar of the proposed framework.

Fig. 5 shows how the system detects the grammar error and suggests the possible correction.

The statement that has a grammar error will be flagged with a blue underscore to make the user alerted and take proper action. The grammar suggestion will be shown when right-clicked on the flagged text. However, those statements written with a correct grammar rule will not be flagged.



Akka Waqgaariin jedhutti hidhamtoonni siyaasaa Oromoon
16 mana hidhaa inni keessaa bahe keessatti hafaniiru. Aadde
Liyaan garuu kanallee ni waakkatu. Reebicha irra gaheen

miidhaa gahaa ture. Tasa waraana nurratti
bananii, leettiikoo fi obboleessakoo quxisuu
bakka tokkotti ajjesan.

Fig. 5. Detection and Correction of Grammar Errors.

2) Evaluation: The developed system is evaluated to check whether the objectives of the research are achieved or not. To evaluate the performance of the systems, two documents named doc1 and doc2 are prepared. These documents are used for testing and evaluation purposes, where each document contains about 500 sentences. All of the words and sentences within the first document (doc1) are grammatically correct, whereas the second document (doc2) contains the possible wrong spelling and grammar of doc1. The evaluation task is done in two phases, and the first phase evaluation is applied to test the detection and suggestion capability of the system for the spelling error within a sentence. The second phase is evaluated to check the system's performance for grammar error detection and correction suggestions made to the identified error.

a) Evaluation of Phase 1: The performance of the system for spelling checking has been evaluated at this phase. The document with 50 words has been prepared, and of these, 25 words were wrongly spelled while the rest 25 correctly spelled. The system is expected to suggest at least three correctly spelled words related to the detected spelling error.

b) Evaluation of Phase 2

- Grammar Error Detection: The framework is tested against doc1 to identify the grammatically wrong statements within the text, whereas doc2 is used to handle false alarms.

- Correction Suggestions: The correction suggestions evaluation has been done to evaluate the system's performance for suggesting the possible correct grammar of the detected errors. The system is tested by using the document containing the wrong grammar statements (doc1). Depending on the error detected, the number of correction suggestions may vary. However, the system is evaluated to suggest a minimum of two correct suggestions per error.

3) Confusion matrix: To demonstrate the performance of the proposed system, a confusion matrix has been used. The confusion matrix is a commonly used technique to describe the classifier's performance based on test data [9]. Table I shown below, describes the confusion matrix result for the system performance.

The performance measure shows the detailed description for the activities of the systems such as; checking the spelling error, suggesting the correction for the spelling error, grammar checking and correction are shown in the Fig. 6, 7, 8 and 9.

Evaluation matrix performance can also be explained using f-measure, precision and recall values. Following are the formulas used for these calculations.

$$Precision = \frac{TP}{(TP + FP)}$$

$$Recall = \frac{TP}{(TP + FN)}$$

$$F - Measure = \frac{(2 * Precision * Recall)}{(Precision + Recall)}$$

Table II is focused on the results of the evaluations.

TABLE I. PERFORMANCE MEASURE DESCRIPTION

S. No.	Evaluation Parameters	TP	FP	FN	TN
1	Have a Spelling Error	19	5	7	6
2	Spell-Checker Correction Suggestion	56	15	16	35
3	Have a Grammar Error	86	4	96	10
4	Predicted Correction Suggestion	122	28	78	50

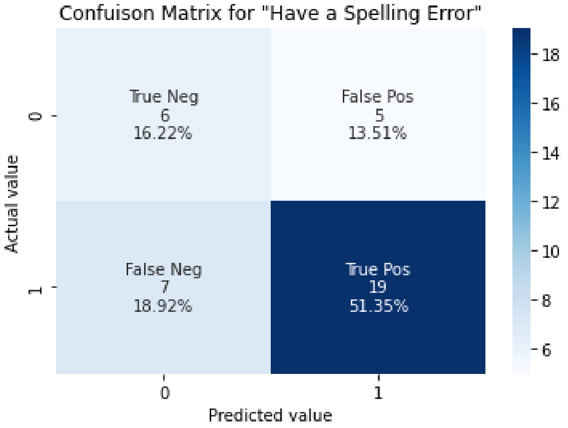

Fig. 6. Have a Spelling Error.

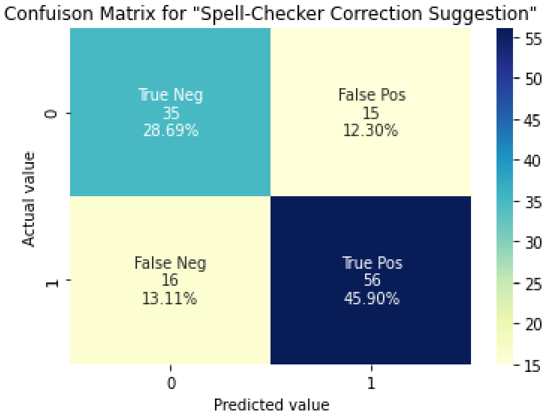

Fig. 7. Spell-Checker Correction Suggestion.

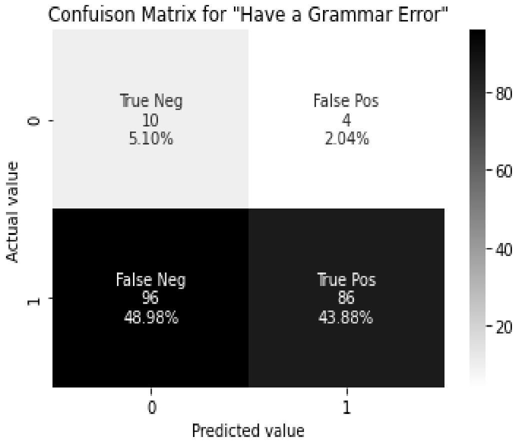

Fig. 8. Have a Grammar Error.

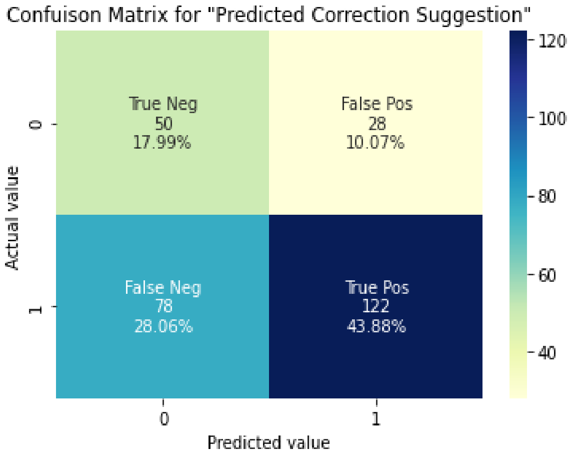

Fig. 9. Predicted Correction Suggestion.

TABLE II. PERFORMANCE EVALUATION MATRIX

S. No.	Parameters Used	Evaluation Result		
		Recall	Precision	F-Measure
1	Checking Spelling Errors	0.73	0.76	0.75
2	Suggesting Correction	0.78	0.62	0.70
3	Checking Grammar Errors	0.47	0.90	0.68
4	Suggesting Correct Grammar	0.61	0.71	0.66

VI. DISCUSSION

The developed system has been evaluated on four basic tasks: checking spelling errors within the text, suggesting the correct spelling for the detected error, checking grammar errors, and suggesting the correct grammar for the identified grammar errors. Accordingly, the confusion matrix result for checking the spelling error has scored 51.35% TP, 13.51% FP, 18.92% FN, and 16.22% TN, whereas spell-checker correction suggestion 45.90% TP, 12.30% FP, 13.11% FN and 28.69% TN score. But, for checking the grammar error and suggesting the possible correct grammar, the system has scored 43.88% TP, 2.04% FP, 48.98% FN and 5.10% TN result of confusion matrix measurement.

The performance evaluation result of the system, which is evaluated by the confusion matrix measurement, is described by using the f-measure, precision and recall values. So, for checking the spelling errors, the score is 73% recall, 76% precision and 75% f-measure. To suggest the correct spelling for the detected error, it has scored 78% recall, 62% precision and 70% f-measure. For checking grammar errors, the system has scored recall 47%, precision 90% and f-measure 68%, whereas, for the task of suggesting the correct grammar for identified error, it has 61% recall, 71% precision and 66% f-measure.

According to the experimental result presented, the framework has performed well for handling false alarm issues than error detection. The main reason that false alarm handling tasks scored higher than error detection tasks is that the written rules are primarily focused only on the common errors that mislead the meaning or make the statement meaningless. The evaluation performance for the task of grammar error detection within a statement scored lower performance. The problem with the task of error detection happened as a result of uncovered cases within the rule. Within a given statement, if the grammar problem is a semantic error, it will not be detected and/or corrected by checking only the sentence structures. To find and/or correct the semantic errors of the statement, it is must to analyze the semantic structure of the sentence. Therefore, it's possible to solve a challenge to detecting grammar errors due to the dynamic occurrences of the error.

VII. CONCLUSION

This study has developed an integrated model to develop a grammar checker for Afaan Oromo using a rule-based. Approach integrated a spell-checker along with a morphological analysis on Afaan Oromo grammar checker to improve its performance. Data has been collected from various sources such as Oromia Broadcasting Network, BBC Afaan Oromo and other sources used for designing and implementation purposes.

The experimentation was done in two phases: spell-checking & correction phase and grammar-error detection & correction phase. The system is evaluated on detecting wrong spelling and grammar from the text and the possible suggestion made to the error. As a result, the evaluation result for detecting grammar errors in a statement has a low score than other activities. One of the main reasons is due to the uncovered cases within the rule for detecting the error.

VIII. RECOMMENDATION

The designed prototype for improving the Afaan Oromo grammar checker has a promising result. Even if the model performance showed a good result, there is still work that needs to be done to improve the performance. The following are recommended as a future research direction.

- The grammar error can be syntactic, related to the structure of a sentence and/or semantic, which is related to the meaning of the sentences. But this work attempted to solve the grammars having only syntactic errors. Therefore, further research work has to be done on the Afaan Oromo Grammar checker that can check the semantic analysis of the sentences.
- Since it is difficult to catch all of the grammar errors using only a set of rules, it must implement another method. Therefore, machine learning methods combined with a rule-based approach may improve the performance of the Afaan Oromo grammar checker.

***Abstract*—Internet of Things (IoT) Soil Monitoring based on Low Range (LoRa) Module for Palm Oil Plantation is a prototype that sends data from the sender to the receiver by using LoRa technology. This realises the implementation of Industrial Revolution 4.0 in the agriculture sector. Also, this prototype uses the TTGO development board for Arduino with built-in ESP32 and LoRa, pH sensor and moisture level sensor as main components. The prototype utilises the LoRa communication between the sender and the receiver. The sensors will detect soil pH along with the moisture level. The data then will be sent to the receiver, where it will be displayed in the Organic Light-Emitting Diodes (OLED) display. At the same time, the data will be uploaded to the database named ThingSpeak by using wireless communication. Users can monitor the data collected by accessing ThingSpeak's website using smartphones or laptops. The prototype is easy to set up and use to help users monitor the pH level and moisture level percentage. For future enhancement, the project can be enhanced by combining temperature and tilt sensors to get comprehensive data about the soil's condition.**

Keywords—Internet of Things (IoT); Low Range (LoRa); Organic Light-Emitting Diodes (OLED); ThingSpeak; Arduino

I. Introduction

This project concerns an Internet of Things (IoT) soil monitoring system using Arduino based on LoRa (Low Range) technology. The project is created for future technology "Industry 4.0" to boost efficiency in palm oil plantation by adopting the IoT in the agriculture sector [1]. Most of the oil palm plantations are in a rural and secluded area where the internet is scarce. Hence, LoRa introduces a new method to realise IoT in the agriculture sector. This is the contribution of this paper. Up to now, palm oil workers manually check and monitor every crop, covering a vast area measuring thousands of hectares [2]. This can be less efficient to monitor each crop for the soil moisture level because oil palm is challenging to grow.

Moreover, after they harvest the crops, they will chop off the old crops to plant new crops. This practice leads to many problems, such as boycotts from climate activists. With the existence of this project, it can reduce the frequency of replanting when monitoring alerts you exactly as soon as it is due for replanting. Oil palm has already been a staple crop, with thousands of hectares being planted and manually monitored by the workers, but it is not the most efficient way to implement it. The workers need to manually check and maintain the appropriate soil moisture level throughout the year. The farmers mostly rely on the little knowledge they gain from experience or by observing crops with naked eyes. This leads to misjudgment, causing devastation to the crops. If a sufficient level of moisture is not maintained, it can be damaging to the crops. For example, maintaining the water supply is crucial to the crops [3-7]. With LoRa and a few sensors, the moisture readings can be viewed easily while also saves time. The design of the monitoring system is utilising the sensor module comprising of temperature sensor and moisture level sensor positioned in the soil that will capture the data taken from the soil. The data then will be transferred to the Arduino development board using the LoRa module.

LoRa is an important part of this project because the plantation lacks internet access and cellular coverage. LoRa was first introduced in the previous work in [8], where the LoRaWAN platform had shown the potential to replace the use of IoT infrastructure on the existing 802.11 Wireless Standard. In [9], an animal movement tracker prototype that used LoRaWAN as a medium to transfer the GPS location of the farmed animals had been built to support smart agriculture. Hence, using LoRa will help to cover the wide radius of the plantation. Unlike the prototype in [10], where the IoT soil monitoring prototype used wireless connectivity as the medium, the LoRa module will act as a network connection to connect to Arduino by using radiofrequency. After that, the data will be kept in the database to be monitored by the plantation workers using mobile devices or laptops.

The scope of this project is to develop an IoT project with the implementation of the LoRa module as the main network connectivity. Using LoRa, the system will have the benefit of low power consumption. Besides, it supports a longer range of coverage area. For measuring data, a pH sensor is needed to measure acidity or alkalinity with a range from 0 to 14. Another sensor is a moisture sensor, which is needed to detect moisture level in the soil and manage irrigation systems (the system will turn on when moisture level falls below a certain predefined threshold value) if available. A mobile application will be developed as well to present the data for the workers.

In summary, this project is created to provide a solution to overcome the manual monitoring system used by the workers for a very long time. The IoT monitoring system will ensure to increase productivity and efficiency of the planter at the tip of their finger.

*Corresponding Author

This paper will discuss the methodology of the project, the hardware and software development, the results and discussion and the conclusion.

II. Methodology

The research methodology section provides a step by step guideline to complete the project. A suitable methodology for this monitoring system can ensure the success of the project. In this section, the explanation of the chosen methodology as shown in Fig. 1, along with the description of how it is applied in developing a prototype, will be discussed. The result will also be discussed to gather as much information as possible about soil monitoring using the LoRa module. Fig. 2 is the flowchart of the project.

A. Feasibility Study

A feasibility study is an analysis or evaluation for the project proposed, either it is feasible to be implemented. Thus, the feasibility study consists of the problems statement, objectives, and phases to complete the project. The developer must have various strategies or mitigate planning if something wrong happens in terms of resources required, such as the cost of development and the development time.

B. Requirement Analysis

In this phase, all of the possible requirements and information regarding the project was collected and documented. The important thing to do in this phase is to identify the project's objectives, requirements, and specifications to proceed to the next phase.

C. System Design

In the design phase, the prototype was designed. The design must meet the requirements stated in Table I. It will have TTGO ESP32 with a built-in LoRa module, pH sensor, and moisture sensor on the transmitter side. For the receiver part, it will be designed to have TTGO ESP32 with a built-in LoRa module. ThinkSpeak will act as a database to store the data.

D. Coding

In the coding phase, the transmitter sent data; the receiver must receive the data. The transmitter (client) hardware consists of a pH sensor and a moisture sensor; both were fixed to the soil, while both the sensor and LoRa module will be installed to the TTGO ESP32. On the other hand, the receiver side consists of Arduino UNO and installed with the LoRa module to receive data from the transmitter. A database was configured with ThingSpeak to store the data. A mobile application was installed in the receiver to view the data. The TTGO ESP32 was configured by using the Arduino IDE from a laptop. The connectivity enables the data to be sent and received by using the LoRa module.

E. Testing

The project was tested to identify any defects in the system. Each of the connected sensors was tested whether it is working properly. Any defects found in the system were fixed and tested again to ensure that the defects were fixed. The test was conducted by using natural material (soil) to ensure the correct data was collected. This ensures the objectives are achieved. LoRa module was tested to ensure the connectivity between the transmitter and the receiver. ThinkSpeak was able to store the correct pH and moisture level readings.

F. Maintenance

In this phase, a maintenance phase was conducted to correct any errors discovered during the product development phases. This ensures developers always improve implementation and enhance the functionalities of the system.

III. Hardware and Software

In this project, the hardware, as shown in Table I, is necessary for development. This step explains the project's purposes, requirements, and specification, including tooling and software. This phase is important for gathering project information to progress to the next phase.

A. *TTGO LoRa SX1278 with ESP32*

TTGO LoRa SX1278, shown in Fig. 3, is the main component for both the transmitter and the receiver. This board is built-in together with LoRa SX1278 and ESP32. Thus, the board is working on LoRa and WiFi communication. The device was used in both the transmitter and the receiver to act as a medium to transmit and receive the data over LoRa communication.

B. *Analogue pH Sensor*

Based on Fig. 4, pH sensors are connected to the board TTGO LoRa. There were three pins involved to connect the pH sensor to the TTGO LoRa board.

- VCC = +5.5V pin
- GND = GND pin
- GPIO = 35

This sensor can be used to detect the pH value from soil and water. An example can be seen in Fig. 4. The test was made to test the pH value from the distilled water.

TABLE I. Hardware and Software

	Item	Unit
Hardware	pH sensor	1
	Moisture sensor	1
	TTGO LoRa SX1278 ESP32 (OLED)	1
	TTGO LoRa SX1278 ESP32	1
	Jumper cable	1
Software	Arduino IDE	-
	Laptop	-
	ThinkSpeak	-

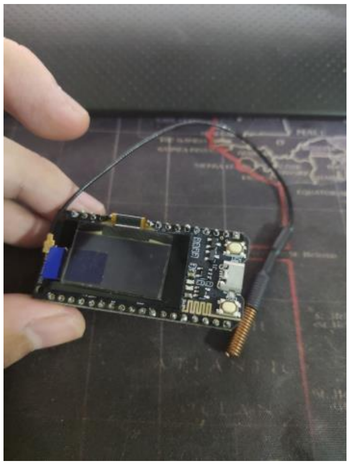

Fig. 3. TTGO ESP32 Build-in LoRa Module.

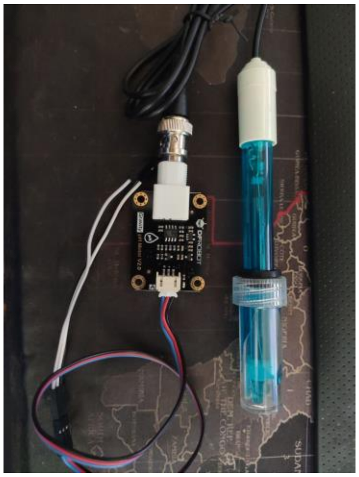

Fig. 4. pH Sensor by DFRobot.

C. *Moisture Sensor*

Based on Fig. 5, this sensor has three pins: VCC, GND, and Analog Output, to connect the sensor to the TTGO board.

- VCC = +5.5V pin
- GND = GND pin
- GPIO = 32

This sensor can be used to detect the moisture of water. The sensor will be read in the form of voltage. From the voltage, the higher reading can be interpreted as a high level of moisture. To facilitate reading, the data will be converted into a percentage.

D. *ThingSpeak*

A database is needed to ensure the data received can be collected and processed, and ThingSpeak, as shown in Fig. 6, is the best choice for this. The user accessed the ThingSpeak website to register and create a database channel.

Simple coding, as shown in Fig. 7, was needed at the receiver to ensure the data received was properly sent to the ThingSpeak database. The “apiKey” can be found from the channel. “MY_SSID” & “MY_PWD” were set up based on the network that connected to the internet.

const char* MY_SSID = "Aznorainy66";
const char* MY_PWD = "QweAsdZxc123";
int sent = 0;
```

Fig. 7. Code for ThingSpeak.

IV. Result and Discussion

Fig. 8 shows the results retrieved from the sensor, stored in the channel's database. In Fig. 8, there were four columns. The first column is to show the exact time when the data was collected. The second was the "entry_id", which was the sequence of data collected. The third was the "field1", the data retrieved from the pH sensor. The last column was "field2", which was the data from the moisture sensor. All of the data was retrieved together in a packet.

A. Results

Fig. 9 shows the data from the pH sensor, which was plotted to a line graph along with the numeric value. For the line graph, the x-axis is the date as per data being collected, while the y-axis is a range of numbers of the pH readings, which ranged from zero to 14. The line graph will show us the flow of data collected through the duration setup. The graph was set up to show the latest ten collected data. The numeric value will show the latest data retrieved to make it easier to read.

Fig. 8. Database Table.

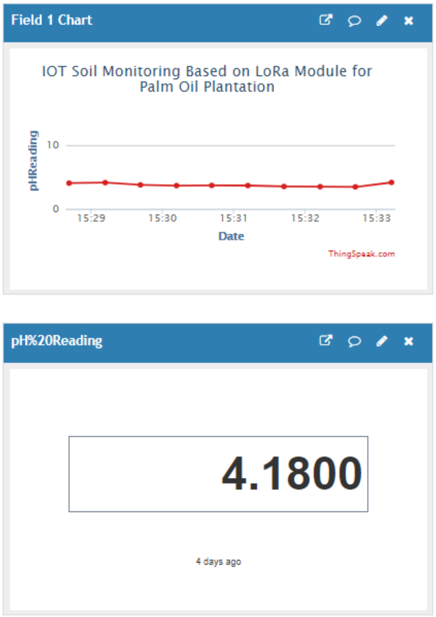

Fig. 9. pH Graph.

In Fig. 10, the data from the moisture sensor was plotted to a line graph, and a numeric value was also displayed. Referring to the line graph, the x-axis is the date as per data being collected, while the y-axis was the range of numbers from zero to 100, which corresponded to percentages of the moisture level. The graph was set up to show the latest ten collected readings. The numeric value showed the latest data retrieved for ease of reading.

Fig. 11 showed the database could be accessed via smartphones. It has a similar interface as the PC browser interface, which consisted of a line graph and a digital reading of pH and moisture level. Thus, the users can understand and view the data from their smartphone.

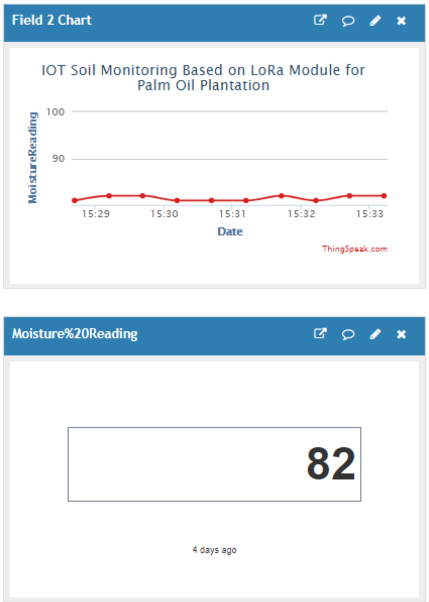

Fig. 10. Moisture Graph.

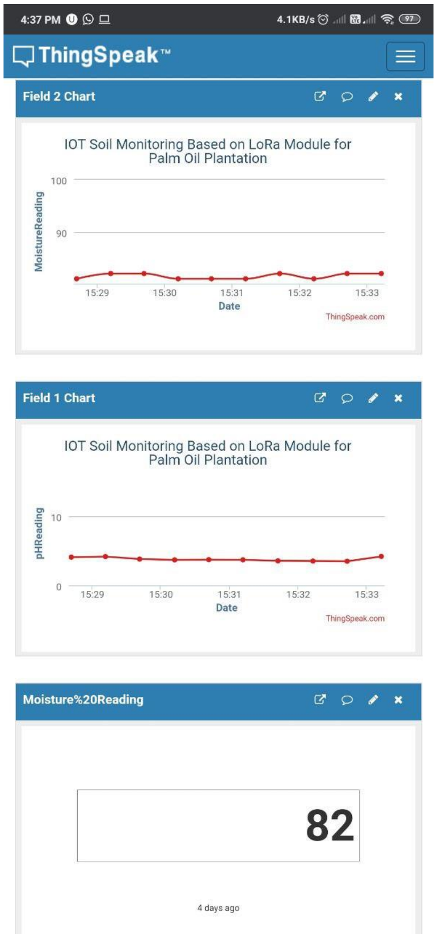

Fig. 11. ThingSpeak via Smartphone view.

B. Analysis

1) Recommended soil pH: Fig. 12 shows the soil pH readings from the ThinkSpeak database in tabular form. The ideal recommended soil pH for oil palm is between 4.3 to 6.5 [6], which is more acidic. Other readings, aside from the recommended values, will be harmful to the crops. From the table, the entry_id readings between 471 and 481 are ideal. When the readings are between this range, the worker doesn't have to do anything. The worker only takes action if the reading from the sensor is outside the recommended value.

2) Recommended soil moisture: Fig. 13 shows the soil moisture reading from the ThinkSpeak database in tabular form. 80% [7] soil moisture level is the recommended reading for oil palm. Taking the data from the table as an example, the readings of entry_id between 490 and 494 were sufficient, while the readings between 485 and 489 were insufficient, as this meant that the soil was so dry and can cause the crops to die due to lack of water. Thus, the worker needs to water the plant to moist the soil to the recommended moisture level.

3) LoRa signal analysis: Fig. 14 shows the map of the checkpoints for the testing sites. For this test, there were six different locations to test out the LoRa connectivity. The test sites were located around the residential area and high-rise buildings.

Fig. 13. Soil Moisture Database.

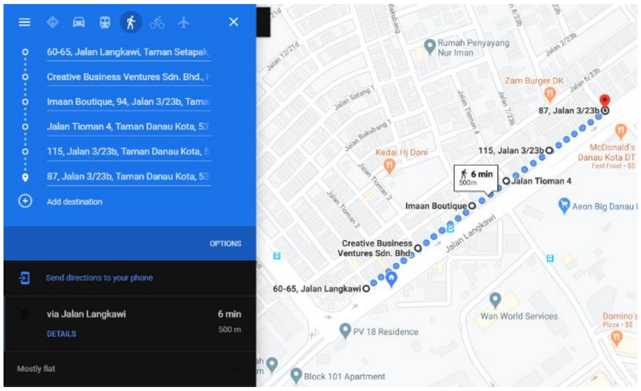

Fig. 14. Checkpoint Test Location.

Table II shows that the distance for each checkpoint, A through G. It showed that maximum LoRa connection was available up to 500 meters, and the connection was lost at checkpoint G. This might be due to interferences coming from cars, motorcycles, trees or might be due to the loss of Line of Sight (LOS). Next, for the received signal strength indicator (RSSI) measurements, the signal was much better as the signal value neared 0 dBm. At checkpoint A, the RSSI reading is -79 dBm, while at another checkpoint, RSSI's was greater than -100 dBm. When the signal is -100 dBm, and below, the signal strength is not good as the better signal strength readings should be closer to 0 dBm.

TABLE II. LORA CONNECTIVITY RESULT

	A	B	C	D	E	F	G
Distance (m)	5	100	200	300	400	500	700
Connectivity	✓	✓	✓	✓	✓	✓	x
RSSI	-79	-114	-117	-116	-110	-116	x

V. Conclusion

Palm oil production is vital for the Malaysian economy, which is the world's second-largest producer of the commodity, after Indonesia. Thus, the implementation of IoT in this agriculture sector will greatly increase the profit to the country. As internet connectivity is scarce in rural area, where most agriculture sectors are located, Lora had been identified as the solution for data transmission. Using this project, we can monitor every aspect of oil palm management and plantation. With the increasing application of IoT in the sector, the efficiency and productivity will be increased and the profit margin of the palm oil industry. Workers can view and monitor real-time soil condition along with various other agriculture variables via apps or websites. This is because of the sensors installed in the plantation; with the telemetry, all of the data can be displayed on the screen ready to be analysed, and solution can be searched for should there be any problem with the data obtained. Also, unnecessary and troublesome travels across the plantation to monitor the condition of the crop can be minimised. Adding more sensors such as tilt and temperature sensors such as in [11] will result in a more comprehensive prototype that can test the soil's condition more accurately.

Abstract—**Many algorithms were developed to perform visual localization and mapping (SLAM) for robotic applications. These algorithms used monocular or stereovision systems to solve constraints related to the navigation in unknown or dynamic environment. The requirement of SLAM systems in terms of processing time and precision is a factor that limits their use in many embedded applications like UAVs or autonomous vehicles. Meanwhile, trends towards low-cost and low-power processing require massive parallelism on hardware architectures. The emergence of recent heterogeneous embedded architectures should help design embedded systems dedicated to Visual SLAM applications. It was demonstrated in a previous work that bio-inspired algorithms are competitive compared to classical methods based on image processing and environment perception. This paper is a study of a bio-inspired SLAM algorithm with the aim of making it suitable for an implementation on a heterogeneous architecture dedicated for embedded applications. An algorithm-architecture adequation approach is used to achieve a workload partitioning on CPU-GPU architecture and hence speeding up processing tasks.**

Keywords—Simultaneous localization and mapping (SLAM); Bio-inspired algorithms; CPU-GPU workload partitioning; embedded systems; visual acuity (VA); hardware/software codesign

I. INTRODUCTION

The robot navigation is not always possible in some special circumstances, due to the unavailability of a map or because the environment keeps changing. Hence, for its localization, the robot needs to know its pose accurately which is not possible without a map, which brings us back to the initial issue. The dilemma of what should come first the map, or the pose is complex to solve, because it needs to calculate the pose and construct the map at the same time. A solution to this navigation problem is a Visual Simultaneous Localization and Mapping system also called V-SLAM [1]. The implemented algorithms use data inputs from different sensors mounted on the mobile robot, like cameras since they provide much more information about the environment.

To run a Visual SLAM algorithm, the minimum hardware requirement is a CPU based architecture and a monocular camera. Usually, as depth cannot be observed with one camera, most of systems use multi-view techniques to allow map reconstruction. Camera data is used to perform the scene photogrammetry and rebuild the trajectory map. This sensor presents several advantages (price, availability of a high amount of information) compared to other sensors it also has constraints such as the need for calibration, and sensitivity to light changes and intensity.

Bio-inspired approaches are based on learning concepts from nature and applying them to design an enhanced real time SLAM system. Hence most of these algorithms are aiming to simulate the biological retina and brain-based methods for features detection and description, which make the model complex and also its parallelization a real challenge.

Eyes represented by cameras are used to provide inputs data for front-end operations, but images are processed in a different way compared to classic methods. It can be categorized into simple eyes with one concave photoreceptor lens like for humans, and compound eyes like for some insects with multiple lenses [2]. This study is limited to simple eyes because it is the most feasible to be simulated in a mobile robot. Binocular and stereo vision systems can be then considered as a reference.

Simple eyes are grouped into two known categories based on their photoreceptor's cellular construction. Therefore, human and rodent were selected because they are both on the top of each group, since they are representing the best visual acuity (VA) [3].

In previous studies [4 - 5], bio-inspired approaches were proved to be very competitive methods, in term of accuracy and execution time compared to classic ones. This paper is sharping these results by studding two different models: the retina model HOOFR-SLAM [6] and hippocampal model for rodent RAT-SLAM [7].

The contribution is:

- an efficient partitioning model of a bio-inspired algorithm on a heterogeneous CPU-GPU architecture to improve the processing time performance.
- the evaluation of this model on a dedicated architecture based embedded application.

The aim is to be able to determine if bio-inspired V-SLAM methods can be used on a real-time application, despite their algorithmic complexity.

The reported resulting values are given based on the mean of 20 run results for at least 1000 timestamps. Datasets used are from the well-known KITTI benchmark [8] and Oxford New college opensource dataset [9]. Calibration and other algorithm parameters were adapted accordingly to each dataset to always have the maximum performance.

II. Background

One of the advantages of Rat-SLAM navigation system is its ability to run in dynamic environment using cheap camera sensor, due to the nature of Rat retina that has a low Visual acuity (VA) compared to the human one [3]. From another hand the use of odometrical data in this algorithm is mandatory in order to combine visual scene matching and a semi-metric topological map representation. The used image model is a simulation of a biological rat retina perception. HOOFR-SLAM doesn't need any odometrical data and can rely only on inputs provided by a well calibrated camera.

Human vision is trichromatic because it has three types of color cones: long-wavelength “red”, middle-wavelength “green”, and short-wavelength “blue”. Rat's vision is dichromatic because, they have only two wavelengths: a shorter blue wavelength than human but shifted toward and middle "green". Therefore, rats can see into the ultraviolet, this doesn't mean that they are color blind, they just have different color perception compared to human.

It is very important to understand how images are seen by each bio-inspired system. So, based on above, RAT-SLAM have to spend less time to convert images to gray scale than HOOFR-SLAM, with better adaptation to lower light environment, but accuracy is also lower, since human Visual Acuity (VA) is higher, this is why the use of an additional sensor (odometer) is needed.

Since Rats have eyes on both sides of the head, the vision is binocular, the field is large and panoramic. So, a representation in a simple flat screen will distort the image, since computer screens are flat and adapted to human forward-facing eyes which have a smaller visual field and more binocular vision. Due to these facts, running the same dataset on HOOFR-SLAM and RAT-SLAM will be a real challenge due to the difference in image perception and cameras position, and must be converted and adapted to each bio-inspired system before use, also the dataset will never have the same length, making a direct comparison simply not possible.

Now, after standing up on all the differences related to visual performance and image perception, the next sections are describing the Rat-SLAM and HOOFR-SLAM algorithm concept and the details of each model front end, back-end, kernels and evaluate their algorithmic complexity.

Finally, a parallelization and an implementation on a single CPU, multi-cores CPU and CPU-GPU on laptop, then a Jetson TX1 system on ship (SoC) architecture.

III. The RAT-SLAM

A. Algorithm Inputs

The Rat-SLAM system as defined by [7] use a self-motion sensor data to create a representation known as experience map, also used to facilitate the exploration. This technic is used in robotic when the human intervention is not or low needed. This navigation system has two goals, short term goals using a local obstacle map, and long-term goals relaying on experience map, with the aim to reach the desired destination. These two steps can be resumed to Matching [10] and mapping processes, if compared to HOOFR-SLAM as per Fig. 1.

The RAT-SLAM algorithm uses two different sensors, as a main data input source; a camera and an odometer. If a robot operating system (ROS) is used, both inputs will be then received as ROS messages. Also, for simulations reasons, both inputs camera and odometrical messages derived from the mobile robot wheels encoders are provided together in a dataset file (*.bag file), therefore in this case a visual odometry functional block will not be used, this data is included in the opensource dataset benchmark from [9].

Cameras are placed on both sides of the robot to simulate rat eyes position, the vison is binocular, so the depth is calculated using information on head direction, calibration, functional regions of the hippocampus and surrounding areas. The camera motion is limited to the translational and rotational speed and it is estimated via an image comparison process, more details on how it is done are provided by [11].

The rotational velocity estimation is done by minimizing horizontal offset of two consecutive scanline profiles that are generated by summing the images in the vertical direction represented by *f* as follows:

$$f(S,I^j,I^k) = \frac{1}{w-|s|}\left(\sum_{n=1}^{w-|s|}\left|I^j_{n+\max(s,0)} - I^K_{n+\min(s,0)}\right|\right) \quad (1)$$

where S is the profile shift, I^j and I^k are the scanline intensity profiles to be compared, and w is the image width. The pixel shift S_m in consecutive images I^j and I^k is the value of s that minimizes *f* for those two profiles.

$$S_m = \underset{s\,\epsilon|\rho-w,w-\rho|}{\operatorname{argmin}}\ f(S,I^j,I^k) \quad (2)$$

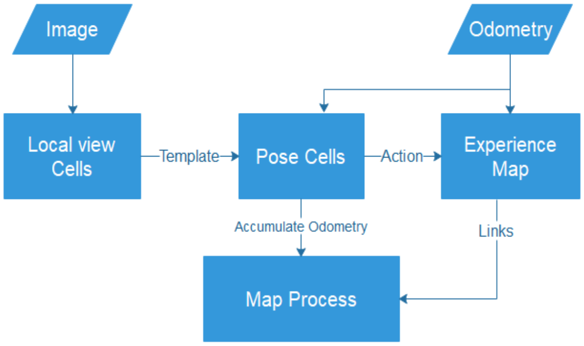

Fig. 1. Rat-SLAM Vision System Diagram with Inputs and Outputs Related to each Functional Block (FB), Local view Cells and Pose Cells are the Font-end and can be Considered as the Tracking Process, using Camera Image Data Plus Odometry as Inputs to Extract Features (Neural Approach) and Provide Actions as Output to the Experience Map. The Mapping Process uses Both Pose Cells Cumulated Odometry Outputs and Links to Avoid Infinity and to Close the Loop.

where ρ is the offset that ensures that there is enough overlap between the profiles. The translational velocity estimation is limited to a maximum value to prevent large changes in illumination and done by multiplying the minimum difference by a scaling factor. Two ROS message are then provided to the system: sensor_msgs::CompressedImage and nav_msgs:Odometry.

B. Main Functional Blocks

RAT-SLAM is a robust bio-inspired navigation algorithm, used when dependence on human assistance is not or low needed, based on sensor inputs message data described above. The algorithm has three main functional blocks and sub-functional blocks as per Fig. 2. They are identified as follows:

Local view cells: This node uses image data from camera, to make a matching process, by using a comparison technique in order to determine if the visualized scene is familiar or novel. The block algorithm sequence is the following:

Local view cells algorithm:

```
Image Conversion, Cropping, sizing and Matching (FB1)
{
 Convert image to gray scale ()

/* For Rat-SLAM the input image is already converted Remove visually bland features like roads */

 Cropping image ()
 Convert_view_to_view_template ()

/* cropping to specified region of the original camera image */

 Do patch normalization ()
 Create_template ()

/* Calculate the sum of absolute difference between current view template that represents the current camera image, and all previously learnt templates*/

 Compare ()
}
```

Pose Cells: as per Fig. 1, it uses the odometric data, visual template from local view cell, to provide actions to make decisions used by experience map node. This node has two inputs and one output that are processed as follows:

- Template: is the output of the local view cell image comparison process, if the templates already exist it is directly injected into associated location in the pose cells, if not a new a local ID is associated to the pose cell network. Also, in case of a successive detection of the same template for a long period of time, it could be understood as the robot is not moving.
- Odometric: inputs are processed in Pose Cells; the functional block algorithm sequence is described as follow:

Pose Cells Algorithm:

```
Check templates and update template database (FB2)
{
 if (New Template)
 create_view_template ()
 else (Template exist)
 give a local template ID ()
 }
Local and global excitation, path integration, action and energy management (FB3)
{
 Local excitation ()
/*Add energy around each active pose cell */
 Local inhibition ()
 /*Remove energy from around each inactive pose cell */
 Global inhibition ()
 /*Remove energy from all active pose cells above zero */
 Network energy normalization ()
 Path integration using odometrical information ()
 Get_current_exp_id ()

/* Identify the centroid of the dominant activity packet in the network */
 Get_action ()
 Update_scene ()
 }
```

Experience Map: Manage based on both local view and pose Cells outputs, the graph building, relaxation and path planning. This block has three main outputs:

1) A path message with information on the trajectory to the goal.

2) A list of nodes and edges that makes a representation of the experience map.

3) The robot poses in the experience map.

4) Get the goal way point

The experience map algorithm is the following:

Experience Map algorithm:

```
Update experience map get new target (FB4)
{
 Update Experience map ()
/* update the current position of the experience map since the last experience*/

 Calculate_path_to_goal ()
 Get_goal_waypoint ()
 }

 Map Converging, add new goal (FB5)
{
 CREATE_NODE
 CREATE_EDGE
 SET_NODE
 iterate ()
 /* iterate the experience map. Perform a graph relaxing algorithm to allow the map to partially converge */
Set_goal_pose_callback ()
Add_goal ()
/* Setting and handling goals */
 }
```

According above description, RAT-SLAM software architecture allows a multithread processing; therefore it can be parallelized in an heterogenous System on chip (Soc). However, the proposal is to proceed with the code profiling first, to stand on every function block use rate, calculate accurately the number of times each function is called and get an overview on the memory usage for each block.

C. Code Profiling and Workload Identification

In order to have better understanding about how the algorithm is behaving once run on a CPU, the source code has been profiled using a profiling tool to measure the processing time of the functional blocks, the parameters dependencies and hence the functional blocks that could be parallelized.

Profilers are designed tools for analyzing and improving performance of code execution. They allow analyzing the algorithm, to measure, while the code is running, how long a routine takes to execute, how often it is called, where it is called from and how much of total time at some spot is spent executing that routine.

By using the opensource Callgrind profiling tool [12], which is considered as a binary instrumentation profiler, the call history could be recorded among functions for every main functional block. Data collected and represented in Table I, correspond to the CPU and memory workloads using an Intel® core i7 @1.8 GHZ CPU with 8 GB RAM. Also, the cache memory usage for reading and writing operations is given. This information is important because it reveals about congestion in different memory buses.

A fast information is then given about the algorithm behavior, to target where the code parallelization can be more efficient, of course an adequation architecture algorithm analysis is mandatory to have a deeper understanding and make the maximum optimizations that can be done.

TABLE I. RAT-SLAM C++ WORKLOAD ON A CPU

FB	CPU workload %	Cache memory reads %	% Cache memory writes %
Pose cells	28.98	28.30	29.99
Local View Cells	41.61	42.77	39.70
Experience Map	29.41	28.93	30.31

D. CPU-GPU Parallelization

Computing architectures have known the generalization of the concept of parallelism thanks to their significant technological evolution in recent years. Parallelization has spread to the level of processor architectures, notably with multicore processors and superscalar computers. In this context, founders and manufacturers of graphics processors have developed their architectures to be able to use them in applications with generic processing by designing GPGPU (General Purpose Graphic Processing Unit). Development languages like CUDA, OpenCL or OpenGL have been designed to use the potential of these processors for massively parallel computing purposes.

To our knowledge, in the state of the art, there is no study on the performance evaluation of a bio-inspired SLAM algorithm on GPU-based architectures.

The interest here is to explore hybrid architectures based on CPU-GPU for the implementation and parallelization of a bio-inspired SLAM algorithm. A first challenge lays in the complex data structure which results in the nature of the studied algorithm. Another interest lies in the specificity of the parallelization and programming of CPU-GPU architectures, which differs from conventional methods of parallel programming requiring mapping optimization and processing synchronizing with different coprocessors and shared memories.

Hence, the RAT-SLAM algorithm was divided into blocks with well-defined inputs and outputs (in number, type and size of data). An algorithm consists of a processing description, so it is the same for the blocks composing it.

The modeling in this work is based on a graph representation that illustrates the dependencies between the different blocks of the algorithm.

In the case of a heterogeneous architecture, the execution time of each functional block and therefore of the algorithm strongly depends on the mapping, otherwise on the way in which the functional blocks are distributed between the different processing units. The goal of the mapping optimization is to find one or more implementations allowing to reach defined constraints of real-time.

Given the results about the workload of each functional block, knowing the cache memory number of read/write accesses, measuring the execution time of each block and sub-functions, and taking into consideration the algorithmic complexity analysis, the nature of interaction between functional blocks can be understood. So, functions that needs to be sent to GPGPU for a parallel processing are separated from the ones that need to remain on the host, because processing them on CPU will be adequate due to the sequential processing and to make benefit from the higher frequency of CPU.

So, based on the above, this study propose an optimized parallelization targeting a CPU-GPGPU heterogenous architecture, where all time-consuming functional blocks related to image processing, visual template generation, intermediate map creation, pose cell experience and matching, have been transferred to the GPGPU device as explained in Fig. 2. The CPU is then managing the sequential processes and acting as a host.

As per Fig. 2, the selected functions for a parallel computing were converted to CUDA. Also, for evaluation purposes, the algorithm is executed first on a laptop (see Table II for hardware specifications), then on a Jetson TX1 which is often used in automotive applications due its better performance compared to its predecessor TK1 (see Table III for Jetson Tegra X1 hardware specifications).

IV. HOOFR-SLAM

HOOFR is a bio-inspired binary detector, inspired from human retina. As introduced by Nguyan et al. [6], it is a novel model inspired from Hessian ORB - Overlapped FREAK (HOOFR) and based on the combination of the ORB detector [13-14] and the FREAK bio-inspired descriptor [15]. HOOFR use a similar method as ORB except that for filtering features it uses, instead of Harris filter, a Hessian Matrix represented by equation 3, together with Gaussian represented by equation 4 for smoothing.

$$H = \begin{bmatrix} \frac{\partial^2 I}{\partial x^2} & \frac{\partial^2 I}{\partial x \partial y} \\ \frac{\partial^2 I}{\partial x \partial y} & \frac{\partial^2 I}{\partial y^2} \end{bmatrix} \qquad (3)$$

Where I is the pixel intensity and $\partial x, \partial y$ are the derivative in x and y direction, respectively.

$$G(x,y) = \frac{1}{2\pi\sigma^2} exp\left(-\frac{x^2+y^2}{2\sigma^2}\right) \qquad (4)$$

Where G(x,y) is a Gaussian 2D distribution and σ is the standard deviation of the distribution.

Because the human retina has a better visual acuity, the rotation estimation is done based on the sum of gradients over a selected pair, by using long pairs to compute the global orientation, whereas select pairs are mainly with symmetric receptive fields with respect to the center, as per Fig. 3.

The set of selected pairs is done according to the following equation 5:

$$O = \frac{1}{M} \sum_{P_0 \in G} \left(I\left(P_0^{r_1}\right) - I\left(P_0^{r_2}\right)\right) \frac{P_0^{r_1} - P_0^{r_2}}{\left\| P_0^{r_1} - P_0^{r_2} \right\|} \qquad (5)$$

where M is the number of pairs in G and P is the 2D vector of the spatial coordinates of the center of receptive field. However, compared to classical binary descriptor (like BRISK), HOOFR retinal pattern has more error in the orientation due to a larger receptive field allowing more estimation error, but this issue is solved by discretizing the space of orientations in much bigger steps, leading to more than 5 times smaller memory load (about 7 MB against 40 MB), and therefore a smaller execution time.

The main difference between Rat-SLAM and HOOFR-SLAM matching method, is that the first algorithm is comparing the template image against the source image by sliding it, then a sum of square is calculated to give the movement direction, so this method is operating directly on the pixel value, while HOOFR, from the other hand, use a feature matching method. In general, for this kind of techniques, the accuracy and efficiency are strongly dependent on the used detector and descriptor. An evaluation has been done in [4-5] show the impact of execution time and accuracy by using different feature detectors/descriptors combination. Fig. 4 is schematizing the flow of each algorithm front-end process.

Unlike RAT-SLAM, HOOFR-SLAM has been parallelized in a previous work [16] and implemented in different heterogenous architectures, so it is re-evaluated on a laptop, in order to determine the acceleration rate in a the same hardware architectures, and to have a fear comparison with results obtained for Rat-SLAM.

Since both bio-inspired algorithms has different images perception and since the camera position in HOOFR is frontal but lateral for RAT, any comparison using the same dataset will not be equitable, even after a modification, because the number of evaluated templates will not be the same. Therefore, a corresponding dataset is used for each algorithm in order to get time spent per iteration, images examples are given by Fig. 5.

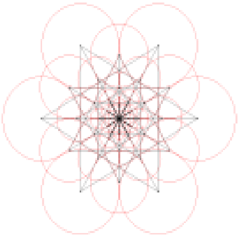

Fig. 3. Illustration of the Pairs Selected to Compute the Orientation.

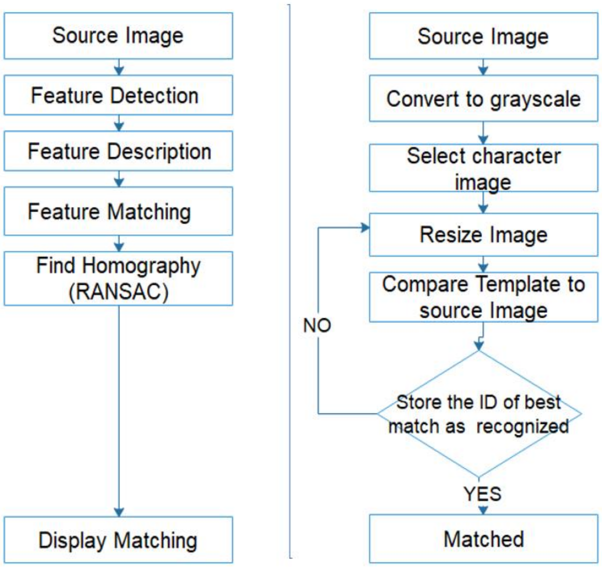

Fig. 4. Front End Process flow Diagram Showing differences between HOOFR-SLAM Feature Matching (Right) and RAT-SALM Template based Matching Method (Left).

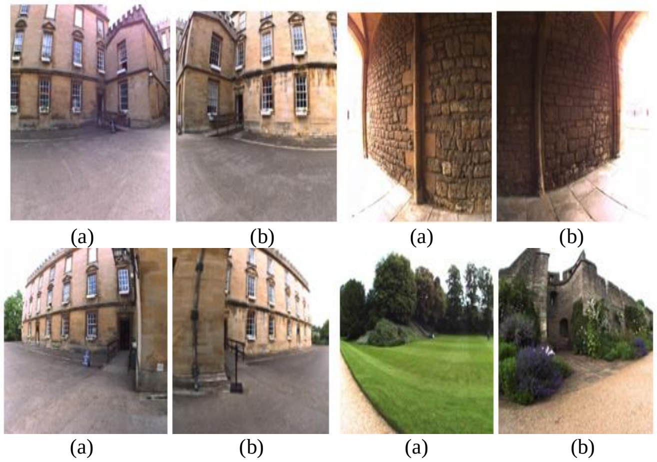

Fig. 5. Left and Right Images taken at different Lighting Conditions, by a RealSense Stereo Camera System, Simulating Rat Eyes and Placed in Lateral Position to have Similar Visual Perception as for a Rat. Right (a) and Left (b) Images used for RAT-SLAM, Images are Panoramic and May Appear Distorted to Human Eyes.

The evaluation was based on outdoor sequences where different lighting conditions are applied for better performances check.

V. Experimental Results

A first evaluation for both selected bio-inspired algorithms is done based on a Multi-core Intel CPU and an NVIDIA GPGPU with a high-end 64-bit implementation. This configuration shown previously in Table II, allows the evaluation of different run modes on a CPU, multi-cores CPU and CPU-GPGPU combined. All presented results are the mean values of 20 runs.

Tables IV and V gives the processing times per iteration when the functional blocks are transferred to GPGPU as shown in Fig. 6.

TABLE IV. Average Processing Time (MS) Evaluation for RAT-SLAM with Parallel Implementation on a Multi-core CPU, and a CPU-GPGPU Laptop

		Intel® core i7	NVIDIA GeForce MX110	Acceleration %
		Multi Core CPU	CPU-GPGPU	
Local View	FB1	183.17	31.93	82.57
Pose cells	FB2	0.75	0.22	70.67
	FB3	38.49	22.32	42.01
Experience Map	FB4	133.93	84.81	36.68
	FB5	0.16	0.08	50.00

TABLE V. Average Processing time (MS) Evaluation for RAT-SLAM with Parallel Implementation on an ARM CPU, and CPU--GPGPU using ARM-Nvidia TX1

		ARM®Cortex -A57	NVIDIA Maxwell™	Acceleration%
		Multi Core CPU	CPU-GPGPU	
Local View	FB1	111.76	32.24	71.15
Pose cells	FB2	0.75	0.29	61.33
	FB3	26.59	20.94	21.25
Experience Map	FB4	113.82	86.86	23.68
	FB5	0.13	0.09	30.73

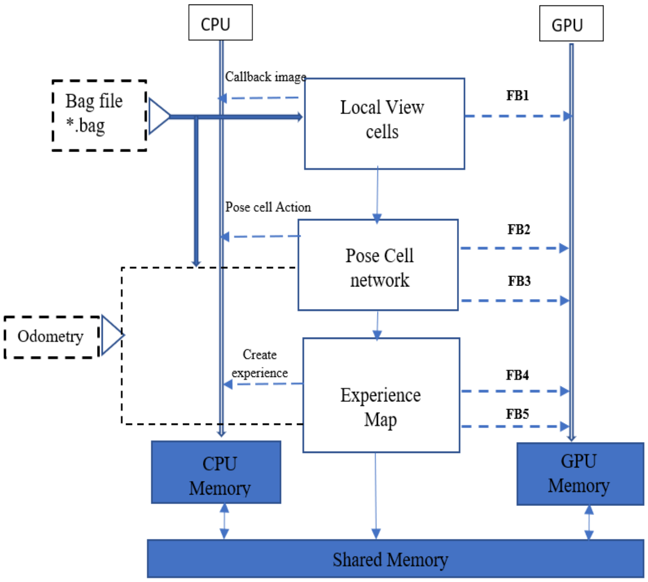

Fig. 6. Simplified Schematic Representation of Functional Blocks Sent to GPU and the One Remaining on CPU for Rat-SLAM.

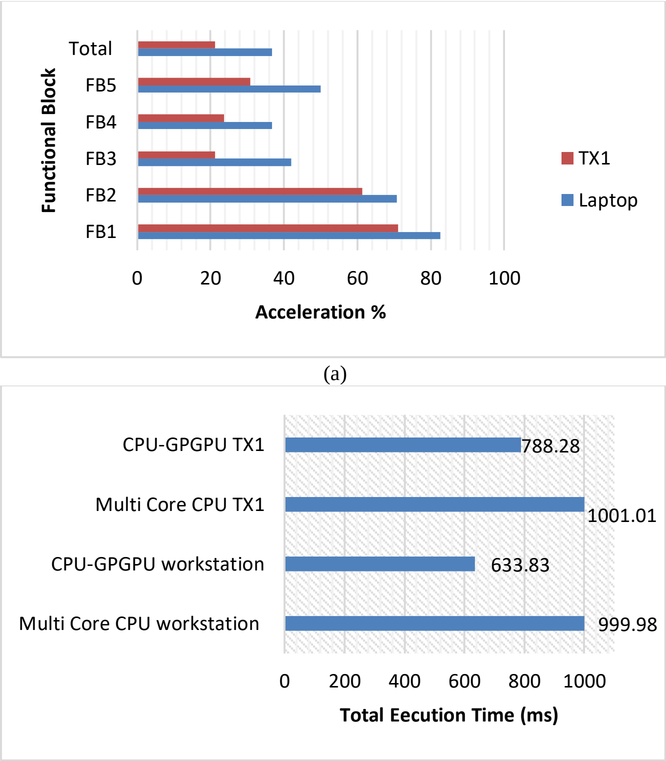
The evaluation was achieved using the well-known open-source dataset Oxford New College, 2008 [9], settings and camera calibration parameters are shared by the same source. Images are panoramic and were converted to gray scale to match the most the rodent eyes perception to comply with the template matching process requirement.

Based on above results, the processing time of the most time-consuming functional blocks is drastically reduced using a parallel implementation by 36.68% on the laptop and 23.68% for TX1, this is due to the higher GPU performance and number of cores on the laptop compared to TX1, Fig. 7 is a graphical representation of the total execution time speed up for the algorithm on GPGPU.



(a)

(b)

Fig. 7. Comparison of Acceleration (A) and Total Execution time (B) for Oxford New College [9] on Laptop and on TX1 Hardware.

Below, graphs in Fig. 8, 9 and 10 represent the average execution timing measurement related to NVIDIA GeForce MX110 GPGPU and on ARM Cortex-A57 on TX1, also the power consumption in Watts for both Laptop CPU and GPU.

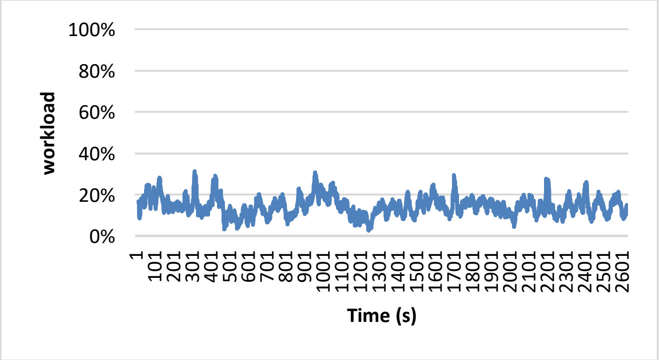


Fig. 8. Average Workload Evolution for RatSLAM on Laptop NVIDIA GeForce MX110 GPU, the Workload Everage is around 20% during the Total Execution Time of the Selected Dataset [9].

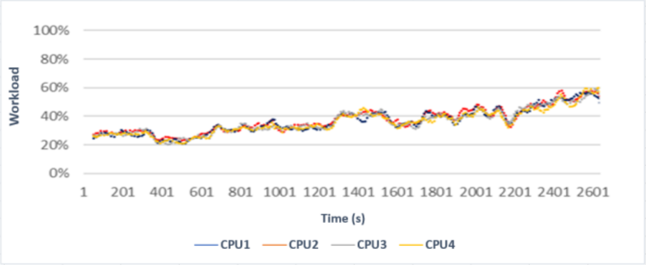

Fig. 9. Average Workload Evolution for RatSLAM on Laptop Intel Core i7 CPU, the Workload Everage is Variating between 20% and 60% during Execution of the Selected Dataset [9].

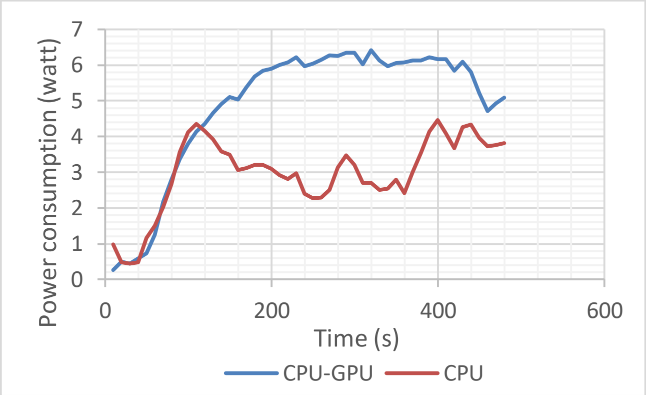

Fig. 10. The CPU-GPGPU Power Comsumption is Calcuted only for RATSLAM Algorithm when the Power Resulting form Operating System is not Considered.

As per above graphs , the CPU workload has been reduced by an average of 20% when running the RatSLAM algorithm, by running parallel functional blocks on GPGPU, but due to the nature of the algorithm some blocks cannot run on GPU because they are sequential and therefore are kept on CPU.

As expected the temperature will also increase on the CPU in the same way as per below Fig. 11, which can be considered as a week point for implementation of Rat SLAM in an embedded architecture where the use of a cooling system is not always possible.

An evaluation of HOOFR-SALM using KITTI-07 open source dataset, gives the results shown in Tables VI and VII.

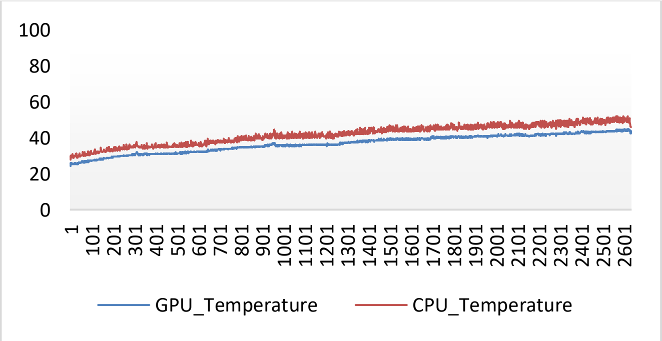

Fig. 11. Temperature Profile for Laptop CPU and GPU, it Increases Over Time Due to the Amount of Input Data.

Loop detection	21.92	16.47	25
Map Processing	0.58	0.4	31

VI. CONCLUSION

This paper presented an algorithmic complexity study for two bio-inspired algorithms. It proposed an optimized parallel implementation on a CPU-GPU by studying, in a practical way, optimization possibilities for workload partitioning. It also presented understanding of bio-inspired algorithms with necessary techniques to accelerate there processing times for real time SLAM applications.

From one hand, based on above temporal evaluation results, a first conclusion is that the use of multiple CPU's cores cannot accelerate much the algorithm compared to one CPU core. This is due to the congestion of data in buses at the on-chip memory level since it is a shared resource for all CPU's cores. The memory is considered as a bottleneck in this case and using a higher CPU frequency or more memory will not help much.

From another hand, considering a real time sequence where the frequency is higher than 30fps, and based on the experimental results when executing both algorithms, it is clearly seen that despite the considerable acceleration, Rat SLAM still cannot fulfill the real time expectation as it should be executed in less than 33ms per frame, due to the matching sequence that is dependent on the number of images perceived by the camera sensor. Furthermore, the algorithm needs to keep previously seen templates in the memory for localization and to fine tune the map (loop closing), which has an impact on the final execution time.

In the case of HOOFR-SLAM, which is a feature-based approach that doesn't depend on the dataset size, the matching process time is not increased by increasing the number of input images. This is very important because the processing time will remain practically the same for all iterations and therefore the parallelization is more efficient.

These two studies covering the exploration of hybrid architectures based on GPU-CPU for the implementation and parallelization of bio-inspired SLAM applications, allowed to draw conclusions about the challenges to be met related to the complexity, the structure of data and the nature of the algorithms studied. The results presented in this paper confirm that future heterogeneous architectures will represent potential candidates to embed complex algorithms such as those of bio-inspired SLAM applications.

Future work will focus on the implementation of selected functional blocks on FPGA architectures in order to bring defined processing closer to the sensor and hence allow image processing on the fly and reserve the GPU for massively parallel processing.

***Abstract*—The Scientific Cultural Heritage (SCH) of the Drâa-Tafilalet region in south-eastern Morocco is a rich source of data testifying to the ingenuity of an older generation that has shaped the past of the region. These data must be preserved for future generations, particularly with new technologies and the semantic web. Recommendation systems (RS) are intended to assist prospective users in recommending the most suitable services based on their profile and expectations. The collaborative filtering (CF), content filtering (CB) or hybrid filtering (CF) RS has shown promising results in order to explore the problems experienced especially in CH. However, there are some limitations to be resolved, mostly due to the ability of these methods to build a stable and complete framework, which can provide a complete image of the user profile and suggest the most appropriate offers. This paper presents a hybrid recommender system for SCH data; a field little explored despite its historical importance and the value it generates. The results presented in this paper belong to the data collected from the region of Drâa-Tafilalet in southern Morocco.**

***Keywords*—Cultural heritage; CIDOC-CRM; ontologies; OWL; recommender system; semantic web; RDF**

I. Introduction

Given the many features and applications developed in the Big Data age, a Recommender System (RS) is an essential and effective user support tool. The user loses a considerable amount of time because the access to relevant information is difficult and the value of the services offered is challenged. An RS is a data filtering method that defines a collection of resources that are important to a particular user. There are three different forms of RS to think about. Content-driven SRs monitor user behavior and make suggestions for new items based on the user's interests. The guiding forces behind this work are the need to protect the Drâa-Tafilalet heritage. A region with a rare richness and diversity in its tangible and intangible cultural heritage, the use of which was restricted to a few a number of projects, without noticeable effects, by some public institutions. Using emerging technology will help make this heritage known, preserve it and make it a valuable added vector for a country with practically non-existent economic activities. Technologies for semantic web, Linked Data, for example, will go a long way toward resolving some of the issues that have arisen in several applications of this type. In particular, the lack and dispersion of data sources and the redundancy of information available on the web in data sources held by the public sector and private organizations. Using link tools, we can expect to have a single complete Moroccan Heritage data source utilizing multiple data sources. As a result, the stored data is automatically processed to extract useful information for the end-user, adding a significant dimension to the proposed system's architecture [1]. This document is structured as follows: Section II provides a synopsis of how SRS works for CH. Section III deals with some terminologies on Drâa-Tafilalet's unique and rich SCH. Section IV describes the architecture of the proposed system

and presents some results obtained, while Section V presents a conclusion and some future directions.

II. Related Works

The literature includes a limited number of works discussed by machine learning (ML) [13] algorithms for the issue of SCH conservation. This study focuses on the creation and testing of a SCH recommendation framework based on ML algorithms and semantic data through the use of a CIDOC CRM-reference model. The use of SRS in CH has been widely debated by researchers. In view of the great demand displayed, especially for cultural tourism, many players, especially in the last 10 years, continue to express their interest. In the semantic integration of the Draa-Tafilalet area CH data from a generic Big Data architecture a complete analysis was carried out and applied [2]. It is the primary motivation for this work as well as a rich source of data for the future works. The authors in [4] propose a novel methodology for implementing a route planner within cultural sites such as museums by combining recommendation facilities with agent-based planning techniques. No clear idea is provided on the data collected and its nature. The PCS data is not illustrated in this case. The authors present INTHELEX, an application of a first-order logic incremental learning system that allows learning the automatic identification rules of a wide range of essential document classes and their related components in [5]. When the set of documents is constantly expanded, incrementally plays a critical role. The Folksonomy-based Item Recommender System (FIRST) [24] is a CHAT-developed content-based recommender system. The goal is to propose a

*Corresponding Author

method for adaptive exploitation of digital libraries based on a flexible architecture that allows the recommendation of artworks located in the Vatican Picture Gallery (Pinacoteca Vaticana), providing users with a personalized tour of the museum based on their preferences.

CHAT-Bot [9] is a chatbot that recommends adaptive tourist itineraries with points of interest and associated services based on the tourist's profile and contextual factors. The authors of [10] present a Big Data architecture supporting popular applications for CH (query, content analysis, navigation). The objective is to propose a new user focused approach to suggest different cultural artifacts. SMARTMUSEUM [17] is a mobile application that offers customized, contextual knowledge and content suggestions to museum visitors using geo-location, Near Field Communication (NFC), and Radio Frequency Identification (RFID) techniques. In most of the works reviewed, CH is dealt with in a general manner or, alternatively, by taking into account a case study concerning a particular object that may be part of the tangible or intangible heritage. Processing of SCH objects such as zawyas, khizanas and oulamas is almost absent or in the majority of the cases treated from its historical and cultural side. This is devalorizing given its importance in the history and civilization of a generation that has tried so hard to make this heritage known. The use of new technologies of the semantic web such as RDF graphs and ontologies will surely allow attributing to the SCH data an interesting semantic side and therefore benefiting from all the advantages and advances that these technologies offer.

In this work, we focus on the SCH data. The number of objects belonging to this type of data and the dimension of each object are two important factors. This justifies the choice to focus on the objects: Medersas, Zawyas and Oulamas. Each Zawya may contain a Khizana or library containing documents of several types (books, manuscripts, documents, maps...)

The SCH objects processed can be classified according to the structure given in Fig. 1.

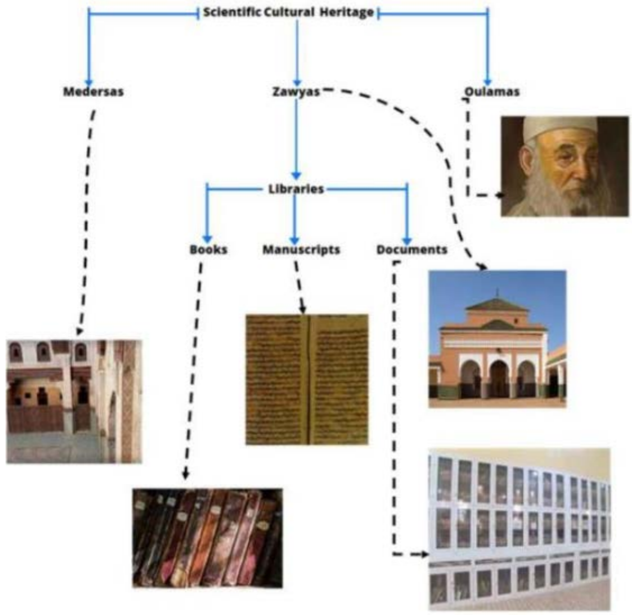

Fig. 1. The Different Forms of the Moroccan SCH Considered.

III. Terminology and Basic Functionalities

A. Scientific Cultural Heritage

Drâa-Tafilalet region in Morocco has a diverse and rich SCH. This heritage includes objects, buildings, and monuments from various periods and architectural styles, including religious architecture, funerary architecture, military architecture, and domestic architecture.

1) Zawya: Zawya is a Moroccan term that refers to the location where Sufi disciples congregate in the presence of Sufi sheikhs to "purify the soul and refine behavior." The Zawya is a scientific, social and religious entity that has received special attention because of a historical relationship between Morocco's rulers and the Zawya's sheikhs, who played an important role in the country's political stability and spiritual security. In general, every Zawya has a library with its name. The library contains books, old manuscripts and documents that reflect the country's history and culture. There are dozens of Zawyas in the region, many of which are still active and have been for centuries. Some of them still keep their extensive libraries.

2) Oulamas: The Oulamas are Muslim scientists who have worked in a variety of fields, including science, literature, and law. They have left an indelible mark on Moroccan history, as well as the history of all Islamic countries throughout history. Ultimately, the goal of this research is to identify the Oulamas associated with the Tafilalet region who lived within its walls, refine their talents and abilities, and improve their knowledge and achievements in Shari'ah and related sciences. It is therefore another type of CH of the diversity of the Drâa- Tafilalet region.

3) Medersa: A "medersa", "Madrassa" or Koranic school is a Muslim theological school operated by a religious foundation known as "waqf". The Merinid medersa of Morocco, located in Fez, is the most notable among them, with impressive architecture. In addition, those from the Drâa-Tafilalet region, who is main function is to teach the Koran and the Hadith. Semantic web references such as RDF/RDFS and Owl are used to represent the region's collected scientific heritage data. Several knowledge bases are included to enrich the information presented to the end user and ensure semantic consideration of user queries, regardless of formalism or language used. Table I illustrates a semantic representation of some SCH concepts.

These semantic equivalences are exploited to provide rich and optimized content since some descriptions of some commonly used cultural objects will derive from reference knowledge bases such as DBpedia. In Fig. 2, an overview of the representation of the Zawya NASSIRIYA library in Tamegroute is illustrated.

B. Basic Functionalities

In general, a SRS integrates the following main functionalities:

TABLE I. EXAMPLES OF SOME CONCEPTS AND THEIR SYNONYMS USED IN THE SCH

Concept	*related terms*	*DBpedia source*
Khizana	bibliotheque Maktaba	https://dbpedia.org/page/Library
Medersa	School Koranic school Madrassa	https://dbpedia.org/page/Madrasa
Book	Livre Kitab	https://dbpedia.org/page/Book
Manuscript	Manuscrit Makhtout Makhtouta	https://dbpedia.org/page/Manuscript

1) Acquisition/learning: Acquisition and learning are the first step of every SRS. It is a delicate and necessary step since any system's output depends on the quality and volume of input data, and it consumes the majority of the time spent on a project. The geographical dimension and constraints associated with the region of study, as well as the nature of the data collected, are also important considerations.

2) Creation of the user profile: The development of a user profile takes place according to the previous stage and the interactions an actor has in the system, particularly if the SRS is of hybrid type as in the study. One of SRS's most difficult challenges is the cold start problem, where the machine does not have details about the actor who is supposed to use it. This issue is addressed by assigning a default profile to each new user based on the semantic average of what is visited and what is most desired by other users, owing to the semantically close relationship between the objects manipulated by the system.

3) Extracting objects of interest: The next step is to extract the most interesting things for the user. Several techniques are used in SRS to ensure the semantic side of extracting the items of interest, which is dependent on the capacity of the system to interpret and understand user interactions (ontologies, RDF graphs, SPARQL queries, etc.). CIDOC-CRM standard was used for the integration of CH data of the study area. CIDOC CRM is the most widely used ontology and offers several advantages, which make it a reference, justifying its use in our case. The use of ontology aims to identify objects that are semantically linked to the user's interest items in order to ensure as rich as content as possible. The actor may be interested in the historical aspect of a KHIZANA from the area. However, he may be more interested in this one's content, which is rich in historical and cultural data.

4) Classification: The classification helps for the organization of the extracted objects based on their continuously modified profile and their importance to the end user. A number of algorithms were used in the literature to accomplish this mission, based on expected features and performance. The advantages of ML and DL technologies have been demonstrated in a wide range of fields, especially in CH (CNN, Naive-Bays, SVM, CNN, etc.) (Fig. 3).

5) Recommendation: A list of items that can interest the end user is produced in the recommendation process. This list is typically presented in the order of relevance based on the user's created profile. Based on the user's interactions with the system, this profile is constantly updated. A semantic link depth is defined to prevent the end-user from becoming lost in the massive amount of data presented to him. The best depth is currently defined by what is observed practically through user interactions, but it will be the subject of a much more in-depth study based on what is observed.

In this paper, we represent each object O_1 by a set of n features (f_1; f_2. . .; f_n). We note ***d*** the distance function used to compare objects. if D is a Database (relational DB and Knowledge base) of objects, the k-nearset neighbor of an object noted q can be described by :

$$NN(k,q,D) = \begin{cases} s \in D \backslash \forall\, r \in D\ d(q,r) \geq d(q,s)\ if\ k = 1 \\ NN(k-1, q, D \backslash NN(k-1,q,D)\ if\ k \geq 2 \end{cases}$$

The user through his interactions with the system identifies the inputs. The new connections are automatically assigned a set of concepts extracted from his profile or a generic profile. This algorithm is of the KNN type, and the number of k closest neighbors shown in the output adapts to the display device used by the end user. The depth is limited to three levels of semantic links extracted from the SCH concept semantic representation, as shown in Fig. 2. This restriction was imposed following a series of experiments and tests. The semantic distance is calculated for each extracted concept, and if it is less than a certain threshold, the item is added to the output list.

Algorithm 1 : Best item recommendation

```
Inputs     Target User : U
           Set of Concepts : C
           Number of items to recommend $n \in \mathbb{N}$
           $p \longleftarrow 3$ (link depth)
Outputs
foreach    $x \in C$ do
    $pr \longleftarrow depth\ (x, U)$
    If $pr \leq 3$ then
        $d \longleftarrow measure(x, U)$
        If $d \leq \epsilon$ then
            R.add(x)
        end
    end
end
```

C. Algorithms of ML for CH

A preliminary study was carried out on the various ML algorithms used to process cultural heritage data (rule-based algorithms, genetic algorithms, SVM, KNN, etc.). The goal of this part is to find the most efficient algorithms to use for the CH of the study region and to increase the performance of the proposed system. This paper describes nine ML algorithms, which are as follows:

- SVMs (Support Vector Machines) [21]: This is a set of supervised learning algorithms that are frequently used for regression or classification. SVM is an algorithm based on statistical learning. These algorithms search for all data points similar to those in the other classes. These data points, known as support vectors, are used for the classification task, the others data points are ignored. The best dividing line, known as the decision boundary, is then defined.

- Naive Bayes (NB): This is a statistical approach founded on the theorem of the probabilities of Bayes. NB employs statistical functions to determine the likelihood that input is relevant for a specific predefined class. This algorithm returns the most likely class.

- Decision Tree (DT) [15, 19]: As a logic-based algorithm, DT models data sets in hierarchical structures using a series of if/else statement comparisons. Each node in the tree is made up of either decision nodes that contain terms (or objects that are more complex) or leaves that contain class label predictions. The weight of each word or object is labeled on the branches.

- KNN (K-Nearest Neighbors)[6, 19, 21, 22, 30]: this is a statistical method for predicting new input by calculating the similarity between the test data and the new instance by locating the closest data points (or data objects) in the training dataset based on certain distance functions. K denotes the number of closest data points (i.e., neighbors). The value of K is frequently determined using experimental test data.

- Rule-Based (RB) [5] classifications are algorithms in which collections of rules represent the data set. In contrast to DTs, which use a strictly hierarchical approach, RB classifiers allow for overlaps in the decision space. These rules are divided into two sections: the left side is made up of conditions, and the right side is made up of classes. The dataset is used to generate these rules.

- CNN (Convolutional Neural Networks) [20, 21, 23, 25, 30, 31] are widely used for image or video processing, including image classification. The term “convolutional network” refers to a mathematical concept known as the convolution product. In simple terms, we apply a filter to the input image, and the parameters of the filter are learned as we go. Following that, a learned filter will be used to recognize and classify a more complex image or object. To classify architectural heritage images, the authors propose and implement a pre-trained CNN such as GoogLeNet, resnet18, and resnet50 in [31]. The goal is to improve image database management and make it easier to search for a specific element, thereby facilitating the study and analysis of the relevant heritage object.

- Genetic-Based (GB) [6, 7]: GB algorithms are a subset of evolutionary algorithms. The goal is to use an optimization mechanism to approximate the solution to an NP-complete problem. The GB Algorithm begins with a population of candidate solutions known as individuals, which evolves from generation to generation until the first one contains the best solutions. Each individual has unique characteristics that can be influenced by genetic mutations (mutation, crossing, etc.). Each individual is evaluated, and its fitness value is used as a criterion for survival from generation to generation.

- Conditional Random Fields (CRF) [19] are statistical modeling techniques used in machine learning. A classifier predicts a single sample label without taking into account the context, whereas a CRF can. The prediction is represented as a graphical model, the type of which depends on the application, and it incorporates dependencies between predictions.
- Gaussian Mixture Models (GMM) [18,19] are probabilistic models that distribute points into different groups using the flexible clustering approach. GMMs assume a large number of Gaussian distributions, each of which represents a cluster. As a result, a Gaussian mixture model tends to cluster data points that belong to the same distribution.

In comparison to generic quadratic programming (QP) algorithms, Sequential Minimum Optimization (SMO) [19, 21] is a simple and efficient algorithm used to solve the learning problem in SVMs vectors. At each step, SMO decomposes the global QP problem into QP sub-problems and solves the minor possible optimization problem. Fig. 3 describes a summary of the outcomes obtained by distinguishing between tangible and intangible heritage objects. SRS is a type of semantic information filtering that has benefited greatly from the significant progress made in the semantic web world (ontologies, RDF/RDFS, OWL, etc.). A study was carried out in order to gain a clear picture of the most recent advances and technologies used in SRS for CH and its algorithms. Table II summarizes the findings.

The following are the most relevant comparison criteria that have been identified in terms of the basic functionality that any SRS for CH must provide:

- The objects of CH used: Cultural places, Tripes, Museum, painting, events, etc.
- The form of CH: Tangible (TCH) or intangible (ICH)
- Methods and Algorithms used: Artificial Intelligence (AI), Machine Learning (ML), Deep Learning (DL), Semantic Web (SW), etc.
- Type of Recommendation: Context-Based, Collaborative-Based, Hybrid, etc.
- Proposed GUI: Web, mobile, etc.
- Date: Date of start or publication of the first works and prototypes.

This will provide an idea of the historical side of the system.

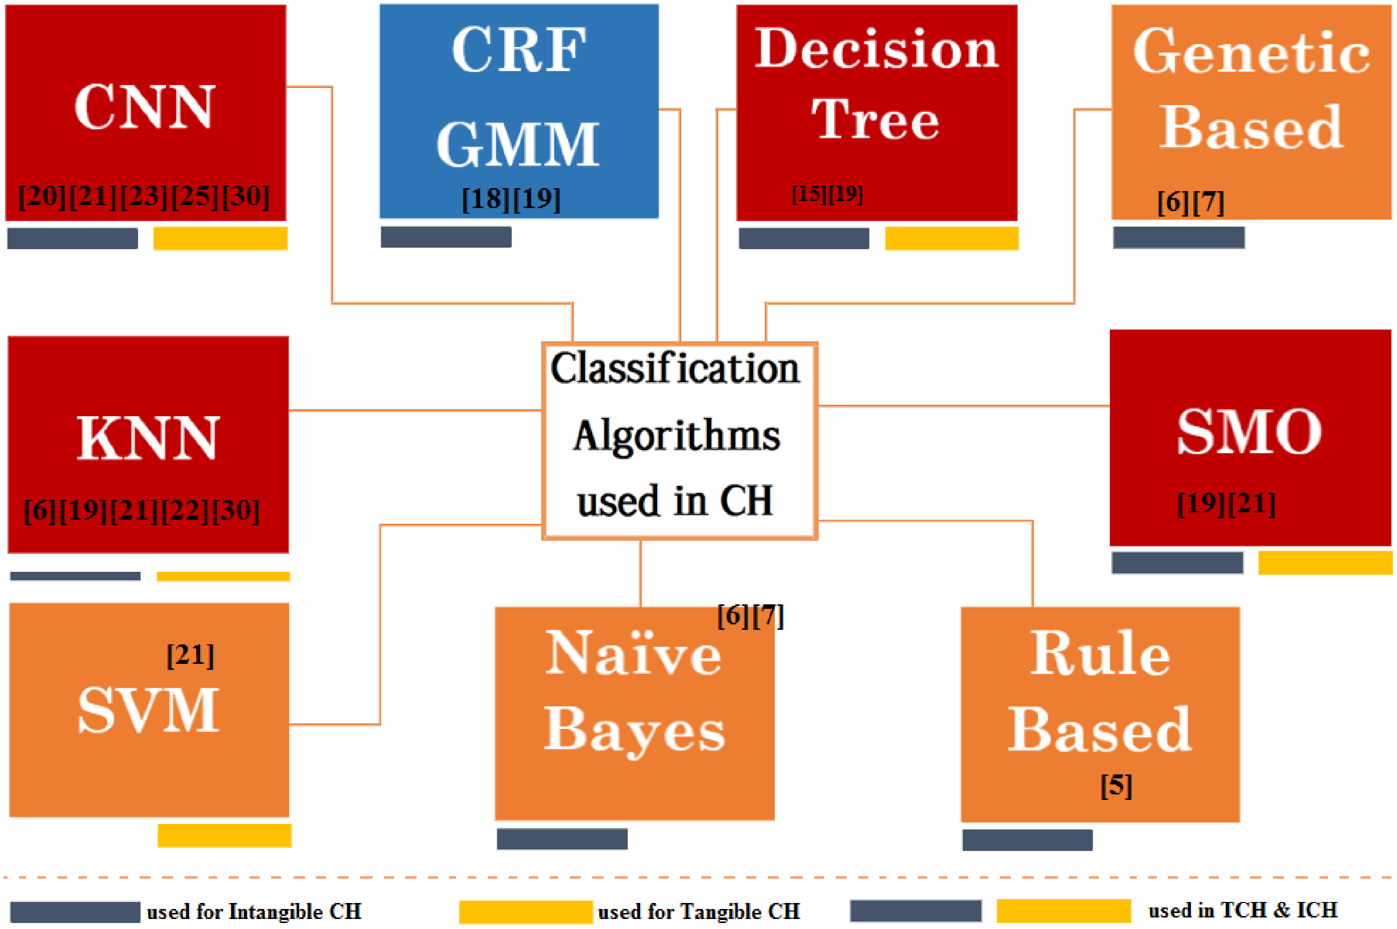

Fig. 3. Most used Classification Algorithms in the Field of Cultural Heritage.

IV. Results and Discussion

The developed system offers two options for support: a mobile application for Android systems and a web application. The end-user can access the rich content via a simple graphical interface, which provides relevant information on the KHIZANAS of the study region (Libraries). Each KHIZANA contains a number of documents (manuscripts, books, maps, geometric drawings, etc.). The user can also operate a query on the available data. Following that, three functions are carried out: Acquisition to extract keywords from a query and then detect important concepts implemented to feed the user profile or, if necessary, create a new profile. Several data sources are queried based on the entries of the users (database, knowledge base, .etc.). Based on the CIDOC CRM repository, an ontology was created at the start of this project to represent the SCH of the study region. The goals of this ontology are as follows:

- Integrate the semantic aspect to the system to guarantee complete handling of the user request.
- Have a controlled vocabulary for all the concepts used and their semantic links.
- Extract concepts semantically linked to those extracted from the user query (according to a predefined link depth) to provide more prosperous and more relevant content.
- Once this task is completed, the system provides adaptive content as recommendations that may interest the final user. The activation of one of these contents will help to enrich the profile already created.

The proposed system's architecture (Fig. 4) allows a user to interact by formulating queries and collecting the responses directly as SCH articles. It also makes recommendations based on the user's previous activities and, if necessary, the history of visits by other users if no profile has yet been created, reducing the cold start problem that any SRS must deal with. This is because SCH data is already semantically close, and the recommended objects have a high likelihood of being accepted by the current user. A particular work is done in the background to ensure the consistency of the recommendations provided. The back-end is primarily made up of algorithms that allow for the extraction of relevant concepts, their classification, and recommendation algorithms by implementing knowledge bases that allow for a semantic representation of the items related to the SCH and the various data collected, as well as the various records stored in various formats. The system administrator creates profile prototypes that correspond to the developed system preferences and functionalities and have a close relationship with the various SCH's forms that have already been introduced. The main problem that recommender systems face is the cold start problem. This is solved by creating a default profile (SCH) for each new user. This profile is increasingly customized to provide more targeted and relevant recommendations and services based on its interactions (and the history of other users) with the system (requests, consultation of proposed assets, comments, etc.).

TABLE II. Comparison of some Semantic RS

	System	Date	Objects used	Type of CH	Algorithms & techniques used	Type of RS	Proposed GUI
[27], [28]	-		Artifact, movies, books, music (songs & artists)	TCH	Linked Open Data techniques	Hybrid	
[5]	INTHELEX	2004	CH Documents	TCH	Graphs, Object identity, ML	CF	Web app
[4]	-		Museum objects	TCH	multi-agent systems	Hybrid	-
[17]	SMARTMUSEUM		Museum	TCH	Geopositioning and NFC/RFID techniques	CF	
[11]	EventAware	2018	Events	ICH	Tags extraction, profile learning, Tag-based filtering	Hybrid	Mobile app
[9]	CHATBot	2020	Cultural sites	TCH	Text analysis	Hybrid	Mobile app
[16]	-		Painting and Sculptures	TCH	Social affinity graph	CF	
[14]	Ifar		Castles (The graz castle)	TCH	Serious games, AR, VR	CF	Mobile app
[24]	FIRSt (CHAT project)		Museum objects, movies, music, books,…etc.	TCH (Digital libraries)	Semantic analysis(Tags), ML	Profiling and CF	
[8]	-	2018	Cultural places	TCH	ML algorithms		Mobile app
[26]	Apollo		Museum	TCH	Minimax approach, ML, AI	Hybrid	
[12]	Père		Places & services	General	Semantic web technologies (RDF/OWL, SPARQL)		Web app
[10]	CHIS	2018	Cultural places	General	Big Data algorithms	CB	Mobile + web portal
[29]	-		Trips, attraction places		AI algorithms	Hybrid	Mobile app

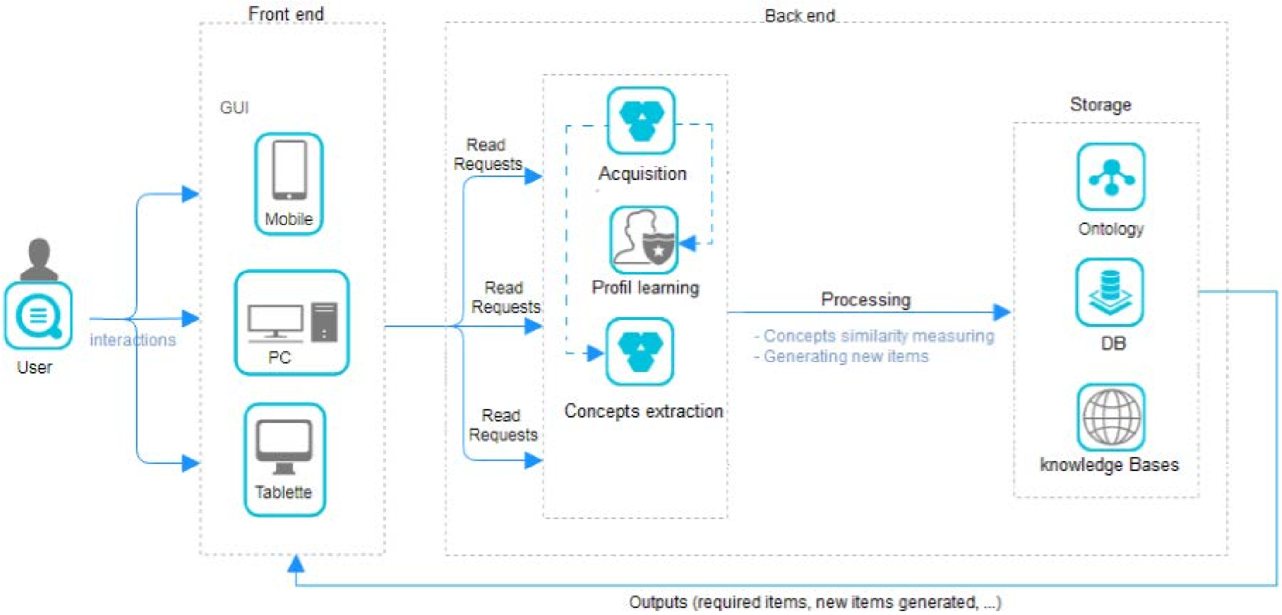

Fig. 4. The Architecture of the Proposed System.

Fig. 5 shows the results of integrating several semantic levels in the case of users interested in Books, resulting in a recommendation of objects with the same level of semantic depth (Books in this case) or higher levels (Manuscripts in this case) based on the semantic knowledge base already developed. Fig. 6 shows an example of a recommendation based on a user's interactions with objects of type: Khizana (Libraries), in this case, the Khizana Nassiriya, one of the world's oldest Khizana and houses to incomparable historical documents. In this case, the user will see recommended Khizana from the same category; it is the case where the semantic depth leads to objects from the same category.

V. Conclusion

Until now, very few works in the literature have focused on the valorization of the SCH of a region very rich in heritage data that has remained ignored. The added value of this work consists largely in the exploitation of some ML algorithms for the realization of an intelligent system allowing the recommendation of SCH objects. This will allow the preservation of this heritage and make it recognized by a maximum of actors. In this perspective, a Semantic RS for SCH has been implemented and tested for Drâa-Tafilalet region. The process of creating and assigning profiles considers end-user preferences. The process enables semi-supervised (content based) profiling, which is then refined using other available profiles (based on user collaboration (history of other users)). The system automatically adjusts the content to the user's terminal (mobile or web). The proposed system will enable the valorization of a little-known CH despite its significant potential in several fields of the economy of a region whose primary source of income is tourism. The majority of the functions described in this paper are already operational, and test data was used to validate the final prototype. The next step is to incorporate this component into the overall system in order to achieve the primary goal of this study: to have a comprehensive system for preserving and presenting the CH of the study region. Another point to raise, which will serve as the foundation for future work, is the incorporation of an interface that will allow cultural heritage specialists in the region to validate available data before it is explored via the platform.

Comprehensive Survey and Research Directions on Blockchain IoT Access Control

Hafiz Adnan Hussain[1], Zulkefli Mansor[2], Zarina Shukur[3]
Faculty of Science and Information Technology
The National University of Malaysia
Bandar Baru Bangi, 43000
Selangor, Malaysia

***Abstract*—The Internet of Things (IoT) is a widely used technology in the last decade in different applications. The Internet of things is wirelessly or wired to communicate, store, compute and track various real-time scenarios. This survey mainly discussed the core problems of Internet of things security and access control to unauthorized users and security requirements for IoT. The Internet of things is a heterogeneous device and has low memory, less processing power because of the small sizes. Nowadays, IoT systems are not sure and powerless to protect themselves against cyber attacks. It is mainly due to inadequate space in IoT gadgets, immature standards, and the lack of protected hardware and software design, development, and deployment. To meet IoT requirements, the authors discussed the limitations of traditional access control. Then the authors examined the potential to spread access control by implementing the safe architecture accommodated by the Blockchain. The authors also addressed how to use the Blockchain to work with and resolve some of the standards relevant to IoT security issues. In the end, an analysis of this survey shows future, open-ended problems, and challenges. It offers how the Blockchain potentially ensures reliable, scalable, and more efficient security solutions for IoT and further research work.**

***Keywords*—Blockchain; Internet of Things; IoT; access control; access control management**

I. Introduction

Internet of Things (IoT) is an infrastructure of smart things that exchange information over the Internet. In a different world, the Internet of things is used to obtain data, and certain events are triggered. The linked IoT devices are expected to be 50 billion in late 2020, according to CISCO. As the entire world population grows, the advancement of IoT devices is rapidly evolving. There seem to be enormous data produced by IoT devices. The infinite interlinking between physical and virtual objects notably stimulates processing, storage, and data exchange on the IoT. It is a primary base for rendering services in critical areas such as hospitals, cars, bridges, schools, retail outlets, public constructions, communities, and even within human bodies in the form of wearable devices. The foremost issues are how can efficiently handle services and data collected by IoT devices because they can contain personal information or even save people's lives. There are many difficulties in implementing IoT. In numerous IoT implementations, uniformity, interoperability, data management, processing, user authentication, identity, confidentiality, completeness, affordability, protection, and privacy are among the several open challenges. One of the famous approaches for data protection and privacy is making sure only validated and accredited users can see that data [1]. Data is coming massively from these devices, storing data to make sure it is secured and protected from hackers, and authenticating the user who wants to access that data is the correct user on the server. The authenticated user must have limited access to limited data.

Access control is a collection of rules and policies that enable a nominated user to be enabled or not accessed by users, services, procedures, or other approved mechanisms to access or limit access to an information system's resources. It decides whether or not the requirement for access to the related order is allowed [2]. Various concepts, like access control policy, layout, and method, have established a basis for developing an access control system. The access control policies form the basis for access arrangements implemented through the mechanisms for access control. The essential parts of the access control system are the object, subject, and owner of the thing. The current element is a subject that requests access to objects. The object is a receptive element in a system that is petitioned by the subject. The connection to an object determines access to documents, areas, directories, programs, and network nodes to its information. The network is also recognized as objects-related devices, including smart devices, routers, and mechanical elements. The owner of each entity defines access policies and supplies the necessary authorizations.

In IoT access control systems, certain restrictions are imposed because they have a complex and clustered infrastructure that does not meet the wide variety of IoT gadgets and the versatility situation in which nodes can connect and drop the network. IoT devices often need a lightweight low-latency access control system for CPUs, memory, and battery life [3]. Numerous literature attempts to create a distributed IoT control monitor utilizing edge paradigms such as Adhoc Web Cloud and Fog Computing by reducing the mentioned problems. However, due to the absence of trusted entities working to provide arbitrary services, the security problem persists. For example, a group of vehicles can accommodate road security assistance to other transports under traffic networks.

Blockchain is a Peer-to-Peer (P2P) distributed and decentralized public ledger over the network [4, 5]. It is used to store transactions, events, and smart contracts. The smart contract includes a programable code that any customer can create and publish in the Blockchain as a transaction [6]. It has a specific number assigned by Blockchain. The contract is executed when the Blockchain user or smart contract calls it, and the smart contracts can communicate, among others. The first Blockchain scenario is a shared P2P digital currency. It is a service for high-security distributed applications with the introduction of a smart contract framework. Therefore, to make a distributed IoT access control, this paper can exploit the latest use of Blockchain as a distributed and decentralized infrastructure.

The rest of the paper is organized as in Section 2; related research work based on Blockchain in IoT access control like problems and limitations of traditional access models are identified. The security requirements for IoT are described in Section 3. Analysis and discussion of the entire survey are summarized in Section 4. Future research directions and open challenges are described in Section 5. The paper concludes with a conclusion of the work done in Section 6.

II. Related Research Work on Blockchain-based Access Control for IoT

A. Access Control and IoT

Reference [7] provides a full detailed review of various IoT access control solutions. The study shows that the new access control method employed in IoT and claims that Internet protocols widely used cannot be extended to compelled environments. Based on its comprehensive review of the literature, [7] Identify and Lines of 3 access control and decentralized authorization solutions: the IBM Adept (Autonomous Decentralized P2P Telemetry) [8] framework, DOAuth (Decentralized Open Authentication), and FairAccess [9, 10]. However, in these references, the author explained the OAuth-based access control solutions are the heavy mechanism for IoT situations because of their low processing overhead and communications. Lastly, IBM Adept offers a collaboration and file storage system to develop IoT apps without creating a process for access control. Further, [7] passed over the work has done in the IETF called CoAP Management Interface (CoMI) [11], and the result is done by the Open Mobile Alliance (OMA) called LWM2M [12] CoMI and LWM2M are primary mechanisms in a centralized environment for IoT device management.

B. Blockchain and IoT

This paper identified two main access control patterns using Blockchain, access control depending on the transaction and access control depending on the smart contract. Their pros and cons are summarized in Table I.

1) Access control depending on the transaction: Conoscenti et al. [13] performed systematic literature on the new technology Blockchain for the IoT. The study mentioned many articles that handle the data gathered from IoT devices. For example, [14] shows a method for verifying the status of the data, and [15] reports the procedure for maintaining the data holding of IoT gadgets. None of the mentioned research articles suggest an architecture. The administrators can control the entire IoT life cycle access policies rather than their roots or location. The best of experience, the old work relevant to Blockchain access control for IoT, is [9] that shows a cryptocurrency Blockchain access control structure called FairAccess. Nevertheless, Access Control Policies describe the creation of transactions for that Smart Contract by creating various Smart Contracts for the Access Control Policy of each source request pair that are not suitable for the IoT environment.

The authors in [16] suggested a new method of Authentication of access control and a user to make IoT secure and safe for illegal users and get open access to information. The proposed system is based on the following: i) Registration Authority (RA), and ii). Home Registration Authority (HRA). The RA was created to simplify the authentication system for IoT gadgets. Each device should be registered with the RA.

The authors in [17, 18] suggest a multi-tier Blockchain base system for sharing data between communities and individuals for users and IoT gadgets. The mentioned design has three key components: data management protocol, data storage mechanism, and message services. The data management system offers a structure for the data manager, data requestor, or correspondence channel. The messaging tool used in this context increases device scalability by publishing / subscribing patterns. In the end, Blockchain uses data storage systems to store data anonymously.

In [19], The author proposed the Blockchain base design to enforce the access control mechanism based on the attribute. The policies are formulated by XACML and processed in Blockchain as compressed transactions. The smart contract codes all the elements needed for policy assessment. Authors design storage and maintenance feature by utilizing innovative contracts. It reflects self-assessment procedures pursued straightforwardly and transparently when the user is requesting access. This method merges smart contract and transaction structures to create an access control system that allows users to understand the policies that affect their access requests. It offers a centralized audit system and identifies sections that are fraudulently modifying the rights given by executable policies. Proof of the concept (PoS) implemented in the above method by using the Ethereum Blockchain to show and verify the proposal's validity.

2) Access control depending on smart contract: In the Alphand, Amoretti [20] architecture based in Blockchain, the authors propose secure management of access resources from end to end, named IoT Chain. Resources servers of resource owners hold their resources through a proxy server in an encrypted and signed format [21]. The third party who requests access to protected resources is the customer. It calls for a critical server decryption key, which checks that a blockchain is allowed to contain. The approval process works in the following way: the resource owner establishes and publishes an intelligent contract for customers in the Blockchain. If certain conditions are met, the customer calls the relevant, intelligent contract to produce an access token. The permission tokens are not sent to the customer but stored in the permanent memory of the transaction. The Client must seek the appropriate key to decrypt resources of the critical server, a node Blockchain, and hold a duplicate file of the Blockchain ledger once a token has been stored in an internal Contract database. At this point, the critical server tests that the Client has a token and transfers the key using a DTLS mode on Blockchain's smart contract system. The Client then installs and decrypts the encrypted device from the proxy server—this approach is primarily designed to replace a trusted ACE request system with a secure Blockchain permit.

In [22], the authors: described the main issues in the IoT access management system. The first is due to the core architecture, and the second is because access policies are handled dynamically. If the data is satisfied by the requester's access policies, the control contract is executed automatically, and a token of authorization is created and allocated to the requester. The input information relates to trust and reputation safety parameters to assists the resource owner in dynamically develop or change security policies. Order in verifying its validity; however, the model proposed requires evidence of description.

In [23] proposed the machine learning algorithms, and Smart contract access management checks the efficiency of multiple user access to a shared resource by maintaining sophisticated access control. The network architecture is made up of a single Judge Contract (JC), multiple Access Contracts (ACCs), and one Register Agreement (RC). Per ACC describes a subject-resource pair access control system and applies to update access control rules. A record of misconduct is maintained in the ACC smart contract for each property. It describes the actions of the subject matter of this platform, with several requests being identified in a short time and the decision of the Judge Contract (JC) penalty. The ACC is performed once an individual has been appointed to obtain access, and the ACC reports to the JC contract if the misconduct is detected. Based on an incorrect evaluation method, the contract for JC shows the appropriate penalty as a temporary blocking of subject access.

The author in [24] performed an access control and smart contract verification to tackle an IoT device security scalability problem. In reality, one or more IoT devices are operated by a customer, and each device needs its credentials. In this instance, however, the user should authenticate independently on each unit. This approach results in overhead verification and is challenging to measure. The main reason for using a smart contract is the validation of the user and IoT. The user signs up for the smart contract, verifying device identity by using the Ethereum wallet address. It is performed and examined in the blockchain environment of Ethereum. [25] introduces the Blockchain-enabled fog nodes for user authentication and authorization. The fog nodes manage and validating the authenticity of access to IoT devices on the Ethereum network interface. The system manager uses a smart contract to map all of the registered fog nodes and their associated IoT devices. Besides, it consists of the collection and permissions for entry to registered users. The arrangement includes the functionalities of registration, Authentication, and access control IoT device user link with a contract to verify the validity of the user. A token with access parameters is created if Authentication is successful. The next step is to sign the token and send it to the fog node to monitor the resource. The signature and token specifications are verified, and user access to the IoT gadgets is then granted or denied. A safe SSL connection between the user and the IoT device will be established for data exchange.

TABLE I. PROS AND CONS OF REFERRED ACCESS CONTROL SOLUTIONS

Ref.	Pros	Cons	Security Measures	Implemented
[7]	The authors highlighted how each solution produced various security specifications. They declared that centralized and distributed methods could complement each other.	Access Control Policies describe the creation of transactions for that Smart Contract by creating various Smart Contract to assign different Access Control Policy of each resource-request pair that are not suitable for the IoT environment.	VL	NA
[16]	IoT safe and secure for unauthorized users and open access This approach is secure for a man-in-the-middle attack	Critical scalability: The need for every device to have a RA and, similarly, for every user to have HRA could be a constraint for scalability	M	NO
[17]	Keep data privately Decentralized, open, and accessible data collected from data storage and architecture elements	Simple to do, but not feasible in all situations, as a large amount of computer power is needed for every node. It sends to the "Server," which decrypts an encrypted version of the info.	H	YES
[19]	Self-assessment policies continued in a straightforward and transparent way This model connects transactions and smart contract structures to create an access control system.	It offers a centralized audit system and identifies sections that are fraudulently modifying the rights granted by enforceable policies	VL	NO
[20]	Blockchain-focused IoTChain with ACE and OSCAR (IoT Object Security Architecture) authority. The suspect method to handle approval when OSCAR uses the public registry to create multidisciplinary groups for authorized customers.	Difficult to preserving the availability of the IoT	M	YES
[23]	To carry out centralized, secure access management for IoT networks, the author proposed a smart contract-based architecture composed of different access control contracts, an authority contract, and a registered agreement.	A large amount of contract requirements for a massive crowd is a daunting task.	M	YES
[24]	In a smart contract, users are authenticated, and an IoT token is issued. The contract decides whether the user will access the services and transmits tokens to the consumer and the required IoT computer.	For large IoT networks, this method suffers from the scalability problems associated with Blockchain. Ethereum smart contracts have the biggest drawback of fluctuating Ethereum rates, which is a problem for the consumers.	H	YES

III. Security Requirements for IoT

Various mechanisms and parameters must be considered, as listed below, for a secure IoT deployment.

A. Data Integrity, Privacy, and Confidentiality

When IoT data move across multiple hops throughout the network, a conventional encryption process is needed to guarantee data confidentiality [26]. Since systems, frameworks, and networks are configured differently, data held on a device are susceptible to protection and privacy infringement by disturbing live IoT network nodes. Attack vulnerable IoT devices may enable an intruder to contact data integrity by malicious data handling.

B. Accounting, Authentication, and Authorization

Authentication is needed for two parties to interact with each other to secure communication in IoT. Applications must be encrypted for exclusive access to services. The variation of IoT authentication procedure lives primarily because of different heterogeneous architectures and environments that help IoT gadgets. Such conditions pose a complexity in defining the standard global IoT authentication protocol [27]. Same as the authorization mechanisms guarantee that authorized persons have access to the systems or information. Usual authorization and authentication results are implemented in a stable environment that guarantees a protected communication environment. Moreover, accounting for the use of resources, reporting, and auditing produces a secure network security system.

C. Available for Services

Attacks on IoT devices will avoid general denial of service attacks involving utilities. Different tactics have led to IoT's consumers, including sinkhole assaults, jamming rivals, or replay attacks use IoT components on various levels to deteriorate the level of service (QoS) [28, 29].

D. Trustworthy

To maintain the end-to-end integrity of data gathered and related communications, the IoT applications require trust mechanisms that cover these scales. In addition to the capacity to evaluate these processes and interactions, the transparency of data collection systems and relevant experiences are the key to satisfying these criteria [30]. Both the requirements of clarity and auditing drive Blockchain to create trust in IoT.

E. Energy Efficiency and Cost-Effective

IoT gadgets are generally restricted to resources and have a lower capacity to store data. The author in [31] attacks on IoT systems may result in improved electricity consumption by intravenous or false service inquiries and by exhausting IoT resources.

F. Single Points of Server Failure

A significant number of single points of vulnerability That may depreciate service provisioned by IoT may be exposed by the ongoing development of heterogeneous IoT connectivity networks [32]. It includes designing a strategic framework for a broad category of IoT gadgets and implementing new methods for utilizing a network of fault tolerance.

IV. Analysis and Discussion

Based on the literature analysis and survey, Blockchain technology may be seen as a new bearing in IoT access control. The incentive to use the Blockchain is to help its stable and secure distributed nature that solves many IoT access requirements. In this survey, the authors also defined two ways of access control for Blockchain in IoT perspectives.

The first one consists of the transaction system to request, receive, assign, and revoke connections. In essence, the transaction is used to make a connection between the asset owner and the subject. Connection decisions may be made directly by the owner of the asset. If this is not the case, the access request shall be transferred to the external entity responsible for assessing the appeal, making the decision, and returning it to the asset owner, as stated in [33, 34]. In this case, Blockchain's primary aim is to securely transfer the access token by defining individuals' access rights and guaranteeing to check and trace all access transactions. The power delegate is often an essential method in the collaboration framework, which can be delegated to the new topic from the current issue in a verifiable manner depending on the transaction. It implies the freedom of a subject to pass partly or entirely the right to access another individual. The delegated receiver is then allowed to carry out the delegating customer's activities. To restore the transaction-based access regulation, unified access token management can fix the dual cost issue and guarantee the trackability of all transactions. However, The recognition of an entry is rendered by a single person who may be the property owner or another agency identified by the Access Control Model application. The model can be called hybrid and not distributed.

The second approach evaluates a user control demand using a smart contract definition. It takes an access option depending upon the rules defined by the property owner and applied in the agreement. The contract is executed until the customer requirement is met with the access agreement, and the effect is a consumer consent authority token. Ultimately, the token is sent to the permission applicant utilizing a particular operation. The principal objective of this strategy is to return a single permission server with a distributed smart contract to construct a distributed permission network [20]. All-access control functions may be executed on the authenticated and recorded contract in the registry of Blockchain. Blockchain nodes can establish a mutual copy and carry out a contract without a mediator. Distributed smart contract ownership per the delivery and implementation by Blockchain will solve a single point of server failure in a centralized access control manner.

In comparison, the corresponding studies investigate the feasibility of producing dynamic access control evaluation by smart contracts that incorporate a machine-readable algorithm to find and detect behavioral subjects [22]. However, there is no approved smart contract access control paradigm validated and examined in specific application domains such as Intelligent Transport System or Smart Cities to prove its viability. Most of the proposed approaches show that they are applied using one of the Blockchain platforms, such as Bitcoin and Ethereumare, not evaluated in real environments.

For future access control, the Blockchain would be the essential engine. It has new dynamics and technologies that solve big systems problems. This is only the start, and approaches to measure their success should be tested. The goal is to build a transparent access control platform built on Blockchain, which will enable the future generation of the distributed network.

V. Future Research Directions and Open Challenges

This segment explains the proposed issues for the efficient implementation of IoT security.

A. Limitations of Resources

IoT's resource-restricted nature had been a significant obstacle to identifying a reliable security mechanism. Cryptographic algorithms can only operate under these powers, unlike normal ones. By [35] ensure efficient implementation of IoT security and communication protocols over the network, any communications or multicasts needed to transfer the key or certificate, storage and resources must be dealt with it. It means that these protocols are optimized to be lightweight and energy-efficient, given the need for sophisticated computation and advanced energy harvesting techniques.

B. Heterogeneous Devices

A multi-layer security structure must be discussed, as with heterogeneous sensors, exceptionally compact, high-end servers, and low-power sensor systems. The structure will first adjust to new resources and selections on the collection of IoT layer security mechanisms even before services are granted to end-users [36]. Such a flexible and compact structure requires information that is dependent on the uniformity of IoT architectural tools.

C. Single Points of Server Failure

For heterogeneous systems, structures, and protocols, the IoT standard is risky to single-point-of-server-failure than any other system. There needs to be more research work required to ensure appropriate IoT elements, especially in mission-critical applications. It would need devices and guidelines to perform continuity in mind the trade-off among values and the functionality of the entire infrastructure.

D. Interoperability of Security Protocols

Protocols intended at various layers require interoperation within the requirement of translation mechanisms to regulate the global security structure for IoT [37]. The active synthesis of safety measures on each layer can then be determined in the worldwide system framework, taking into account architectural limitations.

E. Trusted Updates and Management

Scalable and reliable software management and upgrades to millions of IoT gadgets lead to open issues for future research. Besides, problems associated with the safe and trusted IoT device supply chain, ownership, and data privacy are the main research concerns that need to be tackled by the researchers to raise significant and broad IoT acceptance [38]. These IoT security solutions are also available in Blockchain technology. However, blockchain technology itself claims to face problems in scalability, accuracy, arbitration/regulation, and essential collisions.

F. Hardware/Firmware Culnerabilities

The IoT structure becomes vulnerable to hardware flaws when the low-cost and low-performance system is traditional. It is not just a physical malfunction, but it must be verified before IoT deployment to implement security algorithms in hardware, routing, and packet processing operations [39]. Some Security flaws exposed since launch have displayed challenging to identify and mitigate. The regular confirmation protocol is, consequently, a requirement for the use of IoT security.

G. Blockchain Vulnerabilities

Despite affording robust solutions to IoT security, blockchain systems are also exposed [40]. The consensus mechanism based on the hacking capacity can be violated to enable the attacker to handle the private database keys with minimal randomness that may also be used for blockchain accounts negotiation [41, 42]. There is still a need to develop efficient mechanisms to protect transactions' privacy and prevent race attacks, resulting in duplication of transaction costs.

VI. Conclusion

In this survey, the authors first study the various security problems and challenges in IoT applications and access control for authorized and unauthorized users. Secondly, the authors have deep dive into previous research to figure out their solutions and existing problems. From the survey, it was found that some of the research has been already done in IoT access control by using Blockchain, and found that IoT systems are vulnerable and powerless to defend themselves. Due to insufficient resources in IoT gadgets, immature standards, and the lack of reliable software and hardware development, design, and deployment, as well as trusted updates and managements. The authors have acknowledged the restrictions of old access control to reply to IoT demands and investigated the ability to use the secure Blockchain system to manage access control. The authors demonstrate how the Blockchain can address and resolve some of the fundamental IoT security problems. The article also explains and recognizes future issues and challenges that the researchers need to provide reliable, effective, and scalable IoT security solutions.

Acknowledgment

***Abstract*—Cloud computing offers several services, such as storage, software, networking, and other computing services. Cloud storage is a boon for big data and big data owners. Although big data owners can easily avail cloud storage without spending much on infrastructure and software to manage their data, security is a big issue, and protecting the outsourced big data is challenging and ongoing research. Cloud service providers use the attribute-based access control model to detect malicious intruders and address the security requirements of today's new computing technologies. Anomalies in security policies are removed to improve the efficiency of the access control model. This paper implements a novel clustering approach to cluster security policies. Our proposed approach uses a rule-specific cluster merging technique that compares the rule with the clusters where the probability of similarity is high. Hence this technique reduces the cost, time, and complexity of clustering. Rather than verifying all rules, detecting and removing anomalies in every cluster of rules improve the performance of the intrusion detection system. Our novel clustering approach is useful for the researchers and practitioners in the ABAC policy validation.**

Keywords—Anomalies; attribute-based access control model; big data; cloud storage; clustering; intrusion detection system; security policy

I. Introduction

Cloud storage is one of the most beneficial services to leverage and manage big data efficiently [1]. Large-scale enterprises, governments, and commercial organizations use the cloud to store and manage their big data without spending much on implementing infrastructure. Data privacy and security are essential, and securing the shared big data is a real challenge in today's emerging computing technologies [2] [3]. We have surveyed about challenges, security issues, and existing methodologies for addressing the security requirements [4]. Data breaches, data loss, account hijacking, denial of services, and malicious insiders are some attacks, and various encryption techniques are used to protect the data in the distributed cloud storage [5] [6]. Cloud service providers use various access control models to implement the Intrusion Detection System [7] [8]. The access control model is a function that identifies whether a requested operation on a shared object(resource) is legal or not [9]. In other words, the access control model is a protection technique that categorizes the authorized and unauthorized users and protects the shared resources based on the Access Control List (ACL) or security policies. The access control models use rules to determine which user can get what types of accesses for a shared resource. It manages all access-rights and access-conflicts over the shared resources [10]. The term object refers to the shared resources in a distributed environment. The access control models use the term subject to refer to the process being executed for a single user or an organization, which requests access for the object. Fig. 1 shows the working mechanism of the access control model. Many access control models are developed, and each is good in some situations and gives performance up to their level [11]. In this paper we described the major four access control models Discretionary Access Control (DAC), Mandatory Access Control (MAC), Role Based Access Control (RBAC), and Attribute Based Access Control (ABAC) models.

Made decision (allow/deny)
Allowed or Denied
Intermediate mechanism

Fig. 1 A Working Mechanism of Access Control Model.

Discretionary Access Control (DAC) allows the owner of the object to specify the access rights of the user for their object. Thus the resource-owner decides and determines the security policies directly and explicitly unlike non-discretionary access control models. In non-discretionary access control models, rather than the resource-owner, the administrator determines the security policies [12]. DAC creates and maintains ACL for every individual resource to determine the access privileges of the user for that resource. ACL of each resource is a table of records and each record specifies the information about the user(or group of users) and the access rights [2]. The process of specifying ACL in DAC is very flexible, easily updatable, and reduces the administrator's work but the level of security is less[6]. The operating systems WINDOWS, LINUX use DAC. DAC meets the security requirements when the number of resources and users are limited but it fails to address the security requirements of today's computing technologies. The delegation feature of DAC has even more benefits like offering cooperation between users and the resource-owner [8]. But it leads to loss of confidentiality, integrity, and availability of resources if any user made a wrong decision while granting access to other users. As DAC requires a resource-owner for each object to determine the access rights, fulfilling this requirement is difficult in new computing technologies like cloud and fog computing [9][10].

Mandatory Access Control (MAC) is a central authority system where the administrator or the authorized person only can set access rights. The access rights cannot be specified or updated by the user like DAC. MAC uses a security label for each resource and subject. There are two pieces of information in a security label. The first piece of information called classification-segment determines the nature (public or private) of the resource or subject. The second segment category specifies the information about the process or application. MAC allows the requested operation on the object if the security labels of the object and subject match. The administrator only can determine the characteristics or attributes of the subject and object. Even the allowed users cannot specify or change the attributes. While DAC fails to give security on sensitive and confidential data, MAC meets these security requirements of the business and government organization. MAC is capable of managing trojan horses to protect the shared resources. Unlike DAC, the integrity and confidentiality of the resource are preserved by MAC. The feature reference monitor of MAC stores all security labels and policies in the database and monitors the access rights of every request for the object. The operating system Security-Enhanced Linux implements MAC to protect the objects. If the communication between the subject and object is high, then managing security labels and policies is a challenging issue. DAC and MAC are efficient when the size of data and the number of users are small [11]. MAC increases the complexity in managing security policies for large applications [2].

RBAC introduces a new concept of assigning roles between users and resources. RBAC (Role-Based Access Control) uses the permission-role and role-subject association to protect shared resources, whereas ABAC(Attribute-Based Access Control) uses security policies [13]. RBAC meets the security requirements of large applications. RBAC determines the security policies or access rights based on the role or job of the subject. Thus this access control model specifies the possible access rights (permissions) to the role. The subject can get access to an object based on his role or job. RBAC performs two assignments thus it first assigns all permissions required for a particular job or role for an object and second it assigns a role to the user or subjects. RBAC provides two efficient features least privilege and separation. The feature least privilege means RBAC assigns access rights or permissions required only for the role or task being processed on the object. As no additional access rights can be availed by the role, it prevents unauthorized access and preserves the integrity of the data. Another feature separation of duties distributes the process into various roles or duties and assigns the duty to the subject. As the subject can perform his/its assigned role only, RBAC prevents the entry of fraud intruders [14]. Hence no subject can perform all permissions or access rights of the shared object rather than the central authority (administrator). It increases the security level and RBAC has the capacity of ensuring whether the end-users can do their permitted transactions. Using the feature of grouping rules reduces the complexity of the administrator's work. Government sectors, military, and private organizations use RBAC to protect databases, web services, and all shared resources [15].

As RBAC performs constant or permanent associations (permission-role and role-subject), it fails to address the security needs of the computing technology that requires the dynamic associations and role-independent security policies. ABAC addresses this issue and is capable of performing dynamic relationships and generating role-independent security policies. ABAC security policies are generated with the attributes of the categories subject (who requests the operation of a resource), object (resource is shared in a distributed environment), and environment (time, the importance of the request, etc.). Both RBAC and ABAC address the security needs of large-scale applications or organizations, but ABAC fulfills the complex security requirements of today's computing technologies [9]. It gives better security even if the communication between the subjects and objects is increasing exponentially [16]. It has many features fine and coarse-grained access, dynamic mapping (subject-object), and flexibility. With the properties efficiency, flexibility, granularity, and security-level [17]. We gave a summarized analysis of the above-described access control models in Table I.

TABLE I. ANALYSIS OF ACCESS CONTROL MODELS

Access control model	Granularity (accuracy level of the model)	Flexibility (how the security policies are generated, expressed, and updated)	Efficiency (how quickly and correctly a decision is performed on the subject's request)	Security level (how the shared resources are protected)
DAC	Good at small scale applications	Good	Poor	Low
MAC	Good at small scale applications	Good	Poor	Better than DAC
RBAC	Good at large scale applications	Good	Good	Good
ABAC	Good at today's computing technologies and big data	Good	Good	Good

Most of today's computing technologies cloud, fog, edge, and IoT use ABAC to meet the security requirements. But the anomalies in the ABAC security policies dilute the reliability and efficiency of the mechanism [18]. Detection and elimination of all possible anomalies in security policies or rules improve the efficiency and accuracy of security. We can improve the performance of the detection mechanism by detecting anomalies in every cluster of similar rules, instead of detecting in every rule. This paper implemented a new approach to cluster similar ABAC security rules. The scopes of our approach are:

- Tool to generate ABAC Policies.
- Ability to measure the similarity of rules.
- Reduces the generation of more clusters.
- Avoids avoidable-redundancy (the same rule is contained in many clusters).
- Avoids the conflict clusters (not all rules in clusters are similar).
- Less time-complexity.
- Ease of implementation.

We use Section II to describe some clustering approaches already used in various research works, and Section III presents the fundamental concepts of the ABAC model and our proposed clustering approach. We use Section IV to describe the system architecture of our implementation. We analyzed output and discussion about the outcome of our approach in Section V. Finally, we concluded in Section VI.

II. Related Work

Bhatia and Vandana surveyed Nearest Neighbor techniques (NN). NN technique is simple, effective, and robust to noise. This approach generates clusters of nearest neighbors where the nearest neighbor is identified by some calculated value. The KNN(K-Nearest Neighbor) is an unsupervised clustering technique and determines the nearest neighbor based on the k-value. They categorized the NN techniques into two groups; Structure less NN techniques and structure-based NN techniques. Structure less NN determines the nearest neighbor from the training and sample data. In structure-based NN, the nearest neighbors are determined based on the structure of data such as top-down or bottom-up like a k-d tree or bell tree. Both categories are the extended or improved version KNN techniques. They conclude that researchers can improvise the NN technique based on their research [19]. Ahalya and Pandey analyzed various clustering algorithms such as the K-means algorithm, Hierarchical algorithm, self-organizing map (SoM) algorithm, and expectation maximization(EM) algorithm. They described some tools used to implement the clustering algorithms. They compared and analyzed the above algorithms based on the type and size of the data set, the number of clusters, implementation tools, and accuracy. They reported that k-means and EM give better performance than other approaches and the SoM algorithm gives more accuracy than others [20].

MaryemAit El Hadj, Mohammed Erradi, and their team proposed an approach to cluster the security policies and additionally used the information of access log to detect the fraud intruders. They used the KNN algorithm to cluster the security rules and applied the rule-sub-module-reduction technique to minimize the count of rules in each cluster [21]. MaryemAit El Hadj and his team proposed a clustering approach to cluster XACML (eXtensible Access Control Markup Language) policies. XACML is an efficient markup language to express ABAC policies. They cluster the rules based on their similarity. Every pair of rules is clustered if the similarity value of the pair or rules is greater than the threshold value of 0.8 [23]. This method ensures that each rule must be clustered once, and the same rule may be contained in more than one cluster. There must be non-empty clusters only. The above approach may produce a maximum number of clusters and clusters with a maximum number of rules [22]. In contrary to the above research, we proposed and implemented a novel approach that our approach uses the basic technique of hierarchical clustering algorithm [24]. Rather than using the distance between the new rule (data point) and the cluster center, we use the similarity value of the new rule and the existing rules in the previous cluster. We use a rule-specific-cluster-merging approach instead of using the rule-sub-module-reduction method. Thus if the similarity value of two rules Rule-1 and Rule-2 is above the threshold value, then we create a new cluster if and only if Rule-1 and Rule-2 are new rules that are not yet clustered. If Rule-1 (or Rule-2) is already clustered and Rule-2 (or Rule-1) is not clustered and matched with all rules of the existing cluster, which contains Rule-1 (or Rule-2), then Rule-2 (or Rule-1) is merged with that existing cluster. Our enhanced approach reduces the generation of more clusters, redundancy (the same rule is contained in many clusters), and avoids the conflict-clusters (not all rules in a clusters are similar). Table II summarizes our approach and the researches done in previously.

TABLE II. SUMMARIZATION OF PREVIOUS RESEARCHES TOWARDS CLUSTERING INCLUDING THIS PAPER

References	Proposed work
[19]	Surveyed Nearest Neighbor (NN) clustering techniques. The nearest neighbor is identified by the calculated value. Concluded that the NN technique is efficient, simple and robustness and researchers can use and improvise the NN techniques based on their research.
[20]	Compared and analyzed various clustering algorithms such as the K-means algorithm, Hierarchical algorithm, self-organizing map (SoM) algorithm, and expectation maximization(EM) algorithm based on the type and size of the data set, the number of clusters, implementation tools, and accuracy. Reported that k-means and EM give better performance than other approaches and the SoM algorithm gives more accuracy than others.
[21]	Proposed an approach to cluster the security policies using the KNN algorithm and additionally used the information of access log to detect the fraud intruders. Applied rule-sub-module-reduction technique to minimize the count of rules in each cluster.
[22]	Proposed a clustering approach to cluster XACML (eXtensible Access Control Markup Language) policies based on the similarity value. Pair of rules are clustered if they are similar rules. This approach generates an increased number of clusters and also the cluster contains an increased number of rules. A rule may be contained in more than one cluster (redundancy) and not all the rules in a cluster are similar (conflict-cluster).
This paper	Proposed novel approach that uses the basic technique of hierarchical clustering algorithm. We use a rule-specific-cluster-merging approach instead of using the rule-sub-module-reduction method. Our enhanced approach reduces the generation of more clusters, avoidable redundancy (the same rule is contained in many clusters), and avoids the conflict clusters (not all rules in clusters are similar).

III. PRELIMINARIES

The fundamental concept of the ABAC model is described in this section. This also section describes how the ABAC rules are expressed and how the similarity value of pair of rules is calculated.

A. ABAC Model

This section describes the basic concepts of the ABAC model and the simple authentication process. The common simple authentication process is making a decision (allow or deny) by using the information like username and password of the subject or user for the request to access the shared resources such as files, databases, software. This simple process of checking the identity of the subject is not sufficient to meet the security needs of today's emerging computing technologies. RBAC and ABAC are the models used to address the complex security requirements of new computing technologies like cloud and fog computing. While RBAC fails to generate dynamic mappings between subject and object and also it is a role-independent model, ABAC or the combined features of RBAC and ABAC can be used for the protection of shares resources [25]. In this paper, we use the ABAC model and we aim to detect and eliminate the anomalies in ABAC security policies. This paper proposes an enhanced approach for clustering the security policies to simplify the process of detection and removal of anomalies. Fig. 2 and Fig. 3 show the simple standard authentication system and the ABAC model.

Fig. 3 The Architecture of ABAC Moel.

ABAC model has a set of determined security policies where each security policy consists of security rules. In general, the security rule of the ABAC model is expressed with the decision (allow or deny), operations (read, write, print, etc.), and the attributes of subject (who requests the access), object (shared resources), and environment conditions (time, the importance of the operation, etc.). The decision either allowing or denying the subject’s request is made based on the attributes of the subject, object, and environmental conditions specified in the rules. In our research work additionally, we added one parameter Priority-level to each security rule to avoid the demand on a single object. The priority level is assigned based on the subject’s attributes and the importance of the operation on the object. The most common jargons used in the ABAC model are:

1) *Subject and its attributes:* The term subject refers to a single or group of users or organizations or the process that requests the resource. The attributes of subjects are the important credential information about the subject like name of user or process, designation, department, affiliation, etc.

2) *Object and its attributes*: Shared resources (operating system, network, file, software, and database) are named as objects. The information like name, type, owner, and date of creation are the attributes of objects.

3) Operation: The task (read, write, etc.) on the object is requested.

4) Environmental conditions: Other information such as date of request, current time, waiting period, etc.

5) Rule and decision: Constructed with the above three categories subject, object, and environmental conditions. In our proposed approach, we included the additional parameter priority-level assigned based on the attributes of the subject. The rule takes the decision (allow or deny) based on the attributes of the subject, object, and environmental conditions.

6) Policy: It is a set of rules established for the protection of objects in an organization.

B. Expression of ABAC Security Policy

The security policies of ABAC are constructed with a set of rules. Every rule contains the attributes of the subject, objects, and environment. The decision (allow or deny) is made based on the values of the attributes specified in the rule [26]. We added one additional parameter priority-level in every rule to avoid the anomaly conflict-demand. Thus more requests on a limited object are referred to as conflict-demand. The parameter priority-level is a non-negative integer. The demand for a limited object is handled based on the value of the priority level. Thus the rule or request which has the highest priority value will be allowed to get access. The pair of rules is not clustered if the priority-level of the two rules are not equal. The security policy set of the ABAC model is expressed by JavaScript Object Notation (JSON) as follows:

```
Policy-Set: [ {
Policy: <policyID>,
Rules: [{
<ruleID>,
Action: <actionName>,
Operation :<operationName>,
Subject: <subjectID>,
Resource: <resourceName>
Environmental :<environmentID>},
        }]
    }]
```

Extensible Access Control Markup Language (XACML) is the most common acceptable and widely used language to express the security policies. Each attribute is expressed with the pair key and value using a markup language. Key is the attribute name (eg. Department) specified as the tag and value (eg. Urology) is the value of the attribute name specified within the key-tag. The ABAC policy set can be expressed by XACML as follows:

```
<PolicySet>
 <Policy PolicyID=”P1”>
   <Rule RuleID=”R1” Decision=”Allow” >
     <Operation>
             <Operation-1>read</Operation-1>
             <Operation-2>write</Operation-2>
     </Operation>
     <Subject>
             <Department>urology</Department>
             <Designation>surgeon<Designation>
      </Subject>
      <Object>
                                   <ResourceName>

    PatID_005_Urine_Culture_Report
             </ ResourceName >
      </Object>
      <EnvironmentalCondition>
             <Duration>8:18</Duration>
      </EnvironmentalCondition>
    </Rule>  ………// more rules can be specified
  </Policy>   ………// more policies can be specified
</PolicySet>
```

In the above example, rule R1 states that security policy allows the surgeon in the department of urology to read and write the file ‘PatID_005_Urine_Culture_Report’ during the time 8:18 hours. The following standard is usually used to write the rules.

Rule$_1$= {Allow$_{read}$ | Designation = {duty-doctor, surgeon}, Department = { hematology}, File-Name = {pat_007_blood_report}, Time= {8:18}, PriorityLevel=2}

Rule$_2$ = {Allow$_{read}$ | Designation = {head-nurse}, Department = {hematology}, File-Name = { pat_007_blood_report }, Time= {8:18}, PriorityLevel=1}

The above rules Rule$_1$ and Rule$_2$ are security rules represented including the parameter PriorityLevel. The attributes Designation and Department are the categories of subject, File-Name is the attribute of category object, and the attribute Time is the category of environment. The rules state that the file ‘pat_007_blood_report’ can be read by the users ‘duty doctor, ‘surgeon’ and ‘head nurse’ belong to the department ‘hematology’. When all these three subjects are trying to get access to the file, ‘duty doctor, ‘surgeon’ will get access first due to the highest priority. The relationship diagram of security policy and working principle of ABAC model is shown in Fig. 4. This security system provides two stages of authorization. The first stage performs the common traditional authorization process where the second stage completes the ABAC mechanism to increase the level of protection.

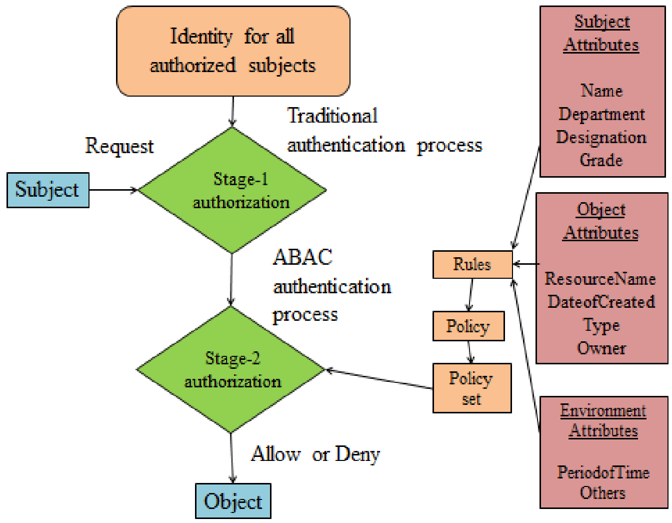

Fig. 4 The Security System Provides Two Stages of Authorization.

C. *Measurement of Similarity Value*

We used the following formulae to measure the similarity value of the pair of rules[27]. The similarity value (S) of the pair of rules R_1 and R_2 for an attribute ‘atr’ is calculated using formula-1.

$$S_{atr}\ (R_1, R_2) = \frac{NSV}{NDV} \quad (1)$$

Where NSV (Number of Same Values) is the number of the same values of the attribute ‘reappeared in both the rules R_1 and $R_{2.}$ The variable NDV (Number of Distinct Values) is the number of distinct values of the attribute ‘atr’ in the rules R_1 and R_2. The similarity-value (S) of two rules for category C (Subject, Object, and Environment) is measured using the formula-2.

$$S_C\ (R_1, R_2) = \sum_{atr \in \{ATS\,(R1) \cap ATS\,(R2)\}} P_{atr}\, S_{atr}\ (R_1, R_2) \quad (2)$$

where ATS(R_1) and ATS(R_2) are a set of attributes of R_1 and $R_{2,}$ respectively. ‘$P_{atr'}$ is the probability of the attribute (P_{atr} =1/number of the common attribute in both R1 and R2). The variable ‘atr’ is the set of attributes that appeared in both R1 and R2 under the category C. The similarity-value (S) of the pair of the rule is measured by the formula-3.

$$S\ (R_1, R_2) = \begin{cases} P_{subject}\, S_{subject}(R_1, R_2) + \ P_{object}\, S_{object}(R_1, R_2) + \\ P_{environment}\, S_{environment}(R_1, R_2) \end{cases} \quad (3)$$

The variable P is the probability of the category (subject, object, and environment). As equal probability is applied, the probability of each category is 1/3. The similarity value of the above-mentioned rules $Rule_1$ and $Rule_2$ is calculated as,

$$S(Rule1,Rule2) = \frac{1}{3}S_{subject}\ (R_1,\ R_2) + \frac{1}{3}S_{object}(R_1,R_2) + \frac{1}{3}S_{environment}(R_1,R_2)$$

$$= \frac{1}{3}\times (0.25+0.5) + \frac{1}{3}\times 1 + \frac{1}{3}\times 1$$

IV. System Architecture

Fig. 5 shows the system architecture of our proposed method. It contains the rules-clusters storage and management module, rule generation module, and rule clustering module. The functional operation, task, requirements of each module, and relationship among the modules are described in the following sections.

Fig. 6 Schema Diagram of Specification of ABAC Policies and Clusters.

A. Rules-Clusters Storage and Management Module (RCSMM)

We created relations (tables) in Oracle11 (Oracle 12c is for an in-memory database environment). The schema diagram of RCSMM is shown in Fig. 6. The relation 'Subject' is used to store and manage the attributes and values of the subject. Likely the relation 'Object' and the relation 'Environment' store and manage the attributes of the resources and the environmental conditions respectively. The generated security policies are stored and maintained in the table 'Rules'. The information about the request of operation for a resource is maintained in the relation 'Operations'. The generated security rules are clustered and stored in the relation 'Clusters'. Table III, Table IV, Table V, Table VI show the sample records of the relations Subject, Object, Environment, and Clusters.

Table VI illustrates that rules 1 and 2 are clustered in cluster-1 and cluster-11 consists of rules 32 and 33. We created a relation for each category (Subject, Object, and Environmental Conditions) to store and manage the value of all attributes. We have written stored functions to measure the similarity value of pair of rules for an attribute (e.g. Department), the similarity value of pair of rules for each category (e.g. Subject) and finally to measure the similarity value of pair of rules.

TABLE III. ATTRIBUTES OF SUBJECT

Relation: Subject		
RULENO	RULENO	RULENO
9	9	9
35	35	35
501	501	501
720	720	720

TABLE IV. ATTRIBUTES OF OBJECT

Relation: Object	
RULENO	RESOURCENAME
9	Pat00005_blood_report
35	Pat00007_urine_report
501	Pat00008_thyroid_report
720	Pat00039_blood_report

TABLE V. ATTRIBUTES OF ENVIRONMENT

Relation: Environment		
RULENO	TIMEFROM	TIMETO
9	8	18
35	6	14
501	8	18
720	7	19

TABLE VI. CLUSTERS OF RULES

Relation: Clusters	
RULENO	CLUSTERLABEL
1	1
2	1
32	11
33	11

The above-stored function measures the similarity value of pair of rules for the attribute Department. The stored function call nsv_department(r1,r2) returns the number of values that are the same for the attribute 'Department' in both r1 and r2. The stored function call ndv_department(r1,r2) returns the number of distinct values for the attribute 'Department' in both r1 and r2.

Stored function sv_department(r1 number,r2 number)

```
create or replace function sv_department(r1 number, r2 number)
return float is
sv float;
nsv number(3);
ndv number(3);
begin
nsv:=nsv_department(r1,r2);
ndv:=ndv_department(r1,r2);
if nsv=0 or ndv=0 then
sv:=0;
else
sv:=nsv/ndv;
end if;
return sv;
end sv_department;
```

We have created stored functions to measure the similarity values of all attributes. The stored function sv_rules(r1,r2) measures the final similarity value of two rules r1 and r2. In this procedure p is the probability where we use equal probability of all the categories (Subject, Object, and Environment) and sv_subject(r1,r2), sv_object(r1,r2), sv_environment(r1,r2) are the similarity values of Subject, Object and Environment.

Stored procedure function sv_rulet(r1 number,r2 number)

```
create or replace function sv_rule(r1 number,r2 number)
return float is
sv float;
p float;
sv1 float;
sv2 float;
sv3 float;
begin
p:=1/3;
sv1:=sv_subject(r1,r2);
sv2:=sv_object(r1,r2);
sv3:=sv_environment(r1,r2);
sv:=(p*sv1)+(p*sv2)+(p*sv3);
return sv;
end sv_rule;
```

B. Rule Generation Module (RGM)

We designed the module RGM in java for automated rule generation. RGM is an admin interface in java to generate or specify the security policies for all shared resources. The admin can easily set the rules for a resource with the attributes of the categories Subject, Object, and Environment. This module is flexible for the admin to update the rules easily. This module allows the admin to create, or delete or update the entities of the subject, object, and environmental conditions. The priority of the rule is determined based on the role of the subject. The subject-attribute 'grade' is assigned with the value (low or high or middle) based on the attribute designation. The priority of the rule or request is determined based on the attribute 'grade'. We have written a rule generation procedure in Java to generate ABAC rules.

Fig. 7 shows the interface of rule generation. The generated policies are stored in the relations Rules, Subject, Object, Environment, and Operations. Fig. 8 shows the sample of generated rules.

C. Rule Clustering Module (RCM)

We implemented our enhanced clustering algorithm in java to cluster the security policies. In our previous work [28] [29], we applied a direct clustering approach that every rule R_i (from top to bottom) is paired with the rule R_j (from the next successive rule of Ri to the last rule in the database). The pair of rules are clustered if the similarity value of the pair of rules is above the threshold value and the difference between the priority-level of those rules is zero (priority-level of two rules are equal). The introduction of the parameter priority-level reduces the size of the clusters [30].

Although the previous approach clusters the rules efficiently, it produces more clusters, and the same rule is clustered in multiple clusters. In our enhanced approach, we follow the top-to-bottom approach thus we start from the first rule to last (1,2,3,..,n) and for each rule R_i we made the pairing of the rule R_i with every R_j (j=i+1,i+2,..,n}. If two rules R_i and R_j are similar rules based on the condition (similarity-value(R_i, R_j)>0.8 and priority-level(R_i) is equal to priority-level(R_j)), then we follow the following criteria to cluster the pair of rules R_i and $R_{j.}$

- The rules R_i and R_j are stored in a new cluster if R_i is not yet clustered. (first similar rule of R_i)
- In the case of the rule, R_i is already clustered in $C_{k,}$ and R_j is not clustered: (rule-specific-cluster-merging technique)
    - the rule R_j is merged with the cluster C_k if R_j is similar to all the rules in the cluster $C_{k,}$
    - otherwise, R_j and R_i are stored in a new cluster.
- Every rule should be clustered, and any cluster should not be empty.

The enhanced clustering algorithm is written as follows:

Algorithm: Rule-Specific-Cluster-Merging Approach (RSCA)

```
Input : Security rules $R_1$, $R_2$,…, $R_{n\,,}$ // n is number of rules
 Output: Cluster of Rules $C_1$, $C_2$,.., $C_k$ // k is the number of clusters
K=0; // K is the number of clusters
T={$R_1$, $R_2$,……$R_n$} /* T is the table of records and each record
$R_i$ contains information of single rule */
For each rule $r_1$ in $R_1$ to $R_n$ loop   //form first record to last
record
    For each rule $r_2$ in $R_{i+1}$ to $R_n$ loop
        Compute Similarity-value($r_{1\,,}$ $r_2$)
        If Similarity-value ($r_1$ $_,r_2$)>0.8 and  priority-level($r_1$) = 
            priority-level($r_2$) then
            If $r_1$ is not yet clustered then
                K=K+1; $C_k$={ $r_1$, $r_2$}
            Else if $r_1$ is already clustered and  $r_2$is not clustered
            then
                Found the cluster $C_F$ such that $r_2$ is similar to
                all the  rules in $C_F$ where $r_1$ is the member of
                this cluster
                If such cluster $C_F$ is found then
                    $C_F$= $C_F$ U {$r_2$}
                // is merged with the existing cluster.
                Else If such cluster $C_F$ is not found then
                    K=K+1;$C_k$={ $r_{1,}$ $r_2$}
                // new cluster is created to store $r_1$ and $r_2$
                End If
            End If
        End If
    End Loop
    If $r_1$ is not yet clustered then
        // none of the rules is similar to $r_1$
        K=K+1;$C_k$={ $r_1$} // $r_1$ is clustered in a new cluster
    End If
End Loop
End
```

The implementation of our enhanced clustering approach clusters the given set of rules. Fig. 9 shows the results of our implementation. We managed six tables Rules, Operations, Subject, Object, Environment, and Clusters to store the detail of rules, operations on objects, subjects, objects, environments, and clusters respectively. The creation of an individual table for every entity avoids the redundancy of data and null values.

Rule clustering module (RCM) proposes an approach to cluster ABAC Policies before policy validation to improve the performance of the model (Resolving the policy errors in every rule is a time-consuming and complex process). We used only the basic technique of the hierarchical clustering algorithm. We introduce a novel clustering (rule-specific-cluster-merging) and resolved the two major problems of clustering: avoidable-redundancy (the same rule is contained in many clusters), and avoids the conflict clusters (not all rules in clusters are similar). The scopes of our approach are:

- We used a rule-specific-cluster-merging approach (instead of using the rule-sub-module-reduction method or cluster-merging method). (time complexity is low).
- If two rules are already clustered, our approach will not entertain the clustering once again (reduces the number of clusters and a rule is not stored in multiple clusters unnecessarily).
- If a pair of rules are similar and anyone rule is already clustered, then we are seeking to cluster the next one with the specific clusters where the clustered rule is a member. (improves the performance of the process).
- A rule is merged with the existing cluster if all the rules of the existing clusters are similar only (avoids conflict-clusters-not all rules in a cluster are similar).

Fig. 9 Sample Result of Clustering.

V. Results and Discussion

We described and compared our approach with the hierarchical clustering algorithm. Fig. 10 illustrates the example of the hierarchical clustering algorithm.

We took eight rules {R1,R2,R3,R4,R5,R6,R7,R8} for clustering. In the first step, the hierarchical algorithm considers each rule as a cluster. At each iteration, every cluster is compared with other clusters and the similar clusters are merged. This is a continuous process while there are comparable clusters. Let we consider.

C is the cluster to be compared,

k is the number of current clusters,

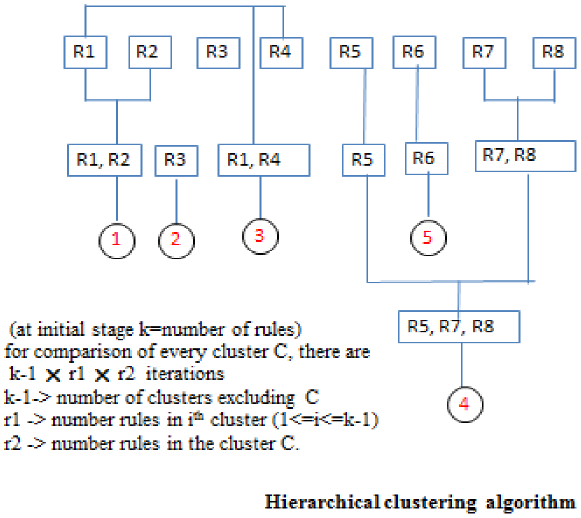
k-1 is the number of clusters excluding C,

r1 is the number of rules in the ith cluster (1≤ i≤ k-1) and

r2 is the number of rules in C.

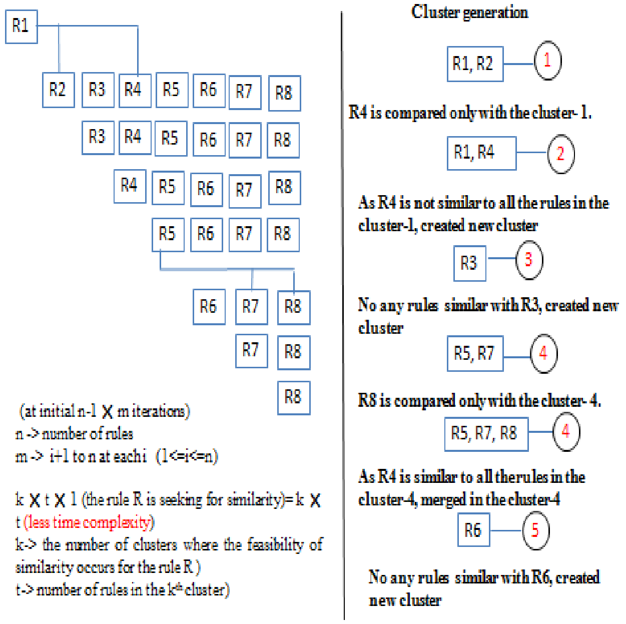
The comparison of every cluster C, this approach performs k-1 × r1 × r2 iterations. Thus each cluster is compared with all other clusters at every iteration and similar clusters are only merged. The clusters {R1} and {R2} are merged. The cluster {R3} and {R6} are not similar with all other clusters. The clusters {R1} and {R4} are merged. The clusters {R5}, {R7} and {R8} are merged in a cluster. The generated clusters are {R1,R2}, {R3}, {R1,R4}, {R5,R7,R8}, and {R6}.

Fig. 11 illustrates the same example of clustering eight rules with our proposed approach. In the first step of our approach, we compare every rule R_i (1≤i≤n-1, n is the number of rules) with Rj (i+1 ≤ j ≤ n). At each iteration, the un-clustered rule is compared only with the specific clusters, not all the clusters. Thus if R1 and R2 are similar rules, R1 is clustered and R2 is yet to clustered, then R2 is compared with the clusters that contain R1. If k is the number of specific clusters (where the feasibility of similarity occurs for the un-clustered rule) and t is the number of rules in the kth cluster, then our approach requires k×t comparisons only. Hence our approach reduces the number of comparisons and consumes less time than the other approaches. For the discussion of our proposed approach, we took five rules as a sample (listed in Table VII) to make the discussion easy and understandable.



(at initial stage k=number of rules)
for comparison of every cluster C, there are
k-1 × r1 × r2 iterations
k-1-> number of clusters excluding C
r1 -> number rules in ith cluster (1<=i<=k-1)
r2 -> number rules in the cluster C.

Fig. 10 Example of the Hierarchical Clustering Approach.



R1
R2 R3 R4 R5 R6 R7 R8
R3 R4 R5 R6 R7 R8
R4 R5 R6 R7 R8
R5 R6 R7 R8
R6 R7 R8
R7 R8
R8
(at initial n-1 X m iterations)
n -> number of rules
m -> i+1 to n at each i (1<=i<=n)
k X t X 1 (the rule R is seeking for similarity)= k X t (less time complexity)
k-> the number of clusters where the feasibility of similarity occurs for the rule R)
t-> number of rules in the k^th cluster)
Cluster generation
R1, R2

R4 is compared only with the cluster- 1.
R1, R4
2
As R4 is not similar to all the rules in the cluster-1, created new cluster
R3
3
No any rules similar with R3, created new cluster
R5, R7
4
R8 is compared only with the cluster- 4.
R5, R7, R8
4
As R4 is similar to all the rules in the cluster-4, merged in the cluster-4
R6
5
No any rules similar with R6, created new cluster

Fig. 11 Example of Our Proposed Clustering Approach.

The similarity value of each pair of rules are (1,2)= 0.83, (1,3)= 0.33, (1,4)= 0.33, (2,3)= 0.33, (2,4)=0.83, (2,5)=0.83, (3,4)=0.33, (3,5)=0.33, (4,5)=1. The workflow and result of the above sample rules are described in Table VIII. Our novel clustering approach produces three clusters C1={2,5,4}C2={1,2} C3={3} for the above five rules. In our proposed approach, all rules in every cluster are similar. Thus a rule is merged if it is similar to all the rules already exist in that cluster. In some previous researches, the number of clusters is very high. Also, only minimum rules are similar in a cluster, and this leads to complexities in detecting and removing anomalies [22]. Unlike the rule-sub-module-reduction method [21], we merge the cluster at the time of the creation of the cluster itself, which increases the performance of the approach. In our previous work [28], we introduced the parameter priority-level to avoid the anomaly conflict-demand and reduce the more number of clusters. Although our previous research reduced the number of clusters, this enhanced cluster with the cluster-merging technique decreases the creation of more clusters and also maintains the constraints that all rules in a cluster are similar only.

Fig. 12 illustrates the comparison of our novel rule-specific clustering approach (RSCA) with the previous approaches 'Cluster-based approach' (CBA) and 'Log-based clustering approach' (LBCA) [21][22] (Maryem Ait El Hadj, Mohammed Erradi). CBA generates more clusters than LBCA and RSCA. Comparing to the hierarchical clustering algorithm(HCA) and other discussed previous approaches, our proposed clustering approach reduces the generation of more clusters and the number of comparisons, hence this result shows that our proposed approach consumes less time and increases the performance of the clustering technique and this helps to improve the efficiency of the ABAC model. Fig. 13 gives the comparative analysis of the existing approaches with our proposed approach based on the time complexity (Time is represented as Nanoseconds).

Table IX shows the qualitative analysis of clustering approaches. We used rule-redundancy-clusters (the same rule is clustered in multiple clusters), conflict-clusters (not all the rules in a cluster are similar), high-cluster-generation (more number of clusters are generated), and less time-consuming (measured based on the number of comparisons and iterations) to perform this qualitative analysis.

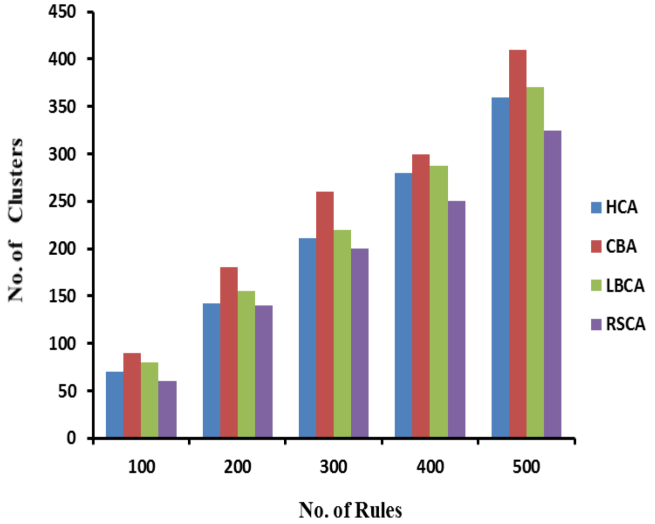

Fig. 12 A Comparative Study based on the Size and Number of Clusters.

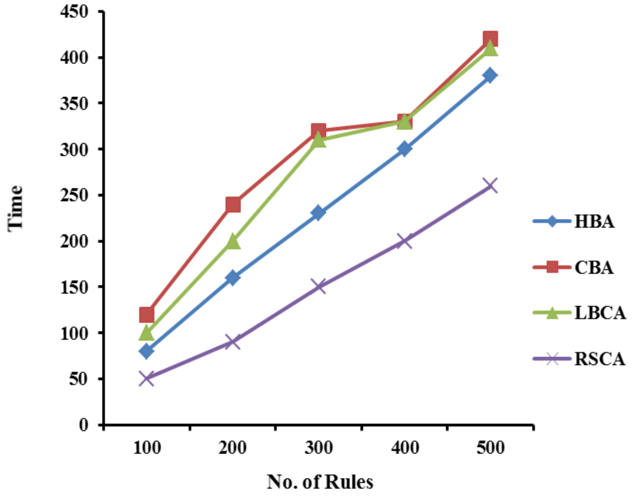

Fig. 13 A Comparative Study based on Time Complexity.

TABLE VII. SAMPLE ABAC RULES

RuleNo	Decision	PriorityLevel	Designation	Department	ResourceName	Time
2	allow$_{read}$	1	db_admin, typist, sys_asst, duty_doctor	diabetic, hematology	james_blood_report	8:18
3	allow$_{read}$	0	Office assistant	medicine_3	james_blood_report	7:19
5	allow$_{read}$	1	typist	diabetic	james_blood_report	8:18
1	allow$_{read}$	1	sys_asst, db_admin	hematology	james_blood_report,	8:18
4	allow$_{read}$	1	typist, duty_doctor	diabetic	james_blood_report	8:18

TABLE VIII. RESULT OF OUR PROPOSED CLUSTERING APPROACH WITH A SAMPLE OF THE ABOVE FIVE SECURITY RULES

Pair of rules	Clusters generated	Discussion

(2,3) (2,5) (2,1) (2,4)	C1={2,5}
	C2={2,1}
	C1={2,4,5}
		(2, 3) is not similar. (2,5) is similar and clustered in C1. (2,1) is similar and tried to merge with the existing clusters (C1) where rule 2 is a member. But the rule 1 is not similar to all the rules in C1, so (2,1) is stored in a new cluster C2={2,1}. As (2,4) is similar and matched with all the rules in the existing cluster C1where rule 2 is a member, and rule 4 is merged with C1. C1={2,5,4}

(2,3) (2,4) (2,5)	C1={2,5,4} C2={1,2}	(2, 3) is not similar. (2,4) and (2,5) are similar pairs but already both are clustered
(3,4) (3,5)	C1={2,5,4}C2={1,2} C3={3}	(3,4) and (3,4) are not similar pairs. Hence 3 is clustered in new cluster C3={3}
(4,5)	C1={2,5,4}C2={1,2} C3={3}	(4,5) is similar but already it is clustered.

TABLE IX. QUALITATIVE ANALYSIS OF EXISTING ABAC POLICIES CLUSTERING AND OUR APPROACH

References	Technique	Reduces rule-redundancy-clusters	Avoids Conflict-clusters	Reduces high cluster-generation	Less time-consuming
M. A. El Hadj et al. [22]	A rule is clustered with all similar rules, comparable clusters are merged.	No	No	Yes	No
M. A. El Hadj et al. [21]	Enhanced approach and used rule-merge sub-module clustering	No	No	Yes	No
Hierarchical Clustering [24]	No centroid. All elements are considered clusters. At each cycle, comparable clusters are merged	Yes	Yes	Yes	No
Our approach	Rule-specific-cluster-merging approach	Yes	Yes	Yes	Yes

VI. CONCLUSION

Cloud service providers use many access control models in the implementation of the intrusion detection system to secure big data and other shared resources in the distributed environment. ABAC model meets the security requirements of advanced computing technologies like cloud computing, fog computing, and the Internet of Things (IoT). Detection and Removal of Anomalies (DRA) in the policies improve the efficiency and reliability of the model. Applying DRA in every cluster of rules rather than in every rule enhances the performance of the approach highly. Existing DRA approaches have the inability to prove the efficiency of the model, due to applying the poor clustering approach or the approach which not properly detect and resolve all considerable anomalies. Our research contribution consists of three modules: 1) developing a tool to generate ABAC policies; 2) Storing and managing ABAC policies in the database; 3) applying a novel rule-specific-cluster-merging algorithm to cluster ABAC policies. In previous researches, clustering methods produce more clusters and cluster a rule in multiple clusters. The previous approaches generate conflict clusters thus not all the rules in a cluster are similar, which results that in increases the complexity of the approach and degrades the performance too. Our novel approach with the rule-specific-cluster-merging technique reduces the generation of more clusters, avoids the clustering of the same rule in multiple clusters and conflict clusters. With our RSCA algorithm, we decrease the number of comparisons. Hence our approach gives high performance and reduces the complexity in applying DRA. The additional parameter priority-level in every rule avoids the anomaly conflict-demand. This is only our part of research towards improving the performance and efficiency of the ABAC model. Our future work is to detect and resolve the rule redundancy at the time of clustering to decrease the complexity in the clustering mechanism. In the future, we will propose an approach to detect and resolve all considerable policy errors to improve the efficiency of the ABAC model and intrusion detection system.

***Abstract*—One of the most important challenge in Robotic Flexible Manufacturing Systems (RFMS) is how to develop a Multi-Robot based control system in which the robot is able to take intelligent decision to a changing environment. The problematic is how to ensure the flexibility with the proposed multi-robot based control system based on triggering strategies. The flexibility of the whole system is expanded by the capacity of the flexible robots to effectively ensure tasks assigned to it. Through this paper, three contributions can be presented: (i) the RFMS based Control Architecture by presenting in details the main components and methods, (ii) the planning model, and (iii) the different levels of flexibility in RFMS.**

***Keywords*—Robotic Flexible Manufacturing Systems (RFMS); multi-robot based control system; RFMS control architecture; planning model; flexibility**

I. Introduction

Nowadays, Flexible Manufacturing Systems (FMS) are facing widely frequent market changes determined by world-wide competition, new customers' requirements, continuous evolution of software and hardware, and the rapid introduction of new products [1]. Flexible Manufacturing Systems must ensure high quality products at acceptable costs and react rapidly to new market and products changes [2]. FMS can meet product changes, but they cannot respond to structural changes. In fact, the manufacturing systems are not able to face the dynamic changing environment due to their static control structure [3-5]. To react rapidly to the quickly changing environment, Robotic Flexible Manufacturing Systems (RFMS) based on multi-robot control system is considered as a good solution having the properties such as adaptability and flexibility [6]. Multi-robot based control system is an emerging solution which is becoming more and more popular as it helps to decentralize the decision in the control system [7]. Nowadays, there is a huge number of research activities that has been approved in this sense [8-10]. It is basic for Robotic Flexible Manufacturing Systems to have capacities such as autonomy, flexibility and adaptability. The RFMS framework based on Multi-Robot based control is intended to meet these criteria. A flexible manufacturing system can be applied either on static or dynamic system [11]. Robotic Flexible Manufacturing Systems can be used in many fields such as: medicine [12, 13], thermodynamic domain [14], optimal numerisation [15], motion [16], assembly system [17], automotive [18], fuzzy system [19].

The Robotic Flexible Manufacturing Systems can be based on either customisation or design. Robotic Flexible Manufacturing Systems based on customisation means satisfy the customers' needs during the design process of manufacturing systems leading to more time and effort before completing it [20].

Robotic Flexible Manufacturing Systems based on design means the ability of the change to obtain new robotic manufacturing systems based on existing ones as required, simply and economically [21]. The flexibility in design permits generating new manufacturing systems effortlessly by ensuring the required modifications from the existing ones, and the development cost can be significantly decreased [22].

In this paper, the architecture as well as the behaviour of intelligent flexible robots are presented. Therefore, the contributions are based on the following operations: (1) Firstly, design of flexible software architecture especially for a flexible robot. (2) Secondly, specification of the planning model ensured by the flexible robot. (3) Thirdly, the different levels of flexibility in Robotic Flexible Manufacturing System. To approve these contributions, the proposed methodology is applied to a benchmarking system.

Step 1: Define the high-level architecture of the RFMS.

On the basis of the control and flexibility objectives, the multi-robot control system is designed till the single controlled device and the related automation tasks. It is important for the system to be designed in a way ensuring capabilities such as flexibility. To do so, the multi-robot control system is conceived to incorporate several self-flexible levels to respond quickly to any changes occurring in the environment.

Step 2: Define the planning ability.

In the Multi-Robot Based Control System, the planning ability is considered as a very important point to study that's why it is defined how it is implemented. In fact, a plan is considered as a state-transition model.

Step 3: Define the flexibility ability.

In the Multi-Robot Based Control System, a Flexible Robot is defined what means. After that, a study on how the Flexible Robot ensures the flexibility. In order to cover a wide range of the production policies, the flexible robot must ensure several flexibility levels that can be categorized in the following ways: the product family, the product variant, the plan, the task, the skill, the failure, the production control, the adaptation and the configuration. These different levels of flexibility will be detailed later in the paper.

The remainder of this paper is organized as follows: Section 2 introduces the state of art. Section 3 presents the production system benchmark used as running example. Section 4 describes the Multi-Robot based Control Architecture. Section 5 defines the planning model. The Section 6 presents the different levels of flexibility in RFMS. Finally, the conclusion and future work are summarized in the last section.

II. State of the Art

To define well a robot control system, a special attention is given to its architecture. A huge number of research papers was presented to define it. The first classification is based on Knowledge Utilisation based on the way the robot uses its knowledge to perform action. In this first classification, there are Competitive approach and Collective approach. The competitive approach is based on the use of a single criterion to take decision [23]. The Collective approach enables to take in consideration many criteria to make decision [24]. The competitive approach can be categorized into five types, namely lookup-based [25], finite state machine [26-27], priority-based or hierarchical-based [28], goal-based [29] and utility-based competitive approaches [30].

The second classification is based on Knowledge Design. The intelligent robot can be represented through a defined architecture that can be deliberative, reactive or hybrid. The deliberative architecture (called also hierarchal architecture, top-down, knowledge-based approach, or explicit-based approach) is the most used in the artificial intelligence [31]. The deliberative architecture consists of vertical layers where each layer is based on the data sent by the previous one. In general, a robot senses the environment, plans and executes to achieve a goal.

The reactive architecture (called also bottom-up, behaviour-based architecture or implicit-based approach) is based on a mapping between perception (provided by sensors) and action. The reactive architecture is considered as horizontal architecture where the different behaviors can be executed in parallel [32].

The hybrid architecture is more commonly used especially to control robot as the reactive aspect permits to take action in real-time to the perception of the dynamic environment and the deliberative aspect enables to plan future actions to satisfy a goal [33].

Each architecture has its own strengths and weaknesses. The deliberative architecture is likely to have higher computational cost than the reactive approach due to data sent between vertical layers. In addition, the deliberative approach is more complicated due to a complete knowledge has to be provided. However, the reactive architecture is less flexible than the deliberative one because behaviors cannot be modified as much as in the deliberative architecture (although it is considered easy to implement). Therefore, purely deliberative and reactive architecture are not considered suitable for a complex system. In this context, the hybrid architecture gets strengths as well as weaknesses of the two approaches, thus why we focus on how to balance the two approaches in this paper.

III. Production System Benchmark

As much as possible, the contribution will be illustrated with a simple current example called RARM [34]. It is described informally, but it will be used as an example of the various formalisms presented in this article. The production system benchmark RARM is depicted in Fig. 1.

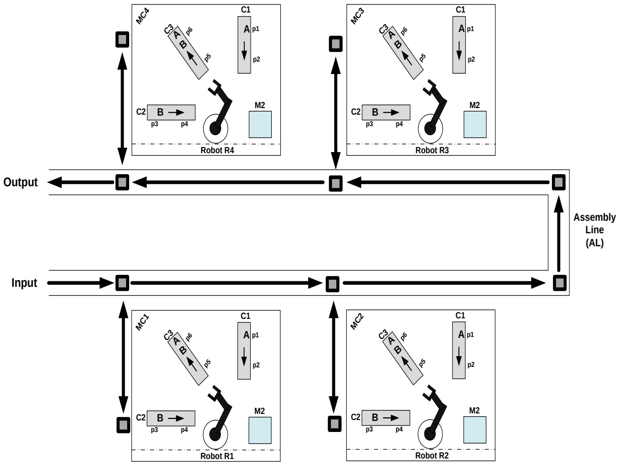

Fig. 1. The Production System Benchmark RARM.

The whole manufacturing system is divided into two main parts (Fig. 1): Assembly Line (AL) and Manufacturing Cell (MC). The Manufacturing Cell named as MC1, MC2, MC3 and MC4 are connected through the Assembly Line (AL) to enable the flexible robots moving from one MC to another.

Each Working Place contains three conveyors (C1, C2 and C3), a processing–assembling unit (machine M), a flexible robot R and additional sensors. Workpieces to be treated as they come irregularly one by one. The workpieces of Type A are carried via the conveyor C1, and the workpieces of Type B, via the conveyor C2. Only one workpiece can be on the input conveyor. The flexible robot is used to load and unload workpieces between the processing–assembling unit and the storage equipment (Input/Output). Firstly, the flexible robot carries a workpiece from the Input storage to the processing–assembling unit, which is processed by the machine M. After processing, the flexible robot transports the finished workpiece to the Output storage.

IV. High-Level Robot-based Control Architecture

The traditional methodology in designing robots has been to design the hardware and the software according to what it should do. Traditional robots can execute specific tasks, but they are not flexible, and therefore applications assigned to them depend on their physical structure and their controller abilities. Creating Flexible Robotic Manufacturing System is facing hardware and software challenges.

While existing survey papers on Flexible Robotic Manufacturing System have studied the architecture and hardware feature of robots, in this paper, a special attention is given to the challenging issues emerged when developing flexible robots. Thus, the main problem to resolve is arising when the flexible robot perform tasks through some flexibility abilities.

To react rapidly to the quickly changing environment, it is basic for the framework to have such capacities as adaptability and flexibility. The Multi-Robot based control framework is designed to meet these needs. To ease the system flexibility, robots would be itself flexible. To do so, every Flexible Robot belonging to the Multi-Robot system has its own Goal to achieve and can generate a plan associated to this goal. This policy helps the Flexible Robot to select an appropriate plan of tasks to be executed.

In Fig. 2, a Flexible Manufacturing System Meta-Model is presented. Each Product is assumed to have its own Family. A Product_Variant is considered as a specific case of Product_Family. To ensure a Product_Variant, a list of Plan has to be executed and is composed of Task_Manager. Each Task_Manager has some inputs which are Events and uses some Resources, perceive data through Receptors and execute commands by Effectors. The flexible robot needs to have some specific Skill_Manager to execute well a task.

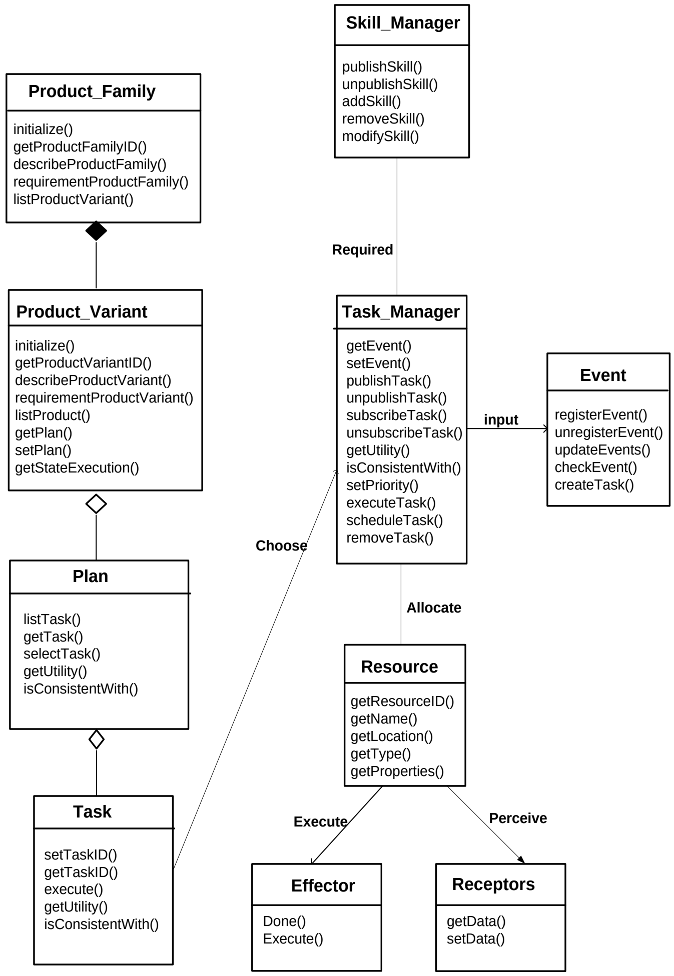

Fig. 2. Conceptual Meta-Model for a Flexible Manufacturing System.

Where

- Product_Family: It is a set of similar products having common tasks. In the production system RARM, it is possible to produce two potential product families simultaneously. To produce these product families, three types of machines need to be installed: Drill, Load, and Assembly. All of these machine types have a modular structure that allows adding/removing services. Based on these services, each machine type can have different configurations with different abilities and/or skills. Therefore, the flexible robot chooses the right machine configuration and decides the best production policy based on the machine availability and their cost structures.

Running example: In the benchmarking production system, two types of product families are defined: product family type and product family type. It is possible to process the two potential product families simultaneously. The product family type is treated firstly by RMC1 and then by RMC2. The product family type is handled firstly by RMC2 and then by RMC3. As for RMC1 (resp. RMC2, RMC3), it consists of a drilling machine (resp. milling machine, assembling machine). The buffer can store the finished workpieces and workpieces waiting to be processed.

- Product_Variant: is the same product but having different size, color, materials.

Running example: For the product family type , there are three possible product variant (i) the first production variant consists of inserting an A-work piece (through the conveyor C1) into the processing center M to be treated, then it is evacuated by the robot to the output conveyor C3; (ii) the second production variant consists of inserting a B-work piece (through the conveyor C2) into the processing center M to be treated, then it is evacuated by the robot to the output conveyor C3; (iii) the third production variant consists of inserting an A-work piece into the processing center M to be treated, then a B-work piece is added in the center and the two work pieces are finally assembled.

- Plan: The Flexible robot may have many tasks which are inconsistent. Therefore, the plan is composed of consistent tasks. The plan is composed of a set of tasks for a given product variant that can be either fixed or variable. The aim is to regroup as much as possible of tasks to be included in the same plan. Thus, the ***selectTask*** method is used to add a task in the Plan and the ***getTask*** method permits to return all the tasks related to the same Plan. Similar to Task, the ***isConsistentWith*** method is used to verify the consistency between two plans and the ***getUtility*** method enables to choose a plan among many concurrent existing Plans. If a plan has been chosen, the ***commitGoal*** method is used to create a new Goal instance.

- Task: In general the task objects are associated to the event object. There is a relation one-to-many between task and event. The methods ***setEvent*** and ***getEvent*** are used to set a link between task and associated events. To check the consistency between two tasks, the

isConsistentWith method is used. The Flexible robot has to choose between several tasks existing at the same time (which some of them can be inconsistent) based on the task's utility through the ***getUtility*** method. In some circumstance, the Flexible robot decides to select one or several consistent tasks to constitute a Plan with the use of ***selectAsPlan*** method. For each task, all exceptions are enumerated and trigger events are determined.

Running example: The set of actions is {Ci1_left, Ci1_right, Ri1_left, Ri1_right, Ci2_left, Ci2_right, Ri2_left, Ri2_right, Ci3_left, Ci3_right, Ri3_left, Ri3_right, takei1, takei2, takei3, loadi1, loadi2, loadi3, puti1, puti2, puti3, processi1, processi2}

Where:

- Ci1_left (resp. Ci1_right) means a workpiece of type A is moved to the left of conveyor Ci1 from position p1 (resp. p2) to position p2 (resp. p1).
- Ri1_left (resp. Ri1_right) means the Robot ri taking a workpiece of type A is moving to the left (resp. to the right) from the position p2 of conveyor Ci1 (resp. the processing unit Mi) to the processing unit Mi (resp. the position} p2 of conveyor Ci1).
- takei1 (resp. takei2, takei3) means the Robot ri is currently taking a workpiece of type A (resp. B , AB).
- loadi1 (resp. loadi2, loadi3) meansthe fact of loading a workpiece of type A (resp. B , AB).
- puti1 (resp. puti2, puti3) means the Robot ri is currently putting the workpiece of type A (resp. B , AB).
- processi1 (resp. processi2) means the fact of processing a workpiece of type A (resp. B).
- Event: the Flexible robot can update its knowledge about the environment through sensors. The Flexible robot can register to a specific event (this is done by the ***registerEvent*** method) or unregister (through the ***unregisterEvent*** method). The events associated to the robot are considered independent. Whenever the Flexible robot receives a new event, it checks firstly if there is a need to create a new task (this is done by the ***checkEvent*** method). If the condition is satisfied, a new task is created (this is ensured by the ***createTask*** method). All tasks arise from the Flexible robot's perception.
- Resource: Each manufacturing system is composed of a set of resources (e.g., machines, tools, grippers, conveyors, transport devices, etc.). Each resource performs a distinct function. It is possible to find a pool of more than one resource that has the same function.
- Receptor: the flexible robot knows its environment through sensors. Thus, the data provided by the sensors present the robot's vision of its environment. The perception parameters have to be defined and the robot must know how to interpret the data.

Running example

- The sensor sens1 (respectively sens2) is used to verify if there is a workpiece at the position p1 (respectively the position p2) on the conveyor C1;
- The sensor sens3 (respectively sens4) checks for the existence of a workpiece at the position p3 (respectively the position p4) on the conveyor C2.
- Effector: the flexible robot can execute the task using the effector. For each effector, a behavior is proposed to judge the requests to it.

Running example

- The effector act1 (respectively act2, act3) ensures the movement of the conveyor C1 (respectively C2, C3);
- The effector act4 rotates a robotic agent;
- The effector act5 elevates the robotic agent arm vertically.

V. Planning Model

The planning model means how the flexible robot should act to decompose the problems into subproblems to obtain the whole solution that the flexible robot must apply. The planning model of the flexible robot leads to a very huge number of possibilities which the flexible robot will have to take in consideration again in order to retain only the valid possibilities that should be kept.

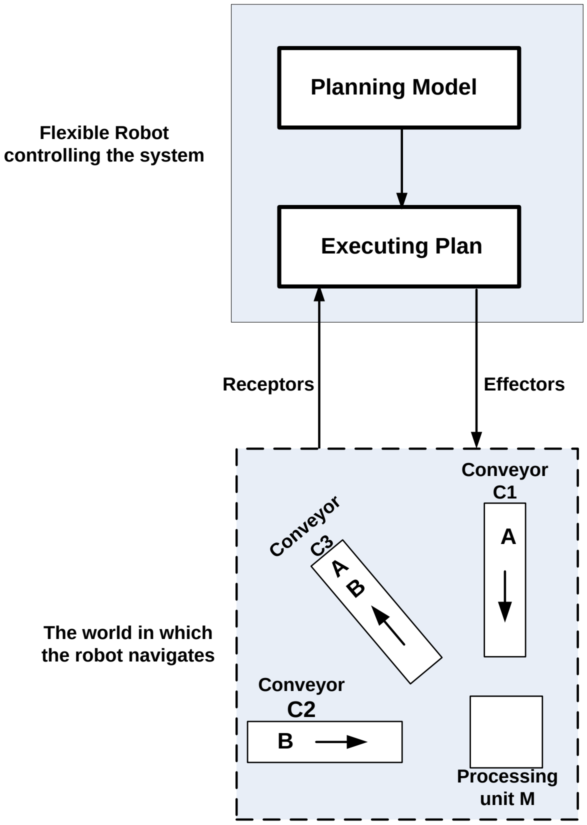

Fig. 3. The Conceptual Planning Model.

The planning model is based on two necessary elements: the receptors (i.e. a set of sensors to get data about the external environment in which the flexible robot is existing) and the effectors (i.e. a set of actuators to realize the flexible robot's tasks) [35]. Fig. 3 shows a conceptual model of the flexible robot including two components: the planning model, and the executing plan [36, 37]).

To be more specific, the planning model is based on state-transition model where Σ representing the world is a finite state-transition system, i.e., a triple Σ = (S; A; γ), where S is a finite set of states, A is a finite set of actions, $\gamma : S \times A \rightarrow 2^S$ is a state-transition function. If (s, a) = $\varnothing$; then it is said that a is not applicable to s or not executable in s.

Given a state transition system Σ , the aim of planning is to determine which actions to execute to which states in order to realize some objectives when starting from a given situation. A plan is a solution that determines the appropriate actions to reach the goal. The objective can be specified by a goal state s_g or a set of goal states Sg. The objective can be obtained by any sequence of state transitions that ends at one of the goal states. The planning model necessitates the descriptions of , the initial state before applying the plan, and the desired objectives (e.g., to reach a set of states that satisfies a given goal condition). Therefore, the planning model's objective is to produce a plan (i.e., an ordered finite sequence of actions) that puts Σ into any one of some finite set of states Sg.

More formally, the plan π is any sequence of actions π = (a1 , … , ak), where k $\geq$ 0.

The length of the plan is $|\pi|$ = k is equal to the the number of actions. If π 1 = (a1 , … , ak) and π 2 = (a'1, … , a'j) are plans, then their concatenation is the plan π 1. π 2 = (a1 , … , ak, a'1, … ,a'j). The state produced by applying π to a state s is the state that is produced by applying the actions of π in the order given.

The plan π is executable in a state s0 if there is a sequence of states (s0; s1; … ; sn) such that for i = 1; … ; n,

$s_i = \gamma(s_{i-1}, a_2)$. In this case it is said that (s0; s1; … ; sn) is π's execution trace from s0, and $\gamma(s_0, \pi) = s_n$ is defined. If sn satisfies the goal g, then it is said that π is a solution for the planning problem P = (O; s0; g).

The quality of a plan is measured by length, where the shorter of two plans is better under the same satisfaction degrees.

An action or a plan posts a set of goals G = {g1; g2; ...; gn}. This invokes the following process:

1) Loop over each goal gi:

a) Determine the set of plans filling the goal gi.

b) Keep only the plans which pre-conditions are satisfied.

c) For each remaining plan, check its mandatory resources.

2) Order the different goals gi according to its priority.

3) For every goal gi in order of priority.

a) If only one plan P realizes gi

then apply P

else // several plans

b) order each plan achieving the goal gi based on the length of the plan and how many resources it uses.

c) Choose the plan having the highest scoring.

Running example

Giving (S, A, Gs) where S = {si , i=1...n } is a set of states, A= {Ci1_left, Ci1_right, Ri1_left, Ri1_right, Ci2_left, Ci2_right, Ri2_left, Ri2_right, Ci3_left, Ci3_right, Ri3_left, Ri3_right, takei1, takei2, takei3, loadi1, loadi2, loadi3, puti1, puti2, puti3, processi1, processi2 i=1...n } is a set of actions, and Gs is the problem goal.

If the goal g = {workpiece in the processing unit} and the robot is at the initial position s1. Let:

- π 0 = (Ci1_left, takei1).
- π 1 = (load_i1, put_i1, process_i1, Ci1_right).
- π 2 = (Ci1_left, take_i1, load_i1, put_i1, process_i1, Ci1_right).

Then

π 0 is not considered as a solution because the final state is not a goal state;

π 1 is not a solution because it is not applicable to s1;

π 3 is the only solution because it is applicable to s1 and the final state is a goal state.

VI. How does the RFMS Ensure Flexibility?

The flexible robot controls the system through an event-triggering policy which means whenever an event related to the system (for example a resource failure), the flexible robot decides to take the right decision. In order to cover a wide range of the production policies, the flexible robot must ensure several flexibility levels that can be categorized in the following ways:

- Product Family flexibility means that the flexible robot is able to change-over production families to produce a new Product family which is feasible in terms of requirements (that means manufacturing facility procedure to ensure the production of each product family). In fact, Flexible Manufacturing Systems are designed to achieve several operations on many products grouped in families according to their operational requirements.

As it is illustrated in Fig. 4, each Flexible Robot has some Product to achieve. To do so, it determines the appropriate production plan and the tasks that can be executed. The internal behaviour of the Robot is defined as follow: firstly, the Flexible Robot evaluates the feasibility of the new product. If it is not feasible, then the Flexible Robot generates error, else it determines the list of tasks to be executed. Each task needs some resources. If the Flexible Robot fails in achieving this task due to some missing resources, it can ask help from other robots able to provide the requested resources which are considered as Helping Robots.

Running example the flexible robot can switch from the product family type α to the product family type β.

In [38], the authors present a methodology to group products into families depending on similarities through a modified Jaccard similarity index.

$$S_{ij} = \frac{\sum_{m \in i} \sum_{n \in j} S_{mn}}{N_i N_j} \tag{1}$$

Where

i,j families,

m (resp. n) products of family i (respectively j)

Sij degree of similarity between families i and j

Smn degree of similarity between products m and n

Ni (resp. Nj) number of products in the family i (resp. j)

Fig. 4. Flexible Robot Behavior.

- Product Variant flexibility means that the flexible robot is capable to define the different possible configurations for the same product family (i.e. alternative configurations for each product family).

Running example the flexible robot can switch from the first production variant to the second product variant in case of shortage of workpiece A.

To measure the similarity degree between two products m and n, the Jaccard similarity coefficient Smn [38] is used which is defined.

$$S_{mn} = \frac{a}{a+b+c}, 0 \le S_{mn} \le 1 \tag{2}$$

Where a represents the number of common machines used to produce both the products m and n; b defines the number of machines used to produce the product m; and c represents the number of machines used to produce the product n.

- Plan flexibility means that the flexible robot is able to define the order of execution of the tasks to ensure the same plan.

Running example the flexible robot can switch from the following plan {C2 left, take2, load2, process2} to a new plan {load1, put1, process1, C1 right}. The following algorithm obtains a valid plan constituted by a task sequence (T1, .., Ti, Tj, .., Tn) where Ti.post-condition = Tj.pre-condition.

```
Algorithm Graph_generation()
Input: Node t(acti, pre-condi, post-condi), Precedence Graph G = (T, R)
Output: Precedence Graph G = (T, R)
Add t into T
For j in 1 to length(T) do
    If (post-condj = post-condi )
            Add r = (actj , acti) into R
    End if
End for
```

- Task flexibility means that the flexible robot has the ability to manage the task switching with minimal effort.

A Task Precedence Graph G = (T, R) is used to provide a simple visual representation of a complex system by modelling the interactions and precedence relations among the different tasks where T is the set of tasks and R is the relationship between Tasks (precedence order).

Fig. 5 shows Task Precedence Graph composed of night Tasks (from T1 to T9), and illustrates how is the final production system configuration.

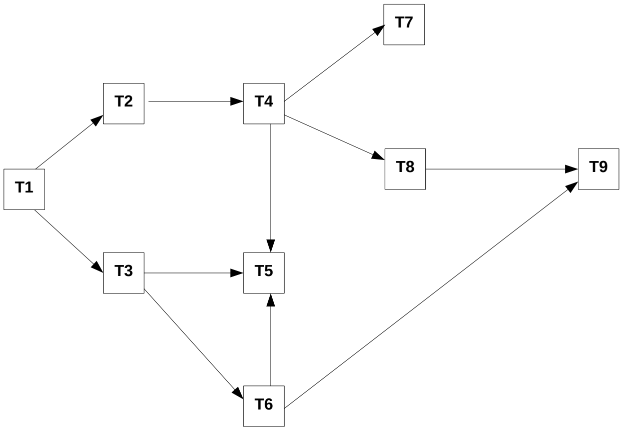

Fig. 5. Task Precedence Graph.

The list of tasks that can be executed is determined through the following algorithm.

```
***Algorithm*** Task_Choice()
Input: Precedence Graph G = (T, R)
// T is the whole tasks
// R is the relationship between Tasks (precedence order)
Output: set of tasks can be executed by end actuators
Repeat
    For each t in T do
        If (indegree(t)=0) & (t. actuator = available) then
                Return t
        End if
    End for
    If (t.state = executed) then
      t.actuator ← available
      T ← T – {t}       //Remove t from the whole tasks T
      R ← R – t.outgoingEdge //remove its outgoing edges from R
    End if
Until all tasks are executed
```

- Skill flexibility means that the flexible robot has the ability to change its different skills i.e. adding new skills, removing others, and modifying of several services composition, e.g., redesigning the services by adding a new one and eliminate others to be more flexible with the environment evolution.

Running example the flexible robot has the moving skill (forward/backward), it is possible to add on it the new skill turning (left/right).

- Failure flexibility describes the aptitude of flexible robot to deal with breakdowns and consequently guaranteeing continuation of production.

Running Example. The flexible Robot controlling the production system RARM consider many scenario in case of faults happen to physical components such as actuators, conveyors or machines.

- The first scenario involves a single conveyor C1 that transports A-work pieces to be processed by the machine unit.
- The second scenario involves a single conveyor C2 that transports B-work pieces to be processed by the machine unit.
- The third scenario involves two conveyors C1 and C2 that transports A and B-work pieces to be processed by the machine unit.

If the conveyor C1 is broken in the RARM Production System, then the flexible Robot has to apply the second scenario. If the conveyor C2 is broken in the RARM Production System, then the flexible Robot has to follow the first scenario. If the conveyor C1 and C2 are functioning well, then the flexible robot can apply the third scenario (Fig. 6).

Fig. 6. Flexible Robot Behaviour in Case of Failure.

- Adaptation flexibility: Fig. 7(a), represents the normal case where there are: (i) two flexible robots, each one is existing in a station, (ii) Robot repository to help other robot facing problems and (iii) Gripper repository which permit robot to accommodate the product family (depending on the form and the geometry of the workpiece to be handled). This normal case is considered as the starting point upon which all adaptation scenarios are based.

In Fig. 7(b), rather than stopping the manufacturing system to repair the broken robot, the robot facing a problem can be substituted by another one. In Fig. 7(c), if the robot is broken and there is no other available robot, then the workpiece can be transferred to the second workstation to be processed.

In Fig. 7(d), a new suitable gripper is used to be convenient with the form of workpiece. The use of new grippers for the transfer of the workpiece facilitates the adaptation flexibility.

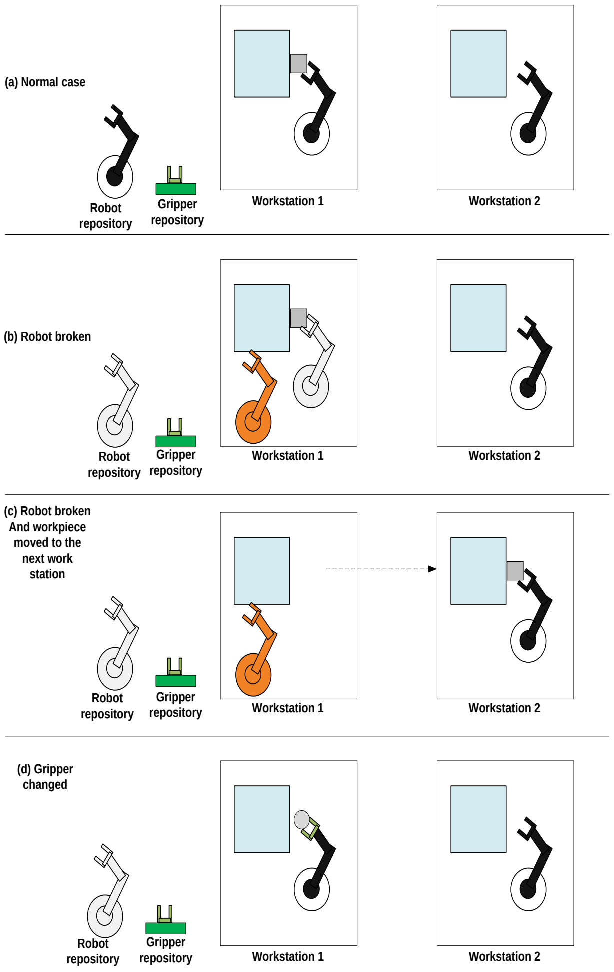

Fig. 7. Adaptation Scenarios.

- Configuration flexibility: Fig. 8 illustrates a decision graph representing all the set of possible configurations that can be executed by the flexible robot. It comprises six levels: (i) the first level represents the different product families (for example here, there are only two); (ii) the second level defines whether the Product Family is possible or not, (for each product family, there are two alternatives Possible or Not Possible); (iii) the third level specifies the different product variants that can be executed related to a specific Product Family if it is possible of course; (iv) the fourth level defines the availability to execute a product variant (for each product variant, the input indicates if is available or not); (v) the fifth level represents the different plans that can be executed for each product variant if it is available; (vi) the sixth level represents the different tasks to be executed for each plan. Each node of the tree graph is a decision point.

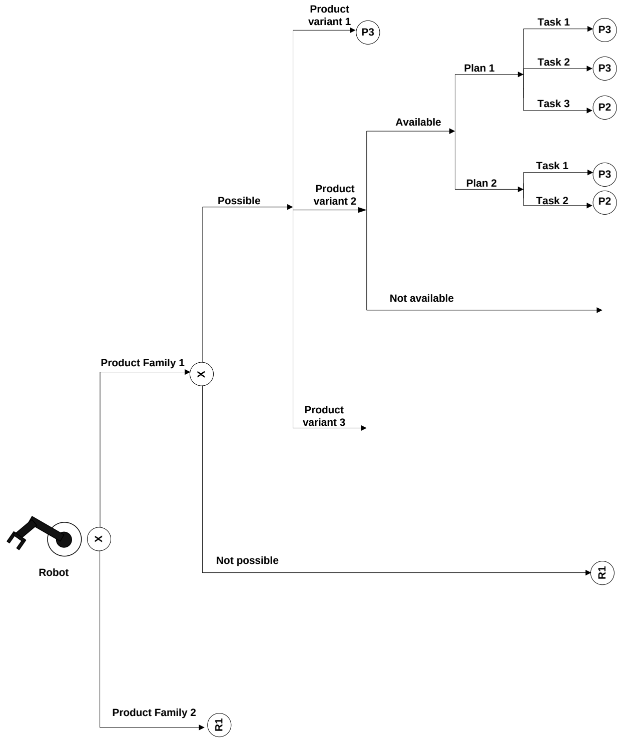

Fig. 8. Intelligent Robot Control Decision Making..

The total number of alternative solutions for each intelligent robot can be represented as:

$$R = \prod_{i} \prod_{s} \prod_{j} \prod_{a} \prod_{p} \sum_{t} R_{i,s,j,a,p,t} \qquad (3)$$

Where

- R is the total number of possible configurations for the intelligent robot,
- i, is the product family index,
- s, Boolean parameter to indicate if the product family is possible (true or false),
- j, is the product variant index,
- a, Boolean parameter to indicate if the product variant is available (true or false),
- p, is the product variant plan,
- t, is the task index.
- Ri,s,j,a,p,t, is the complete configuration that the intelligent robot can choose. Based on the above analysis for each Product family, Product variant, Plan and the identification of suitable tasks to be executed in order.

VII. Conclusion

Robotic Flexible Manufacturing Systems (RFMS) is a suitable solution to accommodate changes and meet customers' needs such as autonomous decision, control, and flexibility to react rapidly to the quickly changing environment.

Through this paper, we consider the challenge how to implement RFMS, the proposed approach presents the following contributions: (i) firstly, the general approach is designed to define the basic architecture of RFMS by presenting in details the main components and methods, (ii) secondly, the control robot is defined how to deal with the planning, (iii) thirdly, the different manners in which the flexible robot can adapt the system are proposed. The robots behave more like they are thinking, by making a decision about action selection and predicting the effects of actions. Therefore, the problem is divided into three parts: the robot-based architecture, the planning model and the flexible robot behaviour.

The future work will be as the following. The methodology can be expended to include human-computer interaction. The Multi-Robot based control system can be ameliorated to allow robots to participate in multiple collaboration at the same time.

Professor, Department of Computer Science and Engineering, GSSS, Mysuru, Karnataka, India

***Abstract*—The Internet-of-Things consists of heterogeneous smart appliances connected by global network with self-configuring capabilities requiring interoperable communication schemes while performing inter-domain routing. A review of existing interoperable approaches shows that there is still a large scope of improving IoT interoperability. The proposed system introduces Interoperable Communication System (ICS) by developing a novel inter-domain routing in IoT using two schemes. Preemptive and Non-Preemptive Communication scheme targets mainly emergency-based routing, which demands faster transmission, and dedicated transmission, demanding accountability in communication. A simulation study carried out for the proposed system shows that it offers approximately 90% reduced delay, 57% increased packet delivery ratio, and 98% faster processing time when compared with existing approaches to accomplish interoperability in IoT.**

***Keywords*—Internet-of-Things (IoT); interoperability; heterogeneous; gateway protocol; inter-domain routing**

I. Introduction

The term Internet-of-Things (IoT) refers to technological advancement, which connects various virtual and physical things using the internet's existing infrastructure [1]. It consists of network infrastructure globally-connected, characterized by self-configuring capabilities considering interoperable communication systems [2]. IoT devices are generally considered smart appliances integrated with different platforms to assist in operating various applications, e.g., transportation, utilities, agriculture, healthcare, commerce, and industrial buildings [3]. In this aspect, the concept of interoperability is a much-discussed topic under the roof of research and development in IoT. If two IoT platforms are incompatible, then an application's operational features cannot be fully established [4]. The concept of IoT interoperability is perceived in the form of a platform, semantic, syntactic, networking, and device interoperability [5]. In the present time, the state of interoperability in IoT is managed using different approaches. The primary approach is to work on gateways and adapters that mechanizes intermediate software and tools to bridge the communication among the IoT devices with respect to different standards and data [6]. Existing gateway protocol in IoT offers one gateway to communicate with others. Still, it suffers from significant scalability issues, especially in multiple and massive smart appliances, which results in higher design complexity. The second approach uses overlay-based techniques to integrate the actuators/sensors with other IP-based objects to carry out seamless operation [7]. It can also be carried out using a virtual networking system that permits device-based communication with an end-to-end approach; however, it also suffers from scalability issues. The third approach uses different networking technologies using IP-based approaches, Software-defined approaches, network function virtualization, fog computing, etc. [8]-[10]. The fourth approach uses service-oriented architecture to offer syntactic interoperability among all smart appliances [11]. The fifth approach is to make use of semantic web technologies [12]. Apart from this, various other research work is being carried out to investigate interoperability issues in IoT. It is still in progress, and no definitive solution has yet arrived. There are various problems associated with interoperability from existing research trends which are as follows: i) existing trends of the solution is more inclined towards considering specific case study which is somewhat unpractical from practical IoT deployment, ii) in the presence of a large number of smart appliances, it is eventual that the communication has to be carried out using the application-domain approach, which is not considered much in existing trends of research, iii) although, all the major investigation towards interoperability of gateway node, they have ignored the consideration of amending the search and data translational services when gateway communicates with multiple application domains.

Existing studies in IoT towards interoperability focuses on specific communication environment without considering capabilities of devices included in it. This is a significant limitation of existing system. Therefore, this paper introduces a simple yet efficient inter-domain routing scheme in IoT that emphasizes achieving interoperability. The investigation contributes to evolving a new methodology where heterogeneous communication systems are considered while performing inter-domain routing. This paper's contribution is mainly to introduce a simplified framework that can support interoperability of communication systems in IoT, not current times. The organization of the paper is as follows: Section II discusses existing research approaches towards interoperability in IoT, Section III discusses identified research problems, Section IV discusses proposed research methodologies, Section V discusses system design along with algorithm discussion. Result analysis is carried out in Section VI, while the paper's conclusive remarks are provided in Section VII and future work description in Section VIII.

II. Existing Approaches

At present, various approaches have been implemented to address multiple ranges of issues in IoT [13]. This section specifically discusses the issues about interoperability in IoT. The recent work carried out by Xu et al. [14] has presented a technique for improving throughput performance, specifically concerning industrial IoT systems using cognitive networks. The study has used a convex optimization process in order to address resource allocation issues in industrial IoT. The technique also considers scheduling of IoT devices in order to achieve better fairness control. A similar direction of study towards resource provisioning to achieve interoperability in IoT is also presented by Zhou et al. [15]. This approach makes use of the Lyapunov optimization scheme with delay awareness. Without having any form of dependencies towards predefined information of statistical data of cloud system, this technique reports provisioning of IoT application of different types. The approach finally claims a cost-effective operation considering practical world traces of traffic information. The current study also emphasizes security and interoperable conditions in IoT where signcryption is used for the multi-receiver system over the mobile system in IoT (Qiu et al. [16].

Another study carried out by Behera et al. [17] has developed an enhanced communication scheme focusing on the heterogeneous network in IoT. Considering the wireless sensor network case study, this implementation mainly deals with selecting cluster-head for performing data aggregation in the heterogeneous network in IoT. However, the scheme is restricted to addressing issues associated with energy efficiency only in IoT. Considering the case study of healthcare in IoT, the work carried out by Ray et al. [18] has used broker services for message queueing in order to perform service provisioning. A unique gateway testbed has been constructed, which includes various wireless networks for usage in translational services. The complete study has been carried out in prototyping form using real-time sensors. The work carried out by Diez et al. [19] has presented a validation framework in order to assess the fact of proper alignment of data with standards of the data model. It has also been seen that messaging protocols play an essential role in interoperability in IoT. Al-Masri [20] has discussed the dependency of multiple messaging protocols to establish proper communication among heterogeneous devices in IoT.

There is also dedicated research being carried out towards assessing the testbed of IoT. One such research work is carried out by Lanza et al. [21] where experimentation in the form of services has been presented for IoT. Existing studies have also been carried out towards assessing the trustworthiness of gateway systems in IoT, as seen in the work of Fraile et al. [22]. The approach discusses security architecture for device drivers along with faster visibility of the node. Yang et al. [23] have presented an optimization scheme towards industrial IoT operation where the Poisson process is used for developing the work distribution in IoT. The adoption of convex optimization principle is used for performing analysis. A combined study towards network security and quality of service is carried out by Sood et al. [24] in order to enhance the heterogeneity in the serviced rendered by Software Defined Network in IoT. The technique also performs transformation of the controllers of heterogeneous form to the homogeneous form using mathematical modelling. Heterogeneity is also studied with respect to security over physical layers in IoT as seen in work of Wang et al. [25]. The work carried out by Leu et al. [26] have emphasized over achieving stability in messaging services in IoT in order to enhance the heterogeneity in Service-Oriented Architecture. The technique makes use of shortest processing time in order to carry out scheduling of the IoT messages in web-based services.

Study carried out by Nguyen et al. [27] has used network codes in order to investigate the impact of energy consumption over IoT performance. In this study, the author has investigated the use of random linear network coding targeting to improve the throughput performance in IoT. A unique study presented by Wu et al. [28] discusses the use of tree concept in presenting sensor network over IoT considering case study of healthcare assessment. In this work, a unique tree structured is developed with indexing policies where a neural network is applied in order to perform feature engineering for facilitating interoperable operation in IoT. Such learning based approaches towards heterogeneous network are also witnessed in work of Yang et al. [29]. This approach makes use of radio frequency in order to cater up the QoS requirement using Markov decision process. The study also uses reinforcement learning scheme for further optimizing the outcome. Adoption of swarm intelligence is also reported to carry out optimization operation in IoT. Work of Ni et al. [30] have used dragonfly algorithm in order to plan the communication path considering multiple robotic system of heterogeneous form. An indepth investigation towards various optimization algorithm towards improving hardware architecture for heterogeneous IoT is carried out by Krishnamoorthy et al. [31]. Noori et al. [32] have carried out investigation towards slotted ALOHA protocol for improving the communication performance in heterogeneous IoT. Finally, Asad et al. [33] have improved the quality of service using provisioning of quality of service over multiple radio access technology using game theory concept. The idea is to offer a seamless access among heterogeneous devices in IoT.

Hence, it is seen that existing system mainly make use of heterogeneity concept in order to achieve better interoperability in IoT. Heterogeneity doesn’t necessarily address interoperability issues in IoT. A closer look into existing system shows beneficial approaches and outcome when it comes to addresses considered problem. However, all the essential problems are not considered in generalized environment of IoT. The next section discusses about research problem.

III. Limitation of Existing Studies

After reviewing the existing approaches of interoperability in IoT, following research problems has been noticed:

- Although, there are certain degree of work being carried out towards addressing interoperability problem in IoT, but they are very much specific to singular environment of communication. However, practical application in IoT demands more towards inter-domain communication scheme, which unfortunately is very less. Existing solution are highly inclined towards either network layer or device level. This is not sufficient to deal with various emergency communication systems in IoT.

- Existing system offers minimal emphasis over capabilities of smart appliances or IoT devices while working on interoperability. There is a need of evolving up with standard of communication over IoT which are not present at this moment in order to cater up the demands of communication associated with the low end devices in IoT. It is essential to understand that a practical form of solution for interoperability should not be purely dependent on available network entity. Another biggest challenge is also associated with the existing gateway system in IoT which is not compatible with the changes when a new smart appliance is added or new services are edited. Apart from this, there is an emergent need of flexible interoperability within the gateway system for boosting up machine-to-machine communication system with higher range of scalability.
- The third challenge explored in existing studies is that they consider single of two platform in the form of application domain. In the practical concept of large scale scenario of IoT deployment, there are possibilities of multiple number of application domain and IoT nodes within this domain are required to establish communication process dynamically. A better and effective approach should be highly practical with facilitation of scalable operation over the multiple number of application domains. Adding of new domain should not affect the scalable performance of the gateway node.
- There are various routing scheme in IoT; however all the existing protocols suffers from the challenges associated with fault tolerance, context awareness, presence of multiple network standards, node deployment, intermittent connectivity, multihop communication scheme. Apart from this issue, existing routing scheme cannot actually differentiate dynamic demands of the large scale distributed communication system. It works in similar way for all kinds of communication demands. Interoperability is achieved by a predefined environment in IoT which is impractical.

Hence, the statement of problem is "It is challenging to develop scalable, interoperable routing scheme which justifies all forms of traffic demands in unbiased fashion in large scale IoT environment."

IV. Research Methodology

The proposed system adopts an analytical research methodology where the idea is to construct a framework which can jointly address the both preemptive and non-preemptive communication system in IoT. The novelty of the proposed methodology is that it offers higher degree of flexibility to achieve interoperability in achieving communication in IoT. The prime aim of the proposed study is to offer a significant range of interoperability among the heterogeneous smart appliances, also called as IoT nodes. It is a continuation of our prior implementation where scalability factor has been achieved [34]. Fig. 1 highlights the architecture implemented for this purpose to develop Interoperable Communication System (ICS).

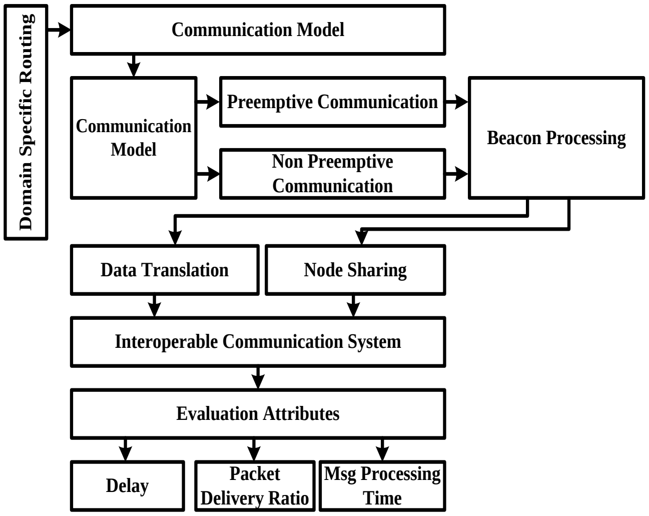

Fig. 1. Architecture of ICS.

Fig.1 highlights the composition of prominent block of operation of ICS. The first block of IoT Topology mainly incorporates IoT environment with presence of IoT nodes deployed in the form of group. The second block of Application Domain clusters all the IoT nodes within the IoT environment. The common block of IoT Routing considers the deployment of any communication protocol within application domain. Each domain is assumed to execute discrete IoT local routing. The next important block of operations is preemptive and non-preemptive communication scheme. The former scheme is used for processing emergency transmission while the later scheme is used for dedicated transmission in IoT. The idea is to develop a framework which can cater up communication demands of maximum situation in IoT. The next block of operation is Gateway Node Management which is mainly used for translational services for facilitating interoperability in the system. In case of preemptive approach, the gateway node performs data translation while in case of non-preemptive approach; addresses of the node are shared. The study outcome is finally. The further discussion of methodology of proposed system is illustrated in next section with respect to system design.

V. System Design

This part of the study illustrates about the system design as well as implementation being carried out towards developing Interoperable Communication System (ICS) in IoT. The complete implementation is carried out considering the practical environmental scenario of using different forms of smart appliances deployed in IoT environment. The study considers heterogeneity in the devices being connected where achieving interoperability in communication system is still an open-end problem. For this purpose, the complete ICS is designed considering two states of communication demands i.e. preemptive and non-preemptive stage. This section elaborates about the system design deployed for this purpose.

A. Preemptive Communication Scheme

The prime purpose of the preemptive communication scheme is to offer instantaneous communication establishment during any form of emergency circumstances (Fig. 2). It is based on the hypothesis that when a large number of heterogeneous smart appliances are connected in an IoT, either in small and large scale, achieving faster communication is quite a challenging aspect. Hence there is a need of preemptive mechanism which can ensure that an emergency communication always takes place irrespective of any situation of some of the IoT nodes owing to any reason. This scheme also considers that only few IoT nodes could possibly exhibit degradation in its performance of data forwarding either due to resource depletion or due to any miscellaneous reasons. Apart from this, it should also offer supportability of mobility condition of IoT nodes.

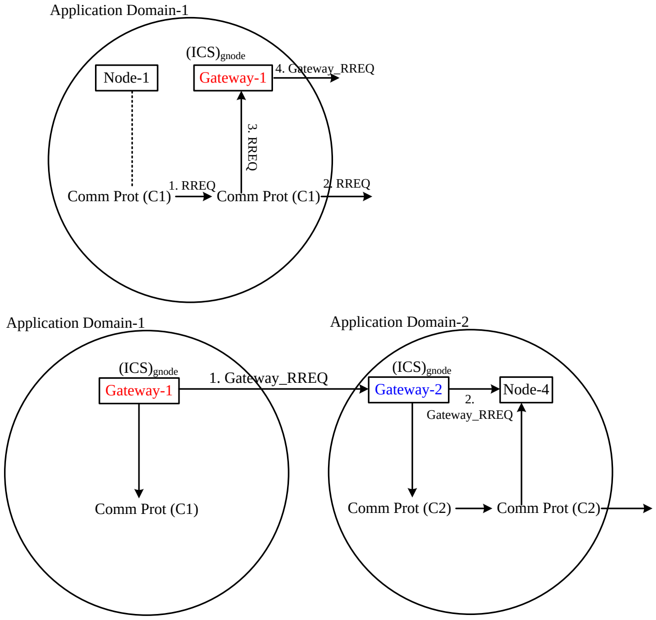

Fig. 2. Preemptive Routing Scheme in IoT.

Fig. 2 highlights a practical implementation environment where a smart appliance $node_1$ is a part of application domain α_1 which sensed an event-data and now it is required to transmit this data to $node_4$ that is part of different application domain α_2. The environment also considers usage of two different communication scheme β_1 and β_2 followed by all IoT nodes in domain α_1 and α_2 respectively. The transmitting $node_1$ broadcast the beacon for route discovery first considering the presence of an IoT gateway node γ. It should be noted that the study considers a single gateway node in one deployment zone γ which offers translation services for two application domain by offering two discrete sub-gateway services i.e. $\gamma=(\gamma_1, \gamma_2)$. This gateway node carries the addresses associated with identity and position of their respective registered smart appliances followed by establishment of connection. The proposed system constructs an algorithm which initiates processing of the request of data forwarding where gateway protocols assists in establishing preemptive routing. The algorithm implemented for this purpose is shown as follows:

Algorithm for Preemptive Communication Scheme

```
Input: $n, \gamma, \beta, Cv, f$
Output: $d$
Start
1. For i=1:$n$
2.   Formulate $\alpha$=1: $m$
3.   $\alpha_i$=[ $\alpha_1, \alpha_2, \ldots \alpha_m | m<n$]
4.   alloc $n_i \rightarrow \alpha_m, \gamma \rightarrow \alpha$
5.   For $\alpha$=1:$m$
6.     $n_{1i}$ forwards msg($C_{v1}$)
7.     $C_{v1}$ forwards msg($\gamma(\alpha)$)
8.     $\gamma(\alpha_i) \rightarrow msg_1(\gamma(\alpha_{i+1}))$
9.     $\gamma(\alpha_{i+1}) \rightarrow f(C_{v2}) \rightarrow (d)n_{2j}$
10.  End
11. End
```

The above mentioned algorithm takes the input of n (number of smart appliances), γ (gateway node), α (application domain), Cv (Communication vector), and f (function for data translation), which after processing leads to generation of d (transmitted data). The algorithm considers all the sensor nodes (Line-1) and formulates m number of application domain α (Line-2 and Line-3). It should be noted that number of application domain m is considerably less compare to number of IoT nodes. The algorithm further allocates specific number of sensors n_i to all m number of application domain (Line-4). Considering all the number of available application domain α (Line-5), the IoT node initially forwards the message in the form of communication vector C_v (Line-6). The variable msg will mean control message or beacon used for route discovery process (Line-6). This is carried out in the form of broadcasting and this information is then passed on primary gateway node γ of the parent application domain (Line-7). The parent domain accesses the information from the message to find out the location of the destination node within different application domain (Line-8). The implementation considers the fact that each application domain exercises a unique routing scheme where the gateway node assists in data translational services in cross-application domains. It is also assumed that each gateway node possess information of its respective IoT nodes. Therefore, when a request to forward data to a specific node arrives for a gateway node from different gateway node, there are two further possibilities viz. i) if the destination node is present than the data d is subjected to data translation using function f(x) (Line-9) and finally data is forwarded, and ii) if the destination node is not present than the gateway node passes the route request message to the next gateway node and this search continues until and unless the destination node is found. It should be also noted that all the gateway nodes performs an exchange of their information after a certain interval of time. This will reduce the search time as updated information will be always available.

B. Non-Preemptive Communication Scheme

This is another alternative of the routing scheme where the circumstances demands dedicated routing of the data among heterogeneous IoT devices.

This part of the implementation considers exactly the similar deployment of application domain, gateway node, and IoT devices. According to the representation shown in Fig. 3, the transmitting node node$_1$ transmits the control message for the purpose of route discovery process. When the parent gateway node receives this request, it is forwarded to neighboring gateway node of different application domain. This is done if the primary gateway node is located far from destination gateway node which has destination node. If the target gateway node is located near to primary gateway node than the message is forwarded directly to the destination gateway node. Different from preemptive communication scheme, this scheme basically emphasizes on the address information of all the nodes involved in communication process in order to offer more accountability in communication process. Another uniqueness of this technique is that it offers bidirectionality of the communication process. Apart from this, the study also contributes towards assisting in exchanging routing table information between the transmitting and destination node located in different application domain. This makes the process of updating routing operation quite faster.

The algorithm responsible for this purpose is as follow:

Algorithm for Non-Preemptive Communication Scheme

```
Input: $n$, $\gamma$, $\alpha$, $C_v$, $\lambda$, $\tau$.
Output: $d$
Start
1. For i=1:$n$
2.   Formulate $\alpha$=1: $m$
3.   $\alpha_i$=[ $\alpha_1$, $\alpha_2$, …. $\alpha_m$| $m$<$n$]
4.   alloc $n_i \rightarrow \alpha_m$, $\gamma \rightarrow \alpha$
5.   For $\alpha$=1:$m$
6.     $n_{1i}$ forwards msg($C_{v1}$)
7.     response of $C_{v1}$ is forwarded to $n_{1i}$.
8.     $C_{v1} \rightarrow \tau(\gamma(\alpha_i))$
9.     $\gamma(\alpha_i) \rightarrow \tau_1(\tau(\gamma(\alpha_i)))$
10.     $\gamma(\alpha_i) \rightarrow \lambda(C_{v2})$
11.     $C_{v2} \rightarrow \tau(n_{1i})$
12.     transmit $d$
13.   End
14. End
```

The algorithm takes the input of n (IoT nodes), γ (gateway node), α (application domain), C_v (Communication vector), λ (process of sharing address), and τ (information of address), which after processing yields an outcome of the d (transmitted data). The unique aspect of this routing scheme is that it mechanizes a method which performs embedding of the routing information to the IoT devices present in the network. In order to facilitate a dedicated communication path, the proposed algorithm ensures that each communicating nodes should have an access to the address information of all the nodes involved in path establishment via different gateways. The gateway node is responsible for sharing the address information among each other. Therefore the non-preemptive process of communication differs from preemptive communication scheme by facilitating the gateway node to carry out mutual exchanging of positional information among each other. The preliminary steps of operation are nearly equivalent to preemptive operation. Considering all the IoT nodes and application domain involved in it (Line-1 and Line-2), the proposed system initiates it process when node$_i$ in domain α_i attempts to communicate with node$_j$ in application domain α_j. The IoT node nodei transmit its control message using communication vector C_v (Line-6). The respective response is forwarded to node node$_i$ and instantly transmits the information about the address along with it to node$_i$ via the gateway node γ_i in application domain α_i. The request for routing is not forwarded to the application domain but they only share information of its addresses. The gateway node associated with the α_j share its own information as well as adjacent IoT devices after it receives the information of address for the node$_i$ in the form of response. Once this information about address is received, the gateway node share the equivalent information with an assistance of communication vector C_v that make use of method of sharing address which is further forwarded to transmitting IoT node. One of the significant characteristic of this algorithm is that it is capable of generating maximum number of addresses of all connected IoT nodes with the gateway node. Therefore, there are minimal utilization of the network resources as well as there are lesser dependencies in processing this algorithm in contrast to preemptive routing scheme. Another potential contribution of this algorithm is that it facilitates inter-domain routing specific to those nodes which are registered under established entries in more secured manner. The proposed system also performs specific way to exchange the message. The proposed approach carries out forwarding of the beacon for collecting the associated information of the IoT nodes followed by sharing of the control message along with the gateway nodes. In this process, the sequence number as well as address of IoT node is used for formulating the structure of beacon used in proposed study. The proposed system considers IP address as the address of the IoT nodes while freshness of data is represented by the sequence number.

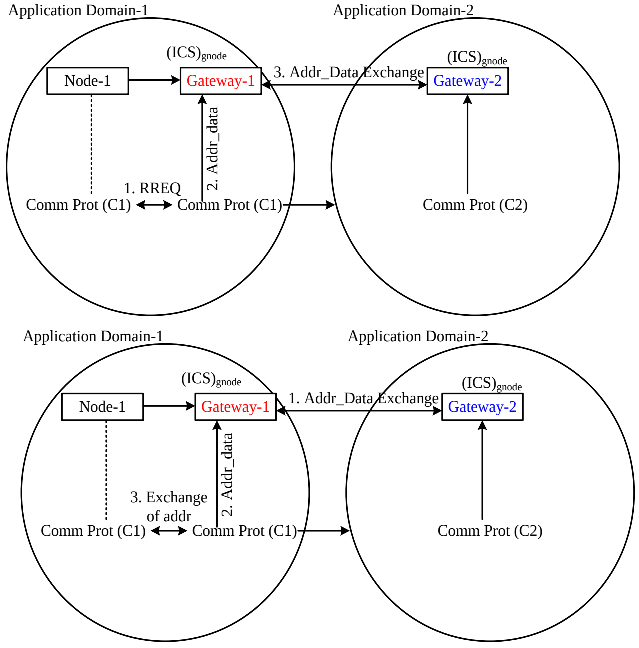

Fig. 3. Non-Preemptive Communication Scheme.

VI. Result Analysis

This section discusses about the outcome obtained after implementing the proposed ICS. The implementation of the proposed system is carried out considering 500 IoT nodes deployed in 1000 x 1000 m^2 simulation area where the transmission range is considered as 200m with assessment period of 1000s of iteration. As the proposed system mainly presents a modelling for communication scheme; therefore, it considers the equivalent standard performance parameters of delay, packet delivery ratio, and overall processing time. In order to perform a measurable assessment, the outcome of the proposed system is compared with the existing standards which are related to IoT. The first existing standard considered for processing is RFC 3221 which is responsible for performing inter-domain routing in IoT [35]. The second existing standards which are related to IoT is RFC 8352 which is responsible for implementing gateway scheme in IoT [36]. This section illustrates all outcome achieved.

A. Outcome of Delay

Delay is one of the prominent performance parameters to signify the communication effectiveness. Communication carried out in large scale scenario in presence of gateway and uneven traffic can significantly increase delay. Hence, the assessment of delay is carried out by forwarding 2500 bytes as experimental data. Fig. 4 highlights that the proposed system excels better outcome in contrast to existing approaches. The prime reason behind this is the underlying mechanism of message control in proposed ICS with availability of both the schemes. Presence of preemptive scheme always results in lower delay but at the same time, non-preemptive scheme too assists in reducing delay as once the path is set via accessing addresses, then data transmission becomes almost seamless in this dedicated path of inter-domain routing.

It is to be noted that the gateway node of proposed system contributes towards collecting individual address of the IoT devices and it performs periodic exchange of information with its adjacent gateway node. Therefore, proposed system can ascertain routing of maximum quantity of data over shorter range of time. Apart from this, the duration for obtaining information of communication vector from other IoT devices is also reduced. There is no potential overhead in the gateway as it only permits the exchange of the address information of IoT device. On the other hand, RFC 3221 offers overhead control in IoT, but there is no updating process towards the routing information in the memory of routing table. Apart from this, no information is shared with its adjacent nodes. The existing approach of RFC 8352 assists in performing gateway protocol implementation standard by opting for highly stabilized communication channel which is carried out using index of mobility criterion. It should be noted that gateway node is tracked via index of mobility to find out if they resides within the coverage of network. This calls for increasing search process which further increases the delay to a higher value. Therefore, the proposed system offers approximately 90% improved delay reduction when compared with existing standards of interdomain routing in IoT for targeting better interoperability.

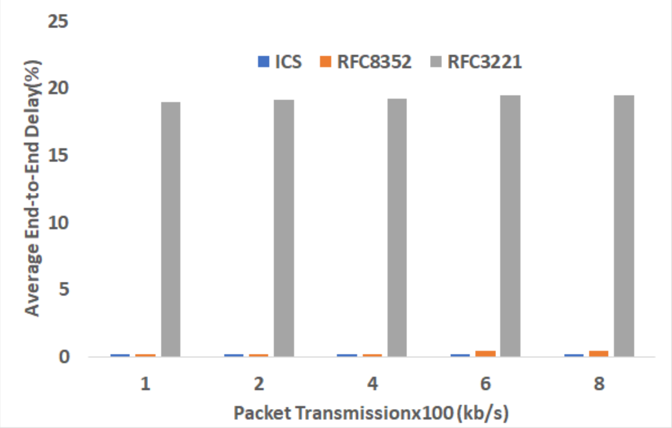

Fig. 4. Analyzed Outcome of Delay.

B. Outcome of Packet Delivery Ratio

Packet delivery ratio is considered another performance parameter which is assessed by considering amount of data which is already being forwarded to the amount of the data received by the recipient. Fig. 5 highlights that proposed system offers approximately 57% of improved packet delivery ratio in contrast to existing system of inter-domain routing. The prime reason behind this outcome is that it offers better form of data processing over the gateway node which makes the system characterized by higher interoperability. The routing tables are generated as well as updated by proposed data translational services into multiple structured which has solution to all the possible alternative communication path between transmitting and receiving IoT nodes.

Apart from this, preemptive scheme assists in node-by-node communication system where data is instantly forwarded to next node during route discovery process itself. Hence, it constructs a stabilized path whereas the path stability increases multifold when non-preemptive communication scheme is applied. However, no such operation takes place in existing system resulting in inferior packet delivery ratio.

C. Outcome of Processing Time

Processing time is one of the essential performance parameter to measure the computational complexity as well as to assess the overall response time of the system. It gives a fair idea of effectiveness of proposed model over practical network environment. The proposed evaluation considers processing time as the cumulative amount of time needed for the gateway node in order to perform processing of the data transmission from source node of one application domain to destination node of another application domain. Hence, there is higher feasibility of different ranges of processing time for different set of communicating IoT nodes. Considering multiple rounds of simulation, the assessment of the processing time is carried out to evaluate the effect of various traffic behaviour, its load, and variable data over the processing time.

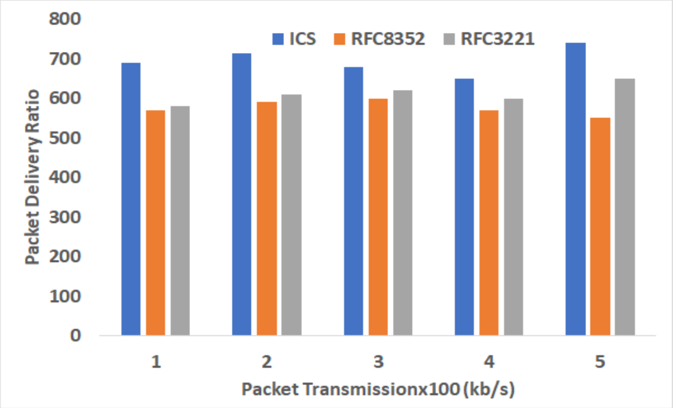

Fig. 5. Analyzed Outcome of Packet Delivery Ratio.

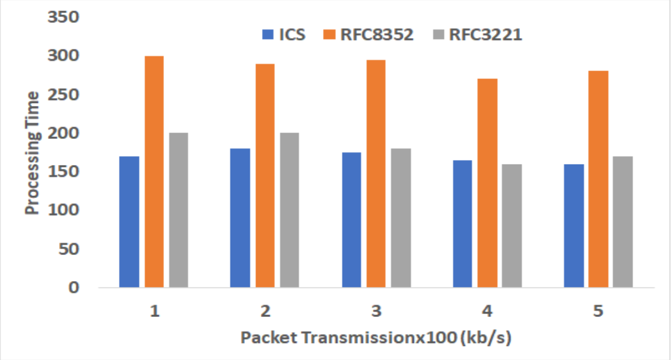

Fig. 6. Analyzed Outcome of Processing Time.

Fig.6 showcase that the proposed system accomplishes approximately 98% of reduced processing time in comparison to existing system. The justification behind this outcome is that the developed gateway system of ICS can cater up the demands of any form of dynamic environment. The proposed ICS solve the problem associated with intermittent breakage of link in dynamic topology of IoT. This is made possible when there is communication exchange between gateway nodes of different application domain. However, such forms of route management is not taken care of by existing standards in IoT. Another essential contribution of proposed system is that IoT nodes are freed from any form of duty towards strengthening the connectivity of IoT devices that is also the reason for faster response time.

VII. Conclusion

This paper presents a discussion about a novel framework of facilitating an inter-domain routing in IoT with core emphasis to accomplish full-fledge interoperability. The study uses an analytical approach where an IoT environment is deployed in such a way that the device-to-device (heterogeneous) communication is carried out using gateway. The protocol implemented is executed on gateway node where it facilities two forms of routing scheme apart from its data translation services. Preemptive scheme assists in emergency communication while non-preemptive scheme assists in offering dedicated line of communication in IoT. The study outcome shows better communication performance in contrast to existing schemes deployed in achieving interoperability. The definitive findings of the measure of its significance in the research community is that proposed system offers 90% reduced delay performance, 57% of more packet delivery ratio, and 98% of reduced processing time in comparison to existing system.

VIII. Future Work

The present research work will be continued towards achieving secure communication in data transmission in IoT in compliance of scalability and interoperability aspects too. It is necessary as the proposed system is capable of connecting a vast set of network with another network via a gateway system and hence massive number of data as well as services are exchanged. Hence, future work could be carried out using trust-based data integrity scheme along with privacy preservation.

Security and Threats of RFID and WSNs: Comparative Study

Ghada Hisham Alzeer[1], Ghada Sultam Aljumaie[2], Wajdi Alhakami[3]
Taif University, College of Computers and Information Technology, Taif, KSA

***Abstract*—The Internet of Things (IoT) has garnered significant attention from people with growing changes in human life over the last few years. IoT is a network of a group of smart devices that use sensors to collect information and conduct events in their environments. The information can then be shared on the Internet. IoT uses a range of technologies and finds various applications such as smart homes, environmental monitoring, and healthcare. In this paper, we conducted a comparative study to analyze the difference between two technologies—Wireless Sensor Networks (WSNs) and Radio Frequency Identification (RFID). It is pertinent to note that these technologies would not be effective without incorporating security aspects due to a potential number of threats and attacks on the network. This paper provides a comprehensive review of the recent approaches to securing RFID and WSNs. We have carefully chosen most of these studies to investigate only the recent technique from 2017 to 2020. The paper also highlights common attacks on RFID and WSNs and the secure authentication mechanisms on these technologies. It further provides a different way of detecting varying attacks in RFID and WSNs.**

Keywords—Security; IoT; WSN; RFID

I. Introduction

The Internet of Things (IoT) is a network of a group of smart devices that use sensors to collect information and conduct events in their environments. The information can then be shared on the Internet. IoT has witnessed rapid growth recently; Cisco reported a remarkable increase in the number of IoT devices to nearly 50 billion in 2020 [1]. IoT is used in several areas such as industrial automation (Industrial IoT), sensing applications in smart homes, traffic control, and other applications that deal less with sensors and more with data analysis. Industrial IoT and smart homes deal more with sensors and less with data analysis. The IoT that focuses more on data analysis is used in the transformation of business processes (BPs) such as banking, organizational operations, and healthcare optimization [2][3].

IoT uses a wide range of technologies such as Wireless Sensor Networks (WSNs), Radio Frequency Identification (RFID), and Near Field Communication (NFC), as shown in Fig. 1 [4].

Among these technologies, WSNs and RFID are mainly used and have become the two main pillars [4].

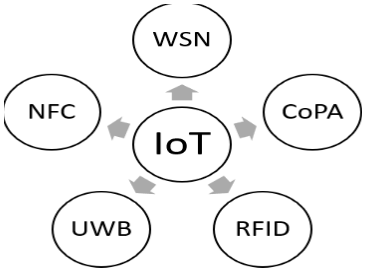

Fig. 1. IoT Technologies.

II. Radio Frequency Identification

RFID can be defined as the nonlinear network system that replaces barcodes and QR codes for a rapid response and relies on radio waves to capture and disseminate information [5]. It was first designed in 1948 and took many years to mature and become affordable and reliable for widespread use. Some considered RFID as the most widespread computing technology in history [6]. Today, it has become an important and integral part of current technologies such as computing and IoT [7], [8]. RFID is composed of four parts: tag, an antenna and transceiver tag processor, a database, and a backend. Tags are connected to items to store their information, the RFID reader reads the data coming from the tag and writes it to the transponder, and the backend database links that data with records. See Fig. 2 [6], [5], [9].

Active tags include a battery that allows automatic data transfer to the readers. On the other hand, passive tags are triggered by the electromagnetic waves of the reader.

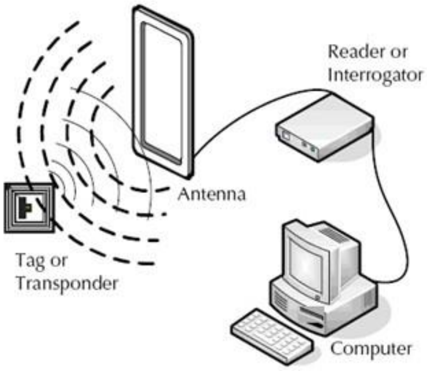

Fig. 2. Components of RFID.

These tags are more commonly used than their active counterparts on the account of their low cost and infinite life. Tags contain read-only memory (ROM), that stores data classified as security data, system ID, and OS instructions and volatile read/write or random access memory (RAM) that stores data during transmission and response [6], [5]. They are used in various applications such as transportation, logistics, manufacturing, healthcare/pharmaceutical industry, processing, and security [9], [7]. With the advent of IoT technology and the development of signal processing technology and distributed network technology for IoT nodes to acquire signals, a model has been established to acquire radio frequency signals within an IoT environment to add more features that are important in many fields [10].

III. Wireless Sensor Networks

WSNs have been becoming the area of interest for various researchers due to the rapid development of wireless technology and embedded electronics. WSN contains node sensors – small devices used to sense their current environment [11]. It is a distinct type of network containing small distributed devices called sensor nodes. They are considered low-power devices that communicate with each other without infrastructure and used for sensing and collecting data through wireless communication [12]. The basic components of sensor nodes include microcontrollers that perform data processing and control other components to perform their functions [13]. Transmitter and receiver use radio waves to send and receive data over wireless networks. Wireless sensors are powered by batteries or a power source. The choice of power source depends on the deployment environment and energy availability of the applications [14]. As provided in Fig. 3, EEPROM or Flash memory [15] are also the key components of sensor nodes.

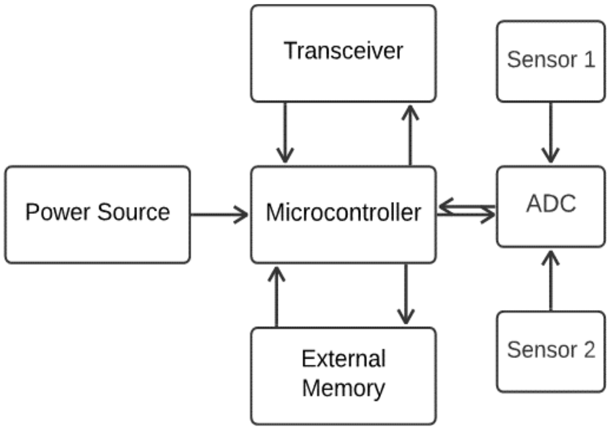

Fig. 3. Basic Components of WSN Node.

IoT model enables computers to access data about objects and the environment without human interaction [10]. Such model involves the integration of ‘physical things’ and IT infrastructure to transfer and collect data through a wireless network. It further allows to understand, interpret, communicate, and exchange data without any communication units and human participation [16], [10]. WSN plays an important role in IoT applications [17], as it provides IoT applications with high sensing and operational capabilities. WSNs are the eyes and ears of IoT; they convert physical phenomena into digital signals and transmit these signals for processing and analysis [18]. Today, there is a myriad of applications that depend on WSN and IoT technology, such as patient monitoring (measuring blood pressure, heart rate, and oxygen concentration) [19] and smart homes and buildings [17]. With the tremendous growth of IoT devices with high connectivity, there has been an increasing concern about their security and the data they store and transmit across various devices. Moreover, there has been an increase in the number of attacks on these devices. The current security challenges of IoT devices are generally due to their limited capacity, processing power, and battery life [20]. These limitations have made IoT devices a target for attackers such as hackers, hacktivists, and cybercriminals. Cybersecurity is therefore important to secure IoT and ensure protection from malicious activities such as data theft, modification, unauthorized access attempt, or network attack [20].

RFID and WSN technologies are widely used in many applications, such as in the scientific or medical fields and even in our home life, so achieving security in them is very important because they may deal with very sensitive data. Therefore, security became sour main motivation in this paper, we discussed the security requirements and how to achieve them, the common attacks based on current research also discussed protection and detection mechanisms suggested by other researchers. Our research paper is one of the few that discusses both RFID and WSN in terms of security requirements and common attacks.

This paper is divided into nine sections: Section IV introduces the required security applied in RFID and WSNs. The common threats and attacks on RFID and WSNs are presented in Section V. The following Sections VI and VII, respectively focus on the security of RFID followed by WSNs for achieving secure authentication, ensuring confidentiality, and detecting common attacks on both. In Section VIII we discussed the papers mentioned in our paper from various aspects. Lastly, we mentioned our future work on RFID and WSNs in Section IX.

IV. Security Requirements of Internet of Things

To secure IoT deployment, we classified IoT security into three categories as listed in Fig. 4.

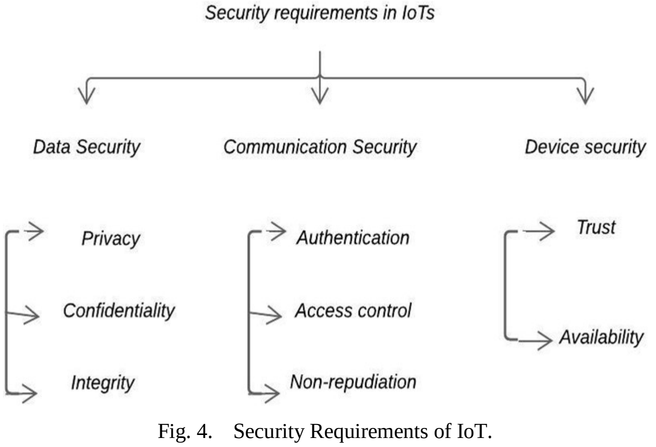

Fig. 4. Security Requirements of IoT.

A. Data Security (Privacy, Confidentiality, and Integrity)

Privacy includes the ability to hide personal information and control the use of that information [21]. There are several techniques to deal with data privacy, such as pseudo-random number generators, block and stream cipher, and anonymization [22]. Confidentiality, on the other hand, means that the communication between the sender and receiver must be protected from any malicious or unauthenticated users [23]. The integrity of data stored on remote servers must be protected on the IoT framework that preserves stored data, ensures its correctness, and provides protection from any loss or tampering. Many protocols were designed to achieve data integrity by using either encryption or anonymization techniques [24].

B. Communication Security (Authentication, Access Control, and Non-repudiation)

Authentication before communication is the key to the success of IoT and an important component of any security model [25]. The two parties must authenticate their communication [26]. It ensures the identification of these parties before making any contact [25]. Identity verification is carried out using several methods such as passwords, digital certificates, lightweight cryptography algorithms, or biometric identification [27]. IoT authentication is a complex process as it involves heterogeneous network authentication. Before joining a network, identification and authentication must be applied to all objects or sensors. It is imperative to note that IoT requires a unique code (UID) to identify each entity in the network [28]. Access control involves the authorization of users. A system administrator specifies access privileges for different users with which they can only access the relevant parts of system resources to protect their resources and information [29]. Access control algorithms can be divided into five types [22]:

1) Task-based Access Control (RBAC): RBAC manages all user-assigned access to roles and grants multiple user permissions to roles. For more efficiency, roles can be organized into a hierarchy, allowing some roles to inherit permissions from others. RBAC is generally used to simplify access control. It reduces complex protection management and endorses the analysis of user-assigned permissions [30].

2) Organization-based Access Control (OrBAC): An improved version of the RBAC model. However, it has a time limitation and supports the periodic activation of roles [31].

3) Capability-based Access Control (CapBAC): CapBAC gives each user a capability – a key that gives access rights. The admin then decides if the user can access the network by checking the validity of the key [32].

4) Attribute-based Access Control (ABAC): Depending on the characteristics of the requester and resource, users do not need to know the resources before they submit the request. ABAC has become significant recently, particularly in web service applications [33].

5) Trust-based Access Control (TBAC): It gives users a high level of trust to support dynamically changing permissions assigned to them [34]. Non-repudiation refers to a situation where data must be checked in a way that a sender has sent a message and it can be rejected or a receiver cannot refuse receipt of the message [35]. It can be achieved using Public Key Cryptography (PKC) and Digital signature [36].

C. Device Security (Trust and Availability)

Trust is critical to achieving security in an IoT system. Additionally, IoT devices must be trusted to prevent unwanted actions by malicious nodes [37]. The stages of trust-building start from the establishment stage to the operational and transmission stages of IoT. This trust is formed by two mechanisms – key generation and token. A key generated by the entitlement system is allocated to each new unit and introduced by a consumer device. Token, on the other hand, is generated by the owner or producer and coupled with an RFID indication of the device. [38]. In IoT, the availability of hardware and software remains essential. Hardware availability implies to the availability of devices for IoT applications at all times. Software availability is the ability to provide services at any place and time [39]. Moreover, in IoT devices, all data should be available to users whenever they need it. The devices and services must also be available and reachable whenever the users need them at the right time to achieve IoT expectations [38].

V. Attacks on Radio Frequency Identification and Wireless Sesnsor Network

In this section, we highlight some of the common attacks on RFID and WSNs.

A. Security Threats and Attacks on Radio Frequency Identification

The author in [40] summarized several threats directed towards RFIDs. A key reason behind most of these attacks is the security of the communication channel between the user and tags. A group of famous attacks on RFID is revealed below:

1) Action threat: In this type of threat, the tags possessed by an individual are monitored and predicted for his future intentions and actions.

2) Association threat: Electronic Product Code (EPC) tag is a unique number for each product. When a consumer purchases a product, a link between the consumer’s identity and the product is created.

3) Location threat: By tracking the tags associated with a user’s site, an attacker could obtain the exact location of the user.

4) Preference threat: It is possible to obtain consumer preferences illegally by tracking unique EPC tags for each product that identify company name and product type.

5) Constellation threat: It is one of the threats where the illegal parties track transactions between users.

6) Breadcrumb threat: Also known as electronic breadcrumbs, this threat occurs when a consumer buys a product that creates a link between his/her identity and EPC tag product number. Consequently, when the consumer gets rid of this product, the link is not broken and can be used.

Some common attacks on RFID systems mentioned in paper [41] are summarized in Table I.

TABLE I. SUMMARY OF SECURITY ATTACKS ON RFID TECHNOLOGY

Attacks	*Descriptions*
Temporariy disabling tags	The signs may be unintended – any event due to natural factors or interference of frequencies. They may also be intentional, such as Passive Interference and Active Jamming.
Removal or destruction of RFID readers	Because of its small pilgrimage, an RFID reader is vulnerable to attackers who use it to obtain data or modify it.
Relay attacks	Also known as MITMA; the intruder intercepts the radio signal between the sender and receiver and may modify it.
Attacks on the tags	Making a copy of the tag (Cloning) or impersonating the tag (Spoofing).
Reader attacks	Impersonating a legitimate reader (Impersonation) or recording the legitimate RFID tags (Eavesdropping).
Unauthorized tag reading	Since authentication protocol RFID tags are not supported, an attacker can read the contents of the RFID tags.
Tag modification	The data on RFID tags can be modified or deleted by the attacker.
Middleware attacks	The attacker uses RFID tags to either cause an attack (Buffer Overflows or end RFID middleware) or spread malicious code with an attack (Malicious Code Injection)
Covert channels	Using RFID tags, an attacker could create unauthorized channels for transmitting data.
DoS	The attacker blocks or disconnects RFID tags service from users.
Traffic analysis	Attacks by monitoring and analyzing traffic patterns
Crypto	Uses encryption methods to break encryption algorithms and access data
Side-channel	Leverages the physical application of encryption algorithms

B. *Security attacks and challenges of Wireless Sensor Networks.*

Fig. 5 [42] generally demonstrates the classification of the common security threats and attacks in WSNs.

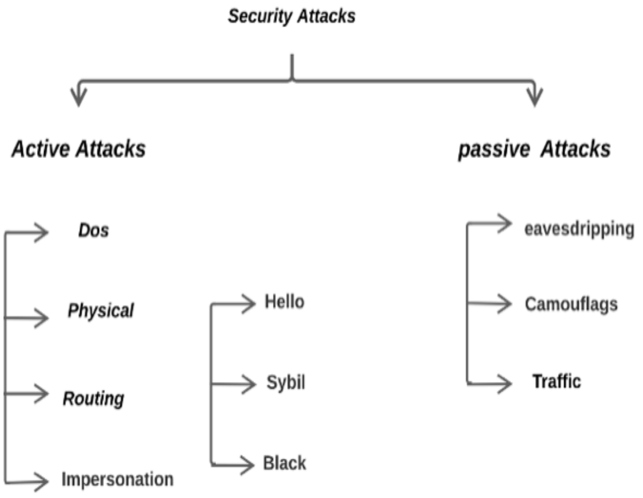

Fig. 5. Security Attacks in General.

The author in [43] notes Sybil attacks as the most common attacks observed in WSN, followed by wormhole and DoS attacks. DDoS attacks are relatively less on this type of network. The authors of paper [42] mentioned some common attacks on WSN systems, as shown in Table II.

TABLE II. SUMMARY OF SECURITY ATTACKS ON WSNS

Attacks	*Descriptions*
DoS	The attacker tries to sabotage the data and disable the system that reduces network efficiency
Sybil	In WSN networks, there are several sub-tasks such as duplicating information that you do not perform and assigning it to one node This node is attacked by Sybil Attacks, targeting the schemes of fault tolerance.
Blackhole	It is more severe than a Sally attack, as the attacker offers a shorter path to the nodes, acts as a black hole, and completely captures the data traffic. The attacker can also affect the data traffic.
HELLO Flood	This attack occurs in the network layer where the attacker fabricates hello, sends it to convince the sensor in WSN, and then changes the scenario
Wormhole	A common attack that occurs in two separate nodes carrying important parts of the message when a low-latency bandwidth is directed to them

VI. SECURITY IN RADIO FREQUENCY IDENTIFICATION TECHNOLOGY

This section includes an overview of previous works on RFID network security divided into several sections:

A. *Authentication Protocols for Radio Frequency Identification*

In [8], the authors introduced a new authentication protocol that offers an acceptable level of protection. It is also resistant to the risks reported in the article and evaluates the security of mutual authentication suggested by Wang and Ma. This review demonstrates the key security pitfalls of the protocol. Firstly, they presented two methods used by an opponent to make valid readers believe that they are dealing with a valid database. Next, they demonstrated how an adversary can turn an RFID reader into a legal database and introduced a new adversary model. Finally, they implemented an improved server method named ISMAP and demonstrated that this protocol provides sufficient protection against different types of attacks including the current adversary model discussed in the article. Additionally, the authors in [44] introduced a new lightweight RFID security authentication protocol (LRSAS). They analyzed the security properties of the protocol, containing data confidentiality and integrity (DCI), replay attack (RA), desynchronization attack (DA), impersonation attack (IA), tracking attack (TA), denial of service attack (DoS), and forward security (FS). Finally, they compared the LRSAS protocol with other protocols in terms of communications, computation, and storage. The authors also showed that the protocol is efficient in terms of security and cost requirements.

In [45], the authors presented two lightweight RFID protocols that provide security, identity authentication, and privacy and have multiple tag groups. They used a filtering process to decrease collision between tags, sleep activation mechanism, RFID system, and computing load. They also used a pseudorandom number generator (PRNG) and hash function to encrypt all sessions between the reader and tags. These protocols can resist eavesdropping, replay, and desynchronized attacks.

In [46], the authors introduced a group-based authentication protocol for the RFID system. It uses only mod operation and bitwise XOR. Additionally, two standard measures were used to measure the privacy of the system, resulting in anonymity when the opponent conducts numerous operations. Experimental results showed that their scheme maintains a high level of privacy when some tags are compromised. After the analysis, the authors proved that their protocol is safe and effective for a reduced RFID system.

B. *Security Communication in Radio Frequency Identification to Ensure Confidentiality*

In [47], the authors studied elliptical curve coding (ECC) protocol based on RFID security protocol, as it has several important features such as high strength ECC encryption that provides high security for communication and access to tag memory data. The new protocol relies on simple calculations such as XOR and bitwise AND which reduces complex calculations for low-cost tags. The authors analyzed their protocol for security and performance by using BAN logic. The analysis demonstrated that the protocol can provide mutual authentication of the tags and reader at the same time.

C. *Detection Mechanisms in Radio Frequency Identification*

In [48], the authors presented new effective research to preserve the privacy of cloning, as it is relevant and effective to preserve the privacy to explore cloning for all supplies that support RFID technology. They analyzed and evaluated the proposed mechanism through simulations which proved to be effective under various conditions. They then designed and implemented Multilateral Secure Computing (SMC) protocols to implement private-preserving for clone estimate that shows changes in efficiency regarding similar programs inside the existing SMC system. In [49], the authors discussed important problems associated with tag detection in RFID systems, including reader collision avoidance, optimal tag reporting, and optimal tag coverage problems. These issues occur due to the inability of collision intrusion detection and RFID readers that transmit packets created by other readers and poor access to resources in RFID tags on the account of severe limitations.

In [50], the authors presented an approach that implements MAC, routing, and application layer outlier detection processes in three different regions. Multiple invigilator regions executed internal or external detections after data collection. The proposed system has consequently been found to be efficient in terms of performance indicators. These indicators may be internal or external based on service quality. Various internal indicators used to measure the stability of structures are DI, RMSSDI, RSI, SI, CHI, and DBI. Additionally, various external indicators used to measure the stability of structures are FI, NMII, PI, and EI. Both internal and external indicators confirm the formation of structure and external detection processes. Furthermore, two indicators based on QoS (productivity and jitter) are used in this work.

The authors in [51] presented an efficient hash-based RFID authentication protocol that provides miss-tag detection. They presumed that for each user, an authentication system would validate large quantities with RFID tags inside its ranges. Their protocol can detect and reset lost tags if the missing tag can rejoin the system. After analyzing the protocol in terms of security, they proved that it can provide adequate security guarantees, resist various attacks, and offer better performance. Moreover, the protocol achieves both security and performance characteristics. See the summary of security in RFID technology in Table III.

TABLE III. DIFFERENT SECURITY TECHNIQUES ON RFID

Paper	Year	Techniques	Contribution
[8]	2020	GNY Logic and Scyther	The authors introduced a modern authentication protocol that offers an acceptable level of protection and is immune to security risks.
[44]	2020	Hash function, PRG, SKINNY encryption algorithm	The authors introduced a new lightweight RFID security authentication protocol (LRSAS). They analyzed security properties of the protocol that contain Data Confidentiality and Integrity (DCI), Replay Attack (RA), Desynchronization Attack (DA), Impersonation Attack (IA), Tracking Attack (TA), Denial of Service Attack (DoS), and Forward Security (FS).
[45]	2020	Hash function, PRG, activate-sleep mechanism,and filtering process	The authors presented two lightweight RFID protocols that provide security, identity authentication, and privacy.
[46]	2020	XOR operation	The authors introduced a group-based authentication protocol for the RFID system.
[47]	2016	XOR and bit wise AND	The authors studied elliptical curve coding (ECC) protocol based on RFID security protocol as it has several important features
[48]	2010	Algamal encryption system	The authors presented a novel efficient, private information mechanism to detect clones for RFID-enabled supply chain operations.
[49]	2009	Tree flow algorithm	The authors discussed many important problems associated with tag detection in RFID systems, such as reader collision avoidance, optimal tag reporting, and optimal tag coverage problems.
[50]	2019	DI, RMSSDI, RSI, SI, CHI, DBI, FI, NMII, PI, and EI	The authors presented an approach that implements MAC, routing, and application layer outlier detection processes in three different regions. The multiple invigilator region executes internal or external detections.
[51]	2018	Hash function	The authors presented an efficient hash-based RFID authentication protocol that provides miss-tag detection.

VII. Security in Wireless Sensor Networks

In this section, many papers written on the security of WSNs have been compiled and divided into several sections as shown in the following:

A. *Authentication Protocols for Wireless Sensor Networks*

In [52], the authors mentioned weaknesses in traditional authentication methods found in IoT and suggested the use of a system based on WSN identity authentication and blockchain technology. Blockchain is a book of accounts that cannot be modified or tampered with and where transactions or data are generally recorded. They integrated blockchain decentralization with the nodes that formed the IoT structure. In a public blockchain, several private blockchains are connected and each private blockchain is connected between the cluster heads of a WSN. In the end, we have a hybrid blockchain for the whole network. The authors also created a model where the identification data was recorded between cluster head nodes and ordinary nodes. Finally, a connection authentication is done between these nodes. After analyzing the model, it became clear that the system has a greater and more efficient level of safety.

The researchers in [53] submitted a proposal to make the use of authentication protocols in WSN more secure and focused on reducing the cost as compared to other conventional protocols. They used the Altera DE2 demo board and implemented several corresponding device structures such as the Altera Cyclone II field-programmable gate array. Finally, they showed the waves produced from this process – 16702A – a logic analysis device. Additionally, the process XOR was used for encoding the key. The results showed the effectiveness of the experiment.

Paper [54] also mentioned many concerns about the difficulty of preventing smartcard stolen and off-line guessing attacks. To prevent these attacks, the paper suggested using a protocol that uses honey-list technology and relies on three-factor authentication. As the sensor performance is limited, the protocol also encodes the elliptic curve that relies on the public key and uses only hash functions. The authors performed a formal security analysis using the real-or-random (ROR) and Burrows Abadi Needham (BAN) models. For verification, they used simulation software called Automated Validation of Internet Security Protocols and Applications (AVISPA) that resulted as a safe protocol.

The author in [55] focused on lightweight and cost as the two main features; the authors saw that WSN devices need strong and light authentication protocols that can withstand any difficult environment. They proposed a model that uses XOR and hash functions. This model was effective in terms of reducing the use of resources and speed while maintaining data security.

B. *Secure Communication in Wireless Sensor Networks to Ensure Confidentiality*

There has been a growing need to guarantee the high security of WSNs used in various applications such as home, industrial, and healthcare. Therefore, paper [56] proposed a protocol that improves the security of WSN by distributing the main keys, identifying the node, and verifying the identity of messages in WSN. The password is updated and changed for the message verifier and connected to the dynamic node on the network. The authors concluded that this method outperformed previous methods. Subsequently, paper [57] used a scheme based on additive homomorphic encryption algorithm in WSN, whereby a symmetric-key homomorphic is used to provide more protection for the confidentiality of data. This key also combines the data with a homomorphic signature to achieve integrity. After decoding, the data is classified according to various symmetric-key homomorphic. Furthermore, after analyzing the results, it became clear that using this method is effective in reducing cost and increasing effectiveness in terms of protecting the data from any tampering during its transmission and ensuring the accuracy of its collection.

The author in [58] suggested the use of hybrid technology from Diffie-Hellman key exchange and Elliptic Curve cryptography. The combination of these two technologies allowed for increased security of data traffic, confidentiality, authentication, and time savings. These techniques are simulated, applied to a Java platform, and implemented in a WSN environment. The authors of [59] directed their efforts towards solving the security problems of sensitive data, as it traveled through WSN for various applications, by applying new technologies. They integrated discrete chaotic map and genetic cryptography as 2DES and 3DES for WSN, which increased the security regardless of limited resources. For a text and visual data, Henon map encryption was used due to its strong encryption. They encoded these processes under the Arduino microcontroller and determined that the attacker might need time depending on the speed of his device. They concluded that using random numbers increases the robustness of the system and prevents attacks. They preserve the confidentiality of data from unauthorized disclosure and collect it with high accuracy, as shown in Fig. 6.

To increase security and make IoT devices more independent, the authors in the paper [60] suggested the use of blockchain security features such as availability to users, data integrity, and various cryptographic tools. The model was applied to the WSNs that were used to measure moisture and temperature. It was found that the transmission of information between the nodes became more secure, independent, and less vulnerable to various types of attacks such a DoS and MITM attacks.

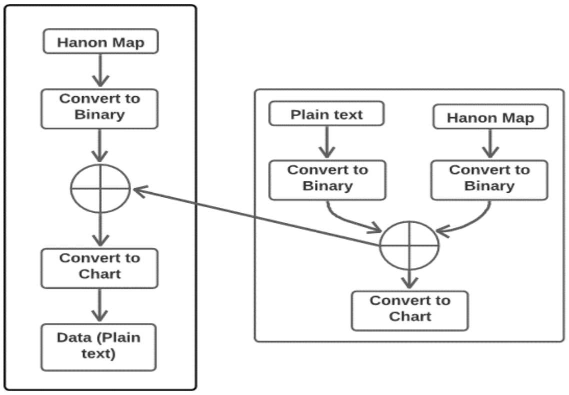

Fig. 6. General Block Diagram of Henon Map.

C. Detection Mechanisms in Wireless Sensor Networks

DoS jamming attack is one of the common attacks on WSN, as discussed in [61]. It aimed at sending many signals to jam the main signal. A denial of service occurred consequently and caused disruption of functions in the WSN nodes.

The authors in [61] proposed an exponentially weighted moving average (EWMA). They deployed an exponential moving variable that detects any change occurring in the traffic. The authors concluded that this model can accurately detect different jamming attacks and be used in situations where sensitive instantaneous information is transmitted.

Due to the sensitivity of information transmitted through WSN, a solution has been proposed in [62] to discover the unauthorized and intentional sequences of WSN. The sequence detection methodology in this paper relied on the use of MATLAB Simulink that uses an artificial neural network. In the first session, a large discrepancy in node values makes them a harmful contract for WSN. For the second session, the results of the regression of the artificial neural network for both packet delivery ratio (PDR) and energy consumption variables were analyzed. It was observed that ANN-based PDR is stronger and quicker than ANN-based energy usage. However, the results for both were good.

In the survey paper [63], a part of its objectives was to provide a comparison of different intrusion detection protocols of each WSN and IoT. It mentions the uses and efficiency of each type.

The authors in [65] aimed at using a new system that detects the sequence and has a longer residence time by adding a low-power resistance and survival continuity to IDS. The paper showed that nodes continue to work efficiently on algorithm strength, mobile nodes, and attack strength. See the summary of security in WSNs in Table IV.

TABLE IV. DIFFERENT SECURITY TECHNIQUES ON WSNs.

Paper	Year	Techniques used	Contribution
[52]	2020	Hybrid blockchain	The authors mentioned weaknesses in the traditional authentication methods of IoT and suggested the use of a system based on many WSN identity authentication with blockchain.
[53]	2015	XOR arithmetic	The researchers submitted a proposal to make the use of authentication protocols in WSN more secure and focused on reducing the cost as compared to other conventional protocols.
[54]	2020	Honey-list, three-factor authentication	The paper suggested using a protocol that uses honey-list technology and relies on three-factor authentication for preventing smartcard stolen and off-line guessing attacks.
[55]	2020	XOR and hash functions	The authors saw that WSN devices need strong and light authentication protocols and that can withstand any difficult environment.
[56]	2017	The protocol distributing the main keys, identifying the node and verifying the identity	The paper proposed a protocol that increases the security of the WSN by distributing the main keys, identifying the node also verifying the identity of the messages in the WSN.
[5]	2015	Symmetric-key homomorphic, homomorphic signature	The authors proposed a scheme based on an additive homomorphic encryption algorithm in WSN for the confidentiality of data.
[58]	2018	Diffie-Hellman, Elliptic Curve	Suggested the use of hybrid technology from Diffie-Hellman key exchange and Elliptic Curve cryptography. The combination of these two technologies allowed for increased security of data traffic, confidentiality, authentication, and time savings.
[59]	2020	Discrete chaotic map, genetic cryptography, Henon map	Solving the security problems of sensitive data, as it traveled through WSN for various applications, by applying new technologies. The authors integrated discrete chaotic map and genetic cryptography as 2DES and 3DES for WSN which increased security regardless of limited resources.
[60]	2020	Blockchain	To improve security and make IoT devices more independent, the authors suggested the use of blockchain security features such as availability to users, data integrity, and various cryptographic tools.
[61]	2018	Exponentially weighted moving average (EWMA)	The authors proposed an exponentially weighted moving average (EWMA). They deployed an exponential moving variable that detects any change occurring in the traffic. It can accurately detect different jamming attacks.
[62]	2020	Artificial neural network, MATLAB Simulink	Due to the sensitivity of information transmitted through WSN, a solution has been proposed by researchers to discover the unauthorized and intentional sequences of WSN. They relied on the use of MATLAB Simulink which uses an artificial neural network.
[63]	2019	Survey (e.g. Intrusion detection by cluster head, Hybrid anomaly detection..)	The paper provides a survey comparison of various intrusion detection protocols in both WSN and IoT. It mentions the uses and efficiency of each type.
[64]	2015	Low-power resistance and survival continuity to IDS	The paper aimed at using a new system that detects the sequence and has a longer residence time

VIII. DISCUSSION

This part focuses on discussing the above-mentioned recent techniques for protection and detection mechanisms. The discussion section has been divided into two parts:

A. Critical Review of Radio Frequency Identification Security

This section discusses the most important recent approaches which aim to secure an RFID environment. These approaches are selected as the most relevant and have novelty. For example, many research papers have discussed authentication and their protocols are distinguished using lightweight encryption algorithms. They consume fewer resources during calculation and are more efficient compared to traditional encryption algorithms. They are also suitable for devices with limited computing power such as RFID. The authors in papers [8] took a few measures to overcome some of the flaws and introduced an improved protocol using Scyther and GNY Logic. These are two excellent ways to assess security for the protocol of cryptography. However, the protocol has a drawback – it does not take into account multi-server or multi-reader environments. In two other researches [44] [45], the authors used hashing function to encrypt all session between tags and reader that ensures data integrity. They also used a pseudo-random number process to strengthen the encryption, making it difficult for the attacker to guess the key used. Both protocols proved effective in protecting against many types of attacks such as restart attack (RA), trace attack (TA), denial of service attack (DoS), and security forwarding (FS). The difference between the two papers is that the authors in [45] used the SKINNY encryption algorithm for the data used by the tag and reader to achieve mutual authentication. In our opinion, their protocol was good because it balanced security requirements and costs. Additionally, the use of SKINNY was well-suited for a scenario where the server is connected to numerous lightweight devices. In [44], we liked that they used the activate-sleep mechanism efficiently and filtering process which reduced collision on the tags. In the paper [46], the authors not only used a pseudo system that provides a feature on the side of the tag but also used that feature in the reader to generate the nonce. Their protocol only uses bit-wise XOR operation in the authentication stage along with symmetric encryption and decryption. It was an excellent protocol, as it uses fewer resources in the tags to achieve arithmetic work and store data. Moreover, it maintains a high level of privacy when attacking some tags.

In the next section, we discussed RFID security communication to ensure confidentiality. The authors in [47] presented a protocol based on an elliptical curve for coding. From our point of view, their protocol has several advantages. It provides mutual authentication for the tag and reader and is good at resisting some of the common attacks related to RFID technology. Additionally, their protocol only relies on a few simple operations such as XOR and bitwise AND which reduces the complexity of computation in low-cost tags. In the following section, we discussed several research papers regarding detection mechanisms in RFID. The researchers in the [48] presented a novel, reliable, privacy-preserving mechanism for detecting clones for RFID-enabled supply chain operations. They used the Algamal encryption system, which is an asymmetric encryption system, in their protocol that achieved both authentication and confidentiality. Their protocol has been effective at detecting RFID supply chain clones. However, from our point of view, their protocol has many weaknesses such as the need for more robust hardware. They also need to reduce the security level to n/2 to improve the performance of their protocols. The authors in [49] provide a distributed and localized algorithm. They used a tree flow algorithm centered on the recursive direction of the binary tree for tag identifiers and the problem of tag collision where the reader initially sends a broadcast including the string of "0". The ID of all these tags in the interrogation space starts with a "0" bit. When an answer is received or a collision of the tag is observed, the reader will iterate on both sub-trees "0" rooted at "00" and "01" However, if there is no answer, the reader assumes that there is no "0"-tags preceded in their interrogation region and sends a question "1" afterward. For the reader, the difficulty of TWA is proportional to the number of tags in TWA. The researchers introduced in [51] the protocol for dealing with lost tags. Their protocol depends on lightweight cryptographic techniques and the key size is taken into account. In their protocol, RFID tags and key size are the two main factors that affect the entire group authentication process. From our perspective, their protocol is unique because they considered the effect of key size on authentication efficiency, assuming the presence of a large number of RFID tags. They also proved their protocol efficient, as it requires less time to authenticate the tag, provides resistance to a replay attack, and all the tags are independently verified. In another in research [50], the authors suggested a scheme. It was found to be effective in terms of performance indicators. These indicators can be internal, external, or QoS-based. Internal indicators that have been used to measure structural stability are DI, RMSSDI, RSI, SI, CHI, and DBI. External indicators that were used to measure the stability of structures are FI, NMII, PI, and EI. Two additional indicators were also used based on service quality (productivity and jitter). One of the advantages of their model is that it observed an improvement of 0.15% in minimum and 14.9% in maximum in the case of network instability without outliers compared to that of the network with outliers. It has further proven high efficiency.

B. *A Critical Review of Wireless Sensor Networks Security*

After addressing the security requirements of WSN, we are reviewing various scientific papers focusing on their security. It was noted that in terms of authentication, blockchain technology is considered one of the leading modern techniques. Some researchers [52] used the technology in several ways; some used it as a blockchain structure linked to the head node. It is followed by the blockchain linked to sub-nodes that formed a structure distinguished by its effectiveness in the authentication. However, it can take more time in the case of a large number of nodes and become immune to the attacks of concurrent guessing against IDs and passwords. Some [60] have applied this technique to other ways on the IoT, but its effectiveness cannot be confirmed when applied to WSN, except through experience. It was also noticeable that the AVISPA tool was used [54], which aims to analyze the Internet safety protocols on a large scale and increases the strength of the experiment results. The authors were also focused on making security protocols that are lightweight, affordable, and offer high security in return. However, lightweight protocols may not be able to detect harmful nodes in WSN. Concerning secure communication in WSN, one of the research papers [57] suggested the use of homomorphic encryption. However, this type of encryption is known to be vulnerable to compromise attacks. To solve this dilemma, you can attempt to split the data into pieces and send them to different aggregators. Another type of encryption was also mentioned in one of the papers [58] that merges Diffie-Hellman key exchange and Elliptic Curve cryptography. It was an effective method in terms of time-saving, data security, and authentication. Another paper [59] proposed encryption based on data clutter that uses Hénon map to generate random numbers. However, it can break after several attempts, depending on the ability of the attacker. One work [51] mentioned updating the key periodically without the need for any sync, but the work did not mention time and efficiency factors. In the algorithms for the detection of attacks, Exponentially Weighted Moving Average (EWMA) [61] was used and the results were accurate, indicating the superiority of this method. Sequence attacks were detected in one work using algorithms [62] and in another work [64] using resistances placed on nodes. Both the studies gave positive results. We noticed a difference between RFID and WSN; in terms of security techniques, most of the references we discussed on RFID used a simple approach to achieve security, as the RFID tag has a short reading range from 5 meters (ideal conditions) to less than 1 meter (not ideal conditions). In contrast, a more sophisticated approach was used in most of the literature we discussed on WSNs. It is observed that authentication is different in these two technologies the reason behind that the different capabilities of them e.g., we can apply only lightweight approaches on RFID while we can apply the complex algorithms on WSN. This paper provides a comprehensive review of the recent approaches for securing RFID and WSNs.

IX. Conclusion

IoT technology has become an essential part of our era. It is defined as the set of devices connected for collecting and analyzing data from their environments. The types of technologies that use IoT are bifurcated. In this paper, we have highlighted the security and attacks of both WSNs and RFID since they are parts of the IoTs environments. The goal of providing a comprehensive study and investigate the recent research related to the security of WSN and RFID technologies in terms of security requirements, detection techniques, and prevention of attacks against them are accomplished. Thus the comprehensive discussion of these technologies of research observed in terms of efficiency, comparison of protocol security, cost, and weight is included.

In the future, we will keep up with the new approaches, further investigate, and compare the performance and security mechanisms of RFID and WSN.

Proposal of a Method to Measure Test Suite Quality Attributes for White-Box Testing

Mochamad Chandra Saputra[1], Tetsuro Katayama[2]
Dept. Materials and Informatics, Interdisciplinary Graduate School of Agriculture and Engineering,
University of Miyazaki, Miyazaki, Japan

***Abstract*—As an important asset in software testing, measuring quality attributes of the test suite is important to describe the quality of software. This research proposes a method to measure the test suite quality attributes for white-box testing. The attributes are usability, efficiency, reliability, functionality, portability, and maintainability that are selected from 28 attributes in software quality. By using the proposed method, the test suite quality attributes are calculated with various results of level of quality. The result of test suite quality attribute measurement then proves the validity of its result by the reliability analysis. It is used Cohen's kappa coefficient to validating the result of test suite quality attributes measurement based on the level of agreement between the result of measurement and expert assessment. Reliability analysis on test suite quality attribute finds the attribute that strongly related based on the minimum percentage of level of agreement value are usability, reliability and functionality. Hence, our proposed method is useful to measure test suite quality attributes.**

***Keywords*—Test case; test suite quality attributes; white-box testing; reliability analysis; software quality**

I. Introduction

The quality of software is confirmed by systematically exercising the software in carefully controlled circumstances especially in testing phase[1]. During the testing, test suite which contains several test cases play a very important role to check various aspects of the software such as actual program structure and the software functions as per the specification[2]. The test cases are usually developed by a set of inputs, execution preconditions, and expected outcomes for a specific objective. Testing in software development is one of the ways to ensure quality of the software.

The main activity of software testing is verification and validation[3]. In software development life cycle, verification and validation aim is to help the software development build software with good quality. Verification ensures the specific function of the software is correctly implemented. Validation ensures the software are suitable to customer requirement. One of the software testing approaches is white-box. The white-box testing approach aims to ensure that the program is successfully tested based on the internal structures of the software[4].

Software quality is defined as the whole of features and characteristics of a product or service that able to satisfy stated or implied user needs[1]. As an important asset in software testing, measuring the quality of a test suite is important to describe quality of the software. Software testing is one of the quality approaches to control the program before its delivery or installation at the user with an acceptable level of quality. Various software quality attributes have been used on software quality models to define the degree of quality. Software quality attributes are multipurpose attributes that mean any area of software development process can use the attributes. Examining code programs by using the test suite is one of the methods to assure their quality. Test suite quality measurement is necessary to gain information on the test suite performance.

The big problem with quality attributes is uncertainty attributes and their measurement for informing the degree of test suite quality. Currently, measuring the attributes of test suite quality is one of the interesting problems in software testing. The aim of test suite quality attributes measurement to provide useful information about the degree of test suite quality.

The objective of this research is to find and propose the test suite quality attributes measurement and then validate its measurement by the reliability analysis. The research concern with quality attributes for test suite in white-box testing. The research provides a questionnaire for the expert to assess the test suite quality attribute based on their experience. The reliability analysis uses Cohen's kappa coefficient approach. Cohen's kappa coefficient is used to analyze the reliability of test suite quality from test suite quality attributes measurement result and expert assessment. The level of agreement is presenting the reliability of the test suite quality attributes measurement with the expert assessment. This research uses only the test suite for white-box testing. The results of the reliability analysis are the test suite quality attributes that have strongly agreed to the quality of the test suite.

The rest of the paper is organized as follows. Section 2 describe the highlight work done by others that somehow ties in with this research. Section 3 describes the principle and formula to measure test suite quality attributes. Section 4 describes the reliability analysis of test suite quality attribute by using Cohen's kappa coefficient. Section 5 describes the research methodology to validate the test suite quality attributes by using the level of agreement between the result of the measurement and expert assessment. Section 6 describes for experimental activity and its result. Section 7 explains the result of the questionnaire to test suite quality attributes measurement. Section 8 describes the conclusion and future work of the research.

II. Related Works

Test suite consists of a set of test scripts or test procedures known as test case to be executed in a specific test run[2]. Test script in test suite is related to the test case that consists of expected results based on the inputs. The difficulties in software testing quality especially in white-box testing approach vary depending on the size and complexity of the program being tested[5]. It was a great idea to measuring the degree of test suite quality by using the attributes from software quality. Several studies have been reported in the scope of quality attributes of test case that focus on increasing the testing effectiveness consider to mutation testing[6]. The usability especially identification error with effective and efficient is important to enhance software quality[7][8]. Efficiency of test suite is related to number of redundant test cases in the test suite and reducing redundant test cases possible to improve the efficiency in testing[9]. Reliability is considered to number of mutants because the result on mutants coverage could be used to find the true reliability of a program[10][11]. Functionality in the testing approach is to ensure the method in the program satisfies functional requirements and assesses the quality itself[12]. The study on test suite reusability is related to portability has been reported that in the test suite reuse effective at discovering and repairing bugs inserted during pragmatic reuse[13]. Reducing number of test cases and ability of the test cases reused to examine another object should be considered to improve the maintainability[14][15].

With respect to previous work, this research analyzes the quality attributes for test suite to ensure the quality of the test suite. As we already introduced, this proposal a method to measure the test suite quality attributes is adopted the quality attributes from software quality which related to test suite, especially in white-box testing approach.

III. Test Suite Quality Attributes

Software quality defines as the degree of software, component, or process to establish the customer requirement under specific conditions[2]. Successful software testing activity is achieved by collaborative activity between testing activity and quality assurance activities[16]. One of the important assets in testing activity is test suite. Software quality has many approaches such as McCall's Model (1977), Boehm's Quality Model (1978), ISO 9126 Standard Quality Model (1986), FURPS (1987), FURPS+ (2000), Capability Maturity Model (CMM 1991), Ghezzi Model (1991), IEEE Model (1993), Dromey's Quality Model (1995), SATC's Quality Model (1996), Bansiya's QMOOD Model (2002), Aspect-Oriented Software Quality Model (2006), Component-based Software development Quality Model (2008), DEQUALITE Model (2009), Sehra S. K Model (2011) and SQuaRE's Model (2011)[17].

Software quality attributes are multipurpose attributes that mean any area of software development process can use the attributes. Examining code programs by using the test suite is one of the methods to assure their quality. The most used attributes on the software quality model are usability, efficiency, reliability, functionality, portability, and maintainability that selected from 28 attributes. The principle of test suite quality attributes on white-box testing in this research is related to the software quality principle. The research proposes the following formula and definition for test suite quality attributes. To simplify the formula, the research uses the following notation.

- SRTC : Successful Reused Test Cases
- DCC : Distinct Code Coverage
- OT : Objects Tested
- NOLOC : Number of Original Line of code
- NOTC : Number of Test Cases
- NOMut : Number of Mutants
- NOMutK : Number of Mutants Killed
- NOR : Number of Redundant Test Cases
- NOMet : Number of Method
- NOMetExec : Number of Method Executed

The parameters for measuring the test suite quality attributes are gathering from the test suite examination that enhances the accuracy of test suite quality measurement. The result of test suite quality attribute measurement is numerical which ranges from 0 to 1. The experiment assumes that the test suite quality attribute has three levels of quality such as low, medium, and high. The result of test suite quality attributes divided into those three levels which begin from 0 – 0.33 for low quality, 0.34 – 0.66 for medium quality, and 0.67 – 1 for high quality. One of the criteria of good test cases in the test suite related to white box testing is that the test cases can achieve 100% code coverage. The test suite quality attribute measurement additionally considers code coverage on its measurement.

1) Usability as test suite quality attribute: Usability defines as the degree of a program able to be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use[18]. The research assumes that the test suite usability should consider for the effectiveness and efficiency related to previous definition. In other words, test suite usability defines as the extent to test suite is successfully examine program by the software tester to guarantee that all statements have been exercised at least once and validate the internal data structure with effectiveness and efficiency. By using the notation, the formula for test suite usability as follows.

$$Test\ Suite\ Usability = \frac{(1-(\mathrm{NOR}/\mathrm{NOTC}))+(DCC/NOLOC)}{2} \tag{1}$$

2) Efficiency as test suite quality attribute: Efficiency defines as the capability of the software product to provide appropriate performance, relative to the number of resources used under stated conditions[2]. Number of resources in the case of test suite is related to number of test cases. Redundant test cases in the test suite are one of the problems that can reduce efficiency value. The previous research conducted the identification and elimination process of redundant test cases in the test suite[19]. The efficiency in this research is related to the degree of redundancy of test cases on the test suite. The test suite efficiency defines as the level of test suite redundancy to complete a certain task. The redundant test cases exist when both of the two test cases are executed in the same lines of code. By using the notation, the formula for test suite efficiency as follows.

$$Test\ Suite\ Efficiency = \left(1 - (NOR/NOTC)\right) \quad (2)$$

3) Reliability as test suite quality attribute: Reliability defines as the ability of the software to operating required functions in specific conditions and time, or number of operations[2]. One of the causes of the inability of the software product to perform a required function is mutant. Mutants define as changed/mutated statements of the source code. The capability of the test cases kills the mutants to ensure the quality of test cases in terms of reliability. Test suite reliability is defined as the probability of test cases in the test suite killed the mutants in testing that consider to its coverage. By using the notation, the formula for test suite reliability as follows.

$$Test\ Suite\ Reliability = \frac{NOMut}{NOMutK} \quad (3)$$

4) Functionality as test suite quality attribute: The functionality defines as the capability of the software to perform functions that are related to user requirements with specific conditions[2]. The research analyzes the terms function in Java program related to the white-box testing is a method that also considers the coverage of the test suite. The test suite functionality is defined as the capability of test cases on the test suite to performs the behavior of the program. The test suite has performed the behavior of the java program when a high number of the method examines by the test suite. The formula for test suite functionality measurement as follows.

$$Test\ Suite\ Functionality\ = \frac{NOMetExec}{NOMet} \quad (4)$$

5) Portability as Test Suite Quality Attribute: Portability defines as the capability of software that can be reused from one hardware or software environment to another[2]. Test suite portability is defined as the capability of the test cases in the test suite to run on a new program without change. Portability is related to the degree of reusability of test suite. The test suite reusability defines as the capability of test cases in the test suite to examine several or all paths of method that should be tested on diverse objects.

This research uses the clones of Banker's Algorithm with code clones type 1, 2, 3, and 4 [20][21]. The test suite portability measurement is applied on code clones because the portability of the test cases in the test suite needs to use the same characteristic of input for the program. Code clone type 1 (exact clones) are identical clones with no differences with original code. Code clone type 2 which the differences from the original code are renamed identifiers, literals, types, layout, and comments but the structurally and syntactically are similar. Code clones type 3 are modified the statement such as statement insertions/deletions in addition to changes in identifiers, literals, types, and layouts. Code clone type 4 has been modified on code fragments to perform the same objective but different syntactic variants. By using the notation, the formula for test suite reusability as follows.

$$Test\ Suite\ Portability = \frac{\sum SRTC + \sum DCC}{(\sum OT \times \sum TC) + \sum NOLOC} \quad (5)$$

6) Maintainability as test suite quality attribute: Maintainability defines as the capability of software to be modified for correct defects, meet new requirements, make future maintenance easier, or adapted to a changing environment with less effort to maintain[2]. Test suite maintainability is related to the capability of the test suite that suitable to test another program with less effort to maintain by avoiding redundant test cases. The maintainability considers to reusability and efficiency(non-redundant test cases) of the test suite. By using the notation, the formula for test suite maintainability as follows.

$$Test\ Suite\ Maintainability$$

$$= \frac{1 - (NOR/NOTC) + \left(\frac{\sum SRTC + \sum DCC}{(\sum OT \times \sum TC) + \sum NOLOC}\right)}{2} \quad (6)$$

IV. Reliability Analysis

Reliability analysis in this research is to validate the formulas of test suite quality attributes measurement. Validation of those formulas is to observe the result with the real condition based on the expert assessment. Reliability analysis objective is to validate the level of agreement from the result of measurement to the expert [22]. The validation refers more specifically to the consistency of measurement that involves the expert.

Cohen's kappa coefficient is generally for assessing agreement between raters. Cohen defined the coefficient as "the proportion of chance-expected disagreements which do not occur, or the proportion of agreement after chance agreement is removed from consideration"[23]. Cohen's Kappa has used a quantitative measurement of reliability for two raters that are rating the same thing, corrected for how often that the raters may agree by chance. The formula for Cohen's kappa coefficient as follows.

$$k\ = \frac{p_0 - p_c}{1 - p_c} \quad (7)$$

where,

p_0 = the proportion of units for which the judges agreed (relative observed agreement among raters)

p_c = the proportion of units for which agreement is expected by chance (chance-expected agreement)

TABLE I. COHEN'S KAPPA CONTINGENCY MATRIX

		Rater 1	
		Category 1	Category 2
Rater 2	Category 1	a: number of agreements on category 1 P(a) = a/N	b: number of disagreements (judge 1 and category 2, and judge 2 and category 1) P(b) = b/N
	Category 2	c: number of disagreements (judge 1 and category 1, and judge 2 and category 2) P(c) = c/N	d: number of agreements on category 2 P(d) = d/N

TABLE II. COHEN'S KAPPA INTERPRETATION

Kappa Statistic	**Strength of Agreement**
<0.00	Poor
0.00 – 0.20	Slight
0.21 – 0.40	Fair
0.41 – 0.60	Moderate
0.61 – 0.80	Substantial
0.81 – 1.0	Almost Perfect

Distribution of the frequency for two raters on Cohen's kappa coefficient is represented by the contingency matrix as shown in Table I [23]. Based on Cohen's kappa contingency matrix, p_o and p_c are calculated as follows:

p_o=P(a)+P(d) $P_{category1}$=(P(a)+P(c))*(P(a)+P(b))

p_c=$P_{category1}$+$P_{category2}$ $P_{category2}$=(P(b)+P(d))*(P(c)+P(d))

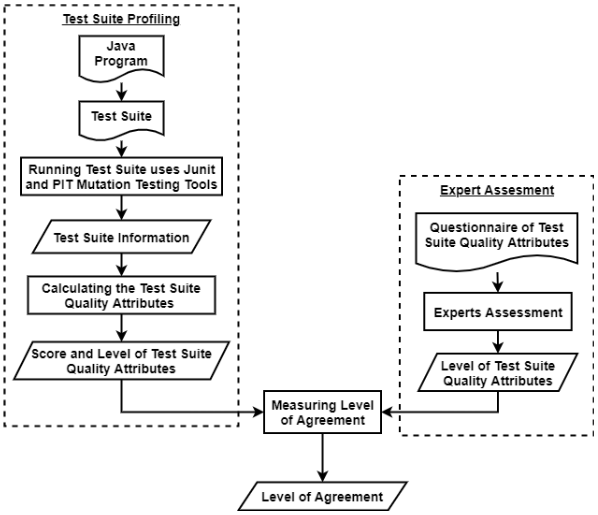
The value of Cohen's kappa coefficient is positive when the value greater-than-chance agreement and negative when less-than-chance agreement. The maximum value for Cohen's kappa coefficient is +1.0. Its value related to the strength of agreement as shown in Table II.

V. Research Methodology

This section explains the research methodology to measure the test suite quality attributes and then validate the result by using the reliability analysis. The reliability analysis is used Cohen's kappa coefficient to validate the result of test suite quality measurement based on the level of agreement from the result of measurement and expert assessment. Fig. 1 shows the test suite quality attributes measurement and validation activity that consists of two main activities such as test suite profiling for test suite quality measurement and expert assessment for validating the result of measurement.

A. Proposed Test Suite Quality Measurement Activity

The objective of test suite profiling is to collect the important and useful information of the test cases in the test suite for the test suite quality attributes measurement in white-box testing. Test suite profiling uses the Java program and given test suites then running the test suite which has been implemented on Junit to test the Java program and the result is test suite information. The test suite information contains such as follow.



Test Suite Profiling
Java Program
Test Suite
Running Test Suite uses Junit and PIT Mutation Testing Tools
Test Suite Information
Calculating the Test Suite Quality Attributes
Score and Level of Test Suite Quality Attributes
Expert Assesment
Questionnaire of Test Suite Quality Attributes
Experts Assessment
Level of Test Suite Quality Attributes
Measuring Level of Agreement
Level of Agreement

g) Number of methods

h) Number of method executed.

Test suite information uses to calculate test suite quality attributes. Test suite quality attributes calculated in this research is usability, efficiency, reliability, functionality, portability, and maintainability. The result of the calculation is the score and level for test suite quality attributes.

B. Validation

Validation aims to prove the validity of test suite quality attributes measurement results with expert assessment. The expert assessment activity objective is to assess the quality of the test suite based on the experience from the expert. The questionnaire contains information and question that should answer by the expert such as how long the experience in software engineering and his work. The questionnaire provides information such as the explanation for test suite quality attributes, Java program and given test suites, and the result of test suite examination. The expert answers the question of test suite quality attributes assessment based on their experience, and knowledge. The expert assesses the quality of the test suite by choosing the level of quality such as low, medium, and high quality.

The level of test suite quality attribute from the test suite quality attributes measurement and expert assessment then analyze the reliability by using Cohen's kappa coefficient. The profiling and expert assessment for test suite quality attributes are used the same dataset. Cohen's Kappa coefficient and percentage of agreement are used to measure the level of agreement for test suite quality attributes. The result of measurement is the value of Cohen's kappa coefficient and percentage of agreement from test suite quality attributes measurement and expert assessment.

VI. The Experiment

The purpose of the experiment is to collect the test suite information for test suite quality attributes measurement for white-box testing. The result of measurement then validates the level of agreement from the result of measurement by using the result of expert assessment.

A. Dataset

The experiment uses Banker's Algorithm Java program as shown in Fig. 2 and given two test suites for the dataset as shown in Table III that contains the number of test case (TC), input data, and expected output. Banker's Algorithm is developed by Dijkstra for resource allocation and deadlock avoidance algorithm[11], [24]. The number of test cases is seven for each test suite. The test suites are implemented on Junit to examine the Banker's Algorithm. The test suite mutants information gains by using PIT mutation testing tool[25] and Junit for code coverage information.

B. Experiment Works

The Banker's Algorithm java program is examined by the given test suites in which test cases implemented in Junit. The test suite examination result is code coverage information and mutation coverage for profiling the test suite. The code coverage information for each test suite is collected by executing the Junit in Eclipse IDE that presents the information of lines of code executed by the test case in the test suite and percentage of code coverage.

The test suite mutants information is collected by using PIT mutation testing tool. PIT mutation testing tool are greatly manipulated bytecode to generates mutants and examine the test suite or test case to know the capability of the test suite to kill the mutants[25]. The mutants are killed by the test case in the test suite by showing different behaviour, and live when they are not. The ratio of mutants in the test suite is calculated in PIT mutation testing tool. The ratio of mutants is calculated by the mutants killed over the total number of mutants. The mutation score is used in test suite reliability measurement by combining with code coverage. Test suite quality attributes such as usability, efficiency, reliability, functionality, portability, and maintainability are calculated by using the formula that explains in Section 2.

The experiment uses the questionnaire to gathering the test suite quality attributes information from the expert assessment. The questionnaire contains the introduction and aims of the test suite quality attribute assessment, dataset, result of the test suites execution, and summary of the test suites examination. The question is focused on assessing an aspect of the level of test suite quality attributes from an expert view with seven questions. They are designed from the definition of test suite quality attributes and the result of all test suites examination. An example of the question is as follows.

```
public class Banker {
private final int need[][], allocate[][], max[][], avail[][], np, nr;
public Banker(int[][] need, int[][] allocate, int[][] max, int[][] avail, int np, int nr) {
 if (need.length != np || allocate.length != np || max.length != np || avail.length != 1|| need[0].length != nr ||
allocate[0].length != nr || max[0].length != nr || avail[0].length != nr) {
 throw new IllegalArgumentException("The matrices should have \"np\" rows and \"nr\" columns. \"avail\" should have only one
row.");}
 this.need = need;
 this.allocate = allocate;
 this.max = max;
 this.avail = avail;
 this.np = np;
 this.nr = nr;}
 private int[][] calc_need() {
  for (int i = 0; i < np; i++) {
   for (int j = 0; j < nr; j++) {
  need[i][j] = max[i][j] - allocate[i][j];}
 }
 return need;}
 private boolean check(int i) {
 for (int j = 0; j < nr; j++) {
  if (avail[0][j] < need[i][j]) {
  return false;}
 }
 return true;}
 public boolean isSafe() {
  calc_need();
        boolean done[] = new boolean[np];
        int j = 0;
        while (j < np) {
         boolean allocated = false;
         for (int i = 0; i < np; i++) {
         if (!done[i] && check(i)) {
          for (int k = 0; k < nr; k++) {
avail[0][k] = avail[0][k] - need[i][k] + max[i][k];}
 System.out.println("Allocated process : " + i);
 allocated = done[i] = true;
  j++;}
}
  if (!allocated) {
   break;}
}
return j == np;}
}
```

		Expected Output	fail("Expecting exception: IllegalArgumentException")			Expected Output	fail("Expecting exception: IllegalArgumentException")

"The efficiency of test suite usability in this research is related to the degree of redundancy of test cases on the test suite. The test suite efficiency defines as the level of test suite redundancy to complete a certain task. The redundant test cases exist when both of the two test cases are executed in the same lines of code.

Based on the definition and the summary of test suites examination, what is the degree of test suite efficiency for test suite 1 and test suite 2?".

The expert will choose one answer such as low, medium, high for each test suite. The questionnaire collects the personal information of the expert like name, kind of experience in software engineering. Result of the questionnaire is presenting the level of each test suite quality attributes of every test suite.

TABLE IV. RESULT OF TEST SUITE INFORMATION

Test Suite Information	Test Suite-1	Test Suite-2
Number lines of code	33	33
Distinct lines of code executed	33	3
Number of test cases	7	7
Number of mutants	41	41
Number of mutants killed	32	3
Number of methods	4	4
Number of methods executed	4	1
Number of object reused test suite(test cases)	4	4
Number of successful reused test cases for all object tested	28	28
Number of redundant test cases	3	6

TABLE V. RESULT OF TEST SUITE QUALITY ATTRIBUTES MEASUREMENT

Test Suite Quality Attributes	**Test Suite-1**		**Test Suite-2**	
	Score	Test Suite Quality Attribute Level	Score	Test Suite Quality Attributes Level
Usability	0.79	High	0.12	Low
Efficiency	0.57	Medium	0.14	Low
Reliability	0.78	High	0.07	Low
Functionality	1.00	High	0.25	Low
Portability	1.00	High	0.51	Medium
Maintainability	0.79	High	0.33	Low

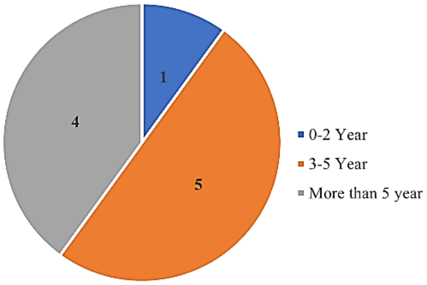

Fig. 3. Expert Time Experiences in Software Engineering.

The result of level test suite quality attributes and expert assessment is used to calculate the level of agreement by using Cohen's kappa coefficient and percentage of agreement. The contingency matrix for Cohen's kappa coefficient contains several conditions. True positive condition is the total number of instances that both raters said correct. False positive condition is the total number of instances that the result of test suite quality attribute measurement said incorrect, but experts said correct. False negative condition is the total number of instances that the result of test suite quality attribute measurement said correct, but the experts said incorrect. True negative condition is the total number of instances that both the result of test suite quality attribute measurement and the experts said incorrect. The value in the contingency matrix is used to calculate Cohen's kappa.

The percentage of agreement is calculated based on comparison data from the result of the level of test suite quality attributes measurement and expert assessment. Criteria of the match agreement if the result from the expert is the same as the measurement. The result from Cohen's kappa coefficient and percentage of agreement is to enrich the analysis of reliability in test suite quality attributes.

C. Experiment Result

The dataset from Banker's Algorithm and given test suites then examines by using Junit and PIT mutation testing tool, the result of test suite information is shown in Table IV. The test suite information consists of the number of lines of code, number of lines executed by the test case, distinct number of lines executed, number of methods, and number of method executed. Table V shows the result of test suite quality attributes measurement for usability, efficiency, reliability, functionality, portability, and maintainability by using the formula in Section 2 and their quality level.

The level of agreement is analyzing by Cohen's kappa coefficient and percentage of agreement. The Cohen's kappa coefficient in this research is to present the degree of agreement. The percentage of agreement is to enhance detailed information about the percentage of test suite quality attributes agreement. The number of experts is ten with different year experiences as shown in Fig. 3. Most of the experts have experience 3-5 years in software engineering. Time experience in software engineering from the expert helps to answer the question.

Calculation of Cohen's kappa coefficient uses the value of true positive, false positive, false negative, and true negative on contingency matrix from the result of the questionnaire as shown in Table VI. The percentage of agreement is measured with the proportion of experts who respond that identical or similar, lower or higher than the result of test suite quality attributes measurement as shown in Table VII. Similar terms in Table VII means that the result from the expert is the same as the measurement result, lower means that the result from the expert is lower than the measurement result, and higher means that the result from the expert is higher than the measurement result.

TABLE VI. CONTINGENCY MATRIX FOR ALL TEST SUITE AND EACH TEST SUITE

Cohen's Kappa Coefficient											
All Test Suite				Test Suite -1				Test Suite-2			
	Expert				Expert				Expert		
Measurement	Yes	No	Total	**Measurement**	Yes	No	Total	**Measurement**	Yes	No	Total
Yes	31	40	71	**Yes**	28	4	32	**Yes**	4	37	41
No	29	20	49	**No**	20	6	26	**No**	1	19	20
Total	60	60	120	**Total**	48	10	58	**Total**	5	56	61
Po	0.425			**Po**	0.586			**Po**	0.377		
Pc	0.5			**Pc**	0.533			**Pc**	0.356		
Kappa	-0.15	Less than Chance Agreement		**Kappa**	0.112	Slight Agreement		**Kappa**	0.032	Slight Agreement	

TABLE VII. RESULT OF PERCENTAGE OF AGREEMENT FOR ALL TEST SUITE AND EACH TEST SUITE

Quality Attributes	Similar		Lower		Higher	
	Total	Percentage	Total	Percentage	Total	Percentage
Usability	11	55%	6	30%	3	15%
Efficiency	6	30%	1	5%	7	35%
Reliability	10	50%	3	15%	7	35%
Functionality	13	65%	2	10%	5	25%
Portability	8	40%	7	35%	9	45%
Maintainability	4	20%	7	35%	9	45%
All Attributes	52	43%	26	22%	40	33%

VII. DISCUSSION

This section provides implications from the result of the questionnaire to test suite quality attributes measurement. The Cohen's kappa coefficient result for all test suites is – 0.15 which means less than chance agreement or no agreement as shown in Table VI. Negative value of Cohen's kappa coefficient is represented great disagreement between measurement and experts. Disagreement means that the observed agreement is less than chance agreement. There is no strict lower value for the kappa coefficient and its meaning. The weakness for a negative value of kappa has no fixed threshold for a lower value that difficult to have suitable interpretation from the assessment especially on the level of agreement.

The kappa coefficient is measured for each test suite. Table VI shows the result of kappa coefficient is 0.112 for test suite 1 and 0.032 for test suite 2 which has similar meaning is slight agreement. The slight agreement means that condition is needed to consider the result from the experts and measurements. Interpretation of the kappa coefficient for indicated the good agreement is not easy because in the terms of accuracy from a single kappa analysis itself.

The research analyzes that level of agreement by kappa coefficient is incompleted to represent the level of agreement between test suite quality attributes measurement and expert assessment. This research uses the percentage of agreement to complete the analysis. The percentage of agreement has improved the result of positive value of kappa coefficient. Table VII shows the percentage of agreement for all and each test suite quality attribute.

The result from all quality attributes measurement and the expert shows that 46% are similar to the test suite quality attributes measurement which means that the expert 46% agree with the principle of test suite quality attributes measurement. The highest attribute which similar is reliability with a percentage of 70%. The lowest attribute which similar is maintainability with a percentage of 20%.

The result of test suite quality attributes measurement for each test suite and expert assessment are confirmed for slight agreement. This result is approved by the result of the percentage of agreement. The research assumes that the level of agreement is strongly agreed when the percentage of the agreement greater than or equal to 50%. The result shows that usability with 55%, reliability with 50%, and functionality 65% which means that strongly agreed.

VIII. CONCLUSION AND FUTURE WORK

This research investigated the quality attributes for test suite based on the attributes of software quality. The attributes are usability, efficiency, reliability, functionality, portability, and maintainability that are selected from 28 attributes in software quality. The test suite quality attributes measurement uses the result of test suite examination as parameters and input. The experiment uses the Banker's Algorithm by using given two test suites. The result of test suite quality attributes measurement is presented by score and level of quality as the degree of test suite quality.

The experiment uses reliability analysis to prove the validity of test suite quality attributes measurement. The reliability analysis uses Cohen's kappa coefficient and percentage of agreement. Cohen's kappa coefficient analyzes the reliability of test suite quality based on test suite quality attributes measurement result and expert assessment. The result of Cohen's kappa coefficient measurement is – 0.15 for all test suites, 0.112 for test suite 1, and 0.032 for test suite 2. The result of test suite quality attributes measurement for each test suite is confirmed for slight agreement. This result is approved by using the result of the percentage of agreement. The research assumes that the level of agreement is strongly agreed when the percentage of the agreement greater than or equal to 50%. The result shows that usability with 55%, reliability with 50%, and functionality 65% which means that strongly agreed. Hence, our proposed method is useful to measure test suite quality attributes.

Our approach is a method to measure test suite quality attributes for white box testing which is specifically contained usability, efficiency, reliability, functionality, portability, and maintainability as attributes. In the future, it's important to consider the weight of each test suite quality attribute to define a formula that can measure test suite quality more accurately.

Intelligent Scroll Order Generator Software from View Movements in People with Disabilities

Juan Ríos-Kavadoy[1], Harold Guerrero-Bello[2], Michael Cabanillas-Carbonell[3]
Facultad de Ingeniería
Universidad Privada del Norte
Lima, Perú

***Abstract*—People with motor disabilities face problems such as being able to move around independently, as well as having difficulties to take advantage of the technological tools developed for their rehabilitation. This research is based on computer vision and robotics, and was carried out with the objective of generating displacement orders using smoothed and binarized algorithms to assist the displacement of disabled people. The intelligent software for people with disabilities or motor deficiencies generates movement commands for an acceptable time through visual commands made by the person, by means of communication between the camera and the software, constantly capturing images. The results obtained for the scene (image) is cropped according to the face scene, then the view scene is cropped according to the face scene, and by means of necessary algorithms the pupil must be found; The complexity lies not only in locating the pupil, but also in identifying when a command is being sent and when it is not. Finally, the unit processes the movement command (left and right) to turn the LEDs on and off.**

Keywords—Displacement; motor disability; pupil; computer vision of images

I. Introduction

According to the UN and WHO [1]–[3], around the world, more than 1 billion people have disabilities, about 15% of the world's population, of whom more than 200 million suffer from motor difficulties, being 3.8% considered to be severely disabled. According to Hawking [3], who has suffered from motor neuropathy since adulthood, he states that this motor disability has not been an obstacle to achieve his goals, being technology his support to lead a normal life.

In Peru [4], there are different types of diseases that prevent people with disabilities from carrying out their activities normally, representing 59.2% of the total population with disabilities, preventing them from moving from one place to another, climbing stairs, going down stairs, etc. In everyday life, orders or actions are performed by different means, such as voice, for example, to activate the cell phone, open/close the door of the house, etc., and all that the world of home automation has to offer. But little in eye tracking is to give the same orders as voice, hand, etc.

Motor difficulty (movements in the hands, feet, etc.) also called as coordination disorder which prevents the generation of movement commands to the body due to chronic neurological impairment [5], [6]. There are different options to be able to capture the brain's orders, one of which is by means of nerve impulses, brain waves where physiological orders can be carried out by means of these [7], [8], another option is to use eye movements by means of visual perception.

The interaction between the brain and the computer allows the patient with motor disabilities to increase their cognitive abilities and self-sufficiency; however, accuracy problems are often encountered [7]. To solve these problems we propose the use of eye movements translated by the computer into physiological movements by training algorithms for greater accuracy and for the efficient operation of external devices such as wheelchairs.

Taking the last mentioned, the present project is intended to cover 02 areas of Artificial Intelligence (digital image processing [9] and robotics [10]), two problems were encountered to carry out the orders by means of the view, the first one is to be able to discriminate the orders of those that are not, considering that at a certain moment it can be visualizing a landscape, but not generating an order, therefore it is desired to find the recognition of orders, and second problem encountered is that the orders of displacement carried out are correct, carrying out the action in the indicated direction.

As a background to the study, the following studies have been considered, an important contribution presented in Panama, is the SOLCA software [11], which supports people with disabilities in the use of hands, for this purpose is agency of sight to be able to manipulate a computer. Another relevant contribution presented in USA [12], is the design of a virtual environment used as a simulator contributing to be a support tool in the rehabilitation of people with some degree of motor disability, based on virtual reality. It was obtained that increased confidence in patients.

In research [13], a drawing interface for human-computer interaction was realized where image processing was used, interface control was developed by tracking the patient's nose. As a result, it was found that young patients found the system easy to use, but in adult patients there was a lack of familiarity with the software.

Although there have been several previous investigations on the case, carried out with a variety of methods with the aim of helping the patient in his rehabilitation, it has been identified that most of the patients show some difficulty in adaptation, this is due to the lack of familiarity of the patient, to the unfriendly environments of the interfaces that cause the disabled person to make some physical effort.

The present research aims to provide a trained algorithm from which a digital image processing was performed, typical of artificial intelligence, where information has to be extracted from a scene, in order to be implemented in the future to a wheelchair. It also has an applicative justification since it works with hardware that is used for people with motor disabilities, as valuation we have that it can be scalable and can be used by a greater number of people and also has a social justification, since this research is born from a problematic reality for the support of people with motor deficiency providing a non-invasive and easy to use support for the patient.

II. Methodology

The main functions to be performed are to locate the eyes and analyze the position of the pupil within the central position of the eye by listening to the left (i) and right (d) commands, to subsequently switch on the LED defined for the left and right position and start processing the scene and improving the captured image, finally identifying the commands.

The research conducted is of a pre-experimental type, which allows to optimally administer the treatment to a group [14], applying a stimulus (intelligent software) for the resolution of the problem.

A. *Population and Sample (Materials, Instruments and Methods)*

The population is made up of 100 realized visual orders, as trials the orders are left and right. Therefore, the object of study is given by the visual orders. To obtain these visual orders, 5 attempts of order of each side are considered, performed to 10 persons, therefore 10 attempts x 2 sides x 10 persons, in total 200 orders of displacement, which will be submitted to evaluation of the certainty.

B. *Techniques and Instruments for Data Collection and Analysis*

1) *Data collection*

a) Transfer technique: It consists of recording the data that are obtained in the instruments called files, which are duly prepared and organized and contain most of the information collected in a research, and therefore constitute a valuable auxiliary instrument in this task [15].

b) Record card: Evaluation card of visual displacement orders generated and evaluated according to their result.

c) Validity: The degree to which an instrument actually measures the variable it intends to measure.

d) Data analysis: Applied research refers to scientific study that seeks to solve practical problems [16]. It is used to find solutions to everyday problems, cure diseases and develop innovative technologies.

C. *Procedure*

For the present investigation, two techniques will be taken into account: Observation and Record Card, considered for the acquisition of data, as shown in the data table, where the data obtained from the attempts to generate visual orders are observed, identifying which of them have really been visual orders.

1) *Data Collection Before using the Intelligent Software*

a) Indicador 1: Rate of recognition of travel orders. Data collection before using smart software for the travel order recognition rate indicator (see Table I). Correctly Generated Visual Commands (CGCOs).

b) Indicator 2: Orders performed correctly. Data collection before using smart software for indicator correct orders made (see Table II).

2) Development of the intelligent software methodology

This section describes the phases to develop a visual command generator system, using computer vision and digital image processing with Python software and Arduino hardware making use of algorithms and functions from the OpenCV library. This research project is developed under the cascading life cycle [17], through the following stages:

a) Analysis: To identify the visual commands, an analysis of pupil movement was performed, using digital image processing to locate the eyes on the face and fix a pupil position within the central position of the eye, as well as to generate visual commands.

b) Design: In this phase the methods and techniques are determined in the different phases of image processing for the generation of visual orders.

3) Scene capture: An 18 Megapixel camera was used to capture the scene. The process is shown in Fig. 1.

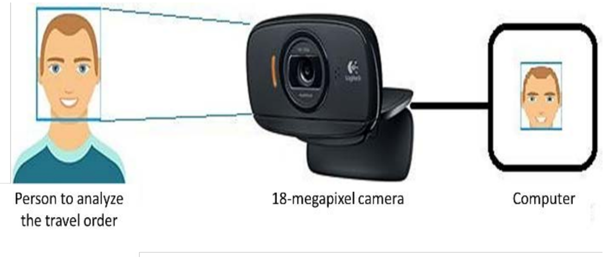

Fig. 1. Process of Capturing the Scene of the Face.

- Interface for software operation: Interface shows the capture of the scene by the camera, to process the image, to find the face, the eye and the pupil. Fig. 2 shows the precise moment when the command is given to the left side. Note that the left side is with respect to the screen, but not to the person.

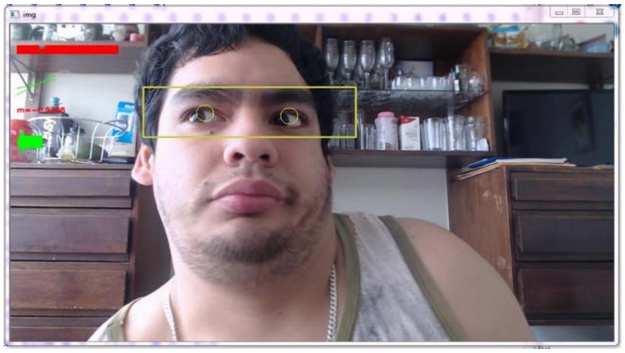

Fig. 2. Scene Interface as it Generates Visual Order.

- Fig. 3 shows the diagram of the hardware device made for this project.

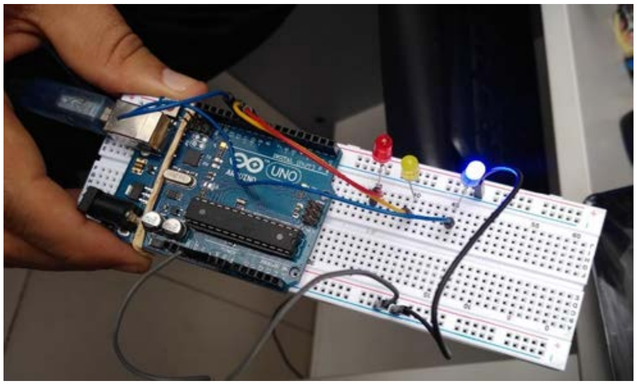

Fig. 3. Arduino Hardware Developed for the Project.

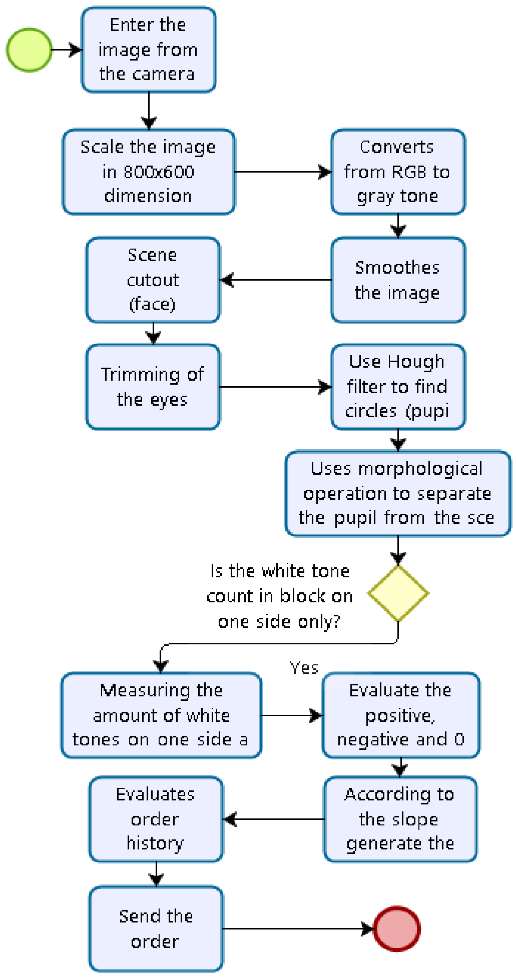
4) Processing: A flow chart was made to explain the process to send an order captured by the camera. (see Fig. 4)

5) Segmentation: It allows to highlight the scene in gray tone, necessary to be able to analyze the position of the pupil, in Fig. 6, it can be seen at the end of the process as the RGB graph changed to gray tone. The following Python source code was used for this purpose:

```
gray = cv2.cvtColor(img, cv2.COLOR_BGR2GRAY)
```



Enter the image from the camera
Scale the image in 800x600 dimension
Converts from RGB to gray tone
Smoothes the image

Fig. 4. Flow Chart of the Order Generation Process.

6) Description: Feature extraction technique. This is necessary to identify which is the necessary technique for the extraction of particular characteristics in a scene, and by means of it to locate the object in question helping to make a decision, for it is supported by the hough model and thus to be able to find the pupil.

First the image was obtained in gray tone, then the search was performed by the circular shape of the pupil (Hough filter) for this a morphological operation was used to extract the pupil from the environment, the amount of white tones at the ends of the pupil was counted. Finally, a slope line was generated to give order (+,-,0) = (d,i,e), this process is shown graphically in Fig. 10 and 11.

7) Visual order recognition: For the identification of movement orders (see process in Fig. 5), the number of pixels obtained as a gray tone (previously binarized) must be taken into account, therefore, it can be counted by means of the number of gray tones 1 (or 255) and 0 (or 0), for each column of the image, which in turn can be represented by the statistical method of dispersion, finding the line that represents that set of statistical values and thus finding the slope of that line created.

Fig. 5. Diagram of Visual Order Identification.

Considering the values of the orders of the slopes generated by the line of the white shades, to consider an order it is necessary to have a statistic of them.

- Order classification using digital image processing: To recognize the visual order it is necessary to consider the amount of gray tone data that are blank in order to identify them, then use the variance method for the amount of orders.

$$S_X^2 = \frac{\sum_{i=1}^{N}(X_i - \bar{x})^2}{N-1}$$

Being X1, X2,...,Xn, the set of N data, and x is the mean of these data. It is analyzed if S is 0, therefore, there is no variance, this implies that there is an intention to give an order, but if the data are different from 0 it implies that it has different types of orders, therefore, it does not generate an established order; this may be because it is looking at one side and then the other, etc.

Fig. 6 shows that the first step is to analyze whether there is a "Face" in the scene, for this it is necessary to locate and cut the scene in its position and size. Then it is necessary to reduce the scene to locate the eyes and detect the order that is performing, we proceed to the segmentation of the face, from the middle of the face upwards. In the third step of the process, the eyes are extracted in their position and size. Then the cut is made to perform the analysis. Finally, the pupil is identified to see its position and size, then it is changed to gray tone and the order is processed.

8) Implementation: For the implementation of the system based on digital image processing for the generation of visual orders, the following was considered:

a) Applied Technologies: Python 3.7.5 and OpenCV

b) Tests: The tests have been performed by means of the black box to measure the results of the application, detailing below with an example of test performed specified in Fig. 10 and 11.

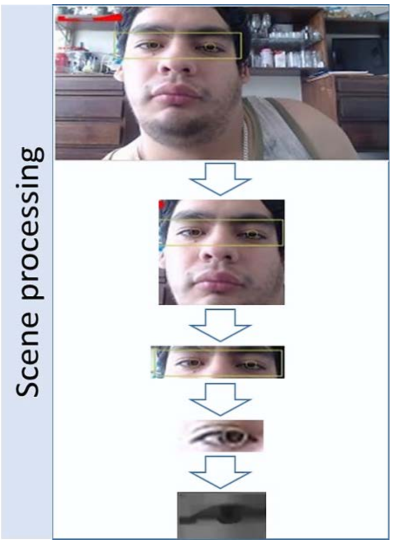

Fig. 6. Architecture for the Identification of the Visual Order.

Fig. 7, 8 and 9 detail the process for obtaining the evidence after the order is sent.

b) Indicator 2: Orders placed correctly. Data collection after using the intelligent software for the indicator of correct orders placed specified in Table VI.

Finally, calculations were made based on the formulas of the indicators.

- For indicator: Travel Order Recognition Rate

$$IRO = \frac{CGCO}{TO} x100 = \frac{169}{200} = 0.85$$

IRO: Index of Recognition of Travel Orders

CGCO: Correctly Generated Visual Commands.

TO: Total orders

- For the indicator: Correct visual orders carried out.

$$CVC = \frac{CO}{TOP} = \frac{145}{169} = 0.85$$

CVC: Correct visual orders.

CO: Correct Orders

III. Results

A. Descriptive Analysis

In the study, an intelligent software (Independent Variable) was applied to evaluate the order recognition index and the correct orders carried out for the displacement order (Dependent Variable); for this purpose, a Pre-Test was applied to know the initial conditions of the indicator; subsequently, the intelligent software was implemented and the order recognition index and the correct orders carried out for the displacement order were recorded again.

1) Order recognition index indicator: The descriptive results of the order recognition index. In the pre-test a value of 60.25% was obtained, while in the post-test it was 84.5% as shown in Fig. 14; this indicates a great difference before and after the implementation of the intelligent software (see Fig. 12).

Regarding the dispersion of the order recognition index, in the pre-test there was a variability of 0.15; however, in the post-test there was a value of 0.11.

2) Indicator - Number of correct orders placed: The descriptive results of the number of correct realized orders. In the case of the number of correct orders to generate displacement orders, in the pre-test a value of 29% was obtained, while in the post-test it was 86% as shown in Fig. 15; this indicates a great difference before and after the implementation of the intelligent software (see Fig. 13).

Regarding the dispersion of the number of correct orders, in the pre-test there was a variability of 0.21; however, in the post-test there was a value of 0.13.

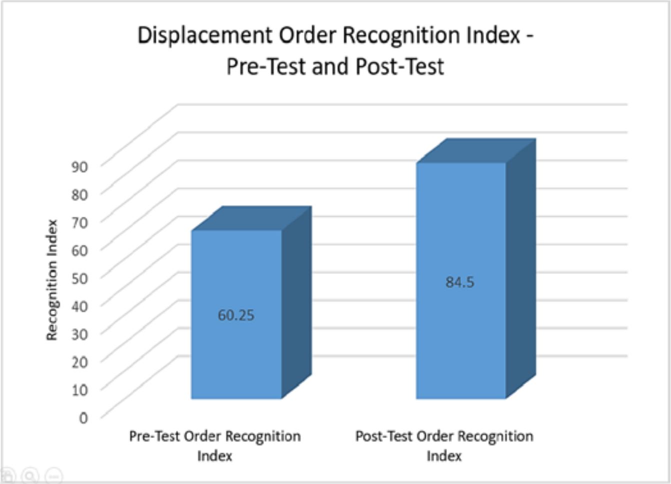

Fig. 12. Displacement Order Recognition Index - Pretest and Posttest.

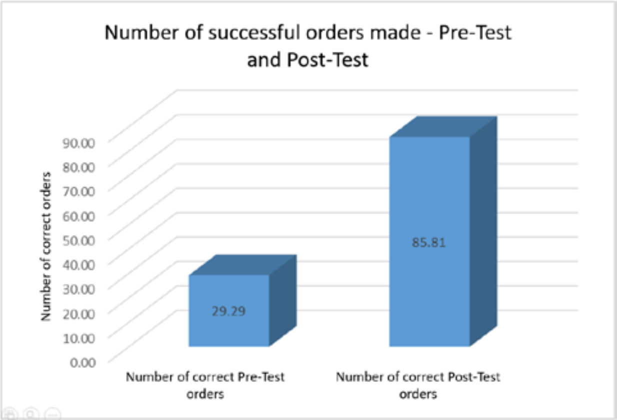

Fig. 13. Number of Correct Orders Placed, Pretest and Posttest.

B. Order Recognition Index

The order recognition index according to the data in Table V and Table III is shown in Fig. 14.

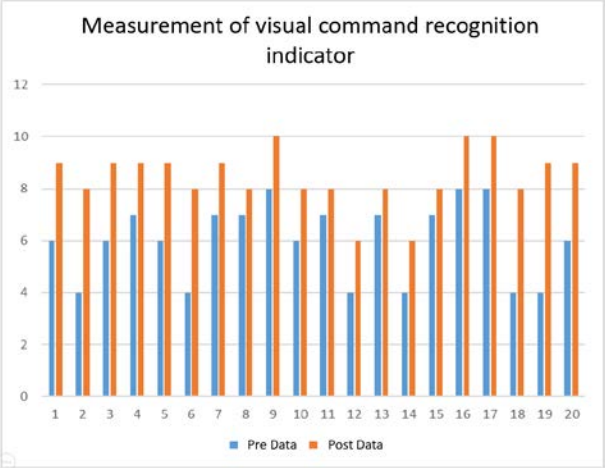

Fig. 14. Measurement of the Visual Command Recognition Indicator.

1) Indicator of correct visual orders: The number of orders recognized according to the data in Tables VI and IV is shown in Fig. 15.

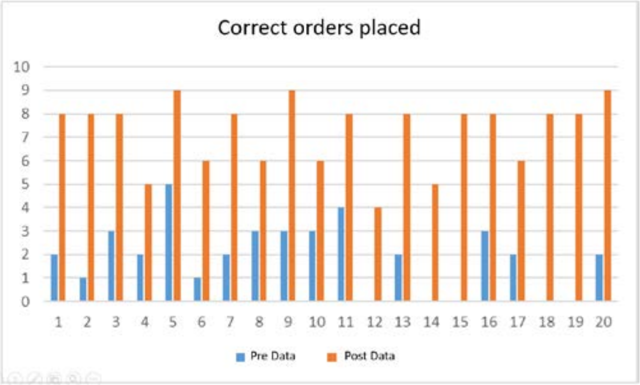

Fig. 15. Measurement of Order Recognition Rate.

IV. Discussion and Conclusion

The influence of intelligent software on the intelligence degree dimension of visual command recognition for people with disabilities according to the visual command recognition rate of 169 correct recognitions out of 200; therefore, using the appropriate model and algorithms results in a visual command recognition rate of 0.85. The influence of intelligent software on the visual order dimension of recognizing the correct orders was demonstrated for people with disabilities according to the rate of recognition of correct visual commands obtained in the tests, which were 145 correct recognitions out of 169; therefore, it is obtained with respect to the rate of generation of correct visual commands of 0.86.

Based on the results obtained, we can infer that the solution can be applied to another person with a disability. Based on the results obtained, we can infer that the solution can be applied to another person with a disability. In addition, the intelligent software had a positive influence on the recognition of movement commands from movements.

This prototype serves as a basis for new knowledge concerning digital image processing and external devices such as sensors.

Recommendations

The present research can be used as a background to find the order recognition rate taking as a reference an effectiveness rate of 0.845 and a rate of correct orders placed of 0.858 plotted.

It is recommended to use a general model to be applied in software for anyone who wants to use it, regardless of whether they have a motor disability, as well as using devices such as Raspberry Pi, to try to become independent with a portable hardware.

***Abstract*—The world's growing population leads the government of Pakistan to increase the supply of food for the coming years in a well-organized manner. Feasible agriculture plays a vital role for sustain food production and preserves the environment from any unnecessary chemicals by the use of technology for good management. This research presents the design and development of a multi-spectral imaging system for precision agriculture tasks. This imaging system includes an RGB camera and Pi NoIR camera controlled by a raspberry pi in a drone. The images are captured by Unmanned Aerial Vehicle (UAV) and then send images to the Java application. Images are processed to sharp, resize by application. The Normalized Difference Vegetation Index (NDVI) is calculated to determine the crop health status based on real-time data. The Deep Learning (DL) technique is used to recognize the onion crop growth stage using the captured dataset. We express how to implement a progressive model for the deep neural network to recognize the onion crop growth stage. The performance accuracy of the system for batch size 16 is 96.10% and for batch size 32 is 93.80%.**

***Keywords*—UAV; deep neural networks; onion crop; NDVI; crop monitoring; VGG16**

I. Introduction

In all homes around all the year, Onion is one of the essential condiments broadly used. Recent research has recommended that in the diet, onions may play a part in avoiding heart disease and other illnesses. Onion is one of the essential crops in all continents with worldwide production of about 25 million tons. In Pakistan, there has been a progressive growth in the area and production of onion and is commercially grown with a production of 1.8 million tons on an area of 131.4 thousand hectares. The major onion growing districts are Hyderabad, Badin, Mirpurkhas, Nawabshah, Sanghar, Shikarpur, Nosharo Feroze, Ghotki and Dadu in Sindh; Kasur and Vehari, in Punjab; Chaghi, Kalat, Killa Saifullah, Nasirabad, Mastung, Khuzdar, Kharan, Turbat, and Jaffarabad in Balochistan and Swat and Dir in Khyber Pakhtun Khuwa [1, 2]. The general objective of the Agriculture Division is to grow farm yield and guarantee increased incomes for the farmers, particularly smallholders. With the predictable growth in the country's population and per capita income, marketing is usual to play an important role in guaranteeing that clients obtain food at reasonable costs and what is the food quality.

Remote sensing can be described as the obtaining of information about an object through sensors without approaching in to direct interaction with it [3]. Since the last part of the 1980s, incredible advancement has been made in remote sensing in precision agriculture [4]. Precision agriculture can be measured as a management methodology of temporal and spatial inconsistency in fields utilizing communication and information technologies [5] with the means to improve sustainability agro-environmental services. In this respect, expanding the accessibility of technological solutions are obtainable to remotely fetch and transfer environmental parameters [6, 7]. Unmanned Aerial Vehicle (UAV), usually identified as a drone, is an aircraft without a human pilot on panel. UAVs are a module of an unmanned aircraft system (UAS), which consists of a UAV, a ground-based controller, and a method of communications between both. The airlift of UAVs may function with several grades of autonomy: either control by a human with help of remote control or automatically with help of onboard computers denoted as an autopilot [8]. In previous years, a variety of UAV models running on military and civilian applications [9]. The essential fact related to UAV technology is, it has been probably 75% of UAVs like drones from 2016 to 2024 will be used in applications related to the precision of agriculture. Reliable and fast information of crop fields by capturing Images through UAV. The "Fig. 1" shows the drone which is used in this research to capture images with help of RGB and Raspberry Pi NoIR Camera and both cameras are embedded with Raspberry Pi 4.

Now a day, Farming is done in the traditional ways in Pakistan. The reality is that our farmers are mostly non-technical persons or poor persons and they have lack of appropriate information that makes it more unreliable. A big part of farming activities is depending on the guesses and these guesses mostly fail on time. Therefore, we come with an idea of crop monitoring via UAV. We consider that this idea becomes standard in the agri-business cause of its reliability and remote monitoring. With the help of this idea, we try to digitalize agricultural activities and farming, and farmers can test on necessities of the crop and perfectly calculate the growth of the crop. We believe that our idea will confidently speed up their business to reach new heights and it will be more profitable. The implementation is mostly based on awareness among farmers, which will be produced due to its various benefits. In precision agriculture applications, the use of UAV [10] has been increased in the last three years. This is primarily due to UAV ability is to deliver the farmers essential information regard crop condition (health) for good input management.

VGG16 is a variant of Visual Geometry Group (VGG) [11] with 16 convolution layers and is very attractive because of its very unvarying architecture. It is presently the most preferred choice in public for extracting features from pictures. The weight formation of the VGGNet is widely accessible and has been utilized in several other applications and challenges as a baseline feature extractor. Instead of having a big number of hyper-parameter, they concentrated on having convolution layers of 3 X 3 filter with a stride 1 and every time utilized comparable padding & maxpool layer of 2 X 2 filter of stride 2 and this is the most inimitable thing about VGG16. It follows this procedure of convolution & maxpool layers regularly through the entire model. At last, it has 2 Fully Controlled (FC) layers tailed by a softmax for results.

Considerable damage is done to onion crops by using high or low quantities of fertilizers and water. Farmers are facing difficulties in the crop monitoring field at a bigger scale, therefore the use of UAV will allow farmers to constantly monitor their crop. This research aims to design UAV-based application to improve the health and production of onion crops. One of the major goals of this research was to achieve a state of the art classifying results using widely helpful data and models, with transfer learning to speed up training processes & balances the limited sample size so that the latest hardware can deliver sensible outcomes. This paper shows monitoring of onion crop, through the use of Near-Infrared (NIR) & RGB imagery captured by Unmanned Aerial Vehicle.

II. Related Work

A brief overview of a few significant contributions from the existing literature is provided in this section.

A. Montes, et al. [8] proposed a Low-cost multispectral imaging system for crop monitoring. The author used digital & NIR cameras to calculate orthomosaics images from NIR & RGB images using built-in software FIJI. The limitation of this system is the use of JPEG format images which makes final NDVI representation lower as compared to the TIFF format.

Gaetano Messina et al. [12] proposed Monitoring Onion Crops Using Multispectral Imagery from UAV. The author used a fixed-wing UAV, fitted out with Multispectral Camera Sequoia Parrot (R-G-RedEdge-NIR). The results of the analysis of the three datasets showed a high correlation of Green Normalized Difference Vegetation Index (GNDVI) and NDVI with Soil-Adjusted Vegetation Index (SAVI). The use of a higher resolution sensor might probably have partly solved these problems.

Kim et al. [13] proposed Machine vision-based automatic disease symptom detection of onion downy mildew aim to train the Deep Neural Network (DNN) model for detection of disease symptoms using Pan, Tilt, Zoom (PTZ) camera, wireless transceiver, a motor system, and image logging module. They achieved an accuracy of 90.7%.

Chauhan, S. et al. [14] proposed Wheat lodging assessment. This study’s main object was to analyze spectral changeability of the features derived for UAV data and their capability to differentiate between dissimilar grades of lodging severity. Using an object-based segmentation result, the nearest neighborhood classification was executed with an overall accuracy of 90%.

Raeva, Paulina Lyubenova, Jaroslav Šedina, and Adam Dlesk [15] proposed monitoring of Corn, Barley crop fields. The author used multispectral and thermal cameras to monitor these crop fields. 3 vegetation indices were determined. Furthermore, 2 thermal maps are existed to show the relation between vegetation and soil temperature. The conclusion is that the values vegetation indices obey with definite growth of crops as known from certainty. It means that thermal & multispectral imagery has great potential in agriculture.

Biao Jia et al. [16] proposed “Use of Digital Camera to Monitor the Growth and Nitrogen Status of Cotton”. The objective of this study was to develop a non-destructive technique for monitoring the growth and nitrogen status of cotton crops using an RGB camera. The use of digital cameras as a tool for near-ground remote sensing in precision agriculture is a new field of research.

C Y N Norasma et al. [17] proposed Rice crop monitoring using multi-rotor UAV and RGB digital camera at the early stage of growth. The paper's objective is to monitor rice crops by using UAV and RGB digital camera in Kelantan.

Shan et al. [18] purpose to predict Covid-19 in Computed Tomography (CT) scan by utilizing the deep learning model named VB-Net. They used 250 images for training, and 300 pictures for validation. A precision of 91.6% they achieved.

III. Materials and Method

In this section, we have discussed in detail our proposed methodology. The “Fig. 2” shows the Overall System Architecture based on the two phases. In the 1st phase, a UAV is used to capture images of the onion crop using both Raspberry Pi NoIR and RGB camera from the field and send these images to the application for further processing. The 2nd phase is to develop an application that monitors onion crop health and recognizes the onion crop growth stage. The dataset is also collected from different fields of onion crops with different growth stages. Images captured by the UAV are further processed in the application where an image sharpen filter is applied and resize the image to get more accurate results. After that application provides two features, NDVI & recognizes the onion crop growth stage.

To calculate NDVI (Normalized Difference Vegetation Indices) values of the captured images of onion crop using the application. The NDVI is computed as following expressions:

$$NDVI = \frac{NIR-RED}{NIR+RED} \quad (1)$$

Where NIR resembles to the Near-Infrared's reflectance values and RED correspond to Red radiations imitated by plants. Images containing NIR and RED radiations from vegetation are mandatory to obtain NDVI.

To recognize the onion crop growth stage, we use the deep neural networks method (VGG16) consisting of a convolution layer, maxpool layer, fully connected (hidden layer), and an output layer. The "Fig. 3" gives details of the VGG16 model.

A. Input Layer

The input layer is responsible for fetching a pre-handled onion crop picture dataset. It carries primary data into the system for additional processing by following layers of deep learning. The input layer is the very starting layer of the workflow of Deep Learning (DL) [19].

B. Convolution Layer

This layer will perform most computations that why this is the critical layer in our proposed DL model. Convolution layers are the significant building blocks utilized in deep learning. Convolution is the basic application of a filter to an input that outcomes in an activation. This layer's main purpose is to recuperate features from the dataset of images and to preserve the spatial relationship between pixels.

C. Max Pool Layer

Max pooling is a pooling process that chooses the most extreme component from the locale of the feature map covered by the filter. Accordingly, the outcome after the max-pooling layer would be a feature map having the most noticeable features of the past feature map.

D. ReLU Layer

This layer generates the non-linearity plan of the DNN features. The aim is to put the negative values of a pixel with 0 in the convolved features.

E. Fully Connected / Hidden Layer

All activation functions of the previous layer are associated with the neurons of this layer. The principal assignment of this layer is to order the gathered features in the predefined classes from the image data sets.

F. Softmax Layer

This layer is purely used to deliberate the conceivable values of the preceding layer activation function. The values can be taken in four sets of 'Initial Stage', 'Middle Stage', 'More than Middle Stage', and 'Final Stage' in the recognition case.

G. Output Layer

The output / final layer of the DL model can be categorized with outcomes of previous layers. It results in the recognition of the onion crop growth stage, for example, Initial Stage, Middle Stage, More than Middle Stage, and Final Stage.

The "Fig. 3" shows the VGG-16 architecture of the RGB images. Convolutions are used to expand the 3rd dimension but 1st and 2nd dimensions are regularly remains untouched. Pooling layers are used to reduce (dividing with 2) 1st and 2nd dimensions (Height X Width) & left 3rd dimension unaffected. VGG-16 has convolution kernels of uniform size 3 X 3 with stride as 1 just applies them several times. Using equation (2), it's not difficult to obtain comparable values.

$$ConvMat = \frac{OriMat+2*P-F}{S} \quad (2)$$

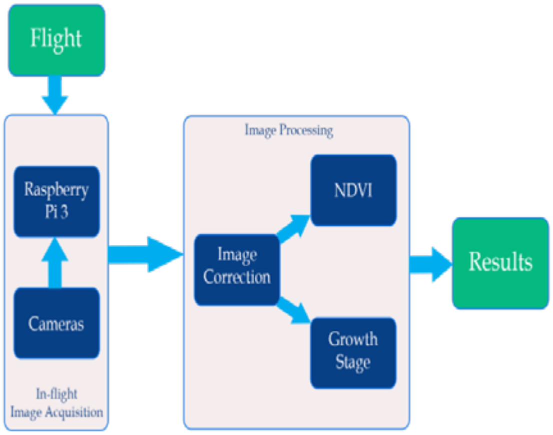

Fig. 2. Overall System Architecture.

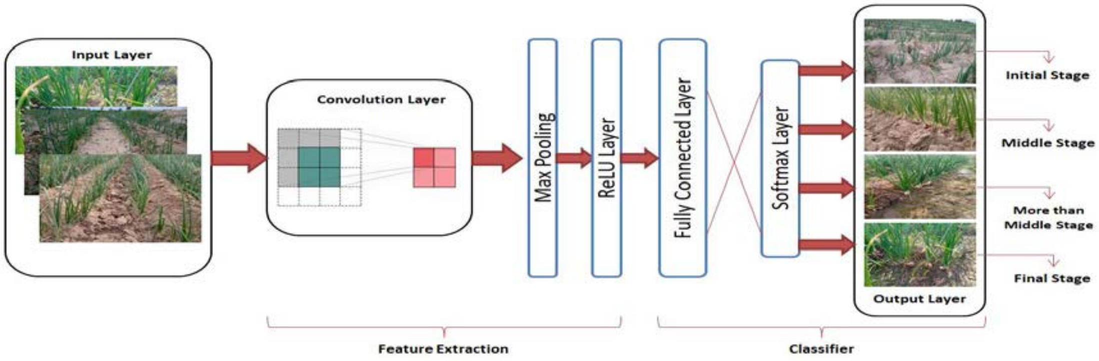

Fig. 3. VGG16 Model to Recognize Onion Crop Growth Stage.

Where ConvMat is convolutional matrix dimensions, OriMat is the original matrix, P is the padding number, S is the striding number of positions and F is the filter dimensions.

IV. Results and Discussion

We demonstrate and discuss the outcomes of our system developed and tested under preset conditions in this section. This study was conducted in an onion field located in Hala New, Sindh, Pakistan. The total field acreage was 6 acres with a well-organized plot.

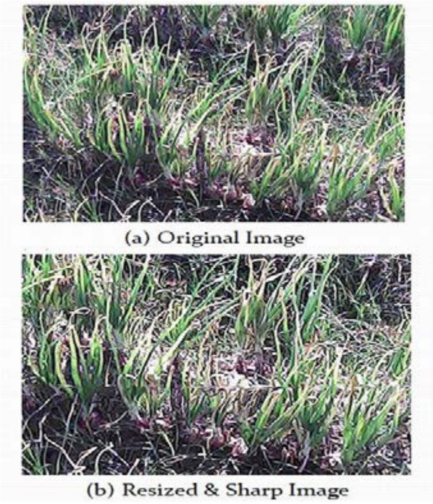
A. Flight Plan and Image Pre-processing

The UAV takes a flight of 2 minutes with an altitude of 7 feet and captures the images with Raspberry Pi NoIR camera for NDVI calculation with a 10-second interval in an acre of field and after that, it reduces altitude to 3 feet and again starts capturing the images from 3 feet altitude with RGB camera for Crop Growth Stage and send these images to the application. After sending images to the application the image sharpens filter is applied, resize the image and then process the images for NDVI calculation & Onion Stage recognition.

The “Fig. 4(a)” is the original image captured by the RGB camera and then the RGB image is sharped and resized to process and recognize the crop growth stage by application. We have the sharper image, as shown in “Fig. 4(b)”, the edges are visible to recognize the image correctly and results will be accurate. We have also sharper the NIR images to compute NDVI results accurately because the images are taken from 7 feet height with UAV. The “Fig. 5(a)” is the original image capture by the Raspberry Pi NoIR camera and “Fig. 5(b)” shows the sharper image by using the image sharpening technique through the application.

B. Compute NDVI

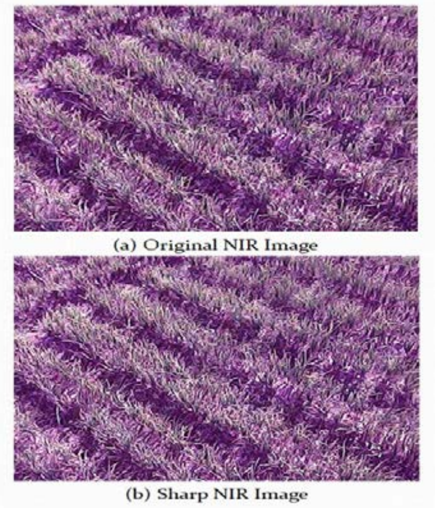
The NDVI computation outcomes range from -1.0 to 1.0. Negative values relate to regions with rocks, manmade structures, snow, water surfaces; simple soil typically comes in between 0.1 to 0.2 ranges, and plants will constantly have positive values 0.2 - 1.0. Healthy plants should be above 0.5, and damages and unhealthy plants will most likely come in between 0.2 to 0.5.



(a) Original Image

(b) Resized & Sharp Image

Fig. 4. RGB Image Processing.



(a) Original NIR Image

(b) Sharp NIR Image

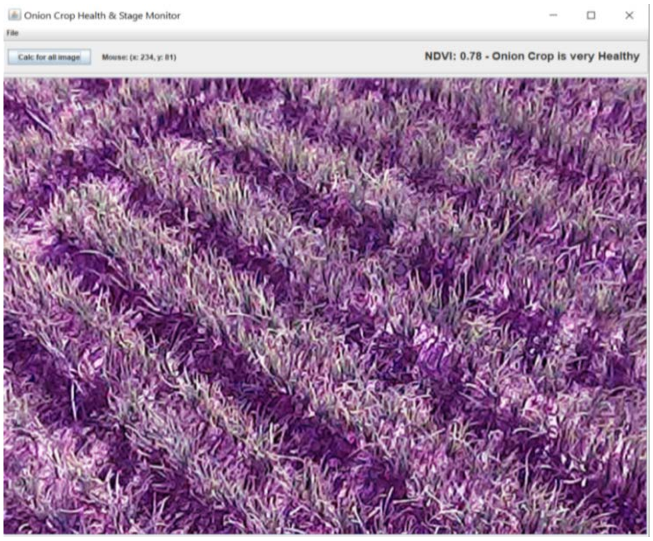
Fig. 5. NIR Image Processing.

The “Fig. 6” shows that we take the near-infrared image, process it using the NDVI calculation algorithm, and then we calculate the NDVI of the processed image. The system shows NDVI of 0.78 – Onion Crop is very healthy.

C. Onion Crop Growth Stage Recognition

In our dataset, the total number of 4000 images of the onion crop stored. 798 are classified as Initial Stage, 1022 are classified as Middle Stage, 1209 are classified as more than Middle Stage and 971 are classified as Final Stage. The images stored in the dataset have the same size of 1024x768. Brightness, Contrast, and subject finding are all very inconstant in the dataset. The dataset used in this research for recognition of the onion crop growth stage is shown in “Fig. 7”.

The RGB images are processed to recognize the onion crop growth stage. Computer Vision problems tend to be difficult to resolve with an incredible improvement of deep learning. Neural Networks (NN) are attempting to learn profoundly complex functions as much as possible, like image recognition or image object detection.



Mouse: (x: 234, y: 81)

NDVI: 0.78 - Onion Crop is very Healthy

Fig. 6. Computed NDVI.

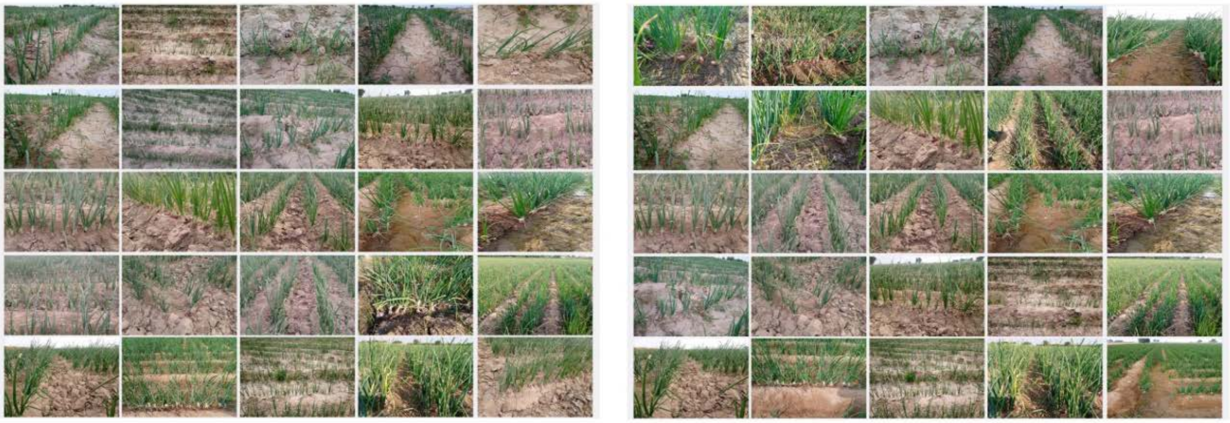


Fig. 7. Dataset of Different Growth Stages of Onion Crop.

It is one of the motives of the NN. We have a cluster of pixel values, and from that point; we might want to sort out what is in the image, so this is an unpredictable issue. We are reusing previously successful architecture by decreasing the required time for selecting alternate neural hidden layers, convolution layers, and other configuration parameters, for example, learning rate. We used java deep learning to train our system that system is capable to recognize the onion crop growth stage. For use on distributed GPUs & CPUs, Deep Learning for Java (DL4J) fetches Artificial Intelligence (AI) to business environments. By creating a java application, the methodology was established. The execution was GPU defined. All trials were done on an HP Elite Book AMD PRO A10-8700B R6, 10 Compute Cores 4 CPU + 6 GPU of 1.8 GHz, 12 GB of RAM. All research trials were carried out with 80% of the data-set for training while 15% of the dataset for testing the leftover 5% is for validation.

Now we train our system with java DNN because DNNs capability is to achieve record-breaking accuracy. The “Fig. 8” shows the feature extraction with help of the convolution layer. VGG-16 is capable to predict 1000 classes of images, while we require only 4 classes that are Initial Stage of Crop, Middle Stage of Crop, More than Middle Stage of Crop, and Final Stage of Crop. We have slightly modified this model to results in only four classes instead of 1000. The “Fig. 8” shows the feature extraction from images by inserting some convolutions and pooling layers that are utilized to train a big neural network with FC / hidden and Softmax layer to recognize the output from the image. A batch size of 16 & 3 epochs we are using. 1 epoch is a complete traversal throughout data and one loop is one forward and one backward propagation on batch size (16 images). This model trains with small strides of 16 images and each time get smarter and more intelligent. As we know every Machine Learning (ML) [20, 21] issue begins with the data. For the performance of the system, the quantity and nature of the data are very crucial and most of the time; it needs excessive deal exertions and resources.

Testing accuracy is a prediction that demonstrates the precision and accuracy of any selected deep learning model. The outcome of the testing and training model is shown below. “Fig. 9(a)” shows the accuracy with batch size 16 & “Fig. 9(b)” shows the accuracy with batch size 32. Using equation 3, the accuracy of the model computed. The model provides an accuracy of 96.10% for batch size 16 and 93.80% for batch size 32.

1) Accuracy: The important metric for the results of Deep Learning classifiers, as stated in equation (3). It’s the sum of true positive and true negative divided by the total values.

$$Accuracy = \frac{TPos+TNeg}{TPos+FPos+TNeg+FNeg} \quad (3)$$

2) Precision: To provide the relationship between the TPos estimated values and total positive estimated values as denoted in equation (4).

$$Precision = \frac{TPos}{TPos+FPos} \quad (4)$$

3) Recall: is the segment between the true positive values of prediction and the sum of probable TPos & FNeg values as shown in equation (5).

$$Recall = \frac{TPos}{TPos+FNeg} \quad (5)$$

4) F1-score: As denoted in equation (6), F1-score is a total degree of correctness that chains the precision and recall. F1-score is the twice of the fraction between the multiplication to the sum of recall and precision metrics.

$$F1 - Score = \ 2\,X \frac{Precision\ X\ Recall}{Precision+\ Recall} \quad (6)$$

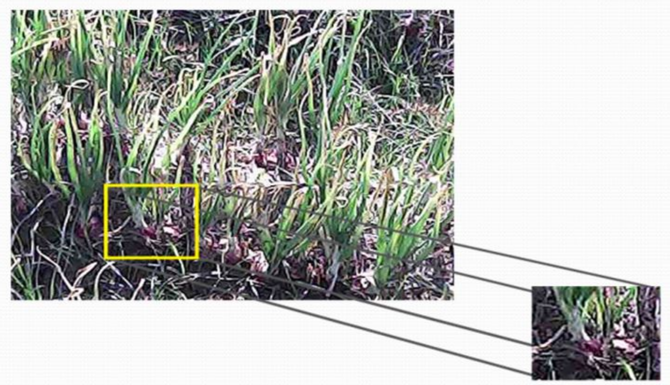

Fig. 8. Feature Extraction.

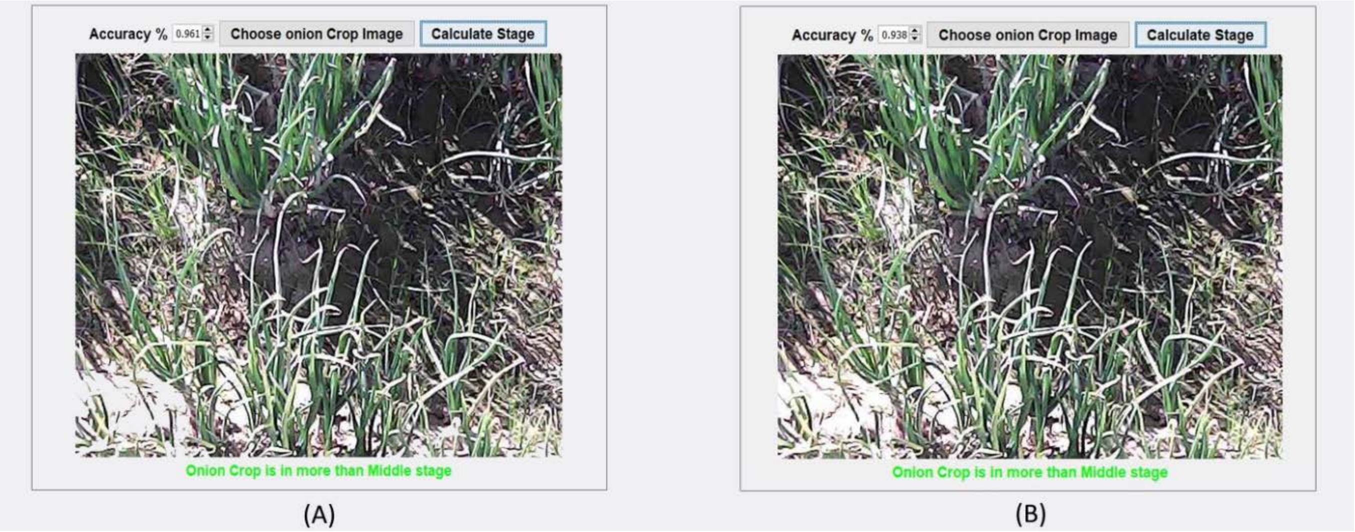

(A) Accuracy % 0.961

Onion Crop is in more than Middle stage

(B) Accuracy % 0.938

Onion Crop is in more than Middle stage

Fig. 9. Results of Onion Stage Recognition.

Table I gives the information about the performance of the model in terms of accuracy, precision, recall, and F1-scores respectively.

TABLE I. PERFORMANCE OF THE MODEL

Batch Size	**Accuracy**	**Precision**	**Recall**	**F1-Score**
16	96.10%	98.31%	98.05%	96.88%
32	93.80%	97.64%	96.93%	98.06%

VGG-16 has a total number of 138 million parameters. The significant point is that all convolutional kernels are of fixed size 3 X 3 and max-pool kernels are of size 2 X 2 with a stride of two. VGG-16 [22] has a fixed size of convolutions that’s why it takes less training time & predicts high accuracy.

V. CONCLUSION

A full imaging system has been established to get NDVI & Growth Stage information of the onion crop using an Unmanned Aerial Vehicle. A pair of cameras is used, one of both has been modified to capture NIR images and the other captures the RGB images. If images taken are not corrected, then so image sharpening techniques have been used to clarify the image and we have got accurate results. In upcoming years, it is probably expected to use a fixed-wing aircraft in place of a UAV to cover the large areas of the crop fields. Also, another camera could be used to capture red edge radiation and calculate the Normalized Difference Red Edge (NDRE). Different outcomes are achieved as shown in Table I, due to variation of some parameters. From the present research, the interpretations accomplished verified that the recommended method is capable and can be more applied to the multi-step on the estimate of a various group of disease factors of the onion crop.

ACKNOWLEDGMENT

We would like to thank the Mehran University of Engineering and Technology, Jamshoro, Pakistan, for providing us the necessary assets to conduct this research.

Combined Non-parametric and Parametric Classification Method Depending on Normality of PDF of Training Samples

Kohei Arai[1]
Faculty of Science and Engineering
Saga University, Saga City
Japan

***Abstract*—Classification method with combined nonparametric and parametric classifications which depends on the normality of Probability Density Function of training samples is proposed. The proposed classification method is also based on spatial information for high spatial resolution of satellite based optical sensor images is proposed. Also, a classification method which takes into account not only spectral but also spatial features for LANDSAT-4 and 5 Thematic Mapper (TM) data is proposed. Treatment of the spatial-spectral variability existing within a region is more important for such high spatial resolution of satellite imagery data. Standard deviations in small cells, such as 2x2, 3x3 and 4x4 pixels, were used as measures to represent the spatial-spectral variabilities. This information can be used together with conventional spectral features in a unified way, for the traditional classifier such as the pixelwise Maximum Likelihood Decision Rule (MLHDR). The classification performance of new clear cuts and alpine meadows which are very close in spectral space characteristics and difficult to distinguish them by conventional methods are focused. Through experiments, it is found that there is a substantial improvement in overall classification accuracy for TM forestry data. The Probability of Correct Classification (PCC) for the new clear cuts and the alpine meadows classes rose by 7% to 97% correct. The confusion between alpine meadows and new clear cuts was reduced from 9% to 3%.**

Keywords—Spectral information; spatial information; maximum likelihood decision rule; satellite image; image classification; classification performance; instantaneous field of view

I. Introduction

Maximum Likelihood Decision Rule-based classification method: MLHDR is widely used for satellite imagery data classification. There are some assumptions of the MLHDR, such as (1) there is no correlation among the pixels, (2) Probability Density Function: PDF of the training samples is normal distribution, and so on. These assumptions, however, are not always true. There are pixel-to-pixel correlations and spatial information which can be extracted from the satellite imagery data and can be used for image classification are followed by non-normal distribution. The proposed image classification method uses not only spectral but also spatial information and allows classification with non-normal distribution of PDF of the training samples.

Spatial resolution of spaceborne based optical sensors is improved remarkably. Classification performance is getting down because the variances of the specified class categories are getting large in accordance with spatial resolution which results in increasing overlapped areas among the class categories in the feature space for classification. It might be possible to improve classification performance by including spatial information into classification (Spatial information is getting large in accordance with spatial resolution).

Due to the increased spatial resolution of TM (30m compared with 80m for Multi Spectral Scanner: MSS), the number of ground cover spectral classes which are included in the Instantaneous Field of View (IFOV), decreases comparatively. This implies that spatial spectral variability for TM data increases in comparison to MSS. With the increase of the number of spectral bands and quantization bits of Landsat Thematic Mapper: TM (30 m of Instantaneous Field of View: IFOV (spatial resolution) of optical sensor), the discrimination ability or classification accuracy of the surface observation object improved [1], [2], [3]. However, improvement in spatial resolution does not always have a favorable effect on classification accuracy. The spatial frequency components of the object to be observed are widely distributed. The spatial frequency components are integrated with an area corresponding to the spatial resolution and sampled to obtain image data. At this time, the variance of the data increases as the spatial resolution increases.

Therefore, with the improvement of spatial resolution, the class variance in the feature space increases, and the classification accuracy tends to deteriorate [4]. Each institution has proposed a method that can cope with this [5]-[14], but here the author proposes a method that also uses the spatial information that has been increased together with the spectral information as the spatial resolution improves.

Spatial information can be roughly divided into (1) Context and (2) Texture, both of which use feature values defined within a relatively large window area. This is because the size of the feature quantity depends on the size of the window area, and a large window is required for the spatial resolution of the MSS. However, in the TM image, the spatial information is increased, so that even a small window is effective, and the physical meaning of the variation or difference in the spectral information between the surrounding pixels and the immediate pixel is clear. Furthermore, the definition of spatial information that has already been proposed and its application to classification methods are often complex, and require a lot of processing time.

Based on the above, this paper defines the standard deviation of pixel values in a small window (cell consisting of several pixels) as spatial information, adds it to the dimension of the spectral information in the feature space, and uses the maximum likelihood classification. The author proposes a method to do it. Although the standard deviation within this cell was proposed by Strahler et al [15], the basis for using the standard deviation was not clear [16], and the consideration of the optimal cell size, the probability density function, its normality, etc., was lacking [17]. In this paper, the author clarifies these and mention the effect and practicality of this method based on statistical features [18].

In the following section, related research works and research background including motivation of the research are described. Then, the proposed context classification method is described followed by experimental method together with experimental results. After that concluding remarks and some discussions are described.

II. Related Research Works

Classification by re-estimating statistical parameters based on auto-regressive model is proposed for purification of training samples [19]. Meanwhile, multi-temporal texture analysis in TM classification is proposed for high spatial resolution of optical sensor images [20]. On the other hand, Maximum Likelihood (MLH) TM classification taking into account pixel-to-pixel correlation is proposed [21].

Supervised TM classification with a purification of training samples is proposed [22] together with TM classification using local spectral variability is proposed [23]. A classification method with spatial spectral variability is also proposed [24] together with TM classification using local spectral variability [25].

Application of inversion theory for image analysis and classification is proposed [26]. Meanwhile, polarimetric SAR image classification with maximum curvature of the trajectory in eigen space domain on the polarization signature is proposed [27]. On the other hand, a hybrid supervised classification method for multi-dimensional images using color and textural features is proposed [28].

Polarimetric SAR image classification with high frequency component derived from wavelet multi resolution analysis: MRA is proposed [29]. Comparative study of polarimetric SAR classification methods including proposed method with maximum curvature of trajectory of backscattering cross section in ellipticity and orientation angle space is conducted and well reported [30].

Comparative study on discrimination methods for identifying dangerous red tide species based on wavelet utilized classification methods is conducted [31]. On the other hand, multi spectral image classification method with selection of independent spectral features through correlation analysis is proposed [32]. Image retrieval and classification method based on Euclidian distance between normalized features including wavelet descriptor is proposed [33].

Image classification considering probability density function based on Simplified beta distribution is proposed and evaluated its performance [34]. Meanwhile, maximum likelihood classification based on classified result of boundary mixed pixels for high spatial resolution of satellite images is proposed [35]. Also, context classification based on mixing ratio estimation by means of inversion theory is proposed [36]. Optimum spatial resolution of satellite-based optical sensors for Maximizing Classification: MLH performance is discussed [37].

III. Research Background

A. Problems in Classifying High Spatial Decomposition Images

When the class defined for the Multi Spectral Scanner: MSS (80 m of IFOV of optical sensor onboard the same satellite of Landsat) image is directly applied to the TM image, for example, if the same training area is set for both data obtained by observing the same object at the same time, the TM image has a larger class variance. This is due to the high radial and spatial resolution of TM. Both data can be obtained by sampling and quantizing the observation object that is continuous both spatially and radiometrically. However, when the sampling frequency and the number of quantization bits increase, the variance of the observation value increases.

However, the class variance also increases, leading to a decrease in the degree of separation between classes, and as a result, the classification accuracy decreases. On the other hand, the spatial information included in the image increases as the sampling frequency and the number of quantization bits increase. Therefore, an improvement in accuracy can be expected by considering spatial information in the classification of high-resolution images.

B. Classification Method in Concern

Image classification methods can be divided into the following four categories.

1) Supervised / Unsupervised.

2) Use / do not use spatial information.

3) Assuming probability density function (parametric) / not assuming (non-parametric).

4) Image unit (pixel-wise) / cell unit (cell-wise).

In this paper, the author examined the supervised maximum likelihood method per plane element which was effective for Landsat MSS data for the following reasons.

1) Unsupervised classification is difficult to interpret the physical meaning of the class after classification, and is suitable as a preliminary classification. However, correspondence with classes according to purpose of use such as wheat fields, paddy fields, soybean fields in agricultural areas is difficult.

2) Since the radiometric resolution of TM is improved compared to MSS, the spectrally homogeneous spatial region is narrowed, and cell-based classification is not effective.

3) Nonparametric methods generally require more computation time and storage capacity than parametric methods.

On the other hand, when applying the maximum likelihood method using only the spectrum information per plane element to the TM image, the following points need to be considered.

1) Definition of spatial information and its application to classification methods.

2) Multidimensional normality of probability density function of observation vector.

3) Furthermore, surface element correlation in spectrally homogeneous regions.

In this paper, especially for (1), the author proposes a method that defines the standard deviation in the cell as spatial information and uses it as one dimension of the feature space.

IV. Proposed Method

A. Process Flow of the Proposed Classification Method

The proposed method is based on MLHDR which is based on multi variate normal distribution of probability density function [16] which is expressed with equation (1) and (2).

$$D_{ij} = \int_{-\infty}^{\infty} log\left\{\frac{p(x|w_j)}{p(x|w_i)}\right\}\{p(x|w_i) - p(x|w_j)\}dx \qquad (1)$$

$$p(x|w_i) = \frac{1}{(2\pi)^{p/2}|\Sigma_i|^{1/2}} exp\left\{-\frac{1}{2}(x-\mu_i)^t|\Sigma_i|^{-1}(x-\mu_i)\right\} \qquad (2)$$

where *Dij* denote separability between class *i* and *j* and *p* is the number of dimensions, *Σi* is the covariance matrix of the class, x is the observation vector, *μi* is the mean vector of class *i*, and *t*, -1 are the transposed matrix and the inverse matrix, respectively.

The degree of separation between classes is tested using only spectral information, and the following method is applied only to classes that do not show a satisfactory value (for example, divergence of 500 or more). That is, by selecting the spectral band exhibiting the largest variance and examining the spatial frequency components of the class, the optimal cell size is determined, and the standard deviation within the cell is calculated by moving the cell by one pixel. The leverage result is added to the spectrum space as a new dimension (this is called an integrated feature space). After that, the multidimensional normality in the integrated feature space is tested again to confirm the degree of separation, and then the result of classification is applied by applying the maximum likelihood classification to this result, and the final classification image is obtained.

Fig. 1 shows process flow of the proposed classification method.

B. Standard Deviation in the Cell in Concern as a Texture Information

The variance of pixel values in a cell is essentially equal to "contrast" *c*, one of the well-known texture measures, with a constant multiple.

Fig. 1. Flowchart for the Proposed Classifier.

$$\sigma_c^2 = \sum_i \sum_j (x_{ij} - \bar{x})^2/N \qquad (3)$$

$$c = \sum_{i,j} \sum_{k,l} (x_{ij} - x_{kl})^2/N_p \qquad (4)$$

where *i* and *j* are the pixels and line numbers, *N* is the number of pixels in the cell, *Nρ* is the number of pixel pairs in the cell, x_{ij} is the value at pixel position *ij*, and} {is the average value in the cell. is there.

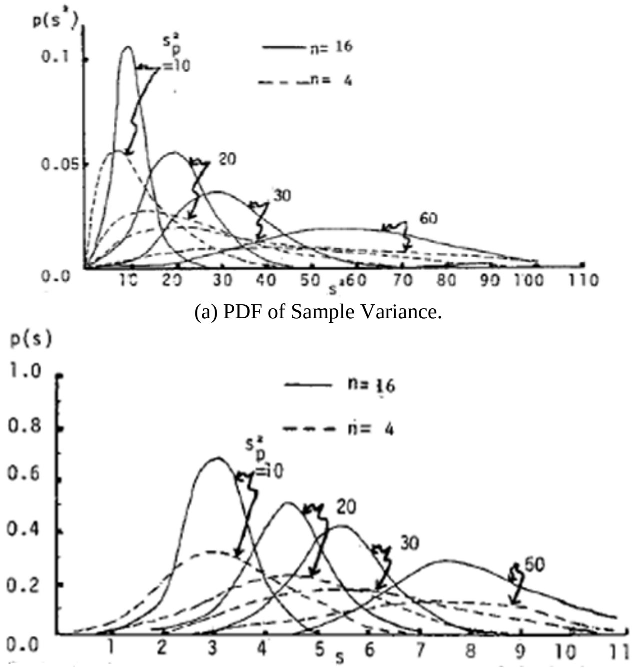
According to Percival's theorem, the following equation holds between the power spectrum and $\sigma_c{}^2$.

$$\int_{-\infty}^{\infty} |f(x)|^2 dx = \int_{-\infty}^{\infty} |F(s)|^2 ds = \sigma_c^2 + \bar{\bar{x}}^2 \qquad (5)$$

where, *f (x)* is a value at a pixel position *x*, and *F(s)* is a function obtained by performing Fourier transform in a frequency domain. Eq. (5) shows that the variance of the pixel values in the cell is closely related to the power spectrum and the contrast as texture information.

C. Probability Density Function of Standard Deviation and Variance in the Cell in Concern

Assuming now that the observed value population follows the multidimensional normal distribution, the probability density function of the sample variance and sample standard deviation in the cell is obtained, and each normality is tested. Fig. 2 shows an example of calculating each probability density function (see Reference [17]) for a population variance S_p^2 of 10 to 60, using the cell size *n* as a parameter. Here, assuming a square cell, *n* = 4 (2 × 2) and 16 (4 × 4) were selected as parameters.



(a) PDF of Sample Variance.

(b) PDF of Sample Standard Deviation.

Fig. 2. Comparison between Probability Density Functions of Sample Standard Deviation s and Variance s^2 where n: Sample Size (Cell Size), $s_p{}^2$: the Population Variance.

The normality improves as this approach infinity. From the viewpoint of normality, it is known that the standard deviation (square root transformation) is superior to the variance, and that the cubic root transformation is optimal. (On the other hand, since the tendency tends to be the opposite from the viewpoint of spatial information, if normality is satisfied, it is better to use the flat-root transformation and the variance itself than the cubic root transformation. Standard deviation was used, and the normality of a single variable was judged to be satisfied if the χ^2 value was less than 5 in the χ^2 test.

V. Experiment

A. Data used

The data used for analysis is TM data acquired by Landsat 5 on August 15, 1984, and an image processing system maintained at the Canada Center for Remote Sensing: CCRS; radiometric and geometric corrected, Geocoded data by MOSAICS system. Geocoded Data is proposed for the first time in Canada and has pixel intervals determined so that it can be easily combined with not only heterogeneous sensor data (aircraft, satellites, etc.) but also topographic maps and administrative information. This is the corrected map reference data.

The analysis area is a forested area at Spruce-Balsam in Cranbrook, British Columbia, Canada. These include logging areas, alpine meadows, rocks, rivers, small lakes, etc., in addition to forests. Fig. 3 shows a forest polygon overlay (dark blue) on the Landsat-5 TM data. Spruce-Balsam polygons have been extracted and used as a mask to cluster the TM data. The inhomogeneity of the polygons is demonstrated by the multiple classes (red, yellow, white, blue) found inside the polygons (arrow).

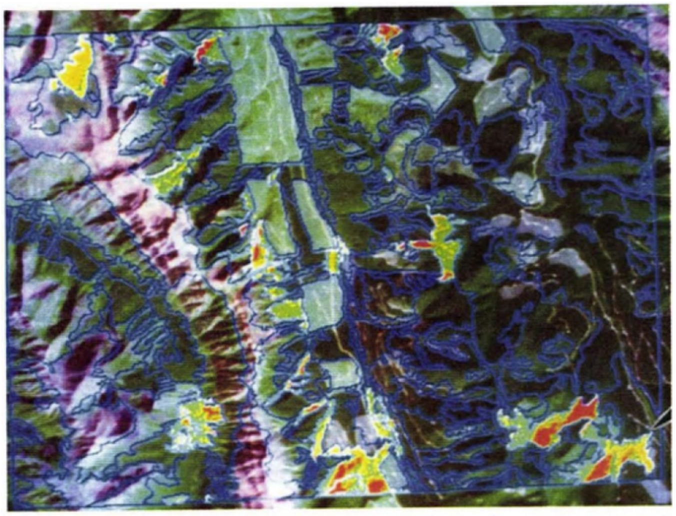


Fig. 3. Forest Polygon Overlay (Dark Blue) on the Landsat-5 TM Data. Spruce-Balsam Polygons have been Extracted and used as a Mask to Cluster the TM Data.

Logging areas are further divided into two types: those that are less than 5 years after logging and those that are 5 to 40 years later. The former is called the new logging area, and the latter is called the old logging area. The former consists of topsoil, grassland, stumps, clumps of cut down trees, roads, young trees with low height, etc. The latter consists of young trees with relatively high heights, grassland, roads, etc. Therefore, four classes were set up here: (1) new logging area, (2) old logging area, (3) alpine grassland and (4) forest.

B. Separability between Classes

From the components and their ratios, the spectral characteristics of the new cutting area and the alpine meadows are expected to be very close. Fig. 4(a) shows the class distribution in the feature space of TM bands 4 and 5 (TM-9, 5), confirming the above prediction. Here, the size of the training field of each class is 956, 270, 435, and 1377 pixels for the new logging area, old logging area, alpine meadows, and forests, respectively.

The contour in the figure corresponds to twice the standard deviation of the two-dimensional normal distribution. From this figure, it can be seen that the freshly cut area and the alpine meadows are short in distance and the dispersion is relatively large, so the degree of separation is low.

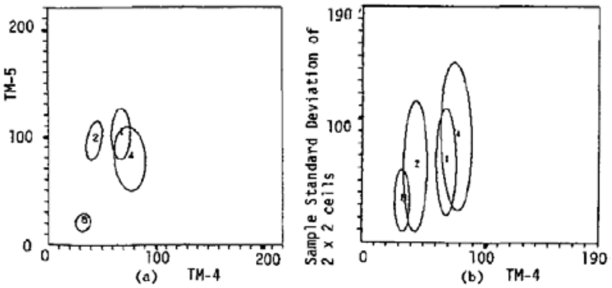

Fig. 4. An Example of the Scatterogram showing the difficulty of Distinction between New Clear Cuts and Alpine Meadows Classes. (a) is for the Original Data Set, (b) is the Scatterogram between TM-4 and Sample Standard Deviation of 2 x 2 Cells for TM-4. The Classes are: 1) New Clear cuts, 2) Old Clear Cuts, 3) Alpine Meadows and 4) Forest.

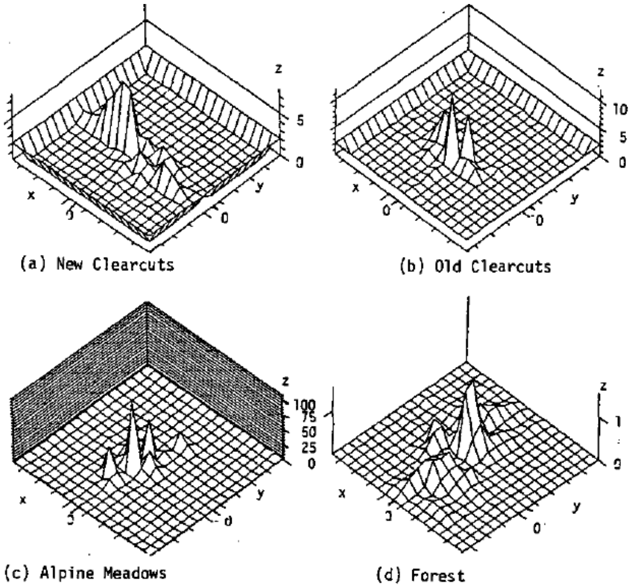
Fig. 4(b) shows the distribution of each class in the space between the TM-4 and the standard deviation of the pixel values in the 2x2 cell of the TM-4 image. It suggests that the degree could be improved.

Fig. 5 shows a typical 16 × 16 pixels window in the training field of each class, and the power spectrum is displayed by removing the DC component in the TM-4 window from each pixel value is there.

The display method makes it easy to see the difference in spectrum between each class by subtracting the D.C. component of the dominant power spectrum. Table I shows the average and standard deviation of TM-4 and power spectrum.

From the above, it can be seen that it is difficult to separate classes between the newly harvested area and the alpine meadows using only spectral information, but it is possible to improve the degree of separation by adding spatial information to this information. Here, the standard deviation is obtained by normalizing the minimum / maximum value in an image composed of 512 × 512 pixels to data of 0 to 255 (8 bits).



(a) New Clearcuts

(b) Old Clearcuts

(c) Alpine Meadows

(d) Forest

Fig. 5. Power Spectrum of the Typical Sample Area for Each Class, Subtracted Mean Value from Original Image (TM-4 of B.C. forest). Spatial Variability for the Class of Alpine Meadows is Larger than those for the Other Classes. The x and y Axes Correspond to the Wave Numbers for the Horizontal and Vertical Axes in the Frequency Domain and the Z Axis Corresponds to the Power Spectrum of the Image with the Mean Value Subtracted from the Original Image.

TABLE I. MEAN AND STANDARD DEVIATION (S.D.) OF THE EXTRACTED SUB-IMAGE FOR EACH CLASS, MEAN AND STANDARD DEVIATION OF THE POWER SPECTRUM (P.S.) OF THE IMAGE WITH MEAN VALUE SUBTRACTED FOR TM-4 IN THE 16X16 WINDOW

Class	TM-4		PS	
	Mean	SD	Mean	SD
New Clear-cut	66.15	22.2	0.26	2.37
Old Clear-cut	39.8	22.42	0.26	2.95
Alpine Meadow	60.52	58.7	1.79	25.04
Forest	27.48	12.06	0.08	0.48

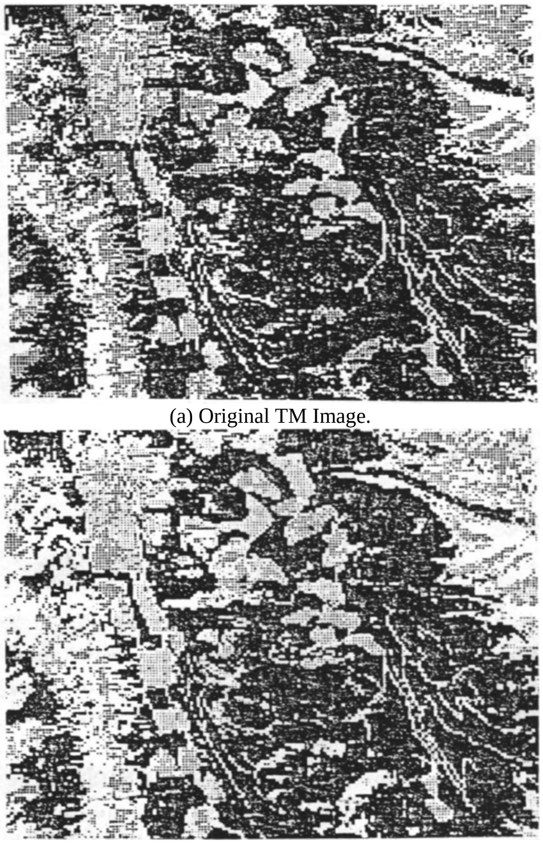
C. Improvement of Percent Correct Classification: PCC

Fig. 6 shows the case where only the spectral information of TM-1 to TM-5 and 7 is used, and the case where the information indicating the standardized standard deviation within 2 × 2 cells for TM-4 is added 3 shows a maximum likelihood classification image.

Table II shows the discrimination efficiency matrices for both data sets. The average discrimination efficiency can be improved by about 3.7% from 94.81% to 9828% by adding the information of the standard deviation, and the misclassification rate between the new cutting area and alpine meadows can be reduced from 9% to 3% understood.

When spectral information was limited to TM-4 and 5, the discrimination efficiency * for newly felled areas and alpine meadows was 65.3% and 87.1%. When the standard deviation was added, it became 83.2% and 91.4%, and it was found that the discrimination efficiency of 27.4% and 4.9% was improved.

The discrimination efficiency is an element of the discrimination efficiency matrix (confusion matrix), and is a percentage ratio of the pixels in the set training region and the region set for the discrimination efficiency evaluation in each class.



(a) Original TM Image.

(b) Combined Image of Original TM and of Standard Deviation of 4x4 Pixels Windows of TM.

Fig. 6. Examples of the Classified Images with Original and Combined Data Sets. Clear Cuts Areas which are Located at Upper Left around the Center of this Image Tend to Classify to the Alpine Meadows Class for the Original Data Set, but the Classified Image with the Combined Data Set Shows the Improvement on the Distinction between Alpine Meadows and New Clear Cuts.

TABLE II. CONFUSION MATRICES FOR THE ORIGINAL AND THE COMBINED DATA SETS

(A) CONFUSION MATRIX OF ORIGINAL TM IMAGE (PCC=94.81%)

Class	New Clear-cut	Old Clear-cut	Alpine Meadow	Forest
New Clear-cut	92.98	2.22	8.82	0
Old Clear-cut	0	95.56	0	0
Alpine Meadow	4.97	2.22	90.69	0
Forest	0	0	0	100
Unassigned	2.05	0	0.49	0

(B) COMBINED DATA OF ORIGINAL TM AND STANDARD DEVIATION OF 4X4 PIXELS OF TM IMAGE (PCC=98.28%)

Class	New Clear-cut	Old Clear-cut	Alpine Meadow	Forest
New Clear-cut	96.06	0	2.94	0
Old Clear-cut	0	100	0	0
Alpine Meadow	3.42	0	97.06	0
Forest	0	0	0	100
Unassigned	0.51	0	0	0

D. Effect of Cell Size

The standard deviation within a cell increases with cell size. Therefore, if the region is limited to a region having the same spectrum, the discrimination efficiency of each class monotonically increases as shown by the solid line in Fig. 7. However, if a cell exists at the boundary between classes, the spatial information is not class specific. Therefore, the discrimination efficiency of the area within the range of the cell size from the boundary is affected by this.

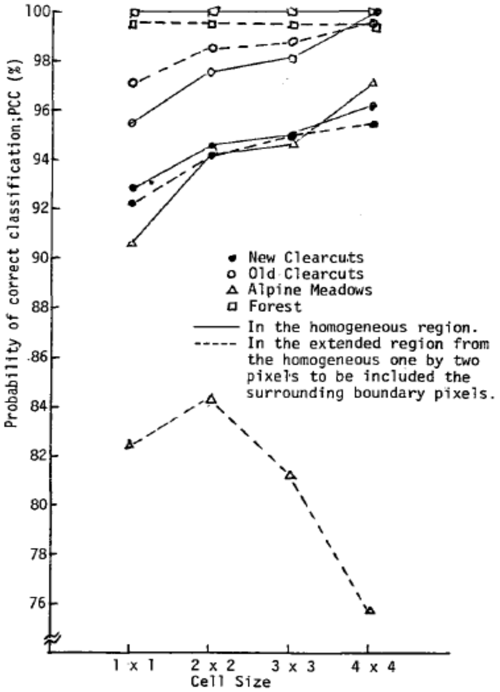


Fig. 7. Cell Size Effect on the Probability of Correct Classification.

This effect depends on the difference between the spatial information of adjacent class questions, the boundary shape, and the like, and can be reduced by reducing the cell size. If the area is set to include the boundary and the relationship between the cell size and the discrimination efficiency is determined, the result is as shown by the broken line in Fig. 6. By size, discrimination efficiency shows a peak. For this reason, a 2 × 2 cell size is set as the optimum value here, but the optimum cell size is generally determined based on the spatial frequency components of the class to be classified.

VI. CONCLUSION

The proposed method using the spectral information and the standard deviation of the pixel values in a small cell has the following features:

1) The spectral characteristics are very similar, and are effective for classes with different spatial information, respectively.

2) Unlike the other texture measures, the standard deviation of the pixel value in the cell is relatively close to a normal distribution, so that it can be simply used together with spectral information.

3) Therefore, compared with the classification method using other spatial information, it does not require complicated processing and is practical.

Also, the proposed image classification method allows classify images whose PDF is not followed by normal distribution because it supports nonparametric classification.

VII. FUTURE RESEARCH WORKS

The proposed method is adopted in the real earth observation satellite imagery data, and it is a future subject to realize a more usable classification method.

ACKNOWLEDGMENT

The author conducted this research at the Canada Center for Remote Sensing from 1985 to 1987 as a Canadian Government Scholarship Student (Postdoctoral Fellow) of the NSRC (Natural Science Research Council of Canada). The author would like to thank Dr. D. G. Goodenough, Dr. J. Iisaka, Dr. B. Guinden and their staff who participated in the discussion for distorting valuable suggestions. The author, also, would like to thank Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post-Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a counselor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 55 books and published 620 journal papers as well as 450 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. http://teagis.ip.is.saga-u.ac.jp/index.html

Online Training and Serious Games in Clinical Training in Nursing and Midwife Education

Galya Georgieva-Tsaneva[1]

Angel Kanchev University
Ruse, Bulgaria

***Abstract*—The article examines the application, methods, and trends in online training of health care and medical professionals in Bulgaria. Attention is paid to modern methods for the effective application of online training and the extent to which online training can replace traditional training. The article presents the results of a survey for online training conducted in April 2021 at universities in Bulgaria Health Care professional field, specialty Nurse and Midwife. The results of the survey can serve to improve online education in Bulgaria by including in it educational resources recommended by respondents. The creation of new web-based educational resources (video materials, serious games, virtual simulations, video presentations, webinars, etc.) can complement the traditional methods of training in the students in the Health Care professional field, specialties Nurse and Midwives in Bulgaria.**

***Keywords*—Health care; medical education; serious educational games; nurse; midwife; online training**

I. Introduction

In today's technological age, new diverse methods of online learning are increasingly being integrated into higher health care and medical education. the questions about which are the most effective methods for online training, which technologies would be most suitable for students of the specialties Midwife and Nurse (Health Care professional field) are to be studied. Online learning of students today is influenced by the development and application of modern communication information technologies in all spheres of life, by advances in medical sciences in the detection and treatment of diseases, and by the improvement of the quality of health services.

An important issue in online learning is the implementation of learning strategies based on classical real learning, modern online learning, and practical training, which in the field of training of medical professionals can not be completely replaced by online innovation. The assessment of online learning can be made based on the degree of satisfaction of the learner (from the learning objectives and content, format, and effectiveness of learning resources), the learning outcomes (assessment of knowledge and skills of learners), improving the effectiveness of learning (improvement of practical skills) and the real health results when working with patients (changes in the behavior of patients and improvement of their health indicators as a result of the practical skills of the learners).

Online learning [1, 2] is learning mediated by the World Wide Web, intranet, and multimedia computer applications. Central to online learning is the online learning resources used by students: illustrations, videos, medical images, virtual patients, and others. Medical and health care universities are looking for effective approaches to optimize online learning, which will become more widespread.

The purpose of this report is to give an idea of the online training of health care students in the academic year 2019/2020 and 2020/2021 (until April 2021) in higher universities in Bulgaria, professional field of Health Care, specialty Midwives, and Nurse. The results shown were obtained by conducting an online survey of students in these specialties at the following medical universities: Varna, Plovdiv, Sofia, Pleven, Stara Zagora in Bulgaria; University “Angel Kanchev” in Ruse, Southwestern University "Neofit Rilski" - Blagoevgrad, Burgas University “Asen Zlatarov” (these three universities are not medical, but are accredited to teach in Health Care professional field).

The results of the study provide an opportunity for practical planning of future online training of health care students at universities. The differences between the theoretical views on online learning and its practical results can be correctly assessed by surveying the opinions of the students involved in online learning.

The rest of the paper is summarized as follows: Literature survey is shown in Section II. The use of serious games in medical and health care education is presented in Section III. The survey results are shown in Section IV. The conclusion is presented in Section V.

II. Trends in the Entry of Online Training in Medical Education

Online medical and health care education uses the advances of information and communication technologies to transmit knowledge at a distance. In the field of medicine, teaching and acquiring practical professional skills and habits cannot be completely replaced by online learning. It can be used as complementary training, such as a lecture or demonstration complemented by an online lesson. The use of serious games in the form of quizzes for testing students' progress, the use of serious simulation games in order to consolidate theoretical knowledge and improve students' practical skills through training of real manipulations in an artificial environment is applicable. Digitized learning resources, digital libraries, and databases with learning resources are available on the web.

In Bulgaria from March 2020 to April 2021 (when the survey was conducted), in connection with the emerging epidemiological situation, much has been done to enter and improve the quality of online education in health care education. Online learning is integrated into the curricula and a blended learning strategy is created. Many digital repositories of e-learning materials are being set up around the world, some of which are peer-reviewed, where instructors or developers can submit materials for widespread use.

Study [3] of the Liaison Committee on Medical Education in the U.S. shows an increase in the use of educational software products in medical education, as well as an increase in the number of websites that use integrated online learning. There is an increase in the effectiveness of training [4] using web-based knowledge and an increase in consumer satisfaction with online learning.

Initiatives are being created [1] to create a digital repository for peer-reviewed electronic resources for public distribution.

It is proposed to create a mechanism for sharing quality resources for online learning between individual educational institutions and stimulating the work of teachers through peer review processes. Providing learning materials in various formats - using video, audio, other technologies, or software in the form of serious educational games [5] – these are tools that can make learning more interesting and also allow students to improve the quality of their learning.

As a professional, the health care and medical specialist must contribute to [6]:

- promoting healthy habits;
- carrying out disease prevention;
- treatment of patients;
- to work for the rehabilitation of the recovered patients;
- to conduct a constant process of learning everything new.

The main principles of medical and health care education are the acquisition of education leading to the first professional degree; clinical education, which is preparation for a general medical and health care practice or specialty and obligatory continuous, lifelong training of every higher specialist. According to [7] continuing medical education is a very important requirement for the development of medical professionals.

Internet technologies enable the distribution and use of digital content among many users simultaneously at any time and from anywhere in the world. For employed medical professionals [8], the ability to learn when they can or need information is highly desirable. The educational needs in the field of medicine are diverse: providing easy, fast, and timely access to textual content or photos; inclusion of serious games in the form of virtual reality systems, virtual learning techniques, and virtual patient care in health care and medical education.

Research reported in [9, 10] shows that effective learning can be achieved by combining traditional learning with distance learning.

There is a continuous growth in knowledge of the structure and function of the human body. In many areas of application, there is a simultaneous rapid growth of various innovative methods. Today, many factors in higher education make teaching and learning difficult. This includes a shorter hospital stay for critically ill patients and limited time for medical professionals to work with each patient. There is a shift from traditional practical medical actions to computer-based manipulations or images due to the modernization of technology.

According to [11] free access to medical education sites, online medical journals, textbooks, and the latest information on medical innovation, the use of serious games also encourages learning and research.

The development of clinical informatics [12] aims to improve patient care through the use of modern technologies and increase the efficiency of both patient care and safety.

E-learning began to be used about 20 years ago. From then until today, it has undergone significant development - from its original idea to the modern experience in an electronic or web-based application. E-learning enters all stages of education and then continues in the form of lifelong learning. At the beginning of the creation of the web, e-learning included a virtual learning environment (Virtual Learning Environment), expensive software, work plan, and tested. At this earlier stage of development, e-learning is oriented to the interests and goals of the educational institution.

The development of e-learning in the coming years is already oriented to the needs of the learners themselves, who become active participants in this bilateral process. Learners share ideas, offer solutions to problems, collectively use different sources, and can participate in the creation of new knowledge. In this way a learning community is already created, the aim is to support the interaction not only between the teacher and the students but also between the students themselves. According to [13] upgrading on the already acquired knowledge of the learners, stimulating creativity, creative thinking, spontaneous reaction, and working on breaking the traditional education by introducing an element of fun. The role of the teacher and the trainer is expanded and enriched, the qualitative characteristics of the education are put in the foreground, new methods for increasing the motivation of the students are sought.

The study, conducted in [14], aims to examine the extent to which online resources are used by medical graduates and ways to increase interest in them. The authors point out as a conclusion the need to integrate information technology into traditional education, change the curriculum, transition to structured computer training of medical students.

III. Serious Games as a Method for Effective Learning

Computer games, which, unlike games created for entertainment, serve to achieve certain useful goals, supporting the formation of professional knowledge, skills, and competencies, and are called serious games [15, 16]. Serious educational games differ from entertainment games mainly in the presence of pre-set pedagogical goals. According to [17], the serious game is “an interactive computer application, with or without a significant hardware component, that has a challenging goal, is fun to play with, incorporates some concept of scoring, and imparts in the user a skill, knowledge or attitude which can be applied in the real world”. Serious games are gradually becoming a popular modern development [18], due to the support they provide to educational processes, attracting and retaining attention to the learning material and provoking useful behavior in students. Along with the acquisition of knowledge, learners develop problem-solving skills, cooperation, communication, and interaction in a competitive environment, lead to improved creativity and strengthen their participation in the learning process.

Traditional lecture-based teaching [19] emphasizes the transmission of information and the use of memory to achieve educational effects. Serious learning games are attractive to their users because they are not based on the traditional teaching methods that are boring for learners today. Traditional learning is increasingly perceived by learners as ineffective and cannot hold their attention. The games confront students with a problem that engages their attention and interest and offer possible ways to explore the problem situation. In this way, students have the opportunity to upgrade their knowledge. Game design elements are designed to attract students' attention [20] and challenge them to solve problems.

Looking to the near future we can note the implementation of Gamification in education, which can be defined as a learning platform [21] that aims to give additional motivation to learners, provide feedback and use as incentive rewards (points, badges, boards for leaders, progress lanes, etc.). In gamification [22], the whole learning process becomes a game in order to motivate and interact students through game mechanics and game elements. Unlike gamification, game-based learning uses games only as part of the learning process. To the goals of gamification can be added the achievement of an attractive learning process, provided by performing fun activities, gaining a modern learning experience.

The authors of [19] in 2019 conducted a study of the use and impact of serious games scientific education, using mixed qualitative and quantitative data. The opinions of students and parents about the influence of serious educational games were studied. The obtained results show positive results on the motivation of students in the learning process.

Today, web technologies are influential factors in students' lives and learning. Interaction in online and offline media, which offer a modern educational environment, creates significant changes in students [23]. Online educational platforms play a key role in changing students' values, beliefs and behavior.

Modernization of technologies leads to mandatory integration of technology with education and educational systems need to be constantly changed and improved. This leads [24] to the emergence of new approaches to learning and teaching.

According to [25], any serious game must have the following characteristics: a method of communication between the person and the game; assessment by the number of correct answers; conflict (challenge); the ability of users to change the game (controllability); environment; history or fiction; interaction between users; immersion in the game; rules and goals of the game provided to the user.

In the training of health care and medical professionals, it is essential that students be able to enhance their practical skills through the use of games involving virtual simulations of real activities [26] performed on patients. Thus, the trial and error method has no negative consequences on the patients themselves.

Despite the entry of serious games into training [27], game developers do not pay enough attention to validating the effect of using serious games.

Works [28, 29] examined the barriers in web space and the accessibility of serious training games for students with visual impairments.

IV. Results of the Study on the Online Training and Serious Games in Clinical Training

A survey on the issues of online training education and serious games in clinical training in Bulgaria was conducted in April 2021 with students learning in the specialties nurses and midwives at health care and medical Universities in Bulgaria. Teachers' and students' views on virtual methods were surveyed using a survey created using the Google Forms application. The survey includes 486 respondents, health care students in Bulgaria. The online survey was conducted on a voluntary and anonymous basis. The survey was conducted among respondents from the Faculties of Public Health and Health Care of Universities in the Republic of Bulgaria, that train specialists in the professional field of Health Care, such as Ruse University “Angel Kanchev”, Southwestern University "Neofit Rilski" - Blagoevgrad, Burgas University “Asen Zlatarov”, Varna Medical University (and its branches in the country), Universities in Plovdiv, Sofia, Pleven, Stara Zagora. The questions in the survey are 15 in number.

Table I presents the characteristics of the respondents according to their training course. The survey was conducted among students who in April 2021 are studying in the 1st, 2nd, 3rd, and 4th year at higher universities in Bulgaria. The 1st and 3rd year students were the most active in filling in the questionnaire.

Regarding the degree of satisfaction of students with the online training conducted in the academic year 2019/2020 and 2020/2021, 51.4% believe that they like online training completely. 24.3% think that they are not satisfied enough and expected more, and 22.2% cannot give a clear assessment. According to other students who indicated an open answer, online learning cannot replace face-to-face learning (0.8%), 0.6% say they are satisfied with online learning but prefer to learn face-to-face. Several students point out the importance of attending the internship and exercises during the online training. Overall, 67.5% (238) of the students indicated that they preferred the present form of education to online learning.

TABLE I. COURSE OF TRAINING

Course	1	2	3	4
% (Number of participants)	32,9 % (160)	23% (112)	32,5% (158)	11,5% (56)

The study of what students liked the most in online learning is presented in Fig. 1. The question allows you to choose several answers. According to 294 (60.5%) respondents, the biggest advantage of online learning is the created opportunity for Accessibility to learning materials (platforms, online resources, presentations, video materials, etc.). This shows the desire of students to use web educational resources. This opportunity can be for them provided and through real training and lead to an increase in its quality. The opportunity to learn from home is essential for 246 participants, which is more than half of the surveyed students. Respondents point to the advantages of greater independence and flexibility in learning and the ability to use modern technologies.

The study on the shortcomings of online learning according to students is presented in Fig. 2. The question allows you to choose several answers. According to the respondents, the biggest shortcomings are: the lack of direct contact with their teachers (according to 61.7%); the lack of a real hospital environment in which to learn skills for manipulations (according to 56.8%); in training in higher health care specialties, real training is necessary and very important (according to 53.5%); the lack of daily direct contact with fellow students is essential for 51% of respondents.

Fig. 3 shows the degree of response of the respective university in its transition to online learning. According to 48.6% of the respondents, their university immediately switched to online education, while 44% of the students stated that the transition was gradual. 7% of students say that in their higher university there was a distance form of education even before the pandemic.

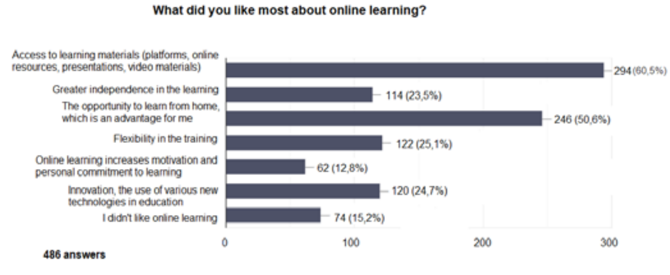

Fig. 1. Exploring the Benefits of Online Learning.

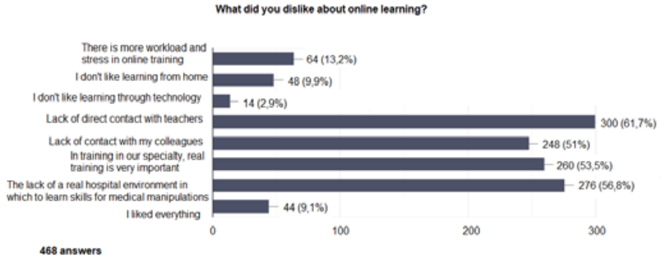

Fig. 2. The Studying the Shortcomings of Online Learning.

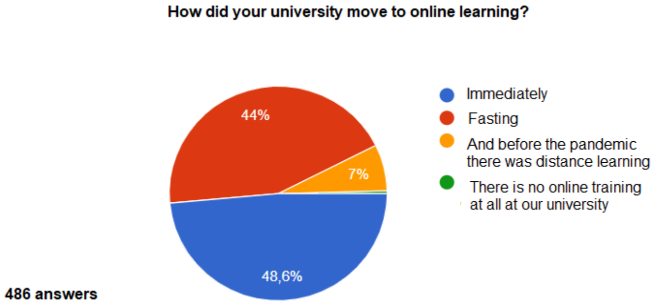

Fig. 3. Studying the Speed of the Transition to Online Learning.

Fig. 4 presents the means of communication through which students connected with their teachers during online learning. According to respondents, the most commonly used means of exchanging information is e-mail (63%), followed by Google Classroom (37%), Viber (74%), and Phone (35.8%).

Fig. 5 shows the degree to which students coped during the online training in mastering the material and practical health care manipulations. 41.6% of the respondents state that they have not encountered problems with online learning, 36.6% declared that they had difficulties at the beginning of online training, which they then coped with, according to 11.1% of students online learning creates difficulties in mastering the health care procedures that require real clinical practice.

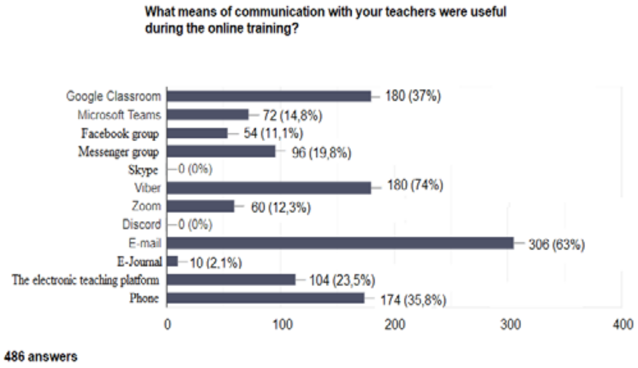

Fig. 4. Means of Communication.

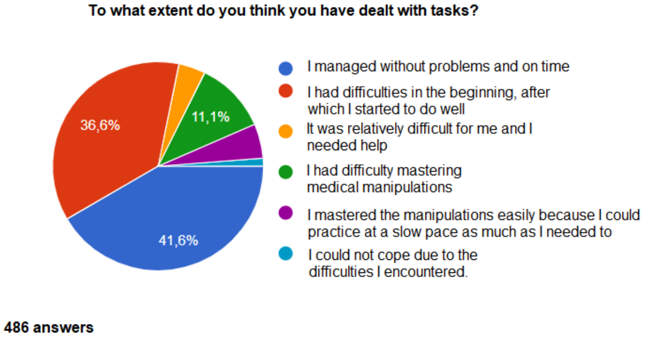

Fig. 5. Degree of Coping in Online Learning.

Fig. 6 presents the useful learning tools that can be used in future online learning according to the respondents. The largest part (68.7%) of the surveyed students believe that the video materials on the respective medical disciplines will be of great help to them in the online training. According to 56.4% of the respondents, video presentations prepared on the lecture material will be of great benefit in their training. 44.4% of the respondents indicate the websites with educational resources uploaded on them as a useful tool in mastering the study material. 24.28% of respondents point to serious games as a modern learning tool.

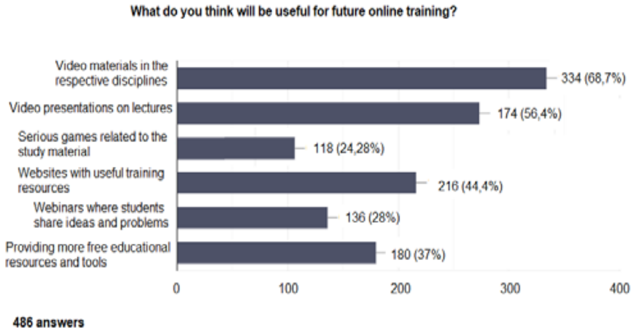

Fig. 6. Useful Tools for Future Online Training.

Regarding the device with which they conducted their training, 65% (316 participants) indicated a telephone, 90.1% (438 participants) used a laptop, 9.9% (48 participants) used a computer, 9.1% (44 participants) used a tablet. The questionnaire allows you to choose more than 1 answer to this question.

According to the survey, 17.3% of students report that they have had problems with the Internet connection, 63% believe that sometimes the connection has been interrupted, and 19.8% of the respondents, the connection has always been good.

V. Conclusion

In today's technological society, the inclusion of innovative interactive digital tools in the process of training in medical specialties is imperative and undoubtedly contributes to improving the quality of teaching. In periods requiring online learning as the only method, it is necessary to use the Internet effectively with all its advantages: access to digitized online learning resources, creation and use of appropriate videos, presentations, webinars, serious educational games, video simulations, and much more.

The results of the survey conducted among students trained in specialties Midwife and Nurse show that higher universities in Bulgaria have done well in the periods of compulsory online training in 2020 and 2021 (until April, when the survey was conducted) and have offered effective, quality training to their students.

The results of the survey can be a tool for assessing and improving the quality of online learning and serve as a corrective in the next periods of online learning in higher universities in Bulgaria.

Future plans and recommendations for the future development of the education of health care and medical students. One of the most important conclusions made as a result of the research is that the real education of health care students cannot be replaced by sufficient quality online education. This shows that the training program for health care students must be carefully considered and include all opportunities for real involvement of students in clinical practice, where they can gain real experience in working with patients.

The results of the study also indicate the positive aspects of the introduction of technology in the education of Health Care students and the application of online learning. The creation of new web-based educational resources (video materials, serious games, virtual simulations, video presentations, webinars, etc.) can complement traditional teaching methods and make higher education in medicine in Bulgaria high quality, modern, effective and attractive for future health care and medical professionals.

***Abstract*—Today, we live in the Big Data age. Social networks, online shopping, mobile data are main sources generating huge text data by users. This "text data" will provide companies with useful insight on how customers view their brand and encourage them to make business strategies actively in order to maintain their trade. Hence, it is essential for the enterprises to analyse the sentiments of social media big data to make predictions. Because of the variety and existence of data, the study of sentiment on broad data has become difficult. However, it includes open-source Big Data platforms and machine learning techniques to process large text information in real-time. The advancement in fields including Big Data and Deep Learning technology has influenced and overcome the traditional restrictions of distributed computing. The primary aim is to perform sentiment analysis on the pipelined architecture of Apache Spark ML to speed upward the computations and improve machine efficiency in different environments. Therefore, the Hybrid CNN-SVM model is designed and developed. Here, CNN is pipeline with SVM for sentiment feature extraction and classification in ML to improve the accuracy. It is more flexible, fast and scalable. In addition, Naive Bayes, Support Vector Machines (SVM), Random Forest, Logistic Regression classifiers have been used to measure the efficiency of the proposed system on multi-node environment. The experimental results demonstrate that in terms of different evaluation metrics, the hybrid sentiment analysis model outperforms the conventional models. The proposed method makes it convenient for effective handling of big sentiment datasets. It would be more beneficial for corporations, government and individuals to improve their great value.**

Keywords—Big data; sentiment analysis; machine learning; apache spark; ML pipeline

I. Introduction

The success of Smart devices' makes people's daily lives more focused to mobile services. People use mobile devices to collect information about firms, products, deals and recommendations. Online consumer reviews for a wide variety of goods and services are widely accessible and evaluating the sentiment in customer feedback has become greatly useful for business, where companies can monitor positive and negative feedback about the brand which allow themselves to assess its over-all success and can also perform a major role in evaluating sales and optimizing business marketing approaches. Reviews from customers are one of the massive amounts of information. Since it includes millions of reviews from different websites, and the number of reviews is rising every day. This vast amount of data that increases every moment is known as big data, which involves modern technologies and architectures to capture and evaluate process to derive value from it [1]. Big data analytics is essential for the purposes of business and society. Big data requires strong machine learning methods, and environments to accurately analyses the data. A large amount of data cannot be processed by conventional methods, so to handle the huge amount of information, a new computing platform for big data, such as Apache Hadoop and Apache Spark, are intended to incorporate machine learning systems to attain high performance [2], [3]. Apache Spark, established in 2009 at University of California, is an open-source processing system. It has been one of the main frameworks in the world for large-scale data processing and analytics, achieving high efficiency for both batch and stream data. It is an API that is simple to use and run-on large datasets. For large-scale data processing, Spark is 100 times faster than Hadoop by utilizing memory computing and other optimizations. Sentiment Analysis of huge volume of data has become more and more significant and drawn many researchers. Sentiment Analysis, also referred like opinion mining, is characterized as a task to identify the views of authors on specific entities [4]. Sentimental analysis is used in various places, for example: To analyse the reviews of a product whether they are positive or negative, If a political party strategy has been successful or not, evaluate the ratings of a film and analyse information of tweets or another social media data [5]. Sentiment analysis is all about having people's real voice of a particular product, programs, organization, movies, news, events, problems and their characteristics. Social media monitoring apps in businesses rely primarily on sentiment analysis using machine learning to help them gain insights into mentions, brands and goods [6]. The machine learning is a subset of AI [7]. It trains the computers to learn and behave like human beings with the assistance of algorithms and data [8]. Machine learning is the science of preparing a system to learn and act from data [9]. Machine learning is being used by wide variety of applications, and the trend is rising every day and often denoted to as fixing the model with knowledge is the method of training the model. Fig. 1 depicts two sub-sections of machine learning algorithms.

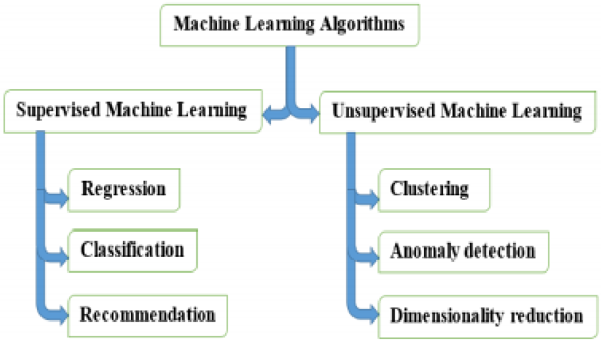

Fig. 1. Machine Learning Algorithms.

Supervised machine learning refers to working with a set of labelled training data to learn [7]. Every observation has a collection of features and label in the training dataset. Algorithms for supervised machine learning can be classified into regression, classification and recommendation engines. Unsupervised machine learning has been used when a dataset is un-labelled, means when a model does not require labelled data that is referred to unsupervised learning. These types of models try to learn or discovering hidden structures in un-labelled data or reduce the data down to its most important features [9]. With unsupervised learning there is no right or wrong answer [7]. They are commonly used during clustering, detection of anomalies and reduction of dimensionality. Sentiment analysis is recognized as a problem of classification and it can also be solved by the method of machine learning techniques [10]. In this work, MLlib by Spark, that is the machine learning libraries developed on top most layer of Spark to provide great-quality and high-speed machines. MLlib utilized Java, Scala, and Python, so that this may incorporate it into full workflows [8] that can be used for data analysis of large scale and since Spark's MLlib is a recent library developed in 2014. According the limited awareness of researchers, A small number of researches have been carried out to measure the sentiment of large-volume data using Spark's MLlib, so more analytical work is necessary for this field. The purpose of this study is to have new sentiment classification experiments on large volume of data by the Spark ML and DL with TensorFlow by implementing deep-learning models and evaluating their performance with existing algorithm. The rest of this paper is laid out as follows. In Section 2, we begin with a related work by Apache Spark ML. The core components of Apache Spark architecture are then introduced in Section 3. Section 4 introduces Apache Spark's machine learning library and computation. The ML pipelines for machine learning in Spark are discussed in Section 5. Then, for the suggested solution in Section 6, we move on to custom DL pipelines. Following that, Section 7 discusses some of the ML classifiers. The proposed methodology for sentiment analysis through big data analytics using hybrid CNN-SVM with spark DL is implemented in Section 8. Dataset, pro-processing, and word embedding are all discussed in Sections 9, 10, and 11. Section 12 and 13 describes the experimental setup, results, and discussions. Finally, summary and conclusions of this paper is presented.

II. Related Work

There is also a large amount of research on distributed systems for solving big data problems, particularly using Apache Spark. Sentiment analysis is the most ongoing research field in recent years that researchers have concentrated on, and several researchers have used various methods to perform sentiment analysis. The enormous interest in the field of sentiment analysis is largely dependent on availability of information and the developments in the internet. Advances in new techniques and algorithms have shown that combining sentiment analysis with machine learning can provide greater potential to predict the success of newly released products. Baltas et al. [8] implemented a Twitter data sentiment analysis system that used Spark MLlib for classification. On real Twitter info, three algorithms were used: decision tree, Naïve Bayes and logistic regression with binary and ternary classifications were evaluated. The Pre-processing of data is handled to maximize performance. The framework was tested on various sizes of datasets and various features. The authors suggested Naïve Bayes is superior than other classifiers and then the size of the dataset could influence the output of the classifiers. Sayed and et al [11] discovered in their paper that the Spark ML has an attraction over Spark MLlib in the performance and accuracy of big data analytics problems. Al-Saqqa and et al [12] examined about sentiment classification of big data using Spark's MLlib. In terms of efficiency, they find that the SVM is higher than other classifiers. AL-barznji and et al [13] addressed sentiment analysis using algorithms such as Naïve Bayes and SVM to evaluate the text with Apache Spark's aids. They discovered that in all situations, the SVM is more specific. Some recent works on deep learning models using Apache Spark as follows. The authors in [16] used a deep learning approach to detect the sentiment of Arabic tweets. Their approach relies on the utilization of pre-trained word vector representations. In [14], The ensemble model that combines both Convolutional Neural Network (CNN) and Long Short-Term Memory (LSTM) models. LSTM is a special type of RNN which can learn long-term dependencies. LSTM was developed to prevent the long-term dependency problem that exists in standard RNNs. The results show good improvements in the accuracy and f1-score measurements over some other flat approaches. Alsheikh et al. [17] proposed a deep learning model for mobile big data analytics using Apache Spark. This model suggested the deep model parallelization by slicing the MBD into several partitions in spark RDD. The results illustrated the achievement of a better implementation using deep learning models through the Spark system compared to traditional lighter models. Various methods discussed in this paper for sentiment analysis are mainly based on results regardless of time complexity. If the size of the information is small, the analysis will be finished within the time limit. But time is a significant constraint when analyzing broad corpus, so the proposed structure would decrease the time required for sentiment analysis. This approach is much simpler and fully utilizes the capabilities of Spark ML framework. It is the Spark-based large-scale approach to sentiment analysis of product review data set without the need to build a sentiment lexicon or proceed with any manual data transcription.

III. APACHE SPARK ARCHITECTURE FOR BIGDATA

Apache Spark is a platform for bigdata analytics that can offer an enhanced substitution to the Map Reduce model. In contrast to map reduce model, Spark does not push the data to a disk for every step. The data is gathered in the memory till it is fully stored. If the memory is full then the data flows over to the hard drive. Therefore, the advantage of in-memory processing applied in Spark can make its processing very fast. The architectural layout of Spark is described in Fig. 2.

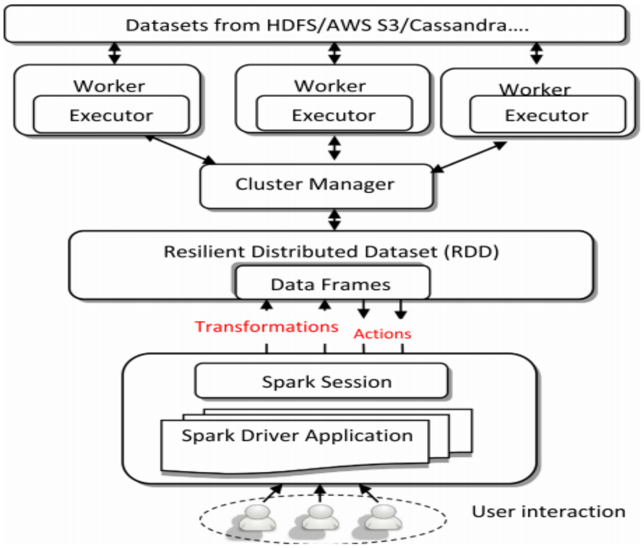

Fig. 2. Spark Architecture.

The Spark System utilizes a master/worker layout in which the master node handles the worker nodes. If the spark is mounted on the cluster, the executors mostly in worker nodes are automatically constructed and then the task is executed according to the instructions provided by the cluster manager. In the context of the Spark Session, the driver serves as the user interface from which the user transmits and receive the instructions. The Spark Session serves as the primary gateway for all communication. Spark operates at the centre on the basis of RDD idea. RDD's include applications like distributed data processing, the ability to use multiple data sources, fault tolerance and parallelism. Spark conducts two fundamental activities, i.e., transformations and actions. The transformations perform the RDD work, which transforms the input data using activities such as mapping, joining and key reduction to return the final output to RDD's and actions received the data from RDD's.

IV. SPARK MACHINE LEARNING LIBRARY

Apache Spark is a very powerful tool for analytics of big data and presents excellent performance in terms with running time. MLlib is the first library supplied with Spark for machine learning shown in Fig. 3. Unlike single node machine learning frameworks, it is much efficient and scalable. MLlib also offers distributed processing options through parallel processing as well as facilitates the use of distributed architectures for big data analytics. This criterion would reduce the processing time needed but, at same time, control the duration to evaluate analytical results. If the role of machine learning has several predictions to measure and it is highly important. It provides some of the big data tool attempts to break down each machine learning section can also be used by the distributed architecture to decrease the total running time.

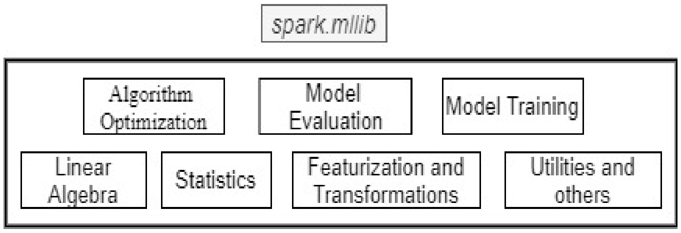

Fig. 3. Spark MLlib.

Integration is an additional benefit of Spark MLlib, this means that MLlib benefits from many software components accessible in the Spark ecosystem. It includes Spark GraphX, SQL, Spark Streaming and large spectrum of highly organized documents are freely accessible to the machine learning community. The basic machine learning utilities offered by spark MLlib are shown in Fig. 3. Spark Machine Learning Libraries provide executions of many algorithms and it is used for basic machine learning methods includes classification, regression, clustering, reduction of dimensionality, extraction and transformation of features, regular mining of patterns, and recommendations.

V. SPARK ML PIPELINES

Apache Spark ML is open-source platform for fast processing of large-scale data. Here Spark ML offers high-level APIs made on top of Data Frames for scalable data processing. In order to extract and predict the features, Spark uses the ML Pipeline to pass the data via transformers and estimator to implement the model.

Transformer: It is an algorithm to converts one Data Frame into next Data Format. Transformers are used here to convert text data with a feature vector.

Estimator: It is an algorithm to fit for the Data Frame to generate transformer. Estimators are used to train the model, which can convert input data to do the predictions.

Pipeline: The pipeline connects several transformers with estimators together to describe the ML workflow and it provides the mechanisms to build, evaluate and fine tune pipelines.

ML pipeline consisting of a set of pipeline stages to make it simpler using multiple algorithms to be merged into a single pipeline or workflow to be operated in a particular order. Spark is completely consistent with applications based on Java, as it uses Scala which runs on Java Virtual Machine. Using PySpark, it can work with RDD in Python programming language also. Further, Spark MLlib contain RDD format-based implementation of machine learning algorithms. Spark ML is based on datasets and enables us to use Spark SQL with it.

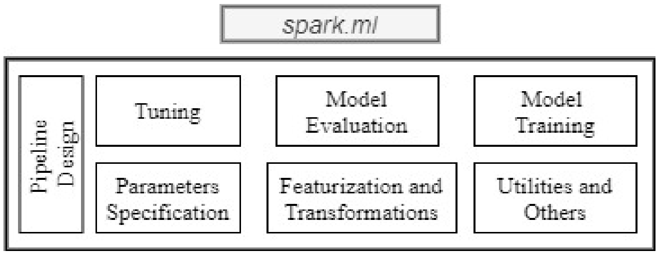

Fig. 4. Spark ML.

Feature extraction and manipulation tasks are very simple, as Spark SQL queries can now handle a lot. Typically, Dataset is in an extremely raw text, and this data usually goes through a loop or workflow where it is pre-processed, transmuted, and transformed until it is consumed for model training. The complete work flow of data transformation and its stages are fully encapsulated with the concept of ML Pipeline shown in Fig. 4. The ML libraries provide high-level API for implementation and fine-tuning of various machine learning pipeline models. It also allows us to save and load machine learning algorithms, trained models and pipelines so that it could reuse the results of previous steps to generate new results without the need to start the whole process from scratch.

VI. Apache Spark Custom DL Pipelines

The Deep Learning Pipelines is a high-level framework, which is applicable through Apache Spark MLlib. It facilitates the implementation of popular deep learning workflows. Furthermore, Databricks is an establishment started by the originators of Apache Spark provided the open-source library called DL pipelines and it support to develop deep learning models using python. It is a large-scale API integrate with the power of deep learning libraries such as TensorFlow and Keras. Both ML and DL provide a consistent collection of high-level APIs assembled on top of Data Frames to help users to build and tune functional pipelines for machine learning and deep learning models. To achieve the best outcomes in deep learning, experimenting with different training parameter values is an essential step called hyperparameter optimization. Since deep learning pipelines allow the exposure of deep learning training to Spark machine learning pipelines as a step, users can also rely on the integrated tuning work for hyperparameters.

VII. Spark ML Classifier

A. *Naive Bayes (NB)*

Naive Bayes algorithms are mostly used in sentiment analysis, spam filtering, and recommendation systems. They are quick and simple to implement. This is a basic multiclass classification algorithm based on Bayes' theorem. The conditional probability from each class function is calculated first and then the theorem of Bayes is employed to predict an instance's class label. Naïve Bayes is highly suitable for large dataset. Usually, the accuracy of NBC is increased when the data size increase.

B. *Support Vector Machine (SVM)*

It is a supervised algorithm for classification. The SVM is an efficient classifier that has been successfully used in all aspects of text classification. Documents of text are denoted by a vector. The classification is achieved via defining the hyperplane that raises the margin among two categories, and the support vectors are the vectors that describe the hyperplane. Based on the mined features of the training dataset, the model seeks to find the hyperplane defined by vectors that divide the positive and negative training vectors with largest probability.

C. *Logistic Regression (LR)*

Logistic regression is a model of regression where one value out of specific number of values can be taken by the dependent variable. It determines the relationship between the instance class and the extracted input features using the logistic function, while it is commonly used for binary classification, it can also be used to solve problems with multiple classes.

D. *Random Forest (RF)*

This supervised algorithm is also known as random decision forest and is commonly used for classification, regression, and other tasks. A forest is described as a grouping of trees. It consists of a large number of separate decision trees that work together to form an ensemble. All tree in the random forest is given a class prediction, and the model prediction is made using the class with the most votes. Random decision forest has been considered a robust and reliable classifier due to the principle of bagging and bootstrapping.

VIII. Proposed CNN-SVM using Spark DL

CNN is an artificial neural network that shares their weight. This creates CNN more analogous to the Network of biological neurons and decreases the complexity of both the weight and the network model. A fully connected soft-max layer is utilized as the classification layer for sentence level sentiment classification in CNN proposed by Kim [11]. This classification layer, however, has become too simple for the task of classifying sentiments. Fortunately, the CNN pooling layer output values are considered as function vectors of the input word. They may use as the input of some other classifiers. In this article, we propose an SVM classifier based on CNN that considers CNN as an automated feature learner and SVM as the classifier of sentiment. CNN outputs, the distributed function illustrations of the input terms, are considered to be features of SVM shown in Fig. 5.

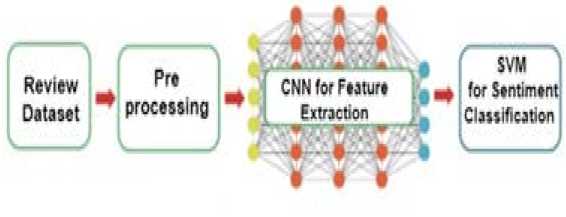

Fig. 5. Proposed Hybrid CNN_SVM Pipeline.

The CNN consists of four layers, namely the input, convolution, pooling and fully connected layer. To create feature map in the convolutional layer, all the available windows of words in the sentence are included. A max-over-time pooling operation is introduced to the function map following the convolution operation. This operation represents the pooling layer and gets a function vector of the m-dimension where the filter size is m. This operation establishes the layer of pooling and gets a vector of m-dimensional feature, where n is the total number of filters. Multiple filters of various window sizes are used in the CNN model. Then these features are moved to the last sheet, such as the fully connected layer, the output of which is the distribution of probability between labels. The pre-trained word embedding is fine-tuned throughout the training processing of the CNN by back propagation. Fine-tuning helps them to learn quite detailed word representations. If the terms may not exist in the embedding of pre-trained words, they are arbitrarily prepared. The vectors of the completely linked CNN layer are considered to be representations of the distributed sentence function, and then these representations of sentences are considered to be feature vectors of SVM classifier. The SVM classifier is trained using the feature vectors labelled with this sentiment. When this method is established for sentiment classification, the incoming sentences are converted to distributed feature representations, which are then fed into the SVM classifier for classification. It is predicted that such a pipeline model will join the benefits of CNN and SVM.

IX. Dataset

The Amazon online product review of about 100,000 reviews is used as data set for this study. This dataset contains products reviews of various domains like electronics, home appliances and books collected from amazon.com websites. To estimate the generalization error, the datasets is divided into two parts: training and testing data. After loading the datasets into the system, before applying and evaluating models the datasets are split into 80 % train dataset and 20 % test dataset randomly. In which, the training dataset is used to build a model, that is used for training the models to get predictions or recommendations. But testing dataset is independent of the training dataset, which is not used in the process of the building a model. The test dataset is to determine the efficiency of the proposed model.

X. Pre-Processing

The pre-processing of the data is the most key step. The purpose of the steps is to make data more machine-readable. Hence, uncertainty is reduced in feature extraction. In addition, to convert the streaming input to a data frame in order to run a pre-processing pipeline that includes the following steps:

Removing null reviews: This involves deleting any reviews with a null value.

Tokenization: The text is subdivided in to smaller tokens based on separator characters like white space, comma, tab, and so on in this phase.

Noise removal: This step involves removing any irrelevant information from the text that could affect the classifier's performance, including such numbers, punctuation marks, URL links, and special characters.

Stop-words removal: Non-descriptive words that can be displaced within the bag-of-words approach are known as stop words. Articles, prepositions, conjunctions, and pronouns are removed because they are not semantically necessary to characterize the viewpoint.

XI. Word Embedding

The interesting properties inside the data which you can use to make predictions are known as features. The process of converting raw data into inputs for a machine learning algorithm is known as feature engineering. For use in Spark machine learning algorithms, Features must be translated into feature vectors, which are numerical values that represent each feature's value. But for deep learning model, a neural network is a collection of neuron layers with the output of one layer being fed into the next layer. Each layer passes on the modified version of data to the next layer to promote more informative features further. Neural networks can't process direct terms; instead, they operate with word embeddings, or more precisely, feature vectors that represent certain words [15]. Neural networks can apply to any domain while learning features from the task at hand. Word2Vec is a predictive model for learning word embeddings from unstructured text that is computationally efficient. The first layer of CNN is the embedding layer converts words into real-valued feature vectors (embeddings) that take morphological, syntactical and semantic information of the words. the CNN use word embeddings feature as an input for the system. Each and every word was thus encoded as a 300-dimensional word vector that was supplied to the network. Word2vec is for word level embedding. Word level embedding is expected to obtain syntactic and semantic details, and character level embedding is projected to grab type and morphologic details. Data source on Google News (approximately words of 100 billion) is used to train the vectors in the proposed technique.

XII. Experimental Setup

Spark ML and DL have been used (open-source Bigdata tool) as development environment for performing the experiments. SparkFlow will take advantage of Spark ML's most important machine learning feature, which is the ability to combine deep learning pipelines with TensorFlow. SparkFlow allows users to train deep learning models in Spark and then link the trained model to a pipeline for smooth raw data predictions. The CNN models have been developed using TFLearn (a deep learning library) and it is pipeline with SVM using Spark ML pipeline.

Fig. 6 represents the major stages of this approach. The proposed method starts with data pre-processing and feature extraction, followed by the use of machine learning classifiers, Naïve Bayes, Support vector machine and logistic regression separately under Spark ML and proposed CNN-SVM using Spark DL environment. Finally, different metrics are used to measure the results. The PySpark library is built with the necessary Python API to run applications on top of the Spark. In order to estimate the efficiency of the proposed model, a series of tests were carried out, specifically, in terms of running time and classification results. There are five models are utilized for classification such as Naive Bayes, Logistic Regression, SVM and Random Forest and proposed hybrid CNN-SVM. Hyper parameter tuning is a technique for deciding the best parameters for achieving the highest degree of precision for the proposed model. Grid-Search with 5-fold cross validation has been applied on training data. The scalability and speed of the method is investigated in this experiment. The experiment is run four times: 1000, 2000, 4000, and 8000 reviews to see how easily Apache Spark can process data using the algorithm.

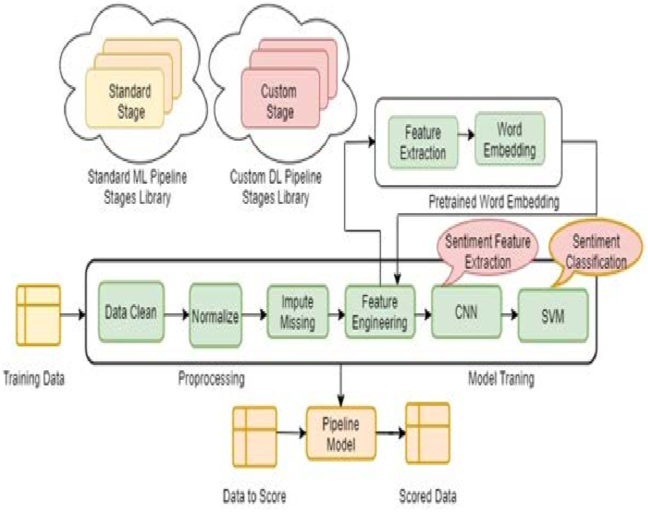

Fig. 6. Hybrid CNN_SVM using Spark DL Pipeline.

XIII. Result and Discussion

The results obtained based on processing time in Table I illustrate that in comparison to other sentiment analysis models, the proposed CNN-SVM has the fastest speed. Each algorithm's execution time is registered. There is a positive relationship between the amount of review data and processing time as it increases.

The classification accuracy of the models' performances is assessed using the random split method. Assuming that accuracy is influenced by a variety of factors, Table II displays average results of 5 algorithms based on assessment parameters such as average. For single-node systems, the values are taken into account. The model created with the CNN-SVM classifiers outshines the other classifiers. The outputs produced through this hybrid CNN_SVM Pipelined technique show higher rates of accuracy. Spark MLlib is a versatile method for analysing big data as evidenced by the findings of this research.

It presents spectacular performance in terms of running time and sentiment analysis of domain independent datasets shown in Table III. It is predictable that much greater performance is achieved in multi-node start-up configurations, as it is evaluated in ten node environments with much larger data sets. It also compared running time on growing number of nodes with varying size of data.

Table IV and Fig. 7 display the experimental outcomes. First, the computational efficiency of Spark is rising as the number of nodes in the computing cluster increases, and the subsequent experimental results indicate that the running time decreases. Secondly, the improvement of computational performance is stronger when this method is adopted to larger data. The results indicate that our proposed system performed well both in accuracy and running time.

TABLE I. Processing Time vs No of Reviews on Single Node

Algorithm	Time taken for no. of Reviews (seconds)			
	1000	2000	4000	8000
Naive Bayes	21s	29s	36s	50s
Logistic Regression	17s	18s	20s	22s
Random Forest	16s	16s	17s	19s
SVM	15s	15s	15s	16s
Proposed CNN-SVM	10s	10s	11s	11s

TABLE II. Accuracy of Various Models on Single Node

Algorithm	Accuracy for no. of Reviews				Average Accuracy
	1000	2000	4000	8000	
Naive Bayes	0.73	0.76	0.77	0.76	0.75
Logistic Regression	0.68	0.69	0.70	0.71	0.69
Random Forest	0.75	0.76	0.77	0.77	0.76
SVM	0.89	0.88	0.90	0.91	0.89
Proposed CNN-SVM	0.94	0.95	0.96	0.96	0.95

TABLE III. Evaluation Metrics for Various Domains

Domain	Performance Metrics			
	Precision	Recall	F-Score	Accuracy
Electronics	0.95	0.94	0.96	0.95
Kitchen Appliances	0.94	0.95	0.96	0.96
Books	0.94	0.93	0.94	0.94

TABLE IV. Number of Nodes vs Running Time

Nodes	Running time in seconds (50,000 Reviews)	Running time in seconds (1,00,000 Reviews)
(1)	240	461
(2)	148	266
(3)	110	180
(4)	89	154
(5)	61	102
(6)	52	84
(7)	45	72
(8)	42	63
(9)	40	55
(10)	35	50

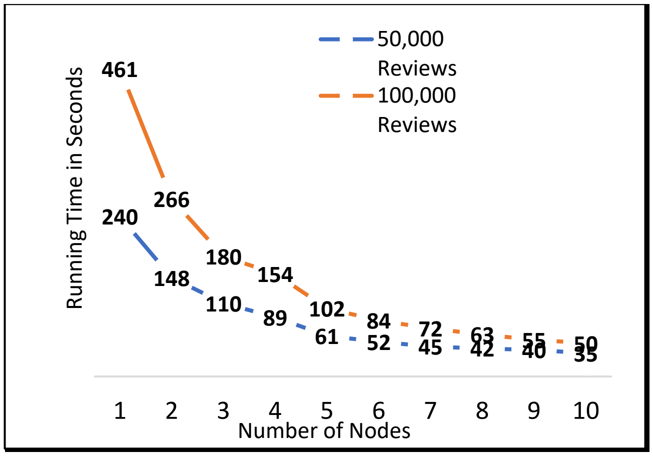

Fig. 7. Number of Nodes vs Running Time.

XIV. Conclusion

The main focus in this study was on rapidly implementing sentiment analysis on the Big Data sets. Spark MLlib has been used for handling a large volume of data as it is scalable. This paper offered new studies to classify sentiment on large amounts of data using Spark's MLlib with TensorFlow by implemented the proposed deep learning CNN-SVM model and the performance of this model is compared with different machine learning classification algorithms. Four classifiers were compared with our proposed model in terms of accuracy. The evaluation result shows that the proposed model has improved performance over the other classifiers. This work was implemented on multi node configuration with larger dataset. As part with our role in the future, we are working to perform an experimental evaluation of Spark MLlib in a number of programming languages (e.g., Python and R), and Software configurations that use a collection of large datasets with a range of data characteristics. In addition, we will develop a better deep learning model to extract optimized features in order to boost performance against other classification methods at a faster rate under large data volumes. The accuracy could be pointed for further development in future.

***Abstract*—With the exponential increase in connected devices and its accompanying complexities in network management, dynamic Traffic Engineering (TE) solutions in Software-Defined Networking (SDN) using Reinforcement Learning (RL) techniques has emerged in recent times. The SDN architecture empowers network operators to monitor network traffic with agility, flexibility, robustness and centralized control. The separation of the control and the forwarding plane in SDN has enabled the integration of RL agents in the networking architecture to enforce changes in traffic patterns during network congestions. This paper surveys major RL techniques adopted for efficient TE in SDN. We reviewed the use of RL agents in modelling TE policies for SDNs, with agents' actions on the environment guided by future rewards and a new state. We further looked at the SARL and MARL algorithms the RL agents deploy in forming policies for the environment. The paper finally looked at agents design architecture in SDN and possible research gaps.**

Keywords*—Software defined networking; reinforcement learning; machine learning; traffic engineering

I. Introduction

The emergence of fifth generation (5G) networks has propelled the growth of Internet of Things (IoT) in recent times. IoT is a rapid evolving technology that connects billions of devices to the internet [1]. With 5G, the rapid deployment of new and smart IoT applications are expected to reach 22.3 billion by 2024 and generate about 163 zettabyes (ZB) of data by 2025 [2] [3]. These new and dynamic applications are expected to benefit from the services 5G networks will provide: ultra-reliable and low latency communication (URLLC) [4], enhanced mobile broadband (eMBB) [5] and massive machine type communication, massive MIMO [6].

As shown in Fig. 1 and Fig. 2, the dynamic nature and requirements of IoT devices has necessitated a network deployment shift from the traditional networking architecture which are difficult to configure and manage to a more flexible programmable domain [7]. Software-Defined Networking (SDN) is a new networking paradigm that separates the data plane from the control plane [8] [9]. This separation makes the network more agile with centralized responsibility given to the controller [10]. The controller communicates with the application plane via the northbound APIs and the forwarding devices via the southbound APIs (OpenFlow). The automation and programmability of the SDN architecture helps to configure, secure, and optimize network resources [11] quickly whiles maintaining a good Quality of Service (QoS) [12] and Quality of Experience (QoE) [13].

Traffic Engineering (TE) in SDN involves the analysis of the networks state by the SDN controller to act on flow data through the rapid change in flow table information for forwarding devices [14]. Rerouting flows periodically to balance the loads on the network minimizes congestion and improves the overall network performance. A network experiences two kinds of traffic flows: elephant flows and mice flows [15]. The elephant flows are heavy traffic flows that requires more network resources whiles the rapid aggregation of the mice flows can equally degrade the network. These traffic flows continuously needs dynamic resource allocation for the efficient utilization of scarce network resources through TE.

With the advent of machine learning, port-based [16] and payload-based [17] flow classification techniques have become ineffective due to the dynamic port usage of IoT devices. The negative impact of packet out of order and packet loss in traditional TE techniques even worsens the case for the network operator.

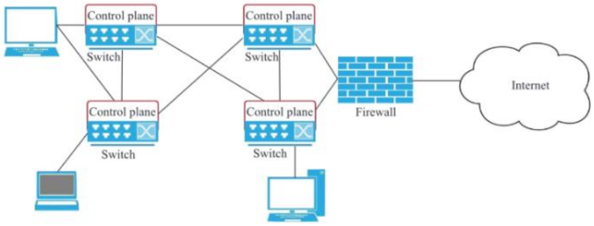

Fig. 1. Traditional Networking Architecture [7].

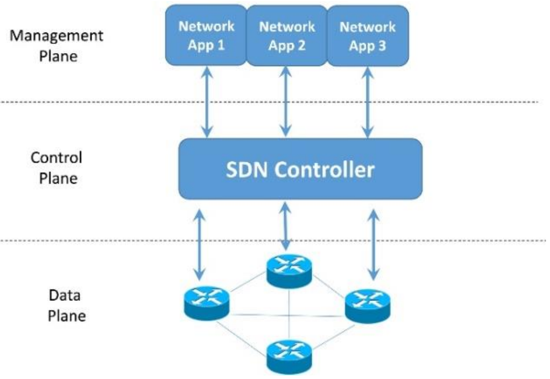

Fig. 2. Software-Defined Networking (SDN) Architecture [7].

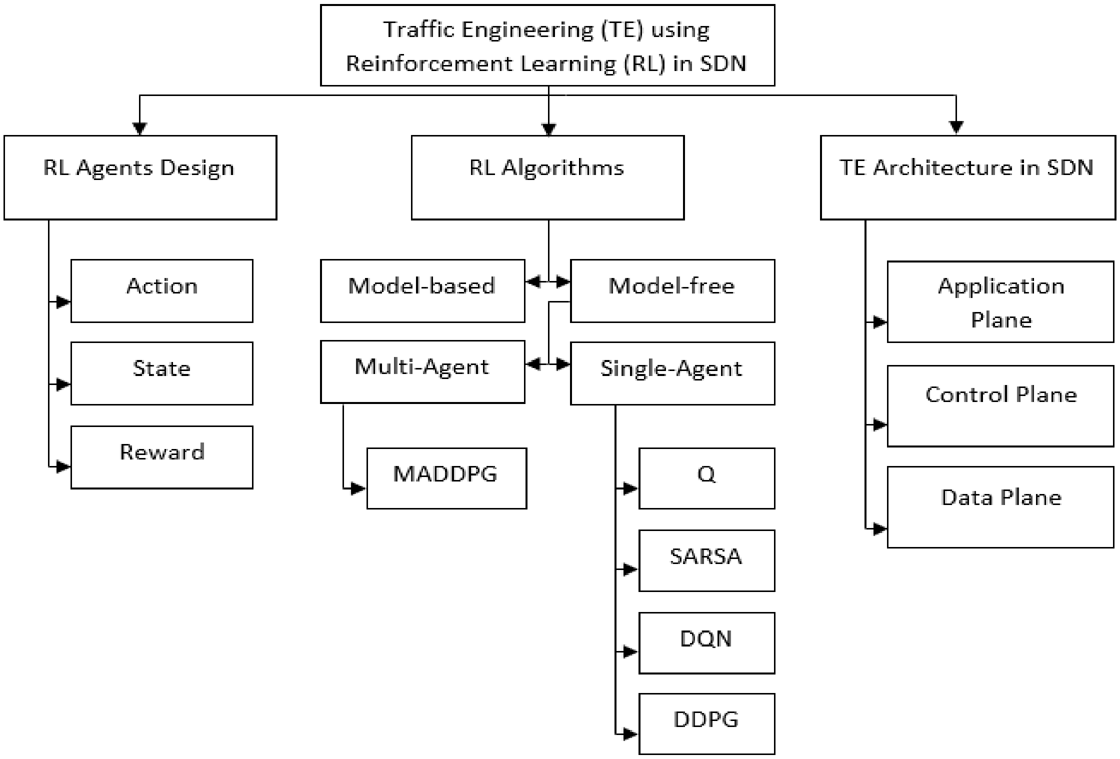

Fig. 3. TE using RL in SDN – Review Outline

Currently for TE, machine learning algorithms are adopted for intelligent flow re-routing with an efficient feature selection criterion [18] [19] in network flow analysis. Deploying these machine learning algorithms in the SDN controller will efficiently allocate network resources and formulate policies for optimal network performance with low overheads.

In this survey as outlined in Fig. 3, we reviewed popular Reinforcement Learning (RL) techniques used in SDN architecture for Traffic Engineering with limitations on parameters chosen and approaches for future research. The rest of the paper is organized as follows: Section II discusses the justification of RL for TE; Section III analysed the TE architecture integration in SDN based on policies and performance. Finally, Section IV looked at the research gaps identified from the survey.

II. Machine Learning with Reinforcement Algorithms

With the advent of Machine Learning [101] where automation modelling using data remains relevant, traditional algorithms [102][103][104] used in solving SDN-IoT related task is unfeasible. In supervised learning [103] agents are trained with a labeled dataset and later tasked to make predictions out of the learned data. Increased complexity in a dynamic environment with new IoT devices and variance in data will negatively affect the accuracy of supervised learning algorithms and predictions. Even worse is the time factor in retraining and relabeling of new data variance in an attempt to still adopt classification algorithms. With unsupervised learning [104] that uses unlabeled dataset, there is no guidance regarding the accuracy of the clustered dataset. Clustering algorithms alone is inefficient in an SDN-IoT environment that requires efficiency in diverse IoT applications. Reinforcement Learning (RL) defines the true automation of agents in an environment [20][105] with rewards as guidance on how well the agent is performing. Though complex, RL agents adapts to changing conditions in the environment by learning to solve tasks through trial-and-error approach. As the episodes progresses, agents adapt to successful actions through exploration and exploitation [106][107] on the stochastic environment. With the recent success of DeepMinds AlphaGo RL agent [108] that defeated the Go champion in 2016, the application dimensions of RL have become enormous. The only way packets can be routed intelligently in a network with varying and emerging IoT devices is to deploy RL agents to learn varying network state patterns with no exclusive data labels but with policies and actions.

III. TE using Reinforecement Learning in sdn

Reinforcement Learning (RL) is an area of machine learning where an agent is modeled to take sequence of actions informed by policies [20]. As shown in Fig. 4, the agent learns in an interactive environment and receives a reward through its actions [21, 22]. The set of actions presents a new state with corresponding reward to the agent. Unlike supervised learning [23] where a set of correct actions are provided as feedback to the agent, RL uses rewards and punishment as signals for positive and negative decisions. The goal is to use trial and error methods in getting positive rewards or build a suitable model that will maximize cumulative rewards for the RL agent.

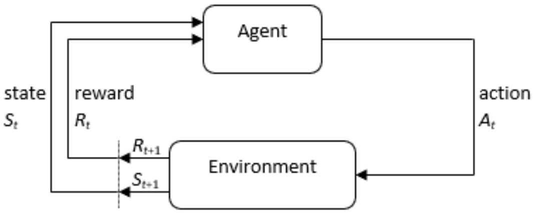

Fig. 4. Reinforcement Learning.

SDN provides centralised control with a unique advantage for intelligent TE framework implementation using RL. Network policies can easily be generated from the centralized control with corresponding TE rules to forwarding devices. With RL, the modelling of the agent's action on the environment with rewards fits into the network architecture of SDN and this expedites network control and management.

A. RL Agents Design

This section details the mathematical modelling of the state space with respect to actions and rewards. Agent design requires the environment to be monitored.

An agent based on the monitored metrics takes actions informed by policy decisions with a new state and a corresponding reward in guiding the next policy.

1) Action-State-Reward: RL agents are implemented in RL frameworks and modelled in SDN to learn critical network packet flow policies and provide routing solutions to forwarding devices. The agent takes an action on the environment and evaluates the actions based on rewards. Using its policy π , the agent performs an action *a,* which alters the environment state *s to s'*[24]. Based on the reward *r*, the agents policy is updated. In arriving at optimal policy, RL agents use Markov Decision Process (MDP) [25] to model actions on the environment with corresponding rewards. MDP is an intuitive and fundamental formalism for decision-theoretic planning (DTP) [26] and RL in stochastic domains. The MDPs have become the de facto standard formalism for learning sequential decision control problems [27].

Algorithm 1 Markov Decision Process (MDP)

```
An MDP is a 5-tuple $(S, A, P, R, \gamma)$, where;
    $S$ is a set of states
    $A$ is a set of actions
    $P\ (s, a, s')$ is the probability that action $a$ in state $s$ at time $t$
    will lead to state $s'$ at time $t + 1$
    $R\ (s, a, s')$ is the immediate reward received after a transition
    from state $s$ to $s'$, due to action $a$
        $\gamma$ is the discounted factor which is used to generate a discounted
                                reward
```

For TE in SDN, RL agents are implemented differently based on the agents policy and the metrics for measuring TE success. The actions of the agents on the environment are rated by the rewards associated with it as the episode progresses.

CFR-RL agent [28]

State Space $s_t = TM_t$ (1)

Action Space $\{0, 1, \dots, (N * (N - 1)) - 1\}$ (2)

Reward Function $r = {}^{1}/_{U}$ (3)

The CFR-RL agent resides in the controller of the SDN architecture. The RL agent uses a traffic matrix that contains the traffic demand of each flow as state. The objective is to avoid packet link congestion. As shown in equations 1 - 3, the CFR-RL agent samples K critical flows for a given stage s_t within N nodes. The CFR-RL agent then reroutes these critical flows and obtains maximum value in link utilization U as reward.

Q-DATA RL agent [29]

State Space $S_i \triangleq \{(f_i, \Delta f_i) : 0 < f_i \leq f_{capi}; -f_{capi} \leq \Delta f_i \leq f_{capi}\}$ (4)

Action Space $A_i \triangleq \{a : a \in \mathcal{F}\}$ (5)

Reward Function $\begin{cases} \frac{\sum_{x=1}^{f_i} \Theta_x}{f_i}, & 0 < f_i < f_{capi}, \\ 0, & f_i = f_{capi}, \end{cases}$ (6)

The Q-DATA agent resides in the application plane of SDN. As shown in equations 4 - 6, the Q-DATA RL agent has a defined state space where f_i is the current total number of flow entries in switch *i*; Δf_i is the number of flow entry changes between two consecutive observations and f_{capi} is the maximum number of flow entries in switch *i*. $(f_i, \Delta f_i)$ represents the state of an SDN switch *i*, as a tuple. For its action space, a represents a traffic flow matching scheme change related to a destination host and $\mathcal{F}$ denotes a list of all feasible match field combinations. With the reward function, f_i is the current total number of flow entries in the switch *i*; and Θ_x is an integer number representing the number of enabled match fields in flow entry *x*. An action has no reward if that action leads to the total number of current flow entries in the SDN switch *i* reaching the limit f_{capi}.

Mu [30]

State Space $s_i = (flow\_freq_i, flow\_recentness_i)$ (7)

Action Space $a_{flow\_freq_i}^{increase} = (flow_{freq_i}{}^{increase}, flow_{recentness_i})$ (8)

Reward Function $r_t = Compare(overhead_{current_{best}}, overhead_t)$ (9)

In [30], the RL agent resides in the controller of the SDN. As shown in equations 7-9, $flow\_freq_i$ represents the frequency of matched flows and $flow\_recentness_i$, an indication of flow duration in the memory of the switch. These are defined for the state space. The action space denotes an increase action on the flow frequency parameters. With the reward function the $overhead_{current_{best}}$ denotes the current best network control overhead obtained. A configuration with less overhead returns a positive reward, 1 to the RL agent otherwise a negative value -1 is returned. If $overhead_{current_{best}}$ and $overhead_t$ are equal, a reward value of 0 is given.

Huang [31]

State Space $s_f = (bandwidth_f, jitter_f, packet\_loss\_rate_f)$ (10)

Action Space

$$a_s = \ action_{bandwidth_f}^{routing\_path} \tag{11}$$

Reward Function

$$r_s = \{MOS_{customer}, QoE_{customer}\} \tag{12}$$

With [31], the objective of the RL agent is to maximize the cumulative QoE of customers by dynamically allocation traffic in a multimedia environment. The RL agent resides in the controller of the SDN architecture. As shown in equations 10 – 12, the state of the environment refers to the state of flows and covers the following metrics: allocated bandwidth, the delay, the jitter and the packet loss rate of flows. The action includes: the path chosen (routing path) and the bandwidth adaptation of flows. The mean opinion score (MOS) [32] used to evaluate the QoE represents the reward function. A multi-layer deep neural network (DNN) is used to map the network and application metrics to the MOS.

Choi [59]

State Space

$$s_i = (sampling\_period_i) \tag{13}$$

Action Space

$$a_i^{increase} = (\,sampling\_period_{increase}) \tag{14}$$

Reward Function

$$r_t = \begin{cases} 1, & hit\_ratio_{t-1} < hit\_ratio_t \\ 0, & hit\_ratio_{t-1} = hit\_ratio_t \\ -1, & hit\_ratio_{t-1} > hit\_ratio_t \end{cases} \tag{15}$$

In [59] RL framework is modelled to minimize the number of overflow occurrences. As shown in equations 13 - 15, the state space represents the size of the sampling period with a unit size of 500 ms. This ranges to 5,000 ms with a total of 10 states. The action space has three options: (i) increase sample period by unit size; (ii) decrease sampling period by unit size; (iii) maintain the sample period. Based on the percentage of table hits, three rewards are given. A reward of 1 is given when the measured hit rate is higher than the hit rate pre-action. If low, a reward of -1 is assigned. A reward of 0 is assigned if there is no change in the hit rate.

Fu [71]

State Space

$$State = \left\{s = \left[FT_{sw_i,t_j}, PS_{pk,sw_i,t_j}\right]\middle|\, i\ \in [1,n], j\ \in [1,m], k\ \in [1,z]\right\} \tag{16}$$

Action Space

$$Action = \{a_{p1}, a_{p2}, \dots\ a_{pk} \dots a_{pN}\} \tag{17}$$

Reward Function

$$\begin{gathered} R_{elephant} = \ \alpha * (1 - PLR) + \ \beta * TP \\ R_{mice} = \ \lambda * (1 - PLR2) + \mu * (1 - DL) \end{gathered} \tag{18}$$

In [71], flow table state and port state are responsible for collecting network statistics. The channels of the network represent the flow table utilization and its respective port rate of switches at current and previous states. For the state space modelling n, m and z respectively identifies the number of switches, moments and ports of a single switch. FT_{sw_i,t_j} represents the flow table utilization rate of switch i at the moment t_j and ranges from 0 to 1. PS_{pk,sw_i,t_j} represents the port rate of port k in switch i at the moment t_j. The action space comprises of $p_1\ to\ p_N$ which indicates all paths in the network, $a_{pk}\ \in \{0,1\}$. If $a_{pk} = 1$, the current flow is assigned to path k else $a_{pk} = 0$. For the reward function, the elephant-flows PLR, represents the average packet loss rate of elephant-flows in the network, TP is the average throughput of elephant-flows after processing. α and β are the weights of the PLR and TP respectively. With the mice-flows, $PLR2$ indicates the average packet loss rate of mice-flows and DL represents the normalized average delay. λ and μ identifies the weight of the $PLR2$ and DL , respectively.

Zhang [86]

State Space

$$s = (nc, src, dst, avail) \tag{19}$$

Action Space

$$a = (a_1,, a_i \dots, a_j, path) \tag{20}$$

Reward Function

$$r = \frac{1}{L}\sum\nolimits_{l=1}^{L}(2\frac{bl}{bw_l} - 1) - \beta\frac{2}{\pi}\arctan(\sigma) + 1 \tag{21}$$

In [86] the state comprises of four components; name of the requested content, source, destination and available link bandwidth.

With the action, a_i denotes the i^{th} destination node split ratio and relates to the content request sent to that destination node using selected transmission links. The reward is meant to improve load balance and throughput. The $\frac{1}{L}\sum_{l=1}^{L}(2\frac{bl}{bw_l} - 1)$ reveals throughput impact in relation to available normalized bandwidth. The - $(\frac{2}{\pi})\arctan(\sigma) + 1$ indicates the load balance with normalized variance of available bandwidth. A value close to 1 signals a preferred action with a reverse value close to -1, a penalty. β = 1 is a factor used to balance the throughput and the load balance.

B. RL Algorithms

In this section, we reviewed the algorithms the RL agents use to formulate policies that informs the action taken by the agent on the environment as the episode progresses. For effective TE and policy enforcement on the environment, RL agents learns to take the best actions for traffic optimization in respect to cumulative future rewards. RL algorithms are distinguished into two main classes: the model-free (direct) and model-based (indirect) methods [33, 34, 35].

1) Model-based RL methods: Model-based RL algorithms utilizes a model when the RL agent interacts with the environment. The model keeps track of transition dynamics of the network to derive optimal actions and rewards [35]. When the model is referenced, the RL agent can make predictions about the next state and reward before an action is taken. Model-based RL methods are data efficient but struggles to achieve asymptotic performance for real-world applications [36]. For model-based RL methods, the interaction between the RL agent and the environment is modeled as a discrete-time Markov Decision Process (MDP) $\mathcal{M}$ and defined by the tuple [36]:

$(S, A, p, r, \gamma, p_0, H)$. Where S is the set of states, A the action space, $p(s_{t+1}|\, s_t, a_t)$ the transition distribution, $r\ :\ S \times A\ \rightarrow \mathbb{R}$ as a reward function, $p_0\ : S \rightarrow \mathbb{R}_+$ represents the initial state distribution, γ the discount factor, and H the horizon of the process. The return function is defined as the sum of rewards $r\,(s_t, a_t)$ along a trajectory τ: = $(s_0, a_0, \dots, s_{H-1}, a_{H-1}, s_H\,)$. The goal of the reinforcement learning is to find a policy π: $S \times A\ \rightarrow \mathbb{R}^+$ that maximizes the expected return. The model-based learns the transition distribution from the observed transitions using parametric approximator $\acute{p}_{\o}(s'|s,a)$. The parameter $\o$ of the dynamic model are optimized to maximize the log-likelihood of the state transition distribution. Though model-based RL methods are data efficient, they have high computational complexity and the degree of potential error in maximizing a reward is compounded..

2) Model-free RL methods: Model-free RL algorithms do not utilize a model and thus the rewards and the optimal actions are derived through trial-and-error approach with the environment [37]. These set of algorithms operate over an unordered list of actions, with a positive or negative reward value. The RL agents that utilizes model-free algorithms increases the value associated with a positive action which helps the agent to learn from direct experience. Agents in model-free RL are represented with policy optimization and Q-learning approaches [38]. With policy optimization, the agents learns directly the policy function that maps state to action without a value function. The Q-learning approach learns the action-value function $Q(s,a)$; how good to take an action at a particular state. A scalar value is assigned over an action *a*, given the state *s* [39]. Model-free RL methods have low computational complexity but more data dependent. For TE, model-free RL methods are frequently used for RL agent sequencing and to implement policies on the environment.

3) Single Agent Reinforcement Learning (SARL): In a SARL, there is only one agent that interacts with the environment to maximize rewards. The SARL implementation is suitable for simple network management with slower convergence and learning experience. The SARL implemented algorithms are either value-based, policy-based or both [48]. As shown in Fig. 5, the SARL through the SDN controller collects information from the environment through the forwarding devices.

The agent upon receiving the state information performs a set of actions on the environment through the SDN controller. These actions are guided by policy algorithms. The episode results in a new state and rewards.

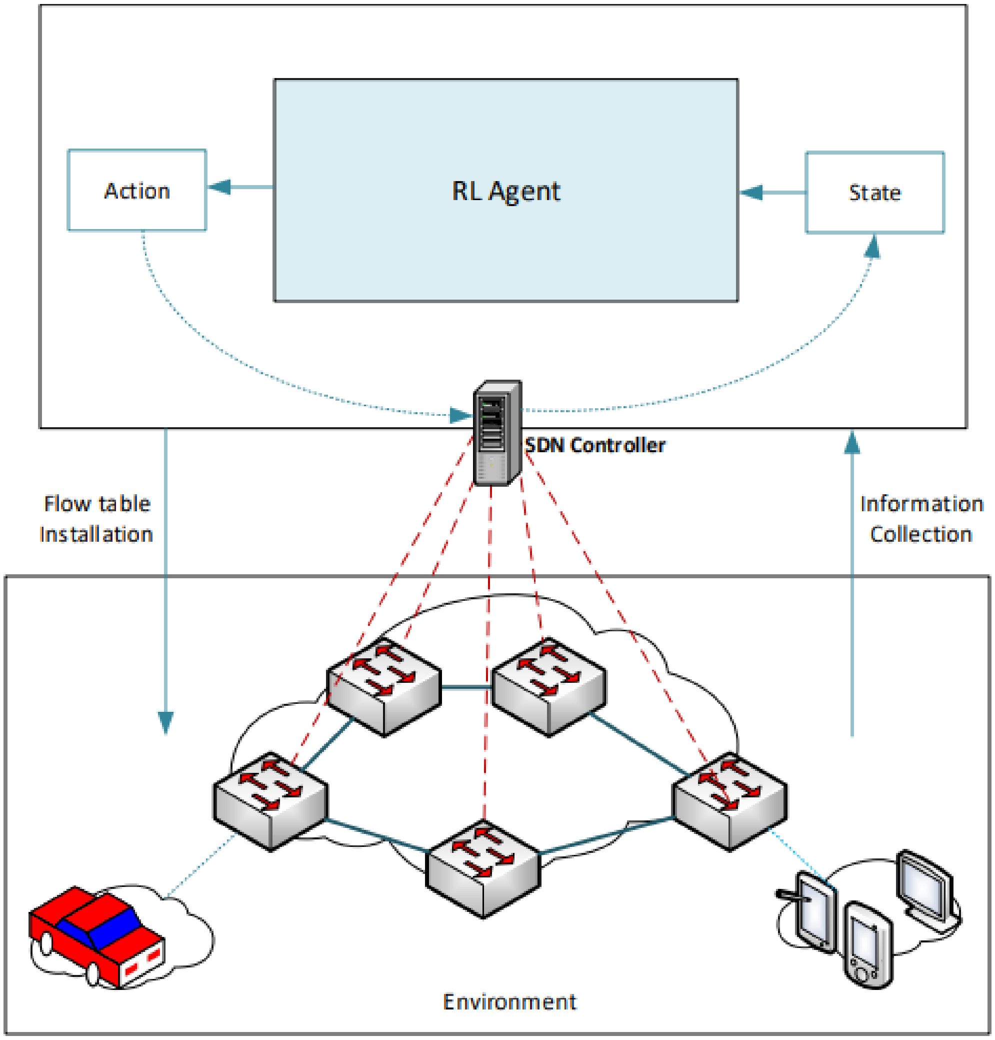

Fig. 5. SARL.

a) Q-learning Algorithm: Q-learning [40] is an off-policy, value-based algorithm that takes a random actions based on the $\epsilon - greedy$ policy, where the probability of a random decision is determined by the value of epsilon ϵ. During the learning phase, the Q-learning agent initializes the Q-table for all state-action pairs and updates it using:

$$\begin{aligned}\mathcal{Q}\_(t+1)\,(s\_t, a\_t\,) = {} & \mathcal{Q}(s\_t, a\_t\,) + \alpha[\,\mathcal{R}\_i\,(s\_t, a\_t\,) \\ & + \gamma max \mathcal{Q}\_t\,(s\_(t+1), a\,) \\ & - \mathcal{Q}\_t\,(s\_t, a\_t\,)]\end{aligned} \tag{22}$$

The Q-learning agent generates the optimal policy $\pi^*(s)$ for a state s representing an action a that needs to be taken to maximize the value of the $\mathcal{Q}_*(s,a)$ function, $\pi^*(s) = arg\,max_a\, \mathcal{Q}_*(s,a)$.

Algorithm 2 Q-learning [40]

```
Inputs: $\mathcal{F}$; for a state-action pair $(s,a)\ \forall s \in S_i, a \in \mathcal{A}_i$,
initialize a $Q$-table entry arbitrarily; initialize values of $\alpha$, $\gamma$ and $\epsilon$,
respectively.
loop
    Current state $s_t$.
    Executive action $a_t$ according to an exploratory policy ($\epsilon$).
    Obtain a new state $s_{t+1}$ and an immediate reward $\mathcal{R}_i$.
    Update the $Q$-table entry for $\mathcal{Q}(s_t, a_t)$.
    Update $s_t \longleftarrow s_{t+1}$.
end loop
Outputs $\pi^*(s) = \arg max_a\, \mathcal{Q}_*(s,a)$.
```

Phan *et al.* [29] proposed the Q-learning algorithm in maximizing traffic flow monitoring in SDN switches. It embeds a Support Vector Machine (SVM) [49] algorithm in the application plane of the SDN architecture to predict the performance degradation of the switches as the episode progresses. To reduce the long-term control plane overhead capacity limitation of Ternary Content Addressable Memory (TCAM) in OpenFlow switches, [30] proposed a Q-learning algorithm for SDN flow entry management. The framework determines the forwarding rules that remains in the flow table of the SDN switches and those processed by the controller in case of a table-miss on the switches. In [50] a Q-learning algorithm is proposed to reduce the latencies and improve the bandwidth utilization in the UbuntuNet Alliance National Research and Education Network (NRENs) SDN switches. The proposed framework adapts forwarding devices by learning from experience using multipath propagation. In dealing with bandwidth overhead caused by Dijkstra's shortest path first module [51] in an OpenDayLight (ODL) architecture meant for efficient packets delivery, [52] proposed a congestion prevention mechanism using Q-learning in SDN. With [52], the set threshold values are defined in SDN controllers to enable threshold bandwidth detections. The optimal path chosen is delivered to the OpenVSwtiches (OVS) after Q-routing by the controller during network congestion. To balance the network load in SDN, [53] proposed a Q-learning approach to reduce the number of unsatisfied users in a 5G network architecture. The researchers used a flow admission control technique with a fairness function to enhance the per-flow resource allocation in the network. In [54] a load balancing architecture is proposed for SDN networks that uses supervised Bayesian Network (BN) to solve the problem of Q value local maximum [55] in a Q-learning RL algorithm. The combination of the BN in Q-learning helps the controller select the most optimal strategy for network load balancing during congestion. For TE load balancing optimization in master controllers, [56] proposed a dynamic switch migration algorithm to slave controllers using Q-learning in SDN. The switch migration problem (SMP) is modeled and used to redefine the Q-learning parameters. The Q-learning is then used to learn the current status of SDN to select the best switches for load migration. For an efficient path selection technique in load balancing, [57] proposed a Q-learning algorithm for path selection and flow forecasting [58]. It has an integrated centre that uses Deep Neural Networks (DNNs) to process uncertain network traffic and uses Q-learning to resolve the optimal path based on the results of the DNN. The DNN path selection are obtained from the bandwidth utilization ratio, packet loss rate and transmission latency which forms the inputs to the DNN. The output which is fed into the Q-learning is derived from the corresponding link score. For timely eviction of inactive flow entries and to avoid overflows in the memory of SDN switches, [59] proposed a Q-learning User Datagram Protocol (UDP) [60] flow eviction strategy for UDP flows. The Q-learning is used to dynamically resize the sampling period as the most critical parameter in the RL architecture. This advertently maximizes the table hit rates of the UDP flows in the SDN.

b) State-Action-Reward-State-Action (SARSA): SARSA [61] is an on-policy algorithm which uses the action performed by the current policy to learn the Q-value. As shown in Eq. 23 [61] and Eq. 24 [40], the update rule for SARSA varies from that of Q-learning algorithm in the execution of actions. In SARSA, update estimates are based on the same action taken whiles in Q-learning, the update estimates are based on the number of possible actions that maximizes the post-state Q function, $\mathcal{Q}(s_{t+1}, a')$.

$$\begin{aligned}\mathcal{Q}(s_t, a_t) \longleftarrow {} & \mathcal{Q}(s_t, a_t) + \alpha[r_{t+1} + \gamma \mathcal{Q}(s_{t+1}, a_{t+1}) \\ & - \mathcal{Q}(s_t, a_t)]\end{aligned} \tag{23}$$

$$\begin{aligned}\mathcal{Q}(s_t, a_t) \longleftarrow {} & \mathcal{Q}(s_t, a_t) + \alpha[r_{t+1} + \gamma max \mathcal{Q}(s_{t+1}, a') \\ & - \mathcal{Q}(s_t, a_t)]\end{aligned} \tag{24}$$

For dynamic load balancing in multiple controllers due to switch migration conflicts, [62] proposed a SARSA-Bayesian RL algorithm for a multi-controller cluster design in SDN. With knowledge of the real-time load and controller's communication consumption, a request response model using the Bayesian [63] algorithm is combined with the SARSA RL mini-framework in a switch migration technique to the lighter controller. For a multi-layer hierarchical SDN to be effective in handling traffic, [64] proposed the SARSA algorithm for QoS provisioning. With each pre-flow, the switch contacts the SDN controller. The controller uses the SARSA algorithm to implicitly detect the QoS requirement of each flow and computes the corresponding optimum traffic path based on the needed QoS requirement. The next hop in the switch forms the basis for the next action from the source to the destination switch. To convey a massive IoT data through a limited bandwidth efficiently [65] proposed a SARSA algorithm for resource allocation through cognitive communications in the SDN-enabled environment. The SARSA agent communication is modelled with a buffer metric that manages the aggregator's output queue transmissions and reflects dynamically in the IoT data demands. This modification targeted at Publish/Subscribe (Pub/Sub) paradigms preserves the Pub/Sub bandwidth with less computational resources. In order to adapt VS-routing [67] optimization to SDN networks, [66] proposed a network hop count technique to improve the reward function of SARSA algorithm. The VS-routing introduces an $\varepsilon - Greedy$ function in the network hop count which is calculated to select the optimal route and avoid the long package queue of network links in the SDN architecture.

c) Deep Q-Network Algorithm (DQN): With the advent of Artificial Neural Networks, (ANNs) a class of RL agents that utilizes Q-learning with Deep Neural Networks (DNNs) [41] in discrete domains for TE has emerged. DQN uses feedforward neural networks with three components: (i) Neurons that are interconnected using direct links to form a network, (ii) Weights associated with each connection, (iii) Layers consisting of a number of neurons and multiple hidden layers.

Algorithm 3 Deep Q-Network Algorithm [41]

```
Pre-condition:
    Initialize experience memory $M$
    Initialize action-value pair $Q$ with random weights
    Initialize state $s_t$
    Initialize goal $\mu$
Procedure:
    improvement = 0
    repeat
        for (step = 0; step < learning_iteration; step++)
            Get action $a_t$ from $s_t$ using $\epsilon - greedy$ policy
            Get parameter $param_t$ from $s_t$ using $\epsilon - greedy$ policy
            $\epsilon = \epsilon -$ (step / learning_iteration)* $\epsilon$
            Take action $a_t$ on $param_t$ and receive reward $r$, control
            overhead $c_t$
            Observe new state $s_{t+1}$
            Store experienced memory $(s, a, r, s_{t+1})$ into $M$
            Sample $n$ random transitions $(s', a', r', s'')$ from $M$
            Update $transition\ tt \longleftarrow r' + \gamma * \max(s'' - a'')$
            Update the $param_t$ of $\theta_i$
            Train the $Q$ network using $loss = (tt - Q(s', a'))^2$
            $improvement =$ get_improvement ( $best_t, worst_t$)
        end for
    until improvement > $\mu$
```

The DQN has an experience memory for storing experienced transitions (s, a, r, s') unlike the Q-learning. The discount factor γ and the state of the Q-Network in the ith iteration, θ_i are used to update the experienced transitions with a training principle using a loss function. The $\epsilon - greedy$ policy helps select the action based on the highest Q-value associated with that action after the training. For the RL agent to choose random actions, the ϵ value is set to 1 at the start of the learning process but decreased over time in order to maintain a fixed exploration rate. The DQN keeps track of the chosen parameter corresponding to the Q-value of each action with a terminal, μ..

In [28], the DQN is used to learn a policy to select critical flows based on a given traffic matrix. The Critical Flow Re-routing-Reinforcement Learning (CFR-RL) agent then reroutes the selected flows for a balanced link utilization using Linear Programming (LP). For an efficient SDN flow entry level management with a TCAM enabled OpenFlow switches [30] proposed a DQN algorithm to obtain the flow entries and reduce the long-term control plane overhead between the SDN switch and the controller. The DQN agent automatically finds the values of decision parameters that effectively selects the candidates rule in the switch's flow table for a higher table-hit rate. For flexible network management through TE, [68] proposed a DQN based dynamic controller placement caused by flow fluctuations in SDN. The D4CPP agent in [68] integrates historical network data into the controller deployment. The real-time switch-controller mapping decisions is then triggered with inherent adaptation to the dynamic flow fluctuations in the network. For effective TE among distributed controllers in SDN, [69] proposed a DQN based switch and controller selection scheme for switch migration and switch-aware reinforcement learning-based load balancing (SAR-LB). The SAR-LB adopts the utilization ratio of diverse resource types in both controllers and switches as inputs to the neural network for a dynamic load distribution among the controllers in the network. Yao *et al.* [70] proposed a DQN-based energy-efficient routing solution for full load software-defined data centers. The optimization is for the DQN to find energy-efficient routing paths and load-balancing between controllers in reducing energy consumption in the network. The enhanced DQN-based energy-efficient routing (DQN-EER) algorithm learns directly from experience. At the same coordinated time, it selects the arriving flows and the energy-saving control path at the in-band control mode whiles detecting the energy-saving routes for the data center. Fu *et al.* [71] proposed the detection of mice and elephant flows in an SDN-enabled data center using two DQNs. The DQNs are built and trained to generate efficient routing strategies using convolutional neural networks (CNNs) [72][73] to avoid possible network congestion. For efficient latency management in SDN, [74] proposed a DQN agent that inherently predicts optimal traffic paths and future traffic demands through the SDN switches. Whiles formulating the flow rules placement policy as an Integer Linear Program (ILP), [74] used a traffic prediction module with a long short-term memory (LSTM) [75][76] neural networks algorithm. To further minimize network delay, a proposed DQN-TP (traffic prediction)-based heuristics defect-tolerant routing (DTR) [77] algorithm interacts dynamically with the DQN agent module in the controller of the SDN architecture.

d) Deep Deterministic Policy Gradient (DDPG): In combining policy gradient and Q-learning, Deep Deterministic Policy Gradient (DDPG) [42][79] is used as an off-policy, actor-critic technique consisting of two modes; actor and critic as shown in Fig. 6. The actor is the policy network and the critic, the Q-value for training the actor network.

Algorithm 4 Deep Deterministic Policy Gradient (DDPG) Algorithm [42]

```
Input: Initial policy parameters $\theta$, Q-function parameters $\phi$, empty replay buffer $\mathcal{D}$
Set target parameters equal to main parameters $\theta_{targ} \leftarrow \theta, \phi_{targ} \leftarrow \phi$
repeat
    Observe state $s$ and select action $a = \text{clip}\ (\mu_\theta(s) + \epsilon, a_{Low}, a_{High})$, where $\epsilon \sim \mathcal{N}$
    Executive $a$ in the environment
    Observe next state $s'$, reward $r$, and done signal $d$ to indicate whether $s'$ is terminal
    Store $(s, a, r, s', d)$ in replay buffer $\mathcal{D}$
    If $s'$ is terminal, reset environment state
    if it's time to update then
        for however many updates do
            Randomly sample a batch of transitions, $B = \{(s, a, r, s', d)\}$ from $\mathcal{D}$
            Compute targets
                $y(r, s', d) = r + \gamma(1 - d) Q_{\phi\text{targ}}\ (s', \mu_{\theta\text{targ}}(s'))$
            Update Q-function by one step of gradient descent using
                $\nabla_\phi \frac{1}{|B|} \sum_{(s,a,r,s',d)\in B} (Q_\phi\ (s, a) - y\ (r\ s', d))^{2}$
            Update policy by one step of gradient ascent using
                $\nabla_\phi \frac{1}{|B|} \sum_{s\in B} (Q_\phi\ (s, \mu_\theta(s))$
            Update target networks with
                $\theta_{\text{targ}} \leftarrow \rho\phi_{\text{targ}} + (1 - \rho)\phi$
                $\theta_{\text{targ}} \leftarrow \rho\theta_{\text{targ}} + (1 - \rho)\theta$
        end for
    end if
until convergence
```

DDPG uses DQNs replay buffer to gather offline unrelated experiences obtained by the agents whiles performing actions on the environment. At each time step, the actor and the critic are updated by uniformly sampling a minibatch from the replay buffer. DDPG uses soft target, θ_{targ} updates rather than directly copying the weights to the target network. DDPG further utilizes batch normalization which helps normalize each dimension across the samples in a mini-batch to have unit mean and variance. DDPG algorithm is suitable for continuous action space and state representations.

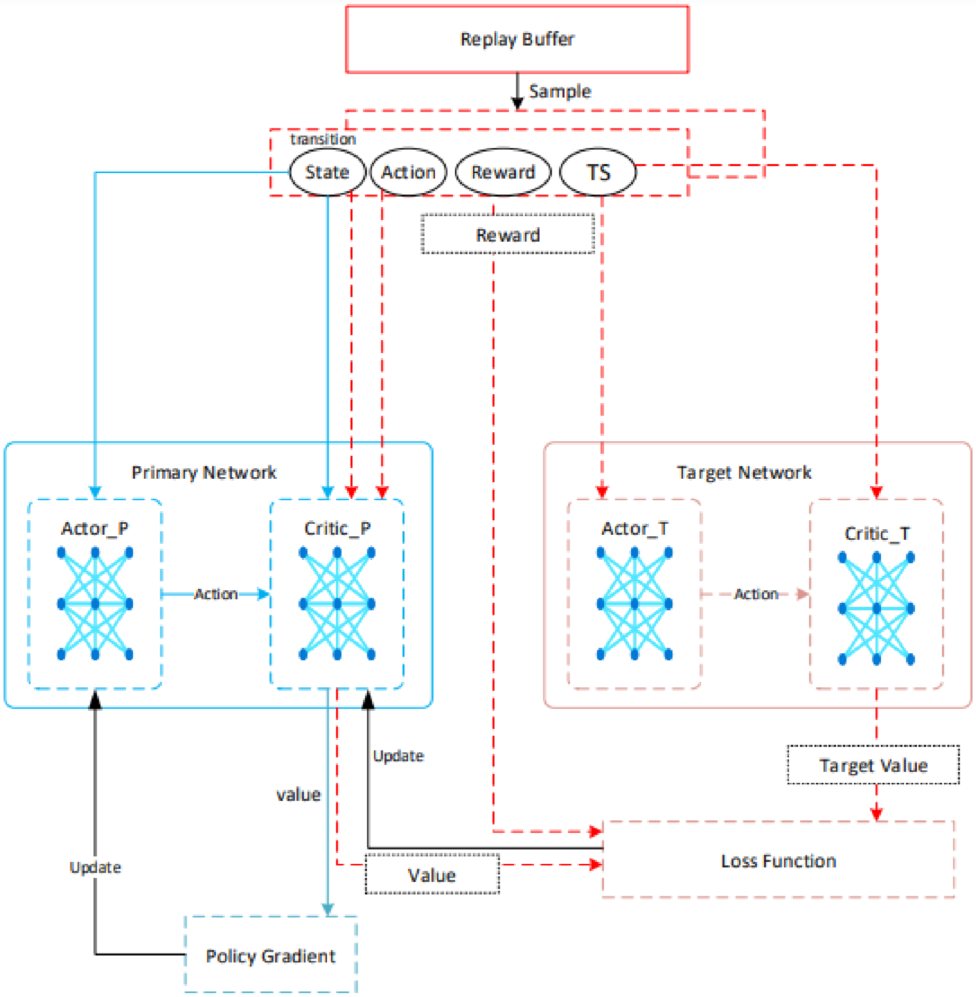

Fig. 6. Actor-Critic Model of DDPG [31].

In [31], the DDPG algorithm is used for multimedia traffic control with the objective of maximizing cumulative Quality of Experience (QoE) for network users. The DDPG agent enforces bandwidth adaptation and path chosen actions for all multimedia flows in the SDN-enabled environment. To maximize the QoE for users, a multi-layer deep neural network is used to map the network and application metrics to the mean opinion score (MOS) [78] obtained from users. Stampa *et al.* [80] proposed a DDPG agent for dynamic routing in SDN. The architecture embeds an integrated fully-connected feed-forward neural network (FFNN) [81] in the framework to re-define the feature extraction of the actor-critic network. To improve the learning rate of DDPG for effective routing optimization, [82] proposed a dynamic planning of the experience pool capacity with respect to the current iteration number. This accelerates the growth rate of the previous pool by reducing its capacity in affecting subsequent learning rates. In [83] a deep-reinforcement-learning-based quality-of-service (QoS)-aware secure routing protocol (DQSP) is proposed using DDPG algorithm. The DQSP adds an intelligent layer above the control layer which generates the routing policy and evaluates the network performance through the rewards obtained by the DDPG policy. The DQSP protocol guards against gray hole attack [84] and DDoS [85] whiles ensuring an efficient routing planning through the environment-aware module of the control layer. Zhang *et al*. [86] proposed a DDPG-based intelligent content-aware TE (iTE) which leverages on information centric networking (ICN) [87] to optimize traffic distribution in SDN. The DDPG agent together with other TE algorithms are embedded in a parallel decision-making (PDM) module in the controller. This module receives the cache information and the link bandwidth from the switches to activate and update its neural networks with a reward feedback. In [88] a DDPG-based network scheduler for deadline-specific SDN heterogenous networks is proposed. The DDPG agent receives a deadline-ware data transfers from the SDN switches and schedules the flows by initializing a pacing rate at the source of the deadline flows. The actor-critic model in the DDPG agent handles larger and a more generalized scheduling problem that maximizes and assigns the aggregated utility value to each flow if the deadline is met. For intelligent routing in software-defined data-centers (SD-DCN), [89] proposed a deep reinforcement learning based routing (DRL-R) consisting of DDPG-DQN agent to perform a reasonable routing adapted to the network state. DRL-R agent efficiently allocates cache and bandwidth in the network to improve routing performance by delay reduction. This is done through the quantification of the overall contribution score in the network and a change in the routing metric from a single link state to the resource-combined state.

4) Multi-Agent Reinforcement Learning (MARL): In MARL systems, multiple agents collectively learn and collaborate in a deterministic or a stochastic environment [90, 91, 92]. Multi-agent systems are seen in domain applications including: network resource management, computer games, distributed networking, cloud computing and intrusion detection systems. Experience sharing and faster convergence has necessitated a shift in research direction from SARL to MARL in recent times. With a coordinated policy, multi-agents learn and optimize towards an accumulated global reward [93, 94] in the network framework. As a result, the dynamics in state transitions in MARL are dependent on the joint action of all active agents as shown in Fig. 7.

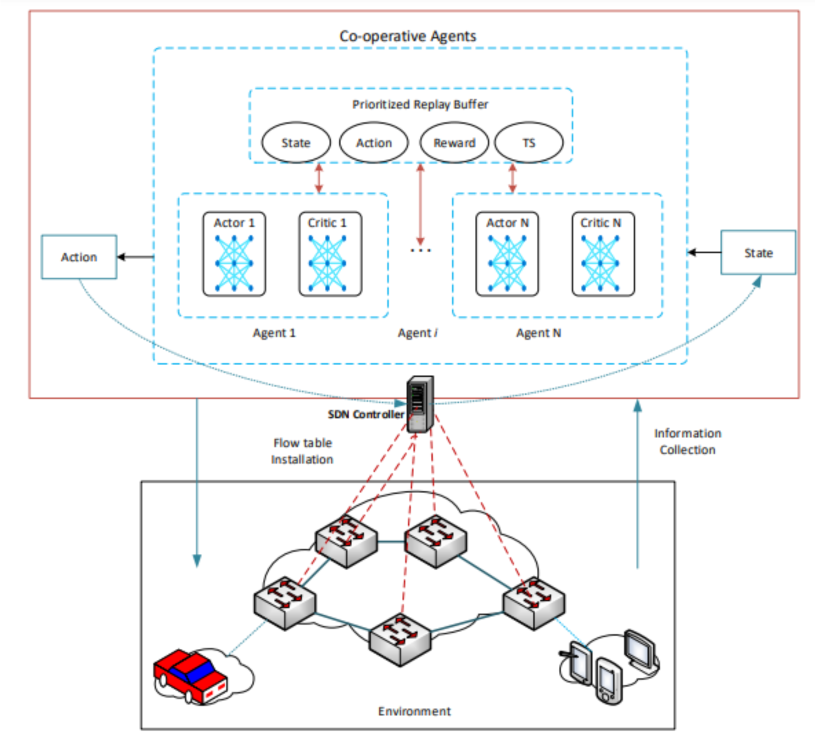

Fig. 7. MARL

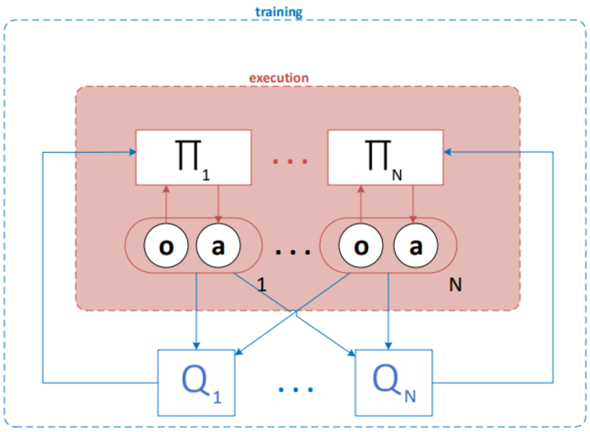

Fig. 8. MADDPG.

a) Multi-Agent Deep Deterministic Policy Gradient (MADDPG): MADDPG [95, 96, 97] is an actor-critic multi-agent extension of DDPG where the critic network is augmented with information from other agents in a decentralized execution. In MADDPG actor-critic architecture, each agent has its own actor and critic network. The critic network of each agent has full visibility of the actions and observation of other agents.

The actor network on the other hand only executes the action for its local agent given the state. In Fig. 8, the actor π_n takes an observation, o as state to give an action, a whiles the critic network, Q_n takes an observation and the action of the actor, to train the actor. The critic has dependent view from other critic networks whiles training the actor network.

Algorithm 5 Multi-Agent Deep Deterministic Policy Gradient (MADDPG) [97]

```
for episode = 1 to $M$ do
    Initialize a random process $\mathcal{N}$ for action exploration
    Receive initial state $x$
    for $t = 1$ to max-episode-length do
        for each agent $i$, select action $a_i = \mu_{\theta_i}(o_i) + \mathcal{N}_t\ w.r.t.$ the current policy and exploration
        Executive actions $a = (a_1, \ldots., a_N$ and observe reward $r$ and new state $x'$
        Store $x, a, r, x'$ in replay buffer $\mathcal{D}$
        $x \longleftarrow x'$
        for agent $i = 1$ to $N$ do
            Sample a random minibatch of $S$ samples $x^j, a^j, r^j, x'^j)$ from $\mathcal{D}$
            Set $y^j = r_i^j + \gamma Q_i^{\mu'}\left(x'^j, a'_1, \ldots., a'_N\right)|a'_k = \mu'_k(o_k^j)$
            Update critic by minimizing the loss $\mathcal{L}(\theta_i) = \frac{1}{S}\sum_j(y^j - Q_i^{\mu}(x^j, a_1^j, \ldots., a_N^j))^2$
            Update actor using the sampled policy gradient:
                $\nabla_{\theta i} J \approx \frac{1}{S}\sum_j \nabla_{\theta i}\mu_i\left(o_i^j\right)\nabla a_i Q_i^{\mu}(x^j, a_1^j, \ldots., a_N^j)|a_i = \mu_i(o_i^s)$
        end for
        Update target network parameters for each agent $i$
            $\theta'_i \longleftarrow \tau\theta_i + (1 - \tau)\theta'_i$
    end for
end for
```

In [98], a MADDPG-based traffic control and multi-channel reassignment (TCCA-MADDPG) algorithm is proposed for the core backbone network in SDN-IoT. The TCCA-MADDPG algorithm reduces the channel interference between links by considering the policies of other neighbouring agents using a cooperative multi-agent strategy. To maximize network throughput and minimize packet loss rate and time delay, the TCCA-MADDPG uses a joint traffic control mechanism modelled with a partially observable markov decision process (POMDP) to optimize traffic performance. Yuan *et al.*, [99] proposed a dynamic controller assignment using MADDPG for effective TE in Software Defined Internet of Vehicles (SD-IoV) [100]. For controllers to make local decision in coordination with neighboring controllers, a real-time distributed cooperative assignment approach is used via the actor-critic model of the MADDPG. To get a faster MARL global convergence whiles minimizing delay, a centralized training approach using global information to attain optimal local assignment is adopted in the model development.

C. TE Architecture in SDN

In this section, we looked at the design placement of the RL agents in the SDN architecture and the communication principles adopted with the controller. The architecture of RL systems varies based on the RL agent policy algorithms, the actions selected and the environment. The agent frameworks are designed to enhance positive rewards and proactively prevent network performance degradation through forwarding devices. Different components of the RL agents design in SDN are situated in the application plane, control plane and the data plane.

1) RL agent in control plane: For easier policy formulation and faster communication between the controller and RL agent, most TE SDN designs [28][30][31][52][54][57][70][86][89] situate the RL agent in the control plane of the SDN architecture. In [28], the CFR-RL agent resides in the controller and uses a neural network trained with reinforcement algorithm [43] to map a traffic matrix to a combination of critical flows. After training, the CFR-RL applies the critical flow selection policy to each real time traffic matrix provided by the controller. The SDN controller then reroutes the selected critical flows by installing and updating flow entries of the switches whiles the remaining flows continue the normal route using Equal-Cost Multi-Path (ECMP) [44] TE technique by default. In [30], the RL agent is deployed in the controller and utilizes the flow match frequency and the flow duration to determine the flow entries that should be kept on the switch. To maximize the long term reward, the RL agent lowers the configuration overhead and the number of table-miss events. To achieve the expected reward, the RL agent splits the pool of flow entries into two parts: the local switch entries and the remote controller entries. This will reduce the control plane overhead given the Ternary Content-Addressable Memory (TCAM) [45] size of the SDN switches. With [31] the RL agent is the controller and serves as the centralized control to collect stats, make decision and take actions. The state reflects the situation in the environment and covers metrics: allocation of bandwidth, delay, jitter and the packet loss rate of flows. The action involves the path chosen and the bandwidth adaption for multimedia flows. The reward is the QoE received from the environment. To evaluate the QoE, the multi-layer deep neural network is used to map the network and application metrics to MOS [46]. [52] also proposed the controller is the RL agent and programmed with the Q-learning algorithm to detect network congestion and find optimal path to be delivered to the OpenVSwitch (OVS). In [57] the control layer has an intelligent center connected to the SDN controller. For efficient load balancing, the intelligent center uses the Q-learning algorithm to find optimal paths and returns aggregated path routing decisions to the controller. The DQN-EER architecture [70] has the RL agent programmed in the SDN controller using the DQN algorithm. The DQN is modified with deep convolutional neural networks (CNNs), empirical replay to train the agent and independent target networks to train the primary critic network. In [86] the intelligent content-aware traffic engineering (iTE) RL agent is deployed in the controller of the SDN architecture. It received cache information from the ICN-enabled switches and uses parallel execution module embedded with multiple DRL-based TE algorithms to determine the best routing paths for the flows in the network.

2) RL agent in Application Plane: For easier system failure checks in SDN, [29] [71][83] TE frameworks situate the RL agent in the application plane. The Q-DATA [29] framework architecture has a built-in forwarding application located in the control plane and a Q-DATA application residing in the SDN application plane. Initially, the built-in forwarding application module is instructed by the Q-DATA application through a REST API to apply the Full Matching Scheme (FMS) strategy at the switches. The Q-DATA application has a statistics collector module which periodically collects raw information about traffic flows at the SDN switches from the SDN controller. The statistics is then forwarded to a statistics extractor and distributor module for extraction and distribution to other modules. The SVM based performance degradation prediction module anticipates the performance degradation of the SDN switches before it occurs and provides the prediction results to the Q-learning based traffic flow matching policy creation module and the MAC matching only scheme control module. The MAC matching only scheme control module monitors and checks conditions for a traffic flow matching scheme change to FMS in the SDN switches. In [71] the AI Plane is used as the Application Plane in the SDN architecture. The RL agent is embedded in the AI Plane and uses the DQN to learn the best optimal routing paths for the mice and elephant flows by obtaining the flow type, network state information and network performance evaluation from the control plane of the SDN architecture. In [83], the DQSP architecture has an agent layer that is embedded in the application layer of the SDN architecture. The DQSP agent through the controller is aware of the underlying network environment and generates routing policies for the controller to executive. It receives the reward evaluation and adjusts policy parameters until optimal routing strategy is achieved.

TABLE I. TE IN SDN USING RL – SUMMARY OF FINDINGS

TE in SDN	Agent Algorithm	Main Contribution	MDP	Limitations	Plane
[29]	Q-learning, Support Vector Machine	The authors proposed an enhanced traffic flow monitoring in SDN using Q-learning and Support Vector Supervised Machine Learning Algorithm	Yes	The statistics tracker should have factored in control link and data link capacity utilization of the SD Networks	Application
[30]	Q-learning, Deep Q-Network (DQN)	The authors addressed the TCAM capacity issue in OpenFlow switches by determining which forwarding rules remains in the flow table and those processed by the SDN controller	Yes	The $\epsilon - greedy$ policy should have given more value for exploration to balance the dynamics of the action taken.	Controller
[50]	Q-learning	The authors improved bandwidth utilization and reduced flow latencies – NRENs case study network	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	Not stated
[52]	Q-learning	The authors addressed network congestion in SDN by reselecting flow paths and changing flow table using predefined threshold	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	Controller

[53]	Q-learning	The authors introduced fairness function in SDN for load-balancing in peak traffic conditions	Yes	One type of user that should not be ignored is a compromised user with network intrusions.	Not stated
[54]	Q-learning, Bayesian Network	The authors used the Bayesian network to predict the degree of congestion and Q-learning for optimal action decision in SDN load-balancing framework	Yes	The rate of packet-in messages from the switches is enough parameter to predict the load congestion to the controller. Using the Bayesian Network will impede the idea of Reinforcement Learning	Controller
[56]	Q-learning	The authors proposed a dynamic switch migration algorithm with Q-learning in scaling the load on SDN controllers	Yes	No reward graph per episode to define the training and validation accuracy of the agent.	Not stated
[57]	Q-learning	The authors used an integrated DNN in Q-learning for load-balancing in SDN through flow forecasting	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	Controller
[59]	Q-learning	The authors maximized table hit rates in a UDP flow entry eviction strategy in SDN by dynamically resizing sampling periods of critical parameters.	Yes	The scope of the state space definition is limited. Aside the size of the sampling period, the state of flows in the network will be an added metrics since UDP operates at the transport layer.	Not stated
[62]	SARSA, Bayesian Network	The authors proposed a switch migration prediction method based on Bayesian network and used with SARSA algorithm for overload-lighter load controller migration.	Yes	Comparing the modified SARSA algorithm to Q-learning in the research will have given a more comparative insight into the results of the research.	Not stated
[64]	SARSA	The authors proposed a QoS-aware adaptive routing scheme using SARSA to provide fast convergence in QoS provisioning in SDN	Yes	The reward function of the MDP is not well defined. Secondary, comparing the results with other known algorithms will have given more credence to the α, γ values	Not stated
[65]	SARSA	The authors proposed a resource allocation technique in massive IoT through cognitive communication in SDN-enabled environment	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	Not stated
[66]	SARSA	The authors proposed a network hop count technique in SDN to improve VS-routing through $\varepsilon - Greedy$ function	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	Not stated
[68]	DQN	The authors proposed a flexible network management through dynamic controller placement technique in SDN	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	Not stated
[69]	DQN	The authors used a DQN based switch and controller selection scheme for switch migration in distributed SDN controllers	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	Not stated
[70]	DQN	The authors used DQN to find energy-efficient routing paths and load-balancing between SDN controllers	Yes	Though energy-saving and load balancing are metrices defined in this research, the extent of a controller's ability to balance the load can be added to the reward functionality.	Controller
[71]	DQN	The authors used two DQN agents to detect mice and elephant flows in an SDN-enabled data center	Yes	A comparative analysis using packet-in and packet-out messages in defining the state-action-reward pair will have added higher scope to the research.	Application
[74]	DQN	The authors proposed a DQN agent that predicts optimal traffic paths and future traffic demands using LSTM neural networks.	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	Not stated
[31]	DDPG	The authors proposed an SDN architecture to maximize QoE using DDPG agent to enforce bandwidth adaption and path chosen for all multimedia flows	Yes	There is little mathematical modelling of the DDPG algorithm used in this research. The pseudocode is not stated mathematically for this research. The parameters for simulation set up was not well defined in this	Controller

				research	
[80]	DDPG	The authors adopted the DDPG agent for dynamic routing in feature extraction with FFNN in the actor-critic network of the agent.	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	Not stated
[82]	DDPG	The authors proposed a DDPG-EREP algorithm with dynamic planning of the experience pool capacity using the current iteration number of the sampling size	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	Not stated
[83]	DDPG	The authors proposed a DQSP using DDPG algorithm with added intelligent layer above the control layer for routing policy optimization in SDN	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	Application
[86]	DDPG	The authors proposed an iTE which leverages on ICN to optimize traffic distribution in SDN through the PDM module in the controller	Yes	The action space definition should have included the flow path selection procedure aside the split ratio for the i-th destination node.	Controller
[88]	DDPG	The authors used a DDPG agent to receive a deadline-aware data transfers from SDN switches and schedules subsequent flows by initiating a pacing rate at the source of the flows	Yes	This research can be extended to multi-path routing using AOMDV protocol	No stated
[89]	DQN, DDPG	The authors proposed a DRL-R based on DDPG-DQN agent to allocate cache and bandwidth in the SDN to improve routing performance	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	Controller
[98]	MADDPG	The authors proposed TCCA-MADDPG algorithm to reduce the channel interference between links by considering the policies of neighbouring agents using multi-agent strategy	Yes	The TCCA-MADDPG should have been compared with DDPG and not DQN since both TCCA-MADDPG and DDPG work in continuous environment.	Not stated
[99]	MADDPG	The authors proposed a MADDPG for effective traffic load engineering in SDN-IoV using a real-time distributed cooperative assignment approach via the Actor-Critic network	No	Since MDP was not used to mathematically define the network parameters, the measuring metrics for success is not well defined.	No stated

IV. Open Research Issues

In this section, we looked at the research gaps identified after the review. From the review summary shown in Table I, it is conclusive that, SDN-based TE solutions using RL agents has the potential to eliminate completely network degradation and provide a network recommender system for end users. From this review, some future research issues exist.

A. RL Agent Implementation

From the review RL agents are designed and situated at the control or application plane of the SDN architecture. For a more efficient and pro-active TE solutions, new SDN design architectures can situate the RL agent as mini-embedded applications adapted to dedicated forwarding devices with oversight from the SDN controller. With performance comparison based on end-to-end delay and response time [47], data plane based RL agents will enable a faster network congestion detection and prevention since the agents are closer to the forwarding devices.

B. RL Agent Algorithm

For TE, most RL agents use model-free based algorithms for policy enforcement and rewards. Though model-based algorithms have high computational complexities, a hybrid architecture that enables the RL agent to select either algorithm based on reward has a research value. Using trial-or-error and referencing a model will give more intelligence to the RL agent. The agent will have the capacity to decide the algorithm to activate based on network complexity and the priority of applications.

C. Multi-Agent Reinforcement Learning

For faster convergence and collaborative learning, MARL solutions in TE though complex is the future in solving network related routing and load-balancing in SDN architecture. The advent of connected devices will only increase with time. MARL agents from review have limited research [98][99] TE solutions in SDN. MARL when proposed efficiently can segment the network into smaller units with multi-agent capabilities.

V. Conclusion

Software-Defined Networks (SDN) has emerged to give more control in network management by separating the control layer from the forwarding devices. This separation has given a centralized programmable supervisory role to the controller and a flexible management of network flows in forwarding devices. In regulating the behaviour of data transmitted over the network, we discussed the relevance of Reinforcement Learning in SDN for Traffic Engineering. This paper explained major reviews using RL techniques in network traffic management and the action of agents on the environment for rewards and new states. The review further detailed the mathematical modelling of agents and environment using the Markov Decision Process (MDP). We illustrated with diagrams SARL and MARL agents and detailed their importance in regards to TE.

With Reinforcement Learning, agents are modelled in a controlled loop to take sequence of actions on the environment to receive future rewards and a new state. The agent must exploit and explore the stochastic environment through determined actions that will lead to a faster convergence. From the review, the paper offers future research options for optimal Traffic Engineering solutions in SDN.

How Enterprise must be Prepared to be “AI First”?

A pragmatic approach for AI adoption

Mustapha Lahlali[1], Naoual Berbiche[2], Jamila El Alami[3]
Laboratory of Systems Analysis, Information Processing and Industrial Management
Higher School of Technology 11000- Salé, Mohammed V University, Rabat, Morocco

***Abstract*—Among disruptive technologies, Artificial Intelligence (AI), Robotic Process Automation (RPA) and Machine Learning (ML) play a very important role in Businesses Transformation and continues to show great promise for creating new sources of wealth and new business models. The reality of AI in the company is not reduced to a simple process optimization. In fact, AI introduces new organizational schemes, new ways of working, new optimization niches, new services, other ways of thinking about interactions with customers and therefore a new way of doing business. It thus reshuffles competitive data and imagine innovative processes to create new business models, offering new opportunities not only for IT solution providers but also for innovators, investors and business owners. Even if the contribution of Artificial Intelligence is not to be proved, many companies face difficulties in adopting this technology, mainly due to the lack of a pragmatic approach highlighting the roles and responsibilities of the various stakeholders, especially IT professionals and business owners and the key steps to follow to make this experience a real success. This research aims to answer fundamental questions, in particular: What will bring the implementation of this technology to the business of the company? How to prepare for this adoption? and if the decision to go is confirmed, what kind of adoption approach should companies follow? and finally how can Enterprises monitor this shift to the Intelligent edge.**

***Keywords*—Artificial intelligence; machine learning; RPA; business transformation; AI adoption**

I. Introduction

Artificial Intelligence was certainly born several decades ago, but its rhythm of adoption has clearly accelerated in recent years. Indeed, this technology is no longer reserved only for the scientific world and its rich, varied and innovative applications are a delight for many companies.

This acceleration was primarily driven by the explosion in the amount of data and the digital transformation, and also by the company's enthusiasm to adopt disruptive technologies in their growth strategy. Indeed, many companies, in order to remain competitive, have been forced to rethink the way they operate by integrating technological innovation into the daily process as an enabler for creating value.

Artificial Intelligence fully expresses its potential through various functionalities: it optimizes existing processes, automates routine tasks, allows assisted monitoring, detects abnormal phenomena, predicts future actions, and interacts more and more "naturally" with humans, thanks to recent developments in natural language processing.

This article aims to illustrate how AI can bring a tangible value to the enterprise by answering pragmatic questions. It shows, in a pragmatic approach, how companies can meet the challenges and takes benefits of adopting this technology by making the most of its contributions while minimizing the associated risks.

II. Artificial Intelligence in Business: For What Purposes?

The development of Artificial Intelligence (AI) technology widens the limits of business practice for companies, thus promoting the transformation of information technology to optimize decision-making and operations. Recent research findings [1][2] presents several main developmental trends of the technology and the resulting challenges and show how dynamic AI capabilities can improve operational efficiency and business performance.

AI is definitively not a technological subject. It’s, at the first level, a business matter aiming to improve the business performances and capabilities. Fig. 1 shows the main expectations of business managers towards the adoption of AI.

Artificial Intelligence can support three important major business needs: processes automation, cognitive signals, and cognitive engagement [4].

A. Process Automation

Robotic Process Automation paradigms (RPA) bring the opportunity to integrate robots inside the enterprise chain of value. RPA is not aiming to replace human, it’s mainly designed to increase human productivity by automating repetitively and costly tasks [5]. Basically, RPA robots correspond to software programs acting as a digital worker and ensuring many kinds of tasks including:

- Automating customer relationship management and ensuring clear and comprehensive customer data collection and structuring.
- Ensuring that multiple data are correctly updating different systems, for example, blocking immediately customer identity in case of ID lost reclamation by customers.
- Verifying the integrity of data manipulated in different systems to ensure the authenticity of information managed in different business lines, for example, verifying automatically inside the billing system, the amount of a settlement check provided inside the supplier bills.

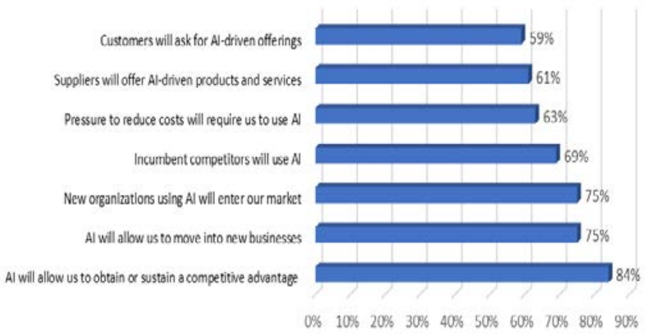

Fig. 1. Reasons for Adopting AI [3].

RPA is usually considered as the least expensive and easiest to implement module of the cognitive technologies and typically brings a quick and high return on investment.

Some enterprises launched RPA pilots in accounts payable, automatic settlement check controlling and validation, automation of IT daily tasks by avoiding manual operations and minimizing human intervention.

In all cases, RPA is not a Human predator [6]. It's a new way to let Human making valuable tasks and being supported by robots to do well and correctly daily tasks. The cost killing objective is usually forecasted by enterprises beside the use or not of the RPA. For this reason, the outsourcing/offshoring sector will be challenged by this paradigm and maybe the job losses impact can be felt more in those areas [7].

B. *Cognitive Signals*

Cognitive signals can detect patterns in vast volumes of data and interpret their meaning (e.g., predicting purchasing habits, identifying credit card frauds, determining trends, qualifying data quality,..).

Cognitive signals provided by Machine Learning are stronger and more sophisticated than those provided by analytics for those three principal reasons:

- The huge amount of data.
- The ability for Machine Learning-based systems to learn from the data collected.
- The prediction capabilities to anticipate features.

It should also be noted that Machine Learning bring new capabilities and features like text and voice recognition. In the past, a lot of efforts had to be made to collect and to manipulate structured data. Today, Machine learning brings a significant contribution to do these tasks more intelligently for both structured and unstructured data thanks to the important developments in computing power.

Cognitive signal applications are typically used to improve performance on jobs and tasks only machines can do, so we can therefore imagine a fruitful collaboration between humans and machines.

C. *Cognitive Engagement*

Smart assistants are revolutionizing the daily lives of individuals and businesses. With their ability to interpret and understand human language through Machine Learning capabilities, they enable the following opportunities:

- Intelligent agents [8] ensuring customer assistance every day by supporting simple to complex queries via quick and concise responses.
- The product offering is enhanced by learning from the various customer questions addressed to chatbots, allowing the company to anticipate customer demands and to differentiate itself from the competition.
- Internally, the distance between the company and its employees is reduced by setting up intelligent channels of exchange and support for daily queries (e.g., Administrative HR assistance, IT help desk,…).

Fig. 2 shows the different types of AI adoption within Companies. It gives a clear visibility on the current use and forecasts of the future uses of the intelligent technologies on which the AI is based to transform the business processes.

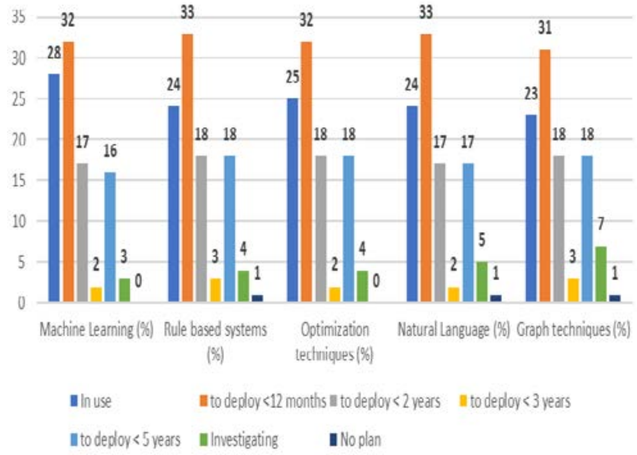

Fig. 2. AI Adoption by Type [9].

III. Challenges Facing AI Integration and Adoption

Companies must put in place the necessary prerequisites for the success of its AI integration projects, which are related, in particular, to technological, financial, organizational and human aspects.

It should be noted that once the technology adoption process is successful, the impact on the business can be very important. For example, in the retail industry, a lot of champions made a significative growth by adopting IA like Amazon and Walmart [10].

A. *Understanding the Technologies*

Before going in depth and embarking on AI adventures, companies must ensure that they have a thorough understanding of the technology and be able to make a distinction between different paradigms and their potential for value creation. For example, RPA offers no ability intelligence or learning, it automates the cumbersome and repetitive tasks, unlike the deep learning where there is a strong element of intelligence. In all cases, AI-driven companies will have the potential to compete by looking beyond the initial product or service to the full potential of the technology available [11].

From talent management perspective, companies must prepare task forces which are necessary to manage these AI projects. From Data Scientist to AI Architect, each role has a specific mission to leverage one or multiple sides of the technology in order to succeed in AI projects. Unfortunately, this is not enough. The construction of an ecosystem made up of experts and industrialized product offerings is considered as a fundamental pillar in the mastery of technology and a guarantee to ensure its viability.

B. Financial Effort

Experimentation of the Machine Learning and Data Intelligence subjects require a significant financial effort which must be justified from the point of view of viability. In fact, to make this successful, companies are called upon to mobilize a lot of expertise which requires large expenses. The whole challenge lies in the adequacy between the expenditure and the return on investment which is generally difficult to ensure given the high level of uncertainty that characterizes a large number of AI projects.

Also, thanks to the learning techniques offered by AI (e.g. supervised, unsupervised, by reinforcement) [12] [13], many opportunities are now available to companies to create new business models and offer a new form of value. In this context, the predictive aspect remains an undoubtedly promising axis for designing intelligent systems capable of reasoning, analyzing and perhaps making decisions.

Some questions will arise in terms of risk management accompanying this revolution, but from a business point of view, several possibilities arise for switching approaches from classic IT solutions towards intelligent and augmented solutions.

Faced with increased competition, IT Departments will find themselves at the center of all interests and will transform from a support unit to a profit unit because in the era of intelligence, there mission will not be to support the trades but to transform the whole operational model of the company by making intelligence an axis of wealth. In this perspective, IT teams will find themselves in a new management style of collaborative work and agile implementation with a record speed of change and transformation and also with a drastic impact on the product development methodology and the implementation of intelligent journeys.

It is almost certain that the “Augmented CIO (Chief Information Officer)” is a CIO who will use “intelligence” as a workhorse to enhance its contribution to the company's strategy.

C. Organization Challenges: Internal and External Dependencies

Faced with the diversity of profiles and the complexity of AI subjects, many organizational challenges will be the object of challenge. Some companies have adopted the Chief AI Officer (CAIO) function as an unifying role to create synergy between business, IT and statisticians and make teamwork more fluid and more constructive.

Most AI topics are expert and advanced computing topics which require the collaboration of several profiles from different structures, whether internal to the company or located in its ecosystem (e.g. service providers, partners, IT experts). In this situation, managing relationships between different teams is almost considered as a daily challenge. For example, in terms of big player dependencies, many suppliers are positioning themselves in this segment without necessarily having a solid foundation with commercial promises that are not necessarily tenable. For this reason, many companies consider that Open source-based solutions are an issue that will not depend on the big players, but at the same time it requires the loyalty of internal experts which is not at all an easy task. In this perspective, the real challenge will consist in finding a balance between business ambition, technological capacity and a better organization to co-construct intelligent value.

D. Thinking Platforms

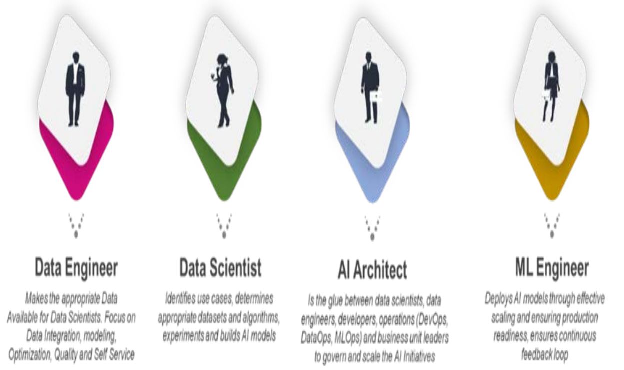
AI is drastically transforming the technological DNA of the company. In fact, the rate of dependence on experts and IT giants remains too high. In this sense, the company must adopt a new approach. The first one is based on internal Labs to develop and retain its own internal experts by associating them with the company's businesses. The second point concerns the implementation approach and methodology. In fact, supplying the process of creating AI products is totally different from traditional IT products, hence from a technical standpoint, the company must adopt a reasoning based on platforms and not on isolated solutions. These platforms will aim to industrialize the entire chain from data collection to the operationalization of machine learning models with the possibility of mixing between the private cloud and the public cloud to optimize production capacities and have a very significative return on investment.

E. Skills and Task Forces

Companies that want to win the race for a successful AI adoption need to be truly convinced that this victory comes first and foremost through the provision of skills, competencies and talents. Furthermore, developing and maintaining smart talents is a very difficult HR subject because it’s about innovation in HR management practices to create suitable policies to smart task forces highly targeted by competitors. Enterprise should protect their internal skills by supporting them and rewarding their efforts.

The availability of qualified resources is a precondition for a successful leap towards the era of intelligence. Different modes of organization are possible such as internal competence centers and Tech accelerators. The intangible capital of the company represented in its human wealth is definitely a sure catalyst for success.

The sheer diversity and complexity of AI projects combined with a requirement for rapid time to production create the need to find key AI roles to achieve successful AI projects. Fig. 3 shows main AI specialist’s roles and responsibilities [14].



Data Engineer
Makes the appropriate Data Available for Data Scientists. Focus on Data Integration, modeling, Optimization, Quality and Self Service
Data Scientist
Identifies use cases, determines appropriate datasets and algorithms, experiments and builds AI models
AI Architect
Is the glue between data scientists, data engineers, developers, operations (DevOps, DataOps, MLOps) and business unit leaders to govern and scale the AI Initiatives
ML Engineer
Deploys AI models through effective scaling and ensuring production readiness, ensures continuous feedback loop

Fig. 3. AI's Core Roles and Responsibilities.

F. *Ethics*

A question that comes up quite often in AI implementation projects concerns the limitation of ethical responsibilities for decisions that might be made by an algorithm based on machine intelligence [15].

For example, administrative, social or financial decisions can be subject to a complaint. Indeed, the decisions taken by human can consider emotional et behaviors factors, even subjective in some cases, that a machine cannot necessarily make. All the effort therefore remains to clearly define the tolerance thresholds and to delimit responsibilities between human and machines.

IV. AI Initiatives and Projects: The Way of Success

The success of an initiative based on AI begins with the identification of opportunities, the determination of the use cases to better achieve these opportunities and finally the choice of the right technology and solutions to meet the expected results.

A. *Creating a Portfolio of Projects and Identifying Opportunities*

AI programs [16] are becoming more and more present in companies' IT portfolios. These programs consist of a several use cases and projects generated, most of the time, after an experimentation phase. This structuring approach helps the company to choose and prioritize AI initiatives and projects according to business needs, market opportunities and needs, team capacity and also taking in account prioritization of intelligence technologies according to the context and providers maturity. The management of these programs allows top management to continuously monitor the evolution of the company's intelligence quotient.

B. *Targeting the use Cases*

To approach AI projects, companies must start with an exploration phase which consists in identifying concrete use cases where intelligence is essential and also which constitute a real axis of improvement and wealth creation.

These use cases will be essentially inspired by the strategy of the company, its operational objectives, the market opportunities and, above all, the trajectories identified to ensure growth.

Basically, the use cases must be proposed and especially well defined in feasibility term correlated to the expected value. The result of this work will offer the company a measured trajectory to appropriate the technology and move slowly but surely towards the intelligent enterprise.

C. *Selecting Tools and the Technology*

One of the major challenges to be faced is to properly identify the right technology through which intelligence will be showcased.

For example, chatbots or digital assistants can be used in certain contexts where the company must be very close to its customers and respond in record time to their requests. As for facial recognition, which is very data-intensive, it is of interest to use in contexts of identification or detection of abnormal behavior. In all cases, AI architects must use the right channel to better achieve the desired impact.

V. Three Steps to Integrate AI in Enterprise Business Applications

Once AI-based initiatives are successful, companies can move up to integrate these use cases into their process. To achieve this objective, companies must first launch pilot projects to clearly identify all aspects related to the implementation of the technology (technical prerequisites, financial impacts, risks, organizational aspects, Human Resources, impact on the Ecosystem,..). The second step relates to the optimization, review and redesign of the processes. The third and last phase obviously relates to the full-scale generalization.

A. *Setting up Pilot Projets*

The creative appetite for intelligent products and services is always faced with the contradiction between promises and real creative capabilities. For this reason, companies from the Test & learn perspective, must test as part of Proof of Concepts (PoCs) the Business impact on a reduced scope before any full-scale realization.

The SENSE-THINK-ACT [17] model can be a suitable tool to challenge AI PoCs, by preparing Data, designing products and creating AI powered solutions.

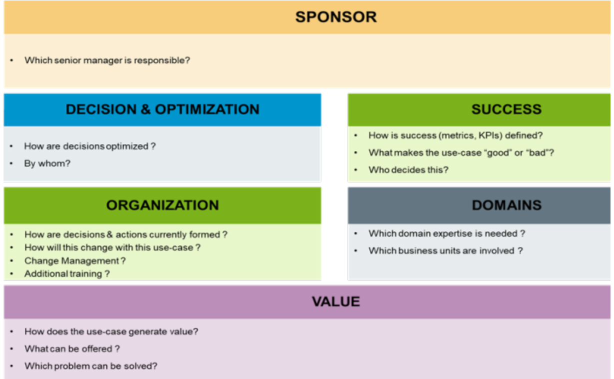
The phase of testing and validating the added value of the technology on the business processes remains a key stage in AI adoption. Companies must in no case derail the rule under the pretext of submitting to external pressure or simply following the fashion effect.

B. *Redesigning Processes*

The implementation of any projects based on Artificial Intelligence does not mean necessarily the fact that the company should automates its processes in an iso functional way. To get the most out of the technology, companies must think about reshaping their way of doing things (thinking out of the box), so that machines and Humans can perform in perfect harmony, because, at the end, each actor should compensate the weaknesses of the other.

Hironori Takeuchia and Shuichiro Yamamoto [18] worked on a Generic business–AI alignment model giving the capacity to integrate AI within the Enterprise architecture and giving a strong and didactic way to facilitate AI integration with business processes.

Today, every business realizes the drastic impact of enterprise architecture on the leap to intelligent enterprise. This integration is illustrated in Fig. 4 according to the Enterprise AI Canvas [19].



SPONSOR

- Which senior manager is responsible?

DECISION & OPTIMIZATION

- How are decisions optimized ?
- By whom?

SUCCESS

- How is success (metrics, KPIs) defined?
- What makes the use-case "good" or "bad"?
- Who decides this?

ORGANIZATION

- How are decisions & actions currently formed ?
- How will this change with this use-case ?
- Change Management ?
- Additional training ?

DOMAINS

- Which domain expertise is needed ?
- Which business units are involved ?

VALUE

- How does the use-case generate value?
- What can be offered ?
- Which problem can be solved?

Fig. 4. Enterprise AI Canvas.

Working in a common framework under solid governance is far from being a choice. Indeed, the orchestration of flows and the orchestration of exchanges is necessary to successfully integrate AI into the company and ensure that all professionals and AI engineers work in perfect synergy.

C. Scaling Up

Several experiences have shown that many companies having passed "successfully" proof of concepts stage, have unfortunately failed to make it a real use case, because the mastery of technology and IT talents cannot be considered as the only factors guaranteeing success [20].

Indeed, before any generalization of an experimentation, companies must put in place the necessary prerequisites for its success, in particular: a perfect synergy and convergence of point of view and vision between the business owners and the IT professionals, an adequate governance framework and a solid change management to allow the appropriate use of the future system.

The Scaling up approach is a mix between the AI adoption degree and the knowledge of the technology as shown in Fig. 5:

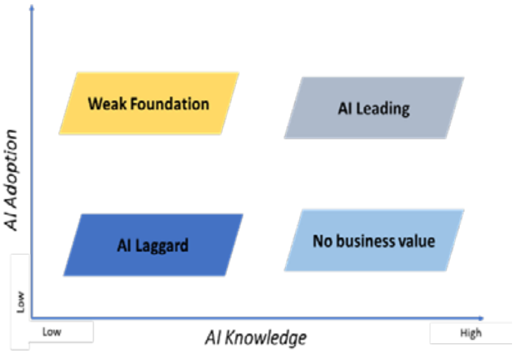


Fig. 5. Blueprint for AI Scaling up.

VI. Conclusion

Today, no one can deny the importance and the contribution of Artificial Intelligence in the transformation of our way of acting, driving our processes and especially of creating value. To take maximum benefits from this technology, companies must prepare the prerequisites for a successful adoption, in terms of understanding the technology, coordinating initiatives, making data available and implementing innovative use cases.

In that way, to make the implementation of AI projects a happy story, company faces many challenges and it is brought to change management issues due to the massive adoption of disruptive technologies, the use of structured and unstructured data and the transformation in the ways of doing business.

Our work aims to implement a Model of AI adoption inside the Enterprise. We call it 2PS Model (Pilot, Project and Scale) giving the opportunity to leverage AI adoption by implementing holistic approach. Each step must be well prepared and well executed to ensure success.

Within this study, we tried to answer a couple of questions regarding enterprise readiness to Adopt AI. At this stage, aspect concerning Explainable AI and Trust AI are not discussed in this paper. In future publication we will challenge those aspects as perspective and evolution of our thinking about this problematic.

Our approach can be compared with some frameworks like Google AI readiness framework which deal with AI adoption from Learn, Lead & Access perspective by challenging tactical, strategic and transformation aspects. We deal with the AI adoption from strategic point of view to give the core capacities to enterprise to deal with AI disruption. The Google framework supposes that enterprise is smart enough to go further in its AI journey. In that way, our work aims to prepare the enterprise to be able to leverage frameworks (like google or other) to create maximum value for user experience and a better contribution for enterprise growth.

Finally, AI platforms are basically based on Data, Machine Learning and Models Operations. So, as another perspective of this research, we aim to analyze how to leverage those capabilities to give a strong enabler for AI adoption through the implementation of a case study to illustrate the disruptive impact of the AI on business process. We aim within the future work demonstrate the power of this technology, particularly these aspects related to Data Science and Machine Learning, on improving both the internal performance of the company and its interactions with its eco-system.

The Effect of Augmented Reality in Improving Visual Thinking in Mathematics of 10th-Grade Students in Jordan

Dr. Fadi Abdul Raheem Odeh Bani Ahmad
Assistant Professor of Education Technology
Middle East University, Amman
Jordan

***Abstract*—Augmented reality is one of the key issues in the area of improving visual thinking in science courses such as Mathematics. Augmented reality also offers a significant and effective role in the educational process. The current study aimed to investigate the effect of augmented reality in improving visual thinking of 10th-grade students in mathematics in Jordan. To achieve the objectives of the study, the methodology used includes the application of the semi-experimental approach and augmented reality technology. The methodology used also includes preparing a test to measure visual thinking comprising (20) multiple-choice items used as a pre-and post-test, and its validity and reliability are verified. The study sample consists of (57) female students purposefully selected from the 10th-grade students at the Jerash Model Schools for the first semester of 2020/2021. The study sample is divided into two groups as follows: one is an experimental group consisting of (28) female students taught by the augmented reality technology, and the second is a control group consisting of (29) female students taught in the traditional method. The results of the study show that there are statistically significant differences at the level of (α = 0.05) in the development of visual thinking in favor of the experimental group students taught by the augmented reality technology. The study also shows that there are differences in the performance of the experimental group students in each skill of visual thinking.**

Keywords—Augmented reality technology; visual thinking development; 10th grade; mathematics

I. Introduction

Augmented reality offers a significant and effective role in the educational process because it is one of the up-to-the-minute and developed technological innovations that depend on smartphones. Augmented reality enables the student to deal with an imaginary or near-reality environment based on simulation between the student and a third-dimensional electronic environment because education is one of the areas strongly affected by technology and digitization.

At present, school and university students no longer want to learn by reading books and copying texts, but rather wish to exploit the advantages of technology for use in the classroom. Therefore, augmented reality has emerged as a development of virtual reality that requires special tools and professionalism for third-dimensional design programs. The augmented reality can be attained by less professional programs, or by using online libraries that contain a lot of previously designed third shapes. Moreover, augmented reality in the classroom contributes to making students busier with the curriculum, learning more deeply, and interacting and cooperating better. It is indicated that augmented reality furnishes the learners with multiple options in representing information dynamically and quickly, helping to increase learners' motivation, and developing their academic achievement [1]. Augmented reality is a form of technology that enhances the real world by merging the textbook with technology, especially a mobile phone. From the viewpoint of emphasizing the educational theories in the domain of educational technology on the significance of using visual thinking and its various tools such as images, shapes, graphs, and diagrams in the education process, this study investigates the possibility of the effect of augmented reality technology in the development of visual thinking among students during the educational learning process.

Augmented reality has always provided a significant and effective role in the educational process because it is one of the contemporary and developed technological innovations that depend on smartphones. With that, an investigation is conducted by the researchers to explore how to address the poor achievement of 10th-grade students in mathematics by interviewing several teachers. The results of the investigation show that the reason for the poor achievement of 10th-grade students is the stagnation that characterizes mathematics and is reflected in the difficulty faced by students in understanding and recognizing the content, and this is evidenced by their low achievement and motivation towards learning in general and learning mathematics in particular. Accordingly, it is necessary to move towards learning that simplifies the presentation of scientific content and lessons in a manner that meets their desires and takes into account their differences, so augmented reality is the choice from the researchers' point of view because it does not require effort, time, and cost to enhance, enrich, and support the environment of the educational learning process. In light of the recommendations of the study, it is noted that augmented reality motivates students to conduct interactive experiments and develops their visual thinking [2]. Also, it is maintained that augmented reality is used in Japan and Austria in the museums of mathematics and science to develop remembering and prediction among learners [3]. It is also recommended that augmented reality contributes to achieving happiness among students in the primary stage, which increases their motivation and ability to learn and read [4]. Based on the investigative process carried out by the researchers, the study problem of the study lies in investigating the effect of augmented reality in improving the visual thinking of 10th-grade students in mathematics in Jordan.

Due to the problem of the study, the following questions are articulated: What is the effect of augmented reality on developing visual thinking in mathematics among 10th-grade students in the Jerash governorate? The second question: What is the effect of augmented reality on the development of each of the visual thinking skills (visual reading skill, visual discrimination skill, scientific deduction skill, the skill of analyzing and interpreting the visual shape) in mathematics among 10th-grade students in Jerash governorate?

With that, the following objectives formatted to answer the questions of the study: Explore the effect of augmented reality on developing visual thinking in mathematics among 10th-grade students in Jordan and examine the effect of augmented reality on the development of each of the visual thinking skills (visual reading skill, visual discrimination skill, scientific deduction skill, the skill of analyzing and interpreting the visual shape) in mathematics among 10th-grade students in Jordan.

Given the significance of augmented reality technology in developing visual thinking among students who have learned to use it, the significance of this study lies in the scarcity of Arab and foreign studies that have investigated the effectiveness of augmented reality technology in visual thinking. Importantly, this study is the first at the level of Jordan and the third at the regional level investigating the increasing knowledge in the area of augmented reality and visual thinking and its effect on students. Accordingly, this paper presents an analysis of the effect of augmented reality in improving visual thinking in mathematics of 10th-grade students in Jordan.

II. Literature Review

In light of the nature of the study, it is necessary to demarcate the literature review into four parts as follows: use of augmented reality technology, visual thinking, visual thinking skills, and visual thinking tools.

A. *Use of Augmented Reality Arachnology*

Augmented reality technology is considered the product of the development of virtual reality, which is the integration of real reality with augmented information, whether it is still images, videos, or texts taking into account that real reality (RR) cannot be ignored to enhance the perception to develop visual thinking of the learner in mathematics. Augmented reality technology is distinguished from virtual reality in that augmented reality is the cutting-edge, easiest, and latest technology used in the educational learning process. Among its key characteristics are providing clear, flawless, and accurate information, the possibility of entering information easily and effectively, the ability to interact between the teacher and the learner in a positive, flexible, and less expensive manner. As put by [5], augmented reality provides an interactive environment that the real world does not offer.

Augmented reality also employs multimedia as digital content augmented with 2D and 3D animations or videos. Moreover, it is indicated that augmented reality takes into account individual differences among learners and is a safe way for children while the impact of learning with the learner's sense of fun [6]. This is confirmed by [4] that the animation used in augmented reality contributes to achieving educational objectives and furnished children with fun and happiness and that the appearance of 3-dimensional models while learning increases their motivation towards learning.

Augmented reality is characterized by the complementarity between the media based on this type of education, which aims to enhance and enrich the real world. The media-based augmented reality such as icons, printed images, and interactive videos contributes to raising the efficacy of academic achievement, allows students to control the presentation, and repeats the scenes that embody the information, ensuring the realization of the principle of visual analysis by controlling the speed of presentation [7]. The augmented reality contributes to achieving the highest degree of interaction between the scientific content and the learner, which is difficult to achieve in traditional learning, especially in learning abstract scientific concepts in mathematics, which are difficult for the learner to understand and perceive, as augmented reality contributes to the survival of the learning effect and the achievement of self-learning [8].

The concept of augmented reality is one of the up-to-date concepts and indicates that augmented reality has expanded in real reality by adding layers of computer-generated information to the real environment, and this information may be texts, videos, or static and animated graphics [9]. Likewise, it is asserted that augmented reality combines the virtual environment and the real environment in a 3-dimensional image for the user to see as a real-world [10]. Moreover, it is believed that augmented reality is a system that allows the integration between the real and the virtual world in the same place, where they interact together at the same time, as students use computers to attain rich environments and meaningful multi-media content related to the context of the educational content [11]. As specified by [12], the fundamental point is the difference between virtual augmented reality and augmented reality is immersion, as virtual augmented reality uses masks and special glasses that immerse the learners in learning and try to convince them that they are inside a real reality, so it is a reasonably convincing illusion, while augmented reality does not ignore the real world but uses a computer to improve it. Augmented reality technology is distinguished from virtual reality in that augmented reality is the cutting-edge, easiest, and latest technology used in the educational learning process [13]. Among its key characteristics are providing clear, flawless, and accurate information, the possibility of entering information easily and effectively, the ability to interact between the teacher and the learner in a positive, flexible, and less expensive manner. As put by [5], augmented reality provides an interactive environment that the real world has not provided.

Importantly, augmented reality provides an opportunity for students to interact with the educational content in general and in teaching and learning mathematics in particular because it includes abstract and complex scientific concepts, where augmented reality can simulate these concepts and embody the information and this is reflected in the development of thinking skills, especially visual thinking, which is one of the most complex types of thinking. This useful and practical aspect of augmented reality has been confirmed by previous studies, including [14] and [15]. Therefore, the development of thinking is one of the most important points that educational institutions focus on to achieve it among students by harnessing all their capabilities in developing thinking of students, which is reflected in students in the conscious and appropriate interaction with life and the circumstances surrounding it. Visual thinking is one of the types of thinking that is no less important than other types of thinking because it depends on the five senses that connect the person with the world around him and we cannot express it in writing [16]. As defined by [17], it is the merging of the senses with thinking to help in explaining a situation, and it is the greatest method of perception and has a direct impact on developing skills and acquiring competencies in teaching and learning. However, it is shown the effectiveness of augmented reality based on mobile learning in developing academic achievement and motivation in science subjects for fourth-grade students is on the rise [6]. As for the study [18], it evaluates student’s achievement and motivation during a high school augmented reality math activity that focuses on dimensional analysis. The use of augmented reality in mathematics and a combination of print and augmented reality also known as interactive printing are demonstrated. Participants in the quasi-experimental study are 61 students and the study instruments are pre and post-achievement tests. The results of the study have supported claims that the use of technology in a mathematics lesson and augmented reality increase student’s achievement and enhance the student’s motivation to learn mathematics and that the impact of technologies on the conceptual use of mathematics demonstrates the need for continued exploration to determine the impact of technologies not only on overall mathematical achievement but also on the specific type of conceptual mathematical activity.

The study aimed to benefit from the ability of virtual reality and augmented reality to visualize 3-dimensional shapes in mathematics where the study has investigated the possibility of using virtual reality and augmented reality techniques to teach the lesson of engineering solids to primary school children [19]. A 30-student sample randomly selected from fourth, fifth, and sixth grades is divided into three groups comprising a control group and two experimental groups. The results show that applying new technologies in teaching virtual and augmented reality improves interaction and students' interest in teaching mathematics, which contributes to increasing learning efficacy and understanding mathematical concepts when compared to traditional teaching methods.

This study identified the effect of augmented reality technology on the achievement of high school students in a unit in the science subject and their attitudes towards teaching the science subject [20]. To achieve the objectives of the study, the quasi-experimental approach is used, and the study is applied to a sample divided into two groups; an experimental group taught using augmented reality technology and a control group taught using the traditional method. The results show that students of the experimental group are more positive and happy about learning and want to continue to use augmented reality applications in the future. The results also conclude that the students show no signs of anxiety when using augmented reality applications. The trends of secondary school learners in Turkey towards augmented reality applications have been explored [21]. The study has also identified the relationship between the trend towards augmented reality and achievement in the solar system unit using augmented reality technology for 4 weeks. The results show that learners have positive trends towards augmented reality technology. They also show that there is a statistically significant relationship between the trend towards augmented reality and achievement. An analytical study of the results of (50) research papers in three databases, namely: Web of Science, Link Scopus, and Springer during 2008-2018 [22]. Factors such as the advantages, uses, challenges, and scope of augmented reality in the educational domain, and the positive or negative effects of its use in learning are analyzed to include students at various educational levels. After analyzing the results, it is concluded that the use of augmented reality for comprehensive education in mathematics is the area in which most studies have been conducted. The study recommends the necessity of conducting pieces of research in other areas of the importance of augmented reality in education.

B. Visual Thinking

Visual thinking is defined as one of the types of thinking that results from what we see around us, whether intentional or unintentional and it is the one that depends on the sense of sight because it is the means of communication that captures images and sends them to the mind and interacts with them, either by distinguishing, analyzing, interpreting or deducting. Visual thinking is constructed on experimental research into the way of thinking of learners by focusing on developing their abilities in changing and translating the visual language carried by the visual shape into verbal, written, or spoken language. This means that the relationship between the cognitive structure and the cognitive representation is a reciprocal relationship based on the influence and effect from the inside through which knowledge is strongly represented because visual representation supports visual thinking in terms of the ability to see the internal relationships of the presented shape and reveal the relative relationships in the dimensions of the shape and the development of inference skills [23].

In the same vein, the impact of augmented reality technology on teaching concepts related to the relationship between the earth and the sun to university students-majoring in geography has been identified [24]. The researchers have used the experimental approach on a 30-student sample from the University of Washington, where models designed with augmented reality technology are presented for the concepts under study. They have also employed worksheets as study instruments to evaluate the development of concepts among students applied pre and post the same group. The study shows that the students’ understanding of realistic concepts related to the relationship between the earth and the sun greatly improves due to the effectiveness of models designed with augmented reality technology. Also, the study shows that the use of this technology contributes to replacing false alternative perceptions of concepts with correct concepts.

The effect of augmented reality and its ability to facilitate the learning of chemistry for students has been revealed so that they can understand abstract concepts [25]. The study has employed the semi-experimental approach on a 96-student sample majoring in organic chemistry at the University of Washington, where they are divided into three groups: (26) students taught through books only, (26) students taught through augmented reality only, and (22) students taught through augmented reality in cooperative pairs. The study instruments are represented in the questionnaire, a chemistry self-efficacy measure, and an achievement test. The study concludes that the performance of a group of students taught using augmented reality only does much better than students taught without using augmented reality, and other students taught using augmented reality in cooperative pairs. The study recommends the need to support education with augmented reality technology in various educational stages other than the university stage.

C. Visual Thinking Skills

There is a multiplicity of visual thinking skills and differs from one study to another according to the nature of the educational situation, as the skills of visual thinking are demonstrated in the following: the skill of visual reading, the skill of visual discrimination, the skill of perceiving spatial relations, and the skill of visual closure [26]. It is asserted that the skills of visual thinking can be summarized as follows: the skill of describing and recognizing the shape, the skill of analyzing and interpreting the shape, the skill of correlating relationships in the shape, the skill of perceiving and clarifying ambiguity, and the skill of inferring meanings [27]. Abd Al-Reda and Fadel (2019) also maintain that the skills of visual thinking are demarcated into the skill of visual reading which is the ability to determine the dimensions and nature of the shape or image presented [28]. It is also the lowest skill of visual thinking skills, the skill of visual discrimination which is the ability to recognize the shapes or images and distinguish them from other shapes or images, the skill of scientific deduction which is the ability to attain new meanings and arrive at scientific concepts and principles through the presented shape, image, or map, and the skill of analyzing and interpreting the visual shape which is the ability of the individual to focus on minute details, pay attention to macro and microdata, and clarify the meanings of shapes, words, symbols, signs and figures, and approximate relations among them.

D. Visual Thinking Tools

At a time when the visual thinking skills are numerous, their tools are also numerous, as the modern digital tools that supported it help and work to capture ideas and organize information, as elucidated by the study of [29]. Visual symbols are likened to three tools: pictures which are one of the most accurate tools in communication, and they are a visual symbolic component of ideas and reality, symbols which are the most widely used and widespread tools in communication, and they are all indications of something and its proxy, and diagrams of shapes which illustrate an idea, are expressed in simple shapes or expressed in lines and include drawings related to pictures, concepts, and comics. Visual thinking is constructed on experimental research in the way of thinking of learners by focusing on developing their capabilities in changing and translating the visual language carried by the visual shape into a verbal language, written or spoken to develop communication skills and creative and logical thinking skills that achieve the learner's confidence in dealing with complex, ambiguous, and diverse opinions. Likewise, these skills enhance perception through discussions that take place across its processes to develop aesthetic practice [30].

Additionally, the ability to think visually overlaps with the skill of critical thinking that helps in solving problems and comprehend concepts, and at long last, visual thinking is seen as a more complex mental activity than the rest of the levels of thinking, as it depends on the representation of the displayed figure with symbols, diagrams, and pictures. Thus, visual thinking is one of the most important matters in the educational learning process as specified by [31] indicating the importance of teaching visual thinking skills to the learner because it works to raise the level of the learner's ability to communicate with others and increase mental ability. Visual thinking skills are regarded as a key to different types of thinking, including innovative thinking and critical thinking. The role of visual thinking skills in raising the level of motivation among the learners is unforgettable, and this is what encourages learners to teach and learn, works to develop science processes such as observation, interpretation, and analysis, helps them to self-learning that takes into account the individual differences between them and also assists to achieve objectives of science such as interpretation and prediction.

Both [28] indicate that there is great importance for visual thinking and its effect on the educational process, as it has replaced a lot of verbal information in pictures and visual shapes, the most important of which is the learner’s ability to develop visual language skills and comprehend all visual messages surrounding individuals inside the classroom, which indicates the scientific and technological development. Also, it can be emphasized that visual thinking is of great importance for people in general and for learners in particular in expanding their perceptions of understanding and imagination, and this helps them speed up the process of understanding and validating the information and facilitating its retrieval [32].

The educational theories in the area of educational technology have emphasized the importance of using visual thinking and its various tools such as images, shapes, diagrams, and graphs in the education process as the most important theory that focuses on the importance of using graphics in the education process is the theory of information processing. As put by [33] based on the learning styles used by the learner, thinking is classified into (Visual-Aural-Kinesthetic Model) which is auditory thinking, emotional thinking, and visual thinking. Visual thinking in the previous classification mentioned by [33], explained in detail by [34], and graphically represented by [35] helps in transferring the information to the human brain and processing inside it, and then expressing it in various methods. It turns out that the sense of sight controls the largest amount of information transferred to the brain, which indicates that thinking that depends on the sense of sight and is called visual thinking is the most used and the most important among the thinking styles in this classification. As defined by [36], visual thinking is an individual's skill to visualize and present an idea or information using pictures and drawings instead of the much stuffing and redundant wordiness used in communication.

Visual thinking skills are considered three main skills, namely vision, visualization, and drawing, where sub-skills branch out of these three main skills, and this is what [37] emphasized, as the three main skills are the origin of all skills and sub-skills change according to the types of sciences that belong to them. The visual sub-skills of computer science, for example, are different from the visual sub-skills of mathematics. Among the studies examining augmented reality and its effect on visual thinking is [38], which has investigated the effectiveness of a program based on augmented reality technology in developing visual thinking skills in science subjects for 9th-grade students in Gaza. Due to the nature of the study, the experimental method has been used. The study instrument is a one-group design with a pre-post measurement, where the study population consists of all the 6894 9th-grade students in schools of the Ministry of Education in the Gaza Strip. The Yarmouk Basic School (A) for boys in Gaza Governorate is randomly selected, and one class is also randomly selected, as the study sample consists of (43) students from the 9th-grade school. The study shows that there are statistically significant differences at the level of ($\alpha = 0.01$) between the average scores of the students in the pre and post applications on the visual thinking test. The study also shows that the employment of the program based on augmented reality technology achieves high effectiveness (Black's Modified Gain Ratio = 1.2) in developing visual thinking skills.

Against this, based on the importance of the primary stage among the stages of the educational process, the use of augmented reality technology has an effective effect on expanding the students’ perceptions of visualization and visual thinking. Therefore, the basic 10th-grade students are selected to teach them mathematics because this subject is the closest to reality, needs sensory experiences, and focuses on developing students’ thinking skills in general and visual thinking in particular. Intending to investigate the effect of augmented reality technology on visual thinking, augmented reality hopefully has great importance and effectiveness in the development of the educational learning process, as it is expected to provide an interactive learning environment filled with vitality, positivity, and excitement.

III. Research Methodology

Due to the nature of the study, the quasi-experimental approach is used for its suitability for the study. The independent variable (augmented reality technology) is subjected to test and its effect on the dependent variable (visual thinking) is measured for the students of the experimental group.

A. *Study Sample*

The study sample is purposefully selected from Jerash Model Schools of the Education Directorate of Jerash Governorate. The study sample consists of (57) male and female students randomly distributed into two sections: one of them is experimental taught using augmented reality technology and consists of (28) male and female students, and the second is the control group taught by the traditional method and consists of (29) male and female students.

B. *Study Instrument, Validity and Reliability*

The study instrument comprises a visual thinking test consisting of (20) items of a multiple choice of geometry unit in mathematics for the 10th grade of the academic year (2020/2021). This test is prepared and developed by researchers of the paper, where four skills are identified: visual reading skill, visual discrimination skill, scientific deduction skill, the skill of analyzing and interpreting the visual shape. A specification table is prepared and illustrated in Table I.

TABLE I. Specifications for the Visual Thinking Test

Skill	Number of Questions	Percentage (%)
Reading skill	5	25%
Visual discrimination skill	6	30%
Scientific deduction skill	5	25%
Skill of analyzing and interpreting the visual shape	4	20%
Total	20	100%

To verify the validity of the test (apparent and content), it is presented in its initial form to a group of 10 experienced and specialized validators, and their observations are strongly considered. Also, the reliability of the test is verified by applying the test to the reliability sample outside the study sample, consisting of (31) male and female students through the calculation of the Kuder-Richardson 20 (KR-20) reliability coefficient, and the Test-Retest Reliability coefficient, and the results of the analysis are shown in the table.

Table II shows that all the values of reliability coefficients are high, enhancing the accuracy of the instrument and its suitability for application to achieve the purposes of the study.

TABLE II. Results of Reliability Coefficients Analysis

Study Instrument	Calculated Reliability Coefficient	
	Kuder-Richardson 20 (KR-20)	Test-Retest
Achievement Test	0.923	0.931
Visual Thinking Test	0.961	0.934

IV. Results and Discussion

Results and discussion of the first question of the study “What is the effect of augmented reality on developing visual thinking in mathematics among 10th-grade students in Jerash governorate?”

To answer the first study question, the values of the arithmetic means and standard deviations of the performance of the two groups (experimental and control) in the pre and post-performance are calculated. Table III shows the results of the analysis.

Table III show that there is a noticeable convergence between the two groups in the pre-performance of visual thinking skills, while there are apparent differences between the two groups in the post-performance of visual thinking skills, as it is noticed that the value of the post arithmetic means of the performance of the experimental group students is (18.50) which is the highest compared to the post arithmetic mean of the performance of the control group students which is (11.50).

This result is due to the effect of augmented reality technology in developing visual thinking in the teaching of the geometry unit for several reasons, including the technology's ability to display the model and check it from all directions and its movement, which has helped students attain the approximate sense of realism. This technology also assists to attract students' attention, as it is accompanied by sounds, videos, colors, and 3-dimensional images enhanced with information and concepts related to pictures, which helps in developing visual thinking skills, allowing interaction with the application individually or collectively and giving them sufficient opportunity for visual thinking, and positively increasing their interaction. Importantly, the application helps in providing images of geometric shapes that are unavailable in the 10th-grade textbook, which broadens the perceptions of thinking in general among the students. The positive result of the current study in bringing about diversity and a paradigm shift in favor of the use of augmented reality technology in visual thinking is consistent with the results of many studies, including the studies of [24], [25], and [39] that have investigated the effectiveness of a program based on augmented reality technology in developing the students' achievement.

Results and discussion of the second question of the study "What is the effect of augmented reality on the development of each of the visual thinking skills (visual reading skill, visual discrimination skill, scientific deduction skill, the skill of analyzing and interpreting the visual shape) in mathematics among 10th-grade students in Jerash governorate?"

Table IV shows the values of the arithmetic means and standard deviations of the performance of the members of the experimental group in the pre-and post-test according to each skill.

It is evident from the results of the analysis of Table IV that the values of the arithmetic means of the performance of the members of the experimental group in the post-test are high (4.00 -5.20) in all skills compared to their performance in the pretest. The visual discrimination skill is ranked first with an arithmetic mean of (5.20) and a standard deviation of (0.76), while the visual reading skill is ranked second with an arithmetic mean of (4.73) and a standard deviation of (0.52). Also, the scientific deduction skill is ranked third with an arithmetic mean of (4.57) and a standard deviation of (0.50). As for the last rank, it is the skill of analyzing and interpreting the visual shape with an arithmetic mean of (4.00) and a standard deviation of (0.00).

To find out the indications of the differences between the arithmetic means of skills, the Analysis of Covariance (ANCOVA) is used as illustrated in Table V.

The results mentioned in Table V show that there is a difference in the post-performance between the two groups, where all the values of (F) are statistically significant at the level of ($\alpha = 0.05$). In detail, the difference is in favor of the experimental group, as the arithmetic means of their performance in the visual thinking skills test are higher compared to the arithmetic mean of the performance of the control group. The value of the practical significance of the combined visual thinking skills is (0.674). This indicates that (67.4%) of the variance between the two groups is due to the effect of the experiment. This result is to the fact that visual thinking is a mental capacity associated with the visual perceptual aspects, where it occurs when there is mutual harmony between what the learner sees in terms of shapes, drawings, and relationships, and what happens in terms of linking and mental output based on seeing the presented drawing and this is what the augmented reality technology focuses on, and this is what is confirmed by [23] and [26].

TABLE III. VALUES OF THE ARITHMETIC MEANS AND STANDARD DEVIATIONS OF THE PERFORMANCE OF THE TWO GROUPS IN THE PRE- AND POST-PERFORMANCE

Visual Thinking Skills	Group	Sample Size	Number of Items	Pre-Performance		Post-Performance	
				AM	SD	AM	SD
Total Performance	Experimental	30	20	11.43	7.30	18.50	1.43
	Control	30		11.07	7.09	11.50	3.25

TABLE IV. VALUES OF THE ARITHMETIC MEANS AND STANDARD DEVIATIONS ARRANGED IN DESCENDING ORDER DUE TO THE ARITHMETIC MEANS

	Pre-Performance		Post-Performance		Evaluation
Visual thinking skills	AM	SD	AM	SD	
Visual discrimination skill	1.43	0.86	5.20	0.76	High
Visual reading skill	1.70	1.49	4.73	0.52	High
Scientific deduction skill	1.50	0.78	4.57	0.50	High
The skill of analyzing and interpreting the visual shape	1.83	1.05	4.00	0.00	High
Total Performance	11.07	7.09	18.50	1.43	High

TABLE V. RESULTS OF THE ASSOCIATED ANALYSIS OF COVARIANCE (ANCOVA)

Source of Variance	Sum of Squares	Degree of Freedom	Average of Squares	Value of F	Level of Sig.	Eta=Squared
Visual Reading Skill	0.067	1	0.067	0.074		0.695
	117.544	1	117.544	129.679	0.000*	
	51.666	57	0.906			
	169.333	59				
Visual Discrimination Skill	1.328	1	1.328	1.203		0.624
	104.495	1	104.495	94.636	0.000*	
	62.939	57	1.104			
	170.933	59				
Scientific Deduction Skill	0.699	1	0.699	1.052		0.649
	69.952	1	69.952	105.294	0.000*	
	37.868	57	0.664			
	108.983	59				
The skill of analyzing and interpreting the visual shape	1.569	1	1.569	3.019		0.564
	38.4	1	38.4	73.869	0.000*	
	29.631	57	0.52			
	69.6	59				
Total Performance	11.957	1	11.957	1.931		0.674
	729.659	1	729.659	117.806	*0.000	
	353.043	57	6.194			
	1100.000	59				

* means a statistically significant function at the level of statistical significance (α = 0.05).

The way of thinking of students who have learned with augmented reality focuses on developing their abilities in translating the visual language embedded in the visual shapes presented in the lessons into verbal written or spoken language, developing communication skills that achieve the learner's confidence in dealing with complexity, ambiguity, and diversity of opinions, as well as increasing and enhancing perception through discussions that take place across their operations to develop aesthetic practice, and this will help in developing the visual thinking skills, and this is confirmed by [38] and [39]. The information offered in the study unit (geometry) in the textbook of the 10th grade has helped to develop the visual reading skill among the students of the experimental group represented by the ability to determine the dimensions and nature of this shape on the one hand. On the other hand, it has helped students to perceive the shape and distinguish it from other shapes and this represents the development of the visual discrimination skill, and this is confirmed by [17]. The development of the scientific deduction skill is represented by the ability of students to attain new meanings and scientific concepts and principles through the shape. Students learn, through this technology, to focus on the minute details, pay attention to geometric shapes and the subject of the study unit, and get geometric properties through their shapes. The augmented reality technology has its effect on the visual representation of ideas from shapes and drawings as an incentive for students to discover the meaning of the presented contents in the front of them, and this leads to better thinking, a progressive development towards creativity, and an indication of the conceptual developmental structure. Reading the visual shape aims to understand the meaning and includes understanding in reading the shape, linking, symbol, meaning, and organizing the read ideas. Reading the visual shape is a set of activities that allow the analysis of the information given in the form of conceptual connections in the presented shape, that is, a set of activities linking new information with previously acquired data stored in memory as these understanding models are closely related to the representation of the presented shape and or drawing.

V. CONCLUSION

The current study investigates the effect of augmented reality in improving visual thinking of 10th-grade students in mathematics in Jordan. In light of the results of the study, the objectives of the study, i.e. exploring the effect of augmented reality on developing visual thinking in mathematics among 10th-grade students in Jordan and examining the effect of augmented reality on the development of each of the visual thinking skills (visual reading skill, visual discrimination skill, scientific deduction skill, the skill of analyzing and interpreting the visual shape) in mathematics among 10th-grade students in Jordan have been achieved. Thus, the current study recommends using augmented reality technology in education in general, and in mathematics education in particular, organizing the content of mathematics curricula in line with augmented reality technology, which helps in developing visual thinking skills, paying attention to designing electronic lessons in mathematics and producing them using augmented reality applications, and holding training courses for mathematics teachers and encouraging them to learn how to integrate technology with education and develop visual thinking.

VI. Future Works

The area of augmented reality needs to be extended in other current works, with new approaches in the future work. This domain can be applied in other scientific areas such as physics or other detailed issues in mathematics.

***Abstract*—Medical applications increasingly require complex calculations with constraints of accelerated processing time. These applications are therefore oriented towards the integration of high-performance embedded architectures. In this context, the detection of cardiac abnormalities is a task that remains a high priority in emergency medicine. ECG analysis is a complex task that requires significant computing time since a large amount of information must be analyzed in parallel with high frequencies. Real-time processing is the biggest challenge for researchers, when talking about applications that require time constraints like that of cardiac activity monitoring. This work evaluates the Adaptive Dual Threshold Filter (ADTF) algorithm dedicated to ECG signal filtering using various embedded architectures: A Raspberry 3B+ and Odroid XU4. The implementation has been based on C/C++ and OpenMP to exploit the parallelism in the used architectures. The evaluation was validated using several ECG signals proposed in MIT-BIH Arrhythmia database with a sampling frequency of 360 Hz. Based on an algorithmic complexity study and a parallelization of the functional blocks which present significant workloads, the evaluation results show a mean execution time of 7.5 ms on the Raspberry 3B+ and 0.34 ms on the Odroid XU4. With an efficient parallelization on the Odroid XU4 architecture, real-time performance can be achieved.**

Keywords—ECG signal denoising; ADTF algorithm; OpenMP programming; embedded architectures

I. Introduction

ECG is an essential element in the diagnosis and the detection of cardiovascular disease or also in the monitoring of patients [1]. However, it is often correlated with different types of noise, which generates a distortion of the signal and a loss of valuable information. To simplify the interpretation task, several processing and filtering algorithms are proposed in the literature [2-6]. Digital Filters (FIR and IIR), Empirical Mode Decomposition (EMD), Wavelet Transform denoising techniques as Discrete Wavelet Transform (DWT) and the Adaptive Dual Threshold Filter (ADTF) [7-8].

Using digital filters, some useful information in the signal can be affected, particularly the R wave [3,9]. The EMD and the DWT give satisfying results, but they are characterized by their algorithmic complexity that requires more hardware resources and important computation time [10-11]. The ADTF proposed by W. Jenkal et al. in [7] has a great denoising capacity, especially when the signal is mixed with the high-frequency noises. The advantage of this technique is the very low complexity. Hardware implementation of this algorithm on FPGAs is presented in [8] using Hardware Description Language (VHDL). The author divided the algorithm into 3 main blocks: The first consists of Real-time data loading module with an acquisition frequency of 360 Hz as he uses signals from MIT-BIH database. The second is used for ADTF features calculation. The third is for Test and Assignment. To respect real-time processing, a frequency of 3.6 kHz is used in the second and third blocks, which is ten times greater than the acquisition frequency. This implementation indeed respects real-time, but this is related to the processing frequency which is fixed by the author not given by the architecture.

Abbreviations

ADTF: Adaptive Dual Threshold Filter
DWT: Discrete Wavelet Transform
DT-WT: Dual-Tree Wavelet Transform
ECG : Electrocardiogram
EMD : Empirical Mode Decomposition
EEMD : Ensemble Empirical Mode Decomposition
EEMD-GA: EEMD and Genetic Algorithm
FIR: Finite Impulse Response
FPGA: Field Programmable Gate Array
GPU: Graphics Processing Unit
Ht: Higher Threshold
IIR: Infinite Impulse Response
IMF : Intrinsic Mode Functions
LA : Left Atria
Lt: Lower Threshold
LV: Left Ventricle
MSE: Mean Square Errors
PRD: Percentage Root-mean-square Difference parameter
RA: Right Atria
RV: Right ventricle
SNR: Signal to Noise Ratio
VHDL: VHSIC Hardware Description Language
WGN: White Gaussian Noise

This work deals particularly with the real-time ECG denoising. Real-time systems differ from others by considering time constraints and compliance, which is as important as the result's accuracy. In other words, the system should not just deliver exact results; it should also provide them within a set timeframe. This notion takes on its importance when it comes to human health. So, the design of processing algorithms that meet these constraints is therefore essential. In this context, the processing system is considered a real-time system. It must make the necessary correction for sample *n* before the arrival of sample *(n + 1)*. This constraint implies rigorous requirements in terms of performance and speed. In this work, different signals from the Physionet MIT-BIH arrhythmia database are used, with 360 Hz of sampling frequency to test the reliability of the algorithm. This means that the time constraint is of the order of 2.77 ms. The Matlab simulation gives a processing time average of 150ms for one sample, which is too far from being in real-time.

In order to ensure real-time processing, OpenMP parallel programming is used, which gives excellent results compared to C/C++ naive implementation and Matlab implementation. So, for Desktop with OpenMP programming, just 0.34 ms is needed to process one sample. But desktop is not always a good solution in biomedical monitoring because of its size, weight, and power consumption, especially when the objective is the home monitoring to facilitate access to care for the elderly or in regions lacking medical personnel, prevent hospitalizations and improve patient control and quality of life.

We opted to use Low-cost embedded architectures such as XU4 and Raspberry. The given results show that the optimal choice is the XU4 board with an average processing time of 2.34ms instead of 7.5 ms in the case of Raspberry 3B, which greatly satisfies the time and energy consumption constraints.

The paper is formulated as follow:

1) The first section exposes an overview of ECG signal denoising techniques and related work.

2) The second section depicts a detailed evaluation of the ADTF algorithm and describes its implementation.

3) The third section puts on view the results and discussion of the processing performance of the embedded implementations on different embedded architectures.

4) Lastly, conclusion and future work are the objects of the fourth section.

II. ECG Signal Processing: An Overview

A. *ECG Signal Processing*

The ECG signal or electrocardiogram is a widely used exam in cardiology field. It describes the electrical activity of the human heart and has a high clinical value for diagnosing cardiac arrhythmias. From the ECG signal processing, several parameters can be extracted. As a rule, different waves' durations and shapes can indicate some cardiac abnormalities [3]. Fig. 1 represents the formation of the ECG signal, which reflects the different deflections and contractions of the heart muscles, making it possible to diagnose a patient's cardiac state. As shown in the Fig. 1, RA, LA, RV, and LV represent respectively the right and left Atria and ventricle.

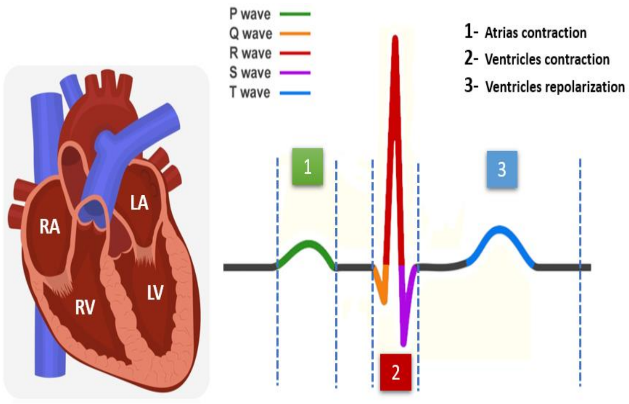

Fig. 1. ECG Signal Formation.

To make the best use of ECG data in large quantities, intelligent diagnostic systems have appeared. These systems can improve the quality of the signal; extract useful information, and offer a diagnosis that can help doctors make the right decisions.

The biomedical engineering revolution forces researchers to enhance the automatic diagnosis by optimization of ECG processing algorithms in order to ensure real-time monitoring of cardiac data [12-16]; and their implementation on embedded systems as recent technological resources [8,17-19].

The ECG signal is characterized by low frequency and a small amplitude. So, it is often affected by various kinds of noise as interference due to electrical appliances, high-frequency noises produced by muscles activity, and low-frequency noises of body movements in relation with respiration, which distorts its morphology, resulting a wrong diagnostic of the heart state of the patients [5,20]. To overcome this problem, the ECG signal must first go through a precise and effective preprocessing step.

The preprocessing step aims to remove or reduce the different noises. In this context, many methods are used such as Digital Filters (FIR/IIR) [21-22], Empirical Mode Decomposition (EMD) and Ensemble EMD (EEMD) based techniques [10, 23-25], Discrete Wavelet Transform (DWT) [26-27, 3], Dual-Tree Wavelet Transform (DT-WT) [28] and Adaptive Filtering [29,8].

B. *Related Works based ECG Denoising*

Digital filters are represented by Finite Impulse Response (FIR) and Infinite Impulse Response (IIR). They are used to denoise ECG signals. Their names are originally linked to the mathematical definition, and their expressions are given respectively by (1) and (2):

$$Y(n) = \sum_{k=0}^{N-1} \mathrm{b(q)X(n-q)} \qquad (1)$$

$$y(n) = \sum_{k=1}^{M} a_k\, y(n-k) + \sum_{k=0}^{N} b_k\, x(n-k) \qquad (2)$$

The implementation of FIR filters can be done without feedback as it is shown in Fig. 2 where X(n) presents the input signal, Y(n) is the filtered signal, Z^{-1} operator is a delay in the Z transformation, N is the filter order, and b_q are the coefficients of the filter transfer function. Various windowing techniques are used, as example: Rectangular window, Kaiser window, Hamming window, Hanning window and Blackman window. IIR filters are designed using filters as Chebyshev filter, Butterworth filter, Inverse Chebyshev filter [30]. The major difference between them is that FIR filters are stable for any input signal. However, IIR filters can alter to unstable due to the feedback as shown in Fig. 3. Where a_n and b_m are the filter transfer function coefficients.

Most of the works used FIR or IIR filters by selecting a bandwidth related to the utile data from the ECG signal. From different papers, it can be deduced that that FIR filter with Kaiser Window eliminates noises from ECG signal with less alteration in the waveform [4,20]. FIR filters' problem is the high computational due to the number of coefficients needed to achieve excellent denoising result and a group of delay in response, which is the main challenge in real-time systems [4].

Wavelet methods have proven to be more common and effective than FIR/IIR filters [31]. Wavelet methods simultaneously characterize time and frequency information. They decompose the signal to different resolutions using low pass filters (H[n]) to get the approximations (A) and high pass filters (g[n]) to get the details (D) as it's explained in Fig. 4. The ECG signals are denoised using thresholding techniques. But they have some limitations since they reduce the signal amplitude, which can affect the R waves.

To overcome this limitation, methods based on EMD are used, the signal is disintegrated into a sequence of intrinsic mode functions (IMFs), and noisy IMFs are removed, but this technique can remove some useful information when eliminating the noisy IMFs. EEMD is used to overcome this problem by removing the mode-mixing [32].

To deal with the problems of complexity in ECG denoising, W. Jenkal et al. developed a new approach inspired from image denoising [33]. This approach is an adaptive dual threshold filter which is dedicated to removing high-frequency noises [34-35]. This method aims to compute three elements for a selecting window (the average of the window, the higher threshold, and the lower threshold) and then the correction of the window's median value using the thresholding. The process is explained in the following block diagram shown in Fig. 5.

The performance evaluation of this method is made in [8] based on the SNRimp result comparison between the ADTF and techniques based on EEMD. This evaluation shows that the ADTF gives very good results compared to the EEMD denoising algorithm presented in [36] and a competitive SNRimp results to the enhanced EEMD method (EEMD-GA) published in [37].

The main characteristic of the ADTF algorithm is its low complexity compared to the cited methods. The ADTF presents a linear complexity C(n) depending just on the signal size n. A comparative study of the complexity between the EMD, the EEMD, and the ADTF methods is presented in [8]. The conclusion of this study shows that ADTF presents a low complexity, unlike EMD and EEMD, which is related to various parameters, namely, the length of the signal, the number of the noisy signals, the number of IMFs, as well as the number of sifting processes. Comparing with the DWT, it also has linear complexity, in the manner of EMD/EEMD, it's related to other parameters not only the size of the signal, we are talking about the wavelet mother's coefficients, the number of decomposition's level and also the thresholding technique [38].

In the next section, a detailed study of the ADTF is presented as well as simulation results.

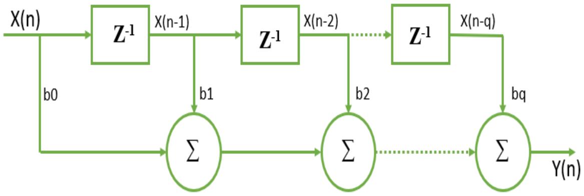

Fig. 2. FIR Filter Conception.

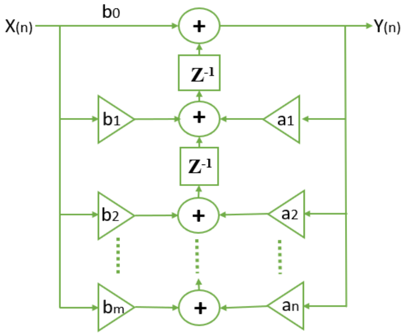

Fig. 3. IIR Filter Conception.

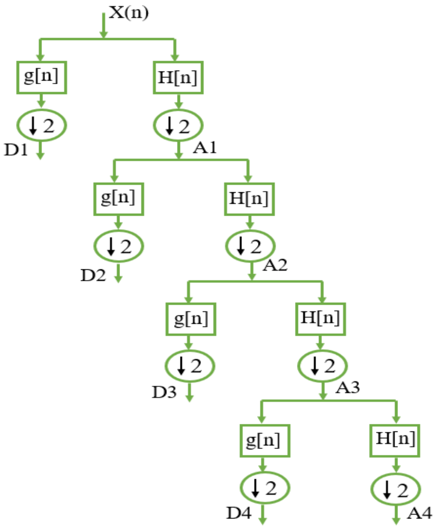

Fig. 4. DWT Decomposition.

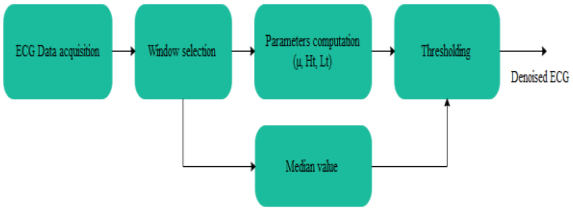

Fig. 5. ADTF Algorithm Overview.

C. The ADTF Technique

As described above, the ADTF algorithm aims to compute the average of the selected window (μ), the lower threshold (Lt), and the higher threshold (Ht). Hereinafter, they are presented respectively by (3), (4), and (5).

$$\mu = \frac{1}{W}\sum_{i=n}^{n+W} \mathrm{Input(i)} \quad (3)$$

$$\mathrm{Lt} = \mu - [(\mu - \mathrm{Min}) * \alpha] \quad (4)$$

$$\mathrm{Ht} = \mu + [(\mathrm{Max} - \mu) * \alpha] \quad (5)$$

Where the window size is W, Input (i) is the noisy signal, and n presents the signal length. Min is the minimum value of the window, Max is the maximum value of the window, and α is the thresholding coefficient with:

$$0 < \alpha < 1$$

α is essentially used to adapt the thresholding. According to the filtering process, α varies between 0% and 100%, lower values are recommended for a high concentration of noise, and higher values are tolerated in the opposite case [7].

The window selection is not arbitrary; it's used to compare the median sample to his left and right regions, as stated in [7], a window of five samples gives the best results in terms of MSE and SNRinput.

Fig. 6 shows the result of the ADTF filtering applied on the signal n° 234 from the MIT-BIH Arrhythmia database corelated with white Gaussian noises of 5 dB, using a window of 5 samples, an α coefficient of 5%. The compilation is done using Matlab R2019a.

The algorithm validation is done using Matlab coding [7], but this remains a functional validation, while in biomedical engineering, Real-time processing is required in most cases, especially ECG signal processing. The time constraint is related to the sampling frequency of the used signals. In the MIT-BIH Arrhythmia database, the signals are sampled 360 Hz which leads to an interval of 2.7 ms between the samples. Using Matlab coding, 150 ms is needed to process and correct each sample. Thusly, with Matlab implementation, the system is too far from being in real-time.

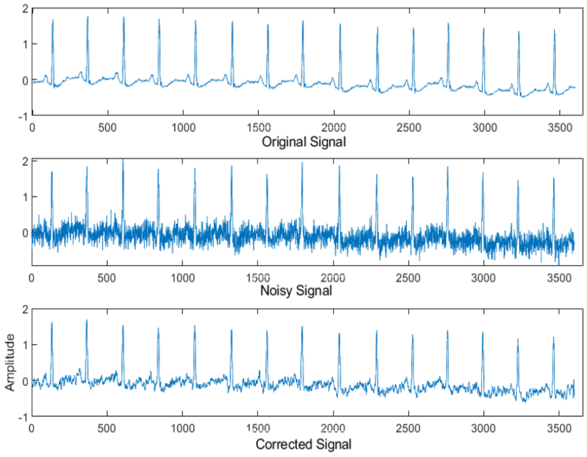

Fig. 6. The Denoising Results of the Signal n°234 of the MIT-BIH Arrhythmia Database Correlated with 5 dB of the WGN.

We have opted for C/C++ optimization using OpenMP parallelization in order to optimize the code. As follows a comparative study of the obtained results using Matlab, C/C++ non-optimized algorithm and OpenMP optimized algorithm on different architectures.

III. Results and Discussion

A. System Specification

In this paper, ECG signals from MIT-BIH Arrhythmia, the international database Physionet, which incorporates 48 half-hour records are used. These signals are converted to numerical values at 360 Hz with a resolution of 11-bits. Different signals with additive White Gaussian Noise (WGN) at SNR levels of 10dB and 20dB are used. Table I presents the used signals for both the Matlab and the C/C++ validation.

The validation of the algorithm was performed using Matlab. In order to ensure a reliable and accurate real-time processing, OpenMP programming is used in the implementation to ensure parallel programming on a shared memory multiprocessor system. The parallelism is achieved by creating a set of threads; these treads execute independently and simultaneously the appointed tasks. Using OpenMP, the program could be optimized to evaluate processing times using three different architectures.

The work is based on Raspberry 3B and XU4 architectures; the choice of these architectures was based on the low energy consumption and also a low weight for embedded application. Despite the desktop giving excellent processing time results, but it's not a good solution for biomedical monitoring because of its size and portability in the real case. Good results can also be given using TX1, TX2, and AGX Xavier boards; notably, with GPU part, we can decrease the processing time [39]. But the major problems are their cost and power consumption. Raspberry and XU4 present a low-cost embedded system with low power computation [40]. The rest of this study will allow to make the right decision by comparing the found processing times for the two architectures. Table II presents the used architectures specifications.

TABLE I. ECG Signal Records

Signal number	**The corresponding Signal from MIT-BIH**
1	Record n° 100
2	Record n° 100 + 10 dB of WGN
3	Record n° 100 + 20 dB of WGN
4	Record n° 101
5	Record n° 101 + 10 dB of WGN
6	Record n° 101 + 20 dB of WGN
7	Record n° 103
8	Record n° 103 + 10 dB of WGN
9	Record n° 103 + 20 dB of WGN
10	Record n° 113
11	Record n° 113 + 10 dB of WGN
12	Record n° 113 + 20 dB of WGN

TABLE II. DESKTOP, RASPBERRY AND XU4 SPECIFICATIONS

Type	Desktop	Raspberry	XU4
Processor	Intel® Core™ i5-4200M	Broadcom BCM2837B0	Exynos 5422 big. LITTLE
Cores	Quad	Quad	Octa
CPU	I5 4200M	ARM Cortex-A53 (ARMv8)	ARM Cortex A15/A7
GPU	HD Graphics 4600 /AMD Radeon R5 M230	Broadcom Videocore-IV	Advanced Mali
Support Language	C/C++/OpenCL/ OpenGL	C/C++	C/C++/OpenCL/OpenGL
Frequency	2.50 GHz	1.4GHz	2GHz/1.4GHz
Weight	2.6 kg	50 g	60 g
Energy	90 w	15.5 w	5W
Dimensions	377 x 250 x 34 mm	85 x 56 x 17 mm	82 × 58 × 22 mm

B. Experimental Results

To evaluate the denoising performance of the C/C++ code of the ADTF algorithm, Mean Square Errors (MSE), Percentage Root-mean-square Difference parameter (PRD), and Signal to Noise Ratio (SNR) are computed for 12 records of ECG of 10s from the MIT-BIH arrythmia database. Their expressions are presented respectively by (6), (7), and (8).

$$MSE = \frac{1}{N}\sum_{i=1}^{N}\big(Input(i) - Output(i)\big)^2 \qquad (6)$$

$$SNRout = 10 \times log10\left(\frac{\sum_{i=1}^{N}(Input(i))^2}{\sum_{i=1}^{N}(Output(i)-Input(i))^2}\right) \qquad (7)$$

$$PRD = \sqrt{\frac{\sum_{i=1}^{N}(Input(i)-Output(i))^2}{\sum_{i=1}^{N}(Input(i))^2}} \times 100 \qquad (8)$$

Where input(i) represents each input sample and output (i) the filtered sample, N is the size of signal.

The experimental results in Fig. 7, 8, and 9 show that the C/C++ program provides concrete denoising than the Matlab code in terms of good SNR with less MSE and PRD.

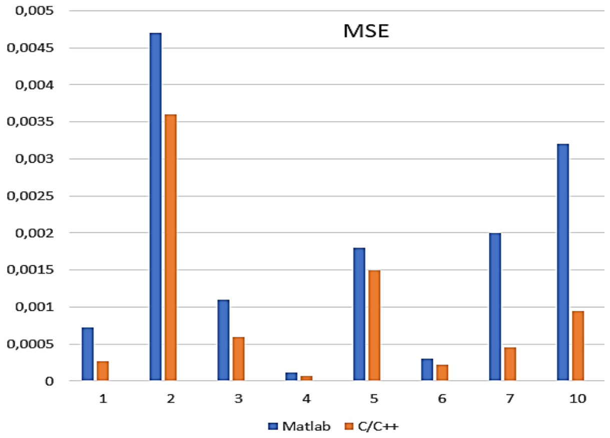

Fig. 7. MSE Comparison of Denoised Signals using Matlab and C/C++.

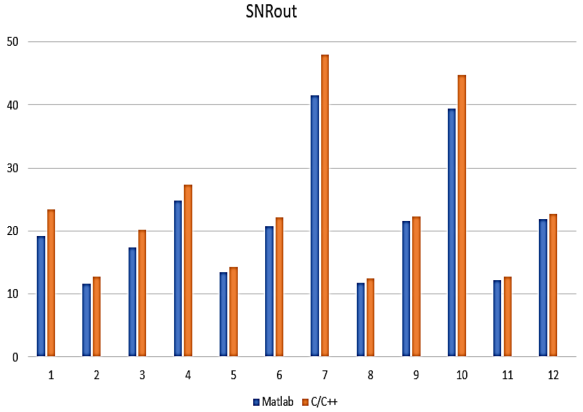

Fig. 8. SNRout Results Comparison of Denoised Signals using Matlab and C/C++.

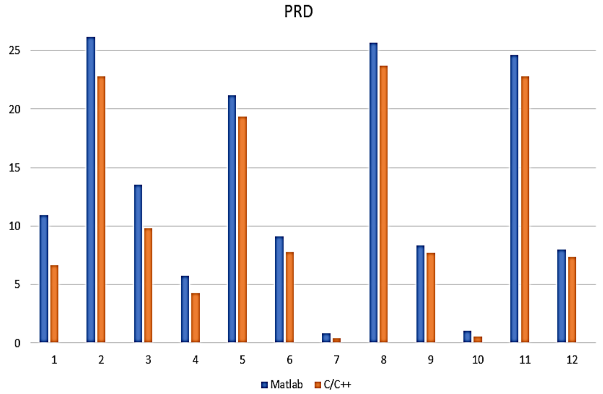

Fig. 9. PRD Comparison of Denoised Signals using Matlab and C/C++.

As shown, the C/C++ gives better performance in noise reduction. As follows, a comparison study of the execution time on Desktop is presented in Table III. It presents the needed time to process each sample of the signal based on nine iterations of time average calculation. The obtained results show that using OpenMP on the desktop, the results showed a ×4 speed-up compared to the time obtained with the naive C/C++ implementation. In Fig. 10, the execution time of Matlab is added to visualize the interest of parallel programming in this case.

TABLE III. EXECUTION TIME IN DESKTOP

C++		Open MP	
Iteration	*Time (ms)*	*Iteration*	*Time (ms)*
1	1.21	1	0.25
2	2.01	2	0.4

C. Performance Evaluation using Embedded Architectures

Performance evaluation implementing embedded architectures is the main of this work. After proving the algorithm performance in noise reduction, a reliable real-time implementation is necessary.

The Matlab implementation was used for the algorithm validation and results interpretation, but the very high execution times lead us to exclude any software optimization in order to speed up processing in this implementation. Then we opted for C/C++ programming. The implementation is done, as cited above using a Desktop, a Raspberry 3B and XU4 boards. The C/C++ implementations results are too much better than those given by Matlab implementation, but they stay a little far from the real-time as it appears in Fig. 11, with 1.56 ms for Desktop, 9.2ms for Raspberry and 6.8 ms for XU4.

The block diagram of the parallelized algorithm is presented in Fig. 12. The first block is the ECG signal acquisition which is not the subject of this paper. The second aims to divide to the input signal by the thread number (A). Here a test is done; if the number of signal samples is not divisible on A the system searches for the optimal signal size by adding a few samples at the end of the signal. The added samples can be calculated using the values of the last window of the signal, an average of the window can be calculated to replace missing samples. The third block consists of memory allocation and parameters initialization as the α coefficient and the window size.

Block 4 is the core of this work; it aims to execute the denoising procedure. This is where the parallelism is applied, ECG signal is divided by the number of threads, each thread runs the denoising program on a portion of the signal instead of the whole signal. The last blocks present the denoised signal's exploitation step either for additional processing, storage, display, or transmission.

To optimize the given execution times, OpenMP is used. Fig. 13 depicts the pseudo code of the OpenMP-based parallel computation algorithm.

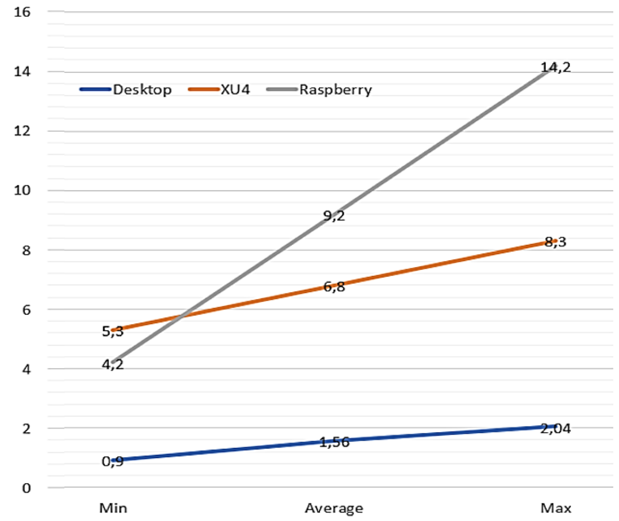

Fig. 11. Min and Max Processing Times using different Architectures.

The first step is to determine the optimal size that can give a divisible value over the number of threads. Thereafter, we set the input and output signals that will be written in the output file. This output file will be plotted subsequently using Matlab in order to display the errors and compute the different evaluation metrics.

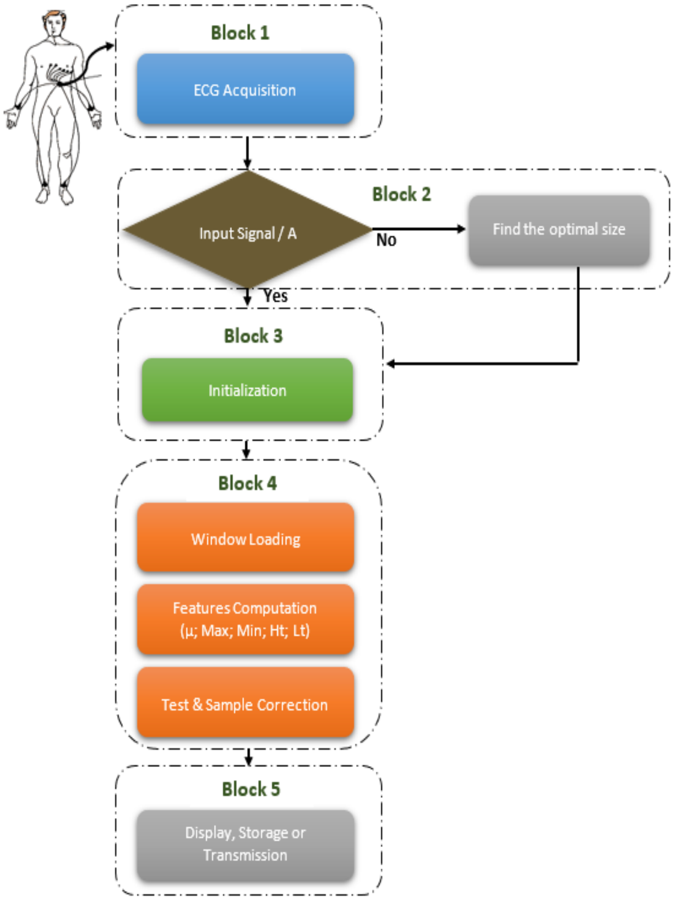

Fig. 12. The Algorithm Block Diagram.

```
ALGORITHM
#define NUMTHREADS
#define NAME_FILE "INPU_ECG"
#define NOM_SORTIE1 "OUTPUT_Signal"
#define Alpha
Input:  ECG Signal.txt
        Find the optimal signal size
        X(i)  <=  Input(i)
        i=1;
        α, W Initialisation
        Threads = NUMTHREADS
        #pragma omp parallel for shared (Min, Max,
         µ, Ht, Lt,) num_threads (threads)
          for i=1 to N-W
              Compute Min, Max, µ, Ht and Lt
              If X (i+W/2) > Ht Output (i+W/2) =Ht;
              If X (i+W/2) < Lt Output (i+W/2) =Lt;
              Else
              Output(i+W/2) = Input(i+W/2)
              i= i+1;
          End for
        Output(N-1) = X(N-1)
        Output(N) = X(N)
End.
```

Fig. 13. Pseudo Program of the Algorithm using OpenMP.

Fig. 14 shows processing time using OpenMP implementation. A time of 7.5 ms is achieved for one sample processing using Raspberry architecture, 2.34 ms using XU4 architecture, and 0.34 ms using the desktop. The time constraint posed by the acquisition system forced us to process each sample with a delay less than 1/360Hz, which implies trying to process each sample within 2.77ms. The results allowed to eliminate the choice of raspberry due to the processing times, which exceed 2.77ms. Despite their low energy consumption and weight, the time evaluation has shown that this architecture cannot process the algorithm in real-time. The desktop gave a very low processing time, 0.34ms, which shows the desktop's high performance, but the drawback here is the high-power consumption, which makes this type of system does not meet the reliability requirement. On the other hand, the XU4 architecture met the time constraint, making it the best choice for this application. In addition, its low power consumption and low weight confirm the choice.

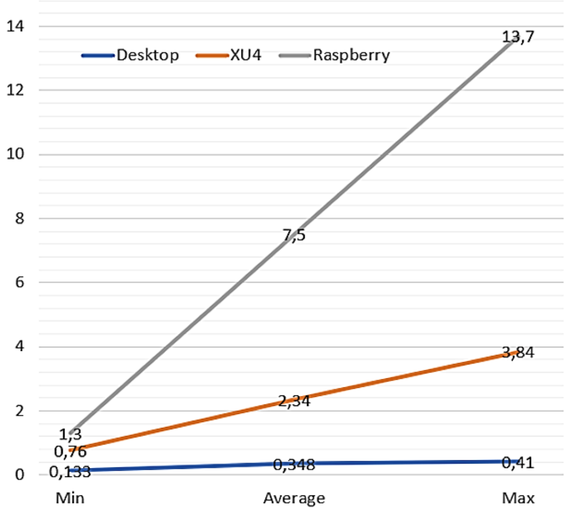

Fig. 14. OpenMP Executing Time.

TABLE IV. DIFFERENT EXECUTING TIMES

Executing time (ms)	Desktop	XU4	Raspberry
C/C++	1.56	6.8	9.2
C/C++ - OpenMP	0.34	2.34	7.5

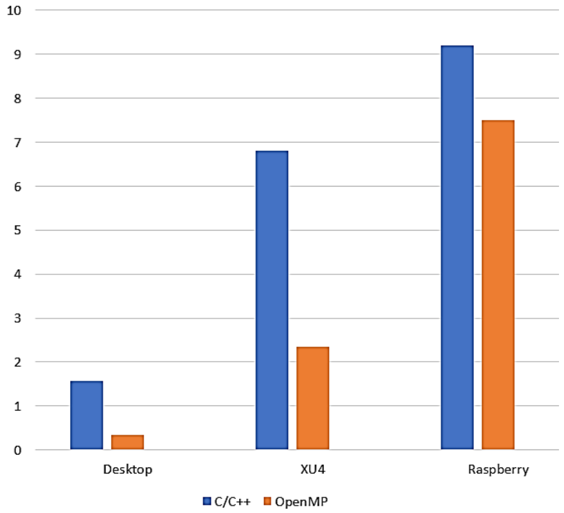

Fig. 15. Mean Processing Times (MS) based on different Architectures.

Table IV and Fig. 15 shows a comparison of all processing times using the different architectures and both C/C++ and OpenMP parallel implementation.

The optimization of the algorithm on the XU4 architecture proves to be very efficient and makes it possible to speed up processing and achieve real-time processing times in addition to its power consumption advantage.

IV. Conclusion

In this paper, a complex algorithm-based ECG signals processing is studied in order to meet the requirements of monitoring applications in terms of real time and portability on a low power architecture.

The evaluation of the algorithm using Matlab allowed validation of the algorithm and the evaluation of the different metrics (MSE, PRD, and SNR errors).

The approach followed by the algorithm parallelization on an adequate architecture is effective to process signals at 2.34ms/samples using a 360 Hz frequency acquisition.

This study opens up research perspectives to design a system integrating sensors and a SoC whose architecture is similar to that of the XU4 and which integrates an FPGA in order to carry out on-the-fly signal processing without data storage.

***Abstract*—Realistic real-time rain streaks rendering has been treated as a very difficult problem because of various natural phenomena. Also, for creating and managing many particles in a rain streak, many resources had to be used. This paper propose am efficient real-time rain streaks simulation algorithm by generating view-dependent rain particles, which can express a large amount of rain streaks even with a small number of particles. By creating a 'constrained view frustum' depending on the camera moving in real time, particles are rendered only in that space. Accordingly, particles rendered well even if the camera keep moving or rotating rapidly. And a small number of particles are used, since the simulation is performed in a user-viewed limited space, an effect of simulation many particles can be obtained. This enables very efficient real-time simulation of rain streaks.**

***Keywords*—View-dependent rendering; realistic real-time simulation; view frustum**

I. Introduction

When a digital content is produced for a specific weather from among various weather conditions, the audience or user who encounters the medium can immerge to the content more easily. There are many types of weather conditions such as sunny, cloudy, rainy, and snowy days. There are two main methods of rendering them: off-line rendering and on-line rendering. In the case of movies, since it is a medium that does not communicate with the audience in real-time, so even if it takes a lot of time, it pursues realistic rendering results so that the results naturally melt into the filming scene. On the contrary, in content such as games, even if the factual point is relatively less important, it emphasizes real-time, so it pursues somewhat lower quality rendering results compared to that of movies.

This paper proposes a real-time simulation algorithm for rainy scene. When it rains, complicated and diverse phenomena should be considered, such as droplets, splashes, rainbows, and clouds. Although the graphics hardware has been improved drastically in recent years, real-time simulation of rains is still very difficult problem considering the various conditions and the governing physical law to simulate them. Moreover, considering the physical properties of raindrops or water, the entire simulation process becomes very complicated. Therefore, most of real-time rain simulation focuses only on specific phenomena among various phenomena in rainy weather, and many different technical methods have been proposed to obtain real-time simulation performance by approximating the required parameters. Many of them have presented for modeling realistic raindrops based on the physical properties [1]. This enables realistic rain simulation as well as raindrop modeling. Also, they could present various phenomena including collision detection between raindrops and objects but gave the disadvantage of inefficiency because calculations related to raindrops became heavy due to unnecessary invisible rendering on the screen [2]. To fix it, various studies have been proposed such as defining and rendering only specific region for efficient simulation, but when the camera is moving outside of the region, there are awkward discontinuities where raindrops are not visible or rendered outside of the space [3, 4, 5].

This paper proposes an algorithm that complements the aforementioned shortcomings by mapping rain streaks textures to particles and creating a particle system that depends on the position and FOV (field of view) of the camera. Also present a method of interaction between rain and light sources, which is a simple light scattering technique for changing color of rain streaks. In this work, the particles are rendered even when the camera is moving and rotating. Therefore, it can avoid awkward rendering where rain can be rendered only in certain spaces, which requires only a small number of particles, but appearing to be rendered in very large quantities. This enables more efficient real-time rain-streaks simulation in a 3D space.

II. Related Work

Many research methods have been proposed in realistic rain simulation, and most of them focus on certain parts of the phenomenon of rain. There are two main types of rain simulation: rendering rain streaks with translucent white quads. The other method is to map precomputed rain streak textures to quads. The rain streaks texture rendering model proposed by Garg et al. presents a vibration model for raindrops. The rain streaks texture rendering model proposed by Garg et al. presents a vibration model for raindrops. As a result, they made a database of high-quality renders for many values of the illumination parameters [1]. Then, they used simple image-based algorithms from the depth map, camera parameters, and user input for viewpoints to synthesize the final images. This method showed the performance of 10 sec/frame, which was unsuitable for real-time simulation. This study used their database but implement rain simulation in real-time. Also, for randomness of the rain streaks, hundreds of textures are used to randomly map to the particles.

Weber *et al*. focused on the relationship between raindrops and trees. In their techniques, through-fall simulation is

*Corresponding Author

analyzed phenomenologically, and rendering is done based on the amount of water stored in the tree canopy and leaves [2]. Furthermore, in the study of Nanko *et al.*, the distribution of dripping through-fall was considered temporally and spatially [6]. The through-fall was largely divided into two different water. The first water was the raindrops in the natural state. This was a free through-falling without hitting anything other objects. The second one was the water splashes stored by hitting the canopy and leaves and then re-appeared in phenomenological and hydrological condition. In their study, through-fall was implemented very similar to the actual phenomenon. But there was no explanation for the calculation of raindrops occurring outside the camera's FOV.

Rousseau et al. proposed a model representing the refraction of light occurring inside the raindrop [7]. For completion, the reflections should also have been considered when designing raindrops. However, since they thought the reflection was negligible enough, they implemented only refraction [8]. In their approach, rain streak textures extracted from the video were modified to match the camera of a scene and then blended into the image to make the artist's intention for the scene more effective. But, real-time performance was not guaranteed. In addition to this, dynamic scenes were not suitable for these methods because the texture must be transformed to fit the resulting screen.

Tariq further simplified Garg's rain textures and map them to the quads [3]. This processing was done on the GPU using DirectX, and each particle was rendered using a geometric shader at each frame over times. Tariq also made lights glow to show more realistic simulation of rain under the lights, but the relationship with the light source and rains was not described mathematically, therefore rain was not rendered properly as the camera moved or rotated.

Puig-Centelles *et al*. proposed a new real-time rain simulation technique in which a rain area was defined as an ellipse and all rain simulation was limited to a semi-cylindrical sub-volume [4]. Due to observer's movement, the update of new particle position was forced to inside the sub-volume, while their density was adapted to reduce the number of particles needed. Furthermore, they separated the close rain and far rain and added a transition area in between for a natural and realistic change [9]. The switch was made depending on whether the observer is in a rain area or not. If the camera is located in the rainy area from a very long distance, awkward scene could be rendered, with certain area raining and others not raining.

Unlike the above studies, the model proposed in this paper checks the position of the camera and then create a rain space for the camera in which particles are generated inside. This ensures that even if the camera keep moving or rotating rapidly, it makes illusion that rain is rendering over the entire scene. Other benefit is that can use only small number of particles to create heavy raining, which improves the rendering performance. On the top of that, this study presents a model for the interaction between particles and the light source, which can represent the light scattering effect.

Fig. 1 is a captured scene of the proposed model. The four red lines indicate the volume of view-frustum, and the intersection point where four lines meet together represents the actual camera position. In the Fig. 1, particles are generated only in the frustum of the FOV and when the camera rotates or moves, the location where the particles are generated is also moved according to the camera.

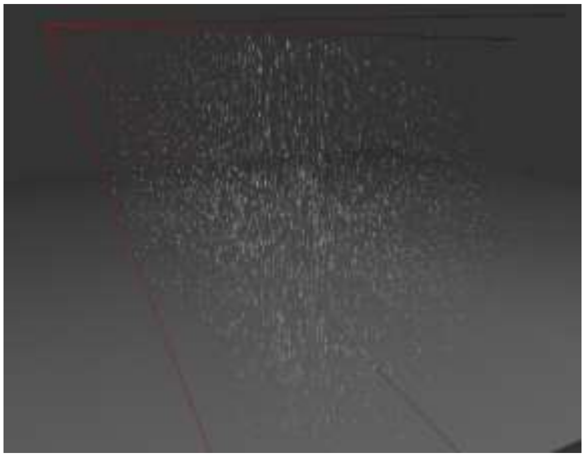

Fig. 1. Particles Rendered only in the Constrained Area.

III. ALGORITHM

In this study, we propose a real-time rain simulation method that creates a constrained rain space depending on the current camera so that particles representing the rain streaks are generated only in the camera frustum. Because of this, even when a small number of particles are used, suggested algorithm is able to synthesize seemingly heavy rain for users.

This chapter describes the detailed algorithm of the proposed model. The overall algorithm is briefly described in Fig. 2. Each procedure is as follows:

1) *Scene configuration:* Compose the overall scene such as background and model loading(street lamp, plane).

2) *Particles initialize and configuration:* In this model, the KTX(Khronos Texture) format is applied. More details in in Sec. 3.D, and the particle system was constructed using transform feedback from openGL [10, 11].

3) *Create constrained rain area:* Under the perspective projection, to make area for the rain fall, this method compute the 8 vertex positions of the truncated pyramid shape of the view frustum and the normal vectors of 6 faces. At the same time, it creates a virtual sphere in the frustum for enforcing a constraint to limit the area for generating particles.

4) *Set the initial particle positions in the rain area:* Set the initial positions of the particles in a constrained rain area. Particles are updated in position from top to bottom(-y).

5) *Set the rain streak colors by calculating the scattering of particles with the light source:* Depending on the relative position between particles and light soruce, the method of handling scattering from particles is different. In this paper, only spotlight is considered among the types of light sources.

6) *Real-time simulation:* Particles are created and rendered in constrained rain area. Calculating the rain space is handled by the CPU, but scattering and calculation of particle is handled by the shader.

Fig. 2. Algorithm Overview of Proposed Model.

First, explain the frustum and rain area, apply texture to particles generated only in space. After that, this paper discusses methods for light scattering in this section.

A. Create view-dependent Rain Area

To create the rain area from the camera's frustum, this method first need to calculate the height, width, center point of the far and near planes of the frustum. If the distance from the camera to the far plane increases, the size of the frustum increases as well. Therefore, the density of the particle created in the frustum is very low. In this case, it is different from what we wanted because algorithm has to make lots of particles to increase the density. Also, particles generated near to the far plane are rendered too small or almost invisible. Therefore, the distance from the camera to the far plane for a particle should be set as small as possible. In this paper, it was set to 50.0. After that, we need to find the positions of the 8 vertices that make up the frustum, which can be got from following formula:

$$f_{lr} = C_f - \{\vec{U} * (h_f * 0.5)\} + \{\vec{R} * (w_f * 0.5)\} \tag{1}$$

$$f_{ll} = C_f - \{\vec{U} * (h_f * 0.5)\} - \{\vec{R} * (w_f * 0.5)\}$$

$$f_{ur} = C_f + \{\vec{U} * (h_f * 0.5)\} + \{\vec{R} * (w_f * 0.5)\}$$

$$f_{ul} = C_f + \{\vec{U} * (h_f * 0.5)\} - \{\vec{R} * (w_f * 0.5)\}$$

$$n_{lr} = C_n - \{\vec{U} * (h_n * 0.5)\} + \{\vec{R} * (w_n * 0.5)\}$$

$$n_{ll} = C_n - \{\vec{U} * (h_n * 0.5)\} - \{\vec{R} * (w_n * 0.5)\}$$

$$n_{ur} = C_n + \{\vec{U} * (h_n * 0.5)\} + \{\vec{R} * (w_n * 0.5)\}$$

$$n_{ul} = C_n + \{\vec{U} * (h_n * 0.5)\} - \{\vec{R} * (w_n * 0.5)\}$$

where, C is the center point of far and near face, h, w is the height and width of each face. $\vec{U}$ is up vector of camera, and $\vec{V}$ is direction of camera. Also, $\vec{R}$ is a cross product and normalized vector of $\vec{U}$ and $\vec{V}$. Each vertex is described in Fig. 3.

Using the 8 vertices, this paper can find the normalized vectors for the four faces of the frustum, excluding the near and far plane. This is given subsequent formula:

$$\widehat{RP} = (n_{lr} - f_{lr}) \times (n_{lr} - n_{ur}) \tag{2}$$

$$\widehat{LP} = (n_{ll} - f_{ll}) \times (n_{ll} - n_{ul})$$

$$\widehat{BP} = (n_{ll} - n_{lr}) \times (n_{ll} - f_{ll})$$

$$\widehat{TP} = (n_{ul} - f_{ul}) \times (n_{ul} - n_{ur})$$

Where $\widehat{RP}$, $\widehat{LP}$, $\widehat{BP}$, $\widehat{TP}$ is a normal vector for the right, left, bottom and top faces, respectively, and each vector is normalized. Each face is also described in Fig. 3.

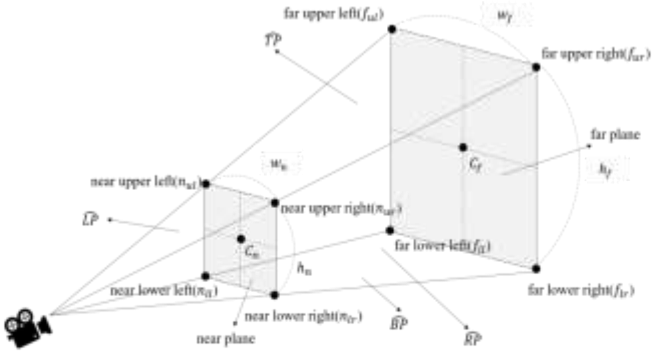

Fig. 3. Vertex and Faces of the view Frustum.

B. Virtual Sphere Setting

To constrained create space where particles will be generated, we need to create a virtual sphere that overlaps the frustum. So, we need to set the center point $C_{vs} = (x_{vs}, y_{vs}, z_{vs})$ and radius r_{vs} of the sphere. The C_{vs} of the sphere is the midpoint of the distance between the near and far faces, so that the sphere and the frustum overlap as much as possible.

As a result, as much space as possible can be defined as rain space on the frustum. Since the C_{vs} the midpoint between the near and far face, the radius of virtual sphere is defined as half the distance between two faces.

Now, algorithm need to decide the initial position $p_{par} = (x_{par}, y_{par}, z_{par})$ where a particle is created. Particle must be created inside a constrained rain space where the frustum and virtual sphere overlapped. To find this location, we first use the equation for converting from the spherical coordinate system to Cartesian coordinate system to create particles in sphere. Before this, we should get the θ and ϕ for coordinate system conversion. θ means azimuthal angle of spherical coordinate and ϕ means polar angle of spherical coordinate. This is shown in as follow:

$$\theta = 2 * PI * randmom\ seed(0,1) \tag{3}$$

$$\phi = \arccos(2 * randmom\ seed(0,1) - 1)$$

Where $\mathrm{random\ seed(a,b)}$ is a function that return on random number between a to b. And now, we can get the $\mathrm{p_{par}}$ and equation is as follow:

$$x_{par} = random\ seed(-r_{vs}, r_{vs}) \sin(\phi) \cos(\theta) + x_{vs} \tag{4}$$

$$y_{par} = random\ seed(-r_{vs}, r_{vs}) \sin(\phi) \sin(\theta) + y_{vs}$$

$$z_{par} = random\ seed(-r_{vs}, r_{vs}) \cos(\phi) + z_{vs}$$

Because of coordinate system conversion, the particles take the form of a virtual sphere. In other words, the particle is randomly set the initial position inside the virtual sphere.

So, now we need to limit the position where the particles are generated to the space where the frustum and the sphere overlap, that is, the rain area. First, select 2 of the 8 vertices of the frustum. Then, two normal vector value are got with the position of the particle as the starting point and the selected vertex as the endpoint. This normal vector is a normal vector later value to determine whether the current position of the particle is inside or outside the frustum. It is obtained as follow:

$$\widehat{PAR\_N}_{ll} = p_{par} - n_{ll} \tag{5}$$

$$\widehat{PAR\_N}_{ur} = p_{par} - n_{ur}$$

In this paper, algorithm used nll (near lower left) and nur (near upper right) vertex.

Using results of (5), calculate the dot product of two normal vectors in (5) and the four faces normal vector of the frustum besides near and far faces. Note that NLL of $\widehat{PAR\_N}_{ll}$ is the bottom left vertex of near face. So, this normal vector should be calculated with $\widehat{BP}$ and $\widehat{LP}$ vectors. Similarly, the normal vector $\widehat{PAR\_N}_{ur}$ works $\widehat{TP}$ and $\widehat{RP}$. This is shown in (5) as follow:

$$n_{ur}RP = \widehat{PAR\_N}_{ur} \cdot \widehat{RP} \tag{6}$$

$$n_{ll}LP = \widehat{PAR\_N}_{ll} \cdot \widehat{LP}$$

$$n_{ur}TP = \widehat{PAR\_N}_{ll} \cdot \widehat{BP}$$

$$n_{ll}BP = \widehat{PAR\_N}_{ur} \cdot \widehat{TP}$$

By checking whether the 4 scalar values resulting from (5) are greater than or less than 0 or not, it is possible to know that the position of the particle is inside of the frustum. If the particles are generated inside the frustum as we wish, the algorithm keeps the position unadjusted and only updates y_{par}. Conversely, if it is created outside of the frustum, then the position of the particle is moved before rendering so that it is created inside the frustum.

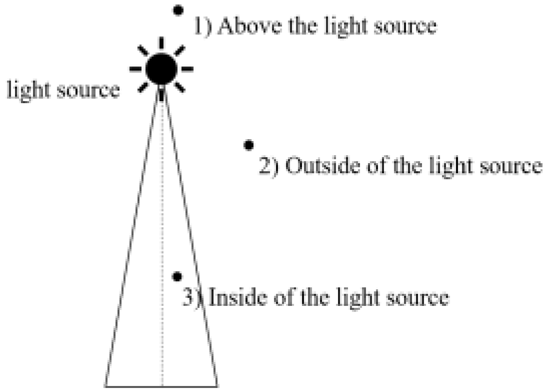
C. Spotlight Scattering

In order to render the rain more realistically under the various light condition, we propose a simple light scattering model between particles and lights. In our approach, we consider only spotlight because it is the type of light that affects the rain streak color significantly. For example, a spotlight such as streetlight can be found easily in real life. Other lights such as direction light and point lights are hardly seen in rainy days. Thus, this paper did not consider those lights in our study.

Fig. 4 shows three different cases when the rain streaks interact with light source. When we calculate the light scattering, the position of the particle must be decided as follows:

- Particles are located above the light source.
- Particles are under the light source but are not affected by the light.
- Particles are under the light source and are affected by the light.

Since the range that the spotlight affects has a shape of a cone, we consider particles that are inside the cone and ignore all other particles outside. To improve the physical accuracy, both 1) and 2) cases must be considered because lights may be reflected from other objects or raindrops, but since this is very insignificant and unnoticeable by the human eye, so those cases are not considered in this paper.



1) Above the light source
light source
2) Outside of the light source
3) Inside of the light source

Fig. 4. Conditions between Particle and Light Source.

1) Particles above the light source: Equation (7) is the equation for calculating a scalar value UD which is the dot product of the normal vector $\widehat{PL}$, which is the normalized vector from the particle to light source, and normal vector $\widehat{D}$ representing the direction of the light source.

$$ab_{light} = \widehat{PL} \cdot \widehat{D} \tag{7}$$

The ab_{light} is the value that determines whether the particle's current position is above or below the light source. If this value is higher than the height of spotlight, it means that the position of the particle is above the light source. So, the particle is not affected at all. Therefore, there is no change in particles at this case.

2) Particles under the light source: When the current particle position is under the light source, there are two cases as shown 2) and 3) in Fig. 4. Most spotlights have a cone shape. A cone is a collection of smaller or lager circles based on a point on an axis. In other words, it can be seen as a collection of circles that gradually getting smaller from the radius of the base. If the particles are in circles, they are scattered under the influence of light source. On the contrary, if particles are outside the circles, they are not affected. For this, the radius r_{circle} of the cone at the current position of the particle along the axis can be obtained using $updown$, which is the result of (7), and h_{cone}, which is height of the cone. It can be expressed as the following (8), where $base\ radius$ is the base radius of the cone:

$$r_{circle} = \left(\frac{ab_{light}}{h_{cone}}\right) * (r_{cone}) \tag{8}$$

And we can get the orthogonal distance $dist_{ortho}$ from the axis of cone to the p_{par}. $dist_{ortho}$, along with r_{circle}, is an important to know whether a particle is inside or outside the cone. To obtain $dist_{ortho}$ is expressed as (9), where $length()$ is a function that return the size of a vector as a parameter.

$$dist_{ortho} = length\{(p_{par} - h_{cone}) - ab_{light} * \widehat{D}\} \tag{9}$$

Now, we can compare r_{circle} and $dist_{ortho}$ to determine whether the p_{par} is inside or outside the cone. If r_{circle} is a larger than $dist_{ortho}$, the particle is inside the cone, which is the case as 3) in Fig. 4. And this case, the color of the particle becomes the same as the color of the light source. Also, because it is affected by light, the color of the particle appears more clearer as the intensity of the light increases.

Contrary, $dist_{ortho}$ is larger, it is the same as 2) in Fig. 4. This case, the particle does not change. The process can be expressed as the following (10) and the contents of each variable expressed in the Fig. 5.

$$if\,(r_{circle} \geq dist_{ortho}) \tag{10}$$

$$color_{par} = color_{tex} \times color_{light} \times intensity_{light}$$

$$else\ if\,(r_{circle} < dist_{ortho})$$

$$color_{par} = color_{tex} \times color_{bg} \times \alpha$$

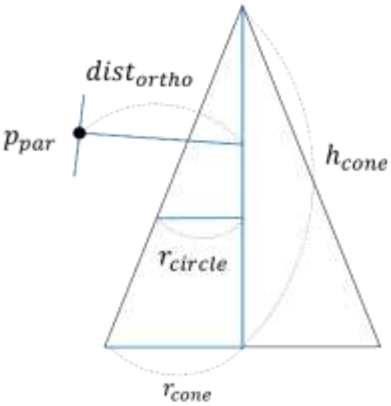


Fig. 5. Structure of Cone (Spotlight Area).

D. Texture Mapping

Garg and Nayer released their rain streaks textures as a PNG files [12]. Since this study used many textures, these files were put into one KTX file invented by the Khronos group, and then the Texture Array was used in OpenGL graphics API [13]. When we use the Texture Array, each texture corresponds to a single layer of the array. Therefore, when initializing particles, many particles are created, and they are allocated a layer for each particle. The condition for assigning a layer is random.

IV. Experiment

The proposed view-dependent rain model calculates the camera position and various parameters continuously. The experiment compares the performance of proposed model with other models after generating random numbers with a seed number. The CPU for the computer in which the experiment was conducted is Intel i7-8700, and the memory size is DDR4 16Gb * 2, a total of 32Gb. Also, the graphics card uses GTX GeForce 1080ti. All experiments were conducted in the same environment.

This study compared our proposed method with two existing models that Creus and Patow-Tariq proposed. Both models used Garg's rain streaks textures in a same way as the proposed model [3, 5]. Although the details of each algorithm may be different, it is enough to compare their FPS because three models used same rain textures. Two other models and proposed model in this paper were tested in the same environment. The changes of FPS according to the number of particles for three models are shown Fig. 7.

The proposed model in this paper, as the number of particles increased, decrease its framerate compared to the other two models. However, in the proposed model, even when a small number of particles was used, since particles were generated only in rain space within the camera's field of view, they were seemingly more than the actual number.

When we compare our result with two other method, the visual results are obvious as shown in Fig. 6. Although all three models have a fixed number of particles of 10,000, the proposed model looked to render larger number of particles than other models. This means that even with a small number of particles, we can express a large number of particles.

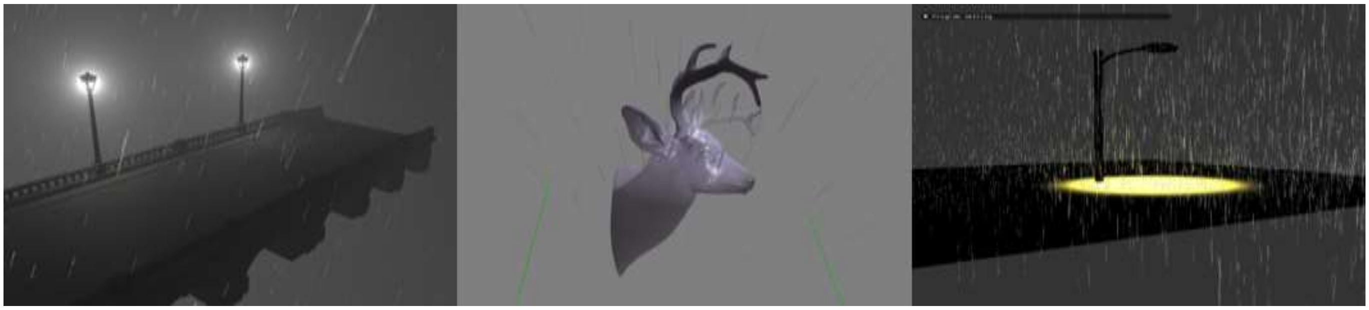

Fig. 6. (a) The Proposed Model (b) Tariq's Model (c) Crues and Patow 's Model. Three Models have the Same Number of Particles.

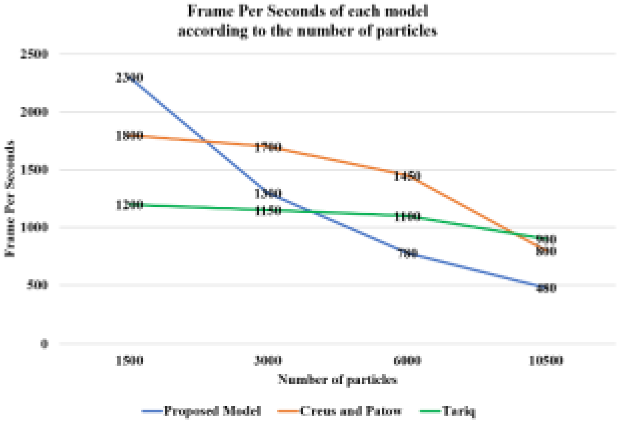

Fig. 7. Graph of Frame Change according to Particle Number.

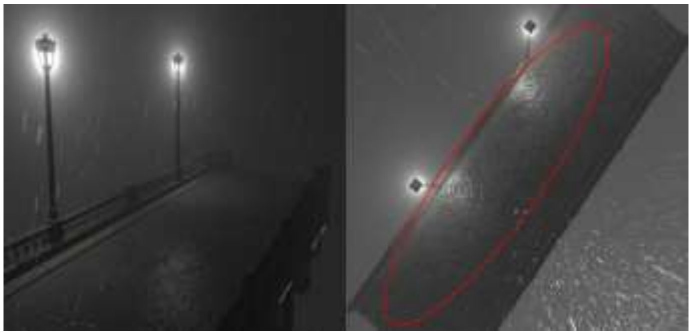
Tariq's model showed very stable performance in terms of FPS even when we increase the number of particles. In addition, a very realistic simulation result was obtained because the glow effect of the light source was considered as shown in Fig. 8(a). However, when the camera was continuously moving, at some point, particles were disappeared as shown in red circle Fig. 8(b).

The algorithm proposed by Creus and Patow, on the other hand, the FPS drops relatively in stable manner as the number of particles increases. Although not shown in the graph in Fig. 7, even when the number of particles was exceeded 10,500, real time performance was still maintained. However, as shown in Fig. 9, there were empty space in the environment where no rain was rendered when the camera is moving around. In addition, particles are keep generating and collisions are still checked even when the camera is not looking at, which degrades the overall performance.

The proposed model in this paper, as shown in the graph of Fig. 6, the FPS looks to drop higher than other two algorithms. This was caused by heavy computation on updating the position of constrained rain space, the frustum, the virtual sphere, and the particle position.

However, as shown in Fig. 10, because our algorithm makes the constrained rain space depend on the camera, even if there are a lot of changes in the camera, particles are still generating in front of the camera. This improves the visual quality of simulation.

Fig. 11 shows that the color and location of light source are fixed, and the number of particles is different. The case of (a) and (b), rendered particles are small, but it seems more than actual number. In the case of (c), rendered particles are 10,500 and it gives a feeling that it is raining quite a bit. In (d), the number of particles is the highest, 49500, and it shows that seems like it is raining a lot.



(a) Before Camera Moving. (b) After Camera Moving.

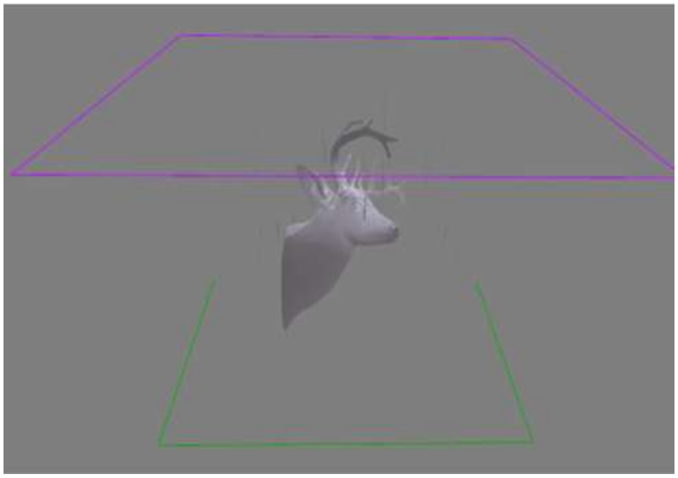

Fig. 9. Creus and Patow's Rendering Result.

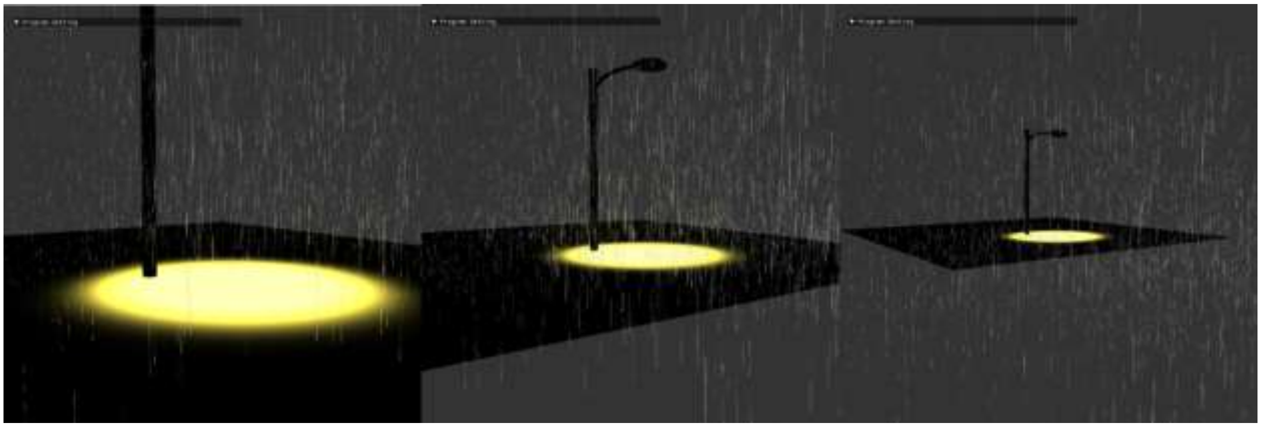
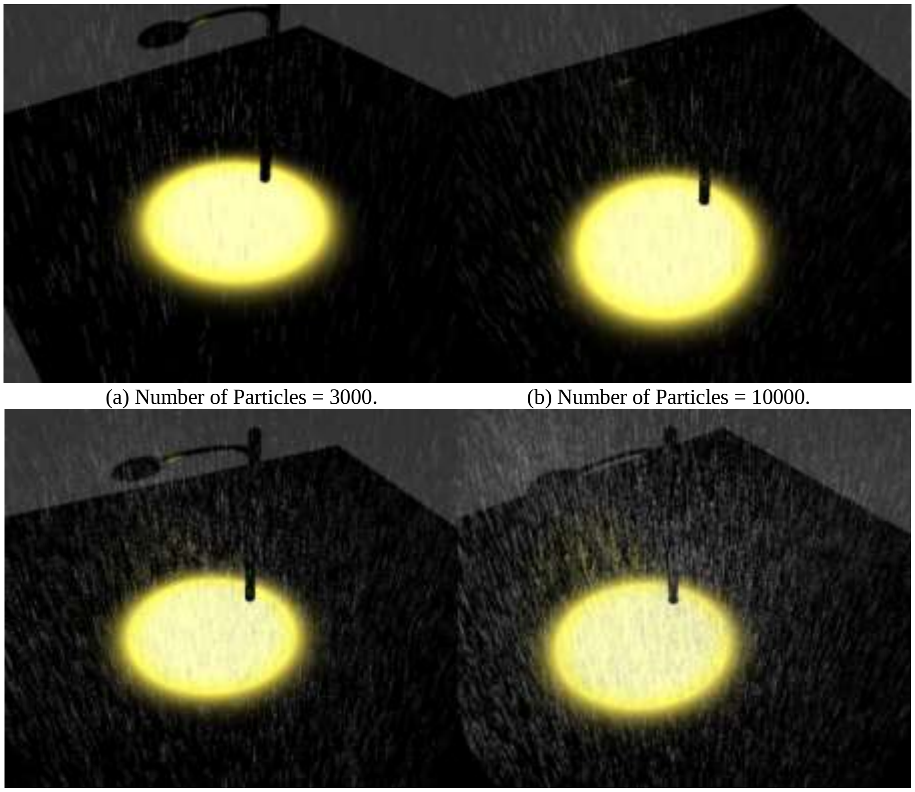


(a) Camera Zoom in. (b) Camera Zoom Out. (c) Camera Zoom Out More.

Fig. 10. Proposed Model Rendering Results as Camera Zoom In and Out.



(a) Number of Particles = 3000. (b) Number of Particles = 10000.

(c) Number of Particles = 20000. (b) Number of Particles = 40000.

Fig. 11. Rendering Results of Proposed Model according to the Number of Particles.

V. Conclusion

As seen in previous experiment chapter, the proposed algorithm is somewhat inferior to other algorithms in terms of performance. However, in other researches, when the camera position is changing, the particle positions are rarely moving along the camera. Therefore, a very large number of particles are required and should be managed, thereby can waste the computer hardware resources. This study, however, creates a camera-dependent rain space that allows particles to be rendered only where the camera is rendered. In addition, it is possible to obtain the effect of making a large amount of rain falling even with a small number of particles.

VI. Future Work

Some limitations remain in our method, though. Particle system made with transform feedback is not intuitive to manage individual particles. Compute shader or GPGPU such as CUDA would provide much more flexibility in managing GPU threads [14, 15].

Another limitation is the way of using rain streaks textures. In our implementation, the textures did not choose according to the particular angle of light and camera conditions, although the texture database does have a lot of textures according to such parameters. Instead, this study randomly assigned one texture layer to one particle. Suggested algorithm ignored them because it turned out that it did not make a big different in terms of visual quality, though physical accuracy may be downgraded.

As future works, we have a plan to use GPGPU APIs to solve the problem of particle system and heavy computation [15, 16]. This allows us to take advantage of the flexibility of the GPU and improve the performance. Also, particle systems will be more intuitive and easier to manage. In addition, next study will consider the angle of light and camera conditions when chose the streak textures. We believe that rain simulation will be more physically accurated, realistic and effeicent.

Dr. Veena S Chakravarthi[2]
Professor, Department of Electronics and Communication Engineering, BNMIT, Bengaluru, Karnataka, India

***Abstract*—Wireless Sensor Network has been increasingly used for remote monitoring system and its adoption in increasing exponentially for larger application too. However, there are various challenges associated with both resource management and security that roots up when the deployment scale goes massive and distributed in order. The proposed system considers a case study of smart city management where the problems associated with data transmission and security has been addressed. This is carried out using the provisioning of urban environment monitoring system that is an essential system for smart city projects to assure the citizens' better-quality well-being. The scalable and effective urban environment monitoring system requires a seamless transmission of the data from the sensor nodes to the analytics engine. The existing architectures are more designed to suit very specifically the use-cases. As a contribution, the proposed system introduces a cost-effective architecture for environmental monitoring in urban zones of smart city named as a Smart Sensor Surveillance System (4S-UEM). The core idea of the proposed system is to offer a balance between resource efficiency and resilience secure communication in large scale deployment of WSN considering smart city as deployment and assessment area. The proposed system makes use of urban geographical clustering process in order to develop an organized structure of sensor nodes. Different from any existing studies, the proposed system introduces data analytical engine followed by secure routing using gateway. The design of the proposed system is carried out using layered architecture of the communication model targeting towards a cost-effective, energy optimal, and secure data transmission to the analytics engine.**

***Keywords*—Wireless sensor network (WSN); sensors; smart city security; secure communication process**

I. Introduction

Urban environment monitoring (UEM) is an essential requirement for smart city projects [1] [2] [3] for various control mechanism applications. All these applications require a Smart Sensor Surveillance System abbreviated as '4S'. There exist multiple technologies for setting up surveillance systems for acquiring the data of importance. The analytics of these data correlates with the environmental changes [4]. Such technologies include surveillance camera systems and ambient-based monitoring technologies that suffer scalability, reliability, and the efficient correlation among spatial-temporal information [5]. The use of wireless sensor networks (WSN) as: "4S for UEM," i e., "Smart Sensor Surveillance System for Urban Environment Monitoring," aims to overcome these challenges and limitations. Therefore, this research study aims to design a standard architecture of WSN that provides a generalized architecture to comply with the "4S for UEM" requirements. The rationale behind arriving at a classic WSN for various 4S-UEM applications is overcoming the bottlenecks of the limitations of the suitability of one application-specific architecture to another. Typically, the data acquisition and analysis of many environmental parameters that include: temperature, humidity, traffic density on the road, vibration exerted on public infrastructure, pH-values in water, and many more parameters which leads to building smart control system for smart home, transportation, the safety of building & bridges, and water quality management, etc. as an actual application required for the smart city projects. Fig. 1 provides a snap-view of "4S-UEM" based applications and the intrinsic requirement.

As seen in Fig. 1, the intelligent system based on the architecture of the 4S-UEM requires four essential characteristics to be met by the suitable design of the 4S-UEM, and those characteristics are: {Lifetime, Accuracy, Coverage, Reliability}. Another additional requirement apart from these four is secure communication so that the realization of the 4S-UEM applications becomes possible in a real-time context. This paper proposes analytical modeling of the design of secure transmission through 4S-UEM to ensure accurate, reliable, and secure communication with optimal coverage.

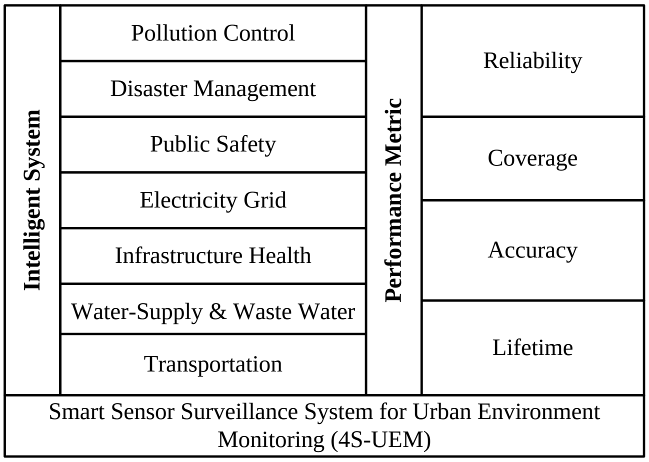

Fig. 1. 4S-UEM based Applications.

II. Review of Literature

This section describes various related work of design and development of the WSN based applications for assessing the methodological briefing of existing urban environment monitoring system (UEMS). The scope of the discussion is only limited to various resource optimization scheme which are considered as best scheme for resource management. It is because if the resource management is enhanced, eventually security scheme will be positively affected. The typical challenge in the UEMS faced is the issue of the optimal deployment of the sensor nodes that ensure maximum coverage and another is the secure communication. To provide a connecting link for transmission, a network of wireless sensor nodes is formed where a hierarchy of nodes as hop nodes, local and global sink nodes are the integral part of the WSN as static or dynamic WSN [6] depending upon the mobility of nodes and application requirements.

It is essential to consider a better network performance while designing the network deployment strategy with optimal coverage and connectivity [7]. The problem of the optimal coverage is formulated either as a greedy algorithm [8] or an integer optimization problem [9], which resembles the localization or placement problem of the facilities [10]. The sensor nodes' optimal numbers are computed using various methods like disk model, sector model, and geometry pattern model [11]. Whereas if the localization is known, then the problem of the optimal deployment in the Urban area of monitoring and deployment of WSN prefer an integer programming where popular method like i) divide-and-conquer, ii) simulated annealing, and iii) Genetic Algorithm, but these methods pose additional overhead of time complexity [12]. Irrespective of these methods, there exist some unique challenges for the deployment of the WSN for UEMS. Another important observation is that in most of the deployment, the base station's position is always fixed, which does not provide an optimal network performance [13].

There is no doubt that there are many research work being carried out towards secure routing in WSN with evolution of different methodologies and techniques. The existing methods are found to offer highly specific issue addressing scheme overlooking different challenges associated with the addressed issues. For an example, secure scheme cannot be only addressed using encryption but it equally demands resource management. Existing studies witness few direction of work aim like this integrated issue. Hence, the prominent research gap explored is that there are few studies which have linked practical energy retention with cost effective secure data aggregation in WSN considering challenging distributed and large scale area.

III. System Model for UEM

To monitor the urban environment, changes concerning temperature (T), pollution (CO2), and environmental parameters are significant for the meteorological department. The applications ranging from dairy farm monitoring to traffic management can be built on a generalized architecture: 4S-UEM, as in Fig. 2.

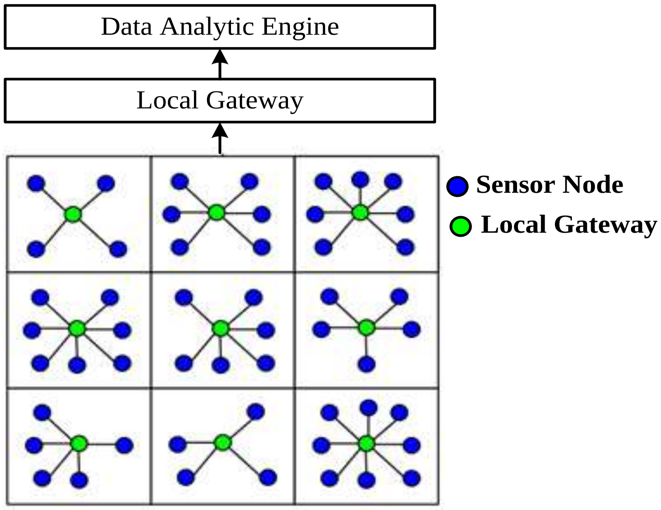

Fig. 2. Generalized Architecture 4S-UEM.

A. *Sensor Node and Data Analytics Engine Deployment*

An essential parameter in this part of implementation is basically number of sensors and simulation area. Introducing a data analytic engine is another contribution of proposed system which processes and analyzes the aggregated data unlike any existing clustering approach. The sensor nodes (Sn) are uniformly randomly distributed across a geographical area (A= L x L) of deployment in the region to monitor urban locality. An explicit algorithm-1 ensures the optimal coverage and connectivity while deploying the sensor nodes (Sn), local gateway (Lg), and data analytics engine (DaE) as intrinsic units of 4S-UEM. The Sn's deployment is modeled as a graph: G(V), where V is the vertex or a point that represents a Sensor node Sn.

Algorithm-1: Intrinsic unit deployment of 4S-UEM

```
Input: n, L,DaE
Output: G(V)
Process:
Start
for $\forall Sn_k \in n$
   [Sn.x,Sn.y]$\leftarrow f$rand(n) x L
   G(V1)$\leftarrow f$([Sn.x,Sn.y])
Initialize, {DaE.x, DaE.y}
   G(V2)$\leftarrow f$({DaE.x, DaE.y})
G(V)$\leftarrow$G(V1) $\cup$G(V2)
End
```

The WSN typically consists of 'n' number of sensor nodes (Sn) so that any sensor node ('Sn')$_k$∈n, s.t $2 \leq n$, where $n \in \mathbb{N}$ as a positive integer. The model takes 'n' and 'L'andDaEasindependent variablesto get G(V) as the dependent variable, i.e., G(V)$\leftarrow$*f*(n,L,DaE). The adjustment of connectivity and coverage of Sn and DaE for optimization takes place with variations in its localization coordinates of Sn and DaEas*(*[Sn.x,Sn.y]*)and* {DaE.x, DaE.y} respectively. The normalization of a logical layer of the architecture of the 4S-UEM is as in the Fig. 3, while the model imitates the process of deployment.

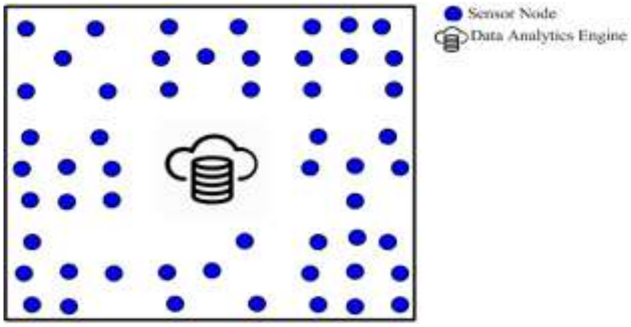

Fig. 3. Normalized Model Imitation for G(V) Containing Sensor Node and Data Analytics Engine.

B. Urban Geographical Clustering

In the smart city projects, the 4S-UEM synchronizes with the many sensor nodes deployed across the city or urban region by introducing an algorithm for Urban Geographical Clustering (UGC) to meet layer-wise communication that distance of communication is reduced. The prominent parameter of this part of implementation is local gateway which is responsible for performing translation services. The very basic requirement of UGC is to select a randomized local gateway (Lg) such that Lg ∈ {Sn}. A probabilistic approach considering the node's energy and the boundary conflict to avoid overlapping of spatial data overload is considered for the designing of UGC and selection of Lg. A straightforward process for the UGC is as in the algorithm 2. This approach establishes the communication between the lower layer of the sensor nodes or actuator with the local gateway.

Algorithm-2: Urban Clustering for 4S-UEM

```
Input: G(V)
Output: Cid, Lg
Process:
Start
Initialize, nC ← {m^2}, where m ∈ N
    $\vec{D} = |(nC - nLg)|$
    [Vmin, Id] ← $fmin(\vec{D})$
    $\vec{B}$ ← fbound(id, L)
    nC ← Id^2
    $\vec{S}$ = 1 to nC with step 1
    $\vec{S}$ ← freshape($\vec{S}$, $\sqrt{nC}$ . $\sqrt{nC}$ )
for membership of ∀ Sn into an urban-Cluster
    if
        $(Sn)_i.x \geq \vec{B}_i \wedge (Sn)_i.x < \vec{B}_{i+1} \wedge (Sn)_i.y \geq \vec{B}_i \wedge (Sn)_i.y < \vec{B}_{i+1}$
        update: Cid for ∀ Sn
    end
visualize the urban clustering
Call algorithm for selection of Lg
    Update: Lg in each communication cycle
End
```

The very basic assumption made while designing the architecture of 4S-UEM is that the number of local gateways (Lg) is as equal to the number of zones in the city or urban geographical region under monitoring i.e. Lg = nC, where nC = number of urban clustering, which is taken as a set: nC = {m^2}, where m ∈ a positive integer number. The nC is finally decided based onthenode with energy and a probabilistic approach, where the boundary constraint $\vec{B}$. To compute Bc, initially, the difference of number of local gateways (nLg) and nCas$\vec{D}$Is computed as in equation 1.

$$\vec{D} = |(nC - nLg)| \tag{1}$$

Then, the index (Id) and minimum value (Vmin) from $\vec{D}$ along with area component L goes to an explicit function to define the boundary as $\vec{B}$, which is a linearly spaced vector of L into Id+1 component, and the nC assigns as Id^2.Further, a series $\vec{S}$ as 1 to nC reshaped to the number of row and number of columns as $\sqrt{nC}$, say if nC = 16, then the $\vec{S}$ is as below:

$$\vec{S} = \begin{bmatrix} 1 & 5 & 9 & 13 \\ 2 & 6 & 10 & 14 \\ 3 & 7 & 11 & 15 \\ 4 & 8 & 12 & 16 \end{bmatrix} \tag{2}$$

To get the membership of ∀ Sn into a specific urban cluster, the localization of each $(Sn)_i \in$ n is taken as basic parameters to define its class membership with the respective urban cluster based on the condition with the boundary constraints $\vec{B}$ as in equation 3.

$$(\Sigma\nu)_\iota.\xi \ \varepsilon \ \vec{B}_\iota \perp (\Sigma\nu)_\iota.\xi < \vec{B}_{\iota+1} \perp (\Sigma\nu)_\iota.\psi \ \varepsilon \ \vec{B}_\iota \perp (\Sigma\nu)_\iota.\psi < \vec{B}_{\iota+1} \quad (1)$$

The corresponding identity to all the Sn is designated as cluster-id (Cid), with a potential of equal probability to be a Lg, and in this way, the urban clustering of all sensor nodes takes place, as seen in Fig. 4.

Section C describes the procedure for Lg selection along with the secure routing process as in Algorithm 3.

C. Secure Routing through Selected Local Gateway to the DaEin 4S-UEM

The very objective of the optimality of the architecture of the 4S-UEM is to meet the energy balance of the nodes as well as the network with the consideration of the optimal routing in the least consumption of energy as well the mitigation capacity for the data integrity against any kind of attacks which ensure the reliability of the data delivery for the analytics engine to provide the correct analysis on the real-time basis.

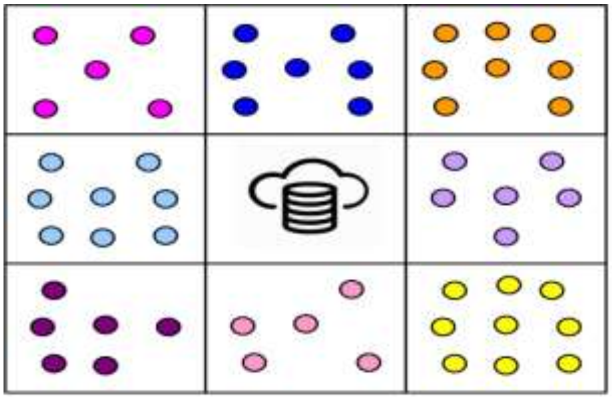

Fig. 4. Membership to each Sensor Node of 4S-UEM into an Urban Cluster.

Algorithm-3: Local Gateway selection in the Cluster of 4S-UEMand Secure Routing

```
Input:nC
Output:Lg
Process:
Start
Initialize the values of each in set:
    P: {Pl, cPl, Etx, ERx, Efs, Eamp, Ea,}
Setup process:
Initialize Pn
    Po← Rn1 x Pn
    Pkc←Rn2 x Pn
Generation of CG
    [CG1, CG2]←farbitary (Pn, ID)
Lg Selection process:
    Initialize ∀Sn  P(Sn | Lg → p %)
Update: Sn with energy in each communication cycle
        ASn←( nSn – nDSn)
        Lg←G(ASn) based on Th
        Th← $\frac{p}{1-p[Ccxmod(\frac{1}{p})}$
Call data authentication process (Algorithm -4)
    Transfer the packets after integrity authentication to DaE
    End
```

The system models take a set of parameters as independent variables, P={Pl, cPl, Etx, ERx, Efs, Eamp, Ea,}, where: Pl = size of the data packet , cPl = size of the control packet, Etx and ERx are energy required for transmission and receiving respectively. Here Efs and Eamp are the respective amplification energy in case of free space communication or dense network deployment, whichever is the case. In many of the current work, it is found that, while designing the architecture of the communication over wireless sensor network, only a basic first radio model is considered with the transmission and amplification energy into consideration [14]. Whereas the system model of 4S-UEMalso considers the energy required for the data to be aggregated or fused at the respective Lg ∈ uC(urban cluster) in the set of P, the performance resembles to the real-time constraints or context.

The characteristic of the sensor nodes (Sn) is a low capacity of computation and memory; thus, a lightweight security mechanism is proposed in the architecture of the 4S-UEM for the data authentication process in line with customized elliptical curve cryptography (ECC), while layer-wise communication. The first stage of this procedure is the setup stages as below:

- *Setup process:* In this process, the prominent parameter is a prime number (Pn) initiates to get the value of a primal Po as a product of a random number (Rn1) and the Pn and a public key center (Pkc) as Rn2 x Pn, where Rn2 is another random number. An explicit function:farbitary()is designed to take the Pnand the ID as an input argument to get the cyclic group. This operation's very basic function is to produce two cyclic groups (CG): {G1 , G2} with a single element Pn such that it produces a set of the invertible values with a single binary operation of property associative. The second stage of the system is the selection process of the Lg.

- *Local Gateway Selection Process:*IntheLg section's typical process, the Sn's energy plays a predominant role. The model validations occur with the varying probability of being Lg such that for ∀ Sn having P(Sn | Lg → p %). Further, the cluster-id (uCId) for ∀ uC and the Sn whose energy(E) < 0 is marked as a node as fault or dead node ID as (DSn) and the total number of such dead nodes = nDSn = ∑DSn. Therefore, the sensor nodes Sn in each cycle of communications to be considered as the nodes with some energy as (ASn) = nSn – nDSn is only considered to be set of the eligible Lg: Lg:→ {ASn}. The selection of the Lg from the set of {ASn} takes place based on a threshold node (Th) as in equation (4):

$$\frac{p}{1-p[Ccxmod(\frac{1}{p})} \tag{4}$$

If the Th < a random number between '0' and '1', the Sn ∈ ASn is treated as Lg from a group of G(Sn). In the equation 4, p = probability % of the ASn to be Lg, Cc = current communication iteration, G(Sn) = ∀ Sn ∈ ASn that has not been chosen as Lg in the last (1/p) communication iteration. This threshold (**Th**) is considered in the state of artwork for hierarchical communication LEACH and its variance [15][16]. Unlike any another traditional approach, the rest of the Sn receives the broadcasted cPl and decides to be part of this Lg based on the energy-based signal strength. The communication process further in the 4S-UEM communication process goes for the data authentication, aggregation then transmission to the DaE as described into the algorithm -4. Fig. 5 illustrates the current stage as Sn, DaE, and urban clustering and selection of the Lg.

It is essential to integrate a data-authentication process in communication to ensure the correctness of the data reaching the DaE, so that correct analysis of the data of the environments records provides accurate input or instructions to the control systems. However, the trade-off here is to handle the timely delivery in optimal energy way as the sensor data collected from the various uC takes some amount of energy that influence the overall network lifetime.

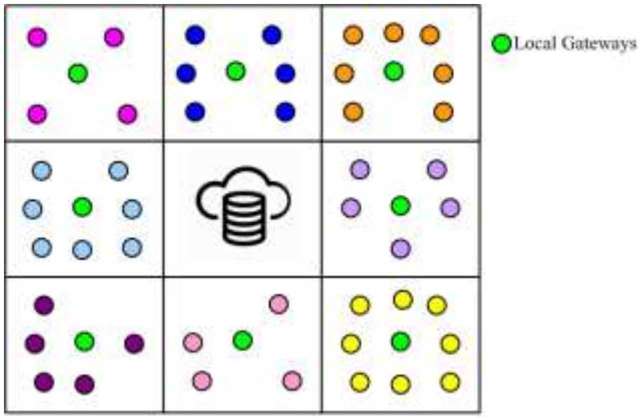

Fig. 5. Selection of Local Gateway (Lg) in the Urban Cluster(uC) of 4S-UEM Architecture.

The unique characteristics of the proposed communication process in the layer-wise approach of data from the individual sensors to the respective Lg and the aggregated or fused data transmission to the DaE in the optimal energy way even if the data gets authenticated by a very lightweight hashing mechanism of data integrity check within the sleep schedule cycle of the Sn, Lg, and DaE to avoid any kind of the collision, which is our future research direction to design an optimal tree-based routing for the channel resource allocation, which is beyond the scope of this stage of the architecture design. The details of the algorithm-4 are as below:

Algorithm-4: Data authentication, Aggregation, and transmission to the DaE as 4S-UEMSecure Routing procedure

```
Input:nC
Output:Lg
Process:
Start
Initialize, Id of Lg, and Id of ASn

    ∀ ASn ∈ uC, record messages as dP
    q ←ƒhash-1( Id-ASn, Pn)
    [q, Pk] ←ƒkeygen(Id-ASn, Rn1 )
Initialize, Signing operation
    Generate a Rn3
    P1 = Rn3 x Pn
    q1 ←ƒhash-2( P1, Id-ASN, dP)
    u1 ← $\sum[Pk,\ (Rn3 \times q1)]$
    Update: Signature
        Sig ←{P1,u1,Id-ASn, dP}
        sAm ←∑ mT x ∑ u1
        CG ∀ Lg: mark Lg → 1 based on Th
    Aggregation Verification:
    Call SPR
    End
```

In this process, the Id of ∀ Lg gets initialized, and for each uC, Initially, the Id of Sn ∈ respective Lg is used for finding the ASn, and further, ∑(ASn) participates in transmitting their data to the Lg for the aggregation process of the data packets. The secure aggregation process includes Lg selection, Sn data generation, signature verification, and routing simultaneously.

For ∀ ASn ∈ uC, the respective data packet (dP) depends upon the application used in a signing process. An explicit function ƒkg( ) takes the Id of ASn and Rn1 as used while creating the cyclic group in algorithm 3. The process of message authentication uses hashing algorithm in the key generation based on Id of ASn and Rn1, where ƒhash-1(Id-ASn) → q, where q = Pn x Id-ASn, which finally provides corresponding private key (Pk) for ASn using Pk = Rn1 x qusing an explicit function *ƒkeygen( )*. The next operation is the Signing operation, which takes {Id-ASn, dP, Pn, Pk}.

Initially, a random number Rn3 is generated in the signing process, which gives a first P1 as P1 = Rn3 x Pn, which passes into ƒhash-2( ), along with Id-ASN and dP, which gives a new hash value q1 as q1 = dP x Id-ASn x P1. Another, primal u1 is computed as in equation 5.

$$u1 = \sum[Pk,\ (Rn3 \times q1)] \tag{5}$$

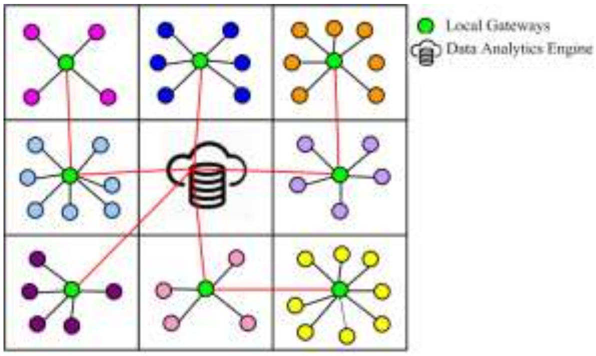

Fig. 6. The Transmission Process of Messages from uC through Lg to DaE of 4S-UEM.

Finally, the signature set includes {P1, u1, Id-ASn, dP} and each intermediate computation stores in message-term (mT) as u1 x Pkc, where Pkc comes from algorithm 3. Finally, ∑ mT x ∑ u1 assigns as a signature for aggregate messages at Lg (sAm).

The cyclic group values of for ∀ Lg which do not participate in the selection, and the flag is set to zero for all Lg, and the process continues with the comparison of a random number between 0-1 and the Th as in equation 4. Finally, the aggregation verification occurs, and the system calls for the shortest path routing either from Lg to DaE or as inter Lg routing. Fig. 6 illustrates the data transmission process of the proposed 4S-UEM.

Fig. 6 clearly illustrates two layers of data transmission as proposed in 4S-UEM. The first layer of transmission takes place between sensor nodes (Sn) to the Local gateway (Lg) and the second layer of transmission takes place between the Lg to the data analytics engine (DaE). In Section 4, observations of energy variation and the network life are described to understand the model's behavior while imitating in a sequential numerical computation platform.

IV. Performance Evaluation

There are two scenarios to validate the model, and these scenarios are 1) Traditional [6]-[13] and proposed approach of data communication without the data aggregation process and 2) Traditional and proposed approach of data communication with data aggregation process. Fig. 7 to 11 represents the graphical representation of numerical outcomes in Tables I to V with an intention towards assessing scalability. The outcomes are represented in the form of energy parameters on y-axis with increasing number of sensors to represents the influence of performance parameters. The outcome shows proposed system with better energy compared to existing approach.

V. Conclusion

The unified architecture proposed in this paper is named 4S-UEM, keeping in mind that to deploy a smart monitoring system for the urban environment monitoring purpose, the entire region of the urban zone is divided into the urban clusters where a local gateway is chosen smartly and intelligently. The local gateway collects the data and sends the data either directly or through inter-local gateway routing with the data verification provisioning. The important findings of this paper are i) proposed system offers approximately 47-58% of energy conservation over a large network of smart city, ii) The clustering model suits well with the public key encryption mechanism implemented unlike any existing methods, iii) the study offers no iterative scheme towards optimizing resources and hence it is highly cost effective. The 4S-UEM model provides a consistent result in terms of the network lifetime with a varying number of node density and the cluster. This work's future direction is to evolve a routing model so that priority-based routing takes place with further energy optimization during the channel allocation and avoidance of the collision of the packets utilizing optimal time slot scheduling of the radio.

***Abstract*—In this era of digital and competitive market, every business entity is trying to adopt a digital marketing strategy to get global business benefits. To get such competitive advantages, it is necessary for E-commerce business organizations to understand the feelings, thinking and seasons of their customers regarding their products and services. The major objective of this study is to investigate customers' buying behavior and consumer behavior to enable the customer to evaluate an online available product in various perspectives like variety, convenience, trust and time. It performs data analysis on the E-commerce customer data which is collected through intelligent agents (automated scripts) or web scrapping techniques to enable the customers to quickly understand the product in given perspectives through other customers' opinion at a glance. This is qualitative and quantitative e-commerce content analysis in using various methods like data crawling, manual annotation, text processing, feature engineering and text classification. We have employed got manually annotated data from e-commerce experts and employed BOW and N-Gram techniques for Feature Engineering and KNN, Naïve Bays and VSM classifiers with different features extraction combinations are applied to get better results. This study also incorporates data mining and data analytics results evaluation and validation techniques like precision, recall and F1-score.**

***Keywords*—Customer comments; behavior mining; data mining; machine learning**

I. Introduction

A. Motivation

This study emphasis on need to develop some mechanism which ensures to get advantages form E-commerce users' generated data. A general approach reveals that to get opinion of other people before buying any product is common in online and offline shopping. But in this digital era, each customer has hundred or sometimes thousands of people readily available to provide valuable opinion and largely effect the decision-making process of new customers. Each customer looks for best product in lowest possible price. Actually, each customer tries to find the best commodity within his/her financial range along with surety of the justifiable quality attributes. Therefore, it is a normal practice to get neutral and genuine opinion of general public that is not generated by selling organization also not tempered by anyone else [1][2][3].

B. Consumer

A customer is an entity or person having an ability or will to buy the products and offered ventures available for purchase by advertising organization so that it may fulfil needs or want of an individual, family or a particular group of similar interests. A famous definition of consumer done by Mahatma Gandhi says, "A consumer is the most important visitor on our premises. He is not dependent on us. We are dependent on him. He is not an outsider to our business. He is part of it. We are not doing him a fulfil by serving him. He is doing us a fulfil by giving us an opportunity to do so" [4][5].

C. Consumer Behavior

Consumer behavior is characterized as "psychological, physical and social acts of potential clients as they have made their minds to access, assess, purchase and inform others about any item and its attributes". Consumer behavior is the study of single buyer, a group or organization about their course of selection, buying, utilization and disposing of commodities, services, ideas or experiences to satisfy his/her needs and also impacts of such process on the consumers and whole society. Consumer behavior varies from individual to the groups (like class students in school or college wear same uniform/dressing) and from group to firms (various groups at same place working together horizontally and vertically and decides collectively whether a product must be user by the firm or not) [6][7]. The customer opinion is often very important for advertising agency/marketer because it influences the market position as well as consumption of the product. Consumer behavior involves services and ideas as well as tangible products.

D. Internet Marketing

Internet marketing is utilization of internet as a medium to assess the showcasing and potential sale of merchandise. It has been proved highly beneficial by apply standard fundamental promotion systems on e-commerce applications [8]. Contrary to physical business strategies, online promotion and advertisement strategies have been proved far better with little hazards comparatively. Web showcasing process not only convenient for business community it also supports green solutions across the globe [9].

E. Purchase Decision

Buying decisions are defined as: "Several stages carried out by consumers before making a purchase decision on a product" [10]. According to the [11] buying behavior means activities of an individual who is involved in exchange of money for goods or services and also it involves some decision-making process to determine those activities. Consumer's decisions in buying a product involves physical and mental activities. The former refers to the direct activities for decisions making process while later involves assessment of product using some particular criteria.

F. Data Mining and E-commerce

It is a substantial undertaking to build a system which take advantages from mined knowledge. Studies revealed that some applications of data mining techniques on e-commerce data is comparatively less challenging as compared to other sort of data. For example, we can develop data mining system in E-commerce with much convenience rather than translating and correcting the data to make it suitable for data mining purpose. As data set is not collected manually or by survey but accessed electronically so it comparatively less noisy or sometimes contains no noise. Moreover, data set contains variety of vast and varied information as shown in "Fig. 1" [12] 1[3].

It has been analyzed that public information over E-commerce platforms play a vital role in success of regression models due to justifiable quantity of varied information. Therefore, E-commerce platforms provide very useful data and its inferences to produce a platform that is trustworthy for E-commerce customers [14]. They have discussed various applications of clustering and fuzzy set theory to determine issues in E-commerce platform through data mining application.

G. Consumer Behavior Mining

Consumer behavior mining is deals with web content mining which is concerned with valuable information extraction regarding users/customers opinion. Consumer behavior mining is almost a new subject in field of data mining as part of web mining and growth of E-commerce business has accelerated its growth significantly across the E-commerce applications, blogs and forums [15][16]. Consumer behavior towards online shopping instead of physical visiting markets and shops has been changed due to growth and profitability of E-commerce business. So along with online shopping habits, many people also prefer to get knowledge about public opinion regarding a particular merchandise before placing online order.

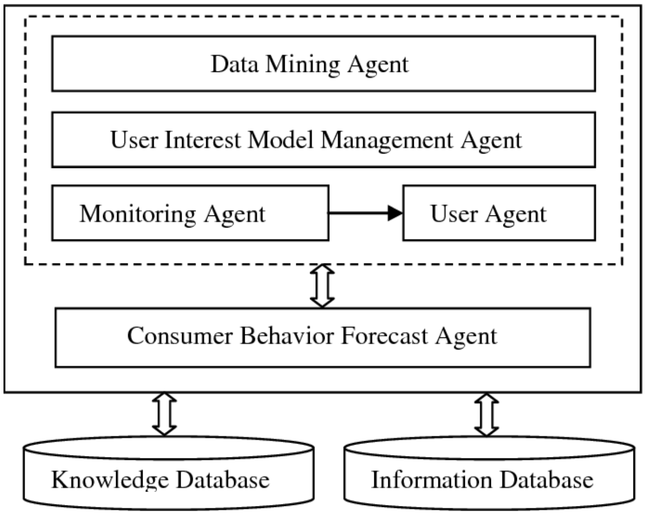

Fig. 1. Social Commerce as Sub Set of E-commerce and Social Media.

Consumer behavior is highly affected by public opinion but at same time availability of desired, accurate and quick information is a problem. Finding thousands of reviews regarding a product is not a big problem but finding summary of user opinion which is true reflection of customers' thought is a still a challenge across the E-commerce platforms [15]. Consumer opinion mining is not only useful at consumer end but also useful for manufacturing and advertisement companies the former get support about decision of transaction while the later are able to use opinions as customer feedback to improve their product accordingly while advertising agencies can easily find about individual customer opinion and post advertisements on his/her pages according to his/her choice [16].

H. Research Problem

Research objective is to identify the Consumer Behavior relevant elements related data in online E-commerce platforms. Validate Consumer Behavior relevant elements' related data with respect to customer opinions. To identity suitable text preprocessing techniques and selection of most relevant features for each Consumer Behavior relevant element. Develop a supervised machine learning based system which extract, classify into major predefined categories and preserve Consumer Behavior related knowledge in order to make this knowledge extensive, versatile, verified, easy to use and up to date.

II. Literature Review

A. Consumer Behavior

Customer experience is very important for every business organization where numerous products and vendors/brands are available. Customer experience optimizes and improves the online shopping experience of people which has been extensively increase after outbreak of pandemic Coid-19 across the world [18]. E-commerce companies and organization has experienced business prosperity due to increase in online demand of merchandise. Each business organization is string hard to improve their marketing by better understanding of customers' needs and priorities through analyzing customer buying behaviors[19][20]. Each organization trying its level best to retain their customers by offering the best shopping choices so that customers do not switch brands and shopping platforms. Organizations are also focusing to identify their potential customers segments by tracking their priorities, selections and expectations regarding products over the time [12]. It is necessary for business organizations to track, collect and organize consumer behavior possible data to develop business and analysis insight to take appropriate actions [13]. Recent studies revealed that enormous research has been conducted and a lot much more is underway to understand consumer behavior or to understand changes in customer activities over the time. Analysis of customer behavior is now an integral part of customer relations management strategies [17]. Data mining methods, tools and techniques are being incorporated to discover useful patterns using large amount of data collected by organizations. There is a variety of data mining models like clustering, association, classification, forecasting, regression, sequence discovery, visualization and machine learning models for data mining models like association rule mining, Logistic Regression, K-nearest neighbor, Neural Networks, Decision Trees, etc. E-commerce and other business organizations are collecting massive amount of data on daily basis in form of sale purchase transactions, customers profiles, cart management and product search data [21]. Such large data owner organizations are keen to unleash the potential behind this data and are also interested in mining the association among different data segments as shown in “Fig. 2”. These organization have firm believe that proper analysis of this large customer data can yield useful knowledge to get insight about consumer behavior [15]. They have proposed a customer segmentation system to discover and analyze frequent items searched by customers and their change over time. Authors employed association rule mining to discover useful and meaningful data patterns using database containing customers transactions records [22]. They also devised a strategy to automatically detect changes using customer profile and sales data of a particular period. The authors also proposed three types of changes in customer behavior: Unexpected Changes, Emerging Changes and Add/Perished Rule [19].

B. Consumer Behavior Mining

Big data technologies and their implementations are becoming cause of an immensely increasing information nowadays. Banking and insurance sector is seeking benefits of big data analytics and data mining to detect defaults and potential risks. In [23], the authors collected 22745 data samples and 14 attributes from Turkish Statistical Institution. This targeted to find the selection of best algorithm for classification to identify risk because of personal characteristics [24]. They incorporated and evaluated the several classification algorithms like Naïve Bayes, J48, Logistic Regression, Random Forest and Multilayer Perceptron were selected and their accuracies were evaluated using several evaluation techniques like Precision, Recall Roc Curve, etc. and most of them were found suitable to deal such type of data. Weka, a renown data mining tools was used to perform experimental methodologies as shown in “Fig. 3”. Data mining is extensively being used in field of medicines to predict various diseases using patient medical records especially detection and prevention of Diabetes Mellitus as it has deteriorated human, social and economic fabrics due its boosting penetration in all societies across the globe. traditional data mining techniques have been integrated with clinical research to advertise adverse effects of various diseases like Diabetes Mellitus, cancer and other diseases. These researches generally incorporate plain combinations or single classifiers. There are many comprehensive efforts are conducted to enhance the accuracy of systems with combination of multiple classifiers. [25][26] classified the diabetes mellitus in individual patients by using a set of risk factors and applied Bagging techniques of natural language processing with Adaboost, Decision Tree as a baseline experiment. The experiment was carried with Canadian Primary Care Sentinel Surveillance and three different adult teams. The Adaboost outperformed the bagging techniques an individual Decision Tree J48. Anarkali [27] have enlisted number of data mining application fields which are popular in recent times. Knowledge Driven Databases (KDD) and data mining are being employed in numerous fields to collect and analysis large chunks of information.

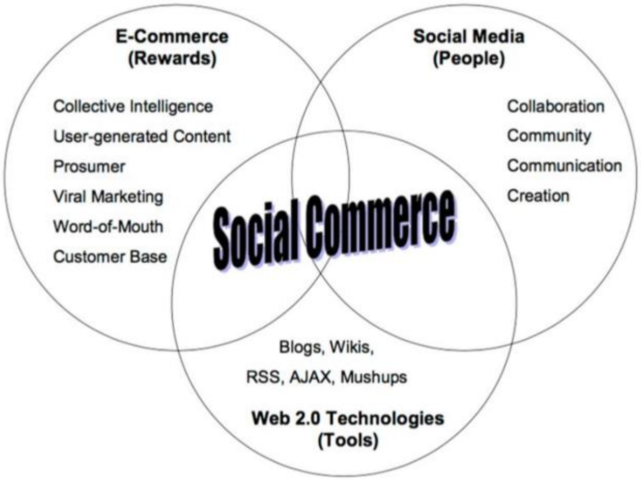

Fig. 2. Social Commerce as Sub Set of E-commerce and Social Media.

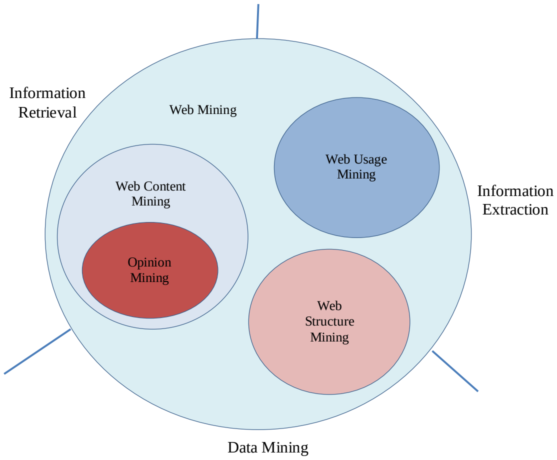

Fig. 3. Information Retrieval using Web Mining.

Integration of big data techniques in E-commerce web applications has also make it easier to collect structured, wide and large volumes of data regarding internal business process, marketing, supplier, venders and shipment. Therefore, big data analytics has open new avenues of opportunities for business companies related to E-commerce [28]. [29] presents many clustering, association and prediction techniques which are highly useful for E-commerce business. Sales forecasting, customer relationship management, customer retention management and basket analysis are common data mining models in E-commerce business. Major objective of this study is to review, implement and evaluate classification data mining techniques on user comments to classify them into different categories to assist online customer in decision making process.

C. Perceived Benefits

There are numerous benefits of internet shopping or online shopping but it there are also some risks involved which affect the consumer behavior towards online shopping [10]. The perceived benefits related to consumer satisfaction and belief that online shopping offers following benefits as compared to combinational shopping.

1) Convenience: Internet has made our life easier due to easy and quick access to the large number of desired products within seconds so we can buy almost everything with convenience. Seiders, Berry and Gresham (2000) says that convenience offers four benefits in buying process: search, access, possession and transaction as convenience is frontline attribute of online shopping which incites the consumer to go for online shopping. Furthermore, it is major predictor which prompts the consumer to go for online shopping. It also creates online buying willingness among customers. In online shopping, consumer does not need to leave his home/job or business and visit market personally for buying anything and consumer is not bound to keep cash in pocket for shopping for 24 hours [30].

2) Trust: Online shopping is characterized by time saving in terms of travelling to shops and then selection by visiting shops one by one. Therefore, online shopping saves time of customer but this statement does not stand true all the times due to late shipment of product. Generally, delivery time is often mentioned with the order and online customer confirms the order after verification of product delivery time [30].

3) Time: The time as perception of consumer that the vendor or seller will provide the best commodity in terms of price, quality, utilization and satisfactions. Most of people lack of trust in online shopping due to cheating and misconduct of e-commerce sellers. As there is lack of E-commerce cybercrime and needful legislation therefore it is sole responsibility of the seller to establish an environment of trust among people. Uncertainty in customers regarding reality of online shopping is one of the major obstacles in success of online business [30].

4) Trust: Online shopping is characterized by time saving in terms of travelling to shops and then selection by visiting shops one by one. Therefore, online shopping saves time of customer but this statement does not stand true all the times due to late shipment of product. Generally, delivery time is often mentioned with the order and online customer confirms the order after verification of product delivery time. But sometimes, due to disaster, natural calamity, power break down, strikes or transportation issues order does not arrive on time. Late delivery of product harms to trust of customer so timely arrival of product boost up customer confidence. Therefore there is strong relationship between time and online shopping but there must be some more attributes to better understand this relationship [30].

III. Methodology

This research aims to develop an E-commerce customer comments knowledge classification system based on consumer behavior attributes (listed as Convenience, Variety, Time and Trust), which depends upon tasks to be customers' comments given under any product on any E-commerce platform. We have targeted the social E-commerce platforms of online shopping to acquire data set where versatile people post variety of comments and answer each other's comments. One cannot only easily find type of his comments and discussion activity by using scrolling on web applications. By using proposed classification system, one can find the consumer behavior (Convenience, Variety, Time and Trust) relevant data and its overall status. Moreover, proposed system is not confine to classify all consumer behavior related comments, rather it is also ready to perform classification of other e-commerce customer comments under the umbrella of other classes or categories.

This study strives to build up an E-commerce customer comment data classification/categorization framework which heavily rely on the customer behavior attributes (listed as Convenience, Variety, Time and Trust). The propose system is developed by incorporating data mining and supervised machine learning text classification methods. This study employs various kinds of machine learning models like K Nearest Neighbor, Support Vector Machine, Naïve Bays, Character Based BOW and N-Gram on the state-of-the-art available data set.

A. Dataset Collection

First of all, data set is collected from E-commerce platforms using web agents or automated scripts by apply X query scripts using XML X paths. It requires up to mark professional expertise to extract exactly required and contextual data from large data dumps. E-commerce platforms contains large quantity of consumer behavior knowledge/comments and it can be utilized for consumer behavior mining (reference). Data set regarding consumer reviews about products which ranges across period from 2018 to 2020 contains almost thousands of comments about single product. But as per research requirement only 2000 total and 500 posts of each activity were included in the experiment.

B. Manual Annotation

E-commerce platforms or knowledge sharing communities and forums provide platform to fresh, experienced and professional online buyers/people to share their knowledge with people of their domain across the world and round the clock without any barrier of distance, language and level of expertise. All the members of an E-commerce platform cannot tag their post/comment with a specific category according to the chart mentioned above. If they do so then it will help the people to easily identify each comment under the umbrella of consumer behavior. By doing so, classification of each new comment will be started and data search and segregation will become easy for people who want to learn about opinions of other customers who have already utilized the product from the same platform. To visualize the comments data and better understanding of data set, it is categorized into 4 major categories and each category contain associated attributes related to consumer behavior. Every comment in selected data set is manually annotated and verified by E-commerce experts.

C. Attributes Associated with Each Class

1) Convenience: Convenience, Best, Appropriate, Easy, Great, Perfect, Useful, Functionality, Effective, Desire.

2) Variety: Variety, Forever, Compatible, Collection, Intended, Different, Diversity, Pack 3-1, Specific, Warranty.

3) Time: Recommend, Comfortable, Reliable, Excellent, Complains, Described, Quality, Satisfaction, Honest.

4) Trust: Time, Period, Delivered, Received, Pair, Come up with, Duration, Deal, Successfully.

D. Text Preprocessing

Customer comments classification process is actually started with data collection from E-commerce platform and then the most important function of data mining is performed that is called preprocessing of data. Data preprocessing is important because machine learning models are very sensitive to the features in each document. So pure and more relevant feature can be extracted by feeding the data set to some programming application. Before providing data to machine learning models, it is preprocessed and in case if data set is obtained from social media or E-commerce platform then it contains useless and noisy data which is mandatory to remove to get good results from machine learning classification models. This noisy data includes hashtags, symbols, domain terminologies, trends, smilies, web link, social media promotions, etc. so such noisy material is mandatory to remove to make the training data set clean. Preprocessing of E-commerce data set that has been manually annotated is made free form punctuations, semicolons, quotes, notations and the above said useless elements of language [31][32].

1) Tokenization: Tokenization process splits the data set text into the single elements or tokens by using a specify delimiter like space as shown in Table I. In this study we have used space in words as delimiter. As a text document is composed of linguistics elements and structures called as sentences and each sentence is further made up of grammatical units which are separated from each using space, full stop, hyphen, comma, slash. etc. Tokenization is first step in text preprocessing in which grammatical unit is converted into the tokens using some delimiter and output of this process is tokenized document [33].

2) Stop words removal: Stop words removal is next step to the tokenization. When all the text data set has been converted into individual tokens then unimportant words are removed because in a text data set, all the words are not important with respect to the document or class context. There are numerous words in the input text document which are less or least informative for the machine learning model [34]. Many words occurs multiple times in the document and such repeating words are also included in the noisy data. These less informative and repeating word are call stop words. Stop words removal is an important step in text preprocessing because stop words affect the features set extraction and ultimately efficiency of machine learning model.

As mentioned above, stop words gives little meaning of a word or context and are not helpful to the machine learning models. Stop words removal reduces the data set volume by removing useless or less important token or elements. Ultimately it reduces the computations coat and time. This technique is simple in use and helpful in increasing classification accuracy. Example of these words are ‘The’, ‘is’, ‘also’ etc which are frequently used in textual data. We remove all stop words in English language by using standard list of stop-words.

3) Identification of hash tags: Hash tags are also part and parcel of social media and E-commerce comments data set. Hash tags are commonly known a trends and it has specialty that it is stated with special symbol and it does not contains any kind of separator like space, comma or full stop. Hash tags are not dictionary words and also do not have any particular meaning so it is a good approach to remove Hash Tags to get useful and meaningful words which are easily recognized by dictionary or Word Net in Natural Language Processing.

4) Spell checking and correction: E-commerce text data set in form of comments or discussion in natural language contains multiple words which are not part of language dictionary but are understandable by the people belong to some specific domain. These words are not recognized by search engine optimization and also natural language processing techniques are confused of such words. Majority of such words is set of words which are not properly written and contain spelling mistakes. This problem of such words can be resolved up to some extent using regular expressions or mutually annotated data.

5) Stemming: Words are used in various forms in the English language text. It base might have different forms or behavior when it is used in different sentence structures like present, past, future tenses, singular, plural, adjectives, pronouns, etc [35][36]. English language has different laws for all these situations of a root word. No doubt each words comes from its root word of dictionary but it is used in different styles in the sentences. If we take an example of a word “Go” then we will come to know that it is used as “go”, “went”, “gone”, “going”, “goes”, etc. But dictionary has a single root word for all these words that is “Go”. These words have different posters or shapes but have same meaning as base word. To check the real frequency of each word in the document, stemming is applied. Stemming converts each word to its root word and so actual frequency of each word is calculated as shown in Table II. Stemming is a natural language processing based approach that is used in search engine optimization and information retrieval system. There are many stemming algorithms which can be used but in our study as E-commerce process activities are reported in English language by filling summary and description fields, we use Porter stemming technique to converts all tokens to their base stems.

TABLE I. EXAMPLES OF E-COMMERCE COMMERNTS

E-commerce Customers Comments
I got product in given time period
They promised me to send this in a duration of 2 months and they sent me

TABLE II. COMMENTS DATA AFTER STEMMING

Comments After Stemming
Get Product give time period
Promise send during month send

E. Feature Engineering

Feature selection and extraction that is collectively known as feature engineering employs multiple techniques to extract useful features from a given text document [37]. This study incorporates Bag of Words (BOW) and N-Gram (1 - 4) for the purpose of feature selection.

1) N-Gram: A text document is a connected sequence of n number of words/token/items/elements [40]. These items refer to some symbols, letters, and pairs of words so n-grams are combination of words patterns. Sequence of words to make a sense in a document is called N-gram where N is number of words in a pattern. Uni-gram describes single word, Bi-gram represents two, Tri-gram shows a sequence of three words and so on. Let's consider example of E-commerce comment: "this is a beautiful camera". Uni-grams of this text are 'this', 'is', 'a', 'beautiful', 'camera'. Bi-grams produced from this comment are 'this is', 'is a, 'a beautiful', 'beautiful camera' post. Tri-grams of this text piece are 'this is a, 'a beautiful camera as shown in Table III.

TABLE III. EXAMPLE OF CONVERTING TOKENS TO BI-GRAM, TRI-GRAM AND QUAD-GRAM

Tokens	I got product in given time period
Bi-grams	I got, got product, product in, in given, given time, time period
Tri-grams	I got product, got product in, product in given, in given time, given time period
Quad-grams	I got product in, got product in given, product in given time, in given time period

2) Bog of words: The Bag of Words (BOW) is also a features engineering model that counts all the useful feature without giving them weight with respect to document as well class corpora [38][39]. It counts the word number times it occur in the document and also does not accounts the sequence and order of words in the document. Each word in the Bag of Word model is independent of the next and previous words. Let's consider an example to understand the Bog of Words feature selection and extraction technique of Natural Language Processing. The cat is better than the dog and: The weather is better than yesterday.

F. Experimental Setup

All the above mentioned experiment are conducted on the same platform and IDE. Same text preprocessing techniques are applied on the whole data set prior experiment execution. Each experiment took 2400 customer comments as training input data set and 1600 customer comments as testing data et. Four classes (convenience, Variety, Time and Trust) were used to label the data set. Each class comprises of 1000 E-commerce customer comments which is further divided into 600 training and 400 testing instances/document/comment.

Preprocessing techniques are applied on the 70% of the data set and also have employed multiple preprocessing methods like tokenization, stop-words removal, word completion and spell checking, stemming are applied to each document of training data.

Initially, our data set was in form of raw comments which were obtained from E-commerce online shopping platforms. We applied tokenization as first step of preprocessing using natural language processing. To implement tokenization, we used 'space' between two words a delimiter. Following the tokenization, removal of stop words and noisy data is removed to sanitize our data set. At end of stop words removal, stemming is applied to get root words of each lingual element. For stemming, standard stemmers are used because each comment contains valid words after former preprocessing steps.

Machine learning model development and implementation steps are followed by preprocessing steps. Supervised machine learning algorithms are trained on the training data set which has undergone from text preprocessing steps. Feature selection and extraction is an important step which is characterized by the selection of most important and meaningful elements from each document with respect to each class. As we have mentioned in literature review and other sections that in supervised machine learning, algorithms are mostly learned on the probabilities. Unique words are selected and extracted from preprocessed training data etc. Frequency of each word is calculated using BOW model. This probability matrix measures the probability of each unique word in any class. Probability for each word is then calculated from training data. Square root of each probability is computed by calculate square root of each value.

1) Experiment 1: The first experiment is performed using Bag of Word Model feature extraction technique. The major goal behind performing the experiment using BOW model approach to illustrate the classification efficiency and accuracy of supervised machine learning model. The experiment is carried out using preprocessed training data set from which features are extracted Bow approach and algorithms are trained on BOW features. The hash map produced from this experiment is given in the following Table IV.

TABLE IV. RESULT OF EXPERIMENT 1 WITH BOW MODEL

Features	No. of Features	Naïve Bayes	SVN	KNN
Bag of Words	2317	71.52	**72.23**	68.95

2) Experiment 2: Experiment 2 is extension of experiment 1 and it yields better results by combining the token by N where N >= 1 & N = <4. The major objective of this experiment is to clearly demonstrate the difference of accuracy of supervise machine learning models from the experiment 1 by incorporating N-Gram technique with BOW approach. This experiment brings into use same data set as used in the previous experiment. In this experiment, the whole programming environment remain same as in previous experiment. It also brings into use preprocessed data set as discussed in previous section. Words with highest frequency carry less information for a class as compared to least frequency. Supervised machine learning model is trained using training data set of 2400 comments and on the basis of this training, unlabeled and unseen comment (testing data set) is classified. Same features along with threshold value are applied as in last experiment. In feature extraction phase, different N-gram patterns are applied. We used N-Gram where value of N ranges from 1 to 4.

- Unigram pattern: consist of one word for extracting semantic information.
- Bigram pattern: consist of two word for extracting semantic information.
- Trigram pattern: consist of three word for extracting semantic information.
- Quad gram pattern: consist of four word for extracting semantic information.

Following the preparation of N-gram pattern matrix is used to compute the score of each individual class which is computed by total number of words in corpus divided by their individual frequencies as shown in Table V. Training model is generated and each classifier used in the experiment.

TABLE V. RESULT OF EXPERIMENT 2 WITH BOW AND N-GRAM MODEL

Features	**No. of Features**	**Naïve Bayes**	**SVN**	**KNN**
Unigram	2317	64.33	71.11	62.02
Bigram	13957	73.68	**82.32**	71.25
Trigram	11695	57.12	53.78	53.39
Quad Gram	17658	43.98	40.35	48.61

G. Comparison of Accuracies of Data Mining Techniques Followed in Experiment

Performance of the proposed classification system in terms of accuracy measures is depicted in Table V. It is showing accuracy measures of all the classifiers along with their N-Gram values. There are three classifiers employed with different N-Gram values from N=1 to N=4. Results reveal that Support Vector Machine (SVM) has outperformed with the best accuracy. SVM gives 71.11% and 82.32% accuracy with uni-gram and bi-gram respectively while KNN is better with tri-gram whereas the over performance of KNN is less than SVM. Naïve Bays stands between SVM and KNN in performance as shown in Tables VI, VII, and VIII.

H. Comparison of Precision and Recall Scores

Precision, recall and F1-score measures for all given algorithms using Uni-gram, Bi-gram, Tri-gram and Quad-gram. All three algorithms are applied one by one on the same data set to get accuracy, precision, recall and F1-score.

We have also performed K-fold (where k = 10) cross validation mechanism to validate the confusion matrix and data set authentications. We have divided our dataset into 10 folds (f1, f2, f3 . . . . f10) of equal size. We trained all the classifiers one by one to f1 to f9 folds and then from f1 to f8 and tested for f9 fold and so on.

The overall performance of all three algorithms are compared and their comparison report is given in the graph below. The Support Vector Machine which has been proved the best algorithm in our text classification system and it has better values for confusion matrix as compared to the KNN and Naïve Bays as shown in Table IX.

TABLE VI. RESULTS EVALUATION FOR NAÏVE BAYS ALGORITHM

Class – Naïve Bayes	**Precision**	**Recall**	**f1-score**
Analysis	0.76	0.75	0.76
Synthesis	0.81	0.66	0.75
Evaluation	0.72	0.57	0.82
Implementation	0.70	0.80	0.40

TABLE VII. RESULTS EVALUATION FOR SVM ALGORITHM

Class – SVM	**Precision**	**Recall**	**f1-score**
Analysis	0.61	0.76	0.69
Synthesis	0.74	0.71	0.10
Evaluation	0.75	0.69	0.51
Implementation	0.62	0.80	0.82

TABLE VIII. RESULTS EVALUATION FOR KNN ALGORITHM

Class – KNN	**Precision**	**Recall**	**f1-score**
Analysis	0.78	0.73	0.75
Synthesis	0.81	0.76	0.74
Evaluation	0.80	0.65	0.83
Implementation	0.72	0.68	0.39

TABLE IX. RESULTS EVALUATION FOR N-GRAM MODEL

Features	**Class – Naïve Bayes**	**Precision**	**Recall**	**f1-score**
Unigram	***Naïve Bayes***	0.71	0.72	0.71
	SVM	0.82	0.66	0.72
	KNN	0.75	0.68	0.64
Bigram	***Naïve Bayes***	0.88	0.82	0.84
	SVM	0.67	0.69	0.68
	KNN	0.68	0.68	0.62
Trigram	***Naïve Bayes***	0.54	0.66	0.60
	SVM	0.48	0.54	0.51
	KNN	0.46	0.48	0.53

IV. Discussion

This study incorporate data mining and machine learning technqiues along with NLP to develop an automated system to categrorize the products w.r.t given classes. We have used N-grams, BOW and TF-IDF technqies for features extratcion. There could be feature engineering tecniques which might improve the system relaibality. Our proposed system is good with proper grammar and well spelled words but in case of slangs in data set might confuse the system. The most important thig to discuss is that this is an initial approach to classify consumer comments under the given classes to assist both, seller and buyer. Therefore, we don't have any benchmark to compare our results.

V. Conclusion

This study has evaluated the proposed machine learning model with various data analytics techniques as mentioned in literature like accuracy, precision, recall and F1-score. Briefly, SVM algorithm along BOW and bi-gram features engineering techniques is proved winning classifier in the proposed E-commerce customer comment classifier. This work opens new avenues to E-commerce customers and sellers to get a quick status of customer opinion in four important contexts which helps many customers to decide the about purchase of product. At the same it assist sellers to improve their product or services in the given four context (convenience, variety, time and trust) using data mining and machine learning and Natural Language Processing. This wok not only demonstrates the usefulness of machine learning and data mining in E-commerce business development and customer assistance but also identify preprocessing techniques and the important features engineering methods.

VI. Future Work

This work is concerned to classification of E-commerce comments data using supervised machine learning model by incorporating BOW and N-gram feature engineering methods. Currently we have selected/preferred those words/features with highest value to its respective class. In future work, we shall employ semantic and syntactic features engineering techniques to select features with contextual relevance. In this way, we will get the improved percentage accuracy i.e. to consider different dimensions of vectors in E-commerce customer's comments classification and other aspects of E-commerce related text classification.

Spoken Language Identification on Local Language using MFCC, Random Forest, KNN, and GMM

Vincentius Satria Wicaksana[1], Amalia Zahra, S.Kom, Ph. D.[2]
Computer Science Department, Bina Nusantara University, Jakarta, Indonesia

***Abstract*—Spoken language identification is a field of research that is already being done by many people. There are many techniques proposed for doing speech processing, such as Support Vector Machines, Gaussian Mixture Models, Decision Trees, and others. This paper will use the system using the Mel-Frequency Cepstral Coefficient (MFCC) features of speech input signal, use Random Forest (RF), Gaussian Mixture Model (GMM), and K-Nearest Neighbor (KNN) as a classifier, use the 3s, 10s, and 30s as scoring method, and use dataset that consists of Javanese, Sundanese, and Minang languages which are traditional languages from Indonesia. K-Nearest Neighbor has 98.88% of accuracy for 30s of speech and followed by Random Forest that has 95.55% of accuracy for 30s of speech, GMM has 82.24% of accuracy.**

Keywords—Gaussian mixture model; random forest; K-Nearest Neighbor; spoken language recognition; MFCC; GMM; KNN

I. Introduction

Indonesia is an archipelago in the Southeast Asia region. Indonesia consists of large islands and small islands spread from Sabang to Merauke, so that the Indonesian State is dubbed the Archipelago State. Indonesia is recorded as having 17.504 islands, therefore, the State of Indonesia has a variety of ethnicities, races, religions and cultures. Because of this diversity, Indonesia has a wide variety of languages, ranging from Javanese, Sundanese, Bahasa Batak, and many more. Therefore, some of regional languages in Indonesia are also extinct because the language is not widely used in the regions anymore. To prevent it from extinction, by collecting the dataset of regional languages to be studied, it can help to prevent extinction of regional languages, because when building a classification technique, a large scale of dataset is needed and by developing the SLI, the application can be used as a leading component of applications such as translators used to classify regional languages, which later can be used in speech-based information systems, speech-based translate, and others.

Referring to the problems above, the need for information technology solutions in the field of Spoken Language Identification is getting higher. Due to the Spoken Language Identification technology, Indonesian citizens who do not understand regional languages when visiting other areas or when tourists come to an area where residents do not understand Indonesian, can be helped by this technology.

In spoken language identification it takes several steps to identify a language, starting from the sound extraction such as MFCC [8] method to techniques for classifying language. Several techniques are used to classify languages, including deep neural networks [1], Gaussian mixture models [2][5][8], support vector machines [3], Random Forest [3], and others. Random Forest, KNN and GMM are technique that is quite widely used for classification, this technique has some parameter that can be tuned, which is very useful to increase accuracy. There has been a lot of research on spoken language identification, but no one has done research on spoken language identification that uses segmented speech. In this study, Random Forest, KNN and GMM will be used for classification techniques, the accuracy will be obtained from segmented speech in 3 seconds, 10 seconds, and 30 seconds. This study will examine spoken language identification using the techniques mentioned above and using the GMM technique which is often used in spoken language identification which is segmented at 3 seconds, 10 seconds, and 30 seconds as the baseline.

II. Literature Review

Spoken Language Identification (LID) [4] is a process for determining the identity of the language spoken. LID [4] is based on the linguistic properties of language obtained from the results of speech extraction. The performance of an LID system depends on the amount and reliability of information and how efficiently it is integrated into the system.

The sound structure of a language can be categorized into acoustic-phonetic, phonotactic, and prosodic. Acoustic-phonetic is one of the structures of the sound which is related to the analysis of the physical properties of the sound being spoken. While phonotactic is a sound structure related to the syllable structure of a language, for example Languages such as Dutch, English, and German allow a large number of consonants at the beginning and at the end of the syllable. In contrast, Maori, which is spoken in New Zealand, only allows syllables consisting of a vowel, two vowels, or a consonant plus a vowel. Prosody is a structure of sound related to rhythm, intonation, and stress of sound, for example, Mandarin has the same letter but has a different intonation, for example the word “ma” with high intonation means mother, while “ma” word with intonation drops later to ride means horse.

In [6], the authors discussed about spoken language identification using Shifted Delta Coefficient and Shifted Delta MLP as feature extraction and using Gaussian Mixture Model and Support vector Machine as classification technique.

In [2], the authors discussed about spoken language identification using Mel-frequency cepstral coefficients as feature extraction and using Gaussian Mixture Model as classification technique. In his research, to improve the performance of the Gaussian mixture model in his research, the total mixture was gradually added to get optimal results. In his research it was also explained that Tamil and Telugu languages have good performance by using mixture values between 128 to 512. Starting with 32 mixtures which produced low accuracy, namely 70% for Tamil and 85% for Telugu. Then the mixture components are increased little by little to get the desired results. When the mixture was increased to 128, the resulting accuracy was almost 100% for Tamil, while for Telugu, it got 100% accuracy. Then the mixture component is increased again to 512 which is the best point for the classification of the two languages, when the accuracy rate of both reaches 100%. If seen from the results above, it can be concluded that by gradually increasing the mixture component, it can improve performance in language identification. Despite of that, research that conducted by [7], discussed that by increasing the mixture component, the performance of the technique will increase, but the higher the mixture component will increase the computation cost or increase the time in computing.

In [3], the classification methods used are Support Vector Machine and Random Forest and for the feature extraction used are MFCC, LPC, and a combination of the two techniques, to find out which technique provides the best accuracy. To conduct an evaluation, [3] used the IIIT-H dataset which contains 5000 samples, consisting of 6 languages, namely Hindi, Telugu, Bengali, Marathi, Tamil, and Malayalam. Then 300 samples were taken randomly from the IIIT-H dataset using a 16kHz sound signal. The evaluation was carried out in 2 phases, the first phase was carried out using the MFCC feature with Support Vector Machine and Random Forest. Meanwhile, for the Random Forest technique, the resulting accuracy is 75.9% and 74.3% for the SVM technique. The second phase is carried out using the LPC feature with the same classification technique. The Random Forest technique used produces an accuracy of 61.5% and 67.16% for the SVM technique. In [3] is not stated why total trees of 300 has the best performance compared to the lower total of trees.

In [9], the study was conducted using a Gaussian mixture model as a technique for classifying languages which will be used to compare feature extraction. For feature extraction, MFCC, SDC, and a combination of both are used. In his research, the database used is the Arunachali Language Speech Database (ALS-DB), which consists of 6 languages, namely Adi, Apatani, Galo, Nyishi, Hindi and English. The experiment was carried out using the GMM with total of 1024 mixture component, MFCC features with 12 cepstral coefficient numbers.

Research conducted by Gupta et al. (2017) using Support Vector Machine and Random Forest. In his research, it is stated that by combining Mel Frequency Cepstral Coefficients (MFCCs) and Linear Predictive Coding (LPC) will increase the accuracy of the language identification. In [3], it is not explained why Gupta et al choose total trees of 300 compared to the lower total trees. In [3], only the total accuracy of the features extracted from the frame is explained, it is not explained how the accuracy from classification using 3s of speech, 10s of speech, and 30s of speech. Therefore, this paper will use MFCC and Random Forest to see the effect of the total trees on the accuracy and expanding the testing method by segment the duration of the test from frame to 3s speech, 10s speech, 30s speech and briefly discusses the performance of computation time when conducting model training using three traditional language from Indonesia. This paper will use KNN as a rarely use technique in language identification to see if its fits as classifier for spoken language identification and use GMM that widely use in language identification as baseline.

III. Proposed Method

A. Dataset

At the data collection stage, speech data collection will be collected both from the internet and from native speakers of the local language. In order to get the correct acoustic of the language, native speakers who are fluent in the regional language are needed. The dataset obtained will be divided into 2 datasets, the first is for the training dataset and the second is the test dataset. With a ratio of 70:15:15 , that is, 70% of the dataset will be used for training the dataset, 15% of the dataset will be used for validation dataset, and the other 15% of the dataset will be used for test dataset. The distribution of the dataset can be seen in Table I below.

The Javanese and Sundanese dataset will be obtained from *openslr* and Minang dataset language will be collected from *youtube* and recorded Speech.

B. Pre-Processing

After the data is collected, the Javanese and Sundanese language dataset will be sorted again. After that, the speech that obtained from YouTube will be processed again.

For Javanese and Sundanese dataset, each dataset will be combined into 80 minutes long. As for dataset that obtained from *youtube*, the first step is to remove the noise, song, background song, and unnecessary item from the recording. Same as Javanese and Sundanese dataset, Minang dataset will be combined or cut to achieve 80 minutes long of training dataset.

For test dataset, each language will have 20 minutes of speech data, the speech data will be divided into 3s, 10s, and 30s of speech data. After the recording is cut, the recorded file will be changed to wav format, because the compressed data produced by wav has a sound quality that is almost the same as the original sound. The sound will be resampled to 44.1 kHz and use a bit rate of 32 kbps.

TABLE I. Total Duration for each Language

Language	Total Duration	Training Dataset Duration	Validation Dataset Duration	Testing Dataset Duration
Sundanese	200 Minutes	140 minutes	30 minutes	30 minutes
Minang	200 Minutes	140 minutes	30 minutes	30 minutes
Javanese	200 Minutes	140 minutes	30 minutes	30 minutes

C. Model Development

Every speech has its own characteristics, to get the characteristics of the speech, feature extraction will be executed. This study will use MFCC feature, the MFCC feature will be extracted from the pre-processed input signal. The MFCC feature will be presented using vector c, which a set of vector C has the value of C_1, C_2, C_3, C_4, C_5, C_6…C_n. In vector C, n represent the total coefficient will be extracted from the speech every frame. This study will use *python* and library provided from *librosa* to extract the MFCC feature. Total coefficient that will be used in the experiment is 13 and the total length of the frame is 25 milliseconds.

After extracting the features from the testing data and training data, a model development will be carried out. The model will be developed using random forest, Gaussian mixture model, and K-Nearest Neighbor. Random forest is a classification algorithm consisting of many decisions' trees. It uses bagging and feature randomness when building each individual tree to try to create an uncorrelated forest of trees whose prediction by committee is more accurate than that of any individual tree. This study will use the random forest, Gaussian mixture model, and K-Nearest Neighbor and the library is provided by *sklearn*. Before using this model, the best parameter was determined for each method.

The Random Forest technique, there are several parameters will be tuned, such as n_estimator, criterion, max_depth, and max_sample_leaf. N_estimator is used to determine the total trees to be used, the random forest that used in [3] will be used as baseline. This total tress parameter will be used to compare the best n_estimator for this dataset. Criterion is used to measure the impurity of a node. Max_depth represents the depth of each tree in the forest. The deeper the tree, the more splits it has, and the more it captures more information about the data. The parameter for KNN will be tuned are the type of weight, total leaf size and number of neighbors and the last classifier is GMM that widely used for LID [2], [7], and [9].

D. Evaluation

In this study, the total percentage of accuracy will be measured. After the experimental process is complete, the evaluation results will be entered into a table for further observation. From table below, method column used to list the method that used, and the duration row is used to classify the average accuracy based on the duration of the speech.

The experiment flow can be seen from Fig. 1 below.

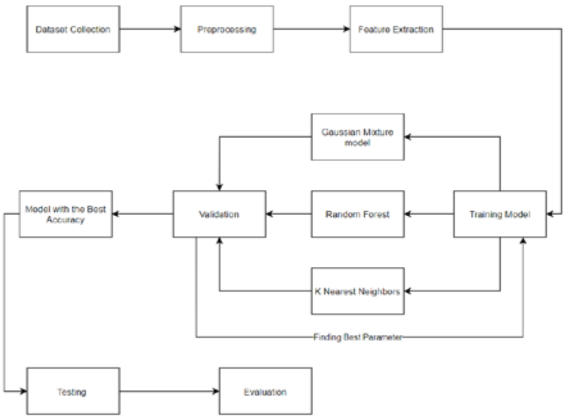

Fig. 1. Experiment Flow.

IV. Result and Discussion

The experiment is focused on comparing performance between three classifier techniques on three segmented duration. Classification was performed on three different language. Once the models are trained and the feature are extracted, the classifier was used to classify the dataset. The accuracy score of classification between three languages are reported in terms of percentage of accuracy. Tuning the min sample leaf parameter for random forest using validation dataset are recorded on Table II.

From Table II, the result shows us that there is no significant accuracy difference between each parameter, so min_sameple leaf will be set to the default value, the default value is 5.

From Table III, the result shows us that the higher max_depth number, the better accuray it has. The accuracy increases periodically as total max depth value increased and reach its peak at total max depth of 50, but from 50 to 100, there is no significant increase between 50 and 100, the score almost similar, so total max_depth of 50 will be used for this parameter.

From Table IV, the result shows us that there is no significant difference between criterion gini and entropy, but Entropy is more computationally heavy than gini, so it will increase the time computation, so gini will be used for this parameter.

TABLE II. Finding Best Parameter for MIN_Sample_Leaf.

Parameters			**Accuracy**		
Min sample leaf	**N_estimator**	**N_jobs**	**3 s**	**10 s**	**30 s**
5	100	16	87.44%	90.18%	94.72%
10	100	16	87.11%	89.90%	94.44%
15	100	16	86.78%	89.35%	94.16%
25	100	16	86.47%	89.07%	93.88%

TABLE III. Finding Best Parameter for Max_Depth

Parameters			**Accuracy**		
Max Depth	**N_estimator**	**N_jobs**	**3 s**	**10 s**	**30 s**
10	100	16	83.47%	83.99%	84.44%
15	100	16	85.16%	86.11%	88.61%
25	100	16	86.44%	88.25%	92.49%
50	**100**	**16**	**88.05%**	**91.29%**	**96.11%**
100	100	16	87.88%	91.57%	96.38%

TABLE IV. Finding Best Parameter for Criterion

Parameters			**Accuracy**		
Criterion	**N_estimator**	**N_jobs**	**3 s**	**10 s**	**30 s**
Gini	100	16	88.00%	91.48%	96.38%
Entropy	100	16	87.78%	90.83%	96.11%

From Table V, the result shows us that there is no significant difference between 100 to 250 totals of trees, so total trees of 100 will be used in this experiment, gini as criterion parameter, min_sample_leaf of 5, and max_depth of 50 for this technique; fFor GMM, the search of the best parameter for number and mixture and covariance type.

In Table VI, full covariance type has the best score rather than the other covariance type. Next, the best parameter for GMM total mixture was tuned. [2] GMM accuracy was used as baseline.

In Table VII, by increasing total number of mixtures, the accuracy increased that is stated in [2]. Despite of that, there is a significant decrease from 128 to 256. In order to confirm that there are no errors in the code, the test was run 3 times and still has the same score, so the test is stopped at 256 and is decided that the total mixture of 128 has the best score for this dataset. Next, KNN is widely used on machine learning, but it is rarely used in language identification, so in this paper, KNN technique was used to determine if KNN is suitable for language identification or not. There are several parameters that will be used, such as K, weight, and size of leaf.

TABLE V. FINDING BEST PARAMETER FOR N_ESTIMATOR

Parameters				**Accuracy**		
N_estimator	**Min_sam-ple_leaf**	**Max Depth**	**criterion**	**3 s**	**10 s**	**30 s**
100	5	50	Gini	87.52%	90.92%	95.27%
150	5	50	Gini	87.63%	90.27%	94.72%
250	5	50	Gini	87.62%	90.09%	94.72%

TABLE VI. FINDING BEST PARAMETER FOR COVARIANCE TYPE

Parameters			**Accuracy**		
Covariance Type	**GMM Mixture**	**N_jobs**	**3 s**	**10 s**	**30 s**
Full	128	16	71.77%	77.77%	82.77%
Tied	128	16	61.86%	66.20%	70.00%
Diag	128	16	64.33%	70.92%	80.27%
spherical	128	16	62.19%	64.90%	64.16%

TABLE VII. FINDING BEST PARAMETER FOR NUMBER OF MIXTURE

Parameters			**Accuracy**		
Covariance Type	**GMM Mixture**	**N_jobs**	**3 s**	**10 s**	**30 s**
Full	16	16	45.45%	44.35%	57.77%
Full	32	16	56.25%	53.05%	63.88%
Full	64	16	75.61%	79.72%	75.55%
Full	**128**	**16**	**76.55%**	**80.09%**	**81.38%**
Full	256	16	46.27%	45.09%	48.33%

From Tables VIII and IX, there is not any significant difference from each parameter, each parameter has similar score, so the default value will be used for type of weight from the library which is uniform and total leaf of 20 because total leaf of 20 has the best better accuracy than 30 and 40, and it has less computation time. Next, the best parameter for K will be tuned for this dataset; the result can be seen from Table X.

From the table above, it can be concluded that by increasing the total of K, it will increase the score. Total k of 10 and 20 has the best accuracy, there is a slight difference between two of them, but the computation time and complexity must be considered, because by increasing the total K, the computation time and complexity will be increased. So, for this technique, total K of 10 will be used to get the accuracy from testing dataset. After getting the best parameter for each technique, each technique will be tested using dataset to get the accuracy result for each technique with tuned parameter.

In Table XI represents performance of feature with different classifier. The KNN classifier gives the highest score from 3 second of speech until 30 second of speech. RF gives almost similar score to KNN. GMM gives the lowest score in language identification from 3 sec, 10 sec, and 30 sec.

TABLE VIII. FINDING BEST PARAMETER FOR WEIGHT

Parameters			**Accuracy**		
Type of Weight	**K**	**N_jobs**	**3 s**	**10 s**	**30 s**
uniform	5	16	86.91%	91.01%	96.11%
distance	5	16	86.63%	90.64%	95.83%

TABLE IX. FINDING BEST PARAMETER FOR SIZE OF LEAF

Parameters			**Accuracy**		
Size of Leaf	**K**	**N_jobs**	**3 s**	**10 s**	**30 s**
20	5	16	86.91%	91.01%	96.11%
30	5	16	88.91%	90.01%	94.11%
40	5	16	87.91%	92.01%	93.11%

TABLE X. FINDING BEST PARAMETER FOR K

Parameters				**Accuracy**		
Size of Leaf	**Type of Weight**	**Total K**	**N_jobs**	**3 s**	**10 s**	**30 s**
30	uniform	5	16	86.36%	90.74%	95.83%
30	uniform	10	16	88.18%	93.61%	98.88%
30	uniform	15	16	85.38%	88.51%	91.38%
30	uniform	20	16	87.83%	91.12%	96.11%

TABLE XI. MODELS ACCURACY

Technique	**Accuracy**		
	3 s	**10 s**	**30 s**
MFCC + KNN	88.19%	93.61%	98.88%
MFCC + GMM	72.35%	80.59%	82.24%
MFCC + RF	87.66%	90.64%	95.55%

V. Conclusion

In this paper, this paper compares the widely use technique in language identification which is GMM and rarely use technique, which is KNN, and another technique called random forest to see if its good in segmentation speech or not.

From Table XI, KNN has the highest accuracy in each segment, with a score of 88.19% for 3s, 93.61% for 10s, and 98.88% for 30s, then followed by RF which has an accuracy score of 87.66% for 3s, 90.64% for 10s, and 95.55% for 30s. And GMM has the lowest score for each segmentation. However, when doing training and testing model for each technique, KNN use longer computation time when compared to Random Forest because KNN is called the lazy learner.

It can be concluded that KNN and RF is better than GMM and has the best accuracy for Javanese, Sundanese, and Minang.

Suggestion for the future research is to get more Minang dataset variation, such as high pitch speech, low pitch speech, and the other and using another feature extraction technique to see if there is a better feature extraction technique for KNN and RF.

***Abstract*—Recent advancements in technologies enabled the development of smart cities to be more effective and possible. Smart cities depend on intelligent systems, artificial intelligence, the internet of things, control system, and many more advanced technologies. Sustainability challenges and problems worldwide, with smart and sustainability concepts, reflect almost mutual goals. It includes improving and providing the essential life services for all people efficiently while depending on sustainable, clean, and renewable energy with considerations of different economic, educational, health, social and environmental aspects in the city. In this research, a cost analysis process has been implemented to ease the implementation and resource utilization of smart and sustainable cities in Africa. The challenges and difficulties of those implementations are summarized.**

Keywords*—Smart cities; sustainable energy; renewable energy; internet of things; artificial intelligence

I. Introduction

Now-a-days, over three-quarters of the world’s population lives in urban areas. It is noticed that the population growth in urban areas is higher than in rural areas. As such, cities are struggling with an overpopulation crisis triggering a shortage in capital resulting in issues across the society due to social and economic imbalance [1]. As technology is evolving, the concept of developing smart communities is becoming more desirable as the use of technologies like Artificial Intelligence (AI) and the Internet of Things (IoT) can help in solving a variety of problems in coexisting societies. For instance, IoT provides new ways for cities to utilize data to control traffic, reduce emissions, and allow better resources to provide people with a safe and clean smart environment. Smartness is a dynamic term that can be expressed as 'green technology.' The term “Smart City” is not just referring to a digital city; it also highlights the need for talented people and residents who are attentive to the priorities of having a smart, prosperous, and resilient city. It also refers to combining intelligence, political strategy, and infrastructure to create holistic urban services. Several aspects can aid in developing a Smart City, some of these aspects are: “Smart Mobility”, “Smart Living”, “Smart Economy” and many more that, when combined and strategized, can translate the practical meaning of having environmentally friendly, sustainable and smart city [2]. In general, no definitive or conclusive method can determine whether a city is smart or not. The significant primary definition relies on Information and Communication Technology (ICT) and the advanced immerging technologies like AI, IoT, etc.

On the other hand, implementing these technologies in underdeveloped countries is heading towards urbanization and industrialization. This implementation requires an understanding of smart city elements and how they are applied across various industries in the cities. This paper introduces a proposed framework and architecture in underdeveloped countries that can emphasize the use of new technologies and their performance to improve the quality of life in these inhabitants.

II. Literature Review

During the 2000s, cities worldwide radically changed, where the concentration turned to the vast development in digital technologies, knowledge, and the increase in environmental awareness and concern. Along with this development, new concept and model for the cities have been introduced. Over the last decades, these connected issues related to digital development started to initiate a new heading towards Smart Sustainable Cities.

According to [2], smart cities arise due to the intelligent use of technologies in different ar, such as the education field, health sector, transportation, and energy use.

Sustainability and sustainable city's urban development concept brings awareness of the production and use of available resources required in industrial areas, transportation, education, health, business, and investments.

Sustainable urban concept collaborates in increasing environmental awareness in naturally available resources in smart cities [3].

The author in [4] demonstrates that evaluating a smart city should be based on different factors like encompassing sustainability and quality of life and the collaboration of technological elements.

The concept of sustainable cities became popular in the 1990s [5]. It refers to the relationship between the conversion of resources exploitation to be consistent with the present and future requirements and the development of countries' economic and environmental sustainability aspects.

Considering all the aspects, sustainable urban development can be defined as the combination of urban modernization to be smart with the use and protection of available sustainable resources.

The energy system for smart cities requires a significant share of renewable energy in the different aspects of the city. The energy system becomes more diverse, and it could be integrated into other areas with a crucial impact on the cities' development process.

There are several examples of smart and sustainable cities worldwide on different continents, as illustrated in Fig. 1 [6].

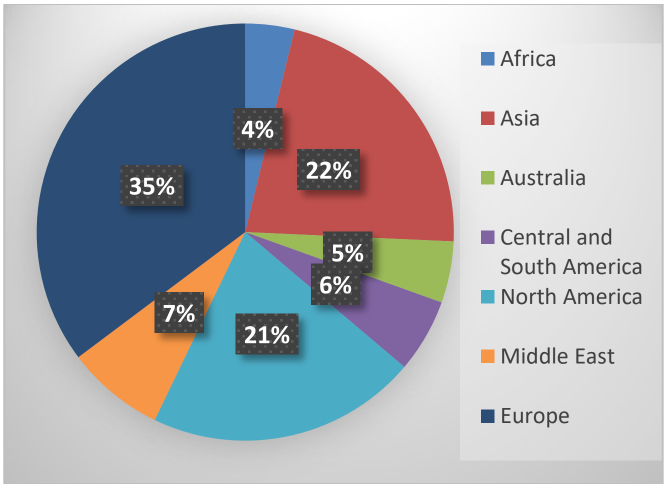

Fig. 1. The Total Sustainable and Smart Cities from Arcadis's.

Although Europe seems to lead the transformation of traditional cities to smart and sustainable cities, around 35% of the total cities engaged in sustainable and smart cities, 65% of the cities are moving forward steps to convoy the technology advancement and development. For example, a city like Dubai in the Middle East has a problem with the dramatic increase of the population, leading to a significant increase in environmental pollution. That is why Dubai is integrating an energy strategy action plan to depend on renewable energy and reduce energy demand and waste by 30% by 2030. But what about the underdeveloped countries in Asia and Africa?. Do they have the ability to be transformed into smart cities? Could technological advancement provide optimal solutions to develop the cities' urban?. Do underdeveloped countries modernize their infrastructure and work based on an intelligent system?.

Building cities' innovative transformation requires applying the most effective, advanced, and developed information and communication technologies. In addition, artificial intelligence and the internet of things are also needed. The underdeveloped overpopulated countries have significant challenges when providing innovative transformation technologies.

A future smart city in the population urban in India is dramatically increasing. Around 50% of the population is expected to be in cities by 2030. This has a significant challenge for the government because of the wasted resources and the weak infrastructure. Based on global studies in [7], one in eight people lives in slums, while in India, one in six people live in slums where they lack access to safe drinking water, food, and homes. The Indian government aims to build 100 smart cities to provide essential services for inhabitants.

Moreover, many cities worldwide cannot supply the city's infrastructure with artificial intelligence and internet of things technologies. The cities aim to be innovative by providing essential services to the people depending on the available resources.

III. Material and Methods

Building smart and sustainable cities in underdeveloped countries require significant effort to extract and set a strategic plan for efficient use of available resources so that these resources can be used to develop intelligent systems that provide the essential services for people.

The sustainable resources are different in each country. For example, Africa holds 65 percent of the world's arable land, and over 70 percent of people depend on forests and woodlands. Thus Africa can use the wood with the help of solar energy as a renewable resource to build a sustainable and intelligent system. Examples of countries in Africa are Egypt and Sudan, located geographically on the AL-Nile River, which is the longest river in Africa. It could be an efficient resource to transform the cities to be smart.

Several countries in Africa lack electricity and internet services, and electricity is only provided for essential life services. Thus those countries cannot provide electrical energy to build intelligent systems or implement Internet of things technologies in the cities, as using these technologies requires a considerable budget. These countries can benefit from utilizing their different available resources to provide power for intelligent systems.

Let's set one of Egypt's cities as an intelligent city target. Egypt's population is over 100 million in 2020, where this considerable population percentage indicates the availability of various resources, a high ratio of traffic jams and accidents exists. Taking these indications, Egypt can utilize its resources to build a smart city efficiently.

For example, Egypt can utilize the water in the Al-Neil River to generate electrical energy. The requirements are a hydraulic turbine to convert flowing water into mechanical energy and a hydroelectric generator to convert the mechanical energy into electrical energy. Still, the pressure on the available water in the Al-Neil river is severed, that's why we need to utilize more resources to produce electricity. Now the question is, how can Egyptian cities become smarter with the help of the population?. The human body contains a massive quantity of energy. This energy works as a fuel for our everyday activities, but how can we generate electrical energy from the human body's movement?. The movement of human bodies generates kinetic energy that can be converted to power that can be later used to power electrical devices. The conversion of energy can be achieved via using piezoelectric sensors, electromagnetic, and electrostatic effects [8], thus adding these sensors in different ways to crowded places like streets, airports, malls, gyms, hospitals, schools, etc., can help in producing a sufficient amount of electricity.

Moreover, solar energy cannot be ignored where it is proofed that the sun is a powerful, sustainable resource to generate power.

Integrating Internet-of-things and artificial intelligence technologies in cities means that the city infrastructure, including many different objects, will be connected. Artificial and machine learning techniques, including advanced sensors and controllers, are utilized in smart cities to create smart and connected buildings, autonomous vehicles, connected vehicles, smart education, smart health framework, and smart industries [9].

IV. Proposed Framework for Smart and Sustainable City

A. Smart and Sustainable Transportation System

The intelligent transportation system in smart cities focuses on autonomous vehicles and connected vehicles that are extensive research. Many big companies built autonomous cars with different features and implemented advanced technologies. Autonomous vehicles have many significant features, such as mobility for disabled and older people to drive safely for long distances. Also, autonomous vehicles are charged electrically, which makes them eco-friendly. Accordingly, implementing an innovative, sustainable, and connected transportation system requires strong internet connections and sufficient electrical energy to be charged. Thus, sustainable resources play a vital role in converting the transportation system to a smart system. But here, two questions arise, how to generate electricity to charge the cars and power the internet connectivity? And how to implement an intelligent transportation system in Egypt?

There are many ways to charge cars and build a connected transportation system. Let us assume that all the vehicles in Egypt, whether public or private cars, taxis, or buses, are transformed into smart autonomous and electrical vehicles. They can be charged by adding a solar panel above the vehicle connected to the battery. It can help in reducing the need to set it in an electrical charging station. Still, we need to provide different options for charging, for example, adding a piezoelectric sensor which is a sensor that converts the pressure of the cars on the street to electrical energy. This electrical energy can be consumed in recharging the electric vehicles, turning street lights on or supplying the internet service provider to strengthen internet connectivity. Additionally, the connectivity between vehicles that are usually implemented via the internet connection, the connection method could be changed by making the vehicles that are close to each other for a specific distance connected, and they can communicate with each other via Bluetooth connectivity. The connected vehicles can communicate in case of an emergency situation, car accidents, bad weather conditions, or any different unexpected situation. In addition, sharing between vehicles can help exchange information about the other vehicle positions, speeds, routes, stopping, and decided to change lanes. It can be implemented using advanced machine learning algorithms and the internet of things technologies. Still, to ensure the efficiency of the connectivity, the communication also could be implemented through a mobile application installed in each driver phone; in this case, the energy consumption to provide robust internet connectivity is reduced [10].

B. Smart Connected and Sustainable Infrastructure

Smart and connected buildings are a new component introduced in smart cities where smart buildings contain many advanced and various embedded devices for proper control. Smart building concept means providing a safe and comfortable environment for people. Thus smart buildings will have different components and objects that maintain the comfort level for people who require less time and effort, including efficient and interconnected heat, ventilation, and cooling systems for individual floors in the buildings or other areas in the building and the smart metering of electricity, gas, and water, occupancy monitoring systems and hybrid vehicle charging technology.

Moreover, automation and wireless technology are essential in smart buildings. People communicate with the building’s components like doors, windows, lights, machines via different control options like mobile application, voice, and radio frequency identification, which can help in reducing the percentage of diseases that could be transmitted by touch.

A question arises here, how to supply these buildings with electricity and internet connectivity consistently?

According to previous research [11], global energy consumption in commercial and residential buildings has steadily increased between 20% and 40% in developed countries. Moreover, as the population grows, the higher the percentage of power consumption, governments, especially in undeveloped countries, should follow different strategies to provide electrical energy for buildings.

There are many different ways for generating consistently electrical energy in buildings, such as adding solar panels on the roof of the facility connected with batteries to be used later. In addition, depending on the kinetic energy generated from human body movement to be converted to electrical energy could be a good solution. Generating electrical energy from a human could be implemented in several ways. For example, they are adding a piezoelectric sensor in the shoes, where shoes now can convert the kinetic energy into electrical energy stored in a portable battery to be used later in charging the smart devices like phones or watches. Accordingly, this will reduce the power consumptions used in charging smart devices. Furthermore, a piezoelectric sensor could be added to mats in the entrance and the exit buildings where this generated energy could be used later in controlling the intelligent doors, windows, lights, and so on.

In addition, some buildings can specify space for people to do their sports. This space can be utilized sufficiently if a piezoelectric sensor provided the specific space to produce electricity while people are running or using doing their daily workouts. Also, there is an additional energy source, where a generator can be connected to bicycles to gain benefits from the mechanical energy generated by humans to be converted to electrical energy that can be used in the smart buildings [12]. Moreover, a simple, sustainable, intelligent system could be implemented in Egypt, connecting solar panels and light sensors to the streets' light. Thus the light will be charged from the solar panels, and it will be turned on and off based on the sunlight availability so that the lights will be off during the morning and afternoon time, and it will be on at the evening time.

All these options can be implemented to power the intelligent systems that will control the essential services in the building, whether the building is a mall, gym, park, school, hospital, or home.

C. Smart and Sustainable Health Framework

Smart hospitals are applying extensive use of new intelligent systems and technologies to improve healthcare quality at less cost.

Concentrating on and implementing new technologies like artificial intelligence, robotics, 3d printing, augmented and virtual reality, and telemedicine plays a vital role in immediate requirements like reducing cost and high efficiency and long-term goals like greater precisions, fewer errors, and better outcomes.

The healthcare framework is changing due to the increasing number of today's patients because of vital viruses who require healthcare services.

The change in healthcare framework to be smart includes embedding many new technologies into hospitals' design and operations to improve patients' experience, embedding new technologies to improve healthcare, and create an interconnected system between all hospitals. A question arises here: how to integrate new technologies in Egypt where electricity is not consistently available, thus using renewable and sustainable resources and green practices could be challenging.

Several suggestions that could convert the hospital nowadays in Egypt to smart and sustainable hospitals such as hospitals can implement the same intelligent system in smart homes: the HVAC system and patient record to control room's temperature. When the room in the hospital is empty, the system is adjusted to the minimum ventilation settings. When the patient is in the room, he can control the temperature via remote control or voice. Although hospitals' HVAC systems help in electricity consumption reduction, at the same time, this system helps in reducing the injuries percentage by patients who are in need to leave the bed to adjust the room temperature.

Moreover, as the hospitals and medical centers are usually crowded places, thus converting the kinetic energy of people who are entering the hospitals to electrical energy could help in reducing the electrical energy consumption in the hospitals. Moreover, hospital buildings can include the same feature as smart buildings, solar panels, fuel cells, and an underground water system.

But what about the intelligent healthcare system?. In addition to the use of generated electricity from different resources to power the smart devices used in intelligent systems, a part of the healthcare system can be converted to a virtual system and gain benefit from telemedicine technology, where there will be an artificial intelligence virtual health assistant persist in a mobile application that can talk and respond to people questions and situations, if it is a simple health problem that the virtual assistant could solve, then the problem could be easily solved. Otherwise, a human assistant will be presented to aid in suggesting the patient's problem. Furthermore, in medicine, artificial intelligence-based analytics for supporting the decision-making process is required, that is why an example of an artificially intelligent algorithm recently developed to rapidly detect Covid-19 by combining patient's chest scan with clinical information like age, blood report and contact information, the system can help in evaluating the infected patients [13]. Moreover, intelligent systems can assist in work management like scheduling and planning clinical staff working time and allowing the clerk desk laborers to reduce their intensive tasks by replacing their work with automation and artificial intelligence algorithms.

D. Smart Education System

Intelligent systems and the internet of things can provide significant communication between virtual and physical objects, thus implementing artificial intelligence and internet of things technologies in the education system plays an effective role in converting the traditional education systems into a smart system for both teaching and learning process.

Transforming the education system means integrating new technologies like artificial intelligence, simulation, and virtual and augmented reality. A smart education system enables customized learning, which means students get a learning plan based on their skills, strengths, and interests to upgrade students' learning capacity for knowledge. Smart learning system includes many software and hardware tool like online resources, analytical tools, smart devices, interactive whiteboard, e-books, and e-bag.

Additionally, a smart education framework means converting the learning environment to be smart, including classrooms, schools, universities, etc.

The author in [14] explains some applied examples of smart learning, such as smart classrooms, including electronic and smart devices like internet connectivity, smart whiteboard, tablets, e-books, and a projector. While smart laboratories should have special smart devices like virtual reality glasses and computers to simulate different subject topics and requirements, for example, simulating the global wars in history subject could be in a very interesting way in virtual reality simulator, or simulating human heart with all its parts using augmented reality. Also, in university, virtual reality and simulation can positively affect university students by converting all the theory parts to either simulated or practically applied in labs which assist in a better understanding of their major. Using these technologies in schools, students will be more satisfied with understanding lectures, doing presentations, and conversing with others. At the same time, teachers will be more confident and comfortable while giving the lessons and explaining the new concepts and ideas. Moreover, some applications transform the education system to smart such as:

- Smart surveillance system: this system could be applied in schools or universities to collect information from daily classes by using a camera, microphone and artificial intelligence algorithm to extract the information from the retrieved records from cameras to be then stored in the cloud for future use and for absents students to attend the classes through his/her smart device.
- Smart attendance system: collecting the attendance information in school or university requires time, especially in big classrooms or universities, that is why a smart attendance was developed that work based on RFID (Radio Frequency Identification) system where an RFID reader will be in each classroom and an RFID card with each student, thus the students need to pass their cards on the RFID reader to be recorded as attending. Also, the attendance system can be implemented through NFC (Near Field Communication), where NFC will be embedded in each student's phone, and an NFC scanner is placed in each classroom. Thus the attendance is recorded by scanning the NFC in each phone to store the information later in a specific server.

Implementing these systems requires a consistent amount of electricity to power the systems. The school building can be provided with the same sustainable techniques and ways to use smart buildings like solar panels and human energy harvesting. Converting students' energy to electricity would generate a good amount of energy.

After the text edit has been completed, the paper is ready for the template. Duplicate the template file by using the Save As command and use the naming convention prescribed by your conference for the name of your paper. In this newly created file, highlight all of the contents and import your prepared text file. You are now ready to style your paper; use the scroll-down window on the MS Word Formatting toolbar's left.

E. Smart Industry

The industry sector in smart cities had an incredible revolution that made changes in manufacturing. Many new concepts have been introduced, such as industry 4.0, which is the outcome of the shift of digitalization and automation in the manufactory sector. These concepts enabled self-optimization, cognition, and customization in the industry field, where communication with machines and computers is possible. It is implemented through the internet of things, machine learning, autonomous robots, the internet of services, big data management, and cloud computing.

The internet of things is an essential component in the industry field in smart cities. It enables systems connectivity, communication between different objects and machines and can be accomplished by controlling other parts in the industry like controlling temperature, light, devices, and remote control. In contrast, the internet of service (IoS) is presented as the "service vendors" which provide digital services through the internet according to the business type.

Moreover, big data management and analysis play a vital role in the revolution of the industry sector, where a vast amount of data and information are produced daily in the industry. Big data management and analysis are used through utilizing new technologies to make analyses that can be further used in the development process of the produced products.

Furthermore, robotics automation is the technology that has dramatically changed the world, where robots, machines, and automation reduced the employers' number, effort, and time with high proficiency and accuracy.

On the other hand, developing the industry field in Egypt with implementing these technologies requires a good amount of energy consistently. It is something that is not easy to be provided. That is why a new adaptive way of generating electricity is required, as solar panels or human energy harvesting is not enough to power on giant machines during the manufacturing process!

Commonly, in countries worldwide, the manufacturers are built far away from the residential areas. Thus in Egypt, the populations are the most near to Al-Nile river where the government is producing the majority of electrical power from the water of Al-Neil, but how the manufactories will be provided with a sustainable resource of electricity far away from the Al-Nile river?

As the significant area of Egypt is desert, a good amount of electricity could be produced from the sand. According to [15], and is used to generate and store energy in Italy, where the plant is supposed to be as a concentrated solar panel that focuses sunlight on heating sound. The hot sand produces around 500 kilowatts of energy with one turbine added which is enough to power a small village, and more turbines can be added to increase the power, in this case, a reduction is made in the unsustainable electricity consumption, where the city can develop the smart industry sector without huge consumption of electricity.

V. Results and Discussions

After introducing the five essential parts of smart cities and the way, they are developed in underdeveloped countries, and create a relationship between developing these parts and sustainability. The author in [16] explains the smart city architecture as illustrated in Fig. 2.

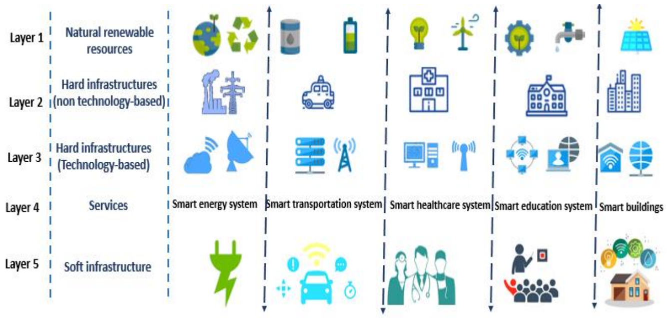

Fig. 2. The Smart City Architecture.

The smart city architecture includes four different layers:

Layer 1: Natural resources in the environment include the renewable resources available in the city, such as water, sunlight, fuel, and wind.

Layer 2: Physical infrastructures and services that are existed in the city. These physical infrastructures do not depend entirely on technology in their daily operations, such as transportation modes like cars, trains and buses or buildings, schools, offices, hospitals, etc.

Layer 3: Physical infrastructures and services that are technology-based and depend on technology to perform daily operations, such as communication networks, sensors, security cameras, etc.

Layer 4: The new smart services and applications developed based on the latest and advanced technologies and are used daily, such as smart transportation systems, smart health systems, smart energy systems, etc.

Layer 5: Soft infrastructures are individuals and communities living in urban areas such as stakeholders, companies, and other people utilizing smart applications and services.

Developing smart cities and implementing the smart city architecture with smart applications and services require performing a cost-benefit analysis (CBA) that is used to estimate the value of the cost and the benefits of developing and implementing a project. We can finalize whether the project is worthwhile or not.

Cost-benefit analysis is a systematic quantitative method of assessing the desirability of new projects or policies that are important for the long term and might have future effects on society.

The cost-benefit analysis is essential for stakeholders as it provides a comprehensive overview of the cost and benefit of a project. The cost-benefit research includes the following:

A. *Project Lifetime*

The project lifetime varies for different projects and depends on whether the project is private or public. The project's lifetime usually changes if the project is continually improved and modified, such as cars, buildings, highways, etc.

When the cost-benefit analysis is applied to investments in transportation systems, the project lifetime assumptions should consider that the transportation system project should have an infinite lifetime [17].

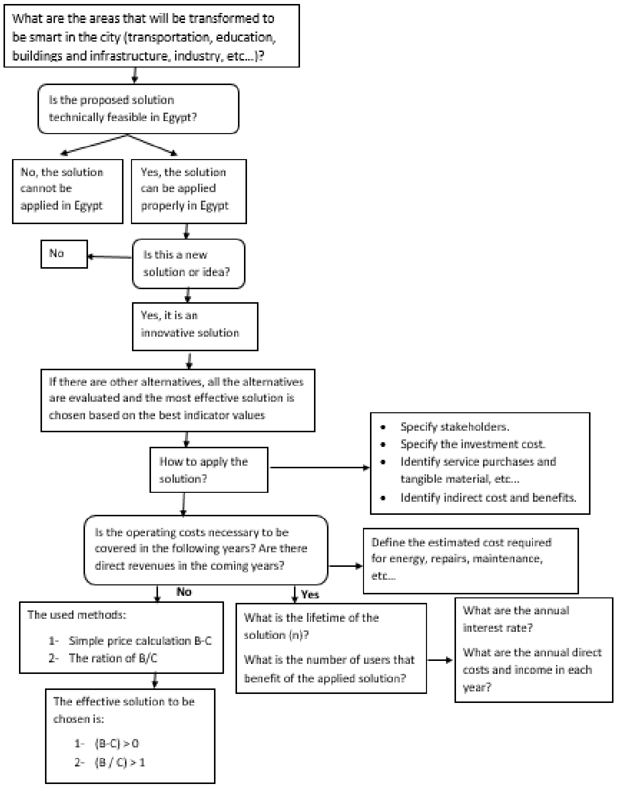
There are some examples shown in Table I of public projects' lifetime.

As illustrated in Table I, the energy and environment sectors have more life than the industry sector projects. The energy and environment sectors depend on renewable resources; thus, it can last for a long time, but for the industries that rely on systems or machines like telecommunication and industry sectors, the improvements for the project can aid in increasing the project lifetime limited period.

Thus, we need to consider the lifetime for different sectors for implementing a smart transportation system as the transportation system is related to the seven sectors mentioned in Table I.

B. *Cost-Benefit Analysis Process*

The cost-benefit analysis concept is used to evaluate the efficiency of the proposed solutions within the smart cities. The CBA is a general platform that constructs many questions and answers to provide the basic information for the construction and formulation of smart solutions. Fig. 3 illustrates the primary analytical framework of a simple CBA model designed to determine the efficiency of the solutions.



What are the areas that will be transformed to be smart in the city (transportation, education, buildings and infrastructure, industry, etc…)?
Is the proposed solution technically feasible in Egypt?
No, the solution cannot be applied in Egypt
Yes, the solution can be applied properly in Egypt
No
Is this a new solution or idea?
Yes, it is an innovative solution
If there are other alternatives, all the alternatives are evaluated and the most effective solution is chosen based on the best indicator values
How to apply the solution?
• Specify stakeholders.
• Specify the investment cost.
• Identify service purchases and tangible material, etc…
• Identify indirect cost and benefits.
Is the operating costs necessary to be covered in the following years? Are there direct revenues in the coming years?
Define the estimated cost required for energy, repairs, maintenance, etc…
No
Yes
The used methods:
1- Simple price calculation B-C
2- The ration of B/C
What is the lifetime of the solution (n)?
What is the number of users that benefit of the applied solution?
What are the annual interest rate?
What are the annual direct costs and income in each year?
The effective solution to be chosen is:
1- (B-C) > 0
2- (B / C) > 1

Fig. 3. The Primary Analytical Framework of Cost-benefit Analysis for a Smart Solution in a Smart City.

TABLE I. THE PROJECT LIFETIME FOR DIFFERENT INFRASTRUCTURE SECTORS

Infrastructure sector	**Project lifetime (years)**
Energy	25
Environment	30
Railways	30
Roads	25
Ports and airports	25
Telecommunications	15
Industry	10

Using the primary analysis of the CBA, several questions arise such as:

1) What are the areas that the smart solutions will be applied in?

2) Is the solutions technical could be applied in Egypt?

3) Are there any other alternatives for the solution to be considered?

4) What are the possible ways of implementing the solution? Specify all the input requirements, costs, and stakeholders.

5) Will it be necessary to cover the operating costs in the upcoming years? And what are the direct benefits in the coming years? If yes, what are the lifetime (years) of the solution and the number of users that the services will concern?

6) What are the annual interest rate and the annual indirect, direct cost yearly?

For example, let us suppose that a smart transportation system will be applied in a smart city in Egypt; what are the cost and benefits of the project, and how to evaluate the efficiency of the project?

According to [18], Egypt is planning to build smart cities on the cusp of the nation's sustainable development strategy in 2030.

Suppose we suppose that a smart city will be placed in Great Cairo city, the largest urban city in Africa, the Middle East, and the Arab world. A plan has been set to develop the urban in the city where there is a study performed to illustrate the major indicators of the Greater Cairo Region in 2022, shown in Table II.

TABLE II. MAJOR INDICATORS OF GREATER CAIRO REGION IN 2022

Socio-Economic Indicators	**2022**
Population (Million)	20.7
Motorization (Million Vehicles)	2.50
Trip Generation (Million Trips)	25.1

The development plan includes:

- Improvement in the road network and urban expressway network.
- For the public transport: extending the metro lines, satellite cities corridors, super tram system, network improvements, and optimized route structure.

To evaluate the development plan, the variables in implementing the project should be specified: the cost and the benefits of a smart transportation system.

The cost of the smart transportation system includes the following:

1) Capital cost: the capital cost means the initial cost of planning, designing, and implementing a project. The capital cost includes the design cost for roads, cars and systems, construction cost, electrical and electronic engineering cost, programmer cost, labor cost, and equipment purchasing cost in the smart transportation system.

2) Maintenance cost: Maintaining the technical parts for proper working conditions is required.

3) Operating cost: it is the cost of the advertisements, rent payments, and license fees needed annually.

4) Other costs: in addition to the operation and maintenance costs, more costs are to be considered. Specifically, there is additional cost related to smart solutions, technologies, cybersecurity, control and intelligent systems, and power generation systems.

That means the total cost of a smart transportation system in Egypt = $C_{capital} + C_{maintainance} + C_{other}$

The benefit is the revenue of the investments in a project, many benefits come from the smart transportation system in a smart city such as:

Travel time and cost reduction: The goal of any project is to gain the maximum benefit and pay less cost and efforts, thus the smart transportation system help in reducing the cost of traveling by lowering the payment amount for fuel consumptions, at the same time, the time of travel is reduced due to the connected cars' systems that are designed to reduce the traffic congestion time and reduce the traffic accidents as much as possible. According to the cost-benefit analysis, the financial value of the travel time reduction for different transportation modes can be expressed as:

$$V_{Time} = \sum_i (\Delta t_i \ x \ w_{time\ i}) \qquad (1)$$

Where Δt_i is the reduction in the travel time of each mode i.

Fuel and energy consumption: The primary challenge of developing a smart city in Egypt is providing the required energy to power the proposed intelligent systems. Thus we want to generate the maximum amount of renewable energy and reduce the consumed amount of fuel which is something difficult to be implemented especially for the transportation systems that depends on fuel for its daily operation, but converting the transportation system in Egypt to be sustainable system and replacing the mechanical cars with smart electrical cars means the fuel consumptions should be reduced, especially if a renewable resources generate the electrical energy.

For the smart transportation systems, the annual cost of the reduction in energy and fuel consumption is illustrated in this equation:

$$V_{Fuel} = \Delta G_{Fuel} \ x \ w_{Fuel} \qquad (2)$$

Where ΔG_{Fuel} is the amount reduced of fuel every year and the w_{Fuel} is the average price of fuel.

Reduce the gas emission: According to [19] the annual percentage of the energy-related carbon emission will be 10% higher than the percentage of emissions in 2014, but with the advancement in hybrid and electrical cars, the percentage will be decreased in 2030, as there are more concerns about the energy efficiency spreads and carbon reduction policies.

The author in [20] evaluates the development plan in the transportation system in Cairo by comparing cost-benefit analysis of the transportation system in 2001, committed project 2022, and the optimum result in 2022. It has been found that the development plan will help in recovering the average trip speed to around 18 kilometers per hour with the increase in the transport demand in 2022, with road congestion around 1.0. Moreover, the passenger of public transport in 2022 will be around 20.3 million per day compared to 18.2 million per day in 2001. In comparison, the carbon emission will be reduced by 15% compared to the percentage of emission in 2001.

The development plan and the CBA in Table III in Cairo transportation system does not cover the intelligent systems and the internet of things techniques and the smart energy generator systems, also the CBA ignores the future prices, population, requirements and improvements.

Where the smart and intelligent transportation system determines to install advanced and modern cameras, sensors, solar panels and internet connectivity.

Table IV shows the actual price of sensors and cameras used in smart cars and smart transportation systems collected from different online shops.

To reduce the cost of implementing an intelligent transportation system in Egypt, we must consider that not all the citizens can replace their car with a new smart electrical car which cost around 10,000 USD to 20,000 USD for small cars such as TESLA cars according to their prices online, but if the government announces clearly that, all citizens who live or work in new Cairo smart city must drive an electrical smart car, the citizens will either buy a new smart electrical car or transform their cars by installing an electric motor which cost around 6000 USD and adding large batteries about 1000 USD – 3000 USD, then installing sensors and cameras are required to be a smart car as well which costs around 1000 USD to 1500 USD based on the prices in Table III, thus the cost of transforming the cars or buying a new smart electrical car will cost almost the same.

Thus, based on the number of motorization in new Cairo in Table II, and based on the cost of transforming or buying new smart electrical cars, the cost of the system will be around 26 billion dollars, which is the capital cost for an intelligent transportation system in the high population new Cairo city. Also, the development of the city cost will be added to the cost of the intelligent transportation system according to Table III is 59.8 billion.

Furthermore, the cost of renewable energy resources which will be used in the cars, roads and in generating electricity from water or wind to be used later in charging the electrical cars such as the solar panels, wind turbine generator, Hydro generators and piezo electric sensor are shown in Table V.

According to Tables III, IV and V, the capital cost of developing smart sustainable transportation system in new Cairo will exceed 100 billion USD. Comparing the capital cost of the intelligent transportation system in Egypt 2022 with the capital cost for a smart transportation system in United States with lower population in Newark city 2015 [21] which is a developed city, where the capital cost was 100 billion without depending on the sustainable and smart energy systems, thus we can figure out that, the result of the capital cost calculation in Egypt is reliable.

TABLE III. THE COST ANALYSIS FOR THE DEVELOPMENT PLAN OF GREATER CAIRO

Scenario	**The transportation system in 2001**	**Committed transportation system project 2022**	**The optimum scenario of the developed transportation system**
Cost (LE billion)	-	18.2	59.8
Benefit-Cost Ratio	-	-	1.77
Trip speed (Km/hr)	19.0	11.6	18.0
Sharing percentage of public transport	70.9	61.7	57.9
Number of public transport passengers (million / day)	13.3	18.2	20.3
Vehicle-kilometer (million pcu-km/day)	62.8	127.3	139.7
Volume /Capacity Ratio	0.74	1.11	1.00
Population within 800m of Public transport (million)	2.04	3.09	8.20
Employment within 800m of public transport (million)	1.11	1.70	4.20
Students within 800m of public transport (million)	0.74	1.08	2.70
Carbon emission (million ton)	12.2	15.9	13.6

TABLE IV. THE ACTUAL PRICE OF SENSORS AND CAMERAS USED IN SMART CARS AND SMART TRANSPORTATION SYSTEMS

Sensors	**Actual price**
Ultrasonic sensor x4	16 USD to 40 USD
Automotive mono-camera	100 USD to 1000 USD

TABLE V. PRICES OF RENEWABLE POWER GENERATORS

Power generators	**Actual price**
Solar panels	200 USD to 300 USD
Hydroelectric generator	3,000 USD to 80,000 USD
Wind turbine generator	2,000 USD to 4,000 USD
Piezo electric sensor	40 USD to 60 USD

VI. Challenges for Smart and Sustainable Cities

It is widely known that to implement smart city projects, we have to combine information technology with internet-connected technologies. This case is especially true for underdeveloped countries that this paper focuses on. Smart city projects combine several technologies and applications that help improve management like waste management and smart grids [22]. Suppose smart cities became the 'modern standard'. In that case, decision-makers might need to navigate through different fields like connectivity, infrastructure, data, and security as cost and development are challenging. With technology and standards continually changing and quickly evolving, municipalities will need to avoid being trapped in using integrated solutions from a single provider, which ultimately leads to information and resources silos, making it even harder to exchange data with other municipalities. Thus, understanding that building a smart city goes beyond automating internal systems and introducing new applications. Implementing the concept of smart and sustainable cities in a country comes with various obstacles, including specific city criteria, variation of technologies, connecting infrastructures and conserving resources.

A. *Infrastructure Modernization*

The term "city infrastructure" includes housing, sanitation, water, and sewer supply, waste management, transport, energy supply, and distribution. The difference between smart and conventional infrastructure is the ability of smart infrastructure to adapt intelligently to changes in the environment without disregarding user needs to achieve improved performance. Smart city infrastructure provides the basis for all smart city themes, including transportation, economy, government, environment, and citizens. The smart infrastructure design depends on how modernized or developed a country is.

For a city in an underdeveloped country, developing a smart infrastructure will require considering cost, space and other factors to promote better management and development of resources. For example, to create smart transportation infrastructure, a massive amount of data must be gathered to redesign the transportation network and build new applications. Thus, requiring a large amount of capital from a country that is moving to develop and could not afford high costs. These countries can maintain the city's current infrastructure and focus on optimizing existing infrastructure resources and monitor performance. For example, establishing renewable energy infrastructure to the existing one to manage natural resources like water and utilize wind and solar energy to improve waste management. However, in both developing and developed countries, the primary reason behind smart infrastructure applications is adapting to society's demands for sustainable growth. Table VI summarizes some of the sustainable challenges and smart infrastructure solutions proposed for modernization.

B. *Security and Privacy*

Data is a core component of Smart Cities. Sensor networks, smart meters, cell phones and IoT devices all produce massive quantities of data. These generated data could be converted by the city government to create new insights that could be monetized and shared with various stakeholders. Smart urban infrastructure components pose risks and safety issues, as smart infrastructure may be vulnerable to hacking and unauthorized access. The problem of protecting people's privacy is also a significant concern in this regard. Many of the widely mentioned risks include stealing users' data and implementing ransomware. Of course, the hazard level grows as IoT systems become more controllable and more autonomous. In these latter situations, cybercriminals can exploit vulnerabilities to remotely control IoT devices to alter sensor or system actions, sabotage these devices, or even cause physical damage to the surrounding environment [23]. Such activities result in cyber hackers having more access to confidential data that expose customer behavior trends. We might also see more mobile device robberies, as more can now have physical access to homes and workplaces. As IoT ecosystems are built and often include several stakeholders and vendors, and customers, it is necessary to be aware of possible compliance problems if either confidential data is hacked or these sensors and devices are themselves regulated by cyber criminals [23]. Organizations and municipalities must identify and explicitly recognize each other's positions, obligations, and standards in terms of data protection and even in the event of data breaches within IoT ecosystems. To expand current cybersecurity strategies, a risk control policy should be developed so that both organizations in the public sector obtaining these systems and in the private sector developing them will need to be take into consideration the ramification of developing and obtaining these technologies and the data protection and AI threats that will need to be resolved by effective governance steps [24].

TABLE VI. Challenges with Infrastructure Modernization

Sustainable Challenges	**Proposed Smart Infrastructure**	**Description**
Improving Energy infrastructure	Smart Meter	Monitor behavior regarding electric energy and measure consumption
	Smart Grids	Manage variable renewable power supply
Affordable, good quality connectivity	High-Speed Internet	Cellular and Low Power Wide Area (LPWA) technologies
Environmental Performance	Environment Sensor Network	Collect data regarding environmental condition and level of pollutants
Health and Education	Telemedicine, Remote healthcare, and Online Education	Services and products to access education and health services remotely

C. *Internet Connectivity*

Introducing smart city technologies requires a robust and efficient broadband network. This shows the need to continue bridging the digital gap to utilize and take advantage of smart applications (apps). Mobile broadband networks play a key role in a shortage of fixed networks. Smartphones revolutionized smart cities as several "apps" were developed to ease users in handling several facilities like road and transportations, health and fitness, and electricity and water.

Due to increased sensor and data used, robust and high connectivity is needed to maintain and accommodate it. This is where 5G shines and provides the essential structure, capability and service that provide cases underpinned by technological features like high bandwidth, absolute reliability, wide availability, and responsive connectivity. Such utilization of technology is limited to a city's budget, which is the case with underdeveloped countries [25].

D. Funding and Financing

Conceptualizing smart cities provides a digital layer on any capital asset, opening the way to unparalleled possibilities, technological improvements, and increased profitability. One significant factor that can make a smart city design productive is the consistent path to steady revenue (its revenue model). A reliable funding source is particularly important if the project is pursuing private financing. When planning the project, it is important to be mindful of the difference between the terms "Financing" and "Funding". The government provides particular money for specific reasons with free charges and no interests in terms of funding. In comparison, the term financing refers to financial/private institutes that grant a project a certain amount of "funding" as equity to be returned later with interests. For underdeveloped countries in Africa, it is crucial to think about revenue and cash flow, how funds can be recovered from the overall revenue, the value created, and how to monetize it. That's why it is important to strategize a plan to secure funds and finances from different investors, as some might focus on infrastructures like roads and transportation while others might focus on different sectors and themes.

E. Energy Management

Cities that have high population densities in a country like Egypt generally require a huge power source. Once these cities are developed as smart cities, renewable energy resources will be integrated with the city's electrical infrastructure to support the economy and life-quality growth. Smart cities can help sustain energy and environmental challenges that produce a proportion of carbon emissions. It is generally known that cities play an increasingly decisive role in addressing climate and environmental challenges. Cities are naturally able to grow to face the world's many energy and environmental problems. Human and intellectual capital, along with economic and political influence, can fuel the increased use of renewable energy. The primary constraints that might be faced make these cities hubs for technical and social creativity to drive change globally. Energy and environmental considerations are key that drives (and limit) all facets of urban planning [26].

VII. Conclusion

This research claim that implementing the smart city model could provide an opportunity for underdeveloped countries to handle the effects of rapid urbanization, including their economic and environmental implications and the decrease in quality of life. Achievement of sustainability and enhancement of quality of life in underdeveloped cities varies from one country to the other. According to the findings, no standard criteria determine a city's smartness, and analysis must be performed before settling on smart projects and systems. This research analyzed the cost and benefits of making New Cairo, Egypt into a smart city. Also, this research discussed how utilizing the rich resources in Africa and investing in smart technologies makes the underdeveloped countries across the continent leap urban revolution. We finalized that in smart city projects, sustainability becomes interwoven with various objectives and priorities, all of which interfere and influence each other, generating potential feedback loops and unforeseeable results.

Abstract—**In the guild of guitarists, it is common to work with guitar synthesizers because the emulation of a great variety of sounds that are produced by different musical instruments, starting from just playing the guitar, which means, a piece of music is played with a guitar, but other musical instruments are actually heard such as, a saxophone, a violin, a piano or percussions, depending on the instrument that has been selected. The problem that arises in this article is that synthesizers are expensive and due to their size, the transportation of the equipment is often impractical. As mentioned, the development of a mobile application that has the function of a monophonic synthesizer is proposed as a solution. In this way, the cost is greatly reduced, and additionally, the user is able to install the application on a mobile device with Android operating system and connect it to an electric or electro-acoustic guitar through an audio interface; obtaining as a result, a functional technological instrument by offering guitarists an alternative with respect to conventional synthesizers. The construction of this application used the Fast Fourier Transform Radix-2 as a signal recognition algorithm, which allowed obtaining the fundamental frequencies generated by the guitar, which were transformed into MIDI notation and later used in sound emulation.**

Keywords—Monophonic synthesizer; guitar; sound emulation; mobile application

I. Introduction

The advent of tablets and smart cell phones has opened a range of possibilities in all areas of knowledge. In the field of music, technological development has occupied a privileged place by having mobile applications that help in tuning musical instruments, in measuring time to practice, in recording and editing music, among other aspects.

The rise of technology has allowed the creation of tools in order to support musicians in a vast diversity of ways. The tool that is interesting to highlight in this article is related to the emulation of monophonic sounds of musical instruments or other types of sounds, which is obtained through the use of synthesizers. The Royal Academy of the Spanish Language defines synthesizer as: "Electronic musical instrument capable of producing sounds of any frequency and intensity and combining them with harmonics, thus providing sounds of any known instrument, or sound effects that do not correspond to any conventional instrument" [1]. Synthesizers are very useful devices because when connected to the guitar, are able to provide a great variety of sounds, increasing the possibilities of musical interpretation of the guitarist.

Two of the problems that arise are its portability and its high cost; Due to the mentioned, based on computer science and mathematics, it was decided to develop a monophonic synthesizer, using a mobile application, which allows the guitarist to use a synthesizer through a mobile device such as a smart cell phone or a tablet, which can be transported easily, without having to make an additional expense.

Music can be classified into two main categories: monophonic and polyphonic. Monophonic music is made up of a single melodic line, which means, only one musical note sounds at a certain time, while polyphonic music is made up of more than one melodic line, which means, two or more musical notes sound at the same time [2]. The present study focuses on monophonic music.

The guitar is a musical instrument that allows its player to express musical notes in different ways. The guitar, like other instruments such as the piano or the violin, generates analog sounds, which need to be converted to digital sounds in order to be read by the computer. From this digitization, it is possible to apply signal recognition techniques for different purposes and in this case, to detect the fundamental frequencies generated by the guitar. A transformation was applied to these frequencies using the notation mentioned in the Musical Instrument Digital Interface (MIDI), to obtain a discrete representation of the musical notes, which are defined in an interval that goes from 0 to 127, where each number corresponds to a musical note.

The overall objective of this study was to develop a portable tool that allows the guitarist to emulate monophonic sounds of other musical instruments or other types of sounds using the guitar, all this through computational and mathematical techniques. For this purpose, the following specific objectives were proposed:

- Recognize frequencies generated by guitars making use of hardware and software resources of mobile devices.
- Transform frequencies generated by guitars to MIDI notation.
- Emulate monophonic sounds of musical instruments or other sounds based on the obtained MIDI notes.

This article is divided into 4 sections. The second section shows some synthesizers available on the market, as well as some application programming interfaces that have been developed in order to recognize signals and to support the execution of MIDI sounds. The third section deals with the theoretical references about the recognition of monophonic sounds and the transformation of frequency to MIDI notation. The fourth section shows the methodology used for the development of the monophonic synthesizer following the stages of the incremental Software Engineering model. Subsequently, the results obtained from the tests carried out are shown and finalized with the conclusions.

II. Related Work

At present, there are independent synthesizers for guitar, which means, mounted on electronic circuits, some of them are: MEL9 [3], SY-300 [4], GR-55 [5], among others; However, when it comes to mobile applications that perform the function of a guitar synthesizer on the Android operating system, there are no formal alternatives to it.

On the other hand, there are some application programming interfaces (APIs) aimed at the Android operating system, which can be useful for the construction of a synthesizer, for example, those that serve to perform frequency recognition and those that serve to execute MIDI sounds, some of these interfaces are: TarsosDSP [6] and MIDI Driver [7] respectively.

In the present mobile application, it was chosen the frequency recognition through the Fast Fourier Transform Radix-2 algorithm, according to [8], making use of the native Java development kit, while for the execution of MIDI sounds, the model that was done in [7] was retaken.

III. Theoretical Aspects

In this section, reference is made to the techniques used to recognize monophonic sounds and, on the other hand, the digital interface of musical instruments (MIDI) is presented, which shows a notation that serves to discretize frequencies.

A. *Monophonic Sound Recognition*

Due to in this article the monophonic sounds generated by the guitar are taken as a basis, some algorithms that can be used for the recognition of monophonic sounds are specifically mentioned.

There are mainly two approaches that are used to perform monophonic sound recognition. One of them consists in analyzing the signal samples in the time domain, and the other in analyzing them in the frequency domain. A widely used method in the time domain is autocorrelation, which compares a signal with delayed versions of itself at successive intervals to find the highest amplitudes within the signal and measure the distances between them. Through these distances the period of the wave can be inferred, and with it, the present frequency of the monophonic sound can be detected. On the other hand, there is the analysis of signals in the frequency domain, where algorithmic implementations of the Discrete Fourier Transform are used, with which a set of frequency intervals and their amplitudes are obtained. A simple way to detect the frequency of the monophonic sound present quickly is to select the frequency with the greatest amplitude [9].

In this article, the signals in the frequency domain are analyzed, so some algorithms that can be used to recognize the monophonic sounds generated by the guitar in that domain are specifically mentioned.

B. *Fast Fourier Transform (FFT)*

Fast Fourier Transform is an efficient mathematical implementation of the Discrete Fourier Transform (DFT), which is a particular case of the Fourier Transform for sequences of finite length in which the spectrum is evaluated only in a few specific frequencies, and therefore, a discrete spectrum is obtained [10, 11].

Over time, several FFT algorithms have been developed such as: prime factor, split radix, vector radix, split vector radix, Winograd Fourier transform, etc. [12].

The FFT algorithm used to develop the mobile application of the monophonic synthesizer is the Radix-2. The Radix-2 algorithm is considered the most used for the FFT calculation, it works when the number of data samples is a power of 2, in case the number of samples does not satisfy this criterion, the missing spaces are filled with value 0, this does not alter the calculated frequency spectrum. The input and output of an FFT are expressed in complex numbers, in this case, for its implementation, two arrangements are accepted to store the real and imaginary components in them, when using the recording tools of mobile devices, all the bytes of audio information are obtained, which are used within the real components, while the imaginary components are always filled with zeros, the output of the algorithm is contained in two other arrays, one corresponding to each type of component, where the frequency spectra are stored, since only the actual samples are used for input, only the first half of the components need to be analyzed. Each component of the frequency spectrum is related to the previous component, since it is the sampling frequency divided by the number of samples of the FFT [8].

In order to recognize monophonic sounds, the power or amplitude spectrum (Xp) is analyzed, selecting the frequency f with the greatest amplitude, which is calculated through the sum of the squares of its real (Xreal) and imaginary (Ximag) components, as shown in (1),

$$Xp = Xreal(f)^2 + Ximag(f)^2 \tag{1}$$

The FFT algorithm used to develop the mobile application is Radix-2, which means that it must work on a group of samples whose number is a power of two [8].

C. *MIDI*

Musical Instrument Digital Interface (MIDI) is a music notation system that allows computers to communicate with musical synthesizers. MIDI files contain instructions to create the pitch, volume and duration of the notes, this based on a sequence of events called: note_on and note_off [13].

Musical notes are not encoded by their names, instead numbers from 0 to 127 are assigned as shown in Table I. For example, the number 57 corresponds to a musical note A with a frequency of 220 Hertz (Hz).

Equation (2) shows the transformation of frequency in Hz to MIDI note,

$$MIDINote = round(69 + 12 \times \log_2 (f / 440)) \tag{2}$$

TABLE I. MIDI NOTES ASSOCIATED WITH ITS NAME AND FREQUENCY IN HZ [15]

Name	MIDI note	Frequency (Hz)
D	38	73.42
D♯/E ♭	39	77.78

F	89	1396.91
F♯/G ♭	90	1479.98
G	91	1567.98
G♯/A ♭	92	1661.22
A	93	1760.00

Where round is a function of rounding to one digit, factor 12 is the resulting linear pitch space per octave, factor 69 is note A (440 Hz), which is taken as reference, $\log_2$ is used according to the logarithmic pitch perception in humans and the variable f is the input frequency that will be converted to a MIDI note [14].

General MIDI is a standardized specification for electronic musical instruments that respond to MIDI messages. General MIDI was developed by the American MIDI Manufacturers Association (MMA) and the Japan MIDI Standards Committee (JMSC) and first published in 1991 [16].

Within the general MIDI specification 128 sounds of musical instruments or other types of sounds are included, and these are divided in sections such as: Piano, Chromatic Percussion, Organ, Guitar, Bass, Strings, Ensemble, Brass, Reed, Pipe, Synth Lead, Synth Pad, Synth Effects, Ethnic, Percussive and Sound Effects which are used in this mobile application and are shown in Table II.

TABLE II. SOUNDS OF THE GENERAL MIDI SPECIFICATION [16]

00 - Acoustic Grand Piano	32 - Acoustic Bass	64 - Soprano Sax	96 - FX 1 (rain)

31 - Guitar harmonics	63 - Synth Brass 2	95 - Pad 8 (sweep)	127 - Gunshot

IV. METHODOLOGY

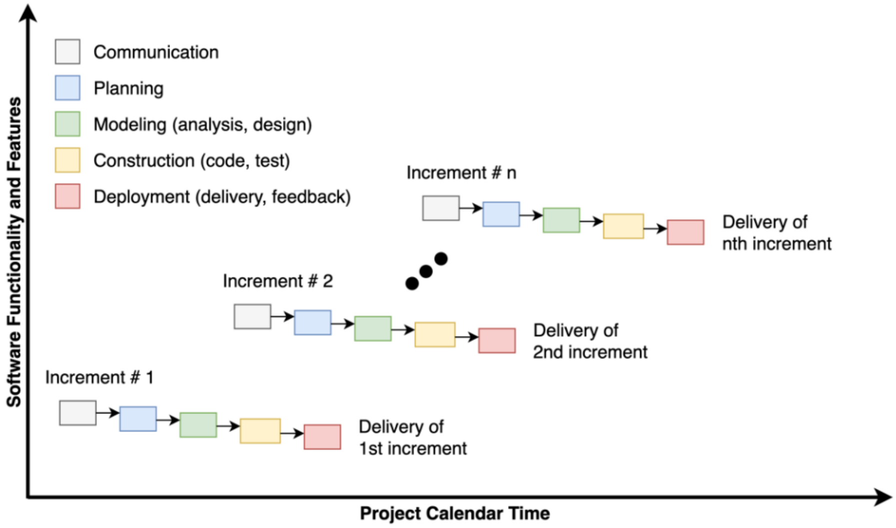
The mobile application was developed using the phases of the incremental Software Engineering model, which applies linear sequences in a staggered manner as the calendar of activities progresses. Each linear sequence produces deliverable software increments [17]. The diagram in Fig. 1 describes the stages used for this development.

According to what Mall [18] points out, first of all a simple system is built and delivered which implements only a few basic characteristics. During a few successive iterations, improved versions are deployed and delivered, until the desired system is finally realized.

The software requirements are first divided into several modules or features that can be built and delivered incrementally. This is graphically represented in Fig. 2.

Returning to what Pressman and Mall [17, 18] point out, 3 modules were created as part of the development of the mobile application.

In the first module, the recognition of the frequencies generated by the guitar was carried out, for which the Fast Fourier Transform Radix-2 algorithm was applied, making use of the hardware and software resources of mobile devices. When playing a musical note with the guitar, the fundamental frequency corresponding to said musical note was obtained in real time, showing it on the mobile application interface.



Communication
Planning
Modeling (analysis, design)

C
A, B, C are modules of a software product that are incrementally developed and delivered.

Fig. 2. Incremental Software Development.

In the second module, the transformation of frequencies to MIDI notes was carried out, for which equation 1 shown in the MIDI section was applied, obtaining as a result, discrete values of frequencies within a range from 0 to 127, showing the aforementioned transformation together with at the fundamental frequency in the mobile application interface.

The third module allowed to emulate the monophonic sounds of musical instruments or other types of sounds, based on the MIDI notes obtained. The note_on and note_off events of the digital interface of musical instruments were used to execute and stop the MIDI notes. Consequently, the moment the user plays a musical note with the guitar, the note_on event is activated, with which the sound chosen by the user within the 128 included in the mobile application must be heard; for example, a saxophone, a trumpet, a violin, among others; whereas when there is an absence of sound, the note_off event was activated to keep the mobile application silent.

For the construction of all these modules, the Java programming language was used together with the Android Development Kit (SDK).

A. *Logical Block Diagram of the Structure of the Mobile Application*

Fig. 3 shows the block diagram of the mobile application. As can be seen, an audio input is required, which goes through a sampling process to obtain the discretized signal, making use of the audio recording tools offered by the Android operating system. Subsequently, the filter allows to eliminate the peaks of the signal, which means, it eliminates the unwanted noise, and then to apply the Fast Fourier Transform and thus obtain the fundamental frequencies. From these fundamental frequencies, the transformation to MIDI notation is carried out. From this moment, the sound chosen by the user can be emulated through the execution of the note_on and note_off events.

B. *Operation of the Mobile Application*

Fig. 4 represents the operation of the mobile application. In order to use it, it is necessary to connect it to an electric or electroacoustic guitar through an audio interface, the last one is connected to an audio output device such as an amplifier.

Execution of note_on and note_off events

Fig. 3. Block Diagram of the Mobile Application.

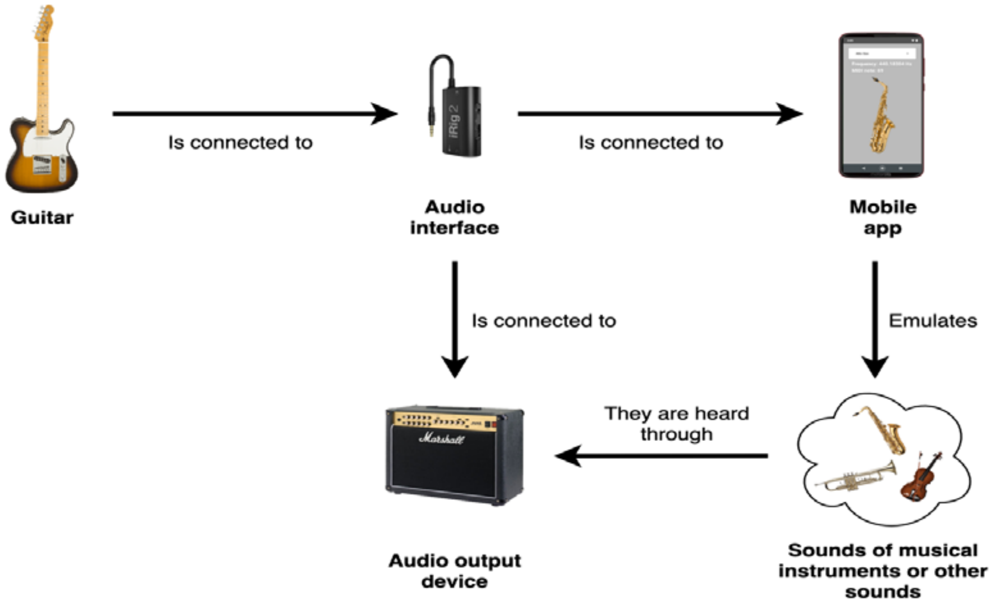

Fig. 4. Mobile Application Operation.

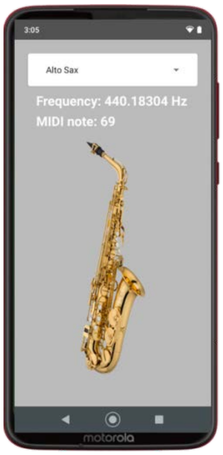
V. Results

The mobile application has been developed using the Java programming language in order to run on mobile devices with the Android operating system. The tests were carried out on a device from the Motorola brand, a Moto G7 Plus model with 64 GB of storage and 4 GB of RAM, with the Android 10 (Android Q) operating system installed.

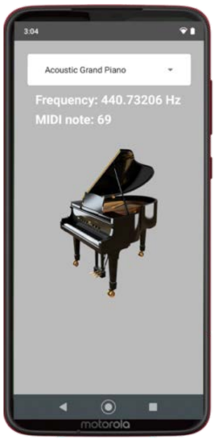
The work was carried out with a sample of three guitarists to carry out the tests of the operation of the mobile application. Two of the guitarists used an electric guitar and the remaining guitarist used an electro-acoustic guitar. The musical instruments were connected to the mobile application through an iRig 2 audio interface. The guitarists selected in the list of the main interface of the mobile application, several of the 128 sounds that were available to be emulated and they played the guitar obtaining the sound expected. Additionally, they were able to observe the frequency of the note played, as well as its transformation to a MIDI note in real time.

The mobile application was subjectively evaluated with the feedback obtained from the guitarists, who pointed out the great usefulness of this mobile application because it broadens their possibilities of interpretation with their musical instrument, without requiring more than their mobile device and an audio interface. On the other hand, they mentioned that they noticed a slight latency between the moment they played the guitar and the emulation of the chosen sound, which could be reduced using a low-level programming language. Two examples of the mobile application in operation are shown in Fig. 5 and Fig. 6.



Frequency: 440.18304 Hz
MIDI note: 69

Fig. 5. Example of the Execution of a Musical Note a 440 Hz with the Guitar using the Alto Saxophone Sound through the Mobile Application.



Frequency: 440.73206 Hz
MIDI note: 69

Fig. 6. Example of Playing a Musical Note a 440 Hz with the Guitar using the Acoustic Grand Piano Sound through the Mobile Application.

VI. Discussion

The mobile application was developed with the Java programming language. Due to Java uses a virtual machine (Java Virtual Machine, JVM), which processes the instructions before being executed [19], a considerable latency was obtained in the results. To those who want to return to this article for their research, they are advised to use a lower-level programming language such as C or C++, with which the latency would be reduced considerably and obtain better results, because the instructions are executed directly. Guitar effects pedals commonly use recommended programming languages [20].

VII. Conclusion

The development of mobile applications has acquired great relevance due to the variety of areas where they can be used. As mentioned, there are applications that allow communication between people, planning travel routes, requesting food delivery and entertainment, to name a few examples. Additionally, the applications have allowed people to count with tools that provide the opportunity to explore, grow and develop in other areas such as music, which contributes to their comprehensive training. The mobile application presented in this work benefits this aspect because the user has a synthesizer in the palm of his hand that is capable of emulating monophonic sounds of different musical instruments or other types of sounds with a guitar. This synthesizer, unlike the ones available on the market, is affordable, easily transportable and usable anytime, anywhere. Applications as the one described above allow the practice of music to be accessible to huge number of people.

It has been considered as future work, to make this mobile application a polyphonic synthesizer, where to obtain the polyphony generated by the guitar, the frequency spectrum obtained by the FFT Radix-2 algorithm will be taken up, and search and decision mechanisms will be used. It is also planned to adapt the mobile application to a lower-level programming language like C++ for lower latency.
