***Abstract*—Predicting sales is one way to get company profits. Tokopedia Indonesia is one of the marketplaces that is included in the type of e-commerce customer to customer (C2C). This research was conducted in order to help sellers in the Tokopedia Indonesia marketplace to predict the sales of their merchandise, so that sellers can prepare or stock items that are predicted to increase in sales by implementing Artificial Neural Networks. Artificial neural networks can help predict future sales values. The data is divided into training data and testing data. The results of the analysis of this study indicate that the network model obtained reaches an accuracy rate of 95%.**

***Keywords*—Forecasting; e-commerce; backpropagation; artificial neural network**

I. Introduction

Sales data and information are very important to company to plan sales to be come, for example: customer data, number of vehicles, price cars, spare parts, types of vehicles and those that are not inferior its importance is deep government policy provide vehicle taxes as well as fuel subsidies vehicle [1,2]. The report of the research company said that in early 2017, it increased 51% from 2016 internet users which recorded around 132.7 million internet users [3]. From this data it is known that 24.74 million internet users have shopped online. It is recorded that from 2016 to 2017 internet users spent around IDR 74.6 trillion to shop on various e-commerce (Aditya, 2017). Rebecca (2016) there are six types of e-commerce with different characteristics, namely business to business (B2B), Business to customer (B2C), Customer to Customer (C2C), customer to business (C2B), Business to administration (B2A), and online to offline (OZO) [4]. The C2C e-commerce type model will be the author's focus in this study. Rebecca (2016) state that Tokopedia Indonesia is one of the marketplaces that is included in the C2C type of e-commerce that allows anyone and anywhere to be a seller or a buyer. Tokopedia Indonesia provides various tradable items such as electronic devices, baby equipment, men's and women's clothing, cellphone accessories, laptops, computers, and others. Based on www.alexa.com, it is known that Tokopedia is in the first place for this type of marketplace after the 8th Top Sites on the Alexa Rank [5].

In the Tokopedia marketplace, there is information on the number of items that have been sold, the number of people who have seen the item's page, how long it will take for the goods to be sent to the courier, the number of customers, the description of the goods, the number of people who favor the item and so on [6]. The prediction of the number of sales is an important factor that determines the smooth running business of a company. This prediction is very useful for determining how much goods to be ordered in the following month. Common problems faced by a company is how to predict or forecast sales of goods in the future based on previous sales data. The prediction is very influential to determine sales targets that must be achieved. Planning that effective both in the long term and in the short term depending on the forecast demand for products to be sold [7].

Forecasting techniques are widely used for the planning process and decision making, a prediction trying to predict what will happens and that will be needed. There are artificial neural networks forecasting technique that is often used namely Backpropagation. This technique usually used in multilayer networks with the aim of minimizing error in the output generated by network [8]. Not all items that are seen or favored by many people will experience high demand, but sometimes high enthusiasts are not only seen or favored by many people so that there is an out of stock of goods. To solve this problem, information is needed to those who sell goods and services on Tokopedia by making an analysis that can provide information related to the sales volume for a product or service being promoted. So that with this information, parties who sell goods and services on Tokopedia can provide stock that matches the predicted interest of an item being promoted. One method of overcoming this problem is by designing an artificial neural network architecture or commonly referred to as an artificial neural network. One type of algorithm for this artificial neural network is backpropagation [9]. Backpropagation is an artificial neural network model that is often used and in great demand as a multi-year learning algorithm related to identification, prediction, pattern recognition and so on. The backpropagation algorithm is a type of supervised learning algorithm where the output of the network is compared with the target output so that an error is obtained. Then the error will be propagated back to modify or improve the weight of a network in order to minimize errors. Based on this background, the authors are interested in applying the artificial neural network method with the backpropagation algorithm to predict sales volume on Tokopedia [10].

II. Theoretical Framework

The research entitled analysis of the backpropagation method and radial basis function to predict rainfall with artificial neural networks was carried out by Vincent Rinda Resi (2014). This study discusses the very high rainfall prediction model. The prediction model will be used for various things, one of which is flood prevention. The results obtained from the two methods found that the backpropagation method was able to provide better accuracy, namely 99% than the radial basis function method [11]. [12,13] in their research discusses the prediction of members' interest in a cooperative product. Today's cooperatives, especially the PTPN VII Musi Landas Cooperative, are very much needed by the community because they play an important role in their daily life. The constraints faced by the cooperative are in determining the products that are of interest to its members. If the cooperative can predict this, it will reduce losses and will increase sales which will have an impact on cooperative income. So this research applies a data mining which can predict the interest of members in a product. The data mining technique applied is classification using the decision tree method with the C4.5 and DTREG algorithms. Based on this research, several conclusions were obtained, one of which was to produce information about product categories that were of interest to the members of the PTPN VII Musi Landas Cooperative.

Further research related to artificial neural networks with backpropagation algorithms is a study conducted by [14,15] discuss the backpropagation application discussed to predict the movement pattern of earthquake points in Indonesia from January 2015 to April 2015. The data used is daily data from the Meteorology, Climatology and Geophysics Agency. The conclusion is that the network with momentum and adaptive learning of 0.9813 shows pretty good results with an MSE value of 0.047735 on the 104th iteration/epoch with a maximum of epoch = 10000, learning rate = 0.3, and mc = 0.8. The results of the mapping of the predicted position of the earthquake point are at latitude 0.0405 LU, longitude 124.4015 LS and magnitude 3.26 SR which are in one zone with earthquakes that occur on the same day and date, namely latitude 0.84, LU longitude 126.28 latitude and magnitude 4.8. [16,17] Discusses how to predict the stock prices of Bank Central Asia, Gudang Garam and Indofood. In this study, it was concluded that the artificial neural network parameters obtained MSE with the smallest value obtained with window size 10, hidden neurons 10, and 10000 iterations for all test cases data PT Bank Central Asia Tbk, PT Gudang Garam Tbk and PT Indofood Sukses Makmur Tbk. The results of each test produce MSE 0.002708159 for BBCA data test cases, 0.001074818 for GGRM data test cases and 0.002440852 for INDOFOOD data test cases [22]. Further research is related to the comparison of methods conducted by [18,19] discuss the performance of the three methods in predicting the price of gold because gold is an item that can be used for investment, so an understanding of the shifting of gold prices is needed in order to be able to get a profit. Of the three methods, backpropagation is the best algorithm for predicting gold prices with an accuracy of 95% [20].

III. Research Methodology

The target population used in this study is all data on the Tokopedia Indonesia website. Then the researchers took randomly from one of the categories of goods in Tokopedia Indonesia, namely the computer accessories category. From the data obtained, three types of computer accessories categories will be analyzed by researchers, namely mouse, speaker & sound, and bag & case. The data is obtained by opening the goods web page one by one, then by means of scraping, the researcher selects the features that are considered to affect the variable (Y), namely the number of items that have been sold. The selected features will be used as the supporting variables (X) needed, namely the type of item, the price of the item, the number of people who saw the item, the time of delivery of the goods to the courier, customers from the goods shop, the number of people who have favored the rating. This scraped data is an item that has been advertised on Tokopedia until February 11, 2021. The data analysis method used in this study is an Artificial Neural Network with a backpropagation algorithm to predict buyer interest patterns on the Tokopedia Indonesia website, especially in the computer accessories category. Software used by researchers to analyze the data using Microsoft Excel and RStudio.

IV. Results and Discussion

Preprocessing data is the first step in an analysis to check and correct when there are missing values before starting the learning process [21]. When there is information that is not available on one or more object variables or certain cases, data correction will be carried out. The researcher examined the missing data, can be seen in Table I, as follow:

In Table I, it can be seen that all variables do not have missing data, which means that the next steps can be taken, namely data transformation and data sharing.

Data sharing is intended to divide data into two parts, namely training data and testing data which have their respective functions. The training data is used to train the learning algorithm during the training process. This data distribution is not divided equally, but the percentage for training data is greater than the test data. The following Table II is related to the percentage of data sharing used.

TABLE I. Checking Missing Data

Variable	Valid	Missing	Percentage Valid
Sold	281	0	100%
Type	281	0	100%
Price	281	0	100%
Seen	281	0	100%
Time Send	281	0	100%
Customer	281	0	100%
Favorite	281	0	100%

TABLE II. Data Partition

	Percentage	Total
Training data	80%	224
Test data	20%	57
Total	100%	281

Source: processed data

Table II above can be seen that the percentage of training data is greater than the test data because the learning algorithm while carrying out the training process works optimally.

The determination of input and output patterns is based on the formulation of this research problem. So that there are seven variables as input that are considered influencing the target (output). Determining Network Architecture and Parameters Artificial Neural Network has an architecture consisting of the number of layers and the number of neurons in each layer, as for the case of backpropagation using multi layers consisting of input, hidden, and output. The number of hidden layers 1 alone is sufficient to produce output that matches the target [23,24]. So that the network architecture designed for this research is 3 layers (input, hidden, and output) with 7 neurons for the input layer, 3 neurons for the hidden layer, and 1 neuron for the output layer [29].

Initialization of weights and bias is given before carrying out the training process of an existing network system in an artificial neural network. This initial initialization weight is given to each neuron that is interconnected. This weight factor defines the relationship between neurons with one another, where the greater the weight value of a relationship between neurons, the more important the relationship between the two neurons. Initialization of initial weights and bias is done randomly. Table III show the initial weights and bias of the input layer against the hidden layer and Table IV show initial weights and bias on the hidden layer to the output layer [25,26].

Training with the backpropagation algorithm is an algorithm with a supervised learning process. After obtaining the initial initialization weight and bias, a training process will be carried out on a network that has been designed for architecture and the parameters that have been determined using the training data that has been determined; the percentage is 80% of the total data. There are three phases of the training process for the backpropagation algorithm, namely feedforward, backpropagation, and weight modification. Feed forward (feedforward) at this stage, an error will be searched for the output in the forward direction (forward). Each input unit Xi (i: 1, ..., n) will receive the input signal xi then pass it to the hidden unit. Then all the weighted input signals will be calculated including the bias in each hidden unit Zj (h: 1, ..., p). The following is the input signal to the weighted hidden layer, including its bias.

After the hidden layer receives a weighted input signal (Table V) including the bias, the output signal will be calculated in the hidden layer from the input signal using the activation function. The following is the output signal on the Hidden Layer.

Then the output signal in the hidden layer in Table VI will play a role as an input signal in the output layer. The input signal will be forwarded to the output layer with the weights and bias hidden in the hidden layer against the output layer for each output unit.

After the output layer receives the input signal (Table VII) from the hidden layer, the input signal will be activated using the activation function. Table VIII shows output signals at the output layer.

Once activated in the output layer, the output will be distributed to all units in the output layer.

To calculate the error between the input target and the output generated by the network with the result of the error factor () of -0.022507221. The error factor will be used to correct the weight (Wjk) and bias (W0k) in the lower layer (hidden layer) with the learning rate (α). The results of the weight improvements in the hidden layer to the output layer are as follows. Table IX show correction of weights and bias in the hidden layer ot the output layer.

Each hidden unit Zj accepts input delta weights and bias from the layer above it (output layer). The weight and bias delta input will be used to find the error factor in each hidden unit. Table X is the result of calculating the error factor in each hidden unit.

Input from the error factor in the hidden unit such as Table XI will be activated using the activation function with the following results.

After obtaining the error factor that has been activated with the activation function, the error factor will be used to correct or correct the weights and biases in the lower layer, namely the input layer to the hidden layer with calculations as in equation 16. Table XII shows correction of weights and bias in the input layer against the hidden layer, as follows.

TABLE IX. CORRECTION OF WEIGHTS AND BIAS IN THE HIDDEN LAYER OF THE OUTPUT LAYER

The artificial neural network predicts sales volume in the Tokopedia Indonesia marketplace with training data first to find out the accuracy of the network before testing the network. The prediction results using an artificial neural network model obtained using training data.

TABLE XIV. PREDICTION RESULTS OF THE NETWORK MODEL

No	Data To	Actual	Predictions	Time Range (Month)
1	56	78	78	32
2	166	62	61	9
3	218	45	61	13
4	90	73	62	33
5	90	73	63	8
.				
.				
.				
243	28	38	39	17
244	13	87	74	9
245	231	70	64	15

The results of the training data prediction using the network model obtained as shown in Table XIV above in predicting sales volume in the Tokopedia Indonesia marketplace with a span of time in months. Obtained is an accuracy rate of 95.75%. Testing of artificial neural networks with the backpropagation algorithm obtained after calculating the weight until it reaches optimal then testing the network obtained will be carried out. The network will be applied to the test data to determine the network's performance in predicting sales volume on the Tokopedia Indonesia's marketplace. The percentage of test data was 20% of the total data used, namely as many as 57 test data. The following are some of the results of the prediction of sales volume on the Tokopedia Indonesia marketplace using the network obtained [28].

TABLE XV. PREDICTION RESULTS OF TESTING DATA USING A NETWORK MODEL

No	Data To	Actual	Predictions	Time Range (Month)
1	1	77	71	29
2	6	101	56	24
3	75	79	78	14
4	76	56	61	11
5	159	68	79	16
.	.	.	.	
.	.	.	.	
.	.	.	.	
46	175	69	62	29
47	229	62	63	31
48	269	49	63	22

The prediction results from network testing using this test data show the network performance obtained. From the results of the prediction of sales volume in the Tokopedia marketplace with a span of time in months using test data, an accuracy rate of 95.75% is obtained. The network model obtained with the optimal level of accuracy is found when testing the network, so it can be said that the resulting network performance is very good. Regarding the sales volume prediction made, the seller at Tokopedia can provide stock according to the predictions obtained with the time span listed in Table XV, so that the seller can minimize the occurrence of losses and will increase their income [18, 29].

V. CONCLUSION

Based on phenomenon, research question, result and discussion the conclusion as follows:

1) The results of this study indicate that Backpropagation has a good level of accuracy in predicting sales.

2) The Artificial Neural Network method has an adaptive nature, namely the network tries to achieve data stability to achieve the expected output value.

3) The resulting artificial neural network architecture design results consist of three layers which include six neurons in the input layer, three neurons in the hidden layer, and one neuron in the output layer. The parameters used to form the network model include the learning rate with a value of 0.02 and the activation function used is binary sigmoid (logistic).

4) The resulting level of accuracy when testing the obtained network reaches an accuracy rate of 95.75%.

5) The sales forecasting process is to enter the estimated future sales data, to be processed using the backpropagation neural network to produce the desired data.

***Abstract*—Technological developments can encourage children to learn easily and help solve problems that often arise in the learning process. Sunday School students need learning media to make it easier to understand Christian Education. The method used in Sunday Schools still uses conventional methods which include face-to-face teaching and learning in class. This method often faces various challenges such as student's lack of focus. One of the solutions that are proposed in this paper is to design an Android-based learning application that will support the learning process. Application User Interface and User Experience (UI/UX) design will be built based on the Elements of User Experience methodology. The Elements of User Experience method will be used in the analysis and design process to maximize the usability and engagement level of the application. The learning materials will be designed based on Attention, Relevance, Confidence, and Satisfaction (ARCS) framework. ARCS will help the material design process to ensure the clarity and appropriateness of the material. The application will be implemented and tested on students to measure its effectiveness. The application trial has shown a promising improvement especially in student's engagement toward the materials.**

***Keywords*—Christian education; Sunday school; element of user experience; ARCS; android application**

I. Introduction

Christian Education nowadays is built on several objectives such as increasing student's religious knowledge and understanding of the Bible's contents and applying Christian values in their daily life [1]. Christian Education is implemented in many Christian churches through Sunday Schools. Sunday School is a Christian religious education activity intended for children aged 5-15 years and is usually held once a week every Sunday. Christian character is the concern of Christian parents in shaping the character of their children. The standard of Christian character to be achieved is a standard based on the Bible, not based on world philosophy [2]. Sunday school service is usually held in conjunction with the Public Service and is divided into several classes according to age ranges. The purpose of this class division is to adapt the material provided to suit the psychological age of each child. The teaching system in Sunday Schools also faces several problems. In modern and digital times, the teaching methods and media in many Sunday schools are considered to be lagging behind. Most students who are familiar with digital communication media such as cell phones and electronic tablets are more interested in accessing the internet and playing online games than in attending classes and activities in Sunday School. The teaching methods in most Sunday schools still use conventional methods. Teaching and learning activities include the teacher giving and presenting the material in front of the class. Teaching materials are given in written form on whiteboard in front of the class. As a result, many of the children did not pay attention to what the teacher gave because they were considered less attractive and the teachers also did not involve each child to contribute in the teaching and learning process. Sunday Schools are expected to be able to innovate so that the material taught becomes more interesting and relevant for children.

One of the innovations that want to be applied to overcome this problem is through designing a learning application for Sunday School using the Elements of User Experience methodology. The Elements of User Experience is a methodology used to develop a user interface and user experience (UI/UX) system which is divided into 5 stages, including Strategy, Scope, Structure, Skeleton, and Surface [3]. After the application is implemented, the next step is to measure the level of usability of the application and how effective it supports the learning process in Sunday Schools. This research is expected to provide solutions to overcome the problems faced in the learning process in most Sunday schools.

Several studies have been conducted in the application development process using the Elements of User Experience methodology. Most of the existing studies focus more on general-purpose applications and very few focus on educational applications especially for Christian Religious Education for Children. This research is expected to contribute in particular to combining application development methods with educational methods for children.

II. Previous Study

Several studies have been conducted based on the Elements of User Experience methodology. This method can be applied in web and mobile-based applications and several studies have tried to apply it. Ecelbarger, Hamlin, and McMcGrath have done this in the case of a web-based scheduling application [4]. Tong, Cui, and Chen have applied it to a more interactive mobile application like museum simulations [5]. Both studies have reported better results in terms of user experience. However, the application of this method is still very limited for educational-purpose applications. The biggest challenge in designing education-based applications is how to ensure that the applications made can increase the engagement of the learning process being carried out. Similar research was conducted by Nurul and Norasykin to develop a computer-programming learning application but it is more aimed at an adult audience with a simple and minimalistic user interface [6].

This research has its challenges because it has an audience of children aged 5-10 years who have a different application development approach to the adult audience. Several phases have to be modified to make a better approach to the problem. One of the main modifications is to combine the ARCS methodology at the phase of determining the application structure [7]. ARCS serves to ensure that the teaching materials provided are suitable for the intended learning abilities of the students.

III. Methodology

A. Elements of User Experience

The Elements of User Experience consists of five stages and starts from the lowest stage, Strategy stage. This stage is used to collect data related to system development that will be carried out to get product objectives and user needs. This stage determines the purpose of the application being made and the specific needs of Sunday School children in order to be able to design an appropriate system and suitable to user needs.

The second stage, Scope stage aims to determine the scope of the system you want to build and clearly define the system requirements. The strategy to be used is to design system requirements in accordance with the results of the questionnaire that was implemented in the previous stage.

The Structure stage contains a systematic design for how the system will run and how the system responds to users. The method used to describe interactions with users is to use a use-case diagram to explain in detail how users interact with the system being built, and for the information storage process, ER Diagram is used as an explanation of how the information will be stored.

The Skeleton stage is the stage for designing a system prototype to provide an overview of how the system works. The method will use mockups to explain how the existing display in the application will be developed.

The Surface stage is the final stage for designing the final result of the application being built. The entire process can be seen in Fig. 1.

B. Design Process

The stage of making the application structure provides functional description of how the system works. The functional description of the system is manifested in the form of a simple interface design of an application mockup. Mockups are structured models or replicas that describe the appearance of the application and the flow of application functions. An example of the application mockup can be seen in Fig. 2.

C. Implementation Process

At the implementation stage, mockups that were developed in the previous stage will begin to be built using the selected technology, React Native and MySQL database. React Native is a framework that allows mobile application development using the JavaScript programming language [8].

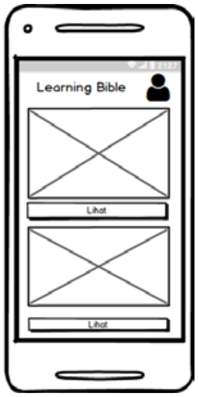

Fig. 2. Application Mockup.

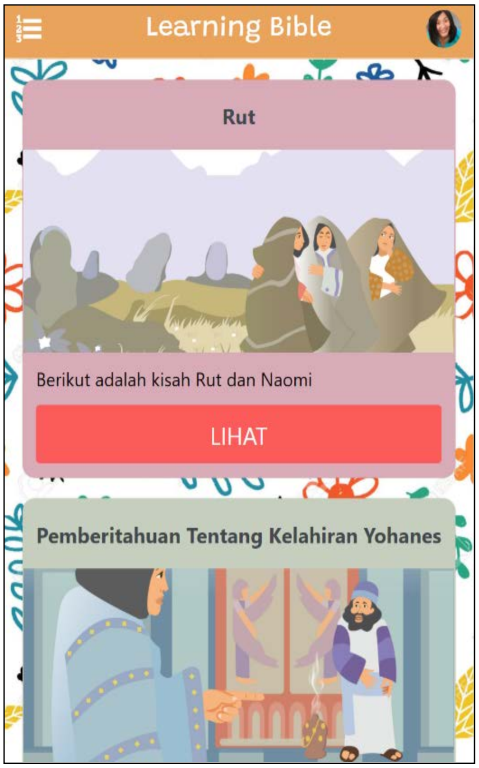
User interface implementation is the final stage of The Elements of User Experience methodology. The mockup created in the previous process will be manifested as a user interface and becomes the blueprint of the actual application display development process. The existing application is designed to be as simple and attractive as possible, with relatively bright colors, considering the relatively young age range of users. An example of a user interface that has been developed can be seen in Fig. 3.



Berikut adalah kisah Rut dan Naomi

Pemberitahuan Tentang Kelahiran Yohanes

Fig. 3. Application user Interface.

D. Testing Process

This test was carried out at the Toraja Church in Samarinda, East Kalimantan. Tests will be carried out on students of the Toraja Church Sunday School who are in the age range of 5-10 years. Sunday School students will also be accompanied by teachers during the testing process. The method used in testing is the System Usability Scale (SUS) [9].

SUS is a method of testing the usability of an application containing 10 questions with an assessment range between 1 and 5 [10]. The SUS list of questions contains questions to determine whether the application is easy enough to use by its designated users, especially children. A list of SUS questions can be seen in Table I.

TABLE I. SUS QUESTIONS

No	Questions
1	I think I will use this application often
2	I think this application is too complicated but can be simplified
3	I think this application is easy to use
4	I think I need help from a technical person to be able to use this application
5	I found that there are various features that are well integrated in this application
7	I think there are many things that are inconsistent with this application
8	I think the majority of users will be able to learn this application quickly
9	I find this application very impractical to use
10	I really believe that I can use this application

After the user has filled in, the method for calculating the SUS score is as follows:

- For each odd question, the score given by the user must be reduced by 1 (formula: X-1).
- For each even question, subtract the value given by the user from 5 (formula: 5-X).
- The value obtained from each question is then added and multiplied by 2.5.
- The result is a SUS score and should be in the 0-100 range General guidelines on the interpretation of SUS scores can be seen in Table II.

TABLE II. SUS GUIDELINES

SUS Score	Grade	Predicate
> 80,3	A	Excellent
68 – 80,3	B	Good
68	C	Okay
51 – 68	D	Poor
< 51	E	Awful

IV. RESULTS AND DISCUSSION

After the application design process, the application was tested on 24 user respondents. The trial was carried out for 30 minutes for each respondent where 20-25 minutes was the application trial stage and 5-10 minutes was used to fill out the questionnaire. The questionnaire was designed based on the System Usability Scale (SUS) method which has 10 questions. Each respondent was also accompanied by a Sunday School teacher to assist in the testing process and filling out the questionnaire. The results of the application trial can be seen in Table III.

TABLE III. SUS GUIDELINES

QUESTIONS	Score Given by User Respondents				
	1	2	3	4	5
I think I will use this application often	1	1	2	16	4
I think this application is too complicated but can be simplified	2	16	3	2	1
I think this application is easy to use	0	4	1	17	2
I think I need help from a technical person to be able to use this application	3	15	5	1	0
I found that there are various features that are well integrated in this application	0	1	1	16	6
I think there are many things that are inconsistent with this application	2	16	6	0	0
I think the majority of users will be able to learn this application quickly	0	1	2	16	5
I find this application very impractical to use	4	17	2	1	0
I really believe that I can use this application	0	2	2	16	4
I have to learn many things first before I can use this application	3	17	2	2	0

The trial results were then calculated to obtain a score for each question. For odd questions, the formula used is X-1 where X is the score given by the user. The sum is then divided by 24 (according to the number of respondents). On the other hand, for even questions, the formula used is 5-X. The sum is then divided by 24. The SUS Calculation Results can be seen in Table IV.

TABLE IV. SUS CALCULATION RESULTS

Questions	**SUS Calculations**					**Score**
	1	**2**	**3**	**4**	**5**	
I think I will use this application often	0	1	4	48	16	2,88
I think this application is too complicated but can be simplified	8	48	6	2	0	2,67
I think this application is easy to use	0	4	2	51	8	2,71
I think I need help from a technical person to be able to use this application	12	45	10	1	0	2,83
I found that there are various features that are well integrated in this application	0	1	2	48	24	3,13
I think there are many things that are inconsistent with this application	8	48	12	0	0	2,83
I think the majority of users will be able to learn this application quickly	0	1	4	48	20	3,04
I find this application very impractical to use	16	51	4	1	0	3,00
I really believe that I can use this application	0	2	4	48	16	2,92
I have to learn many things first before I can use this application	12	51	4	2	0	2,88
Final SUS Score (Total score x 2.5)						72,19

The score obtained from each question is then added and multiplied by the constant 2.5 and the final SUS score is 72.19. The score based on Table II shows an outcome with a good predicate. A good SUS score indicates an increase in the ease of the learning process.

V. CONCLUSION

The Elements of User Experience allows the development of an Android-based application that suits the needs of users, especially students in the age range of 5 to 10 years old. The testing result using the System Usability Scale (SUS) method produces a final value of 72.19. Based on the SUS score guidelines, the score shows a good result that indicates an increase in the ease of the learning process.

These results also show that the Element of User Experience method can be applied to the development of mobile-based applications for educational purposes. This method will increase the usability of the application which is a major factor for its designated users.

Further research can be carried out using the same method but in different cases and age ranges. This study is focused on target users with an age range between 5-10 years old. Research at different age ranges will provide useful information on how effective this method is at younger or older ages.

***Abstract*—This study proposed a new method in gait acquisition and analysis for autistic children based on the markerless technique versus the gold standard marker-based technique. Here, the gait acquisition stage is conducted using a depth camera with a customizable skeleton tracking function that is the Microsoft Kinect sensor for recording the walking gait trials of the 23 children with autism spectrum disorder (ASD) and 30 typically healthy developing (TD) children. Next, the Kinect depth sensor outputs information is translated into kinematic gait features. Further, analysis and evaluation are done specifically the kinematic angles of the hip, knee, and ankle in analyzing and visualizing the pattern of the plots versus the kinematic plots acquired from the marker-based that is the Vicon motion system gait technique. In addition, these kinematic angles are also validated using the statistical method namely the Analysis of Variance (ANOVA). Results showed that the ρ-values are insignificant for all angles upon computing both the intra-group and inter-group normalization. Hence, these findings have proven that the proposed markerless-based gait technique is indeed apt to be used as a new alternative markerless method for gait analysis of ASD children.**

***Keywords*—Autism spectrum disorder (ASD); kinematic; marker-based; markerless-based; gait analysis**

I. Introduction

Autism Spectrum Disorder (ASD) is a development disorder that can be characterized by several difficulties such as in the learning process, communication, as well as social skills [1]. Note that the deficiency can be seen in early childhood, for instance as early as two years old [2] & [3]. Recently, there has been a growth in the literature regarding unbalanced and sensory disturbances, especially during walking for the ASD children [4], [5] & [6]. Due to the sensory conflicts, researchers face challenges in performing gait assessments to further provide suitable care and treatment [7]. On top of that, ASD children are found to face more challenges in receiving both the treatment and care as compared to other children with developmental delays, especially the requirement for these children to be examined in an unfamiliar testing environment [7], [8] & [9]. Here, gait analysis involving ASD children is indeed vital. This is because reliable gait information will help determine the level of deficit specificity as the evaluation tools [5].

II. Related Work

There are two categories of gait techniques namely the marker-based technique and markerless-based technique. The marker-based technique includes an optoelectronic system with synchronization between the camera(s) and the system. This system works by tracking the movement through an optical sensor (infrared camera) by identifying the position of the markers attached to the body or object followed by post-processing via specialized software [10]. This technique also offered an accurate three-dimensional (3D) model and is normally performed inside the laboratory [10] & [11]. Moreover, the position of the markers must properly adhere according to the system's template to produce accurate gait data and analysis [12]. For example, Hasan et al. [13] has placed 35 retro-reflective markers on the ASD and typically healthy developing (TD) subject’s body to analyze the gait pattern from two groups whilst, Eggleston et al. [14] used 19 retro-reflective markers to perform analysis of gait symmetry specifically at the lower body during the over-ground walking for the ASD children.

On the other hand, researchers attempt to overcome the limitation from the marker-based techniques with marker-free or markerless gait techniques and thus giving greater freedom of movement to the users [15]. This technique offers a low-cost system as compared to the marker-based technique [16]. The analysis for marker-less technique is based on the movement analysis specifically the subject’s silhouette in contrast to the background [17]. Thus, markerless requires post-processing analysis to enhance the appearance of the silhouette or to translate the movements into a three-dimensional (3D) coordinate point that can be mapped by the computer [17] & [18]. For example, Vilensky et al. [19] used two high-speed cameras, with one camera was placed perpendicularly with the walking track while the other camera was facing the track to measure gait disturbance between the normal and autistic children at the hip, knee, and ankle joints. Meanwhile, Zakaria et al. [20] performed ASD gait classification based on the calculated distance between joints captured by the depth camera.

In another study, Al-Jubouri et al. [21] classify full-body movement of the ASD and normal children based on the four-stage approaches which are augmentation, feature extraction, dimension reduction, and rough set. Based on previous researches, it was found that there are not many studies conducted related to the gait features using the markerless-based technique as reported in [22] & [23]. On top of that, there is a need to validate and evaluate the markerless-based features to provide an accurate analysis and evaluation method [24] that further can be used as the evaluation tools for ASD [5]. Earlier, the validity of the Kinect sensor was compared with the Vicon system as reported by Abiddin et al. [25]. The validity has been measured for the assessment of postural control based on several different types of movements. Here, selected body points from Kinect were imposed with the marker trajectories from Vicon to measure the outcome of anatomical landmark displacements or changes in angle relative to the ground [26]. Based on the Pearson correlation, the r-values obtained were greater than 0.90 for the majority of measurements as reported in [26]. In a different study, the intra-class (ICC) and Pearson analysis (r-value) of the vertical displacement of the knee marker for Parkinson Disease (PD) patients obtained using the Vicon system and Kinect sensor were compared and it was found that both techniques achieved ICC and r greater than 0.9 for walking on the same spot [27]. On the other hand, Cocchi et al. [28] have estimated the sagittal joints kinematics of children with cerebral palsy as well. In this study, the validity of the marker-less kinematic features was verified by comparing the markerless gait features with the marker-based gait features and results showed that the differences were heavily affected by the presence of the offset attained at the mean values of the joint kinematics. However, upon removing the angular offsets, the Pearson correlation specifically the r-values obtained were between 0.8 and 1, which indicated a good result [28]. To the extent of our knowledge and based on findings from previous studies, there is no formal study that has been done related to evaluation and validation for ASD using the markerless gait feature. Therefore, this study aims to evaluate and validate the kinematic gait features of both ASD and TD groups using a viable method like the Kinect sensor and the gold standard Vicon gait system. The use of the markerless-based gait technique can be of benefit to ASD children since most of these children often confront physical challenges such as lack of focus and anxiety during the laboratory gait trials acquisition and experiment.

III. Methodology

This section elaborated in detail the method used and the overall process methodology in this study. The experiment was conducted in the Human Motion and Gait Analysis (HMGA) Premier Laboratory of Universiti Teknologi MARA (UiTM), Shah Alam, Selangor. In this study, data acquisition consists of 23 ASD and 30 TD children. Prior to this study, parents were given an information sheet that needs to be completed in the Consent Form based on recommendation and approval by UiTM Shah Alam Ethics Committee.

The mean and standard deviation (SD) of the subjects is tabulated as in Table I. The ASD children have a mean age, height, and body mass of 8.391 (0.396) years, 1.267 (0.028) m, and 32.957 (3.485) kg accordingly. Meanwhile, the TD children have a mean age, height, and body mass of 9.021 (0.319) years, 1.316 (0.025) m, and 32.493 (1.991) kg, respectively.

For the laboratory layout, the HMGA Laboratory has an 8.3-meter wooden walkway with two force plates embedded at the center of the walkway as depicted in Fig. 1. Two digital video cameras which are installed on tripods were placed perpendicularly to one another for recording the walking trials from the side and front views as the subject walk along the walkway. In addition, all the infrared (IR) cameras of the Vicon System were wall-mounted approximately 2.5 meters above the floor level to ensure that the capability of the volume area to be captured at the center of the lab based on the length, width, and height of 4 meters, 3 meters, and 2 meters respectively. Meanwhile, the Kinect sensor is placed on a stand located 0.5 meters in height from the floor and is facing the walking direction, with a working range between 1.2 and 3.5 meters view from the camera at 57° horizontal wide and a vertical view of 43°. For this laboratory setup, the walking direction started at the point “A” and finished at the point marked as “B”.

A. Data Acquisition

For the data acquisition stage, a depth camera namely the Microsoft Kinect camera is used as a motion-sensing device for the markerless-based gait technique. The camera is equipped with a depth sensor, Red-Green-Blue (RGB) camera, microphones, and a tilt motor to provide full-body motion sensing for 20 primary body landmarks or coordinates. In addition, this device works at a frequency of 30 Hz. The IR depth sensor gives the Kinect its depth measuring capabilities. The emitter emits infrared light beams and the depth sensor reads the IR beams reflected to the sensor. The reflected beams are converted into depth information measuring the distance between the body and the sensor within its capture volume with a resolution of 640×480 to acquire the skeletal data. On the other hand, Vicon Motion System is used as a motion-sensing for the marker-based gait technique and also as the gold standard to establish the accuracy of the Kinect. Refer to Fig. 1, the Vicon system is equipped with eight optical cameras labeled as C1 – C8 (MX T-Series camera), wall-mounted, and operated at 100Hz. This Vicon system is also integrated with two force plates, a host computer is installed with the Vicon Nexus 1.8.5 software, and two digital video cameras namely DV1 and DV2.

TABLE I. SUBJECTS DISTRIBUTIONS

Items	Mean (SD)	
	ASD Group	TD Group
Gender	21 Male & 2 Female	14 Male & 16 Female
Age (year)	8.391 (0.396)	9.021 (0.319)
Height (m)	1.267 (0.028)	1.316 (0.025)
Weight (kg)	32.957 (3.485)	32.493 (1.991)
BMI (kg/m²)	19.509 (1.297)	18.206 (0.644)

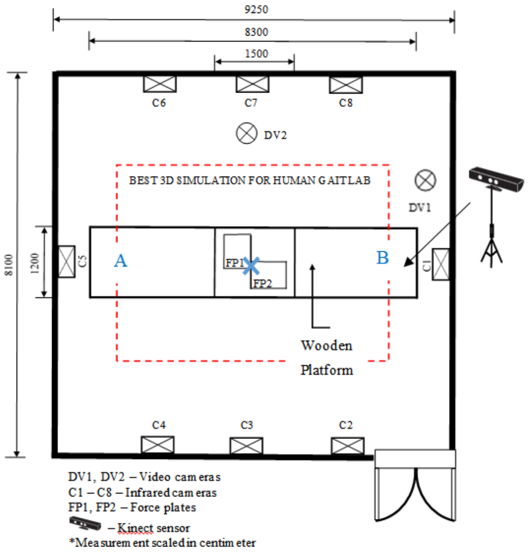

Fig. 1. Schematic Lab Layout.

B. Procedure

For the Vicon system, the subject's preparation was done before the experiment started. A total of 35 retro-reflective markers were attached to the subject‘s body based on the plug-in-gait full-body marker set that further produced the skeleton output or stick-figure model. Here, subjects need to perform a T-pose stand with the complete sets of markers so that the system can recognized and able to create the model based on the markers as in Fig. 2(a) [29]. On the other hand, a skeleton function was used to create the model from the Kinect device as shown in Fig. 2(b) [30].

Further, each subject performed walking trials while being concurrently monitored and captured using both the Kinect sensor and Vicon system. Refer to Fig. 2(c), for the walking task, subjects were required to walk freely barefooted with their comfortable normal speed to ensure their walking behavior is natural, without any assistant or walking aid. The walking task was carried out and repeated several times until all the ten successful trials per subject were completed. A successful trial is defined once the subject can successfully walk from point A to point B as in Fig. 1, without stopping or pausing during the walking trial or assisted by the caretakers. During the experimental, a walking trial is captured and saved simultaneously by both Kinect and Vicon systems.

C. Data Analysis

Data from the systems were screened and time-synchronized visually before data extraction. At this stage, a single gait cycle for the same walking trial session was acquired to represent each subject's walking pattern from both systems. For the data acquired via the Kinect sensor, the angles were derived using the cosine rule. As for the Vicon system, the output angles of the gait were extracted. Further, the kinematic angles from both systems were computed and analyzed.

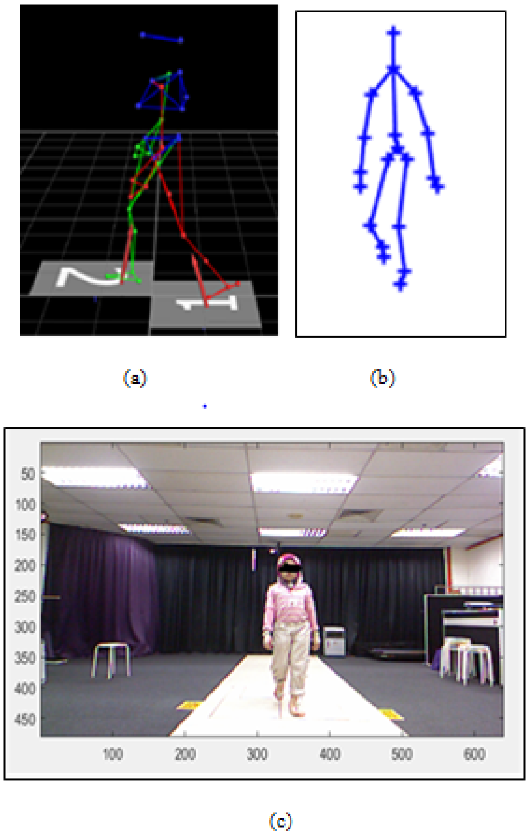

Fig. 2. Example of Stick-Figure Model from (a) Vicon System, (b) Kinect Depth Camera and (c) Subject Performed Walking Trial.

In order to analyze, evaluate and validate the walking gait among these subjects, the interpolation technique is used to standardize the number of frames that is fixed at 30 frames for all trials and further is expressed as the percentage of the gait cycle. Additionally, two types of normalization techniques are implemented before the evaluation of the gait data. Firstly, the intra-group normalization, x_{intra} was calculated to eliminate the influence of the subject‘s gait patterns which are different for each person and are expressed as in Equation (1) [31]. On the other hand, the inter-group normalization, x_{inter} was computed in minimizing the effect of gait patterns among the group as given in Equation (2) [31].

$$x_{intra} = \frac{x_i}{x_{\max(intra\ class)}} \qquad (1)$$

$$x_{inter} = \frac{x_i}{x_{\max(inter\ class)}} \qquad (2)$$

Further, the kinematic plots for the hip, knee, and ankle angles from both Kinect and Vicon systems are visualized based on the plot pattern. The *F*-statistic was used to assess the quality of variances by computing the ratio of variation between the sample means and variation within the sample means. Then, the Analysis of Variance (ANOVA) test set as the significant value, ρ is less than 0.05 ($\rho < 0.05$) with the null hypothesis as the mean values of the kinematic plots are similar for both systems was used to test any mean differences in all angles. Here, the mean differences indicated that the plot is not similar in terms of its form or magnitude.

IV. Experimental Results and Discussion

This section presents the results of the evaluation and validation of the gait data from both the gait techniques utilized in comparing the kinematic plots of the markerless-based gait technique that is from the Kinect sensor and the marker-based gait technique which is from the Vicon system. Fig. 3 showed the kinematic plots of the hip, knee, and ankle angles for the original, intra-group, and inter-group normalization gait data for both the ASD and TD children. The green color line represents the markerless method specifically the Kinect sensor while the magenta color line is for the Vicon system that is the marker-based technique. Further, the ANOVA results for all the kinematic plots of Fig. 3 are tabulated in Table II.

Firstly, the plots based on the original gait data similar shapes are visualized for the knee angles of the walking gait generated from both techniques in the ASD as well as the TD group. As for the plots for the hip angle, the plots are also similar however the amplitude values between the two gait techniques differ for both groups. The same goes for the ankle angle plots which are not similar using both techniques for the ASD and TD groups. Based on the original gait data, the differences in the knee angles and ankle angles of the kinematic plots are supported by the statistical results computed as tabulated in Table II. For the ASD group, the ANOVA value for *F* is 577.55 with ρ equals to 0.00 for the hip angles whilst the TD group with *F*=375.09. As for the ankle angles, the computed *F* values are 84.450 and 81.70 respectively for both the ASD and TD groups. These values resembled significant differences for the knee and ankle angles using the markerless and marker-based techniques for both the ASD and TD groups and matched results of the visualized plots. This showed that the hip and ankle angles owned large group means relative to the within-group variability as compared to the knee angle. Next, for the knee angles with *F*=1.443 and ρ is equal to 0.23 for the ASD group and with *F*=1.26 and ρ=0.23 which is larger than 0.05 resembled that there is no significant difference between both techniques for the ASD and TD groups. These values supported and proved that the visualization of both plots also showed similar patterns. Recall that this study is to prove that there are no significant differences amongst the kinematic features with the ρ-values must be greater than 0.05 since similar plots showed that the proposed markerless-based technique is similar to the gold standard which is the marker-based gait technique utilized.

Furthermore, the intra-group and inter-group normalization were computed to analyze and eliminate data redundancy thus maintains the same information that adheres to a common standard approach for datasets. All three angles of the hip, knee, and ankle of the kinematic plots are as plotted in Fig. 3 for both intra-group and inter-group normalization. As explained earlier, for the hip angle the magnitude gaps differ, however upon normalization, the differences between the magnitudes are significantly reduced especially towards the end of the gait cycle in both the ASD and TD groups. Next, the plots revealed that the knee flexion during the swing phase (60% to 100% of the gait cycle) has improved. However, there is a difference in flexion and extension that existed during initial contact (0% of the gait cycle) between the ASD and TD groups for the knee angle using the proposed markerless-based approach. As for the ankle angle plots, the normalization process failed to enhance or improve the plots. The only improvement based on the visualization of these plots is the similar shapes of the ankle dorsiflexion and ankle plantarflexion during the stance phase that is between 0% to 60% of the gait cycle and towards the end of the gait cycle. The ANOVA results for the intra-group and inter-group normalization showed that the mean of the hip, knee, and ankle angles for both gait techniques is similar for both groups, which means that there are no significant differences in the mean for the respective angles. The *F*-statistic revealed a small ratio for the hip, knee and ankle angles with *F*=0.00 respectively. Once again, the small *F*-value indicates that the group means are similar with minimal variability. Also, the ρ-value that evaluated the mean differences showed that there were no significant mean differences for the hip, knee, and ankle angles since the ρ-value was greater than 0.05.

TABLE II. ANOVA Results using the Marker-based Technique Versus the Proposed Markerless-based for both ASD and TD Groups using the Original Gait Features, Intra-group and Inter-Group Normalization

Item	Kinematic Gait Parameters	ASD		TD	
		F	**ρ**	***F***	**ρ**
Original Gait Data	Hip	577.55	0.00	375.09	0.00
	Knee	1.443	0.23	1.26	0.26
	Ankle	84.45	0.00	81.70	0.00
Intra-Group Normalization	Hip	0.00	1.00	0.00	1.00
	Knee	0.00	1.00	0.00	1.00
	Ankle	0.00	1.00	0.00	1.00
Inter-Group Normalization	Hip	0.00	1.00	0.00	1.00
	Knee	0.00	1.00	0.00	1.00
	Ankle	0.00	1.00	0.00	1.00

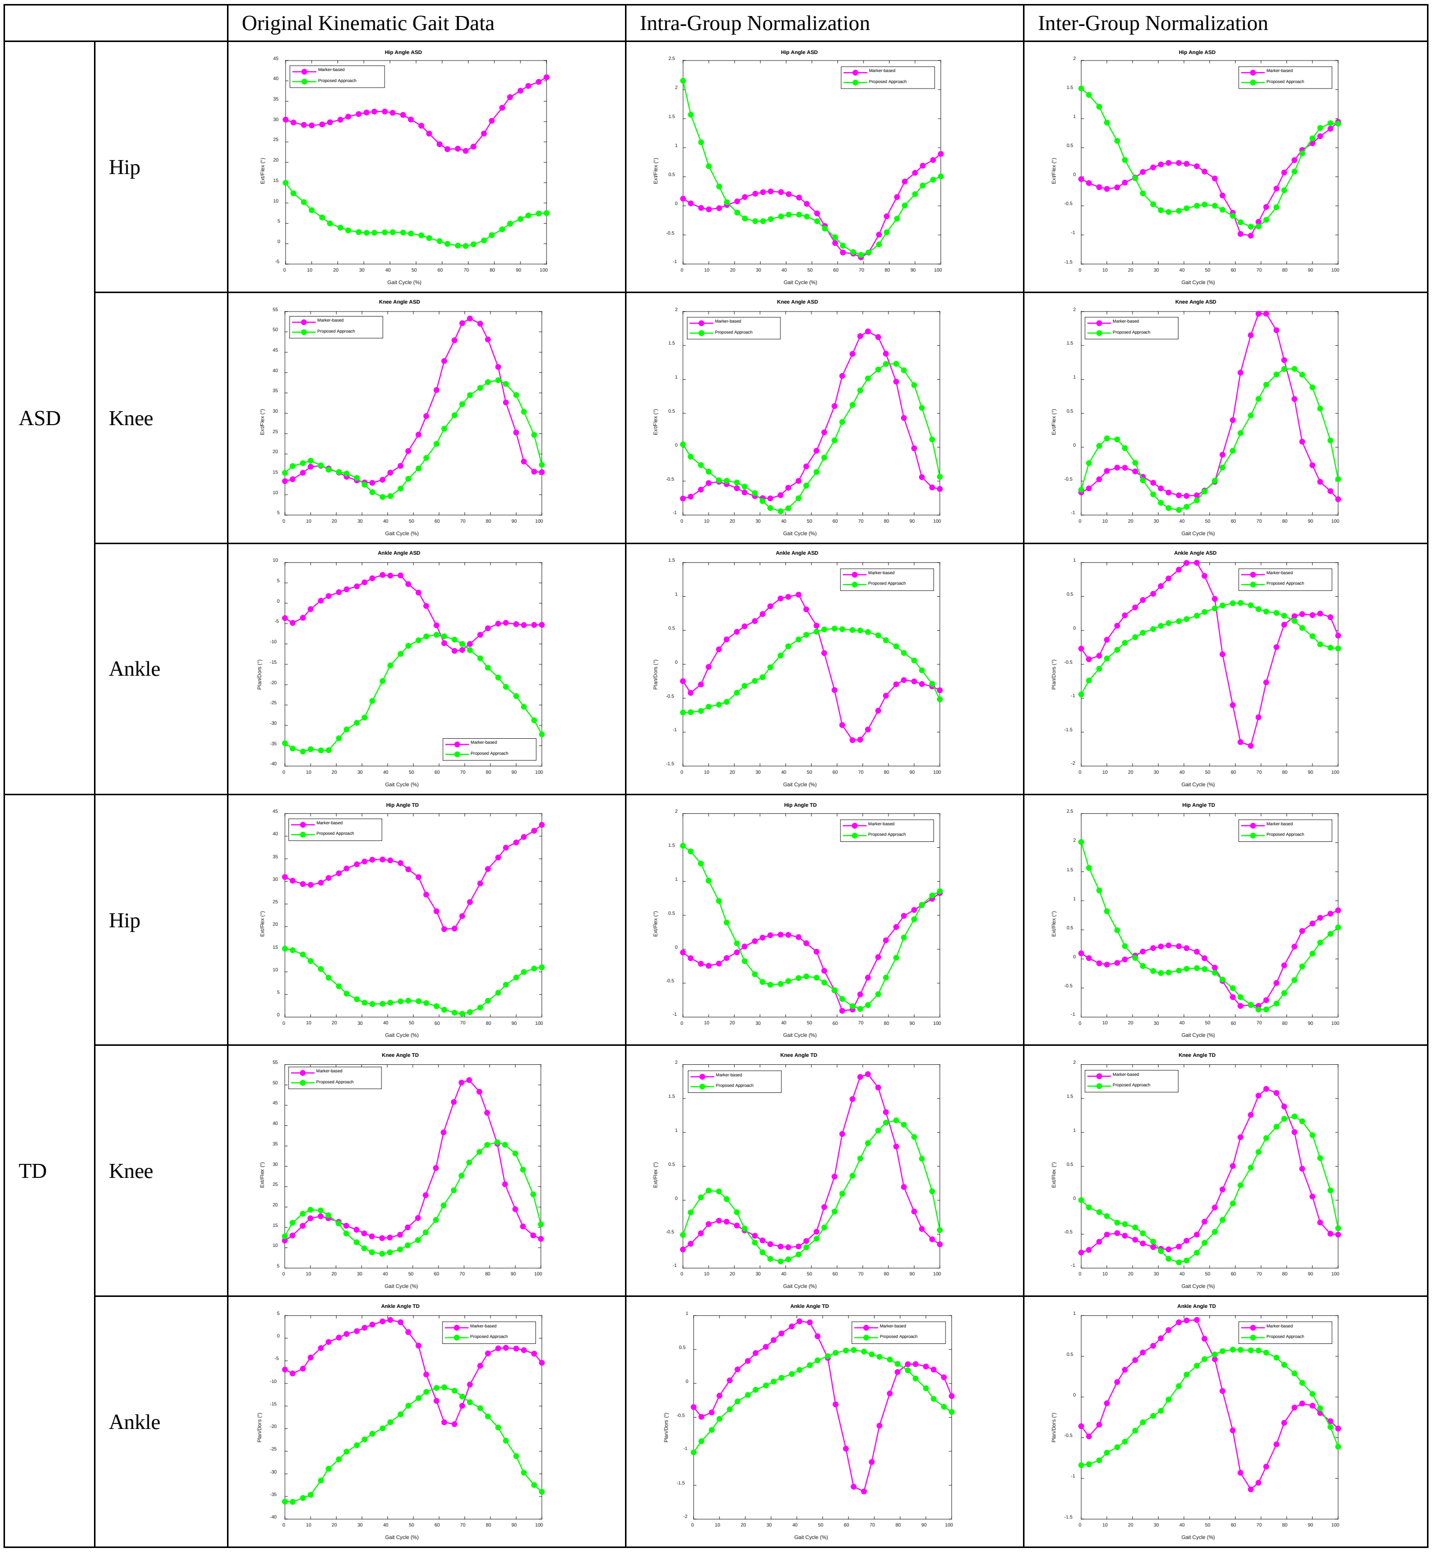

Fig. 3. Visualization of the Plot Pattern of the Kinematic Gait Angels using the Marker-based Technique (Magenta Color Line) Versus the Proposed Markerless-based Technique (Green Color Line) for both ASD and TD Groups using the Original Gait Features, Intra-Group, and Inter-Group Normalization.

VI. Conclusion

In conclusion, an evaluation and validation of gait data from the Vicon system versus the proposed markerless-based model are analyzed. Kinematic features namely the hip, knee, and ankle angles are evaluated based on visualization of the angles plots as further verified based on ANOVA. From the plots, the hip, and ankle angles showed differences between the two gait techniques for both ASD and TD groups. Further, the ANOVA test was performed to measure the significance of these angles between the marker-based and the proposed markerless approach.

The ANOVA results showed that there are significant differences for both the hip and ankle angles and these findings are in accordance based on the visualization of these plots. Further, the intra-group and inter-group normalizations are performed to minimize the data redundancy as well as maintaining similar information of the kinematic plots for both the marker-based and the proposed markerless technique. Upon normalization, the kinematic plots for the hip, knee, and ankle angles of both techniques showed similar shapes. With the ρ equals 1, hence these confirmed that there are no significant differences between these plots of gait features upon normalization. This showed that the proposed markerless-based gait technique is indeed suitable and potentially can be used as gait analysis for ASD children. The proposed markerless method is easy to set up, non-intrusive and portable as well. The next stage of work will include the use of the proposed markerless-based technique for Parkinson's disease (PD) or cerebral palsy (CP). This new proposed markerless gait approach could further assist in developing more suitable gait analysis intervention programs for autistic children and offer great research opportunities related to pathological gait.

***Abstract*—The robustness of the security algorithm is one of the most important properties that determines how difficult it is to break it. Increasing the robustness of the algorithm directly affects the degree of secrecy when it is used for confidential transmission. The paper analyzes the steganographic algorithm Least Significant Bit, represents a method of counteracting the algorithm of the "visual attack" and statistical methods used against stego-containers generated using the LSB algorithm. To prove the increase in resistance, the study used the PSNR index, Chi-square test. The proposed technique involves the use of a uniform distribution and compression method. The paper presents the results of computer experiments demonstrating the effectiveness of the proposed technique.**

Keywords—Steganography; steganalysis; visual attack; least significant bit

I. Introduction

Steganography is the science of methods of transferring information or storing it, in which the fact of transfer or storage is hidden [1]. Currently, such directions as digital steganography (hiding information in digital objects) and network steganography (hiding information using the features of network protocols) are developing. Modern steganographic systems use steganography and cryptography algorithms together in order to not only encrypt and protect a message [2-4], but also to transmit it secretly.

Some steganographic algorithms have become widespread, such as algorithms for applying digital watermarks, which used to embed an image into an image and provide protection against illegal copying or dissemination of information [5]. The most famous and simple steganography algorithms have obvious drawbacks, for example, replacing the color of the hidden message with the background color, such a substitution is easy to notice and reveal the hidden data [6-7]. The book cipher (or its modifications, for example, the book cipher of Aeneas), in which each character of the secret message is replaced by a pointer (for example, the number of a row, column or table), has several significant disadvantages: transmission of small volumes of a secret message; storage and transmission of the key, which can be used to collect a "scattered" message from the so-called stego-container, weak degree of security [8]. Methods of hiding secret information in special fields of attributes of files of various formats or in service fields of network packets are also popular, but these methods have a significant limitation on the amount of information transmitted per unit of time [9-10]. Along with these methods, steganography includes various algorithms are based on distortion (introduction of changes into the structure of a digital object), statistical methods of concealment [11] and structural methods.

Specialized attacks are carried out on steganographic algorithms, the main purpose of which is to reveal the presence of an embedded secret message. The statistical method has become widespread, which makes it possible to determine the characteristic distortions both in the file structure and in the semantic information of a digital object [12]. Attacks are usually directed against specific vulnerabilities of a particular steganographic algorithm [13]. When hiding information in the service part of files or transmitted packets, an attacker can compare with reference values or empty containers to identify potential corruption [14-15]. In modern steganalysis, separate areas of investigation to identify hidden messages have been formed.

Reliable masking algorithms are being developing to counter attacks, for example, one of them hides secret information during a "handshake" when using the TCP data transfer protocol in a response packet [16], but this method is describing theoretically, is implementing only as part of the study and has small bandwidth.

Within the framework of this work, a technique makes it possible to reduce the efficiency of steganalysis methods of the "visual attack" type. The Least Significant Bit (LSB) method [17-18] was chosen as the most illustrative example of a steganographic algorithm. LSB is an efficient algorithm used to embed information into container files [19-20]. A hypothesis was put forward, according to which the algorithm can become more resistant to the mentioned types of attacks if the modified bytes are uniformly distributed in the container image. However, when using a uniform distribution of a large number of bytes, a large number of zones with a high density of modified bytes will inevitably appear [21-22]. Lossless compression methods are using to reduce the number of modified bytes.

II. Steganographic Algorithm least Significant Bit

LSB (Least Significant Bit) is a method of embedding a secret message into an image. The algorithm includes the following steps:

- Conversion of secret message into a binary code, followed by splitting into separate bits or into blocks of two bits.

- Replacing the last bit or two bits in the bytes of the container image with the corresponding number of bits of the transmitted secret message.

For example, the binary form of the secret message looks like this: 101101. We form groups of two bits: 10, 11, 01. We get three groups, the number of modified image bytes is equal to the number of groups, and therefore, the last two bits in the three bytes will be replaced in the container image. Suppose the bytes of the container image look like this: ... 10111010 11010001 10000011 ..., the last two bits in the given bytes will be replaced with bits from the previously received groups. The transformation will look like this: the set 10111010 11010001 10000011 goes to 10111010 11010011 10000001. This transformation leads to changes that a person does not perceive during normal visual observation.

Such conversions can be carried out with graphic file formats that do not compress data (BMP, PNG), otherwise the hidden information will be lost. The algorithm described above is also applicable to the WAV format [23], similar conversions can be performed with video clips and sound files.

For containers, either a unique digital object is often used, or images and sound files that are distributed over the network in a variety of ways. If you select objects that are in the public domain in the most common variant, then an attacker will be able to compare the source file with the container and reveal secret information.

III. Methods of Detecting the Fact of Transfer of Information

There are a number of attacks on image containers that reveal the presence of a hidden message. One of the common attack methods is "visual attack" [24-25]. The essence of the attack is the formation of new images from the low-order bits of the original image with amplification of values (maximization), an example of an image without hiding is shown in Fig. 1(a). At the same time, areas with a high data density usually appear on the images that are generated on the basis of stego-container files with an existing hidden message, as can be seen in Fig. 1(b). The embedded message is located in the areas of visual distortion.

When using a small container image (242 976 bytes), the result of a visual attack is more apparent. For example, when the container is filled by 30% (Fig. 2(b)), one can see a characteristic difference from the result of a visual attack on the original image (Fig. 2(a)).

To identify hidden information usually use method that named the Chi-square statistical test [26]. In steganalysis, the use of the criterion, which based on the fact that two neighboring colors (colors are adjacent if they are different only in the least significant bits) differ significantly in the number of points relative to the untransformed image [27]. Fig. 3(a) shows a chi-square rendering of an original container image. The clear difference between the rendering results of the original image and the image processed with classical LSB is shown in Fig. 3(b).

Because both steganalytical methods are based on identifying dependencies throughout the digital object, the research was aimed at finding modifications to the algorithm that would allow disguising the introduction of distortions when placing a steganographic message under random distortions or noise. To do this, it was necessary to achieve two parameters of the algorithm: to increase the coverage of the involved parts of the container, but at the same time to reduce the total number of modified bits. To increase the coverage of the involved areas of the container, a uniform distribution of modified bytes in the container image was used (Fig. 3(c)). This solution only partially improves the overall picture when performing visual attacks, as well as Chi-square analysis. To reduce the number of modified bytes, it was decided to use lossless compression methods.

(b)
(c)

Fig. 3. Chi-Square Visualization: (a) – The Result of the Analysis of the Original Image; (b) – The Result of the Analysis of the Standard LSB; (c) - is the Result of LSB Analysis using a Substitution Table.

Studies have shown that for small messages, the size of the container has practically no effect on the result of the attacks described above. In other words, the attacks themselves are ineffective in finding low-capacity messages. The study of the results of the modified steganographic algorithm was tested on examples of hiding medium and large messages in the corresponding containers.

IV. Analysis of Compression Algorithms

To solve the problem of compression, several methods, which perform lossless data compression [28], have been considered. All the considered compression algorithms were implemented in the C ++ programming language and tested on several samples of medium and large texts.

Run-length encoding (RLE) [29]: An easy-to-implement algorithm with the best, average and worst compression ratios equal to 1/32, 1/2, 2/1. Test #1 results: text 608 characters long and 1115 bytes in size was converted to 1135 bytes. Test #2 results: a text of 3040 characters long and 5575 bytes in size was converted to 5669 bytes. Test #3 results: text 9120 characters long and 16725 bytes in size was converted to 17028 bytes. The increase in volume is due to the construction of key-value pairs. With a small number of repetitive sequences, the size of the original file will grow. This algorithm shows satisfactory results with texts containing repetitive sequences.

Compression of information based on binary coding trees (Huffman compression) [30]. Test #1 results: text 608 characters long and 1115 bytes in size was converted to 1321 bytes. Test #2 results: a text of 3040 characters long and 5575 bytes in size was converted to 3499 bytes. Test #3 results: text 9120 characters long and 16725 bytes in size were converted to 8944 bytes. With an increase in the volume of text, the compression ratio increases, but the work of the algorithm with medium-sized texts does not give positive results. This specificity is due to the implementation of the algorithm based on binary trees.

Sliding window compression (LZ77) [31]. Test #1 results: text 608 characters long and 1115 bytes in size were converted to 704 bytes. Test #2 results: text 3040 characters long and 5575 bytes in size were converted to 792 bytes. Test #3 results: text 9120 characters long and 16725 bytes in size were converted to 1009 bytes.

According to the results of the analysis (Table I) and testing of the methods, the LZ77 method is the most optimal for solving the problem of compressing medium and large texts.

TABLE I. COMPARISON OF THE RESULTS OF THE COMPRESSION ALGORITHMS

Compression algorithms	Text No. 1 608 characters, 1115 bytes	Text No. 2 3040 characters, 5575 bytes	Text No. 3 9120 characters, 16725 bytes
RLE	1135 bytes	5669 bytes	17028 bytes
Huffman compression	1321 bytes	3499 bytes	8944 bytes
LZ77	704 bytes	792 bytes	1009 bytes

V. KEY-GENERATED REPLACEMENT TABLE

The use of a uniform distribution of compressed data does not sufficiently improve the robustness of the steganographic algorithm, since any steganographic algorithm has the property of symmetry, in other words, it is possible to extract hidden information performing the reverse actions of hiding. To solve this problem, an analogue of the secret key was introduced. A byte replacement table in the container image is formed based on this key. The number of elements in the table is equal to the number of groups of two bits formed from the binary representation of the compressed bytes of the secret message. The replacement table forms a uniform distribution of the modified bytes in the container image (Fig. 4(b), 5(b)), due to which the embedded compressed message is similar to the noise that occurs in the image when it is projected in different channels. The important thing is that the receiver and the sender generate the table independently of each other, using only a shared secret key that both parties know. In this case, the replacement table for both sides is generated the same. This property is very important because transferring and storing such a large table is difficult, and the key is easy to use.

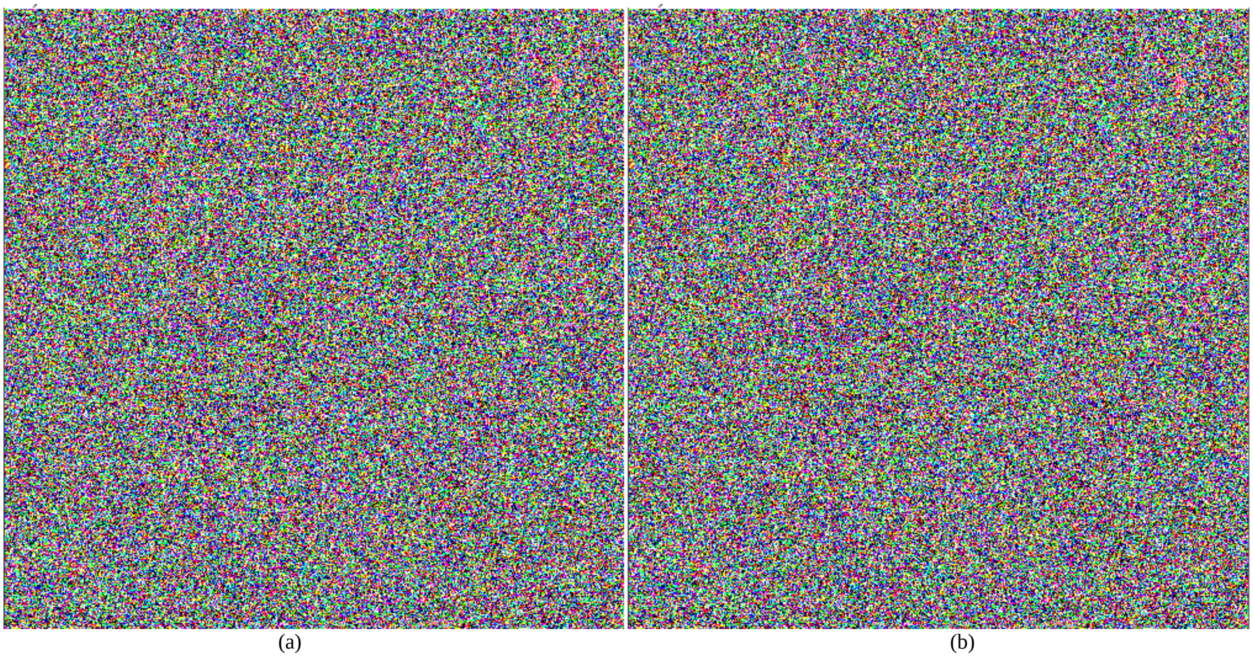

Fig. 4. Visual Attack on Images: (a) – Original Image; (b) – Image Filled with Improved LSB Method.

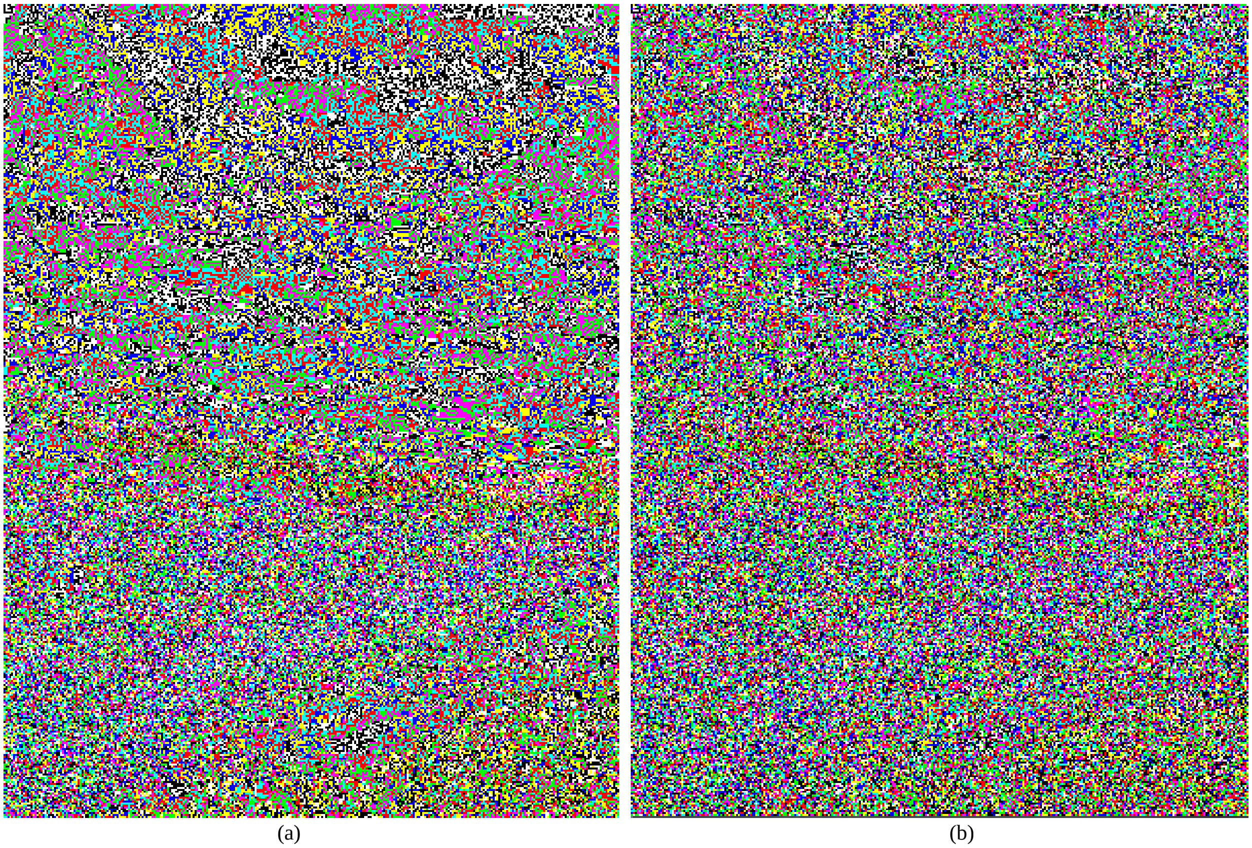

Fig. 5. Visual Attack on Small Images: (a) – Original Image; (b) – Image Filled with Improved LSB Method.

VI. Results of a Computer Experiment

A program that implements an improved version of the LSB hiding method was written in the Python programming language as part of the study. The results of testing this program are shown below. For comparison, the result of executing the original LSB algorithm will be shown. The comparison will be carried out on the same compressed data (the original text is 150 474 characters long, the text size is 150 948 bytes; the compressed text is 58 364 bytes).

VII. The Effectiveness of the Developed Method

For an objective assessment of the improvement of the algorithm, it was decided to use the PSNR (Peak Signal to Noise Ratio) index [32]. The index value indicates the similarity between the two images, and therefore, the higher the value, the more the similarity. When calculating the index, you need to calculate the mean square error (MSE) between the images.

$$MSE = \frac{1}{\mathrm{N}}\sum_{i=1}^{N}(X_i - Y_i)^2$$

X and Y are equal to the values of the original image and the container image, N is the number of pixels in the image.

$$PSNR = 20\log_{10}\frac{MAX}{MSE}$$

MAX is the maximum value that the pixel color can take, equal to 255.

During the study, the index between the original image (Fig. 1(a)) and the image processed with the standard LSB (Fig. 1b) was calculated, which is 57.72449648521831. The index between the original image and the image processed by the improved LSB algorithm (Fig. 4(b)) is 61.39096278660813, which indicates a greater similarity with the original image. There is a slight improvement when calculating the index between the smaller images. So the index between the original image (Fig. 2(a)) and the image processed with the standard LSB (Fig. 2(b)) is - 49.47831069914614. The index between the original image and the image processed by the improved LSB algorithm (Fig. 5(b)) is 50.5708622069228. A brief comparison of the results of the computer experiment is presented in the Table II.

TABLE II. Comparison of PSNR Indices

	Standard LSB algorithm	**Improved LSB algorithm**
Large volume of hidden message, medium container volume	49.47831069914614	50. 5708622069228
Large volume of hidden message, large container volume	57.72449648521831	61.39096278660813

VIII. Conclusion

The study compared two aspects: PSNR index and security. Based on the results of calculations and comparison of visualizations of various types of attacks on images processed by the standard LSB method and images processed by the improved LSB method, we can conclude that the use of a substitution table with a uniform distribution gives a structural result similar to the original container image. Distortion areas are minimized, and fragments with a high data density have disappeared, from which it is possible to calculate the fact of information transfer, an analogue of a secret key has been added, without which an attacker will not be able to extract useful information from the container image. The PSNR index when using the improved algorithm increases by ~ 5.9% in the best case and by ~ 2.16% in the worst case. In addition, visualization of the result of the improved LSB algorithm by the Chi-square criterion also indicates an increase in steganographic resistance. Computer experiments have shown that the improved LSB algorithm is more resistant to visual attacks and the use of statistical analysis methods.

The improved algorithm can be applied to process a large number of images, for example, the covert transmission of information in social networks and services for storing and transmitting images.

In the future it will be analyzed the applicability of various distributions to increase the PSNR index and adapt the algorithm to other data formats, including video file formats.

Twitter based Data Analysis in Natural Language Processing using a Novel Catboost Recurrent Neural Framework

V. Laxmi Narasamma[1], Dr. M. Sreedevi[2]
Department of Computer Science and Engineering, Koneru Lakshmaiah Education Foundation,Vaddeswaram, Guntur, Andhra Pradesh, India-522502

***Abstract*—In recent years, the sentiment analysis using Twitter data is the most prevalent theme in Natural Language Processing (NLP). However, the existing sentiment analysis approaches are having lower performance and accuracy for classification due to the inadequate labeled data and failure to analyze the complex sentences. So, this research develops the novel hybrid machine learning model as Catboost Recurrent Neural Framework (CRNF) with an error pruning mechanism to analyze the Twitter data based on user opinion. Initially, the twitter-based dataset is collected that tweets based on the coronavirus COVID-19 vaccine, which are pre-processed and trained to the system. Furthermore, the proposed CRNF model classifies the sentiments as positive, negative, or neutral. Moreover, the process of sentiment analysis is done through Python and the parameters are calculated. Finally, the attained results in the performance parameters like precision, recall, accuracy and error rate are validated with existing methods.**

Keywords—Natural language processing; sentiment analysis; twitter data; Catboost; recurrent neural network

I. Introduction

In recent, several Artificial Intelligence (AI) [1] techniques are worn in NLP for many purposes like, sentiment analysis, question and answering system and so on [2]. The major reason of using NLP in big data is to reduce the time complexity. Moreover, the big data is applicable in all online application [3], so to handle the big data is the great deal. In this, the sentiment analysis is a key topic to evaluate sentiment values in customer suggestion in online application [4].Thus the sentiment analysis are processed in three levels that are document, sentence and feature level. Here the advanced level of sentiment analysis is feature level [5], which is proved in all research implementation, because it achieved high accuracy than document as well as sentence level [6]. In that, one of the broad social networking sites is twitter, a person uses the twitter for short message communication called tweets [7]. Twitter is defined as the online platform where publics can develop the messages, post, read, and update the text, which is called tweets. Moreover, the sentiment investigation based on the twitter statistics is mentioned as the scientific study of the tweets semantic parts. Subsequently, the sentiment analysis is the method of attaining data from numerous sources that are classified based on the sentiments. Generally, the tweets are reflecting the opinion from public based on the particular data about product, or any topic.

The public opinion is normally categorized into positive, negative and neutral tweets. However, the categorizations of tweets are very difficult for large quantity of data. In addition, if any one continuously following your tweets then your message is liked or attracted by the particular person [8], the twitter analysis is shown in Fig. 1. Even it has lot of facilities, the analyses of data in twitter is challenging task because of large volume of data [9]. This reason turned the interest of researchers towards this area [10]. Thus several researchers found much solution but it is not applicable for long time due to data complexity [11]. Also, in NLP text summarization is one of the schemes to identify the uniqueness of each document [12]. So, in NLP text summarization frame work is elaborated in better way: several machine learning techniques and vector based word embedding models were studied for the better classification [13, 30]. But for the complicated data these approaches are misbehave because the error removing model is not available in all machine learning model [14].

So, it failed to prune the error, this cause the difficulties to specify the sentiment value of data. The computer does not know the people language [15], so to make the human machine interaction machine learning is the advanced topic. In addition, the data can train the system in the form of 0 or 1 [16]. Because the machine only knows the binary value 0's and 1's, so the classification of sentiment value is in the form of decision making [17]. The sentiment analysis using the large quantity of data is done through the machine learning approaches [18]. Several machine learning approaches are found but still the issues are not end [19]. Thus, the present research work aimed to develop an efficient machine learning model to classify tweets data based on their sentiment values.

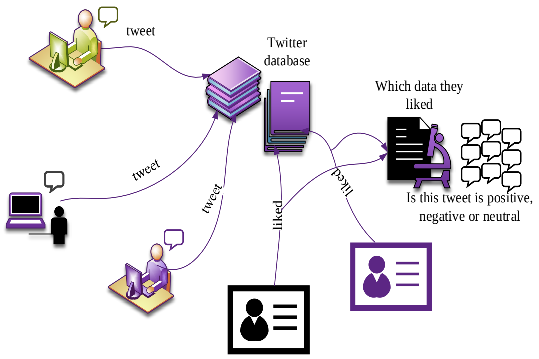

Fig. 1. Twitter Data Analysis.

This research work is organised as follows. The recent literature works based on sentiment analysis using twitter data is detailed in section 2. Also, the system model and problem statement is mentioned in section 3. Moreover, the developed methodology is elaborated in section 4 and the attained outcome of the proposed work is declared in section 5. Thus, section 6 detailed the end of the entire research.

II. Related Works

Several literature works correlated to the twitter data analysis is summarized below and detailed in Table I.

Ruz et al [21] introduced the bayes aspect manner to produce high real network. When comparing to the random forests and vector support in machine it gives competitive sentiment prediction result. However, approach cannot able to differentiate it behave in Spanish or English in RF and SVM. Finally conclude that, this network also allow to determine relation in the words, historically it gives interested quality data and catch socially the main headline of the dynamic act, accuracy in result and also reduce the exposure of misinformation.

Prediction of visiting next location using machine leaning by utilizing twitter information developed ensemble classified approach (ESA) has proposed by Kumar et al [22]. Moreover, this proposed work is utilized the twitter data for predicting the next visiting location of the user. Also, the developed ESA model attained the outcome of the prediction based on various classification models. For this prediction model, the voting technique is adopted to enhance the accurate sentiment calculation. This approach predicts accurate result with high desirable but it lack in security.

In recent, to assign a text for an emotion in classes automatically based on soft classified approach Hasan et al [23] developed a learning framework. That includes two tasks i.e., online and offline task. The result shows that the 90% of correct emotion of text can be created for real time. Finally, it gives best performance comparing to other approaches and also it doesn’t depend on other system. However, it attained high error rate.

TABLE I. Summary of Literature Survey

Author and year	Technique	Merits	Demerits
Ruz et al [21], 2020	Bayes aspect	Better information recall	It takes more time
Kumar et al [22], 2019	Ensemble classification approach	Accurate prediction	It attained Less privacy rate.
Hasan et al [23], 2019	Soft classification approach	Maximum Probability	High error rate
Barker, J. L. P., and Christopher JA Macleod [24], 2019	Prototype social geodata	Awareness during flood	Some time it lack in signal to predict the rain fall rate
Li al [25], 2019	patent analysis and twitter data mining	It required less time to process the mechanism	More complex

Barker, J. L. P., and Christopher JA Macleod [24] created prototype based social geo data from twitter to make the people aware from flood or huge disaster. Also, the decision mechanism is used to specify the rain fall and flood based data. Also, this model establishes the sentiment analysis using the twitter data based on pipeline extract tweets that involves 420000 tweets. Moreover, this supports a people lot to get aware about flooding.

Analysing the data is important in big data, Li et al [25] proposed patent analysis to determine the trends change in perovskite solar tech, and to identify response, expectation and sense is monitor using information from twitter mining. Finally, the comparison is made to identify the development of trends how the twitter users interested, this offer better in understanding and also it helps to find the development of trends in future but it may weak in capturing signals.

The key metrics of the proposed model is mentioned as follows,

- Initially, the twitter data based on the user opinion about COVID-19 is collected and trained to the system.
- Moreover, the novel CatBoost Recurrent Neural Framework (CRNF) is developed for analysing the sentiment value of twitter data.
- Subsequently, the developed CRNF model is utilized to remove the error while removing the leaf node layer that has increased the classification rate.
- Thus, the proposed approach effectively classifies the sentiments as positive, negative, or neutral.
- Additionally, the performance metrics such as recall, F-measure, accuracy, precision, and error rate are calculated and validated using existing approaches.

III. System Model and Problem Defination

Normally, the sentiment analysis or data analysis in natural language processing is done over big data dataset such as Facebook, twitter, etc. Moreover, sentiment analysis for large volume of data is some more difficult as because of its complexity and part of speech classification [20]. In addition, the sentence which contains positive words may also end with negative sentence. Thus the opinion or sentiment classification is one of the important tasks in NLP, which is mostly helpful for online service because the success of online business is based up on the customer review. Moreover, the process of sentiment analysis using twitter data is explained in Fig. 2.

Also to predict the uniqueness of each sentence, thus the classification of sentiment measure is more important. This motivate this research to find the scientific solution to enhance twitter data analytics using sentiment analysis in Natural Language Processing to reduce all kinds of issues

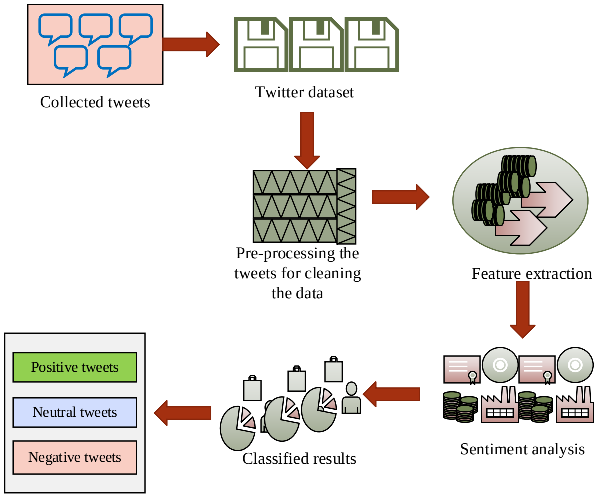

Fig. 2. System Model for Sentiment Analysis using Twitter Data.

IV. Proposed CRNF Methodology

In general, the sentiment analysis is one of the predictive modeling tasks that are trained with sentiments or textual data. However, the sentiment analysis using large data is the difficult task that provided lower efficiency for classifying the sentiments. In this research, the novel CatBoost Recurrent Neural Framework (CRNF) is developed for analysing the sentiments using twitter data. Here, the tweets are collected based on the COVID-19 vaccine from twitter that is utilized for training.

Moreover, the procedure of the developed CRNF approach is detailed in Fig. 3. Also, the developed CRNF approach is pre-processed the trained dataset and finally classifies the sentiment while removing the error. Thus, the proposed CRNF model is to remove the leaf node layer using pre-processing function and to enhance sentiment classification rate.

Fig. 3. Proposed CRNF Methodology.

A. Dataset Description

The proposed approach utilized the Twitter data for analysing the sentiments. Here, the twitter data based on COVID-19 vaccine tweets are collected from the kaggle.com that is processed in this research. The utilized dataset details about the 38460 numbers of tweets that involves the user name, location, description, friends, followers, favourites, text, tweet date, hashtags, and so on. In this, the collected tweets are based on the category of positive reviews, negative reviews and neutral reviews. Moreover, the collected dataset is given to the developed CRNF model for further processing.

B. CRNF Process for Sentiment Analysis

The proposed CRNF approach is processed on the twitter dataset for analyzing sentiments. Here, the developed catboost recurrent neural framework can reduce the error in the dataset, which is utilized for enhancing the classification accuracy [26, 27]. Here, the developed model performs the functions are pre-processing, feature extraction, and classification. The proposed CRNF model is the neural architecture that can reduce the training error, which is utilized to classify the sentiments in an effective manner. Furthermore the occurrence of CatBoost in the recurrent neural model can attain the enhanced classification accuracy as well as precision rate. Primarily, the dataset is initiated in the input layer of the network that is mentioned in eqn.(1),

$$d_T = \{(P_k)\}, k = 1,2,..., N \tag{1}$$

Where, P_k denotes the N^{th} quantity of tweets in the dataset d_T that involves positive, negative and neutral tweets. In this work, the dataset training process is done in the input layer. Here, P_k is the input and the output of the input layer is h^k that is given to the next layer. Moreover, the attained dataset having several errors or noise that should remove for attaining better results. So, the proposed model performing the pre-processing function.

- Pre-processing

This process is carried on the next layer of the network that is necessary for the dataset to remove the unnecessary data by cleaning the tweets, which involves the functions such as normalization, stop words removal and tokenization. Here, normalization process is utilized to remove the special characters, URLs, and emojis from the dataset. Also, the stop word deletion is processed to split the tweets that are compared using the stop words library, which involves the words not affects the original meaning the utilized sentences. Moreover, the raw is fragmented into the sentences or words with the use of tokenization process, which is employed to understanding the original meaning of text. Thus, the training errors in the tweets $(k = 1,2,3,...., N)$ are mentioned as H^{k-1} using additive manner that is represented by $H^k = H^{k-1} + \alpha h^k$ through the step size α and h^k utility removed the mistakes that is mentioned in eqn.(2),

$$h^k = d_T \left[\arg\min_{h \in H} \left(R^{k-1} + r_k \right) \right] \tag{2}$$

Where, the errors are mentioned as $\left(R^{k-1} + r_k\right)$ the repeated words r_k and the value of h^k is removed the errors and repeated words in a sentence, which are done in the hidden layer.

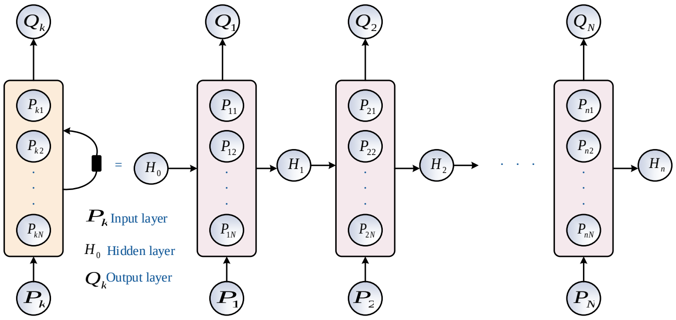

Fig. 4. Process of CRNF Network Model.

The dataset is given to the input layer of the proposed CRNF network that can be processed through the system. Moreover, the pre-processing and feature extraction function are done in the hidden layer of the network. Thus, the errors in the sentences are removed in the pre-processing process that is removed the leaf node layer. Additionally, the classification layer is utilized for classify the sentiments and finally, the output is obtained from the output layer of the network, which are represented in Fig. 4.

- Feature extraction

The pre-processed dataset is processed the feature extraction method that is done using the layer of the CRNF model. Here, the feature extraction is utilized for extracting the features from the dataset. Moreover, these features are utilized to identify the polarity of the sentences. In this approach, the feature extraction process is done using the factor φ_k and the activation function tanh that calculation is mentioned in eqn.(3),

$$f_k = \tanh \min \sum_{k=1}^{N} \left\{ \left(P_k \varphi_k \right) \right\} \tag{3}$$

Thus, the leaf node layer is removed while completing the pre-processing and feature extraction process. Moreover, the attained output is given to the classification layer that is performed the sentiment analysis process.

- Classification

The proposed method classifies the tweets like positive tweets P_t, negative tweets N_t, and neutral tweets N_l. The proposed model CRNF classifies the sentiments using the aspect terms in the sentences. Finally, the classification of sentiments is done using eqn.(4),

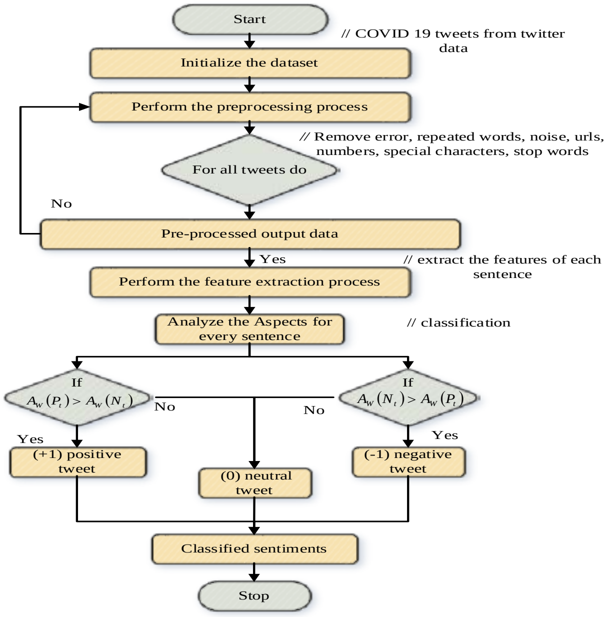
$$Q_k = d_T \rightarrow \sum_{k=1}^{N} P_k \left(A_W \left(P_t, N_t \right) \right) \tag{4}$$

Algorithm: CRNF for sentiment analysis

```
Input: COVID-19 Tweets from Twitter data
Output: classified output $(Pt, Nt, Nl)$
//where, $Pt$ -positive, $Nt$ -negative, and $Nl$ -neutral
Start
{
Initialization ()
        Initialize the dataset $d_T$ // COVID-19 Vaccine Tweets
        Import the dataset
Preprocessing()
        For all $d_T$ do
        Remove error, repeated words, noise, urls, numbers, special characters, stop words
        If misspelled (word) then
        Replace the word by correct word
        End if
        End for
Feature extraction()
        For all $d_T$ do
        Extract the features of the words
        End for
Classification()
        Mentioned the aspect terms $A_W(P_t, N_t)$
        If $A_W(P_t) > A_W(N_t)$ then
        $Sentiment \leftarrow P_t$ //(+1) positive tweet
        Else if $A_W(N_t) > A_W(P_t)$ then
        $Sentiment \leftarrow N_t$ //(-1) negative tweet
        Otherwise
        $Sentiment \leftarrow N_l$ // (0) neutral tweet
        End if
Classified sentiments
}
Stop
```

In this, the positive and negative aspect terms are saved in the layer that words are utilized to analyze the sentences. If the sentence having positive aspects then it is the positive tweet and if the sentence has negative aspects then it is negative tweets otherwise that sentence is considered neutral tweets. Finally, the results are attained from the output layer of the proposed network. Moreover, the positive tweets are represented as (+1), negative tweets are represented as (-1), and neutral tweets are represented as (0).

Thus, the sentiments have classified by the proposed catboost recurrent neural framework. The complete procedure of the proposed CRNF technique is detailed in the algorithm 1 and the flow chart is represented in Fig. 5.



Start
// COVID 19 tweets from twitter data
Initialize the dataset
Perform the preprocessing process
// Remove error, repeated words, noise, urls, numbers, special characters, stop words
For all tweets do
No
Pre-processed output data
Yes
// extract the features of each sentence
Perform the feature extraction process
Analyze the Aspects for every sentence
// classification
If $A_w(P_t) > A_w(N_t)$
No
No
If $A_w(N_t) > A_w(P_t)$
Yes
Yes
(+1) positive tweet
(0) neutral tweet
(-1) negative tweet
Classified sentiments
Stop

Fig. 5. Flow Chart for CRNF Model.

V. Results and Discussion

In this work, the developed CRNF approach is simulated with the use of Python; moreover, the efficiency of the proposed strategy is evaluated with prevailing manners. Here, the comparison is carried out in the performance metrics like accuracy, recall, F-measure, precision, and error rate. In this, the developed is effectively classifies the sentiments using the proposed CRNF approach.

A. Case Study

In this paper, the sentiment analysis is done using the twitter data. Here, the tweets for COVID-19 are collected and processed using the proposed CRNF model. Several samples are for COVID-19 tweet and the classified results are mentioned in Table II. Here, the utilized dataset is initially pre-processed and feature extracted in the layers of the proposed CRNF network.

Subsequently, the positive and negative aspects are mentioned for classifying the sentiments. For example, vaccine, immunity, protect, etc., are considered as the positive aspects and sick, side effects, death, spread, etc., are considered as the negative aspects. Based on the considered aspects, each sentences are classified as positive tweet (+1), negative tweet (-1), and neutral tweet (0).

B. Performance Matrics

This research work performed the sentiment analysis using the developed CRNF approach, which is implemented using Python. Moreover, the performance metrics are calculated that are compared using existing methods for identifying the efficiency of the developed approach. Thus, the parameters like accuracy, precision, and error rate of the proposed model is validated with prevailing methods like Tree Augmented Naive Bayes (TAN) [21], Bag of words using machine learning (BOW-ML) [28], and Attention using Bidirectional CNN-RNN Deep Method (ABCDM) [29].

TABLE II. CLASSIFIED RESULTS FOR TWITTER DATASET ABOUT COVID-19

S.No	Text about COVID-19	Positive	Negative	Neutral
1	There are presently more than fifty COVID-19 vaccine contenders in the trials.	+1	-	-
2	The developed vaccine may cause the various side effects, which is related to the symptoms and signs of COVID-19.	-	-1	-
3	The Vaccine about COVID-19 is manufactured in Australia, which is supplied to the citizens at no cost. AFP quotes Prime Minister	+1	-	-
4	Got my CovidVaccine today. Ready to end this pandemic Protect your families.	+1	-	-
5	Got my covid vaccine! Tired, mild headache - work those antibodies, immune system	-	-1	-
6	Presently more than 50 numbers of COVID-19 vaccine candidates in trials.	+1	-	-
7	COVID-19 affected people develop mild to moderate disorder and recover without hospitalization.	-	-	0
8	Third stage of Russia's Covid-19 vaccine may initiate in seven to ten days	+1	-	-
9	COVID-19 is easily spread from one person to another like friends, family, and surrounding peoples.	-	-1	-
10	Masks are used to protect the people from COVID-19.	-	-	0

1) Accuracy: validation is utilized for determining the efficiency of the proposed framework. Also, it is identified the effectiveness of the developed model for classifying the sentiments, which is computed using eqn.(5),

$$Acc = \left(\frac{T_P + T_N}{T_P + F_P + F_N + T_N} \right) \tag{5}$$

Where, T_P represents the true positive that is the calculation for the total quantity of properly classified positive tweets, T_N is the true negative that represents the total quantity of properly classified negative tweets, F_P is the false positive that symbolizes the total quantity of improperly classified positive tweets, and F_N is the false negative that represents the total quantity of improperly classified negative tweets.

The accuracy calculation of the proposed CRNF model is compared with existing methods like TAN, BOW-ML, and ABCDM that are mentioned in Table III. The existing approaches TAN and BOW-ML approaches are attained lower accuracy as 80.8% and 85%.

Also, the ABCDM approach achieved nearly 93% accuracy. Thus, the proposed CRNF approach has attained high accuracy as 99.34% than other models while considering tweets data from twitter, which is represented in Fig. 6.

2) Precision: The calculation of precision is utilized for identifying the effectiveness of the proposed classifier. Here, the lower precision value denotes the high false positives and high precision rate denotes the less number of false positives. Moreover, the precision value of the proposed model is calculated using eqn. (6),

$$P = \left(\frac{T_P}{T_P + F_P} \right) \tag{6}$$

The precision value of the proposed CRNF model is validated with existing methods and the values based on the quantity of tweets are mentioned in Table IV.

TABLE III. COMPARISION OF ACCURACY

No. of tweets taken	Accuracy (%)			
	TAN	**BOW-ML**	**ABCDM**	**CRNF [proposed]**
100	80.8	85.1	93.40	99.34
200	79.96	84.87	92.68	98.65
300	76.48	84.05	91.97	97.89
400	75	83.79	89.63	95.76
500	73.27	83.27	87.67	93.56

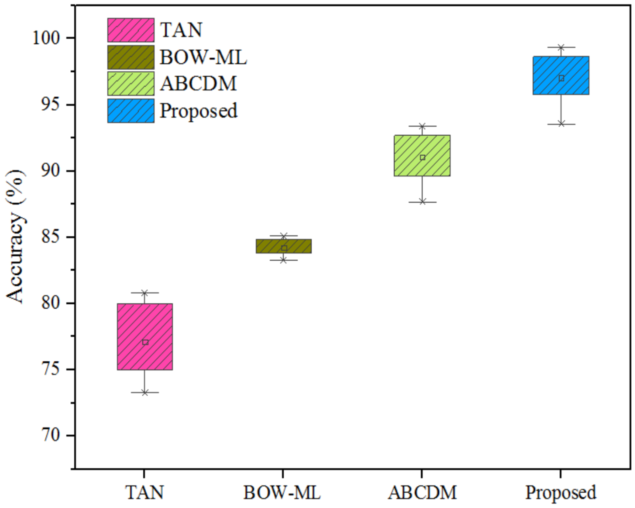


Fig. 6. Comparison of Accuracy.

TABLE IV. COMPARISON OF PRECISION

No. of tweets taken	Precision (%)			
	TAN	**BOW-ML**	**ABCDM**	**CRNF [proposed]**
100	90.6	83.6	95.70	98.38
200	88.04	82.87	93.78	97
300	85.58	80.96	93.27	96.78
400	83.47	79.67	92.09	96.07
500	82.97	77.86	90.83	95.36

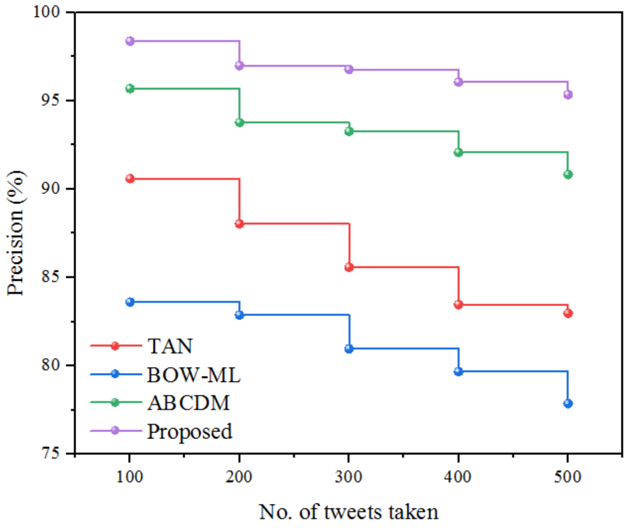

Fig. 7. Comparison of Precision.

Also, the existing BOW-ML model attained lower precision as 83.6%, TAN approach achieved 90.6% precision, and ABCDM model attained 95.7% precision value. Hence, the proposed CRNF model has achieved high precision rate as 98.38% than other methods that is represented in Fig. 7.

3) Recall: The calculation of recall is utilized for identifying the sensitivity or the completeness of the proposed classifier. In this, the lower recall value denotes the high false negatives and high recall rate denotes the less number of false negatives. Moreover, the recall value of the proposed model is calculated using eqn.(8),

$$R = \left(\frac{T_P}{T_P + F_N} \right) \tag{7}$$

The recall value of the proposed CRNF model is validated with existing methods and the values based on the quantity of tweets are mentioned in Table V.

Also, the existing BOW-ML model attained lower recall as 88%, TAN approach achieved 85.4% recall, and ABCDM model attained 90.88% recall value. Therefore, the proposed CRNF model has achieved high recall rate as 97.45% than other methods that is represented in Fig. 8.

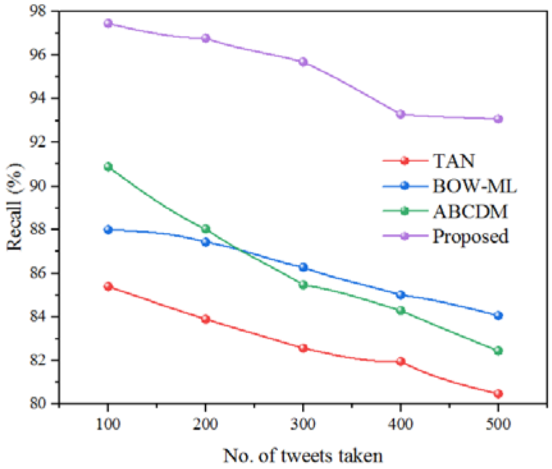

Fig. 8. Comparison of Recall.

TABLE V. COMPARISON OF RECALL

No. of tweets taken	Recall (%)			
	TAN	BOW-ML	ABCDM	CRNF [proposed]
100	85.4	88	90.88	97.45
200	83.9	87.43	88.04	96.78
300	82.57	86.28	85.47	95.69
400	81.96	85	84.30	93.29
500	80.48	84.07	82.45	93.08

4) F1-measure: The calculation of F1-score is defined the combination of the calculated precision and recall values, which is computed using eqn.(8),

$$F1-score=\left(2\frac{P*R}{P+R}\right) \tag{8}$$

The F1-measure value of the proposed CRNF model is validated with existing methods and the values based on the quantity of tweets are mentioned in Table VI.

Also, the existing TAN approach achieved 87.9% F1-measure value, BOW-ML model attained lower F1-measure value as 85.8%, and ABCDM model attained 92.22% lower F1-measure value. Moreover, the proposed CRNF model has achieved high F1-measure value as 97.91% than other prevailing approaches that are characterized in Fig. 9.

5) Error Rate: This calculation is utilized to identify the classification error of the proposed model, which is computed using eqn.(9).

$$Error\_rate=\left(\frac{F_P+F_N}{T_P+T_N+F_P+F_N}\right) \tag{9}$$

The error rate value of the proposed CRNF model is validated with existing methods and the values based on the quantity of tweets are mentioned in Table VII. These prevailing methods are attained higher error rate for classifying sentiments using twitter data.

TABLE VI. COMPARISON OF F1-MEASURE

No. of tweets taken	F1-measure (%)			
	TAN	BOW-ML	ABCDM	CRNF [proposed]
100	87.9	85.8	93.22	97.91
200	86.35	84.08	92.76	96.88
300	87.39	82.78	92.94	96.23
400	85.28	83.49	91.67	94.65
500	84.37	82.08	91.06	94.20

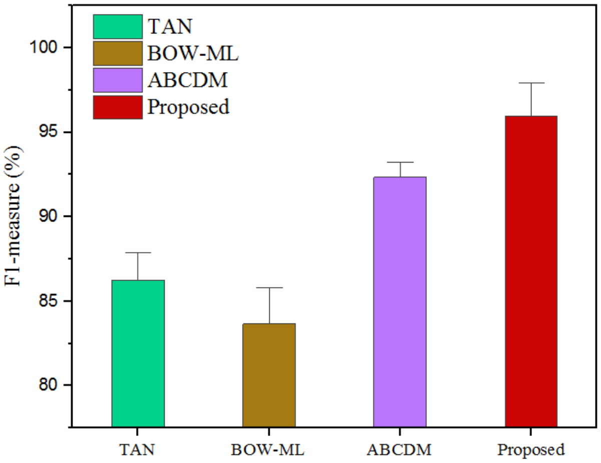

Fig. 9. Comparison of F1-Measure.

TABLE VII. COMPARISON OF ERROR RATE

No. of tweets taken	Error rate (%)			
	TAN	BOW-ML	ABCDM	CRNF [proposed]
100	19.2	14.9	6.6	0.66
200	20.04	15.13	7.32	1.35
300	23.52	15.95	8.03	2.11
400	25	16.21	10.37	4.24
500	26.73	16.73	12.33	6.44

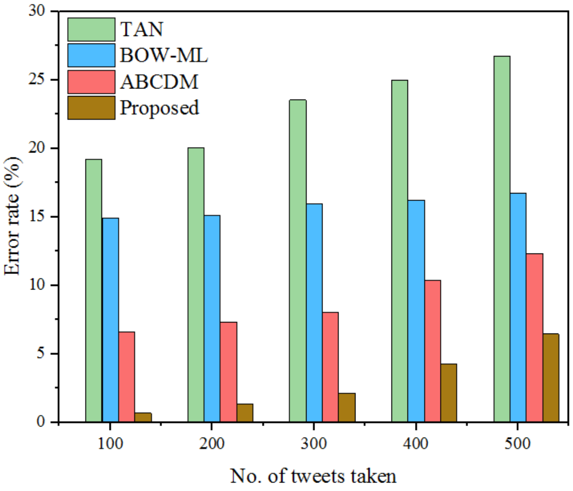

Fig. 10. Comparison of Error Rate.

Also, the existing TAN approach achieved 19.2% high error rate value, BOW-ML model attained 14.9% error rate value, and ABCDM model attained 6.6% error rate value. The comparison of the error rate value is characterized in Fig. 10. Moreover, the proposed CRNF model has achieved lower error rate value as 0.66% than other existing methods for classifying the sentiments using twitter data for COVID 19.

VI. Conclusion

In this research, the novel Catboost Recurrent Neural Framework (CRNF) is developed for performing sentiment analysis in the twitter dataset. Here, the tweets about COVID-19 are considered as the dataset that is utilized for classifying the sentiments as positive tweets, negative tweets, and neutral tweets. The noise, error, url, repeated words, stop words, numbers, special characters are removed by the pre-processing process. Also, the feature extraction method is utilized to extract the characteristics of each sentence. Subsequently, the classification of sentiments is done in the layer of the proposed CRNF model using the aspects words. Hence, the proposed model has achieved high accuracy as 99.34% with lower error rate as 0.66% than other existing approaches.

***Abstract*—Agriculture on earth is the biggest need for human sustenance. Over years, many farming methods and components have become computerized to guarantee quicker production with higher quality. Because of the enlarged demand in the farming industry, agricultural produce must be cultivated using an efficient process. Onion (Allium cepa L.) is an economically valuable crop and is the second-largest vegetable crop in the world. The spread of various diseases highly affected the production of the onion crop. One of the serious and most common diseases of onion worldwide is purple blotch. To compensate for a limited amount of training dataset of healthy and infected onion crops, the proposed method employs a pre-trained enhanced InceptionV3 model. The proposed model detects onion disease (purple blotch) from images by recognizing the abnormalities caused by the disease. The suggested approach achieves a classification accuracy of 85.47% in recognizing the disease. This research investigates a novel approach for the rapid and accurate diagnosis of plant/crop diseases, laying the theoretical foundation for the use of deep learning in agricultural information.**

Keywords*—Disease detection; disease classification; artificial intelligence; inceptionv3; deep convolutional neural network

I. Introduction

Farming production is the utmost important sector in many countries for contributing to domestic incomes [1]. It plays a significant role in stimulating the economy of agricultural countries like India, Bangladesh, Indonesia, Iran, Turkey, Afghanistan, and Pakistan which depend heavily on crop quality and growth [2]. Productivity in agriculture is the backbone of a country's economy. With a population of more than 220 million people, Pakistan is the sixth most populated country on earth. Approximately 64% of the population, around 140.8 million lives in rural areas [3]. Agriculture plays a crucial role to guarantee food safety for a relatively enormous and increasing population. In the agriculture market, vegetables are of prime importance. The share of vegetable production in Punjab is 95.4% for potatoes, 19.9% for onions, 21.1% for chilies, and 15.9% for tomatoes [4]. Punjab is by far the largest province for the farming industry in Pakistan. The total area under agriculture in Punjab is 40.55 million acres, which makes 71.53% of Pakistan's total agricultural area [5, 6]. Sindh, in particular for tomatoes, chilies [7], and bananas [8], is the second most important province for agricultural production. Onion prices have been falling in the global market in 2020 since February, as logistical problems from covid19 [9] hampered trade and demand in major producing countries, India and China remained lukewarm. Though demand in America has improved, the recent onion outbreak may have an impact on the United State (US) and Mexico export situation. Mexico's onion harvest is divided into two seasons, the spring season lasts from March to June and the fall season from August to January. The volume of onion exports to the US, its main importing destination has increased significantly over past years with a nearly 80% increase from April to July compared to the same period last year. Since the outbreak began demand for onion in the US has been stable with the bulk of it coming from retailers. Onion cultivation in the US appears to be quite consistent with no weather anomalies. According to the onion business the coronavirus had little influence on US onion shipments to Asian countries because the season extends from August to January the remaining seasons are supplied by New Zealand. With the increasing cargo charges moving the product across the country could be difficult but the foodservice business is warily hopeful about reopening which might handle the onion that began packing in August. During the early stages of covid19, trade flows were restricted due to logistical issues that made it difficult to export Chinese goods and lockdowns in Asian countries that slowed down exports. However, the trade situation has now returned to normal.

In Pakistan, a brief overview of the main crops is highlighted in Table I. Onion (Allium cepa L.) is the world's second-largest vegetable crop with an international supply of approximately 74.25 million tons [10] and is commercially the most important crop of the Alliaceae family [11]. Onion is the main relish commonly used throughout the year in all homes [12]. Recent research has shown that dietary onions can help prevent heatstroke and other disorders [13]. The onion bulb [14] is abundant in carbohydrates, calcium, and phosphorus.

Table II indicates the composition of the onion bulb. Food historians agree that onion originated in central Asia 5000 years ago, some suggest onion was initially grown in Iran and West Pakistan [15, 16]. Since onion has grown wild in different areas it has probably been eaten for multiple years all over the world [17]. Onion may be one of the initially cultivated crops since they were simple to harvest, less fragile, transportable, grown in a diversity of climates and soils than other crops [18] as shown in Fig. 1.

Fig. 1. Fresh Onion.

Besides, onion was beneficial for human life to be sustained. Onion avoided thirst when food gets scarce could be dried and stored for later consumption. Onion helps lower blood pressure [19], lessen the occurrence of cancer [20], insect bite antiseptic, anti-diabetic, anti-aging, and stimulate hair regrowth [21]. The total world production of onions is 742.5 million tons with Pakistan ranked 7th [22] as presented in Table III.

TABLE III. WORLD TOTAL ONION PRODUCTION

S No.	**Countries**	**Million tons**

TABLE IV. STATUS OF ONION (PROVINCE-WISE) 2006-07

Province	**Area (HA)**	**% share**	**Production (Tones)**	**% share**	**Average Yield t/ha**
Punjab	35.6	27	315.7	17	8.9
KPK	12.0	9	206.1	11	17.2
Sindh	45.6	35	593.1	33	13.0
Balochistan	38.2	29	701.6	39	18.4
Pakistan	131.4		1816.5		13.8

Onions are generally grown in the field with a 10-12 cm seedling gap and 25-30 cm out in flatbed rows. To generate huge bulbs, space the crops 10-15 cm out in a row. Maintain onion weeds free by hoeing and shallow cultivation. Planting seeds directly in the field where the crop will mature, planting in a seedbed from which the plants will be moved subsequently to the field, and planting sets are the three most distinct techniques of planting onion. These sets can be bought or cultivated from seed by the grower. For early production, the transplanting approach is widely used. Onion is grown commercially on an area of 131.4 thousand hectares, producing 1.8 million tons [23]. The onion status (province-wise) for 2006-07 is shown in Table IV.

22 districts account for over 77% of Pakistan's total onion production [24]. In the world 66 syndromes including 38 fungal, 10 bacterial, 3 biological, 6 nematodes, 1 sponging plant, and 1 phytoplasmal ailment, 7 various infections and ailments are affecting onion. Numerous serious infections such as soil-borne ailments are becoming extensive and sufficiently extreme to restrict onion production worldwide. Fungi and bacteria can cause a variety of diseases in onion. Crop rotations, climate, storage, drying conditions, and disease control measures disease intensity. Botrytis blight, botrytis neck rot, black mold rot, pink root, botrytis bulb rot, bacterial soft rot, iris yellow spot virus, fusarium basal rot, purple blotch, translucent scale, and downy mildew are onion diseases worldwide [25]. Many onion diseases start on crops in the field and progress to the bulbs during transportation and storage. Understanding that postharvest diseases arise in the field is the first step toward effective control. Controlling onion diseases require suitable cultural practices such as removal of contaminated onion, crop rotations, culls, debris, and cultivar range [26]. Some common onion crop diseases found worldwide are presented in Table V and Fig. 2.

Following are the main contributions of this paper:

1) We demonstrated the feasibility of our approach by creating a dataset of 1000 images of onion crops.

2) Proposed an enhanced InceptionV3 classification model, which is used to identify purple blotch affected onion based on their images.

3) To improve classification accuracy, various pre-processing and training techniques are used.

4) The proposed model is created to aid in more accurate and efficient detection of onion disease (purple blotch).

TABLE V. COMMON DISEASES OF ONION CROP FOUND WORLDWIDE

Diseases	Caused By	Pathogen
Botrytis Blight	Fungus	Botrytis Squamosa
Botrytis Neck Rot	Fungus	Botrytis Allii
Purple Blotch	Spores Of The Fungus	Alternaria Porri
Fusarium Basal Rot	Fungus	Fusarium Oxysporum F. Sp. Cepae
Translucent Scale	Regular High Relative Humidity, and High Temperature (i.e. >90° F)	
Downy Mildew	Fungus	Peronospora Destructor

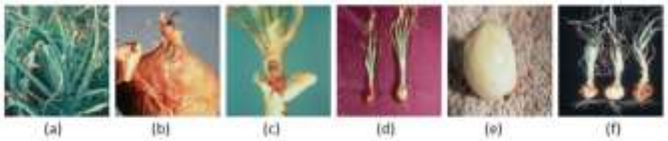

Fig. 2. Common Onion Crop Diseases (a) Botrytis Blight (b) Botrytis Neck Rot (c) Purple Blotch (d) Fusarium Basal Rot (e) Translucent Scale (f) Downy Mildew.

The remaining article is arranged as follows: Sections II describes onion disease (purple blotch). Section III presents and summarizes related work. The state of art models for disease detection is discussed in Section IV. Section V explains what knowledge is needed to analyze the proposed model. Section VI gives a dataset description. The implementation details, performance metrics, and experimental results are described in Section VII. Lastly, Section VIII presents the outlines of the article's findings.

II. PURPLE BLOTCH DISEASE

Younger leaves are more vulnerable than older leaves. Water-soaked lesions with a white center are the first signs of the disease. Lesions edges turn brown to purple the leaves above and below the lesions turn yellow. Dark brown to black concentric rings form over time inside the lesions. The fungus sporulates in these regions. Lesions can girdle the leaf as the disease progresses causing it to collapse and die as shown in Fig. 3. Seed stalks exhibit similar symptoms and infected stalks may collapse resulting in shriveled seed growth. The most common route for bulb infection is through the neck. If the fungus infects the bulb the infected area appears bright yellow at first, but then turns a distinctive red wine color.

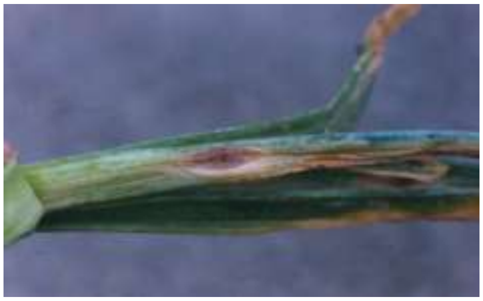

Fig. 3. Onion Disease (Purple Blotch) [27].

a) Circumstances for Disease Expansion: In leaf debris and cull piles the fungus survives the winter as mycelium. During humid nights leaf wetness cycles exceed more than 12 hours spores are developed. When the morning dew evaporates spores become airborne and spread to vulnerable onion tissues. It takes 1-4 days for signs to appear after infection. During extended periods of leaf wetness, disease production is at its peak.

b) Overcome: A broad-spectrum protection fungicide spray program can provide good protection before infection. Reduce disease growth by reducing leaf wetness using surface irrigation rather than sprinkler irrigation, good field drainage, and proper plant spacing. Rotating onions to unrelated crops for many years can also help to minimize disease.

III. RELATED WORK

Nihar et al. [28] suggested a neural network-based system for detecting plant disease that will aid in the development of the agricultural system which can properly determine whether a plant is infected or healthy and has a 97.7% accuracy. This technology enables the user to detect diseases faster allowing them to take acceptable precautionary steps and save crops.

Sangeetha et al. [29] compare different methods of image processing (K-mean clustering, artificial neural network (ANN), support vector machine (SVM), and fuzzy logic) then examine and summarize crop disease types. This study provides a thorough explanation of the machine learning (ML) models that were used to identify various agricultural diseases.

Liu et al. [30] presented a kiwi RGB-NIR-D dataset containing multi-modality associated images of kiwi fruits in farms. They suggested a unique method for using RGB-D sensors to combine associated near-infrared reflectance (NIR) and RGB images with deep learning (DL) techniques for fruit recognition. Using two modalities of aligned RGB and NIR images from the dataset faster region-based CNN is designed and deployed for kiwi fruit recognition.

Kim et al. [31] have proposed an image-built automated field monitoring method. Based on a weekly supervised learning approach the deep learning model was trained to identify crop disease. Using the field monitoring method the model was trained using captured onion crop field images, 6 groups including the sign of the disease were classified. As an ideal disease symptom localization threshold, 60% of the extreme value in the class activation map was calculated. The efficiency of recognizing disease symptoms was evaluated by intersection over union (IoU) using the mean average precision (mAP) metric.

Sharma et al. [32] enhanced decision-making with convolutional neural network (CNN) for various paddy crop diseases to prevent disease at initial stages and avoidance of mass loss in yield productivity. Paddy crop conditions are very fatal and can have serious effects on crops if initial treatment is not taken into account.

Karthik et al. [33] have used two distinct profound architectures to diagnose tomato leaf infection. To learn essential characteristics for classification the first architecture relates to residual learning. On top of the residual deep network (RDN) the second architecture applies an attention function. Experiments were carried out over 3 diseases namely leaf mold, late blight, and early blight from the plant village dataset. Using the attention mechanism, the suggested work exploited the features acquired by CNN at different handling hierarchies and accomplished a whole accuracy of 98% in the 5-fold cross-validation on the validation sets.

Pattnaik et al. [34] suggested a transfer learning system for the classification of pests in tomato plants based on an existing deep CNN structure. The database for the analysis was obtained from 859 images in 10 groups from online sources. A comprehensive contrast of the performance of 15 existing CNN models has been offered. The test results showed that 88.83% of the maximum classification accuracy was achieved with the DenseNet169 model.

Francis et al. [35] offered a detailed summary of the prevalent applications of DL and computer vision (CV) techniques in the field of farming demonstrating the need to recognize and classify diseases using a dataset of leaf images. It is proposed to clarify its working principle with a novel classification system. A new collection containing gradient images is created using the multi-space image reconstruction input. Through the original and reconstructed images, high-level semantic structures are mined by convolutional layers that are convolutional and depth-wise separable. Finally, for classification SoftMax was used. The hyper-parameters and the expense of computation are calculated mathematically providing researchers with an insight innovation. The output of the system is compared and estimated with the related works on the openly accessible dataset of apple leaf images.

In this article, we have presented a methodology to detect onion disease (purple blotch) by using CNN classification. The feasibility of our approach has been demonstrated by using a dataset of 1000 images for healthy and infected onion crops. Two different types of experiments were taken using an improved InceptionV3 for classification with different batch sizes. Experiment trials used 70% of the dataset for training, 25% of the dataset for testing, and 5% of the dataset for validation. The proposed method recognizes the disease with a classification accuracy of 77.05% and 85.47% for different batch sizes.

IV. The Proposed Method

The proposed method uses CNN to classify purple blotch disease in an onion crop. Finding an optimal architecture for CNN is one of the main challenges. Therefore we have used transfer learning where a model established for a mission is reprocessed as the beginning point for another task [36]. We have used a pre-trained CNN for recognition. This model is a functional model with multiple layers. The architecture of this model is shown in Fig. 4. This model is used to analyze the images and reliably detect them.

A. Input Layer

In image processing, it usually represents the image's pixel matrix. The parameter determines the dimension of the image (244×244×3) and due to data limitations, we augment our dataset by randomly generating images, adjusting the zoom and shear parameters of the original images. All images are duplicated five times. These copies are then fed into a pre-trained model, which is described further down.

B. Conv2D + ReLU Layer

Convolution is a linear procedure consisting of the multiplication between a two-dimensional (2D) weight array (filters) and an input data array of a weight set. We have 3 layers in the suggested design with zero padding and a filter of size 3×3. ReLU is abbreviated as a rectified linear unit that relates to the feature of non-saturating activation. It eliminates unwanted values from an activation map efficiently by setting them to nil. Without influencing the receptive fields of the convolution layer it rises the nonlinear assets of the resolution function and the whole network as specified in equation (1).

$$\text{ReLU} : f(x) = \max(0; x) \quad (1)$$

C. Pooling Layer

The pooling layer performs down-sampling feature maps by summarizing the presence of characteristics in the feature map patches. There are two kinds of pooling approaches max pooling and average pooling. We have used average pooling in the suggested design to determine the extreme value for each function map in each patch. The pooling average is set to 2×2 with 2 strides.

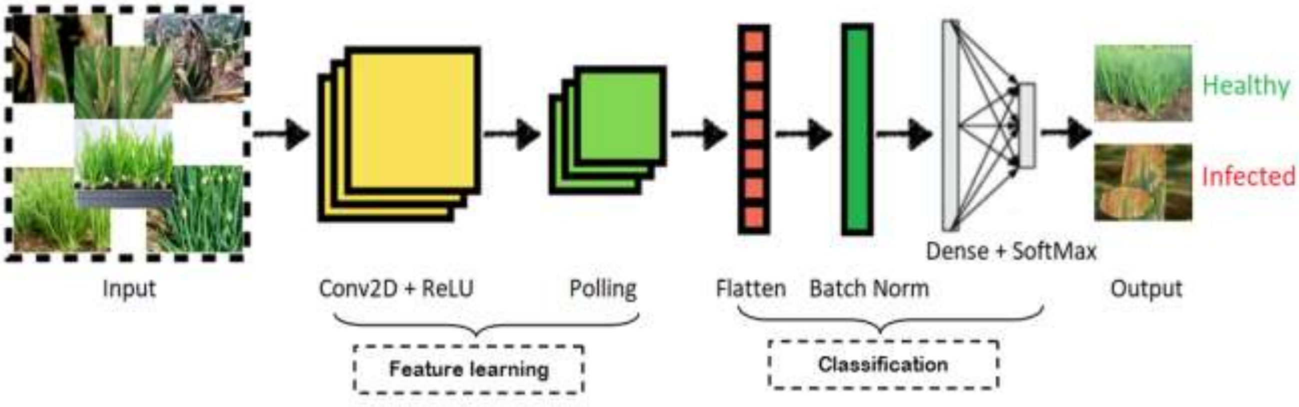

Fig. 4. CNN Architecture.

D. Flattening Layer

Flattening reduces file size by combining all apparent layers into the ground layer or transforms the data into a 1-dimensional array that is passed to the fully connected layer. To create a particular long feature vector we have dense the output of the convolutional layers.

E. Batch Normalization Layer

The batch normalization layer allows each layer to learn more individually. Learning becomes more rapid when batch normalization is utilized it can also be employed as a regularization to prevent model over-fitting. To standardize the outputs/ inputs, the layer is added to the model.

F. Dense + SoftMax Layer

The dense layer enhances an exciting non-linearity property, so any math function can be modeled. Though, they are always restricted in the logic that we still get the same output vector for the same input vector. On similar data, they can't identify recurrence in time or generate dissimilar responses. SoftMax layer is used to deliberate the feasible values of the preceding layer activation function. The values can be represented in two classes '0' and '1'. The logistic regression model is typically used for binary classification, although the SoftMax classification method is used for multi-classification. The classifier SoftMax is essentially an exponential normalized function as shown in equation (2).

$$\sigma(\hat{z}) = \frac{e^{zi}}{\sum_{j=1}^{K} e^{zj}} \tag{2}$$

Where

$\sigma = \text{Softmax}$

$\hat{z} = \text{Input vector}$

e^{zi} = Standard input vector exponential function

K = Number of multi-class classifier classes

e^{zj} = Standard output vector exponential function

G. Output Layer

The output layer manages of generating the result. In a neural network, there must always be one output layer. The output layer receives the inputs from the layers above it executes the calculations using its neurons and then computes the output.

V. Model Consideration

One of the main goals of this research is to achieve state of art classification results using diverse transfer learning (DTL) models to both compensate for the small size of the trial data and to speed up the training procedure so that on modest hardware this can be achieved practically. These prototypes are all conveniently accessible as part of the Keras API and individually support TL in the form of support for pre-application to the model of the ImageNet weight.

A. Densenet201

DenseNet201 (dense convolutional network) is a 201 layers deep CNN that accepts an image input size of 224×224 [37]. DenseNet201 is a ResNet enhancement that requires dense connections between layers. In a feed-forward fashion, it ties each layer to every other layer. DensNet201 has $\frac{L(L+1)}{2}$ straight connections unlike typical CNN with L layers that have L connections. DenseNet has been able to boost efficiency compared to conventional networks by raising the necessity for computing, dropping the number of parameters, facilitating the reuse of features, and improving the propagation of features.

B. Inception-ResNet-V2

Inception-ResNet-V2 is a trained CNN on over a million ImageNet dataset images [38]. It is a cross procedure that incorporates the structure of residual connection and inception. The model takes a 299×299 dimension image and a list of approximate class probabilities in its output. The benefits of Inception-Resnet-V2 are the conversion of inception units to residual inception chunks and the adding of a new inception unit (Inception-A) to the stem module.

C. VGG16 and VGG19

VGG16 and VGG19 [39] are CNN architectures aimed to attain high accuracy in significant image identification applications with very narrow convolution filters (3×3). The depth [40] of the max-pooling, convolution, and fully connected layers vary between two implementations: 16 layers in VGG16 and 19 layers in VGG19.

D. MobileNet-V2

MobileNetV2 is an enhanced version of MobileNetV1 [41] it is consists of 54 layers and has an image input size of 224×224×3. Its key feature is that it uses two 1D convolutions with 2 kernels rather than having a single kernel 2D convolution. This implies that less storage, parameters, small and efficient model are needed for training. Two types of blocks can be distinguished: the first is a residual block with a stride of 1 and the other is blocked with a stride of 2 for downscaling. There are layers for each block: the first layer is ReLU6 1×1 convolution, the second layer is the deep convolution and another 1×1 convolution is the third layer but deprived of any non-linearity.

E. ResNet50

The ResNet was developed by executing a method of skip connections among layers known as residual learning to avoid the disappearing gradient problem characteristic in deep neural networks [42]. This design results in a network that trains extra effectively enable the design of deeper networks that have a positive effect on the accuracy of the model. ResNet50 is such a system implementing residual learning with 50 layers.

F. InceptionV3

The goal of InceptionV3 was to maximize the usage of computing assets within the network by raising the network's depth and width while retaining constant computing operations [43]. To define an enhanced network structure with avoided connections that are used as a building block the designers of this network coined the word 'Inception modules'. By assembling with max-pooling layers, [44] this initial module is spatially repeated to minimize dimensionality to a reasonable smooth for calculation.

G. Xception

The "extreme" type of Inception model was developed by Google Inc [45]. Xception is consisting of 71 deep layers. Only depthwise detachable convolution layers are used in the Xception architecture.

VI. Dataset Description

On our image dataset, we applied our offerings for instinctive binary classification. The following section gives the steps of our contribution in detail.

A. Dataset

This present work introduces an image dataset that contains onion crop images. Under the guidance of Dr. Imtiaz A. Nizamani, Department of Plant Protection, Sindh Agriculture University, Tandojam, Pakistan images of onion crops were gathered from Tandojam, Sindh onion fields for this study. In this case, there are a total of 1000 images (png and jpeg format) with 600 images of healthy crops and 400 images of infected crops with 'purple blotch disease' which affects onion. However, when evaluating the onion crop will only reveal whether it is healthy or unhealthy. When it is unhealthy the onion crop will display four stages (low, medium, high, and fully infected). The crop becomes highly unstable, leaf length diminishes, flower excision occurs, and so on. To protect the land the sick crop should be separated from the healthy crop. Fig. 5 illustrates an example of the dataset used in this research where (a) shows infected onion images (b) shows healthy onion images. For splitting of data, we used in this experiment 70% of the dataset for training, 25% of the dataset for testing, and 5% of the dataset for validation. We guarantee that the images selected for validation are not used throughout training to accomplish the binary classification task. Furthermore, we perceived that our database is unprovoked certainly 40% of the images represent the infected onion class. To overwhelmed this issue by using data augmentation we re-sampled our dataset. We produced two new images with various augmentation techniques from each single input image. The total quantity of images was therefore increased by two times in the healthy and infected onion classes.

B. Data Augmentation

After dataset splitting, and pre-processing for the training process data augmentation is used it helps to prevent the possibility of over-fitting. The image of the onion was resized to 224×224. To prevent distortion the black background of 224×224 pixels was applied to the images with various pixel ratios to accomplish a comprehensive transformation. Low-contrast images of the whole onion crop were omitted. To make the requisite variety to help CNN's generalization competencies, data augmentation is mandatory. In particular, the images are arbitrarily rotated by a maximum of 10^o and randomly moved vertically or horizontally in either direction by an all-out of 20 pixels. In this way, CNN acquires to be flexible in the variation of position and orientation alteration. Besides, geometric transformations such as rotations, re-scaling, shears, shifts, flips, zooms are the methods we have used, shown in Table VI.

TABLE VI. Data Augmentation

Argument	Explanation
Rescaling	Rescaling images from integers 0-255 to float 0-1
Rotation	Degree variety of the arbitrary rotation
Shift	Shifts vertically or horizontally by (10%) and is the fraction of given dimension
Shear	Permit being sheared the angle in an anti-clockwise
Zoom	Permits the image to be “zoom-in” or “zoom-out”
Flip	Permitted the input to be flipped vertically or horizontally throughout the training procedure
Fill	The neighboring pixel value is repeated and chosen for all the vacant values

C. Data Limitation

Some drawbacks are faced by the dataset which has to be listed. Infected onion crops are incorporated into a relatively small sample. Moreover, the onion field with severe symptoms may be used to generate this sample analysis which is required. In the existing dataset crops with minor symptoms are absent which is due to the strategy of people with onion fields who have slight disease indications.

D. Classification and Training Dataset

When data pre-processing, data augmentation, and data splitting techniques are done our training onion dataset size is increased and arranged for the feature extraction phase with the model proposed to extract the necessary and applicable features. To construct vectorized feature maps the features extracted from the suggested model are compressed together. To classify the image into the corresponding groups the generated feature vector is transferred to a multi-layer perceptron. Lastly, on test images using the training model the efficiency of the proposed method is assessed. Each experiment is replicated three times and we report the average performance.

VII. Experimental Setup

Our experiments have been carried out based on the following criteria for automatic binary classification established on our image dataset. All images in the dataset have been redimensioned to 224×224 pixels. We have set the batch size 8 and 16, the epochs are 500 to train our model. The samples are 155 and 90 respectively, for the training and validation. For optimization adam β1=0.89, β2=0.98, and learning rates are set at 10-5 and reduced to 10-6. Besides, we used decay weight to reduce our model over-fitting. The regularizers are supplied from Keras. The performance was specific to GPUs. Dell Inspiron Core(TM) i5-8250U CPU (8 CPU's) of 1.6 GHz, 16 GB Ram running on a Microsoft Windows 10 Professional (64-bit) is used in the implementation of the proposed model. The authors used Anaconda Navigator (Jupyter Notebook) version 3.7.4 to perform their research Keras, TensorFlow, OpenCV, NumPy, sklearrn are used for simulation as a backend for deep learning.

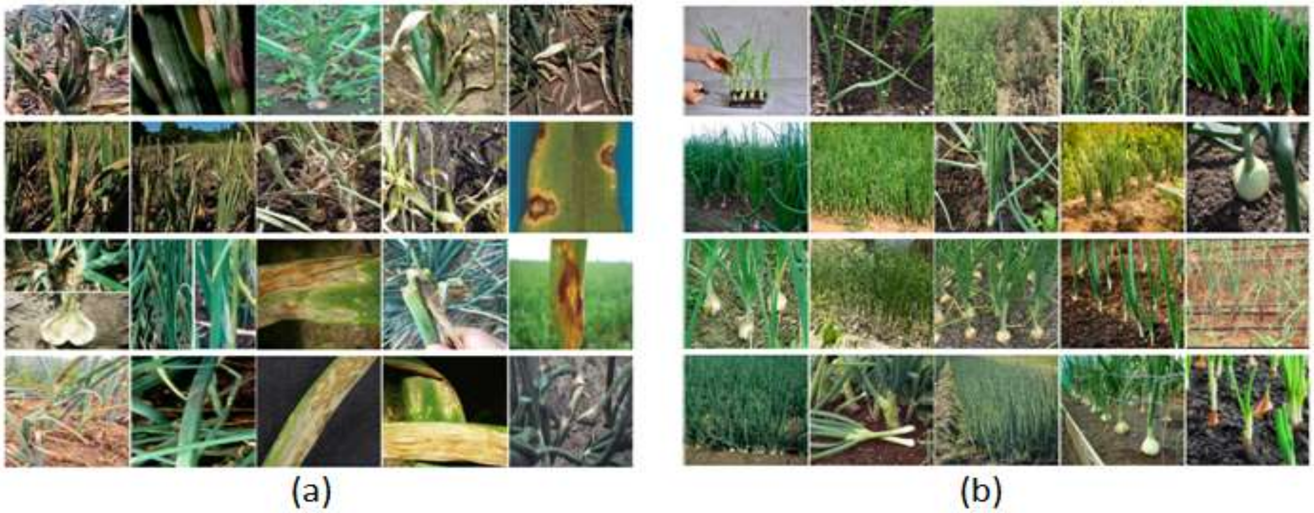

Fig. 5. Sample of Images used in Research (a) Infected Onion, (b) Healthy Onion.

A. Performance Metrics

The evaluation metrics that were used to measure the model's classification efficiency are explained in this section. For this, we use confusion matrix-based metrics [46]. Accuracy, recall, precision, F1-score, specificity, and sensitivity are examples of these metrics. We require the count of the following quantities to evaluate these measures: true positive, false positive, true negative, and false negative.

1) Accuracy: The ratio of correctly predicted predictions to the total number of predictions shown in equation (3).

$$\text{Accuracy} = \frac{\text{TP+TN}}{\text{TP+TN+FN+FP}} \tag{3}$$

2) Precision: The ratio of true positive prediction compared to overall positive predictions shown in equation (4).

$$\text{Precision} = \frac{\text{TP}}{\text{TP+FP}} \tag{4}$$

3) Recall: The ratio of a true positive prediction made by the suggested model to the total number of predictions made shown in equation (5).

$$\text{Recall} = \frac{\text{TP}}{\text{TP+FN}} \tag{5}$$

4) F1-Score: The harmonic mean of recall and precision is shown in equation (6).

$$\text{F1} - \text{Score} = 2 \times \frac{\text{Precision}\times\text{Recall}}{\text{Precision+Recall}} \tag{6}$$

5) Sensitivity: Measure the fraction of true positives correctly recognized shown in equation (7).

$$\text{Sensitivity} = \frac{TP}{\text{TP+FN}} \tag{7}$$

6) Specificity: (Also called TN rate) trials are performed on the fraction of true negatives properly-recognized shown in equation (8).

$$\text{Specificity} = \frac{TN}{\text{TN+FP}} \tag{8}$$

7) Confusion matrix: It is the evaluation of the model's results. It contrasts the true and predicted values in terms of true positive, false positive, true negative, and false negative shown in equation (9).

$$\begin{bmatrix} \text{TP} & \text{FP} \\ \text{FN} & \text{TN} \end{bmatrix} \tag{9}$$

- True Positive (TP): True positive predictions are those that were initially positive and were also predicted to be positive by the AI model.
- False Positive (FP): False positive predictions are those that were initially negative but were predicted as positive by the AI model.
- True Negative (TN): True negative predictions are those that were initially negative and were predicted as negative by the AI model.
- False Negative (FN): False-negative predictions are those that were initially positive but were predicted as negative by the AI model.

B. Experimental Results

Our research aimed to classify purple blotch disease from onion crop images using an improved InceptionV3 classifier we present the result for the binary classification in this section. Besides, several experiments are carried out on the onion crop disease (purple blotch) dataset to verify the efficiency and robustness of the suggested model. The findings are shown separately in Fig. 6 and Fig. 7 using the accuracy, loss, and receiver operating characteristic (ROC) curve of training and validation. The experiment is detailed described in Table VII. It indicates the overall outcome of the first trial batch size 8 and 500 Epochs. Accuracy and loss are calculated each after 100 epochs. We present the two most used parameters of computer vision and deep learning before discussing these results: Train curve is considered from the training dataset that gives an idea of how well the model is learning, while the validation curve is considered from a hold-out validation dataset that gives an idea of how well the model is generalizing. Besides, the loss of validation and training is defined as a summing up of the errors made in the training sets of each case. The loss is not a fraction in comparison to accuracy. To summarize, the model that simplifies well, this is neither under-fitting nor over-fitting. The confusion matrix also displays a comprehensive illustration of what occurs to images later classification. We have observed that the accuracy increases until the value is 83.48% for the train and test accuracy from epoch 0 to epoch 7. The accuracy begins to be stable after epoch 10 were 87.01% and 84.42% for training and testing data respectively. In either the fast-growing interval from epoch 0 to epoch 32 where the loss is 2.98% or in the other interval where the decrease is slow and converges to 1.76% a good fit can be found for the loss curve of train results. As shown in the confusion matrix in Table IX, the model was able to classify 80 images as infected and 1 image as healthy for the infected onion class. The model with an improved InceptionV3 could predict 14 images as healthy and 27 images as infected for the healthy onion class. Similarly, Table VIII shows the overall result of the second trial with batch size 16 and 500 epochs. Likewise, accuracy and loss are calculated each after 100 epochs. We have observed that the accuracy improves until the value is 88.98% for the training and testing from 0 epoch to 45 epoch. The accuracy is stable at epoch 38 where it is equivalent to 87.79% for training data and 86.87% for testing data. The loss curve of train data can be seen as a good match in the steadily rising interval between 0 and 100 epoch where the loss is 1.388% at the other time the decrease is gradual and converges to 1.14% at the end converges to 0.756%. As illustrated, confusion matrix in Table IX. The model can classify 78 images as infected and 1 image as healthy for the infected onion class. It can be shown that the InceptionV3 model was capable of predicting 22 images as healthy and 16 images as infected for the healthy onion class.

In the last, a comparison is made between batch sizes 8 and 16 as shown in Table IX predicted results are shown in Fig. 8. Generally, the outcomes of this trial show that the model pays complete courtesy to the features of the spot disease and achieves excellent onion disease recognition efficiency and it is very clear that batch size 16 provides approximate results.

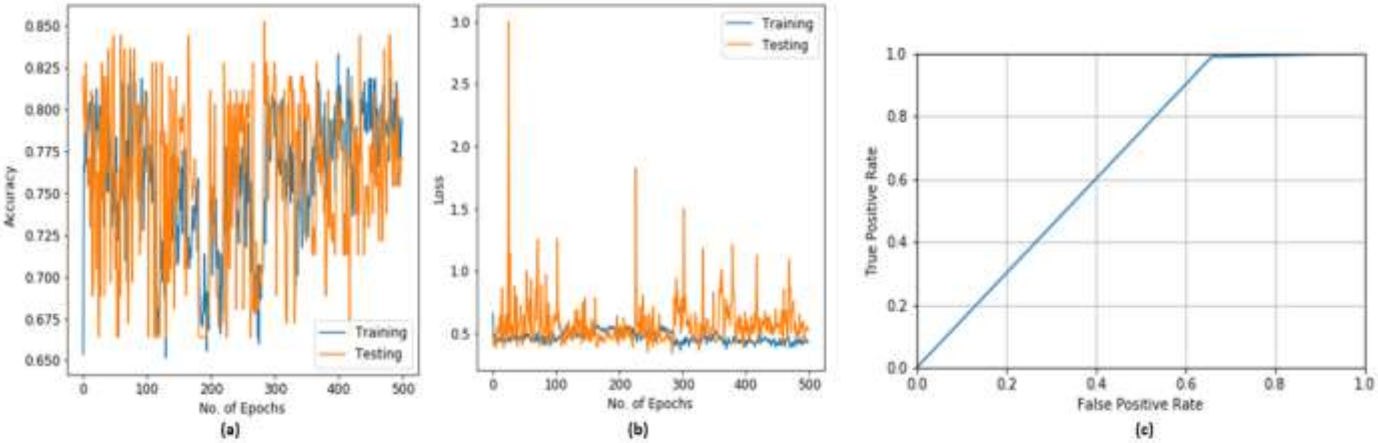

Fig. 6. CNN Model with Batch Size 8 (a) Accuracy, (b) Loss, (c) ROC Curve.

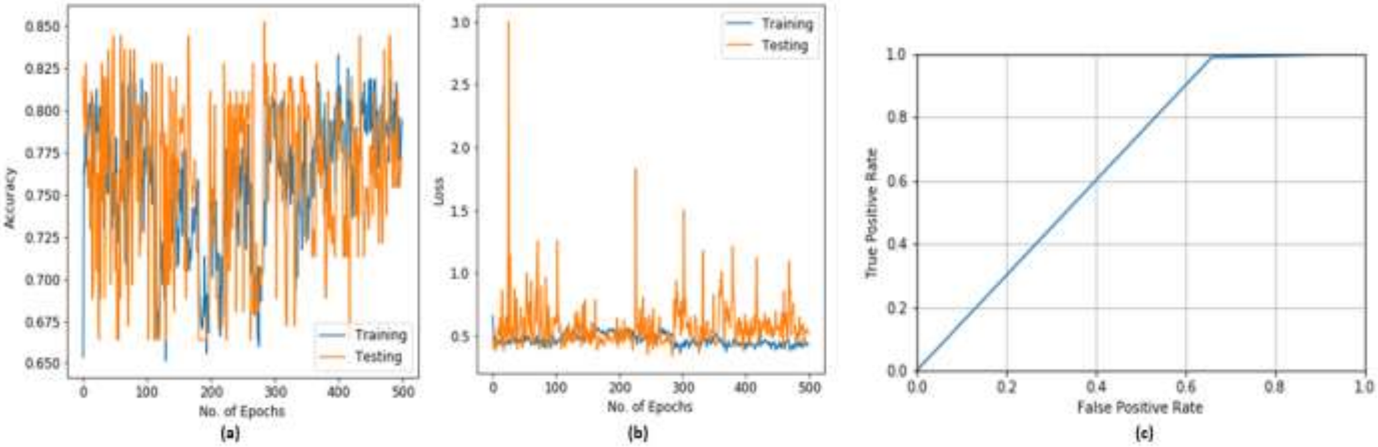

Fig. 7. CNN Model with Batch Size 16 (a) Accuracy, (b) Loss, (c) ROC Curve.

TABLE VII. RESULTS OF EXPERIMENT NO. 1

After	Accuracy/Loss
100 epochs	78.68% / 0.6275
200 epochs	81.15% / 0.4401
300 epochs	82.79% / 0.5441
400 epochs	78.68% / 0.5717
500 epochs	77.05% / 0.5197

TABLE VIII. RESULTS OF EXPERIMENT NO. 2

After	Accuracy/Loss
100 epochs	85.47% / 0.4114
200 epochs	87.18% / 0.4993
300 epochs	84.62% / 0.3868
400 epochs	84.62% / 0.6148
500 epochs	85.47% / 0.4337

TABLE IX. COMPARISON OF DIFFERENT BATCH SIZES

Batch Size	8	16
Confusion Matrix	[[14 27] [1 80]]	[[22 16] [1 78]]
Train Accuracy	79.38%	87.31%
Accuracy	77.05%	85.47%
Specificity	34.14%	57.89%
Sensitivity	98.76%	98.73%
Precision	74.76%	82.97%
Recall	98.76%	98.737%
F1-score	85.106	90.17

VIII. CONCLUSION

Alternaria porri is the fungus that causes purple blotch on onion crops. Leek, garlic, and chives are also affected by this fungus. On onion crops, spores germinate and create a thin water-soaked spot that turns brown. On several other crops, the oval-shaped lesion enlarges turns purplish, and forms the target spot appearance that Alternaria is known for (like early tomato blight). A yellow zone could encircle the margin. During wet weather, the surface of the lesion may be coated in brown to black masses of fungal spores. Infections in plants are a significant risk to worldwide food supplies. Extreme diseases in plants result in annual agricultural yield losses. The identification of diseases in plants at an initial stage is therefore very necessary for the avoidance of such dramatic losses in the future. This paper demonstrates the technical probability of deep learning to allow automatic infection analysis by image classification using the CNN approach. A new approach was discussed in this paper to use deep learning methods to spontaneously identify and detect crop disease from an image. The model established was able to differentiate between healthy and infected crops which can be diagnosed visually. The complete process was defined from the selection of images used for validation and training to the augmentation of images lastly, the deep CNN training procedure. We summarized the final results and concluded that through deep learning detection, segmentation, and classification our improved InceptionV3 achieves the highest precision as well as accuracy, F1-score, and recall. A deep CNN is accomplished to identify onion crops with a classification accuracy of 77.05% for batch size 8 and 85.47% for batch size 16 using our dataset of onion crops. Ongoing work aims to create a complete framework for crop monitoring. Besides, the performance can be improved by using a large dataset for biomedical image segmentation more advanced feature extraction techniques based on deep learning will be developed.

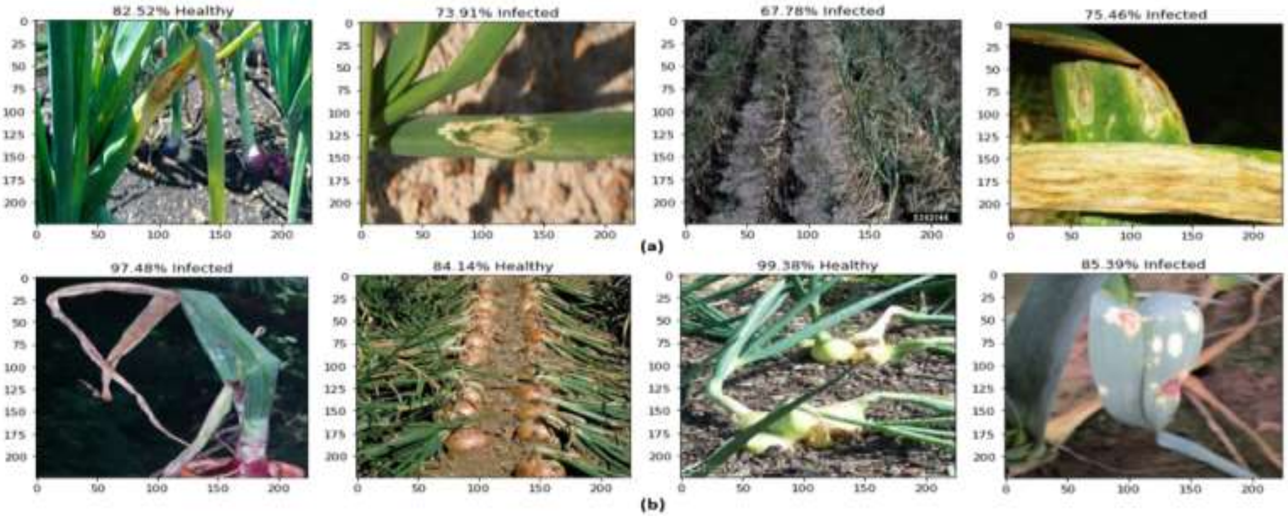

Fig. 8. Predicted Results from (a) Batch Size 8, (b) Batch Size 16.

IX. Future Directions

1) Diseases and pests manifest themselves in different ways at different stages of growth. As a result pest and disease images should be differentiated with greater caution diseases, and pests of the same class should be divided according to the growth cycle as a rule. The division of the dataset will be improved in the future.

2) The next step will be to collect a huge number of high-quality images of diverse types of diseases and pests refine and adapt the model and extend it to other crops/plants to improve the practicability.

3) The disease detection efficiency of the enhanced InceptionV3 model will be improved even further. The goal of early diagnosis and detection of onion diseases can be accomplished by capturing lesions in real-time detection.

Acknowledgment

The authors are extremely grateful to Dr. Imtiaz A. Nizamani, Department of Plant Protection, Sindh Agriculture University, Tandojam, Pakistan for helping in the collection of the onion dataset and their valuable clinical assessment throughout the study. We would like to thank Dr. WajeEha SidDiqui (WS), Peoples University of Medical and Health Sciences For Women, Nawabshah, Pakistan for her assistance and for providing us with the resources we needed to complete this study.

***Abstract*—Recently, the best antenna structures have considered microstrip patch antenna due to their simple construction, low cost, minimum weight, and the fact that they can be effortlessly integrated with circuits. To achieve multi-band operation an antenna is designed with an etching rectangle and circle slot on the surface of the patch to achieve multi-band frequency capabilities in mid-band 5G applications. Inset-fed structure type of fed of all antenna printed and fabricated on the brow of the Rogers RT5880 substrate. Then, prototype structures of the microstrip patch antenna were acquired during the design process until achieving the desired antennas. The antenna_1 achieved tri-band characteristics covering the WiMAX band including 2.51 – 2.55 GHz, WLAN, and S-band including 3.80 – 3.87 GHz and C-and X-band including 6.19 – 6.60 GHz. The antenna_2 gives dual-band characteristics covering C-band and X-band including (6.72 – 7.92 GHz) with a peak under -45 dB suitable for mid-band 5G applications. High impedance bandwidth increases between (70 MHz-1.25 GHz) for wireless applications. The proposed microstrip patch antennas were simulated using CST MWS-2015 and were experimentally tested to verify the fundamental characteristics of the proposed design, it offers multiple-band operation with high stable gain and good directional radiation characteristics results.**

***Keywords*—Band-width; microstrip; multi-band; notch slot; rectangle slot; 5 G**

I. Introduction

Generally, the microstrip patch antenna is an important component of communication systems that require characteristics such as compact size, lightweight, easy process of fabrication, and wide bandwidth. The microstrip patch antenna is primarily made of copper material or a perfect electric conductor (PEC). There are various types of geometries like a circular, rectangular, triangular, elliptical, square, ring, cone, etc. Nevertheless, the most commonly used shapes are rectangular and circular. The size of the patch antenna depends upon the substrate constant dielectric material (Ɛr). A Higher substrate dielectric constant leads to the lower size of the antenna [1][2]. The 1G /2G/3G/4G and Five generations (5G) introduce faster data rates, density connection higher, low latency [3]. Compact patch feeds square microstrip with right-angled isosceles Koch fractal antenna geometry on the edges is suitable for U-wide frequency band applications. The antenna is put on FR4-epoxy, (Ɛr = 4.4) substrate with dimensions 60 x 55 x 1.59 mm3. The antenna works at 4.3, 5.0, 6.1, 7.4, 8.9, and 9.2 GHz, this design is limited in bandwidth and gain, therefore required to strive to improve them [4]. Propose the patch antenna in the form of a Sierpinski fractal antenna, which can work in multi-band frequency, this design is limited in bandwidth and gain, therefore required to strive to improve them [5]. The designed microstrip antenna using CPW feeding technique, the microstrip antenna operates resonates at this is bands 0.45 GHz for GSM, 1.35, 1.92, 2.57 GHz for, WLAN, WiMAX, Walkie-Talkie. The antenna dimension is 46.32×25×1.6 mm3, substrate type is FR4 with Ɛr=4.3. The design is limited in bandwidth and gain, therefore required to strive to improve them [6]. The proposed microstrip is fabricated using an FR-4, the height of the substrate is 1.6 mm, and Ɛr =4.4. The ground plane and substrate dimension are the same, i.e. (70×60 mm2), the proposed microstrip antenna operates at desired frequencies 5.73, 1.8, 3.6, and 4.53 GHz, which can be used for many applications of the wireless [7]. Design patch antenna for satellite applications and operating frequency at 15 GHz with diverse slots cutting on microstrip antenna. The antenna achieving bandwidth frequency at 1.14 GHz, with S11 of -30.6 dB. The gain and directivity are 3.488, and 3.544 dB respectively. The RT duroid material size 9.5 x 8 x 1.6 mm3 to design microstrip antenna with Ɛr =2.2 have loss tangent 0.0009 [8]. The microstrip patch is fabricated and tested on substrate FR-4 with size 70×70×1.6mm3, Ɛr= 4.4. The choice bands are designed at 2.478, 2.313, and 2.396 GHz, and they have −10 dB impedance bandwidths of 2.42, 2.14, and 2.50%, respectively [9]. The microstrip patch antenna in the shape of the rectangle there is an array of L-slots and inverted them slot for multiband frequency is considered. The microstrip was designed for TM010 mode of frequency operation at 2.1 GHz. The configuration produced the best results at Penta frequency bands:1.48, 1.25, 1.8, 2.25, and 2.9 GHz. And they have -10 dB impedance bandwidth 3.4%, 3.2%, 3.33%, 4.3%, and 3.1%, respectively [10] All the design there is limited in bandwidth and gain, therefore required to strive to improve them. Design a simple microstrip antenna (UWB) for the wireless satellite. The design process is achieved in three steps. Firstly, a conventional antenna for 2.4 GHz FR4 substrate with Ɛr = 4.4 has been defined with dimensions of 50 × 55 × 1.6 mm3. Bandwidth is achieving between (2- 9.7 GHz) for different wireless applications [11]. Design microstrip a slotted pentagonal for multi-band applications. Designed on substrate material textile type with a dielectric constant is 4.4. Dimension size is 50 × 50 mm2 and thickness (h= 1 mm). The resonate frequency at 4 GHz with S11 is -31.84 dB. The antenna is achieved more directivity of 2.932

dBi and bandwidth from 2.85 to 9.30 GHz [12]. Simulated and fabricated a rectangular patch is introduce designed for 915 MHz band applications includes ZigBee and Bluetooth. A printed antenna on FR-4 epoxy substrate with a small size 60 × 30 × 1.6 mm3, with Ɛr =4.4. Achieving bandwidth from 902 MHz to 925 MHz for the ZigBee band applications. The results of the simulation are radiation pattern directivity is 2.83 dBm, the gain is 2.73 dBm, and return loss is -35 dB [13]. Design a novel broadband microstrip antenna printed on the FR-4 substrate with Ɛr =4.4. The simulated result of the patch gives four resonance frequencies at 1.59, 1.71, 1.81, and 1.986 GHz respectively, achieve a bandwidth of 29.6 % [14]. The microstrip U patch antennas on substrate Alumina 60 × 60 × 12.5 mm3 with dielectric constant Ɛr = 9.6 for wireless communication. The improvement in antenna bandwidth is recorded at 20 MHz, and efficiency 99.6%. The antenna operating frequency of the antenna is 3.8 GHz (3.06 –5 GHz), the antenna operates at single-band [15]. Design of a two-band patch using substrate PTFE, with a thickness of 0.8 mm, the dielectric constancy is 2.55. The patch antenna works at dual-band 9.96 GHz –12.84 GHz and the bandwidth of the antenna is 270 and 550 MHz respectively. The simulation result gives less value of S11 at f1 = 9.96 GHz and f2 = 12.84 is -33.6 and -39.1dB respectively. The bandwidth of the patch is 9.83 GHz and 12.57 GHz respectively [16]. Design of packaging of single antenna fed asymmetric slot-loaded triple-band patch antenna with LHCP and RHCP at two bands at (1.77645 GHz) for GPS L5 and (SDARS) at (2.320-2.345 GHz). The dimensions of the designed antenna 51 × 52 × 1.6 mm3 with substrate FR-4 material, and Ɛr = 4.4 [17]. Design a monopole antenna and implement them to operate at multi-band for 5G wireless communications and service. The antenna substrate dimension is 43 × 38 ×1.588 mm3 with dielectric constancy 4.4. The S11 parameter of the patch antenna is high than -20 dB, and VSWR is < 2 [18]. The design of the microstrip antenna is based on substrate RT/Duroid 5880 material with relative permittivity Ɛr =2.2. The patch designed and fabricated to operate in X-band is (8-12 GHz) and 60 GHz frequencies. The microstrip antenna was printed on two substrate heights (0.75- 1.57 mm) operate at 10 GHz and, (0.127 - 0.254 mm) for frequency band 60 GHz. Designing approach satisfied wideband and high gain antenna The antenna work at dual-band, but required to improve in bandwidth and achieve best reflection coefficient (S11) [19]. The microstrip patch was put on Duroid 5870 substrate h= 1.575 mm, a Ɛr of 2.33, and a dielectric loss of 0.0012, dual-band to cover K-band applications [20]. Design patch antenna printed on Rogers RT5870 with Ɛr = 2.2, and operate at 2.4 GHz. The thickness of 0.787 mm for applications such as IEEE 802.15.1 Bluetooth, ZigBee, WiFi, wireless USB. Bandwidth achieved 25.5 MHz with return loss -22.5 dB. The design is limited in operating at single band, bandwidth, and gain, therefore required to strive to improve them [21].

In this work, a new design approach is objective to realize tri-band and dual-band MPAs appropriate for 5G wireless applications. Two Compressed simple microstrip patch antennas (MPAs) have been designed to cover multiple frequency bands for wireless applications. The design idea of these microstrip patch antennas is almost based on rectangular patch antenna and are namely rectangular patch etching two rectangle slots antenna (antenna_1), and notch rectangle patch etching circle slot (antenna_2). All these antennas are fabricated on Roger RT5880 substrate and they are built the model and analyzed by using the tool of the CST MWS simulator [22]. The CST simulated result exposes that the proposed microstrip antennas are designed to guarantee the best performance results. In terms of resonant frequency bands and directional patterns as well as high gains, improvement impedance bandwidth, and total radiations efficiencies. The rest content of this work is orderly as follows. In section II, discussion the configurations of the proposed patch and the analysis process for designing these microstrip patches are offered in detail. Section III and IV are review discussion the performance of the experimental and simulated results along with the features of the designed patch antennas and parametric study. Conclusions and future work are drawn in Section V and VI.

II. Proposed Patch Antenna Design and Configuration

The simulation models of the two proposed design microstrip antenna structures are in Fig. 1(b) and Fig. 2(b), this is antennas, called the rectangular antenna etching two rectangle slots (antenna_1) etching on the reference (conventional) antenna (RA), and notch rectangle antenna with circle slot (antenna_2) by etching rectangle notch on corner of reference antenna and cutting circle slot on the middle of the patch antenna. The slot on the microstrip antenna is analyzed. The slot on the microstrip patch can be firm by using a duplicity relationship between the dipole and the slot [23] [24] [25]. The fabricated antennas are printed on the front side of the Roger RT5880 substrate. The height hs of 3.18 mm, relative permittivity Ɛr=2.2. The constant Ɛr of microstrip material should be between 2.2 and 12 for antenna designing [1]. The height of the substrate, h << λ0 (where, λ0 equal operating wavelength) [1]. The resonant frequency fr=2.4 GHz. The total substrate size (Ws x Ls) of all antennas is (94 × 78mm2). Each patch structure of these antennas size of patch (Wp) x length (Lp) of (47 × 38 mm2). The inset feeding type is used for the design because of its ease of fabrication in the PCB form, and easy matching with the existing system. The proposed microstrip antennas are configured to improve impedance bandwidth outcomes due to changes in substrate height and dielectric constancy. If the substrate height is increased the bandwidth of the antenna is also increased. This is because the bandwidth of the antenna is directly proportional to the substrate height. The feed width wf and length Lf, while the characteristic impedance is 50 Ω. A full ground plane is on the backside of the substrate material. Copper is used as the conducting material for patches and ground. The dimensions of the proposed microstrip antenna are calculated by using the well-known microstrip patch antenna formulas using this equation from (1) -(5) [1].

The width of the microstrip patch antenna (w_P) is given by the following equation [1].

$$w_P = \frac{c}{2 f_r \sqrt{\frac{\varepsilon_r + 1}{2}}} \tag{1}$$

Sub. ε_r=2.2, c=3x10^8m/sec, f_r= 2.45GHz

The effective dielectric constant ε_{reff}:

$$\varepsilon_{reff} = \frac{\varepsilon_r + 1}{2} + \frac{\varepsilon_r - 1}{2}\left(1 + 12\frac{h}{w_p}\right)^{\frac{-1}{2}} \tag{2}$$

Effective length due to fringing effects:

$$\Delta L = 0.412h \frac{(\varepsilon_r + 0.3)\left(\frac{w_p}{h} + 0.264\right)}{(\varepsilon_{reff} - 0.2680.3)\left(\frac{w_p}{h} + 0.8\right)} h \tag{3}$$

The effective length of the patch (L_{eff}):

$$L_{eff} = \frac{c}{2 f_0 \sqrt{\varepsilon_{reff}}} \tag{4}$$

The actual length of the patch:

$$L_p = L_{eff} - 2\Delta L \tag{5}$$

To determine the ground plane dimensions length (L_g) and width of the ground plane (w_g)

$$L_g = 6h + l_p \tag{6}$$

$$w_g = 6h + w_p \tag{7}$$

Where W_p the width of the microstrip patch, f_r = 2.45GHz is the resonant frequency, ε_r =2.2 is the dielectric constant of the substrate material, h_s =3.18 mm is the height of substrate material. The patch antenna L_p= 38 is the length of the patch and w_p= 47 mm is the width of the patch. After many series of optimization by using CST simulator, then, the final parameters and the optimized value of the parameters are illustrated in Table I.

Reign successively conventional patch antenna (MPA) was designed founded and based on the equations (1) -(5) for resonating frequency at the proposed frequency. Initially, MPA is designed with the same geometrical parameters. The obtained CST simulated reflection coefficient(S_{11}) and radiation pattern realized gain of reference antenna (RA) shown in Fig. 1(a) or 2(a) and 3, an antenna is resonating at f_r = 2.45 GHz with -10 dB S_{11} impedance bandwidth 70 MHz ranging from (2.43 – 2.50 GHz) for (WiFi), return loss is -23 dB, and radiation pattern of the antenna. It is demonstrated from observations in Fig. 4 that the RA inset-feeding technique with a full ground plane has a better gain of 7.31 dB and, a boresight directional radiation pattern suitable for wireless communication application.

III. DISCUSSION OF SIMULATION RESULTS

After that, the procedure for microstrip patch antenna structures in the previous section is suggested for the proposed antennas for operating in the wireless communication WLAN, WiMAX, C- band, and -X band frequency ranges for mid-band 5G wireless applications [27]. The proposed design concept will be Verified by the main performance parameter results concluded to gain, reflection coefficient (S_{11}), and current distribution on the patch as well as the radiation pattern directivity and realized gain.

A. Reflection Coefficient

The proposed microstrip patch antenna structures are realized in simulated of the CST Microwave Studio ver. 2015. Its time-domain solver is used to obtain these results. The reflection coefficient (S_{11}) for the proposed microstrip antennas, antenna_1 and antenna_2 is discussed and investigated in detail. The results of the return loss of the whole prototype proposed antenna structures have been recapped in Fig. 5 and 6, shows the S_{11} plot for intermediate antennas that belong to each type of the two proposed antennas. Observed that the antenna_1 covers tri-band characteristics, whereas the antenna_2 gives dual-band. The frequency bands of the proposed antennas can be summarized as follows:

1) Antenna_1: Cover WiMAX band 2.53 GHz (2.51 – 2.55 GHz, 1.5%) and WLAN/C-band and S band 3.86 GHz (3.80 – 3.87 GHz, 2%). C-band 6.45 GHz (6.19 – 6.60 GHz, 6%) for 5G application [26].

2) Antenna_2: Cover C band and X band for mid-band 5G service [27], 6.92 and 7.707 GHz (6.72 – 7.92 GHz, 17.5%).

Thus, these microstrip antennas cover the helpful frequency bands that useful for wireless communication.

VSWR results proposed microstrip antenna have been shown in Fig. 7. Their quantitative analysis in terms of f_r, f_l, *and* f_h, between RA and their proposed antennas, is listed in Table III. The realized gain respect to frequency for the proposed microstrip patch antennas at desired frequency bands is observed in the experimental result in section 3. Then the gain of antenna_1 at the lower frequency band is the less one whereas it is the greater one in the high band.

TABLE III. THE PROPOSED ANTENNAS TO RA COMPARISON FROM THE BANDWIDTH, (FL- FH), FR PERSPECTIVE IN (GHZ)

Antenna	Band 1	Band _2	Band 3	B.W (MHz)
RA	(2.43– 2.50), 2.45 GHz	------	-------	70
antenna_1 (Tri-band)	(2.51–2.55), 2.53 GHz	(3.80 3 .87), 3.86 GHz	(6.19-6.60), 6.45 GHz	50,70,410
antenna_2 (Dual-band)	------	(6.75-7.92), 6.92 GHz	(6.71-7.94), 7.707 GHz	1250

B. 2-D and 3-D Radiation Pattern

Fig. 8 shows the 2-D radiation pattern in terms of E- or yz-plane and H-or xz -plane at band 1, band 2, and band 3 observed at Table III. It is observed from this figure that all antennas have a directive radiation pattern in H-plane and E-plane at the lower band (2.53 GHz), and near to omnidirectional at all other middle and higher frequencies (3.86 GHz & 6.45 GHz) bands. The radiation pattern in E-plan shown in Fig. 8(a) at 2.53 GHz shows close to bidirectional nature with angular width (3) of 75.0 deg., and main lob directional 1.0 deg. Whereas, the radiation pattern at 3.87, 6.45 GHz shown in Fig. 8(b) and Fig. 8(c) shows close to omnidirectional nature with greater angular widths 59.2 and 31.6 degrees respectively. Besides, the main lob directional 4.0 and -5.0 degrees respectively. Therefore, the radiation pattern is changed from bidirectional to omnidirectional when the angular width is reduced.

Fig. 9 shows the 3-D radiation pattern for tri-band frequency (a) for 2.53 GHz, (b) 3.86 GHz, (c) 6.45 GHz.

Fig. 10 shows the 3-D radiation pattern for dual-band frequency (a) for 6.92 GHz, (b) 7.707 GHz.

The simulated results verified that the proposed antennas are achieved multi-band antennas. Table IV shows the simulation results of proposed antennas that have a good radiating element antenna, return loss less than -20 dB, good realized gain, VSWR is less than 2, and good impedance bandwidth.

C. *Surface Current*

To analyze the effectiveness, of the proposed microstrip patch antenna, the higher modes make nulls and some side effects lobes this is due to the effect of the vertical and horizontal distributions current on the surface slotted microstrip antenna, as the operating band frequency increases. The surface current of antenna_1 shows in Fig. 11, and analyzed at frequency band in Fig. 11(a) shows the surface current distributed have mainly flowed throw feed line part and in a horizontal line on the patch at a lower frequency. However, the path and the direction of the density are entirely changed with the insertion of two rectangle slots. As shown in Fig. 11(b) the current distribution along with two rectangle slot more concentrated interior slot and exterior of two rectangle slot, mainly flows along feed line part. Thus, two rectangle slots modify the surface current distribution to generate resonance at 3.86 GHz. Fig. 11(c) shows the distribution mainly on the feed line part and inside two rectangle slots of the patch in relatively higher frequency (6.45 GHz). From Fig. 11(d), it can be observed the surface current distribution the path, and the direction of the current are entirely changed with the insert of the circle slots. The current distributed concentrated throw feed line under an arc of the circle and its below. The current distributed interior edge of the circle and outside of circle slot, and less current density throw the notch.

D. Parametric Study

To reach up with a final design of acceptable performance worked at in-demand frequencies; dense simulations to test the insight of each antenna dimension and slots on its performance have been done using parametric sweep –time-domain solver CST simulator. The antenna_1 is optimized to operate at triple-frequency bands.

Fig. 12 shows the effects of variation on S_{11} characteristics, it indicates that the second resonant at 3.86 GHz is the most affected resonant, and its value increased -29.30 dB as w_1 increased. While the first and third resonance for the patch itself; is not nearly affected. The rectangle length-shaped slot of antenna_1 is l1 changed in two rectangle slots to find its effect on antenna_1.

Fig. 13 shows the effects of variation in l_1 on S_{11} characteristics. The center frequency of the second resonance is increased return loss is -35.29 dB at 3.86 GHz as l_1 increased while decreasing when the value l_1 decreases and the center frequency of the third frequency varies to change according to change the value of l_1. But first band resonance for the patch itself; is not nearly affected.

It can be observed that the impedance fractional bandwidth is wider for the third frequency band at a different value of l_1. Bandwidth 440 MHz (6.17 - 6.61GHz, 6.87%) is resonating at 6.45 GHz achieving a return loss of −27.19 dB is obtained when (l_1 = 18 mm). The effects result of variation in l_1 for impedance bandwidth and S_{11} are tabulated in Table V.

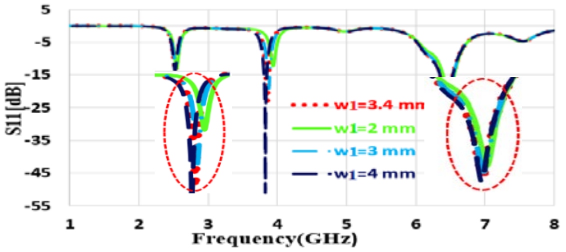

Fig. 12. Simulated S_{11} for Antenna_1 with Variation of width of slot (w_1).

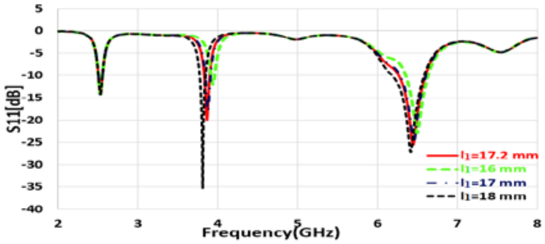

Fig. 13. Simulated S_{11} for Antenna_1 with Variation of l1=16 -18 MM.

TABLE V. COMPARATIVE RESULTS OF ANTENNA_1 VARIED LENGTH L1= 16 - 18 MM

l_1(mm)	Return loss (dB)	Triple resonant freq. (GHz)	Bandwidth MHz
l_1=18	-14.13 -35.29 -27.19	2.53 3.81 6.41	(2.50-2.55 GHz) is 50 MHz (3.77-3.83 GHz) is 60 MHz (6.17-6.61GHz) is 440 MHz
l_1=17.2	-14.13 -17.97 -24.93	2.53 3.87 6.44	(2.50-2.55GHz) is 50 MHz (3.82-3.91GHz) is 90 MHz (6.25-6.61GHz) is 360 MHz
l_1=16	-14.13 -11.63 -22.87	2.53 3.94 6.49	(2.50-2.55GHz) is 50 MHz (3.90-3.91GHz) is 100 MHz (6.35-6.63GHz) is 280 MHz

From Fig. 14, it can be observed the circle slot parameter sweep has also its influences on the antenna_2 performances. The radius slot of the circle (r = D/2) is selected to be presented the effects of variation in r on S_{11} shown in Fig. 14. The first frequency band at 6.92 and 7.707 GHz resonances are which respond to any change in the dimensions of the slots by shifting up/down or degrading/ improving the return losses. The analysis reveals that as the radius of a circle (r =9.2 and 9.25 mm), the wideband characteristic of the antenna represents dual-band at 6.933 and 7.707 GHz the fractional bandwidth increases. While radius value (r = 8.5 and 10 mm) the bandwidth decreases. The maximum bandwidth (1.25 GHz) of 16% (from 6.72 – 7.94 GHz) resonating frequency at 7.707 GHz, given reflection confections, return loss of -55 dB is obtained when r = 9.2 mm and -16.92 dB at 6.93 GHz. After the optimization, the parameter of the proposed antennas has the best bandwidth and return loss for a radius value of r = 9.2 mm. The effects of variation in r on impedance bandwidth and S_{11} are tabulated in Table VI.

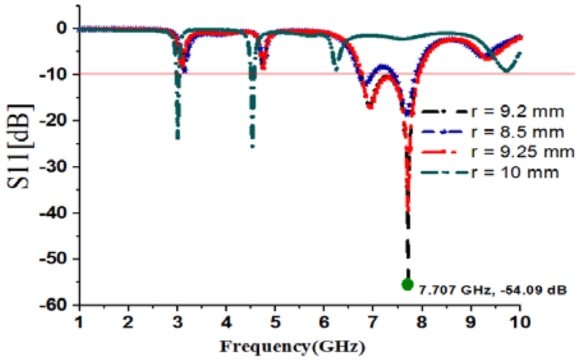

Fig. 14. Simulated S_{11} for Antenna_ 2 for Variation of r.

TABLE VI. COMPARATIVE RESULTS OF THE RADIUS OF A CIRCLE(R) FOR ANTENNA_2

Radius of circle	Return loss(dB)	Resonant freq.(GHz)	Bandwidth(MHz), %
r= 8.5 mm	-18.60 -12	7.68 6.83	450 MHz, 6% 260 MHz, 5%
r =9.2 mm	-55 -16.92	7.707 6.93	1250 MHz, 16%
r=9.25 mm	-39.60 -16.92	7.69 6.933	1170 MHz, 16%
r= 10 mm	-23.72 -25.50	2.99 4.53	50 MHz, 2% 50 MHz, 2%

Continue to study the effected of reflection coefficient (S_{11}) concerning frequency for proposed microstrip patch antennas with the different substrate material will be shown in Fig. 15. Observed from this figure, the return loss vs frequency response is verified by applied different substrate materials Roger RT5880, FR-4, and Roger RT5870, without changing the dimensions of slots. Whereas, after optimization and from a results acts comparison between them, it is that Roger RT5880 material realized best results of reflection coefficient (dB) and better wider impedance bandwidth respect to these of the other substrate materials used.

E. Comparison with other Studies

From Table VII, it can be observed analysis comparison between the proposed multiband rectangular microstrip patch and other rectangular antenna structures over previous multiband patch antenna design, such as [4], [5], [6], [7], [8], [9], [10], [15], [19] and [21]. The design recorded in [4-5-6-7-9-10] the patch antenna work in multi-band frequency, but band-width and gain less than compared with the proposed design. Reference [8-21] in this works antenna operates in single-band therefore, bandwidth, gain and reflection coefficient (S_{11}) less than comparing with multiband frequency proposed antenna. The design recorded in [19] the patch operates in dual-band compared with proposed multi-band antenna. The objective of this work to design a microstrip patch antenna that operates at multi-band realized high gain and enhanced bandwidth for wireless applications.

IV. Experimental Results

The fabricated prototype of two proposed antennas, the first antenna has a tri-band and the second has dual-band frequencies. The proposed patch antennas are fabricated and measured to verify the performance of the proposed multi-band microstrip antenna printed on the dielectric constant of 2.2 of Rogers RT5880 substrate with a loss tangent of 0.025 and a 3.18 mm thickness. a copper layer thick of 0.07mm on each side for the patch and ground plane for the proposed microstrip antennas. The front side view and measurement of the proposed antennas are shown in Fig. 16.

The prototype model structure is fabricated at the national telecommunication institute (NTI) Cairo Egypt, while the experimental verification of the S_{11} results and the far-field measurements are carried out using the anechoic chamber at Microwave lab, Ain-Shams University, Cairo Egypt.

The measured return loss(S_{11}), VSWR, realized gain, directivity, and far-field results of antenna_1 and antenna_2 are realized in good agreement with simulation results illustrated in Fig. 17. Fig. 17(a) shows the measured return loss(S_{11}) exhibits good tri-band frequency response, and experimental results verified multi-band frequency. The measured S_{11} and impedance bandwidth is shown in Table VIII.

The measured impedance bandwidths for antenna_1 are shown in Fig. 17 (a) as (2.36 -2.477 GHz, 5%) at the 2.402 GHz, (6.32-6.63 GHz, 4%) at the 6.55 GHz band, and (7.077-7.387 GHz, 4.5%) at the 7.25 GHz band.

Fig. 17(b) shows S_{11} of antenna_2 which exhibits a good dual-band frequency response. The measured S_{11} impedance bandwidth is 1.42 GHz (6.518-7.949 GHz, 20%) at 7.707 GHz, which is better than the simulated bandwidth (1.25 GHz) valid for C-band and X-band for 4G, and suitable for mid-band 5G wireless applications. The measured results and simulated S_{11} microstrip are comparisons presented in Table VIII.

The experimental results return loss (S_{11}) is in close with its simulation result. However, there, exist some slight discrepancies caused during the implementation of the microstrip patch antenna precision and interface deviation due to loss material, Rogers RT5880 plate for the manufacture of the antenna prototype which is not typical in each country. The fabricated method and measurement techniques generate the differences between simulated and measurement results. Also, S_{11} levels are accredited to tolerance during the fabricated and measurement steps.

TABLE VIII. The Experimental Measurement and Simulated Comparison Results, TRI-Band of Antenna_1, and a Dual-Band of Antenna_2

antenna_1	**Resonant freq. (GHz)**	**Directivity (dBi)**	**Realized Gain (dB)**	**Bandwidth (MHz)**	**antenna_2**	**Resonant freq. (GHz)**	**Directivity (dBi)**	**Realized Gain (dB)**	**Bandwidth (MHz)**
Measured	7.25 6.45 2.40	12 8.5 8.9	9 6.5 7.2	310 240 50	Measured	7.44 6.80	8.5 6.9	6.5 5	1420
Simulated	6.45 3.86 2.53	10.62 8.22 8.34	10.5 7.97 8.18	410 70 50	Simulated	7.707 6.93	7 6.9	6.22 5.56	1250

Illustrates the performance of measured VSWR from Fig. 18, for the proposed patch antennas, which verified value less than 1.5 at all resonant frequencies compared with simulated results. At all frequencies, minimum reflected power is inferior to -20 dB. The conclusion derived from the analysis of both Fig. 17 and 18, measured results of return loss and VSWR respectively, confirms that the designed multi-band microstrip patch antenna ensures obtaining good performance.

From Fig. 19, it can be observed realized gain plots vs frequency measured and simulated for the antenna_1 and antenna_2. The simulated gain is 10.6 dB at high frequency (6.45 GHz) and 8 dB at low frequency (2.53 GHz). The measured gain of 7.2 dB at 2.402 GHz frequency, while 6.5 dB at 6.55 GHz frequency is shown in Fig. 19(a).

Fig. 19(b) shows the experimental and simulated result realized gain of antenna_2. The measured gain is 5 dB at 6.8 GHz, 5.6 dB at 7.44 GHz, while the simulated realized gain is 5.56, and 6.22 dB at 6.93, 7.707 GHz, respectively.

Fig. 20 shows the measured and simulated directivity against frequency for the antenna_1 and antenna_2.

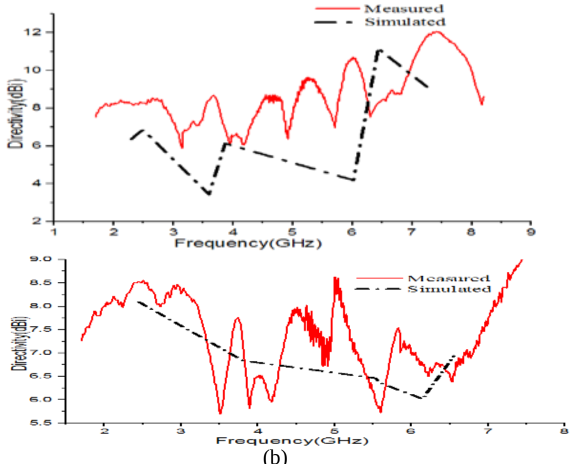
Fig. 19. Measured and Simulated Realized Gain of (a) for Antenna_1, and (b) for antenna_2.



(b)

Fig. 20. Measured and Simulated Directivity for (a) Antenna_1, and (b) Antenna_2.

The realized gain, directivity, and impedance bandwidth of proposed antennas are tabulated in Table VIII.

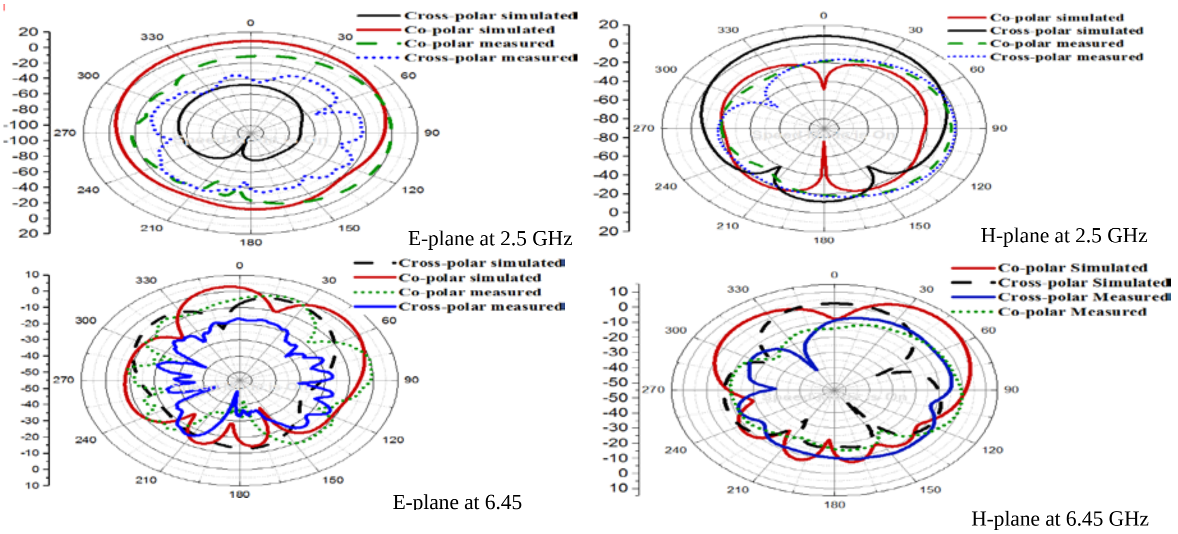
Fig. 21(a), (b) display the experimental measurement and simulation radiation patterns for the antenna_1 along with two elevation cuts (xz and yz planes) exhibit dual-polarization, E and H-plane co and cross-polarization at frequency bands 2.53 and 6.45 GHz.

Fig. 22 displays the experimental measurement and simulated radiation patterns for an antenna_2 along with two elevation cuts (xz and yz planes) exhibits dual-polarization, E and H-plane co, and cross-polarization at 7.707 GHz. The deviation of the measured results from the simulated results may be attributed to fabrication imprecision and measurement errors. Besides, the dielectric slab will be cause-effect, with little differences in the side lobes of the radiation patterns between measurements and simulation results.

From Fig. 21 and 22 discussions of co-polarization and cross-polarization between measurement and simulated for proposed antennas. Co-polarization is defined as the polarization the antenna was intended to radiate, while Cross its perpendicular pair [1].

The cross-polar and co-polar in E and H-plane for antenna_1 have been shown in Fig. 21(a) and Fig. 21(b) at 2.53, 6.45 GHz respectively, which is close to omnidirectional nature. Fig. 21(a) has shown radiation pattern in E-plane, simulated co-polar radiation angular width 27.3 deg. has been measured with an angular width (3) of 25.3 degrees at 6.5 GHz. But simulated cross-polar 39.7 deg. and measured 35.5 deg. at 6.5 GHz. While the measured co-polar in E-plane angular width of 68.8 degrees at 2.5 GHz and simulated angular width of 75.0 GHz at 2.53 GHz. But radiation pattern in E-plane the measured cross-polar angular width about 58.8 degrees at 2.5 GHz and simulated 76.2 degrees at 2.53 GHz.

Fig. 21(b) shows simulated co-polar in H-plane of 68.5 degrees and measured 75.2 degrees at 2.53 GHz whereas, the simulated cross-polar in H-plane angular width 68.8 degrees at 2.5 GHz, and measured angular width of 63.4 degrees at 2.5 GHz.



E-plane at 2.5 GHz

H-plane at 2.5 GHz

E-plane at 6.45

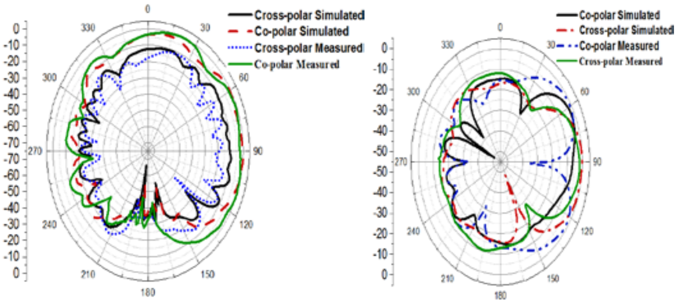
H-plane at 6.45 GHz

Fig. 21. Measured and Simulated Co-polar and Cross-polar of Antenna_1 at 2.5 and 6.45 GHz.

The simulated cross-polar in H-plane angular width of 58.0 degrees at 6.45 GHz and measured 59.8 degrees at 6.5 GHz. Whereas, simulated co-polar in H-plane of 41.8 degrees at 6.45 GHz and measured of 58.3 degrees at 6.5 GHz. It is possible to omission the far-field radiation in E-plane, compared to H-plane at frequency band 2.53 GHz, whereas, it is noted that the cross-polarization of the E-plane is lower than the cross-polar in the H-plane. Similarly, the cross-polar in far-field at 6.45 GHz band in the E-plane is lower than the cross-polar in H-plane**.** Therefore, the angular-width is reduced when the far-field radiation pattern is changed from Omni-to-bidirectional.

Fig. 22 has shown co-polar and cross-polar in the H-and E plane. Fig. 22(a) illustrated measured a co-polar 74.5 degree and simulated 70.1 degrees at 7.707 GHz. Also, a measured cross-polar angular width of 49.7 degrees and simulated angular width of 51.0 degrees at 7.707 GHz has been shown.

Fig. 22(b) shows measured co-polar in H-plane angular width of 54.8 degrees and simulated 58.3 degrees. Also, the cross-polar angular width of 35.2 and 38.3 degrees was measured and simulated respectively at 7.707 GHz.



(a)

(b)

Fig. 22. Measured and Simulated Co-polar and Cross-polar for Microstrip Antenna_2 at 7.707 GHz, (a) E-plane, (b) H-plane.

V. Conclusion

In this work, we design and fabricate two proposed microstrip antenna covers multi-band microstrip patch antennas. These proposed antennas cover the useful frequency band of modern wireless communication systems. Antenna_1 covers tri-band frequency, for WiMAX band 2.53 GHz (2.51 – 2.55 GHz), WLAN/C-band band 3.86 GHz (3.80 – 3.87 GHz), and C-band 6.45 GHz (6.19 – 6.60 GHz) which has potential for C- band in 5G services. Antenna_2 covers dual-band for C- band, and X-band 6.92/ 7.707 GHz (6.72 – 7.92 GHz, 1420 MHz) which is serving for C- band and suitable for mid-band 5G application. The proposed design of microstrip patch antennas is characterized as simple structures to be manufactured (94 × 76 × 3.18 mm^3). Besides, Experimental results verified good conformity with simulation results such as return loss, gain, bandwidth, and radiation pattern of these antennas.

VI. Future Work

Simulation the antenna on another simulator and compare the simulation results obtained with two simulators: Improvement the bandwidth and radiation pattern; Fabricated microstrip antennas with other material is low cost.

***Abstract*—Parkinson’s disease (PD) is a neurological progressive disorder and is most common among people who are above 60 years old. It affects the brain nerve cells due to the deficiency of dopamine secretion. Dopamine acts as a neurotransmitter and helps in the movement of the body parts. Once brain cells/neurons start dying due to aging, then it will lead to a decrease in dopamine levels. The symptoms of Parkinson’s are difficultly in doing regular/habitual movements, uncontrollable shaking of hands and limbs may encounter memory loss, stiff muscles, sudden temporary loss of control, etc. The severity of the disease will be worse if not diagnosed and treated at the early stages. This paper concentrates on developing Parkinson’s disease diagnosing system using machine learning techniques and algorithms. Machine Learning is an integral part of artificial intelligence it takes huge data as input and train by making use of existing algorithms to understand the pattern of the data. Based on the recognized pattern, the machine will act accordingly without any human intervention. In this work, two major approaches have been employed to diagnose PD. Initially, 26 vocal data of PD affected and healthy individual datasets are obtained from the UCI Machine Learning data repository, are taken as initial raw data/features. In pre-processing, the mRMR feature selection algorithm is employed to minimize the feature count and increase the accuracy rate. The selected features will further be extracted using the Stacked Autoencoder technique to improve and increase the accuracy rate and quality of classification with reduced run time. K-fold cross-validation is used to evaluate the predictive capability of the model and the effectiveness of the extracted features. Artificial Immune Recognition System – Parallel (AIRS-P), an immune inspired algorithm is employed to classify the data from the extracted features. The proposed system attained 97% accuracy, outperforms the benchmarked algorithms and proved its significance on PD classification.**

Keywords*—Immune algorithms; Parkinson’s disease; stacked autoencoder; airs-parallel; machine learning

I. Introduction

Parkinson's disease is a complex neuro-related disorder, having more prevalence among elderly people around the world. It is essential to diagnose it early to treat it accordingly. Although it has several treatments, medications, and surgery, it is always better to recognize the symptoms at the early stages. So, it helps in better recovery of the PD affected patients. Medication plays an important role in controlling the symptoms of PD. Medications include Dopamine Promoter, Anti-depressant; Anti-tremor can help in overcoming the effects of PD. The most prescribed medicine is L-dopa (Levodopa) combined with Carbidopa. The medicine will be converted into dopamine by the brain cells and thus it balances the level of dopamine needed for the motor actions of the nervous system. However, recognizing the symptoms of PD and early diagnosis helps to control the severity before it gets worse.

The genetic mutations and environmental factors may be the genesis for Parkinson’s disease. The usage of herbicides, fungicides, and pesticides is the emergence of acquiring Parkinson’s disease. The related studies unveiled the 70% of the people affected by the PD due to the excessive usage of the pesticides. There are several transformations obtain in the brain of Parkinson’s Disease afflicted people includes, including the clumps of some certain element in the interior of brain cells called Lewy bodies. Lewy bodies retain the key value to identify the genesis of the PD. Despite the possibility of many elements present in the Lewy bodies from the elements the vital protein termed asalpha-synuclein (a-synuclein). Alpha-synuclein is encountered in Lewy bodies in a clustered form, the cells in the clumped formcould not be decomposed.Various genes are decisively linked up with the Parkinson’s disease such as LRRK2, DJ-1, PRKN (Parkin), PINK1, GBA (Glucocerebrosidase – beta) and SNCA. Parkinson's disease is closely similar to other diseases such as Progressive supranuclear palsy (PSP), Corticobasal degeneration (CBD), and Multiple System Astrophys (MSA). The above three can be described as the name of Parkinson’s plus Disease.

Attributable to Parkinson’s plus disease, it is challenging to diagnose Parkinson’s disease from Parkinson’s plus diseases. PD diagnosis is elicited from either neurological examination, lab tests, or scans of the brain. As a consequence of not having the proper treatment to treat the PD, surgery, or medication is the possible one to improve the health of PD affected people. Several medications procedures are followed. Surgery will be prescribed when the medications are no longer good enough. Deep Brain Stimulation is the type of surgery used presently. In the future, some potential treatments will explore the areas in particularly neural (cell) transplantation, Gene therapy, and

Immunotherapy. In Neural Transplantation, displace the affected and dead brain cells with the new cells. The new cells can develop and increased. The outcome of the research holds the partial result, some peoples are getting improvement in the health and some of not. Gene therapy is another research area; this technique is also having some complications to implement effectively. Research is still on the horizon to cure Parkinson's disease entirely [1].

Computer-Aided Diagnosis (CAD) is rapidly emerging in these days to help people to check the early symptoms on their own with needed reports and data. This paper is one such diagnosis system developed using Artificial Intelligence, Machine Learning, and neural network schemes. For, we employ Stacked Autoencoder and AIRS parallel to extract the raw features and classify PD affected persons from healthy individuals by applying the feature vectors.

The upcoming part of the work is compiled in the following manner. Section 1 of the paper is Introduction has already been discussed. Section 2 discusses the existing works that inspired this paper. Materials and methods will be Section 3 as it mainly concentrates on the technical aspects of the proposed work and employed algorithms. Results, Simulation, and Comparison are done on Section 4 of the paper. Section 5 concludes with the summarization, significance, and importance of the work based on the results and existing works.

II. Literature Survey

In this part, the prevailing literature is conducting and preforming review and on it. The associated works mainly explore diverse feature extraction methods and classification algorithms on the healthy data.James Parkinson who wrote the initial medical depiction for Parkinson's disease in 1817. But it was further processed by Jean-Martin Charcot Parkinson's disease. Jean-Martin dissociated Parkinson's disease from other disorders and is characterized by tremors. It is a neurological progressive disorder. The person whose age is more than 60, Parkinson's disease is common to them. It mainly affects the brain nerve cells due to the deficiency of dopamine secretion. Dopamine acts as a neurotransmitter and helps in the movement of the body parts. Because of aging, the human brain cells start to perish, it will lead to a decrease of dopamine levels. The major symptoms of Parkinson's are difficultly in doing regular/habitual movements, uncontrollable shaking of hands and limbs may encounter memory loss, stiff muscles, sudden temporary loss of control and facial expression changes are recognized. The severity of the disease will be worse if not diagnosed and treated at the early stages.To diagnose the PD, there is a limited diagnostic test are an avail.

To diagnose the motor disorders of PDDaTscan is the only way out. To make the diagnosis ineffective way, machine learning provides an efficient way. In this paper, the voice dataset is used for diagnosing the PD by the use of supervised learning. The dataset found from the UCI machine learning repository. The overall dataset consists of 195 vowel voice records. Among the dataset, 48 voice records from healthy people and 147 from affected persons. 22 features are selected for preprocessing. 10 features are selected based on the Filter-Based Feature Selection algorithm from 22 features. The specific algorithm used was the Pearson Correlation scoring method is implemented to correlate the features with the label. K-fold cross-validation is used to perform training and testing on all data to increase the efficiency of the outcome.The dataset employs the following models Averaged Perceptron, Bayes Point Machine, Decision Forests, Locally-Deep SVM,Boosted Decision Tree Logistic Regression,Boosted Decision Tree, Neural Networks, and SVM. From these models Boosted Decision Tree provide the most accurate result when compared to other models. This paper concludes the voice recordings are feasible to diagnose Parkinson's disease.

Artificial Immune Recognition System is a modern supervised learning algorithm, inspired by the immune system. AIRS provides the best outcome for classification problems. AIRS is the fusion of artificial intelligence and biological inspired computation evolved from the metaphor and the heuristic knowledge of the biological immune system [2--6]. The AIRS is the first AIS procedure used to solve the classification problems. AIRS has somespecialized characteristics such as Self – Regulation, Generalization, Performance, and Parameter Stability. AIRS has many biological terms such as antigens, B-cells, T-cells, clonal selection, etc., the implementation level of AIRS is a very complicated one. The procedure of the AIRS algorithm is needed to prepare a collection of memory cells. Those memory cells are needed to train the data. The developmental process of the AIRS algorithm has the following steps: 1) Construct the data for the training process and the data should be normalized, use Euclidean distance measures for calculating the affinity measures, then select the antigens randomly for memory pool. 2) Training the memory cells by antigens. 3) From the selected memory cells are mutated clones, such clones are moved to ARB (Artificial Recognition Ball). 4) Competing for the limited resources 4. Selecting the memory cells. 5) The classification has to be done by implementing the k nearest neighbor method. The above life cycle of AIRS produces better accuracy in diagnosing the disease early. This paperconcludes, the AIRS has provideda good accurate result when compared to the rest of the classifiers [2].

This paper describes the Parallel AIRS. Parallel AIRS is one of the AIRS algorithms. AIRS 1 and AIRS 2 are the serial versions of the AIRS algorithm[7-9]. Both algorithms relying on a single processor to train the memory cells. But Parallel AIRS has multiple processors, so more than one processor can perform their task-parallel. AIRS 1 and AIRS 2 algorithm have the nine steps [10-13] worked in a single processor. The following steps are done by the parallel AIRS. Step1: From the root read the training data Step 2: Distribute the training the data to np (number of processes). Step 3: Each processor executes from step 1 to step 9 based on the serial processuntil the training data obtained. Now each processor holds the trained memory cells. Step 4: Collect the memory cells from each processor and the memory cells are merged and back to the root (initial stage). Speed up is achieved without any loss of accuracy in the classification. The efficiency of Parallel processor can be stated as E(P) = T(1) / P * P(T), where P is the total number of processors, T(1) is the time for AIRS 1 and AIRS 2, T(P) is the time for the algorithm of a parallel version. The AIRS algorithms (AIRS 1, AIRS 2, and Parallel AIRS) implemented on datasets in the WEKA platform [14]. The classification accuracy of Parallel AIRS shows the best when compared to the other AIRS algorithms.

Autoencoder is one of the unsupervised machine learning algorithmsin a deep neural network. The output values should be equal to input values. It is used to deplete the size of our inputs as a compressed form, by performing the reconstruction the original data is evolved. The architecture of the Autoencoder is of three parts, encoder, hidden layer, and decoder. The encoder compresses the input data into latent space representation [15-20]. It reduces the original dimension of the data. Hidden layers refer to code it holds the compressed input and the decoder, it reconstructs the code from latent space representation to produce the output. The autoencoder is used to extract some specific features from the data and produce the output. So, the autoencoder used as feature extraction. Stacked Autoencoder consists of various sparse encoder layers. Each is placed one after another like a hierarchical format. Each input of successive bottleneck (hidden or internal) layer connected to each bottleneck layer of output [21-22]. The algorithm of stacked autoencoder mainly follows three steps: First, obtained the trained data from the autoencoder. Second, trained data of the previous layer is used as an input to the successive layer, this process will continue until the training should be completed on all input data. Finally, after the completion of training in all internal layers, fine-tuning is attained. This paper employs Stacked Autoencoder to diagnose Alzheimer’s disease (AD), mild cognitive impairment (MCI). By training the data employing the Stacked Autoencoder improves the level of accuracy.

III. Materials and Methods

This segment discusses the process implemented in the paper to discern the best classifier for PD. It explains the dataset, feature extraction algorithms, k – fold cross-validation, and AIRS - Parallel classification algorithm. Fig. 1 represents the complete workflow of the proposed model.

A. Dataset Information

The examining work is started with acquiring the samples of voice recordings of PD affected peoples and healthy peoples from the UCI repository. The dataset is taken from the University of California and the Irvine Machine Learning repository. It contains 20 patient details with healthy people has 20 samples with 10 females and 10 males and the affected people 16 females and 14 males. The finalized version of the dataset holds 1040 instances and 26 attributes. The details about the dataset are given in Table I.

B. Feature Selection

In pre-processing, feature selection is the first step, where the raw data will be analyzed by a particular algorithm and the features will be further reduced based on the quality and clarity of the data. mRMR is the feature selection algorithm used in this work. For comparative analysis, two further feature selection algorithms called Correlation Feature Selection and Genetic Algorithm were employed. In general, the feature selection technique with the least number of features selected will mostly be considered as an optimized one [22-25]. Table III shows the numbers of features by this technique.

TABLE I. DATASET DESCRIPTION

Dataset Source	***Department of Neurology, Istanbul University***
Disease Type	Parkinson's Disease
Total Number of Samples	1040
Total Number of Features	26
Classes	Binary Value 0 - Not PD, Value 1 – PD
Dataset Characteristics	Multivariate

Minimum Redundancy - Maximum Relevance (mRMR) is a technique, here used to select the optimum feature subsets. The core mechanism of the algorithms is; it selects the features highly relevant to the necessary classification yet features are mutually having less relevance it implies minimizing redundancy between the feature data. This technique fetches high accuracy with mutually unrelated features having more details about the problem. It helps in the precise classification of the data. The final subset S is identified based on the following equation.

$$mRMR = max_{F_i \notin S}[M(F_i;t) - \frac{1}{|S|}\sum_{F_j \in S} M\,(F_j;F_i)] \qquad (1)$$

C. Feature Extraction

When the input data is too large to process if it is repetitive it can be manipulated into a compressed set of features called feature extraction. Some of the feature extraction techniques are Latent semantic analysis, Partial least squares, principal component analysis, Multifactor dimensionality reduction. Autoencoder is one of feature extraction, it produces the output by eliminating unnecessary interruptions or noise. A stacked autoencoder is one of the methods of the autoencoder. In this paper, stack autoencoder is used as a feature extraction method. The stacked autoencoder receives the input as a voice signal from the big data source. The input is compressed by applying encoder layer this can be done by several layers and stored the values in the hidden layer, In the hidden layer, the data has to be trainedonce the training is done with it the output is then reconstructed from the hidden layer making use of decoder layer and it produces the output, the output should be equal to the input. Here, the number of feature 22 is given as an input and it performs the compression and it extracts the output with 8 features, here the remaining 14 features are considered as a noisy signal and eliminate those signals. This autoencoder model employs a cross-entropy loss function, and it suits well for this binary classification task. The parameters of the SAE are given in Table II. The general equation of the cross-entropy is represented below.

$$L\ (x, \bar{x}) = -\sum_{i=1}^{d}[x_i log\overline{x_\imath} + (1 - x_i)\log(1 - \bar{x}_i)] \qquad (2)$$

D. K- Fold Cross-Validation

K fold Cross Validation is also known as Rotation Estimation. It is one of the statistical methods used in machine learning to evaluate the skill of the particular model. This method holds a single variable "k". k refers to the total number of the groups the data has to be split for validation purposes. It has a simple procedure to work with k fold cross-validation. It randomly shuffles the input dataset, then it split into 10 groups (if k=10). Acquire one group for testing the data, the remaining group is undergone training the data by applying the model on it. Once it is trained then the group moves to test the data. After the completion of the test data, evaluate the score of the test data set. The evaluated score has been reserved and eliminate the models. Based on the value of the score, the model skills have to be analyzed.

TABLE II. PARAMETERS OF STACKED DENOISING AUTOENCODER

Parameters	***Values***
Epochs	100
Learning Rate	0.05
Momentum	0.40
Activation Function	Sigmoid
Reconstruction Error	Cross-Entropy Measure

E. AIRS-Parallel

In this system, AIRS Parallel is used as a classifier to diagnose the disease effectively. It is one of the AIRS methods. The training data set has to be given as an input to the AIRS Parallel after the completion of k fold cross-validation runs. It divides the dataset into many processors. Each processor holds some dataset randomly. Each processor performs the serial version of the AIRS process on the dataset. After the process completion on each processor, it gathers memory cells from each processor. Performing the merging operation on the memory cells into a single pool of memory cells. The memory cells in the pool are further divided into classes. In each class, an affinity pairwise calculation has been performed between the memory cells. If the affinity is less between the two memory cells then the affinity threshold scalar is a product by affinity threshold (aff(mc1, mc2) < afft * affts). As a result, only one of the memory cells is retained in the last pool. The outcome of this algorithm provides better accuracy to diagnose Parkinson's disease. The model skills have to be analyzed. In Table IV, the parameters of the artificial immune algorithm AIRS is given.

Algorithm: Stacked Autoencoder

Input: *S_i= Signal data, f_{sam} = Factor Sampling, n = Total number of Autoencoder, Target signal ($T_{s)}$ = f_{sam} sample signals, w= Weight, I_n = Internal node, H_e = High Epchos, SR = Sparsity Regularization*

```
$I_n$ =   Choose the number of SAE layers
$H_e$= Choose the number of SAE layers
w= Choose the number of SAE layers
SR= Choose the number of SAE layers
Train the Stack Autoencoder
Autoren = trainAutoencoder(2- n)   /* Train the Autoendcoder of n */
Test the input vs output
(a) Test the input signal (S) against Target Signal
(b) Calculate the error from the predicted output as a Target Signal
        if |err| ≥ level of tolerance
              repeat step 15
else
Finish training
```

IV. EXPERIMENTAL RESULTS

In this section, the classification performance of the proposed combination will be evaluated and compared with the existing techniques. In summary, initially, the training dataset contains 26 featured vocal datasets obtained from 20 PD affected patients and 20 healthy individuals. It contains various kinds of 26 sound recordings of the voluntary individuals, in turn, forms 1040 overall voice recordings. The sound recording consists of sustained vowels, words, numbers, and small sentences. The test dataset consists of 6 voice samples that have been recorded from 28 PD affected patients. These 6 voice samples contain only sustained vowels 'a' and 'o' every three times and it has a total of 168 voice recordings. The dataset is obtained from the UCI Machine Learning repository. To narrow down the dataset for more accurate prediction and with comparatively reduced run time, the dataset will be pre-processed before the classification stage. In, pre-processing of the feature dataset, the 26 features have been reduced to 13 feature subsets. Furthermore, the selected 13 feature subset has been reduced to eight feature vectors deploying stacked autoencoder by performing compression and dimensionality reduction mechanisms. The extracted features have been estimated through the K-fold cross-validation technique to evaluate its predictive accuracy utilizing the existing dataset [26]. Here 5 folds were used to test and train the model to predict the accuracy. Fig. 2 represents the number of features selected by different feature selection methods.

For comparison of the proposed with the existing techniques, quality metrics need to be employed to determine the accurate performance analysis of the proposed work and its significance. For the reason that 4 major metrics were used to evaluate the proposed Stacked Auto encoder-AIRS Parallel technique. The main goal is to attain better disease classification accuracy to prove the importance of this work. The metrics are accuracy, specificity, sensitivity, and the confusion matrix plot. The parameters of the AIRS Parallel algorithm for Parkinson's disease need to be disclosed earlier. Table I represents the parameters used in the proposed algorithm with values

A. Performance Evaluation

Also referred to as an error matrix, it contains a table used to express the performance of the classifier on a test dataset for true known values. A confusion matrix has actual information and predicted information has been classified by applying the classification algorithm [27]. Based on the available data in the matrix, the performance of the model will be analyzed. The following table represents the confusion matrix for a binary classifier and the next table represents the outcome confusion matrix of the proposed work.

True Positive (TP): Detected as a patient diagnosed with PD by medical experts.

True Negative (TN): Detected as normal and categorized as healthy by medical experts.

False Positive (FP): Detected as patient and categorized as healthy by the medical experts.

False Negative (FN): Detected as normal who diagnosed with PD by medical experts.

Accuracy decides the overall performance of the system by classifying the PD affected individuals from the healthy ones and the accuracy was determined in percentage, higher the percentage, higher the accuracy [28-30]. The classification accuracy for the datasets of this study was calculated using the below equation.

$$Acc = \frac{TP + TN}{TP + TN + FP + FN} \tag{3}$$

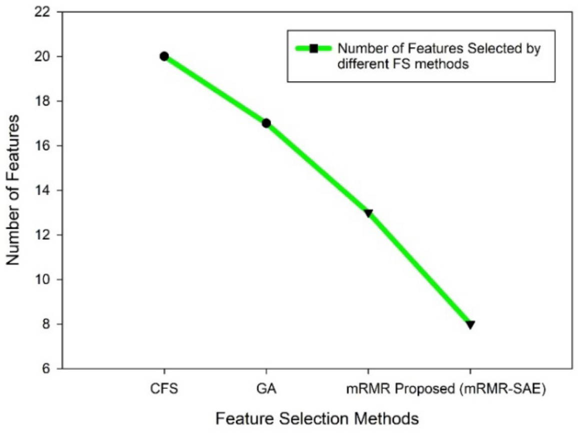

Fig. 2. Number of Features Selected by different Methods.

The sensitivity (sen) and specificity (spec) are calculated from the following equations.

$$Sen = \frac{TP}{TP + FN} \tag{4}$$

$$Spec = \frac{TN}{TN + FP} \tag{5}$$

The overall significance and importance of the model will be exposed only by comparing the results with the existing model's performances. Seeing, AIRS, and AIRS 2 algorithm with stacked auto encoder's performances will be taken to compare the results with the proposed combination. The results of AIRS – Stacked Autoencoder, AIRS 2 – Stacked Autoencoder, and the proposed AIRS Parallel –Stacked Autoencoder were presented as the Table V for comparison.

From the results given in Table V, it is evident thatthe proposed model outperforms the compared combinations in terms of Classification Accuracy, Specificity, and Sensitivity. Also, the proposed model can be further compared with the previous work, CFS-ACO with SVM classifier. Table VI shows the comparison values.

In Fig. 3, the scores of different validation metrics attained by different immune algorithms on the selected features is plotted. It is visible the proposed work comparatively classifies the disease better than CFS-ACO- SVM combination [31]. Insensitivity, the previous work seems to perform better than the proposed work but it gives a better percentage of results in terms of accuracy and specificity. This section highlighted the peculiarity of the work and from the experimentation results; the numbers in percentage clearly show the need for the work for better progress in the future.

TABLE V. COMPARISON OF RESULTS ATTAINED UNDER DIFFERENT AIRS ALGORITHMS (%)

Classifiers	***Acc***	***Sen***	***Spec***
AIRS	0.85	0.82	0.87
AIRS 2	0.9	0.86	0.92
AIRS Parallel	0.97	0.94	0.99

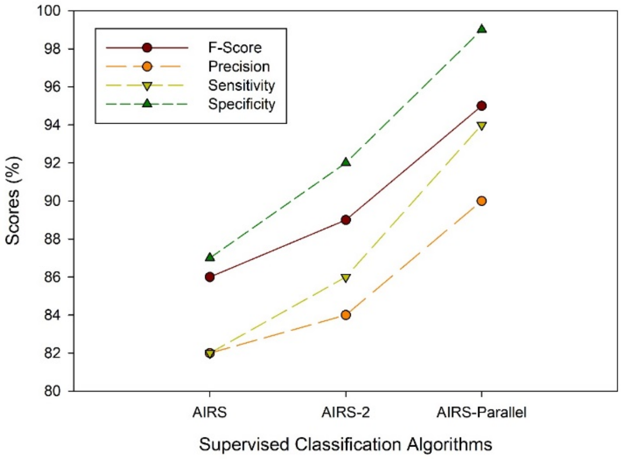

Fig. 3. Performance of Classifiers under different Evaluation Metrics.

TABLE VI. COMPARISON OF RESULTS FROM EXISTING STUDIES AND PROPOSED WORK (%)

Classifiers	**Acc**	**Sen**	**Spec**
CFS - ACO – SVM	0.95	0.96	0.98
Proposed	0.97	0.94	0.99

V. COMPARATIVE ANALYSIS OF FEATURE SELECTION TECHNIQUES BASED ON QUALITY METRICS

To benchmark, the performance of the proposed mRMR-SAE model, two other feature selection methods have been employed over mRMR. The performance is tested with SAE having the same configuration of the proposed algorithm. The techniques are shortly briefed below.

A. Correlation-based Feature Selection

Correlation-based Feature Selection (CFS) evaluates and selects the feature subsets from the given data using a unique selection process. The feature selection was done based on acquiring an effective feature subset, it having more correlation with the classification and less or uncorrelated to the existing features [32].

B. Genetic Algorithm

Genetic Algorithm (GA) is a nature-inspired, search based selection technique derived from Charles Darwin's evolution theory. GA resembles the ideology of nature by selecting the fittest individuals for procreation of the forthcoming generation. GA has five main phases for a successful selection process. They are Initial Population, Fitness Function, Selection, Crossover, and Mutation. Each phase plays a significant role in GA for an optimal selection, thus resulting in healthy offspring reproduction. The performance of CFS and GA with stacked autoencoder is represented in Table VII and the accuracy of feature selection methods on AIRS-P is given in Fig. 4.

TABLE VII. PERFORMANCE OF AIRS-PARALLEL UNDER DIFFERENT FEATURE SELECTION TECHNIQUES (%)

FS Techniques	**Acc**	**Sen**	**Spec**
CFS-SAE	0.88	0.87	0.89
GA-SAE	0.92	0.93	0.92
Proposed	0.97	0.94	0.99

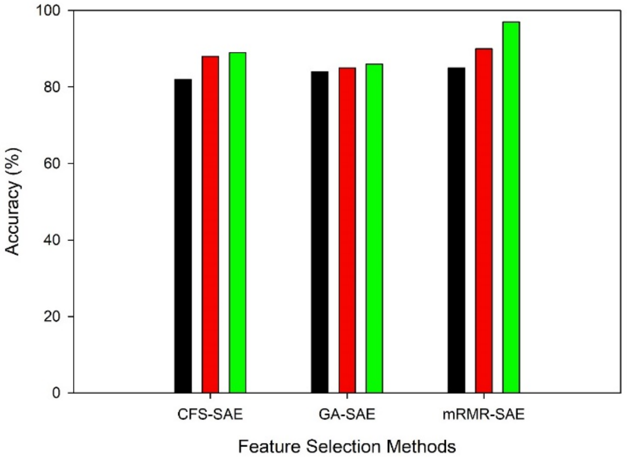

Fig. 4. Accuracy of Feature Selection Methods under different Classifiers.

VI. CONCLUSION

In this paper, the voice and speech recordings of PD affected and healthy individuals are analyzed with different statistical feature selection methods and neural network models. The 26 feature instances are pre-processed by deployingmRMR and Stacked Autoencoder - a neural network-based auto encoder technique used to reduce the noise in the data and compress the information of the data to reduce the number of attributes present in the original dataset. After dimensionality reduction of the dataset, the classification ability of the compressed vectors was evaluated with the K-fold cross-validation technique. Finally, the 8 feature vectors will be classified by the AIRS Parallel algorithm. The result of the proposed work was compared with AIRS, AIRS 2, and CFS-ACO-SVM combination. From the comparison, we can visibly conclude, the proposed AIRS Parallel with Stacked Autoencoder technique comparatively outperforms the employed techniques in all given quality metrics with 97% accuracy. It denotes the importance of this classification system for PD. Any Artificially Intelligence machine learning system will not be able to attain a 100% classification accuracy rate. But, the run time and other aspects of the system can be improvised in the future works. As the next step to this diagnosis/classification model, a Computer-Aided Diagnosis system can be developed, inspired by this proposed model to get a better classification accuracy rate with less run time and memory space usage.

VII. CONFLICT OF INTEREST

Authors declare no conflict of interest.

Gender Diversity in Computing and Immersive Games for Computer Programming Education: A Review

Chyanna Wee[1], Kian Meng Yap[2]
Department of Computing and Information Systems
Sunway University, Bandar Sunway, Malaysia

***Abstract*—This paper provides a review of the current state of the gender gap in computer science and highlights how immersive games can mitigate this issue. Game-based learning (GBL) applications have been shown to successfully incite motivation in students and increase learning efficiency in both formal and non-formal educational settings. With the rise of GBL, researchers have also used virtual reality to provide pupils with a more immersive learning experience. Both GBL and virtual reality techniques are also used for computer programming education. However, there is a paucity of applications that utilize these techniques to incite interest in computer science from a female perspective. This is a cause for concern as immersive games have been proven to be capable of inciting affective motivation and fostering positive attitudes towards specific subjects. Hence, this review summarises the benefits and limitations of GBL and virtual reality; how males and females respond to certain game elements; and suggestions to aid in the development of immersive games to increase female participation in the field of computer science.**

Keywords—Computer science education; game-based learning; gender; virtual reality

I. Introduction

The projected number of degrees awarded to females was estimated to increase from 39 percent in 1966 to 61 percent in 2019 [1]. Despite the increasing number of degrees awarded to females, only about 35 percent of them are enrolled in Science, Technology, Engineering, and Mathematics (STEM) courses [2]. To make matters worse, the dropout rate for female students is 23 percent higher than for males in STEM courses [3]. The gender gap is most prominent in the field of computer science, where estimates of the ratio of male to female enrolment at tertiary level are approximately 70:30 as of 2019 [4]. This may be attributed to the gender gap in computer science advance placements (AP) test-takers where there were 52,574 males to just 17,111 females in 2019 [5]. Collectively, all this data means that females make deliberate decisions when it comes to not pursuing a career in the computer science field. Although there are several contributing reasons for this, the main factor stems from stereotypical representations of STEM-related fields that implicitly deter females and give them an incorrect perception of what the field is made of [6].

Due to low female enrolment rates in computer science, there is a lack of diversity in the computing workforce. According to data provided by the United States Department of Labour's Bureau of Labour Statistics (BLS), computer-related jobs are projected to rise by 12.5 per cent from 2014 to 2024 [7]. However, there is still a substantial difference between the number of female employees and the number of male employees in computing professions, with approximately 1,226,000 females compared to 3,578,000 males [8]. This is also prevalent in the field of academia, where only 15 per cent of professorial computing positions are held by females [8]. Ultimately, this implies that the consequences of low female enrolment rates in computing courses reflect upon the workforce. This is a cause for concern as diversity is crucial to stimulate and trigger innovative solutions to problems in the field.

II. Related Works

In recent years, the game-based learning (GBL) technique is widely used in educational contexts to foster knowledge acquisition, skill acquisition, and engagement in students [9]. To further enhance student participation in the learning process, GBL is also frequently combined with virtual reality and augmented reality. Previous reviews ([10], [11], [12]) have covered the benefits of the use of games for programming education. There have also been reviews ([13], [14]) that highlighted the use of virtual reality in education. More recently, there are also reviews ([15], [16]) that discussed the prevalent gender gap in computer science and virtual reality-based research. However, there is a relative paucity of reviews that explored the possibility of utilizing immersive games to increase female participation in the field of computer science.

Therefore, this review aims to foster more research in the development of immersive learning applications to reduce gender gaps in computing. Fig. 1 provides an overview of the topics discussed in this review, starting with why diversity is important in computing and factors that influence female participation in computing. Other major topics can be found in the "Results" section in this review where GBL and virtual reality are explored concerning their application in education and computer programming education to determine if the utilization of these techniques may aid in increasing female participation in the field of computer science. Furthermore, an overview of how males and females perceive game elements are also discussed to further aid in promoting the development of more female-centric immersive games on computing education.

III. Importance of Gender Diversity in Computing

With technological advancements in recent years, more jobs in the field of computing are expected. With 598,700 job openings annually from 2018 to 2028, compared to 290,200 jobs for non-computing STEM subjects, the demand for computing graduates has increased and will continue to grow for several years to come [17]. Since this is the case, the enrolment rates for computing courses have also increased by 5.4 percent in 2019 since the previous year [18]. Even so, just 27 percent of females are working in computer-related careers [19]. The gap is more significant in academia, where it is estimated that it would take about 118 years to close the gender gap between authorships and publications related to computer science [20]. This is a cause for concern because diversity will bring different perspectives to the table in terms of understanding and designing solutions for a wide variety of individuals. Take car crash dummies, for example, that are modelled based on a man's body. According to a study by the University of Virginia [21], females have a 47 percent greater chance of facing serious injuries compared to males due to the inaccurate representation of the female body through the dummies. This issue persists in technology where females are more likely to suffer from virtual reality headset-induced motion sickness at 77 percent compared to 33 percent for males [22]. The authors conclude that this is due to the difference in physiological structure of both genders and suggest that manufacturers address aspects of design that are related to one's ability to stabilize their bodies. Ultimately, if these issues continue to persist, the accessibility of new and upcoming technology will only be limited to only part of the population, further perpetuating the already wide gender gap in the field of computer science.

IV. Factors Affecting Female Participation in Computer Science

Throughout history, the field of computer science has been inherently dominated by males. This is largely due to traditional perceptions of how certain genders are deemed more "suitable" for the pursuit of certain fields. For example, the fields designed to be better suited for females include nursing, teaching, and homemaking. Undoubtedly, this propels them to pursue the previously mentioned careers as parental approval directly influences one's career choices [23]. This, in turn, increases the gender gap and further decreases the sense of belonging of female students in the field of computer science. Because the sense of belonging is a strong motivator for the interest of female students in the field of computer science, this creates a never-ending cycle [24]. The lack of female representation also accelerates the lack of interest in females to pursue computer science. In a study conducted by Hussain et al, female role models can help remove the negative consensus related to computer science [25].

Furthermore, how computer science classes are conducted can also be unappealing to females. In a study conducted by Giannakos et al, poor teaching, excessive workload, and boring classes also contributed to high dropout rates [26]. Syllabi that include real-world problems instead of abstract ones are crucial in making the class seem more interesting [27]. This can be achieved by addressing relevant topics of interest to females, such as developing applications, that may help people or animals. Other than that, grouping strategies that foster cooperation and discussion can also be effective [28]. This is because females prefer to work in groups and have a lower level of confidence in themselves and their abilities [29]. As for their male counterparts who have a higher level of confidence in their skills, they often prefer to work on their own [29]. However, because there are often more males than females in computer classes, collaboration can also be an issue. In combination with stereotypical perceptions, females may feel shunned and are therefore unable to participate in class [30]. According to Hoegh and Moskal, the most likely step in eliminating the declining numbers in computer science enrolment is to understand the students' attitude to the field [31]. Despite having equal access to computers as their counterparts, females generally have a negative attitude towards computing and are found to be less concerned about anything that involves computing [32]. Consequently, Jo Tondeur et al found that females also have a less positive attitude compared to males towards computers in general [33]. The societal perceptions of computing-related careers can also increase cynicism in females. For example, students are made to believe that those with computing careers have to face computers all day long and that it will make them seem unsocial [34]. This problem stems mainly from a lack of understanding on what professionals do in different fields of computing. Researchers at Carnegie Mellon University found that many students picture computer science students to be intense hackers, which can also be unappealing to those that have aspirations to do more than technical work [35]. In response to this, changes were introduced in the curriculum to emphasize that there is more to computer science than just being a "hacker". Since then, from just seven female students from a total of 95 students in 1995, it was reported that 105 female students were enrolled into the computer science course from a total of 211 students in 2018 [36].

Lastly, the lack of exposure at an early age also contributes to the gender gap issue. Most computer games and early educational software have been developed and designed predominantly with boys in mind [37]. This, in turn, could explain why males today are more familiar with computers and seem to have a head start in classes. This, coupled with the stereotyping that has been mentioned, may intimidate females and lead to early termination of the computer science class or course in higher levels of education. This can also cause a decrease in the confidence of one's technical skills and abilities, which in turn, further inhibits female participation in the field of computer science. However, in a study conducted by Chen, although males had more motivation than females due to prior experience, males were outperformed during the performance evaluation [38]. This means that given the right instructional simulations, even learners without computing experience can outperform those with computing experience effectively. Consequently, according to LaBouliere et al, females may also face a dip in confidence if they are unable to observe their finished product [39]. Hence, to address these concerns, immersive games can be developed to foster interest as well as motivation in computing.

V. Survey Methodology

Now as we understand the importance of diversity in computing and the factors that affect female participation in computing, the aim of this review which is “to foster more research in the development of immersive learning applications to reduce gender gaps in computing” becomes more important. To support the aim of this review, the following research questions were constructed.

RQ1: What are the benefits of GBL and VR on computing education and how can this reduce the gender gap in computing?

RQ2: What are proposed game elements that can be employed in immersive learning applications to reduce the gender gap in computing?

To answer the research questions posed above, this review will be conducted systematically according to the steps as detailed in sections IV A to C.

A. *Definition of Keywords*

To determine how GBL and VR can promote female participation (RQ1), keywords and search terms such as “Game-based learning AND Education” and “Virtual reality AND Education” were first used to first identify how immersive techniques affect learning in general. Keywords such as “Game-based learning AND Computer education” and “Virtual reality AND Computer education” are then used to identify how both GBL and VR affect computing education. Furthermore, to determine elements that should be employed in immersive learning applications in promoting female participation (RQ2), the keyword “Gender AND Games” were used.

B. *Literature Sources*

The search for literature is done through Google Scholar to ensure that there are no biases towards certain databases. It is estimated that almost sixty percent of systematic reviews published fail to retrieve ninety-five percent of available and relevant literature [40]. Hence, the use of a search engine such as Google Scholar would ensure the review includes a more comprehensive sample of literature. To ensure that only the most relevant literature is collected, searches were limited to twenty pages deep and were sorted by relevancy.

C. *Inclusion and Exclusion Criteria*

In this review, literature was also analysed through specific inclusion and exclusion criteria as listed below.

Inclusion criteria

- Literature relevant to keywords specified.
- Literature that is written in the English language only.

Exclusion criteria

- Literature that is duplicated.
- Literature with an abstract only.

Moreover, to ensure that the sources were relevant and suitable for this review, literature was also further analysed through the steps detailed below:

- Analysis of title and abstract.
- Analysis of introduction and conclusion.
- Analysis of entire article.

VI. Results

Fig. 2 below shows the breakdown of the number of studies selected for each research question during each step of the screening process. Articles that were found to have satisfied all the criteria are discussed in the sections below.

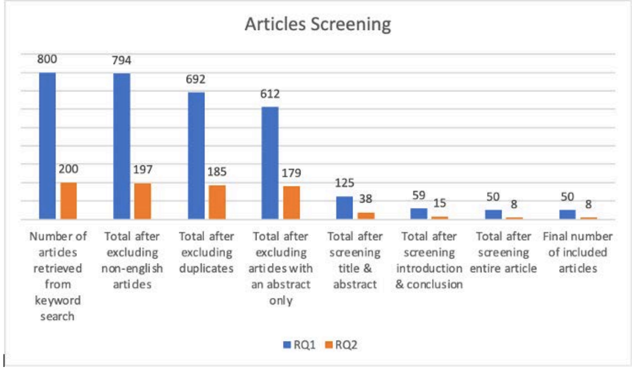

Fig. 2. Article Screening Overview.

A. *Game-based Learning in Education*

Contrary to more conventional forms of teaching, those who use educational games or simulations for learning have exhibited positive feedback on knowledge acquisition [41]. Educational games are considered a more organic way of learning because those engaged in gaming from an early age acquire cooperation and thinking skills [42], [43]. For instance, Li et al [44] developed a quiz game resembling “Who wants to be a millionaire” to engage students to learn the Chinese language. The feedback from elementary school students who played the game is mostly positive since students have enjoyed learning through games. Consequently, Yan and Tam [45] also observed the same results after employing a game based on Chinese history. About 81 percent of the participants liked to learn through games and 70 percent conveyed that they gained knowledge from the game. Hence, by using educational games in a classroom environment, students can be more engaged and encouraged to actively participate in lessons because GBL focuses on students instead of teachers [46]. This, in turn, will improve students' success from a learning perspective [47], [48], [49], [50].

Apart from engaging students, inciting motivation is also important to ensure that students continue to enquire and participate in the learning process. Cezar et al [51] proposed a Role-Playing Game (RPG) in which participants are required to solve calculus problems to advance through the game. About 83.3 percent of the participants felt motivated to finish the game. Similarly, according to a survey conducted by Yong et al [52] on the feasibility of digital games in mathematics education, 51 percent agreed that mathematics could be more interesting with the use of games. Furthermore, 48 percent agreed that digital games could help with the learning process. Consequently, Lo and Lin [53] proposed a digital board game where the player is allowed to move forward if the mathematical question raised to them is answered correctly. The findings from this study showed a significant difference in attitude before and after the games were played. By incorporating games into the learning process, students will be exposed to interactive learning experiences, increasing interests towards a particular subject matter.

The use of games in the learning process can also be used for the achievement of motor, spatial and cognitive skills. Hogle et al [54] found that those who were trained using a laparoscopic simulator showed an improvement in operative performance and depth perception compared to those who did not use the simulator. Similarly, Stefanidis et al [55] also showed positive results in which participants achieved suture proficiency by using a simulator. In the case of secondary tasks, longer training times are needed to achieve higher proficiency. Furthermore, research done by Green and Bavelier [56] has shown that frequent gamers are more proficient when it comes to tracking simultaneously two more items than those who often don't play. This is also seen in another experiment conducted by Feng et al [57], where the results have shown that when female players were exposed to an action game, both spatial and attentional skills were increased. Barlett et al [58] found that cognitive skills such as memory and auditory perception can also be improved despite playing for a short time only. This fact is supported by Piaget [59] who states that play is integral and evolves with the different stages of cognitive development.

B. *Disadvantages of Game-based Learning*

The advantages of GBL, however, depend very much on the design of the game itself [60]. The game must be designed in such a way as to force the player to achieve learning objectives while not being bogged down by the objectives of the game itself. Simply put, this is a contradiction that is difficult to overcome, considering that games are played only for fun, while GBL requires the players to accomplish external goals that are not "fun" [61]. Another limitation to GBL is that players can get bogged down with the idea of the game itself that they cannot think about what they've learnt [62]. For example, students may tend to focus on how their scores compare to that of their classmates rather than the learning objectives that are set for them to achieve. Other than that, GBL applications are usually infused with narratives to engage users. However, this can lead to confusion on the part of the user, as it is often difficult to distinguish between fiction and non-fiction. This phenomenon is prevalent in the results of the research conducted by Huizenga et al [63], in which pupils participate in a game to learn the history of medieval Amsterdam. The team incorporates fictitious narratives to further engage the pupils. This resulted in some confusion as to the actual historical facts and fictional elements of the game.

C. *Virtual Reality in Education*

Virtual reality is also prominent in tertiary education, where it is used in a variety of fields. Dinis et al [64] proposed a software program that allows students to design their three-dimensional virtual environment. By doing so students would be able to explore and apply what they have built up in civil Engineering situations. Likewise, Kharvari and Hohl [65] used virtual reality methods for reproducing the virtual form of a building for architecture students to study the precedents of a particular structure without the need for a field visit. The fact that virtual reality is capable of replicating how lightning behaves in a room also favours lightning education as proposed by Boyles et al [66]. Students would be able to interact with different lightning scenarios that are unlikely to exist in the real world.

Furthermore, intending to increase the engagement of students in the field of history, Zhang et al [67] suggested the use of the popular building game, "Minecraft" to build exact replicas of historical monuments. With this, students would be able to map the virtual experience to the knowledge they have gained in a traditional classroom setting. Hence, with the ability to directly interact with the virtual environment, students would be more willing to participate in lessons. By the same token, Lugrin et al [68] developed a virtual reality-based museum where visitors can experience interactive exhibitions without the need to travel to the actual museum. Since virtual reality is capable of effectively reproducing real-life scenarios, Caluya and Santos [69] proposed an authoring tool to study clouds for weather reporting purposes. Depending on the behaviour and appearance of the clouds, the participants in this study are exposed to different sky conditions and how these two factors relate to each other.

Moreover, virtual reality technology is widely used in medical training where live biomedical samples are not always available for training purposes. For instance, Seo et al [70] developed a virtual experience focusing on canine skeletal systems in which participants were able to freely observe and assemble the corresponding limbs. Similarly, de Mauro et al [71] proposed a simulated neurosurgical microscope to train and educate brain surgeons. The simulation focuses mainly on surgical procedures, as well as brain tissue-mimicking to help surgeons determine normal and low-grade glioma tissues. Comparably, Rajeswaran et al [72] developed a virtual experience to instruct medical professionals on endotracheal intubation surgery. Dong et al [73] proposed the integration of virtual reality and haptic feedback to simulate the preparation of cryogenic samples. With haptic feedback, biomedical professionals would be able to learn the best way to handle samples, as the equipment involved in Cryo-Electron Microscopy is expensive and delicate.

In summary, virtual environments can be developed to provide access to inaccessible places and tools for educational purposes. The utilisation of virtual reality in education also makes the learning process more interactive, which can increase student participation.

D. Disadvantages of Virtual Reality Utilisation in Education

Despite its advantages, the use of virtual reality in the context of education also has limitations. According to Mathur [74], despite being able to provide access to inaccessible medical resources, specialised virtual reality systems in the medical field are still prohibitively expensive for widespread adoption. To counteract this, low-poly graphics could be used to build an application because they require less processing power and can make the game run smoothly. This is especially essential for virtual reality games developed for education, so as not to deteriorate the learning experience. Furthermore, because virtual reality applications use Head Mounted Device (HMD) conventional input devices, such as mouse and keyboard, are no longer usable and are instead replaced by controllers. This can be seen in a virtual experience designed by Lei Wei et al [75] that uses Microsoft Kinect controllers. The controllers have been reported to be inaccurate and counter-intuitive, which has undermined the experience of the participants. Virtual reality education systems may also not be sufficiently engaging for users to continue to use them. For example, applications developed by Hsiao et al [76] and Hsieh et al [77], who developed a virtual campus for educators to teach online and a virtual museum respectively, reported a lack of engagement from participants.

E. Game-based Learning for Computer Programming Education

To make programming more engaging and improve learning, GBL is also often integrated into programming lessons. For instance, Mathrani et al [78] employed the "LightBot" game which required participants to control an animated robot to the end of a maze with the use of blocks representing commands that are similar to code. With a total of twenty participants, the consensus regarding the game was positive in which they found the game to be interesting, fun, and ranked the game as effective in instilling programming concepts like conditionals, functions, and recursion. Olsson and Mozelius [79] tested a memory game that involves matching values to particular data types and a syntax error "bombing" game on sixty-five total participants. Results from the study indicated that both games were successful in effectively helping students practice data types and Python syntax. More specifically, a total of forty-nine students found the games helpful for learning.

Wong and Yatim [80] developed a game called "The Odyssey of Phoenix" to aid in the learning of Object-Oriented Programming (OOP) concepts. This is done by mapping game processes to concepts. For example, the concept of inheritance is mapped to the crafting element in the game where resources required by both the main and nose gear can be shared since they both belong to the gear category. To measure the effectiveness of the game, pre and post-tests results were compared and analysed from 214 first-year students. Results from the study showed improvements in terms of learning effectiveness, leading to the conclusion that GBL is a great tool for knowledge acquisition. Papadakis and Kalogiannakis [81] developed a quiz platform based on multiplayer online role-playing games (MMORPG) where students can complete programming-based quests and challenges. By conducting surveys on thirty participants from a high school in Greece, the study concluded that the participants were engaged and motivated when completing the challenges presented to them. The authors concluded that GBL is useful in promoting learning outcomes for typically strenuous and difficult subjects. Furthermore, Oyelere et al [82] developed a "MobileEdu-puzzle" game for programming education. The game works by making students arranging misarranged lines of code. Over fifty-one students who participated in the study, seventy percent expressed that they were able to effectively learn programming with the experience.

These findings make GBL an ideal tool to motivate and increase participation when it comes to learning how to program. According to Santos et al [83], students appreciate the challenges that come with programming-based games as well as the achievement system to keep them motivated. Furthermore, Taylor et al [84] found that the development of computational thinking skills can also be enhanced by incorporating block-based programming into GBL applications. However, students with prior programming experience have found games with increasing difficulty levels to be tiring. It is therefore important to consider the participants' knowledge of programming when developing a programming-based game. Various approaches discussed in this section are summarised in Table I.

TABLE I. SUMMARY OF GAME-BASED LEARNING APPLICATIONS FOR COMPUTER PROGRAMMING EDUCATION

Author(s)	**Methodology**	**Outcome**
Mathrani et al [78]	Programming a robot with command blocks	Improved learning effectiveness and engagement
Olsson and Mozelius [79]	Memory game to teach data types	Improved learning effectiveness
Wong and Yatim [80]	Mapping OOP concepts to in-game activities	Improved learning effectiveness
Kalogiannakis [81]	Programming based quiz game	Improved learning effectiveness and engagement
Oyelere et al [82]	Programming based puzzle game	Improved learning effectiveness

F. Virtual Reality for Computer Programming Education

Alternatively, virtual reality can also be used to make programming classes more immersive and efficient. Pears et al [85] argued that visualisation is necessary to reduce the distance between the programming language and the student's mental models. For example, Vincur et al [86] combined both VR and game elements with block-based programming to introduce basic programming concepts called "Cubely". Cubely consists of cubes that represent programming concepts that can be arranged to form blocks of code. In other words, students must build code from code blocks to control the character to overcome challenges. Results from this study showed that over nineteen participants, eighteen preferred using Cubely due to the ease of use over typical code bootcamps available online.

Tanielu et al [87] developed a VR experience called "OOPVR" to reduce the abstractness of OOP concepts with analogies. To help students better understand the relationship between classes and objects, OOPVR uses a blueprint of a house to represent a class where many houses can be built from the same blueprint, signifying that multiple objects can be instantiated from a class. Various analogies were done in a similar manner throughout OOPVR to represent concepts like encapsulation, methods, and instances. To evaluate if the house analogy was effective in visualizing OOP concepts, the authors analysed results from a total of seventeen participants. Compared to the pre-questionnaires, post-questionnaires revealed that the participants showed higher confidence when it comes to visualizing OOP concepts. Bouali et al [88] developed a VR game called "Imikode" to help students familiarise themselves with OOP concepts. The system allows students to create virtual worlds with code. For instance, to instantiate an object, the command "fox = new Fox()" is used, creating a fox in the virtual world. The authors, however, have not yet done tests to determine the effectiveness of the system.

Consequently, Chen et al [89] developed a VR game that allows students to create levels to challenge their peers. Before starting the game, the student playing the role of the level creator will write codes in the virtual environment to place robot characters around the environment that will act as obstacles. Students who then play the game are required to acquire hints scattered around the virtual environment while overcoming the obstacles set up by the previous student. In a sense, students will be able to judge the effectiveness of their own code depending on how the system reacts. The authors claim that students of age nine to thirteen who tried the game have provided positive feedback in terms of engagement and learning effectiveness. Segura et al [90] developed a VR game called "VR-OCKS" that requires students to use code functions represented with blocks in the game to complete puzzles. To test the effectiveness of the system, twenty participants that have played VR-OCKS and another twenty participants who didn't play the game were recruited. Each group of twenty participants was further halved to complete challenges synonymous with the puzzles presented in VR-OCKS in "Kodu" and "Blockly", two popular systems that utilise visual programming to help students learn programming. Results indicated that those who played VR-OCKS before were able to complete twenty-five percent more levels than those who didn't. A summary of the approaches discussed in this section is shown in Table II.

G. Gender and Games

Throughout the years, many studies have been carried out regarding games and gender. The results of these studies have shown that gender preferences are a key motivator when it comes to playing specific game types [91], [92]. Considering how GBL has proven to be an effective tool for education, gender preference considerations are important in ensuring equal participation. Thus, the purpose of this section is to shed light on factors that appeal to a specific gender when it comes to games, specifically digital games. Lastly, game characteristics that are disliked by females will also be presented in this section.

To determine the preferred game design characteristics of different genders, Spieler and Slany [93] compiled programs developed by participants on the Pocket Code platform using a visual programming environment. In terms of game genre and themes, it is found that both females and males used the adventure genre in their games. However, males prefer the space theme whereas females prefer the nature-based themes. As for game mechanics, both genders used experience points as rewards and challenges in the form of missions in which there is an achievement system. The presence of leaderboards in male-created games is a key difference between the genders. This fact is supported by Hassouneh and Brengman [94] who argued that males value achievement more than females. Consequently, although challenges in games remain the main motivator for both genders, young men are more motivated by games that engage players to reach higher levels as well as beating the game [95]. When it comes to game aesthetics, the narrative, sensation, and fantasy elements are used by both genders but are more apparent in female-created games. The exploration element is, however, exclusive to games created by female pupils, where challenges of the game will lead to the discovery of new parts of the virtual world. This statement also coincides with the argument of Zhou et al [96], where games that include exploration and experimentation elements are generally preferred by female players.

TABLE II. SUMMARY OF VIRTUAL REALITY APPLICATIONS FOR COMPUTER PROGRAMMING EDUCATION

Author(s)	Methodology	Outcome
Vincur et al [86]	Code blocks to solve challenges	Users preferred this approach over traditional online bootcamps
Tanielu et al [87]	Mapping OOP concepts to in-game activities	Users showed higher confidence in understanding OOP concepts
Bouali et al [88]	Forming worlds virtually with code	No findings
Chen et al [89]	Level creation with code	Improved learning effectiveness and engagement
Segura et al [90]	Solving challenges with programming blocks	Improved learning effectiveness

TABLE III. SUMMARY OF FINDINGS REGARDING GENDER AND GAMES

Author(s)	Findings
Spieler and Slany [93]	Space and nature themes preferred by male and females correspondingly.
Hassouneh and Brengman [94]	Males value achievement more than females.
Lucas and Sherry [95]	Males focuses on reaching higher levels and beating the game.
Zhou et al [96]	Females prefer exploration and experimentation.
DeCamp [97]	Violence is preferred by males.
Hanh [98]	Females do not appreciate negative portrayals of female characters.

Most games portray female characters as weak individuals who are often rescued by males to attract players. As a result, females do not enjoy or avoid games because they do not appreciate the negative portrayals of female characters [97]. Similarly, violence in games is also one of the main factors contributing to a low number of female gamers. Whereas males are more interested in violence in games, females are less interested in violence [98]. In essence, the low rate of female participation in computer science means that there are more male game developers, who in turn, design and develop games that mainly attract males. This, in turn, lowers the number of female gamers that creates a negative cycle. Table III shows a summary of all the findings from the studies mentioned.

VII. Discussion

Inaccurate stereotypes that are instilled by society regarding computing have negatively affected females in many ways. Stereotypical depictions of computing foster negative attitudes towards the field, perpetuating the already large gender gap. This issue also affects females who are already in the field where they are often deemed as less capable compared to their male peers. This lowers their confidence levels and sense of belonging which often leads to student dropouts. Ultimately, this is the root of the issue that must be immediately resolved.

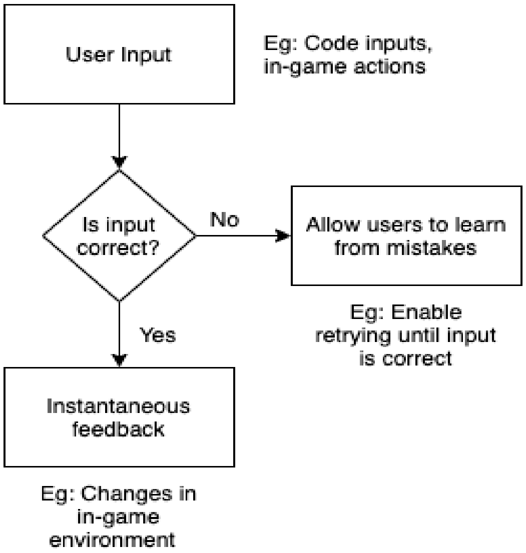
Furthermore, it is worth discussing how the use of GBL and virtual reality or combinations of both techniques can help solve issues related to the gender gap in computing (RQ1). In section VI A, it is seen that the utilisation of games in education is capable of increasing student motivation. When lessons are presented in the form of games, students are more willing to participate in lessons. As seen in section VI C, virtual reality enables students to experience unconventional situations that may be inaccessible in real life due to costs and safety reasons. Compared to learning from a textbook, the unconventional presentation of lessons in the virtual environment can also lead to increased participation. It is also important to note that the combination of both GBL and virtual reality techniques may solve some limitations related to one or both approaches. For example, some virtual learning experiences ([76] and [77]) were reported to be non-engaging. Considering that game-based applications are capable of engaging students, this problem can potentially be fixed by employing game elements into the virtual experience. Moreover, both GBL and virtual reality applications specifically developed for computing education have reported outcomes such as increased learners' satisfaction and general improvements to the learning process (Table I and Table II). Seeing how females often lose interest in computing due to boring and abstract lessons, the use of immersive games can be used to simulate how code can be used to solve real-world problems that are more interesting. Immersive games can also foster cooperation with multiplayer modes that are beneficial in increasing the sense of belonging of females in computing. Thus, this makes GBL and virtual reality or the combination of both techniques suitable for increasing female participation in the field of computer science.

Unfortunately, outcomes such as increasing female participation remain scarce in immersive programming games-based research. Existing applications highlighted in this review are mainly focused on learning syntax and programming concepts. While existing solutions are effective in retaining those, who are already enrolled in computing-based courses, it does not provide the necessary "appeal" to initiate female interest towards the field. Hence, we require solutions that are specially catered to increasing female participation as it is found that females are more likely to play games that are designed with them in mind [99]. To aid in fostering more research in this area, the "Gender and games" section aims to help future researchers employ game elements that are more appealing to a female audience (RQ2). As seen in Table III, some of the game elements that should be implemented to foster female interests when developing immersive games pertaining to computing education include implementing exploration, experimentation, space, and nature themes. Other than that, the application developed should not feature any violence, negative portrayals of female characters and should not focus too much on achievements.

VIII. Suggestions for Future Work

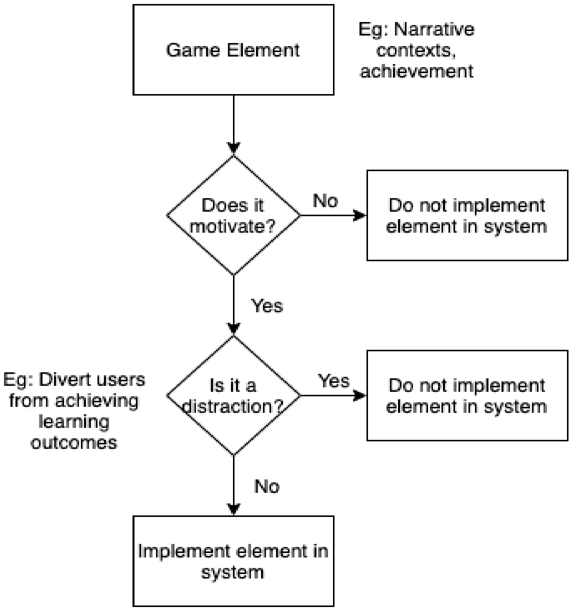
There are multiple takeaways from the literature reviewed in this paper. To increase the sense of belonging of females in the field of computing, immersive games developed especially for this purpose should focus on promoting confidence. Since the relationship between confidence and sense of belonging is directly proportional, future work should be done by keeping this fact in mind [100]. This may be done by accessing potential factors that demote confidence and using elements of immersive games to mitigate the issue. For example, [39] observed that females face a dip in confidence when they are unable to immediately observe the results of their work. A potential solution for this is to develop a system that allows users to instantly see the effects of their code writing as seen in Fig. 3. In both game and virtual environments, this can be achievable by changing or slightly altering in-game environments to match user-written code.

To ensure female students do not lose motivation when learning computer programming, retention is important. Hence, it would be worthwhile to develop frameworks that can effectively balance the "fun" and "learning" components of game-based applications. This is important in educational contexts as the system should be able to foster motivation to learn without being too distracting to users. In other words, in-game goals should not overpower learning outcomes. Fig. 4 shows a general flow diagram of how to determine the game elements that motivate but do not distract users to balance the "fun" and "learning" elements mentioned previously. Essentially, researchers should use the flowchart depicted in Fig. 4 to determine, first, if a specific game element incites motivation, then to determine whether that element is also non-distracting before deciding to implement that element in their system. As far as virtual reality is concerned, future works should be aimed at developing experiences for the masses. Regarding software, the use of low-poly graphics should be explored in such a way as to allow accessibility for those with lower-end peripherals. This is necessary to ensure that female students would be able to utilise these tools, regardless of their socio-economic backgrounds.



User Input
Eg: Code inputs, in-game actions
Is input correct?
No
Allow users to learn from mistakes
Eg: Enable retrying until input is correct
Yes
Instantaneous feedback
Eg: Changes in in-game environment

Fig. 3. Flowchart of a System that Allows for Instant Feedback.



Game Element
Eg: Narrative contexts, achievement
Does it motivate?
No
Do not implement element in system
Yes
Eg: Divert users from achieving learning outcomes
Is it a distraction?
Yes
Do not implement element in system
No
Implement element in system

Fig. 4. Decision Flowchart Determines whether Game Elements are Capable of Inciting Motivation without being Distracting.

To aid female students who do not have prior programming knowledge, further research can be done to identify the issues faced by students when learning introductory programming. Specifically, determining why it is difficult for students to understand the concepts of variables, arrays, loops, and if statements. As it stands, most research concerns factors such as lack of intrinsic motivation, perception, and socio-economic backgrounds as a reason for students not to do well in computer programming. Hence, a deeper insight into how students perceive programming concepts without the use of immersive games is necessary to develop appropriate solutions.

Finally, to further increase female participation in the field of computer science, more research should be done to determine how different genders respond to the elements of the game in an educational context. For example, one can continue to determine how males and females react to a high scoreboard in an educational immersive game. Consequently, it is also possible to find out how the high score board impacts the confidence levels in both genders. By doing so, it will be possible to decide whether to include certain elements when developing the system. Specifically, this is useful for developing educational systems for fields of study with large gender gaps, as in the case of females in computing.

IX. Conclusion

This paper provides a review that highlights reasons affecting female participation in computing with a focus on how stereotypical perceptions of computers prevent females from seeking careers in computer science. Additionally, the advantages of GBL, such as the ability to foster intrinsic motivation and knowledge acquisition, are also discussed in detail, along with their disadvantages in educational settings. Existing game-based applications for computer education are also highlighted, looking at how they work and how they compare to each other. This review also sheds some light on existing virtual-game-based applications and how virtual reality is used in education, specifically in the computing field. Lastly, a summary of how males and females respond to different game elements and their preferences is also discussed.

Along with this, discussions and several suggestions have been made regarding further research that can be done. Suggestions include a flow-chart to increase female self-efficacy and sense of belonging to the use of computing immersive games, developing frameworks that balance “fun” and “learning” elements in immersive games, identifying how students struggle with understanding programming concepts and analysing how different genders react to certain game elements. The purpose of this review is to encourage more research in the development of immersive learning applications to reduce gender gaps in computing.

Fairness Embedded Adaptive Recommender System: A Conceptual Framework

Alina Popa
The Doctoral School of Marketing
The Bucharest Academy of Economic Studies, Bucharest, Romania

***Abstract*—In the current fast paced and constantly changing environment, companies should ensure that their way of interacting with user is both relevant and highly adaptive. In order to stay competitive, companies should invest in state-of-the-art technologies that optimize the relationship with the user using increasingly available data. The most popular applications used to develop user relationship are Recommender Systems. The vast majority of the traditional recommender system considers recommendation as a static procedure and focus on a specific type of recommendation, being not very agile in adapting to new situations. Also, when implementing a Recommender System there is the need to ensure fairness in the way decisions are made upon customer data. In this paper, it is proposed a novel Reinforcement Learning-based recommender system that is highly adaptive to changes in customer behavior and focuses on ensuring both producer and consumer fairness, Fairness Embedded Adaptive Recommender System (FEARS). The approach overcomes Reinforcement Learning's main drawback in recommendation area by using a small, but meaningful action space. Also, there are presented two fairness metrics, their calculation and adaptation for usage with Reinforcement Learning, this way ensuring that the system gets to the optimal trade-off between personalization and fairness.**

Keywords—Algorithmic fairness; reinforcement learning; recommender systems; system adaptability

I. Introduction

In the current constantly changing business environment, companies are required to respond appropriately to challenges that appear and adapt quickly to customers new needs and expectations in order to stay “top of mind” with prospects and clients. In retailing, a family of applications called Recommender Systems (RecSys) can help businesses stay relevant to their customers by leveraging the existing data about users and/or different items in order to help users find the right item for them [1]. One disadvantage of the current approaches of RecSys like Collaborative filtering or Content-based recommendations is that these strategies consider only the two elements, users and items when delivering recommendations, making impossible to detect important patterns that include other elements and to adapt it to the context or changing environment. Also, each of the recommendation approaches has its own limitations. Items recommended through Content-based filtering are always similar to the items previously bought or consumed by the user [2], while Collaborative filtering provides a good solution only under static scenarios when there are many users that bought or consumed the same product [3]. Hybrid recommender systems combine two or more recommendation strategies in different ways to benefit from their complementary advantages [4] and overcome the limitations of individual components. Another limitation of RecSys, regardless of strategy is the assumption that user's underlying preferences remains unchanged, thus the recommendation procedure is a static process [5, 6].

One of the best-known approaches that allows to include adaptability in a system is Reinforcement Learning (RL) [7-9]. There is a series of publications that explore the usage of RL in the area of RecSys. Out of which there are those that focus on user-item interaction sequence or user's browsing history and use it to create a state that later is fed to the RL model [10-15]. A different approach is to use user and item sets which are obtained from bi-clustering as environmental states [6]. An earlier paper is using both user information and item information vectors and refers to it as context [16]. Important work on integrating negative influence of irrelevant recommendations is done by using negative rewards [12, 13, 15, 17].

Machine Learning technologies are increasing their presence in our daily lives and have serious implication and influence in a lot of areas. Because these systems are used in many sensitive situations and can lead to life-changing, high stake decisions, it is crucial that algorithms' outputs do not reflect discriminatory behavior. Which is why, alongside with developing new ML use-cases, researchers have done efforts to formalize fairness and sources of bias in ML [18-27], propose fairness evaluation metrics [18, 19, 28-33] and processing methods to mitigate undesirable biases in relation to the proposed definitions [19, 28, 31, 34-37].

It is worth noting that based on literature review, there are no works as per knowledge of the author that explore simultaneously the following elements of an efficient and fair recommender system: 1) focus on customer relationship development 2) adaptability to new situations 3) optimization for long term customer engagement using negative rewards where appropriate and 4) awareness of both consumer and provider fairness.

Thus, in this paper, it is presented the design of a Fairness Embedded Adaptive Recommender System (FEARS) that has its main aim the development of customer relationship. The conceptual framework is combining multiple recommendation strategies through leveraging extensive information about user, items and context. The recommendation strategies are combined and used as the action space by a RL Agent. This way, the system has the ability to automatically learn the optimal policy through trial-and-error; by recommending and receiving reinforcements from user's feedback. This will allow the system to quickly adapt to the changing needs of the customers and will try to come up with a more long-term recommendation strategy to build a fruitful relationship with the client. Not least, the rewards of the RL engine are defined in such a way that both consumer and provider fairness is being ensured.

II. Related Work

In this section, firstly it is described the basic problem of Recommender Systems. Next, each of the recommender strategies specifics, latest advances and limitation are presented. Then, it is introduced the Reinforcement Learning practice and an analysis of it's to date usage and limitations in the recommendation area.

Also, an exploration of the different fairness formalizations for ML and recommendation systems is done in order to give an overview on how these definitions are translated into implementation.

A. *Recommender Systems (RecSys)*

In the human decision-making process, obtaining recommendations from trusted sources is a critical component. Usually, this role is played my family, friends or subject-matter experts. The goal of a recommender system is to create and give relevant recommendations of items or products to users. Depending on the structure of the learning system, traditionally there are distinguished following types of systems[4]:

- Collaborative Filtering: In this type of systems, a user is recommended items based on the previous ratings of the users that bought/ used the product.
- Content-based Filtering: These systems recommend items that are similar to items the user has liked in the past.
- Hybrid approaches: These methods try to combine both collaborative and content-based approaches into one in order to overcome the individual limitations of each of the approaches.

Currently, the architecture of RecSys and their evaluation on real-world problems is an active area of research.

B. *Collaborative Filtering*

Collaborative filtering (CF) systems collect user feedback in the form of ratings or ranks and makes recommendations to the active user based on items that other users with similar preferences liked in the past [38].

The aim of any recommendation system is to suggest elements that are relevant to users by extracting latent variables [39-42].

Latest advances in the field include using graph encoding, Stochastic Shared Embeddings, large-scale Pairwise Collaborative Ranking, Sequential Recommendation Via Personalized Transformer [43] that mainly solve the problem of scaling to massive datasets, learn user and item embeddings and think about the problem as a sequence of actions, not one-shot recommendations. The user and items embeddings are mainly a different way to refer to latent variables and a series of work leverage the power of Neural Networks to try and learn them [44-46].

C. *Content-Based Filtering*

The intuition behind a content-based recommendation is to suggest to a customer a product similar to those the user has previously purchased. Method tries to extract similar objects. There are two main types of measures used to estimate this relationship: measures of distance and measures of similarity between objects [47].

Most of the advances in the content-based recommendation area is based on finding best ways to represent an item through a vector, or, in other words, get their embeddings [48-53].

D. *Recommendation of Complementary Products*

*W*hen recommending complementary products, the system tries to leverage the transactions history of customers [54, 55] through Association Methods like APRIORI.

The APRIORI algorithm remained essentially unchanged since its introduction to the research community, although there are sporadic efforts to extend it [56, 57].

E. *Reinforcement Learning (RL)*

Reinforcement Learning is an area of machine learning that has been inspired by behavioural psychology. The field focuses on how a software agent (hereinafter agent) should take actions and how to interact with an environment so as to maximize a total reward function.

An agent can interact with the environment and learn through trial and error, just like humans and animals. Every action that the agent performs in an environment influences the future state of the agent. Also, each action is rewarded with a reward, and this is the only response the learner receives [58]. The mechanism that generates the reward and the transition from one state of the agent to another refers to the dynamics of the environment [47].

The agent's goal is to maximize his total long-term reward in the way he responds to his environment. This can happen if an agent explores the environment and tries to learn its dynamics.

Formally, the environment is a mathematical model known as the Markov Decision Process (MDP) encountered primarily in dynamic programming. The difference between the classical methods of dynamic control and RL is that the latter does not know the MDP model and can be used if these processes are very complex and other methods are unfeasible [59]. The basic MDP model contains the following components:

- A set of environmental states S1, ..., Sn ∈ S: These can refer to the inherent characteristics of the agent or objects that surround and interact with it.

- A set of actions that the agent can take, A1, ..., Am ∈ A: These refer to all possible actions that the agent controls.
- Transition function from one state to another: Being a Markov process, the next state of the system depends only on its previous state and the action taken, not on the whole history.
- The reward function represents the value of the reward obtained after acting with At in St.

An agent is a computer program that is able to observe and interact with the environment defined by the MDP. The agent perceives the environment as a set of observations that define a state. The agent interacts with the environment in a feedback loop pattern by following the steps below:

1) The agent observes the characteristics of the environment that define the current state, St.

2) The agent chooses an action from the set of possible actions, At, with which it responds to the environment in the current state St.

3) The agent enters a waiting state until the characteristics of the environment change with the St + 1 state and the agent receives the Rt+1 reward.

4) Steps 1-3 are then repeated.

The agent's behaviour or the way he interacts with the environment is described by a function called action policy or simply policy [60]. It specifies the actions to be taken when the agent is in a certain state. The agent's learning goal is to find a policy that maximizes the total reward.

F. Recommender Systems using Reinforcement Learning

As previously mentioned, in the literature there are already RecSys that include an RL engine. It is useful to formalize the problem of RL in the RecSys area and see the differences in the approach of the different research.

As mentioned above, formally, the RL problem can be defined as a mathematical MDP model. For that it is needed to specify the States, Actions and Rewards.

States are defined in different ways in the existing literature. They can reflect a mapping of previous user-item interactions into a hidden state [15], user’s recommendation and ad browsing history [13], previous items that a user clicked [12], the sequence of visited and recommended items [10] or a more detailed interaction sequence that contains clicking, purchasing, or skipping, leaving [14]. An interesting approach is to define states as the cluster resulted from the co-clustering or biclustering of users and items [6] or to extend the state to include user demographics [5]. Efforts are as well invested in how to best represent the state in a RL RecSys [61]. Currently, and as to the knowledge of the author, in the current literature there is no approach where the recommendation context, user demographics, behavioral patterns and recent browsing/interaction history is taken into account in the state definition.

Actions are mostly defined as selecting an item to be recommended from the whole discrete action space which contains the candidate items [12, 14, 15] or even whether to give a recommendation or not, and if yes, what would be the item to recommend [13]. There are authors that consider recommending a list of items [5, 11, 61]. One of the most different approaches it to recommend items from neighboring clusters to the user-items one [6]. As mentioned in multiple articles [62, 63], RL in RecSys has a common issue of efficiency that comes from the fact that the action space is too large, consisting of all candidate items, and thus huge amount of interaction data is required for learning an optimal policy.

The reward function is heavily dependent on user feedback and actions he takes, for example user can click or purchase a recommended item and receive a positive reward or to skip it and get a different reward value [10-13, 15]. Reward can consist of immediate user feedback, but as well as a longer-term objective [14]. Most of the rewards are not deterministic and depend very much on how the user is reacting, but there are also formulations when this is seen deterministically as the Jaccard distance between the user vectors of the time t and t+1 state [6].

It is important to note the research direction as well towards using negative rewards. This can help the learning agent into searching for a policy that would be appropriate for overcoming the information fatigue [12, 13, 15, 17].

G. Fairness in Machine Learning

In the same way as people, algorithms are vulnerable to biases that exist in data and can lead to an unfair decision or outcome. More than 20 types of biases in ML were extracted, categorized and explained by researchers [24, 26] in order to motivate and accelerate the process of mitigating them.

Putted simple, in the context of high stakes decision-making, fairness is the absence of any prejudice or favoritism towards an individual or a group based on their inherent or acquired characteristics that are considered sensitive variables. Thus, a fair algorithm is one whose decisions are not skewed towards a particular group of people. GDPR, UK Equality Act, Fair Housing Act and Equal Credit Opportunity Act define protected classes such as race, gender, age or disability and state the fairness and equality principles [64].

The most simple and straightforward definition of fairness is “fairness through unawareness”: “A ML model is said to achieve fairness through unawareness if protected attributes are not explicitly used in the prediction process”.

Although these variables are not used in developing the ML model, this doesn’t mean that the information cannot be retrieved from other variables. Chiappa & Isaac [65] emphasize that fairness should be expressed both in terms of sensitive variables, but also considering corelated or proxy variables. Not considering these proxy variables has been shown to increase the risk of discrimination [27].

Mehrabi et al. [66] distinguish three different types of fairness definitions: 1) Individual Fairness where the system should give similar outputs to similar individuals, 2) Group Fairness where ML system treats different groups equally and 3) Subgroup Fairness which intends to obtain the best properties of the group and individual notions of fairness.

Group fairness equal treatment can be in turn defined through [66, 37]: 1) Equal Opportunity where the probability of a person from a positive outcome class of being assigned a positive outcome should be equal for both protected and unprotected group members, 2) Demographic Parity where the likelihood of a positive outcome should be the same regardless of whether the person is in the protected group or not, 3) Disparate Impact considers the ratio between unprivileged and privileged groups likelihood of a positive outcome. Disparate impact uses the “not less than 80%” rule to define if a process has disparate impact or not.

Main approaches for tackling unfairness are differentiated into three groups: 1) pre-processing, 2) in-processing and 3) post-processing [37]. Pre-processing methods are extracting representations from the data in order to remove undesired biases [27]. Then, this unbiased data is used for model development. Some of the methods in this family are adversarial learning, causal methods, relabeling, perturbations, resampling, reweighing, transformation and variable blinding [27]. The in-processing methods are constraining a model to produce fair outputs by including fairness into the learning mechanism like adversarial learning, bandits, constraint optimization, regularization or reweighing [27]. The post-processing methods are working with model outputs to make them fair using calibration, thresholding and transformation approaches [27].

H. *Fairness in Recommender Systems*

As presented in a previous section, RecSys make recommendations to support decision making by studying user behavior and historical patterns. Because it is widely applied in various fields like recommending music, books, people to hire or jobs, an impartial view of the system towards any of the involved sides can be detrimental [67, 68].

Since these systems use past data, they are also inheriting the 1) Historical Bias, which is the already existing bias in the world [26], 2) Representation Bias when the used sample from a population is not representative for the whole population [26] and 3) Social Bias when other people’s actions or generated content affect another person’s opinions [69]. Alongside with these biases, the system itself displays: 1) Popularity Bias when items that are more popular tend to be exposed more [70], 2) Algorithmic Bias when the bias is not present in the input data and is added later by the algorithm in the way it works [69], 3) Presentation Bias when the way items are presented impacts the attraction those items get (e.g., users can click only what they see, thus, items presented more often will get more clicks) [69] and 4) Ranking Bias when top ranked items are perceived as more interesting and thus, receive more traffic [71]. In Fig. 1 it is shown how different types of biases feed each other in a RecSys.

Considerations of fairness have been actively studied in the context of recommender systems. Burke [72] introduced the multisided view of fairness in recommender systems. In the case of recommendations, the system is facilitating a transaction between parties [73]. Fairness towards all the involved parties is important and a balanced point should be found. Burke et al. [74] divide stakeholders of any given recommender system into three categories: 1) Consumers are the individuals that receive recommendations 2) Providers are those that stay behind the recommended items or products and gain from consumer’s choices and 3) System is the platform itself that tries to match providers with consumers and by doing this in a successful way is gaining benefits.

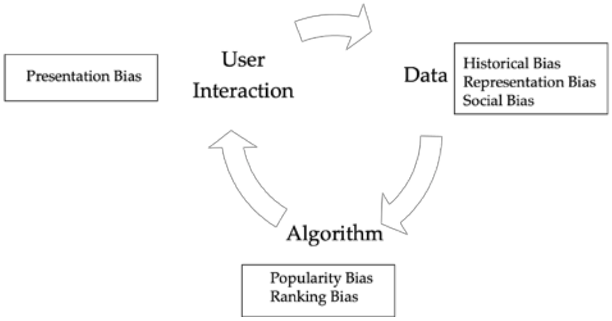

Fig. 1. Different Types of Biases that Appear in a Recommender System. Source: Adaptation after Fig. 2 [115].

Recommender system’s objective for a consumer is to give the best items for his needs, through personalization, in such a way that these items are not constraining him in getting a higher overall utility compared to people from other groups, thus in a fair way. For a provider, recommender system needs to ensure that his items get sufficient exposure and that items are shown to the consumers that have the highest probability of buying or consuming them, thus in a relevant way. Platform’s utility is also important, because this is the initial motivation of having the recommender system in place. A key issue that arises in recommender systems is the tension between a personalized view of recommendation delivery and fairness objectives [74, 75].

Provider’s fairness in recommender systems is typically defined for the objects or subjects to be ranked. It has been explored and formalized as:

1) the bound of the number of items related to each of the protected attributes that are allowed to appear in the top k positions of the ranking [76],

2) a sufficient presence of items belonging to different groups [77],

3) a consistent treatment of similar items [77],

4) a proper representation of items from both protected and unprotected groups [77].

5) exposure, disparate exposure and group fairness disparity; all three proportional to the merit of the item defined as relevance to the query [78],

6) pairwise fairness that expresses the likelihood of a clicked item being ranked above another relevant unclicked item is the same across both groups [79],

7) pairwise statistical parity represents that if two candidates from different groups are compared, then on average each group has an equal chance of being top ranked [79],

8) set-based fairness at discrete points in the ranking with logarithmic discount that emphasize the fact that fairness at top ranks is more important than at lower ranks [80], *9)* difference in acceptance rates measures whether a relevant item from the advantaged and disadvantaged class are accepted at the same rates [81].

In the area of consumer fairness, there are the following metrics that can be used:

1) value unfairness which occurs when one group of users is consistently given higher or lower predictions than their true preferences [82]. Value unfairness becomes large when predictions for one group are consistently overestimated and predictions for the other group are underestimated.

2) absolute unfairness, which measures inconsistency in absolute estimation error across different user groups [82]. This means that the advantaged group has the unfair advantage of good recommendations, while the other groups have poor recommendations.

3) non-parity unfairness is computed as the absolute difference between the overall average ratings of disadvantaged users and those of advantaged users for recommended items [82].

4) balanced neighborhood that expresses the fact that recommendations for all users are generated from neighborhoods that are balanced with respect to the protected and unprotected classes [74].

5) disparate impact of recommendation [74, 37].

Overall, the consumer fairness is less represented in the literature.

There are efforts in the area of mitigating bias and ensuring fairness in recommender systems by using regularization terms [82, 83, 84], reinforcement learning [78, 85] and neighborhood balancing [74].

Although the literature of methods is rich in methods to mitigate unfairness, not all of them are applicable to the dynamic nature of recommender systems. Ge et al. [85] show that by enforcing fair decisions through static fairness criteria metrics, the system leads to unexpected unfairness in the long run and that fairness cannot be defined in a static setting without considering the long-term impact and evolution. Same as with the need to bring adaptability into the recommender system results, the need to have a dynamic view over fairness can be solved by using reinforcement learning.

The practice of using Reinforcement Learning to ensure fairness is an emerging research area [27]. In terms of implementation, fairness dimension can be given to the RL agent as a reward that can be positive in the case of fair outputs and negative otherwise [86, 87]. Other approaches construct the problem as a Constrained Markov Decision Process [85].

III. Proposed Approach

In this section, it is proposed a conceptual framework for the Fairness Embedded Adaptive Recommender System that aims to balance between personalization and fairness for long-term customer engagement. Firstly, the objectives of the recommendation system are introduced with possible solutions. Then, based on this, a novel architecture for this type of systems is proposed. Next, it is described how fairness dimension can be introduced into the RL engine and how the personalization-fairness trade-off can be solved.

A. Fairness Embedded Adaptive Recommender System

In the present paper, the objective is to create a conceptual design of a recommender system that holds a series of requirements:

- System is focusing on customer relationship development.
- System is incorporating an adaptivity functionality.
- System is optimizing for long term customer engagement.
- System is ensuring consumer and provider fairness.
- System is using a small action and state space in the RL engine.
- System is solving the personalization and fairness trade-off.

B. System Overview

Once converted, the relationship with a new customer must be developed for it to become profitable. In simple terms, this means understanding and covering client's needs.

The objective of the application is to extract consumer preferences and use this knowledge to find the most appropriate products and / or content that will be recommended through communication and interaction with the customer. Same time, the recommended content should bring to user the maximum utility and give him equal opportunities compared to people from other social groups.

C. System Components

The framework used follows next steps: 1) Database creation 2) Preprocessing 3) Recommendations generation 4) Recommendation’s combination 5) Reinforcement Learning Engine 6) User Recommendation 7) User Feedback incorporation.

1) Database creation: The application starts by setting up data sources (Fig. 2, 1). The information considered mandatory in a recommender system application is a) consumer data, b) their past interactions, c) data on provider’s items characteristics, d) items’ reviews and e) metadata about the current browsing session.

2) Preprocessing: The next step is to prepare the tables in the form in which they will be used in different recommendation components. This means that a series of tables having different structures will be created: a) The Customer-Item Matrix Table contains information about the items purchased or consumed by a consumer during the analysis period b) The Transaction-Item matrix is typically stored in transactional format where a transaction contains several rows, c) The items characteristics table contains all the tangible and intangible characteristics of an item as well as statistics about how many times it was recommended, clicked, bought from recommendation lists etc.

3) Recommendation Components: Once all the main tables are prepared (Fig. 2, 2), three recommendation components are developed, and their results are merged and combined to create the action space for the RL Engine (Fig. 2, 3-4).

4) User-oriented collaborative filtering recommendation (Fig. 2, 3.1): The method starts from the assumption that similar users have similar preferences [88] and reflects the real situation when recommendations from friends are more effective. Model tries to explain the Customer-Item Matrix Table using a set of latent factors. Latent structures are automatically deduced from the matrix, as long as the number of factors is specified [88]. Once the factors are discovered, the model associates the belonging of an item to a factor and the user's inclination towards the same factor. For each customer, the model will recommend products that have values close to "1" in the reconstructed matrix and have not been purchased in the past.

5) Content-based recommendation (Fig. 2, 3.2): In the case of new users or items, because of no prior history, the recommendation strategy is using the Items characteristics table. For example, one can use all available information about the tangible and intangible properties of the item, including embeddings extracted from unstructured data.

6) Complementary item recommendation (Fig. 2, 3.3): In this step, rule sets are extracted from transactions using association algorithms. This is extremely useful as it emphasizes the context of using/consuming the initial item. This as well brings completeness to customer's need by saying "if you want to use this, do not forget about that".

Following these recommendation strategies, the outcomes are combined between them in order to create the action space for the RL model (Fig. 2, 4). As it can be seen, there is also the "Random Recommendation" component (Fig. 2, 3.4) and "No Recommendation "(Fig. 2, 3.5) that will bring exploration and novelty into the recommendation landscape as well as will keep the system from harming stakeholders through unfair decisions.

7) Reinforcement Learning Engine: The next task of the system is to choose the most appropriate action for a particular use. In other words, the question that needs to be answered is: "For this user, what is the best action to take? Recommendation of a product that corresponds to the latent structures of the user? An item similar to what user consumed/liked before or a complementary item?". The answer can be as well that the best action is no action.

The solution that could combine user information, past behavior and interaction in order to choose the best action is to use a RL engine (Fig. 2, 5). RL problem is defined as a MDP system.

The set of environmental states is represented by the finite clusters over the vector space extracted from the characteristics of the environment:

- The socio-demographic characteristics of the user.
- User past behavior and interaction with focus on indicators like diversification, appetite for novelty, previously liked items.
- The details of the period in which the browsing and recommendation is made. This can include time of the day or year, browsing device, browsing session time etc.

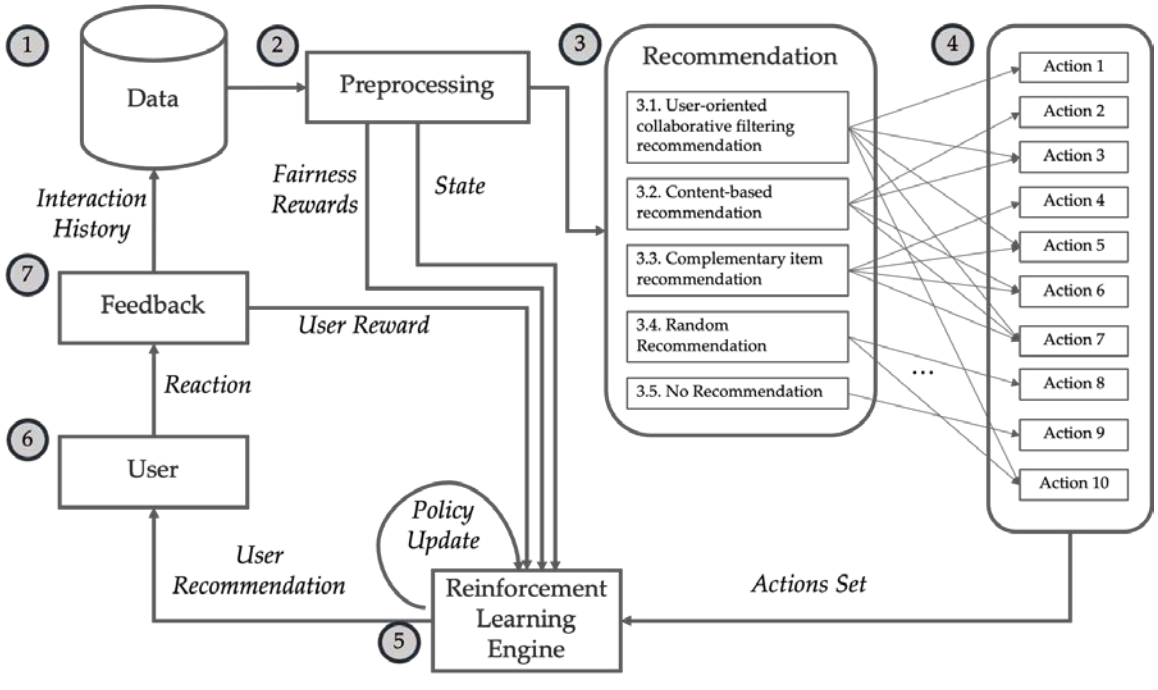

Fig. 2. Design of a Fairness Embedded Adaptive Recommender System.

The set of actions represents all possible actions that the recommendation system controls. As defined before, the set of actions is represented by the individual recommendations or combinations of them (Fig. 2, 4).

The advantages of formulizing the actions like this are: 1) the low complexity given by action space: instead of having all the candidate items, 2) keep the personalization as a key focus, 3) include novelty for consumer and fairness for provider (random product action and no recommendation action).

The reward function is conditioned by the user's response to the recommendation received (Fig. 2, 6-7), but also by fairness rewards of the system.

The reward value at time t+1, Rt+1, after the agent takes At in St is compounded out of three terms:

- Reward coming from user response
- Reward coming from fairness value towards consumer
- Reward coming from fairness value towards provider

Next, the individual terms are defined, because they are the key for embedding fairness and consumer relationship in the system.

User response rewards are linked to the action that user is taking after seeing the recommended item. There can be distinguished the following actions that a user is taking in response, each with a different associated reward. The associated reward will be decreasing as per user feedback reaching a negative value if user ends the communication with company:

- User clicks on the recommended product, and buys/consumes it.
- User clicks on the recommended product, but does not buy/consume it.
- User is adding the item into wish list/buy latter/favorites lists.
- User marks the recommendation as inappropriate.
- User closes the recommendation/searching session without taking any other action.

Consumer fairness reward is linked to a particular item recommended and is known in advance; thus, it is deterministic. Consumer fairness reward is calculated for each item based on Disparate Impact formula as defined in [37]. This particular formula was used because it is easy to adapt and integrate as a reward into the system. Also, the metric encodes the demographical parity idea in a RL workable manner. But the main reason why this particular metric was chosen out of all presented previously is its unique advantage of being deterministic, thus known before taking any action. Considering the act of recommending a particular item being a treatment, this means that the ratio between the likelihood of a positive outcome (presentation of an item) for different groups should ideally be close to 1:

$$Disparate\ Impact(item)$$

$$= \frac{P(recommend\ item=1\mid group=protected\ group)}{P(recommend\ item=1\mid group=privileged\ group)} \quad (1)$$

$$= \frac{P(recommend\ item=1\mid group=protected\ group)}{P(recommend\ item=1\mid group=privileged\ group)} \quad (1)$$

The Disparate Impact for an item is updated every time an item is being recommended using equation 1, and although it is item linked, is actually expressing the consumer fairness. By integrating this metric, it is ensured that individuals with different backgrounds are treated the same, thus they receive same type of items and content recommendation. A good example of a situation that was not fair towards consumer is the study that shows that female users of Google had a lower chance of being recommended and presented hiring ads for high-paying executive jobs [67].

In order to integrate the Disparate Impact into the RL engine, first is needed to adapt it to express the undesirable practice of having either positive or negative bias. Although most of the metrics are focusing on supporting the unprivileged group, this can lead to a turn of the situation, such that the focus here is on not having any type of bias and treating individuals from different groups equally. The equation of calculating the consumer reward is given by equation 2.

$$R_{t+1}consumer\ fairness\ (item) = -|Disparate\ Impact(item) - 1| \quad (2)$$

For the provider fairness, it is desired to ensure that exposure is a function of relevance. For this purpose, difference in acceptance rates is being used (DAR) [81] and is calculated as the pairwise difference of the ratio of true positives divided by the predicted positives for each class. The latest is also called Precision in binary classification evaluation [47] and reflects the fraction of relevant cases. The reason why it was decided to go with this particular metric, is the fact that it is the only metric out of the presented ones that can be used in other recommendation settings besides ranking.

By incorporating DAR into the RL engine there will be ensured that items are presented proportionally to how relevant they are.

$$Relevance\ (item) = P(y = 1\ |\hat{y} = 1) \quad (3)$$

In order to actually use DAR as rewards, for each item, the relevance as defined in equation 3 is calculated. The updated relevance is simulating the situation on recommending an item, while it will not be clicked on. Secondly, DAR (equation 4) is calculated using the newly updated relevance for the item, while maintaining the relevancies for other items ceteris paribus. There will be a DAR value associated with each of the items that can potentially be recommended. Finally, this value is taken with a negative sign (equation 5) in order to count for provider fairness. If there are big differences between items relevance, they will sum up and bring to a high negative reward, thus the agent will try to choose an item that leads to a smaller DAR. The overall reward function is given by the equation 6.

$$Difference\ in\ acceptance\ rates\ (item) = \frac{\sum_{i=0}^{I}\sum_{j=0,j\neq i}^{I} dist\left(Relevance(item_i), Relevance(item_j)\right)}{I(I-1)} \quad (4)$$

$$R_{t+1}provider\ fairness\ (item) = -|Difference\ in\ acceptance\ rates(item)| \quad (5)$$

$$(S_t, A_t) = P(R_{t+1}user\ response|\ S_t, A_t = item) + R_{t+1}provider\ fairness(item) + R_{t+1}consumer\ fairness(item)$$

$$R: S\ x\ A \rightarrow\ R \quad (6)$$

For solving this problem formulation and extracting the optimal policy, one can use Temporal Difference Methods [89] as they are appropriate for continuous tasks having discrete state and action spaces or Deep Q-Learning Networks [90] if one wants to include the reward values into the state.

IV. Results and Discussion

In the current paper, it was presented the design of a Fairness Embedded Adaptive Recommender System (FEARS) which allows to create a fruitful relationship with the client by optimizing for long-term goals while making sure to keep both the consumer and provider fairness.

The gaps in the current conceptual practice were presented in the related work chapter. The desired functionalities of the system were stated in the proposed approach section and in the Table I it is shown how requirements were translated into implementation solutions along with potential issues and limitations that should take the form of further work.

The system was designed to use holistic user information including his socio-demographics and past buying behavior patterns. This was integrated into the system by encoding it into the state of the RL MDP model. As per author knowledge, this is a novel addition to the RecSys using RL approach. Another important detail is the inclusion of the recommendation context expressed through browsing time metadata (ex. time of the year, hour of the day). The way states are used in the RL engine, by clustering the initial vectors, allows overcoming the most common RL limitation of non-efficiency and non-convergence.

Another way to ensure optimal policy convergence is to take control over action state space. This was stated as a clear problem in the literature reviewed and by using an elegant approach of defining actions as recommendation strategies and combination of those, the action space is downside from the number of all items to a maximum of 11 actions.

Although the individual recommendation components are traditional and straightforward, together they are covering the whole scene of consumer interest: similar, complementary, high interest or random products. The way these strategies are combined, namely through an RL engine, brings both adaptivity and ensures reaching long term objectives into the system. A detail that emphasizes the customer relationship health and importance is the practice of using negative rewards into RL component. This means that system will try to optimize for users to be recommended products that they are likely to buy but also play quite safe and not causing information fatigue that can lead to termination of relationship. Another addition is the fair view both towards consumer, but also with respect to items providers. Stated as a clear problem in the reviewed literature, the conflict between personalization, consumer fairness and exploration is solved by introducing not only consumer satisfaction rewards, but also fairness specific rewards.

In this paper, it was presented a conceptual framework that can be adapted to a large range of use cases, from e-commerce companies to both news, article and media items recommendation. Another set of application area may consist of those where the decisions and recommendations are linked to life-changing, high stake situations like hiring, job recommendation or financial lending.

The approach tries to overcome limitations of both individual traditional recommendation systems as well as RL usage in the RecSys by having an integrated view over consumer, a focus on the long-term engagement and a strong enforcing of a sustainable and fair recommendation practice.

TABLE I. System Requirements and Implementation Solutions

System Requirements	*Functionality Implementation*	*Potential issues/ limitations with the solution*
System is focusing on customer relationship development	Usage of an RL engine that has the reward function linked to customer relationship goals.	The reward function is not reflecting accurately the desired objective.
System is incorporating an adaptivity functionality	Usage of a RL engine that takes complex states in account when recommending an item.	High complexity and search space that comes with all the additional information.
System is optimizing for long term customer engagement	RL engine is using negative rewards where appropriate in order to decrease information fatigue and optimize for long term objectives.	Negative rewards are too small in comparison with positive rewards affecting their efficiency
System is ensuring consumer and provider fairness	RL engine reward function is containing fairness metrics and outputs a higher reward in case of fair recommendations.	N/A
System is using a small action and state space in the RL engine	Action space is represented by individual or combinations of recommendation strategies. State space is discretized by using clustering techniques.	Oversimplification of the action and state spaces that could lead to pattern loss
System is solving the personalization and fairness trade-off	Reward function contains both recommendation relevance metrics and fairness metrics.	Inappropriate balance between the two objectives

Future research should involve implementing the approach and use it in real-world situations for evaluating the degree in which it reaches its multisided objectives. Also, different streams of work linked to potential issues presented in Table I should be carried.

V. Conclusions

Major contributions of this paper are presented as follows:

- A reinforcement learning based framework FEARS for better recommendations that focus on both revenues and relationship with the customer was introduced.
- The framework has a holistic view over customer and recommendation landscape ensuring a highly personalized, relevant and positive user interaction.
- Two relevant, adapted fairness metrics are defined and a way to compute them is presented.
- The relevant fairness metrics are embedded into the system as corresponding rewards.
- A RL problem definition was given that overcomes the common RL in RecSys issue of non-efficiency by using a limited, but relevant action space and discretized and clustered state space.

Overall, the system has all the necessary levers to overcome limitations of individual components, solve the personalization-fairness conflict, ensure long-term customer engagement and avoid the typical RL issue.

Same time, the framework should be tested in real-world situations or simulated data and appropriate design changes should be made. This is a conceptual starting point for developing FEARS.

Al-Ahliyya Amman University
Amman, Jordan

***Abstract*—Because of Covid-19, many countries shutdown schools in order to prevent spreading the virus in their communities. Therefore, schools have opted to use online learning technologies that support distance learning for students. As consequences, Ministry of Higher Education and Scientific Research encourages higher education institutes to adopt blended learning in their programs. However, different students react in different ways to online learning. Some students were able to make productive use of online learning strategies more than others. A conceptual model based on 15 variables was constructed based on UTAUT2, TAM, and other models to investigate and to study the factors that affect students' acceptance of online learning. 29 hypotheses were investigated to study the relationships among the variables that affect online learning acceptance and online learning community building in Al-Ahliyya Amman University. The collected responses were analyzed using a structural equation modeling (SEM) approach. SPSS and AMOS were used to analyze the data.**

Keywords*—*Online learning; technology acceptance; learning assistance; learning community building assistance

I. Introduction

Since Covid-19 (Coronavirus) started spreading, many countries decided to shutdown schools and move to online learning solutions [1, 2]. Moving to distance learning because of the virus became necessary in order to keep providing education to students. Different distance learning paradigms were implemented to support distance learning such as live-streaming lectures [3], the use of Massive Open Online Courses (MOOC) [4], and the use of worksheets and animations [5]. Additionally, some educational gamification [6, 7] websites and computer applications were adapted to support online learning. Unfortunately, not all students accept the online learning in place of face-to-face classes.

Based on the online learning feedback during Covid-19, Ministry of Higher Education and Scientific Research developed a plan to adopt online and blended learning in the higher education institutes. As consequences a three-year action plan (2021-2023) was developed to manage adapting synchronized and asynchronized online learning to be blended in higher education. The plan included training faculty members from private and public university. However, moving from traditional lecture-led classes to online learning would cause to move from lecture-centric to learning-centric paradigms. Therefore, students need also to be training and to adapt to the new learning paradigms.

Although the members of Generation Z, who are familiar with various technologies accessing the internet, are the majority of students, it is very important to study the factors that affect their intention to use their technical knowledge in digital learning [8]. It is very important to know the factors that are affecting users' adoption of technologies in order to achieve the objectives of the proposed technology. Many models, such as the Unified Theory of Acceptance and Use of Technology (UTAUT) [9, 10], were proposed to explain users' behavior in utilizing technologies. However, the factors that affect the use of a technology are vary based on the environment [11].

In this research, a model is constructed using 15 variables to investigate its effects on the online learning in Al-Ahliyya Amman University. The model was developed based on UTAUT2 [10], the conceptual TAM (Technology Acceptance Model) [12-15], and a conceptual model proposed by Vululleh [16]. Based on the defined variables, the research model was constructed, and 29 hypotheses were investigated and analyzed using a structural equation modeling (SEM) approach in SPSS and AMOS.

II. Literature Review

One of the widely applied models to study the factors that affect using a technology is UTAUT [9]. It was developed by investigating eight different models. The eight models are the model of PC utilization (MPCU) [17], social cognitive theory (SCT) [18], Technology Acceptance Model (TAM) [19], innovation diffusion theory (IDT) [20], the combined theory of planned behavior/technology acceptance model (C–TPB–TAM) [21], and the motivational model (MM) [22]. As a result, UTAUT was formulated based on four factors: performance expectancy (PE), effort expectancy (EE), social influence (SI), and facilitating conditions (FC). Also, UTAUT considered four moderators: gender, age, experience, and voluntariness of use. In 2012, UTAUT was extended to UTAUT2 [10] by adding hedonic motivation, price value, and habit factors to the model. Later, the Values-Enhanced Technology Adoption (VETA) model [23] extended UTAUT2 by adding new variables to UTAUT2 variables. Although UTAUT and UTAUT2 are widely used to study the acceptance of technology, they need to be adapted to the context of eLearning.

Islam [13] investigates the effects of learning management systems (LMS) on achieving learning outcomes by developing a model based on TAM. The model suggests that LMS may assist students in learning and building a collaborative network in hybrid courses which combine both face-to-face education and online learning. Learning assistance and perceived community building assistance were added to TAM. The model was formulated using five factors: Perceived Usefulness, Perceived Ease of Use, e-Learning Use, Perceived Learning Assistance, and Perceived Community Building Assistance. The model did not consider the design of online courses nor the factors which can affect the learner community building.

Since online learning is usually web browser-based or based in mobile applications, a model developed by Liu, et al. [12] added new variables that may affect the acceptance of online learning to TAM. The new variables are related to the technology design and the user experience with technology. The model used the following constructs: Perceived Usefulness, Perceived Ease of Use, and Intension to Use (from TAM). The following constructs were developed: Online Course Design, User-Interface Design, Previous Online Learning Experience, and Perceived Interaction. The model integrates the effects of online course design and interface design with TAM. However, the model did not consider the effects of the variables such as hedonic motivation, price value, community building and habit factors.

Vululleh [16] studied students' acceptance of e-learning technology in Liberia. The research model was based on TAM, which proposes that users' Behavioral Intention to adopt a technology is controlled by their beliefs of Perceived Usefulness (PU) and Perceived Ease of Use (PEOU). Additionally, the model extended TAM by adding two factors, Social Influence (SI) and Quality of Life (QL). Therefore, the conceptual model studied the effects of four factors: PU, PEOU, SI, and QL on the Behavior Intention (BI) to use e-learning. Like Liu, et al. [12] and Islam [13], Vululleh [16] proposed a model based on TAM. Factors such as design, interface and community building were not considered.

Some models studied the differences of acceptance in different environment. For instance, Lee [14] examines the difference between Korean and American students' perceptions of online education. The model was based on TAM using the two factors Perceived Usefulness (PU) and Perceived Ease of Use (PEOU), and adding the two factors Perception of Online Learning Acceptance and Student Satisfaction (OLAS) and Online Education Support Service Quality (PSQ). The model found that the (PSQ) directly influenced behavioral intention toward online learning acceptance and student satisfaction. However, the impact of service quality on the behavioral intension toward e-learning in different cultures was limited. The model investigates the direct and indirect effects of PSQ on PLAS; however, more variables such as design, interface and community building need to be considered.

The model proposed by Ratna and Mehra [15] examines the behavioral intention of the university students in India for using e-learning. The model was based on TAM using the factors of Gender, Student Major, and Monthly Family Income. It examines the applicability of TAM among university students in India and found that Perceived Ease of Use (PEOU) has a significant effect on Perceived Usefulness (PU), Attitude (ATT), Behavioral Intention (BI) and Actual Use (AU). Also, PU has a significant effect on ATT, BI, and AU. Moreover, ATT has a significant effect on Intention to Use (INT). Finally, this model found that BI has a significant effect on AU. Like the aforementioned models, this model is also based on TAM and limited to study the effects of four variables only.

III. Model Development

The proposed model is based on 15 variables that were utilized in several studies [9, 10, 12-16, 19, 24, 25] to investigate the factors that affect the adoption of technologies:

1) Performance Expectancy is how technology benefits users to perform certain activities [10], and Perceived Learning Assistance (PLA) is how an online learning component can help the individual's learning [13]. Therefore, in our research model, these two factors are combined into one factor.

2) Perceived Community Building Assistance (PCBA) refers how the online learning helps individuals to have social interactions with others [13]. Liu, et al. [12] defines Perceived Interaction as interpersonal interaction and human-system interaction. The interpersonal interactions include interactions with peers and instructors. In our conceptual model, we opt to include Perceived Community Building Assistance and interpersonal interaction into one factor.

3) Online Course Design (OCD) refers to the types and quality of the materials that can be included in the online course [12]. Since the online course is web browser-based or based in a mobile application, it can include different types of material such as images, animation, and video. Therefore, the quality of these materials can have great impact on users.

4) When developing software, User-Interface Design (UID) plays crucial role in the success of the software. In online course, User-Interface Design refers the organization and arrangement of the online course content and visual design [12].

5) Effort Expectancy is how ease the use of the technology affects users [10]. Effort Expectancy is also called by other researchers such as Liu, et al. [12] as Perceived Ease of Use. Hence, only one of them (PEU) is included in our conceptual model to find the effects of ease of use of e-learning technology on the intention to use it.

6) Social Influence (SI) is how other people, such as family and friends, influence users' decisions to adopt the technology [10].

7) Facilitating Conditions are the resources and the support that are available to the user to use the technology [9]. These include both physical and environmental factors [26] that help students to learn using online resources. In our model, the Perceived Service Quality (PSQ) variable represents all the factors that help the students to use the online resources.

8) Hedonic Motivation (HM) is defined as the fun, enjoyment, or pleasure that the users of a technology can have [10]. This variable was not in UTAUT [9], but it was added to UTAUT2 [10] and was considered the most important added variable to UTAUT2 [27].

9) Quality of Life (QoL) is how online learning processes can affect the students' faith [26]. This includes saving time and costs when using or downloading the online learning materials.

*10)*Price Value (PV) is the monetary costs assigned with the use of the technology [10].

*11)*Habit and Experience (Habit) is the user's ability to use the technology without the need for training because of learning and previous experience [10].

*12)*Behavioral Intention (BI) measures students' acceptance of online courses in the present and in the future [26].

*13)*Technological Experience (EXP) represents the skills that students need to use online courses. Martinho, et al. [24] classify Technological Experience into two external variables: Base Technological Experience and Advanced Technological Experience. However, since basic computer skills are taught in schools starting from the elementary grades, we opt in the proposed model not to distinguish between Base Technological Experience and Advanced Technological Experience.

*14)*Perceived Usefulness (PU) is the degree to which students believe that online learning will enhance their job performance [13]. This variable was introduced in TAM [19].

*15)*Previous Online Learning Experience (OLE) [12] including using technology, internet, and online learning resources can affect learners' intentions to use online learning.

Based on the aforementioned variables, the following hypotheses were proposed.

H1: OLE will positively affect students' BI to use online courses.

H2: OLE will positively affect students' PU of online courses.

H3: OLE will positively affect students' PEU of online courses.

H4: OCD will positively affect students' PU of online courses.

H5: OCD will positively affect students' PEU of online courses.

H6: OCD will positively affect students' PCBA of online courses.

H7: PSQ will positively affect students' PU of online courses.

H8: PSQ will positively affect students' BI to use online courses.

H9: PSQ will positively affect students' PEU of online courses.

H10: UID will positively affect students' PEU of online courses.

H11: UID will positively affect students' PCBA of online courses.

H12: PU of online courses will positively affect students' BI to use online courses.

H13: PU of online courses will positively affect students' PLA to use online courses.

H14: PU of online courses will positively affect students' PCBA of online courses.

H15: EXP will positively affect students' PU of online courses.

H16: EXP will positively affect students' PEU of online courses.

H17: PEU of online courses will positively affect students' PU of online courses.

H18: PEU of online courses will positively affect students' BI to use online courses.

H19: PEU of online courses will positively affect students' PLA to use online courses.

H20: PEU of online courses will positively affect students' PCBA of online courses.

H21: SI will positively affect students' PU of online courses.

H22: SI will positively affect students' BI to use online courses.

H23: BI to use online courses will positively affect students' PLA to use online courses.

H24: BI to use online courses will positively affect students' PCBA of online courses.

H25: QoL will positively affect students' BI to use online courses.

H26: HM will positively affect students' BI to use online courses.

H27: PV will positively affect students' BI to use online courses.

H28: Habit will positively affect students' BI to use online courses.

H29: PCBA will positively affect students' PLA to use online courses.

IV. Methodology

Quantitative methods were utilized, in the form of non-structured survey questionnaires with closed questions using a 5-point Likert-type scale where 1 is highly disagree and 5 is highly agree. The questionnaire was constructed of 15 variables and 69 items in total. The items included in the questionnaire were collected from prior studies. Prior to the survey, a pilot study was conducted to assure the reliability and validity of the questionnaire. The entire instrument demonstrated acceptable reliability; Cronbach's alpha was 0.962. The questionnaire was randomly distributed to Al-Ahliyya Amman University students. The final accepted questionnaires for analysis were 462 out of 517 from the submitted responses. The data were analyzed using SPSS version 25 and AMOS version 23.

A. Data Analysis

There are nine colleges in Al-Ahliyya Amman University: Faculty of Information Technology, Faculty of Pharmacy, Faculty of Architecture & Design, Faculty of Allied Medical Sciences, Faculty of Arts & Sciences, Faculty of Engineering, Business School, Faculty of Law, and Faculty of Nursing. The responses, which were used in the analysis according to the colleges, was as followings: Faculty of Information Technology (36%), Business School (22.7%), Faculty of Pharmacy (19%), and the other colleges (22.3%) (see Table 1).

Faculty of Engineering and Faculty of Pharmacy are five-year colleges, while the other colleges are four-year colleges. The responses that were used spanned the following student levels: First Year (24%), Second Year (25.8%), Third Year (21.6%), Fourth Year (17.7%), and Fifth Year (10.8%) (see Table 2).

Table 3 illustrates the previous student experience with online courses. 60 students (13%) had never ever studied with any online course, while 402 (87%) students had studied using some online courses. 205 students studied one or two online courses. 165 students studied 3 to 5 online courses. 32 students studied 6 or more online courses.

TABLE I. STUDENT DISTRIBUTION OVER COLLEGES

College	Frequency	Percent
Faculty of Information Technology	167	36.1
Faculty of Pharmacy	88	19.0
Faculty of Architecture & Design	21	4.5
Faculty of Allied Medical Sciences	13	2.8
Faculty of Arts & Sciences	24	5.2
Faculty of Engineering	19	4.1
Business School	105	22.7
Faculty of Law	18	3.9
Faculty of Nursing	7	1.5
Total	462	100.0

TABLE II. STUDENT LEVELS

Level	Frequency	Percent
First Year	111	24.0
Second Year	119	25.8
Third Year	100	21.6
Fourth Year	82	17.7
Fifth Year	50	10.8
Total	462	100.0

TABLE III. STUDENT EXPERIENCE WITH ONLINE COURSES

Online Course	Frequency	Percent
Never studied online course	60	13.0
studied 1-2 online courses	205	44.4
studied 3-5 online courses	165	35.7
Studied more than 6 online courses	32	6.9
Total	462	100.0

B. Hypotheses Testing

The model is consisted of 15 variables that were measrured in a questionnare of 69 items. The variable averages (ranging from 3.5 to 3.9) and standard deviations (ranging from 1 to 1.3) are listed in Table 4. The variables Cronbach's Alpha if Item Deleted was ranged from 0.958 and 0.962. Since total variable Cronbach's Alpha is 0.962, all variables were included in the model and none of them need to be dropped. Many indexes were measured to test the model fitness (see Table 5). Since all the minimum values of the indexes were achieved, the model fits enough to measure the hypotheses. All factor loadings were above 0.6; therefore, all items were used in the analysis.

TABLE IV. THE MODEL VARIABLES

Variable	Mean	Std. Deviation	Cronbach's Alpha if Item Deleted
PU	3.4654	1.04352	.959
PEU	3.4802	1.04912	.959
PLA	3.5415	1.13455	.959
PSQ	3.5584	1.12182	.958
EXP	3.9446	1.24697	.960
PCBA	3.5361	1.10217	.958
OCD	3.5000	1.16716	.958
UID	3.5260	1.24651	.958
OLE	3.6075	1.25583	.959
SI	3.5216	1.14455	.958
QoL	3.5628	1.18976	.958
BIs	3.6129	1.17900	.958
PV	3.4726	1.19596	.962
Habit	3.5476	1.07761	.959
HM	3.5440	1.29309	.960

TABLE V. MODEL FIT RESULTS

Index	Value	Recommended values
Degrees of freedom	2203	> 0 [17]
Discrepancy Chi-Squared	4031	> .05 [17]
Relative Chi-Squared	1.83	< 5.0 [18]
Comparative Fit Index	0.915	≥ 0.9 [18, 19]
Tucker Lewis Index	0.909	≥ 0.9 [17, 20]
Incremental Fit Index	0.915	≥ 0.9 [17, 20]
Root Mean Square of Error Approximation	0.042	≤ 0.08 [17]

The 29 hypotheses were tested using AMOS. 15 hypothses were supported while 14 hypothese were rejected. The result is illustrated in Table 6. H17, which states that Perceived Ease of Use of online courses will positively affect students' Perceived Usefulness of online courses, has high impacts; if Perceived Ease of Use goes up by 1 unit, Perceived Usefulness of online courses goes up by 1.204. In addition, if Perceived Ease of Use goes up by 1 unit, PLA goes up by 0.839 unit. Therefore, Perceived Ease of Use is considered a very important factor in online learning.

On the other hand, the effects of the factors in H7, H14, and H18 have negative effects. In H18, Perceived Ease of Use will negatively affect Behavioral Intentions. When Perceived Ease of Use goes up one-unit, Behavioral Intentions goes down by 0.822. Thus, when the students feel that online courses are too easy to use, they will use them less. In short, H7, H14, and H18 will be stated as following:

H7: Perceived Service Quality negatively affects students' Perceived Usefulness of online courses.

H14: Perceived Usefulness of online courses negatively affects students' Community Building Assistance of online courses.

H18: Perceived Ease of Use of online courses negatively affects students' Behavior Intention to use online.

V. Limitation and Conclusion

The study was conducted in a private university, Al-Ahliyya Amman University. Online learning has become a necessity after the spread of Covid-19. Therefore, this study can be extended to include responses from students in different educational institutions, including public and private institutions and K-12 institutions. All responses were collected from students. The study can be extended to collect responses from instructors as well. Finally, the moderator affects, such as age, gender, and experience, were not considered in this study because there studies such as Liao, et al. [21] and Kharma [22] found that there were no significant effects of these moderators in online learning models. However, when extending the study to include different categories of educational institutions, there might be impacts of these moderators on the relations in the model.

The study proposed a theoretical model to investigate the effects of 15 variables on online learning acceptance. Based on these 15 variables, 29 hypotheses were tested. Only 14 hypotheses were supported. The final model is shown in Fig 1. Four variables: Perceived Usefulness, Social Influence, Quality of Life, and Habit had positive effects on Behavioral Intention to use the online course. The highest estimated beta value of these was of Perceived Usefulness. In other words, in order to increase students' behavioral intention to use an online course, they should know the importance of the online courses in learning. The role of academic advising can help in increasing students' awareness of the usefulness of online learning and how it can affect the learning process by accessing the online material at anytime and anywhere.

Moreover, the study found that the course design and ease of use of the course affect the online collaborative learning. Therefore, in order to enhance peer-learning and group-learning, the online courses should include in the design simple and easy features that allow students to communicate with their classmates. Additionally, ease of use positively affects students' perceptions of online learning. Hence, the ease of use of online learning components and environment is crucial to increasing students' intent to learn from online learning components and to cooperate with their classmates.

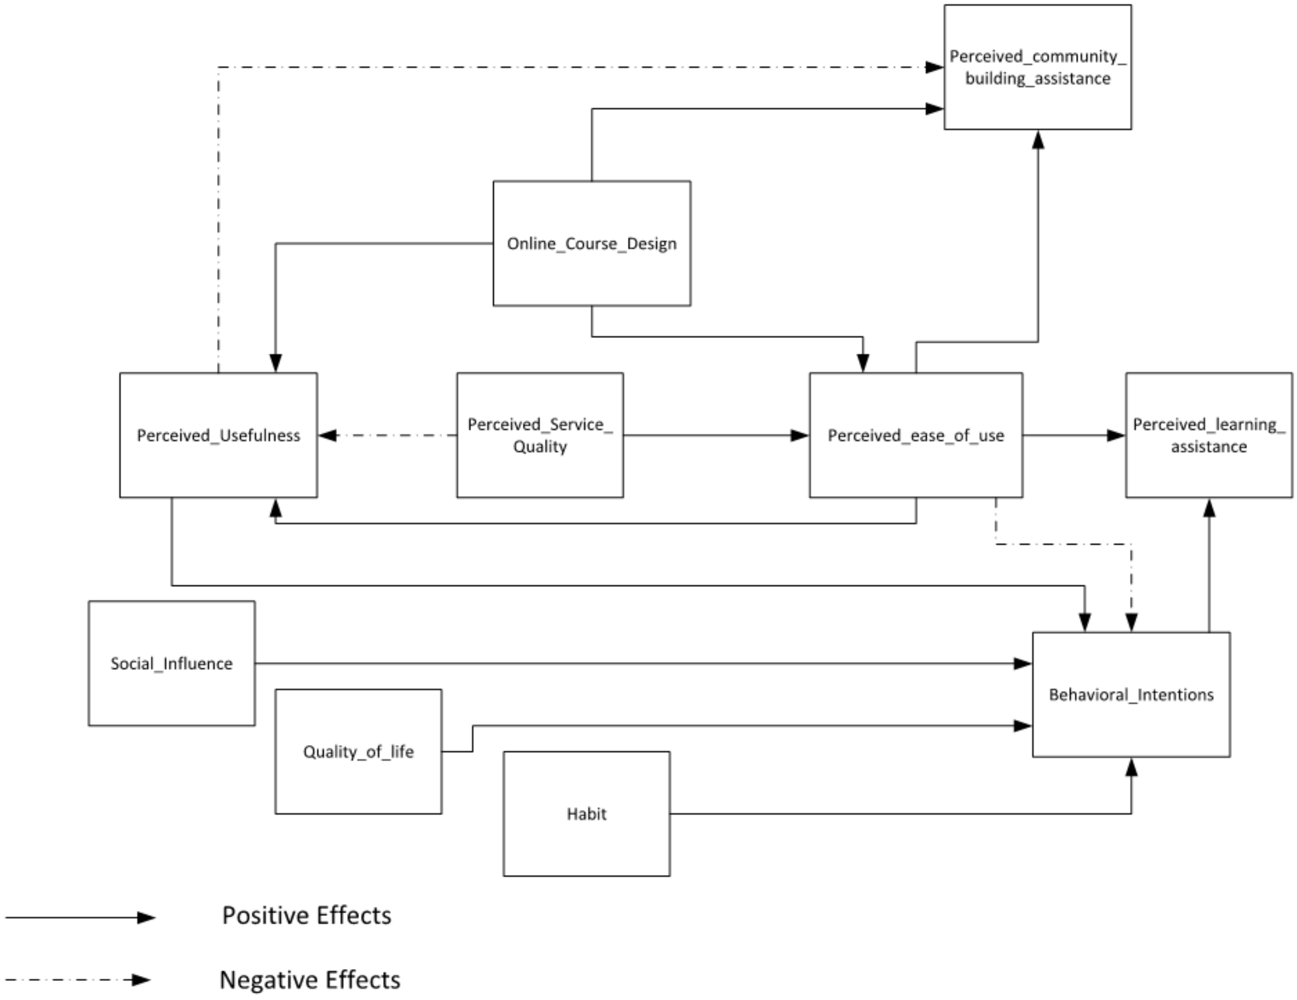

Fig. 1. Final Model.

Three relations had negative effects in the model. The first one is that the more assistance in using the online course, and more physical requirements to access the online course, the less usefulness the online course has. The second is that the more assistance in using the online course and more physical requirements to access the online course, the less collaboration there is with others. Finally, if the students feel that the online course is too easy, they won't be as interested in the online course. Therefore, the physical requirements and the technical assistance should be minimized. For instance, online courses should use good compression to minimize the usage of internet bandwidth and hardware requirements. Additionally, online courses should not be too easy. The students like some challenges in the learning process.

Finally, the effects of Hedonic Motivation were not supported. This finding agrees with Mehta, et al. [23]. College-level students do not use online learning for fun. However, further investigation is needed to study the effects of Hedonic Motivation in different educational system levels, such as K-12 schools.

Data Analytics in Investment Banks

Basma Iraqi[1]*, Lamia Benhiba[2], Mohammed Abdou Janati Idrissi[3]
Mohammed V University in Rabat
ENSIAS, Rabat
Morocco

***Abstract*—Capital Markets are one of the most important pillars of worldwide economy. They gather skilled finance and IT professionals as well as economists in order to take the best investment decisions and choose the most suitable funding solutions every time. Data analytics projects in Capital Markets can definitely be very beneficial as all optimizations and innovations would have a financial impact, but can also be very challenging as the field itself has always incorporated a research component, thus finding out what could really be of an added value might be a tricky task. Based on a comprehensive literature review, this paper aims to structure the thoughts around data analytics in investment banks, and puts forward a classification of relevant data analytics use cases. Lastly, it also discusses how transforming to a data-driven enterprise is the real change investment banks should aim to achieve, and discusses some of the challenges that they might encounter when engaging in this transformation process.**

Keywords—Capital markets; data analytics; data analytics use cases; data-driven transformation; investment banks

I. Introduction

Capital markets are one of the most important and complex fields in worldwide economy that involves multiple stakeholders, among which investment banks are the main actor. These later play the role of the mediator between enterprises looking for funding and others willing to invest. They advise their clients on the best approaches to collect funds and manage their investments, thanks to a very thorough understanding of the client profile, but also the ups and downs of the markets and the economy.

Faced with troubled economic times, investment banks, like all other financial actors, have been pushed, more than ever, to rethink their products and services and improve their quality by analyzing further all the available data on clients and markets [1]. The interest towards data analytics comes therefore naturally as this is where magic happens with the data. Through the different types of analytics possible, the algorithms and techniques developed, there is opportunity for investment banks to improve their relationship with their clients and enhance their overall revenues.

Nevertheless, starting data analytics projects can be a challenging step as these are usually initiatives where the output is not known from the beginning and the return on investment not determined. Thus, it is important to do thorough research beforehand to identify the types of analytics that could be of interest to the organization, as well as find out similar success stories in order to define the scope and get inspired before starting the experimentation.

Research on data analytics in investment banks have continuously focused on specific use cases' implementations, but the topic has never been addressed from a broader perspective. For the financial services sector, no comprehensive guides are available to help investment banks in approaching data transformation from the beginning, by identifying the problems they can resolve and the types of analytics they can implement in order to choose use cases from.

This paper aims therefore to provide a classification of relevant data analytics use cases for investment banks, and discusses the importance of engaging in a data-driven transformation and some of the challenges that could be faced in this process. The rest of this paper will be organized as follows: Section II presents capital markets and investment banks, Section III outlines the motivations behind adopting data analytics in investment banks and Section IV proposes a classification of the most relevant use cases that can be deployed in this sector based on a review of the literature. In the last section, a discussion is initiated about some of the challenges that investment banks may encounter when initiating the data-driven transformation, in order to provide better guidelines for investment banks in this process.

II. Introduction to Capital Markets and Investment Banks

Capital markets are markets where demand and supply for funding based on different instruments are organized. These instruments are grouped in different asset classes and quoted in different markets [2].

The main objectives of Capital Markets are to secure funding for national economy, structure liquidity and savings, enable firm restructuring, mergers and acquisitions, cover multiple kinds of risks and provide and represent the main references for all asset values [3].

Out of all the activities performed in capital markets, portfolio management is one of the most important ones. It focuses on decision making with regards to investments for individuals or institutions, taking into account the investment policy, objectives, asset allocation, risk and performance [4]. The science behind it enables measuring performance, and consequently making consistent improvements based on continuous learning, controlling risk and ensuring consistency and discipline throughout the process and the portfolio lifecycle.

*Corresponding Author

In order for the different stakeholders in the Capital Markets to decide on the strategies they will work with and manage their portfolios appropriately, they also rely greatly on different economic indicators which represent some of the most important signals and raw data influencing the capital markets' activities. That is because it is these same indicators that explain the motivation behind the need for funding, investing or restructuring among others. These indicators could be of the following three types: (1) Supply indicators, (2) Demand indicators and (3) Inflation, Money and financial indicators [5].

Modeling and predicting how changes in the values of economic indicators impact the investment strategies adopted and how the change in the prices of the different instruments due to economic variations affect the value of the investment portfolio and its risk vulnerability is how Capital Markets function on a daily basis.

In capital markets, investment banks play a very important role. In fact, they are the main intermediary between large corporations or governments that need funding, and the market investors. Based on the financial challenges of each, investment banks advise their clients on the best approaches to raise capital taking into account the current investment climate as well as the client's needs [6]. This also applies to mergers and acquisitions' scenarios where businesses are often looking to restructure by purchasing their competitors.

As such, the main departments of an investment bank are mainly [6]:

- Trading and Sales: the department in charge of executing deals on behalf of the clients, but also the one responsible of trading the bank's own money on the different financial instruments.
- Asset Management: referring to portfolio management for large institutions, insurance companies or pension funds.
- Wealth Management: the function of advising wealthy families and individuals in ways to fulfill their financial long-term objectives and needs by investing in capital markets.
- Securities Services: the department responsible for all services related to assets held or issued by the clients. These services include custody, clearing, settlement and fund administration among others.
- Research: the function of collecting all kinds of information about the market and the different corporations in order to generate recommendation reports on some stock buy or sell.
- In addition to the risk management, internal controls, accounting and IT functions among others.

Given their very diverse missions, investment banks' departments often have opposite views on market trends, look for different opportunities, offer various services to the same clients, and thus collect distinct data inputs as well as analyze and process them differently.

III. Data Analytics in Investment Banks

Analytics is a buzz word. It is used almost everywhere and in very different contexts. There are even many research papers which only aimed at finding the right definition to analytics. One of the best descriptions one could find in the literature regarding analytics is the one provided by CETIS (the Center for Educational Technology and Interoperability Standards) which defines "Analytics [as] the process of developing actionable insights through problem definition and the application of statistical models and analysis against existing and/or simulated future data" [7].

Actionable insights shed the light on the importance of action in analytics. Analytics' results should go beyond reporting or descriptions to opportunities and conclusions that prompts users for action. That's actually the main difference between Analytics and Analysis, which are the most confused concepts in this regard. Indeed, while "Analytics aim to project the future based on past performance, analysis rather presents a historical overview of past data" which is equivalent to what descriptive or diagnostic analytics could render [8]. An example of an actionable insight is the outcome that goes with A/B testing initiatives of E-commerce websites (such as Amazon or eBay) in which they test variations of their websites in samples of users in order to analyze their sentiments and reactions to the changes made.

The literature distinguishes four types of analytics [9]:

- Descriptive analytics: which answers questions such as: what is happening? What is it about? What does it mean? What are its attributes? About the data and content being analyzed.
- Diagnostic analytics: are answers to the following questions: why did it happen? What are the triggering events? What are the preliminary conditions for each context?
- Predictive analytics: are more focused about the future, thus answering questions like: what is likely to happen? What happened in similar situations throughout the past? What could be the results of such actions or decisions?
- Prescriptive analytics: come after predictive analytics to discuss and suggest potential alternatives fix problems or capitalize on opportunities. Questions answered in prescriptive analytics include: what should I do about it? What can I do prevent it? How can I best exploit it?

The capital markets, and investment banks more particularly, have been one of the first and most important users of data analytics. That is not a surprising finding as the field does not manufacture any physical product and data is really its main asset [10]. In fact, statistics in 2016 have even showed that the field is the number 1 consumer of data services with a share of 13% of the global data analytics use cases implemented [11], and that is because data is used and generated tremendously every second of the day in this field, and that analytics could definitely help making sense of data that could never be processed exhaustively.

In addition, the interest in Data Analytics within investment banks is also the result of a tight conjuncture which led to weak returns compared to earlier times. Indeed, according to a study by Accenture, the financial sector and capital markets more specifically, has witnessed since a few years a stagnation of revenues given the fall of margins and the rising complexity of regulations. Also, the Fixed Income, Currencies and Commodities business, which has historically filled the largest share of revenues, witnessed an important share shrinking for the same reasons. Last, new bank competitors have arisen, making the pressure on old banks even tighter [1].

Data has therefore made it at the center of the banks' analytics projects because it promises [12]:

- A better risk management: investment banking is the sector where resources are heavily invested in risk because the consequences of a bad risk assessment could be devastating. The 2008 financial crisis and its impact on the global economy is the best example to illustrate the high importance of this business line. This applies to all types of risks, whether it be related to [1]: (1) Fraud detection: where big data could be leveraged in order to identify patterns of fraudulent transactions or atypical operations and alert the appropriate personnel in order to investigate further. (2) Liquidity: where analytics could be used to keep track of the short- and long-term liquidity every time, assess the impact of transactions on liquidity in real time and run simulations and stress tests regularly in order to make sure that the necessary funds for banks to function correctly are always available. (3) Credit risk: where internal data about clients and counterparties is enriched with external data from the web, social media and the news in order to get an exhaustive feel of their financial situation and ensure that the hazards are well managed and known if any.
- A pleased and Loyal Customer: this is where sentiment analysis comes to play in order to better understand the needs of the customers and address them correctly. Thanks to all the data available in the web, including the news, social media, research reports and corporate websites, it is now possible to anticipate what the client might or might not appreciate, and direct them to the most suitable products (cross and up selling) at the right time. This not only enables an improved customer loyalty, but also makes attracting prospects a more successful process.
- A secure ecosystem: Analytics enables a very large and thorough monitoring where patterns of incidents and problems are identified through machine learning algorithms, thus making their handling and resolution a much straightforward process.

Since it is usually very expensive to start collecting all relevant data for the bank before making any use of it, all organizations, whether they are in financial services or in another industry, usually proceed in a different way. Companies start by defining a business objective linked to a strategic goal they want to reach thanks to analytics, and then reverse the process to identify the data to capture in order to achieve the goal. This specific application of data analytics is what a use case refers to, and it is the most common approach to address analytics as it offers a scope and a project perspective to the data application and enables the association of KPIs and governance that are very important to the monitoring of data analytics initiatives.

Despite these promising benefits, there are unfortunately fewer Analytics initiatives deployed in the capital markets sector, and especially in investment banks. That is because the challenge of finding interesting use cases is real, and the technical complexity that comes along the execution of these use cases is also more pronounced and different from the challenges that could be faced in other environments. So, what business problems could Data Analytics fix or optimize in investment banks? And what problems could be faced when implementing them?

In fact, based on the literature review of the use of analytics in investment banking, it came out that a brainstorming around business use cases of data analytics in investment banking is actually missing. As much as there is a lot of material when it comes to fields like retail banking, insurance or even industry, there is significantly less work in the investment banking sector given its business complexity and specific characteristics.

The focus of the remainder of this section is to describe data analytics use cases that can be of interest to investment banks, based on a review of research papers, of data analytics use cases worldwide as well as the authors' professional experience. These papers will be discussed following a proposed classification, which puts each use case in one of the 7 categories described below (from A to G) and indicates whether it is a deployed solution or is still the object of ongoing research. The research papers included in this study are the authors' selection of the most relevant papers in each category, based on the assessment of their added value according to the authors' financial expertise. Last, throughout this section, both internal bank data and external economic data will be proven to be equally important in implementing data analytics in investment banks, and the methods and data processing techniques that can be used to generate insight from this data will also be discussed.

A. *Prediction of Financial Market Patterns*

The investment banking sector is very tied to market data and economic indicators. It is based on this data that traders and portfolio managers decide each day whether to buy or sell. Therefore, predicting the market shifts and movements is a very valuable information for the actors to anticipate their investment strategies and act accordingly.

Predicting market patterns can be done based on the history of transactions, current and historical market data as well as indicators of the economic sector. The idea behind this use case is to identify if the current scheme is somehow similar to an old one in order to learn from the mistakes made by then and make the most out of it. This use case can be implemented by labeling the dataset based on sets of conditions and feature engineering in order to output the knowledge needed. Then techniques like clustering to group alike data together or game theory to evaluate how each variable in the dataset influences the model positively or negatively can be used [13].

Another method to predict the patterns of financial markets is to build models which, based on input financial indicators, predict values of the output ones. An example of this approach is the article “Big Data Analytics for Financial Market Volatility Forecast based on Support Vector Machine” [14] which zooms on high frequency data or real time data, which is data that is generated on a very high velocity. This type of data has been proved to be very rich in terms of information, but its treatment has always been difficult given the high number of problems that must be fixed beforehand. In this article, the focus was put on volatility as an important indicator of high frequency data on financial markets, and it suggests predicting the short-term volatility via a model of the jump volatility. The technique used for this purpose is Support Vector Machine. It takes eight input indicators in order to model the price and predict the next day’s price, and thus its short-term volatility. It also applies several kernel functions, which happen to have different prediction results on different markets.

On this category of use cases, JPMorgan Chase has been able to deploy a NLP project for equity investing. Indeed, in order to improve the research capabilities of their portfolio managers on equity, JPMorgan launched a Natural Language Processing project specialized on equity investing. The tool is fed with news articles on equity markets and generates insights on the data such as identifying enterprises which have new products to launch or the ones currently in difficulty. According to JPMorgan, the investments based on this tool have outperformed those based on the NASDAQ50 index [15].

B. Detection of Crisis Situations

Detecting crisis situations is technically a very similar use case to the prediction of market patterns. Indeed, it just focuses on a specific label of the data which is the crisis or the most alarming ones. The how-to is therefore the same, and the only difference consists in shedding light on the weak signals only in order to anticipate any future challenges or problems that may occur and set a backup plan in advance. This use case can be particularly of interest to the risk teams who need to anticipate and adjust their measures in case of problems or disasters.

An example of use cases in crisis detection is the paper “Monitoring Banking System Connectedness with Big Data” [16], where the authors came up with a solution to model connectedness between individual firms based on firm-level information in order to ensure better supervision and monitoring of financial stability since connectedness between economic agents has become one of the most addressed topics in the sector. The methodology applied for this purpose is a decomposition of the outcome measure into multiple components, and then a network construction based on indicators of connectedness in the US banking system. The first step is simply based on linear regression of CAPM framework using the French-Fama model, and the second step is about network construction and analysis. This latter is done through many measures in order to provide the best insight possible to the banking system stability state.

C. Client Risk Profiling

In portfolio management, there are two main inputs which define how the investment strategy should be: The first is the performance level wanted and the second is the risk appetite. Determining how much risk the client is willing to take is yet another challenging task that portfolio managers have to realize. Indeed, a portfolio manager could find cases where a client is unable to evaluate their risk appetite or one who underestimates his willingness to take risks or vice versa.

For such problems, there are multiple solutions. Scoring algorithms can be used which, based on questionnaires, determine the weights and risk scores to assign to every question and answer. An example of algorithms that does so is the self-organizing map, which belongs to the artificial neural network family and is based on unsupervised learning for model training. Another solution to the risk profiling use case is to apply classification models to the client data in order to put them on a risk group based on a set of attributes. Here, algorithms like KNN, Decision Trees or SVM can be used. And last, clustering can also be used on the historical transactions authorized by the client in order to actually find out what other clients they are similar to and adjust their risk profile accordingly [17].

One paper that addressed this topic in a different way is “The value of big data for credit scoring: Enhancing financial inclusion using mobile phone data and social network analytics” [18]. This paper comes up with a new approach to estimate credit scores, which is based on mobile call records and social data. In fact, the paper suggests that the use of mobile data just like social media data can have an interesting impact on the clients' credit scores. The data is modeled as a network where nodes represent people in the log. Labels as well as other information are extracted from by using link-based features as well as a personalized page rank. The methodology is then evaluated statistically and economically. In fact, the tests proved that the combination of call network data with conventional data has given better results in credit scoring. The data by itself (without conventional data) has even rendered satisfying outputs. The paper claims that this methodology is especially interesting in developing countries where historical financial data is rare or inexistent. The only limitation to this approach is the availability of data, especially given the tight regulations in place in many developed countries.

On this family of use cases, CitiBank has been able to deploy a Credit-Sentiment Monitor from news media. This tool, which name is CitiVelocity, is based on the news articles published in Thomson Reuters. The objective behind such a tool is to provide Citi staff with insights on the companies that are mentioned positively and negatively in the press. This information would then be used to evaluate indices of Credit Default Swaps in which these companies are included [19].

D. Product Recommendation for Clients and Prospects

Investments banks, at the opposite of retail banks, do not have huge numbers of clients as the business is mainly B2B (Business To Business), thus a thorough understanding of the client needs and profile is required to maintain a good and continuous relationship with the client, especially for the senior bankers and the client relationship management team, who represent the front interface of the bank with its clients. For that, a 360º vision of the client is necessary. This latter should be composed of the client history, which consists of all client transactions and exchange logs with the bank, its risk profile and its strategic orientations. These could be deduced from the sentiment analysis of the client activity on their website or social media accounts or its interaction with the bank's website.

Recommendation systems in such case are based on collaborative filtering algorithms, and the model used could be matrix factorization, neural matrix factorization or singular value decomposition among others. The rationale behind is to give an implicit score to all products for every client, such that the higher the score, the higher are the chances that the client will be satisfied from the recommendation [20].

The paper "an investment portfolio recommendation system for individual e-commerce users" has come with a new recommendation system implementation, where aside of the investor's risk preference, parameters such as gender, education or location are taken into consideration. The system is built based on the collaborative filtering algorithm and the VaR (Value at Risk) method for risk measurement. The particularity of the recommendation system used is based on the rapprochement with the behavior of other e-commerce investors with similar preferences [21].

Among investment banks, UBS has succeeded in providing a free investment consulting service based on recommendation engines. They implemented a tool called SmartWealth based on machine-learning algorithms which is meant to provide prospects with a free advisory service on online investment in order to increase their chances of becoming clients. In order to realize such a service, UBS asks the client to answer a set of questions, and then the algorithm assigns the client a risk segment and invests its money in an adequate fund [22].

Goldman Sachs had also transformed its whole approach of identifying investment opportunities for the clients based on three aspects: (1) Momentum, where techniques of industry sentiment are applied in order to identify correlations between businesses in the same sector; (2) value, which takes into consideration sector information in addition to financial data in order to define the intrinsic value of the firm; and last (3) profit, which concerns e-commerce companies and enables to evaluate them based on the patterns of web traffic [23].

E. Client Satisfaction follow up

Client satisfaction is also an important brick of the bank client relationship, but also a difficult one as it is not straightforward to evaluate the client satisfaction from the bank services. There are three main sources from which client satisfaction could be inferred: the bank portal, where client complaints are processed, emails and phone calls exchanged with the client and their online posts and articles or interaction with the bank's social media accounts.

Determining whether the client feedback is positive or negative is processed using machine learning and sentiment analysis, where after cleaning the data extracted from the identified sources, embedding is performed, then model training is realized through algorithms like decision trees, neural networks or naïve bayes among others. Such insights could be of interest to all the bank departments, but to the senior bankers more especially who can use the lessons learnt from the client satisfaction measures to better approach them and handle their inquiries.

The fanciest way to follow up on client satisfaction today is to have chatbots. The role of the chatbot is to answer client questions automatically or to log and route their complaints to the relevant staff. The paper "AI-Based chatbot service for financial industry" has suggested an approach based on machine learning in order to automate the communication between the bank and the client regarding product sales or customer support, such that the robot agent keeps accumulating knowledge throughout the process [23].

On the same application of chatbots, J.P.Morgan and Morgan Stanley have all implemented chatbots for their production environments. The beginning is not easy, but the result is worth it. Indeed, thanks to conversational agents, Morgan Stanley for instance, has been able to answer many of the Research-related questions of their clients (analyst profile, research coverage, etc) thanks to well-trained agents who answer efficiently all the questions [25].

F. Simulation and Recommendation of Market Trades and Investment Strategies

For their daily activities, traders and portfolio managers are always handling the trade-off between their stock and the changes in market data and economic indicators. Market data being on movement in real time, it is just a matter of seconds before a good buy is not anymore or the opposite. That is why, the main struggle in such a use case is to constantly have at hand data that is enriched by market data, transformed taking into consideration all the market and economic changes and customized by filtering the economic indicators that have an impact on the positions on hand.

For that purpose, applications for real-time computations of risk metrics, limits or price predictions are all interesting. Machine learning models like K-means for clustering are a good fit to select assets while taking portfolio diversification into consideration. Reinforced learning or deep learning can also be used to control the dynamics of the system in an optimized way [26]. Last, recommendation systems can be applied, such that based on historical transactions, returns and economic factors, recommendations of new operations can be made based on techniques like matrix factorization [27]. A paper that has also worked on the topic is "An equity fund recommendation system by combining transfer learning and the utility function of the prospect theory". Actual transaction data is used to test the technique suggested, and the result is to answer the main question “what to buy?” given inputs of the operations and the market [28].

On the side of investment banks, MAN Group has also used artificial intelligence algorithms in order to define the best investment strategies on her AI-Managed funds. Based on millions of data points including transactional data, the tool developed by MAN identifies patterns to improve and adapt to the market changes. According to Bloomberg, this algorithm is behind more than 50% of MAN profit on its biggest funds [29].

G. *Optimization of Internal and Support Processes*

Finally, besides all the benefits that the main business lines can realize, the support functions can also make huge gains out of business analytics. Audit and Internal Control departments can get their controls automated, IT can have their system and technical incidents and problems automatically detected and resolved, and compliance and legal teams can make use of better fraud detection models among others. And for this family of use cases, all kinds of techniques could be used depending on the problem at hand.

One paper that handled a similar use case is “Automatic Detection of Relationships between Banking Operations using Machine Learning” [30], which solved the problem of matching operations in different systems. In fact, because there are different contexts in which the banks make use of the same operation (such as accounting, risk, internal control), banks end up having the same operation in different formats in multiple systems, and it is impossible for humans to figure out which transactions actually point out to the same operation. The contribution of this article is therefore a framework that enables operation matching thanks to machine learning mechanisms. The framework proposed is divided into 4 stages: Stage 1 is pre-processing, which consists of preparing the data from the data lake by selecting candidate operations, identifying possible records, merging and filtering. Stage 2 is machine learning based on ANN algorithms, and stage 3 is post-processing where a summary and combination of all results of the classifiers is performed in order to generate an exhaustive report of all matching operations. In order to test this framework, the authors applied it to 3 different scenarios, and they all ended up with at least 99,58% accuracy.

BNP Paribas Securities Services automatic trade matcher is definitely one of the best illustrations of this use cases’ category. In fact, BNP Paribas built a tool named Smart Chaser in order to match trades between the Clients and Brokers. The tool, based on predictive analysis, has allowed BNP Paribas to identify patterns of mismatches in order to avoid them beforehand, thus reducing manual intervention on the trades [31].

Table I summarizes all the research and enterprise use cases discussed within this paper:

TABLE I. DATA ANALYTICS USE CASES IN INVESTMENT BANKS

Use Case Family	***Use Case***	***Problem***	***Technique Used***	***In production or ongoing research?***
Prediction of financial market patterns	Big data analytics for financial Market volatility forecast based on support vector machine [14]	Analytics on high-frequency data	Support Vector Machine	Ongoing research
	NLP project for equity investing – JP Morgan Chase [15]	Research in equity investing	Natural Language Processing	In production
Detection of crisis situations	Monitoring Banking System Connectedness with Big Data [16]	Monitoring of firm connectedness	Linear Regression and Network Construction	Ongoing research
Client risk profiling	The value of big data for credit scoring: Enhancing financial inclusion using mobile phone data and social network analytics [18]	Credit scores’ estimation	Network modeling	Ongoing research
	CitiVelocity – CitiBank [19]	Credit-sentiment monitor from news media	Sentiment Analysis	In production
Product recommendation for clients and prospects	An investment portfolio recommendation system for individual e-commerce users [20]	Investment portfolio recommendation	Collaborative filtering algorithm	Ongoing research
	SmartWealth – UBS [22]	Product recommendation for prospects	Machine learning algorithm	In production
	Investment opportunities approach – Goldman Sachs [23]	Investment opportunities definition for clients	Sentiment Analysis	In production
Client satisfaction follow-up	AI-Based chatbot service for financial industry [24]	Customer support	Machine Learning	Ongoing research
	Conversational agents – Morgan Stanley [25]	Client research questions	Machine Learning	In production

Based on this summary, the most important dimensions for an investment bank transformation emerge and structure the business and strategic objectives behind the data analytics. In fact, from a high-level perspective, one can isolate the external environment from the internal one within the bank; and within each environment, another detailed partitioning can be made. On one hand, the external environment includes market and economic data in addition to client information, whether it be their financial results or their perception of their relationship with the bank. On the other hand, in the internal environment side, one can distinguish between three main components: the product, the transaction and the risk metrics. All these dimensions combined give a 360° view of the investment bank's processes and enable a transformation impacting all the key factors. It is then up to each bank and depending on its context and pain points that the focus can be put on one or some of the use case families instead of all of them.

This being said, data today has become the backbone of all innovative and successful banking projects and the key element in order to take advantage of any of the use cases previously mentioned is to switch the whole decision-making process to one that is based primarily on figures and facts generated through analytics. As such, information technology projects within the bank should be strategically aligned with the business objectives, and all means and technological capabilities to achieve this cross-disciplinary cooperation should be deployed. In other words, the turning point for investment banks would rather be to transform to data-driven enterprises where data lies at the core of any process and is the most crucial factor in all business choices. This transformation is the only genuine change that can guarantee that all data sources, whether they are structured or unstructured, are being used and combined in order to create rich and insightful input data, and that analytics are achieving the best possible outputs in a timely manner through very fast and efficient data processing. However, this transformation does not come easily as there are various challenges to overcome, some of which will be discussed briefly in the next section.

IV. Challenges of becoming a Data-driven Investment Bank

A. Use Case Prioritization

One of the first challenges investment banks face when starting analytics use cases is how to prioritize them. In fact, as illustrated by the use cases listed in the above section, there are so many inter-dependencies between the use cases because they mostly rely on the same data: a mix of internal deals and operations with market and economic data. Thus, deciding on what use cases should go first is not only a matter of business priorities but also a matter of technical constraints, mainly related to data availability.

B. Data Availability

This first point leads to the second concern of data analytics projects in the field, which is ensuring that all data is accessible. In fact, all the magic of analytics in capital markets lies in the correct combination of internal and external data, which is not always available in internal databases, and is rather found in data providers' platforms, social networks and websites of regulatory entities, ministries, national agencies and clients.

C. Cloud Integration

Besides, given the large amounts of data investment banks may end up processing due to the broad scope of external data needed for analytics, the nature of the data repository / data lake used can also be a difficult decision to make, and one that significantly impacts the long-run and cost of the analytics initiatives. There is an important trade-off to make between the strict regulations on investment banking and data confidentiality they require, and the big data volumes to process, in which a big chunk is mainly public and already available to everyone on the net.

D. Data Architecture

Another problem to consider is the technical and technological architecture of the environment hosting data analytics use cases. In fact, the peculiarity of the external data needed for investment banks is that it is mostly presented in numerous files (pdf, word or excel) of small or medium sizes, since every publication comes in a separate document. The block storage, that is mostly used in data analytics in all other domains, is not necessarily the best or most straightforward option as it is not initially designed for the storage of small files.

E. Event Sourcing

Last, when it comes to internal data, reproducing and replaying historical events is a must for analytics projects. However, the investment banks mostly rely in their IT departments on vendor software which are developed based on architectures that do not enable such options. Therefore, in order to get the most out of internal data too, a lot of work has to be done on the data within the IT systems in order to transform it to fit into an event-driven architecture, which is the only architecture that can answer all the analytics needs.

III. Conclusion and Future Work

This paper describes why, now more than ever, launching analytics initiatives is important in investment banks. It presents also use cases that could be of interest to them and the processing techniques used by these use cases. It is meant to be a first-hand guideline for investment banks that are willing to engage in the process of data-driven transformation, and raises the challenges and problems they might face in this process, especially in terms of use case prioritization, data availability, cloud integration, data architecture and event sourcing.

As a future work, a deeper investigation of investment banks' data driven transformation will be performed by shedding light on its principles and key aspects and proposing solutions to the different challenges raised in order to complete the guideline. On the challenges' part, a special attention will be given to use case prioritization as it should serve all types of investment banks (those who are willing to transform to data-driven enterprises or those who are just looking for data analytics use cases to implement). This will be done by defining the most significant criteria to consider in this process depending on the bank's profile and strategic orientations and building a model to sort the different alternatives accordingly.

***Abstract*—Plant diseases enormously affect the agricultural crop production and quality with huge economic losses to the farmers and the country. This in turn increases the market price of crops and food, which increase the purchase burden of customers. Therefore, early identification and diagnosis of plant diseases at every stage of plant life cycle is a very critical approach to protect and increase the crop yield. In this paper using a deep-learning model, we present a classification system based on real-time images for early identification of plant infection prior of onset of severe disease symptoms at different life stages of a tomato plant infected with Tomato Mosaic Virus (TMV). The proposed classification was applied on each stage of the plant separately to obtain the largest data set and manifestation of each disease stage. The plant stages named in relation to disease stage as healthy (uninfected), early infection, and diseased (late infection). Classification was designed using the Convolutional Neural Network (CNN) model and the accuracy rate was 97%. Using Generative Adversarial Networks (GANs) to increase the number of real-time images and then apply CNN on these new images and the accuracy rate was 98%.**

Keywords—Plants diseases; deep learning; early detection; convolutional neural network; generative adversarial networks

I. Introduction

Quality crop production is an essential feature of any country's economic growth. The agricultural sector provides jobs for many people; in addition, it accounts for a large part of the Gross Domestic Product (GDP) in many countries around the world [1]. For example, it is clear that there is a rapid and wide agricultural development and land reclamation in Egypt, with increased application of technological advances. There has been remarkable increase made in agricultural sector, such as the 1.5 million Acres Project, the El-Alamein project, and the lake and Fayoum projects. The use of modern methods and technologies in agriculture, significantly increase crop production and yield, and increase protection of plants from insect pest infestation and disease infections at all stages of planting, harvesting, and post-harvesting till successful marketing [2]. In a fast-growing world population, although there are many improvements in large production and access to food, food security is threatened by a different set of factors such as a decreased fertility of soil and lands, decreased plant pollination efficiency, insect and other arthropod pests, and plant diseases. Plant diseases are classified as follows: bacterial diseases (bacterial speck, bacterial spot, bacterial canker) [3], fungal diseases (early blight, late blight, sectorial leaf spot, and Anthracnose fruit rot) [4], and viral diseases Tomato Mosaic Virus (TMV) [5]. The early detection and accurate diagnosis of plant diseases at every stage of the plant life cycle and the extent of infection until reaching the most infectious stage or appearnce of severe disease symptoms, and easily classifying them is very important, as shown in Fig. 1.

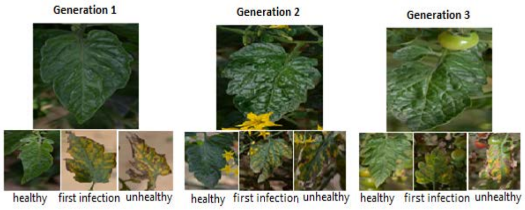

Fig. 1. The Age Stages of the Plant and the Stages of Infection.

Our Deep Learning (DL) model uses leaf images to detect diseases in plants by CNN to extract features from images, such as horizontal edges, vertical edges, Red Green Blue values, etc. A plant disease diagnosis system that uses machine learning techniques can correctly identify diseases plants healthy or unhealthy only [6]. Automatic detection of plant diseases at every age is an important research, analytical, and applied topic because it can help in monitoring large fields of crops in short time with high accuracy. Therefore, disease detection can discover symptoms visually and mechanically in the earliest time they appear on the leaves or other parts of the plant [6], as reported in numerous research publications and reports. CNN is believed to be the best DL neural network for extracting visual features [7]. The CNN-based network can be trained to discover diseases in plants by providing a large number of real-time images. In the case of lacking enough and good quality data or number of images, other techniques such as GANs can be used to generate the needed data for analysis and comparison with real-time data collected from the field. Both healthy and diseased plants and a future training model can be used to predict diseases in plants using plant leaf images [8].

II. Related Work

Recent advances in agricultural technology have led to a demand for a new set of automated, non-destructive methods for detecting plant diseases. Hence, several methods have turned to computer visual and machine learning (ML) techniques to create a rapid method for detecting plant diseases when symptoms appear [9]. Classifying plant diseases can be a very complex task because it depends mainly on published and used classification systems and also by experience of farmers and researchers.

Developing a reliable system that can be applied to many plant classes is a difficult task. To date, most automatic plant disease classification methods have depended on ML algorithms and basic feature engineering. These methods usually focus on specific environments and are suitable for a smaller number of categories, as some small changes in the system can lead to a severe drop in resolution. Recently, CNNs have shown impressive results in many image classification tasks that have allowed researchers to improve the classification of agriculture and plant diseases [10]. CNN is a technology that mixes artificial neural networks (ANNs) and up to date DL strategies [11].

In deep learning, CNN is at the center of spectacular advances. This ANN has been applied to several image recognition tasks for decades and has attracted the eye of the researchers of many countries in recent years; as CNN has shown promising performances in several computer visual and ML tasks [12]. This paper describes the underlying architecture and different applications of the CNN.

In Y. Kawasaki, ET. al. [13], the authors introduce a novel plant disease detection system based on CNN. Using only training images, CNN can automatically acquire the requisite features for classification and achieve high classification performance. A total of 800 cucumber leaf images are used to train CNN using the proposed techniques. Under the 4-fold cross-validation strategy, the proposed CNN-based system (which also extends the training dataset by generating additional images) achieves an average accuracy of 94.9 % in classifying cucumbers into two typical disease classes and a non-diseased class. In this study, the authors proposed a novel plant viral disease detection system using CNN and confirmed its effectiveness. They also asserted that the strategy for training CNN has significantly improved the accuracy of its classification. This work will free system users from paying extra attention to the details of plant shooting conditions.

In Y. Kawasaki, et. al. [13], future the system makes a large contribution in the agricultural field. Data augmentation is an essential part of the training process applied to DL models. The motivation is that a robust training process for DL models depends on large annotated datasets, which are expensive to be acquired, stored and processed. Therefore, a reasonable alternative is to be able to automatically generate new annotated training samples using a process known as data augmentation [14]. A GAN model consists of two important factors: the discriminator (D), and the generator (G). The generator and discriminator have opposite objectives during training. The discriminator is trained toward distinguishing between synthesized and real-time data while the generator is trained to fool the discriminator with synthesized data, as shown in Fig. 2.

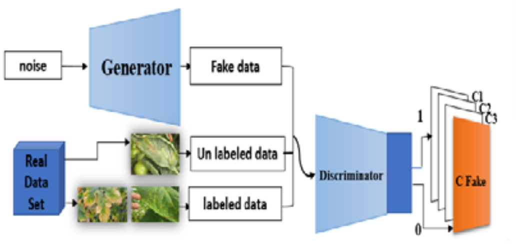

Fig. 2. GANs Architecture.

In D. Farm. [15], the authors propose a synthetic sampling solution is presented at the data level to identify them from small and unbalanced data sets using GANs. The reason for using GANs is the challenges in different fields as they deal with small data sets and volatile amounts of samples per category [16]. As a result, GANs offer an approach that can improve learning regarding data distributions, reduce bias resulting from class imbalance, and change classification. Resolution limits towards more accurate results. The method of [16] was trained on a small dataset of 2789 images of highly perishable tomato plant diseases with a class imbalance in 9 disease categories. Moreover, they evaluated their results in terms of different measures and compared the quality of these results for stratified excellence. GANs are an exciting and quickly changing field, delivering on the deal of generative models in their capacity to generate realistic examples across a range of problem domains. In 2014, conditional GANs was extended to a conditional model if both the generator and discriminator are conditioned on some extra data. They can perform the conditioning by data feeding into both the discriminator and generator as additional input layer [17].

In 2016, the Auxiliary Classifier GAN (AC-GAN) has received much interest due to easy and extensibility to different applications. AC-GAN integrates the conditional information (label) by training the GAN discriminator with an additional classification loss. AC-GAN is able to generate high-quality images and has been extended to different learning problems. However, the difference between the generated samples by AC-GAN going to decrease as the number of classes increases; hence limiting its power on large-scale data [18].

In 2016, the Information Maximizing GAN (Info-GAN) integrated the output of the generator to a component of its input called the hidden codes. Uncovering some successful and unsuccessful configurations for generating images using Info-GAN [19] are shown in Fig. 3.

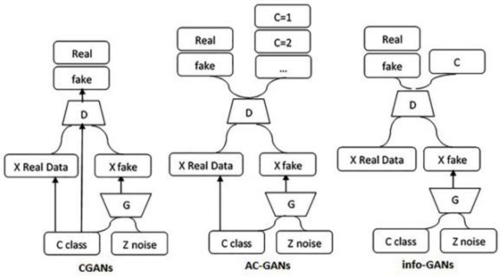

Fig. 3. Types of GANs.

III. Methodology

This methodology works on three steps:

First step: divide the plants into three class's generation (G1–G2–G3) with respect to the age stage.

Second step: each generation contains three Phases (Pi) of plants according to its pre-symptoms (uninfected P1 - early infection P2 – late infection P3).

Third step: Prediction and early detection of diseases to apply it to each generation, as shown in Fig. 4.

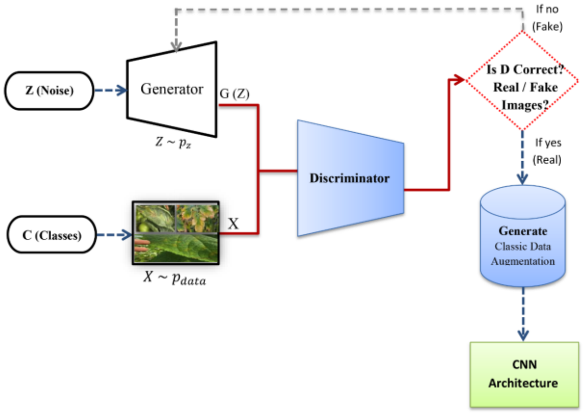

Fig. 4. The Model of Plants Generation/Phases.

Description of the model of plant generation/phases:

- p_{data} Represents all data set.
- Sample a noise set and a real-data set that includes classes (G1, G2, G3), each with size m.
- X represents the real sample belonging to the distribution $X \sim p_{data}$.
- Z denotes a random series belonging to the distributionp_z, which obeys a normal distribution. D and G represent the discriminator and generator respectively.
- The output of the generator is *X* fake (Data).
- The generator to make synthetic samples G (z) extremely approach to the distributionp_{data}.
- To increase the data set apply the discriminator on this data and extract the global polling and hidden layer to get extra real data.
- Global polling layer is inserted in front of the discriminator network's output layer to extract representative features with 512 dimensions.
- The discriminator input is (*X* and G (z)) and they are compared until get the output discriminator.
- The final output of the discriminator is real/fake images.
- When data is fake, the discriminator and generator are trained alternatively. For the training process of the generator, the synthetic samples G (z) is taken into the discriminator and the produced loss value loss G is transmitted back to the generator one more time.
- When the data is real, it is entered into the data augment repository and then after that it is transferred to the CNN structure.
- The final model output is the data augmentation as a shape class to using in CNN mode.

The following results were collected from the use of these images on the CNN, as shown in Table I.

IV. Experiments And Results

In this section, the study concludes the Experimental setup for our synthetic task generates data to detect diseases early:

1) Dataset: These images were collected from agricultural lands and it is a real data set that was used in this work to prove the growth stages of the plant and also increase the data from the original data and determine the stages of plant disease, there is a total of 5400 real images of diseased and healthy plants. These images covered all growth stages of plants and the extent of disease infection.

2) CNNs are proposed to reduce the number of parameters used and adapt the network architecture exactly to visual tasks. CNNs are usually composed of a set of layers that can be grouped by their functionalities; a CNN is typically composed of four types of layers: Convolution Layer, ReLu and sigmoid functions, Pooling, and Fully Connected Layer [20, 21, 22].

TABLE I. Apply CNN on the Groups of Images According to their Generation/Phases

Generation	Phases	Number of images	Loss	Vall_Loss	Accuracy	Vall_Accu	Max_Accu
G1	P1	600	0.0936	2.9398	0.9726	0.4200	0.9726
	P2	600	0.0725	2.8965	0.9701	0.3811	
	P3	600	0.0664	2.8356	0.9689	0.2147	
G2	P1	600	0.0861	2.7649	0.9601	0.2641	0.9754
	P2	600	0.0845	2.8527	0.9754	0.3979	
	P3	600	0.0689	2.8950	0.9742	0.4215	
G3	P1	600	0.0621	2.6691	0.9597	0.2954	0.9748
	P2	600	0.0859	2.9184	0.9726	0.4021	
	P3	600	0.0746	2.8302	0.9748	0.4593	

Table I shows that the highest percentage in healthy cases is in the first age early stage (uninfected) of plant growth. The highest percentage in cases of the first virus infection (early infection) is in the second age stage. The highest percentage in diseased cases (late infection) is in the third age stage.

The plant in the first age stage is in the sterilization stage and healthy hybridization and not exposed to a large pesticides spraying, taking into account the appropriate weather for cultivation. After that, in later stages of growth, the plant is exposed to larger spraying with pesticides and exposed to different climate factors as well as poor workmanship (farming), its stage will be the highest complete unhealthy rate. The data was divided into 70% training and 30% testing, and determining the number of batches required for the model. The accuracy rate and the loss rate were deduced as shown in the Fig. 5.

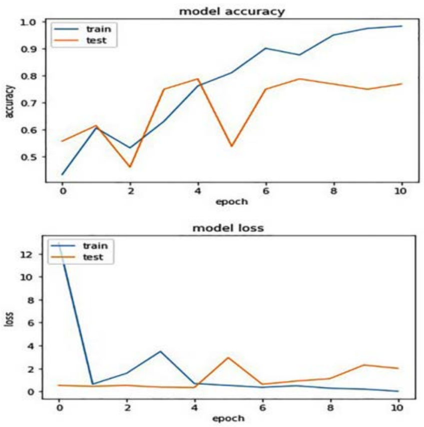

Fig. 5. Model (Accuracy and Loss).

The number of the expected data on the actual data was clear in the following table, and it was found that the second growth stage is the most vulnerable stage to viral infection through the distribution of data by 70% training and 30% testing, as shown in Table II.

['Gen2Phase1', 'Gen2Phase3', 'Gen3Phase3', 'Gen3Phase2', 'Gen1Phase2', 'Gen2Phase2', 'Gen1Phase3', 'Gen3Phase1', 'Gen1Phase1'].

Computed fusion matrix: Heterogeneous data sources can be collectively mined by data fusion. Fusion can focus on a specific target relation and exploit directly associated data together with data on the context or additional constraints [23], as shown in the Fig. 6.

TABLE II. TEST RESULT BY CNN WITH TRAINING AND TESTING

Prediction	G1	G2	G3	All
Actual				
P1	240	210	90	540
P2	120	300	120	540
P3	70	230	240	540
All	430	740	450	1620

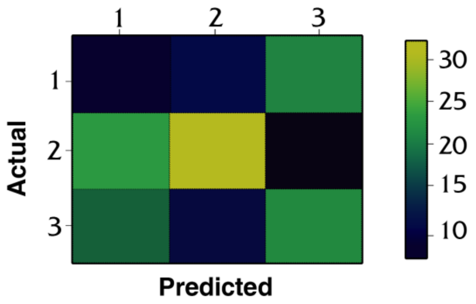

Fig. 6. Computed Fusion Matrix.

3) Generative Adversarial Networks (GANs): After the CNN stage of classification and prediction was completed, the stage of increasing data into by using the (GANs), and during this stage, the experiments were done on the real data and the steps of this stage were as follows:

- Prepare Dataset:
  - import numpy as np
  - import pandas as pd
  - import os
  - print(os.listdir("TomatoDB"))
- Generator and Discriminator for Dataset:
- Image Samples:
  - SAMPLES_TO_SHOW = 8
  - Input: (60, 64, 64, 3), as shown in the Fig. 7.

Fig. 7. Images Sample Complete Description.

- Code implementation steps, as shown in Table III:

	Losses	Accuracy
GANs:	2.1%	97.9%

V. CONCLUSION AND FUTURE WORK

To summarize, DL was used in early prediction to detect diseases in different plant growth stages using the CNN algorithm for classification and prediction. Here, using the tomato infected with TMV as a model, the accuracy rate of TMV infection was 97%. The GANs used to increase the size of data and prediction accuracy rate by 98% when compared to the original data. For each plant growth phase, it became clear that the most growth stage group is vulnerable to viral infection is the second group. Therefore that determining the growth stages in this paper helped at obtaining results that prove the age group most susceptible to Unhealthy by determining the stages of Unhealthy also (healthy - first infection - Unhealthy), Thus, the study has concluded the previous results by applying to a set of real data that was collected manually from one of the farms in Egypt. Future work will include several DL models for early detection and classification of plant diseases due to using the rapid progress and improvements in DL models, transfer learning techniques, and CNN frameworks. Larger real-time dataset of TMV-infected tomato plants, and other important plant-disease system will be tested for attaining highest prediction accuracy. . Building a robust and accurate digital and computer-based plant pest-infestations and microbial disease-infections early-detection and warning system, will significantly help plant protection in early stages, with increased yield, quality, local marketing, and international exporting competitiveness.

***Abstract*—There is a significant development in computer-aided detection (CADe) and computer-aided diagnostic (CADx) systems in recent years. This development coincides with the evolution of computing power and the growth of data. The CAD systems support detections and diagnosis of significant diseases, including cancer. Breast cancer is one of the most prevalent cancers influencing women and causing death around the world. Early detection of breast cancer has a significant effect on treatment. The typical CAD system goes through various steps, including image segmentation, feature extraction, and image classification. Image segmentation plays an important role in CAD systems and simplifies further processing. This review explores popular mammogram segmentation techniques. A mammogram is medical imaging which uses a low-dose x-ray system to see inner tissues of the breast. There are many segmentation techniques used to segment medical images. These techniques can be categorized into five main categories: region-based methods, boundary-based methods, atlas-based methods, model-based methods, and deep learning. A ground truth image is needed to measure the performance of the segmentation algorithm. Different performance measurements were used to evaluate the segmentation process, including accuracy, precision, recall, F1 score, Hausdorff Distance, Jaccard, and Dice Index. The research in mammogram segmentation has yielded promising results, but there is room for improvements.**

Keywords*—*Mammogram; medical imaging; segmentation; preprocessing; breast cancer

I. Introduction

Over the years, Artificial Intelligence (AI) algorithms have been improving and having impact on every aspect of human life. In recent years, there has been a significant development in machine learning techniques and high-performance computers, along with a massive increase in digital data in various fields. Diagnosing diseases through radiology is an important medical application of AI algorithms. An example of this application is CADe and CADx systems. The CAD systems are used to assess patient's diagnostic images by clinicians and radiologists. Most CAD systems consist of the following steps: image preprocessing, segmentation, feature extraction, and classification. There are many studies conducted in using a CAD system to diagnose and detect breast cancer from medical imaging [1]. This review discuss different aspects related to mammogram segmentation. The rest of the review is divided into the following sections: Section II provides background about medical imaging and mammogram. Section III includes a description of some public mammogram datasets. Section IV explains performance measurements used in mammogram segmentation. Section V discusses different segmentation techniques used in mammogram images. Section VI is a discussion of studies mentioned in the review. The last section concludes the paper.

II. Background

This section provides background about medical image analysis, breast cancer, and mammogram images.

A. Medical Image Analysis

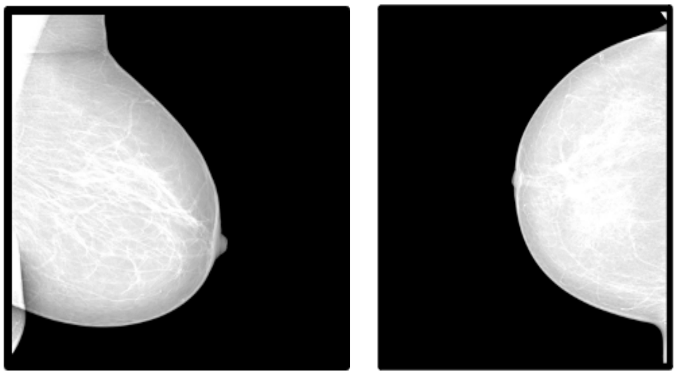
Medical images are different from regular photos; they represent physical features measured from the human body. Therefore, the analysis of medical images must be guided by particular expectations and follow a medical reference. AI has been used in medicine since the 1980s [2]; later on AI medical applications are continuously expanding. Nowadays, medical image analysis has become a branch of artificial intelligence. There are books, academic journals, and conferences for medical image analysis research. There are various types of medical images, including X-ray imaging, magnetic resonance imaging, ultrasound, nuclear imaging, optical microscopy, etc. X-ray Imaging uses electromagnetic waves with a wave-length above the visible spectrum to produce a diagnostically meaningful image. Fluoroscopy and angiography, Computed Tomography (CT), and mammography are kinds of X-ray imaging [1].

B. Breast Cancer

Breast cancer is a disease caused by an abnormal growth of breast cells [3]. It is one of the most prevalent cancers influencing women and causing death around the world [4]. Early detection of this disease increases the recuperating rate significantly [5]. Three main types of examinations are commonly used to detect breast cancer: 1. self-examination performed by the patient herself, 2. a clinical examination conducted by well-trained specialists, 3. a radiology examination conducted by a radiologist using visual evaluation. Studies show that the most accurate radiologic procedure for early detection of breast cancer is the mammogram [4].

C. Mammogram Images

A mammogram is medical imaging that aims to see inside tissues of the breast by using a low-dose x-ray system [3]. There are two imaging modalities of mammograms: digital mammogram and screen-film mammography. The screen-film mammography (SFM) contains conventional analog mammography films. Usually, SFM contains labels and markers in the background, which considered as noise and need to be removed. The digital mammograms are also called Full-Field Digital Mammography (FFDM) images. The FFDM is more recent and does not include labels [2]. Moreover, mammogram images can be found in several formats including LJPG, DI- COM, PGM, and TIFF. In the stander view for each breast, two X-ray images need to be taken on both sides. Therefore, four images of both breasts need to be examined. These four images are called: LEFT CC, LEFT MLO, RIGHT CC, RIGHT MLO [6], [7]. The Craniocaudal (CC) view is obtained from top horizontally compressed breast (head-to- foot picture). The CC view captures the medial portion and the breast's outer lateral region as much as possible. The Medio Lateral-Oblique (MLO)–side view–captures the whole breast and usually contains the lymph nodes with the pectoral muscle. Fig. 1(a) and 1(b) show the example of CC and MLO views. And Fig. 2 illustrates the angle of each view [8].



[(b) MLO view] [(a) CC view]

Fig. 1. FFDM View.

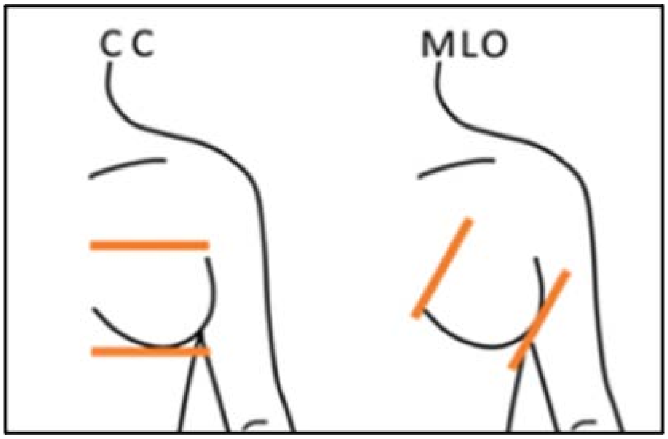


Fig. 2. The Different between CC and MLO Views.

III. Public Mammogram Datasets

There are several mammogram datasets publicly available. Following is a brief description of the most used datasets, which are referenced in studies cited in the review.

A. Mammographic Image Analysis Society (MIAS)

The Mammographic Image Analysis Society (MIAS) is a research group from the UK interested in studying mammograms. This group generated a small mammogram database in 1994 called mini-MIAS or MIAS for short. The mini-MIAS consists of 322 digitized films stored in the PGM image format. Every image has a resolution equal to 1024 × 1024 pixels [9].

B. Digital Database for Screening Mammography (DDSM)

The DDSM project is a collaborative effort between the Massachusetts General Hospital, the University of South Florida, and Sandia National Laboratories. The dataset includes 2620 cases. A case consists of between 6 and 10 files. These are an 'ics' file, an overview "16-bit PGM" file, four image files compressed with lossless JPEG encoding, and zero to four overlay files [10].

C. INbreast

INbreast is a full-field digital mammographic database. The cases were collected from Centro Hospitalar de S. Joa o [CHSJ], Breast Centre in Portugal, in 2011. The database includes 115 cases with a total of 410 images. The resolution of images was 3328 4084 or 2560 3328 pixels and saved in the DICOM format. The region of interest (ROI) was annotated by two specialists and stored in separate .roi and .xml files [11].

D. Breast Cancer Digital Repository (BCDR)

The IMED Project supported the creation of BCDR. The IMED project was supported by FMUP-CHSJ University of Porto, Portugal, INEGI, and CETA-CIEMAT Spain, from March 2009 till March 2013. The BCDR includes 1734 cases with mammography and ultrasound images. Also, it includes clinical history, mammogram lesion segmentation, and selected pre-computed image-based descriptors. The dataset is subdivided into Full Field Digital Mammography-based Repository (BCDR-DM), and Film Mammography-based Repository (BCDR-FM) . Mammogram images were saved in the TIFF format. The BCDR-FM part has a resolution of 720 x 1168 pixels and 8 bits depth. While the BCDR-DM resolution is equal to 3328 x 4084 pixels and 14 bits depth [12].

E. Curated Breast Imaging Subset of DDSM (CBIS-DDSM)

CBIS-DDSM is an updated and standardized version of the Digital Database for Screening Mammography (DDSM) stored in the DICOM file format [13]

Table 1 summarizes the datasets mentioned.

TABLE I. Public Mammogram Datasets

Dataset Name	Size	Format	Type	Published Year
MIAS	322 images	PGM	Digitized	1994
DDSM	2620 cases	PGM, JPEG	Digitized	1998
INbreast	410 images	DIOCM	Digital	2011
BCDR	1734 Cases	TIFF	Hybrid	2012
CBIS-DDSM	2620 cases	DICOM	Digital	2019

IV. Performance Measurements

There are several ways to measure the performance of the segmentation technique. If the ground truth image of the target area is available, then the Dice similarity coefficient or Jaccard Index can be used. Dice Similarity Coefficient (DSC or dice): equivalent to twice the number of elements common on both sets divided by the sum of the number of elements in each set. DSC is usually used for auto-segmentation models and computed by this equation:

$$Dice(A,B) = \frac{2|A \cap B|}{|A|+|B|} \quad (1)$$

Where A represent the segmented image resulted from the algorithm, and B represent the ground truth image. Jaccard Index or Intersection over Union (IoU) is another similarity measurement. IoU computes the similarity ratio of elements in two sets, A and B, as set intersection over the number of elements in the set union:

$$IoU(A,B) = \frac{|A \cap B|}{|A \cup B|} \quad (2)$$

Hausdorff Distance is also used to assess the medical image analysis algorithm's performance. This measurement used when outliers need to take it into account. The Hausdorff distance, h (A, B), is given by Equation (3):

$$h(A,B)=\max \left[max_{a\,\in A}\, min_{b\,\in B}\ d(a,b), max_{\,b\,\in B}\, min_{a\,\in A}\ d(a,b) \right] \quad (3)$$

where d (a, b) is the Euclidean distance between the points a and b [14].

Other performance measurements used in CAD systems are accuracy, sensitivity, specificity, precision, recall, and F1 score. Following are equations for these measurements.

$$\text{Accuracy}=\frac{\text{Number of examples identify correctly}}{\text{Total number of example}} \quad (4)$$

To compute precision and recall, the confusion matrix must be created first. A confusion matrix is a table used to describe the performance of a classification model. The table II illustrates the confusion matrix:

Positive here mean a target class, for example in brest cancer detection problem the positive class is a cancer or abnormal masses, and negative class is the mammogram with no cancer detected [15].

$$\text{Precision} = \frac{TP}{TP+FP} \quad (5)$$

$$\text{Recall} = \text{Sensitivity} = \frac{TP}{TP+FN} \quad (6)$$

$$\text{F1score} = 2\times \frac{\text{Precision} \times \text{Recall}}{\text{Precision}+\text{Recall}} \quad (7)$$

$$\text{Specificity} = \frac{TN}{TN+FP} \quad (8)$$

False positive per image compute by following equation:

$$\text{FP/Image}=\frac{\text{Number oF identified}}{\text{Total number of images}}$$

TABLE II. Confusion Matrix

		Predicted Class	
		Positive	Negative
Actual class	Positive	True positive (TP)	False Negative (FN)
	Negative	False Positive (FP)	True Negative (TN)

V. Medical Imaging Segmentation

Image segmentation aims to simplify further processing by partitioning the digital image into regions that share similar characteristics. Fig. 3 shows a block diagram of the standard CAD system. There are many segmentation techniques used in segmenting mammograms. These techniques can be categorized into five primary types: region-based methods, boundary-based methods, atlas-based methods, model-based methods [16], and deep learning [17], [5].

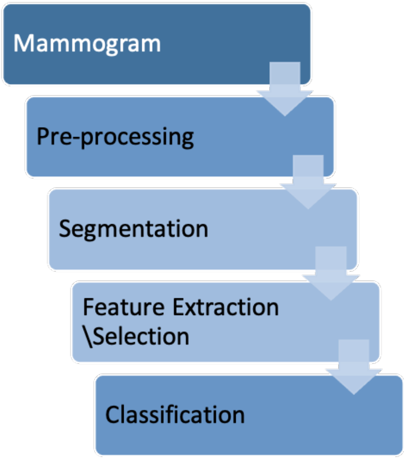

Fig. 3. CAD System Block Diagram.

A. Region based Segmentation

In region-based methods, a segmentation is done based on similarities between regions. Thresholding, Region-growing, watershed, split and merge, and clustering are types of region-based segmentation methods [16].

1) Thresholding: Thresholding is mostly used to separate an image into a background and foreground object. First, a specific value T is selected as a threshold value based on image histogram and local properties. All pixels below T will be considered background, and all pixels equal to or greater than T will be considered foreground. Using multilevel thresholding gives a better result, the authors in [18] proposed a CAD system detecting suspicious mass lesions in the mammogram. The proposed system starts with three pre-processing steps. First, the median filtering with a 3 x 3 window is used to remove noise. Second, morphological operations are applied to remove artifacts and background. At the last preprocessing step, a single-seeded region-growing algorithm is used to remove pectoral muscles. The second phase in the proposed CAD is detecting mass using Dual-stage adaptive thresholding. The performance was measured by sensitivity and false-positive per image (FP/image). The evaluation was done on DDSM and MAIS datasets. The result was sensitivity= 93, FP/image = 0.84. The work [19]. proposed a hybrid approach based on Otsu's multi-thresholding and Watershed Segmentation (WSS) to mine the suspicious sections from mammograms. They used images from the MAIS dataset and measure the performance with many measurements includes Root Mean Square Error (RMSE) and Normalized Absolute Error (NAE). Different thresholding levels were tested; however, th=4 gave the best results, RMSE= 21.7732 and NAE= 0.2429. The authors in [20]. developed a fully automated pectoral muscle segmentation method. This method consists of four steps. First, capturing a small rectangular region in the top-left corner of mammograms and enhancing it using the fractional differential method. Second, segmenting a rough binary boundary of the pectoral muscle in the rectangular region, using an improved iterative threshold method. Third, adapting a rough contour with the least-squares method based on points of the rough boundary. Finally, evaluate the local active contour to acquire the final pectoral muscle segmentation line. The dataset consists of 720 MLO, which are FFDM. The overall performance of this method in the Dice coefficient equal to 0.986±0.005. The authors in [21] , proposed multilevel thresholding based on the electro-magnetism optimization (EMO) technique to segment pectoral muscles. EMO is an evolutionary method that mimics the attraction-repulsion mechanism among charges to evolve the members of a population. The first step is to crop the mammogram image. The second step is extracting a region of interest (ROI) using the stepwise contrast limited adaptive histogram equalization (CLAHE) algorithm. Also, the CLAHE method is used to enhance contrast in mammogram images. The third step is to enhance the image using the histogram equalization technique. In the fourth step, the EMO algorithm with Otsu objective function and Kapur objective function is applied. Finally, the straight-line estimation is used to identify the pectoral muscle. This segmentation was tested on the MAIS dataset and gave an accuracy = 96.58%. The work [22] proposed an adaptive hysteresis thresholding method to detect mammogram masses. This method was applied on MAIS and DDSM datasets and gave sensitivity equal to 96.6%, 96.4%, respectively.

2) Region growing: In a region-growing segmentation, algorithm starts with seed points representing each class of image (e.g., background and foreground classes). Each class grows according to the homogeneity of neighboring pixels; this process continues until reaching homogenous and connected regions [23]. The work [24] ,proposed an automated mammogram segmentation based on region growing and sliding window algorithm (SWA). First, the authors prepared the MIAS dataset by removing artifacts and labels using the opening morphological operator and binary mask. Then remove pectoral muscle using SWA and segment mammogram ROI using Dispersed Region Growing Algorithm (DRGA). The overall accuracy of this approach equals 91.3%. The authors in [25] , proposed a pectoral muscle segmentation and tumor detection approach. This approach starts with the Otsu method to remove artifacts. The region-growing method is used to eliminate the pectoral muscle. Then estimate the number of classes based on the LBP Technique and classify mammogram objects using K-means clustering. Finally, they extract the tumor by a hidden Markov model. The proposed approach was tested on the MAIS dataset, and the overall accuracy = 91.92 %. The work [26] aapplied an adaptive fuzzy region-growing algorithm on two FFDM private datasets to segment suspicious lesions and characterize them. The performance was measured by sensitivity and specificity, and the results were 91.67%, 58.33%, respectively. After detecting suspicious lesions, k-NN and SVM classifiers were used to classify masses as benign masses or malignant tumors. The classification results for k-NN and SVM achieved sensitivity = 84.44% and 85.56%, specificity = 91.11% and 91.67%, FPsI = 0.54 and 0.55 respectively. The authors in [27] , proposed another method to detect the lesion's boundaries in mammogram images based on the region-growing algorithm. The MAIS dataset was used in this work. The performance was measured by accuracy, specificity, sensitivity, and overlap, and the results were 91%, 97 %, 83%, and 79%, respectively. The work [28] , proposed an automatic breast cancer detection approach consisting of four amin processes applied on the MAIS dataset. The first phase is the preprocessing, enhancing images, and removing noise using median filtering. The second phase is mammogram segmentation using region growing. The third phase is feature extraction. Finally, the classification phase uses an optimized fuzzy logic classifier. The performance was measured for the segmentation and classification phase. The segmentation accuracy = 0.98%, and the fuzzy classifier accuracy = 0.91667 %. The authors in [29] proposed a segmentation method based on region-growing techniques. The proposed method included four main steps and was applied on MAIS and DDSM. The first step was extracting the Region of Interest from mammogram images. At the second step, automatic thresholding was applied to binarize the image. The third step was determining the seed points automatically using the density of the pixels' value. Finally, they calculated the threshold value for region creation in seed region growing. The results show that the Dice Similarity Coefficient (DSC) =94.8, 94.6, and Relative Overlap (RO) = 90.2, 89.8 for MAIS and DDSM, respectively.

3) Watershed: The key behind using the watershed transform for segmentation is this: Change the image into another image whose catchment basins are the target objects. Watershed Algorithm is based on simple morphological operations [23]. The work [30] , proposed a two-phase micro-classification segmentation approach. First, detection microcalcifications used morphological operations. Second, the micro-calcification shape was extracted using the watershed. This approach was applied on DDSM, and the overall performance in dice (similarity index) equals 80.5%. The authors in [31] proposed another segmentation approach based on the watershed algorithm. This approach consists of four stages. In the first stage, the ROI images were cropped to 200 x 200 pixels, and the background was removed. In the second stage, the Principal Component Analysis (PCA) method was applied on the cropped image to remove the noise. In the third stage, the Fuzzy C-Means (FCM) was applied to partition the ROI images into the foreground and background clusters. The foreground includes the abnormality region, which will be used in the final stage. In the last step, marker-controlled watershed segmentation was performed with three various structuring elements: disk, diamond, and octagon shapes. The dataset used in this study was obtained from the National Cancer Society of Malaysia. The performance was measured by computing Jaccard Index, Dice Similarity Coefficient (DSC), and Figure of Merit (FOM). The Jaccard index = 0.0452 and DSC = 0.0231 in both disk and octagon structures; in diamond structure, Jaccard index = 0.0405 and DSC = 0.0207. The result of FOM was 0.9594, 0.9700, 0.9842 for disk, diamond, and octagon structures, respectively. The work [32], proposed a semi-automatic segmentation of masses from mammogram images. The proposed approach includes three main stages. First, the median filter was applied to enhance image quality. Second, an initial segmentation was composed based on canny and watershed algorithms. Finally, the boundaries of tumors were extracted using the region- growing algorithm. The MAIS dataset was used and the performance measured by overlap value was equal to 81.3%.

4) Splitting and merge: Split and merge depend on the tree structure, the image splitting successively into quadrants tree based on a homogeneity criterion. Then similar regions are merged to create the segmented result. The work [33] , used a blended approach of region-based method and splitting and merging technique. The proposed approach is applied on MIAS mammogram images. First, the morphological operation is used to remove the noise from images. Then, the splitting step is performed based on the region's growing method (seed points). Finally, at the merge step, the binary values are reconstructed to form a structured mammogram image. The structured image is completed for finding the seed point and grown points. The performance measured by five statistical parameters: mean = 0.0759, variance = 0.0702, entropy = 6.521 standard deviation = 0.2649, and correlation = 0.7869.

5) Clustering: In clustering, pixels are grouped into clusters, in which pixels in the same cluster are more similar to each other than to those in different clusters. The two types of clustering used in image segmentation are K-means clustering, and fuzzy C means clustering [23], [16].

a) K-means clustering: The K-means clustering algorithm start by setting K centroid points (or pixel values). Then assign the remaining pixels to their closest cluster center for each cluster. Based on the resulting cluster, reset a suitable centroid of each cluster. These two steps repeat until the algorithm meets the chosen criteria. In segmentation, the value of k depends on the number of objects want to be extracted.

b) Fuzzy C means clustering: Fuzzy C means (FCM) is a kind of clustering in which a single data point can belong to more than one cluster [34]. The authors in [35] applied FCM and K-mean clustering algorithms on the MAIS dataset to segment mammogram images. The performance was measured by accuracy. The accuracy of FCM was 94.12%, while K-mean accuracy was 91.18%.

B. Boundary-based Segmentation

Unlike region-based segmentation, boundary- or edge-based segmentation depend on differences between regions. There are variety boundary-based segmentation techniques. Roberts, Sobel, Prewitt, Laplacian, and Canny edge detection are examples of boundary-based segmentation techniques [23], [16]. The work [36] proposed a method that segments the breast boundary and pectoral muscle in mediolateral oblique (MLO) views of mammograms automatically. The proposed method consists of three main stages. The first stage removes noise from mammogram images by applying median and anisotropic diffusion filters. The second stage segment the mammogram using Canny edge detection. Finally, the overestimated boundary caused by artifacts was handling by a proposed post-processing stage. Three public datasets were used to evaluate this method including MIAS, INbreast, and BCDR. Experimental results show that dice similarity coefficients on breast boundary and pectoral muscle estimation were equal to 98.8% and 97.8% for MIAS, 98.9% and 89.6% for INbreast, and 99.2% and 91.9% for BCDR respectively.

C. Atlas-based Segmentation

Atlas-based segmentation is an algorithm that aims to extract the relevant anatomy from medical images and to present it in an appropriate view [37]. The atlas-based approach is suitable for segmenting images with unclear associations between regions' and pixels' intensities [38]. The authors in [14] ,proposed an atlas-based algorithm to segment breast area from mammogram images. The preprocessing step includes standardizing mammogram images by flipping the left breast mammograms so that all mammograms had the same orientation. Then make the images square by padding on the left and right, then remove this padding and determine the breast region. The main algorithm consists of two stages. In the first stage, select a set of atlas mammogram images using the K-means clustering algorithm. The number of clusters is determined by applying 2D projection using tributed Stochastic Neighbor Embedding (t-SNE). In the second stage, they used atlas mammogram images with a deformable registration algorithm to segment the images. They tested this algorithm on mini-MIAS and DDSM datasets. The performance measurements used were Hausdorff Distance = 13.34 and Jaccard Index= 0.94.

D. Model-based Segmentation

Model-based segmentation, or energy functions, are based on deformable models. We can define the deformable models as curves that deform due to some external or internal force [16]. This group of segmentation techniques has the ability to integrate high-level knowledge with information from low-level image processing. There are two classes of deformable models, parametric and non-parametric. The parametric deformable model is also called the active counter model. The work [39] , proposed a bimodal level-set formulation-based approach for mammogram segmentation. They used the mini-MIAS dataset and drew ground truths manually using a hand-based polygonal tool. Compared with the Chan-Vese and Zhang models, the pro- posed approach achieved Precision AVG = 0.9448, Recall AVG = 0.975 within only 4-6 iterations, while the other two models required more than 60 iterations to get such results. The authors in [40] , proposed a preprocessing method for the mammogram CAD system, include pectoral muscle segmentation. The proposed method consists of four phases. First, remove noise using median and mean filters. Second, enhance image quality using the CLAHE algorithm. Third, remove radiopaque artifacts and labels present in mammograms by applying thresholding and morphological operations. Finally, using active contours to remove pectoral muscle. This preprocessing approach was tested on two datasets, mini-MIAS and INbreast. The results show that accuracy equals 90%, 98.75% for mini-MIAS and INbreast, respectively. The work [41] , provided an automatic mammogram image segmentation approach based on the Chan–Vese model. The target ROI consists of three classes. The mass class contains pixels pertaining to the mass. Background class includes background pixels which not pertain to the mass class.The remaining pixels, which separate the mass from the background belong to the contour class. The proposed approach consists of the Contour initialization step, fuzzy contours estimating step, and Contour optimization step. In the Contour initialization step, the gamma correction was used to improve the image contrast; then, Otsu thresholding was applied to binarize the mass region. The fuzzy contours estimation step aims to refine the initial contour. The last step is contour optimization using the Chan–Vese model. The accuracy of the proposed method was 93.96%, while precision and recall equal 88.08%, 91.12%, respectively.

E. Deep Learning

Deep learning is an artificial intelligence technique that can learn a pattern from raw data [42]. A typical deep learning algorithm is called artificial neural networks or multi-layer perceptron (MLP). Artificial neural networks (ANNs) is a mathematical model developed to mimic the operations of the human neurophysiological structure [43]. The authors in [44] , proposed a neural network framework to deal with complex shape variations of the pectoral muscle boundary in mammogram segmentation. This framework consists of a convolutional neural network inspired by Holistically Nested Edge Detection network (HND). The main benefit of HND is that it can deal with edge and boundary ambiguities of the object. The performance of this approach was measured by computing Jaccard and Dice metrics. Four public datasets were used in the study, including MIAS, INbreast, BCDR, and CBIS-DDSM. On average the Jaccard equals 94.6%, and dice similarity equals 97.5%. The work [45] proposed automated mass segmentation from mammograms based on a multi-level nested pyramid network (MNP Net). The proposed MNPNet divided into three subsections and employed an Encoder-Decoder framework. In the first section, the atrous spatial pyramid pooling (ASPP) module encoding was used to solve the intra-class inconsistency. In the second section, the multi-level feature pyramid produced by CNN was used to improve inter-class indistinction. In the last section, different ResNet structures were used to perform feature extraction, and the ResNet34 was the best. The proposed segmentation is applied on INbreast and DDSM-BCRP and achieves dice index equal to 91.10% and 91.69%, respectively. The authors in [46] , proposed an approach to segment breast tumors within mammograms' ROI using a conditional Generative Adversarial Network (GAN). They tested the model on two datasets INbreast and a Hospital Sant Joan de Reus private dataset. The cGAN network learns a complex pattern from simple data and has two subnetworks, generative and adversarial networks. The generative network recognizes the tumor area and generates the binary mask that detects it, while the adversarial network distinguishes between real (i.e., true) and synthetic segmentations. The performance of the cGAN model on mammogram segmentation task was measured using dice and intersection over union (IoU) performance metrics. For the INbreast dataset, the dice and IoU on the full mammogram image were 68.69% and 52.31%, respectively. After generating mask images, these images feed to a Convolutional Neural Network (CNN) to classify the tumor into one of four types: irregular, lobular, oval, and round. The The overall accuracy of the CNN classifier was 80%. The work [47] ,proposed an automated segmentation to detect microcalcification from mammograms. This approach consists of five steps; image enhancement, removing skin and air boundary, segmenting pectoral region, selecting suspicious region, and U-net segmentation. First, the Laplacian filter was applied to enhance mammogram images. Second, skin and air boundaries were removed using horizontal line fitting and the image erode method. Third, the breast region is segmented from the pectoral region by K-means pixel-wise clustering. Fourth, suspicious regions were selected using the fuzzy C-means clustering algorithm and were divided into positive and negative patches. Fifth, the U-net was trained on the positive patches of the previous step. Finally, the trained U-net was applied to segment the micro-calcification regions automatically from mammograms. This approach was applied on the DDSM dataset and measured by F-measure = 98.5%, Dice score = 97.8%, and Jaccard index = 97.4%. The authors in [48], used the Dense U-Net algorithm to segment suspicious breast masses from mammograms. The evaluation was done on the DDSM dataset. The performance was measured by F1-score, sensitivity, specificity, and overall accuracy and results equal 82%, 77.89%, 84.69%, and 78.38% respectively. The work [49] also used U-Net to detect mass from mammograms. Moreover, they used different data augmentation techniques, such as image zoom, extracting nine regions of interest, and horizontal reversal. The training and evaluation were done on the DDSM dataset. The overall accuracy was equal to 85.95% and the Dice was equal to 79.39%.

VI. Discussion

The investigations mentioned in this review were selected to meet the following criteria:

1) The date of publication should be after 2016.

2) It was published in the ISI magazine or the ACM or IEEE

3) The work should contain precise quantitative performance.

Several segmentation techniques were discussed in this review. Table III summarizes them. As seen from Table III, there are different targets of segmentation. Some segmentation techniques aim to detect suspicious lesions (mass or tumor). Other methods aim to remove background or pectoral muscles. Moreover, there are segmentation techniques that target microcalcification. Table III categorize the segmentation techniques based on the target area. Table IV lists the pre-processing techniques used with each segmentation. The pre-processing techniques include filtering, applying morphological operations, performing data augmentation, and some other enhancement methods. Median filter, Gaussian filter, Bayesian non-local mean filter, Anisotropic Diffusion filter, and Laplacian filter were used to enhance mammogram images. Also, the morphological operations were used in most mentioned works. The data augmentation was mostly used with deep learning-based segmentation techniques. Moreover, Transformer (Intensity, Gamma) and the CLAHE method were used in some papers [18] [49], [21], [40]. The threshold is mostly used as a segmentation technique, but also could be used as a pre-processing step to remove unwanted regions in mass detection techniques [26], [41]. Also, the principal component analysis PCA was used to denoising images [31]. To simplify the processes, many researchers used to resize or cropping in the pre-processing step.

Some papers combine different segmentation techniques such as watershed and region growing. Among different mass segmentation techniques, improved region growing [28] gave the highest accuracy, while Canny edge detection [36] outperforms other approaches in pectoral muscle segmentation. Although studies in mammogram segmentation have yielded good results, there is room for improvement.

TABLE III. Segmentation Techniques Summary

Technique	**Year**	**Target**	**Enhancing**	**Augmentation**	**Dataset**	**Performance**
A Region-based segmentation *1. Thresholding*						
A dual stage adaptive thresholding [18]	2017	Mass detection	√	–	MIAS and DDSM	Sensitivity=93.0, FP\Image=0.84

VII. Conclusion

In this review, an elaborate coverage has been performed in mammogram segmentation techniques. First, we provided an overview of medical image analysis and described the mammogram images. Then we gave a brief description of MIAS, DDSM, INbreast, BCDR, and CBIS-DDSM datasets. We discussed region-based segmentation, boundary-based segmentation, atlas-based segmentation, model-based segmentation, and deep learning approaches for segmentation; we gave an ex- ample from recent papers for each of these segmentation techniques. Then we explained the most-used performance measurement in the segmentation process. Finally, we summarized different mammogram segmentation works in table III, including the preprocessing step, dataset(s), and performance results for each one.

Abstract—**Textual similarity among documents often leads to copyright issues. Manual measurement of similarity among documents is a time consuming infeasible activity. In this paper, we proposed a technique for measuring similarity at sensed-lexicon level for documents written in Punjabi language using Gurumukhi script. 50 Punjabi document pairs were manually collected with the help of Punjabi native writers. The proposed technique consisted of major 4 levels. Level 0 consists of data collection phase. Level 1 consists of noise removal and stop word removal sub levels. Extracted tokens were stemmed, lemmatized and synonyms were replaced based on part of speech tagging in level 2. Vector space representation corresponding to each document leads to n-gram generation of documents in level 2. Extracted n-grams were weighted based on term frequency. In level 3, string based token level similarity indexes such as Jaccard Similarity Index (JSI), Cosine Similarity Index (CSI) and Levenshtien Distance Index (LDI) were experimented with weighed tokens. In this work, Human Intelligence Task (HIT) based rating has been utilized for measuring the similarity among documents between 0-100. Results obtained from HIT based rating are compared with results obtained from the proposed technique with various combinations of pre-processing levels. Results revealed that on the basis of majority voting, combination of stop word removal with stemming and 'noun' based synonym replacement leads to the best combination with bi-gram tokens. Statistical analysis indicates strong correlation between CSI and HIT based rating.**

Keywords—Cosine Similarity Index (CSI); Jaccard Similarity Index (JSI); Levenshtien Distance Index (LDI); n-gram; Punjabi; similarity checker

I. Introduction

"It is better to fail in originality than to succeed in imitation" Herman M.

Measuring similarity between words/ terms, sentences, paragraph and document plays an important role in computational linguistics. Similarity measurement is significant component for text classification, search engine, topic modelling, text summarization, legal documents, question answer generation, information retrieval, plagiarism detection and other language related research. Similarity is associated with finding the overlapping index among two documents. This overlapping can be present at sentence level or document level. Similarity among documents can be identified at lexical level and semantic level. In lexical level, words and/or phrases are compared to identify the similarity whereas in semantic level, contextual information associated with words or phrases is extracted and used for comparison.

In general, an automatic document similarity analyzer takes two documents and generates similarity index for them. In this paper, document level similarity is identified at sensed-lexicon level. These documents are written in Punjabi language using Gurumukhi script which adds one more layer of complexity to this task. This work has potential application in plagiarism detection in Punjabi documents. India is the land of languages. Numerous languages and its dialect are being used in spoken as well as written form. Punjabi is one of them. Punjabi falls in Indo –Aryan language category. It is indicated as first language for about 130 million people and is the 10th most spoken language in the world [1-2].

A lot of research has been carried out in area of measuring similarity among documents written in foreign languages, especially English. But this area still needs to be explored in Indian languages. No work has been reported for Punjabi language.

II. Related Work

This section presents different works carried out in area of detecting similarity among documents. Indexes for finding documents similarity are broadly categorized into string based, corpus based and knowledge based measure [5]. String based algorithms perform character level or token level comparison. Corpus based methods detect similarity based on semantic information extracted from large corpus and Knowledge based methods extract semantic similarity based on information extracted from semantic network.

A. Similarity Checking Work in Foreign Languages

Researchers [6] proposed a technique for handling semantically similar words/ paraphrases in Arabic language. Open Source Arabic Corpora (OSAC) was utilized for identifying suspected documents and Word2vec was used for experimentation. Various methods such as Term Frequency-Inverse Document Frequency (TF-IDF), Latent Semantic Analysis (LSA), Latent Dirichlet Allocation (LDA), word2vec, Global Vector Representation (GloVe), and Convolutional Neural Network (CNN) were experimented for paraphrase detection. Another group of researchers [10] used a deep learning based method to detect Arabic paraphrasing. This method consists of pre-processing phase, and word2vec phase. Convolutional Neural Network was used to generate sentence vector. Authors [12] proposed two layer plagiarism

*Corresponding Author

detection method for Arabic documents. This method consists of two layer: Fingerprinting and Word embedding. Documents were weighted using different techniques such as word alignment, POS tags, and inverse document frequency. With recall of 88% and precision of 86%, this method outperformed Plagdet. Different word embedding models were experimented for capturing semantic similarity among sentences. In this work, authors proposed a model (M-MaxLSTM-CNN) for employing multiple sets of word embedding for evaluating sentence similarity. Multi-level comparisons among sentence embedding, generated by multiple word embedding, leads to sentence similarity information. Proposed technique experimented with STS Benchmark dataset and SICK dataset from SemEval and outperform all other existing methods [7].

Saptono et al. experimented with Vector Space Model (VSM) for detecting plagiarism. In this work, cosine similarity method was used to generate the rank of textual paragraphs from query as well as collection vector. Conditional probability concept was utilized to extract number of words from a paragraph. Results revealed that 54.28% average precision and 100% average recall is achieved with threshold value of 0.3 for the conditional probability and 0.2 for cosine similarity [8]. Authors introduced the project ParaPhraser.ru for collecting of Russian paraphrase corpus and organizing a Paraphrase Detection Shared Task. Different techniques were experimented for finding paraphrases among Russian language. Result revealed that traditional classifiers with linguistics features outperformed other methods [13].

B. Similarity Checking work in Indian Languages

Automatic plagiarism software Maulik was developed to check the plagiarism among Hindi documents. Approach used for detecting plagiarism is based on n-grams and comparison with repository and online documents. Input text was pre-processing using stop word removal and stemming. Different values of n were compared with cosine similarity index to find the best value of n. Accuracy reported was 96.3 which is better as compared to existing techniques [3]. Authors proposed Document Synset Matrix for Marathi (DSMM) technique for measuring among Marathi documents. In this work, proses and verses were used for experimentation. Dataset consists of 1206 proses and verses. Different problems such as sense identification of words, polysemy were handled using proposed technique. Accuracy reported was 80 which was better than existing techniques [4]. In this paper, authors presented fuzzy semantic based and Naïve Bayes model for identifying obfuscated plagiarism in English as well as Marathi Language. Semantic relatedness information was analysed based on part of speech tags and WordNet measures. Results revealed that Naïve Bayes Model performed better as compared to fuzzy method [9]. Authors proposed technique for detecting plagiarism in Urdu documents. Reordering of sentences, and inter-textual similarity among Urdu documents was handled in this work. Proposed technique was evaluated using Support vector machine (SVM) and Naïve Bayes (NB). Performance of this proposed method was better as compared to existing techniques [11]. Author proposed Deep learning based methods for handling paraphrase detection task in Indian languages. Convolutional neural network with word embedding, WordNet score and LSTM based methods were experimented [14].

III. Methodology

This section provides the detailed architecture of system for finding similarity among Punjabi documents. Fig. 1 presents the architecture of Punjabi document similarity analyzer. Punjabi document similarity analyzer consists of mainly 4 different levels. Each level (except level 0) takes input from previous level and provides some output to the next level. Working and detail about each level is as follows:

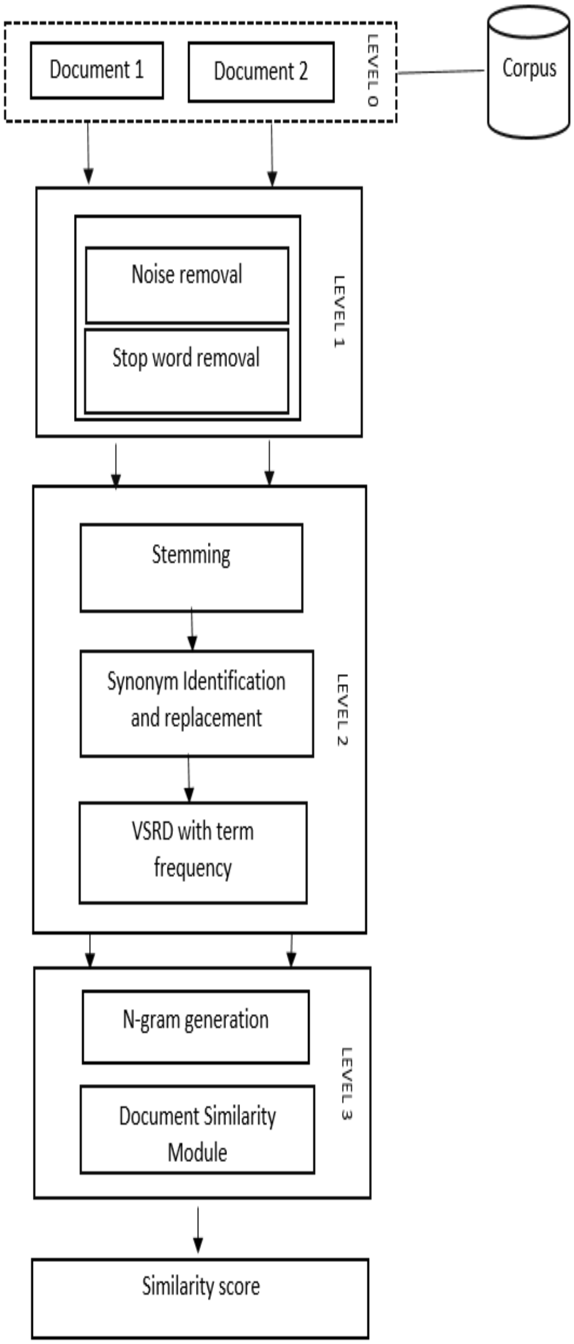

Fig. 1. Architecture of Punjabi Document Similarity Analyzer.

A. Level 0

First step for any kind of analysis is corpus. Due to unavailability of textual similarity corpus in Punjabi, similar document pairs were created. For the creation of these documents, two techniques were followed. In first one, two human annotator (Punjabi native users (writers and speakers)) were requested to write one page on a given topic. As this process was very time consuming, so internet was used as second source for generating similar document pair. Topic selection is versatile from latest topic such as corona virus to festivals of Punjab, from motivational write up to a small story, from real heroes such as Bhagat Singh to real world problems such as pollution, religious gurus to motivational thoughts. Total 50 document pairs (100 documents) written in Punjabi language using Gurumukhi script were collected for further experimentation. Out of 50 document pairs, 26 document pairs were annotated by Punjabi native user whereas, remaining 24 document pairs were generated through internet. Each document pair consists of two documents. So, these two documents D1, and D2 were passed through following phases/levels. Table I provides the statistical details about the dataset.

TABLE I. STATISTICAL DETAILS ABOUT DATASET

Sr. No.	Description	Count
1	Document pair count	50
2	Total documents	100
3	Total token count	12342
4	Unique token count	8976
5	Stop words removed	1679

B. Level 1

D1 and D2 are passed through various pre-processing sublevels. Existing similarity checker for various language (such as English) consists of comparison based on phrases and terms only. Whereas, in this proposed technique, comparison was not just based on exact phrases and but contextual information association with phrases and terms was also checked using IndoWordNet [19]. The purpose of this sub level is to reduce the noise in the input data. So various punctuation marks, symbols were removed from documents (D1 and D2). Stop words were also removed from D1 and D2 [16] [22].

C. Level 2

As mentioned earlier, in this work, document similarity is identified at sensed-lexicon level. Lexical level comprises of lexicons that are being used in both the documents. Lexical features are proven to be effective in Punjabi poetry classification work [17] [21]. Correct sense of these lexicons leads to sensed-lexicon. In next sublevel, remaining words were normalized into their root form. For word normalization, Punjabi stemming rules were used [18]. ND1 and ND 2 (normalized words from document 1 and document 2) were passed to next sublevel. Another important aspect of near copy similarity is synonym replacement. To identify the synonyms replacement among the documents, an algorithm is devised. Detailed steps are presented in algorithm 1. Effect of synonym replacement with stemming is presented separately in the results section. IndoWordNet was utilized for synonym replacement based on Part of Speech (POS) tags [19-20]. In this word, two part of speech tags ('noun' and 'verb') were experimented for identifying the synonym information from document. These normalized words (ND1, ND2) from D1 and D2 represent Vector Space Representation of both documents (VSRD1, VSRD2) [24]. With an intention to give more preference to higher occurring word in document, term frequency (TF) was used to weight the words in D1 and D2. Formula for term frequency is as follows:

$$tf(ND_i, VSRD_i) = count\ of\ ND_i\ appearing\ in\ VSRD_i$$

D. Level 3

In this level, weighted ND1 and ND2 tokens from VSRD1 and VSRD2 were divided into n-grams. Results are presented for n is equal to 1 to 5. Generated n-grams were passed to next sublevel: document similarity level. Lexical similarity between documents was identified through following techniques. Similarity of documents was generated on the basis of scale from 0-100. 0 means no overlapping between the documents and 100 means completely copied document.

Jaccard Similarity Index (JSI): This index was used to measure the similarity between two sets using the formula as given below [24]

$$J(nw - ND_1 \text{ and } \mathrm{nw} - ND_2\,) = \frac{|nw{-}ND_1\ \cap \mathrm{nw}{-}ND_2\,|}{|nw{-}ND_1\ \cup \mathrm{nw}{-}ND_2\,|} \tag{1}$$

Where $nw - ND_1$ and $\mathrm{nw} - ND_2$ represents the n-gram representation of weighted ND1 and ND2.

Cosine Similarity Index (CSI): This index was used to measure the similarity based on angle between two vectors [25] where document were represented as vectors.

$$\cos \Theta = \frac{\overrightarrow{nw{-}ND_1}.\overrightarrow{\mathrm{nw}{-}ND_2}}{\|\overrightarrow{nw{-}ND_1}\|\|\overrightarrow{\mathrm{nw}{-}ND_2}\|} \tag{2}$$

Where $nw - ND_1$ and $\mathrm{nw} - ND_2$ represents the n-gram representation of weighted ND1 and ND2

c. Levenshtien Distance index (LDI): This is edit based similarity index. Number of edits in form of insertion, deletion and substitution is calculated. Overall bounded similarity index is generated between 0 and 1 [26].

$$lev_{(nw-ND_1 \text{ and } \mathrm{nw}-ND_2\,)}(i,j) = \begin{cases} \max(i,j) & if\ \min(i,j) = 0 \\ \min \begin{cases} lev_{(nw-ND_1 \text{ and } \mathrm{nw}-ND_2\,)}(i-1,j)+1 \\ lev_{(nw-ND_1 \text{ and } \mathrm{nw}-ND_2\,)}(i,j-1)+1 \\ lev_{(nw-ND_1 \text{ and } \mathrm{nw}-ND_2\,)}(i-1,j-1)+1 \end{cases} & otherwise \end{cases} \tag{3}$$

It measures first i characters and j characters of $nw - ND_1$ and $\mathrm{nw} - ND_2$, respectively.

Implementation of this entire work was done in Python 3.7 [15]. Different packages such as nltk, inltk, sklearn were used in this work.

Algorithm I: Algorithm for finding synonyms of tokens based on part of speech associated

```
Input: Document1 (D1) and Document2 (D2)
Output: All synonyms replaced in Document2
Step 1: Both documents were tagged based Part of Speech with the help of part of speech tagger.
Step 2: Divide the document D2 into tokens a ($t_1$ …$t_n$) and form Bag of Word2 ($BOW_2$).
Step 3: Extract 'noun'/ 'verb' from document D1 and form Bag of Word1 ($BOW_1$) with tokens ($t_1$---$t_n$).
Step 4: for each token ($t_1$---$t_n$) in $BOW_1$
    If token is present in $BOW_2$
            Continue with the next token in Bag of Word1 ($BOW_1$),
    Else
            a) Find the synonyms of token using IndoWordNet and search the presence of each synonym in $BOW_2$
            b) If match found in BOW2, replace synonym matched with the original token in $BOW_2$
            c) Goto step3
Step 5: End
```

IV. Results and Analysis

The purpose of this research work was to find the most suitable similarity index for Punjabi documents. Similarity between the documents can be identified either at Lexical level or at Semantic level. In this work, similarity between Punjabi documents has been measured at lexical level (indicated with 'A' in this work) with different combination of pre-processing techniques. For finding the similarity index, document vectors of TF weighted n-grams have been used. For evaluating the system, results are presented in two sections. Section 1 consists of results by the algorithm and section 2 consists of evaluation results by human linguistic expert through HIT.

A. Results based on Algorithm

In order to find similarity index at lexical level (A), different measures (as specified in previous section) were experimented with different combinations of pre-processing techniques. These combinations have been labelled with characters a to e. Details of these measures with code are presented in Table II. It is notable that these codes have been coined by us for simplicity.

TABLE II. Coined Codes for different Combinations of Pre-Processing and Normalization Techniques

Sr. No.	Coined Codes	Details of different combinations of pre-processing and normalization techniques
1	A.a	Without any pre-processing
2	A.b	Stop words removed from documents
3	A.c	Stop words removed and tokens are stemmed
4	A.d	Stop words are removed, words are stemmed and 'noun' synonym are replaced using IndoWordNet
5	A.e	Stop words are removed, words are stemmed and 'verb' synonym are replaced using IndoWordNet

Each document pair has been evaluated using 5 combinations of pre-processing techniques (as indicated in Table II) in addition with n-gram values from 1 to 5. For a single document pair, 5x5x3 combination have been tested where 5 were the combinations, 5 n-gram values and 3 similarity indexes. In total, 50x5x5x3 combination of experiments have been performed to analyze the result where number of document pairs are 50. For each document pair, each combination from A.a to A.e was tested with value of n - gram used was 1 to 5. Result of each combination (considering only non-zero results for n-grams have been averaged. Results were analyzed based on two valid findings:

1) *Finding 1:* For more than 38 document pairs, similarity index values have been reported to be 0 for n-gram having value 4 and 5. So, these values were excluded while calculating average.

2) *Finding 2:* By averaging the n-gram results (as per finding1) obtained in each combination, best combination was selected. Although, combination A.a comes out to be the best combination in all of them. But, A.a results were ignored considering the presence of stop words and so is the maximum overlapping. Detail results are presented in the next subsection.

B. Results based on Human Intelligence Task (HIT)

For this work, each document pair was shared among 10 Punjabi language native speakers. Users selected for this research are from technical background and have sound knowledge about plagiarism and similarity. They were requested to rate the similarity between two documents on the scale of 0-100. Rating value equal to 0 or 100 was ignored considering it as outlier, and such values were not considered while calculating Average Human Intelligence Task (AHIT) rating.

C. Analysis of Similarity Indexes

For each document pair, the best combination is selected on the basis of Average Jaccard Similarity Index (AJSI), Average Cosine Similarity Index (ACSI), and Average Levenshtien Distance Index (ALDI). Table III provides the results obtained with algorithm and index value obtained with AHIT score. Values in column AHIT were averaged and rounded off to 2 decimal points.

TABLE III. RESULTS OBTAINED WITH ALGORITHM AND HIT SCORING

Sr. No.	Document Pair	Best Code	AJSI	ACSI	ALDI	AHIT
1	DP-1	A.e	0.068	0.192	0.07	0.17 0.17
		A.d	0.001	0.189	0.021

47	DP-47	A.d	0.021	0.532	0.099	0.52
48	DP-48	A.d	0.023	0.452	0.113	0.47
49	DP-49	A.c	0.033	0.145	0.043	0.12
50	DP-50	A.d	0.083	0.318	0.128	0.39

From Table III, Table IV is derived based on the frequency count of each combination. From Table IV, it can be observed that combination A.c is proven to be the best combination so-far on the basis of majority voting mechanism. Result of combination A.a is ignored as stated in finding 1. *Total value reflected in Table IV is 54 because in DP-1, DP-11, DP-12 and DP-15, two combinations comes out to be the best instead of one.

In second phase of experimentation, all the results for combination A.c were compared for checking the existence of correlation with AHIT obtained. For finding the correlation among these values, distribution of data was identified.

Distribution details were presented in Fig. 2. As it can be observed from Fig. 2, data is not normally distributed, so spearman correlation coefficient method was used for finding the correlation between values obtained by algorithm and human score [23]. Correlation strength values lies between -1 and 1. Table V presents the different strength values.

TABLE IV. FREQUENCY DISTRIBUTION FOR COMBINATIONS

Sr. No.	Combination Code	Frequency Count
1.	A.b	3
2.	A.c	12
3.	A.d	32
4.	A.e	7
Total		54*

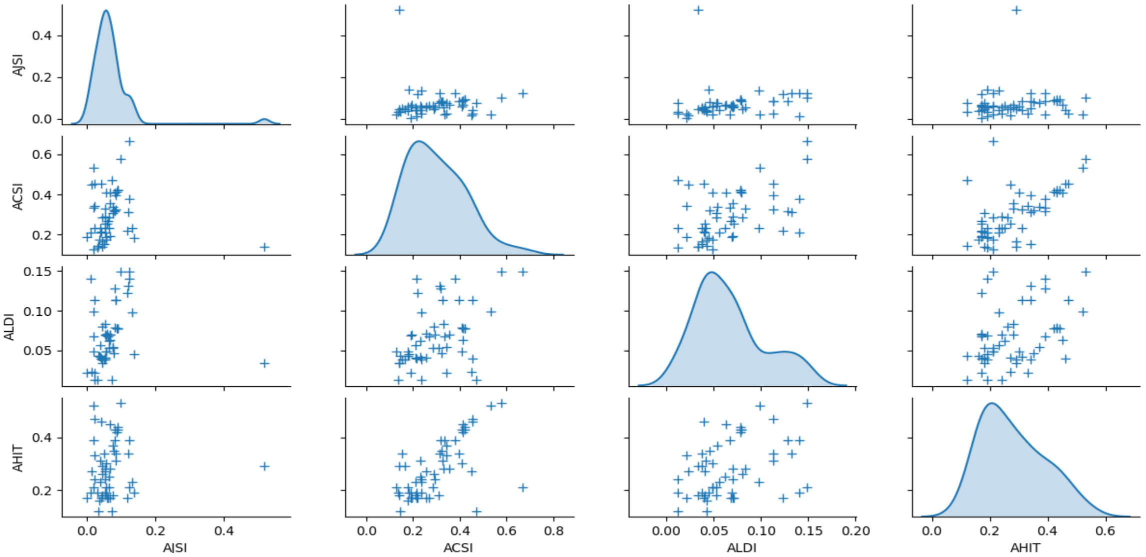

Fig. 2. Distribution of AJSI, ACSI, ALDI and AHIT.

TABLE V. STRENGTH VALUES FOR CORRELATION

Sr. No.	Coefficient Value	Interpretation
1.	0.00-0.19	Very Weak
2.	0.20-0.39	Weak
3.	0.40-0.59	Moderate
4.	0.60-0.79	Strong
5.	0.80-1.00	Very Strong

TABLE VI. COEFFICIENT SCORE

Sr. No.	Correlation Between	Coefficient Value
1.	AHIT and AJSI	0.184
2.	AHIT and ACSI	0.621
3.	AHIT and ALDI	0.351

Spearman correlation coefficient was obtained between 3 similarity index values and average HIT score. Table VI presents the coefficient values. From Fig. 3, it can be observed that highest coefficient value is 0.621 with p-value >0.05. So, AHIT score is more correlated with average cosine similarity index value. So, ACSI values obtained with algorithm has strong association with AHIT (as indicated from Table V values).

D. Analysis of n-gram

In this section, n-gram effect on similarity task is studied. For this work, value of n is taken from 1 to 5. As per assumption specified in result section, results are taken into consideration for n equal to 4 and 5. Analysis is carried out on unigram (n=1), bigram (n=2) and trigram (n=3). Table VII presents the results obtained for 50 document pairs for these n-grams.

For n-gram analysis, n-gram wise result for each combination (A.a to A.e) are averaged. Value for trigrams in document pair 4 and 10 are ignored and are not considered while calculating column average. It can be observed from the Table VII and Fig. 4 that bigram (n=2) gives the best result whereas as n is increased to 3, index values have been reduced.

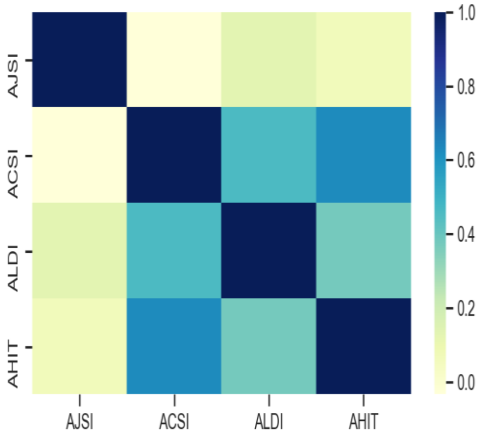

Fig. 3. Correlation Coefficient between Similarity Index Values and Average HIT.

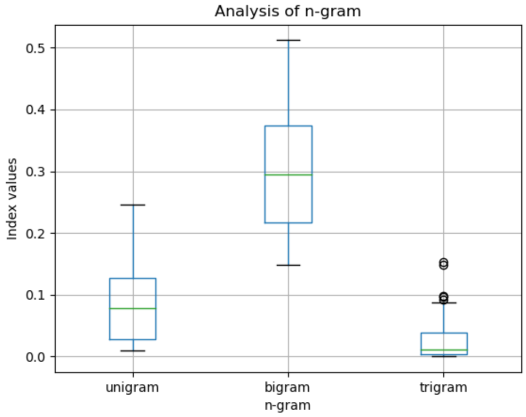

Fig. 4. Analysis of n-gram Index Values.

TABLE VII. ANALYSIS OF N-GRAM VALUES FOR 50 DOCUMENT PAIRS

Sr. No.	Document pair	Unigram (n=1)	Bigram (n=2)	Trigram (n=3)
1.	DP-1	0.127	0.343	0.01275

V. CONCLUSION

As the Punjabi textual content is increasing day by day on web, there is a need to check many of such documents for similarity. Manually detecting the similarity is a tedious task. So, the main objective of this work was to automate the similarity detection process. As there was unavailability of similarity textual corpus, it was created manually through human annotators. 50 document pairs were collected for further experimentation. Each document pair consists of information about the same topic. These document pairs were passed through various pre-processing techniques such as stop word removal, stemming, part of speech based synonym replacement with the help of IndoWordNet. Different combinations of these techniques were tested with n-gram with value of n from 1 to 5. JSI, CSI, LDI and HIT based rating have been used for evaluation. Results indicated that combination of pre-processing technique (stop word removal with root word conversion using stemming and synonym replacement with 'noun' based part of speech tag) proven to be the best combination so-far for detecting similarity among Punjabi documents. Out of the 3 indexes used for experimentation, values obtained for CSI are highly correlated with HIT based rating.

***Abstract*—Intrusion detection has drawn considerable interest as researchers endeavor to produce efficient models that offer high detection accuracy. Nevertheless, the challenge remains in developing reliable and efficient Intrusion Detection System (IDS) that is capable of handling large amounts of data, with trends evolving in real-time circumstances. The design of such a system relies on the detection methods used, particularly the feature selection techniques and machine learning algorithms used. Thus motivated, this paper presents a review on feature selection and ensemble techniques used in anomaly-based IDS research. Dimensionality reduction methods are reviewed, followed by the categorization of feature selection techniques to illustrate their effectiveness on training phase and detection. Selection of the most relevant features in data has been proven to increase the efficiency of detection in terms of accuracy and computational efficiency, hence its important role in the design of an anomaly-based IDS. We then analyze and discuss a variety of IDS-based machine learning techniques with various detection models (single classifier-based or ensemble-based), to illustrate their significance and success in the intrusion detection area. Besides supervised and unsupervised learning methods in machine learning, ensemble methods combine several base models to produce one optimal predictive model and improve accuracy performance of IDS. The review consequently focuses on ensemble techniques employed in anomaly-based IDS models and illustrates how their use improves the performance of the anomaly-based IDS models. Finally, the paper laments on open issues in the area and offers research trends to be considered by researchers in designing efficient anomaly-based IDSs.**

***Keywords*—Intrusion detection system (IDS); anomaly-based IDS; feature selection (FS); ensemble**

I. Introduction

Intrusion detection system (IDS) is one of the widely used security mechanisms intended to protect computers, programs, networks, and information against intrusion, illegitimate access, alteration, or demolition. At a minimum, security systems for computers (host) and networks requires firewalls, antivirus applications and IDSs. Intrusion detection aims to detect acts performed against information systems by intruders, which attempt to gain illegitimate access to a computer asset (data, information, and network). Intruders may involve local or remote intruders: local intruders are network users with some level of legal access which attempts to elevate their levels of access through abuse of unauthorized privileges; while remote intruders refer to users who attempt to obtain illegal access to device data outside the target network [1], [2].

One of the techniques utilized to construct the intrusion detection system in order to track and deter attacks are machine learning (ML) algorithms. These techniques analyze and distinguish between from normal and abnormal packets, are attempting to avoid system harm from the attack.

A. Challenges

Among the main challenges in IDS research are related to the selection of relevant data to be investigated. For training expert machine in IDS datasets, there are some attributes which are irrelevant or may not influence the final results and also increases the execution time. The strain on expert machine is minimized by eliminating these attributes by utilizing dimensionality reduction techniques [3], [4].

The other challenge is to build an appropriate feature subset selection to be used in the process of intrusion detection, which will not only reduce the detection time but also increase the accuracy of detection. In addition, generating proper feature subset helps expert machine by avoiding over fitting issue and enhances predictive performance [5], [6].

Utilizing suitable machine learning algorithms in order to detect the intrusion is another challenge in IDS. Threats and security landscape are become increasingly complex, and strategies based on low-level machine learning are ineffective in coping with rising security issues.

There are various machine learning algorithms and methods but the main challenge is to select the one that yields optimal performance for the IDS model [7], [8].

B. Motivation

The above challenges have inspired the discussion in this review paper, which focuses on application of machine learning algorithms for feature selection and ensemble-based detection in anomaly-based IDSs. The papers are classified base on mentioned issues and addressed their objectives and attributes. This study discusses and compares the models and examines the particularities of each model in order to promote more studies in this area.

C. Previous Study

Numerous existing review articles on IDS concentrated on feature selection or detection mechanism without taking into account the future trends and open topics. Anomaly-based intrusion detection has already been studied in several review articles [9], [10]. They described various elements of IDS but did not discuss articles in-depth, the strengths and weaknesses

*Corresponding Author

in different methods of feature selection and ensemble detection for anomaly-based intrusion detection system. Furthermore, future trends and open issues are also addressed.

D. Contributions

The contributions of this review are summarized below:

- Classification of detection methods in IDS. The methods, feature selection technique used, classification type, evaluation tool and dataset are all mentioned.
- Classification of machine learning techniques used in anomaly-based IDS.
- Identification of feature selection for anomaly-based IDS, as summarized in Tables II and III.
- Identification of ensemble classification for anomaly-based IDS.
- Presentation of future directions on the state-of-the-art anomaly-based feature selection and ensemble classification.

To achieve the mentioned contributions, some research questions are ready for this analysis and the responses are given in the following sections:

RQ1.What are the detection methods utilized for IDS?

RQ2.Which evaluation tools are utilized to assess the effectiveness of the IDS?

RQ3.What are the datasets reported in the review to be used in anomaly-based IDS?

RQ4.Which feature selection methods are used for anomaly-based IDS?

RQ5.What are the machine learning algorithms used for detecting intrusions in anomaly-based detection?

RQ6.What of the ensemble techniques included in the review are reported to be used in anomaly-based IDS?

The remainder of this paper is organized as follows: Section 2 provides an overview of detection methods in IDS. Then, the taxonomy of machine learning algorithms and their methods which are employed in IDS follows in Section 3, while Section 4 reviews and compares different techniques of feature selection. Next, ensemble classification algorithms and their methods which are employed in anomaly-based IDS follows in Section 5. In Section 6, discussions on the open issues and future trends for IDSs are provided, and finally Section 7 concludes this survey.

II. Detection Methods

Intrusion detection methods are classified into four groups based on the detection method used in the system: signature-based, anomaly-based, specification-based, and hybrid. In signature-based detection the IDS identifies threats when the system or network operation matches the threat pattern (called signature) stored in the IDS local databases, and an alert will be activated. Signature-based IDSs are effective and efficient in identifying existing attacks, and their task is simple to comprehend. However, this technique has not been effective in identifying zero day attacks and new variants of previously identified attacks which are still elusive as the associated signature for these attacks [11]. Signature-based schemes offer very strong outcomes for popular, well-known threats. However, they are unable to identify new, unseen attacks, even though they are designed as minimal variants of attacks previously identified. Examples of signature-based IDSs are Artificial Immune System (AIS) [12], Collaborative Block Chained Signature-Based IDS (CBSigIDS) [13], IPFIX-based IDS (FIXIDS) [14].

Anomaly-based detection aims to predict the system's "ordinary" pattern to be covered and produce an anomaly warning whenever the difference between an immediate occurrence and normal pattern reaches a predetermined threshold. The key benefit of anomaly-based detection method is their ability to recognize previously undiscovered attack incidents. Nevertheless, in anomaly-based systems, the rate of false positives (FP), or wrongly defined as attacks is typically higher than that of signature-based method, considering the possible inaccuracy in formal signature specifications. Examples of anomaly-based IDSs are Hybridized Feature Selection Approach (HFSA) [15], Hybrid Anomaly Detection Model (HADM) [16], Unsupervised Heterogeneous Anomaly Based IDS [17].

For specification-based detection method, a human expert manually constructs the desired template which consists of a series of rules (specifications) that aim to evaluate valid behavior of a device. If the parameters are sufficiently accurate, the template may identify unlawful patterns of behavior. In addition, the false positive rate is decreased, primarily because benign behaviors that were not previously observed are not flagged as intrusions in this type of system. Specifications could also be created using some formal tool, for example, with a sequence of states and their transitions, the Finite State Machine (FSM) methodology appears suitable for modelling network protocols [18] [19]. Standard languages of representation such as LOTOS, UML and N-grammars can be considered for this reason.

Hybrid detection aims to benefit from the strengths of each intrusion detection method, minimized their weaknesses and build strong schema to detect the intrusion. A notable aspect in hybrid detection is common uses of a key signature-based detection system in conjunction with an additional anomaly-based model. This integration of the two forms of detection strategies in a "Hybrid NIDS" [20] aims to increase the final accuracy of signature-based models for intrusion detection while eliminating the usual high level of false positives of network-based IDS (NIDS) approaches, hence a hybrid approach is embraced by most existing platforms. Other examples of hybrid are Signature-Based Anomaly Detection Scheme (SADS) [21]' Artificial Bee Colony and Artificial Fish Swarm (ABC-AFS) [22], Hybrid Intrusion Detection Approach In Cloud Computing (HIDCC) [23].

Table I shows the type of detection methods utilized by researchers in IDS. RQ1, RQ2, and RQ3 are all answered in detail in the table. It specifies the detection method, the evaluation tool, dataset used in the articles, and so on. From the table it is apparent that signature-based and specification-based detection methods did not utilize feature selection and ensemble classifier to detect intrusions, in contrast to the anomaly-based detection which utilized both of them. For evaluation tools and dataset, signature-based and specification-based models were deployed and validated using simulation and real data while anomaly-based approaches were evaluated by experiments and standard IDS datasets. The NSL-KDD dataset is the most utilized dataset based on the articles in this review.

III. Machine Learning in Anomaly-based IDS

Machine learning (ML) algorithms are classified into unsupervised learning and supervised learning, depending on the availability of training dataset and the successful outcome of learning algorithms. Fig. 1 illustrates the taxonomy of machine learning algorithms in anomaly-based IDS. Regarding RQ5, it has been noted that most studies focus on the following algorithms for IDS.

In supervised learning, the training function is provided with input and target output pairs, and an expert model is trained to predict the output of functions at minimal expense. Supervised learnings are classified based on learning algorithms, frameworks and objective functions. Support vector machine (SVM), decision trees, and artificial neural network (ANN) are common categorizations.

For unsupervised learning there is no tag or label in the sample dataset. Unsupervised learning algorithms are proposed to simplify the data's key features and shape clusters of natural input patterns due to a particular cost function. Hierarchical clustering, K-means clustering, and self-organization map are the most common unsupervised learning methods. One of the challenges of unsupervised training is that it is hard to evaluate because it does not have a specific educator and therefore does not have labelled test data.

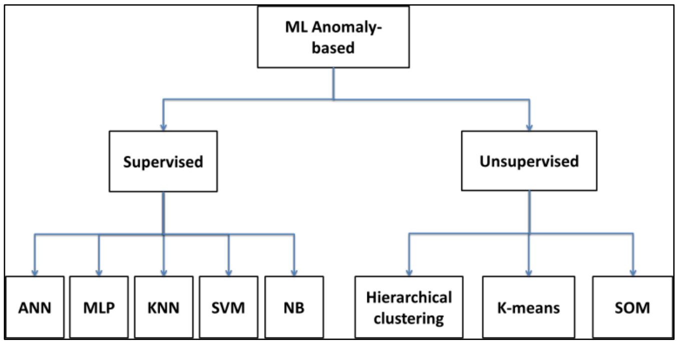

Fig. 1. Taxonomy of Machine Learning Algorithms in Anomaly-based IDS.

A. Supervised learning

1) Artificial Neural Network (ANN): ANN is one of the major algorithms of machine learning which is widely utilized as a detector operator in IDSs in many studies. ANN is used to solve a variety of issues faced by other existing intrusion detection approaches and has been suggested as a substitute for the statistical analysis aspect of detection of anomaly schemes. Initially, the ANN acquires its expertise by training the machine to properly detect pre-selected examples of problems. The neural network result will be checked and the machine configuration will be optimized until the training data neural network response reaches a sufficient level. Besides the initial training phase, the neural network often gains expertise over time as it performs review of the problem-related data [24], [25] . A hypervisor layer anomaly detection system called Hypervisor Detector that employs a combination algorithm that is a hybrid of Fuzzy C-Means clustering algorithm and Artificial Neural Network (FCM-ANN) was introduced to enhance the detection system accuracy [26]. The KDD Cup 99 sample dataset is used to test the design system to test for the reliability of five attack forms. The model was good at finding normal and probe attacks, but did not yield good results for DOS (99.96–5.33), U2R (96.78–3.22) and R2L (93.73–6.27) attacks, even for accuracy and false alarm rate. A reasonable solution using ANN in hierarchical anomaly-based IDS can be pointed to [27], which used neural Self Organization Map (SOM) networks to identify and distinguish normal packet from the attack traffic. The proposed machine was used to configure, train and evaluate the SOM Neural Network for intrusion detection. Detection output was performed to evaluate the SOM efficiency in detecting anomaly intrusion and the findings show that SOM with the KDD Cup 99 dataset can distinguish attack packet from normal one at 92.37%, while with NSL-KDD the detection rate is 75.49%.

The work in [28] tackles detection problems by presenting a simple ANN-based IDS system, utilizing back propagation and feed forward algorithms together with different other optimization methods to minimize the total computing overhead while maintaining a high level of performance. Results of the experiment on the NSL-KDD benchmark dataset showed that the quality of the proposed ANN (accuracy and detection speed) was 98.86% for accuracy and 95.77% for detection rate. An effective method to identify brute force attack in the Secure Shell (SSH) was proposed by [29]. A brute force attack is performed by the implementation into the private cloud of a client-server SSH model and the server captures traffic related to attack and normal. Next, ANN's Multi-Layer Perceptron model extracts indicative traffic characteristics and uses them to distinguish the attack and normal packets. Results obtained from this approach indicate that the suggested framework is able to detect the attack successfully with great accuracy and minimal false alarm.

2) Multi-layer Perceptron Neural Network (MLP): MLP is a supervised learning classifier which utilizes back propagation algorithm in the learning phase to train the model. It can learn a non-linear approximate function for both regression and classification task, by providing a group of features and a target in which one or more non-linear layers called hidden layers between the inputs and outputs are distinguished from logistic regressions [44].

The MLP neurons are positioned in layers with always-flowing outputs toward the output layer, either one layer (called a perceptron) or a multilayer perceptron, if multiple layers exist [45], where every neuron in a single layer has direct connections to the subsequent layer's neurons. The units of those networks apply a sigmoid function as activation function in many applications.

A wrapper-based feature selection is designed by utilizing the Discernibility Function as algorithm for search to construct subsets of feature and the MLP classifier is used to determine the subsets of features. Thus, the C4.5 decision tree and the MLP classifier, which are commonly utilized in the IDS, are used to illustrate better classification rates. With this hybrid method, the findings for the KDD Cup 99 shows improved accuracy of approximately 12% for U2R, 2% for Probe, and 1% for DOS classes [46].

To build effective IDS, a hybrid multi-layer perceptron (MLP) and Artificial Bee Colony (ABC) algorithm were designed. The MLP classifier was used to distinguish among the attack and normal traffic in network. Training and testing have been conducted using the NSL-KDD dataset. Results of the experiments show that the suggested solution gives a high detection rate of about 87.54 % and error rate of 0.124% [47].

3) K-nearest neighbor (KNN): KNN algorithm is a nonparametric technique for classification and is a simple and straightforward machine learning algorithm. It is vast used based on many experiments reported on intrusion detection, pattern recognition, text categorization and countless others [48].

A combination of the Learning Vector Quantization ANN and KNN method for intrusion detection was suggested by [49]. The analysis was performed on the NSL-KDD dataset and the proposed model has a detection rate of 97.2% (five classes) with a false alarm rate of approximately 1%.

4) Support Vector Machines (SVM): SVM is one of the algorithms in machine learning that used labeled instance (packet) to train the model and differentiate the packet to different classes by generating templates that could determine which class a new instance belongs into [50], [51]. SVM's main objective is to discover a linear optimized hyper plane that maximizes the isolation boundary between groups. The SVM then trains the model across sections or portions of the data[52].

A hybrid intrusion detection KPCASVM with GAs design was proposed [53], where KPCA is implemented in the N-KPCA-GA-SVM system to obtain the key data features of intrusion detection, and a multi-layer SVM classifier is used to determine normal or attack behavior. The test was conducted on the KDD Cup 99 dataset and the detection rate was 96%. BIRCH hierarchical clustering SVM-based network intrusion detection framework [54] was proposed for pre-processing of data. Instead of the original large data set, the BIRCH hierarchical clustering could provide the SVM learning with highly qualified, abstracted and reduced data sets. The proposed solution could achieve a 95.72% accuracy with a false positive rate of 0.7% overall, but was not satisfactory with the division accuracy for each attack type (Prob= 97.55%, U2R=19.73% and R2L=28.81%).

A new Combining Support Vectors with Ant Colony (CSVAC) algorithm was proposed to produce cluster classifiers in intrusion detection [55] using two existing machine learning techniques (SVM and CSOACN) to improve overall detection rates and speed. The method is applied and tested using the standard KDD Cup 99 dataset benchmark, and yields a classification rate of 94.86% with a false negative ratio of about 1% and the false-positive ratio of 6.01%.

5) Naive Bayes Network (NB): Naive Bayes (NB) is a simple method of creating classifiers that allocate labels of class to problematic cases identified as values of feature vectors, where class tags are drawn from a restricted set. There is no single algorithm for learning such classifiers but a set of algorithms based on a common concept. A Directed Acyclic Graph (DAG) usually describes the structure of an NB, that each node represents a process variables and each reference encodes one node's control over another [56]. By comparing the decision tree and Bayesian techniques, the decision tree's accuracy is much higher but the processing time of the Bayesian network is low [57]. Therefore, it will be effective to use NB models when the dataset is very large.

A Naive Bayes-based IDS which obtained better findings than neural network IDS while tested on the KDD Cup 99 was proposed by [58]. The average accuracy obtained by utilizing Naive Bayes was 91.52%. While being basic in design, it can produce accurate results. A hybrid intrusion detection system based on Naive Bayes and decision tree was proposed by [59]. The model has been compared and tested using benchmark KDD Cup 99 dataset, the detection rate was 99.63%. A Fuzzy Intrusion Recognition Engine (FIRE) Intrusion Detection System Simple data mining approaches used to process network stimulus data packets and reveal essential anomaly detection indicators was developed by [60]. Such indicators were accessed for each observed value and used afterwards to classify network attacks. An intrusion detection model with information gain for feature selection and SimpleCart algorithm to detect the intrusion was suggested by [61]. First, the features were reduced to 33 and then the SimpleCart algorithm used for detection. The model was applied on NSL-KDD dataset and the detection accuracy was 82.32% and error rate was 17.67%. A hybrid strategy to learning is suggested by integrating Naive Bayes and K-Means clustering classifier. The suggested solution has been compared and tested using the benchmark dataset KDD Cup 99. These combinations learning methodology achieved rather low error rates with an average of less than 0.5% while retaining accuracy and detection rates above 99%. The method is capable of accurately classifying all data except the U2R and R2L attacks. to overcome this limitation, it was recommended to consider the Integrated Intrusion Detection Program which is ideal for identifying R2L and U2R threats [62], [63]. In SSH traffic, a combination of Bayesian Network and Genetic Algorithm was introduced to improve identification of brute force attacks [64]. The proposed method implements brute force attack data obtained in a client-server model. Their findings show that the most effective features were chosen and the final result was better than the benchmark.

B. Unsupervised learning

Unsupervised detection of anomalies (often recognized as outlier detection) employs clustering approaches to classify potentially malicious incidents without previous knowledge in a dataset. Clustering aims to divide a limited unlabeled data into a discrete and finite collection of "natural" unseen structures of data instead of providing a precise non-observed characterization incidents produced within the same distribution probability [65]. In another aspect, the goal of unsupervised algorithms is to divide the data into categories (clusters) that reach great similar internal and external dissimilarities without previous knowledge.

All clustering approaches are based on the following hypotheses for this reason. First, the volume of normal instances in a database surpasses the volume of anomalies. Next, the anomaly packet themselves vary from normal instances qualitatively [66]. Scores are allocated to the installed clusters after the cluster formation. If a cluster's score reaches the threshold pre-defined or automatically determined, a potential anomaly is considered. When clustering is utilized to identify attacks on the network, respectively, one believes that malicious traffic is less than the normal packet and normal packet is distinguished from the malicious one in some way. In other words, the features that characterize the attacks well enough to be defined must be selected concerning to the process of detection. The aim of clustering is to categorize network packets or flows without prior knowledge, but based solely on their relationships. As a result, large normal packet clusters would be formed when attack packets produce small clusters and cases not belonging to other groups. A static or dynamic threshold may be utilized to determine that clusters are deemed to be attack based on the testing and algorithm adjustment used. The main benefit of clustering models is their capability to identify unseen threats without previous information, thereby eliminating the need for labeled traffic. The main disadvantage is their high false-positive rate.

The extraction or selection of features is among the most critical stages of unsupervised detection. The use of clustering techniques to identify a range of attacks by checking alarm records from heterogeneous database was proposed [17], instead of utilizing the attributes of abnormalities that carry specific actions to suit instances or the standard approach of testing and training currently utilized in abnormal detection. Even though it required less time for the three clustering algorithms tested in the system to forecast and build clusters, the clusters' accuracy produced by one algorithm was not consistent across various logs and subsets. The obtained result indicates the way or route to develop abnormal detectors that could use pure activity logs obtained from heterogeneous databases on the tracked network and compare instances through alarm records to identify intrusion.

IV. Feature Selection Techniques

Feature Selection (FS) is a method for removing unnecessary and redundant features and choosing the most suitable feature subset that will result in a better classification of patterns which belong to various classes of attack. So, from researchers' view there are reasons why feature selection needs to be performed:

1) A single selection strategy is not adequate to obtain consistency across multiple datasets, as network traffic activity is changing [67]–[69].

2) An appropriate subset for each attack types should be identified, since one general subset of features is insufficient to properly represent all the various attacks[69]–[71].

3) FS can significantly improve not only the accuracy of detection but also the computational efficiency, where:

a) features which are irrelevant or redundant can result in poor detection rate and overfitting, therefore, reducing them can increase the detection accuracy; and

b) more features for each data point would cause higher computational costs and complexity—reducing irrelevant features will increase the computational efficiency [67], [69]–[74].

4) Ultimately, R2L (Remote-to-Local) and U2R (User-to-Root) attack groups are known to become the most challenging to identify since they are too isolated and could be mislabeled as normal packet. Studies and experiments have shown that FS can solve this issue by defining a feature subset adapted to the behavior of each attack type classes [70], [71], [74].

Methods of FS are generally classified into filter, wrapper and optimization-based FS methods for selecting features. Table II illustrates the advantages and disadvantages of the mentioned features selection methods and Table III summarized the reviewed feature selection for anomaly-based IDS. RQ3 and RQ4 are all answered in detail in the table. It specifies the feature selection methods, the algorithm's origin, subset size, strength, weakness, dataset used in the articles, and so on.

TABLE II. Comparison of different Feature Selection Methods

Method	**Advantages**	**Disadvantages**	**Examples**
filter	• Faster than wrapper • Not dependent on classifier • Less computational complexity than wrapper • Less over-fitting issues • Use statistical methods for evaluation of the attributes	• Lack of interaction to classifiers • Lack of dependency among attributes • Less detection rate compared to wrapper	Euclidean distance, information gain, correlation-based, etc.
Wrapper	• Interact with classifier • Consider attributes dependency • Better detection rate • Use cross validation for evaluation attributes	• Longer execution time • More risky for over-fitting issues	Sequential forward selection, Sequential backward selection, Hill climbing, Stepwise selection, etc.
Optimization-based	• Interact with classifier • Less over-fitting issues • Better detection of global optima • Better attribute selection • Simple to implement	• Difficult to be adjusted to a new situation • Complexity to adjusted different parameters	Ant Colony Optimization (ACO), Particle Swarm Optimization (PSO), Cuckoo Search Algorithm (CSA), Genetic Algorithm (GA), etc.

TABLE III. SUMMARY OF THE REVIEWED FEATURE SELECTION FOR ANOMALY-BASED INTRUSION DETECTION SYSTEM

Author	**Method**	**Algorithm**	**Type of feature subset**	**Subset size**	**Strengths**	**Weaknesses**	**Dataset**
2011 [79]	Filter	Mutual information-based feature selection	Class-based Subset	15 out of 41	Improve relevancy and reduce redundancy for feature selection.	Performance metric is low.	KDD Cup 99
2013 [32]	Wrapper	Wrapper based on Bayesian Network classifier	Single Subset	11 out of 41	Improve the performance metric.	Accuracy of U2R attack was not satisfactory.	NSL-KDD
2015 [102]	Wrapper	Layered wrapper feature selection approach (LAWRA)	Single Subset	16 out of 41	LAWRA utilized external cluster validity indices, F-measure, and Fowlkes–Mallows index, for feature selection.	Overall accuracy (around 83%) and false parameter was not satisfactory. Lack of class-based feature selection.	NSL-KDD
2016 [34]	Optimization-based	Ant Colony Optimization (ACO) and K-Nearest Neighbor (KNN)	Class-based Subset	4 to 8 out of 41	Needs no prior knowledge of features.	False positive was not satisfactory (2.59).	KDD Cup 99 NSL-KDD
2016 [103]	Filter	Flexible Mutual Information Feature Selection (FMIFS) and Least Square SVM	Single Subset exempt Class-based Subset for KDD Cup 99	KDD Cup 99 (12 to 23 features) NSL-KDD (18 features) Kyoto2006+ (-)	Proved the generality of their model by utilizing different datasets.	Accuracy of U2R attack was not satisfactory. Lack of class-based feature selection two dataset.	KDD Cup 99 NSL-KDD Kyoto2006+
2017 [92]	Optimization-based	Hypergraph based Genetic Algorithm (HG-GA)	Single Subset	35 out of 41	HG-GA utilized a weighted objective function to improve performance metrics.	Overall accuracy 97.14%. Lack of class-based feature selection.	NSL-KDD
2019 [104]	Filter/ Optimization-based	Linear correlation coefficient algorithm and cuttlefish algorithm (CFA) and Decision tree	Single Subset	10 out of 41	Integration of filter method with cuttlefish algorithm optimization helps the model to detect the attack with less false alarm.	Overall accuracy 95.03%. Lack of class-based feature selection.	KDD Cup 99
2019 [38]	Filter/Wrapper	CART Algorithm	Single Subset	17 out of 41	Utilizing Gini and CART algorithm.	Overall accuracy 79.7%. Lack of class-based feature selection.	NSL-KDD
2020 [105]	Wrapper / Optimization-based	Genetic Algorithm with Multi-parent Crossover and Multi-Parent Mutation (MGA)	Single Subset	4 out of 41	Propose a new operator, called multi-parent-crossover-mutation to enhance the GA performance.	Lack of class-based feature selection.	NSL-KDD
2020 [94]	Optimization-based	Mutation Cuckoo Fuzzy (MCF) and ANN classifier	Single Subset	22 out of 41	Integrates mutation operator with cuckoo search and Fuzzy C Means (FCM).	Lack of class-based feature selection.	NSL-KDD
2020 [106]	Optimization-based	Pigeon Inspired Optimizer	Single Subset	KDDCUPP99 (7 features), NSL-KDD (5 features), and UNSW-NB15 (5 features)	Proved the generality of their model by utilizing different datasets.	Performance metric was not satisfactory. Lack of class-based feature selection.	KDD CUPP 99 NSL-KDD UNSW-NB15
2020 [40]	Filter/ Optimization-based	Ensemble of (mRMR, JMI CMIM) and Chaotic Adaptive Grasshopper Optimization Algorithm (CAGOA)	Single Subset	ISCX 2012 (20 features), NSL-KDD (19 features) and CIC-IDS2017 (12 features)	This feature selection combination gives good accuracy and less false alarm.	Lack of class-based feature selection.	ISCX 2012 NSL-KDD CIC-IDS2017
2020 [107]	Optimization-based	Multi-objective method (NSGAII) and ANN	Single Subset	NSL-KDD (24 features) UNSW-NB15 (19 features)	Proved the generality of their model by utilizing different datasets.	Performance metric was not satisfactory. Lack of class-based feature selection.	NSL-KDD UNSW-NB15

2020 [6]	Wrapper / Optimization-based	Hybrid of Fruit Fly Algorithm (FFA) and Ant Lion Optimizer (ALO) Algorithm.	Single Subset	KDD Cup99 (12 features), NSLKDD (16 features), UNSW-NB15 (15 features)	This hybrid algorithms increase the diversity of populations, which yields better detection.	Lack of class-based feature selection.	KDD Cup99 NSLKDD UNSW-NB15
2020 [108]	Optimization-based	Many Objective Evolutionary Algorithm and Artificial Bee Colony (MaOEA-ABC)	Single Subset	11 out of 41	Propose an adaptive selection probability approach that will adjust the selection probability and enhance the algorithm's ability to find the best solution.	Lack of class-based feature selection.	NSLKDD
2020 [43]	Wrapper / Optimization-based	Tabu Search and Random Forest (TS-RF)	Single Subset	16 features out of 41	Reducing feature vector by more than 60%. This reduces computational complexity of the proposed solution.	Lack of solving class imbalance problem present in UNSW-NB15. Performance metric was not satisfactory.	UNSW-NB15

According to the reviewed articles in Table III and the result from Fig. 2, it shows that optimization-based methods were mostly utilized for feature selection in the recent years. This method has undergone a significant improvement in terms of feature numbers. Based on the review, NSL-KDD dataset was mostly used by researchers to prove their models. In addition, some research utilized different datasets to highlight the generality of their solutions, like Kyoto2006+, ISCX 2012, UNSW-NB15, and CIC-IDS2017.

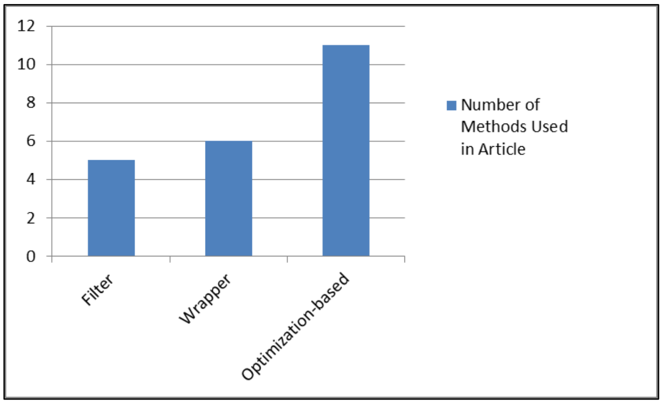

Fig. 2. Number of Studied Feature Selection Methods.

5) Filter: Filter methods use different information theory and mathematical formula for feature selection. Due to their simplicity, ranking methods are used and had good performance for practical applications. The rating of variables is based on an accepted ranking criterion and the threshold is being utilized to eliminate variables just below the value of threshold. The methods of ranking are filtering approaches as less relevant variables are extracted before the classification. A fundamental characteristic of a distinctive feature is the provision of useful information on the various classes of data. This characteristic could be described as a feature relevance[75] which defines a measure of the efficacy of the feature in order to distinguish among various classes. There are different ways to calculate a feature's relevance to the data point or outcome. Different publications [75]–[77] proposed different understandings and measurements for a variable's importance and relevancy. One description that can be listed that would be valuable is ‘‘A feature can be regarded as irrelevant if it is conditionally independent of the class labels.’’ [78]. This clearly stipulates that the data could be distinct but not separate from labels of the class, if the feature is to be relevant. The feature that does not impact class labels can be omitted. As noted above, for assessing specific features, correlation of features plays a key role. The underlying distribution of practical uses is unclear: it is calculated by the accuracy of the classifier. Because of this, an ideal subset of features may not be special because using different feature sets it may be possible to reach the similar accuracy of classifier. An improved feature selection algorithm has been proposed [79] to efficiently classify the attacks behaviors by measuring mutual information. Correlation can also be extended to evaluate of the efficiency of a feature subset, where a subset of features is perfect if the correlation among the classification and the feature subset is significant, but the correlation among the specific feature and the other features within the subset of features is poor. In addition, distance calculation for the selection of features can also be utilized [80]. Widely utilized distance calculation includes Euclidean distance, Martensitic distance and standardized Euclidean distance.

6) Wrapper: Wrapper feature selection use machine learning as a fitness function and determine the best feature subset across all subsets of features. This problem formulation allows generic optimization techniques to be used with the machine learning to rank subsets of feature based on their prediction. Therefore, in the aspect of a machine learning final predictive accuracy, the wrapper method typically surpasses the filter approach. The wrapper technique was widely popularized by [75], and provides an easy but efficient way to tackle the issue of selection of features. However, the wrapper method incurs more computation cost and need more execution time compared to filtering methods. A feature selection method using machine learning algorithms was proposed [81] for efficient intrusion detection, which blends the characteristics of distributed denial of service (DDoS) characteristic-based features (DCF) and consistency set evaluation (CSE). To identify the most relevant features, the NSL-KDD dataset is utilized as an attack dataset and is built on a few selections of feature methods, along with consistency-based evaluation of subsets and DDoS characteristic-based features (DCF). The experimental result shows that their proposed system has greater accuracy and efficiency compared to other approaches.

7) Optimization-based methods: Classic wrapper and filter strategies are independently evaluated and subset chosen. However, some features are not independent, but they are really successful when they work together. Therefore, the classic strategies in this respect are not very successful. Metaheuristic-based methods were already used to select and classify the selected features as a result of its vast improvement capability of in detection [82], [83]. Examples of optimization-based methods are Particle Swarm Optimization (PSO) [84]–[86] entropy of network features [87], Genetic Algorithm [88], [89], ant colony optimization [34], [90] and Kernel Principal Component Analysis (KPCA) [91]. With the increase in the dataset dimension, the space of the problem of selection of feature rises significantly. This leads to a large solution space with additional features. Furthermore, in a wide solution space, a huge proportion of duplicate or uncorrelated features generate several local optima.

A new anomaly based detection model of Hypergraph based Genetic Algorithm (HG - GA) was proposed by [92]. The Hypergraph's attribute was used to generate initial population in order to speed up the quest for the optimum solution and avoid trapping at local minima. HG-GA utilized a weighted objective function to achieve the balance among maximum detection rate and reducing false positive, as well as reducing features number. HG-GA SVM performance was assessed by NSL-KDD dataset.

An Ant Colony Optimization (ACO) for selection of feature method was proposed [34] using K-Nearest Neighbor (KNN) for the classification process and the accuracy was utilized as the assessment function for the model. The studies were performed using the KDD Cup 99 dataset, giving 98.9 % for accuracy and 2.59% for false positive rate.

A learning model for fast learning network (FLN) based on PSO was proposed by [93]. The PSO-based optimized FLN was trained using particle swarm optimization to pick weights. For evaluation, the research utilized KDD Cup 99 dataset to explore the effects of PSO-FLN model. The findings indicated that the model had good impact on intrusion detection.

An enhancement of Cuckoo Search Algorithm (CSA), named Mutation Cuckoo Fuzzy (MCF) was proposed by [94] for feature selection method and multiverse optimization ANN for classification at anomaly-based IDS. For feature selection phase, MCF that integrates mutation operator with cuckoo search and Fuzzy C Means (FCM) clustering was utilized. Through this method, the cuckoo Search efficiency to detect the optimal features was increased. The proposed feature selection choses 22 out of 41 features and for evaluation part well known dataset, called NSL-KDD was used to illustrate the effectiveness of their anomaly-based IDS.

A. *Limitations of the Related Works*

After analyzing the data collected from the literature related to feature selection, some limitations and shortcomings of the works are identified:

1) The optimal detection methods or strategies for various datasets have yet to be established.

2) There is a lack of proper feature subset to train faster with minimal computation and optimal performance in detecting intrusion with high accuracy and less false alarms.

V. Ensemble

The idea of merging results from a collection of learners into one is known as ensemble [95]. To obtain reliable and more accurate predictions, an ensemble can integrate multiple learners. It is possible to use a variety of techniques to generate and incorporate learners. Various datasets could be utilized to train the same training frameworks or the similar dataset could be utilized to learn various frameworks [96]. The biggest issue on the learning of the ensemble is to choose the algorithms that construct the ensemble and the function of decision or fusion that incorporates these algorithms' results. Of course, it is easy to use more algorithms to enhance the fusion results, but bearing in mind the computing cost of adding a new algorithm, it needs careful consideration. Dietterich [95] offered three key explanations for the use of an ensemble-based system. First, the empirical justification is related to the absence of sufficient knowledge to accurately classify the quest space's best hypothesis. Second, the computational description is to resolve the issue that most machine learning methods might be trapped in the local optima when looking for the perfect solution. Finally, the rationale for representation is to resolve the problem of the failure of several machine learning methods to accurately depict the border of the searched decision. Creating an ensemble takes two main parts: creating and combining [97].

The creation process has to construct a collection of base classifiers. The decision on how to integrate the results of the base classifiers into one is taken in the combining process. Many of the well-known modern ML algorithms were constructed around the idea of the ensemble. The three widely used ensemble model are bagging, boosting, and stacking [98]. Such techniques combine various models of learning into a single model so that bagging (variance), boosting (bias) or stacking (predictions) can be minimized. Fig. 3 demonstrates the general design methods of the ensemble.

A. *Bagging*

Among the first ensemble algorithms, one of the simplest and easiest way to accomplish a better efficacy was bagging [99]. When bootstrapped copies were used, varieties of results are generated in bagging, which is to say, various data subsets are randomly selected from the complete dataset of training. A different same type of classifier is designed by utilizing the learning data portion. Using a majority vote on their lists, the fusion of different classifiers is accomplished. Therefore, the decision of the ensemble is the category chosen by the largest number of classifiers for any instance data.

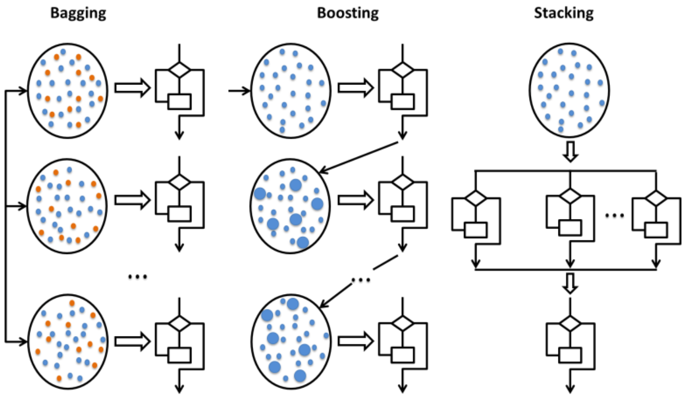

Fig. 3. Three General Ensemble Designs.

Random Forests is a method which is produced from bagging [100]. Training of multiple decision trees and randomly changing parameters relevant to training is a way to create this sort of classifier. As in bagging, copies of the training data could be bootstrapped from those parameters; but, unlike bagging, they can also be unique subsets of features, which is the case in the random subspace process.

From bagging, another method was generated, named "pasting small votes." It was a technique designed to run on huge datasets, unlike bagging [101]. Large size datasets are divided to the small size portions called "bites," used for learning various classifiers.

Small votes have resulted in the design of two combinations: first, named as Rvotes, randomly produces the subsets of data; second, named as Ivotes, creates consecutive datasets, taking into account the importance of the instances. Ivotes has been shown to deliver better results similar to the approach in boosting methods where the classifier advises the most suitable instances for the ensemble component used [109].

New method of ensemble classification [110] are proposed using bagging classifiers and their performance is evaluated with accuracy in mind. A classifier ensemble is built as a base classifier using the Support Vector Machine (SVM) and Radial Basis Function (RBF). The effectiveness and advantages of the approaches proposed are demonstrated through NSL-KDD datasets. The accuracy for bagged RBF was 86.40% and bagged SVM was 93.92%.

B. Boosting

In 1990, Schapire [111] demonstrated a weak learner (algorithm) which produces classifiers that can moderately surpass random guessing, can be converted into a powerful learner that can properly classify all instances except an extremely small fraction. The boosting created a group of classifiers by resampling the data and integrating results by majority voting. Re-sampling in boosting is designed to provide the most detailed training data for successive classifiers. In general three classifiers are created by boosting: a randomized subset of available training data is utilized to construct the first one. For training of the second classifier, knowledgeable subset of data provided to the first classifier is utilized where the knowledgeable data portion includes instances of training dataset, so the first classifier correctly identified half of them and the other half was misidentified. Ultimately, learning information for the third classifier is made up of cases where there was a conflict between the first and second classifiers. The results of the three classifiers would be combined with a majority vote.

A simplified edition of the initial boosting algorithm called "adaptive boosting" or "AdaBoost" was proposed in 1997 by Freund and Schapire [112]. Two algorithms of this group, AdaBoostM1 and AdaBoostR are the most commonly used variants, as they are perfect to cope for problems of regression and multiclass. AdaBoost generates some assumptions and the same assumptions apply to aggregate decisions by weighted majority voting of the groups decided. By extracting instances from a successively updated distribution of training data, a weak classifier is trained to build the assumptions. Updating the distribution ensures that the following classifier examples that were incorrectly identified by the prior classifier are return back to dataset to train other classifiers. Therefore, training data from various classifiers continue to move into instances that are becoming increasingly difficult to classify.

C. Stacking

Many cases are very likely to be miscategorized because they may happen to be in the near neighboring of the decision line and thus are typically located on the incorrect side of the line identified by the machine learning classifier. On the other hand, since it is on the right side and far from the boundaries of the appropriate decision, there may be instances that are likely to be well defined. If a group of classifiers performs with a dataset from an undefined source, could we create a relationship among the classifiers' results and correctly detect groups? The concept motivating generalization of Wolpert's is that the results of a classifying ensemble serve as sources to the next meta-classifier at second level with the goal of learning the manner in which the ensemble's findings are related to the correct label instances [113].

Stacking is the term used for Stacked Generalization [113], which is to find the ideal composition of a base learner set. Stacking is an algorithm class that requires training a "meta-learner" second level to find the combination. Stacking aims to combine solid, different sets of learners, unlike bagging and boosting. Besides, ensemble methods such as boosting and bagging are often utilized to construct alike ensembles, while stacking could be utilized to create diverse ensembles.

D. Other Work

New ensemble methods [114] proposed are Net-GR based ANN-Bayesian approach that implies ensemble of Bayesian Net with Gain Ratio (GR) feature selection approach and ANN. They have applied a variety of single classification methods and their proposed ensemble on NSL-KDD and KDD Cup 99 datasets to evaluate for model's robustness. With 29 features which were selected, a 97.78% and 99.38% accuracy detection were achieved when the model was applied to the NSL KDD and KDD Cup 99 datasets to detect intrusions.

A hybrid approach that combines the synthetic minority oversampling technique (SMOTE) and cluster center and nearest neighbor (CANN) was proposed [115]. Significant features were selected by utilizing the leave one out (LOO) approach. In addition, the research utilized the NSL-KDD dataset and the results illustrate that the proposed approach increases the accuracy of the R2L and U2R attacks as opposed to the benchmark paper by 50% and 94%, respectively.

A Hybrid RBF-SVM ensemble classification was proposed by [110] utilizing Support Vector Machine (SVM) and Radial Basis Function (RBF) as base classification. The efficacy and advantages of the proposed model are presented using NSL-KDD datasets, and their finding illustrates that the proposed ensemble RBF-SVM is superior to single-method approaches in terms of accuracy as it achieved 98.46%.

An ensemble-based IDS model was designed using integrated feature selection approach and an ensemble of ML classifiers comprising Bayesian Network, J48, and Naive Bayes [15]. In this model, features are reduced from 41 to 12, and majority vote is used for combing the findings. The true positive rate (TP) of the proposed model is 98.0% with a false-positive rate (FP) of 0.021%.

A hybrid classification approach was proposed to detect and forecast DDoS threats. Using the KDD Cup 99 dataset as attack data, related features were chosen based on information gain. The experimental result revealed that each step of the threat case is well divided, and they can identify DDoS threat precursors as well as the threat itself [116].

A model for Adaptive Ensemble Learning was proposed by [38] by changing the learning data ratio and constructing a MultiTree algorithm which deploys multiple decision trees. To increase detection efficiency, a number of base classifiers are chosen, including Random Forest, decision tree, deep neural network (DNN), KNN, and an adaptive voting algorithm were developed. For the validation part, the NSL-KDD dataset was used, and the MultiTree algorithm accuracy was 84.2%, while the final adaptive voting ensemble accuracy was 85.2%.

A model called SCDNN combines spectral clustering (SC) and DNN algorithms was proposed by [117]. In this model, k subsets were created from the dataset based on the similarity of the sample utilizing cluster centers as in SC. Then, the distance between data points in the training set and the test set was calculated on the basis of features similarity and was applied into the DNN algorithm to detect intrusion. NSL-KDD dataset was used for evaluation benchmark and the overall accuracy was 92.1%.

A framework with feature selection and ensemble method [118] integrates correlation-based feature selection with Bat algorithm (CFS-BA), and an ensemble of Random Forest (RF), C4.5 and Forest by Penalizing Attributes (Forest PA) is developed for the detection model. The evaluation experiments used the CIC-IDS2017, AWID, and NSL-KDD datasets. The results show that this framework has better accuracy than other research work.

A hierarchical ensemble classifier and knowledge-based method was proposed by [119]. In order to determine the specific attack class, it used a weighted voting fusion technique for specific classes to obtain a more accurate classification. The KDD Cup 99 dataset was used to prove the model. This IDS model has more complexity during the learning phase and it consumes more time in contrast to other work.

A Hybrid IDS of One Class Support Vector Machine (OC-SVM) and C5 decision tree classifier [42] was proposed to detect unknown and known intrusion. To the model was evaluated using the ADFA and NSL-KDD datasets. Their finding demonstrated that the hybrid schema has better performance than other models.

An IDS ensemble model of convolutional neural network, Random Forest, and gated recurrent unit (GRU) was proposed by [120]. NSL-KDD dataset was utilized to prove the performance of the model. The detection accuracy was 76.61% with reduced learning time and resource usage than other schema.

An IDS model with combination of ensemble (Random Forest, J48, and Reptree) and CFS algorithm suggested by [121]. Experimented on the KDD Cup 99 and NSLKDD datasets, their finding illustrates that the proposed ensemble has 99.90% for the KDD99 dataset, and 98.60% detection rate for NSLKDD. However, this model could not handle imbalance data.

A stacked ensemble classifier with a combination of gradient boosting machine, XGBoost, and Random Forest [39] was proposed and experimented on CICIDS-2017, CSIC-2010v2, UNSW-NB15, and NSL-KDD. The result shows that the proposed ensemble model has good impact on detection of attack in a Web application.

Table IV introduces a comparative analysis of different ensemble algorithms used in the literature to handle anomaly-based IDS. The table presents a comprehensive review of several ensemble classifications, showing their methods, strength, weakness and the dataset utilized for evaluation. RQ3 and RQ6 are addressed in table.

According to the reviewed articles presented in the table, different combination of classifiers and algorithms were utilized for ensemble detection. An ensemble with diversity of classifier types had significant improvements in detection accuracy and reduces the false alarm for anomaly-based IDS.

Based on the review, NSL-KDD dataset was mostly used to show the efficacy and advantages of the proposed ensemble models. Furthermore, some articles utilized different datasets to highlight their generality of their solutions, like AWID, ISCX 2012, UNSW-NB15, CIC-IDS2017 and CSIC-2010v2.

Based on the analysis of the studied articles in the review, Fig. 4 illustrates that NSL-KDD dataset was mostly utilized to highlight the effectiveness of their anomaly-based IDS models. The KDD Cup 99 dataset came in second as to be used to evaluate their solutions.

TABLE IV. SUMMARY OF THE REVIEWED INTRUSION DETECTION SYSTEM

Author	Method	Strength	Weakness	Dataset
2013 [27]	Unsupervised Artificial Neural Network	Hierarchical Anomaly-based Intrusion Detection System	Overall detection accuracy of 75.49%. No class-based detection.	KDD Cup 99 NSL-KDD
2014 [110]	Support Vector Machine (SVM) And Radial Basis Function (RBF)	They develop a bagging classifier	Overall accuracy was not reasonable. No class-based detection.	NSL-KDD
2015 [47]	Hybrid Artificial Bee Colony Algorithm and Multi-Layer Perceptron	The proposed model has reasonable detection time and Error rate (0.124%)	Overall accuracy was 87.54 % No class-based detection.	NSL-KDD
2015 [15]	Ensemble of Bayesian Network, J48, and Naive Bayes	The overall accuracy and error rate was reasonable	No class-based detection.	NSL-KDD
2016 [115]	Hybrid cluster center and nearest neighbor (CANN) and synthetic minority oversampling technique (SMOTE)	Reasonable detecting R2L and U2R attacks (50% and 94%,)	Not detect the rest of attacks. Not mentioned about time.	NSL-KDD
2016 [26]	Hybrid of Fuzzy C-Means clustering algorithm and Artificial Neural Network	The model was good at finding normal and probe attacks	The results for other attack types did not yield good results even for accuracy and false alarm rate (DOS (99.96–5.33), U2R (96.78–3.22) and R2L (93.73–6.27)	KDD Cup 99
2016 [46]	Hybrid of C4.5 decision tree and the MLP classifier	Use feature selection by utilizing the Discernibility Function and MLP to provide feature subset	Detection rate R2L and U2R attacks were not satisfactory.	KDD Cup 99 ISCX dataset
2016 [28]	ANN-based IDS with back propagation and feed forward algorithms	The overall accuracy was reasonable (98.86%)	No class-based detection.	NSL-KDD
2019 [38]	Ensemble of Decision Tree, Random Forest, KNN, DNN and MultiTree	Detection based on attack class	Class based accuracy was not satisfactory. Performance metric was low.	NSL-KDD
2020 [118]	Feature Selection CFS-BA and an Ensemble of Random Forest (RF), C4.5 and Forest by Penalizing Attributes (Forest PA)	They train and test their framework with different dataset	Detection rate R2L and U2R attacks were not satisfactory.	NSL-KDD AWID CIC-IDS2017
2020 [119]	Hierarchical ensemble classifier and knowledge base method	The class-based accuracy and error rate was reasonable	The IDS model has more complexity during learning phase and it consume more time in contrast to other work.	KDD Cup 99
2020 [42]	Hybrid of One Class Support Vector Machine (OC-SVM) and C5 decision tree classifier	The overall accuracy and error rate was reasonable	No class-based detection.	ADFA NSL-KDD
2020 [120]	Ensemble of Convolutional Neural Network, Random Forest, and Gated Recurrent Unit (GRU)	The model has improvement on reduction of learning time and resource usage	Overall accuracy was not reasonable. No class-based detection.	NSL-KDD
2020 [121]	Combination of Ensemble (Random Forest, J48, and Reptree) and CFS algorithm	The overall accuracy and error rate was reasonable	The model could not handle imbalance data issue.	KDD Cup 99 NSL-KDD
2020 [39]	Ensemble of Gradient Boosting Machine, XGBoost, and Random Forest	The overall accuracy and error rate was reasonable	No class-based detection.	CICIDS-2017 CSIC-2010v2 UNSW-NB15 NSL-KDD

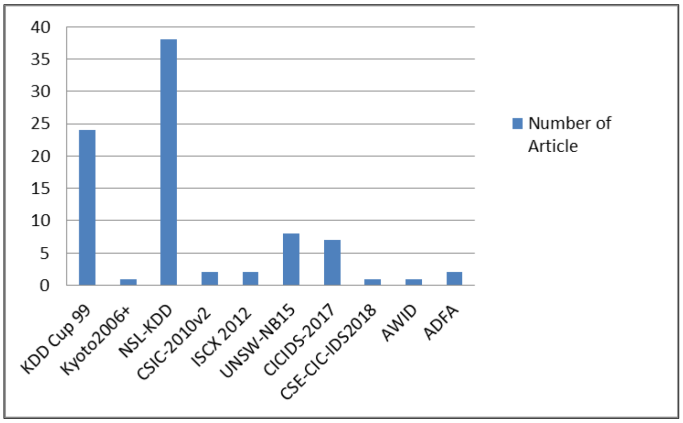

Fig. 4. Number of Datasets in the Reviewed Articles.

1) Limitations of the ensemble classification: After analyzing the data collected from the literature related to ensemble, some limitations and shortcomings of the works are identified and in order to reach maximum diversity with various boundaries of decision, the identified limitation should be considered:

a) Multiple datasets have to be utilized to prove the generality of the ensemble model.

b) In order to handle imbalance data issues in anomaly-based IDS, different types of classifiers have to be deploy in ensemble machine. Therefore, selection of various classifiers and the fusion of their outcomes empower the final result.

VI. Discussion

Upon studying and reviewing the different IDS models, we found challenges that motivate research in utilizing machine learning for feature selection and ensemble techniques in IDS. In this paper, we discuss future trends in anomaly-based IDS, in particular feature selection and ensemble techniques. Some of the critical topics in the existing research with view of future trends are described below:

1) Anomaly-based IDS datasets have a crucial impact on the proposed approaches in terms of performance assessment. To be current, it is necessary to utilized updated datasets to illustrate that the proposed solution works well with new attack types. Although KDD Cup 99 is an old dataset used by most of researchers as benchmark comparisons, the attack packets and even the features are dated 20 years ago. In addition, researchers can deploy their model on different anomaly-based IDS datasets to prove the generality of their model to detect different attacks.

2) Finding the appropriate feature selection schema plays an important role in anomaly-based IDS. Proper selection of feature subset helps expert machine in the learning phase to detect attacks in the testing phase. Optimization-based feature selection aims to acquire an optimal subset of features among all features in different domains. The role of new optimization-based feature selection methods in the success of anomaly-based IDS must be considered.

3) Ensemble-based modern anomaly-based IDS techniques allow multiple combinations of models or algorithms to identify new unseen cases. In the implementation, after a variety of classification models are typically constructed utilizing some portion of datasets, the various classifiers results are merged to form the final conclusion. Various schemes may be suggested for the generation of classifiers and for the combination of the ensembles.

The future trends mentioned above and open issues discussed in anomaly-based intrusion detection system should be considered by researchers in the field of anomaly-based IDS.

VII. Conclusions

Intrusion detection system is a prominent security mechanism designed to prevent intrusion, illicit entry, modification or demolition by intruders. For efficient intrusion detection process vital components like feature selection and detection mechanism have to be considered when designing the model. The article reviews the studies on feature selection and ensemble approaches utilized for anomaly-based intrusion detection systems. We discussed the main challenges in IDS, namely the dimensionality reduction in anomaly-based IDS that reduces irrelevant attributes from dataset; and how to build an appropriate feature subset selection, in order to better detect intrusion by increasing the performance metrics. Consequently, the study categorizes and discusses feature selection methods and presents their performance in detection accuracy. Another important challenge in anomaly-based IDS lies in utilizing suitable machine learning algorithms in the detection process. To illustrate their effectiveness in improving the IDS performance, this paper reviews and categorizes various machine learning schema and discussed their utilization in IDS, giving emphasize on ensemble methods as an emerging trend in anomaly-based IDS. Based on our study on anomaly-based IDS and the assessment and comparison of feature selection and detection module, we can summarize two points about how to boost the performance of anomaly-based IDS as follows:

1) Optimization-based feature selection with excellent combination and well tune up parameters will select the proper feature subset for IDSs. Through this study, it is clear that optimization-based have significant performance to design the optimal feature set. Furthermore, if their parameters are adjusted well, feature selection could be significantly enhanced.

2) Ensemble detection with different types of classification can empower the detection phase and reduce the false alarm rate. If the diversity occurred, a fusion of the outcome has better chance to detect properly.

Finally, we present some open issues and offered research trends, including the datasets used, the role of optimization-based algorithm-ms and ensemble methods, in the area of anomaly-based IDS. We expect that this review paper will furnish scientists with innovative ideas and serve as a springboard for them to undertake better studies. We acknowledge that this article has some limitations due to the scope of the review:

1) This review focused on the feature selection and ensemble detection for anomaly-based IDS.

2) This review does not focus on performance parameter which is utilized at IDS.

3) This article does not study IDS datasets in-depth, like their features, attack types, etc.

Having listed the limitations of the paper, a deep analysis on the following issues can be considered as future work:

1) Other detection methods for anomaly-based IDS, apart from the feature selection and ensemble detection methods that are discussed here, could be studied too, in order to acquire a more holistic understanding of the research area.

2) Extra studies could be performed on performance parameters which are utilized in IDS, and how we can obtain the optimal set of parameters for better detection performance.

3) An in-depth study on IDS datasets could be carried out, such as their features, attack types, etc. to understand the pattern in their attributes that may affect the detection performance.

***Abstract*—This work aims to seek a pragmatic approach to assess electricity consumption at the level of households, buildings and neighborhoods. The main concern consists in proposing aggregation methods based on jump process according to a customer environment that is intrinsically linked to the implementation of a centralized system. The aim of the approach is to present data aggregations that derive their basis from a data model in order to facilitate the processing of electricity data at different scales of analysis. Such a smart meter data management process merits the design of an aggregated database that can store data for a house, a building and a neighborhood. The advantage of this system lies in the facilitation of data interpretation and the ability to guide decision-makers in the management of electricity consumption. An analysis of the behavior of electricity consumption is also proposed based on the monitoring of the electricity consumption of the various devices connected to a smart meter.**

Keywords*—Design; aggregation; analysis; jump process; electricity consumption; smart meter

I. Introduction

The systems for managing data from smart meters remain closed in the way they process data. However, these systems have the merit of presenting detailed output states. This work consists of:

- Analyzing the existing framework in favor of measuring methods for the smart meter in particular.
- Studying and adapting this research work to the documents and output reports made available by data managers of these smart meters.
- Initializing a data model for the management of smart metering data.
- Explaining the treatments of the central system including the various techniques applied and the presentation of data structures for facilitating data aggregation.
- Presenting the aggregation methods implemented using the jump process.

This work follows a previous work [1] related to the design of a multi-agent system for the management of data from smart meters. The advantage of this approach is to deepen the design of the system by providing it with data aggregation methods that would lead to results for the benefit of decision-makers.

In [1], presents a formal framework for storing smart meter data and applying methods for analyzing electricity consumption data. For this, a database model for evaluating the electricity consumption data of a house, a building and a neighborhood is proposed. This work highlights a structured set of measurement data from smart meters. There are many elements to consider for the implementation of a data model [2, 3, 4]. Jaime Lloret and al. propose an integrated architecture based on the Internet of Things (IoT) for the deployment of smart meter networks [2]. This article [3] offers a large number of datasets as well as a web portal for visualizing this data. The work in this publication presents key technological solutions for better data analysis and energy efficiency research. In [4], reviews technologies oriented and adapted to the development of applications for the management of smart meter data. Yi Wang and al. provide insight into the future challenges of descriptive analytics including load analysis, predictive analytics, forecasting and prescriptive analytics for load management [4].

The processing of the data collected is carried out by means of aggregation methods. It is also about presenting data structures that will evolve progressively as needed. This work presents existing studies highlighting the importance of forecasts for a good management of electricity consumption, mainly at the level of end customers [5, 6]. In [5], highlights the need for detailed technical information on the devices used by households in order to measure their impacts on household behavior. Ya Wu and Li Zhang study the factors influencing energy saving in tiered electricity pricing and presents empirical results based on variables such as personal characteristics and living conditions [6].

A survey of studies similar to the approach conducted in this paper help to identify a few cases with different interests from each other. Xiaochen Zhang and al. propose a time-variant load model based on the exploration of a historical database of smart meter data [7]. A relational database management system is set up to leverage information that consumers and utilities can get from smart meters data [8]. The achievement of new energy efficiency services is highlighted by the use of smart meters with smartphones through an infrastructure and a set of algorithms [9]. Ming Dong and al. propose a method to help monitoring energy consumption and identifying individual consumption from large household appliances [10]. Xiufeng Liu and al. [11] propose an innovative ICT solution based on a hybrid architecture, which proves the importance of smart meters in socio-economic surveys and proposes a rational approach to dealing with the complexity of their data. This solution concerns more areas of interest such as geographic locations, weather conditions and user information. Peng Xu and al. propose an ICT solution that aims to highlight the efficiency of smart meters and remote displays through real-time monitoring functions of energy consumption to achieve objectives in environmental and supply security [12]. Juan I. Guerrero and al. provide a method for integrating smart meter data from heterogeneous data sources and modeling the integrated information through an automatic data mining framework [13]. Jinsong Liu and al. [14] present the requirements of the fundamental models for the management of smart metering data and presents a concept of three-mode models as well as the design of the service architecture for accessing to generic models.

The review of work around the evaluation of electricity consumption and its opportunities has made it possible to identify other areas of interest, including studies relating to aggregations, forecasts, evaluation of electrical data and their impacts. There are many approaches of data aggregation that can be temporal, zone and by use. The large volume of these data has also led to the exploration of aggregation methods allowing this data to be represented in other forms while retaining the initial information contained in the raw data [15, 16, 17, 18, 19, 20, 21, 22]. Yi Wang, Qixin Chen and Chongqing Kang provide an overview of research related to the challenges of smart meter data analysis [15]. This work [16] presents a method based on Blockchain and Homomorphic Encryption (HE) technologies to ensure the confidentiality of smart meter data during the data aggregation phase. Mohamed Saleem Haja Nazmudeen and al. aim to adopt the fog computing architecture to reduce the amount of data collected in order to improve the performance of the process applicable to data within the central system [17]. In [18], highlights the need to implement a sub-metering of individual devices in a house to give a better interpretation to the data thanks to a proposed model called the Explicit-Duration Hidden Markov Model (EDHMM-diff). This paper [19] presents a model of data aggregation with fault tolerance, preventing data leakage and demonstrating robustness with negligible cost. Toshichika Shiobara and al. propose a method of reducing the cost of storing and using smart meter data through an aggregation method that reduces the total size of the data and the processing cost [20]. Accurate estimation of the energy [21] requirement forecast based on the amount of load growth and geographic space is carried out based on knowledge of small zone consumption, historical loads and weather conditions. The vector machine algorithm is used for data prediction, classification and analysis using a deep learning approach. Anastasia Ushakova and al. use a set of Gaussian models to aggregate time-series data from smart meters and to understand energy consumption based on the aggregation of data from the target population, particularly by inducing energy-efficient behavior [22].

There are also studies on both long-term and short-term forecasts of electricity demand [23, 24, 25]. In [23], highlights a new method of probabilistic forecasting of electricity demand through a hierarchy with different levels of aggregation such as substations, cities and regions. This study [24] proposes the evaluation of seven algorithms from measurement data collected every fifteen minutes from sensors to predict the electricity consumption of residential buildings in the next hour. This work confirms the best results already obtained from commercial buildings data with methods based on the neural network, unlike the results obtained from residential data. However, the conclusion of this work also shows that the results with the data of residential buildings are better with the Least Squares Support Vector Machines. This article [25] shows the important issue of forecasting electricity consumption by proposing prediction methods based on Short-Term Load Forecast (STLF), the Self-Recurrent Wavelet Neural Network (SRWNN) and the Levenberg–Marquardt (LM) learning algorithm.

Upstream of the aggregation and forecasting of electricity consumption, there is first the need to formalize the data from smart meters in a database model and this is why a set of studies on the evaluation of electricity consumption data from smart meters is presented. The evaluation of electricity data is indeed a major concern and a prerequisite for understanding consumer behavior in order to guarantee energy efficiency at the level of producers, suppliers and customers alike [26, 27, 28, 29]. [26] explores the behavior of electricity customers on the use of heating and cooling. This work also shows the importance of using smart a meter data for understanding a consumer behavior with respect to thermal comfort, particularly in regions where automatic HVAC systems are virtually absent. Ilze Laicane and al. prove the importance of having up-to-date electricity data to determine the profile of households and reduce electricity consumption [27]. This work shows that the energy performance of households depends on the energy efficiency of equipment due to technological progress while highlighting an important part of the change in user behavior in the results observed [27]. In [28], is based on the PROBE and CarbonBuzz initiatives which illustrate that the concept of energy performance for more energy efficiency advocated by the construction industry does not live up to expectations and is biased by taking into account unrealistic factors such as occupancy behavior and facility management relating to the energy models used within these buildings. The study is based on the evaluation of data after occupancy of buildings to establish more realistic energy performance models. In [29], shows the impact of airflow on electricity consumption in computer data centers based on a comparative study of four different cities. Analysis of the cooling periods and energy saving periods yielded results in showing the importance of climatic conditions, energy prices and cooling technologies on cooling efficiency and costs of cooling exploitation.

Likewise, the impacts of the evaluation of smart meter data are numerous [30, 31, 32] and fully participate in encouraging consumers to save energy by identifying different criteria for reducing electricity consumption. This study [30] presents the mistaken motivations of a sample of US grid electricity customers for choosing smart meters and associated technologies in residential homes and discusses the policy implications and risks perceived by customers. Jacopo Torriti shows that the demands of electricity customers using smart meters are 5.2 times lower than those of users of conventional meters using a comparative study carried out on three different floors of the same building in Italy [31]. Gordon Rausser, Wadim Strielkowski and Dalia Streimikien highlight relevant findings for the attention of stakeholders and policymakers on issues to consider in encouraging positive electricity consumption with smart meters [32].

The benefits of analyzing electricity consumption data from smart meters [5, 33, 34, 35, 36, 37] for consumers and for the environment in particular deserve to be highlighted. Iana Vassileva, Fredrik Wallin and Erik Dahlquist focuse on identifying appropriate power saving measures from important data collected and analyzed monthly over a long period from identical buildings [13]. This work consists in defining different behavioral consumption profiles from technical data on electricity consumption, tenant characteristics, energy consumption behaviors as well as type and use of electrical devices [13]. In [33], is a review of the literature that assesses the effectiveness of smart metering in reducing energy consumption while explaining factors related to users behavior. This article [34] is an in-depth analysis of the environmental impacts resulting from the use of smart meters by considering all stages of the life cycle of these meters. In [35], illustrates the importance of electricity consumption data in studying users' consumption patterns in order to classify households according to predefined criteria. This study shows that a priori knowledge of certain criteria such as floor level or number of occupants can improve the accuracy of household classification. In [36], aims to provide industrial consumers with a methodological approach allowing the evaluation and choice of offers from electricity suppliers. The method used is based on characterization of electricity consumption, analysis of tariff offers and forecasts based on energy factors. The results of the study were drawn from the evaluation of fourteen different contracts of electricity suppliers. In [37,] emphasizes the importance of long-term forecasting of electricity demand based on forecasts obtained from multivariate regression analysis of electricity consumption data.

Some works using the jump process among which [38, 39, 40, 41, 42] have been identified. The paper [38] determines the integral transforms of the joint distribution of the first-exit time from an interval and the value of a jump of a process over the boundary at exit time and the joint distribution of the supremum, infimum, and value of the process. Clifford A. Ball and Walter N. Torous show a simplified jump process for common stock returns using the jump process models information arrivals and, as such, stock price jumps [39]. The article [40] explores the use of the Markov jump process to model vehicular mobility at the macroscopic level. Lydia Chabane and al. study the fluctuations of systems modeled by Markov jump processes with periodic generators using large deviation theory; canonical biasing and generalized Doob transform [41]. They show that the asymptotic fluctuations process, called driven process, is the minimum under constraint of the large deviation function for occupation and jumps [41]. Alexander Sikorski and al. present how augmenting the spatial information of the embedded Markov chain by the temporal information of the associated jump times [42]. The approach presented in this work is a very different application of the jump process in a context of electricity consumption management.

II. Principle for the Aggregation Methods of the Smart Metering System

First, it should be noted that the data collection mechanisms both from smart meters and from the customer base make it possible to automatically provide data without duplication and by identifying proven or probable anomalies in the collection process in case of missing data or outliers through business analytics [1].

Data quality assessment should be subject to automated treatments. In addition, the storage of processed data must be possible over periods of time in accordance with the regulations in force in each country.

After data collection, it is necessary to aggregate the raw data as shown in Fig. 1.

- The aggregation of measurement data can be done according to a time step (hourly, daily, monthly, etc.) regardless of any consideration of the zone and use to which the measurements are linked. This temporal aggregation process can be done in the data collection transaction from the smart meters or in a separate transaction from the data collection process. It is sufficient to rely on the arrival date "ARRIVAL_DATE" of each data in the central system for the need of ordering the data of a source [1]. The collection of data from each smart meter requires the storage of the date "LAST_COLLECTION_DATE" of the last measurement data recorded in the source [1]. This mechanism makes it possible to ensure the collection of all data of a smart meter within the source to which it is attached. Several smart meters could also be associated with a single source. However, it is essential for the aggregation mechanism to save in a transaction, the "LAST_AGGREGATION_DATE" parameter for each source data. The "SOURCE" table has therefore been modified by adding the "LAST_AGGREGATION_DATE" field. "LAST_ AGGREGATION_DATE" corresponds to the arrival date in the central system of the last aggregated data for each source. Aggregation is therefore done in order of arrival of data from one or all the smart meters associated with a source as represented in Fig. 2.
- The aggregations are then carried out on the sub-zones of the lowest level towards the sub-zones of the highest level. The aggregation of the data of a bounding zone is conditioned by the aggregation of all its sub-zones.
- Data aggregations are also possible by use. Indeed, the aggregation of an use can be applied to all the measurement data of this use for a given zone.

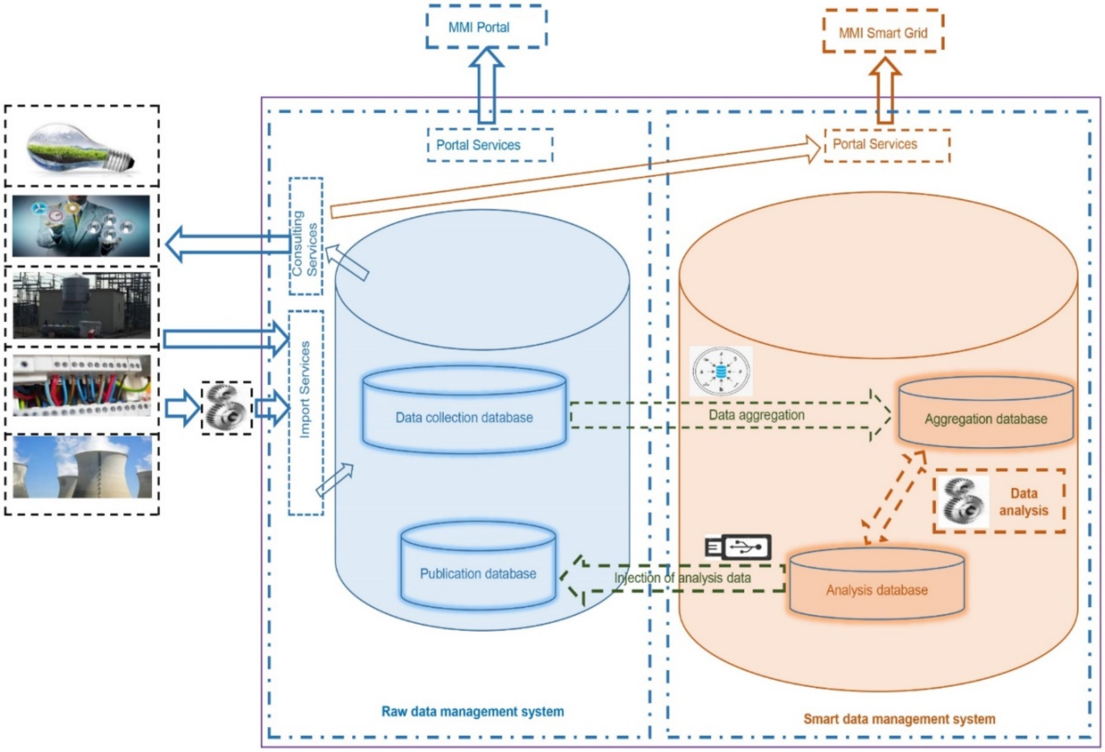

Fig. 1. Functional Architecture of the Electricity System Including Aggregations and Interactions with other Actors in the Electricity Value Chain.

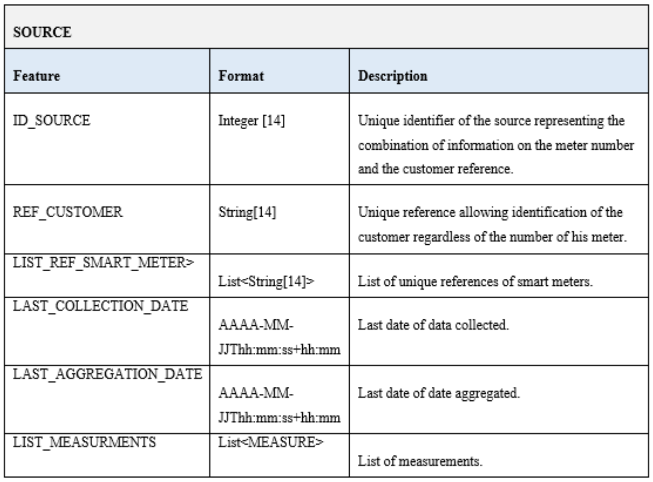
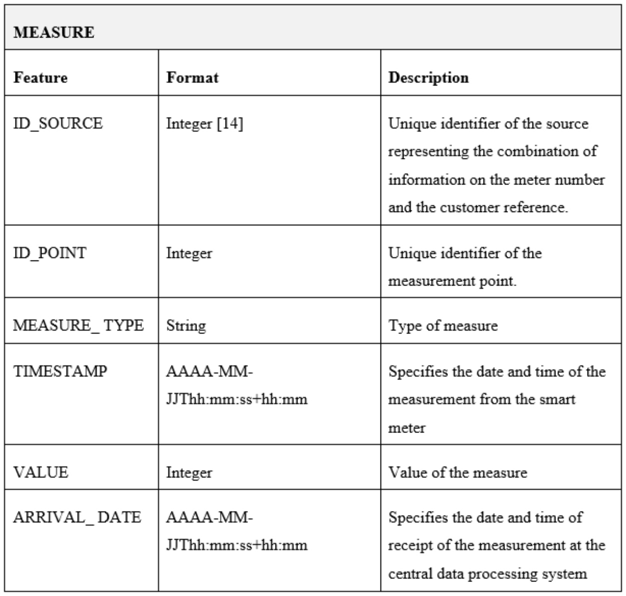


SOURCE		
Feature	**Format**	**Description**
ID_SOURCE	Integer [14]	Unique identifier of the source representing the combination of information on the meter number and the customer reference.
REF_CUSTOMER	String[14]	Unique reference allowing identification of the customer regardless of the number of his meter.
LIST_REF_SMART_METER>	List<String[14]>	List of unique references of smart meters.
LAST_COLLECTION_DATE	AAAA-MM-JJThh:mm:ss+hh:mm	Last date of data collected.
LAST_AGGREGATION_DATE	AAAA-MM-JJThh:mm:ss+hh:mm	Last date of date aggregated.
LIST_MEASURMENTS	List<MEASURE>	List of measurements.

Fig. 2. Representation of a Source.

- It will no longer be possible to integrate data for a validated (procedurally completed) or non-initiated billing period in the aggregated database. This condition helps to limit and avoid the overlap in the collection and aggregation of electricity consumption data over time. This will also make it possible to identify functional and technical irregularities, in particular cases of attempted fraud.

Let's present a view of the measurement data table regardless of its relationship to other entities in the master data model as indicated below in Fig. 3.



MEASURE		
Feature	**Format**	**Description**
ID_SOURCE	Integer [14]	Unique identifier of the source representing the combination of information on the meter number and the customer reference.
ID_POINT	Integer	Unique identifier of the measurement point.
MEASURE_ TYPE	String	Type of measure
TIMESTAMP	AAAA-MM-JJThh:mm:ss+hh:mm	Specifies the date and time of the measurement from the smart meter
VALUE	Integer	Value of the measure
ARRIVAL_ DATE	AAAA-MM-JJThh:mm:ss+hh:mm	Specifies the date and time of receipt of the measurement at the central data processing system

Fig. 3. Representation of the Electricity Consumption of a Measurement.

The analysis of this table highlights the correlation between the volume of data and the time step for collecting the data values for each measurement. The metering data is voluminous and therefore difficult to use.

Reducing complexity involves moving to a more understandable data presentation scale by aggregating data over hourly, daily and monthly ranges. This aggregation consists of the accumulation of consumption data collected over the various intervals for each measurement.

At first glance, collecting the measurements of a house can generate a significant volume of data. The amount of data from a building, or even a neighborhood might be gigantic. Temporal aggregation of data is necessary not only to compress the volume of data but also to facilitate data search, analysis and visualization.

III. Modelization of the Temporal, Zone and use Aggregations of the Data for the Smart Metering System using the Jump Process

A. *Fundamental Principle of Modelizing the System Aggregations by the Jump Process*

The jump process can be used to model the data aggregation of the smart metering system. Indeed, consumption data are recorded at successive and regular times. In addition, the current state of a smart meter is independent of the previous state at each time step of the arrival of electricity consumption data. The jump process thus models the data aggregations as follows:

1) Calculation of the electricity consumption of a smart meter at a time $\boldsymbol{t}$

$Z_t = \sum_{n=1}^{\infty} X_n \mathbb{1}_{[T_{n-1},T_n[}(\mathrm{t})$, electricity consumption at time t.

n the number of data records.

X_n electricity consumption between T_{n-1} and T_n at time t .

$\forall n, 0 = t_1 < t_2 \ldots < t_n$.

$\forall n$, $X_{t_{n-1}}$ and X_{t_n} are independent.

$$\mathbb{1}_A(t) = \begin{cases} 1\ if\ t \in A \\ 0\ otherwise \end{cases}$$

$T_n - T_{n-1} = H$, H being the consumption data recording time step for a given meter. In the case of the jump process $T_{n-1} - T_n$ may not be constant unlike the special case of smart meters.

2) Calculation of the cumulative electricity consumption of a smart meter so far $\boldsymbol{t}$

$$Y_t = \sum\nolimits_{n=1}^{\infty} X_n \mathbb{1}_{T_n < t}$$

Y_t , the total electricity consumption up to time t.

Y_t is a jump process, X_n being the different values of the smart metering system.

B. *Temporal Aggregation of the Measurement*

1) Case of temporal aggregation of data from smart meters.

a) Temporal aggregation of data from a set of smart meters in the metering system at time t.

Let k be the index of any smart meter and Z_t^k be the electricity consumption at time t.

$Z_t^k = \sum_{n=1}^{\infty} X_n^k \mathbb{1}_{[T_{n-1}^k,T_n^k[}$ (t) , X_n^k being the electricity consumption of the smart meter k between T_{n-1}^k and T_n^k at time t.

Let N be the number of smart meters in the metering system and S_N be the total electricity consumption for all these meters at time t.

$S_N = \sum_{k=1}^{N} Z_t^k$ represents the data aggregation for all N smart meters at time t.

b) Temporal aggregation of data from a set of smart meters in the metering system up to the instant $\boldsymbol{t}$.

Let k be the index of any smart meter and Y_t^k be the total electricity consumption up to time t.

$$Y_t^k = \sum\nolimits_{n=1}^{\infty} X_n^k \mathbb{1}_{T_n^k < t}$$

Let N be the number of smart meters in the metering system and R_N be the total electricity consumption for all of these meters at time t.

$R_N = \sum_{k=1}^{N} Y_t^k$ represents the aggregation of data from all N smart meters up to the moment t.

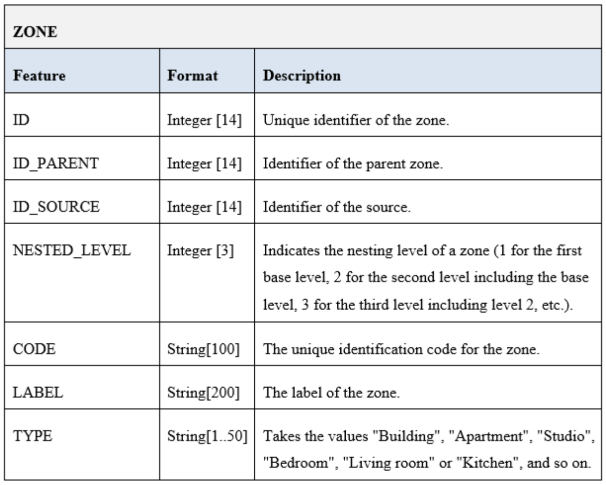
C. *Aggregation by Zone of Measurements*

This section is devoted to data aggregations in relation to zones. This step assumes that the temporal aggregations of the measurement data have already been carried out for a specific time step.

The basic data model does not allow a zone aggregation. For that, the notion of zone is necessary. The zone being a space in which one or more measurements can be counted. A zone is attached to a meter that also makes it possible to determine the customer.

It is also necessary to define the notion of parent zone. This notion is essential in the implementation of a neighborhood data model. It is also possible to locate a zone by its geographic coordinates. The difference between a zone of a residence and that of a neighborhood is made by adding the notion of parent zone for a neighborhood. Indeed, the basic data model is suitable for evaluating the power consumption of a residential zone (house, apartment, building, district, etc.).

The "ZONE" table takes into account the characteristics of a building and a district and is presented as follows in Fig. 4:



ZONE		
Feature	**Format**	**Description**
ID	Integer [14]	Unique identifier of the zone.
ID_PARENT	Integer [14]	Identifier of the parent zone.
ID_SOURCE	Integer [14]	Identifier of the source.
NESTED_LEVEL	Integer [3]	Indicates the nesting level of a zone (1 for the first base level, 2 for the second level including the base level, 3 for the third level including level 2, etc.).
CODE	String[100]	The unique identification code for the zone.
LABEL	String[200]	The label of the zone.
TYPE	String[1..50]	Takes the values "Building", "Apartment", "Studio", "Bedroom", "Living room" or "Kitchen", and so on.

Fig. 4. Representation of a Zone.

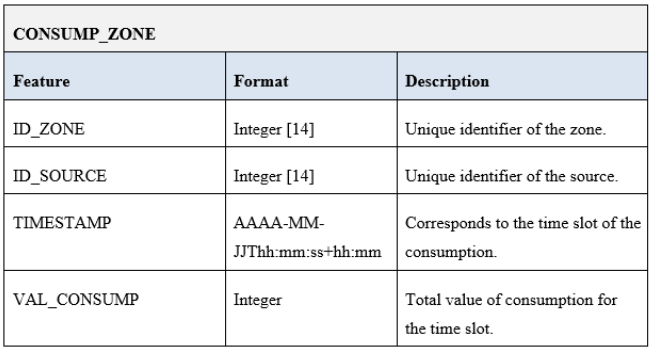
In evaluating the consumption of a building, it is necessary to cumulate the consumption of all the zones of that building. All of the building zones are made up of building zones that do not have a parent zone. Indeed, these zones already take into account the sub-zones, which compose them.

Similarly, the consumption of a district is determined by the cumulative consumption of all the zones of this district that do not have a parent zone (level 0 zone) then come the zones with only one parent (level 1 zone) And so on.

The notion of the “SOURCE” table is also essential for the transition from the basic data model to the district data model.

1) Presentation of zone aggregation structures: Below is the presentation of the “CONSUMP_ZONE” table as shown in Fig. 5. Calculating the consumption of all the zones will facilitate the restitution of the consumption of a building or even a district. Indeed, a building and a district can be considered as a set of independent or combined zones through which the measurements are distributed.

The identifier "ID_SOURCE" has been added to the table "CONSUMP_ZONE" to both take into account the size of the building and the district but also to avoid duplicating zones with the same identifiers and belonging to different sources.



CONSUMP_ZONE		
Feature	**Format**	**Description**
ID_ZONE	Integer [14]	Unique identifier of the zone.
ID_SOURCE	Integer [14]	Unique identifier of the source.
TIMESTAMP	AAAA-MM-JJThh:mm:ss+hh:mm	Corresponds to the time slot of the consumption.
VAL_CONSUMP	Integer	Total value of consumption for the time slot.

Fig. 5. Representation of Total Electricity Consumption over a Slot Time for a Zone.

2) Case of data aggregation by zone from smart meters.

a) Aggregation by zone of data from a set of smart meters in the metering system at the instant $\boldsymbol{t}$

Let k be the index of any smart meter and $Z_t^k(i)$ the electricity consumption at time t in zone i .

$Z_t^k(i) = \sum_{n=1}^{\infty} X_n^k(i)\,\mathbb{1}_{[T_{n-1}^k, T_n^k[}$ (t) , $X_n^k(i)$ being the electricity consumption of the smart meter k between T_{n-1}^k and T_n^k at time t in zone i.

Let N be the number of smart meters in the metering system and $S_N(i)$ the total electricity consumption for all these meters at time t in zone i.

$S_N(i) = \sum_{k=1}^{N} Z_t^k\,(i)$ represents the aggregation of data for all N smart meters at time t in zone i.

b) Aggregation by zone of data from a set of smart meters in the metering system up to time $\boldsymbol{t}$**.**

Let k be the index of any smart meter and $Y_t^k(i)$ the total electricity consumption up to time t in zone i.

$$Y_t^k(i) = \sum_{n=1}^{\infty} X_n^k(i)\,\mathbb{1}_{T_n^k < t}$$

Let N be the number of smart meters in the metering system and $R_N(i)$ the total electricity consumption for all of these meters at time t in zone i.

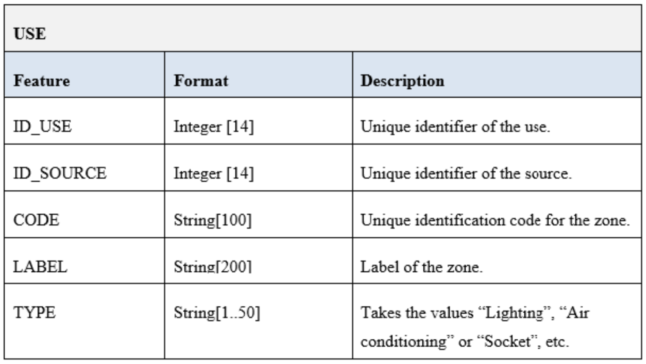
$R_N(i) = \sum_{k=1}^{N} Y_t^k(i)$ represents the aggregation of data from all N smart meters up to time t in zone i.

D. Aggregation by use of Measurements

In this section, the presentation of aggregations in relation to uses is highlighted. These aggregations are limited in space as they are attached to a zone, which can be a building or even a neighborhood. Indeed a district can be described as a set of nested zones or not.

1) Presentation of aggregation structures for an use; Measurement data can be matched to uses. Indeed, the consumption data from each measurement comes from a well-defined type of measure (lighting, air conditioning, a socket, etc).

Each source has a set of uses associated with it as displayed in Fig. 6. The “USE” table therefore takes a reference to the “SOURCE” table.

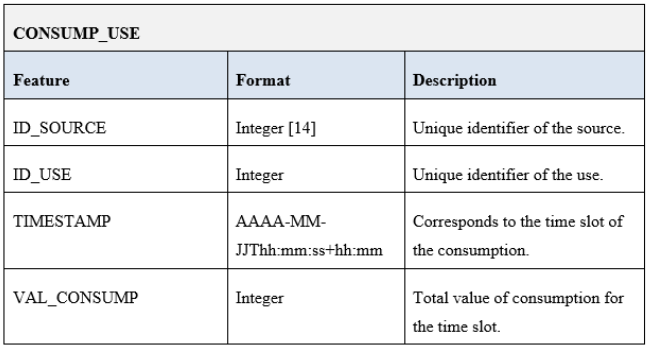


USE		
Feature	**Format**	**Description**
ID_USE	Integer [14]	Unique identifier of the use.
ID_SOURCE	Integer [14]	Unique identifier of the source.
CODE	String[100]	Unique identification code for the zone.
LABEL	String[200]	Label of the zone.
TYPE	String[1..50]	Takes the values “Lighting”, “Air conditioning” or “Socket”, etc.

Fig. 6. Representation for an use of Electricity.

Each measurement is associated with an use. A reference to the "SOURCE" table has therefore been added to the "USE" table, which makes it possible to identify the use for all measurements.

The use information is only define at the source level but not at the smart meter level. Aggregation by use for a building or a district requires the information of the field "ID_SOURCE at the level of the "USE" table to link each measurement to its source of correspondence as observed in Fig. 7. The "ID_SOURCE" field also makes it possible to resolve conflicts in the case of identical identifiers of measurements belonging to different sources.



CONSUMP_USE		
Feature	**Format**	**Description**
ID_SOURCE	Integer [14]	Unique identifier of the source.
ID_USE	Integer	Unique identifier of the use.
TIMESTAMP	AAAA-MM-JJThh:mm:ss+hh:mm	Corresponds to the time slot of the consumption.
VAL_CONSUMP	Integer	Total value of consumption for the time slot.

Fig. 7. Representation of Total Electricity Consumption over a Slot Time for an use.

2) Case of data aggregation by use from smart meters.

a) Aggregation by use of the data of a set of smart meters in the metering system at time t.

Let k be the index of any smart meter and $Z_t^k(j)$ the electricity consumption at time t for use j.

$Z_t^k(j) = \sum_{n=1}^{\infty} X_n^k(j)\,\mathbb{1}_{[T_{n-1}^k, T_n^k[}$ (t) , $X_n^k(j)$ being the electricity consumption of the smart meter k between T_{n-1}^k and T_n^k at time t for use j.

Let N be the number of smart meters in the metering system and $S_N(j)$ the total electricity consumption for all of these meters at time t for use.

$S_N(j) = \sum_{k=1}^{N} Z_t^k\,(j)$ represents the data aggregation of all N smart meters at time t for use j.

b) Aggregation by use of the data of a set of smart meters in the metering system up to time $\boldsymbol{t}$.

Let k be the index of any smart meter and $Y_t^k(j)$ the total electricity consumption up to time t for use j.

$$Y_t^k(j) = \sum_{n=1}^{\infty} X_n^k(j)\,\mathbb{1}_{T_n^k < t}$$

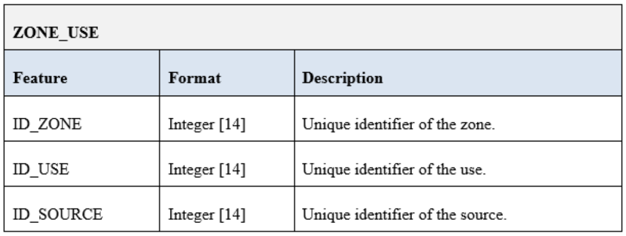
Let N be the number of smart meters in the metering system and $R_N(j)$ the total electricity consumption for all of these meters at time t for use j.

$R_N(j) = \sum_{k=1}^{N} Y_t^k(j)$ represents the aggregation of data from all N smart meters up to time t for use j.

E. Aggregation by Zone and by use of the Measurements

A set of uses constitute the link between a zone and its measurement data. For this purpose, the definition of the ZONE_USE table is necessary. This table contains the references of all uses and measurements attached to each zone.

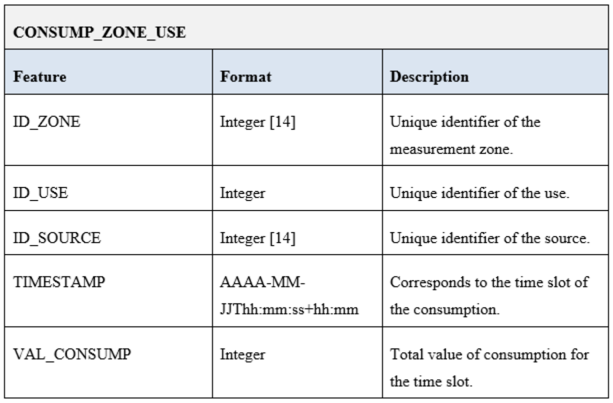
1) Presentation of aggregation structures for a zone and an use: In a zone containing sub-zones, it is necessary to group together all the uses according to the types of uses and sub-zones. This will make it possible to present the consumption of uses for a given zone as a whole but also to highlight the detail of the consumption of uses for a given zone according to its sub-zones. Fig. 8 shows the link between a zone and an use.



ZONE_USE		
Feature	**Format**	**Description**
ID_ZONE	Integer [14]	Unique identifier of the zone.
ID_USE	Integer [14]	Unique identifier of the use.
ID_SOURCE	Integer [14]	Unique identifier of the source.

Fig. 8. Representation of the Relationship for a Zone according to an Electricity use.

Fig. 9 is a view of the table containing consumption by zone and by use:



CONSUMP_ZONE_USE		
Feature	**Format**	**Description**
ID_ZONE	Integer [14]	Unique identifier of the measurement zone.
ID_USE	Integer	Unique identifier of the use.
ID_SOURCE	Integer [14]	Unique identifier of the source.
TIMESTAMP	AAAA-MM-JJThh:mm:ss+hh:mm	Corresponds to the time slot of the consumption.
VAL_CONSUMP	Integer	Total value of consumption for the time slot.

Fig. 9. Representation of the Relationship of Total Electricity Consumption over a Period for a Zone according to an Electricity use.

2) Case of data aggregation by zone and by use.

a) Aggregation by zone and by use of the data of a set of smart meters in the metering system at time t.

Let k be the index of any smart meter and $Z_t^k(i,j)$ the electricity consumption at time t in zone i and for use j.

$Z_t^k(i,j) = \sum_{n=1}^{\infty} X_n^k(i,j)\,\mathbb{1}_{[T_{n-1}^k, T_n^k[}$ (t) , $X_n^k(j)$ being the electricity consumption of the smart meter k between T_{n-1}^k and T_n^k at time t in zone i and for use j.

Let N be the number of smart meters in the metering system and $S_N(i,j)$ the total electricity consumption for all of these meters at time t in zone i and for use j.

$S_N(i,j) = \sum_{k=1}^{N} Z_t^k\,(i,j)$ represents the aggregation of data from all N smart meters at time t in zone i and for use j.

b) Aggregation by zone and by use of data from a set of smart meters in the metering system up to time t.

Let k be the index of any smart meter and $Y_t^k(i,j)$ the total electricity consumption up to time t in zone i and for use j.

$$Y_t^k(i,j) = \sum_{n=1}^{\infty} X_n^k(i,j)\,\mathbb{1}_{T_n^k < t}$$

Let N be the number of smart meters in the metering system and $R_N(j)$ the total electricity consumption for all of these meters at time t in zone i and for use j.

$R_N(i,j) = \sum_{k=1}^{N} Y_t^k(i,j)$ represents the aggregation of data from all N smart meters up to time t in zone i and for use j.

IV. Analysis of user Consumption Behavior

This section focuses on the analysis of the behavior of electricity consumption by users. To do this, A study is carried out on the effects of consumer's daily actions on the use of each device connected to its smart meter.

Let M be the number of devices connected to a given smart meter with index k. Then consider l the index of any device connected to this smart meter k.

Let T_l^n be the duration of consumption for device l in the interval $[T_{n-1}, T_n[$ and let C_l be the consumption per unit of time for this device.

The consumption of the device l in the interval $[T_{n-1}, T_n[$ can then be represented by $\mathrm{C}_l^n = \mathrm{C}_l \times T_l^n$.

The duration of consumption T_l^n is random because the interval $[T_{n-1}, T_n[$ may or may not occur, which makes it possible to deduce that T_l^n therefore follows a continuous law. In addition, the duration which separates two consecutive realizations in a series of independent realizations is modeled by an exponential law of parameter θ. T_l^n is therefore an exponential variable.

The consumption of electricity between T_{n-1} and T_n is independent of the consumption before T_{n-1} and that after T_n.

The duration between any two realizations in a series of independent realizations follows a gamma law with parameter (a, θ), a designates the number of intervals between the first realization and the last realization; and θ denotes the average number of realizations per unit of time. θ is estimated over time by following the consumption history linked to a smart meter.

If the duration of consumption T_l^n is performed only once in the interval $[T_{n-1}, T_n[$, this duration of consumption T_l^n follows an exponential law.

If the duration of consumption T_l^n is carried out several times in the interval $[T_{n-1}, T_n[$, T_l^n follows a gamma law.

$\mathrm{X}_n^k = \sum_{l=1}^{M} C_l^{n,k} = \sum_{l=1}^{M} C_l^k \times T_l^n$ with $C_l^{n,k}$ the consumption read by the meter k for the device l in the interval $[T_{n-1}, T_n[$ [and C_l^k the consumption per unit of time for the device l relatively to the characteristics of the smart meter k.

V. Discussion

The present work is part of an approach to design a formal framework for storing data from smart meters. This study also aims to present an approach for resizing large data from smart meters in order to facilitate their use. Likewise, the processing methods applied to data are presented.

This work shows the importance of data aggregation in the management of smart meters data and proposes a method of aggregating this data, based on the jump process. In addition, the storage structures for raw data and aggregated data are described as well as the mechanisms for recording and updating this data. An analysis of the behavior of electricity consumption is also carried out based on the actions of electricity consumers and the characteristics of the various electrical devices connected to their smart meters.

The research carried out did not make it possible to identify similar work on the aggregation of data from smart meters, on an attempt to present the structures of their databases and even less on the details of the processing applied to their data. It is indeed all these reasons that motivated and led to the completion of this work. This publication aims to promote an understanding of how smart meters work and to provide a basis for further research.

However, there is a great deal of research on the analysis of the behavior inherent in the consumption of electricity from data compiled by existing systems [8, 43]. The publication [8] provides an overview on algorithms and applications applicable to smart meter data. The article [43] shows that the individual predictability of user consumption can be determined with a high degree through time models of energy demand analysis. Likewise, the analysis of electricity consumption in the present publication is distinct from those encountered in similar studies including [8, 10, 12]. It is indeed atypical and is based on the determination of the mathematical law likely to explain the phenomenon of electricity consumption.

It is therefore necessary to underline that the work carried out within the framework of this publication covers several aspects of smart meters data management and provides contributions that can be explored in future publications.

VI. Conclusion

This work made it possible to define the framework for using data from smart meters. It was used to design a data model based on a comparative study of the functionalities of smart meters. The specificity of the data in a metering system has led to the implementation of data aggregation methods to facilitate data processing and analysis. The complexity of the data management of smart metering systems is highlighted by the proposal for a comprehensive approach that includes a concrete case of implementation.

The limitations of this work lie in the lack of an implementation of the metering system. Likewise, this does not make it possible to test the performance of the various algorithms put in place. However, issues relating to the implementation of an intelligent metering system as well as that of data processing are presented. The proposed design makes it possible to process the data collected at the level of a house and a neighborhood.

The originality of this work lies in the presentation of a mechanism for processing centralized data from smart meters, the aggregation of this data by the jump process and the determination of the law determining the behavior of the users on electricity consumption.

The lack of information on smart metering systems makes any comparative study difficult. Indeed, the implementation of these systems remains closed even if the functionalities are well known to the users. The future work will address the issues of factors influencing electricity consumption such as weather conditions, communication, billing, data correction and incident management on smart meters.

Assessing Data Sharing's Model Fitness Towards Open Data by using Pooled CFA

Siti Nur’asyiqin Ismael[1], Othman Mohd[2], Yahaya Abd Rahim[3]
Faculty of Information and Communication Technology
UTeM, Melaka, Malaysia

***Abstract*—This study demonstrates the step-by-step procedure to perform Pooled Confirmatory Factor Analysis (CFA) in the measurement part of Structural Equation Modelling (SEM). CFA is crucial for the SEM measurement model to obtain the acceptable model fit before modeling the structural model. There are two techniques in CFA; individual CFA and Pooled-CFA. Usually, Pooled-CFA is done due to the high number of constructs and items. If the model is too complicated and has so many constructs and items, then it is recommended to perform Pooled-CFA to simplify the model's looks yet easy to understand. The perception of Malaysia Technical University Network (MTUN) academics on data sharing towards open data was analysed by using pooled-CFA. There are three main constructs: data sharing with its 4 sub-constructs; (technological factor, organizational factor, environmental factor, and individual factor), mediator construct (open data licenses), and open data construct was analyzed in this research. Furthermore, second-order constructs' factor loadings towards their corresponding sub-constructs were investigated. This research collected the primary data of 442 respondents using a stratified random sampling technique. This paper will explain the theoretical framework before revealing the results of Pooled-CFA on data sharing towards open data.**

***Keywords*—Pooled CFA; data sharing; open data; measurement model; validity**

I. Introduction

Open data initiatives have become ubiquitous in every country. According to [1], Malaysia has embarked on the open government data framework by The Malaysian Administrative Modernisation and Management Planning Unit (MAMPU) in the year 2015. The initiative is then leveraged to be implemented at the ministries' and agencies' levels. It seems crucial to have an open data framework within the higher education environment as [2] has mentioned that the higher institutions play a significant role and are among the most significant contributors that support the citizen's needs in the education world. In the meantime, [3] has stated that the data producer is reluctant to share data might because it possesses challenges at many levels such as cultural, ethical, financial, and technical. Adding to these challenges, [4] has highlighted that the reluctance of data sharing perhaps due to disinterest from the universities. Thus, this study employs quantitative techniques; survey to Malaysia Technical University Network (MTUN) academics. There were 442 feedbacks received and there was a need to perform Confirmatory Factor Analysis (CFA) to confirm the factor that influence MTUN academics on data sharing.

This research aims to identify the factor influence MTUN academics on data sharing and analysing the open data license, which will act as a mediator between data sharing and open data. This paper will explain in details the theoretical framework developed for this research, the component in structural equation modeling (SEM), the determination of sample size, the fitness indexes of technological, organizational, environmental, and individual construct that determine data sharing and how the procedure of pooled-CFA is done. The reliability and validity indexes also will be measured to indicate the acceptance state.

II. Literature Review

Open data might change the relationship between the government and the public in terms of transparency [5]. This intention can be perceived by accessing the government's data through an open format datasets form. Furthermore, [6] has emphasized that open data enactment will address the existing legal challenges. The challenges include the scope of accessing the data and data ownership.

Since open data has been announced, it has created a sensation worldwide. In [7], the statement is supported by highlighting the potential of open data to improve organization services to the public. Besides that, citizen participation is encouraged in open data towards having a transparent government. As in [8], the approach to embark on open data will be different as every country has a different governance structure, and the organization has its policies regarding open data.

Ministry of Education Malaysia (MOE) has specified that Malaysia's Higher Education Institutions (HEIs) are categorized as Public Universities, Private Higher Educational Institutions, Polytechnics, and Community Colleges [9]. As for this research's scope, MTUN universities include 4 public universities (UMP, UTEM, UTHM, and UNIMAP) where it focuses on the Technical and Vocational Education and Training (TVET) approaches.

In Malaysia, according to [9], 12 National Key Economic Areas (NKEA) have been identified under the government's Economic Transformation Programme (ETP). In [10], it is highlighted that the programme has demanded an additional 1.3 million TVET workers by 2020. This demand has strengthened the need to have MTUN open data framework as this initiative will help the potential worker make an informed decision from the data shared.

As in [11], the open data demand keeps growing in public universities. The demand ensues due to the open data capabilities of removing the barriers to reuse and redistributing the data. On the other hand, it will help the public to make informed decisions. As the results in [2], the economy's deception can be reduced, and universities' accountability can be expected while embarking on open data. To conclude, the data shared are valuable in creating innovations towards having a better university in the future.

This research endeavors to develop an open data framework for MTUN academics. Before that, the factors that influence data sharing, the roles of open data license as a mediator, and the indexes of open data components are measured. This paper will explain in detail the results of factors that influence data sharing towards open data by running pooled-CFA.

III. Theoretical Framework

This study integrates the technological, organizational, and environmental (TOE) framework with the Theory of Planned Behavior (TPB) to determine factors that influence data sharing. According to [12], The TOE framework is an organization-level theory that explains organization structures from 3 perspectives. These 3 perspectives are technological, organizational, and environmental. These contexts were adopted and integrate with TPB theory that examines individuals' perspectives and were analysed as the factors that contribute to the data sharing.

The TPB theory has been useful and considered one of the most influential models in predicting social behaviors [13], [14]. The TOE framework and TPB theory integration were used to develop the MTUN open data theoretical framework as Fig. 1.

Fig. 1 shows how the technological, organizational, and environmental sub-constructs are derived from the TOE framework. Whereby the individual sub construct is derived from TPB theory. From the framework, it can be seen that all of these 4 sub-constructs (technological, organizational, environmental, and individual) are the factors that contribute to the data sharing construct. The open data licenses (ODL) will act as the mediator between data sharing and open data (MTUN_OD). This paper will explain how the pooled-CFA is conducted and how the constructs and items were analyzed by using IBM SPSS AMOS software (version 2.4).

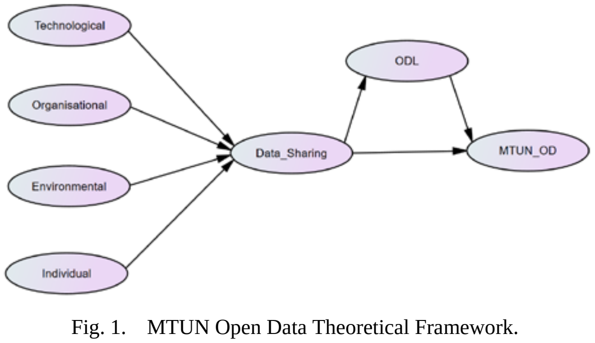

Fig. 1. MTUN Open Data Theoretical Framework.

IV. Structural Equation Modelling

Structural equation modeling (SEM) is a powerful, multivariate technique that has been used widely in scientific investigations to assess and evaluate multivariate causal relationships. According to [15], [16], sometimes, it is also called a statistical methodology where the confirmatory approach is used to analyse the structural theory.

There are 2 main components in SEM: measurement and structural models. These 2 components are used to examine variables in different ways. The measurement model section will relate the measured variables to the latent variables. On the other hand, the structural model section relates the latent variables to one another. SEM combines 2 statistical methods; confirmatory factor analysis (CFA) and path analysis. There are 2 CFA techniques: Individual CFA and Pooled-CFA. This paper focused on the SEM measurement model, assessed through the CFA.

The first step to run pooled-CFA was having to perform the individual CFA for each construct. In [17], [18] has mentioned that the second-order construct was validated using the CFA procedure separately before it’s been simplified into first-order constructs to reduce the model's complexity. As [19] suggested, the pooled-CFA for all constructs was important to perform to assess the discriminant validity among the model's constructs. Thus, this study analyzed the feedback from the MTUN academics survey of data sharing towards open data.

There was 1 main construct (second-order construct) involved in this study: data sharing with its sub-constructs: technological factor, organizational factor, environmental factor, and individual factor. According to [20], that second-order CFA is employed in this study as it involved the assessment of a second-order variable's factor loadings towards its corresponding sub-constructs. By running a second-order CFA, the relationships of data sharing towards its sub-constructs were examined as well. The ODL construct and MTUN_OD construct were identified as first-order constructs as they do not have the sub-construct and was analyzed directly without the need to simplifying it anymore.

V. Material and Method

A. Preface

This study's population target covers MTUN academics from various educational backgrounds and working experiences. Based on [21], the total population of MTUN academics in 2018 was 3818. According to [22], as Table I, the sample needed for this study was 351 for the population of 4000.

As per shown in Table I, the population sample obtained was 442, which was higher than the number of samples required. A total of 442 respondents were chosen randomly. The comprehensive questionnaire for the field study was constructed which was derived from an exploratory factor analysis (EFA). The EFA was executed by using IBM SPSS software. The data collection for the field study is done by distributing the questionnaire to MTUN academics using a stratified random sampling technique.

TABLE I. DETERMINING SAMPLE SIZE FOR A FINITE POPULATION

IBM statistical package for social science (SPSS) and IBM SPSS analysis of moment structures (AMOS) version 24.0 were used to build and analyze the model in this study.

B. *Confirmatory Factor Analysis*

Confirmatory factor analysis (CFA) is a method of factor analysis, most commonly used in social research. It is usually used to examine the consistency of a construct with a researcher's understanding of that construct's factor. CFA's objective is to examine whether the data fit a hypothesized measurement model. This hypothesized model is based on theory or previous analytic research. In CFA, several things need to be tested: reliability, validity, and unidimensionality of the measurement model. The results must meet the stated requirement before modeling the structural model. According to [18], [23], the theorized model must pass 3 types of validities: Construct Validity, Convergent Validity, and Discriminant Validity. The details of validity and reliability indexes are shown in Table II.

Table II shows the validity and reliability test that need to be passed. The construct validity is assessed through the fitness indexes of the measurement model. The convergent validity is assessed by computing the Average Variance Extracted (AVE). The Discriminant Validity is evaluated by developing the Discriminant Validity Index Summary.

Adding to this, several fitness indexes need to be examined as well to evaluate the model fitness. Absolute fit, incremental fit, and parsimonious fit are three types of model fit categories. Below are the fitness of indexes as shown in Table III.

As shown in Table III, [24] has mentioned that the names of indexes that are frequently reported in many research are Root Mean Square Error Approx (RMSEA), Comparative Fit Index (CFI), and Chi-square/degrees of freedom (Chisq/df).

C. *Discriminant Validity*

The discriminant validity needs to be assessed to ensure no construct redundancy occurs in the model. Construct redundancy might occur when any pair of constructs in the model are highly correlated. This redundancy also can happen when one or more constructs assess the same variable. In other words, discriminant validity tests whether the concepts of measurements that are not supposed to be related are unrelated. According to [24], if the redundancy occurs, that particular redundant items in a model need to be deleted. The deletion should start from the lowest value of factor loading until the model is fit.

Besides that, correlation coefficients are used to measure the strength of the relationship between 2 variables. As mentioned in [25], it is also acted as evidence of discriminant validity. A correlation between variables indicates that if one variable changes in value, the other variable tends to change in a specific direction. The variables should not be highly correlated to each other, or else the multi-collinearity problem will exist. Besides, [24] has highlighted that the correlation value among the exogenous variables should not exceed 0.85 to achieve the variables' discriminant validity.

D. *Summary*

There are 2 techniques of CFA in SEM's measurement model: Individual CFA and Pooled-CFA. Individual CFA runs each unobserved construct in the research individually; whereas Pooled-CFA runs all construct simultaneously [26]. Before performing Pooled-CFA, the individual CFA for all constructs need to be done separately. The results must achieve the indexes' fitness as Table II and Table III to make them reliable and validated. The AVE's results were recalculated to get the mean score and were used in Pooled-CFA.

TABLE II. VALIDITY AND RELIABILITY INDEXES

Name of Category	**Name of Index**	**Level of Acceptance**	**Literature**
Convergent Validity	Average Variance Extracted	AVE ≥ 0.5	Zainudin (2015)
Internal Reliability	Cronbach Alpha	A ≥ 0.5	Zainudin (2015)
Construct Reliability	Composite Reliability	CR ≥ 0.6	Zainudin (2015)

TABLE III. FITNESS OF INDEXES

Name of category	**Name of index**	**Level of acceptance**
Absolute Fit Index	RMSEA	RMSEA < 0.1
	GFI	GFI > 0.90
Incremental Fit Index	AGFI	AGFI > 0.90
	CFI	CFI > 0.90
	TLI	TLI > 0.90
	NFI	NFI > 0.90
Parsimonious Fit Index	Chi-sq/df	Chi-Square/ df < 5.0

VI. Results and Discussions

A. Individual CFA

The analysis started with performing Individual CFA. It ran the latent construct one after another to achieve the required model fitness. The CFA can only be performed if the constructs have more than 3 items with no model identification problem. Fig. 2 shows that all these 4 constructs (technological, organizational, environmental, and individual) have met the initial requirement to run CFA. All of the constructs must achieve the fitness indexes required.

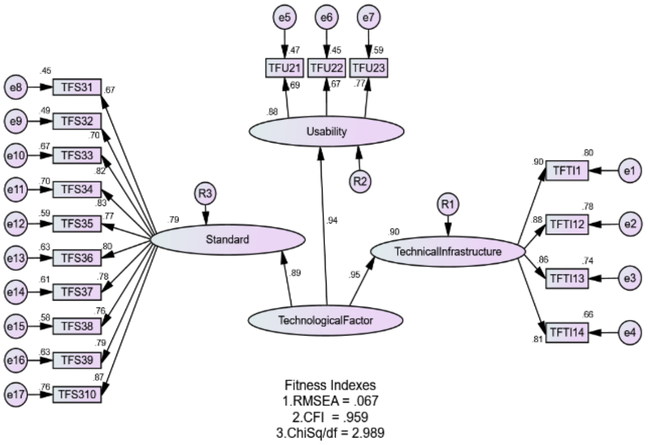

Fig. 2. The CFA Results for Technological Factor Construct.

Fig. 2 shows that the technological factor construct has 3 components; technical infrastructure (4 items), usability (3 items), and standard (10 items). The model fitness of the technological factor construct was overall met the fitness indexes. The value for RMSEA shown was .067, the CFI was .959, and Chisq/df was 2.989.

For the Convergent Validity (CV) assessment, the study needs to calculate the AVE. According to [19], [26], the construct achieved the CV if its AVE exceeds the threshold value of 0.5. Besides in [24], there was a need to compute the CR, and the value should exceed the threshold value of 0.6 for this reliability to achieve. The AVE and CR for the primary constructs and their respective components were computed and presented in Table IV.

Table IV shows that each item's factor loading was high, which above 0.6. The CR value for the technological factor was 0.948, and AVE was 0.859. Meanwhile, the CR value for technical infrastructure was 0.921 and AVE was 0.745. In addition to that, the CR value for usability was 0.754 and AVE was 0.506. Meanwhile, the CR value for a standard was 0.940, and AVE was 0.610.

From these results, we can conclude that technological factors construct together with its components and items have met the CR's requirement, which must above 0.6, and AVE, which must above 5.0. Fig. 3 shows the CFA results for the organizational factor construct.

The organizational factor construct has 4 components; norms (10 items), data sharing policy (3 items), governance (3 items), and resources (5 items). The model fitness of organizational factor constructs was overall met the fitness indexes. The value for RMSEA shown was .067, the CFI was .945, and Chisq/df was 2.988. Table V shows the AVE and CR for the organizational factor construct.

TABLE IV. The AVE and CR for Technological Construct

Construct	Items	Factor Loading	CR (>0.6)	AVE (>0.5)
Technological Factor	Technical Infrastructure	0.95	0.948	0.859
	Usability	0.94		
	Standard	0.89		
Technical Infrastructure	TFTI1	0.90	0.921	0.745
	TFTI2	0.88		
	TFTI3	0.86		
	TFTI4	0.81		
Usability	TFU21	0.69	0.754	0.506
	TFU22	0.67		
	TFU23	0.77		
Standard	TFS31	0.67	0.940	0.610
	TFS32	0.70		
	TFS33	0.82		
	TFS34	0.83		
	TFS35	0.77		
	TFS36	0.80		
	TFS37	0.78		
	TFS38	0.76		
	TFS39	0.79		
	TFS310	0.87		

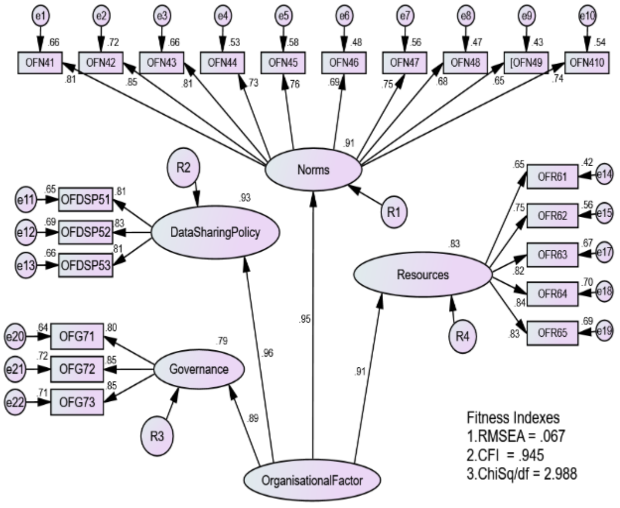

Fig. 3. The CFA Results for Organisational Factor Construct.

TABLE V. THE AVE AND CR FOR ORGANISATIONAL CONSTRUCT

Construct	**Items**	**Factor Loading**	**CR (>0.6)**	**AVE (>0.5)**
Organisational Factor	Norms	0.95	0.961	0.861
	Data sharing policy	0.96		
	Governance	0.89		
	Resources	0.91		
Norms	OFN41	0.81	0.927	0.562
	OFN42	0.85		
	OFN43	0.81		
	OFN44	0.73		
	OFN45	0.76		
	OFN46	0.69		
	OFN47	0.75		
	OFN48	0.68		
	OFN49	0.65		
	OFN410	0.74		
Data sharing policy	OFDSP51	0.81	0.857	0.667
	OFDSP52	0.83		
	OFDSP53	0.81		
Resources	OFR61	0.65	0.886	0.610
	OFR62	0.75		
	OFR63	0.82		
	OFR64	0.84		
	OFR65	0.83		
Governance	OFG71	0.80	0.872	0.695
	OFG72	0.85		
	OFG73	0.85		

Based on Table V, it can be concluded that the CR value for the organizational factor was 0.961, and AVE was 0.861. The CR value for norms was 0.927, and AVE was 0.562. The CR value for the data sharing policy was 0.857, and AVE was 0.667. Meanwhile, The CR value for resources was 0.886, and AVE was 0.610. Finally, the CR value for governance was 0.872 and AVE was 0.695.

From these results, it can be concluded that the organizational factor constructs and their components and items have met CR's requirement, which must above 0.6, and AVE, which must above 5.0. Fig. 4 shows the CFA results for the environmental factor construct.

The environmental factor construct has 2 components; data sharing culture (3 items) and research practice (3 items). The model fitness of the environmental factor construct was overall meet the fitness indexes. The value for RMSEA shown was .066, the CFI was .990, and Chisq/df was 2.925. Table VI shows the AVE and CR for the environmental factor construct.

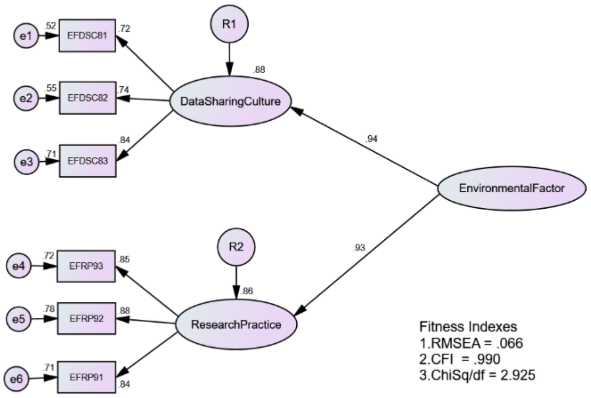

Fig. 4. The CFA Results for Environmental Factor Construct.

TABLE VI. THE AVE AND CR FOR ENVIRONMENTAL CONSTRUCT

Construct	**Items**	**Factor Loading**	**CR (>0.6)**	**AVE (>0.5)**
Environmental Factor	Data sharing culture	0.94	0.933	0.874
	Research Practice	0.93		
Data sharing culture	EFDSC81	0.72	0.812	0.591
	EFDSC82	0.74		
	EFDSC83	0.84		
Research practice	EFRP91	0.84	0.892	0.734
	EFRP92	0.88		
	EFRP93	0.85		

Table VI shows that each item's factor loading was high, which above 0.6. The CR value for the environmental factor was 0.933, and AVE was 0.874. The CR value for data sharing culture was 0.812, and AVE was 0.591. The CR value for research practice was 0.892, and AVE was 0.734. It can be concluded from these results that the environmental factor construct and its components and items have met CR requirements, which must above 0.6 and AVE must above 5.0. Fig. 5 shows the CFA results for the individual factor construct.

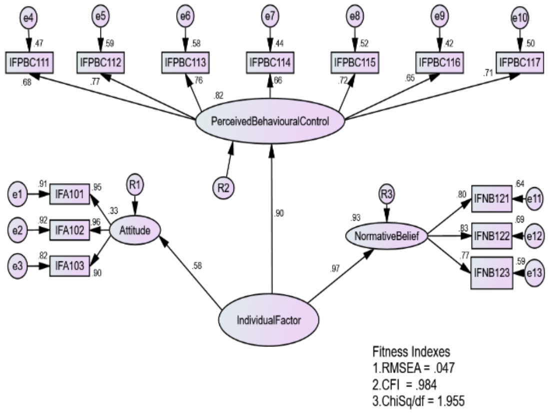

Fig. 5. The CFA Results for Individual Factor Construct.

The individual factor construct has 3 components, which are attitude (3 items), perceived behavioral control (7 items), and normative belief (3 items). The model fitness of the individual factor construct was overall met the fitness indexes. The value for RMSEA shown was .047, the CFI was .984, and Chisq/df was 1.955. Table VII shows the AVE and CR for the individual factor construct.

Table VII shows each item's factor loading was high above 0.6. The CR value for the individual factor was 0.868, and AVE was 0.696. Meanwhile, the CR value for attitude was 0.956, and AVE was 0.878. In addition to that, the CR value for perceived behavioral control was 0.875 and AVE was 0.502. The CR value for normative belief was 0.842, and AVE was 0.641. From these results, we can conclude that individual factors construct together with its components and items have met CR's requirement, which must above 0.6, and AVE, which must above 5.0. Fig. 6 shows the CFA results for the open data license factor construct.

In Fig. 6, the ODL construct has 5 items. Thus, the model fitness of the ODL construct was overall met the fitness indexes. The value for RMSEA shown was .053, the CFI was .995, and Chisq/df was 2.257. Table VIII shows the AVE and CR for ODL construct.

Table VIII shows that each item's factor loading was high, which above 0.6. The CR value for ODL was 0.898, and AVE was 0.639. Thus, from these results, we can conclude that ODL construct and items have met CR requirements that must above 0.6 and AVE, which must above 5.0. Fig. 7 shows the CFA results for the open data (MTUN_OD) construct.

TABLE VII. THE AVE AND CR FOR INDIVIDUAL FACTOR CONSTRUCT

Construct	Items	Factor Loading	CR (>0.6)	AVE (>0.5)
Individual Factor	Attitude	0.58	0.868	0.696
	Perceived Behavioral Control	0.90

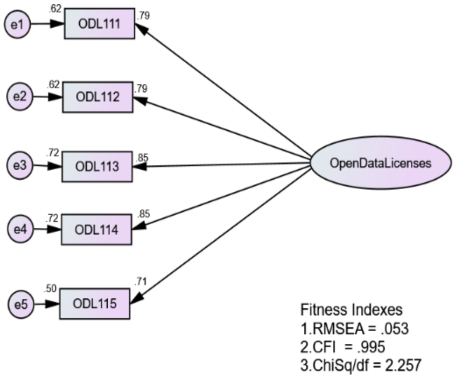

Fig. 6. The CFA Results for Open Data Licenses Factor Construct.

TABLE VIII. THE AVE AND CR FOR OPEN DATA LICENSES CONSTRUCT

Construct	Items	Factor Loading	CR (>0.6)	AVE (>0.5)
Open Data Licenses	ODL111	0.79	0.898	0.639
	ODL112	0.79		
	ODL113	0.85		
	ODL114	0.85		
	ODL115	0.71		

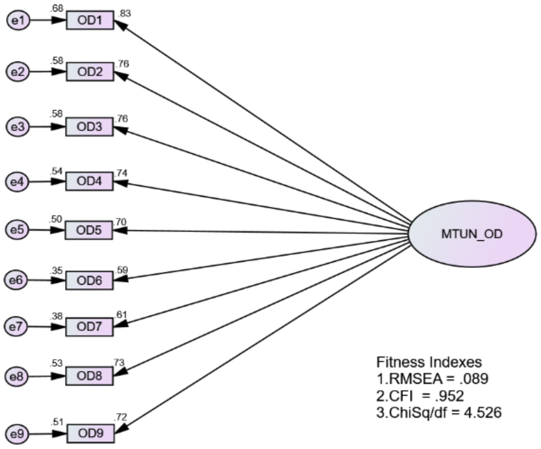

Fig. 7. The CFA Results for Open Data Construct.

In Fig. 7, the MTUN_OD construct has 9 items. The model fitness of the MTUN_OD construct was overall met the fitness indexes. The value for RMSEA shown was .089, the CFI was .952, and Chisq/df was 4.526. Table IX shows the AVE and CR for the open data construct.

Table IX shows each item's factor loading was high, above 0.6. The CR value for the open data construct was 0.909, and AVE was 0.528. Thus, from this result, we can conclude that MTUN_OD constructs and their items have met CR's requirement, which above 0.6, and AVE must above 5.0.

An overall, the technological construct, organizational construct, environmental construct, individual construct, ODL construct, and MTUN_OD construct has met the fitness indexes and passed the measurement of AVE and CR.

TABLE IX. THE AVE AND CR FOR OPEN DATA CONSTRUCT

Construct	Items	Factor Loading	CR (>0.6)	AVE (>0.5)
MTUN_OD	OD1	0.83	0.909	0.528
	OD2	0.76		
	OD3	0.77		
	OD4	0.75		
	OD5	0.71		
	OD6	0.60		
	OD7	0.63		
	OD8	0.74		
	OD9	0.72		

The study needed to simplify the overall measurement model from the first-order construct and pool them together to undergo the CFA procedure at once. This procedure is called Pooled-CFA.

B. Pooled-CFA for all Measurement Model of Constructs

In this pooled-CFA model, as suggested in [24], the measurement model for the second-order constructs was validated using the CFA procedure separately and simplified into first-order constructs to reduce complexity. The reason to perform the pooled-CFA was to assess the discriminant validity among constructs in the model [17], [19], [23], [26]. Fig. 8 shows the pooled-CFA that consists of data sharing (DS) construct, ODL, and MTUN_OD in 1 model.

The result of the analysis shown 3 types of values; fitness indexes for all constructs in the model, the factor loading for every component to the main construct, and the correlation between constructs.

In determining the fitness indexes, the values should meet the threshold as shown in Table III. As in [17], [19], [23], [26] have highlighted that the factor loading for every item should not less than 0.6 and the correlation coefficient of any two constructs should not exceed 0.85. The multicollinearity problem will occur if the correlation between any two constructs exceeds 0.85. In this study, none of the values found to be greater than 0.85. Thus, the multicollinearity problem does not arise.

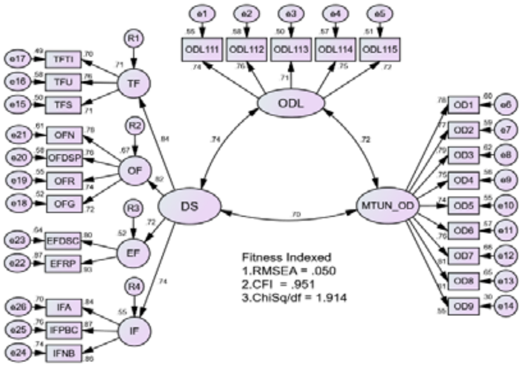

Fig. 8. The 3 Constructs are Pooled Together for the Pooled-CFA Procedure.

The Pooled CFA has merged 3 constructs. From Fig. 8, the model looks much more straightforward and easy to understand. The pooled CFA was also performed to avoid violating regression assumptions. The correlation between DS to ODL was 0.74. Then, the correlation between ODL to MTUN_OD was 0.72, and the correlation between DS to MTUN_OD was 0.70. Thus, no multicollinearity occurs as the correlation between each construct was below 0.85. Besides, pooled CFA's model fitness was overall met the fitness indexes. The value for RMSEA shown was .050, the CFI was .951, and Chisq/df was 1.914. Table X shows the AVE and CR for Pooled-CFA.

TABLE X. THE AVE AND CR FOR POOLED-CFA

Construct	Items	Factor Loading	CR (>0.6)	AVE (>0.5)
Data Sharing	Technological Factor	0.84	0.862	0.611
	Organizational Factor	0.82		
	Environmental Factor	0.72		
	Individual Factor	0.74		
Technological Factor	Technical Infrastructure	0.70	0.767	0.524
	Usability	0.76		
	Standard	0.71		
Organisational Factor	Norms	0.78	0.837	0.563
	Data Sharing Policy	0.76		
	Resources	0.74		
	Governance	0.72		
Environmental Factor	Data Sharing Culture	0.80	0.858	0.752
	Research Practice	0.93		
Individual Factor	Attitude	0.84	0.850	0.655
	Perceived Behavioural Control	0.87		
	Normative Beliefs	0.86		
ODL	ODL111	0.74	0.855	0.542
	ODL112	0.76		
	ODL113	0.71		
	ODL114	0.75		
	ODL115	0.72		
MTUN_OD	OD1	0.78	0.922	0.570
	OD2	0.77		
	OD3	0.79		
	OD4	0.75		
	OD5	0.74		
	OD6	0.76		
	OD7	0.81		
	OD8	0.81		
	OD9	0.55		

Based on the AVE and CR values in Table X, the study found that all AVE and CR exceed their threshold values of 0.5 and 0.6 respectively. Thus, the study can conclude that the AVE and CR for all latent constructs in the model have been achieved.

Proceed to the next validity test, the study needs to measure discriminant validity. The table discriminant validity index summary is developed as shown in Table XI. The diagonal values in bold were the square root of the AVE of the respective constructs while the other values indicate the correlation coefficient between the pair of the individual constructs.

TABLE XI. The Discriminant Validity Index Summary for All Constructs

Construct	Data Sharing	ODL	MTUN_OD
Data Sharing	**0.782**		
ODL	0.74	**0.740**	
MTUN_OD	0.70	0.720	**0.755**

TABLE XII. The Assessment of Normality for All

Variables	Skew	CR	Kurtosis	CR
IFA	-.759	-5.886	1.261	4.892

ODL113	-.009	-.071	-.239	-.928
ODL112	-.265	-2.057	-.099	-.385
ODL111	-.035	-.272	-.285	-1.106
Multivariate			57.862	14.406

Table XI shows the discriminant validity index summary for all constructs. The discriminant validity has been achieved when the diagonal values (in bold) are higher than any other values in its row and column. Since SEM employs the parametric statistical approach of modeling, the study needs to assess all items' normality distribution measuring their respective constructs. According to [17], [19], [23], [24], [26], the value of skewness should fall within the range of -1.5 to 1.5 to make it normally distributed.

Table XII shows the values of skewness for all components in the model fell within the range between -1.5 and 1.5. It means that the distribution does not depart from normality and there were no outliers' data. Thus, the data distribution meets the normality distribution requirement for employing parametric statistical analysis in SEM.

VII. Conclusion

Data sharing in this study that was defined through the combination of technological, organizational, environmental, and individual components. The components were derived from the literature review. However, in this study, the exact components that form data sharing were investigated through the process of survey distribution to MTUN academics that were then be confirmed through CFA. The investigations were then extended to the ODL construct and MTUN_OD construct. As for this research purposes, this study examined the factor influence data sharing and the impact of data sharing on ODL construct and MTUN-OD construct.

In a conclusion, Pooled-CFA is recommended to perform on a complicated model in making it simpler to analyse and easy to understand. The model is considered complicated when it involves many second-order constructs and items. There are 3 important types of validities in this study; CR, Cronbach Alpha, and AVE. The CR is important in this study as its measure of internal consistency in scale items. On the other hand, the AVE is important to employ in this study to confirm that the construct should correlate with related variables but it should not correlate with dissimilar, unrelated ones. In determining the value of CR and AVE for each construct, the analysis results of Pooled-CFA are recalled and it can be concluded that 4 components influence data sharing; technological, organizational, environmental, individual construct.

The technical factor has a CR value of 0.948; which above the minimum accepted value of CR; 0.6 and 0.859; which above the minimum accepted value for AVE; 0.5. The fitness indexed for this construct was achieved with the value of RMSEA was 0.067, which less than 0.1 to make it accepted. CFI was 0.959, which above 0.9 to make it accepted and Chi-sq was 2.989, which less than 5.0 to make it accepted. Meanwhile, the result of organizational factors shown the CR value of 0.961 and 0.861 for AVE. The fitness indexed for this construct was achieved with the value of RMSEA was 0.067, which less than 0.1 to make it accepted. CFI was 0.945, which above 0.9 to make it accepted and Chi-sq was 2.988, which less than 5.0 to make it accepted.

On the other hand, the environmental factor has a CR value of 0.933; and 0.874 for AVE. The fitness indexed for this construct was achieved with the value of RMSEA was 0.066, which less than 0.1 to make it accepted. CFI was 0.990, which above 0.9 to make it accepted and Chi-sq was 2.925, which less than 5.0 to make it accepted. In the meantime, the result of the individual factor shown the CR value of 0.868; and 0.696 for AVE. The fitness indexed for this construct was achieved with the value of RMSEA was 0.047, which less than 0.1 to make it accepted. CFI was 0.984, which above 0.9 to make it accepted and Chi-sq was 1.955, which less than 5.0 to make it accepted.

Besides that, the ODL construct has a CR value of 0.898 and 0.639 for AVE. The fitness indexed for this construct was achieved with the value of RMSEA was 0.053, which less than 0.1 to make it accepted. CFI was 0.995, which above 0.9 to make it accepted and Chi-sq was 2.257, which less than 5.0 to make it accepted.

Furthermore, the result of the MTUN_OD construct shown the CR value of 0.909 and 0.528 for AVE. The fitness indexed for this construct was achieved with the value of RMSEA was 0.067, which less than 0.1 to make it accepted. CFI was 0. 952, which above 0.9 to make it accepted and Chi-sq was 4.526, which less than 5.0 to make it accepted.

An overall, the technological construct, organizational construct, environmental construct, individual construct, ODL construct, and MTUN_OD construct for CFA distinctively has met the fitness indexes and passed the measurement of AVE and CR.

To ensure the overall fitness indexes of the model, this study employed Pooled-CFA. From the result of pooled CFA, the fitness indexed for this overall model was achieved with the value of RMSEA was 0.050, which less than 0.1 to make it accepted. CFI was 0.951, which above 0.9 to make it accepted and Chi-sq was 1.914, which less than 5.0 to make it accepted.

Based on Table XI, it can be shown that the model achieved discriminant validity when the diagonal values (in bold) are higher than any other values in its row and column. As stated, the data sharing value for discriminant validity was 0.782, ODL was 0.740, and MTUN-OD was 0.755. It indicates that each of the constructs was measure distinctively and not related to each other.

Finally, for the normality test, the distribution does not depart from normality and there were no outliers' data. Thus, the data distribution meets the normality distribution requirement for employing parametric statistical analysis in SEM which will be discussed in the next paper.

In a conclusion, the step-by-step to do pooled-CFA must start with performing an individual CFA for every constructs to make it simpler and easy to understand for the complicated model. All the results must follow the table of indexes (Table II and Table III) to indicate that the results are reliable and validated.

These results of CFA will be used to be modeled in SEM. However, for future work, it is advisable to add 1 more component to be measured; data quality which should be determined under technological construct.

Acknowledgment

I want to express my appreciation to the Research Group of Information Security Forensics and Computer Networking (INSFORNET) and Human Computing Centre (HCC-ISL), Centre of Advanced Computing and Technology (C-ACT) Faculty of Information and Communication Technology, Universiti Teknikal Malaysia Melaka for allowing me to conduct this research. I am incredibly thankful to the Public Service Department (JPA) Scholarship and the Ministry of Education (MOE) for funded and support.

***Abstract*—Several technological advancements emerged providing the technical assistance supporting people with special needs in tackling their everyday tasks. Particularly, with the advancements in cost-effective Brain-Computer Interfaces (BCI), they can be very useful for people with disabilities to improve their quality of life. This paper investigates the usability of low-cost BCI for navigation in an indoor environment, which is considered one of the daily challenges facing individuals with mobility impairment. A software framework is proposed to control a wheelchair using three modes of operations: brain-controlled, autonomous and semi-autonomous, taking into consideration the usability and safety requirements. A prototype system based on the proposed framework was developed. The system can detect an obstacle in the front, right and left sides of the wheelchair and can stop the movement automatically to avoid collation. The usability evaluation of the proposed system, in terms of effectiveness, efficiency and satisfaction, shows that it can be very helpful in the daily life of the mobility impaired people. An experiment was conducted to assess the usability of the proposed framework using the prototype system. Subjects steered the wheelchair using the three different operation modes effectively by controlling the direction of motion.**

Keywords—Usability; wheelchair navigation; indoor navigation; mobility impairment; obstacle avoidance; obstacle detection; path planning; BCI; brain-computer interaction

I. Introduction

Independent mobility is an important aspect in the quality of life for individuals with mobility impairments. Though the needs of many individuals with mobility impairments can be satisfied with traditional manual or powered wheelchairs, a part of the impaired community finds it difficult and sometimes impossible to use the wheelchairs independently. This part comprises of individuals with low vision, visual field reduction, spasticity, tremors, or cognitive deficits [1]. These individuals have to depend on another person to push them while they are on the wheelchair, as they often lack the independent mobility to control a powered wheelchair due to the nature of their disability. In the U.S, almost 10% of the legally blind individuals also have a mobility impairment [3], which makes many of them hesitate to visit unfamiliar places since they have no information about the new environment and its accessibility conditions.

Navigation tasks are regarded as one of the critical challenges facing individuals with mobility impairments. According to the Environmental Protection Agency (EPA), the average American spends 93% of their life indoors [2]. The need to consider indoor navigation is even higher in the Saudi local context, mainly for individuals with some cognitive, visual, or physical impairments since 3.73% of the population have some form of functional disability [31].

Moreover, the safety, easiness and usability features in the assistive systems are considered a crucial requirement considering the special situation of mobility-impaired individuals. However, the currently available navigational assistive systems lack these features [32]. Highly impaired individuals, using the powered wheelchair, require an autonomous wheelchair for navigation [4]. Therefore, developing a smart wheelchair that would transport the mobility-impaired individuals to their desired destination without their direct control would significantly improve their quality of life, taking into account that such wheelchair has to plan a quick and a safe path even when faced with an obstacle. Thus, providing the mobility-impaired individuals with some level of independence, by not relying on another person for assistance, as the wheelchair would maneuver through the obstacles by itself. Also, providing the wheelchair's rider the ability to control the wheelchair according to his/her preference is a must. Some riders would like to have a full control on how the wheelchair moves, while others prefer to just sit back and make the electric wheelchair moving autonomously.

Furthermore, the obstacle detection is a key component for any autonomous system, in order to ensure the safety of the individual driving it. Therefore, many research studies, according to [36], have considered integrating different types of sensors in their autonomous systems, in order to detect and avoid the faced obstacles. These sensors can either be ultrasonic, infrared, computer vision type sensors, laser sensors, or a combination of different types.

This paper focuses on the usability engineering of an obstacle avoidance system by combining the new technologies with path optimization techniques taking into consideration the special needs of the target users throughout the development cycle.

II. Background

Assistive technologies are developed according to two approaches: (1) developing special hardware devices designed for disabled people or (2) using existing hardware devices and integrating specific applications to improve some aspects of the individuals’’ daily life. The latter approach is what will be used in this paper.

Smart wheelchairs can either be autonomous, non-autonomous or a mix of both types (semi-autonomous). In autonomous wheelchairs, the TetraNauta [5], and Kanazawa University [6] wheelchairs include a computer for processing along with different types of sensors. They tackled specific problems such as: obstacle avoidance, local environment mapping, and path navigation. With the autonomous control feature, the system analyses the environment, plans a navigation path, detects an obstacle, makes decisions, and controls the wheelchair’s movements [7]. Moreover, several prototypes of smart wheelchairs have been developed and many research papers have been published in this area like in [8] and [9]. However, most of them have hardware and software architectures developed specifically for a particular wheelchair model and usually they tend to be difficult to configure in order to be used by the physically impaired individuals [1][8].

The capability and nature of the user’s disability might become a restriction when operating a wheelchair. Therefore, the spectrum of automation in the brain- controlled wheelchairs (BCW) relate to the level of dependence on the human rider to guide the wheelchair, as compared to the wheelchair guiding itself. Many research studies [35] have investigated the inclusion of different operation modes to the brain-controlled wheelchair (BCW). These modes range from low-level (manual), High-level (autonomous), and shared-control (semi-autonomous). Below is a detailed explanation for each mode:

- Low-level navigation: where the user is in a complete control of the wheelchair as it directly obeys the user’s commands and does not move by itself. The wheelchair is controlled through simple navigation commands, such as “move forward” or “turn left” Also it incorporates basic collision avoidance supports as stopping the wheelchair when obstacles are encountered. Using this navigation mode, users can navigate and perform any path they want, along with having control of the specific movements. In this mode, the system does not assist in the execution of the selected command.
- High-level navigation: where the users have a rough control of the BCW by selecting high-level commands such as “take me to the living room” or “leave this room.” The BCW must have some kind of intelligence so that the specific path to the selected destination is transparent to users, i.e., the user does not select specific low- level commands. Also, it can incorporate basic collision avoidance (stopping the wheelchair when obstacles are encountered) and obstacle avoidance (planning a new path to avoid the obstacle) supports.
- Shared-control navigation: where both the user and the system share the control of the BCW. This can be done in two ways: i) users generate low-level commands, while the system assists the navigation with features such as obstacle avoidance, or maximum likelihood command execution; and ii) users can switch between a low- and a high-level navigation mode. The user in this mode oversees the navigation and issues high-level commands while the wheelchair executes the motions. This enables the user to still remain in charge of the decision-making process, but with less involvement in the execution.

III. Related Work

Recently, considerable amount of research that tackle the operation modes to the BCW have been reported in literature. In the following we report the work that has been done categorized based on the different modes of navigation:

A. *Low-Level Control (Manual)*

The authors in [10] designed a manual BCI-based wheelchair that can be steered by only the users’ brain signals. The designed system utilizes three mental tasks that are turning left, right, and go forward. These commands were achieved through the left and right motor imageries to turn left and turn right, respectively, and feet motor imagery to go forward. Similarly, the authors in [11] developed a manually BCI controlled wheelchair using an onboard computer that is responsible for processing and classifying the captured EEG signals to generate wheelchair steering commands. The onboard computer sends through a serial port the generated commands to the wheelchair's motor drivers. The wheelchair can either move forward, turns left or right, or stops.

On the other hand, Li et al. in [12] presented a hybrid brain/muscle interface to manually control a wheelchair. The authors argue that BCI based on P300 or SSVEP can cause the fatigue and dryness of the eye, and then lead to user's inattention. The developed system distinguishes four user's commands, go forward, turning right, turning left, and stop. These commands are captured from the: (1) two mental states corresponding to the wheelchair’s motion of turning left and turning right, (2) the EMG signal captured from the user’s gritting his/her left teeth and right teeth that correspond to the motion go forward and stop respectfully. The developed wheelchair is equipped with various types of sensors to perceive the environment's context. These sensors are vision camera, and a laser rangefinder (sonar).

The authors in [13], also, developed a hybrid BCI system that combines two types of BCI paradigms (P300 potential and SSVEP) to improve the performance of asynchronous control to instantly and accurately distinguish the control and idle states needed to steer the wheelchair. And considering that the system controls the wheelchair manually, the authors designed the graphical user interface (GUI) to display four groups of buttons, and each group has one large button in the center and eight small buttons surrounding it. When the user concentrates on one group of buttons, both P300 potential and SSVEP can be evoked al the same time. The flickering buttons in each group invoke SSVEP, and the flashing of the four large buttons evoke P300 potential. In order for the authors to produce a go or stop commands in wheelchair control this method was used.

Moreover, in [14] Diez et al. developed a wheelchair that can be controlled through a BCI based SSVEP signals. The designed system can discriminate five classes: top, bottom, left, right and undefined. The detected stimuli can be translated to the first four classes, while the undefined class is chosen when no stimuli are detected. The wheelchair moves manually based on the identified class. For example, it moves forward if the BCI detected the top stimulus, turns left if the left stimulus was detected, turns right if the right stimulus was detected, and finally stops if the bottom stimulus was detected. Moreover, when no stimulus was detected (undefined class) the wheelchair, for safety reasons, stops as well. The system provides the user with online feedback indicating the detected stimulus by translating it to its proper steering direction using a blue arrow on the screen. And in the case of an undefined class, a red circle is shown in the center of the screen.

The authors in [15] developed a BCI based electric wheelchair control system. The proposed wheelchair enabled users to steer the wheelchair in four directions forward, backward, turn left or right by utilizing the eyes closing signal for more than one second and without any pre-training. Users wore an EEG acquisition cap that has four lights corresponding to the four directions. These light flashes in a clockwise loop and lasts for a fixed period of time. Moreover, when the user wants to select a specific direction, he/she closes their eyes as soon as the desired direction flashes.

Moreover, the authors in [16] built upon their previous work of [17] where they combined two types of BCI paradigms (motor imagery and P300 potentials) and controlled the wheelchairs direction and speed. The direction control was achieved through two commands (turning left and right), and the speed control was done by controlling the acceleration and deceleration. The authors' new extension combined motor imagery, P300 potentials, and eye blinking to achieve forward, backward, and stop control of a wheelchair respectively. Their work combined with their previous resulted in having the users choose and navigate from seven steering commands.

Cao et al. in [18] developed a hybrid BCI system that combines two BCI paradigms (motor imagery and SSVEP) to concurrently control the speed and direction of a wheelchair. The proposed system manually steers the wheelchair by providing eight commands for the users choose and navigate from. These commands are turn left, turn right, drive forward, accelerate, decelerate, drive at the uniform velocity, and turn on and off the switch. Similarly, the authors in [19] argue that their proposed system allows the user to implement different types of commands in parallel. The proposed combine SSVEP and MI tasks to develop a new hybrid BCI method. It utilizes two-class MI and four-class SSVEP tasks, in which the user imagines moving his/her left or right-hand and focuses on one of four oscillating visual stimuli simultaneously.

In [20], the authors developed a manual control wheelchair navigation system based on a hidden Markov model (HMM). The developed system steers the wheelchair by capturing the electrooculography (EOG) signal originating from the user's eyeball and eyelid movements. A feature extraction was used to determine whether the eyes are open or closed and whether the eyes are gazing to the left, right, or center. These features are used as inputs to the HMM which generates commands for navigating the wheelchair accordingly. The wheelchair is equipped with a proximity sensor to avoid obstacles and it can move forward and backward in three directions.

Varona-Moya et al. in [21] enhanced an electric wheelchair, by incorporating multiple sensors and emulating its analog 2-axis joystick with a custom-built control board. The enhanced system receives the BCI navigation commands through a TCP connection and then transforms them into low-level movement commands that are fed to the wheelchair. Moreover, a real-time map of the area surrounding the wheelchair was created using the incorporated eleven ultrasonic rangefinders (sonar). Updating the grid-map in real time was achieved using a sonar model, which upon the detection of an obstacle at a given distance; it updates all the grid cells within the obstacle detected vertex.

In [22] Đumić and Kevrić developed a manually controlled wheelchair. The user controls the direction of the wheelchair through a BCI headset that detect an eye blinking action. There are four directions the user can choose from in order to steer the wheelchair, which are: left, right, forward, and backwards. The actual wheelchair was enhanced by using a microcontroller to control the joystick by servo motors.

B. *High-Level Control (Autonomous)*

Define The authors in [23] designed a brain-controlled wheelchair, which interacts with the user using a simple interface. The navigation system proposes a semantic map that integrates the navigation points, semantic targets, and a local 3D map. The semantic targets provide the recognized objects' type, outline and its functionality information, for example, if the object was identified to be a table, then its associated information is that it can be docked. The local 3D map provides a traversable navigation point. The user chooses one of the navigation points from the semantic map as the destination goal using a brain-computer interface (BCI).

In [24], Ng et al. developed a BCI controlled wheelchair based on the steady-state visual evoked potential (SSVEP) paradigm. The proposed system takes the desired destination from the user through a BCI signal and communicates it to the wheelchair navigation system to plan a path autonomously while avoiding obstacles on the way to the destination. The responsibility of controlling the wheelchair is switched from the user to the navigation software, which reduces the number of BCI commands needed to steer the wheelchair to the desired destination.

Zhang et al. in [25] developed an autonomous wheelchair where the user selects a destination from the map using one of the BCI paradigms (motor imagery or P300). Based on the selected destination, the navigation component plans a short path and steers the wheelchair to the desired goal. Furthermore, the user can choose to stop the wheelchair by issuing a stop command using the BCI whenever he/she wants. The authors claim that their system reduces the user's mental burden substantially.

C. Shared Control (Semi-autonomous)

The authors in [26] introduced a shared control architecture that combines the user's intention along with the precision of a powered wheelchair. Their system combines BCI with a shared control architecture that permits users to produce dynamic and simple navigation directions, as opposed to users being seated and relying on a predefined path for most of the navigation time. The shared controller decides what actions ought to be taken, based on the user's input (turning left or right) while taking into account the context of the environment, which was perceived using ten sonar sensors and two webcams. The proposed system was evaluated against four healthy experienced BCI users.

Lopes et al. in [27] propose a robotic assistive navigation wheelchair that integrates the Brain-Computer Interface (BCI) technology, as the Human– Machine Interface (HMI). In their paper, the authors proposed a two-layer collaborative control approach that takes into account both the user and the machine commands to guide and maneuver the wheelchair. The first layer in their proposed approach is a virtual-constraint layer. It is responsible for enabling/disabling the user commands, based on the environment's context. For example, user commands are enabled in the situation of multiple directions that was caused by newfound obstacles in the environment. The second layer is responsible for matching the user's intended BCI commands to a suitable steering command, considering the client capability to control the wheelchair and situation awareness of potential directions at a given location.

Moreover, in [28] the authors proposed a new shared-control approach for a brain- controlled wheelchair. The shared controller switches between two controlling agents, the BCI control agent, and an autonomous control agent taking into consideration both the context of the environment and the intention of the user. The architecture of the proposed approach consists of four layers: the human- machine interface, the global motion planning, the local motion planning, and the motion control. The global motion planning layer comprises of the knowledge database that was built by the SLAM method to store information about the location of obstacles as well as the kinematics of the wheelchair. This layer receives an output from the BCI and determines the path to the goal by using the NRPF algorithm. It also calculates the distances between the wheelchair and the goal as well as the distances between the wheelchair and the obstacle. Moreover, the distance to the obstacle decides the mode of control. For example, the autonomous control agent is activated once an obstacle is detected using a laser scanner, which results in enabling the local path-planning module to return a collision-free path by employing an improved potential field method. Finally, the motion control layer receives direction commands from the local motion-planning layer. The received commands determine the movement of the wheelchair.

Chen et al. in [29] proposed a hybrid BCI scheme based on brain electrophysiology (EEG) signals, a shared control system of a bionic manipulator is designed and a motion planning of the wheelchair. The wheelchair is equipped with an obstacle avoidance system that is composed of 8 photoelectric sensors distributed across the wheelchair. The proposed system is comprised of the human-robot interface and EEG signals that are used to identify the steering command expressed by the user's motion imagery, which is achieved by imaging motions of the left and right legs, left and right hands and so on. The user's expressed commands are translated into the corresponding control actions, which are sent to the actuator of the arm joint motor to realize the motion control of the bionic manipulator.

Moreover, researchers in the field have used a number of different metrics to evaluate their proposed the BCW. However, there are a limited number of research that employ the usability evaluation metrics. For example, from the reviewed literature only [20] and [14] evaluated their BCW using usability, learnability, and measured the user’s experience. The rest of the reviewed papers evaluated their BCW in terms of how accurate their system completed the task and the time it took among other factors.

Furthermore, prior to the test session, most studies performed a training phase to reduce the effect of unfamiliarity to the technology used. The orientation session aims to introduce the participants to the subject in general and to the system in particular. Some studies considered the users’ familiarity with the test BCI technology. Besides, the profile and number of test participants varied among the studies: Lopes et al. [27] recruited 11 participants one of which has a cerebral palsy and motor impairment, Diez et al. [14] recruited 13 participants, with one being a paraplegic participant. While another study in [24] evaluated the system against 37 healthy participant. Other studies in [10]–[13], [15], [16], [18], [21]–[23], [25], [26], [28], [29] recruited lesser number of test participants ranging between one to eight participants.

In summary, the problem of choosing one signal or another depends on a number of factors like presence or absence of a graphical user interface (GUI), the number of commands, and the need to implement a continuous control of the wheelchair. The P300 requires a GUI to be present and has a discrete control mechanism as opposed to the ERD/ERS. Furthermore, we noticed that a few of the reviewed research handled the semi- autonomous (shared level) navigation and combining it with obstacle detection and employing a path planning algorithm to find the shortest path to the goal. Remarkably, most the research (63.16% of the papers) uses a manual (low level) navigation system without adding an obstacle detection and avoidance mechanism. On the other hand, the P300 used mostly high-level navigation commands.

Moreover, some of the reviewed high-level BCWs focus solely on the BCI interface without mentioning the path planning technique used. Similarly, some works like [23], [24], and [25] did not consider applying an obstacle detection and avoidance technique, this might be attributed to the fact that they are building their system to navigate in a static environment without taking into consideration the changes that might suddenly occur in the environment.

It should be noted that the evaluation criteria used in the different studies were heterogeneous, where no standard evaluation metrics were followed. When taking the type of signals into account the BCW that were based on the ERD/ERS or SSVEP paradigms all gave a great importance to the evaluation of accuracy in selection the commands, along with the time it was required to complete the path. On the other hand, half of the BCW adapting the P300 paradigm evaluated the selection time, which is defined as the time it takes the user to select the desired command. However, the selection time cannot be used when evaluating a BCW that is based on ERD/ERS signals, due to the difficulty of exactly knowing when the user starts the selection process.

This paper extends this line of research and proposes a software framework integrating the three different operating modes. A prototype system based on this framework was implemented including three components: the navigation and path planning, the obstacle detection, and the user interface. Finally, the usability of the proposed system was evaluated against standardized evaluation metrics.

IV. Proposed Framework Design and Architecture

This paper proposes to design and develop a software framework for a BCI controlled wheelchair that gives the user the ability to choose one of the three navigation methods: manual/direct control (low level control), semi- autonomous (shared control), and autonomous (high level control).

In the manual/direct (low level control), the user controls the wheelchair by only his thoughts. In the semi-autonomous (shared control), the control takes the user's intention into account while doing the planning and the wheelchair follows the orders feed to it from a planner. The user, however, might express his/her intention to control the wheelchair and steer it by merely using the BCI. When the user's steering intention conflicts with the planner's instructions, the control system will replan the task. Finally, in the autonomous (high level control) the user will only have to select the destination and let the system plan a safe path to the destination while avoiding any obstacles on the way. However, in all the three navigation methods, the wheelchair will be equipped with obstacle detection sensors in order to detect and avoid the obstacle.

A. High-level Framework Architecture

As a typical navigation system, the framework consists of four main components: the indoor positioner component, the navigator component, the obstacle detection component, and the user interface component. The architecture of the whole system is represented in Figure 1.

1) Positioning component: The indoor positioner component gathers relevant information concerning the navigated environment and the user's current position and makes this information available for the other component to use. These components include the navigation component that generates the navigational directions based on the positioner information and the interface component that outputs related contextual information based on the positioner information.

2) Navigation component: Navigation including path planning is a key component to any navigational system, since it is responsible for computing the optimal path to reach the destination selected by the user, taking into account the user preferences including the route length, number of turn and safety priorities. The computed path is then translated to commands fed into the wheelchair to guide the user through the environment. Moreover, Path planning environments can either be static or dynamic, and according to them, two different path-planning approaches exist: local and global path planning. Global planning assumes a prior knowledge of the environment, a predefined map and fixed obstacle and then computes the overall path to destination. This approach assumes a static environment and is usually used for indoor navigation [30]. On the other hand, local planning aims to locally plan an obstacles-free path and determine how to navigate around obstacles. The local planning is usually used in robotics since the construction and maintenance of a global map may become computationally complex for a robot. This component also includes the shared controller which receives commands from the user and the machine, evaluates the situation and the current environment and then makes the appropriate decision. This decision is then translated into commands via the Path Translator to control the wheelchair.

3) Obstacle detection and avoidance component: The obstacle detection component, detects the existence of an obstacle, notifies the user and takes the appropriate action, which is identifying the obstacle on the map and then communicats with the navigator component to plan an alternative path to avoid the obstacle in order to reach to the goal destination. It should be noted that the control is passed when an obstacle is detected to so the wheelchair can manuver around the obstacle autonomously.

4) User interface component: Specifying a component for handling the interaction with the user and ensuring an instant response to user's requests is essential for any system. This component gets the preference of the user on how to plan a path to navigate the environment to reach the desired destination and then communicates with the navigation component so that the user's preference and destination point are fed into the path-planning algorithm. Moreover, the user interface component notifies the user when an obstacle is detected.

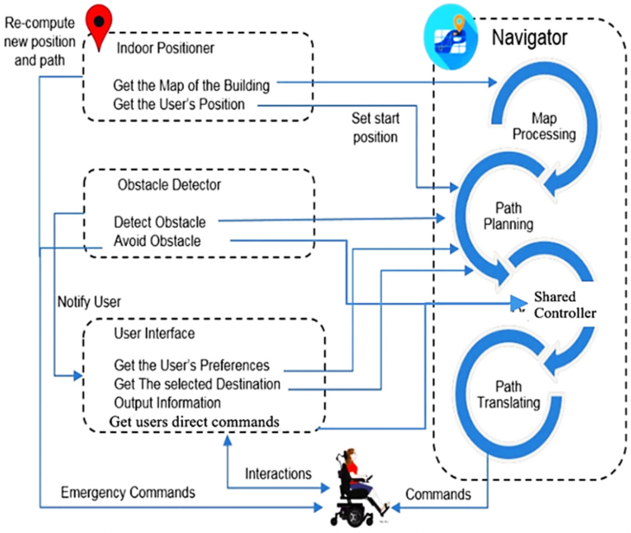

Fig. 1. Wheelchair High-level Framework Architecture.

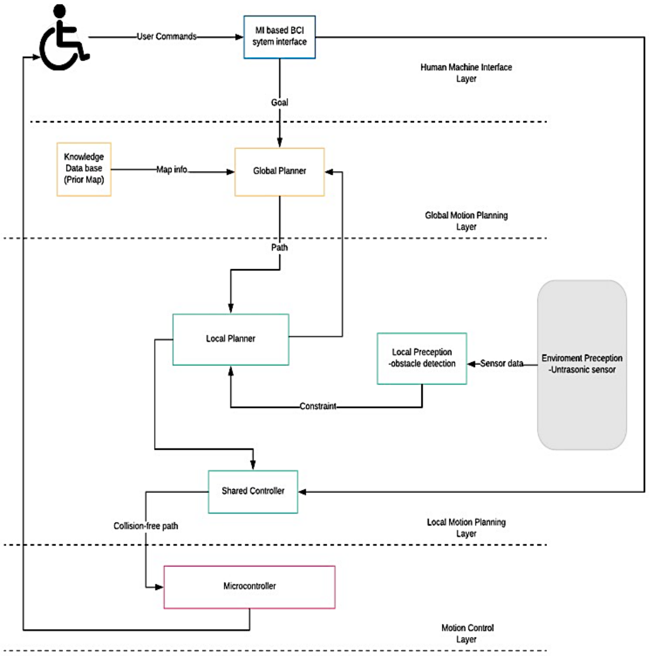
B. Shared Control System Architecture

As the main focus is to study and assess the usability of the shared control navigation, 3 components from the aforementioned components were considered: namely Navigation, Obstacle Detection and User Interface. The architecture of the proposed shared control system was designed in layers to interact synchronously so that each component can communicate independently to send or receive information. The architecture presented in FIGURE 2 is structured in four layers: Human Machine Interface (HMI), Global Motion Planning, Local Motion Planning, and Motion Control.



User Commands
MI based BCI sytem interface
Human Machine Interface Layer
Goal
Knowledge Data base (Prior Map)
Map info
Global Planner
Global Motion Planning Layer
Path
Local Planner
Local Preception -obstacle detection
Sensor data
Enviroment Preception -Untrasonic sensor
Constraint
Shared Controller
Collision-free path
Local Motion Planning Layer
Microcontroller
Motion Control Layer

Fig. 2. The Proposed Shared Control System Architecture.

The first layer implements the input interface of the User Interface component. In this layer, an MI-based BCI is used to provide the user intent, which are the issued steering commands. The Navigator component was implemented across three layers. The global planner determines the path to a predefined goal, based on a priori grid map information. The local planner plans a new path to avoid new detected obstacles in the environment. The shared-controller determines the set of appropriate moves to reach a predefined goal combining both the user and the machine commands. The obstacle detection is implemented in the third layer, along with the local planner, and is performed out based on ultrasonic sensor information.

C. Implemented System Components

The implemented components include the BCI interface, navigation component and obstacle detection.

- BCI Interface Component:

For BCI, hybrid BCI that uses both motor imagery and P300 potential approach was adapted in this system. The idea of hybrid BCI is to activate and control the system by imagining performing specified tasks. First, the device has to be trained in order to recognize the brain patterns of a user (motor imagery). Users were trained in two mental commands: neutral, and push. The choice of having only two mental commands rather than associating each task with a command for itself; is due to the user's difficulty of distinguishing different commands and thus increasing his/her burden.

The neutral command is trained by asking the user to stay idle and think of nothing for two seconds, in which the user does not perform any command. And the push command is trained by asking the user to imagine pushing the cube for four seconds. These commands, however, have to be trained multiple times in order for the commands to have a high confidence.

Furthermore, the P300 was used to control which action of direction the wheelchair has to take (right, left, forward, backward). For example, to turn right, the user imagines push movement while focusing on the right arrow flashing button on the graphical user interface (GUI).

- Obstacle Detection Component

The wheelchair will be equipped with Ultrasonic sensors mounted on its front part in order provide a safety mechanism against collision. If the measured distance to the obstacle is smaller than 50cm, the map is updated with the new obstacle and the local planner will plan a path to avoid the obstacle.

- Navigation Component

o ***Vector Map***

A two- dimensional vector map of the environment will be manually constructed and pre- processed to define the obstacles' locations so that the generated path can avoid intersecting with them later. The map will be segmented into a grid of equal sized cells (1 meter of each cell). It is assumed that all doors and windows on the wall are to be closed and are considered as normal walls. This assumption implies that the wheelchair cannot travel through them.

o ***Path Planning***

The proposed system includes two path-planning algorithms: (1) the global path planner finds the shortest path from initial location to the goal, (2) the local path planner to plan a path around the obstacle to avoid it. The goal (endpoint) is assumed to be selected by the user.

The D*Lite, global path planning algorithm is used to move a robot equipped with an ultrasonic sensor for detecting obstacles in order to move from the start point to a goal point assuming that the environment and all obstacles are known, and the size of each cell equals the size of the robot. For the local planning part, a local repair strategy called path splicing was used. The path splicing strategy finds a path nearby and assumes the path farther away need not be recomputed until we get closer to it. So instead of recalculating the entire path, the first M steps of the path are calculated.

o ***Shared Controller***

The shared controller receives commands from two agents, the user and the machine. The user issues BCI commands using the BCI headset. While the machine commands are issued from the application. However, instead of directly executing the user's commands, the shared control component evaluates the situation first. The current environment, perceived through ultrasonic sensors, is taken into considerations.

The shared controller has two levels of support that are only initiated when the situation calls for them. The two levels of support are collision avoidance and obstacle avoidance that will be activated near obstacles to prevent collisions.

The collision avoidance is thought of as an emergency stop. For example, when the user moves the wheelchair too close to an obstacle, the velocity will be decreased until it comes to a full stop. The ultrasonic sensors, mounted on the wheelchair, are used to determine when to activate this behavior. The activation threshold was set at 0.4m to maintain the safety of the user. If the ultrasonic sensors detect obstacles within this threshold, the collision avoidance behavior will be activated. However, unlike the previous behavior, the obstacle avoidance employed the use of the local planning strategy in order to steer the robot away from the obstacle. This behavior takes both the input of the user and the environment into consideration, to properly assist the local planning strategy.

D. Deployment And Navigation Modes

The proposed system consists of three main nodes. The first node is the Emotiv insight headset to capture EEG signal from the user. The second node hosts the software application that receives the captured EEG signal from the headset and converts it into commands. It also plans an obstacles free path to the destination. The third node is the microcontroller to control the wheelchair movement. However, due to limited funding, the wheelchair could not be acquired and was replaced by a prototyped robot. The robot is a Boe-Bot robot equipped with an Arduino UNO as the microcontroller to operate two motors and several ultrasonic sensors.

When using the Emotiv insight headset, the user was seated and asked to focus his attention to the command he wished to instruct. It is important to note that to know that every person has unique EEG signals. Therefore, every participant has to go through a training session before proceeding with the system. Furthermore, the system's nodes are able to share messages between them via Bluetooth. The software application component can control the robot through sending commands as a string of characters. The commands used in the system are: forward (F), turn 90 degree to the left (L), turn 90 degree to the right (R) , and stop (S).

V. Pilot Usability Evaluation

The (ISO 9241-11: 2018) identifies effectiveness, efficiency and satisfaction as major attributes of the usability. To evaluate the usability of the proposed system, test tasks were designed to assess the metrics for measuring the required criteria. Hence, the effectiveness was evaluated in terms of task completion, the efficiency was measured based on completion time and workload, and the satisfaction was assessed using the System Usability Scale (SUS).

A. Usability Evaluation Materials

A prototype based on a car robot (Boe-Bot) was used to simulate the wheelchair. The robot car is equipped with an ultrasonic sensor to detect obstacles. The assembled robot is shown in Figure 3.

1) Moreover, the Emotiv Insight [33] was used as the BCI headset to read and transmit EEG signals. Additionally, the BCI interface has been designed as a visual oddball paradigm. The paradigm comprises four steering commands, encoded by the following symbols: FORWARD, RIGHT90, LEFT90 and STOP, as shown in Figure 4. These symbols flash randomly. At a given moment, the relevant steering event is the symbol mentally selected by the user, which corresponds to the direction he/she wants to follow, and all other flashing symbols are discarded and considered as a non-relevant-event.

The map for room used for the evaluation is shown in Figure 5. The room is an 8x8 m^2, where the green circle is the starting point and the purple circle is the final destination (goal).

B. Usability Evaluation Method

Each experimental session was designed to last for a duration of about one hour, during which subjects were asked to control the robot using the Emotiv headset. A detailed flow is presented in Figure 6.

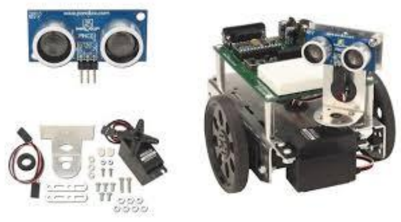


Fig. 3. The Assembled Robot.

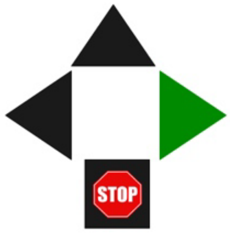

Fig. 4. The P300 GUI.

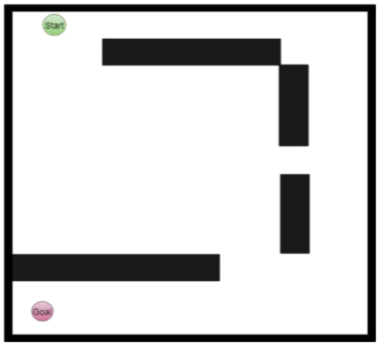

Fig. 5. Experimental Room Mock-up.

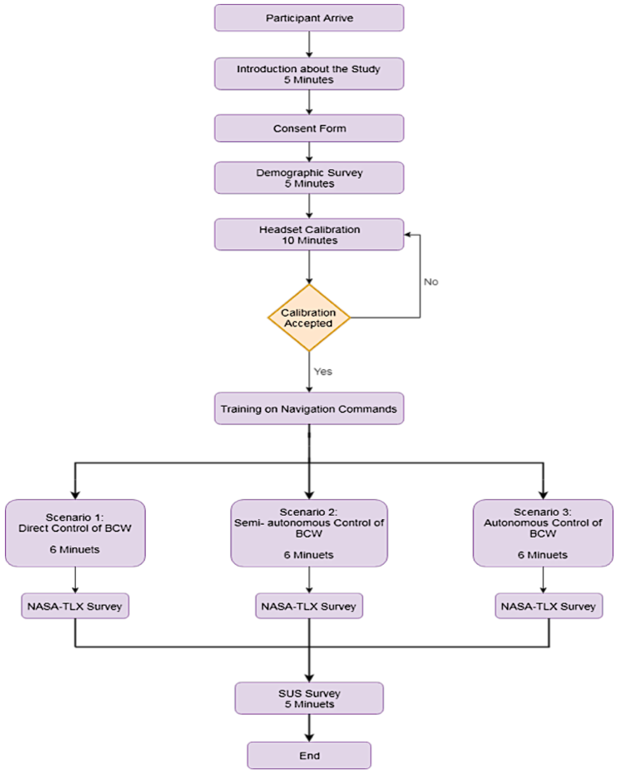

Fig. 6. The Experimental Session Procedure.

Each session began with asking the participant to fill out a demographic questionnaire and sign a consent form. Then, the Emotiv headset was mounted on the participant for calibration. Calibration involves mounting the headset on the participant and ensuring a good signal for each of the five electrodes (green color). In some cases, a fair signal (yellow color) is accepted. Following the calibration and before the online session, each participant was asked to perform an off-line training to control wheelchair, this training was done until the participant's signal recognition accuracy reaches above 85 percent.

After the calibration and off-line training, the participants were asked to perform three real-time navigation scenarios (direct control, semi-autonomous, and autonomous control) for a duration of six minutes each. The navigation scenarios all took place in a structured known environment that included both static mapped obstacles and an obstacle/s new to the environment.

The first navigation scenario, denoted by scenario 1, was to directly control the wheelchair. The participant is instructed to focus on the GUI that has four symbols flash randomly. These symbols correspond to the four steering commands (forward, turn right 90 degree, turn left 90 degree, and stop). When the participant chooses to go forward the robot continues performing this command till the users issues another command or the robot stops due to facing an obstacle. Moreover, in the second navigation scenario, denoted by scenario 2, where the participants share the responsibility of controlling the wheelchair with system. The wheelchair autonomously moves from the starting point to the destination while avoiding obstacles. However, the participants can interfere anytime and change the direction of the wheelchair and steer it as he/she wishes. Once the participant is done with commanding the wheelchair, the system takes back the control and navigates the wheelchair back to the destination. Finally, in the third navigation scenario, denoted by scenario 3. The participant is instructed to sit still while the wheelchair is navigating the environment to reach to the final destination (goal) while avoid the new introduced obstacle. It is also worth noting that the order of the three navigation scenarios was counter-balanced across the participants as shown in TABLE 1

TABLE I. THE SEQUENCE OF THE 3 NAVIGATION SCENARIOS FOR EACH PARTICIPANT

ID	Sequence of Navigation Scenarios
P1	Scenarios 1, 2, 3
P2	Scenarios 1, 3, 2
P3	Scenarios 2, 1, 3
P4	Scenarios 3, 2, 1
P5	Scenarios 2, 3, 1

C. Evaluation Participants

TABLE 2 illustrates the demographics of the participants taking part in the usability evaluation. The participants were mainly recruited through the use of social networks and word of mouth. All the participants took part in an initial calibration task. This initial calibration was required in order to have an acceptable accuracy of the acquired brain signals, which would enable the participants to control the BCW in the navigation task.

TABLE II. THE DEMOGRAPHICS OF THE PARTICIPANTS TAKING PART IN THE USABILITY EVALUATION

ID	Gender	Age	BCI Experience	Degree of Motor Disability
P1	Female	29	No	None
P2	Male	22	No	None
P3	Male	24	No	Fractured leg
P4	Female	66	Yes	None
P5	Female	25	No	None

D. Evaluation Results

The participants were asked to perform the navigation scenario they are presented with. The scenario is considered completed if the participant performs the navigation in less than 6 minutes. Moreover, all the participants have completed the navigation scenarios in a short time period for the direct control scenario (scenario 1) except P1. These results range from 4.9 to 6.2 minutes. It can be seen that P4 completed the scenario in short time which is attributed to the fact that the participant has prior knowledge on how to use the BCI. However, P1 got the highest completion time, which indicates that the user faced some difficulty using the BCI.

Furthermore, it can be seen from FIGURE 7 that the participants' completion time improved and this can be attributed to the learning effect. In addition, it was observed that the sequence of the navigation scenarios that the participants were supposed to follow affected the completion time. P1 and P2 for example took scenario 1 which is the direct control first and that helped them get familiar with how BCW work and got a first-hand experience on how to control the prototype via a sequence of commands. Also, according to the evaluation model this would result in a high efficiency of the proposed framework.

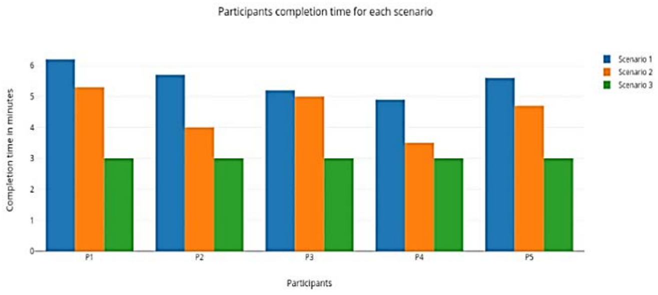

Fig. 7. Navigation Completion Time Periods among Participants for different Three Scenarios.

Moreover, the overall results from the NASA-TLX [34] workload survey showed that the participants' perceived the BCW as having an average physical demand, although, the BCW experiments does not require movement. Therefore, we believe this average score in physical demand was due to fatigue from sitting during the set-up and calibration period, and the increased test length. We believe the increase in mental demand and effort in scenario 1 and 2 was because the BCW experiments required people to focus their attention on making selections, compared to scenario 3 where the participants sat still and let the system do the steering. Nevertheless, it should be noted that in the autonomous navigation, participants reported they felt some frustration, which could be attributed to the fact that the participants might have wanted some navigation control over the prototyped BCW.

The overall analysis reported in FIGURE 8 shows that the workload perceptions increased significantly when the participants were dealing with scenario 1, which is when the workload demand increased.

Moreover, regarding the accuracy in selection the correct command. It was noted that previous experience in using the BCI can affect the accuracy results. P4, which had a previous experience in using a BCI application performed better and had a high accuracy in selecting the right command. However, with more training it is expected that the other participants can perform the same and improve their selection accuracy.

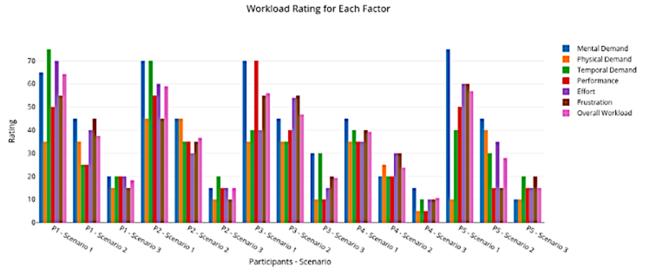

Fig. 8. Workload Rating for each Factor for each Participant/Scenario.

Additionally, according to the SUS questionnaire results, in that were filled by the participants after testing the system to measure the likability of the solution provided. It was found that participants' opinions were diverse in regard to their experience of using the prototyped BCW. While one participant found it difficult to use the system, two found the experience relatively easy and two were neutral in this regard. This applies to their view of the system and whether it can be described as an easy-to-use system or not, despite their own experience with it. Three of the participants believe that they don't require any specialized help in order to be able to use the system. Only two of the participants think that training on the system is required before using it.

Moreover, the majority of the participants agreed the stimuli were easy to distinguish and understand. Moreover, steering the prototyped BCW in an autonomous navigation mod was considered to be easy, similarly, steering the prototyped BCW in a semi- autonomous mode. On the other hand, three of the participants found that steering the prototyped in a direct control mode was difficult. Overall, the participants showed an interest in using the BCW once it becomes available in the market.

Table 3 and Figure 9, that were filled by the participants after testing the system to measure the likability of the solution provided. It was found that participants' opinions were diverse in regard to their experience of using the prototyped BCW. While one participant found it difficult to use the system, two found the experience relatively easy and two were neutral in this regard. This applies to their view of the system and whether it can be described as an easy-to-use system or not, despite their own experience with it. Three of the participants believe that they don't require any specialized help in order to be able to use the system. Only two of the participants think that training on the system is required before using it.

TABLE III. SUS RESULTS (1: STRONGLY AGREE, 5: STRONGLY DISAGREE)

Question	**1**	**2**	**3**	**4**	**5**	**Mean Opinion Score**
I was able to easily perform the tasks required using the BCI	0	2	2	1	0	2.2
I think that it is easy to steer the prototyped BCW	1	1	2	1	0	2.6
I think that I need a help from a technician person in order to be able to steer the prototyped BCW	1	1	0	1	2	3.4
I need a lot of training before trying to steer the prototyped BCW	0	2	1	2	0	3
I was easily able to understand and distinguish the application's stimuli	2	2	1	0	0	1.8
I think I learned to use the system quickly	0	0	2	2	1	3.8
Steering using the autonomous mod was easy	3	2	0	0	0	1.4
Steering using the semi-autonomous mod was easy	3	1	1	0	0	1.6
Steering using the direct control mod was easy		1	1	2	1	3.6
I am likely to use this prototyped BCW when it becomes available in the apps market		2	2	1	0	2.8

VI. CONCLUSION

The work of this research was motivated by number of factors in order to improve the quality of life for individuals with mobility impairments since most of the smart Wheelchairs developed have hardware and software architectures that are specific for the wheelchair model developed and are usually very difficult to configure in order for the physically impaired individuals to start using them.

In this work, we proposed a framework by engineering three components (navigation and path planning, obstacle detection, and user interface) taking into consideration the usability and safety requirements to develop a brain- controlled wheelchair for mobility-impaired individuals to help them navigate their way seamlessly in an indoor environment. However, number of issues were encountered resulting in number of limitations. Among these limitations was that the framework was developed using a prototype rather than a real wheelchair, which is attributed to the limited and late funding. On the usability aspect, the small number and lack of variance within the evaluation sample might, though it is considered as an initial evaluation.

In the future we aim to test the proposed framework with a real wheelchair in addition to increasing the number and variance of the evaluation sample.

***Abstract*—The need for awareness on ethical computing is increasingly becoming important. As a result this challenges all stakeholders in the software engineering profession, including educators, to improve their efforts on the awareness of professional codes of ethics which provide framework for ethical reference. However, the several compromises in the software engineering practice suggest that there are some in the profession, who are not familiar with the profession's codes of ethics and subsequently not able to practice and teach students about them. This research work investigates the extent of codes of ethics awareness by practitioners who are teaching software development courses in an academic environment. An online questionnaire with indicators for measuring awareness on software engineering code of ethics was deployed and responded to by 44 educators. Graphical, univariate and bivariate analyses were conducted on the data to determine the profile of the respondents and the extent of their level of awareness on the codes of ethics. The results indicate that majority of the lecturers (54.5 %) are not aware of software engineering codes of ethics, and those who are aware, majority of them were exposed to through self-study or personal development. Furthermore, the inclusion of codes of ethics in the learning activities is minimal as inhibited by lack of awareness and failure to apply the codes practically. This study recommends that lecturing staff as part of the professional software engineers serving as academic corps, should be placed on programmes for exposing them to professional software engineering codes of ethics. Moreover, the study calls for accreditation of software engineering courses, as it is the case with other professional engineering disciplines, to improve awareness and subsequent practical application of the codes of ethics.**

Keywords—Software engineering ethics; code of ethics; ethics awareness; ethics education; moral development ethics

I. INTRODUCTION

Awareness of the ethical implications of computing by educators in software engineering is increasingly becoming important. This is due to the responsibility educators have to prepare students to practice the trade in a way that reflects ethicality in their technical work [1]. Therefore, educators' role is significant to heighten the efforts in the teaching of ethics in technology courses [2] especially that they are also regarded as software engineers with a duty to promote the profession [3]. Improved efforts in education specifically about the ethical implications of developing software products are more required, as software has evolved to a de facto virtual resident in all areas of human lives due to the indispensable role it plays in devices and systems used by society. Software has contributed immensely to humanity, starting from promotion of human rights through social media [4], operation of machines in dangerous zones such as underground mines [5], saving of lives through computer aided surgeries [6] and usage of artificial intelligence to discover and discern patterns useful in understanding complex situations [7]. However, the list of software ethics violations such as wrongful use of software [8], deployment of badly designed and insufficiently tested software that created catastrophes such as aircraft crashes [9], [10], social media platforms used to drive misinformation for propaganda [11] even misinformation on global health pandemic such as Covid-19 [12] is continuing to haunt the province of computing ethics education. It specifically challenges the capacity of teaching software engineering ethics about the ethical awareness of those who teach software engineering and their ability to practicalise ethics into the curriculum.

Software engineering endeavours consider ethics education as an integral part of the moral development agenda, which, positively contribute to ethical computing awareness [1], [13]. For the software engineering ethics education to flourish, those involved in the teaching should be aware of the codes of ethics [3] as ethics navigation tool, infrastructure and content for teaching ethics. They should also create learning opportunities to assist students to practically internalize the codes alongside their other sources of ethical reference such as personal codes [14]. These opportunities can provide a rich experience on ethical awareness and ethical pluralism. Several frameworks for teaching ethics in computing advocates for the integration of codes of ethics into the curriculum [15]–[19]. These codes of ethics express a profession's disposition on ethics and professionalism, spells out principles to guide professionals and educates the professionals about what the society should hold them accountable for [20]. Therefore, the embracing of ethical codes by those involved in the education of software development can significantly contribute to the improvement of ethical awareness of the future graduates. It is on that note that Barnard *et al* [17] advocate that the teaching of ethics concepts and actions that underpin them should be integral part of the training of any future ICT professional. Therefore, those involved in the teaching of software development should be aware of the profession's ethics so they that can be in a position to teach the students accordingly.

The purpose of this study is to establish the extent to which university lecturers who are involved in teaching of software development courses in a South African University of Technology (UoT) are aware of software engineering ethics code. To help achieve this purpose the following research question and objective were formulated:

Research question:

What is the computing academics' level of awareness and exposure to a code of ethics specific to software engineering?

Research objective:

To determine computing academics' level of awareness and exposure to a code of ethics specific to software engineering.

This study helps to understand the extent of awareness on code of ethics in environments for teaching software development courses by measuring awareness by lecturers. Based on the awareness results, lecturers, industry trainers and employers will have better understanding of their insufficient knowledge of codes of ethics and the subsequent need for improvement. It will also help lecturers in faculties and organizations providing training on software engineering courses to realize the significance of using codes of ethics and the alignment thereof to real life incidents of ethical issues (good and bad), as well as including the codes in the constructive alignment activities related to teaching and learning of software engineering.

II. Literature Review

A. *The Need to Teach Ethics and the Role of Education on Moral Development*

The need for ethics in computing dates back to the days of the need for analysing the nature and social impacts of computing technology, and policies to clarify the ethical use of such technology [21]. However the challenge has always been the lack of practical knowledge and skills on how to apply ethics when faced with dilemmas [22]. University lecturers form an integral part of the ethics awareness program through the role they play in teaching software engineering ethics; and also serving as ethical examples. Therefore, institutions of learning should form the centre of efforts to be evaluated on their effect on moral development of students [23], especially faculty staff who participates in the teaching of ethics in educational environments.

Academic institutions like UoTs contribute to the software engineering business by providing education to graduates who work in the industry. Therefore, it is important for university lecturers to be aware of codes of ethics and include them as part of content used to orientate students about the expectations of software engineering profession in their teaching activities. Though it seems difficult and impossible, Kohlberg and Hersh [23] submit that the teacher bears the responsibility to guide the student to embrace practical moral conflicts, consider various sources for ethical reasoning, contrast personal thinking inconsistencies and inadequacies and means to address them. Several authors identify numerous instructional strategies for adoption in teaching ethics, such as online and face to face classroom discussions [24], writing of codes of ethics [25], service learning and civic engagement [26] case studies [27], evaluation of own project design [28], discussion on case studies and codes of ethics [19] and a combination of various strategies amongst others.

B. *Teachers as Facilitators of Ethical Awareness*

Research has proven the lack of required skills by ICT professionals to adequately apply moral judgements at work [29]. This challenges the adequacy and effectiveness of teaching computer ethics. Teaching staff as software engineers themselves, are obligated to promote ethical and professional approach to the practice [3], [18] through curriculum endeavours and conducting themselves as real life examples. Curriculum guidelines place special emphasis on software engineering teachers to take responsibility to expose students to codes of ethics as an instrument for developing professionalism and ethical competence [30], [31].

Though Harris and Lang [26] implore teachers to ponder on the ill-preparedness of graduates on ethics, several schools of thoughts have emerged regarding the teaching of computing ethics. There are divergent views as to the background of the teachers to be involved in the teaching of ethics and the instructional models to be adopted in teaching computing ethics [2], [32]. In response to these questions, in his essay Tavani [32] captures scholarly views of intellectuals like Jonhson, Dianne and Gotterbarn, whose works provided a detailed engagement on these questions.

Firstly, on the question of who can teach ethics better, it is believed that if the teaching of ethics is sourced from outside the faculty such as from philosophy experts, students may not seriously regard the subject as it may not appear to be mainstream [33]. Secondly, some believe that computer scientists lack knowledge in philosophy from which ethics derive existence, which may deny students opportunities to learn from the best whilst some believe that philosophy teachers lack technical knowledge in computing [32]. Monzon and Monzon-wyngaard [33] points out that both approaches are insufficient to integrate ethics approach.

Following on the question of instructional model, some schools of thought advocate for a single compound course that solely focuses on ethics whilst others prefer for the ethics content to be spread across several computing modules according to the applicability of the topic [32]. However, studies demonstrated that a multidisciplinary approach to the teaching of ethics can immensely enrich students' experience. For example, a study by Reich *et al* [34] which involved instructors from different faculties and industry experts resonated well with the course outcomes. Furthermore, Huyck *et al* [25] show as part of diversifying the teaching of ethics, that inclusion of students from various courses in ethics course generates positive outcomes. In support, Towell and Thompson [27] and Skirpan *et al* [28] respectively show that the functioning of an integrated instruction to ethics education yields success. The fact is, relevantly qualified teachers should be allocated to the teaching of software engineering ethics, sufficient time and faculty strategies should support the development of such ethical reasoning in the software engineering graduates.

To conduct ethics education instruction, the teacher needs to be aware of ethical and social issues technology is likely to confront the society with [17]. Therefore, such awareness should go beyond just the knowledge of principles prescribed by the codes of ethics, but also competently lead students through the ethical analysis learning process [35]. Furthermore, the views on ethics and an inclination to posture in a particular way to ethics is dependent on an individual's self-worth [36], hence it becomes deducible that a teacher who is ethically aware is likely to teach ethics to students better.

C. Research Advances on Software Engineering Code of Ethics Awareness

Due to the evolving ethical concerns in computing, research efforts on ethics awareness and professionalism remain relevant, as observable from previous studies conducted on this subject by [36]–[41]. Factors considered in the studies as having effect on ethics awareness on practitioners included individual characteristics such as age or maturity [42], [43], membership to a professional body [19], company commitment or leadership [44]–[46], and communication and enforcement [39] amongst others. Awareness of ethical codes helps to shape a computing professional, with their inclusion in education being the leading driver of ethical awareness [42].

There are other studies on ethical awareness that were conducted outside the academic environments and they include a study by Valentine and Barnett [37], which was carried out in a sales environment and found that awareness of codes is likely to improve organizational commitment and employees exposed to ethics codes view their work environments as being ethical. For the codes of ethics to have impact, [39] indicate that a relationship needs to exist between the codes of ethics awareness, their communication and their enforcement. Therefore, organizations need to demonstrate ethical leadership and commitment [44].

In the academic environment, a study by Cheng [47] sought to understand lecturers' perceptions toward teaching business ethics, and it found that teachers with greater self-efficacy perceive themselves as inclined to teach ethics in their domain. In relation to software engineering a study by Towell [19] found that majority of educators were aware of professional codes of ethics, and belonging to professional body appeared to be key to the awareness and promotion of such codes of ethics. A follow-up study by [27] revealed that whilst majority of educators were aware of the codes, 41% indicated that teaching of ethics was largely ignored, possibly due to lesser self-efficacy.

Several studies such as those conducted by [25], [48]–[51] studied ethical awareness on students but do not determine if those who are instructing the students, do have the ethical awareness required to teach the students and what their impact is on the students. Barnard *et al* [17] have demonstrated that computing instructors regard the teaching of computer ethics as importantly equal to the teaching of technological topics. We, therefore find it important to determine the extent to which lecturers involved in the teaching of software development are aware of software engineering codes of ethics, which are necessary and in some cases prescribed to instruct students. Furthermore, a study by Rogerson [52] shows that only 3% of professionals in the software development industry belong to a professional body, which implies that there is a possibility that there may be many university lecturers teaching in computing within the 97% who are not aware of the codes of ethics because they do not belong to a professional body.

This research study extends on the above studies as it analyses an environment of teaching software development, particularly in a UoT, in order to determine the extent to which a faculty is aware of software engineering codes of ethics.

III. Research Methodology

Online survey was utilized to collected data used in this study. The collected data formed part of a research project aimed at establishing software engineering ethical awareness climate in South African software development environments, including teaching environments. The data collection instrument was pilot tested with few targeted participants to ensure that the respondents interpreted and understood survey questions correctly. Following the pilot test of the data collection instrument, lecturers from two computing departments in a university of technology were individually invited through emails to participate in the study over a period of 6 months. A total of 103 email invites were sent out to staff members of the two departments, however, 44 participated in the online survey, resulting in a response rate of 43%.

A number of questions were posed to participants to determine their level of awareness of software engineering code of ethics. To ensure that respondents were the intended ones, only participants who chose a job description of a university computing lecturer were allowed to respond to the rest of the questions of the survey.

The study used graphical, univariate and bivariate analyses on the collected data in order to provide answers to the research question posed earlier. Due to the limited number of responses, inferential statistics, which could have enriched the findings of this study, was not be applied that. The next discussion presents the research results of the study.

IV. Research Results

A. Participants' Profile and Job Descriptions

Fig. 1 shows the profile of the 44 participants of this study. The data analysis results revealed that the majority (just over 77%) of participants were males, while females and those who chose not to specify their gender made up the remainder of the participants. On the other hand, 68.2% of the respondents were between 30 and 39 years of age, while 18.2% and 13.6%

of them were between 40 and 49 as well as between 50 and 59 years of age respectively, as shown in Fig. 2.

Seventy five percent (75%) of the participants had a post-graduate qualification; while 18.2% were holders of a degree qualification (see Fig. 3). The remaining 6.8% was split amongst participants who had a doctoral degree, a diploma and those who preferred not to divulge their qualifications. According to Fig. 4, the respondents who had more than 10 years of lecturing experience were 29.5%, followed by those who had between 3 and 5 years of work experience at 25%. The staff members who had between 1 and 2 years of work experience made up 15.9% of the participants, while the lecturers (educators) who had less than 1 year of work experience as well as the ones who had no lecturing experience were 13.6% each of the respondents.

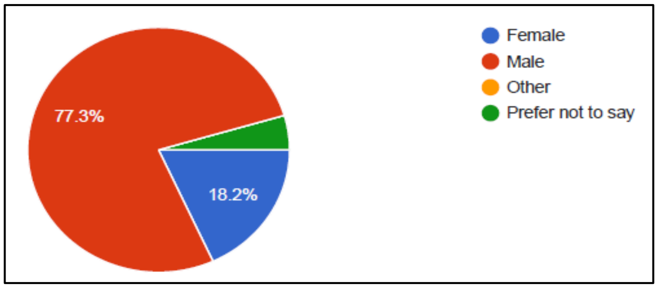

Fig. 1. Gender Distribution of Participants.

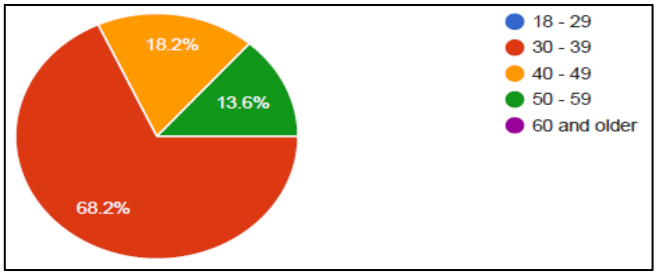

Fig. 2. Age Group of Participants.

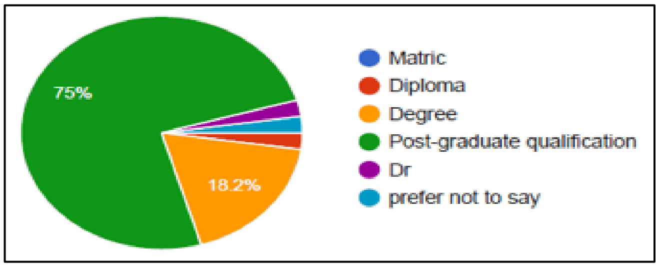

Fig. 3. Qualification Levels of Participants.

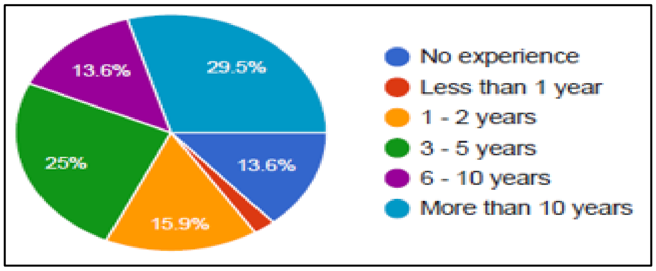

Fig. 4. Work Experience of Participants.

According to Fig. 5, the majority (52.3%) of the participants were holding lecturer positions, while those who held junior lecturer positions were 36.4%. About nine percent (9.1%) of the respondents were senior lecturers, while the remaining 2.2% preferred not to disclose their positions. Since there were participants who chose not to indicate their positions, it is therefore difficult to tell whether the two departments had participants who held professorship positions. If they did, it would have been very few individuals. Fig. 6 shows that only 11.4% of participants had membership with professional bodies, which included Institute of Electrical and Electronics Engineers (IEEE), Engineering Council of South Africa (ECSA), Institute of IT Professionals South Africa (IITPSA) and International Association of Engineers (IAENG). The notable part of these results is the lack of affiliation of any female educator to the professional organizations, as shown in Table I.

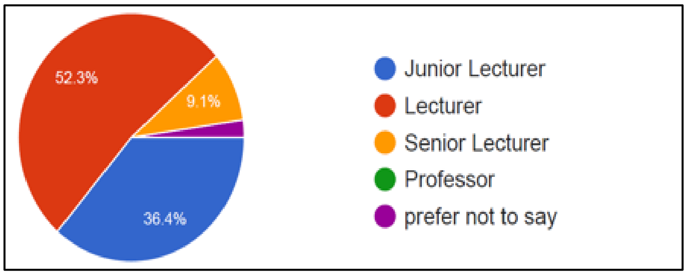

Fig. 5. Job Levels of Participants.

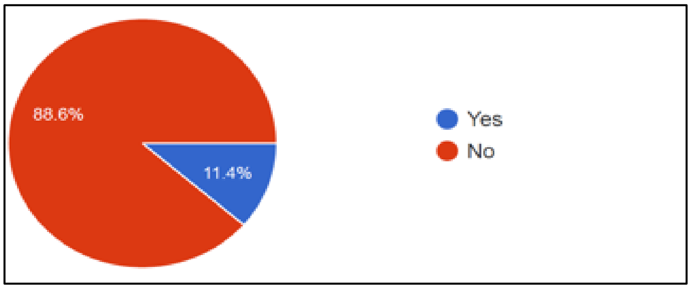

Fig. 6. Membership of Professional Bodies.

TABLE I. MEMBERSHIP OF PROFESSIONAL BODIES

	Gender	Responses	Frequency	Percentage
Membership of professional bodies	Female	No	8	100
		Yes	0	0
	Male	No	29	85.29
		Yes	5	14.71
	Prefer not to say	No	2	100
		Yes	0	0
		Total	**44**	**100**

B. The Level of Awareness and Exposure to a Code of Ethics Specific to Software Engineering

This study used the following measurements to gauge the level of awareness and exposure to software engineering code of ethics:

- Awareness of software engineering unethical incidents reported on the media.
- Previously been made aware of software engineering code of ethics, and if so,
  - How and where did the participant become aware?
  - Inclusion of software engineering code of ethics in current curriculum.
  - Presented software engineering code of ethics related topics.
  - Inclusion of code of ethics in modules offered by colleagues of respondents.
  - Discussions with students about current events related to code of ethics.
  - Code of ethics related learning outcomes in the content taught by participants.

The following discussion presents the responses of the participants, as shown in Table II (see next page), for each of the abovementioned measurements of code of ethics awareness.

TABLE II. RESPONSES OF PARTICIPANTS TO QUESTIONS REGARDING THEIR AWARENESS AND EXPOSURE TO SOFTWARE ENGINEERING CODE OF ETHICS

The level of awareness and exposure to a code of ethics specific to software engineering	**Measurements**	**Responses**	**Frequency**	**Percentage**	**Cumulative**
	Awareness of software engineering unethical incidents reported on media	No	22	50	50
		Yes	22	50	100
		Total	**44**	**100**	
	Previously been made aware of software engineering code of ethics	No	24	54.55	54.55
		Yes	20	45.45	100
		Total	**44**	**100**	
	How and where did the awareness occur	Through self-study and personal development	6	30	30
		Through their tertiary education	5	25	55
		Through short courses or workshops	4	20	75
		Through company policies	2	10	85
		Through membership to external professional bodies	2	10	95
		I don’t know or can’t remember	1	5	100
		Total	**20**	**100**	
	Inclusion of software engineering code of ethics in current curriculum	No: there is no such content in any content	9	45	45
		Yes: it is included in a compulsory course content	8	40	85
		Yes: it is included in an optional or elective course content	3	15	100
		Total	**20**	**100**	
	Presented software engineering code of ethics related topics	No	10	50	50
		Yes	10	50	100
		Total	**20**	**100**	
	Inclusion of code of ethics in modules offered by colleagues of respondents	No	7	35	35
		Yes	13	65	100
		Total	**20**	**100**	
	Discussions with students about current events related to code of ethics	No	7	35	35
		Not sure / Do not remember	5	25	60
		Yes	8	60	100
		Total	**20**	**100**	
	Code of ethics related learning outcomes in the content taught by participants	No	6	30	30
		Yes	14	70	100
		Total	**20**	**100**	

1) Awareness of software engineering unethical incidents reported on media: The respondents were split in the middle in their responses on their awareness of unethical incidents reported on the media – 50% said they were aware, whereas the other 50% claimed they were not aware.

2) Previously been made aware of software engineering code of ethics: The majority of the participants (54.5%) indicated that they were previously not made aware of the code of ethics pertaining to software engineering, while the remaining 45.5% percent said they were made aware. Those who indicated that they were made aware were asked follow-up questions, whose answers are presented next. When the results were interrogated little further, the indication was that, senior staff members (lecturers and senior lecturers) were the most ones (18 of the 27 = 67% of them combined) who were not previously aware of software engineering code of ethics, as shown in Table III.

3) How and where did the awareness occur: Thirty percent (30%) of the participants said they became aware through self-study and personal development, while 25% of the respondents said they became aware through their tertiary education (see Fig. 7). Twenty percent (20%) of the respondents said they were made aware through short courses or workshops that they attended, while 10% of each of the remaining 20% indicated that company policies and membership to external professional bodies played a role in the awareness process respectively. The remaining 5% said they could not remember or did not know.

4) Inclusion of software engineering code of ethics in current curriculum: Sixty percent (60%) of the participants indicated that the code of ethics or any topics related to it were not included in the courses/modules that the participants were involved in (45% of the participants) or if it was included, it was included in an elective module (15% of the participants). Forty percent (40%) purported that it was included in a compulsory course content.

5) Presented software engineering code of ethics related topics: The respondents were split in the middle – 50% said they once conducted a lesson on software engineering code of ethics related topic(s), while the other 50% indicated that they never did.

TABLE III. Level of Ethical Awareness by Job Level

The level of awareness and exposure to a code of ethics specific to software engineering	**Job level**	**Responses**	**Frequency**	**Percentage**
	Junior lecturer	No	6	37.50
		Yes	10	62.50
	Lecturer	No	15	65.22
		Yes	8	34.78
	Senior lecturer	No	3	75
		Yes	1	25
	Prefer not to say	No	0	0
		Yes	1	100
		Total	**44**	**100**

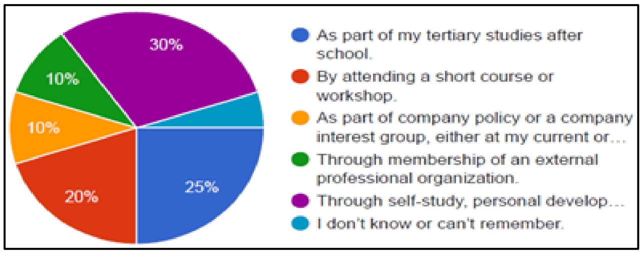

Fig. 7. Source of Ethics Awareness for Participants.

6) Inclusion of code of ethics in modules offered by colleagues of respondents: The majority (65%) of the participants said that they were aware that subjects that were offered by their colleagues had content on software engineering code of ethics, while 35% of the participants mentioned that they were unaware of such inclusion.

7) Discussions with students about current events related to code of ethics: Only 40% of the respondents could confirm that they had discussions with their students on recent (last 12 months) events related to software engineering code of ethics or code breaches. Sixty percent (60%) either never had such discussions (35%) or were not sure or could not remember (25%).

8) Code of ethics related learning outcomes in the content taught by participants: Seventy percent (70%) of the respondents mentioned that they were aware of software engineering code of ethics related learning outcomes (LOs) in the content they taught, while on the other hand, 30% of the participants were not aware of such LOs.

V. Discussion of Research Results

A. *Participants' Gender, Age and Job Profile*

The gender and age profile of participants show that the workforce in the two departments, have high gender imbalances and the workforce is relatively young. The job profile of the respondents indicates that the majority (70.5%) of them held lecturer positions and had no more than 5 years of experience and thus relatively inexperienced. These results should be expected given that the educators were relatively young as mentioned above. Almost 90% of the participants (including all female participants who identified themselves as such) were not members of any professional organization, which promote software code of ethics. Even though these figures are better than those mentioned in a study by Rogerson [52] they are still a cause for concern. This should be worrying because there are (should be) benefits (such as developing code of ethics awareness and individual development) for belonging to such professional bodies. However, the role of the professional bodies in providing code of ethics awareness to their members seems to be minimal given the fact that the results of this study show that only 10% of those who had subscription with these professional organizations received ethical awareness through them. This calls for improved code of ethical awareness campaigns from the professional organizations. Moreover, the professional organizations should have targeted drive to recruit female members.

B. The Level of Awareness and Exposure to Software Engineering Ethics Code

The survey results of this study show that more than half (54.5%) of the educators were not aware of software engineering code of ethics prior to this study, yet they are entrusted with the responsibility of educating students on the same code of ethics. Moreover, the analysis results revealed that the majority of the academics who were unaware of code of ethics held lecturer and senior lecturer positions (see Table III), which should be a concern given that these educators should be the guiding figures on issues of ethics. How can an educator, who is not aware of ethics, be able to lead a student to develop competent ethical reasoning? Furthermore, half of the academics were not aware of media reports of unethical incidents, and this should be worrying because a knowledge of such incidents should enable educators to practicalise the concept of ethics in lecture halls, thus allowing students to internalize and relate with the concept much better. Relating the incidents to students would help ease the difficulty of teaching ethics concepts to students. The awareness and knowledge of unethical incidents would not only demonstrate knowledge of violated principles prescribed by the codes of ethics, but would also assist in leading students through the ethical analysis learning process, as indicated by [35]. The lack of awareness of ethics code could mean such educators are unable to link ethics to practical day-to-day happenings that involve issues of software engineering code of ethics, resulting in failure to make students aware of their ethical responsibility as future software engineers.

There were three leading sources of awareness for the academics who were aware of software engineering code of ethics, and these were self-study and personal development (30%), tertiary education (25%) and short courses or workshops (20%). The organizational policies and professional organizations accounted for 10% each. However, even though tertiary education was amongst the three leading sources of code of ethics awareness it only accounted for a mere 25%, thus showing that tertiary education has little impact in this regard, bringing into question the level of coverage of software engineering code of ethics by our institutions. The majority (60%) of the educators indicated that the code of ethics or topics related to it were not included in the courses/modules that the participants were involved in (45% of the participants) or if it was, it was included in elective modules (15% of the participants). This finding and our observation on ethics coverage by our institutions of higher learning concur with the findings by Marebane and Hans [53] that the coverage of software engineering code of ethics by computing curricula of South African UoTs is inadequate. The preceding discussion has also brought into spotlight the lack of awareness of the code of ethics by the educators who are expected to be crusaders of the awareness campaign. It could also be possible that even though the code of ethics is covered by some modules/subjects in the institutions' curricula (65% of the educators indicated that code of ethics was covered by modules offered by their colleagues), but due to educators' lack of awareness (knowledge) of the code of ethics then the code of ethics topics do not get covered in the teaching. The results also show that of those that were aware of the code of ethics, only 50% (10 educators) of them ever lectured on the subject, meaning that 34 educators were either not aware of the code of ethics (24 educators) or never presented any lecture on code of ethics (10 educators). Another indication that code of ethics seems not to be receiving necessary attention from the educators is the fact that only 40% of those who were aware of code of ethics had a discussion in the last 12 months on code of ethics related events, the other 60% either never had a discussion or could not recall. An interesting finding of this study is that even though 70% of those who were aware of code of ethics knew about the learning outcomes in the content they taught only 50% of them ever presented a lecture on the subject, yet another signal of inadequate coverage of the topic by the educators. These findings reveal and confirm that indeed software engineering education receive marginal attention from our educators and curricula, as also purported by [18].

VI. Conclusion

This study set to answer and meet the following research question and objective respectively:

- What is the computing academics' level of awareness and exposure to a code of ethics specific to software engineering?
- To determine computing academics' level of awareness and exposure to a code of ethics specific to software engineering.

Two major findings of this study, which were presented in the previous section provided an answer to the study's research question and also met its objective. The two findings are:

- The worrying lack of awareness or exposure on software engineering ethics codes by the majority of the educators before this research study. This may be the possible cause for such lecturers not to be able to recognise the importance of including ethics in their curriculum, if they do include, they may fail to teach the principles contained in the codes sufficiently. Secondly, this lack of awareness may inhibit or disable the lecturers' ethical radar. Unfortunately, tertiary education played a minor role in educating lecturers (*who were once junior students*) on principles of software engineering code of ethics. This brings into question the level of coverage of code of ethics by tertiary institutions in their computing programmes. What makes this question even more valid and solid is that majority of the educators mentioned that software engineering code of ethics or topics related to it were either not included in the courses/modules that the participants were involved or were included in elective modules
- Half of the academics were not aware of unethical incidents that were reported on media. This could be the consequence of a disabled ethical radar, which subsequently will prevent lecturers from using such practical examples in their teaching, consequently

depriving students from learning from practical examples.

The concern that these findings highlight is the fact that the same educators who lack awareness of code of ethics are expected to be at the forefront of making students aware of the same codes they knew little about. This limits the ability to practicalise and relate the incidents to the curriculum and codes of ethics. How can they effectively fulfil their moral development educators' role of teaching ethics in technology courses, and to promote the ethicality of the profession when they lack ethical awareness? It is an imaginable expectation that academics who are entrusted with the responsibility of teaching students on the concepts of code of ethics of a profession are themselves in need of such education. To remedy the situation, institutions of higher learning should initiate or promote activities for professional code of ethics awareness for computing lecturers. Furthermore, lack of awareness by educators is likely to graduate software engineers who will fail to behave ethically and degrade the public view of the profession. Collaboration between universities and software engineering professional bodies on ethical practices and accrediting courses for software engineers can significantly improve awareness and ethical practices in the training of future software engineers.

VII. Limitations and Future Studies

The results of this study are based on self-reporting from participants and this has a possibility of biasness. It was also indicated in Section 4 that the number of responses to this study made it difficult to use inferential statistical, which could enrich the findings of the study, however this presents an opportunity for possible future study, which fulfils this requirement.

Automating and Optimizing Software Testing using Artificial Intelligence Techniques

Minimol Anil Job
Faculty of Computer Studies, Arab Open University
Kingdom of Bahrain

***Abstract*—The final product of software development process is a software system and testing is one of the important stages in this process. The success of this process can be determined by how well it accomplishes its goal. Due to the advancement of technology, various software testing tools have been introduced in the software engineering discipline. The use of software is increasing day-by-day and complexity of software functions are challenging and there is need to release the software within the short quality evaluation period, there is a high demand in adopting automation in software testing. Emergence of automatic software testing tools and techniques helps in quality enhancement and reducing time and cost in the software development activity. Artificial Intelligence (AI) techniques are widely applied in different areas of Software engineering (SE). Application of AI techniques can help in achieving good performance in software Testing and increase the productivity of the software development firms. This paper briefly presents the state of the art in the field of software testing by applying AI techniques in software testing.**

Keywords—Software testing; artificial intelligence; testing automation; software engineering; software quality

I. Introduction

Software engineering is the creation and application of sound engineering principles to produce cost-effective software which is both reliable and functional on real machines. A well-managed development process is needed to produce a high-quality software product. Software development is a human endeavor which involves various activities. The activities are; analysis, design, implementation and testing and each of them contributes to the creation of the final product. These activities continue in the development process, and thus producing a working version of the system can be time-consuming. Software testing is one of the principal activities in software development for verifying and validating a software system. Testing assists software developers in ensuring that the developed software fulfills its intended function, as well as determining whether or not the identified problems have been solved. Since the software development life-cycle is a complex process with a crucial need to deliver a new product within the allocated time, the software testing process should be efficient and effective.

In the software industry, automation plays a critical role in increasing testing performance. There are various automation tools available to support the testing activity. Newer technologies like Artificial Intelligence (AI) and Machine Learning (ML) are constantly being used to speed up the software development process. With the advancement of AI technologies, various business domains are accepting and using AI based software. AI systems are developed based on machine learning models and techniques. AI is used to promote automation and reduce the amount of routine activities to create testing phases by applying logic, problem solving, and ML. The purpose of this paper is to present the application of AI techniques in automation of software testing and the impacts. The paper is closed with a conclusion and a viewpoint of future work to enhance the practical aspects of the AI automation tool.

II. Literature Review

Testing is an activity takes place throughout the software development life cycle. The major aim of the software testing is find errors and to ensure that the developed system satisfies the requirements of customers. Software testing a way of evaluating a system by discovering the differences between the identified requirements at the requirement engineering activity and the archived results. There are various techniques used for testing a software to ensure quality. Testing can be done as manual or automated using specific tools [20] [7]. In manual testing, the software tester follows a test plan and complete a set of test cases manually. Manual testing is time consuming and cost effective. The alternative of the manual testing is the automated execution in which a software program runs a pre-defined test cases and shows and saves the results. Automatic testing executes the test-case automation, test-case generation and result verification. [2]. Automation testing tools are used in automatic software testing and the reliability as well as performance are more than manual testing [10] [19]. Software testing using AI techniques has been adopted by software development companies all over the world. The application of AI is wide-ranging branch of computer science that deals with building smart machines which are capable of performing smart tasks with assistance of human intelligence [9].

AI has become an emerging technology which can be applied in ensuring quality assurance (QA) in organizations [26] [15]. AI developments require an approach to validation and verification of software. AI has becoming an important factor in quality assurance and testing in future. [14]. AI is a branch of science and engineering concerned with the computational analysis of intelligent behavior and the creation of intelligent machines. The term AI refers to a collection of tools, techniques, and algorithms [3] [11] [21]. Application of AI techniques are creating impacts in various domains like health, manufacturing etc. Emergence of big data and its management requires strong computing tools and AI helps in improving the efficiency of these activities. AI techniques are applied in different areas of software engineering such as requirement engineering, design and testing [24]. AI in software testing aims to make testing smarter and more efficient. AI and machine learning apply reasoning and problem solving to automate and improve testing. AI in software testing helps reduce time-consuming manual testing, so teams can focus on more complex tasks, like creating innovative new features. Faulty software is mission critical as software becomes an increasingly important component in a wide variety of systems. Since automated test generation techniques are free of the cognitive biases that have been found in human testers, they can be used for software testing [4].

Automating the execution process of the software testing cycle is the most common approach in the automation field. Automated software testing is important and adding more toolkits to make testing phases fully automated by generating test scripts is also equally important. Test cases can be generated to complete the automated testing [22]. The test execution speed will be increased by this tools and the testing process can be applied repeatedly. In manual testing method, developing test scripts is a time consuming process but if the test cases are ready the human tester can complete the testing process quickly [27] [25]. In manual testing, code visibility does not affect test code coverage and fault detection rate12]. It is possible to facilitate a process for eliciting testing requirements and creating test-suites [1]. Various algorithms are used in AI tools. Use of Bayesian probabilistic reasoning to model software reliability is an example probabilistic AI technique. This is used in the discipline of Software Engineering [18] [5] [21]. AI techniques can be applied in supporting automation and decreasing the amount tedious tasks in the software development and testing phase [17].

III. Software Testing

Software testing is one of the crucial stage in the software development life cycle and it is an important method to assess the developed software to ensure quality. Before releasing the final product, it is important to ensure that the requirements identified during the analysis stage have been accomplished as well as the product is defect free. In the context of software development, bug is a name given for the defect which means the developed system is not producing accurate results as per the requirements. Testing plays an essential part in the software development process. Various techniques can be used during the software development process to facilitate testing. Prototyping is one of the approaches in which an experimental software artefact will be developed and that will be discarded after evaluation. Early software artefacts are built on rather than discarded in the Iterative approach [23]. Another approach is using frameworks such as the dynamic systems development method (DSDM) in which best practice processes for iterative and incremental development are documented [13].

A. Categories of Testing

Software developers need to be aware and to be able to use a range of other testing methods, concepts and practices. The four distinct categories of testing are summarized in Fig. 1:

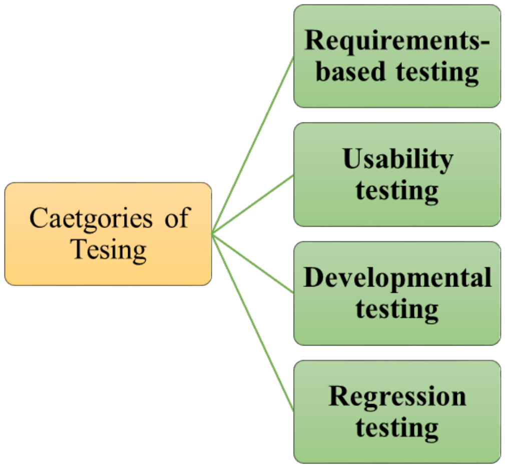

Fig. 1. Categories of Testing.

Table I presents the details of the four categories of testing shown in the above figure.

TABLE I. TYPES OF TESTING

REQUIREMENTS-BASED TESTING
➢ Checks that a system meets the customer's requirements using previously gathered or formulated testable requirements. ➢ Acceptance testing is the final stage to check that the user requirements have been satisfied. ➢ The customer formally accepts the software by ensuring the correct functioning of the acceptance tests
USABILITY TESTING
➢ User interface (UI) is an integral part in every software system. ➢ Various users other than the developers are using the system and the usability testing is essential. ➢ Due to the problems of user interface, the systems may fail. ➢ Usability testing comprises systematically trying out the user interface with intended users
DEVELOPMENTAL TESTING
➢ Refers to the testing carried out by the entire software development team. ➢ The developmental testing is done in three different levels which are unit testing, integration testing and system testing. ➢ Integration testing involves checking that all the tested units are interfaces together correctly.
REGRESSION TESTING
➢ Any form of testing done during the development or maintenance of a system to ensure that fixing one bug does not result in the introduction of new ones. ➢ are needed at unit, integration and system levels depending on the particular development method adopted ➢ Regression tests are critical during the developmental testing and in system maintenance.

B. Software Testing Techniques

Strategies for creating test cases is an important part of validation and verification. The two major strategies are black-box testing and white-box testing. The main objective of black box testing is to ensure each aspect of the customer's requirements is handled correctly by an implementation. The test cases are designed by looking at the specification of the system. The specification includes the details of the systems intended functions.

Grey-Box Testing is another method in which the application is tested with complete knowledge of the overall aspects of the system and limited knowledge of the internal functioning of the system. [12]. The major objective of white box testing is to check that the details of an implementation of the system are correct. The test cases are designed by looking at the detail of the implementation of the system to be tested to check that the system performs its intended functions correctly [8].

While comparing the possibility of automation of black-box and while-box testing techniques, automating white-box testing is easier than black-box testing. The reason is that box in black-box testing, programmer and the tests are dependent and this will affect the automation. Since grey-box testing provides the features of both black-box and white-box testing techniques, it's features and techniques are not considered in detail in this paper.

Fig. 2 depicts the five strategies used in black-box testing and four strategies used in white-box testing.

The different black-box testing techniques are summarized in Table II [17, 22].

The different approaches of White box testing are listed in Table III [17, 22].

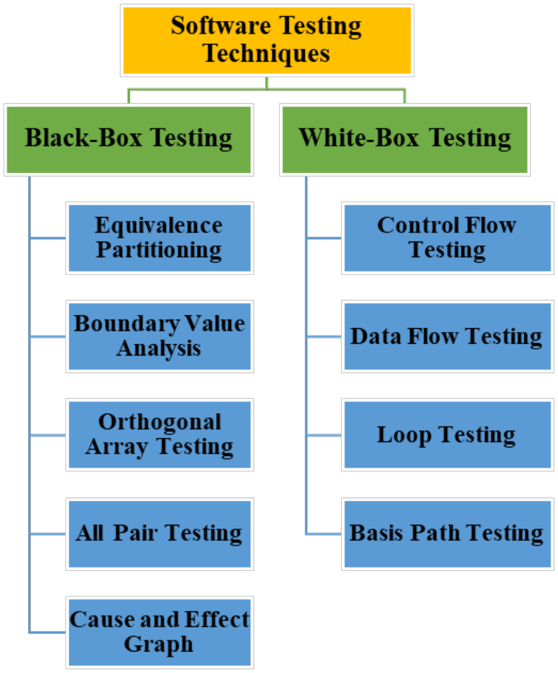

Fig. 2. Black-Box and White-Box Testing Techniques.

TABLE II. BLACK-BOX TESTING TECHNIQUES

Black-Box Testing Techniques
Equivalence partitioning
➢ This technique divides the input domain of the software unit into groups or partitions and generates test cases thus helps in reducing the number of test cases.
Boundary value analysis
➢ Errors at the boundaries of the input domain are tested in this technique. ➢ The boundary values are usually taken the minimum and maximum values in the boundaries and values just inside and outside of the boundaries.
Orthogonal Array Testing
➢ It's a strategy for problems with a limited input domain that are relatively small and cannot be tested thoroughly
All pair Testing
➢ In this method, test cases are created using all possible combinations of each pair of input parameters.
Cause and effect Graph
➢ In this approach, a graph is generated and a cause-and-effect relationship is formed. The cause is the input condition that leads to internal change in the system and the effect is the output condition.

TABLE III. WHITE-BOX TESTING TECHNIQUES

White-Box Testing Techniques
Control Flow Testing
➢ This technique uses a testing strategy in which control flow of the program is involved in the test coverage. Branch coverage, statement coverage and condition coverage are the three methods used in test coverage.
Data Flow Testing
➢ Data movement within the program is focused in this testing strategy and the test paths are determined from the positions of variable definition in the program. This technique helps to detect errors such as undefined variables etc.
Loop Testing
➢ Different types of loops such as simple loops, nested loops are used in most of the programs. Validity of the loops in the programs are tested using this technique.
Basic Path Testing
➢ Basis-path testing is based on the cyclomatic-complexity metric. The number of independent paths in a method body is computed using this metric.

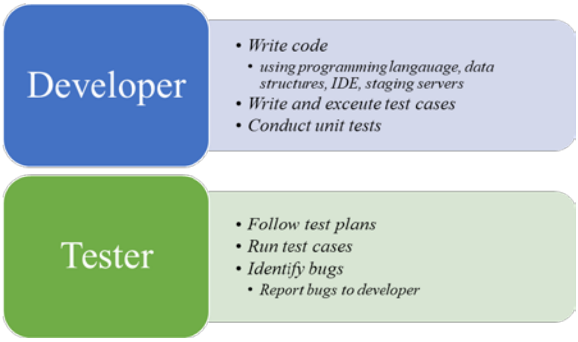
IV. TEST AUTOMATION

The need to make sure that users are really receiving the value promised by the software, many powerful testing tools have emerged, which make it easy to do black box testing in an automated and repeatable manner. The automation is important because the testing process is repetitive and it is recommended to test all possible scenarios. Automating tests will increase the test coverage and improve efficiency. When the testing process is automated, the tests can be executing repeatedly, test different input values and various conditions. The testing resources and time will be reduced. To automate functional, system and acceptance tests, numerous tools are available. Some of them are Selenium, Watir and JMeter. Selenium and Watir are used to test local files using the file:// protocol supported by web browsers, however, JMeter needed the target files to be hosted on a web server.

V. Application of AI in Software Testing

Due to the increasing complexity and features, modern applications require various features in order to achieve the functional and non-functional requirements of the applications. Requirements are the information about what a system will be and do that needs to be known before development starts. Once the requirements are identified and agreed by the developer and the customer, they will be implemented in the software system. Converting the requirements into an application using appropriate tools and techniques is the role of the system developer. The application should be developed without errors and during the coding stage, the developer needs to write down and execute test cases. A software tester is a person who is in charge of putting an application through its paces and ensuring that it performs as intended. Software testers play a crucial role same as the developer in the software engineering activity as they are part of the quality assurance of the software. The software tester sends a report to the development team detailing the bugs found and the sequence of events that contributed to the mistake. As shown in Fig. 3, the Developer‘s responsibility of writing code and writing and executing test cases. The testers will follow the test plans and complete the testing tasks.

Software testing is an important process which ensures the developed system’s satisfaction from the customers. Testing helps to protect the system against any failure which may lead potential impact in organizations’ performance during the operational period. In manual testing, the software is tests are executed by the software tester to discover bugs in the system. Even though exploratory testing is possible in manual testing, it is a time-consuming process by involving human resources and test cases are executed by a human tester and software. Automated testing is considerably faster than manual testing and faster than a manual approach and uses automation tools to execute test cases. As testing is moving more and more towards automation, AI techniques are applied in software testing. AI techniques supports the automation of the testing processes in an efficient way. AI algorithms are supporting the testing environment to be more productive. The AI algorithm encourages the process and helps software testers to find the maximum number of bugs within less period of time. The system can be route to market as reliable and accurate. Fig. 4 and Fig. 5 show the functions of a tester and a developer in manual and AI enables testing environments.



Developer
• Write code
• using programming langauage, data structures, IDE, staging servers
• Write and exceute test cases
• Conduct unit tests
Tester
• Follow test plans
• Run test cases
• Identify bugs
• Report bugs to developer

Fig. 3. Tasks: Software Developer Vs Software Tester.

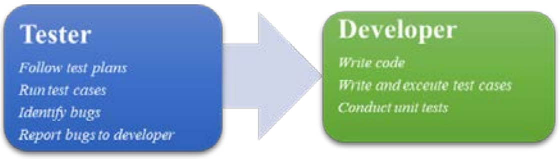


Fig. 4. Functions in a Manual Testing Environment.

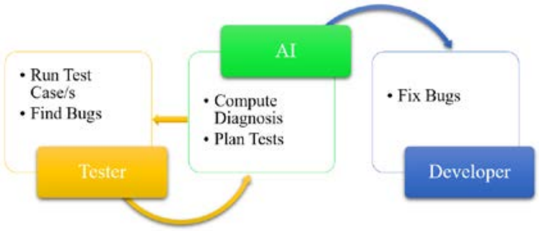

Fig. 5. Functions in an AI Enables Testing Environment.

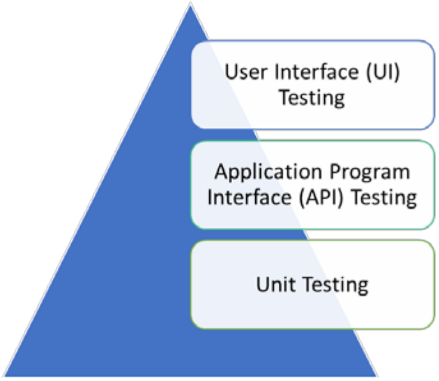
In a manual testing environment, the tester runs the test cases according to the test plans, finds the bugs and reports them to the developer. In the AI based testing environment, the tester runs test cases and finds the bugs. The AI tool do the diagnosis and send notification to the developer to fix the bugs. The AI tool plans further tests automatically and the testers will continue running the test cases and identify bugs.

The functional and non-functional requirements of the product need to be tested by ensuring the full test coverage. In manual testing this will take time and resources and application of AI techniques will reduce the time and also will help to identify poorly designed requirements. Requirements will be thoroughly verified using AI and it will be transferred to the design stage, the next stage in the software development life-cycle. Based on the experience of the software testers, the test selection and quality will vary and the tests are created based on the requirements, use cases and user stories. Application of AI helps to automatically generate test cases and identify the tests for verification and validation of the system. Ai also help to understand the test coverage as well. Missing or inappropriate test can be identified based on the models. Ain addition to this, automatic generation of the test cases will also reduce any eluded bugs and defects also.

VI. Application of AI in Test Automation

Business organizations in various sectors are adopting AI techniques makes their operations efficient. In software development process, automation testing is widely used to improve the test efficiency. There are various ways AI techniques can support the software testing process [6] [16]. The most benefit takes from AI is the black box testing. Applications of AI techniques in software testing is listed.

Fig. 6 depicts the test automation in pyramid shape according to the test types. UI testing is placed in the highest level because and this is the most expensive testing. Test automation can be done in the lower levels both in API and Unit layers to achieve best test coverage and reduce time and cost.



User Interface (UI) Testing
Application Program Interface (API) Testing
Unit Testing

Fig. 6. Test Automation Levels.

User Interface (U) testing: Usability tests are conducted to identify any design inconsistencies or usability issues in the user interface. To build UI tests, AI techniques use image recognition techniques to navigate through the application and visually validate UI objects and components. The test automation tools decode the Document Object Model (DOM) and related code to determine object properties in AI-based UI testing. The UI tests are done after the design and development of the software system. In the pyramid, UI tests are in the top level of the pyramid and the automation is challenging and they are the hardest to automate.

Application Program Interface (API) Testing: In API testing, validation of Application Programming Interfaces (APIs) is done by testing various software quality factors of the programming interfaces such as functionality, performance, reliability and security. Nonfunctional requirements like look-and-feel are not relevant in API testing and focuses on the business logic instead. Without any reference to the user interface, API automation can be used to validate the business logic. Automation of the API allows the software development team to start the testing activity early which helps to identify and fix errors and reducing the efforts in the AI testing.

Creating and updating unit tests: Unit tests are used to ensure that small pieces of code, such as functions or object methods, are correctly executed before they are combined with other units to form a larger functional feature. Developers spend a significant amount of time writing and maintaining unit tests, which is much less enjoyable than writing application code AI-based products for automated unit test development can be beneficial and they can be generated promptly. Automation strategy starts with unit tests. Unit tests are written by the developers using the same application development programming language. Early detection and correction of errors in the unit testing will prevents regression defects.

In addition to the above mentioned testing automation strategies AI can be applied in the following areas of the software testing also.

- AI is used as an adaptive method for detecting element-level changes that will improve the testing suites' robustness.
- aid in the prediction of incorrect test cases that result in total test failures, as well as include recommendations for resolving those issues.
- used in simulating Behavioral patterns.
    - AI techniques helps to simulate the behaviors of people in using the system by geography, devices and demographics as inputs to build test suites.
- AI algorithms are efficient in prediction and automation of test suites.
- used in script Automation.
    - Automating a test script is not required in AI because it is executed from the AI algorithm automatically.
- Helping in mining defects and based on this test suite can be defined. This speeds up the process of making informed decisions about test coverage and test suite optimization.
- Enhances number of tests and their scopes.
- AI techniques are applied in Automation Test Maintenance, Test Data Generation, early feedback in testing etc.

VII. AI Based Test Automation Tools

A. AI Bases Automation Tools

Table IV summarizes 5 AI based automation tools uses in software industry recently.

TABLE IV. AI based Automation Testing Tools

Testing Tool	Application
Testim	This AI tool is used to automate functional testing by using artificial intelligence and machine learning. This automated testing tool speeds up the authoring, execution, and maintenance of automated tests.
Functionize	A cloud based automated testing technology used for functional, performance and load testing. This automated testing tool speeds up the test creation, diagnosis, and maintenance.
Appvance	This AI enabled tool used for automating functional, performance and security testing. The AI integrated tool helps codeless test creation.
Applitools	This AI enabled tool used for User Interface (UI) testing. It provides an end-to-end software testing platform powered by Visual AI and used in Quality Assurance and test automation.
Testcraft	This AI-powered test automation platform supports regression testing and also for monitoring of web applications. The AI technology helps in eliminating maintenance time and cost.
Watir	This is an open Source tool, uses Ruby Libraries to automate tests. Watir is used for testing websites and uses Selenium for browser automation. In addition to this Watir also supports in writing stable and maintainable test scripts.

Functional tests are part of integration tests and designed to evaluate specific tasks. For example, user registration in an online system, the registration function should validate the data entry from the user. Other examples are catalogue search and online payment in an e-commerce application etc. A wide range of test values are required to perform these tests. Performance testing is used for measuring the ability of servers to respond to user demand in a networking environment. A load test is a method of evaluating a server's performance by applying a given load to the application in order to evaluate the response time for individual functions. The aim of security testing is to ensure that the application has authentication and authorization controls in place and is not vulnerable to attacks. User interfaces are usually tested for Navigation errors, presentation errors and control usage problems. Regression testing can reveal defects that recur as a result of software changes that were not planned.

B. Pactical Application: Using Watir

Watir (Web Application Testing in Ruby) has been selected as a software experimenting too to support the technical aspects of the research. l. The Watir supports almost all of the web browsers. The websites and user interfaces can be tested using Watir. The test framework by using Watir follows the following order as shown in Fig. 7.

After installing the required drivers, test scripts for opening browsers have been written in the RubyMine IDE. The test scripts are written in Ruby language. Watir is selected for the practical application because first of all, it is very easy to use open source tool. This tool is developed using Ruby and any web application can be automated irrespective of the browser it is running. There are in-built libraries in Watir to support various activities such as page performance. Fig. 8 depicts the test script for opening Chrome browser.

Fig. 9 demonstrates another sample of creation and execution of test case using Watir. A simple test has been used to test the accuracy of the code. The test script runs successfully.

Fig. 10 shows an example of a test script for the user interface testing. The sample HTML and JavaScript code is shown in Fig. 11 for the page.

The presentation of the web page is done using HTML and a JavaScript function is used for the static feature of the page code using HTML and Fig. 11 shows the code.

Fig. 12 shows the debugging screen of another sample test script with another browser, Firefox using Watir automation tool.

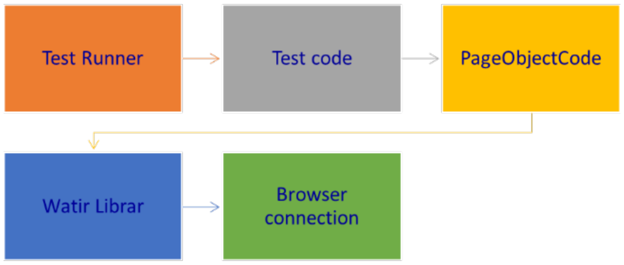


Fig. 7. The Order of Test Framework in Watir.

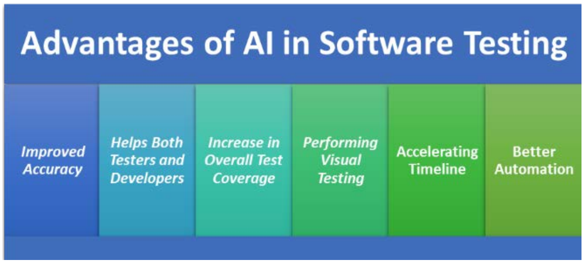
After running the test cases using it can be concluded that Watir allows easy to test file download for the user interface of a web application. Popup test alerts are provided at times as well. Another feature in Watir is, Page Performance can be measured using the performance object. Navigation, timing and memory performance can be measured by getting these details when the application is connected to the browser. Page object feature available in Watir helps reusability of the code basically in the form of classes. This feature of Watir helps the automation of the application without code redundancy. Without opening the browser, the details are obtained in the command line and thus supports the execution of the user interface test cases at the command line prompt.

VIII. Advantages of using AI in Software Testing

Fig. 13 lists the advantages of using AI tools in automating software testing. When the testing of a software system is done manually by even by highly skilled and experienced software testers there is a possibility of making mistakes and experience tiredness. Artificial Intelligent tools are constantly performing tasks effectively even repetitive tasks. Automated testing tools cab ne used by both software developers and testers. If the modifications ad editing of the program source code are cheeked thoroughly software tests will run automatically. For any unsuccessful tests, the developers will be notified and thus saving the time of the developers. AI enables automatic testing can help in improving the overall test coverage and ensure quality of the developed software. The performance of the system can be tested against the expected requirements in an efficient manner. AI enables testing can perform image and pattern recognition. This feature will help in detecting visual errors and make sure all visual elements are working properly. Software testing is a repeating process and source code may change time to time, manual testing will be a time consuming task. AI tools can perform the testing and detect errors with lesser time and AI tools are not expected to make errors and will help to generate more accurate results. Test automation can be done efficiently AI enables testing tools.



Advantages of AI in Software Testing
Improved Accuracy
Helps Both Testers and Developers
Increase in Overall Test Coverage
Performing Visual Testing
Accelerating Timeline
Better Automation

Fig. 13. AI Enabled Testing: Advantages.

IX. Conclusion and Future Work

Producing a quality software to the clients within the specified time by incorporating all the requirements is a crucial task. By using annual testing approach this will not be easy. There are various automation tools available to perform software testing. Artificial Intelligence techniques have significant impact in various stages of software development activity including software testing. Application of AI in test automation is an appropriate solution for software testing activity to produce a defect free software application. This paper presented the role of artificial Intelligence tools in software testing.

The paper also looked into various types of testing techniques for validation and verification of the software system. Selection of an appropriate AI based test automation tools is important based on the type of testing and this paper discusses the features of popular AI enables testing tools. Finally, the paper is presented the advantages of AI testing tools applications in software testing. An extension of this research paper will be presented by evaluating AI based test automation tools by taking into consideration of more technical details. Enhanced practical aspect will be covered by real implementation of the test automation of white-box testing using a mobile application.

***Abstract*—Through digitization, maintaining and promoting cultural heritage is being strengthened. Concerning this background, this study presents a new Indonesia cultural events dataset and automatic image classification for cultural events. The dataset was developed using the Flickr image platform, and the five cultural events image was collected including the Baliem Festival, Jember Fashion Festival, Nyepi Festival, Pacu Jawi, and Pasola Festival. Further, Convolutional Neural Networks (CNN) was developed for the classification method. A comparison of CNN models (VGG16 and VGG19) using several optimization configurations was performed to get the best model. The results showed that the VGG16 with image augmentation and dropout regularization technique performed best with 94.66% accuracy. This study hoped to support the heritage's digital documentation process and preserve Indonesia's cultural heritage.**

Keywords—Cultural events; convolutional neural network (CNN); very depth convolutional network (VGG); multi-class classification

I. Introduction

Cultural events are created based on social systems or cultural wisdom passed from one generation to another [1], [2]. They have historical roots, customs, values, and beliefs influenced by many aspects such as region, social, and culture [3]. Hence, each specific ethnic group can be recognized based on their traditional cultural events. Understanding cultural values benefits maintaining cultural heritage [4]. As stated by The United Nations Educational, Scientific, and Cultural Organization (UNESCO) mission, every country is encouraged to approve the World Heritage Convention and ensure the identification, protection, and preservation of its cultural heritage [5]. Therefore, it is essential to sustain the cultural heritage in the face of rapid globalization in line with UNESCO's mission.

With the rapid development of technologies, the effort to preserve cultural heritage is being supported. By implementing digital documentation, cultural heritage can be quickly promoted and maintained. Several benefits of digital cultural heritage can make possible (a) transformation of heritage objects into the digital form [6], (b) quickly access to digital heritage [7], (c) indexation of historical heritage contents and extraction of their information [8], and (d) permanent preservation of digital objects [9]. Concerning all of those benefits, classification methods play an essential part. Classification refers to developing the classification model that will recognize the instances into categories or classes based on the training data (named supervised learning). The classification model learns from a training dataset and implements the achieved knowledge to classify new data. Therefore, documentation and classification of cultural heritage are essential since each country must save and preserve its cultural heritage.

In Indonesia's context, several issues have been discussed concerning Indonesian cultural heritage, such as foreign country claims to Indonesian regarding the cultural heritage, lack of the inter-generational transfer of knowledge in education, and lack of recognition from the local government [10]. In recent times, several efforts have been implemented to preserve and promote Indonesia's cultural heritage. For example, the Indonesian government strengthened the cultural heritage curricula in education, especially for the young generation. The Indonesian government also promoted the tagline "visit Indonesia" that has the goal to spread Indonesia's cultural events across the globe and targeted to attract visitors to Indonesia [11]. However, the preservation and promotion of cultural heritage are challenging. Indonesia is the world's largest archipelago nation, and it has one of the most varied cultural heritages with more than 300 distinct ethnic groups. Each ethnic group in Indonesia has cultural identities. Because of Indonesian culture's richness, the number of recognizable cultural events is also quite large. Thus, it needs documentation efforts to save and maintain the original cultural heritage of Indonesia.

To the best of our knowledge, no Indonesian cultural events documentation or dataset is available that describes a specific region's cultural events. One study investigated Indonesia's cultural heritage [12]. However, that study did not present Indonesia's cultural events rather than architectural heritage. Consequently, no specific Indonesian cultural events database is publicly available. Also, The Ministry of Tourism and Creative Economic of the Republic of Indonesia (Kemenparekraf RI) struggled to promote cultural events using the website https://www.indonesia.travel/, which primarily focuses on promoting various destinations in Indonesia for domestic and international tourism. However, that website does not promote cultural events.

Therefore, to support cultural heritage preservation, this study aims to present a new Indonesia's cultural events dataset and automatic image recognition for classification cultural events. Several CNN models for multi-class image classification were tested to achieve better accuracy. This paper has several contributions, specifically: (i) this study presents a new dataset of Indonesia's cultural events, and it has been made openly available to replicate this work (see link on the section availability of data and materials). The dataset would also be advantageous for researchers to consider adding a new image class to achieve the large dataset. (ii) The methodology of CNN with different hyper-parameter techniques is presented, and the results of the practical comparison are shown. Those results can be used as a benchmark for future researchers to improve the multi-class classification algorithm. In general, the proposed dataset and automatic classification system hoped can enhance an essential part of the heritage's digital documentation process and support an effort to preserve the cultural heritage.

This paper is organized as follows. Section 2 explains the materials and methods used in this study. Section 3 describes this study's results, followed by the discussion in Section 4. Finally, Section 5 explains the study's conclusions and future work.

II. Related Works

Several studies have developed cultural heritage documentation and implemented different methods to classify cultural heritage [13]. For example, in the study of architectural heritage, the authors proposed the image dataset of more than 10.000 images classified into ten classes, i.e., different architectural heritage types such as columns, domes, gargoyles, and vault [14]. This study compared the deep learning algorithms to categorize cultural heritage images. Specifically, several convolutional neural networks (CNN) were implemented, AlexNet, Inception V3, ResNet, and Inception-ResNet-v2. They achieved good accuracy on the complete training data; ResNet obtained a higher accuracy. In the fine-tuning configuration, the best accuracy was achieved for the Inception-ResNet-v2.

An early study [15] was investigated on a dataset containing 1.227 images dataset of 12 cultural heritage memorials and Pisa landmarks. The image classification was compared by using the k-nearest neighbor (k-NN) classification with different types of the feature extraction, namely Scale Invariant Feature Transform (SIFT), Speed up Robust Feature (SURF), Oriented FAST and Rotated BRIEF (ORB), and Binary Robust Invariant Scalable Keypoints (BRISK). They obtained that the local feature-based classifier achieved good accuracy; on the other hand, the best performance was reached using SIFT concerning the features.

Another study proposed 100 cultural heritage of wall painting images of reflected light for the image classification task [14]. The image dataset was involved in the reflected image, such as visible light, ultraviolet light, infrared light, and visible fluorescence. The authors used Dense SURF, spectral information, and a support vector machine algorithm. They concluded that the higher accuracy was the image in reflected ultraviolet light. Simultaneously, the dense integrating SURF and spectral information obtained the best accuracy than executing them individually.

The previous study [14] proposed an Indonesian cultural heritage dataset for image, audio, and video classification. The dataset includes 100 images, 100 audios, 100 videos, and 100 text files separated into five classes. The deep learning algorithms, Convolutional Neural Network (CNN) and Recurrent Neural Networks (RNN), were executed to classify Indonesian architectural heritage. The CNN was executed for image, audio, and video classification, while RNN was executed to classify text. The results revealed that RNN obtained the best performance regarding the accuracy, classifying 92% of the text data. Concerning CNN, the higher accuracy (76% each) reached for image and video classification, and audio acquired 57% accuracy.

In the study of archaeological sites [16], the author collected the cultural heritage dataset that included 150 images and categorized them into three classes (50 images each category): archaeological sites, frescoes, and monasteries. This study aimed to classify images using several decision tree algorithms such as J48, Hoeffding tree, random tree, and random forest. The authors determined that the random forest algorithm achieved the best performance.

Although several studies have shown advances in researching the cultural heritage for image classification, mainly those research only focused on the architectural building classification as explained in the above. A study involving cultural events or ceremonies was not still profoundly studied. Thus, studying cultural events are necessary to support the way to protect and promote cultural heritage for future generations.

III. Material and Methods

A. Materials

The scrapping image method was performed to collect Indonesia's cultural events using Python programming. The Flickr image service was used for collecting the image datasets. The Flickr images under Attribution-Noncommercial License were collected. Five cultural events were collected: Baliem Valley Cultural Festival, Jember Fashion Carnival, Nyepi the Day of Silence, Pacu Jawi, and Pasola Festival. The dataset consisted of 1.500 images and was divided into 300 images in each class. The image samples from the five classes are shown in Fig. 1. The images represent (a) Pasola, (b) Pacu Jawi, (c) Nyepi, (d) Jember Fashion, and (e) Baliem.

B. Methods

The experiments were performed in Python v.3.7 environments, and the CNN (VGG) model was developed with the Keras library. The experiments were performed under Windows 10 platform, 16 GB Graphical Processing Unit (GPU), 256 GB SSD storage, Core i7 processor 1.80 GHz, and 8 GB of RAM. All images were converted into 200 x 300 image pixels. The distribution of image classes is shown in Fig. 2.

(b) Pacu Jawi Festival
(c) Nyepi the Day of Silence
(d) Jember Fashion Festival
(e) Baliem Valley Cultural Festival

Fig. 1. Examples of Five Image Classes: (a) Pasola Festival, (b) Pacu Jawi Festival, (c) Nyepi the Day of Silence, (d) Jember Fashion Festival, and (e) Baliem Valley Cultural Festival.

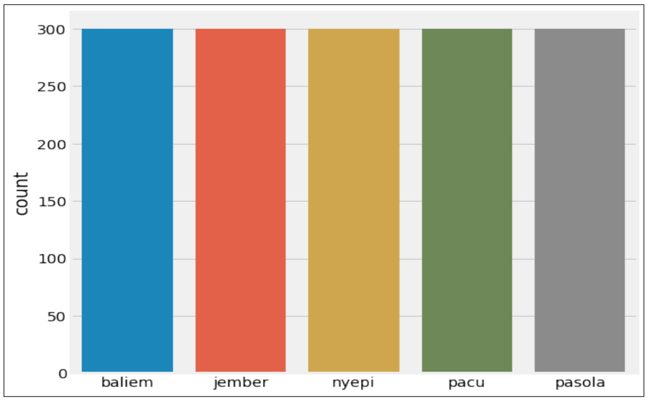

Fig. 2. Distribution of different Classes of the Dataset.

1) Convolutional Neural Network (CNN): CNN is usually applied for computer vision, as it captures images as inputs and extracts features from the images. The CNN typically contains convolutional layers (each involving several kernel sizes and filters). The convolutional layer is along with the pooling layer, decreasing data dimensionality. There are two types of pooling: max-pooling and average pooling. Max-pooling uses the maximum value from the image related to the kernel size, while average pooling utilizes the average of all the values. Once image processing is accomplished across these layers, the features from a two-dimensional matrix are converted into a vector with a flatten layer, and the achieved output is transmitted to the fully connected layer or dense layer [17].

2) Very Depth Convolutional Network (VGG): VGG's name belonged to their lab's name, the Visual Geometry Group at Oxford, and the ImageNet Large Scale Visual Recognition Challenge (ILSVRC) 2014 competition winner [18]. This architecture was designed for deep convolutional network learning. The VGG architecture is created by 3 x 3 Convolutional and MaxPooling layers, with a fully connected block at the end. In the original paper, VGG architecture has shown the depth network's effect on its performance in the large-scale image database. VGG used small (3 x 3) convolution filters in the complete architecture and presented a considerable improvement in the configurations using the depth to 16-19 weight layers [18]. Another advantage of VGG architecture is that they used many filters. The number of filters grows with the depth of the model. They start at 64 and continually increase across 128, 256, and 512 filters at the end of the model's feature extraction. VGG was named for the number of layers: the VGG16 for 16 layers and the VGG19 for 19 learned layers. The architecture for VGG16 and VGG19 is presented in Fig. 3(a) and (b). The summary of the architecture of VGG models as follows: (i) apply small convolutional filters, e.g., 3 x 3 and 1 x 1, (ii) apply max pooling with a size of 2 x 2, (iii) the stacking of convolutional layers concurrently before applying a pooling layer to identify a block, (iv) dramatic reiteration of the convolutional-pooling block pattern (v) development of intense models (16 and 19 layers). The architecture of VGG16 and VGG19 are depicted in Fig. 3. In this work, the VGG 16 and VGG19 models were used for the experiment.

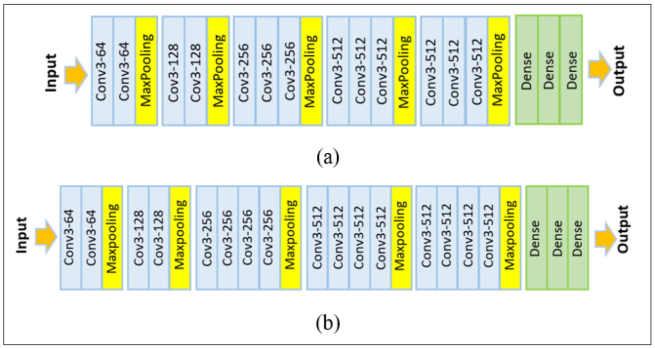

Fig. 3. The Architecture of VGG16 (a) and VGG19 (b).

3) Image augmentation optimization: The image augmentation works to create a new and unique training example. Image augmentation transforms the images' versions in the training dataset corresponding to the same class as the initial image [19]. That transformation involves several image manipulation processes, such as shifts, flips, and zooms. The current deep learning algorithms, such as CNN, can quickly learn the image features. The augmentation technique can improve the algorithm's learning process, and it is usually implemented to the training dataset, not to the test or validation dataset. In this work, the Keras deep learning library was used. That library offers several image augmentations functions via the ImageDataGenerator class. Several augmentation functions were used, such as the horizontal and vertical flip of image (randomly flip training image), rotation (randomly rotate images in the range of degrees), brightness, and zoom (randomly zoom image).

4) Dropout regularization: Dropout is an effective technique to maintain the neural network from overfitting during the training [20]. Dropout is applied by only saving a neuron active with a certain probability *p* and locating it to 0 otherwise. This condition pushes the network not to learn redundant information [20]. Consequently, this method significantly decreases overfitting and presents significant neural network improvements in supervised learning [21]. In this study, the Keras deep learning library was used for importing the dropout regularization class in the VGG model. The drop out was set on 0.5.

5) Transfer learning: In machine learning, transfer learning refers typically to a method where a model trained on a specific problem is implemented in other problems, which is a related problem [22]. Transfer learning has the advantages of reducing the training time for an algorithm model and can produce lower generalization errors. The weights in re-used or latest layers can be used as the initial point for the training process and implemented to answer the new problem. Transfer learning can be helpful when the first associated problem has many labeled data. Several high-performing models have been created for image classification on the annual ILSVRC, such as ZFNet, VGG, GoogleNet, and ResNet [17]. This competition has produced several innovative models in CNN architecture and can be implemented to transfer learning in computer vision applications. Those models have learned over 1.000.000 images for 1.000 classes and achieved state-of-the-art performance. In this study, all VGG model was developed using transfer learning and directly downloaded using the Keras library function into our python environment.

6) Configuration of VGG model: The VGG architecture included 19 weight layers, 16 convolutional layers, and 3 fully connected layers [18]. The channel number of convolutional layers starts from 64 and increases by a factor of 2 after each max-pooling layer until obtaining 512. Finally, SoftMax activation was used in the dense layer. The architecture of VGG16 is similar to VGG19; only the difference is the total number of layers (16 for VGG16). A Method for Stochastic Optimization (Adam) was implemented as an optimizer. In order to avoid overfitting, the early stopping function was implemented with configuration patience 5 and verbose 1. The number of epochs was adjusted to 30. The VGG model used 80% for training data and 20% for validation. The 150 x 150 image pixels were used as an input image for VGG models. The detailed configuration of all VGG models is presented in Table I.

7) Model evaluation: After classification was performed, several evaluation metrics were performed. Specifically, the accuracy, precision, recall, F1 score, and ROC area were used to choose the best model. The accuracy is the percentage of correct instances classified by the algorithm. Precision is the number of instances that fit the respected class and the calculated instances categorized to that class, while recall or sensitivity explains the true positive rate of prediction. The F1 score or F-measure explains the classification accuracy regarding the average precision and recall values. The F1 score values closer to 1 show a better classification accuracy. The measurement methods are calculated as follows in Eq. (1), (2), (3), and (4):

$$Accuracy = \frac{Correctly\ classified\ data}{Total\ data} \tag{1}$$

$$Recall = \frac{TP}{TP+FN} \tag{2}$$

$$Precission = \frac{TP}{TP+FP} \tag{3}$$

$$F1 = 2 * \frac{Precision * Recall}{Precision+ Recall} \tag{4}$$

Where TP is a true positive, FN is a false negative, and FP is a false positive. Finally, the region under the ROC curve shows the proportion of true positives and false positives. This value must be close to 1, indicating a perfect prediction, as the values under 0.5 imply a random guess [23].

TABLE I. CONFIGURATION OF VGG ARCHITECTURE MODELS

VGG16 + Augmentation + Drop Out	Softmax	30	ImageNet	32	Categorical Cross entropy	Adam	Yes	Yes (0.5)	Yes (Patience 5, verbose 1)	Yes
VGG16 + Augmentation	Softmax	30	ImageNet	32	Categorical Cross entropy	Adam	Yes	Yes	Yes (Patience 5, verbose 1)	Yes

IV. Experimental Results

This section explains the analysis of the obtained algorithm's performance on the cultural events dataset. Several algorithms with hyper-parameter were evaluated using the accuracy, precision, recall, F1 score, and ROC area. The performance of the algorithm can be seen in Fig. 4.

	VGG19 Baseline	VGG19 + Augmentation	VGG19 + Augmentation + Dropout	VGG16 Baseline	VGG16 + Augmentation	VGG16 + Augmentation + Dropout
Accuracy	92.00%	92.33%	93.66%	93.99%	94.33%	94.66%
Precision	0.93	0.93	0.94	0.95	0.94	0.95
Recall	0.92	0.92	0.94	0.95	0.94	0.95
F1-Score	0.92	0.92	0.94	0.95	0.94	0.95
ROC	0.99	0.99	0.99	0.99	0.99	0.99

Fig. 4. The Performance of each Algorithm

Based on the results, it showed that VGG16 performed better than VGG19. The combination of "VGG16 + Augmentation + Dropout" performed the best with 94.66% of correctly classified images, followed by "VGG16 + Augmentation" with 94.33%, and "VGG16 Baseline" with 93.99%. On the other hand, the combination of "VGG19 + Augmentation + Dropout" performed with 93.66% of correctly classified images, followed by "VGG19 + Augmentation" with 92.33%, and "VGG19 Baseline" with 92.00%. It also showed that the precision, recall, F1-score, and ROC area were better for the "VGG16 + Augmentation + Dropout" than the other VGG configurations.

After implementing the hyper-parameter optimization, the algorithms performed better than the baseline. The model performance showed a very slight increase in the model's mean accuracy, 92.33% in "VGG19 + Augmentation" compared to 92.00% with the VGG19 baseline model. It also confirmed that dropout regularization performed well. There was a very slight rise in the model's accuracy, 93.66% in "VGG19 + Augmentation + Dropout" compared to 92.33% with the "VGG19 + Augmentation".

A similar improvement is presented in the VGG16 model. The estimated performance of the "VGG + Augmentation + Dropout" model indicated a possible increase in performance compared to the baseline from 93.99% to 94.66%. This study's findings confirm that a hyper-parameter configuration (image augmentation and dropout regularization) can improve the models in line with previous works [24].

In order to detect which of the classes classified correctly, the confusion matrices were performed. The results of the confusion matrices are presented in Table II. The diagonal numbers show the correctly classified images (blue background), while other numbers in rows describe the misclassifications of images. It showed that the "VGG19 Baseline" most accurately classified the Pacu Jawi and Pasola images, while the "VGG19 + Augmentation" and "VGG19 + Augmentation + Dropout" most correctly classified the Jember and Pacu Jawi images. The "VGG16 Baseline" and "VGG16 + Augmentation" accurately classified the Pacu Jawi, Pasola, and Jember images, while the "VGG16 + Augmentation + Dropout" most correctly classified the Pacu Jawi images.

TABLE II. The Confusion Matrices for each Algorithm

Algorithm	**Baliem**	**Jember**	**Nyepi**	**Pacu Jawi**	**Pasola**	**Classified as**
VGG19 Baseline	52	0	3	0	1	Baliem
	4	56	5	0	0	Jember
	3	0	44	0	2	Nyepi
	0	0	0	65	1	Pacu Jawi
	1	0	3	1	59	Pasola
VGG19 + Augmentation	48	0	5	2	1	Baliem
	3	58	4	0	0	Jember
	2	0	47	0	0	Nyepi
	0	0	0	66	0	Pacu Jawi
	1	0	3	2	58	Pasola
VGG19 + Augmentation + Dropout	52	0	3	1	0	Baliem
	3	59	3	0	0	Jember
	3	0	46	0	0	Nyepi
	0	0	0	66	0	Pacu Jawi
	1	0	3	2	58	Pasola
VGG16 Baseline	48	1	4	2	1	Baliem
	1	62	2	0	0	Jember
	1	0	45	0	3	Nyepi
	1	0	0	65	0	Pacu Jawi
	0	1	1	0	62	Pasola
VGG16 + Augmentation	52	0	2	1	1	Baliem
	1	62	2	0	0	Jember
	4	0	43	0	2	Nyepi
	2	0	0	64	0	Pacu Jawi
	1	1	0	0	62	Pasola
VGG19 + Augmentation + Dropout	55	0	0	1	0	Baliem
	2	62	1	0	0	Jember
	5	0	41	0	3	Nyepi
	2	0	0	64	0	Pacu Jawi
	0	1	1	0	62	Pasola

In terms of misclassification, "VGG19 + Augmentation + Dropout" mostly misclassified the Nyepi images, while the rest of the other algorithms misclassified the Nyepi and Baliem images. Based on the results, Pacu Jawi images were most correctly classified among all algorithms, while Nyepi images were most misclassified. Finally, to fully show these algorithms' performance, the accuracy and loss model presented in Fig. 5. As for simplicity only "VGG16 + Augmentation + Dropout" and "VGG19 + Augmentation + Dropout" models are presented.

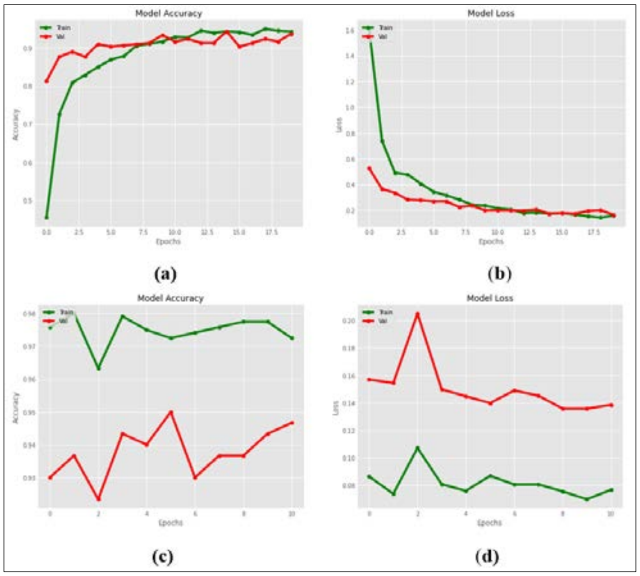

Fig. 5. (a) Accuracy for VGG19, (b) Loss Results for VGG19, (c) Accuracy for VGG16, and (d) Loss Results for VGG16.

As observed in Fig. 5, the VGG19 model performed well, with an accuracy of 93.66 % (a). Both training and validation loss had a reducing trend achieving the value of 0.20 for training and validation in the last epoch (b). On the other hand, VGG16 with 94.66% accuracy seemed to perform well and tended to increase to fit (train and validation line) further after the last epoch (c). The model showed a decreasing trend from the value of 0.16 to 0.14 (d) concerning the validation loss. The model's epoch finished on 18 epochs for VGG19 and 10 epochs for VGG16, regarding no further improvement on accuracy and avoiding the overfitting.

In a survey study, image augmentation has been proved to improve the performance of the models and enhance the limitation of datasets to take advantage of significant data capabilities [19]. In agreement with our results from performance accuracy in Fig. 4, it displayed that model using the image augmentation technique (in both VGG19 and VGG16 models) was better than the baseline model. In their experimental study, Nandini et al. [25] compared the dropout technique for image classification using several algorithms using three different image datasets. They found that the dropout regularization technique accomplished the best results in image classification compared with other classification algorithms. This finding is also in line with our results in Fig. 4 that display the dropout technique's performance, and image augmentation performs best compared to other configuration models.

V. Discussion

This study presents a new Indonesia cultural events dataset and automatic image recognition for classification cultural events. Several findings obtained from this study: (i) the convolutional neural network, with VGG16 architecture, performed well when classifying images compared to the other models (despite that other algorithms accuracy were relatively good accuracy); (ii) all classifiers performed better after adding hyper-parameter configuration (image augmentation and dropout regularization); and (iii) algorithms most correctly classified the Jember and Pacu Jawi images, while Nyepi images most frequently misclassified.

As shown in the previous section, the "VGG16 + Augmentation + Dropout" performed well in all performance measures. It obtained the highest classification accuracy compared to the other algorithms. Also, it performed the best in the other evaluation measures, such as precision, recall, F1 score, and the ROC. Furthermore, the CNN with VGG architecture model showed excellent classification accuracy. Specifically, CNN mainly performs better than other non-neural network algorithms applied for image classification tasks [17], [25]–[27].

Moreover, CNN is suitable for a large dataset. Regarding the overfitting problems, hyper-parameter tuning has been implemented with an early stopping function to avoid the overfitting problem. The Keras library's early stopping function was used to stop training when the training accuracy gets a specific threshold. Hence, the optimal model weights can be achieved and save computation time and power. Although CNN is computationally intensive, it can achieve good performance using several hyper-parameter configurations. Thus, based on this study's results, hyper-parameter configurations are a promising way to improve the algorithm's performance, especially CNN with VGG architecture.

This study could develop cultural events image classification models that could be more efficient and computationally solid. As multi-class image classification usually includes many images and needs substantial computational resources, it must be operated correctly and reliable. Therefore, developing optimized models and reliable classification methods is essential for current and future studies.

As the limitation of this study, the proposed dataset used a balanced class distribution. Thus, our proposed VGG configuration needs to test in an imbalanced classification problem to show the validity of our proposed configuration models.

As future work, this study plans to enhance the proposed image datasets, including different cultural events images from different Indonesia regions. Also, generally, the image classification generally includes large data sets, further work needs to develop large datasets of Indonesia culture's image dataset.

VI. Conclusion

This study presents a new Indonesia cultural events dataset and automatic image recognition for classification cultural events. This study compared several configurations of hyper-parameter configurations of CNN for multi-class image classification. In particular, CNN architecture, such as VGG19 and VGG16, were tested before and after the hyper-parameter configuration. Overall, the VGG19 and VGG16 achieved a good performance, but considering the hyper-parameter optimization, the VGG16 using image augmentation and dropout regularization achieved the best classification with 94.66% accuracy. Other algorithms achieved less than 94.33% accuracy. Despite that, the accuracy of other algorithms was relatively good. This study confirms that CNN with VGG architecture is a better choice for multi-class image classification, and they offer good performance for classification tasks. Finally, this study's findings hoped to support the heritage's digital documentation process and maintain cultural heritage.

Towards using Single EEG Channel for Human Identity Verification

Marwa A. Elshahed
Physics Department, Faculty of Women for Arts
Sciences and Education, Ain Shams University, Cairo, Egypt

***Abstract*—Biometrics is an interesting area of research as a result of tremendous technological advances, especially in security. It is considered as an automated technology used for identification based on biological or behavioral human traits. An electroencephalogram (EEG) is the brain electrical activity signals considered as biological traits used in biometrics systems. The primary goal of this work is trying to find a single EEG channel to be used for human identification purposes. A single EEG channel recording is used for personal identity-based verification mode, which is preferred for many subjects with instant real-time system decisions. Percent residual difference (PRD) is a common quantitative measurement used to determine the human identity-based measures the distance between two signals. The proposed system sensitivity gives 100% using some single channels placed in the parietal and occipital lobes. The proposed system takes a short time in the enrolment process with an instant decision using verification mode, which is preferred with a large number of subjects. Also, using imaginary tasks is preferred for human identity verification.**

Keywords—Biometric; EEG; single channel; verification; brain lobes

I. Introduction

Biometrics is the field of studying the biological or behavioral traits of humans which could be used for personal identification. Biological traits depend on direct measures of shapes or characteristics of biological parts in the human body, such as iris, face, DNA, ECG, etc… Behavioral traits depend on the human behavioral such as gait, signature, voice, etc.

Not all human traits could be used as a biometric, it should be characterized by uniqueness, universality, collectability, permanence, performance, circumvention, and acceptability. There are some traits changes over time, so any biometric system should be updated after some time.

A Biometric system is based on identification or verification modes. The enrolment process is used to build the system database. It was the first and main step for any system. The identification mode is considered as one to many comparisons which takes the extracted trait from the claimed person and compares it with all that stored in the database to get its identity as in Fig. 1, while in the verification mode, which is considered as one to one comparison, takes the extracted trait and ID from the claimed person then only one template from the system database is compared with the extracted one using the ID as in Fig. 2. The biometric system operates in one of the two modes. Some biometric systems are considered as a unimodal system, which depends on only one biometric trait, while others are considered as a multimodal biometric system which depends on more than one human trait.

Electroencephalogram (EEG) signals are considered as physiological biometrics which represent the brain's electrical activity. It has become an interesting area of research for human identification due to the amazing progress in using sensors and wireless networks based on Wireless Body Area Network (WBAN) [1-6]. EEG signal is classified into five waves according to the frequencies based on human activity and this is illustrated in brief in Table I, while other studies classify EEG signals to six waves, the following five waves in addition to Mu waves with an overlapping frequency range [7-11].

The human brain consists of four lobes illustrated in Fig. 3 by four different colors. The frontal lobe (blue) is located in front of the brain, followed by the parietal lobe (yellow) at the top of the head, then the occipital lobe (pink) at the back of the head, while the temporal lobes (green) are located on both sides of the brain above the ears. The five senses' locations are illustrated in brain lobes as in Fig. 3.

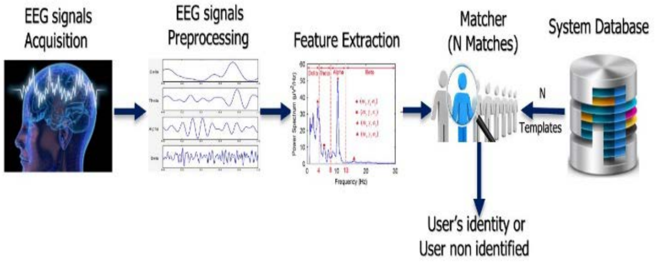

Fig. 1. Identification EEG Biometric System.

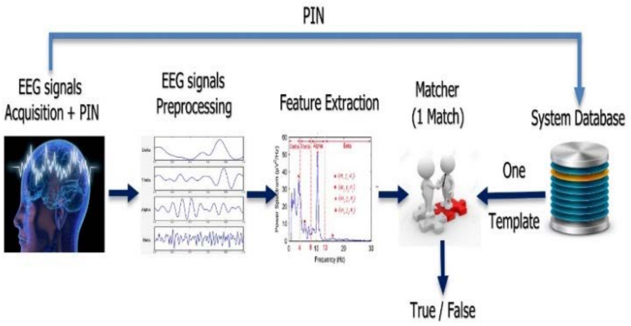

Fig. 2. Verification EEG Biometric System.

TABLE I. EEG SIGNAL CLASSIFICATION [7].

Name	Frequency band (Hz)	State
Δ WAVE	1 ~ 3	Deep sleep
Θ WAVE	4 ~ 7	Shallow sleep
Α WAVE	8 ~ 13	Relaxed state
Β WAVE	14 ~ 30	Active state
Γ WAVE	30 ~	Mental strain

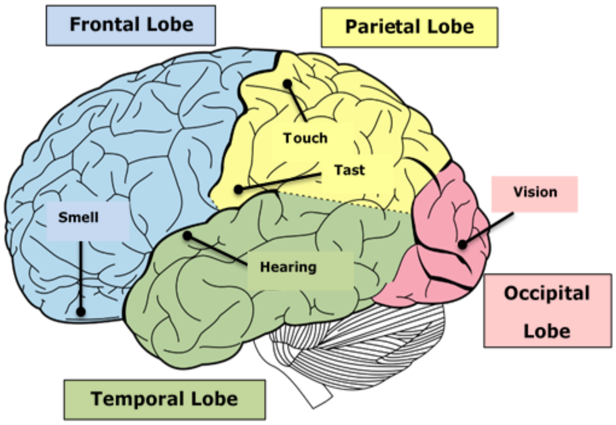

Fig. 3. The Human Brain Four Lobes.

The frontal lobe function is responsible for muscle movements, speaking, judgments, and making plans. It is described as the brain control center. Next, the parietal lobe processes information about taste and touch senses. The Occipital lobe is responsible for vision. The temporal lobe is the fourth lobe that is responsible for receiving sound from the opposite ear [12,13]. EEG signals are extracted from the human brain based on certain positions. There was an international system that illustrates these electrode or channel positions in the human scalp. This work used a database created based on the international 10-20 system as shown in Fig. 4.

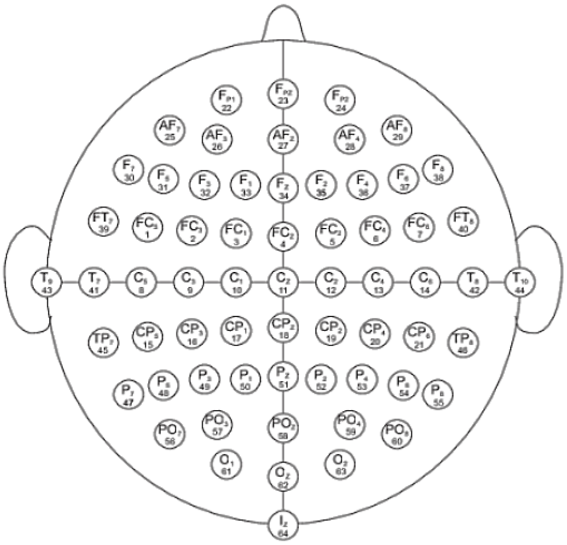

Fig. 4. 64 Electrodes Positioning based on the International 10-20 System [16].

The system depends on the relation between the cerebral cortex area and the electrode location. Also, the distances between the adjacent electrodes are equal to 10% or 20% from the whole right-left or front-back of the skill distance. The electrode name has a letter that refers to the lobe (F-frontal, P-parietal, O-O-occipital, T-temporal, C-for central positions, and Z-for midline positions) and a number that refers to the hemisphere location. The even numbers for right hemisphere positions while the odd numbers for left hemisphere positions [14, 15].

II. Related Work

Authors in [17] obtained a high system accuracy rate using proposed combined Independent Component Analysis (ICA) and AR classifiers. They used only 20 subjects based on sixteen electrode placements on the scalp according to the 10-20 international system. In [18], authors trying to get an EEG single channel to be used in the authentication. They used the same dataset which was used in this work based on open and closed eye states with 109 subjects, the obtained system accuracy in the range of 97-99%. Studying to get a single EEG channel for human identification was proposed in [19] also, which is based on generating a personal identification number (PIN) from the brain activity obtained from a single active EEG channel with 3 subjects only. The high system performance is obtained using channel Cz. New features are proposed in [20] Based on a single Fp1 single channel called the concavity and convexity features in the alpha band using 23 subjects. Authors in [21] propose a new technique for EEG human verification using three channels based on Discrete Fractional Fourier Transform (DFrFT) as a feature extraction method. Their method achieves a 0.22% Equal Error Rate (EER) with 104 subjects. In [22], an EEG biometric authentifier was proposed based on deep learning technique. Only 15 subjects were used with over 40 trials.

The experiment in [23] proposes a self-relative framework based on EEG signal for human identification using 108 subjects with closed eyes in resting state (the same dataset which was used in this work). Autoregressive is used as a feature extraction method while K-nearest neighbor is used as a classifier. They found that the openness condition gives more accurate results for identification. 19 selected channels only are used.

Most EEG biometric systems are based on identification mode. Also, they didn't test their systems for unauthorized subjects. The biometric system performance measures are neglected in calculations except the accuracy of most of them.

The objective of this research is trying to find only one EEG channel recording which could be used in a biometric system to get a personal identity with high efficiency and a short time with a large number of subjects-based verification mode.

III. Research Method

In this research, 109 subjects are used from the EEG Motor Movement/Imagery Dataset (eegmmidb) Database [16]. Table II summarizes the dataset description. The number of authorized subjects used in this work is 100 while 9 are used as unauthorized subjects. 64-channels were used for EEG signal recording based on the BCI2000 system [24].

Subjects performed six motor/imagery tasks. Four of them were repeated three runs, so each subject performed 14 runs. Task 1 for opening and closing left or right fist, Task 2 for imagining opening and closing left or right fist, Task 3 for opening and closing both fists or both feet, and Task 4 for imagining opening and closing both fists or both feet. Task 1 and task 3 are non-imaginary tasks, while task 2 and task 4 are imaginary tasks.

In this work, 12 runs for each subject were used for the four repeated tasks. The first and second runs of the four repeated tasks were used in the enrolment process while the third run was used to test the authorized subjects for each electrode. The Butterworth filter was applied to signals. The difference between two signals was calculated using the percent residual difference (PRD), which is a quantitative measurement:

$$PRD_n = \sqrt{\frac{\sum_{i=1}^{M}(x_0(i)-x_n(i))^2}{\sum_{j=1}^{M}(x_0(j)-\overline{x_0})^2}} \times 100\% \qquad (1)$$

Where: xo is considered as the unknown signal while xn is the enrolled signal for subject n [25, 26].

A verification model was used in this work for personal identification, which is preferred with a large number of subjects to get the system decision in a very short time. PRDth was calculated during the enrolment process for each subject. PRDn was calculated for each imposter (from the third run of tasks). A decision is obtained based on the stored database using the person's ID as illustrated in the proposed method in Fig. 5.

TABLE II. DATA SET DESCRIPTION USED IN THIS EXPERIMENT

Dataset Properties	Information
NUMBER OF SUBJECTS	109
NUMBER OF CHANNELS	64
SAMPLING FREQUENCY	160 HZ
SIGNAL TIME LENGTH	60 s
SYSTEM	BCI2000

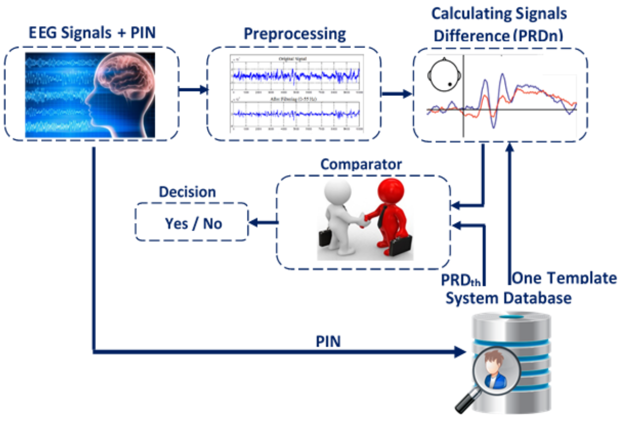

Fig. 5. The Proposed System Diagram.

IV. Experiment and Results

In this study, all 64 channels were used and tested for authorized and unauthorized subjects using the four tasks together and with each task alone as mentioned before. The system was tested five times, namely, system-based all four tasks together, system-based task 1, system-based task 2, system-based task 3, and system-based task 4. The system's performance is evaluated using the following measurements:

$$Accuracy = \frac{Tp+Tn}{Tp+Tn+Fn+Fp} \times 100 \qquad (2)$$

$$FRR = \frac{Fn}{Tp+Fn} \times 100 \qquad (3)$$

$$FAR = \frac{Fp}{Tn+Fp} \times 100 \qquad (4)$$

$$Recall = \frac{Tp}{Tp+F_N} \times 100 \qquad (5)$$

$$Percision = \frac{Tp}{Tp+Fp} \times 100 \qquad (6)$$

$$F-score = \frac{2 \times Percision \times Recall}{Percision + Recall} \qquad (7)$$

Where: Tp is true positive (Accepted knowns), Tn is true negative (rejected unknowns), Fn is the false negative (rejected knowns) and Fp is the false positive (accepted unknowns) [27,28].

The obtained results will be presented in detail in the following sections, starting with task 2 which gives the highest system performance.

A. The Proposed System based on Task 2

The results of the system performance based on task 2 for all 64 channels individually are shown in Table III. The results in this table are arranged in descending order according to the system accuracy. The obtained results show that the channels located in the parietal (yellow) and occipital (pink) lobes give higher system accuracy than channels located in the frontal (blue) and temporal (green) lobes. These selected colors are derived from Fig. 1. This experiment is performed using single-channel mode because the target is trying to find the best one for human identification.

Also, z electrodes located in the vertical center give higher system accuracy (in the parietal and occipital lobes). Four electrodes give 100% system accuracy-based task 2 (Pz, P6, CP3, and CP1). FRR reaches 0% using 12 electrodes placed in the parietal and occipital lobes and FAR reaches 0% using 10 electrodes placed in the same lobes. Recall gives 1 using 12 electrodes while precision and f-score are given 1 using 10 electrodes distributed in the parietal and occipital lobes. The first four electrodes (Pz, P6, CP3, and CP1) in the table are given optimum system performance.

B. The Proposed System based on the Four Tasks together

The system accuracy based on the four tasks together for all 64 channels reaches 99.08 % using 8 channels individually and FRR reaches 0 % using 9 channels placed in the parietal and occipital lobes while FAR gives 0 % using 5 electrodes in the same lobes. Recall gives 1 using 9 channels, Precision reaches to 1 using 5 channels while f score starts at 99.5 %.

TABLE III. SYSTEM PERFORMANCE USING TASK 2

Elect.	Acc. %	FRR%	FAR%	Recall%	Per. %	f score %
Pz	100	0	0	100	100	100

C. *The Proposed System based on Task 1*

The same observations are obtained again by repeating the experiment based on task 1 individually, but the system accuracy decreases and starts at 96.33 %. FAR gives 0 % using 3 channels. FRR is higher than that in the previous experiment. Recall starts from 98 %, precision gives 1 using 3 channels and f-score starts from 96 %, so the system performance based on the four tasks together is better than that based on task 1 alone.

D. *The Proposed System based on Task 3*

It was observed from the system performance-based task 3 for all 64 channels that O2 channel gives the highest system accuracy using the proposed system-based task 3 alone with 0 % FRR and 11.11% FAR. FRR is accepted using all electrodes, especially in electrodes placed in the parietal and occipital lobes than others, while FAR increases gradually and starts at 11.11%. Recall gives 1 using one channel, precision reaches to 99 % and 99.5 % f-score.

E. *The Proposed System based on Task 4*

From the system performance-based task 4 for all 64 channels individually, 9 electrodes give the same system accuracy of 98.17 % with 0 % FAR (100% Specificity) and 2% rejected authorized subjects only and overall, the FRR is accepted based on task4 while FAR increases in frontal and temporal electrodes. Precision reaches to 1 using 12 channels, recall reaches to 98 % and f-score reaches to 98.9 %.

F. The Proposed System Performance Measures

Some measures are calculated for all 64 channels using the four tasks together and with each task individually. Fig. 6 shows the average system accuracy.

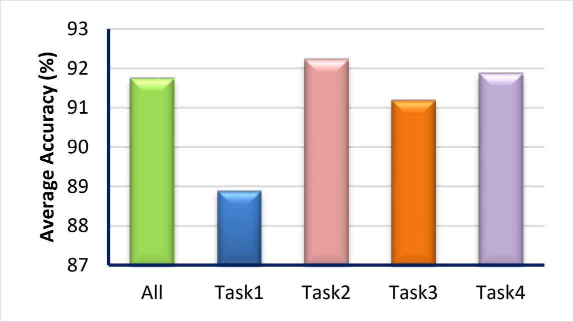

Fig. 6. The Average System Accuracy.

From the above figure, it was observed that the proposed system-based task 2 has the higher system accuracy, followed by task 4. Task 2 and task 4 are imaginary tasks, which means that using the imaginary tasks is preferred for human authentication than non-imaginary tasks. Fig. 7 shows the average system False Reject Rate (FRR).

FRR measures the identification percentage for authorized persons who are incorrectly rejected. The proposed system-based task 3 has the best FRR is 3.8 %, followed by using the four tasks together is about 4% and then task 2, which is 4.45 % as shown in Fig. 7.

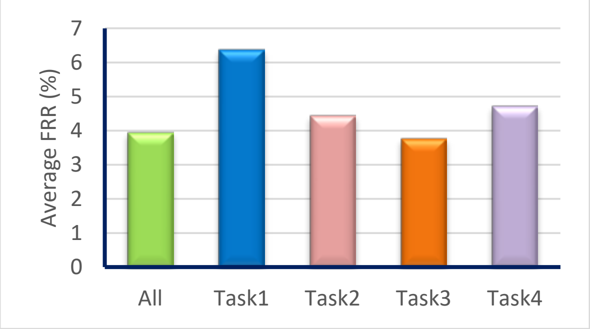

Fig. 7. The Average System FRR.

Fig. 8 shows the average system False Acceptance Rate (FAR). FAR measures the identification percentage for unauthorized persons who are incorrectly accepted.

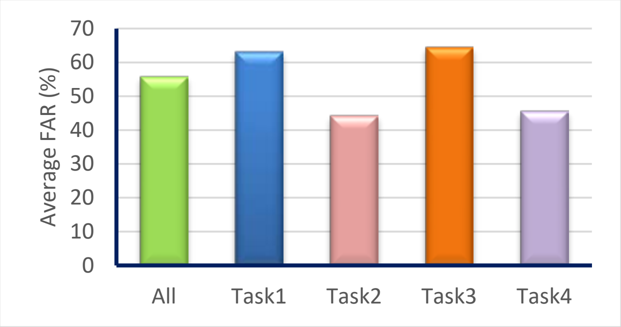

Fig. 8. The Average System FAR.

The system FAR based on task 2 is about 44.4 %, which is lower than others, followed by that based on task 4, which is about 45.7%. More studies will be tried to improve FAR for the proposed system.

Fig. 9 shows the average system Recall, it quantifies the number of authorized persons who are incorrectly rejected.

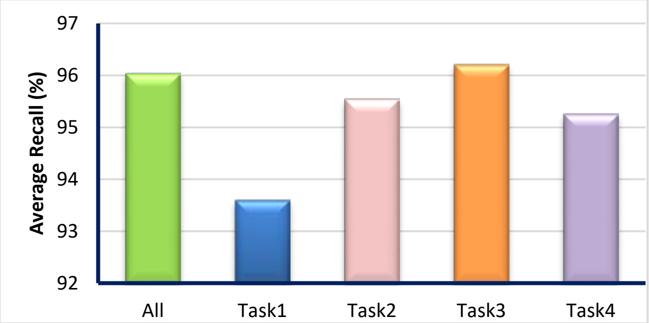

Fig. 9. The Average System Recall.

The average system recall for task 3 is about 96.2 % followed by that based on all tasks together 96 %, then task 2, which is equal to 95.5%. Fig. 10 shows the average system precision. It quantifies the number of authorized persons who are correctly accepted.

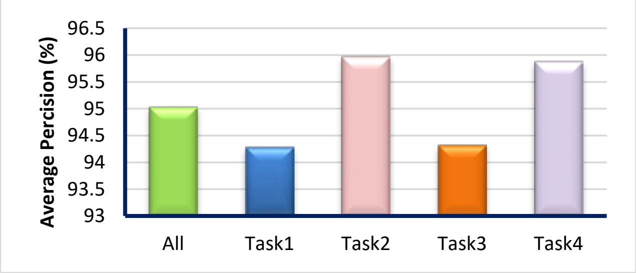

Fig. 10. The Average System Precision.

The average system precision based on task 2 is 95.98% followed by that based on task4 which is 95.89% (approximately the same for imaginary tasks). The average system precision for all tasks together comes after the imaginary tasks, while that based on the non-imaginary tasks gives 94 %.

Fig. 11 shows the average system F-score. It is a single value that gives the balance between precision and recall for the proposed system.

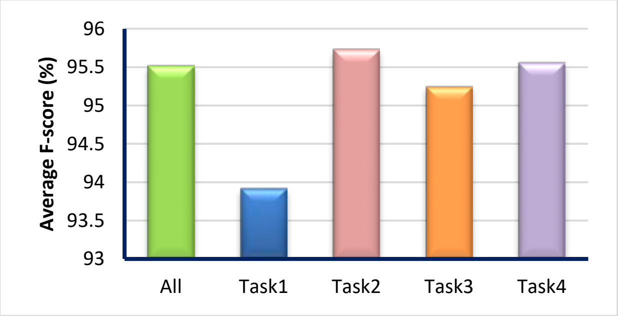

Fig. 11. The Average System F-score.

The average system F-score based on task 2 is 95.7 %, which is the best score obtained by the proposed system, followed by that based on task 4, which equals 95.5%.

From this experiment, it was observed that using EEG signals collected from some electrodes placed in the parietal and occipital lobes gives a good biometric system performance for authorized and unauthorized subjects. While using electrodes placed in frontal and temporal lobes gives accepted performance for authorized subjects only. Also, not all tasks are preferred for human identification based on EEG signal. Only imaginary tasks give better system performance than non-imaginary tasks.

V. Conclusion

Biometric system-based physiological traits were more secure and difficult to mimic or penetrate. Also, using verification mode is preferred with a large number of subjects to save time. EEG signals were used for personal identity. Nowadays, it is easy to send EEG or ECG signals by network using simple sensors. So, using EEG may become a powerful tool for human identification in the next few days. Trying to find a single electrode with high efficiency is very important for using EEG as a biometric trait to become easy to use and fast to make a decision. This work is trying to find this electrode by using existing data. This data presents EEG signals obtained by performing four tasks (two of them imaginary tasks and the others are non-imaginary tasks). This work-based on PRD, which is a simple measurement used to measure the difference between two signals. The proposed system was repeated for five experiments. The first one is based on using the four tasks together to make the system decisions, the second is based on task 1 only, the third is based on task 2, the fourth is based on task 3 while the fifth is based on task 4. Tasks 1 and 3 are non-imaginary tasks, while tasks 2 and 4 are imaginary.

The observations from the obtained results show that the proposed system-based task 2 is better than using other tasks individually and the four tasks together, the system performance-based task 4 is better than that based on task 1 and task 3 individually, which means that using the imaginary tasks is more suitable than using non-imaginary tasks for human authentication. Also, using electrodes placed in the parietal and occipital lobes is better than those placed in other lobes, and electrodes near the vertical brain center give higher system performance. Pz, P6, CP3, and CP1 electrodes give 100% system accuracy-based task 2 individually. It was observed that the proposed system sensitivity (recognize authorized subjects) is good and acceptable using all electrodes and increases as mentioned before in the parietal and occipital lobes electrodes, while the proposed system specificity (recognize unauthorized subjects) is acceptable in some electrodes placed in parietal and occipital lobes only, so more studies needed to improve the proposed system specificity. The proposed system gives instantaneous decision because its construction is based on verification mode, which makes it very suitable for large numbers.

***Abstract*—Technology has revolutionized into connecting "things" together with the rebirth of the global network called Internet of Things (IoT). This is achieved through Wireless Sensor Network (WSN) which introduces new security challenges for Information Technology (IT) scientists and researchers. This paper addresses the security issues in WSN by establishing potential automated solutions for identifying associated risks. It also evaluates the effectiveness of various machine learning algorithms on two types of datasets, mainly, KDD99 and WSN datasets. The aim is to analyze and protect WSN networks in combination with Firewalls, Deep Packet Inspection (DPI), and Intrusion Prevention Systems (IPS) all specialized for the overall protection of WSN networks. Multiple testing options were investigated such as cross validation and percentage split. Based on the finding, the most accurate algorithm and the least time processing were suggested for both datasets.**

Keywords—Internet of Things (IoT); Wireless Sensor Network (WSN); Information Technology (IT); Denial of Service (DoS); Artificial Intelligence (AI); Machine Learning (ML)

I. Introduction

With the rapid expansion of technology, new threats and security issues arise, which become a hot area for research. Wireless Sensor Network (WSN) is composed of distributed wireless sensor nodes that collect raw data from the surrounding environment. Each Sensor node is equipped with a radio transceiver, a small microcontroller, and a power source [1]. These nodes are very small and have limited processing capabilities. They are designed based on low-cost and low-energy consumption that provide limited processing power and limited communication as represented in Fig. 1. Due to the sensors' limitation in memory, processing power, and energy consumption, there are several potential security challenges inherently exist and should be properly addressed. The primary challenge is to protect the WSN without the availability of massive processing power and energy. Traditional security measures such as encryption is difficult to be implemented at the senor's level due to its limited processing capabilities.

With the increased and sophisticated attack types on networks and applications, it is difficult to protect them against such attacks manually or by common Off-The-Shelf software such as firewalls, antivirus, Intrusion Detection System (IDS) or Intrusion Prevention System IPS). This makes artificial intelligence (AI) and machine learning (ML) algorithms popular and ultimately essential in such scenarios. AI in general and ML in specific can be used to protect WSN by identifying and classifying potential attacks by learning previously detected patterns of attacks.

Machine learning is becoming more popular in recent years. It enables machines or computers to work and react similar to what humans do. These systems improve with experience by learning the expected behavior. AI can be applied in many applications such as natural language processing and generation, speech recognition, virtual agent, machine learning, deep learning, biometrics, robotic process automation, text analytics and Neuro-Linguistic Programming (NLP), as well as in many domains such as healthcare, business, education, autonomous vehicles, robotics, government, and public safety and security. Moreover, AI becomes very useful in predictive analysis and plays a fundamental role in the software field and content creation.

This paper investigates different datasets with different machine learning algorithms, namely Naïve Bayes, improved Naïve Bayes, IBK, and Random Forest algorithms in multiple scenarios. The purpose is to identify the best method to mitigate the risks, threats, and security vulnerabilities associated with WSN networks.

The rest of this paper is organized as follows. Section II discusses related work. Section III presents the underlying concepts and proposed methodology. Section IV shows the experimental results. Section V discusses and analyzes the findings. Finally, section VI concludes the paper.

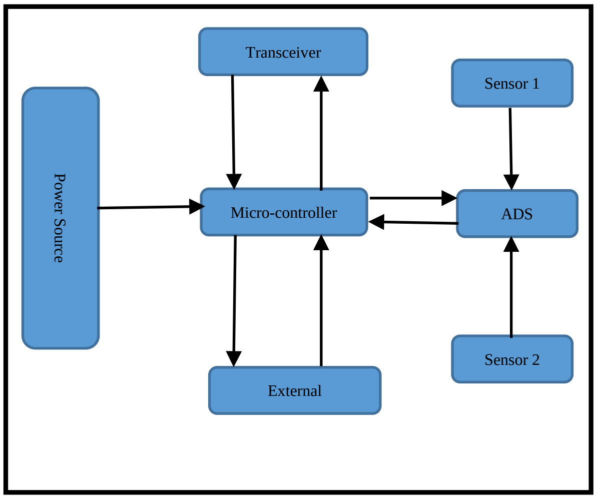

Fig. 1. WSN Mechanism.

II. Related Work

This section presents some researches about various attacks in WSN. In [2], authors have addressed Denial of Service (DoS) cyber-attacks on Wireless Sensor Networks (WSN) and how to mitigate these attacks. The researchers used specialized datasets for WSN constructed for classifying the types of attacks for their research. Four DoS attacks were considered: Flooding attack, Blackhole attack, Scheduling attack, and Gray-hole attack. The main purpose was to help WSN manufacturers to create and develop a system that detects and protects against DoS attacks in WSN. They have also discussed the challenges of protecting these networks due WSN limitations such as low processing, low power, and limited storages. They emphasized on the importance of mitigating and protecting against new and unprecedented attacks [2].

Moreover, the authors in [3] have focused on the classification's accuracy improvement of the Naïve Bayes algorithm, by finding more accurate probability estimation. This helps in solving the lack of the training data. Their approach was applied during the training phase without increasing the classification time. The first phase was building the classical Naïve Bayes classifier then fine-tune it in the second phase. Each training instance was classified, and if it is misclassified, it will contribute in fine tuning the probability value. Therefore, it will be correctly classified in the next round. Based on the findings, results showed an improved classification accuracy of many datasets.

Many researches have defined Wireless Sensor Network (WSN). It is typically composed of sensor nodes. These nodes gather data about the environment and send it back to the sink or the base station node. These data can be in different formats such as thermal, acoustic, optical, weather, pressure, chemical, and much more. It is extremely challenging task to develop an algorithm that is suitable for many applications scenarios in a diverse WSN environment; especially, considering data reliability and aggregation, localization, clustering, fault detection, and security [4].

Furthermore, the authors have highlighted the importance of utilizing ML in WSN for the following reasons [4]:

1) Using ML techniques could help in observing dynamic environments.

2) In some cases, WSN gathers new data in out-of-reach or threatening locations.

3) Accurate models are hard to be obtained in WSN since they are usually applied in sophisticated environments

4) Using ML techniques could be beneficial in extracting essential correlations.

The authors in [5] have emphasized the growing number of services that are providing facilities to humans which make using WSN valuable in many applications such as security systems, fire safety, various military applications, monitoring environmental conditions, and monitoring health condition. However, these WSNs encounter some weaknesses because of the nodes' exposure to various security attacks due to their limitations in power, processing, memory storage, bandwidth, data transmission via other nodes and multiple hops, its distributed nature, and self-organization. These attacks occurs at different levels of the OSI models. Therefore, it is important to build a security defense and monitoring system to protect against these attacks [5].

Similarly, the authors in [6] have discussed WSNs and their crucial role in different applications and usage; the vulnerabilities of the WSN due to their constrained resources. How DoS attack can be carried out at different layers of the network architecture. The authors focused specifically on the network layer because of the diversity of the attack at this layer. The authors reviewed many studies that use machine learning techniques pertaining to the network layer DoS attacks in WSN [6].

IDS and their important role in protecting against malicious attacks that affect the performance of the network have been addressed in [7]. The authors described Mobile Ad hoc networks (MANETs), WSN, and Internet of Things (IoT). The significance of the IDS and the need to protect such networks. Their proposed an IDS that has two stages. One that collects data using sniffers to generate correctly classified instances and in the second stage, a super node process data from different IDSs to differentiate benign from malicious nodes [7].

III. Underlying Concept and Methodology

This section presents the dataset types as well as the used machine learning techniques.

A. Datasets

A dataset is a collection of records that is gathered in a controlled lab environment. In this paper, two different datasets were used. The first dataset is called "KDDCup99 Dataset" which was derived from the DARPA 1998 dataset [8], [9]. It was selected and used to detect network breaches from a network security perspective. A network breach is the abuse of data and information to bypass the security rules and established regulations.

The authors in [10], have explained that the discovery of this interruption is a set of strategies and related activities that enable the progression of perceived methods for the identification of security classification. This dataset was provided by the archive, which was for a data mining competition held in aligning with KDD-99.

The author in [11] indicates that the features were to create a model that detects the bad connections or attacks as well as normal connections. The complete listing of the features defined for the connection records is listed in Table I.

TABLE I. DESCRIPTION OF KDDCUP99 DATASET FEATURES

	Feature Name	*Description*
1.	Duration	Number of seconds of the connection
2.	protocol_type	Type of the protocol, e.g., TCP, UDP, etc.
3.	Service	Network service on the destination, e.g., http, telnet, etc.
4.	Flag	Normal or error status of the connection
5.	src_bytes	Number of data bytes from source to destination
6.	dst_bytes	Number of data bytes from destination to source
7.	Land	1-connection is from/to the same host/port; 0-otherwise
8.	wrong_fragment	Number of ‘wrong’ fragments
9.	Urgent	Number of urgent packets
10.	Hot	The count of access to system directories, creation and execution of programs
11.	num_failed_logins	Number of failed login attempts
12.	logged_in	1 - successfully logged in; 0 otherwise
13.	num_compromised	Number of “compromised” conditions
14.	root_shell	1 - root shell is obtained; 0 otherwise
15.	su_attempted	1 – ‘su root’ command attempted; 0 – otherwise
16.	num_root	number of ‘root’ accesses
17.	num_file_creations	Number of file creation operations
18.	num_shells	Number of shell prompts
19.	num_access_files	Number of write, delete, and create operations on access control files
20.	num_outbound_cm ds	Number of outbound Commands in a ftp session
21.	is_hot_login	1 - the login belongs to the ‘hot’ list (e.g., root, adm, etc.) ; 0 – otherwise
22.	is_guest_login	1 - the login is a ‘guest’ login (e.g., guest, anonymous, etc.) ; 0 – otherwise
23.	Count	Number of connections to the same host as the current connection in the past 2 seconds
24.	srv_count	Number of connections to the same service as the current connection in the past 2 seconds
25.	serror_rate	% of connections that have ‘SYN’ errors to the same host
26.	srv_serror_rate	% of connections that have ‘SYN’ errors to the same service
27.	rerror_rate	% of connections that have ‘REJ’ errors to the same host
28.	srv_rerror_rate	% of connections that have ‘REJ’ errors to the same service
29.	same_srv_rate	% of connections to the same service and to the same host
30.	diff_srv_rate	% of connections to different services and to the same host
31.	srv_diff_host_rate	% of connections to the same service and to different hosts
32.	dst_host_count	Number of connections to the same host to the destination host as the current connection in the past 2 seconds
33.	dst_host_srv_count	Number of connections from the same service to the destination host as the current connection in the past 2 seconds
34.	dst_host_same_srv_rate	% of connections from the same service to the destination host
35.	dst_host_diff_srv_rate	% of connections from the different services to the destination host
36.	dst_host_same_src_port_rate	% of connections from the port services to the destination host
37.	dst_host_srv_diff_ host_rate	% of connections from the different hosts from the same service to destination host
38.	dst_host_serror_rate	% of connections that have ‘SYN’ errors to same host to the destination host
39.	dst_host_srv_ serror_rate	% of connections that have ‘SYN’ errors from same service to the destination host
40.	dst_host_rerror_rate	% of connections that have ‘REJ’ errors from the same host to the destination host
41.	dst_host_srv_ rerror_rate	% of connections that have ‘REJ’ errors from the same service to the destination host

The second used dataset is called “WSN Dataset” [12], which is specialized for WSN. It is used to detect different types of DoS attacks as well as normal behavior. The dataset is collected with different features and divided into different classes such as Blackhole, Grayhole, Scheduling, Flooding, and Normal. Low Energy Aware Cluster Hierarchy (LEACH) is the routing protocol that is used to collect the dataset that contains hundreds of thousands of records in WSN. It is designed to keep energy consumption low which is very important to maintain and improve the lifetime of WSN [13]. The problem or the limitation of LEACH is that it is only suitable for a small size WSN [13]. It assumes that all sensors can communicate with each other and with the sink (base station) as shown in Fig. 2. Table II represents the different WSN dataset attributes.

B. *Machine Learning Techniques*

Machine learning techniques are broadly categorized as unsupervised and supervised learning, which are for clustering, and classification/regression, respectively, as depicted in Fig. 3. Classification is a problem-solving technique for analyzing datasets or data models using algorithms such as Naïve and IBK. Regression is commonly used as a statistical tool to predict potential outcomes. The following subsections demonstrate various machine learning algorithms that were implemented on the above mentioned datasets.

1) Naïve Bayes: Naïve Bayes (NB) is a machine learning algorithm for AI software and computers. NB is based on mathematical calculation of probabilities that uses datasets (raw data or simple facts) to learn a concept. NB is used in a wide range of real applications and automated decision-making processes. A Naïve Bayes classifier is an algorithm that uses Bayes theorem features to classify objects. A NB is also known as simple Bayes or an independent Bayes. These classifiers use regular (or Naïve) independence intervals between the attributes of a data point.

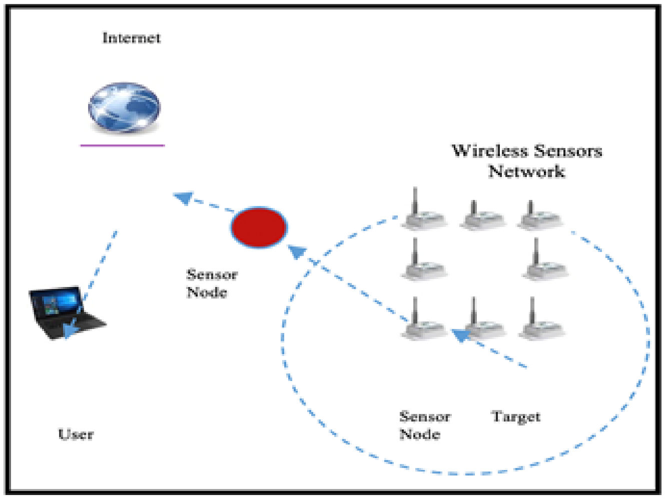

Fig. 2. WSN Network.

TABLE II. WSN-DS DATASET ATTRIBUTES [12]

#	*Attribute Name*	*Attribute Description*
1	Node ID	A unique ID to distinguish the sensor node in any round and at any stage
2	Time	The current simulation time of the node
3	Is CH	A flag to distinguish whether the node is CH or not
4	Who CH	The ID of the CH in the current round
5	Distance to CH	The distance between the node and its CH
6	Energy Consumption	The amount of energy consumed in the previous round
7	ADV_CH send	The number of advertise CH’s broadcast messages sent to the nodes
8	ADV_CH receives	The number of advertise CH messages received from CHs
9	Join_REQ send	The number of join request messages sent by the nodes to the CH
10	Join_REQ receives	The number of join request messages received by the CH from the nodes
11	ADV_SCH send	The number of advertise TDMA schedule broadcast messages sent to the nodes
12	ADV_SCH receives	The number of TDMA schedule messages received from CHs
13	Rank	The order of this node within the TDMA schedule
14	Data sent	The number of data packets sent from a sensor to its CH
15	Data Received	The number of data packets received from CH
16	Data sent to BS	The number of data packets sent to the BS
17	Distance CH to BS	The distance between the CH and the BS
18	Send Code	The cluster sending code
19	Attack Type	Type of the node. It is a class of five possible values, namely, Blackhole, Grayhole, Flooding, and Scheduling, in addition to normal, if the node is not an attacker

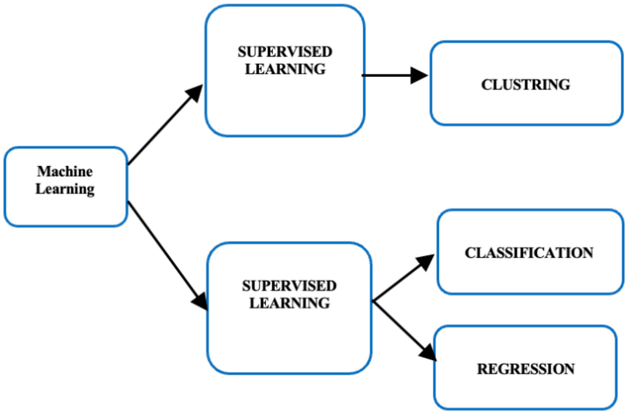

Fig. 3. Machine Learning.

The most common and widespread use of these Bayes algorithm is the use of spam filters or text and medical analysis. As these classifiers are easy to implement, they are most commonly used for machine learning. As stated by [14], Naïve Bayes classification uses probability theory to classify the data and makes use of Bayes theorem in its algorithm. The main feature of this classifier is that there can be an adjustment of the probability of an event as new data is introduced. It also assumes all the attributes that are in consideration are independent of each other. A Naïve Bayes classifier is not a single algorithm, but instead, it is a combination of specific machine learning algorithms in which statistical independence methods are used. A Naïve Bayes classifier makes a proper decision rule classification as long as the required class is more probable than any other present class. This fact is deemed accurate, as there is a slight inaccuracy in the probability estimation most of the times [3].

2) Fine Tune Naïve Bayes (FTNB): With respect to the Naïve Bayes classification, the tuning of parameters is limited, and it is recommended to improve the quality of the pre-processing and feature selection processes. The classifier performance and prediction can be improved by tuning and adjusting the classifier parameters, applying classifier combination techniques, or by monitoring the data fed to the classifier- either adding more data, refining existing one, or improving them [3].

3) Data Parsing (pre-processing): According to [15], the data is a string of raw text presented for each data point. A series of processes and steps convert this data into a structured vector such that the offset shows one feature and the value in the offset is correspondent to the frequency. Stemming, synonym finding and use of neutral words in the raw data text are one of the ways to improve the data parsing or the data processing methods.

a) Selection of Features: According to [16], the use cases for a Naïve Bayes classification like spam filtering are observed and utilized by showing how they fail or quickly can be improved. For assumption, an above average spam filter has a feature like a word frequency in all caps and words in titles or the occurrence of exclamation symbol in the title. The best feature for improvement is the use of long words or a group of more than a single word.

4) IBK algorithm: Instance Base Learner (IBK) algorithm is used in distance measure and classifying instances based on K-nearest neighbors to make predictions [17]. The computation in the test phase is very high and takes a long time, especially for a huge number or instances in the dataset. The default value of neighbors is 1. Sometimes called 1-NN [18].

5) Random forest algorithm: Random Forest or random decision forest algorithm is used for classification and regression of an ensemble of the collection of datasets. In WEKA program, Random Forest can only do the classification part, not the regression task. It operates by building a great number of decision trees in the training phase and perform the classification task. In WEKA, there is no output of the mean prediction or regression of each tree. Random Forest classification mean mapping input data in the dataset or instances to a category. This is also called categorization of the instances. The algorithm that does the classification, especially in the concrete implementation, is called the classifier [19].

IV. Experiments and Result

This section discusses and demonstrates the experiments conducted and their results. Both datasets have been classified using the above-mentioned machine learning algorithms (section III-B) using Cross-validation and percentage split techniques. Cross validation is a standard analysis tool used to verify the validity of the data mining model. It works by dividing the dataset into a number of folds or pieces and hold each fold in turn for testing and training all of the other pieces in the system. In dividing the dataset into layers or folds, it ensures that each layer or fold had the correct portion of class values [20]. Additionally, Percentage split determines the percentage used for training the system [20]. For our experiments, 66% was used for training and 34% was used for testing. The following subsections demonstrate the results obtained by each algorithm conducted on both datasets using cross-validation and percentage split techniques.

A. Naïve Bayes (NB) Algorithm

1) Cross-validation technique: Table III shows the results of running NB algorithm on both datasets (KDDCUP99 and WSN-DS) using cross-validation technique. Table IV demonstrates the weighted average accuracy using cross-validation technique in terms of several factors such as:

- True Positive Rate (TP): the rate that the system or an algorithm correctly classifies an instance as a positive class.
- True Negative Rate (TN): the rate that the system or an algorithm correctly classifies an instance as a negative class.
- False Positive Rate (FP): the rate that the system or an algorithm falsely (wrongly) classifies an instance as a positive class/.
- False Negative Rate (FN): the rate that the system or an algorithm falsely (wrongly) classifies an instance as a negative class.
- Precision: the ratio of correctly classified instances as positive to the instances that are classified by the algorithm as positive.
- Recall: the ratio of correctly classified instances as positive to the positive instances (whether classified correctly or not).
- Receiver Operating Characteristics (ROC): is a technique used as graph or curve to represent or visualize the performance of the classifiers. It is widely used in machine learning, data mining, and decision making. Also, it is used as a method of comparing diagnostic tests.

2) Percentage split technique: In this experiment, 66% of the data was used for training and 34% for testing. Table V shows the results of running Naïve Bayes (NB) algorithm on both datasets (KDDCUP99 and WSN-DS) using the percentage split technique. In addition, Table VI demonstrates the weighted accuracy average using the percentage split technique in terms of TP, TN, Precision, and ROC.

B. IBK Algorithm

1) Cross-validation technique: Table VII shows the results of running IBK algorithm on both datasets (KDDCUP99 and WSN-DS) using the cross- validation technique. Table VIII demonstrates the weighted accuracy average using the cross-validation technique.

2) Percentage split technique: In this experiment, 66% of the data was used for training and 34% for testing. Table IX shows the results of running IBK algorithm on both datasets (KDDCUP99 and WSN-DS) using the percentage split technique. Table X demonstrates the weighted accuracy average using the percentage split technique in terms of several factors.

C. Random Forest Algorithm

1) Cross-validation technique: Table XI shows the results of running the Random Forest algorithm on both datasets (KDDCUP99 and WSN-DS) using the cross-validation technique. Table XII demonstrates the weighted accuracy average using the cross-validation technique.

2) Percentage split technique: In this experiment, 66% of the data was used for training and 34% for testing. Table XIII shows the results of running IBK algorithm on both datasets (KDDCUP99 and WSN-DS) using the percentage split technique. Table XIV demonstrates the weighted accuracy average using the percentage split technique in terms of several factors.

V. DISCUSSION AND PERFORMANCE EVALUATION

In this section, all results will be discussed and analyzed. Overall performance evaluation will be presented as well. Naïve Bayes algorithm, using the cross-validation technique, has classified most of the instances correctly on both datasets. TP in KDDCup99 is about 92.9% and in WSN-DS is 95.3%. The errors or incorrectly classified instances were 7.08 and 4.064, respectively. Therefore, NAÏVE algorithm is more accurate with WSN dataset than KDDCup99 dataset. Moreover, the weighted accuracy average of both datasets is very similar. Using the percentage split technique with the former algorithm on both datasets showed more accurate results as compared with the cross-validation.

Moreover, IBK algorithm was run on both datasets using cross-validation. Both processes took no time at all, less than one second. As can be seen from the results of the correctly classified instances, both datasets were very close even though the number of instances in each dataset are not the same. The TP in KDDCUP99-DS is about (100%) and in WSN-DS is (99.4%). The errors or incorrectly classified instances were (0.552%) in WSN-DS and (0.0453%) in KDDCup99-DS. Whereas the correctly classified instances in WSN-DS is (99.4%) and in KDDCup99-DS is (99.9%) which is an excellent accuracy in both datasets, almost (100%). This is also reflecting on the weighted average of both datasets against the IBK algorithm. The numbers are very similar, almost the same (100%).

With the percentage split, using IBK algorithm was very accurate with KDDCup99 and WSN datasets. The errors or incorrectly classified instances were (0.584%) in WSN-DS and (0.058%) in KDDCup99-DS. And the correctly classified instances in WSN-DS is (99.4%) and in KDDCup99-DS is (99.9%) which is an excellent accuracy in both datasets, almost (100%). To sum up, IBK using percentage split test algorithm is very accurate with KDDCup99 dataset and with WSN dataset compared with the cross validation.

Furthermore, the Random Forest algorithm has been run on both datasets using the cross validation and percentage split options. With the cross validation, the TP in KDDCUP99-DS is about (100%) and in WSN-DS is (99.7%). The errors or incorrectly classified instances were (0.2779%) in WSN and (0.0213%) in KDDCup99. Also, the correctly classified instances in WSN-DS is (99.7%) and in KDDCup99-DS is (99.9%) which is an excellent accuracy in both datasets, almost (100%). For the percentage split, both datasets took few seconds to process (6.24 and 8.45 respectively). The TP in KDDCup99-DS is about (100%) and in WSN-DS is (99.7%). The errors or incorrectly classified instances were (0.2724%) in WSN-DS and (0.031%) in KDDCup99-DS. The correctly classified instances in WSN-DS is (99.7%) and in KDDCup99 is (99.9%) which is an excellent accuracy in both datasets, almost (100%). It can be concluded that Random Forest using percentage split test algorithm is very accurate with KDDCup99 dataset and with WSN dataset.

As an overall performance evaluation among all algorithms and test options for KDDCup99 dataset, the NAÏVE Bayes algorithm with cross-validation test option is the least accurate (92.92%), meaning it has the least correctly classified instances. On the other hand, the Random Forest algorithm with cross-validation test option (99.98%) was the most accurate. Similarly, for WSN dataset, the NAÏVE Bayes algorithm with cross-validation test option is the least accurate results (95.35%), meaning it has the least correctly classified instances and the Random Forest algorithm with cross-validation test option is the most accurate one (99.73%).

Moreover, the accuracy and processing time were recorded for both datasets using all test options as shown in Fig. 4, 5, 6 and 7. The least time taken was using the IBK algorithm using percentage split test option on WSN dataset (0.05) seconds, then with the KDDCup99 dataset algorithm using percentage split test option (0.08) seconds. As for accuracy measurement, the Random Forest algorithm is the most accurate algorithm in both datasets with all test options. The highest accuracy was registered using cross validation on KDDCup99 dataset (99.9787 %), then on WSN dataset (99.7276 %) using the percentage split test option as shown in Fig. 4 and Fig. 6, respectively.

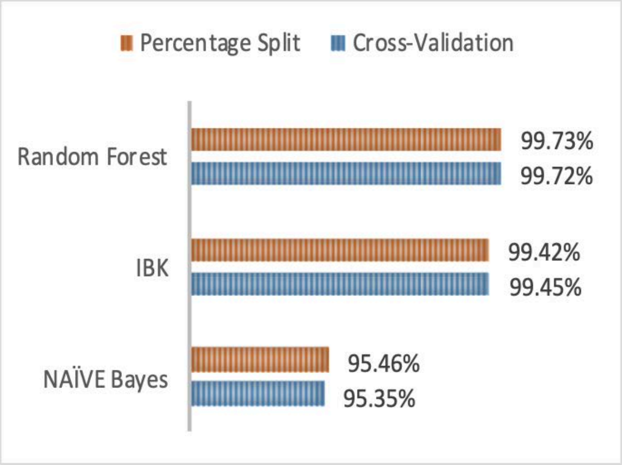

Fig. 6. Comparison of Accuracy on WSN Dataset.

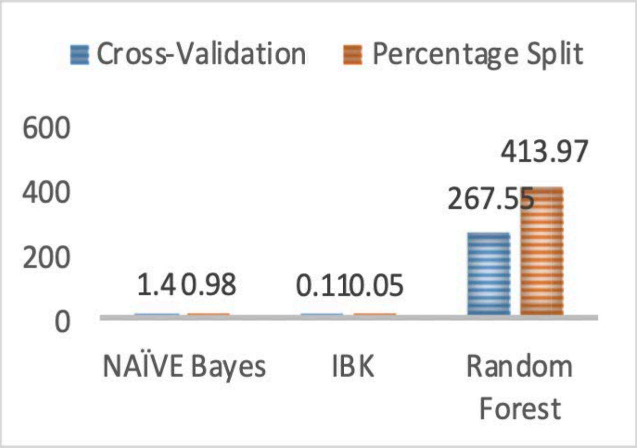

Fig. 7. Comparison of the Processing Time on WSN Dataset.

VI. Conclusion

Due to the importance of protecting WSN against rogue entities of hackers and intruders, taking into considerations all constraints such as limited power, storage, and processing capabilities, a model/dataset needs to be trained to mitigate new or modified attack types in networks.

This paper has analyzed and compared different machine learning algorithms against two datasets (WSN and KDD99) using WEKA tool. The purpose was to further assist in analyzing and protecting WSN networks in combination with Firewalls, Deep Packet Inspection (DPI), and Intrusion Prevention Systems (IPS) that are specialized in protecting WSN networks. Multiple testing options were investigated such as cross validation and percentage split. Based on the finding, the most accurate algorithm and the least time consuming were suggested for both datasets. Future research is needed to create more datasets to characterize various types of attacks in the wireless sensor networks.

***Abstract*—In the design of wireless sensor network (WSN), packet delivery ratio is an import parameter to be maximized. In existing schemes, a secure zone-based routing protocol was implemented for life time improvement in WSNs. In multi - hop communication, a new routing criterion was formulated for packet transmission. Security against message tampering, dropping and flooding attacks was incorporated in the routing metric. The approach skipped risky zones as a whole from routing and chooses alternative path to route a packet in secured manner with less energy consumption. Though energy conservation and attack resilience are achieved, congestion in WSN is increased and because of it packet delivery ratio is diminished. To address this problem, we propose a solution to improve the packet delivery ratio with a multi factor strategies involving routing, differentiation of flows, flow-based congestion control with retransmission and redundant packet coding. Detailed analysis and simulations are undertaken to evaluate the efficiency of the contemplated work compared to the existing solutions.**

Keywords*—*Multi factor strategies; novel routing metric; packet coding; packet delivery ratio

I. Introduction

Wireless sensor network is the collection of sensor nodes which has the capability of wireless data communication. Sensor nodes sense the environment variables depending on the application requirements and send them to sink either directly or through multi hop transmission.

A. *Motivation*

WSN is being increasingly used in many applications like Military ,precision farming, industrial safety, smart home etc. which needs reliable and high speed data transmission . It is required to design WSN applications by considering the requirements like more packet delivery ratio, life time and security.

B. *Earlier Research Work*

In earlier works [1], a zone-based sensor network is designed with the consideration of life time and security. The sensor network is secured against message tampering, dropping and flooding attacks. WSN Life time is increased by optimizing the power usage and packet routing. The network is split to zones and each zone is assigned a score. This score is calculated depending on past security lapses and present residual energy in that zone. A zone with higher score is preferred for routing. In zone based attack resilient routing the network life span and attack resilient capability are improved. But data packets are lost due to higher congestion in WSN. The solution in this work minimizes the packet delivery ratio owing to a significant raise in total numbers hops and node overhead in the network.

The major focus of earlier solutions [1,5,6] is finding the optimal route for data transmission .The identified gaps in the previous works are lower packet delivery ratio, less network life time ,lower throughput. These gaps are addressed in the proposed multi factored approach.

C. *Proposed Work*

Multi factored Secure Routing approach is proposed to improve packet delivery ratio in WSN by addressing the draw backs related to energy efficient attack resilient routing.

In the proposed Multifactor approach, packet delivery ratio is improved by selecting energy efficient route, Differentiation of flows in the network and flow based congestion control and Redundancy & Retransmission management,

The entire WSN is divided in to zones. Energy efficient path from source to sink is selected depending on the preference score calculated at each neighboring zone. The preference score (PS) is measured depending on security score, energy score and reliability score available in the zone. The zone heads are sorted depending on the distance from sink node. Among the neighbouring head nodes, the node whose PS value above threshold $T_1$is selected to send data packet.

In the differentiation of flows Packet flow is split into two categories of high and low priority in the network. At each routing hop, the flow of packets is controlled differently for the packets based on high and low priorities. Packets with high priority are transmitted and low priority packets are buffered during network congestion period.

The low priority packets are buffered to reduce network congestion. This allows for reliable transmission of packets. When a node receives a Packet Forward Success (PFS) message, it calculates the Round Trip Time (RTT). When RTT is above the configured threshold, data flow rate is reduced, when RTT is below the configured threshold, data flow rate is increased.

In Redundancy and Retransmission management data content sent from source is divided into n packets using Reed Solomon erasure coding approach. Even if some packets are lost during transmission, the whole message is reconstructed at the destination without retransmission.

Packet delivery ratio is increased by introducing a weighted routing metric with the consideration of various factors. The goal is to increase the packet delivery ratio applying multiple factors like flow management, retransmission control and weighted routing metric to zone based sensor network.

In the following, Section II presents the related review for proposed solution. Section III elaborates the proposed Multi Factored Strategy, Section IV presents salient features in proposed solution, Results related to proposed schemes are given in Section V. Lastly, section VI explores the conclusions and future scope of the proposed solution.

II. Related Work

An opportunistic routing scheme is presented in [2] to increase the packet delivery ratio in WSN. Relay nodes are selected based on minimization of retransmission. Due to the reduction of retransmission, the overall throughput of the network is increased and thereby reducing the packet loss. Security is not considered for end to end delivery .An opportunistic routing scheme similar to [2] is proposed in [3] with the aim of increasing the reliability and reducing the latency. The best relay satisfying the QoS criteria is selected based on reliability and time guarantee. Less network life time is the limitation for this work. Authors in [4] proposed a distributed multi path algorithm with the goal of higher packet reliability. The path selection is adapted to network changes and failures. With the availability of multiple base stations and routing on multiple paths to these stations, fidelity of packet is improved in this work. Nevertheless, the major limitations are increased network overhead and reduced throughput. An optimal energy efficient routing protocol is formulated in [7].improved Packet delivery ratio and Network Life time is addressed in this solution. A stateless position-dependent routing technique is formulated in [8].Stateless routing is realized using greedy perimeter routing. Geographic routing along with greedy data transmission is able to increase the packet delivery time. Detection of malicious nodes in sensor network is explored in [9, 10]. Network life time is increased by enhanced energy efficient clustering of sensor network in [11]. LEACH algorithm is improved to select the best cluster head to enhance the lifespan of the network. Throughput is less in this work. Ant colony-based routing algorithm is proposed in [12] with the goal of higher packet delivery ratio. The ant colony algorithm uses the fitness function optimized based on communication distance, transmission direction and current residual energy. Packet delivery ratio is increased using opportunistic multipath routing in [13]. Similar to it, in [14] A multi path routing algorithm is formulated to increase packet reliability by forwarding on multiple paths. The solution also uses aggregation to diminish the number of efficient transmissions in WSN.Packet prioritization and optimized back-off MAC protocol is proposed in [15]. Due to reduction of collision in the optimized back-off MAC protocol, packet reliability is improved. The optimized back off MAC works by assigning back off time depending on the packet priorities.A virtual node concept is introduced in [16] to enhance the QoS in WSN based on clustering technique. The scheduling is realized using TDMA in this network. High priority is assigned to certain designated nodes. During higher traffic load, the packets from these designed nodes are given more importance in routing so that latency for those packets is reduced. A stateless opportunistic routing protocol is defined in [17] with the objective of enhancing the packet reliability. Forwarding area for packet is adapted dynamically depending on the density of the sensor nodes, so that reliability is increased. Increased overhead is not addressed. Compressive sensing is used to reduce the packet overhead in [18]. Compressive sensing improves the network utilization and packet delivery ratio. Compressive sensing also minimizes the power usage in WSN.Packet reliability is increased using energy aware Quality of Service (QoS) transmission protocol depending on various parameters in [19]. Energy consumption is reduced by optimal positioning of nodes in [20]. Packet low delivery ratio is limitation in this work. Clustering based energy minimization strategies are explored in [23, 28, 21]. Attack resilient routing in wireless sensor network in discussed in [22, 24, 25, 26, 27].

III. Proposed Multi Factored Strategy

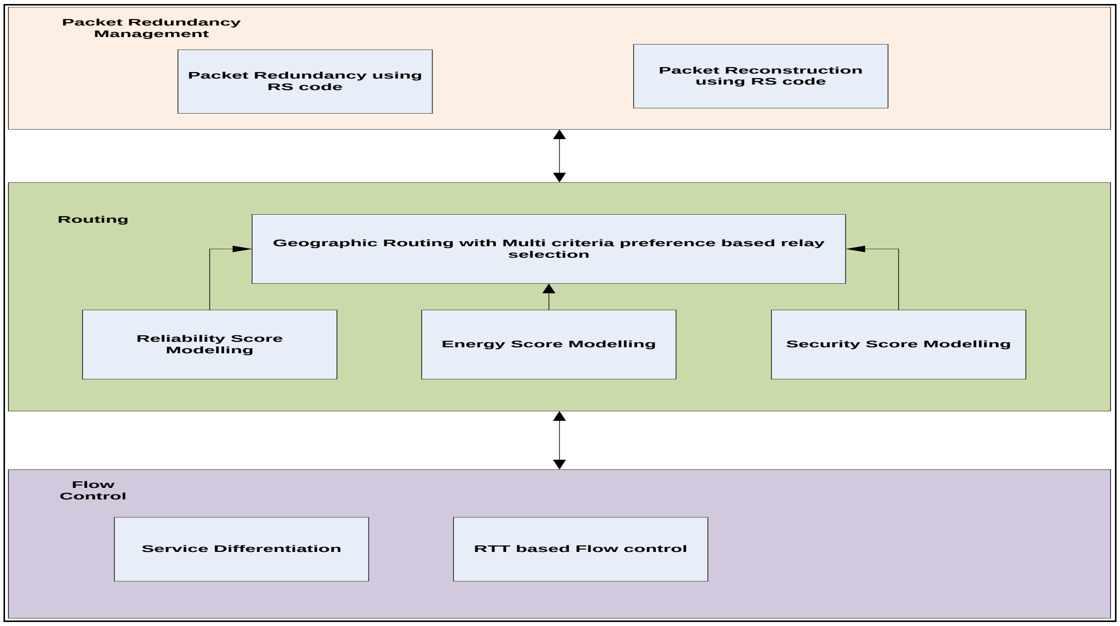
The architectural representation of proposed multi factored approach is depicted in Fig. 1. The architecture represents four important concepts to achieve more packet delivery ratio and life span.

- Selection of energy efficient routing path.
- Redundancy and Retransmission management.
- Differentiation of flows in the network.
- Flow based congestion control.

A. Packet Routing

The Whole area of WSN is split into zones of N×N size. With one hop routing, any node in the zone will connect to any other node. Node close to centre of the zone that can observe all packet transmissions is selected as zone head. The information of nodes within each zone is present in the sink. Three distinct scores, security score, energy score and reliability score are attained in each zone. The value of the scores varies from 0 to 10. The zone with high score is recommended for routing when compared with zone having lower score. The zone scores are calculated based on fuzzy function using the following input variables.

- Packet traversing count (PTC).
- Packet traversing failure count (PTFC).
- Tampered incidence count (TIC).
- No tampered count (NTC).



Packet Redundancy Management
Packet Redundancy using RS code
Packet Reconstruction using RS code
Routing
Geographic Routing with Multi criteria preference based relay selection
Reliability Score Modelling
Energy Score Modelling
Security Score Modelling
Flow Control
Service Differentiation
RTT based Flow control

Fig. 1. Architecture of Secure Routing based on Multi Factored Approach.

These scores are detailed in [1] and the counters are kept at sink node. But these counters are kept at zone head in the proposed solution. The fuzzy function for calculating the security score (SS) of the zone is shown in (1).

$$SS = \mu_1 * Q(PTC) + \mu_2 * Q(PTFC) + \mu_3 * Q(TIC) + \mu_4 * Q(NTC) \quad (1)$$

Where

$Q(x)$: The fuzzification kernel of input x.

The de-fuzzification score is measured by using center of gravity formula as shown in (2).

$$Score = \frac{\int \mu_{\bar{D}r}(x).xdx}{\int \mu_{\bar{D}r}(x).dx} \quad (2)$$

Where x = {PTC, PTFC, TIC, NTC}.

The path security score SS_p (3) is measured as.

$$SS_P = \frac{\sum_{i=1}^{N} SS_i}{N} \quad (3)$$

Where SS_i is the zone security score. There are N zones in the path.

The energy score (ES) of a zone is measured as in (4).

$$ES = \frac{10*(E - TPC * E_c)}{E} \quad (4)$$

Where E is the node's initial energy and E_c is the energy utilized for packet transmission at node. TPC is the total packets transmitted.

The path energy score ES_P is calculated using (5).

$$ES_p = \prod_{\min of\ all\ N} ES_i \quad (5)$$

Where ES_i is the energy score of the path.

Rather than the revised AODV based routing addressed in [1] ,the packets are transmitted using a geographical routing through preference score-dependent path selection. Past packet forward statistics are used to calculate the reliability score for the zone. Packet forward success message is sent by each node with successful forward for packet to immediate hop. Whenever this message is received, packet forward success counter (PFS) is incremented. Periodically, the reliability score (6) is measured as.

$$R_t = \alpha \times R_{t-1} + (1 - \alpha)\frac{PFS}{TPC} \quad (6)$$

With $R_0 = 0$ and α is constant.

Initially the data packet is sent from the source node to the zone head. The head of zone sends a packet containing hello message to other neighbouring heads. The heads of zones receiving 'HELLO' message calculate the preference score and send back a 'HELLO_RES' as response to 'HELLO'. The preference score (PS) is measured (7) as the sum of weighted values of security score, energy score and reliability score.

$$PS = w_1 * SS_p + w_2 * ES_p + w_3 * R_t \quad (7)$$

With $w_1 + w_2 + w_3 = 1$ and $w_3 > w_2 > w_1$

The zone accepting 'HELLO_RES' , selects the zone head with highest PS score as relay hop and route the DATA packet to that zone head.

After the reception of HELLO_RES by zone head, the K nearest neighbour heads are sorted depending on the distance from sink node. Among K neighbouring head nodes, the node whose PS value above threshold $T_1$is selected to send data packet. Data packet is forwarded to all K neighbour nodes, if none of the neighbour has PS values aboveT_1. This process is repeated at every hop until data packet received by the sink node.

Before applying fuzzy function on the input variables PTC, PTFC, TIC, NTC , these variables must converted from numerical to categorical values of Low (L), Medium (M) and High (H) using the transformation functions . Transformation function for the input variable PTC is shown in the Fig. 2.

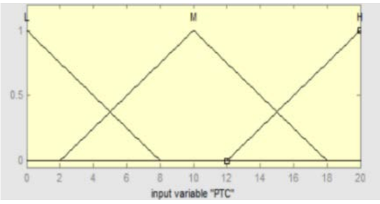


Fig. 2. PTC Transformation Function.

Transformation function for the input variable PTFC is shown in the Fig. 3.

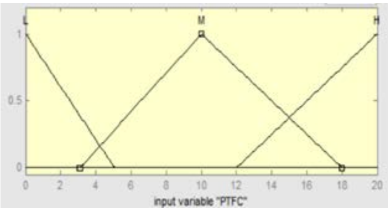

Fig. 3. PTFC Transformation Function.

Transformation function for the input variable TIC is shown in the Fig. 4.

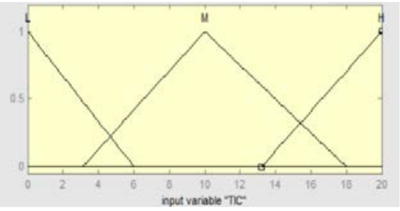

Fig. 4. TIC Transformation Function.

Transformation function for the input variable NTC is shown in the Fig. 5.

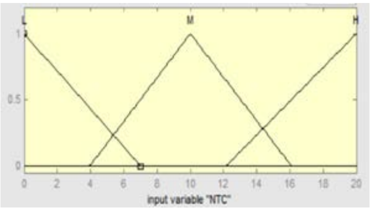

Fig. 5. NTC Transformation Function.

The output variable of preference score is converted from numerical to categorical value using the transfer function given in Fig. 6.

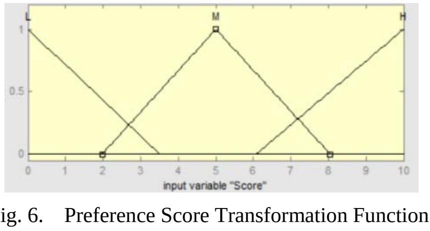

Fig. 6. Preference Score Transformation Function.

The input variables PTC, PTFC, TIC and NTC are mapped with output variable of preference score using fuzzy rule base.

B. Flow Differentiation and Congestion Control

Packet flow is split into two categories of high and low priority in the network. At each routing hop, the flow of packets is controlled differently for the packets based on high and low priorities. Packets with high priority are transmitted and low priority packets are buffered during network congestion period. Due to buffering of low priority packets, network congestion reduces. This allows for reliable transmission of packets. The round trip time (RTT) is calculated, when a node receives a packet forward success response .Based on probability delay, RTT (8) is measured as below.

$$RTT = \begin{cases} \sum_{i=0}^{\infty} f_i(a).f_i(b) \ , x = 0 \\ \sum_{i=0}^{\infty} f_i(a).f_{2x+i}(b) + \sum_{i=0}^{\infty} f_i(b).f_{2x+i}(a), x > 0 \end{cases} \quad (8)$$

Where: a is forward path.

b is backward path.

f is the probability mass function..

Adaptive flow control for the packets is shown in Fig. 7.

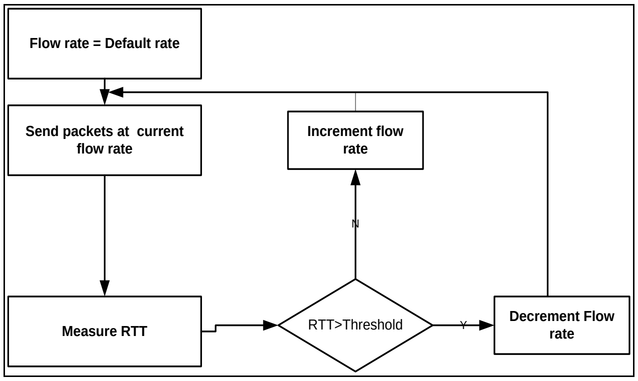

Fig. 7. Flow of Packets.

The flow rate is initially set to the default value and data flow control at each node begins with this value [Fig. 7]. Based on the reception of packet forward success message, round trip delay is calculated. Data Flow rate is decreased when RTT is above configured threshold and increased when RTT is below configured threshold.

C. Redundant Packet Coding

The message content sent from source is divided into n packets using erasure coding (n,k) .Only k of n packets are sufficient for reconstructing the entire message content. The source node sends n packets of the message and if k out of n packets is received at sink, the message can be reconstructed without any necessity for retransmission. This work uses Reed Solomon erasure coding. Use of Reed Solomon code has following advantages.

- The reed Solomon transformed contents are encrypted and secure.
- Retransmission can be avoided to reconstruct the entire message with lesser number of packets.

IV. Salient Features in Proposed Solution

The proposed multi factor strategy has following salient features:

- Packet delivery ratio and network life span are less in earlier works [1],[5],[6] which are addressed in the proposed solution using multi factored approach.
- Risky areas in the network are quantified using scores and routing is adapted to skip those risky areas.
- Packet flow is differentiated and flow is managed to reduce the congestion in the network. Flow management is dynamic to congestion in the network.
- Retransmission is avoided in the network due to erasure coding.
- Attack resiliency is assured with proactive routing in secure paths.

V. Results

The proposed multi factored strategy is simulated in NS2 platform. The simulation parameters used for testing the proposed solution is given in TABLE I.

The performance of the proposed work approach is simulated and evaluated by comparing with the following solutions.

- Secure Energy Efficient Routing is contemplated in [1].
- Optimal Energy Efficient Routing is formulated in [5].
- Secure Localized Routing is defined and implemented in [6].

Performance evaluation parameters considered for comparison are: packet delivery ratio, packet delay, node overhead, network life time and throughput.

Packet delivery ratio (9) measures the ratio of successfully received packets at sink to the total number of packets sent by the sources. It is calculated as

$$PDR = \frac{number\ of\ packets\ recived\ at\ sink}{total\ number\ of\ packets\ sent} \tag{9}$$

The results of packet delivery ratio against number of nodes are given in Table II and Fig. 8.

The packet delivery ratio of the proposed solution is 6.95% more Compared to [1], 14.6% more compared to [5] and 16.51% more compared to [6].

The results of average delay against number of nodes are given in Table III and Fig. 9.

Compared to [1], average delay is lower by 15.38% in the proposed solution, 24.13% lower compared to [5], 37.14% lower compared to [6]. The delay is lower in the proposed solution due to reduction in number of hops in the geographic routing strategy adopted in the proposed work.

The result of network overhead against number of nodes is shown in Table IV and Fig. 10.

TABLE I. Simulation Parameters

Criterion	**Value(s)**
No. of Nodes	50 - 250
Communication range(m)	100
Simulation expanse(m^2)	1000 × 1000
Allocation of Priority (%)	20
Disposition of sensor Node	Random
Time of Simulation	30
Queue size of Interface	50
Medium Access Control(MAC)	802.11

TABLE II. Comparison of Packet Delivery Ratio

No.of Nodes	**Proposed Multi Factored Approach**	**Secure Energy Efficient Routing[1]**	**Optimal Energy Efficient Routing[5]**	**Secure Localized Routing[6]**
50	15	18	21	24
100	14	16	18	22
150	13	15	17	21
200	12	15	16	20
250	12	14	15	18

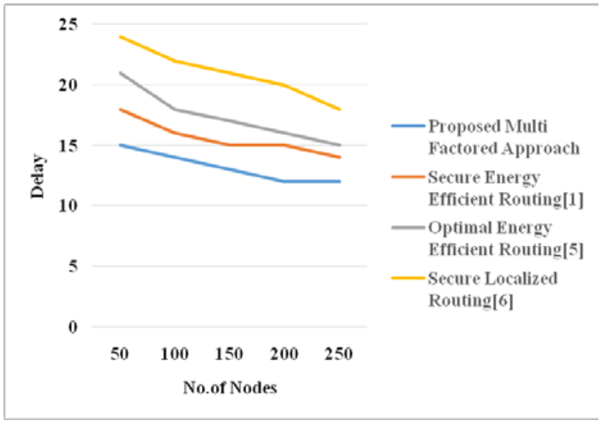

Fig. 9. Delay Comparison.

TABLE IV. ANALYSIS OF OVERHEAD

No.of Nodes	Proposed Multi Factored Approach	Secure Energy Efficient Routing[1]	Optimal Energy Efficient Routing[5]	Secure Localized Routing[6]
50	72	80	82	85
100	85	92	93	97
150	89	97	100	106
200	94	104	108	116
250	97	116	118	127

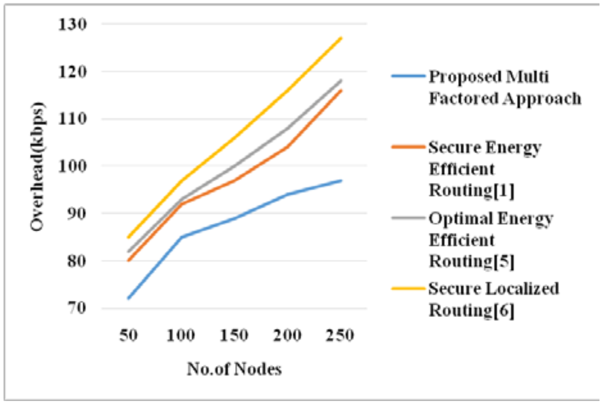

Fig. 10. Analysis of Overhead.

Compared to [1], overhead is lower by 10.63% in proposed solution, 12.77% lower than [5] and 17.7% lower than [6]. Adaptive multi path propagation and geographic routing has reduced the network overhead in proposed solution.

The result of life time against number of nodes is given in Fig.11 and Table V.

Compared to [1], life time is higher by 19.4% in the proposed solution, 72.7% more compared to [5] and 102.1% more compared to [6]. Due to the minimization of number of hops and retransmissions, energy consumption is reduced and this has increased the life span in the proposed work.

The results of network throughput for different rate of packet generation are given in Table VI and Fig. 12.

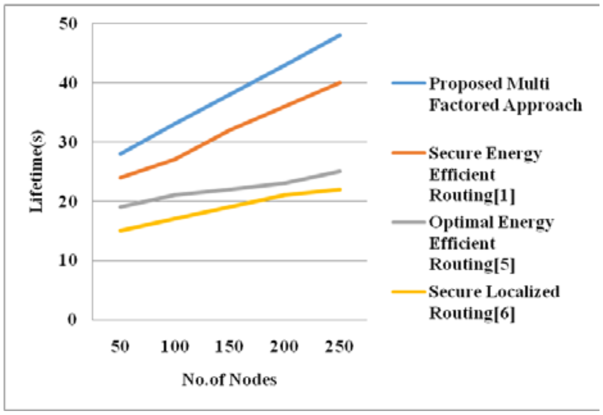

Fig. 11. Life Time Comparison.

TABLE V. LIFE TIME COMPARISON

No.of Nodes	Proposed Multi Factored Approach	Secure Energy Efficient Routing[1]	Optimal Energy Efficient Routing[5]	Secure Localized Routing[6]
50	28	24	19	15
100	33	27	21	17
150	38	32	22	19
200	43	36	23	21

250	224	208	201	195
300	267	251	242	238

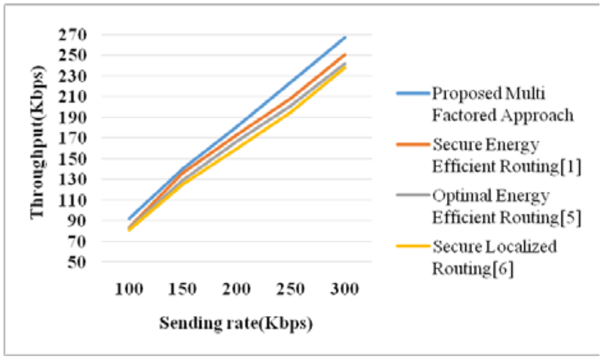

Fig. 12. Throughput Comparison.

The proposed solution has higher throughout in terms of 6.1% more than [1], 9.97% more than [5] and 13.14% more than [6].

The split ratio between high and low priority packet is set to 70:30 and throughput is measured for varied rate of packets from source. The comparison is given in Table VII and Fig. 13.

TABLE VII. COMPARISON OF THROUGHPUT ON 70:30 SPLIT

Total Sending rate (kbps)	Proposed Multi Factored Approach	Secure Energy Efficient Routing[1]	Optimal Energy Efficient Routing[5]	Secure Localized Routing[6]
100	65	52	50	47
150	100	83	82	79
200	130	100	96	90
250	160	120	117	110
300	195	160	157	147

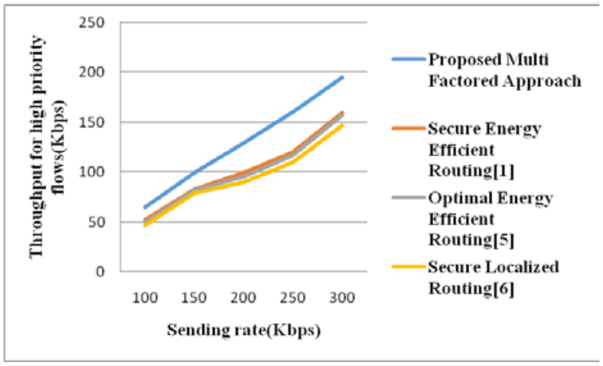

Fig. 13. Throughput Comparison on 70:30 Split.

The proposed solution has higher throughput in terms of 9.97% greater than [1], 29.48% greater compared to [5] and 47.42% greater compared to [6].

VI. CONCLUSION AND FUTURE SCOPE

A multi factored strategy with the objective of providing increased packet delivery ratio in zone-based sensor network is proposed in this work. Geographic routing is adapted with relay selection based on a preference score. Adaptive multi path propagation, flow differentiation and congestion control, redundancy coding are the multi factored strategies proposed in this work. Redundancy in the coding has reduced the number of retransmissions in the network. Flow differentiation and flow control has reduced the congestion in the WSN. Preference score is calculated based on energy availability, security and reliability of the nodes and use of it in routing has increased the packet reliability. Due to multi factored strategy, the packet delivery ratio improved by 6.95% in the proposed work, life time improved by 19.4% and delay reduced by 15.38% compared to the existing works. These results are very much useful for further research in the areas of Military applications, Environmental monitoring etc. In the further enhancement, the proposed solution can be improved to reduce the average energy consumption of nodes within the zone in order to improve packet delivery ratio.

UML Sequence Diagram: An Alternative Model

Sabah Al-Fedaghi
Computer Engineering Department
Kuwait University
Kuwait

***Abstract*—The UML sequence diagram is the second most common UML diagram that represents how objects interact and exchange messages over time. Sequence diagrams show how events or activities in a use case are mapped into operations of object classes in the class diagram. The general acceptance of sequence diagrams can be attributed to their relatively intuitive nature and ability to describe partial behaviors (as opposed to such diagrams as state charts). However, studies have shown that over 80% of graduating students were unable to create a software design or even a partial design, and many students had no idea how sequence diagrams were constrained by other models. Many students exhibited difficulties in identifying valid interacting objects and constructing messages with appropriate arguments. Additionally, according to authorities, even though many different semantics have been proposed for sequence diagrams (e.g., translations to state machines), there exists no suitable semantic basis refinement of required sequence diagram behavior because direct style semantics do not precisely capture required sequence diagram behaviors; translations to other formalisms disregard essential features of sequence diagrams such as guard conditions and critical regions. This paper proposes an alternative to sequence diagrams, a generalized model that provides further understanding of sequence diagrams to assimilate them into a new modeling language called thinging machine (TM). The sequence diagram is extended horizontally by removing the superficial vertical-only dimensional limitation of expansion to preserve the logical chronology of events. TM diagramming is spread nonlinearly in terms of actions. Events and their chronology are constructed on a second plane of description that is superimposed on the initial static description. The result is a more refined representation that would simplify the modeling process. This is demonstrated through remodeling sequence diagram cases from the literature.**

Keywords*—Requirements elicitation; conceptual modeling; static model; events model; behavioral model

I. Introduction

In object-oriented analysis, we identify classes by examining usage scenarios, where classes are determined through nouns or noun phrases [1, 2]. This is followed by analyzing classes with the intent of encapsulation (bundling data and methods) while still keeping data and operations separate. Then, the analysis moves to the task of specifying operations, which define the *behavior* of objects, including the communication that occurs between objects by passing messages to one another. In this phase, requirements might demand examination of how an application behaves as a consequence of external events. A behavioral model indicates how software will respond to external events. According to [2], in general, an *event* occurs whenever the system and actor exchange information; in this case, the event is the fact that information has been exchanged. The creation of the behavioral model necessitates the following steps [2]:

1) Evaluate all use cases to fully understand the sequence of interaction within the system

2) Identify events that drive the interaction sequence and understand how these events relate to specific objects.

3) Create a sequence for each use case.

B. Sequence Diagrams

The UML behavioral representation, the sequence diagram (SD), is the second most common UML diagram that represents how objects interact and exchange messages over time [3, 4]. SDs have been used informally for several decades [5]. The first standardization of SDs came in 1992, and since then, there have been several dialects and variations. SDs show how messages are sent between objects or other instances to perform a task. They are used during the detailed design phase, in which precise interprocess communication must be established according to formal protocols. When testing is performed, the behavior of the system can be described as SDs [5].

Shen [6] observed that the general acceptance of SDs can be attributed to their relatively intuitive nature and ability to describe partial behaviors (as opposed to such diagrams as state charts). SDs plays an important role in helping users understand system operation and visualize the interactions among a system's objects. According to [7], "the reason of their success compared to other formalisms like state machines is that they are easy to use and understand." The SD bridges the UML use case model and the object classes specified in the structural model. In UML, diagrams must be tightly integrated to avoid inconsistencies; however, such tight integration is infeasible and often impractical [8]. UML 2 extended SDs with such features as recent enrichment and new symbols that allowed programmers to indicate additional procedural details [3, 6].

SDs are used for different purposes, such as showing the flows of method calls inside a program or giving a partial specification of interactions in a distributed system [9]. SDs are utilized to automate test case generation [10]. SDs show "how events or activities in a use case are mapped into operations of object classes in the class diagram. Events are basic behavioral constructs of SDs that can be combined to form larger behavioral constructs called fragments" [11].

C. Problems

Many different semantics have been proposed for SDs for various purposes (e.g., in terms of translations to state machines) [9, 11]. In short, there does not exist a suitable semantics-based refinement of required SD behavior because direct style semantics do not precisely capture required SD behaviors, and translations to other formalisms disregard essential features of SDs such as guard conditions and critical regions [11]. It is not easy to select suitable semantics: the various formal semantics for SDs handle even the most basic diagrams quite differently [9]. Thus, there is a need for a refinement of SD behaviors that clarifies the issue of the relationship of the static and dynamic features.

Modeling complex interaction behaviors relies on a good understanding of SDs [11]. However, SDs often pose the greatest difficulties among novices learning modeling [11, 12]. Modeling SDs overwhelms some learners, as it involves a large number of interacting items that must be handled concurrently [13].

Over 80% of graduating students are unable to create a software design or even a partial design [14]. According to [14], “many students had no idea how SDs were constrained by other models. Many exhibited difficulties in identifying valid interacting objects and constructing messages with appropriate arguments. Though students understood the role of objects, messages and arguments individually, they were daunted when considering all constraints imposed by other models, concurrently.”

D. Generalizing SDs

This paper proposes an alternative generalized model to SDs that provides further understanding of SDs, assimilating them into a new modeling language called a thinging machine (TM). The SD is extended horizontally, removing the superficial dimensional limitation of vertical-only expansion to preserve the logical chronology of events. TM diagramming is spread nonlinearly in terms of actions. Events and their chronology are constructed on a second plane of description that is superimposed on the initial static description. The result is a more refined representation that simplifies the modeling process. This is demonstrated by remodeling SD cases from the literature.

For the sake of having a self-contained paper, the next section introduces TM as our main tool in scrutinizing SDs. Sections 3 and 4 present case studies that contrast SDs with the proposed TM modeling.

II. TM Modeling

The TM model articulates the ontology of the world in terms of an entity that is simultaneously a *thing* and a *machine*, called a *thimac* [15-25]. A thimac is like a double-sided coin. One side of the coin exhibits the characterizations assumed by the thimac, whereas on the other side, operational processes emerge that provide dynamics. A thing is subjected to doing, and a machine does.

Thimacs are a source for generic constructs that can be applied in conceptual modeling to describe structure and behavior as a world of systems (thimacs). The generic actions in the machine (see Fig. 1) can be described as follows:

Arrive: A thing moves to a machine.

Accept: A thing enters the machine. For simplification, we assume that all arriving things are accepted; hence, we can combine the *arrive* and *accept* stages into one stage: the receive stage.

Release: A thing is ready for transfer outside the machine.

Process: A thing is changed, but no new thing results.

Create: A new thing is born in the machine.

Transfer: A thing is input into or output from a machine.

Additionally, the TM model includes storage and triggering (denoted by a dashed arrow in this study’s figures), which initiates a flow from one machine to another. Multiple machines can interact with each other through movement of things or triggering. Triggering is a transformation from one series of movements to another.

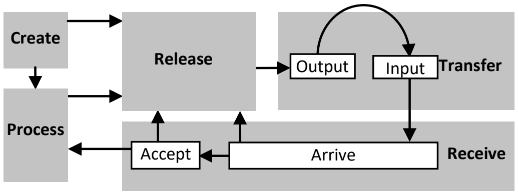

Fig. 1. Thinging Machine.

III. ATM Example

Consider the simple SD for withdrawing cash from an ATM shown in Fig. 2 [26].

A. Static TM Model

Fig. 3 shows the corresponding TM model. The figure illustrates the following:

1) The user inserts his/her card (1), which flows (2) to the ATM to be processed (3). The ATM extracts the card’s number (4), which is sent to the bank system (5).

Note: In the original SD, the message from the ATM to the bank is “verify card”. Here, the message does not state what is sent.

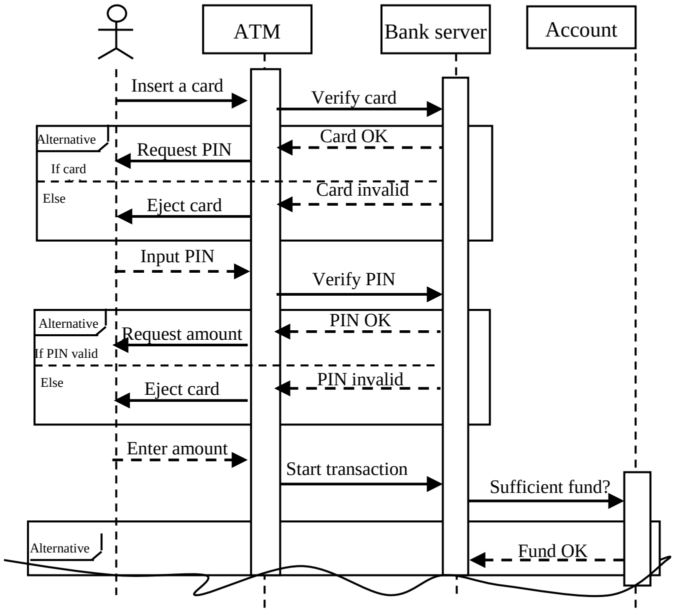

Fig. 2. Sample Sequence Diagram. (Redrawn, Incomplete from [26]).

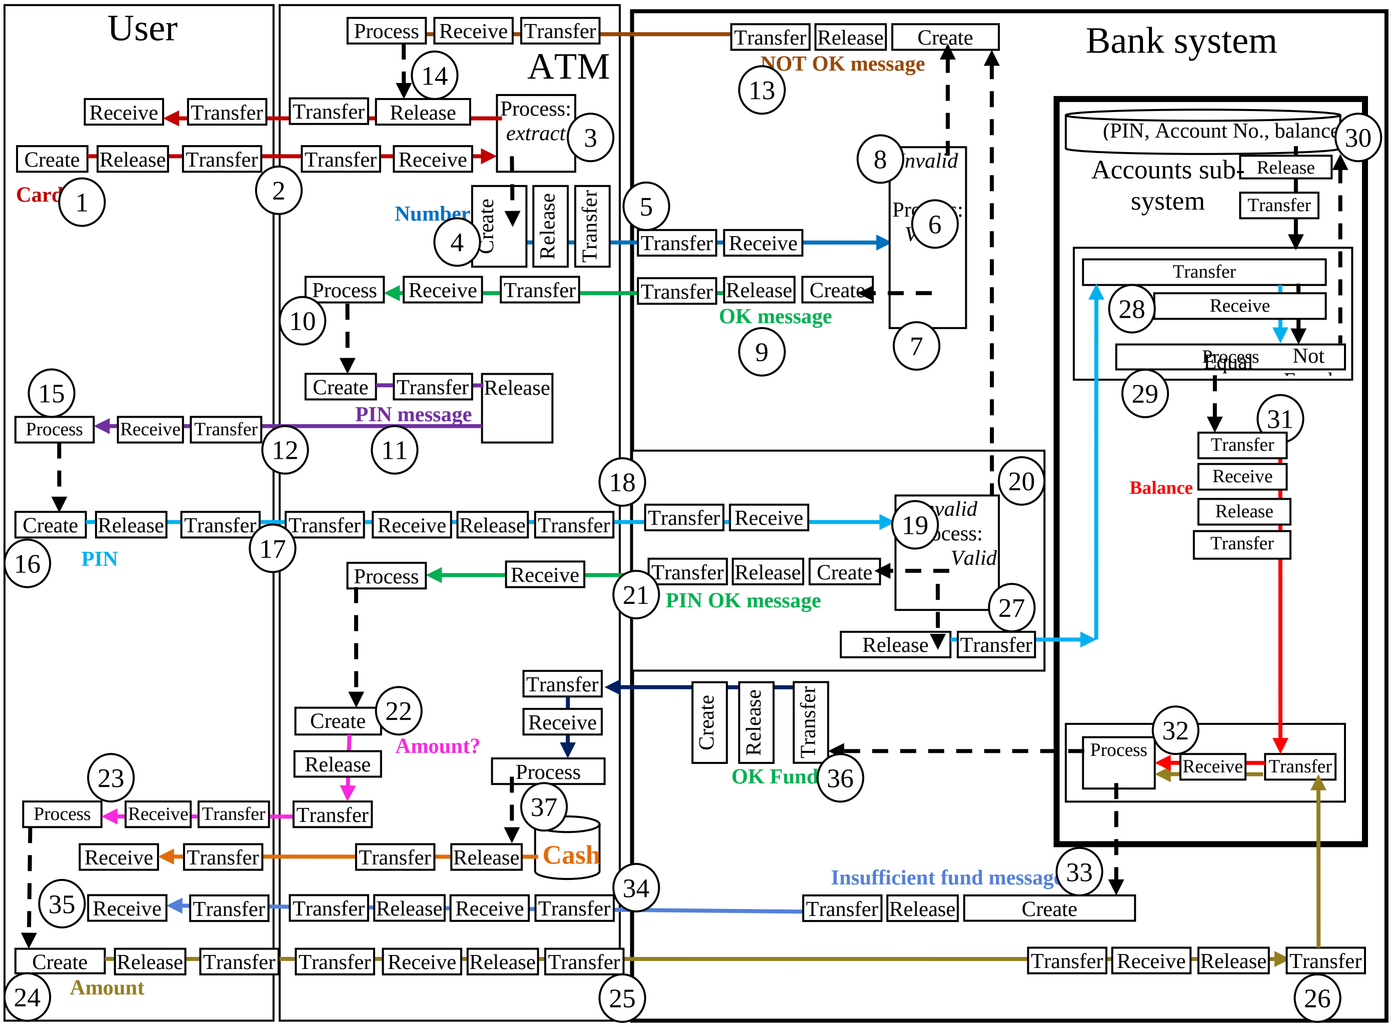

Fig. 3. Static Model of the ATM.

What is sent can be misunderstood as the physical card, which is called a "message". The correct understanding is that the ATM sends the embedded card *number* to be verified. This ambiguity about what is sent can be eliminated by explicitly specifying the process of extracting the number from the physical card. In a TM, the arrow from the user to the ATM is a physical card, and the arrow from the ATM to the bank is a number; these two arrows never cross.

2) The card number is processed (6) in the bank system (not in the bank itself) as valid (7) or invalid (8). If the card number is valid, then an OK message (9) is sent to the ATM. The ATM processes the message (10) and triggers the construction of a request for a PIN (11) that flows to the user (12). If the card number is invalid, then the bank system constructs a "not OK" message (13), which flows to the ATM to trigger the ejection (14) of the card.

Note: This TM part corresponds to *Alternatives* in the SD. The flows of different kinds of things (card, card number, OK/not OK, PIN messages) are separated by triggering.

3) The user processes (reads; 15) the message to trigger the creation of the PIN (16) that flows to the ATM (17), which sends it to the bank system (18). In the bank system, the PIN is processed (19). If the PIN is invalid (20), a not-OK message (13) is sent to the ATM, causing the ejection of the card (14). If the PIN is valid (21), an OK message (22) is sent to the ATM. The ATM constructs a message asking for the amount, which is sent to the user (23).

Note: The above description corresponds to the second *Alternative* in the SD. The TM model does not repeat the process of ejecting the card when a PIN is invalid (13 and 14).

4) The user enters the amount (24), which is received by the ATM and sent to the bank system (25), which in turn sends it to the account subsystem (26).

Note: The account system is a subsystem of the bank system. It is important to know that the bank system stored the previously given, say, PIN because the account subsystem needs such information to allocate the amount and decide whether the account is sufficient. This is performed when the PIN is valid (27). The SD skips over these parts of the scenario, leaving the model either incomplete or disconnected.

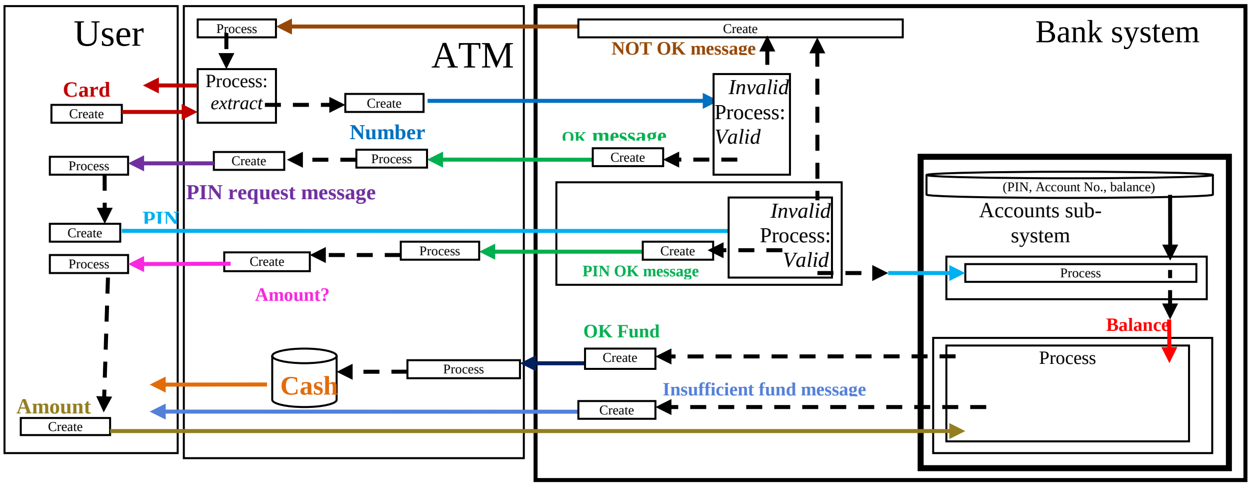

Fig. 4. Simplification of Static ATM Model.

5) The account subsystem receives the PIN (28) and searches for the corresponding account or amount in its database (i.e., PIN, account number, balance). Accordingly, the corresponding balance is extracted (31) and compared (32) with the requested amount. If the funds (balance) are insufficient, then an insufficient funds message (33) is sent to the ATM, which in turn sends it to the user (34 and 35). If funds are sufficient, then an "OK fund" message (36) is sent to the ATM. The ATM releases the corresponding amount of cash to the user (37).

B. *Simplification (if Needed)*

Of course, sequencers will complain that the TM model is more complex than their SD. There is no argument against the model being simple, however—the model must include as many important situations as is practical. Simplicity should not reduce reasonable completeness. In the ATM example, it is reasonable and important to expect that what is sent to the bank would be the number embedded in the card. It is also reasonable and important to indicate that the amount message (sufficient/insufficient) sent by the account system involves searching for a balance in the account database. Such omissions are common in SDs. The additions supplied by the TM model to the ATM problem reflect more or less relevant expansions to the conception of the problem. Fig. 3 can be simplified by assuming that the arrow direction indicates the direction of flow; thus, the transfer, release, and receive steps can be eliminated, resulting in Fig. 4.

C. *Time and Behavior*

Additionally, time in SDs is said to be represented along the vertical dimension. However, this confuses time with logical order. Suppose that the numbers 1, 2, and 3 are listed vertically in order. This does not mean that 1 *happens* at time 1, 2 happens at time 2, and 3 happens at time 3. The relationship among 1, 2, and 3 is the logical relationship "less than" or "greater than", and there are no time-related events involved. To make the relationships among 1, 2, and 3 into events, we must introduce the idea of "existence" or "presence" ("creation" in a TM). Suppose that for a certain system, at time zero, 3 is created (born in the context of the system), and then 1 is created. Then, we can have the events (time zero, 3) and (time zero + 1, 1). In this case, we can say that 3 happened before 1, regardless of the logical relationship between 1 and 3 (e.g., less than). Of course, with this understanding, we can simplify the events and write them as *3* then *1* (without mentioning times explicitly).

Another issue is that the SD forces non-logical relationships. For example, the card and the PIN can be entered in any order or concurrently (e.g., to speed up the transaction). Because these are independent and multiple methods of verification, their order and execution are logically immaterial. Such a situation can be observed clearly when websites ask for an account and password simultaneously: when one of them is wrong, the system does not tell you which one. Incorporating this multi-verification case requires extending the SD. Still, the basic conceptual problems in the SD are claiming that the vertical order is time, failing to define what time is, and failing to define what an event is.

A model exists in time as much as space, and it must situate itself in the temporal. The TM model fuses space and time into a single dynamic model of events. TM modeling involves two planes of modeling: staticity and dynamics. The static model involves spatiality (containerization) and actionality (generic actions). Spatiality involves recognizing the thimac areas that partition the model, taking into account the connections (flows and triggering) between these areas.

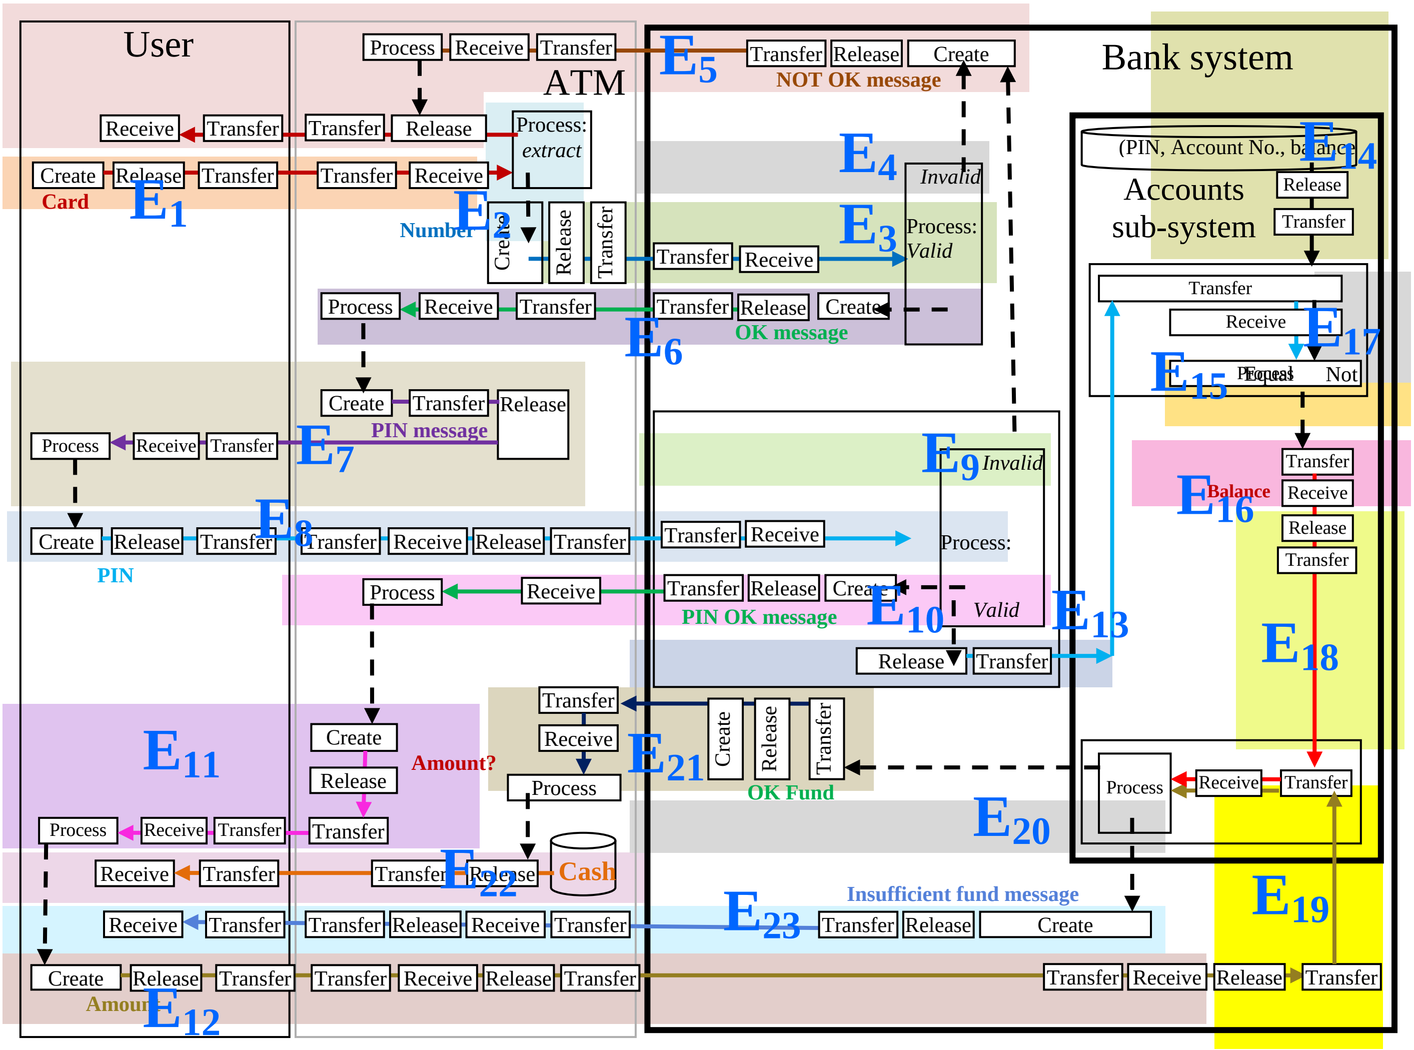

Fig. 5. Dynamic ATM Model, Regions of Events.

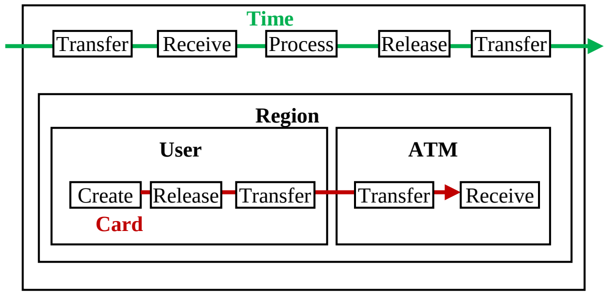

Fig. 6. The Event the user Inserts a Card that is received by the ATM.

A union of TM spatiality/actionality with time defines Event 5. The event blends such a spatiality/actionality thimac with time. Actuality here means the five generic actions. In the ATM example, Fig. 5 shows the machine of the event *the user inserts a card that is received by the ATM*. Accordingly, the static model (Fig. 3) is divided into parts; each represents the region of an event, as shown in Fig. 6.

The SD does not include the notion of time because an event is made up of the time + region of the event, which includes the boundary and actions. We can specify the events in the ATM model as follows.

Event 1 (E_1): The user inserts a card that flows to the ATM.

Event 2 (E_2): The ATM processes the card and extracts its number.

Event 3 (E_3): The card number is sent to the bank, where it is processed.

Event 4 (E_4): The card number is invalid.

Event 5 (E_5): A not-OK message is sent to the ATM, and the ATM ejects the card.

Event 6 (E_6): The card number is valid; hence, an OK card number message is sent to the ATM.

Event 7 (E_7): The ATM requests the PIN.

Event 8 (E_8): The user inputs the PIN, which flows to the ATM, which sends it to the bank.

Event 9 (E_9): The PIN is invalid.

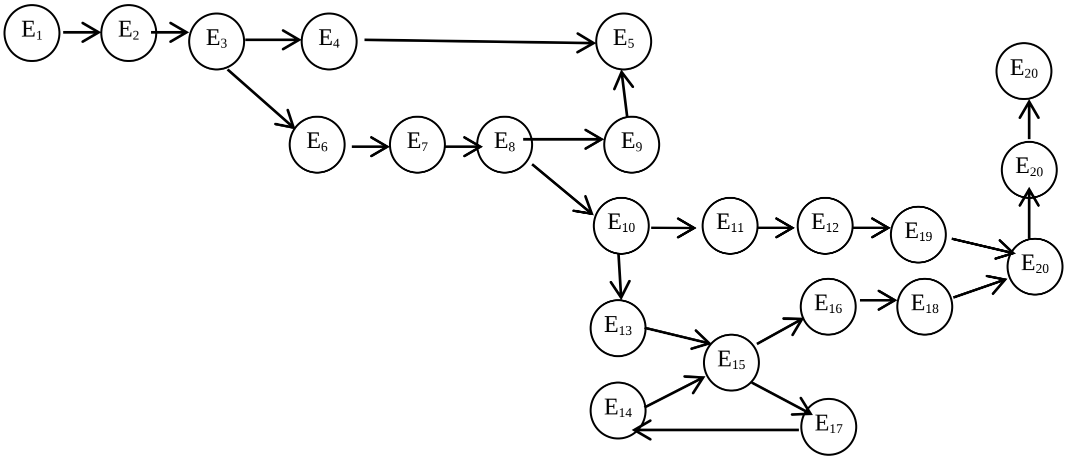

Fig. 7. Behavioral Model of the ATM.

Event 10 (E_{10}): The PIN is valid; hence, an OK PIN message is sent to the ATM.

Event 11 (E_{11}): The ATM requests the amount.

Event 12 (E_{12}): The user inputs the amount, which flows to the ATM, which sends it to the bank.

Event 13 (E_{13}): The bank system sends the PIN to the database system.

Event 14 (E_{14}): The database system retrieves a PIN record.

Event 15 (E_{15}): The database system compares the user's PIN with the record's PIN.

Event 16 (E_{16}): The two PINs match; hence, the corresponding balance is extracted.

Event 17 (E_{17}): The two PINs do not match.

Event 18 (E_{18}): The balance flows to be compared with the amount.

Event 19 (E_{19}): The amount flows to be compared with the balance.

Event 20 (E_{20}): The balance and amount are compared.

Event 21 ($E2_{1}$): The amount of funds is OK; hence, a message is sent to the ATM.

Event 22 (E_{22}): The ATM disburses cash.

Event 23 (E_{23}): Funds are insufficient; hence, a message is sent to the ATM that, in turn, sends it to the user.

Fig. 7 shows the resultant behavioral model of the ATM.

D. *Contrasting the SD with the TM Model*

Consider contrasting the two representations:

- The SD with its objects, messages, communication arrows, events, vertical chronology of events, fragments, activities (e.g., insert, verify, eject, request, input, start, enter, etc.) … (see Fig. 2)
- The TM model with its things, machines, five actions, two types of arrows, events, behavior (see Fig. 3, 6, and 7).

It seems that the TM model is more systematic (coherent whole), with a clear separation of the static and dynamic (e.g., events) aspects of the system. Such a claim will be substantiated further with the modeling case in the next section.

IV. ROLE OF THE SD IN UML

The SD is a UML interaction diagram that *bridges* the user requirements specified in the use case model and the object classes specified in the structural model [27]. Syn [13] discussed the example shown in Fig. 8 to demonstrate the systems analysis process, by which the class diagram is derived from use cases. According to [13], the figure "shows the important role of the sequence diagram. The sequence diagram bridges the requirements specified in the use case model with operations of object classes in the structural model."

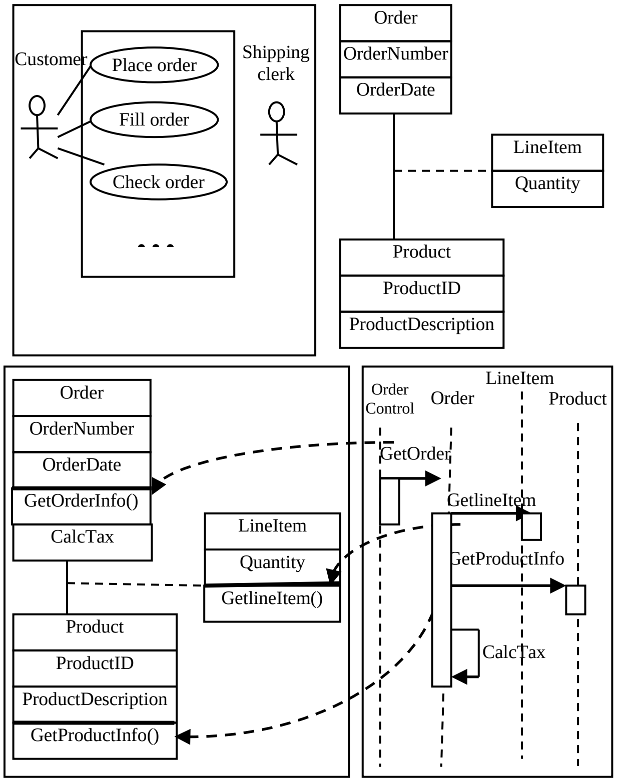

Fig. 8. Sample UML Systems Analysis Process. (Redrawn, Incomplete from [13]).

A. *Static Model*

Fig. 8 reflects how complicated the integration of the UML diagrams is and the role of the SD in such a process. By contrast, a TM has a single diagram that makes it easy to develop an integrated and consistent specification. Fig. 9 shows the static TM model of Syn's [13] ordering system built according to our understanding of Syn's description with minimum additions required to fill the gaps in the given details.

- In Fig. 9, there are two spheres (machines): the customer (Circle 1) and the company (2). The customer creates an order (3). Note that the order structure (4) is similar to a UML class diagram without the methods.
- The order then flows to the company (5), where it is received (6) and processed (7).
- This processing extracts the product number (8) from the order and sends this number to a module (9) that extracts information about that product.
- Accordingly, a process starts for the record of that product in the product database (10). In such a process, a record is retrieved from the product file (11), processed (12), and the product number is extracted (13). Hence, the two product numbers (from the order and from the system file) are compared (14).
  - If they are not the same (15), a new record is retrieved from the database (16).
  - If they are the same, the product price (17) and description (18) are extracted from the product record.
- From the price (17) and the quantity (19 – extracted from the order), the total price is calculated (20). Tax (21) is also calculated. It is possible to develop the invoice here, but because [13] did not mention such an item, we ignore it.
- Finally, the order (22) and the product description (23) are sent to the inventory warehouse to retrieve the actual product (24) and deliver it to the customer (25).

B. *Dynamic Model*

We continue developing the behavior of Syn's [13] ordering system. First, decomposability is applied to form events. Then, the chronology of events is identified to specify behavior. Fig. 10 shows the decomposition of the static model into regions of events. For simplicity's sake, the time flow is not shown. Accordingly, we have the following events in Syn's [13] ordering system.

Event 1 (E_1): A customer creates an order.

Event 2 (E_2): The order flows to the company.

Event 3 (E_3): The order is processed to extract the product number.

Event 4 (E_4): The product number flows to be processed to retrieve the corresponding record from the database.

Event 5 (E_5): A record is retrieved from the product database.

Event 6 (E_6): The product number is extracted from the retrieved record.

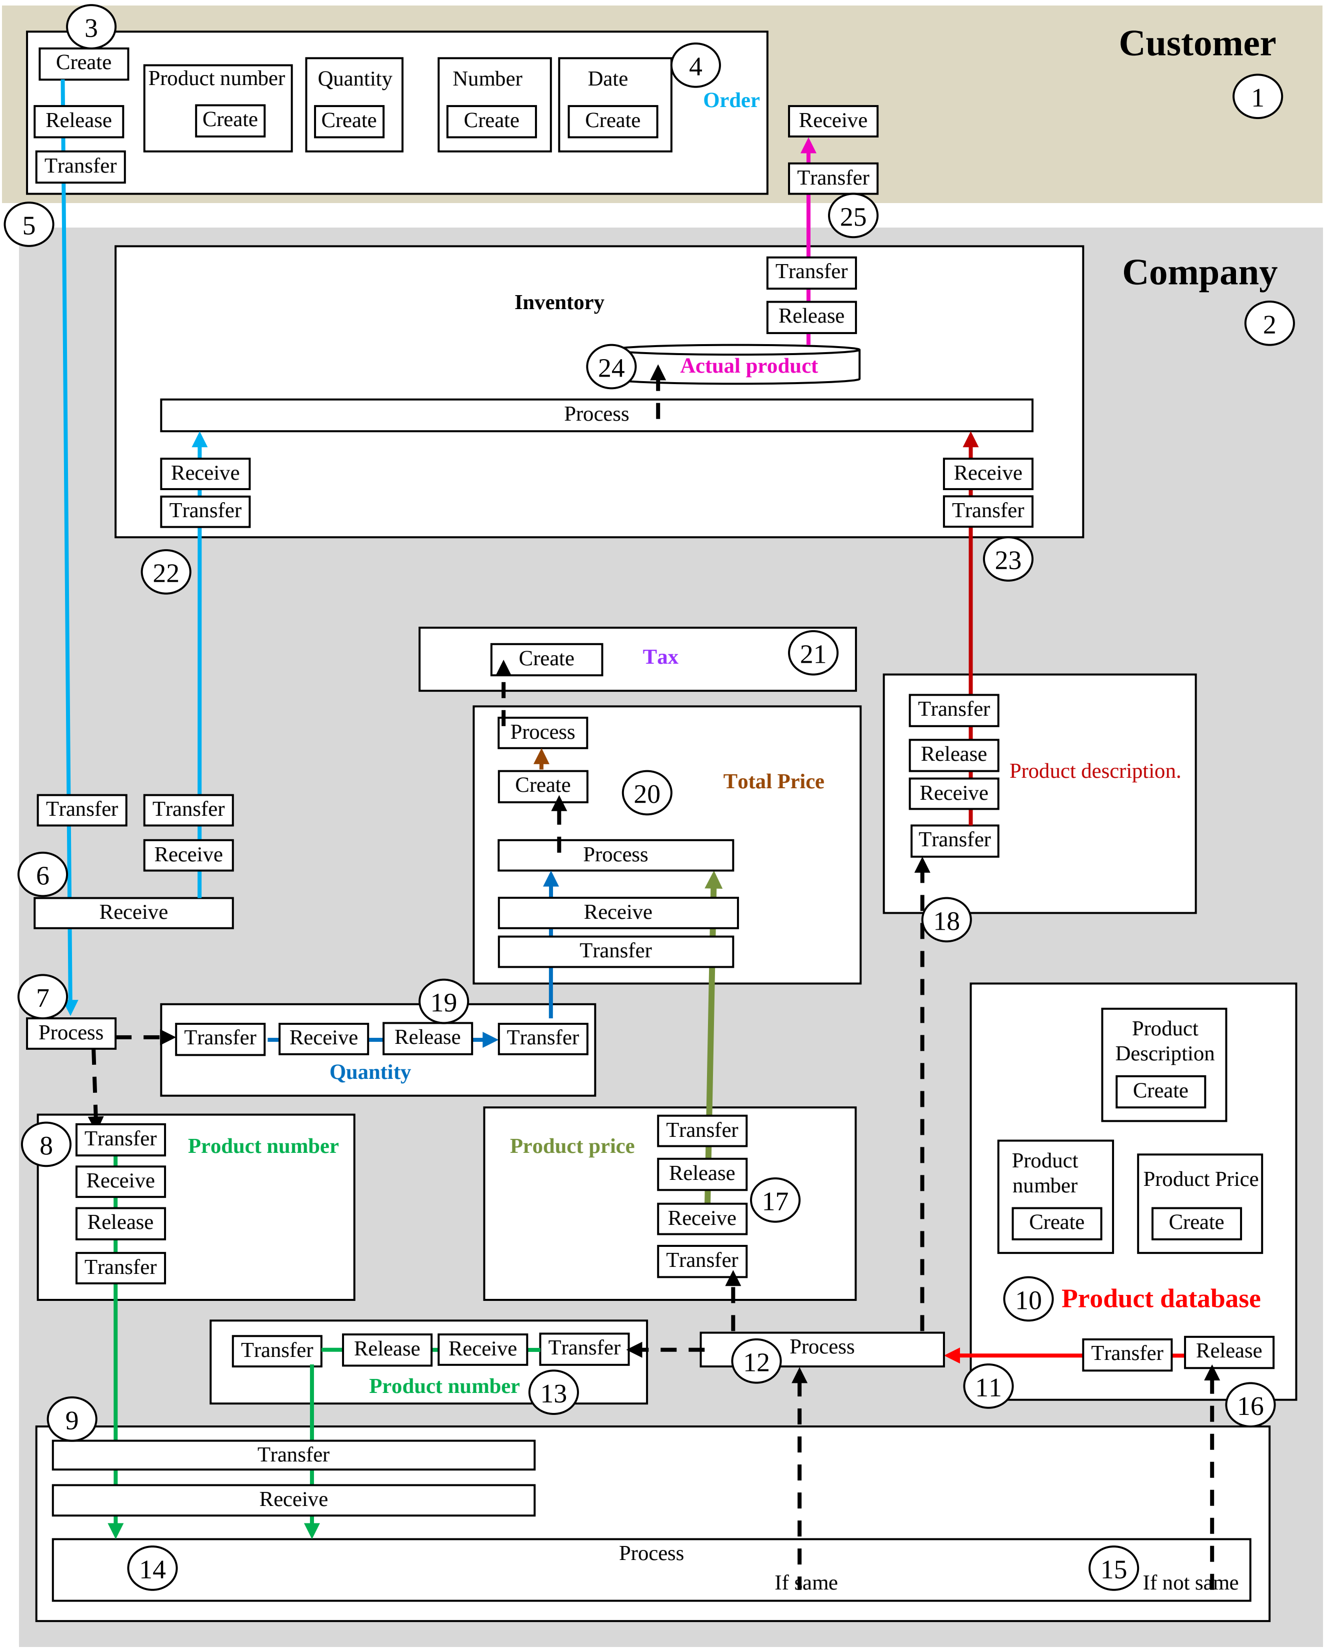

Fig. 9. Static TM Model of Syn's [13] Ordering System.

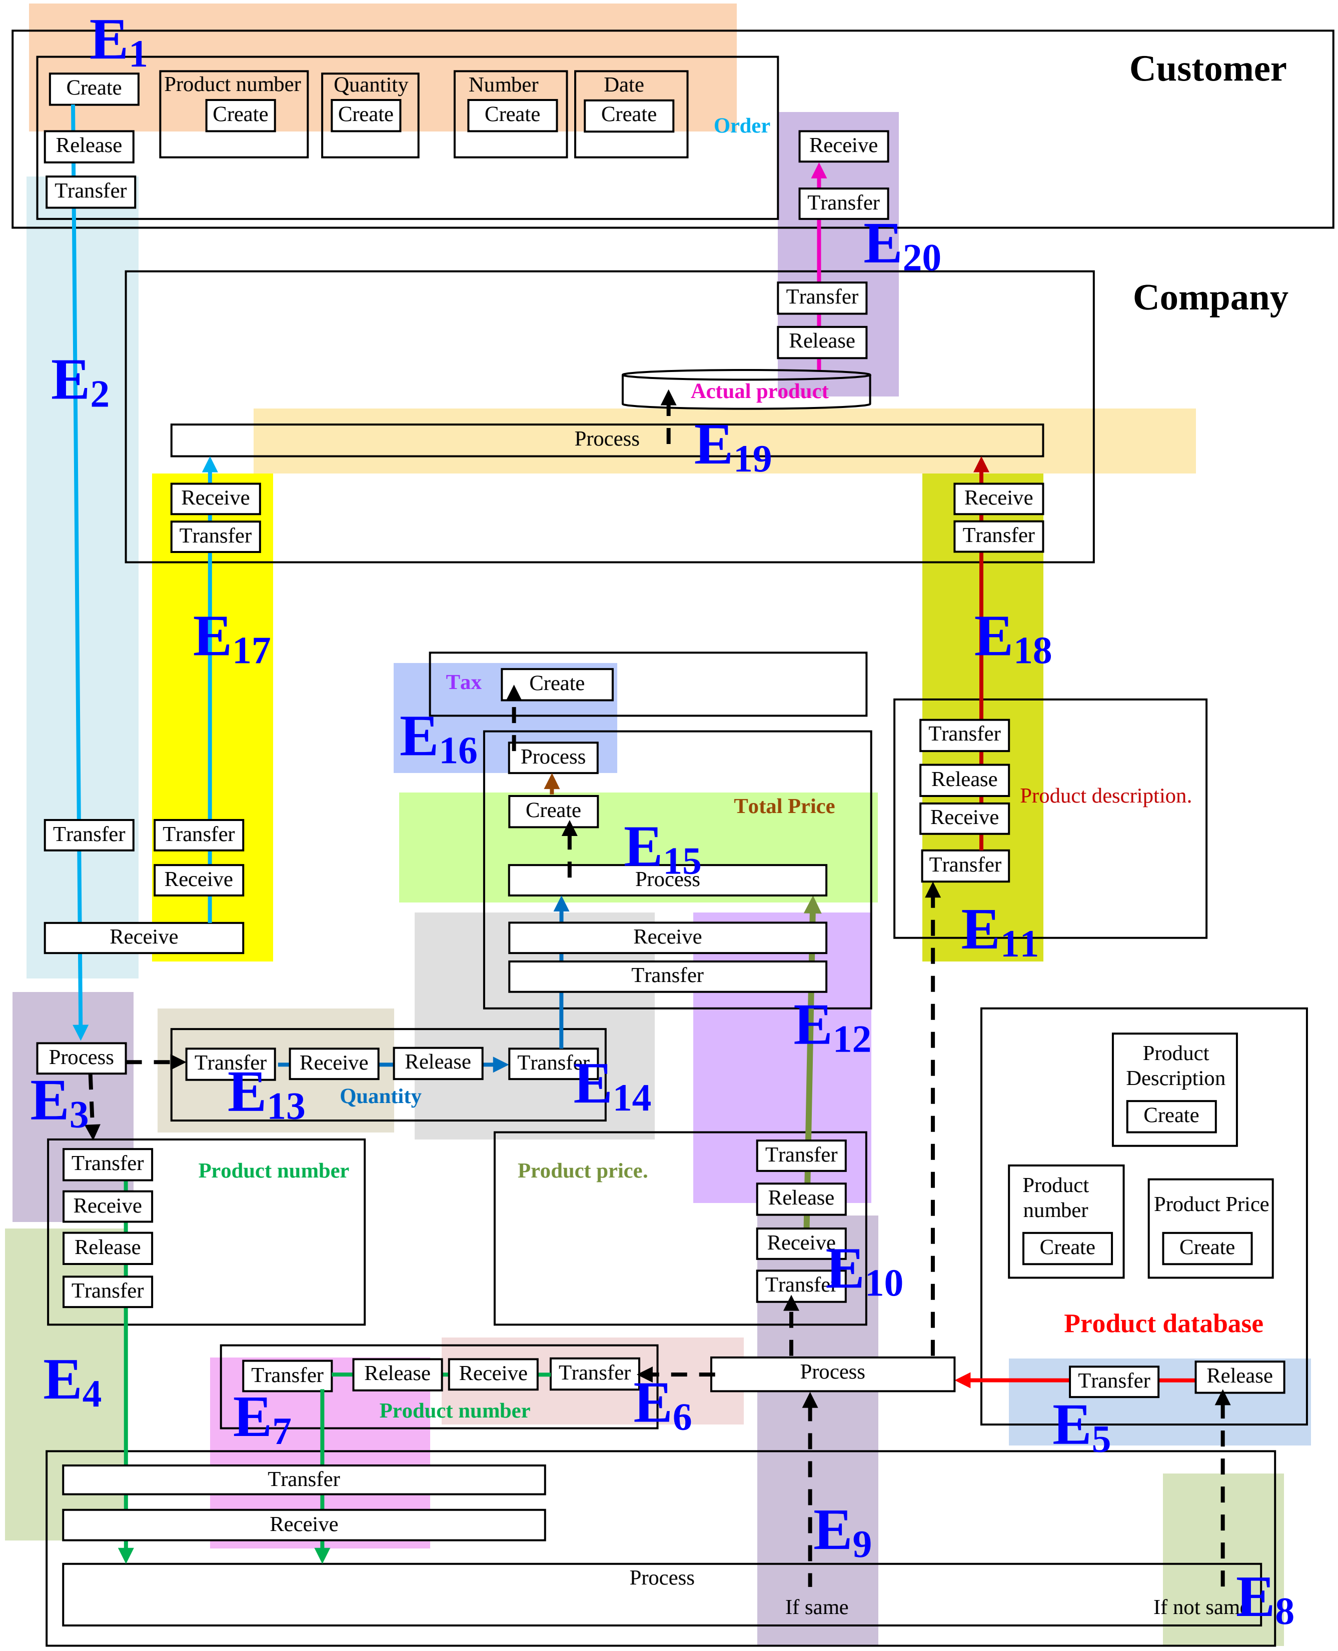

Fig. 10. Decomposition of the Static Model.

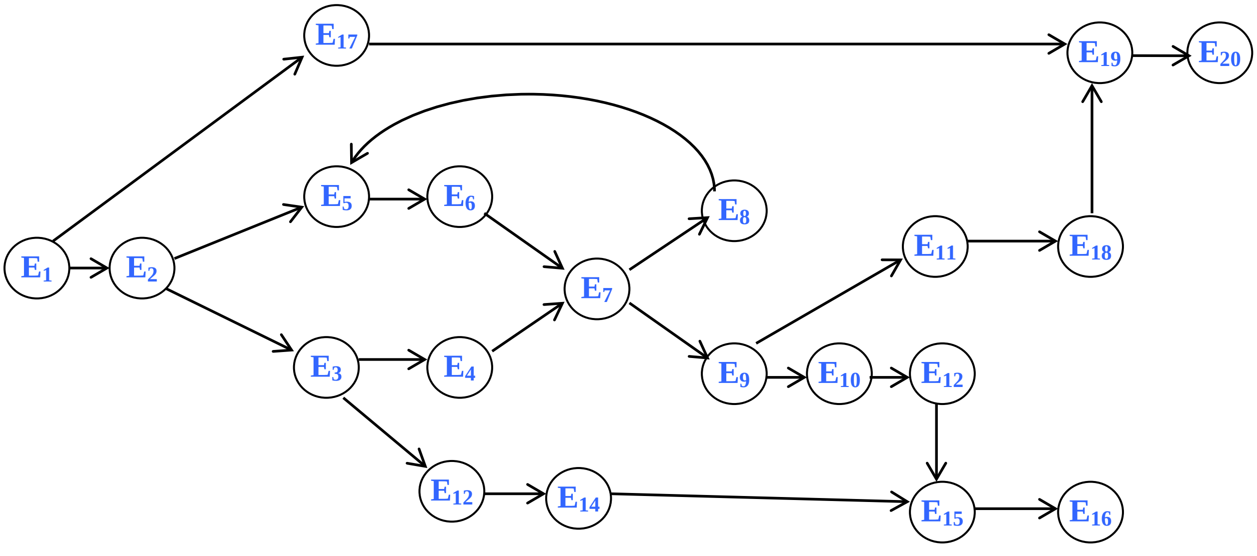

Fig. 11. Behavioral Model of the Ordering System.

Event 7 (E_7): The product number of the retrieved record flows to be compared with the order product number.

Event 8 (E_8): The product number in the order is not the same as the product number in the retrieved record.

Event 9 (E_9): The product number in the order is the same as the product number in the retrieved record.

Event 10 (E_{10}): The product price is extracted.

Event 11 (E_{11}): The product description is extracted.

Event 12 (E_{12}): The product price flows to a procedure that calculates the total price.

Event 13 (E_{13}): The quantity in the order is extracted from the order.

Event 14 (E_{14}): The quantity flows to the procedure that calculates the total price.

Event 15 (E_{15}): The total price is calculated.

Event 16 (E_{16}): The tax is calculated based on the total price.

Event 17 (E_{17}): The order flows to the inventory system.

Event 18 (E_{18}): The product description flows to the inventory system.

Event 19 (E_{19}): The order and the product description are used to retrieve the actual product.

Event 20 (E_{20}): The actual product is sent to the customer.

Fig. 11 shows the behavioral model of the ordering system.

V. Conclusion

In this paper, we proposed an alternative generalized model to the UML SD. This was motivated by difficulties mentioned in the literature regarding developing a suitable semantics-based refinement of required SD behavior. Additionally, studies have shown that graduating students were unable to create software designs, and many students exhibited difficulties in identifying valid interacting objects and constructing messages with appropriate arguments.

The proposed modeling methodology, called TM, extends the modeling process horizontally by removing the superficial dimensional limitation of vertical-only expansion to preserve the logical chronology of events. TM diagramming is spread nonlinearly in terms of actions. Events and their chronology are constructed on a second plane of description that is superimposed on the initial static description. The result is a more refined representation that simplifies the modeling process. We demonstrated this by remodeling SD cases from the literature. TM modeling can be applied to all systems that incorporate SDs. We claim that the results would be a clearer description with better semantics based on the notion of TM actions and events.

The TM model is more systematic (a coherent whole), with clearer separation of the static and dynamic aspects of the system than SD modeling. Our claim is substantiated by the two remodeled study cases above. Accordingly, it seems that adopting this new approach requires studying how to integrate the TM model into the UML diagramming apparatus. Such an issue is a research topic for future work.

***Abstract*—A searching algorithm was found to be effective in producing acutely needed results in the operation of data structures. Searching is being performed as a common operation unlike other operations in various formats of algorithms. The binary and linear search book a room in most of the searching techniques. Going with each technique has its inbuilt limitations and explorations. The versatile approach of different techniques which is in practice helps in bringing out the hybrid search techniques around it. For any tree representation, the sorted order is expected to achieve the best performance. This paper exhibits the new technique named the biform tree approach for producing the sorted order of elements and to perform efficient searching.**

***Keywords*—Time complexities; space complexities; searching algorithm; biform tree; pre-order traversal**

I. Introduction

Data structure performs as fundamental in the area of computing. The efficient search and sort are possible only if the data is organized into the headed process as structured delegacies.

The data organization plot is exemplified as a well-known data structure representation from Fig. 1 and clearly states the individual representation on data-based classification. It also projects the clear representation takes away to the immediate access and handling of data. Understanding data structure and algorithm is very difficult unless searching and sorting are not made and also brought into effect. Each desirable algorithm is chosen based on the data structure type [1]. All searching algorithms lead to efficient retrieval of a specific element from the listed aggregation of elements [2]. Until the desired result is found the search process continuous in all versatile techniques.

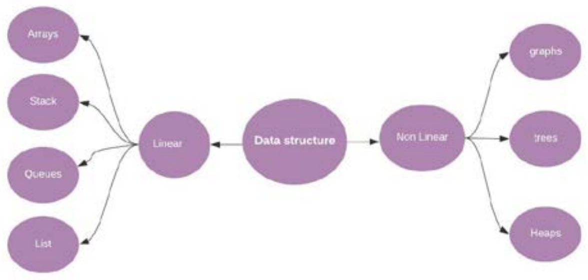

Fig. 1. Data Organization Representation.

II. Searching Techniques

A. Eccentrics of Searching

Searching is a process of accruing and discovering factors from the given list. The searching and sorting algorithms assist in arranging the elements in some order. In deliverance to the efficiency of algorithms including merge and sort technique, sorting is needed [3]. In general, searching is applied to alphabets, strings, and characters other than numbers.

The search algorithms projected in Fig. 2 are on the mind map view featuring significant divisions and classifications of search algorithms that are widely applied on Artificial Intelligence techniques-based algorithms. From the root of the search algorithm, the classification is divided into major divisions as clueless (uninformed) and communicated (informed). The first division clueless of searching explicit the exploration in each step. The goal is to split into each state of activity and explored if not. Less domain knowledge is expected in this type of search and it increases in time complexity. The operations are executed in a brute force method and the result of the current step advances to the next level of implementation. The brute force carries the selective information of traversing from a tree to a festinated step. The communicated search comes with information patterns in each step to find the solution which results quickly in the process. This pattern includes the domain knowledge that results in the heuristic way of approach within fair timing. The complex rich problems are focused and lead to a better solution in this way of approach [4]. The classifications above represent the different searching techniques by all possible means of representing the utmost classification needed.

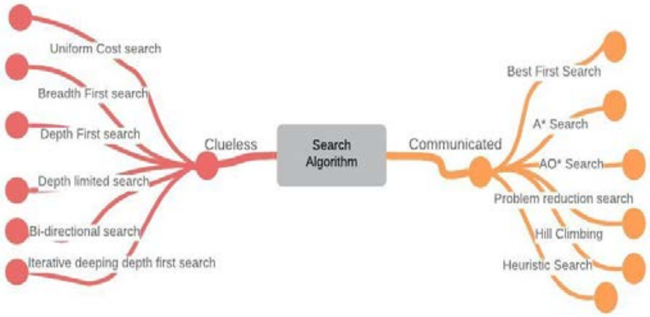

Fig. 2. Searching Types Classifications.

B. Handed-Down (Traditional) Searching Techniques

The search algorithm is one of the class algorithms among the existing classifications on constant, logarithmic, linear, quadratic, and exponential algorithms. The searching is to fill one more piece of the above classifications that are valuable. A searching algorithm is a kind of obvious statement where the word is predominantly mentioned mechanism in the web portal. A search is a way to find a group of items from an implicit or an explicit way of collection. Any searching technique is made easy along with the properties provided. The properties search to reach completeness including the time and space complexities. Every sorting technique comes with a prerequisite in which the effective searching was done looking over the data provided. The comparison is on existing traditional searching techniques assures the complexities they built-in. The searching is made reasonable and efficient through the possibilities as figured and mentioned in search type classifications.

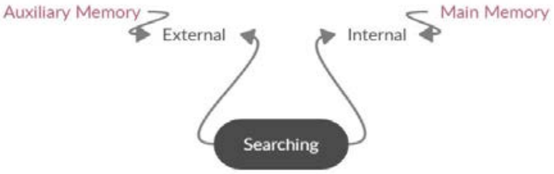

Fig. 3. Searching Proficiencies.

Fig. 3 projects the searching operations on two main classes as external searching and internal searching. The external searching is colligated with auxiliary memory occupies in the files hived away on disk storage. Internal searching is concerned with minimum data that resides on the data processor's main memory [5].

Sorting
Searching

Fig. 4. Searching Classifications.

The searching technique has the base classification of Traditional sorting and searching as projected in Fig. 4. The comparative analysis of the different searching algorithms is possible from the base classification field.

III. Comparative Analysis

A. Comparison on Searching Performance

The performance and efficiency of each algorithm differ based on the data provided for each separate or repeated task. The methodology applied to assess the performance is time & space complexity which have a better modification of words over time and memory space in CPU [6]. Any search algorithms are calculated based on certain attributes of their complexities. Efficient searching fulfills the completeness of the searching algorithm. Table I projects the performance of the binary searching on sorted techniques that is brought through a comparative study in three strategies Performance, effectiveness & output.

TABLE I. A Comparative Study on Different Searching Algorithms over Searching

Algorithm	**Technique**	**Performance**		
		Best-face	***Worst-face***	***Fair-face***
Binary search	Divide &conquer	O(1)	O(log2 n)	O(log n)
Sequential Search	Linear search	O(1)	O(n)	O(n)
Hash Search	Hashing	O(1)	O(n)	O(1)
Tree search	Divide & conquer	O(1)	O(n)	O(n)
Interpolation search	Binary search	O(1)	O(n)	O(n)
Jump Search	Linear search	O(1)	O(n)	O(1)
Hybrid Search	Interpolation & Binary	O(1)	O(√n)	O(n)
Exponential search	Sorting	O(1)	O(log n)	O(log n)
Fibonacci search	Comparison-based	O(1)	O(log n)	O(log n)
DFS	Graph data structure	O(1)	O(|V| +|E|)	O(n+m)
BFS	Graph data structure	O(m)	O(b^m)	O(|V| +|E|)
Heuristic search	Greedy search	G(n)	O(bm)	O(bm)
Bi-directional	Graph search	O(bd)	O(bd/2)	O(bd/2)
Sequential Search	Linear search	O(1)	O(n)	O(n)

{N = 23, 10, 75, 05, 15, 82, 19, 07, 31,100}

Fig. 5. Set of N Random Elements.

The purpose of the comparison table is to equate the different searching techniques based on the individual effective performance. The running complexities include best, worst, and average (fair) cases as a comparative study. Beginning with the binary search each algorithm is classified with the technique built-in. The sequential algorithm derived from linear search finds for a particular element starting apiece, considered to be efficient with classified order. Hashing searching techniques have got their advantage over larger data volume of data sets. The results are implemented without any collision possible actions through open and close addressing methods such as family collisions [7]. Tree search addresses the issue of involving combinations with the basic idea of divide and conquer in better measure and conquer technique and the process continues till it pruned [8]. The interpolation search falls another page from the binary search techniques for the particular data set provided the best effort with the sorted factors. Jump search has a limitation over certain block representations with the intervals and has control as block search. Hybrid search is constructed over the sorted and unsorted distribution of arrays. It blends from the staple of binary and interpolation search for efficient search acquiring the advantage point over both algorithms [9]. The exponential search is selfsame to binary search in which the proportions are equal at the depth of the node, this projects the minor level enhanced by an increasing factor of 2 [10]. This exponents the children at each level in order.

From the classification on different searching algorithms, BST is one of the best-practiced techniques of linear data representation types. BST holds a special name in terms of representing in sorted order which pushes the process much effective & easier. It results in optimal performance for the end-user. The construction of a binary tree protrudes from the root node [11]. The tree has the best picture once it is portrayed in the hierarchy of parent-child with a single character as a parent node (root node).

IV. Proposed Methodology

The success story of each searching algorithm will result in finding the desired element. This paper proposes the construction of effective searching. This methodology was applied to reduce the time complexities of searching principles. This paper effort in the construction of an algorithm that is capable of causing searching efficiently. To achieve such efficiency, the given N random numbers will be converted into binary form and a binary tree for the binary form will be constructed. Performing the technique of pre-order traversal on a binary tree provides a sorted set of output.

A. Phase I: Binary Conversion

The given N numbers will find a sorted position so that any given number is made available in the tree.

The set of N numbers listed is shown as the example for constructing a binary tree. The step begins by involving binary conversion for the given 10 digits into binary form. For the given values projected in Fig. 5, and converted into binary representation in an unsorted order.

B. Phase II: Grouping

The binary conversion is practiced for the set of given N numbers. The presentment of numbers into binary format is projected in Table II. These binary format numbers are grouped based on the number of bits as depicted below representation Fig. 6.

C. Phase III: Biform Tree Approach

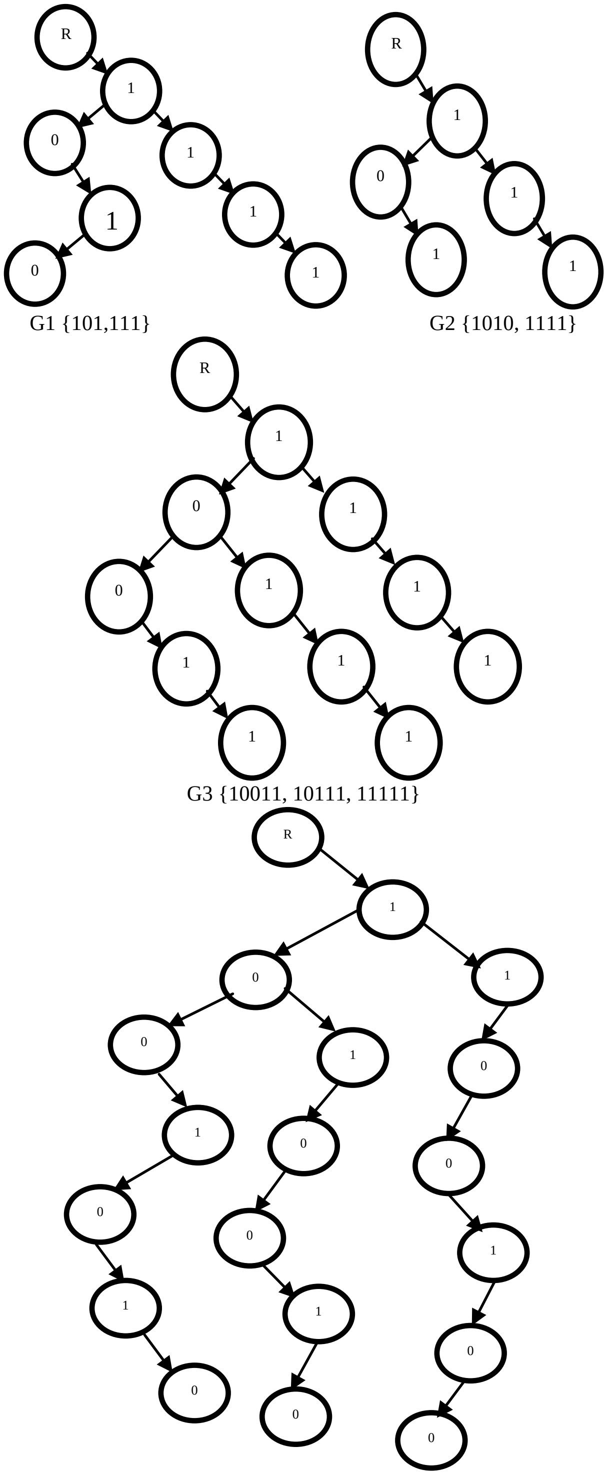
Construction of biform tree for all groups G1, G2, G3, and G4 are projected in the respective Fig. 7(a) to 7(d). The tree construction is initiated from the root node. If the binary number is 1, then it is skewed to the right-hand side of the root node otherwise to the left-hand side of the root node. This operation is continued for all the n bits.

TABLE II. Binary Representation on N Random Elements

N	23	10	75	05	15	82	19	07	31	100
	10111	1010	1001011	101	1111	1010010	10011	111	11111	1100100

G1 = {101, 111}
G2 = {1010. 1111}
G3 = {10111, 10011, 11111}
G4 = {1001011, 1010010, 1100100}

Fig. 6. Elements in Group-Wise.



G1 {101,111}

G2 {1010, 1111}

G3 {10011, 10111, 11111}

G4 {1001011, 1010010, 1100100}

Fig. 7. Biform Tree Representation for G1, G2, G3, and G4.

The effective searching for storing any sorted element is made easy in this way of tree representation. This tree construction helps in making the search faster and effective in paving an easy representation. The grouping of digits will help in looking for the needed elements by avoiding the time in search of the rest.

D. Phase IV: Tree Traversal

As a tree is a self-referential data structure, traversal can be defined by recursion. The traversal algorithm can be broadly classified into depth-first and breadth-first search as shown in Fig. 8. The depth-first algorithm is branched towards pre-order, in-order, and post-order traversal.

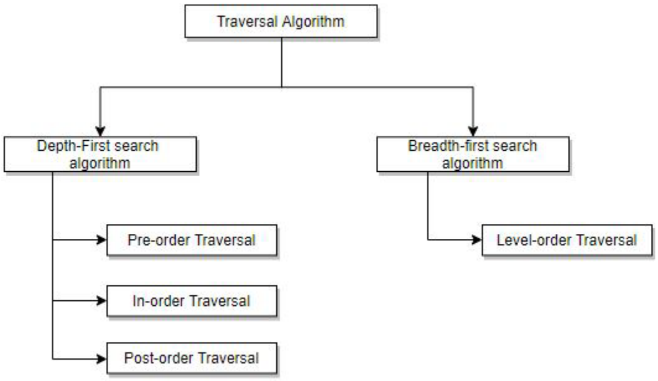


Fig. 8. Traversal Algorithm Classifications.

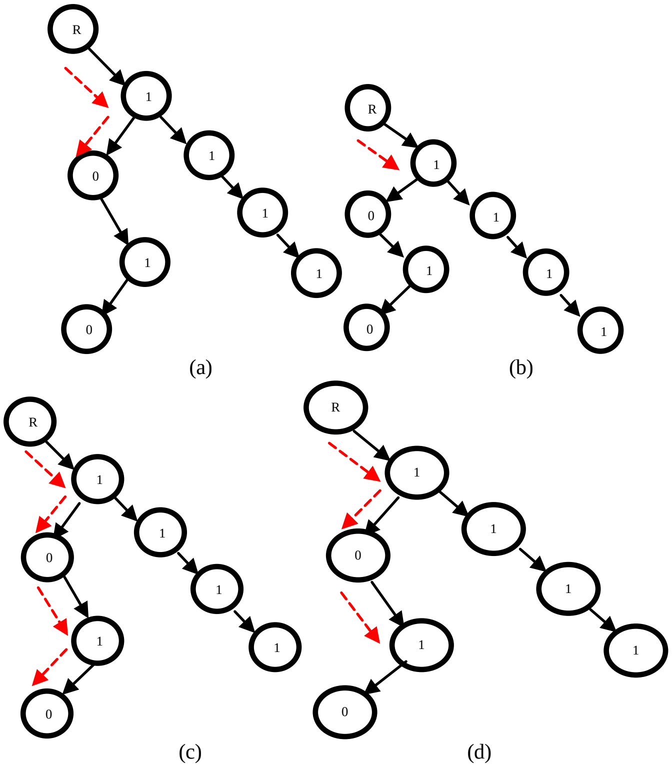
Classifying the traversal techniques from the depth-first search algorithm, this paper utilizes pre-order traversal to receive the numbers in sorted order.

E. Phase V: Searching Outgrowth

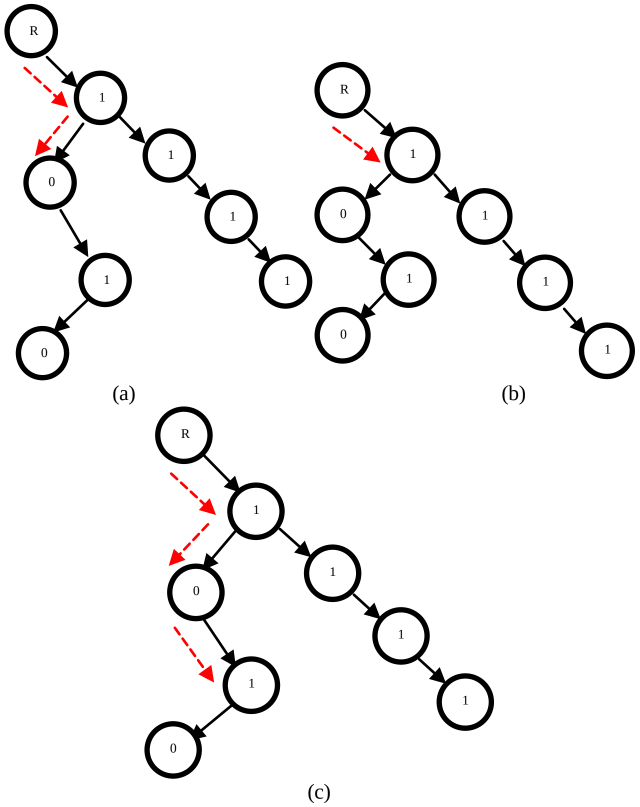
To arrange the elements in sorted order and search, pre-order traversal is performed on the tree in a depth-first manner as projected in Fig. 7. To search the particular element 1010, the list made available in the searching process is to be carried in G2 as follows.



(a) (b)

(c) (d)

Fig. 9. Searching Process of Each Node.



(a) (b)

(c)

Fig. 10. Searching Process of Each Node (a, b, and c) for Element Not Found.

The traversal begins from the root node R and moves towards the left child of its own. Since the unavailability in the left child for R, the tree travels through the right child as projected in Fig. 9(a). The travel continues through the left child of the current node as it is shown in Fig. 9(b) and the process is repeated in the following Fig. of 9(c) and 9(d). The traveling process is completed once it reaches the leaf node. Now arrange the visited node from the root node as 1010. Hence the element is found in G2.

The traversal begins from the root node R and moves towards the left child and proceeds for the right child as imaged in Fig. 10(a) by visiting the right child node labeled 1 and to the left child labeled 0. The travel continues for the right child labeled 1. Instead of the availability for the right child with the label 1, the left child labeled as 0 presence is found in the tree. The conclusion is derived from the unavailability of element 10111 in the G2. In the search made the availability of left child with label 0 is found but not the other child named right with the label of 1. Grouping in order digit representation which the binary conversion is made emphasizes on a searching part, reckon the given element to be searched and let's spot the random element as 82. The element state is to be found and the number of comparisons made here is spotted as second since it has the immediate search of prefix value. In case of the element 84, the search is ineffective resulting in not found status since the given random element is not found in any of the ordered group in particular to G4, instead if it is then the searching group falls under the G4 classification. The searching is made according to the value given as input. Here the given value is 84, in mechanical the search begins at G4 since the value ranged to 84 lies within that region. The immediate result of found or not found status on any random search is made possible by group classifications.

V. Programme Encryption of the Algorithm

The proposed algorithm is assorted into separate parts classifying sort and search functions. The algorithm produced is made effective in the C++ language. The algorithm for sorting and searching is represented easier as the given element pitch in.

VI. Experimental Result

Searching for a particular element is projected clearly under phase II, classifying bit and group-wise respectively. The bitwise operation of search is the best fit in the case of integer data type [12]. Since the main advantage over the proposed algorithm is found to be effective searching and the arrangement of given numbers is on bitwise. Searching is made easier based on group classification.

TABLE III. Algorithm Representation for Sorting

Sorting Representation	
Step 1	*Consider N random numbers*
Step 2	*Convert all N numbers into binary form*
Step 3	*Group the converted binary numbers based on the number of bits. Let it be m.* *G1(m)=3, G2(m)=4, G3(m)=5, G4(m)=7*

Step 4	*Step 4: Construct a binary tree for each Group G*
	for (i = 1 ; i < = m ; i ++) // where m ≥ 3
	{
	insert (Node node, key values) // Insert a new node in the tree
	{
	node ← input node object
	value ← Actual value of the node // values are either 0 or 1
	if (node = = null) then
	return Node (value);
	else if (value [i] = = 0) then
	node.left ← insert (node.left , value)
	Else
	node.right ← insert (node.right, value)
	return node;
	}
	}

Step 5	*Perform the pre-order traversal in the binary tree to receive the numbers in sorted order*
Step 6	*Repeat step 4 and step 5 for all Groups*
Step 7	*Stop the Process*

TABLE IV. Algorithm for Searching a Particular Element in the List

searching representation	
Step 1	*Start a process*
Step 2	*Get the input from the binary trees G_n, where all the numbers in sorted order and n are the number of Groups*
Step 3	*Enter the element to be searched.* *Let it be L.* *Check the element L belongs to which Group.* $\forall_i$ G_i *where 1<= i <=n* *if ($L \in G_n$)* *{* *Start from the root node R* *for (i = 1 ; i <=G_i(m) ; i ++)* *{* *if (L[i] == 0)* *Perform the searching in left sub-tree* *search (root → left)* *Else* *Perform the searching in right sub-tree* *search (root → right)* *}* *Else* *print element L is not available in N* *}*
Step 4	*Stop the process*

The algorithm projected in Tables III and IV on sort and search functionalities is applied to produce the experimented result on comparison over linear, binary, and the proposed search. In the next phases of comparisons, the results are proven over a tried-out study between linear, binary, and the proposed search. The prediction time, an element found and the comparison made are taken as measuring facts for the comparisons. Below Table V shows the comparison involves the searching technique.

Fig. 11. The Experimented Result on the Element Found and Not Found in the Proposed Searching Technique.

Table V focus on emphasizing searching by making a comparison on linear, binary, and the proposed search numbers in an individual search mode. The experimented result is proven with the given number of 10 random numbers Consider the element 18 to be found in binary search, the prediction time taken by the binary search includes 0.00100 seconds where linear carries the same.

The biform approach tree technique is the searching time projected in Fig. 11 consists of 0.000 seconds and considers to be the quickest in delivering the search result compared with the two existing searches. In the case of an element not found represented in Fig. 10, the total time taken for traversal in search of the given element 5 is found to 0.000000 seconds. This includes the tree representation as stated in the above discussion on searching occurrences in the proposed methodology topic.

VII. Graphical Representation

The graphical representation for the effective searching over the above discussed different programming on searching techniques were applied on a set of linear, binary, and the proposed search.

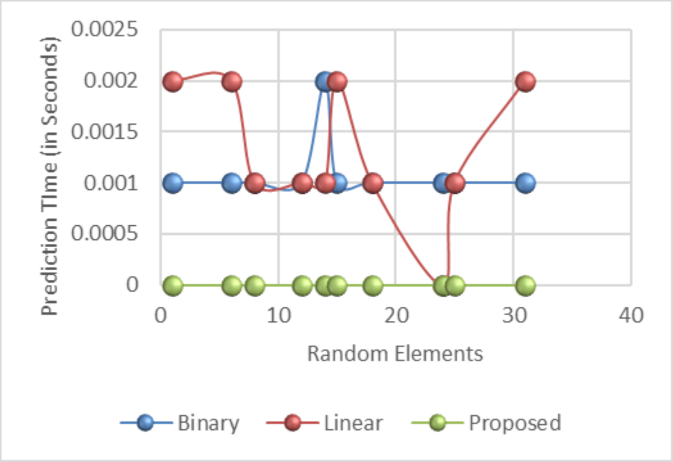

Fig. 12. Graphical Representation of Binary, Linear, and Biform Search.

A. *Graphical Representation of Searching an Element among for 10 Elements*

The graph representation is presented over linear, binary and the proposed search is exemplified as graphical representation in Fig. 12. The X-axis represents the random elements given in numbers and the Y-axis indicates the arrival of searches in seconds. The individual search includes linear, binary, and proposed are represented in separate line charts. The dots connected with blue represents the binary and others simultaneously. The graph withstands the elements up to 10 combinations in a random approach in the above graphical representation. The data projected as X-axis is made an approximate joint on Y-axis in which the total time is taken for each data and mapped into a line chart representation. Similarly, the remaining searches for the given set of random elements take place in the graphical representation.

VIII. Graphical Representation of Searching an Element among for 50 Elements

The graph projected in Fig. 13 explains the prediction time taken for each set of linear, binary, and proposed search techniques. This line chart is represented on 50 random sets of elements. The comparison time increases when the bit sizes get increased in each representation.

The maximum threshold for the binary, linear search is considered as 0.004 seconds while the minimum search happens and succeeds on the proposed search as 0.001 seconds when the given element bit sizes increase. While the elements are distributed in random the classification takes place based on group phases as discussed in the structured methodology. From the given program for efficient searching, the line chart is discussed to prove the efficient technique for searching is on a proposed searching method.

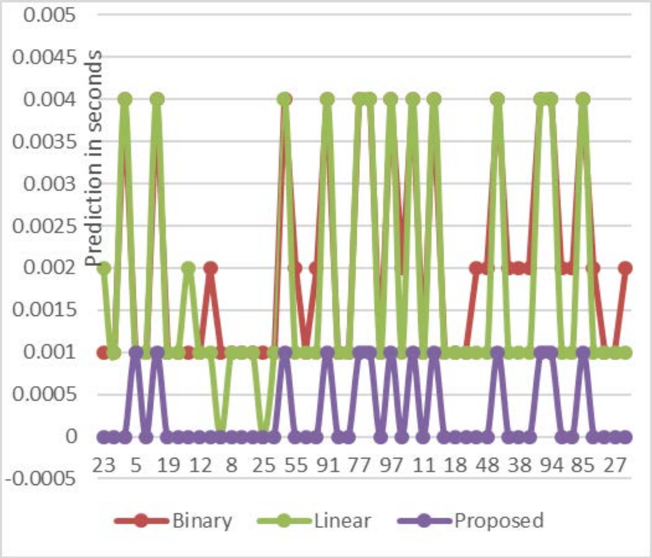

Fig. 13. Graphical Representation of Binary, Linear, and Biform Search Over 50 Elements.

IX. Graphical Representation of Searching an Element among for 100 Elements

The Graphical chart representation of Fig. 14 projects the status for the possible search of carrying a maximum of 100 random values in a given element. Fig. 14 illustrates how the searching takes place as efficient when more elements are into it.

As stated in the combination of more than 50 inputs the same criteria fit in for the case of 100 inputs. Here in Fig. 13 indicates the proposed search goes to the maximum prediction time of 0.001 seconds when the bit size increases in a large volume of size while the linear and binary goes to the extent of 0.004 seconds. From the given every efficient search in the graphical format of presentments the tree structure stood as a prerequisite for easier delegacies. Alike sorted data for binary search, tree structure for the biform tree approach act as a prerequisite inefficient search. All the above three graphical representation initialize and emphasizes on searching techniques that deliver the fast result on any values given in.

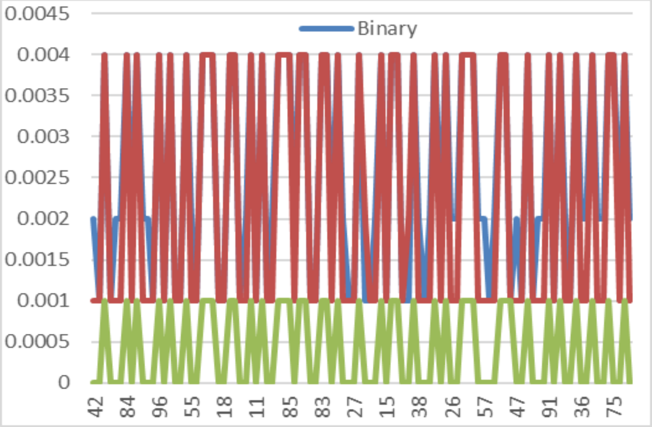

Fig. 14. Graphical Representation of Binary, Linear and Proposed Search over 100 Elements.

X. Practical Applications and Enhancements

The tree structure proposed and experimented in the graphical representation defined for searching any random element will be an effective and efficient way. The tree representation way of organizing the data was brought into effect by searching for any random value and it is highlighted in all the experimented results that search took place. Both the result of found and not found was done efficiently and it was proven in the sample searching on the experimented result page. The time complexity for the biform approach search for best face and fair face is O(log n) and the worst face is O(n).

The biform approach search compared with the existing (linear and binary) will utilize the tree structure that has a binary tree nature in organizing the data that act as an integral to lots of existing applications considering the binary tree node representation. The pointer includes left-right and parent deliberated in space consumption in the large representation of values.

The proposed search was applied in the renowned areas of acquiring knowledge from a knowledge base using tree representation, in the prediction grounded model for directly learn word representation. In the field of synonyms detection and word prediction where the words are evaluated for easy word representation. The tree structure is represented as a prerequisite for any search that is being done in the proposed method. For effective searching, a data structure in the form of a sorted order tree structure is a prerequisite like the existing searches including binary, linear, etc. The biform tree approach search was found to be effective in the finding of the learning content for the learner from the repository. Once the content is identified in the repository the corresponding knowledge graph has been created for the system to understand and learn about the learner to provide the needed learning content. The novel biform tree structure is a prerequisite for efficient searching and also for sorting the elements while doing the pre-order traversal over that tree.

XI. Conclusion

The different searching techniques make way to crystalize and clarify the problem in an effective way. It is an evolutionary method among the infinities in the improvement of time complexities. The biform tree approach inquiry on searching techniques introduces the binary representation in digits that makes the search easier & faster with well-defined generalized fit in by making a comparison table study over performance on the search and the new data structure has a built-in form of tree representation using the searching technique. The beauty of the biform tree approach is the same binary tree is utilized to produce the sorted order numbers and for the element search. The precursor for element searching is provided by the sorted binary tree in which the elements are in sorted order. Altogether searching was made effective over designing a data structure in the form of tree representation which makes the searches an efficient one with the biform approach search.

AUTHORS' PROFILE

S. Celine is a part-time research scholar in the Department of Computer Science, Sacred Heart College, Tirupattur district, and working as an Assistant professor in the Department of Computer Science, Government of Arts College for Men, Krishnagiri, Tamil Nadu. Her area of research is in the field of e-Learning using Deep Learning.

Shinoj Robert is a part-time research scholar in the Department of Computer Science, Sacred Heart College, Tirupattur District, and working as an Assistant professor from 2014 in the Department of Computer Application, Don Bosco College, Yelagiri Hills, and His area of research in the field of Machine learning and E-learning.

Dr. M. Maria Dominic obtained his B.Sc., M.Sc., and M.Phil. and Ph.D. in Computer Science. He has been working in Sacred Heart College, from 1996 onwards in various capacities He has also worked in Multimedia University, Malaysia on a Contractual Basis. He has co-authored a book on OOP using C++ published by Pearson education. He has published more than 20 research articles in International Journals. He has 4 Ph.D. Research scholars working under him in the field of Artificial Intelligence especially in Machine learning and deep learning.

Earthquake Prediction using Hybrid Machine Learning Techniques

***Abstract*—This research proposes two earthquake prediction models using seismic indicators and hybrid machine learning techniques in the region of southern California. Seven seismic indicators were mathematically and statistically calculated depending on pervious recorded seismic events in the earthquake catalogue of that region. These indicators are namely, time taken during the occurrence of n seismic events (T), average magnitude of n events (M_mean), magnitude deficit that is the difference between the observed magnitude and expected one (ΔM), the curve slope for n events using inverse power law of Gutenberg Richter (b), mean square deviation for n events using inverse power law of Gutenberg Richter (η), the square root of the released energy during T time (DE1/2) and average time between events (µ). Two hybrid machine learning models are proposed to predict the earthquake magnitude during fifteen days. The first model is FPA-ELM, which is a hybrid of the flower pollination algorithm (FPA) and the extreme learning machine (ELM). The second is FPA-LS-SVM, which is a hybrid of FPA and the least square support vector machine (LS-SVM). These two models' performance is compared and assessed using four assessment criteria: Root Mean Square Error (RMSE), Mean Absolute Error (MAE), Symmetric Mean Absolute Percentage Error (SMAPE), and Percent Mean Relative Error (PMRE). The simulation results showed that the FPA-LS-SVM model outperformed the FPA-ELM, LS-SVM, and ELM models in terms of prediction accuracy.**

Keywords*—Extreme learning machine; least square support vector machine; flower pollination algorithm; earthquake prediction

I. Introduction

Earthquake is movements and shaking inside the ground that produce energy in rocks. Like many natural disasters, Earthquake causes many damages, financial loss, and injuries [1]. Earthquakes happen daily in various regions around the world. The more susceptible regions to earth-shaking are japan [2], Indonesia, south California, turkey, Iran, and Taiwan [3]. People can feel the Earthquake if its magnitude is more than 2.5, but if the magnitude is less than 2.5, the Earthquake will not be felt. The magnitude of highly caused damaged earthquakes is more than 4.5 [4]. Sometimes earthquakes are responsible for huge numbers of deaths.

So, scientists work hard in this field to prevent these severe effects. The best effort is done to Alert people in time because a wrong alert will cause unnecessary losses. Certainly, people cannot stop the occurrence of earthquakes, but they can adopt protective measures and precautions to minimize the deleterious effects by predicting earthquake magnitude using machine learning techniques. There are a lot of methods that can be applied to predict earthquake magnitude using different sensors, devices, magnetic and electrical waves, or seismic indicators obtained from the processing of the historical data of earthquakes [1]. Really, there is no perfect model that results from 100%, but at least a trial is made to improve the accuracy as much as possible [3].

Artificial intelligence plays an essential role in predicting and classifying problems. A neural network is a very effective tool to solve complicated non-linear issues [1]. Technology and machine learning provide many robust mechanisms to study seismic data and indicators. Data mining and machine learning are highly successful instrument in the prediction domain, especially if massive data is required as weather forecasting, stock prediction, and so on [5]. Dataset plays an essential role in determining the purposed model's quality and performance, so we search a lot to choose the more exact dataset [4].

There are thousands of machine learning algorithms, but no one is always suitable for all issues because there are many factors that affect that, like the number of features (input indicators), number of records of the dataset, and type of problem (classification or regression), so we will apply some machine learning algorithms and compare their results with each other to determine the more suitable algorithm for this issue. The comparison will be applied here to compare our work with other researchers that applied different machine learning algorithms on the same dataset [6]. In this article, the magnitude will be predicted using historical records of south California. Depending on the seismic indicators as an input for machine learning algorithms, which are obtained from performing some statistical and mathematical equations on raw data (time and magnitude) [7]. Machine learning techniques can predict well if provided by a suitable dataset, which is divided into (70%for train and 30%for test) [8]. In this paper, ELM, LS-SVM, and FPA will be used. ELM (Extreme Learning Machine) is a straightforward algorithm because it depends on a feed-forward neural network. The data moves in one direction (forward direction) with only one hidden layer. ELM is a well-known and well-resulted algorithm in classification and regression domains. Unlike other ANN algorithms that face the overfitting problem and the long-running time problem, ELM overcomes these problems and can achieve high accuracy and high-speed results. ELM often uses a sigmoid function, which will be applied in this work.

SVM (Support Vector Machine) is a well-known deep learning tool for regression that depends on kernel methods giving high prediction results. SVM is a developed algorithm of machine learning to avoid ANN shortages. SVM gives optimal global solutions avoiding local minima problems [9].

LS-SVM (Least Square Support Vector Machine) is the edited version of the SVM algorithm. LS-SVM simplifies the SVM method, but it needs kernel parameters, which are important for regression problems. So we need an appropriate way for the optimal choice of LS-SVM parameters, So optimizing LS-SVM with FPA is done [9].

FPA (Flower Pollination Algorithm) was developed in 2012 by Yang, which uses pollination of flowers. FPA was applied for many non-linear problems giving high results [9].

ELM and LS- SVM are optimized by FPA (Flower Pollination Algorithm), enhancing the accuracy and minimizing errors. ELM and LS-SVM are considered supervised learning where they take seven seismic parameters (time is taken during the occurrence of n seismic indicators (T), average magnitude during n events (M_mean), magnitude deficit, which is the difference between the observed magnitude and expected one (∆ M), the curve slope for n events using inverse power law of Gutenberg Richter (b), mean square deviation for n events using inverse power law of Gutenberg Richter (η), the square root of the released energy during T time (DE1/2)), average (mean) time between events (μ) [10] as network inputs and produces the future magnitude as a network output to train well and be able to test after that. No algorithm can predict 100%, but some shortages of ELM algorithm will be removed by using optimization (swarm intelligence) algorithm FPA to get FPA _ELM (the result of optimizing ELM with Flower Pollination algorithm, which optimizes weights of input nodes and biases of a hidden layer of ELM). The optimization of SVM with FPA is applied to enhance the performance of LS-SVM and get the FPA-LS-SVM model that yields high results.

This work is divided into four parts; the first part is processing the raw data to find the seismic indicators. The second part is to input these indicators into machine learning algorithms to predict or output the expected future magnitude. The third part is to optimize the output using artificial intelligence techniques (swarm intelligence). The fourth part is comparing different results using different algorithms.

In the rest of this paper, the related work is showed in Section II, Applied Algorithms in Section III. Data and parameters calculations in Section IV, methodology in Section V, Results and discussion in Section VI, conclusion and future work in Section VII, and finally the references in machine learning and earthquake fields that is helpful in this work.

II. Related Work

Of Course, the earthquake catastrophe takes a large space of scientists' interest, so there are many kinds of research and scientists' efforts which are spent in this domain. Researchers worldwide do their best to predict where and when the Earthquake occurs depending on seismic indicators and other seismic electric signals using machine learning techniques and optimization algorithms.

Adeli et al. applied the probabilistic neural network on seismic indicators to predict the earthquake magnitude. This model predicts well for magnitude from 4.5 to 6 in the southern California region [11]. Moustra et al. who use the artificial neural network to predict earthquake occurrence using time series data and seismic electric signals in the Greece region, there are two case studies which finally led to when appropriate data presented to NN, it can predict accurately [12]. Hegazy et al. optimized ELM with FPA (flower pollination algorithm), which shows a better accuracy when applied to prediction task [13]. In this paper, Ma et al. proposed a genetic algorithm-based neural network giving GA_NN model is applied to six seismic indicators to find the relation between these indicators and the maximum earthquakes in china [14]. Maceda et al. here SVM is applied to earthquake problem. This paper decided that SVM is perfect for solving classification problems using a small-size training dataset [15]. Li et al. depended on the collected data from earthquake stations to be used in machine learning techniques to distinguish between Earthquake and non-earthquake [16]. Rajguru et al. optimized ANN (artificial neural network) with GA (genetic algorithm) to predict the source location and dimensions of the earthquakes giving good results although the complexity of the problem [17]. Wang et al. introduced a deep learning algorithm (LSTM) to find the relation among the earthquakes in different places that is useful in earthquake prediction [18]. Reyes et al. used an ANN model to predict earthquake magnitude in a limited interval or bounded by threshold during the following five days. Applying statistical tests and experiments showed the higher success rate of that method than other machine learning classifiers [19]. Martínez-Álvarez et al. used various seismic indicators as inputs for ANN in different seismic zones, and this showed that the seismic indicators are the best features for earthquake prediction [20]. Zhou et al. showed how efficiently the neural network could predict the earthquake magnitude using the LM_BP algorithm [21]. Morales-Esteban et al. used statistical methods and applied ANN on Earthquake in two seismic regions The Western Azores–Gibraltar fault and the Alborán Sea whether the magnitude is limited in an interval or determined by threshold [22]. Wang et al. proposed a RBF(Radial Basis Function) neural network to earthquake prediction, and the results showed that RBF is an effective tool for that non-linear problem [23]. Alarifi et al. used ANN for earthquake prediction in the Red Sea region, and the results showed the high ability of ANN forecasting than any other statistical models [24]. Asencio–Cortés et al. proposed a machine learning model to predict the earthquake magnitude after the next seven days using cloud infrastructure [25]. Tan et al. proposed support vector machines (SVM) and the results were good and added a new method for predicting earthquakes [26]. Florido et al. interested in processing earthquake data in

Chile. The data were labeled by applying to clustering algorithms. It was easy to identify Earthquakes with a magnitude larger than 4.4 [27]. Last et al. used many data mining methods and time series to predict the magnitude of the highest earthquake event in the following year depending on data from the previous records using a multi-objective info-fuzzy network algorithm [28]. Rafiei et al. was interested in giving early alarm weeks before maximum earthquake event using classification algorithm (CA) combining with mathematical optimization algorithm (OA) whose role is to find the location of the Earthquake with maximum magnitude [29]. Kerh et al. used a genetic algorithm combined with a neural network to evaluate the response of the Earthquake in Taiwan that produces high results comparing to neural network model only [30]. Mirrashid et al. used the system of adaptive neuro-fuzzy inference to predict the coming earthquakes with magnitude 5.5 or higher developed by three algorithms subtractive clustering (SC), grid partition (GP), and fuzzy C-means (FCM). The results showed that the ANFIS-FCM model gives the highest accuracy in predicting the magnitude of the Earthquake [31]. Asim et al. used many models of computational intelligence for earthquake prediction in northern Pakistan, and the feed-forward neural network showed the highest performance compared with other models [32]. Umar et al. combined the Logistic Regression (LR) with Frequency Ratio (FR) to overcome the limitations of each one individually. This model achieved high success and good earthquake prediction in Indonesia [33]. Asim et al. focused on computing the seismic indicators mathematically and then applying the tree classifiers on them to predict the earthquake magnitude in Hindu Kush, showing that the rotation forest gave a good prediction than random forest [34].

Machine learning (ML) methods such as artificial neural networks (ANNs), support vector machines (SVMs), extreme learning machine (ELM), are considered the most commonly used ML models in classification, regression. But these methods may suffer from local minima and overfitting problems due to using local optimization training algorithms such as gradient descent algorithm in ANN [35]. Swarm Intelligence algorithms such as particle swarm optimization (PSO), follower pollination algorithm (FPA), ant colony optimization (ACO), and artificial bee colony (ABC), can solve the problems or drawbacks of machine learning models such as ANN, SVM, and ELM methods [36,37]. Using swarm intelligence or meta-heuristic algorithms in optimizing and training classical machine learning models can enhance the accuracy and generalization ability of these methods [38-43].

III. Preliminaries

A. ELM (Extreme Learning Machine)

This model is a feed-forward neural network with only one hidden layer, a very rapid learning method with solutions for many problems caused by traditional neural network algorithms like overfitting, local minima, slowness, achieving better performance higher accuracy. ELM is a simple model that is performed through three steps.

- First step: ELM chooses the weights of input nodes and hidden biases randomly**.**
- Second step: ELM performs calculations to generate the output matrix of the hidden layer.
- Third step: calculations of the output weight.

ELM uses a single hidden layer with N hidden nodes and f(x) the activation function to learn distinct samples (M) $(\mathbf{x_i}, \mathbf{t_i})$, $\mathbf{x_i}=[\mathbf{x_{11}}, \mathbf{x_{12}} \ldots. \mathbf{x_{1k}}]^{\mathbf{T}} \in \mathbf{R^k}$.

$\mathbf{t_i} = [\mathbf{t_{11}}, \mathbf{t_{12}} \ldots. \mathbf{t_{1d}}]^{\mathbf{T}} \in \mathbf{R^{kd}}$ after that, the non-linear problem is turned to the linear problem:

$$H\beta=T \tag{1}$$

the hidden output matrix H is defined as follow:

$$H=\begin{bmatrix} \mathbf{f}(\mathbf{w_1} . \mathbf{x_1} + \mathbf{b_1}) & \cdots & \mathbf{f}(\mathbf{w_N} . \mathbf{x_1} + \mathbf{b_N}) \\ \vdots & \ddots & \vdots \\ \mathbf{f}(\mathbf{w_1} . \mathbf{x_M} + \mathbf{b_1}) & \cdots & \mathbf{f}(\mathbf{w_N} . \mathbf{x_M} + \mathbf{b_N}) \end{bmatrix} \tag{2}$$

Where $\mathbf{w_j} = [\mathbf{w_{j1}}, \mathbf{w_{j2}} \ldots. \mathbf{w_{jk}}]^{\mathbf{T}}$ is the weight vector between input nodes and hidden ones, **b** is the bias of hidden nodes where j= 1,2 ,..N.

$\mathbf{w_j} . \mathbf{x_i}$ where i=1…M is the inner product of $\mathbf{w_j}$, $\mathbf{x_i}$. β= $[\boldsymbol{\beta_1}, \boldsymbol{\beta_2}, \boldsymbol{\beta_3} \ldots. \boldsymbol{\beta_N}]^{\mathbf{T}}$ is output weights' matrix, but $\boldsymbol{\beta_j} = [\boldsymbol{\beta_{j1}}, \boldsymbol{\beta_{j2}}, \boldsymbol{\beta_{j3}} \ldots. \boldsymbol{\beta_{jd}}]^{\mathbf{T}}$ where j= 1,2,3…..N is the vector of weights connecting the output neuron and a jth hidden one. $\mathbf{T}=[\mathbf{t_1}, \mathbf{t_2}, \mathbf{t_3} \ldots. \mathbf{t_M}]^{\mathbf{T}}$ is targets' matrix. The errors between the estimated value $\mathbf{t_i}$ and the real value $\mathbf{t_i}$ equal to zero using the following formula:

$$\mathbf{t_i} = \sum_{\mathbf{j=1}}^{\mathbf{N}} \boldsymbol{\beta_j}\ \mathbf{f}(\mathbf{w_j} . \mathbf{x_i} + \mathbf{b_j}) \tag{3}$$

weights that link between the hidden layer and output one are estimated by the least square solution to the linear problem using the following formula:

$$B=\mathbf{H^{-1}}T \tag{4}$$

Where $\mathbf{H^{-1}}$ is the inverse of the H matrix using the Moore Penrose method that makes ELM perform better and faster [13].

B. LS-SVM (Least Square Support Vector Machine)

It is one of deep and supervised learning that can classify data and predict values LS-SVM is the new version of SVM that solves SVM issues. Using LS-SVM, the solution can be founded by solving some linear equations rather than a Quadratic programming problem used in SVM. Let x is the matrix of input data. Using training data, LS-SVM plays a good role in creating the function that shows the dependence of the output on the input. The formula of this function:

$$f(x)=\mathbf{W^T}\ \varphi\ (x)+ b \tag{5}$$

where W, φ (x): $\mathbf{R^p} \rightarrow \mathbf{R^n}$ are column vectors with size n*1, and b ∈ **R**. Now LS-SVM calculates that function using the same minimization problem in SVM. Showing the important difference that LS-SVM contains equality constraints, unlike inequality ones in SVM. LS-SVM depends on the least square function [9]. We can minimize the error using this optimization formula:

$$\min j(w,e,b)= \frac{\mathbf{1}}{\mathbf{2}} \mathbf{w^t} w + C \frac{\mathbf{1}}{\mathbf{2}} \mathbf{e^t} \tag{6}$$

$$\mathbf{y_i}=\mathbf{W^T}\ \varphi\ (\mathbf{x_i})+ \mathrm{b} +\mathbf{e_i} \qquad (7)$$

Where e is n*1 column vector, C ∈ $\mathbf{R^+}$ is the parameter between training errors and solution size. In 2 Lagranian is formed that differs according to w,b,e, a where a is Largrangian multiplier, we have.

$$\begin{bmatrix} \mathbf{1} & \mathbf{0} & \mathbf{0} & -\mathbf{Z^T} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & -\mathbf{1^T} \\ \mathbf{0} & \mathbf{0} & \mathbf{C} & -\mathbf{I} \\ \mathbf{Z} & \mathbf{1} & \mathbf{I} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \mathbf{w} \\ \mathbf{b} \\ \mathbf{e} \\ \mathbf{a} \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \\ \mathbf{0} \\ \mathbf{y} \end{bmatrix}. \qquad (8)$$

Identity matrix and Z= $[\varphi\ (\mathbf{x_1}), \varphi\ (\mathbf{x_2}), \ldots \varphi\ (\mathbf{x_n})]^{\mathbf{T}}$

Using four from row 1, we get W= $\mathbf{Z^T}$and from row 3, we get Ce=a.

Note that: the kernel matrix K = Z $\mathbf{Z^T}$And the parameter λ = $\mathbf{C^{-1}}$, the conditions for optimality give the following solution

$$\begin{bmatrix} \mathbf{0} & \mathbf{1^T} \\ \mathbf{1} & \mathbf{K}+\lambda\mathbf{I} \end{bmatrix} \begin{bmatrix} \mathbf{b} \\ \mathbf{a} \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ \mathbf{y} \end{bmatrix}. \qquad (9)$$

Types of the kernel function K:

First: linear kernel

$$\mathrm{K}(\mathrm{x}, \mathbf{x_i}) = \mathbf{x_i}^{\mathbf{T}}\mathbf{x}$$

Second: the polynomial kernel of d degree

$$\mathrm{K}(\mathrm{x}, \mathbf{x_i}) = (\mathbf{1}+\mathbf{x_i}^{\mathbf{T}}\mathbf{x}/\mathbf{c})^{\mathbf{d}}. \qquad (10)$$

Third: RBF kernel (radial basis function)

$$\mathrm{K}(\mathrm{x}, \mathbf{x_i}) = \mathbf{exp}(-\|\mathbf{x}-\mathbf{x_i}\|^{\mathbf{2}}/\ \sigma^{\mathbf{2}}). \qquad (11)$$

Forth: MLP kernel

$$\mathrm{K}(\mathrm{x}, \mathbf{x_i}) = \mathbf{tanh}(\mathbf{kx_i}^{\mathbf{T}}\mathbf{x}+\theta). \qquad (12)$$

C. FPA (Flower Pollination Algorithm) is an optimization technique that uses the idea of pollination of flowers. The pollination process has two directions: biotic pollination, which occurred in 90% of flowers by the spread of pollens using various insects, and abiotic pollination, which occurred in 10% of flowers where the pollens move through water or wind. Two methods do the pollination Self-pollination: occurs when the flower's pollen moves to the same flower or different flowers at the same plant.

Cross-pollination: occurs when the pollen of one flower of a specified plant moves to another flower in a different plant. The steps of the FPA algorithm:

- The cross-pollination (biotic) is called global pollination, where the Levy fight takes place
- Self-pollination is considered as local pollination
- The constancy of the flower can be treated as the probability of reproduction is proportional to two flowers similarity
- There is a switch probability p ∈ {0,1} that determines the pollination process, even local or global.

In global pollination, the pollinators can carry pollens for long distances. This ensures creating the fittest (Best) that obeys levy distribution:

$$x_i^{t+1}= x_i^{t}+ \mathrm{L}(\mathrm{Best}-x_i^{t}) \qquad (13)$$

In local pollination, the pollen can be carried by other factors, and this can be represented using the formula:

$x_i^{t+1}= x_i^{t}+ \mathrm{U}(x_j^{t}-x_k^{t})$ (14) [13],[9]

```
Algorithm 1: Flower Pollination Algorithm (FPA)
1) Initialization of:
    • Population size (n) and the flower population Xi
      (i = 1, 2,..., n) randomly chosen solutions.
    • switch probability p ∈ {0,1}
    • Maximum iterations' number.
    • The best solution in the initial population (Best)
    • Function (fn) applied to each flower
2) randomly initial population generated.
3) while (t < Max_iteration)
    for each flower do
      if (rand<p)
          Draw L (d-dimensional step vector) that
          undergoes a Levy distribution.

          Global pollination for the solution i
          $x_i^{t+1}= x_i^{t}+ L(Best-x_i^{t})$
      Else
          Draw U from uniform distribution in
          [0,1].

          From all the solutions, choose □, k
          randomly.

          Local pollination for the solution i
          $x_i^{t+1}= x_i^{t}+ U(x_j^{t}-x_k^{t})$.
      endif
      Calculate the fitness of each flower.

      Pass each flower(solution) to fn to
      evaluate the new solution.
    end for
        find Best (current best solution)
end while
```

IV. Data and Parameters Calculations

Seven parameters are mathematically and statistically calculated during a specific period of time [10] from the earthquake catalog. These parameters are the inputs for the network to predict the future expected magnitude as the output of the network.

1) Earthquake data: The Earthquake catalog source for south California is available to be downloaded for free using the website (www.data.scec.org.). The historical earthquake data of Southern California is between.

1st January 1950 and 31st May 1978 is divided into 693 periods. Each period consists of fifteen days.

2) Seismic parameters: The seven earthquake indicators are computed for each period of time. This part will show these indicators and their mathematical calculations. The first indicator is the time during the range of n events, which called T.

$$T = tn- t1 \qquad (15)$$

T1 is the time of the first event, and tn is the time for the period's nth event.

The second seismic parameter is the average magnitude of the last n events of the period, which is calculated as the following.

$$M\_mean=\frac{\sum Mi}{n} \qquad (16)$$

Mi is the magnitude of the ith event, and n is the number of events.

The third parameter is $DE^{1/2}$ the square root of released seismic energy is during time T. The $DE^{1/2}$ the parameter can be computed as follow:

$$DE^{1/2} = \frac{\sum \sqrt{E}i}{T} \qquad (17)$$

$\sqrt{E}i$ is the square root of the seismic energy (E) of the ith event where E can be calculated from the following formula:

$$Ei=10^{(11.8+1.5Mi)}ergs \qquad (18)$$

The fourth indicator is b_value, that is, the slope of the curve between the log of frequency of occurred earthquakes and the earthquake magnitudes given from Richter inverse power law.

$$\log_{10} N = a – bM \qquad (19)$$

N is the number of events with M magnitude a,b values are constants.

where b can be calculated as follow

$$b= \frac{(n\sum(Mi \log Ni)-\sum Mi \sum \log Ni)}{((\sum Mi)^2-n\sum Mi^2)} \qquad (20)$$

and a can be calculated from the following formula:

$$a= \frac{\sum(\log_{10} Ni+bMi)}{n} \qquad (21)$$

The fifth parameter is (η value), which is the sum of mean square deviation based on inverse power law. η value can be computed as follow.

$$\eta=\frac{\sum(\log_{10} Ni-(a-bMi))^2}{n-1} \qquad (22)$$

The sixth parameter is the ∆M value, defined as the magnitude deficit (the difference between the observed magnitude and the expected one). ∆M is computed as follow:

$$\Delta M= M_{observed} - M_{excepected} \qquad (23)$$

Where $M_{excepected}$ is calculated from the formula:

$$M_{excepected}={}^{a}/_{b} \qquad (24)$$

The last one μ in the meantime among the characteristic events which is calculated as follow:

$$\mu = \frac{\sum(t_{i\ characteristic})}{n_{characteristic}} \qquad (25)$$

[10].

Now a sample of the dataset from the period from 1st January 1950 to 30th May 1950 that represents ten periods of time will be presented. Each period consists of fifteen days as shown in Table I.

V. Proposed Models

The proposed methods depend on the study of historical earthquake data in earthquake catalogs. By processing these data, seismic indicators that are used as inputs for the network can be obtained. Then the ELM algorithm is optimized by FPA to enable us from an optimal prediction of the occurrence of the Earthquake, and also optimizing LS-SVM with FPA to enhance the accuracy of earthquake magnitude prediction. The network architecture contains seven input indicators, which represent the seismic indicators, and the output shows the predicted magnitude during fifteen days. The description of proposed FPA-ELM, and FPA-LS-SVM algorithms are shown in algorithm 2, and algorithm 3, respectively. The data is used in three manners. First, data is divided into 70% for training and 30% for testing. Then, data is divided into 80% for training and 20% for testing. At last data is divided into 90% for training and 10% for testing. The phases of the used models are shown in Fig. 1. The earthquake indicators which have been calculated from the datasets are shown in Table I.

Algorithm2: The Hybrid Earthquake prediction FPA_ELM

```
Input:   n number of flowers
         N_gen number of iterations
         d dimensions of search variables
         fn function applied to each flower
         Trn Training, Vld Validation datasets
Output:
         fbest optimal hidden weights and biases
         f(fbest) Sum square error for the NN
         over the validation set fbest
1) Initialization:
   • N,N_gen
   • switch probability $p \in \{0,1\}$
   • Function (fn) applied to each flower
2) randomly initial population generated.
3) while Stopping criteria not met, do
   for each flower, do
      if (rand<p)
         Draw L (d-dimensional step vector)
         that undergoes a Levy distribution.

         Global pollination for a solution i
         $x_i^{t+1}= x_i^t+$ L(Best-$x_i^t$)
      Else
         Draw U from a uniform distribution
         In [0,1]

         from all the solutions choose $j,k$
         randomly

         Local pollination for a solution i
         $x_i^{t+1}= x_i^t+$ U($x_j^t$-$x_k^t$).
      endif
      Calculate the fitness of each flower

      Pass each flower(solution) to fn to
      evaluate the new solution

      construct NN given the hidden layer
      weights and biases of flower i

      Calculate the output layer's weights using
      the MP matrix using training dataTrn and
      hidden layer weights and Biases.

      Use the validation data Vld to evaluate the
      NN model
      Compute prediction accuracy
   end for
end while
4) Pass Best to fn
5) Apply ELM.
6) Return prediction accuracy
```

Algorithm3: The hybrid FPA_SVM for Earthquake prediction

```
Input:   n number of flowers
         N_gen number of iterations
         Ub data Upper bound
         Lb  data Lower bound
         d dimensions of search variables
         fn function that applies to each flower to
         improve SVM parameters.
output:  prediction accuracy
         Best global solution
1) Initialization:
   • Population size (n) and the flower population
     Xi (i = 1, 2..., n) randomly chosen solutions.
   • switch probability $p \in \{0,1\}$
   • Maximum iterations' number.
   • Data limits Lb, Ub with dimension d.
   • The best solution in the initial population
     (Best)
   • Function (fn) applied to each flower
2) randomly initial population generated.
3) while (t < Max_iteration)
   for each flower do
      if (rand<p)
         Draw L (d-dimensional step vector)
         that undergoes a Levy distribution.

         Global pollination for a solution i
         $x_i^{t+1}= x_i^t+$ L(Best-$x_i^t$)
      Else
         Draw U from a uniform distribution
         in [0,1].

         From all the solutions choose $j$,
         randomly.

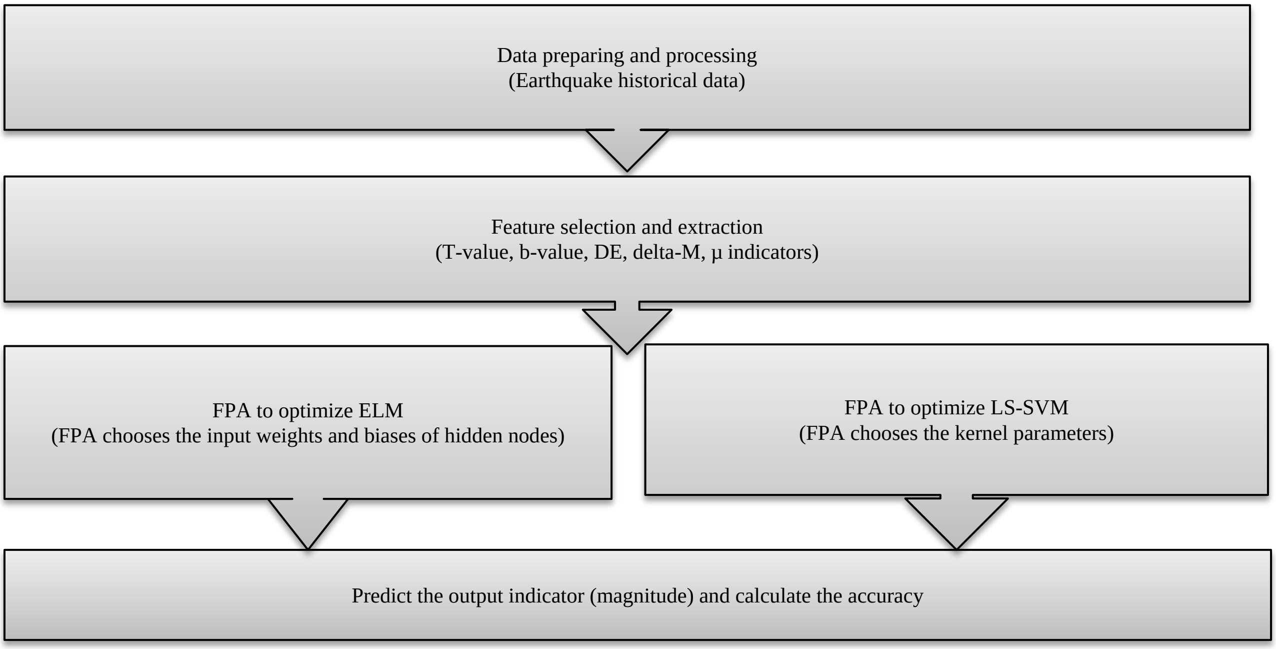
         Local pollination for a solution i
         $x_i^{t+1}= x_i^t+$ U($x_j^t$-$x_k^t$).
      endif
      Calculate the fitness of each flower.

      Pass each flower(solution) to fn to
      evaluate the new solution

      Pass output to SVM parameters

      Apply SVM

      Compute prediction accuracy
   end for
   t=t+1
end while
4) Pass Best to fn
5) Pass output to SVM parameters.
6) Apply SVM.
7) Return prediction accuracy.
```



Data preparing and processing
(Earthquake historical data)
Feature selection and extraction
(T-value, b-value, DE, delta-M, µ indicators)
FPA to optimize ELM
(FPA chooses the input weights and biases of hidden nodes)
FPA to optimize LS-SVM
(FPA chooses the kernel parameters)
Predict the output indicator (magnitude) and calculate the accuracy

Fig. 1. The Phases of Proposed Model.

VI. Results and Discusssion

After processing data and introducing the indicators to the proposed models, the performance of each model is estimated using four performance evaluation criteria RMSE, MAE, SMAPE, and PMRE, which can be calculated through the following formulas [13]:

$$\text{RMSE}=\sqrt{\frac{1}{n}\sum_{i=1}^{n}(\text{Ai}-\text{Fi})} \tag{26}$$

$$\text{MAE}=\frac{1}{n}\sum_{i=1}^{n}|\text{Ai}-\text{Fi}| \tag{27}$$

$$\text{SMAPE}=\frac{\sum_{i=1}^{n}|\text{Fi}-\text{Ai}|}{\sum_{i=1}^{n}\text{Ai}+\text{Fi}} \tag{28}$$

$$\text{PMRE}=\frac{100}{n}\sum_{i=1}^{n}\left|\frac{\text{Ai}-\text{Fi}}{\text{Fi}}\right| \tag{29}$$

First data is divided into 70% for training and 30% for testing and the results showed that the accuracy of FPA-ELM is higher comparing to solely using ELM, as shown in Fig. 2.

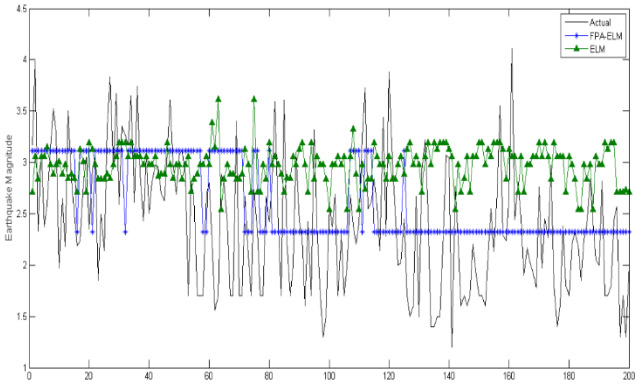


Fig. 2. ELM Accuracy VS FPA-ELM Accuracy when Data is divided into 70% for Training and 30% for Testing.

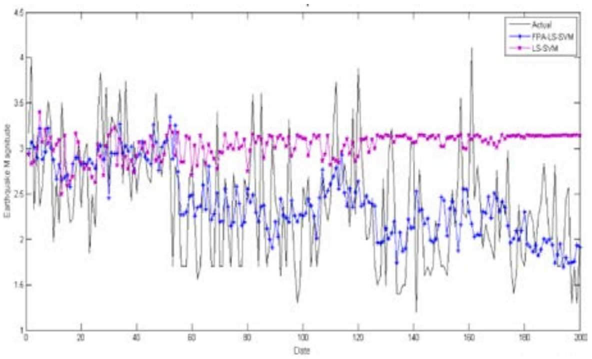

Fig. 3. LS-SVM Accuracy VS FPA-LS-SVM Accuracy when Data is divided into 70% for Training and 30% for Testing.

And the performance of LS-SVM became higher and better after optimizing LS-SVM with FPA as shown in Fig. 3.

After the experiment, the results showed that the performance of LS-SVM is better than the performance of ELM, according to this, FPA-LS-SVM accuracy is higher than FPA-ELM one. This is obvious from the following Fig. 4.

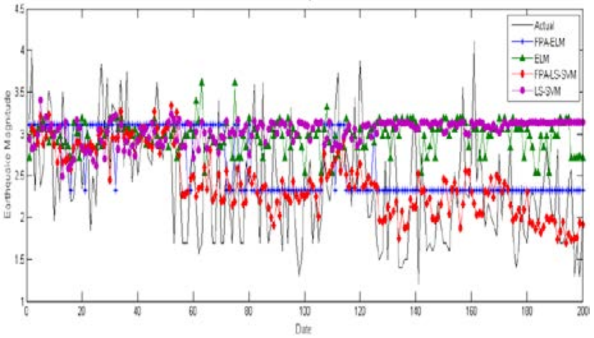

Fig. 4. FPA-ELM Accuracy VS FPA-LS-SVM Accuracy when Data is divided into 70% for Training and 30% for Testing.

TABLE II. EVALUATION CRITERIA FOR THE MODELS WHEN DATA IS DIVIDED INTO 70% FOR TRAINING AND 30% FOR TESTING

evaluation test	**Models**			
	ELM	**FPA- ELM**	**LS-SVM**	**FPA-LS-SVM**
RMSE_test	0.88057	0.645895	0.93642	0.540368
MAE_test	0.73833	0.525306	0.789076	0.434484
SMAPE_test	0.02346	0.030137	0.022373	0.034936
PMRE_test	38.0774	25.12757	40.83974	19.47929

The values of evaluation tests were as follow in Table II:

The column chart that provides the rate of RMSE evaluation criteria for all models when data is divided into 70% for training and 30% for testing is applied as shown in Fig. 5.

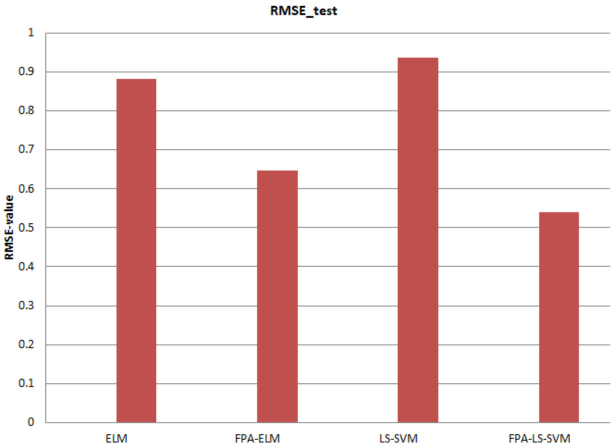

Fig. 5. RMSE Evaluation Criteria for All Models when Data is divided into 70% for Training and 30% for Testing.

The column chart that provides the rate of MAE evaluation criteria for all models when data is divided into 70% for training and 30% for testing is applied as shown in Fig. 6.

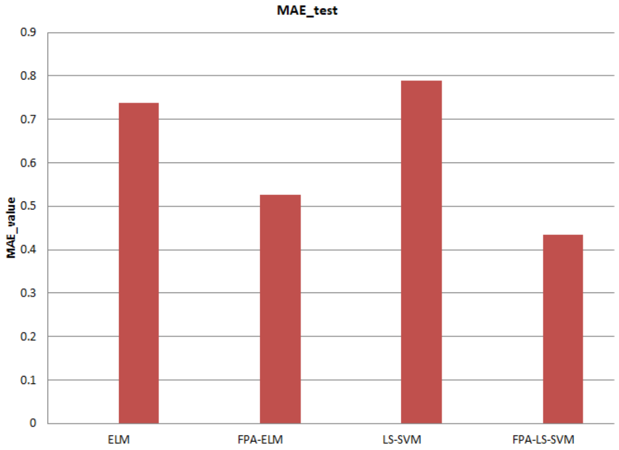

Fig. 6. MAE Evaluation Criteria for All Models when Data is divided into 70% for Training and 30% for Testing.

The column chart that provides the rate of SMAPE evaluation criteria for all models when data is divided into 70% for training and 30% for testing is applied as shown in Fig. 7.

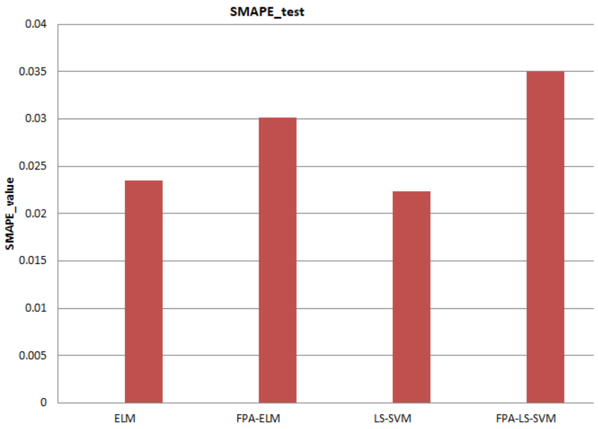

Fig. 7. SMAPE Evaluation Criteria for All Models when Data is divided into 70% for Training and 30% for Testing.

The column chart that provides the rate of PMRE evaluation criteria for all models when data is divided into 70% for training and 30% for testing is applied as shown in Fig. 8.

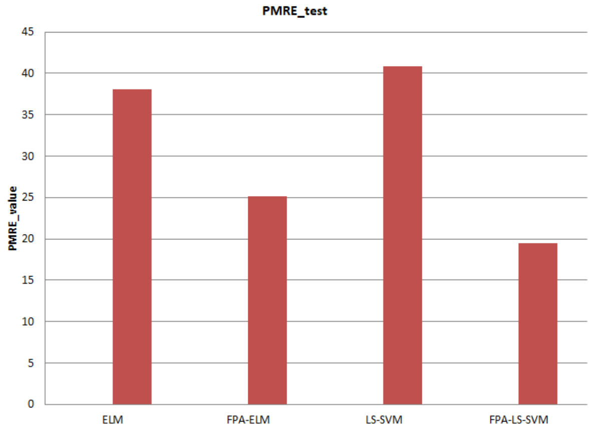

Fig. 8. PMRE Evaluation Criteria for All Models when Data is divided into 70% for Training and 30% for Testing.

Second, data is divided into 80% for training and 20% for testing and the results also showed that the accuracy of FPA-ELM is higher comparing to solely using ELM, as shown in Fig. 9.

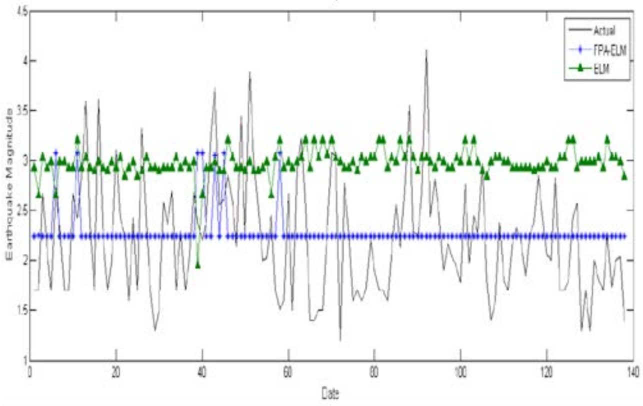

Fig. 9. ELM Accuracy VS FPA-ELM Accuracy when Data is divided into 80% for Training and 20% for Testing.

And the performance of LS-SVM became higher and better after optimizing LS-SVM with FPA as shown in Fig. 10.

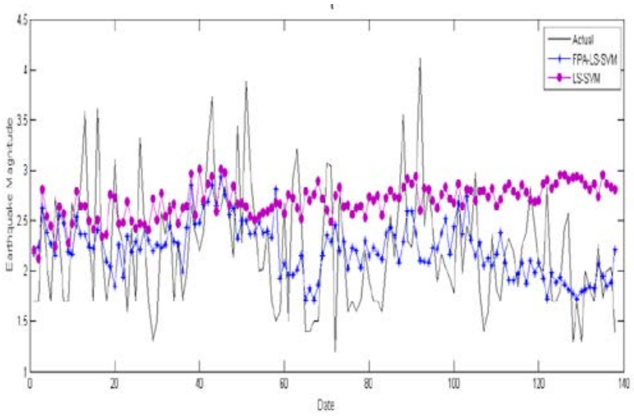

Fig. 10. LS-SVM Accuracy VS FPA-LS-SVM Accuracy when Data is divided into 80% for Training and 20% for Testing.

And FPA-LS-SVM accuracy is higher than FPA-ELM one. This is obvious from the following Fig. 11.

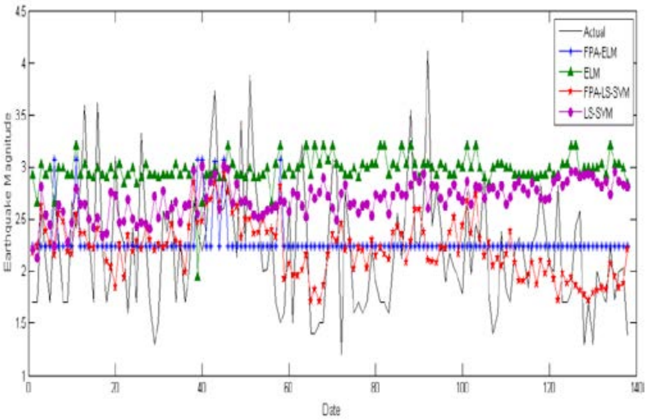

Fig. 11. FPA-ELM Accuracy VS FPA-LS-SVM Accuracy when Data is divided into 80% for Training and 20% for Testing.

In this case the values of evaluation criteria were as follow in Table III:

TABLE III. EVALUATION CRITERIA FOR THE MODELS WHEN DATA IS DIVIDED INTO 80% FOR TRAINING AND 20% FOR TESTING

evaluation test	Models			
	ELM	FPA-ELM	LS-SVM	FPA-LS-SVM
RMSE_test	0.962142	0.598239	0.769138	0.565476
MAE_test	0.845038	0.4836	0.649227	0.447226
SMAPE_test	0.03279	0.045286	0.03779	0.046786
PMRE_test	45.68055	23.49402	34.71175	20.931907

The column chart that provides the rate of RMSE evaluation criteria for all models when data is divided into 80% for training and 20% for testing is applied as shown in Fig. 12.

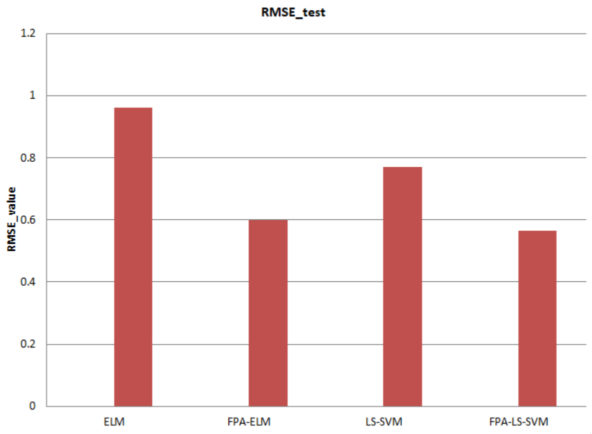

Fig. 12. RMSE Evolution Criteria for All Models when Data is divided into 80% for Training and 20% for Testing

The column chart that provides the rate of MAE evaluation criteria for all models when data is divided into 80% for training and 20% for testing is applied as shown in Fig. 13.

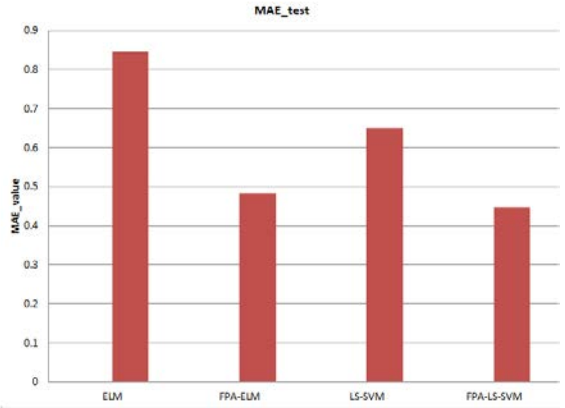

Fig. 13. MAE Evaluation Criteria for All Models when Data is divided into 80% for Training and 20% for Testing.

The column chart that provides the rate of SMAPE evaluation criteria for all models when data is divided into 80% for training and 20% for testing is applied as shown in Fig. 14.

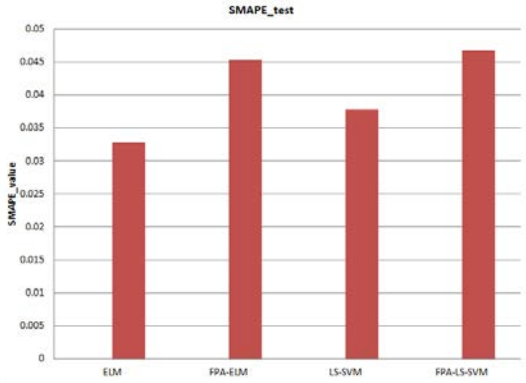

Fig. 14. SMAPE Evaluation Criteria for All Models when Data is divided into 80% for Training and 20% for Testing.

The column chart that provides the rate of PMRE evaluation criteria for all models when data is divided into 80% for training and 20% for testing is applied as shown in Fig. 15.

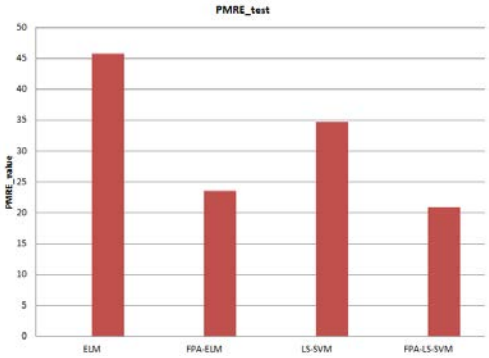

Fig. 15. PMRE Evaluation Criteria for All Models when Data is divided into 80% for Training and 20% for Testing.

At last data is divided into 90% for training and 10% for testing and the results also showed that the accuracy of FPA-ELM is higher comparing to solely using ELM, as shown in Fig. 16.

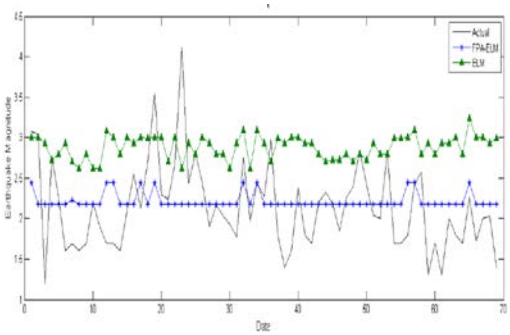

Fig. 16. ELM Accuracy VS FPA-ELM Accuracy when Data is divided into 90% for Training and 10% for Testing.

And the performance of LS-SVM became higher and better after optimizing LS-SVM with FPA as shown in Fig. 17.

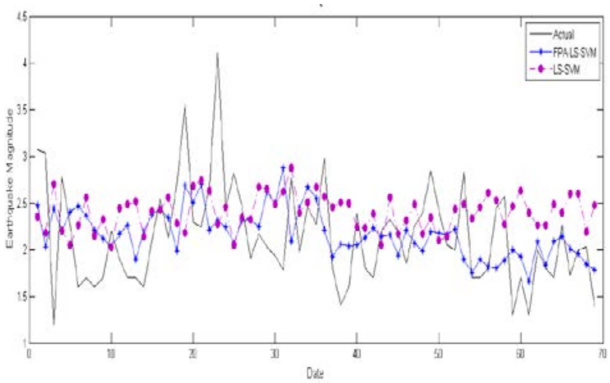

Fig. 17. LS-SVM Accuracy VS FPA-LS-SVM Accuracy when Data is divided into 90% for Training and 10% for Testing.

And also FPA-LS-SVM accuracy is higher than FPA-ELM one. This is obvious from the following Fig. 18.

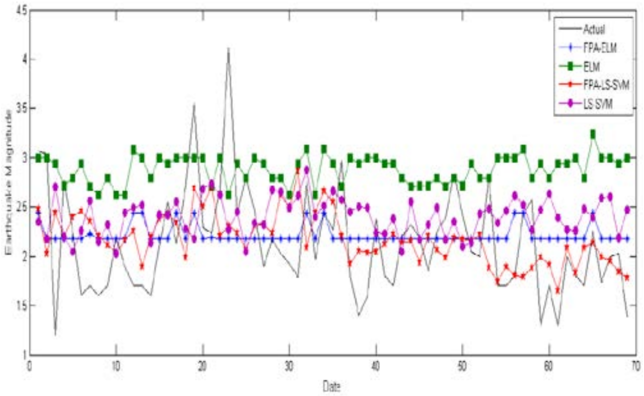

Fig. 18. FPA-ELM Accuracy VS FPA-LS-SVM Accuracy when Data is divided into 90% for Training and 10% for Testing.

In this case the values of evaluation criteria were as follow in Table IV:

TABLE IV. EVALUATION CRITERIA FOR THE MODELS WHEN DATA IS DIVIDED INTO 90% FOR TRAINING AND 10% FOR TESTING

evaluation test	**Models**			
	ELM	**FPA- ELM**	**LS-SVM**	**FPA-LS-SVM**
RMSE_test	0.929831	0.529094	0.651456	0.537101
MAE_test	0.813929	0.417803	0.53825	0.428999
SMAPE_test	0.065945	0.096061	0.082919	0.097089
PMRE_test	44.65868	21.13068	28.38148	20.80531

The column chart that provides the rate of RMSE evaluation criteria for all models when data is divided into 90% for training and 10% for testing is applied as shown in Fig. 19.

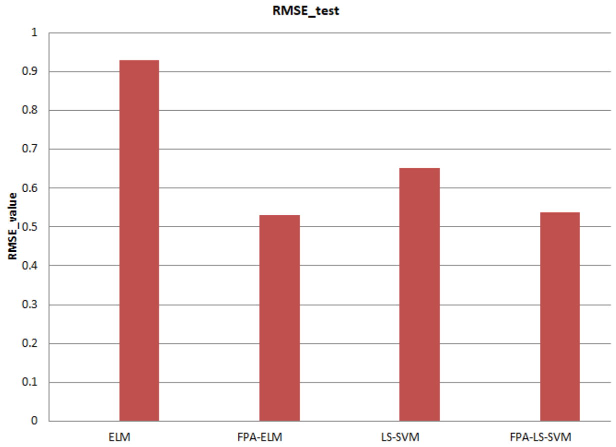

Fig. 19. RMSE Evolution Criteria for All Models when Data is divided into 90% for Training and 10% for Testing.

The column chart that provides the rate of MAE evaluation criteria for all models when data is divided into 90% for training and 10% for testing is applied as shown in Fig. 20.

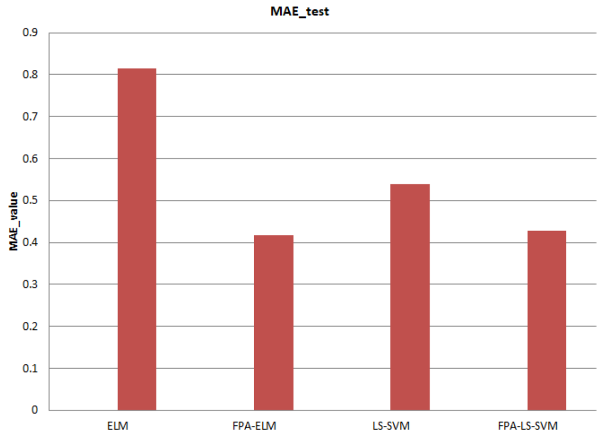

Fig. 20. MAE Evaluation Criteria for All Models when Data is divided into 90% for Training and 10% for Testing.

The column chart that provides the rate of SMAPE evaluation criteria for all models when data is divided into 90% for training and 10% for testing is applied as shown in Fig. 21.

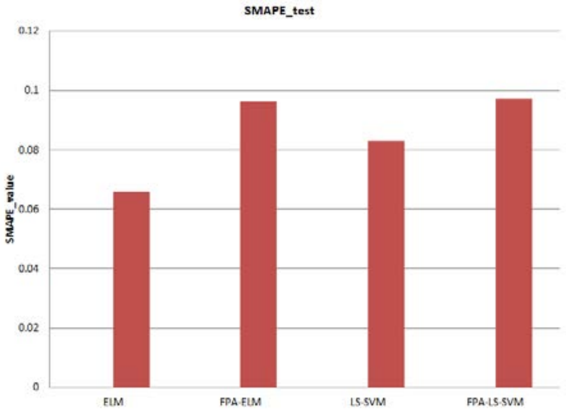

Fig. 21. SMAPE Evaluation Criteria for All Models when Data is divided into 90% for Training and 10% for Testing.

The column chart that provides the rate of PMRE evaluation criteria for all models when data is divided into 90% for training and 10% for testing is applied as shown in Fig. 22.

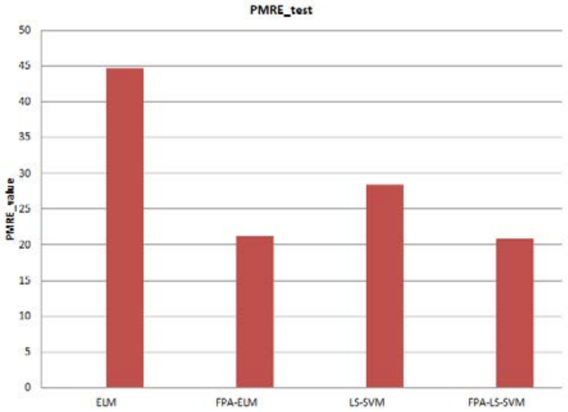

Fig. 22. PMRE Evaluation Criteria for All Models when Data is divided into 90% for Training and 10% for Testing.

VII. Conclusion

In this paper, two hybrid models, FPA-ELM and FPA-SVM, were proposed to forecast earthquake magnitude in the southern California region. Some seismic indicators were generated mathematically and statistically from the dataset to be employed as inputs for the proposed models. The proposed models were evaluated using four criteria. These criteria are RMSE, MAE, SMAPE, and PMRE. The experimental results showed that the accuracy of both ELM and LS-SVM were increased after optimizing it by FPA algorithm. The performance of proposed FPA-LS-SVM outperformed the FPA-ELM model according to all compared criteria. Also, FPA-LS-SVM is the best in reducing the false alarm ratio in earthquake prediction.

New Smart Encryption Approach based on Multidimensional Analysis Tools

Salima TRICHNI[1], Fouzia OMARY[2], Mohammed BOUGRINE[3]
Faculty of Sciences Mohammed V University in Rabat Department of Computer Science
Rabat, Morocco

***Abstract*—In the last decade, with the new situation forced by the Covide-19 pandemic, the information systems are often forced to work remotely, they must communicate and share confidential data with several interlocutors. In such a context, ensuring the confidentiality of communications becomes a complex and difficult task. Hence, the need to have a flexible system that can adapt with different parameters involved in every exchange of information. We recently presented in [1] a new smart approach to data encryption that serves the same purpose. This approach uses the concept of artificial intelligence and apply BNL skyline algorithm to decide about the most suitable algorithm to ensure the best data privacy. However, with the evolution of dimensions and criteria to be considered for this smart encryption, we find that the complexity of the BNL algorithm increase, then, the response time of the application increase and the skyline encryption quality decreases. In this work, we propose a new idea to resolve this problematic. Indeed, this contribution consists in adding another Intelligence brick to dynamically define the Skyline algorithm depending on the type and number of dimensions. Through this paper, we provide an analysis and a comparison of some skyline algorithms for the multidimensional search. The results obtained by this study show the performance of this new approach whether in terms of execution time or in the quality of the dominant encryption solution.**

Keywords—Security; confidentiality; artificial intelligent; smart encryption; cryptography; skyline

I. Introduction

With the enormous development of the communication´s means and the current circumstances caused by the covid-19 pandemic, a new management culture was brutally imposed on almost all institutions, companies and especially manufacturers who have suffered very impacting economic shock. Indeed, this new culture enforced by the health threat, is essentially based on collaboration and remote work to minimize the people´s movements and frequentation. We find ourselves with several new approaches in several areas, namely: e-administration, telemedicine, E-Learning and finally e-commerce which continues its development in the field of online shopping.

On the other hand, this situation forces us to go through telecommunications and technologies in order to share secrets, very confidential and critical data in a private network but most of the time public and not mastered. The attackers (the malicious ones) are more and more active and in constant search of vulnerabilities. Indeed, the percentage of vulnerabilities is increasing every day.

Computer security has therefore become a challenge for any company in order to ensure the continuity of its services. Research in this field has taken a new direction and aims to exploit new technologies in order to support immense digital development. New concepts have emerged, such as the concept of Identity-Based Cryptography (IBS) in which several publications are occurring as in [2] which aims to integrate authentication and integrity in the DNS and eliminates key escrow problem. At the same time, another security approach is also experiencing enormous development. This is the Blockchain. This revolutionary technology using cryptography and ensuring the security of transactions in full transparency is becoming a trend, and several researchers are thinking about how it can be applied in different needs. In [3], for example, the authors are coming up with Industrial IoT (IIoT) and Blockchain for the smart industries. The last component of development in the field of computer security is that which aims to integrate artificial intelligence into cryptographic processes. It is within this context that our research is oriented. In [1], we presented a new approach of intelligent security, adjustable with each information exchange and thus allowing communication with multiple entities regardless of their security protocol. In this system we consider the encryption algorithms as skyline points and we are used the BNL algorithm to choose the best one that best meets our security constraints. BNL works well if the size of the resulting Skyline line is small, and ideally fits into the window that causes the algorithm to terminate in a single iteration. However, this algorithm may require a large number of passes until 'that the complete Skyline is calculated and eventually terminates. So its performance is very sensitive to the number of dimensions and the distribution of the underlying data. Hence the need for a new method to stabilize the performance of this approach regardless of changes in the number of dimensions and their distributions.

The idea of this work consists in proposing a new solution concerning this approach that defines the Skyline algorithm according to the requirement of each communication. So instead of the skyline search algorithm being fixed, we modify it according to the type and the number of dimensions to be considered in each communication.

To present our work we will proceed as follows: First, we will start by citing the work related to our field of research and which integrates artificial intelligence techniques into computer security. Then, we will describe the principle behind the Intelligent Approach of Encryption. In a third section, we will present this new contribution and an experiment study of all basic Skyline algorithm to show their performance according to the parameters of each execution. Finally, in the last section we will discuss about the results and give conclusions.

II. Related Work

Artificial intelligence is a revolutionary technology that has been able to implement applications aimed at mimicking a form of real intelligence in several areas. Particularly in the area of security, several works have been carried out to strengthen and improve the security of information systems.

In general, there are two types of artificial intelligence use in the field of security. The first consists in creating decision support systems in order to control and improve the security policy of companies.

In cybersecurity, different solutions have been designed to overcome vulnerabilities and anomalies in systems. For example, in cyber-attacks, the thesis [4] offers an intrusion detection system in a completely unsupervised environment. This system is based on the Mutual Information algorithm for the selection of features and on the Deep Learning PV-DM model for reading network packets.

In this same area, other solutions are already starting to take their places in the market, such as the AI2 platform which, from the log lines, identifies suspicious activities. AI2 applies unsupervised machine learning algorithms on the input data to nominate potential attacks. Then, IT security analysts intervene to confirm and decide which incidents are real attacks. This system is also capable of continuously generating new models within hours, which can dramatically improve the speed of its cyber-attack detection capability [5].

The article [5] gives a summary and a detailed state of the art on other AI systems used in the field of security whether at the level of infrastructure, network, cloud, terminals, mobile, applications, IoT, or others such as the Web and Identity Management.

All the solutions mentioned above, come to help and facilitate the prediction and / or the detection of the problems and the faults of the systems. On the other hand, there is another category of AI solutions in the field of computer security.

This second category consists of designing systems that provide one or more properties of computer security based on AI techniques.

To ensure confidentiality, for example, in [6] the Google team proposed a solution based on the training of learning machines for the encryption and decryption of messages. Indeed, the authors consider the protagonists Alice and Bob as neural networks that try to communicate with each other in complete confidentiality while preventing a third malicious neural network named Eve from decrypting their messages. This system resembles the principles of electronic games.

The author in [7] represents another way to design an encryption system based on one of the paradigms of artificial intelligence which are on evolutionary algorithms. The Symmetrical Evolutionary algorithm (SEC) is the first variant of this type of algorithm which performs an encoding of the text in the form of positions lists. Then, it applies a set of genetic operators (mutation and crossover) on these positions at the level of each iteration in order to reproduce potential solutions. Finally, and through a well-defined evaluation function, assesses individuals and decides the safest solution. Several extensions of this system have been developed in order to increase the level of intelligence of this system in choosing the most relevant solution. Sometimes by adding difficult problems in the encryption process like the case of [8], and in other cases by modifying the evaluation function like in [9] and [10].

Our approach falls rather in the first category and it consists of a Decision Support System for the encryption of confidential data.

III. Background

A. Skyline Algorithm

1) The concept of dominance: Given a dominance relationship in a dataset, a Skyline query returns objects that cannot be dominated by any other object.

In the case of a dataset made up of multidimensional objects, one object dominates another object if it is equally good in all dimensions, and better in at least one dimension.

Skyline's computation was an algorithmic problem in nature, and all data was assumed to reside in memory.

However, nowadays we are faced with large data sets which are stored in secondary memory. Having the data on the disk, the algorithms proposed for processing Skyline requests are separated into two categories: algorithms not based on indexes and algorithms based on indexes.

2) Algorithms not based on indexes

a) Block Nested Loop (BNL)

A naive algorithm for calculating a Skyline query is to compare each object with all of the other objects in the dataset using a nested loop. However, the quadratic complexity O (n2) makes this algorithm very inefficient (n is the total number of objects in the data set).

The Block-Nested-Loop algorithm [11] applies the same idea, but uses a window (block of memory with limited space), which contains a limited number of data objects. Any candidate object p is compared to the objects of the window.

Three cases can occur:

1) p is dominated by an object in the window! p is eliminated.

2) p dominates one or more objects in the window! These objects are eliminated and p is placed in the window.

3) There are no objects in the window! p is inserted directly into the window. (In case the window is full, a temporary disk file is used to contain the candidate objects).

BNL may require a large number of passes until the full Skyline is calculated and eventually terminate because at the end of each pass the size of the temporary file will be reduced.

b) Divide & Conquer (D&C)

The D&C algorithm [12] [13] calculates the median value of a dimension, and divides the space into two partitions P1, P2.

Then it calculates the Skylines S1, S2 of P1, P2, recursively dividing P1 and P2.

Recursive partitioning stops when there are only one (or a few) objects. The overall Skyline is calculated by merging S1 and S2, and eliminating objects in S2 that are dominated by any object in S1.

c) Bitmap

The Bitmap algorithm as it was proposed in [14] is based on a vector representation of all the dataset.

In order to describe the algorithm, let p be a point in a d-dimensional space represented by a vector of m bits.

$p = \{p.d_1, ..., p._{dj}\}, 1 \leq j \leq d$

From these m bits, each p.di is represented by a number ki of bit slice. Each ki has as many bits as the number of distinct coordinate values of all points in the dataset in that dimension.

After constructing the bit slices, the algorithm performs 3 operations between 2 sets of bit parts. The first set contains the parts of bits Vx, Vy (one for each dimension) where resides the last bit of the point which is equal to 1. The second set contains the slices of bits Vx + 1, Vy + 1. In the case where the bit slices of the previous step are the last in order, we then use the bit slice zero (all bits at zero).

- The first operation A will be an AND operation between Vx and Vy.
- The second operation B will be an OR operation between Vx+1 and Vy+1.
- The third operation C will also be an AND operation between the results.

If the result of the final operation is zero, the tested point is a Skyline point.

3) Algorithms based on Index

a) Index

The index is a B-tree-based algorithm for two-dimensional data, where the data has two ordered indices.

For example, let a tree B and a tree B +, each represent a dimension. The algorithm calculates one over the entire Skyline line by scanning both indices simultaneously and stops as soon as a 'p' object is found in both indices.

Any object that has not been inspected in both indices is certainly not part of the Skyline line, as it is dominated by p. Therefore, candidate objects are those that have already been inspected in at least one index. These objects are kept in a separate set S (the superset of the Skyline line).

b) Nearest Neighbor Search (NN)

The first Skyline algorithm based on a spatial index (as R-tree), is the Skyline NN algorithm, proposed in [15]. It is called NN because of its relevance to the nearest neighbor search. It identifies Skyline objects by repeated NN search, using an appropriate distance measure.

The algorithm iteratively finds the closest object (NN) to the origin in a given region of space based on any monotonic distance function, e.g. the Euclidean distance. During the algorithmic process, entire regions dominated by a candidate object are ignored, and regions that cannot be ignored are added to a task list for further partitioning of space. And so on until the list becomes empty and, thus, the algorithm ends.

B. *Description of Intelligent Approach of Encryption*

The solution proposed in [1] is a decision-making system aimed to ensure the confidentiality of data in the most adequate way.

The following diagram shows the different steps in the framework of this strategy.

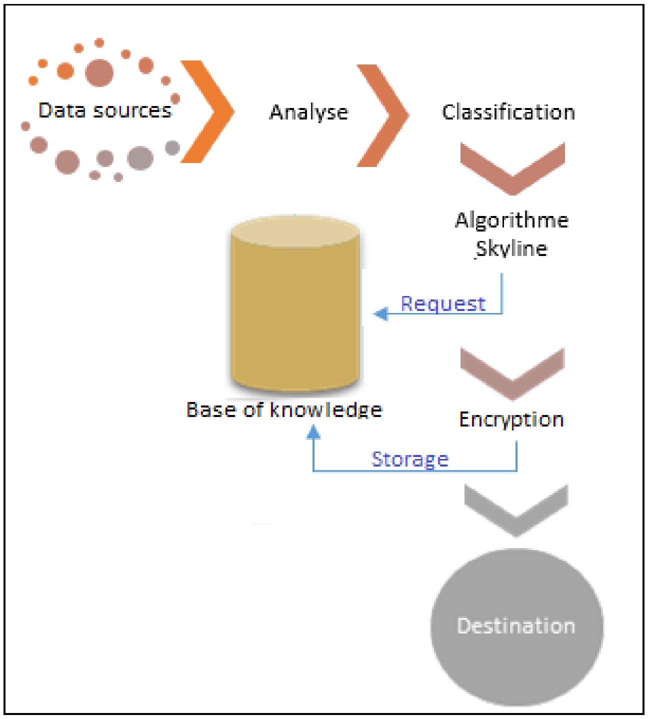

Fig. 1. Steps of the Intelligent Encryption Principle.

To explain the diagram of Fig. 1; we will detail each step in the following:

a) Step1: Analysis

Before proceeding with data encryption, in this solution we propose to rely on several characteristics of the encryption environment to decide the ciphering algorithm that best meets the security criteria to ensure in this communication.

This new encryption method begins with an analysis of the various elements that impact communication security. Indeed, we must analyze this impact at the level of:

- The source environment,
- The transmission channel,
- The destination environment

- The types of data to be transmitted,
- The generation of the keys, if not the possession of the keys.

Each part of this system represents a set of characteristics which considerably influence the security of this communication. Therefore, you have to focus on each part to extract the most relevant information.

b) Step2-Classification

Once this analysis has been carried out, we must move on to the second step which consists of classifying the data and storing all this information in an intelligent business architecture in order to subsequently decide on the most appropriate encryption.

The decisional database is a multidimensional base and knowledge base that includes a large number of experiments to cover the various cases possible.

c) Step3 - Skyline

In the third step, we launch the BNL skyline request on the previously established knowledge base by using the current communication requirement.

d) Step4 – Encryption and Storage

Depending on the chosen encryption algorithm we apply this encryption to our message and send the encrypted information.

Finally, the last step is a consolidation step in which we calculate the robustness of this encryption in terms of possible security indicators. Then, we feed the knowledge base by the feedback that we were able to complete.

IV. Contribution

A. *Problematic Description*

As noted in the previous section, the intelligent encryption approach uses the BNL algorithm to select the most dominant encryption algorithm against the specified criteria. This algorithm is very efficient in the case where one is satisfied with a very restricted set of dimensions with a dataset containing less candidates.

However, with the evolution of the knowledge base and the requirements to be taken into account for the security of communications, the complexity of this algorithm increases considerably and becomes quadratic of the order O (n ^ 2), where n is the size of the dataset to be examined; something that induces degradation of system performance.

In order to remedy this problem, we have carried out an in-depth study on certain Skyline algorithms, however we have come to the conclusion that each algorithm can be efficient and performant under certain conditions.

In what follows, we present this observation in detail and we propose a solution to circumvent this problem and grant a better flexibility of this approach.

B. *Description of Proposed Solution*

This contribution focuses more on step 3 of the Intelligent Encryption Principle. It seeks to optimize the use of Skyline algorithms for better results.

The solution is to add an extra step in this approach to dynamically choose the most suitable Skyline algorithm with respect to the data tuples to be examined.

Then the new process can be described as follow:

Step 1: Analysis of the data source/environment/channel

Step 2: Modeling and data classification in a BI database

Step 3: Building Criteria to Consider in the Skyline Query

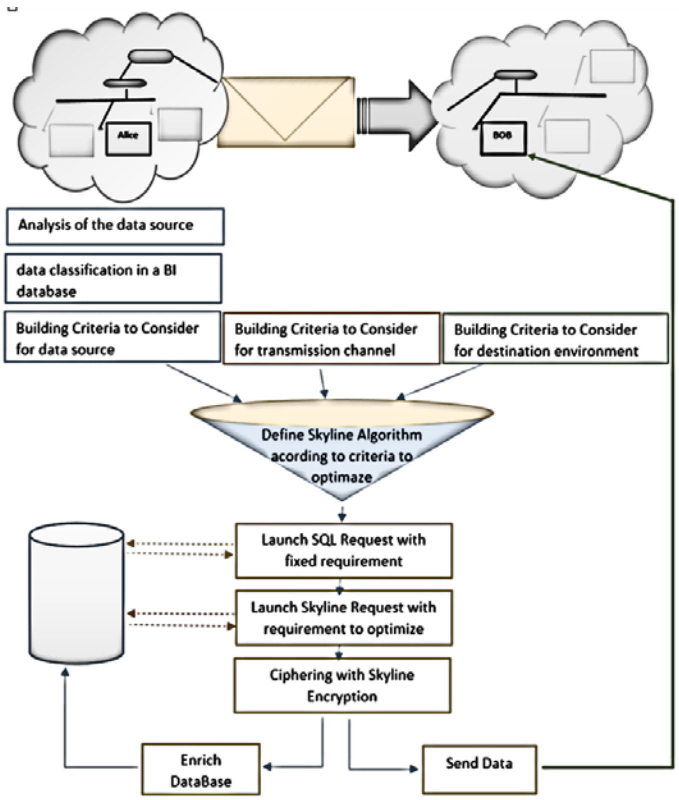
Step 4: Skyline Algorithm Setting

Step 5: Application of the Skyline method

Step 6: Recovery of the most relevant encryption Skyline

Step 7: Evaluate the Solution and Enrich the Knowledge Base.

Below we prensent a summary diagram (Fig. 2) to illustrate how this new approach works to ensure the exchange of sensitive data between two entities (Alice and Bob) on different networks :



Alice
BOB
Analysis of the data source
data classification in a BI database
Building Criteria to Consider for data source
Building Criteria to Consider for transmission channel
Building Criteria to Consider for destination environment
Define Skyline Algorithm acording to criteria to optimaze
Launch SQL Request with fixed requirement
Launch Skyline Request with requirement to optimize
Ciphering with Skyline Encryption
Enrich DataBase
Send Data

Fig. 2. Diagram Summarizes the Steps of Our Contribution.

Now and after having stated the original contribution of this work which lies in adding an intelligent step allowing the configuration of the Skyline algorithm most appropriate to the criteria of our research. We chain in the following by an experimental study to analyze the impact of each criterion / dimension on the performance of the skyline algorithm in order to determine the set of parameters to be considered in the choice of Skyline.

For this, we will consider the following Skyline algorithms:

- Block Nested Loop (BNL)
- Divide & Conquer (D&C)
- Bitmap
- Index
- NN

C. Experiences &Results

To perform these experiments, we prepared a knowledge base with real data. Feeding this database has been made on the basis of an input data sample selected in an arbitrary manner which 100 texts same fixed characteristics.

Then, we applied to each text these five encryption algorithms: AES, Blowfish, DES, TripleDES [16] and ASEC which makes a total of more than a thousand test lines.

1) Specification of requirements: In an approach to optimization of processing, our method runs on two requests to attack the knowledge base as in [23].
The first query serves to minimize the volume of data to be examined in the next step. It uses fixed criteria in the SQL clause "Where" whose values are fixed at the start of each exchange.

The fixed criteria represent the properties of the current communication, for example:

- Type of data to be exchanged
- Characteristics of the source network
- Characteristics of the destination network
- The licenses available.
- The machine capacity of the encryption
- The machine capacity of the decryption
- Robustness of the transport channel between the two networks

The second query executes the skyline algorithm and considers the criteria to be optimized and from which the users' wishes in terms of the level of security to be acquired are made concrete. Hence the distinction between the two types of criteria.

For example: The criteria to be optimized:

- Quality (rate of randomness / entropy)
- The reputation of the algorithm
- encryption utilization frequency
- The cost of encryption / decryption
- The speed of encryption / decryption
- etc.

The test environment is based on an Intel (R) Core (TM) i7-6700HQ, 2.60GHz, 16GB RAM, 64bit OS machine.

2) Application of skyline algorithms: The application of Skyline algorithms was carried out by the Java programming language via the Spring Boot framework for the development of the Back End and Angular for the Front End part.
Through this application, users have the right to:

- Specify the number of dimensions.
- Specify the dimensions.
- Choose the operation to apply on each dimension.
- Choose the preferred algorithm for calculating Skyline points.

The application attacks the knowledge base and executes the chosen Skyline algorithm with the criteria entered as shown in Fig. 3, 4, 5, 6 and 7.

a) Scenario 1: On Two Dimensions

The objective of this experiment is to:

- Minimize encryption time
- Maximize entropy

Fig. 3 until Fig. 7 show the executions carried out for each Skyline algorithm and the output result.

TABLE I. SKYLINE POINT FOR ENCRYPTION ALGORITHM THAT OPTIMIZE ENTROPY AND RUNTIME DIMENSIONS

Algorithm	Ciphering Runtime(ms)	Entropy
BLOWFISH	25	3.8870066417181426
BLOWFISH	27	3.9658710817437597
BLOWFISH	48	4.00235367813974
BLOWFISH	66	4.01642913400371
AES	73	4.026504332171881
BLOWFISH	126	4.027404704120802

- Results & Discussion of Scenario 1:

The results of the different algorithms were all the same and give out 6 skyline points as the dominant solutions. The following Table I summarizes this result:

The most efficient encryption algorithm is BLOWFISH comes after the AES algorithm in second. Indeed, in this case these two algorithms are well known in the community of computer security by their performance and their level of security [17] [18] [19] [22].

Now, if we go back to the performance of the Skyline algorithms, to come up with these results there is a huge difference in the execution time of these algorithms.

The diagram below shows the result of the execution time of each Skyline algorithm.

So from the Fig. 8, we can conclude that the BNL algorithm is the simplest and the best if we do not use the two dimensions encryption time / Entropy.

However, if we change the two dimensions considered in the first experiment and we opt for the following scenario:

b) Scenario 2: on Two Dimensions

- Objective 1: to minimize the decryption time.
- Objective 2: minimize the memory capacity required for decryption.

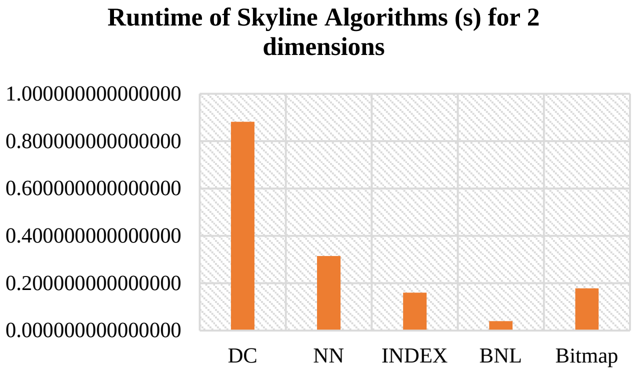

Fig. 8. Comparison of Runtime Skyline Algorithms (s) Executed with Entropy and Runtime Dimensions.

TABLE II. SKYLINE POINT FOR ENCRYPTION ALGORITHM THAT OPTIMIZE DECIPHERING RUNTIME AND USED MEMORY

Algorithm	Deciphering Runtime(ms)	Deciphering Memory used (K)
SEC	48	1695
SEC	56	1841
ASEC	93	2503
AES	243	2517

The application of the Skyline algorithms was carried out in the same way as the first experiment except for the types of dimensions which have just been modified to select the Decryption Runtime and the Memory dimensions.

In this experiment, the results in terms of Skyline points are different,

The Table II below is the summary of the results of the different executions:

- Results & Discussion of Scenario 2:

The SEC encryption algorithm is ranked first, followed by the ASEC (advanced version of SEC) algorithm, followed by the AES algorithm.

The result given by this system seems logical because SEC is an evolutionary algorithm [20] which takes enough time to perform the encryption and generate the key, however, in the decryption process it applies a single operation to the whole text at once. As a result, this type of algorithm performs best with respect to the cost of decryption.

On to the result of the skyline algorithm runtime, the following diagram illustrates the results of this scenario:

From this experience, we can see in Fig. 9 that the Bitmap algorithm performed well in this scenario.

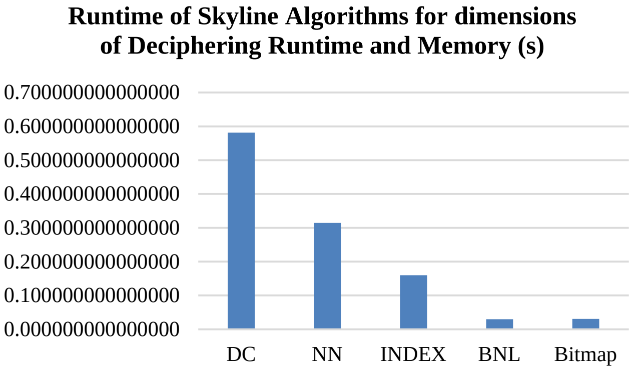

Fig. 9. Comparison of Runtime Skyline Algorithms for Dimensions of Deciphering Runtime and Memory (s).

This is because the Bitmap vector representation for these two dimensions is less complex. In fact, the more the number of values of a dimension are mastered, the algorithm becomes faster and more efficient [21]. In Scenario 1, the entropy dimension had very varied values and therefore the Bitmap vector representation will be very large and complex.

On the other hand, the BNL algorithm always remains efficient even by modifying the type of dimensions considered [21].

c) Scenario 3: for Four Dimensions

- Objective 1: minimize encryption time.
- Objective 2: maximize entropy
- Objective 3: minimize decryption time
- Objective 4: minimize the memory capacity required for encryption.

The diagram below shows the result of the execution time of the skyline algorithms.

- Results & Discussion of Scenario 3

From the results of Fig. 10, we see that the Bitmap algorithm becomes very complex however, the index algorithms become more efficient.

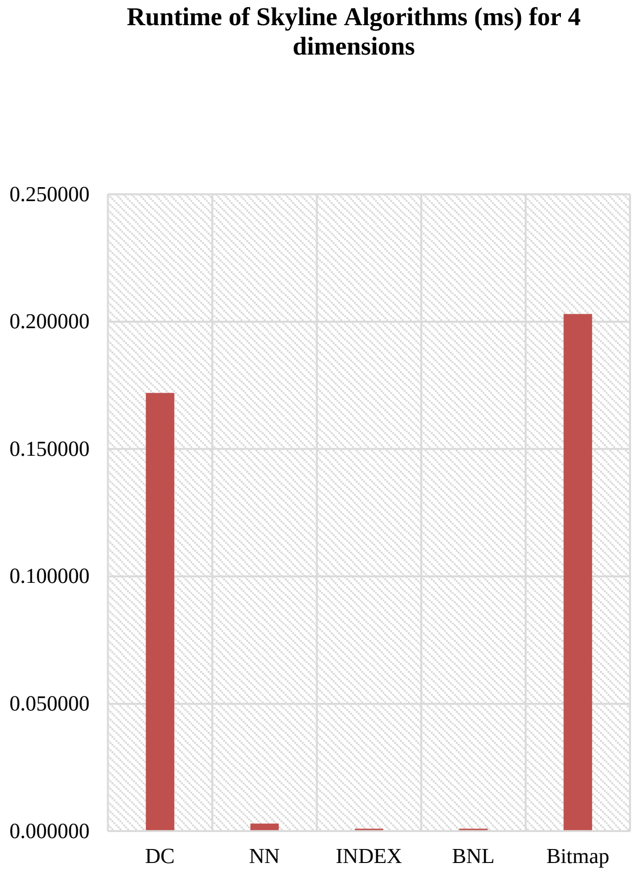

Fig. 10. Comparison of Runtime Skyline Algorithms (s) Executed with 4 Dimensions.

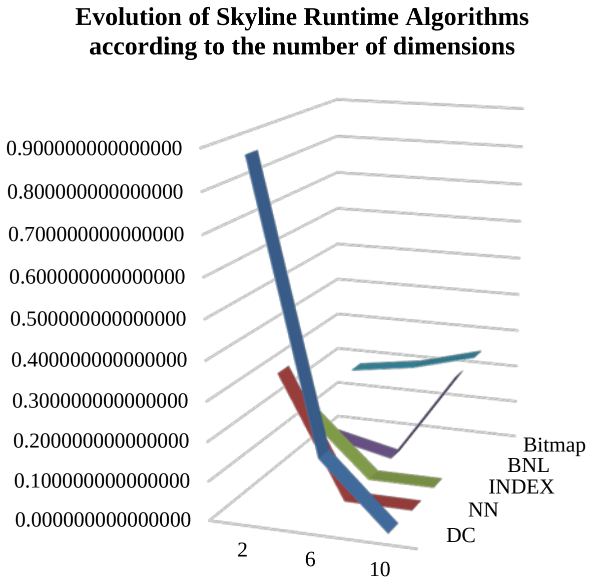

Fig. 11. Compariosn of Evolution of Skyline Runtime Algorithms according to the Number of Dimensions.

And so on, the more we add dimensions, the more the performance of the algorithms changes.

d) Scenario 4: up to 10 Dimensions

In this experiment, we ran the application on several dimensions to assess the impact of the number of dimensions on the speed of Skyline algorithms.

The Fig. 11 below shows the result of the execution time of the skyline algorithms against number of dimensions.

3) Comparison and discussion: As we have presented in previous experiences, we focused on two very important factors for the success of this approach, namely:

- The execution time of Skyline algorithms because it has a very significant impact on the speed of the entire system.
- The quality of the Skyline selected (the encryption to be implemented) because it represents the heart of this approach and embodies the robustness and security of the system.

The quality of the skyline solution can be evaluated based on the following characteristics:

- Guarantee: All returned points are skylines.
- Accuracy: All the points returned meet the criteria previously defined.
- Progressiveness: the sending of results is done instantly regardless of the size of the database are often huge.
- Completeness: at the end, all the points of the skylines are returned.

From this experiment study, we can conclude that there are two main parameters to satisfy all these characteristics and guarantee the performance of the skyline algorithms on encryption problem. These two parameters are:

- The Number of Dimensions
- The rate of variation which means the rate of the difference between numerical values of a given dimension. The greater this difference, the lower the rate of change and vice versa.

For example, to demonstrate the impact of the rate of change on the quality and performance of this approach, we can go back to experiments 1 and 2. In fact, in the first scenario we used two dimensions with different rates of change (the encryption with a normal rate of change and entropy for which the rate of change is very high). While in the second experiment we kept the same number of dimensions but with a normal rate of variation for both. The result of the first experiment favored the BNL algorithm however in the second experiment the Bitmap algorithm performed better. Otherwise, compared to the quality of the returned Skylines, they were all on the same level. In terms of:

Accuracy: criteria met

Guarantee: exact encryption

Completeness: same list of Skylines,

Progressivity: the list was returned all at once however this test is not interesting in this case since the number of dimensions is very low and the size of the base is fixed for the moment.

The two tables, Tables III and IV below summarize these results:

TABLE III. THE CRITERIA FOR CHOOSING THE SKYLINE ALGORITHM IN THE CASE OF 2 DIMENSIONS AND AN UNCORRELATED RATE OF VARIATION

Scenario 1	d=2			
	uncorrelated rate of variation			
	Progressiveness	Guarantee	Completeness	Speed
BNL	oui	oui	oui	1
D&C	oui	oui	non	5
Bitmap	oui	oui	non	3
Index	oui	oui	oui	2
NN	oui	oui	oui	4

TABLE IV. THE CRITERIA FOR CHOOSING THE SKYLINE ALGORITHM IN THE CASE OF 2 DIMENSIONS AND A UNIFORM RATE OF VARIATION

Scenario 2	d = 2			
	uniform rate of variation			
	Progressiveness	Guarantee	Completeness	Speed
BNL	oui	oui	oui	2
D&C	oui	oui	oui	5
Bitmap	oui	oui	oui	1
Index	oui	oui	oui	3
NN	oui	oui	oui	4

The objective behind the other two experiments is to demonstrate the impact of the dimension number on the quality and speed of the system. In fact, in these two experiments, we each time added additional dimensions to our research with different rates of variation.

From the results of these experiments, we find that the NN and D&C algorithms are starting to meet the demanded needs better than other algorithms. The Bitmap algorithm always responds very well in cases of dimensions with uniform rate of change regardless of the number of dimensions. However, the BNL algorithm is no longer favored if the number of dimensions is large.

At the end and to summarize all these results, we can use the Tables V and VI below to decide on the choice of the Skyline algorithm which gives us the most secure encryption:

TABLE V. GLOBAL CRITERIA FOR CHOOSING THE SKYLINE ALGORITHM IN THE CASE OF LESS THAN 4 DIMENSIONS

	d < 4			
	uniform rate of variation			
	Progressiveness	Guarantee	Completeness	Speed
BNL	-	oui	oui	oui
D&C	-	oui	oui	non
Bitmap	-	oui	oui	oui
NN	-	oui	oui	non
	uncorrelated rate of variation			
	Progressiveness	Guarantee	Completeness	Speed
BNL	-	oui	oui	oui
D&C	-	oui	non	non
Bitmap	-	oui	non	non
NN	-	oui	oui	non

TABLE VI. GLOBAL CRITERIA FOR CHOOSING THE SKYLINE ALGORITHM IN THE CASE OF MORE THAN 4 DIMENSIONS

	d >= 4			
	uniform rate of variation			
	Progressiveness	Guarantee	Completeness	Speed
BNL	non	oui	oui	non
D&C	non	oui	oui	non
Bitmap	oui	oui	oui	oui
NN	oui	oui	oui	oui
	uncorrelated rate of variation			
	Progressiveness	Guarantee	Completeness	Speed
BNL	non	oui	non	non
D&C	non	oui	oui	oui
Bitmap	non	oui	non	non
NN	oui	oui	non	oui

Then, if we come back to our new approach (Fig. 2), for the step 4 of this new contribution that consist in 'Skyline Algorithm Setting' we can conclude that we have tree general configuration of Skyline algorithms:

Configuration 1: when performance achieved on a small number of dimensions such as BNL.

Configuration 2: performance achieved if we work on a large number of dimensions such as the DC and NN algorithms

Configuration 3: performance achieved if we work on dimensions with a limited number of different values, then we can use Bitmap algorithm.

V. Conclusion

Despite the significant development of security tools, computer systems still suffer from malicious threats especially with the huge growth of emerging technologies.

To be able to support this revolution, these new technologies must be integrated into the various security components. During this work, we tried to develop a new approach to intelligent encryption that is based on the concepts of artificial intelligence. It uses Skyline algorithms to define the policy to be followed to ensure the confidentiality of exchanges. In this work we proposed a new version of this system included an additional step to define dynamically the Skyline algorithm to be executed for choice the good Encryption Algorithm. So, from the experimental demonstration we deduced that the choice of the Skyline algorithm has a perimeter role in this approach and the use of the BNL algorithm, as in the previous contribution, risks weakening the performance and the efficiency of this encryption system, especially if the variation rate of dimension values or their number increases We applied different Skyline algorithms and we compared the results. Finally, and after several scenarios we concluded that this system must absolutely change the choice of Skyline Algorithm taking into account two main parameters which are: The number of dimensions and the rate of variation.

Natural Language Processing Applications: A New Taxonomy using Textual Entailment

Manar Elshazly[1], Mohammed Haggag[2], Soha Ahmed Ehssan[3]
Computer Science Department
Faculty of Computers and Artificial Intelligence, Helwan University, Cairo, Egypt

***Abstract*—Textual entailment recognition is one of the recent challenges of the Natural Language Processing (NLP) domain. Deep learning strategies are used in the work of text entailment instead of traditional Machine learning or raw coding to achieve new enhanced results. Textual entailment is also used in the substantial applications of NLP such as summarization, machine translation, sentiment analysis, and information verification. Text entailment is more precise than traditional Natural Language Processing techniques in extracting emotions from text because the sentiment of any text can be clarified by textual entailment. For this purpose, when combining a textual entailment with deep learning, they can hugely showed an improvement in performance accuracy and aid in new applications such as depression detection. This paper lists and describes applications of natural language processing regarding textual entailment. Various applications and approaches are discussed. Moreover, datasets, algorithms, resources, and performance evaluation for each model is included. Also, it compares textual entailment application models according to the method used, the result for each model, and the pros and cons of each model.**

Keywords—Textual entailment; deep learning; summarization; sentiment analysis; information verification; machine learning; depression detection

I. Introduction

Textual entailment[1] is the process of importing a text from another one. Textual entailment [2] is an obtaining the relationship between fragments of text when one fragment in some sense implies the other.

Recognition of text entailment (also called natural language inference) is the task of deciding on the allocation of two pieces of text whether the interpretation of one text can be given in another text. Text entailment is a relationship-related activity and sometimes there are threee relationships can occur between two sentences. Entailment- [1, 3] the meaning of one sentence can be combined with another sentence, incorrect entailment - the meaning of one text contradicts the meaning of another sentence, and non-entailment - the meaning of one text does not include or contradict the meaning of another sentence. Or may be categorized to two class (ENTAILS/NEUTRAL).

Textual entailment research mainly contains methods for developing and evaluating algorithmic identification methods of entailment [2]. Text entailment aims at a deeper understanding of text and thinking, which shares the same type of machine learning comprehension, although the structure of the functions is slightly different [4].

Similar to Semantic Textual similarity, in the task of Textual Entailment, the input also contains two sentences (pre-sentence P and hypothesis H sentence), and programs should determine whether the meaning of sentence H can be extended from the meaning of sentence P. In particular, [5, 6] systems are required to assign each line of the phrase or label of CONFIDENCE (when P comprises H, that is, H cannot be false when P is true), the CONTRADICTION label (when P contradicts H, i.e. H is false whenever P is true), or the INDEPENDENT label (where true of H could be determined on the basis of P).

Textual Entailment task is a problem of classification [5]. TE is the latest and best indicator of text acquisition in NLP applications [7].Recent work on Text Entailment work includes (1) models based on linked elements and machine-learning classifiers, (2) sentence-based models that use similar structures such as Semantic Textual similarity, sentence-based function, and (3) other neural network models that do not use Simple RRNs or CNNs as sentence encoders.

Textual Entailment (TE) is an inconsistent relationship between two expressions in which the meaning of one phrase, called Hypothesis (H), derives from another expression called Text (T). The definition of TE is strong in the sense that if H enters from T but has little or no additional information, then the two are treated as unrelated or non-entailed [8].

Text entailment is used in text encryption methods to measure text connections. TE in NLP is a direct relationship between the sections of the text. Relationships are active and effective when the fact of one text fragment follows from another fragment. In the TE framework, integrated and integrated texts are defined as text (T) and hypothesis (H) [7] .

Textual Entailment (TE) is a typical example of a semantic inference, in which the purpose is to determine where a textual hypothesis (H) can be correctly included in a given text (T). While classifying the hypothesis into genes and making an effort to determine where each is differentiated separately by T is called Partial Textual Entailment (PTE) [7].

Partial Textual entailment (PTE) is a possible solution to this problem that defines the interdependent relationships between T and H pairs. PTE relationships can play an important role in a variety of programs to use Natural Language Processing (NLP) such as text summaries and a question answering system by minimizing unwanted information [8].

Recognition of textual Entailment (RTE) [8] is an important function in Natural Language Processing (NLP) research. The key role of RTE includes a question-and-answer system where the nature of the engagement is confirmed by the given answer regarding the expected answer, a summary of multiple texts where the sentences should be deleted, and a retrieval system where only documented questions are required. However, the old definition of TE has two important implications for the relationship. First, the relationship does not coincide where H should be inserted from T. Otherwise the two pair are non-entailed. PTE [9] is a two-way relationship between two expressions in which one expression is inserted or slightly dependent from another expression. PTE expands Textual Entailment (TE) concept.

The rest of the paper is organized as follows: Section (II) provides a literature review about NLP applications that uses textual entailment, in Section (III) provides a comparison between machine learning and deep learning in textual entailment. The paper concludes in section. The paper concludes in Section (IV) with an overview of future work that it was aimed to be done

II. Natural Language Processing Applications using Entailment

Textual entailment is a relationship that obtains between fragments of text when one fragment in some sense implies the other fragment. The automation of textual entailment recognition supports a wide variety of text-based tasks, including information retrieval, information extraction, question answering, text summarization, and machine translation [2].

A. Text Summarization

NLP has several applications, the challenging one is a text Summarization. Summarization is a process of presenting a text's most important and relevant information in precise way. It helps to understand a text very quickly and precisely.

Determining the level of correlation between input sentences will help to reduce the inclusion of meaningless sentences in abbreviated text. The importance of the summary becomes even more important and effective when dealing with events on social media platforms such as Twitter, where information is fast, rich, varied and ever-growing content, no matter where, time and other circumstances.

Any user can post comments or watch, upload videos to any event very quickly. Current methods of measuring sentences only find similarities between words and sentences. These methods only state the correct information for each sentence. Summarizing text helps to understand any major text in a very short time .It is to produce the right summary, there are a few steps to follow, e.g. Lexical Analysis, Semantic Analysis and Syntactic Analysis.

The content of the summary story details depends on the needs of the user. Text Summary Methods can be classified as abstractive and an extractive summarization. The abstractive summarization incorporates key ideas into the document and conveys those ideas in clear natural language. The extractive summarization process consists of selecting key phrases, sentences, paragraphs etc. In the original document and combine those with a short form that maintains a sequential sequence [7].

The main purpose in [10] is to measure sentence similarity, which will help to summarize the text of any language, looking only at English and Bengali. The methods proposed in [10] were extensively tested using several English and Bengali texts, from many online sources. This similarity of sentence is stated. Prior to in-depth analysis the best way to prepare for the operation of both languages used is Unicode.

Model [10] represents a new proposed sentence similarity measuring model for English and Bengali language. Lexical methods have been applied, and a perfect expected result has been found.

Lexical Layer Analysis: The lexical presentation and lexical similarity are major function in lexical layer as shown in the Fig. 1. The model followed by one of the popular deep learning algorithm-Text Rank. Lexical Layer Analysis Model has the following steps as:

- Lexical analysis: brake the sentence into tokens.
- Stop words removal: remove pronoun and article words.
- Lemmatization and Stemming: return all tokens to their entry.

Sentence Similarity: The rating method helps to hear the correlation of words that occur in WordNet times. Send the distance between the two words. Other equations to be used in the same suggested algorithms, in this proposed model use python with NLTK version 3, and WS4J: java API designed for WordNet use [10].

However, Twitter's summary work has garnered a lot of attention from the research world over the past decade as a result of sharing fast and varied responses from millions of users.[9] While, summarization of Twitter event is much harder than traditional texts due to the different type of text that poses many challenges. Like:

- Processing of tweet content : this, standard Natural Language Processing (NLP) tools do not work well in this type of text and create challenges for tweet content processing, design integration and topic by topic due to the high nature of understanding features.
- Sentence Boundary Detection (SBD): A tweet does not consist of a single sentence, instead, it can include multiple sentences. Sometimes, a tweet does not include punctuation even if it includes multiple sentences.

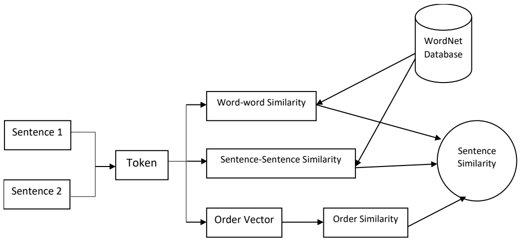

Fig. 1. Lexical Layer Analysis Model[10].

- Information redundancy problem: Events on Twitter attract a large number of tweets making it difficult to find the most important personal tweets. Every event contains incorrect details of an event in the form of a Re-tweet or titter with the full or partial content of another tweet in high volume. To reduce misunderstandings, identifying partially embedded information between tweets is harder than seeing re-tweets or embedded tweets. For example, two sentences are listed below in two separate tweets. The second sentence contains the information included in the first sentence and additional content (highlighted). To reduce the amount of non-reversible information, these two sentences can be combined into one meaningful sentence as shown below.

Model [9] proposes a summarization approach to extracting an amazing event summary from Twitter by providing a solution that can solve the above challenges. Fig. 2 illustrates this summary. This approach follows a detailed design to produce a summary of the most informative and relevant sentences from all event tweets. After they made this model they found that:

- In many previous researches, tweet is considered a summary of work. But in reality, regular tweets include many sentences. In this research the authors extract important sentences by SBD from tweets instead of treating the tweet as a sentence. In order to exclude the most important events of the event, they put all relevant tweets of the event first and convert the top tweets placed into possible sentences.

- To produce an abstract summary, authors filter out invalid data by checking the Partial Textual Entailment (PTE) relationship between sentences. They see peer-to-peer (PE) sentences and a text border that is slightly inserted between sentences. Couples of PE sentences are combined into one sentence by combining PE text. Finally, an abstract summary creates selected sentences in addition to covering high detail, diversity, consistency and readability.

In [9] the proposed model is two phase summarization approach. First phase is key sentence extractor which produces more relevant and informative sentences rather than tweets from the appropriate tweet event set, second phase is abstractive summarizer which produces a desirable summary over the selected sentences after deleting the unwanted information by pointing to the information included or partially included in the sentences. So, authors have seen the quality of the summary is limited by the accuracy of the TE determination. This [7] seeks to overcome these restrictions by using Partial Textual Entailment (PTE) as well. Hence, [7] suggested a modified approach that demonstrated competitive outcomes in standard dataset.

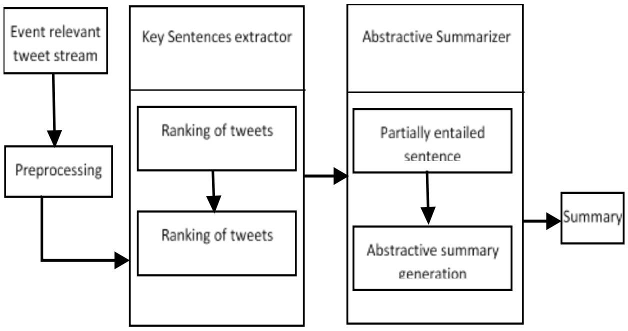

Fig. 2. [9] Summarization Approach.

Therefore model [7] suggests a new and exciting way to summarize one document. It also includes Partial Textual Entailment (PTE) as a way to get the power of expression within a couple of texts. Sentences are divided into units of text for the purpose of TE to compute which is why they are different from complete TE and are called intra-phrase sentences or PTE. Since a graph model is known to capture and present a well-defined structure of information with information shared between interconnected areas within a complex network, so authors will use a graph presentation to illustrate the relationship between different pieces of text. Then authors used the weighted (Minimum Vertex Cover) method of MVC, a graphical algorithm to get a small vertices' set (representing sentences) that make up the cover. And this cover forms their final summary [7].

The text summary function was created as a WMVC problem by them. The input document provided to the system to be compensated and rewritten and labeled as a graph network. They built a targeted, weighted graph model where border instruments could not be considered. Accordingly, the weight w is already expressed in each graph node based on the entailment values obtained. This improved graph form to date is placed under WMVC method [7]. This algorithm works by narrowing down the graphical network so that the cover C is a subset (part) of the smallest sentences weight, meaning the best-placed sentences in the text. The cover that has been found is this result - a summary of the input document. Model [7] Recommended Method of partial Text entailment Used Baseline Weighted Minimum Vertex Cover (PTE-WMVC), shown in Fig. 3 is contained the following key steps:

- Pre-processing step
- PTE score computation
- Salience scores computation
- PTE based graph construction
- Applying WMVC algorithm

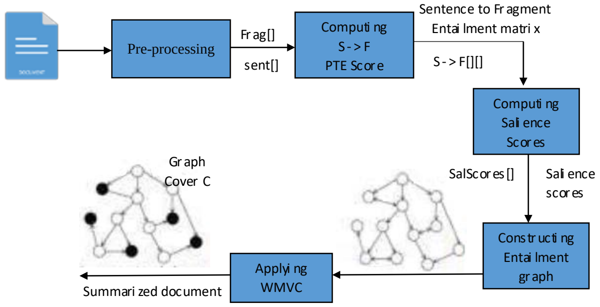

Fig. 3. PTE-WMVC Structure Diagram [7].

Finally, the authors compared the effectiveness of this approach with other leading methods in the field of text summarization. This PTE-WMVC system provided the highest recall value of 50.99% of ROGUE-1 while n-gram size was considered N = 4. The next best performance is provided by WMVC with a recall value of 38.8% followed is PDT at a rate of 34.6%. A very small amount of recall was identified by the program and ATESC as the basis for text processing in the system [7]. In [7], authors introduced an amazing and advanced way of summarizing a single text. Through extensive experiments in the database that showed in this paper the proposed algorithm uses Partial Textual Entailment at its end it uses existing techniques that look at complete textual entailment to establish relationships between sentences.

The suggested algorithm has been used successfully in small sections of sentences, uses Partial Textual Entailment and produces clear and reliable measurements. Building such a system and dealing with the same method of summarizing multiple documents by taking advantage of the functionality of the proposed algorithm involves future work. Future work of [7] will be more focused on summarizing many documents. The creation of a summary requires multiple textual sources and often involves a combination of collections of various texts.

B. *Question Answering*

Question Answer (QA) is an ancient research field in computer science that started in the sixties. In the Semantic Web, most of the suspended data is now available in the form of knowledge bases (KBs). Today, there are KBs on media, publishing, geography, life-science and more. The main purpose of the QA program over KBs is to retrieve the information you want from KB or more, using native language questions.

In summary, most QA programs only work in English and more than one KB. Multilingualism is taken for granted while carrying it can often be taken for granted. The fact that QA systems tend to use existing technologies and require several services to be presented to the end user, leads to the idea of developing QA systems in a general way [11].

Model [12] introduced new data and text implant model, which is derived from the treatment of answering multiple queries in the selection as an input problem. SCITAIL is the first input set created only from natural sentences that already exist independently "in the field" rather than sentences written specifically for the input function. In addition to the required input details, they construct add-ons from scientific questions and related answers, as well as structures from relevant web phrases taken from the larger corpus. These sentences are often a language challenge. This, combined with the high similarity of the baseline and hypothesis in both paired and non-entailed pairs, makes this new entailment work even more difficult.

Model [12] present the largest input data taken directly from the final task and contain text that appears naturally as both the basis and hypothesis. The model new data, SCITAIL, is designed for the final task of answering high school science questions. Each question and their relevant answer is converted into a supporting statement for hypothesis H. they use the retrieval (IR) method to obtain relevant text from the business of large web text documents, and use one of these sentences as Layout P. -H, not all that includes P or “supports” the statement in H. They include annotations for each hypothesis structure head as a support or not, to create SCITAIL input data with 27K examples.

Since both the foundation and the drawings in SCITAIL were written independently of each other and without the inclusion function, the linguistic diversity of the database is not limited to the coverage of handwritten rules or by crowds of clever staff two pieces of text [12].

They show that one can improve SCITAIL accuracy by 5 percent using a new neural model that exploits language structure. And found that current RTE systems, including neural input models, have interoperable functionality in this data, whether they are trained in their data or in SCITAIL. Specifically, their asymmetric Decomposed Graph Entailment Model (DGEM) raises an accuracy by 2.3%. They make the following contributions:

1) A natural input database in which the text and transcripts were written independently of each other and independently of the input function;

2) Initial data taken from the final task of answering multiple questions; and

3) A new model that uses language more recklessly in the hypothesis than the existing strategies in this data.

Recently, text submissions have received significant attention due to their extensive use of retrieval information, commendation programs and answering questions. Information extraction (IE) is an Automatic retrieval of certain information related to a selected topic from the body or bodies of text. Extraction tools enable us to retrieve data from text, information, websites or multiple sources.

Recently, various frameworks for textual entailment recognition have been proposed, ranging from traditional linguistic strategies pertaining to different deep learning methods. However, the deep neural networks that reach the state of the art in textual entailment task look only at the details of the given sentence structure rather than the real world knowledge and information beyond context. In [13], they propose a Knowledge-Context Interactive Textual Entailment Network (KCITEN) that reads graph-level presentations by tying a graph of external information through a graph-focused network. They also propose a Text-graph interactive reading system for neural learning entailment, which allows for unwanted noise and noise and focuses on informative presentations. Examination in the SciTail database shows that KCI-TEN works better than state-of-the-art methods [13].In addition to the practical application of previous studies, textual entailment recognition models have two limitations as follows:

- Underutilize the large-scale real-world knowledge: Existing RTE models may suffer from language challenges due to the high similarity of the lexical premise and the hypothesis of both blocks included and excluded.
- Perform learning and inference between text and large scale KG without explicit interaction: These methods [13] are useful for easy comprehension of concepts but can lead to a lack of communication between text-based embedding and KG-based embedding during the editing process.

To address these two limitations , in [13] proposing a novel representation framework, the Knowledge-Context Interactive Textual Entailment Network (KCI-TEN), which makes full use of the external KG to determine whether a given text incorporates a given hypothesis. Specifically, the proposed approach begins to convert the concepts and basic sentences into KG sub graph, incorporating them into the context and contexts of the environment through a graph attention network (GAT), providing an additional incentive to explore external sources of textual recognition. Thereafter, the included vectors are used to calculate the basis for comparison-hypothesis corresponding to the text level and graph level respectively. Finally, using a method to read the matching representation in size, using practical information from text and KG, and re-inserted into the classifier to get textual entailment [13]. The model concise contributions are:

- Creating an effective RTE communication framework, which directs the external KG to obtain background information and understanding.
- Investigating the feasibility of graph-based submission by approving GAT to carefully insert KG sub graphs.

The results of the experiments indicate that KCI-TEN successfully incorporates the conditions in terms of KG sub graphs [13].

Recognizing inclusion relationships between sentences is an important and common part of language communication. RTE function has been proposed as the solution to this problem. In [14], they introduce the Arabic Recognizing Textual Entailment Tool called Ar-SLoTE “Arabic Semantic Logical Textual Entailment Tool”. Model [14] suggested tool is made up of five modules: pre-processing, linguistic analysis, first-order logic representation, features extraction and entailment decision modules. It produces logical representations of hypothesis / text pairs in order to extract important and informative features, namely, predicting the dynamics of contradictions, exactly the similarities.

Ar-SLoTE is mainly based on Arabic question / answer procedures and the results obtained are very encouraging. Obtaining RTE In many NLP applications is by performing many tests, including the Question-Answering (QA) programs. Therefore, RTE helps to determine whether the given answer entails the question asked or not. There are various methods suggested in the literature to determine which entailment into this field. However, in the Arabic language, there is a shortage of RTE services provided in QA programs.

As long as, in [14] they are introducing an Arabic tool called Ar-SLotTE «Arabic Semantic Logical Textual Entailment Tool». For defining the entailment between a couple of question and answer they propose this tool. The correlation of the entailment is set as "TRUE" when it means how the question can be estimated from the answer and "FALSE" in another way.

Model [14] is based on the first logical presentations of the structure orderly to extract new semantic information from the H-hypothesis and the T-text. Three factors are excluded from the logical expression of T and H namely, the accumulation of Predicates-Arguments, the Semantic similarity and the similarity of the Name entity. A rating is given for each feature. After that, the feature vector is designed for each H / T pair. These doses are passed on to a tree decision reader to guess the category of each couple: «TRUE» if there is an entailment between them, and "FALSE» in another way. Ar-SLoTE is designed to detect the entailment relationships that exist between Arabic H/T. In particular, it sees the entailment between the true response and its answers. Noting that the real question is a question related to an entity with names.

In this situation, the hypothesis indicates the question asked and the text identifies the given answer. Thus, Ar- SLoTE takes, as an input, questions that start with test nouns (من who,ما what, أين where, متى when) and a list of related candidate responses. At the last, the entailment between the question and each answer was indicated. Research correspondent's response is considered an appropriate answer to a question [14].

Fig. 4. Ar-SLoTE Architecture [14].

As shown in Fig. 4 Ar-SLoTE architecture is built on five key modules, namely: pre-processing editing, linguistic analysis, first-order logic representation, feature extraction and entailment decision modules.

Model [14] approach focuses on the exclusion of elements from the two logical pathways taken from T and H, specifically, predicting contradictions, semantic similarities and word similarities. The Ar-SLoTE releases a file from type XML containing the accompanied results of entailment using confidence scores. Therefore, the result can be shown and translated by the user, or by machine.

As the [14] tool is designed for question / answer processes, authors have selected 500 operators of a variety of authentic questions and answers from the AQA-WebCorp Corpus. At first, they turned them into logical submissions. Second, the corpus was divided into two data sets: training set (350 pairs) and test set (150 pairs).

Reported to the following TABLE I, the results obtained by the proposed tool in [15], Ar-SLoTE and LR-ALL. Among the state-of-the-art technology that works for Arabic RTE, the tool proposed in [15] is the only function specifically intended for real-time question / answer systems. LR-All [16] Arab RTE system with highest accuracy. This paper uses traditional embedding features and words. In addition, it is based on machine learning and uses ArbTEDS dataset, the only available Arabic RTE data containing 600 pairs of T-H.

They have been able to be more accurate compared to the previous RTE system which was intended for question / answer applications (Ben-sghaier et al., 2018) [15]. Because the results obtained in [14]show that reasonable representation and appropriate relevance can improve the results of Arabic RTE. Authors said that Ar-SLoTE performance can be improved by integrating, in particular, additional cognitive information. One of authors' plans that focuses on testing their RTE tool on a large computer uses a large number of different questions / answers per pair. As a long-term quest, they aim to look at other types of questions [14].

TABLE I. COMPARISON BETWEEN AR-SLOTE AND OTHER ARABIC RTE SYSTEMS

System	Approach	Dataset	Accuracy
Ben-Sghaier, M. , W. Bakari, and M. Neji [15]	• Machine Learning based . • Use of semantic measure and word sense disambiguation.	200 Question/Answers pairs	70%
Ar-SLoTE	• Machine learning based • Use of logical representation and extraction of features	500 Question/ Answers pairs	73.33%
LR-ALL [16]	• Machine learning based • Use of traditional and word embedding features	ArbTEDS	76.2%

C. Information Verification

As the name itself implies, data verification is a process that verifies the authenticity of a person or company for a particular process that requires verified information. This process helps to verify the current status, including features such as hiring and accommodation, allowing an application that requires specific references to be completed by the preferred person or organization of applications.

Information verification is important because the level of information production is high and growing daily, usually on social media. This also results in social media being included as a mass media. Therefore, data verification in social media becomes even more important [6].

Information verification is a form of journalism investigation in which experts examine claims that have been published by others about their truthfulness. Claims can range from statements made by members of the public to stories reported by other publishers. The ultimate goal of a fact-checking system is to determine whether a claim is true, false or mixed.

In [6], a method of verifying information on Twitter is proposed. The proposed method uses textual entailment methods to improve the authentication methods on Twitter. Separating the effects of entailment methods over state-of-the-art methods can produce tweet verification results. In addition, as the writing style of tweets is incomplete and structured enough for textual entailment, they have used the language model to add tweets with official and appropriate text for textual entailment.

While the methods used to incorporate reinforcement inputs to verify data may have acceptable results, it is not possible to provide relevant sources for all tweets, especially in the past by posting tweets. Therefore, they have used other sources such as User conversational tree (UCT) without using input methods to verify tweet details. UCT analysis is based on pattern release at UCT. Test results show that using entailment methods increases tweet validation [6] as shown in the model architecture in Fig. 5.

Looking at the various challenges in obtaining rumors, they look at the findings of the rumor by the two-source analysis: (1) entailment based classifier, and (2) UCT-based classifier. Then, in each of the two sources, they train two different classifiers separately, and after that, use a weighted ensemble voting classifier, the results of these different classifiers combined to form a new classifier [6].

All in all, contribution to [6] to verify the details on Twitter is:

- Textual entailment is used to confirm rumors on Twitter
- A language model is used to make tweets more acceptable in the style of writing
- Consideration under UCT analysis
- Promote a weighted phase of voting to integrate the results of the inclusion process and UCT analysis

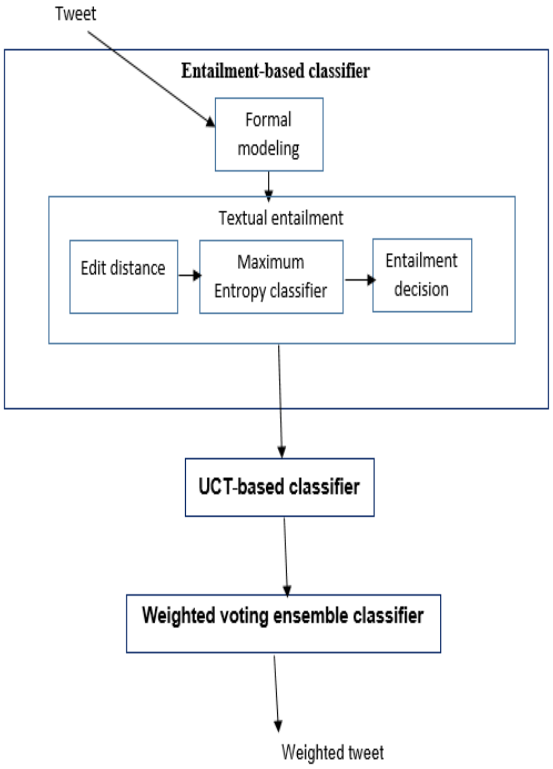

Fig. 5. Model [6] Architecture.

Information on the web is linked to rumors and unverified information. In addition, social networks as a special and broad part of the web have a lot of potential for spreading and creating inaccurate or unauthorized information.

Because of the importance of this issue, as well as improving the effectiveness of data verification, in [17] verification of data on social media is being investigated. Several features and conditions appear to be applicable to the detection of rumors.

Among the functional and structural features, authors consider two important sources of data validation in social media that include user responses and news organizations. User feedbacks as the primary source can be a user conversional tree. Some patterns can be drawn from this tree. Media agencies as a second source are also used for data verification by tools of text entailment. Finally, these two types of factors are combined to separate information into one of three categories true, false, or unconfirmed. This method was tested by checking public data sets. Test results show that the proposed hybrid information verification method can surpass highly recommended methods in data verification [17].

Today, everyone has some doubts about the information broadcast on the web or social media. This is because the amount of information that is visible on the web is wrong or unreliable. Moreover, people are exposed to all kinds of fake and uncertain information. Doubts about the facts of the information available on social media create public concern, especially in difficult situations or disasters. A large number of online false stories have the potential to cause great social problems. Stock markets has been affected by fake information on the web and social media, reduced responses during disasters and terrorist attacks [17]. Typically, bots collaborate to create and disseminate fake or wrong information on a large scale using bots accounting groups that work on a large scale for two purposes:

- by distributing the same content, e.g., by retweeting, to multiple viewers, and
- Increase social status by following each other's accounts and following trust information [17].

Those who try to stop the spread of wrong information are working to create programs that can reduce the way bots and other programs spread lies and slander. Most of the previous methods depend on the selection of the feature from the main text. In addition, the methods studied in the structure of graphs in social media [17] are popular with the rich history of graph reading. Recently, more comprehensive learning approaches have also emerged in this field. For example, recurrent neural networks (RNNs) are used to detect rumors from microblogs.

However, among current methods, the effect of resources on data verification cannot be ruled out. Therefore, in [17] to strengthen the validity of the data verification, the results of the sources are studied. The proposed method of this data in [6] uses the main sources of information, mainly feedbacks, and media sources. Initially, the effect of user feedback and media on the data verification function are studied separately.

Subsequently, these methods' results are gathered to determine the validity of the information. In the user feedbacks, the composition of the marked areas in the user conversational tree (UCT) by four types of tags, rejected, comment, supporting, and query, is considered. UCT is being studied discussed in the following three ways:[17]

- Pattern extraction: For UCT pattern extraction, the unique UCT patterns are calculated by looking at the pattern level in the tree. In these patterns, a tag for each node is selected, too.
- Statistical sequential models: By studying UCT sequencing models, two different types of sequence models are calculated
- Hidden Markov model (HMM)
- Conditional random fields (CRF).
- Edit distance: Set UCT learning methods used as standard K-nearest approaches to UCT classification with data verification function.

The second source of data verification is the media sources, which is useful for textual entailment methods. At this opinion, the text that feels authentic (called the main text) is considered to be either media or not. If not entailed, the main text is considered authentic. When the media compares with the main text, the main text is considered false. Otherwise, the main text is considered unverified. Suggested data verification methods are evaluated using public records by comparing the state-of-the-art-methods.

The results of these comparisons show that the proposed method works better than the existing alternatives presented in [17] database used.

The description of the method starts with the method's full description in the first subsection. After that, the two main parts of the method are explained, that were namely:

- Studying of user feedbacks and various components
- News sources studying

An overview of the proposed [17] approach to data verification activities is shown in Fig. 6. As shown in the figure, the input for data validation is a message from a social network.

After reviewing the input text, you are ready for verification. Using two different steps, verification work will be done: it processes feedbacks of users and new sources.

1) User feedback study: User response research is typically based on the UCT structure. UCT is a tree created when a message is communicated on social media or is often responded to. The root of this tree is the main message its authenticity is being questioned. After all, every response to this message is a child root. Previously, every response of each node in a tree is the next level of UCT.[17]

Thereafter, the UCT tagged is used to predict the final label of the input text using the following three methods in the next three paragraphs. UCT is studied in three ways including:

2) Pattern extraction: UCT derived pattern are considered features. These patterns are below each starting point with a maximum of three. Calculation of each pattern's occurrence is by looking at the weight, which is calculated by the level of the root scale relative to the height of each UCT.

3) Statistical sequential models: HMM and CRF are used in [17]proposed methods. The path label with the most voted priority is false, true, and unconfirmed is considered the last label.

4) Edit distance: Set the distance of each path at UCT calculated the most effective dynamic time strategy. this method uses a powerful planning method [17].

5) Study news sources: recognizing textual entailment

In this case, a source of information should be provided. When the main text, in which the message is confirmed as true message, is entailed from the new source, the source text is the first text. If the new source differs from the main text, then the main text is fake or wrong. Otherwise, the main text is not verified. The following methods of textual entailment are used in [17]:

- Edit distance comp (Fixed Weight Lemma/RES Word Net).
- MaxEnt Tree Skeleton RES (Verb Ocean Tree Pattern/ Word Net Tree Pattern/Word Net Verb Ocean Tree Pattern).
- P1EDA RES: Paraphrase Table.

To compare the [17] method with the state-of-the-art methods in which authors simulate tests similar to those performed in the Semeval-2017 work 8. The test methods are similar to this work, too. Test methods are Score, Confidence, Root mean Square Error (RMSE), and Final Score. The Score is ranked as the most known accuracy measure. Confidence RMSE is the RMSE Classified Confidence.

Existing new sources are critical to the success of this approach. And on some social networks, user feedback is not recorded and in this case this method is bad choice for data verification. In addition, the [17] method only applies to text messages. Examination of the this method of data verification in public dataset showed that the [17] method surpassed those who are technically competent in data verification.

Model [18] introduces ColumbiaNLP's submission of the FEVER Workshop Shared Task. This model is an end-to-end pipeline that delivers factual evidence using Wikipedia and provides a decision on the veracity of the claim based on evidence-based evidence. The FEVER shared function aims to test the capabilities of the data verification system using evidence from Wikipedia. Given a claim that includes one or more items (mapping to Wikipedia pages),the system in [18] must take written evidence (sentence sets on Wikipedia pages) supporting or disputing the claim and using this evidence, they must write a claim as Supported, Refutes or Not_Enough_Info. The shared work dataset is presented by [19] and contains 185,445 claims. *TABLE II* shows three scenarios from a set of claimant data, evidence and decision. The first system that used by [19] uses 3 main components:

- Document retrieval: using the documentation recovery component from the DrQA system that retrieves the adjacent text query using the cosine similarity between attached unigram and the bigram Term Frequency-Inverse Document Frequency (TF-IDF) vectors.

TABLE II. THREE SCENARIOS FOR CLAIM AND EVIDENCE AND DECISION OF [19]

Claim : Claim : Fox 2000 Pictures released the film Soul Food. [**wiki/Soul_Food_(film)**] **Evidence**: Soul Food is a 1997 American comedy-drama film produced by Kenneth "Babyface" Edmonds , Tracey Edmonds and Robert Teitel and released by Fox 2000 Pictures . **Verdict**: SUPPORTS
Claim : Murda Beatz's real name is Marshall Mathers. **[wiki/Murda_Beatz]** **Evidence**: Shane Lee Lindstrom (born February 11, 1994), known professionally as Murda Beatz, is a Canadian hip hop record producer and songwriter from Fort Erie, Ontario. **Verdict**: REFUTES
Claim : L.A. Reid has served as the CEO of Arista Records for four years. [**wiki/L.A._Reid**] **Evidence**: He has served as the chairman and CEO of Epic Records, a division of Sony Music Entertainment, the president and CEO of Arista Records, and the chairman and CEO of the Island Def Jam Music Group. **Verdict**: NOT ENOUGH INFO

- Sentence Selection: [19] simple sentence selection method sets out the similarities between TF-IDF and claim. They set the most similar sentences first and then using validation accuracy on the development set, they accurate a cut-off. Then they test both DrQA and the easy use of the unigram TF-IDF to measure selection sentences. They also examined the effect of sentence selection on the RTE module by predicting the entailment given to the original texts without sentence selection.

- Textual Entailment: It is a multi-layer perceptron (MLP) with a single hidden layer that uses frequencies of term and TF-IDF cosine similarities between claims and evidence as features. To analyze the state-of-the-art in RTE, they have used the decomposable attention model (DA) between the claim and the role of evidence.

Overall, [18] end-to-end model shows an improvement of 19.56 on FEVER results compared to the previous [19] (50.83 vs. 31.27) in the development set. system [18] of utilizes changes in all modules that lead to significant improvements in both development and testing sets:

- Document Retrieval: this step is an important step in establishing an end-to-end authentication and verification system. Missing the correct text can lead to untranslated evidence, while incorrect text can add to the noise of subsequent sentence selection task and textual entailment task [18] . In [18] authors suggest a multi-step approach to retrieving documents appropriate to claims:
    - Google Custom Search API: inspired by previous research [20], the Custom Search API of Google was used first to retrieve documents having information about the claim. The token Wikipedia was added to the claim and produce a query and gather the top 2 results.
    - Named Business Recognition: Identifying an entity name using a previous activity, and after finding the entities that be named in the claim, authors use the Wikipedia python API 3 to gather a high-rated wikipedia document returned by the API for each named entity.
    - Dependency Parse: to increase the chance of finding the right entities in the claim, they get the first sentence of lowercase letters, Reason to emphasize the lower case verb phrase to avoid non-claim entities such as "Finding Dory was directed by X", where the appropriate entity is "Finding Dory" [18].Then they decide to create better accounting models to handle entity ambiguity or entity linkages in the future.
    - Combined: Authors use the documentation union returned by these three methods as the final set of relevant documents to be used by the Sentence Selection. They note that their (combined) method in [18] reached a high accuracy of 94.4% compared to the original method [19] of 55.3%. Because authors do not have best evidence of blind set test they cannot report claim coverage using their pipe.

- Sentence Selection: authors used a component to retrieve translated texts of DRQA [20] to sentences selection using the bigram TF-IDF for binning as suggested by [19]. They extract the top five sentences in the appropriate text k-most the related documents by using TF-IDF vector matching. To solve the previous problem that arose in selecting sentences of [19] authors continued to filter out the top 3 evidence from chosen 5 evidences using distributed semantic representations. Model [21] show how the deep representation of words modulates the complex aspects of word use (e.g., syntax and semantics), and its use in a variety of language contexts. Therefore, converting claim and evidence to vectors using ELMo embedding. then [18] calculated the cosine similarity between the claim and the vector of evidence and produced the top 3 sentences based on their score.

- Textual Entailment: authors did not show evidence, but trained model for each pair of evidence. For textual entailment recognition they used the previous model in their work on the supervised learning of the representation of universal sentences. They use bidirectional LSTMs for max-pooling to encode a claim and evidence. In word matters in pre-trained word embedding it is a major stumbling block to sentence representation. To resolve this they use fast text embedding based on subtitle information. Also, this embedded training in the Wikipedia corpus makes them the right choice for this method. Their final predictions are relied on the next algorithm in Fig. 7.

Because the selected evidence was naturally noisy and this pipeline [18] did not verify the evidence together they chose this rule rather than more prediction to reduce the rule of prediction of the NOT_ENOUGH_INFO class.

```
Algorithm 1 :
if count(Support)=1 and counr(Not_Enough_Info)=2 then
print(Support)
else if count(Refutes)=1 and count(Not_Enough_Info)=2 then
print(Refutes)
else
print(arg max((count(Support), count(Refutes),count(Not  Enough  Info))
```

Fig. 6. Algorithm Used To Make A Decision In Module.

TABLE III. FEVER SCORES ON SHARED TASK DEV AND TEST SET

Data	**Pipeline**	**FEVER**
DEV	[19] module	31.27
	This module	50.83
TEST	[19] module	27.45
	This module	49.06

Module [18] also tried to train a classifier that takes confidence scores from all of the claim/evidence and their status in the text and trained an improved classifier but the accuracy was not improved. Experimentally the rule has given them good results in the development set and thus they used it to get the final label. *TABLE III* shows the total FEVER points obtained by [18] pipeline in development and test sets. In that time ranking [18] system ranked 6th.

The new models cannot rely on models that rely entirely relied on semantics. Although the two sentences are similar, the similarity of the cosine between them is worse because the evidence contains many additional details that may be inconsistent with the claim and difficult for the model to understand. They also found cases where the predicted evidence was accurate but not consistent with best evidence. But this system is being penalized on not being able to match the best evidence. Module [18] has found a few annotations that are incorrect which is why FEVER scores are lower than expected. Sometimes, the lines between SUPPORT and NOT ENOUGH INFO are not cleared enough. This models need a better understanding of semantics in order to be able to distinguish between them in all cases.

D. Sentiment Analysis

Sentiment analysis (emotional AI or mining opinion) refers to the use of natural language correction, text analysis, related languages, and biometric to directly identify, extract, measure, and read the corresponding regions and information.

Sentiment Analysis tools now are slow, and it is the most difficult statistics that make the work well done. Sentiment analysis can be subdivided on the basis of a separate textual text. It can be categorized at three levels discussed briefly below:

- Document Level Analysis: analyzes the contents of the document as a whole to determine its availability.
- Speech Level Analysis: Pays attention to the various sentences of a document by continuing to break it into small word texts to analyze its structure.
- Word Level Analysis: Determines the minimum number of different words in a sentence in relation to an item or event.

Previous work defines hypothetical analysis as research to determine emotional AI. Sentiment analysis work involves finding out the feelings, status, person's opinion, object, product or event that has worked in areas such as academics, business and industry. Sentiment analysis work can be categorized on the basis of different classes - can be analyzed as positive, negative or neutral based on class.

Appropriately, authors cannot accurately measure guidance using TE for a number of reasons such as complexity of sentences and limitations of available language resources. Therefore, (PTE) is using to measure the degree of inclusion whether the text fully integrates the concept or not. The authors plan to use Partial Textual Entailment (PTE) to improve the work of Sentiment Analysis in [22]. It is expected to reduce the amount of work done in analyzing the text view thus providing a better solution for SA work. The method proposed in [23] is to carry out the task of analyzing the sentiment by exploiting the concept of partial text entailment. They suggest using the partial textual entailment to measure semantic similarities between tweets in order to combine the same tweets. The method is expected to reduce the burden of sentiment analysis and make processing faster. Then, authors propose to change the method of partial text entailment that can be adapted to most NLP applications. The purpose of [22] is improvement the task of sentiment analysis using partial textual entailment.

The authors propose a two-part Sentiment analysis approach:

a) A method to improve the PTE recognition process and

b) To improve the Sentiment analysis method using the partial textual entailment.

E. Designing a Method to Improve the PTE Recognition Process

The proposed idea is to expand the add-on model to increase due to the large number of feature builds and produce relevant results that done by deleting helpful words. Elements will be constructed only using the sentence title as the key word in the construction of the elements. This approach is expected to predict the best of text input as the text revolves around the topic of the sentence[22].

1) Choose text and Hypothesis

2) Re-analysis of the text and Hypothesis by removing helpful words

3) Subject identification: Subjects from sentences are selected from the remaining words written separately.

4) Structure construction: by matching the remaining words with the subjects

5) Composition of partial text entailment will be performed

F. Creating a Way to Improve Emotional Analysis using Partial Text Entailment: Authors Discuss the Entire SA Framework using PTE Below

1) Recognizing new models or methods for Partial Textual Entailment: this step will do the job of collecting similar tweets to reduce the burden of sentiment Analyzer which has led to the rapid implementation of updates. Integration recognition will be done using the BIUTEE tool.

2) The result obtained in Step One will be forwarded to a mood analyst to get the feelings of the speech.

The total number of sentences that entail the hypothesis will then be provided as an estimator of how strong the sentiment is[22].

Model [23] aims to increase the accuracy of the entailment of Arabic texts using resolving ignoring of the text-hypothesis pair and determining the splendor of the text-hypothesis pair whether it is Positive, Negative or Neutral. It is noteworthy that the absence of a negation detection factor provides negative results when detecting the correlation of the factor since contradictory returns true.

Contradictory words are considered termination words and are removed from the text-hypothesis pair which can lead to improper entailment decision. Another case that has not been resolved before, it is impossible for the correct text to include the wrong text and also the same for the opposite order. In [23], in order to distinguish the text of the hypothesis pair contradiction, a sentiment analysis tool is used.

Authors show that processing the essence of a text-hypothesis pair increases the accuracy of the entailment. To test [23] method of the ArbTEDS archive (ArbTEDS) dataset which comprises 618 text-hypotheses pairs and shows that the accuracy of Arabic entailment increases by resolving the inconsistencies of the entailment and analyzing the unity of the hypothesis pair. The main problem with the original Arabic texting systems is that they do not see the negation, where negation brings back the truth and does not take the critical side where negative or positive thinking does not convey the opposite feeling. To their knowledge, [23] represents the first attempt to recognize the influence of resolving negation and emotional polarity in the Recognition of Textual Entailment in the Arabic language. They conducted research on the Arab Text Entailment Dataset (ArbTEDS) [24]; shows that the more accurate the discovery obtained by resolving the negation and the more consistent finding of this text-hypothesis.

In this work, authors face the challenge of creating an Arabic text-entry system that produces relevant results. The proposed project in [23] ,that it is shown in Fig. 8,is called Sentiment Analysis and Negation Resolving for Arabic Text Entailment (SANATE) which enhances ATE method (ATE Method is described in [23]).

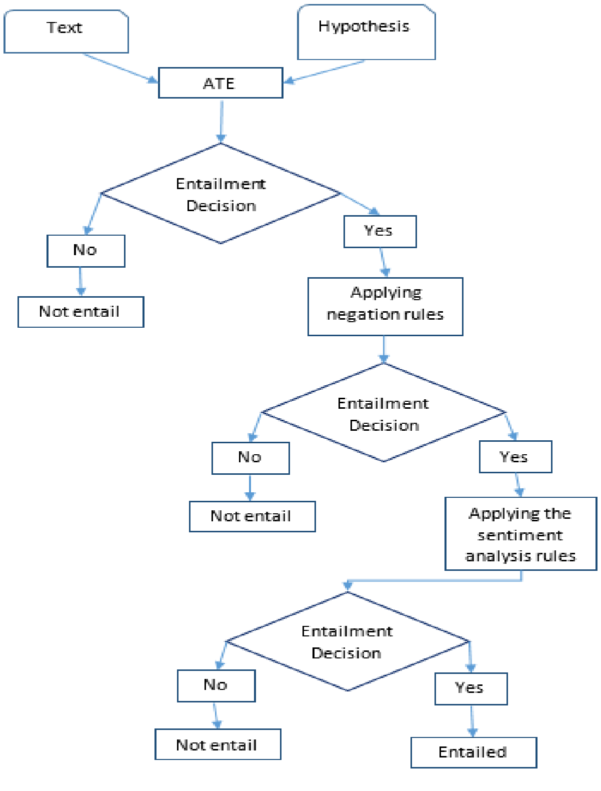

Fig. 7. General Diagram of Sanate System [23].

To improve ATE, they set some rules for negation. If the decision to include ATE is "not entail" then no further consideration is included. If the decision to include ATE says it will be "entail" then a set of rules will be considered. The rules used to do some text and hypothesis entailment include [23]:

1) If negative particles appear before the same action (normal action) in the T or in the H, the judgment will be: not entails

2) If the negative adverbs appear before the normal action in the T and in the H (both), the judgment is: entails

3) If T and H have a different verb and are negative particles appearing before the verb in the T or in the H or in both, the judgment is: NOT entails

4) If the text-hypothesis pair has more than actions (verbs), then:

a) If one of the normal actions is ignored by one of the negative particles in T or H but is not ignored in both (T and H), the judgment is not entail.

b) If the normal action is ignored by one of the negative adverbs in T and H (both), judgment will be entail.

5) If text and hypothesis contain Opinion words (R):

a) If the result R is not the same as T and H which means different variations, the judgment is not entail.

b) If output R is the same for T and H, judgment will be entail.

To analyze how they use it they have used the 618-text-hypothesis archive (ArbTEDS) database. Each pair of ArbTEDS text is integrated into the ATE system and the SANATE system. Calculation of the accuracy for each system is made by the accuracy of the equation: the measure of the determination of the entailment target to the total value of the entailment problem. ATE accuracy is 0.617 and SANATE accuracy is 0.693. From the impact of the ATE and SANATE system, it is shown that resolving disregard and dividing a text by its contradiction by analyzing emotions, improves the effectiveness of co-identification and non-entailment relationships[23].

Authors conducted research on ArbTEDS; which shows that it is a more accurate result to find entailment to negation and to analyze the unity of this text-hypothesis pair. Without resolving the entailment decision to engage in negation authors may argue, because negation gives the opposite of reality. Some texts may have entailed but the presence of negative particles alters the decision of entailment relationships [23].

Another result from this experiment, finding text and hypothesis pair polarity has a significant impact on finding entailment related to non-entailment. It is impossible for a positive idea to combine negative ideas with the opposite[23].

Fundamental topic in psychology is understanding what makes people in a good mood .Previous work has focused on the development of individual reporting estimation tools and relies on experts to analyze estimated reports from time to time. One of the objectives of the analysis is to understand what is needed to promote individual behavioral change in order to improve the well-being of all [25].

In [25], they set an integral approach; with the view that the user incorporates his or her enjoyable moments as short texts, the system can analyze these texts and provide stable user suggestions that may lead to general improvements in his or her well-being. Authors set one required part of such a program, the Happiness Entailment Recognition (HER) module, which takes as an insert a brief description of the event, a candidate proposal, and outputs the decision of whether the suggestion may be appropriate for this user depending on the event specified.

This part is used as a neural network model with two encoders, one for user input and one for sustainable suggestions, with additional layers for capturing psychologically important features during fun and suggestion. The achievement of [25] the AU-ROC of 0.831 and exceeds their base and current AllenNLP Textual Entailment model by more than 48% development, ensuring the distinction and complexity of HER work.The HER module is described in Fig. 9. This module (1) detects candidate suggestion, and (2) identifies which suggestions are reasonable for specific users. As an input in this module, users create short-term journal entries for "good times," proven interventions to improve subjective well-being.

The first task defines proposals as sustainable in the sense that they promote short-term prosperity without harm in the long run, even if the same suggestion is repeated. For example, a user may report that receiving a puppy or buying a new car has made them happy. However, they do not want to recommend doing them again because repetition is impossible. On the contrary, activities such as swimming or walking in the park have the potential to improve the well-being of the user and are repetitive, These activities were viewed as probable suggestions [25]. Such suggestions become part of this DB Proposal. Appropriately, field experts (e.g., psychologists) would be able to create those consistent suggestions, but [25] also develop a classifier that reflects exciting moments with sustainable activities, and ensure that the classifier accomplished AU-ROC of 0.900.

Second task present the problem of the happiness entailment recognition (HER), which is motivated by the problem of recognizing textual entailment (RTE) in the NLP: given a set of fun times reported by the user, and a set of possible activities, which activities can make the user happy? Model [25] is developing an improved neural network (NN) model with information about concepts, agency, and personalities to predict with the AU-ROC of 0.831 whether the suggestion matches the moment of happiness.

"Concepts" represents topics that are common to HappyDB as an important vector. “Agency” and “personality” are binary indications that the author was in control of their happy time, and that there were other people involved, respectively. They say that this classification includes psychological ideas that are important to that task [25]. The results of the experiment [25] indicate that in this task, the proposed approach exceeds the recognition model for the textual entailment, as well as their foundation. The results support that the HER function is very different from normal text entailment task, and that adding a mental view of the model improves performance.

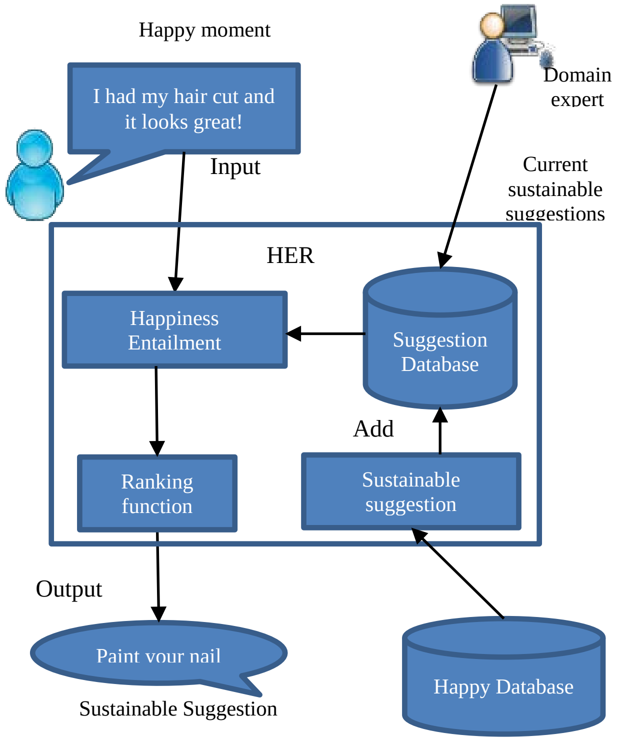

Fig. 8. Her Module and its Inputs and Outputs [25].

III. Machine Learning vs. Deep Learning in Textual Entailment

A. *Machine Learning*

Machine learning is used at different stages in the RTE process (i.e. pre-processing, alignment and decision steps), which is usually combined with previous methods. A general model presents this task as a classification problem that is supervised by two classes (entails, not entail) or three classes (entails, not entails, contradiction). Each pair (text, hypothesis) to check is represented by a feature vector, which includes the scores of several operations applied to the pair at different levels[26].Some of described papers used Machine learning to enhance their models . These techniques are Support Vector Machine (SVM), Glove Embedding, Extreme Learning Machine (ELM), decision tree classifier, Naïve Bayes, and Root Mean Square Error (RMSE). All of these techniques are really enhancing the papers result but still in small datasets, and these results compared to deep learning, deep learning enhanced the model in results and with bigger datasets was detected as shown in next table.

B. *Deep Learning*

Deep learning strategies are becoming increasingly popular in the work of entailment text, overcoming the complexity of different traditional models with complex alignment and ideas. Deep learning in neural networks has become a popular method of machine learning due to the recent success of computer vision, speech recognition, and other areas. This latest achievement is a direct result of being able to train in big data sets, from labeled images for object recognition to compatible machine translation texts. While such information has been widely available from public sources to date, confidential information collected from individuals will not only provide incentives for existing applications, but also provide new impetus for deep learning. Deep learning is a key technology behind the most recent applications. In deep learning the achievement tasks that directly detect text, image or sound can be learnt by computer models. High accuracy was achieved in deep learning models, sometimes exceeding human-level performance. Textual Entailment approaches will help in many of natural language processing applications, including question answering, summarization, text generation, machine translation, and information extraction. In previous described papers that used several deep learning techniques as Text rank, long short-term Memory (LSTM), Multilayer perceptron (MLP), bi-directional Gated Recurrent Unit (bi-GRU), and Graph Attention Network (GAT).these techniques results with shown next.

TABLE IV. TEXTUAL ENTAILMENT PAPERS

Paper	**ML vs DL**	**Method Used**	**Comments**
Sentence similarity estimation for text summarization using deep learning[10]	DL	Text Rank	Use it in sentence similarity
A New Approach for Twitter Event Summarization Based on Sentence Identification and Partial Textual Entailment[9]	ML	Rank SVM	Use Word2vec to measure word-to-vector similarity of a word give high score compared to another techniques during Rouge metrics. word2vec model is not a deep learning model. It just a library in deep learning
Text Summarization using Partial Textual Entailment based Graphs[7]	No		Used only for single document with small fragments of sentences
A textual entailment dataset from science question answering[12]. DGEM	DL	LSTM MLP	to capture the semantics compute the representation for each node This model raises the accuracy to 77.3%.
Knowledge-aware Textual Entailment with Graph Attention Network [13]	Both	GloVE embedding Bi-GRU GAT	Bi-GRU to encode the contextual patterns Using GAT to encode node contexts in various and noisy KG subgraphs instead of using fixed pre-trained embedding for nodes. Its technique raises the higher accuracy of previous method by +0.8
Ar-SLoTE: A Recognizing Textual Entailment Tool for Arabic Question/Answering Systems [14]	ML	Weka DT	Uses a small set than ArbTEDS, and their model get less accuracy than LR-ALL, but compared to another module its accuracy exceeds another module with 3.33%
Information verification improvement by textual entailment methods [6]	ML	ELM	They want to study more special pattern of UCT ELM is used in deep learning networks but researchers argue if it is considered as a deep learning technique by itself or not even it has only one hidden layer as described before
Information verification in social networks based on user feedback and news agencies [17]	Both	ELM Naïve Bayes SVM RMSE	MLP is used in deep learning techniques but it is not considerd as DNN because it only forward direction Work better than another state-of-the-art-merthod that use the same dataset. The results of hybrid method show that it is more efficent than the results of separate use of user's response approach and entailment approach individually.
Robust Document Retrieval and Individual Evidence Modeling for Fact Extraction and Verification [18]	Yes	Bi-LSTM	Blind set, score = 49.06 > baseline's score= 27.45 dev set , score =50.83 > baseline's score = 31.27
Sentiment Analysis using Partial Textual Entailment [22]	No		This method is not implemented yet , using extended The BIUTEE for RTE
A study of the effect of resolving negation and sentiment analysis in recognizing text entailment for Arabic [23]	No		It has a major cons where it can detects polarity of a text and hypothesis pair significantly affects the detection of entailment and non-entailment
Happiness Entailment: Automating Suggestions for Well-Being [25]	Yes	Bi-LSTM	Bi-LSTM = 0.900 is more accurate by 0.133 with the best accuracy (Logistic Regression)

C. Difference between ML and DL[27]

- Data dependencies : Machine learning can trace on less data where deep learning requires large data
- Hardware dependencies : Machine learning can be traced on normal CPU but deep learning requires high performance machines with GPUs to be trained probably
- Feature processing: In ML, most app features must be determined by an expert and entered as data type. Values, shapes, textures, locations, and orientations are features of Machine learning. The performance of many ML algorithms depends on the accuracy of the extracted features. Attempts to obtain high-quality features directly from the data are significant differences between DL and traditional machine learning techniques. Therefore, DL minimizes attempts to design a feature to extract for each problem.so DL has higher accuracy than ML
- Problem solving method : machine learning use many sub-problems and solve them where deep learning is direct end-to-end problem solving
- Interpretability: DL can be tuned in various different ways, while ML has limited tuning capabilities.
- Execution Time: Deep learning in general takes a long time to be trained where some machine learning algorithms have short training and test times.

From the previous comparison, we concluded that deep learning performs better than machine learning. Unlike machine learning, deep learning has proven its ability to handle massive amounts of data. Deep learning can also solve problems that machine learning cannot provide, giving higher accuracy and reducing time. *TABLE IV* shows the textual entailment papers comparison that clarifying method used and whether machine learning or deep learning is applied, including comments on the performance of each method used.

IV. Conclusion and Future Work

Textual entailment is a remarkable field of natural language processing that is used in a variety of applications. Textual entailment applications include text summarization, information validation, question answering, sentiment analysis, etc. This paper spots on famous applications in Textual entailment. By studying previous methods and applications, this survey concludes that deep learning techniques can be used in entailment applications (such as rumor detection and depression detection) to facilitate and enhance the entailment process. It is also concluded that the textual entailment helps to extract data from social media applications and can deal with the huge amount of data more accurately with the aid of deep learning thus, the results are higher in accuracy. When dealing with massive data, more noise and detailed data are found. One text can contain several meanings, and different sentences can show the same concepts. This variation in semantic expression can be considered double trouble of language ambiguity. Textual entailment is the same but minimizes weakness the relationship to be one way. In addition, textual entailment can achieve text understanding in question answering applications. Despite using question answering applications in e-learning, it can be used in creating a clinical dataset by extracting information from regular documents. Also, it can be used to offhand extract patients' data and export it to health insurance applications.

In future, the GRU technology can be used along with textual entailment. Also, a pipeline containing more algorithms can be used. The aim is to automatically fine-tune the algorithms' parameters to achieve a higher percentage of accuracy and confidence, and discover which of those algorithms can fit the used dataset. Another future direction is to combine NLP and textual entailment with deep learning to outperform results in depression detection in social media. In conclusion, considering the promising results when using GRU in knowledge-aware applications, it is hoped to get higher accuracy when using textual entailment in depression detection.

Improved Exemplar based Image Inpainting for Partial Instance Occlusion Handling with K-means Clustering and YCbCr Color Space

Deepa Abin[1], Sudeep D.Thepade[2]
Computer Department
PCCoE
Pune,India

***Abstract*—The images acquired in real time outdoor environment are often subject to uneven illumination conditions, cloudy weather, lighting conditions. The instances of partial occlusions deteriorate the background modeling of such scenes. Varying illumination outdoor scene set of images with partial occlusions are addressed through this investigative work. There is a need for a restoration method that finds improved subjective perception and execution time. The proposed work focuses on novel amended exemplar model to improve the subjective perception. The exemplar inpainting method is improved through the color quantization with K-means clustering approach in YCbCr color space. Experimental validations and proposed method results show better improvement in qualitative and objective measures than existing methods. The average “Peak Signal to Noise Ratio (PSNR)” as 28.2869 and “Structural SIMilarity index (SSIM)” as 0.9759 of the proposed method has shown better results respectively both visually and with a tradeoff in time.**

Keywords*—*Partial occlusion; exemplar inpainting; K-means clustering; YCbCr color space

I. Introduction

This paper presents an improved exemplar inpainting method for partial occlusions in illumination variant scenes. Seeing through the partial foreground occlusions is crucial in computer vision, such as detection and tracking in surveillance [1,2]. Scene understanding has been one of the significant foundations in machine perception. The real-world scenes comprise of multiple objects being occluded by other objects. The objects behind occlusions cannot be completely observed.

Occlusions are restored by regeneration of the gaps or by filling the regions in a visually pleasing way by using the image inpainting methods. Inpainting remains a progressive area in Image Processing domain. It is a kind of technology that uses the image information to remove objects or fill the missing region. After image inpainting, the image can be restored to the original and accord with the human visual sense. The subjective perception is of paramount significance in image inpainting. Substantial amount of work has been carried out in literature. However, extensive research yet needs to be carried out for further enhancing the qualitative results [1-5,8]. The Subjective and Objective Quality assessment of the inpainted images still remains an open problem.

In this work, an amended exemplar inpainting method is used for regeneration of partial occlusions through which the texture and color is preserved. An approach which can help restore the naturalness of a scene with less computation time is the primary objective of this work. The subjective perception is paramount in image restoration methods. This novel amended approach of K-means with exemplar based on the inpainting method has shown a tradeoff in subjective perception and execution time. In literature, quantization with diffusion based inpainting method [3,8,18] and PDE based method[3-4,14] has been attempted. The K-means approach has been used here for the color image quantization. The color image quantization however, is ancillary but still remains very important in image clustering. It is a process to reduce the color distortion quantitatively in the image [6,7,9]. There have been conventional image clustering algorithms in literature and out of these numerous methods, K-means clustering happens to be the simplest and widely used method. It typically focuses on minimization of sum of squared distances from cluster centres to all the points that can further relate to compact clusters. These resultant compact clusters have been further used in our improved inpainting process.

The non-uniform illumination in real scenes poses challenges towards the intrinsic inpainting performance. Visual perception is of supreme relevance in today’s era of digital imaging where numerous applications in computer vision involve illumination variant scenes. The research paper here mainly contributes to the regeneration of background during partial occlusion instances in non-uniform illumination scenes.

The three preliminary contributions of the proposed method have been as follows:

- Improved exemplar based on painting with Color Quantization using K-means clustering approach for non-uniform illumination variant scenes.
- Extension of the proposed method with YCbCr color space.
- Empirical value of ‘K’ in K-means color quantization.

The paper has been ordered as follows: The Section II mainly presents the related work and in Section III the proposed method is presented. In Section IV, the experimental results are thoroughly discussed and have been analysed in a qualitative and quantitative manner. The conclusion is summarized and presented in Section V.

II. Related Work

Here, we discuss the significant image inpainting methods, with major focus on exemplar based inpainting to provide a prerequisite for our approach.

There are different techniques of image inpainting [2-4,12-13,19-21,23,35] existing in literature. Mainly they can be classified into Texture Synthesis Inpainting, PDE Inpainting, Exemplar Inpainting, Hybrid Inpainting and Fast semi-automatic inpainting.

In 'Texture-Based inpainting methods', the missing regions are filled by sampling alongwith copying adjacent pixels [3,30]. There is a constraint in effectively handling edges and boundaries well. The natural scenes are not well addressed using this method, as it is formed of edge based structures.

'Partial Differential Equation (PDE)' is based on an iterative approach [3,14,29], produces good results when missed regions are smaller and time consumption is more when missed regions are larger.

The missing regions are filled in case of a hybrid approach using a combination of texture based synthesis and PDE method. Here, the division is mainly done into separate sections, structure based and texture based regions. The missing regions are filled up using edge propagating algorithms in combination with texture based synthesis techniques. It is computationally exhaustive when larger regions are considered.

The semi-automatic inpainting technique adapts a two-step process. Firstly, user interaction is used to specify missing information by using object boundaries followed by patch-based texture synthesis. The time consumption is relatively more in this method. However, in literature exemplar based inpainting methods has shown better image restorations. Hence, in order to deal with occlusion, the Exemplar based inpainting method is used for selected partial occlusion in the non-uniform illumination images to retain the texture and color. This exemplar based on the inpainting method, can be further improved in time and perception. The exemplar based technique is an efficient methodology to reconstruct larger target regions. The two basic steps comprise of priority assignment and selection of the patch that suits best. The patch that is best suited is selected for the target region and when obtained, the source value pixels are copied to the desired target region. The choice of varied patch matching criterias, size of patch and region filing have a great effect on results. For the missing regions wherein simple structure and texture is included, Exemplar based Inpainting method is observed to produce good results. The papers [16-18], discusses the need for improved exemplar based techniques. K-means clustering finds the the best trade-off between subjective evaluation and time. Due to its simplicity, the K-means algorithm [11], being the most popular amongst the clustering methods, has proved rewarding in enumerous applications. Though K-means is widely used as clustering algorithm, it has been actually considered as a quantization algorithm. The main goal being compression with probability distribution of K points. Higher quality images consume more storage as compared with lower quality images. Color quantization reduces the color quantity in an image where subjective error is minimal when quantized image and the original is considered. The clustering technique is used as a tool for color quantization and produces good quality results.

Out of the many techniques available for compression, K-means Clustering creates clusters comprising of major colors that further adds to computation efficiency.

As in [10-13], Exemplar based on inpainting has experiential better subjective results in comparison with other inpainting methods and this can be further improved with amendment of color quantization with compact clusters.

In the paper [6-8,16-18], the need for color quantization has been discussed to achieve lesser time consumption and the resultant images can be further used for better optimization in results. As in [7-9], there is a need to remove redundant pixels that can improve the quantization process in color space. The PDE method has been used with K-means for quantization [17]. The exemplar based on the inpainting method if further amended with color quantization, the observations can be recorded further[6-8]. In the further section, this amendment has been explored and the results have been quite impressive and thus paves way for further applications using the proposed method.

As in [30],the deep learning inpainting methods might produce meticulous results with usage of convolutional neural network for extraction of high level features. However, these high level features require high complex models with greater number of parameter adjustment, with higher accuracy especially. Recently the angle-aware patch based inpainting method[31], recovers missing regions with texture and structure components with image naturalness. However, the complexity involved in the process can be better simplified and can also be extended to the image compression domain.

In order to synthesize images, as discussed in [32,33], the patches are searched for, using the neighbour searching method. However, the major challenge still remains to maintain image naturalness in the output image, in terms of structure and texture. Though there exists conventional methods that uses image patches from the existing regions, or the diffusion based approach that propagates pixels from highly similarity regions into the whole regions. Though these methods propagate brilliant textures aimed at background inpainting, the high level semantics are however not captured perfectly and thus yields to non-realistic images. Though plausible outcomes are not achieved, but there is abundant scope for better texture regeneration. With recent advancement in generative neural network, inpainting algorithms can be trained to adapt to highly meaningful semantics, to further generate lucid structures for the missing regions, however at cost of high complexity.

Although significant progress has been made in literature, there is still work to be done to handle partial occlusions with minimum computation cost and achieve image naturalness. A systematic comparative evaluation must be made and thus determine the best combination of strategies. The main aim of our work, as discussed further is to improve the existing exemplar method with minimal execution time and retain image naturalness.

III. Proposed Method

The main task of proposed method is to handle partial occlusions using an amended exemplar approach. The performance of the partial occlusions handling relies basically on two primary aspects: the image naturalness and execution time. The contributions of the proposed method have been put forth in three stages:

1) Improved exemplar based inpainting with Color Quantization using K-means clustering approach for non uniform illumination variant outdoor scenes.

2) Extension of (i) with gradient and tensor based methods with YCbCr color space.

3) Empirical value of 'K' in K-means clustering for improved exemplar inpainting.

A. Improved Exemplar based on Inpainting with Color Quantization using a K-means Clustering Approach for Non Uniform Illumination Variant Outdoor Scenes

One of the major key points of the research problem was to handle Partial occlusion using an exemplar inpainting approach with reduced execution time. As per the literature, Color quantization is one of the significant image operations that reduces the amount of color variations in an image. The process merges lesser dominant colors in a particular image into relatively significant color. As a result, the visual error between the quantized image and the original, is substantially low.

The continuous color range can be represented using a finite subset through Quantization. Consider a function f : P → Cs representing an image with a range of colors in Cs. Here quantization would consist of a quantizer function qc : Cs → Q = {qc1, . . . , qcn}, in the color space definition Cs with a finite subset Q ⊂ Cs and qc1, . . . , qcn as quantization levels. The reduction of time and storage efficacy using color quantization could be explored further with an exemplar based inpainting. This paved way for a clustering based on color quantization amendment in an exemplar based inpainting approach and the results were appealing. This improved exemplar approach is novel with the results that could be achieved satisfying the conditions of image naturalness and improved execution time. The clustering based on color quantization method converts the quantization problem of RGB image into a problem of clustering pixels. K-means color quantization with exemplar inpainting method has not yet been explored in literature. The K-means algorithm being unsupervised clustering approach that automatically clusters based on the individual data points similarity is used for color quantization in our proposed method. The K-means algorithm is relatively simple and easier for implementation, alongwith higher efficiency and good clustering outcome. It has good adaptability to a new set of examples which could get experimented in proposed technique. The basic system proposed is putforth as in Fig. 1(a) and Fig. 1(b).

In Color quantization each of the color pixels are grouped into clusters, wherein each cluster represents a unique color in the new image. The K-means color quantization algorithm basically is basically categorized into three steps:

1) Initialization of 'K': The 'K' value depicts the quantitative value of total colors required for color quantization, to represent an image. The constraint however being that value of 'K' should be lesser than the concrete number of pixels in an image. The further classification of colors is carried out using the selected colors that act as the center colors.

2) Data point assignment to nearest centroid: Every data point needs to be assigned to its nearest centroid. Since every color is represented as RGB vector , the euclidean distance measure can be used to compute the distance between the two colors.

3) Color Remapping: Calculate the new centroid of every cluster and resdistribute every data point to the newest centroid. In color quantization, this step is the crux and in this particular step, every pixel in the original image is replaced with center color that has the closest proximity to it. This specific remapping creates an image with only 'K' colors, similar to the original image.

Repeat steps 2 and 3 until no point changes clusters, or until the centroids remain some.

These quantized cluster centres are further used and the RGB matrix with the cluster centres is further used for exemplar based inpainting.

B. Exemplar based on Inpainting on Region of Interest

Image inpainting is crucial for image restoration through the surrounding pixels information. The ideology in this method remains simple to replace the masked region with its neighboring pixels so that it looks like the neighborhood. The image reconstruction starts with identifying the damaged or missing part of an image and then search the image for similar known parts in the same image. These similar known parts of the image becomes the source region for region filling. The target region identified needs to be filled by copying the pixels from the source regions. The filling order remains crucial and determines the overall subjective quality of the image. The priority term of all pixels on boundary regions is estimated. The next step of investigation is to determine the border region pixel 'p' having the largest priority with respect to the patch centred around this point 'p'.

A Region Of Interest (ROI) primarily being a chosen subset of data points in an image defines a location in an image. The partial occlusion instances in an image can be selected dynamically and further exemplar based inpainting can be performed. Steps for gradient-based exemplar inpainting:

- Consider Region Of Interest in an image that has to be inpainted.

- It starts with boundary of the region and fills the region within.
- The neighbourhood region surrounding the pixel is selected to be painted.
- The normalized weighted sum of all known neighbourhood pixels is used to replace the identified pixel and continue for the selected patch region.

Here in the proposed system, the novel approach to improve the exemplar based inpainting method with a tradeoff in time and subjective perception has been put forth. The proposed method has shown comparatively better results as compared to conventional exemplar with gradient based method and exemplar with tensor based method. The experimentation results have been further put forth in Section IV.

C. Improved Exemplar based Inpainting with Color Quantization using K-means Clustering and YCbCr Color Space

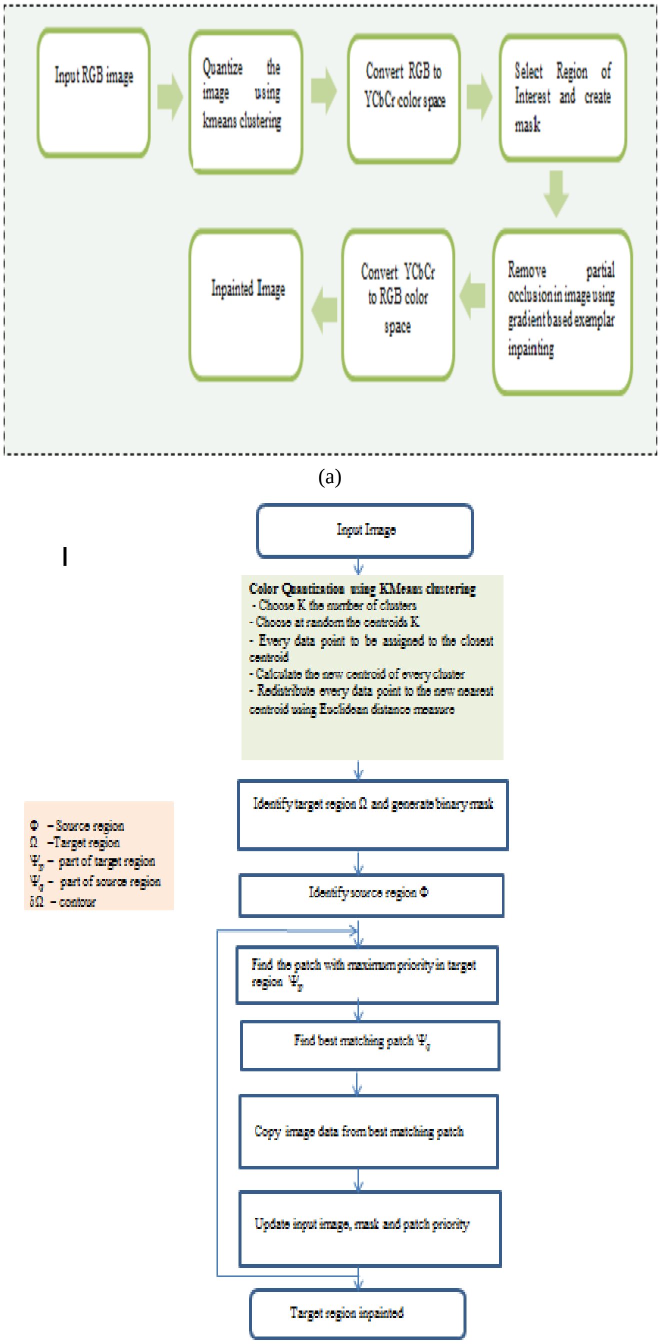
a) Color Space

The redundancies across three color channels of the source RGB image are better suppressed in YCbCr color space [34,35].

YCbCr represents the luminance (Y) chromaticity (Cb and Cr) color space, imitating a better human vision. In this color space, quantization operation shows better results due to the removal of redundancies in the R,G,B color channels. Adversarial perturbations are allocated more in the Y-channel of the YCbCr color space than in the Cb and Cr channels, whereas in the RGB color space, the perturbations are equally distributed between the three channels. Therefore, the natural step is to remove the adversarial perturbation from the Y-channel instead of targeting all channels in the RGB color space. Here in the proposed approach, the quantized outdoor scene set of images in RGB color space is transformed to YCbCr color space and then the exemplar inpainting is further applied to handle the partial occlusion instances as putforth in Fig. 1(a). After performing exemplar inpainting,the resultant image is transformed back to the RGB color space. Efficient representation of images is finally observed in this color space.

b) Empirical Value of 'K' for K-means Clustering for Improved Exemplar Inpainting

The K-means clustering method uses the Eucledian distance measure and for the K classes of the data set, through initial random sampling approach, the initial centroid is calculated. Once the initial cluster is formed, thereafter divide each sample point into the clusters such that it is closest to the nearest center point. With this iterative approach, the center point of all sample points then becomes the center point of the cluster. These steps to be repeated until the center point remains unchanged or reaches the desired set of iterations. The Fig. 1(b) illustrates the flowchart of the proposed system where all the steps have been summarized.



Input RGB image
Quantize the image using kmeans clustering
Convert RGB to YCbCr color space
Select Region of Interest and create mask
Remove partial occlusion in image using gradient based exemplar inpainting
Convert YCbCr to RGB color space
Inpainted Image
Input Image
Color Quantization using KMeans clustering
- Choose K the number of clusters
- Choose at random the centroids K
- Every data point to be assigned to the closest centroid
- Calculate the new centroid of every cluster
- Redistribute every data point to the new nearest centroid using Euclidean distance measure
Identify target region Ω and generate binary mask
Identify source region Φ
Find the patch with maximum priority in target region Ψ_p
Find best matching patch Ψ_q
Copy image data from best matching patch
Update input image, mask and patch priority
Target region inpainted
Φ – Source region
Ω –Target region
Ψ_p – part of target region
Ψ_q – part of source region
δΩ – contour

IV. Results and Discussion

In the section here, the testbed is introduced and then the proposed method is compared with state of the art methods are presented with interpretation and analysis. The sample outdoor scene images were taken form MOT[25] and VV[26] dataset. The proposed method was applied on the selective images form these datasets where partial occlusion evidences could be obtained. A total of twelve outdoor images with non uniform illumination were selected for experimentation. The experimentation analysis is carried out in MATLAB 2020 environment under 64-bit Windows 8.1 operating system, with Intel® Core (TM) i3-4030U and CPU (1.90 GHz) with 4 GB RAM.

The Fig. 2 here illustrates the sample images considered for the experimentation. In this work, the color quantization was performed on each of the images from the testbed for different values of 'K' such as 20, 30, 40, 50 and 60 to find optimal value of 'K' for effective color quantization amendment with exemplar inpainting method and the objective quality metrics with CPU time was recorded.

The efficacy of objective evaluation of proposed method is done using the PSNR[24] and SSIM[24]. As evident from the literature stated [24,36-38], higher PSNR signifies better subjective evaluation of inpainting results. This can be correlated with the subjective perception of image naturalness. Generally, larger the PSNR, lesser the diversity between the inpainted image and the original. Additionally, SSIM measures the similarity between the two images. It has proved to be a sufficient metric for inpainting results. In exemplar based inpainting method, it becomes difficult to recover the object that needs removal completely using any mathematical method. It can hold maximum resemblance to the original and hence the PSNR and SSIM values are crucial objective evaluation parameters [36-38]. Hence, PSNR and SSIM values are relevant to evaluate our work of partial occlusion handling inpainting results. In further subsections, the visual efficacy of proposed method is discussed with execution time and feasibility.

Here, the quantized color image with K-means clustering is used further to determine the partial occlusion instances with ROI method. The mask required for the exemplar inpainting method is generated using this selected ROI. The exemplar inpainting method with structure tensor [4,5] comprises of the intensity information of the neighbourhood region as well as the gradient's transformation directions and degree of coherence of the same. The priority function includes this structure tensor. The linear structure is thus preserved using this priority function along the geometric structures in an image. In large regions, object removal becomes more effective when using structure tensor and also ensures accurate propagation [27,28].

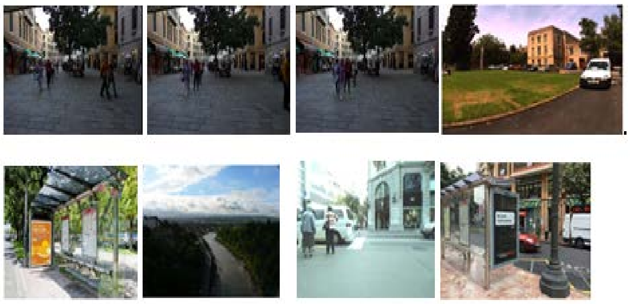

Fig. 2. Sample Outdoor Images with Non Uniform Illumination and Partial Occlusion for Experimentation [23, 24].

The objective evaluation has been put forth as seen in Table I. Here, a clustering approach with 50 region clusters has been considered. The objective and subjective evaluation results with the proposed improved exemplar inpainting method with color quantization using K-means clustering approach is discussed. Here as seen in the Table I, the gradual trend in the proposed method with gradient-based exemplar has shown better average PSNR of 27.8275 and SSIM of 0.9419. The graphical visualization of average PSNR and average SSIM is further putforth in Fig. 3 and Fig. 4.

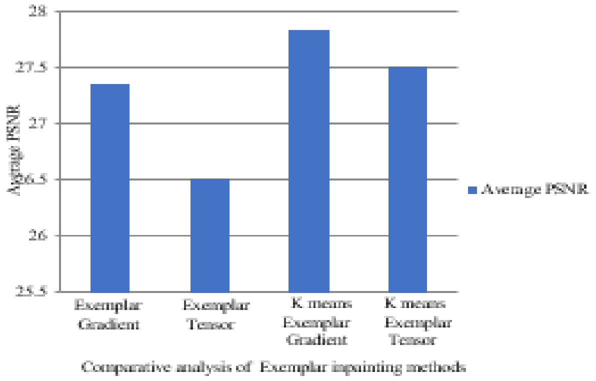

Fig. 3. Comparative Analysis of Average PSNR of Proposed Method with Existing Exemplar Inpainting Methods.

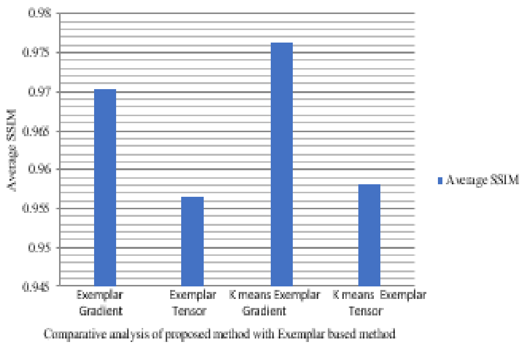

Fig. 4. Comparative Analysis of Average SSIM of Proposed Method with Exemplar Inpainting Methods.

The proposed method when extended to YCbCr color space [22, 34] also demonstrated comparatively better results than the RGB based variant of proposed method. Here as seen in Table II again, the gradient based exemplar has shown better average PSNR of 28.2869 and SSIM of 0.9759 as compared to gradient based exemplar method, tensor based exemplar method and proposed K-means color quantization with tensor based exemplar inpainting method. Here Kmax was fixed to 50 empirically as it was quite enough from a subjective point of view where more number of colors may pose difficulties in color identification itself.

Here as seen in Fig. 5(a) and 5(b) the subjective evaluation results for partial occlusion on selective frames have been put forth. As observed, the proposed method with K-means color quantization with gradient based exemplar method has shown better visual perception than the other considered existing methods.

As putforth in Table III, the method proposed has demonstrated better computation time in seconds as compared with all the other methods. The average time of proposed method with K-means amendment in YCbCr color space has been an average of 0.7580 sec.

Here as the proposed method has performed comparatively with gradient-based exemplar method, further experimentation was conducted to find an empirical value of ‘K’ [17] for the K-means clustering approach. As can be observed, the image naturalness and visual quality of the inpainted image is better preserved using our method. The results were varied for different values of ‘K’ from 20 to 60 and as observed experientially the optimal value of ‘K’ has been 50. The average PSNR and SSIM for K=50 has shown better results as compared to varied values of ‘K’ and has been tabulated as in Table IV.

As observed through the experimentations carried out, the proposed approach with YCbCr color space has shown substantial visual perception and improved execution time that are crucial in inpainting methods. The relative comparison with original images for partial occlusion instances is better handled using the proposed approach. The proposed approach, however, has not shown good results but for the lesser value of ‘K’ below 20 where distortions could be evident. This method can be further applied for image restoration applications where the tradeoff between time and visual perception is crucial.

In this paper, after comprehensive discussion along with subjective and objective evaluation performed on testbed, the improved exemplar based technique with color quantization using K-Means approach has shown comparatively better performance than the existing variation of the exemplar method. The average PSNR for the proposed method has been 28.2869 and SSIM as 0.9759 with an average time for the sample non-uniform illumination variant scenes as 0.7580 sec. An experimental analysis of the obtained results yielded the following conclusions:

- K-means color quantization amended with exemplar based inpainting in YCbCr color space has demonstrated qualitative and quantitative efficacy.
- Improvement in image naturalness and execution time was better achieved.

The experiments performed could demonstrate plausible results for subjective perception. The tradeoff achieved here is of paramount significance. The results achieved here can offer a context for added research that may be undertaken further to improve upon, the presented methods here. In future, the different quantization approaches can be further amended with an exemplar based inpainting method and the results can be observed. Automated restoration methods for complex and overlapping structure with curves and larger curvatures can be further addressed.

V. CONCLUSION

In this paper, after comprehensive discussion along with subjective and objective evaluation performed on testbed, the improved exemplar based technique with color quantization using K-Means approach has shown comparatively better performance than the existing variation of the exemplar method. The average PSNR for the proposed method has been 28.2869 and SSIM as 0.9759 with an average time for the sample non-uniform illumination variant scenes as 0.7580 sec. An experimental analysis of the obtained results yielded the following conclusions:

- K-means color quantization amended with exemplar based inpainting in YCbCr color space has demonstrated qualitative and quantitative efficacy.
- Improvement in image naturalness and execution time was better achieved.

The experiments performed could demonstrate plausible results for subjective perception. The tradeoff achieved here is of paramount significance. The results achieved here can offer a context for added research that may be undertaken further to improve upon, the presented methods here. In future, the different quantization approaches can be further amended with an exemplar based inpainting method and the results can be observed. Automated restoration methods for complex and overlapping structure with curves and larger curvatures can be further addressed.

***Abstract*—A woman's satisfaction with childbirth may have immediate and long-term effects on her health as well as on the relationship with her newborn child. The mode of baby delivery is genuinely vital to a delivery patient and her infant child. It might be a crucial factor for ensuring the safety of both the mother and the child. During the baby delivery, decision-making within a short time becomes very challenging for the physician. Besides, humans may make wrong decisions selecting the appropriate delivery mode of childbirth. A wrong decision increases the mother's life risk and can also be harmful to the newborn baby's health. Computer-aided decision-making can be an excellent solution to this problem. Considering this scope, we have built a supervised machine learning-based decision-making model to predict the most suitable childbirth mode that will reduce this risk. This work has applied 32 supervised classifier algorithms and 11 training methods on the real childbirth dataset from the Tarail Upazilla Health complex, Kishorganj, Bangladesh. We have also analyzed the result and compared them using various statistical parameters to determine the best-performed model. The quadratic discriminant analysis has shown the highest accuracy of 0.979992 with the F1 score of 0.979962. Using this model to decide the appropriate labor mode may significantly reduce maternal and infant health risks.**

Keywords—Childbirth; labour mode; supervised machine learning; maternal death; infant

I. INTRODUCTION

In baby delivery, we want to make sure that the mother and the child are safe. For this safety, the method of baby delivery is very significant. Usually, the corresponding physician chooses the mode of delivery from two options, includes (i) vaginal birth or (ii) Cesarean area (c-section) birth. So, the patient herself cannot contribute to the decision-making procedure. When a child contains a low-risk pregnancy and is in the head-down position, and the patient is at least 37 weeks pregnant, gynecologists suggest attempting a vaginal birth. In this case, a newborn baby usually gets essential gut bacteria from the mother. Besides, it can help press liquid out of a baby's lungs, decreasing the risk of the baby's breathing problem. This way of birthing also helps for breastfeeding and reduces the baby's risk of asthma and obesity. Additionally, parents will be able to avoid the cost and potential risk of surgery. That is why normal birth is most suitable for both the baby's and the mother's health.

On the other hand, there are cases like twins, or the mother has diabetes, high blood weight, HIV, or active herpes, or the baby is not in a head-down position, which complies the patient to have a c-section delivery. However, it increases the risk of asthma from the early childhood of the baby. In other instances, including delivering a comparatively larger baby for the maternal pelvis, or if the baby is not in a head-down position, the c-section delivery becomes an essential mode of childbirth.

However, many times, physicians are more biased for a c-section delivery than a vaginal delivery. The number count of c-sections is increasing day by day, and it got doubled during 1980. Another record says, as of 2015, the cesarean section rate is exceeding by 35.5% than WHO's recommendation [1]. Lately, during the period 2017-2018, the c-section rate in Bangladesh has increased by 51%, and in 2018, 77% of those c-sections were unnecessary [2]. Save the Children, a popular magazine, has recently documented a 51% increment in extraneous c-section delivery in Bangladesh [3]. In addition to that, maternal mortality is also shown and has been a big problem for most South Asian countries. Compared to the developed countries, the maternal mortality rate in Bangladesh is extremely high. In 2017, the maternal mortality rate in the USA was 0.000017 percent [4]. In the same year, this rate was 0.000113 percent in Bangladesh, which is a few times more than in other developed countries. WHO has reported maternal mortality of 194 per 1000 in Bangladesh. This high maternal death rate can be significantly reduced by selecting the birth mode appropriately. "National Low Birth Weight Survey Bangladesh, 2015" has reported that Maternal mortality and cesarean delivery rates have doubled compared to regular deliveries [5]. It gives us the scope to develop a decision-making model to choose the appropriate mode of childbirth.

Both of the processes of childbirth have advantages and disadvantages based on the particular patient's situation. However, the gynecologist decides the birth mode considering the mother's biological factors, including counting, age, ANC, para, partograph, AMTSL, blood circulation, birth weight, BP, PNC-1 presentation, cervix(OS), membrane, and so on. This research proposed a scientific method to decide childbirth mode considering the mother's present situation and earlier records.

The following points denote the main contributions of this research paper:

- We have proposed a computerized method of decision-making for selecting the appropriate mode of childbirth.
- Since this process is computerized and machine learning-based, it will be less error-prone.
- We have used 32 different classifier algorithms to make the decision more accurate and reliable.
- This model can analyze and use such big data for decision-making that it is merely impossible for a human being to analyze.

The rest of the sections are organized as follows: Section II describes the related work. Section III describes the methods and materials used, Section IV depicts the experimental procedure and the model. Section V examines and evaluates the results, and Section VI describes the conclusion and proposes the future direction of this research.

II. Related Work

A lot of research is being done in the machine learning domain for biomedical decision-making. Mboya IB et al. have proposed a machine learning-based method that can predict perinatal death using supervised machine learning algorithms [6]. ML-based model is also being used for predicting a lot of factors of childbirth. For example, Abraham, Abin, et al. described a new technique for gathering various information from EHRs in order to predict singleton preterm birth by applying various machine learning models [7]. Recently, Islam, Muhammad Nazrul, et al. has presented research regarding childbirth mode with two-fold findings: first, the potential highlights for deciding the method of labor, and second, machine learning algorithms for anticipating the suitable way of labor (vaginal birth, crisis cesarean, cesarean birth) [8]. Kowsher, M. et al. has reported good accuracy in applying machine learning-based recommendation system to predict the most appropriate childbirth mode [9]. Also, Khan, Nafiz Imtiaz, et al. have a similar test to anticipate whether the cesarean area is essential with the assistance of information mining and subsequently expand the mother and infant's security during and after labor by staying away from a pointless cesarean segment [10]. Besides, Fu, Yuanqing, et al. had described a model to recognize early life hazard factors for youth overweight/stoutness among preterm babies and decided to take care of practices that could alter the distinguished danger factors [11]. Other researchers also have applied machine learning models to classify various biomedical factors and hence to conclude the adverse effect of c-section delivery. For instance, Siddiqui, Mohammad Khubeb, et al. described that machine learning classifiers could use EEG information and identify seizures alongside uncovering applicable reasonable examples without trading off execution [12]. In addition, Soh, Yan Xi, et al. had explained the relationships among sociodemographic and medicine factors, the concern of parturition, psychosocial wellbeing, and childbirth self-efficacy employing a structural equation modeling approach [3]. c-section delivery may have a postbirth adverse health effect on a mother. Chen, Yanfang, et al. showed the relationship between conveyance and post-traumatic stress problems that yielded conflicting outcomes. This examination is expected to research the relationship between conveyance and post-traumatic stress in an associate of Chinese ladies with a high pace of cesarean conveyance [14].

Zhang, Yiye, et al. propose a machine learning structure for PPD hazard expectation utilizing information extricated from electronic wellbeing records (EHRs) [15]. Later on, Lipschuetz, Michal, et al. presented to decide the customized forecast of vaginal birth after cesarean conveyance utilizing 30 an AI calculation that might help patient-doctor dynamic and 31 increment paces of preliminaries of work [16]. Also, Serçekuş, Pınar, Okan Vardar, and Sevgi Özkan proposed to recognize and think about the dread of labor and related to variables among pregnant ladies and their accomplices [17]. Onchonga, David et al. described a new investigating ladies' experience from maternity specialists drove incorporated pre-birth preparing and its effect on the dread of labor [18]. After that, Liu, Ligue, et al. proposed an expectation model of undeveloped improvement by using machine learning algorithms dependent on authentic case information. In this way, specialists can make more exact ideas on the quantity of patient subsequent meet-ups and give choice help to moderately unpracticed specialists in clinical practice [19]. On the other hand, Lindblad Wollmann, Charlotte, et al. described the predicting vaginal birth in ladies with one earlier cesarean and no vaginal conveyances utilizing machine learning strategies [20].

Unlike their works, we showed and analyzed various methodology of supervised classifiers based on a real dataset of childbirth to figure out the best model to predict the suitable mode of delivery.

III. Methodology

To build our proposed model, we went through four significant phases: Dataset formation, data preprocessing, training the models, the performance analysis of the model. We have collected the data from the Tarail Upazilla Health Complex, a specialized clinic for maternal care located in Tarail, Kishorganj, Bangladesh. First, we determined the features that influence our targeted feature, the mode of childbirth. We kept the most significant of them, and some other features having less impact were deleted as they don't contribute much to the targeted variable. Then the data was split into two sections, i.e., training set and test set, which are later used for training and testing correspondingly. After collecting raw data, we had preprocessing to make it suitable for the machine learning model. Data pre-processing techniques have made the data outliers free and more solid, and it also increases the accuracy. As a result, we used several preprocessing steps such as cleaning data, missing value handling, categorical data handing, feature selection, feature scaling. Having completed all the preprocessing steps, the data becomes ready for the machine learning models. We have used several groups of supervised learning classifiers such as Tree, Ensemble, Neighbors, Naive Bayes, Calibration, Discriminant Analysis, SVM, Linear model, Gaussian Process, and Deep Neural Network. Most of those classifiers have shown good performance with this preprocessed training and test dataset. The methodology of our proposed model is depicted in Fig. 1.

A. Dataset Description

We have used a dataset that is containing the medical records of 13527 women. It has 21 diverse observation values for every pregnant woman counting title, age, address, admission time and time, ANC number of shrouds (by therapeutically prepared supplier), para, the reason of confirmation, amid pregnancy (week), cesarean, breech conveyance, partograph, blood circulation, AMTSL, birth weight, PNC-1(postnatal administrations and the status of the patient), PNC1 (postnatal delivery administrations), BP, introduction, layer and cervix (OS).

Para alludes to the total number count of pregnancies that the lady has carried on the last twenty weeks of pregnancy. This number includes both live births and pregnancy misfortunes after twenty weeks. Gravida referred to the number of times of affirmed pregnancies of a lady, including both live birth and interrupted pregnancies. ANC (ante-natal check-up) implies a routine checkup for the mother to ensure appropriate facility for further safety. ANC is usually conducted in three stages, the first one is between 4th to 28th week, the second one is between 28th to 36th week, and the last one is between 36th to 48th week. There is a possibility that the infant can open its mouth almost 10 cm or over, then it can be conveyed in an ordinary way. On the other hand, if curved (OS) isn't 10 cm, even it is over 12 hours, this patient requires a cesarean conveyance.

PNC implies postnatal care. After conveyance, this is often done by checking the typical state of the mother. Cephalic is for typical conveyance, but in some cases, there's a breach at multi-case, but typical conveyance is done. Cesarean conveyance happens sideways or transverse. Pantographs are utilized to decide the physical condition of the mother and child. After children's birth, Placenta is extricated within the AMTCL strategy. Blood circulation is given on the off chance that the quiet is Iron deficient. Most of the time, the layer remains completely intact. Some of the time, it endures from spilling, burst. Blood weight is watched to screen the typical arrangement of the mother.

B. Data Pre-processing

In machine learning, data preprocessing is in the approach of transferring or encoding the raw data in a phase where algorithms can use the data for building the model. We need to preprocess the data accordingly to make it fit for the machine learning model. A well-processed data gives high accuracy and makes the model more reliable. Here, we have used several stages of preprocessing, which have been illustrated in Fig. 2.

In our dataset, there are lots of incomplete, null, and duplicate values. For this reason, we took three steps to correct these data. Those three steps are described below:

- We have noticed that there are many data points that are repeated in a row. Therefore, we simply removed all the duplicate data other than one single observation.
- We also notice some of the rows and columns are empty. We also erased the entire empty rows or columns from our dataset.
- There were some rows and columns that have 50% or more incomplete or null values. We removed the entire rows and columns to fix this issue.
- There were some columns that have very low variance. We also ignored those columns to make the dataset better suited for our machine learning model.

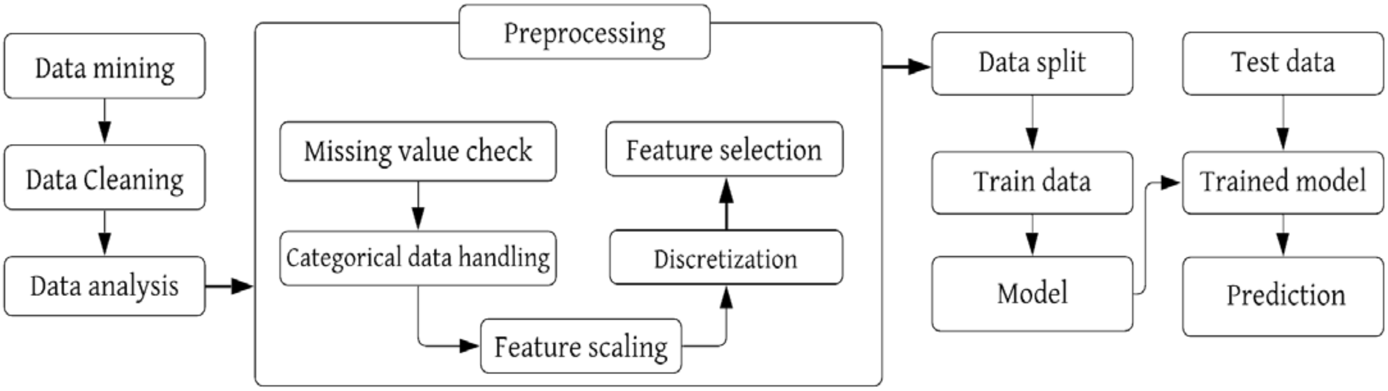

Fig. 1. Workflow of the Proposed Model.

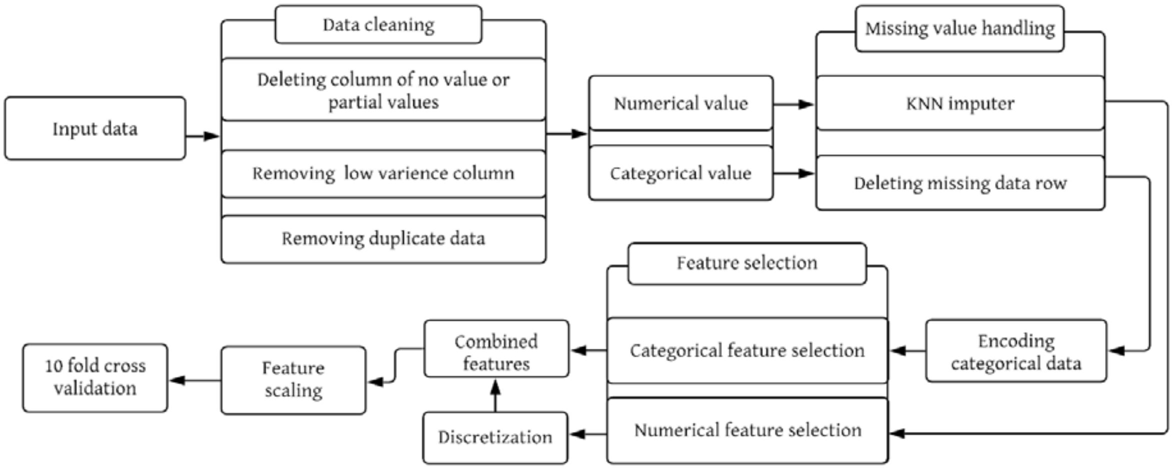

Fig. 2. Data Preprocessing Stages.

Generally, a missing value is defined as the value which is either not stored in the sample or missing partial information. The missing value is commonly seen in any kind of dataset. Our dataset also had some missing values. However, most predictive modeling methods can't handle any missing value. Hence, this issue must be solved before we feed this data into the machine learning model. Sometimes, median, mean, mode methods are used to update a missing value. The selection of the methods depends on the data types and the totals number of observations. However, the most straightforward procedure for dealing with the missing value is to remove the whole row for categorical features and replace the missing value by selecting the nearest neighbors for numerical data. We have used the K Nearest Neighbor aka KNN based method for a more accurate missing value imputation and replaced the NAN data by getting the nearest neighbor value. We have considered three neighbors for KNN algorithm implementation and completed all the missing values using KNN imputer to build a perfect feature matrix. The following Fig. 3 has illustrated the working procedure of the KNN imputer.

Categorical data is a qualitative feature whose values are taken based on the value of labels. So, we need to encode this type of data into numbers so that the machine learning model can implement mathematical operations on it. In our dataset, there are a total of three categorical variables, including "PRESENTATION", "REASON" and "MEMBRANE". We have used one-hot encoding, one of the most popular encoding algorithms, to encode the categorical values into numbers. It is the most general approach, and it works well unless any categorical variable takes a large number of different values. After this encoding, a binary matrix is formed where 1 indicates the presence of any value and 0 indicates the absence of the value.

Feature selection is a critical stage of implementing a machine learning model. It is the process of determining the mathematical relation between the feature variable and the target variable. We have kept the most significant features and dropped some features with less significance on the targeted variable. Reduction in features reduces the computational cost. Our dataset contains 21 features, and we have considered the p-value for finding the probability of the null hypothesis. The features with a p-value less than 0.05have been taken out. After checking multicollinearity, we have maintained a strategic distance from those components, which show repetition and don't back the p-value assumption. Besides, to handle the numerical feature, we took the help of the Pearson correlation coefficient, which is defined in equation -1, and for categorical features, we used the ANOVA F measurement, which is described in equation -2.

$$r = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{\mathrm{X}})^2}\sqrt{\sum_{i=1}^{n}(y_i - \bar{y})^2}} \qquad (1)$$

$$F = \frac{n\sum_{i=1}^{n}(\overline{x_k} - \overline{x_G})^2/(k-1)}{\sqrt{\sum_{i=1}^{n}(x_i - \overline{x_k})^2/(N-k)}} \qquad (2)$$

After performing the feature selection, we had the most relevant nine features, including Para, Age, Cervix (OS), Gravida, Systolic, Diastolic, Reason, FHR(BPM), and Presentation.

In data analysis, it can often be observed that the numerical data are mostly like skewed or non-standard deviation due to outliers, multi distributions, very exponential distributions, and more. We converted the numeric value into categorical behavior to solve this problem. We have applied the discretization method to converts the numerical value into a distribution function.

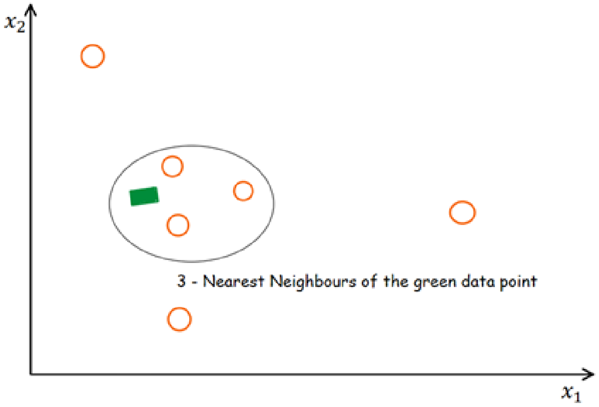

Fig. 3. The KNN Imputer for Missing Value Handling

Feature scaling is one of the crucial techniques that are mandatory to standardize the working data's independent features. Nevertheless, there exist various methods like Min-Max Scaling, Variance Scaling, Standardization, Mean Normalization, and Unit vectors for feature scaling. In our work, we have applied the Min-Max scaling as a feature scaling technique. Here, the transferred range between 0 and 1. The min-max scaling can be written as shown in equation- 3 below,

$$\acute{x} = \frac{x-\min(x)}{max(x)-\min(x)} \quad (3)$$

Cross-Validation is used to assess the models' predictive performance and judge the performance of a new data set. This is often fundamentally a variation of Recursive Feature Elimination (RFE) with cross-validation in each iteration. In RFE, the features are disposed of using a backward selection of the features. It uses a base classifier for selecting the features of data. It starts by building a model with the complete set of features and computes an importance score for each variable. The features with the least imperative score are deleted. The method recursively finds the optimal set of features that gives the most excellent model accuracy. With the cross-validation, the training and test set is divided into k number of folds where the k-1 fold of them is used for training and the rest 1 fold of data is used for testing. After running iteratively for K times, we actually get the average accuracy. This method takes more computation, but we can ensure good accuracy with comparatively fewer data. In our project, we used ten-fold cross-validated features to build our classification models.

C. Model Description

Implementing a lot of diverse models can ensure the best possible accuracy. So, we have applied the 32 most sensible machine learning classifiers, including Tree, Ensemble classifier, Neighbors, Naive Bayes, Calibration, Discriminant Examination, SVM, Linear model, to predict the birth mode Gaussian Process, and deep neural networks. All models are shown in Fig. 4.

Tree-based algorithms are considered to be one of the leading and most used supervised learning methods. In this work, we have implemented a decision trees and additional tree classifiers. In these two algorithms, we utilized "gini" for the Gini impurity, and the splitter is chosen as 'best' to select the part at each node.

Ensemble methods are procedures that make multiple models and combine them to create moves forward. Here, we utilized five ensemble-based classifiers [21]. These are AdaBoost, Stowing, Gradient Boosting, enable hist gradient boosting, Random Forests classifiers. In all these classifiers, in AdaBoost classifiers, the number of boosting estimators is 50 with the SAMME.R as a real boosting algorithm. In the bagging classifier, we used ten estimators. The loss function of Gradient Boosting is 'deviance', logistic regression with probabilistic outputs with the 100 boosting stages. Besides, in the section of random forest three, we use 100 trees as a forest with Gini impurity.

Afterward, we have utilized three neighbors' classifiers of statistical pattern recognition [22]. These are radius neighbor, k-neighbor, and nearest centroid. In KNN, we used five neighbors for every iteration. Besides, the Makowski metric is chosen for all neighbor classifiers.

Naïve Bayes is based on an estimate of the age of the "naive" with a set of learning calculations guided by an application and an estimate of the accuracy between them [23].

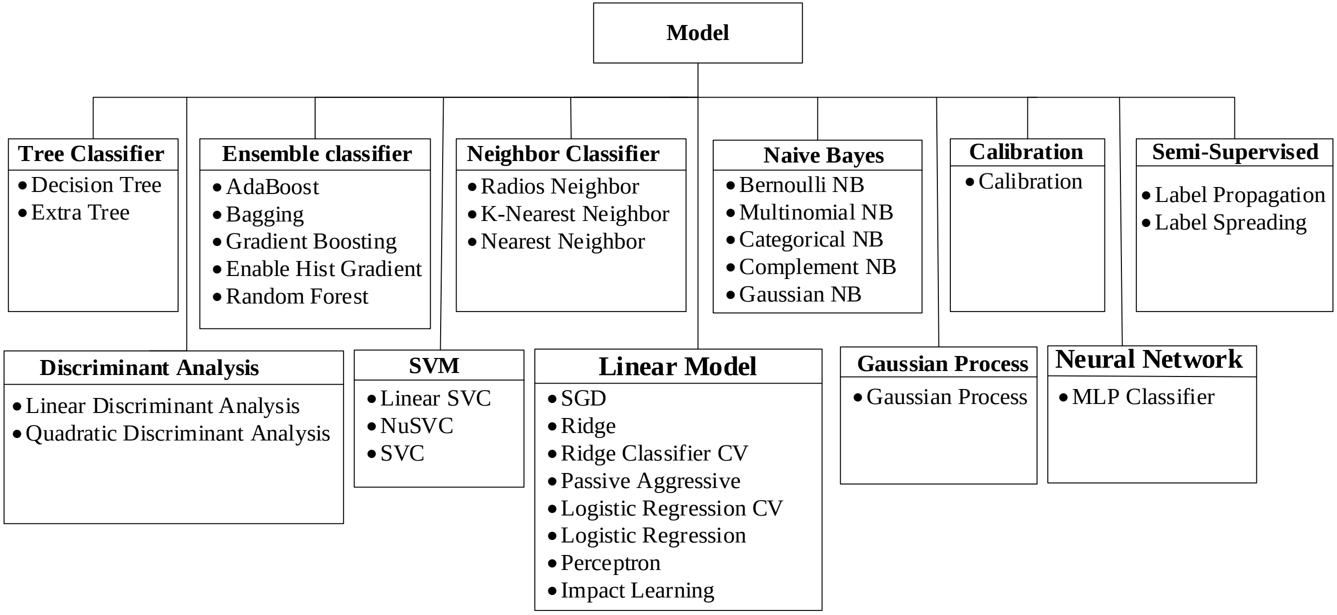

Fig. 4. Tabulation of all the Models.

Here Bernoulli, Multinomial, Categorical, Complement, and Gaussian Naive Bayes are executed to compare the Bayes algorithm on childbirth mode detection. For each method, we have also used the additive smoothing parameter.

Model calibration implies the process where we take a model that is already trained and apply a post-processing operation, which improves its probability estimation. Thus, if we were to inspect the samples that were estimated to be positive with a probability of 0.85, we would expect that 85% of them are in fact positive.

The label propagation and label spreading are used in the area of semi-supervised algorithms. The Gamma Parameter for RBF bit is utilized as 20. The maximum emphasis is 1000, and the neighbor parameters are 7.

The researchers commonly use discriminant analysis to analyze the data when the criterion or the dependent variable is categorical, and the predictor or the independent variable is the interval in nature. Dependent variables should categorize at the moment as well as include predictive or distinct variable natures such that researchers can use them to analyze research data (quadratic inequality analysis (QDA) and linear inequality analysis (LDA) [24].

The support vector machine, aka SVM, is used mainly for exploring a hyperplane in d-dimensional space that notably classifies the data points [25]. In the linear SVC, we used hinge as loss function with l_2 penalty. The numerical value three is used as the polynomial kernel in NuSVC with the RBF kernel type.

The linear model could be a module lesson if it contains diverse functions for performing machine learning linearly [26]. We utilized the eight classifiers such as SGD, Ridge Classifier, Ridge Classifier CV, Passive-Aggressive Classifier, Logistic Regression, Logistic Regression CV, Perceptron, and Impact Learning [27].

The Gaussian process is a stochastic method in probabilistic hypotheses and statistics, such as a common multivariate distribution containing which is a limited random sample collection. The kernel of the gaussian process classifier specifies the covariance function, and the accessible internal optimizers are 'fmin_l_bfgs_b'.

A neural network could be an arrangement of algorithms that endeavors to recognize basic relationships in a set of data through a method that imitates the way the human brain works. The Artificial Neural Network (ANN) is a computing system where neurons inspire people [28]. There are three layers, and these are the input layer, hidden layer, and output layer. The input layer usually takes the input data into the network. The hidden layer is the layer where input and output are connected based on conditions. The output level is decided by considering the respect action, weight, and hidden level. There's no rule of the thumb to select the hidden layer in ANN. We have used sixty-four hidden layers between the input and output layers.

IV. Experiment

In furtherance of our experiment from the proposed work, we have first assembled the model and trained it. Thirty-two classifiers from supervised learning based on different learning methodologies have been implemented to predict childbirth's most applicable mode. This section described different experimental tasks for the performance analysis and evaluation and compared all algorithms. Besides, we have illustrated the experimental setup used to execute the whole task and used 11 statistical evaluation metrics for analysis performance. Finally, we have also compared with other works related to this issue regarding the best version of our work.

A. *Experimental Setup*

We have completed the whole computation in google colab, a python simulation environment provided by Google. This environment comes with parallel computation facilities for fast execution. We have used the most popular libraries to make easy and expressive data structures work well and intuitively with fast, flexible, and time-series data. Finally, the scikit-learn Library contains specialized machine learning and statistical modeling tools, including classification, regression, and clustering algorithms for modeling. We have used a machine learning framework named sci-kit learn and deep learning framework Keras to implement the classification algorithm. Finally, we used Matplotlib for data visualization, graphical representation, and also for data analysis.

B. *Measurement Metrics*

We have used several Statistical metrics [29] for measurements, evaluation, and analysis of the performances and compared all the algorithms. We will define and describe all of those in the following section.

We have analyzed the 11 statistical measurements, including accuracy, F1 score, precision, recall, and so on. Accuracy and F1 score are the most important of them.

Accuracy is a metric that evaluates the matric for the correct prediction rate for the positive class. The expression is shown below in equation 4.

$$Accuracy = \frac{True\ Positive(TP)}{True\ Positive(TP) + False\ Positive(FP)} \tag{4}$$

F1 score conveys the balance between the precision and the recall. It is also called the F Score or the F Measure. A good F1 score indicates that we have low false positives and low false negatives in the results. The expression of the F1 score is shown in equation 5.

$$F1 = \frac{TP}{TP + 0.5(FP + FN)} \tag{5}$$

Recall considers the percentage of correct predictions for all the positive categories. In other words, recall is how many of the true positives were recalled (found), i.e., how many of the correct hits were also found. The expression of recall score is shown below in equation 6.

$$RS = \frac{TP}{TP + FN} \tag{6}$$

The F-beta score is evaluated in the binary classification model based on a configurable single-score for the positive class's forecasts. It's also calculated utilizing precision and recall. The value of the F-beta score can be calculated using equation 7 below.

$$FBS = \frac{(1+\beta^2)\,.(Precision\,.Recall)}{(\beta^2\,.Precision\,+Recall\,)} \tag{7}$$

Hamming loss is designed for multiclass while Precision, Recall, F1-beta score represents one clear single-presentation-value for multiple-label cases compared to the precision/recall/f1beta score that can be assessed only for independent binary classifiers for each label. The expression of Hamming loss is shown below in equation 8.

$$HL = \frac{1}{|D|}\sum_{i=1}^{|D|} \frac{|Yi\,\Delta\,Zi|}{|L|} \tag{8}$$

In the Jaccard similarity coefficient, the union of the two label sets is used to compare the set of labels predicted in y_true to mark the separate intersection as a measure by calculation. The equation of Jaccard similarity coefficient is shown below in equation 9.

$$\mathrm{J}(A, B) = \frac{|A \cap B|}{|A \cup B|} \tag{9}$$

Matthews Correlation Coefficient, aka MCC, is used as a standard for binary and multiclass classification in machine learning. The equation of Matthews Correlation Coefficient is shown below in equation 10.

$$\mathrm{MCC} = \frac{TP\,.FN\,-FP\,.FN}{\sqrt{(TP+FP).(TP+FN).(TN+FP).(TN+FN)}} \tag{10}$$

AUC stands for "Area under the ROC Curve." That is, AUC measures the entire two-dimensional area underneath the entire ROC curve (think integral calculus) from (0,0) to (1,1). AUC provides an aggregate measure of performance across all possible classification thresholds. One way of interpreting AUC is as the probability that the model ranks a random positive example more highly than a random negative example.

The balanced accuracy in binary (BAC) and multiclass classification is usually used to measure the performance if the dataset is imbalanced. The equation of balance accuracy is shown below in equation 11.

$$\mathrm{BAC}=\frac{1}{2}\left(\frac{TP}{P}+\frac{TN}{N}\right) \tag{11}$$

Cohen's kappa (CKS) is a statistic that measures inter-annotator agreement. We can consider Cohen's Kappa as a quantitative measure of reliability for two raters that are rating the same thing. The equation of Cohen's kappa (CKS) is shown below in equation 12.

$$\mathrm{K} = \frac{P_{0-}\,P_E}{1-\,P_E} \tag{12}$$

V. Result Analysis

Our experiment improved the methods of decision-making. We have implemented thirty-two classifier parameters to gain the best possible performance. After getting the performance matrix from all the models, we have tabulated the data into a table. We have analyzed the 11 statistical measurements, including accuracy, F1 score, RS, PS, FBS, HL, JS, MS, AUC, BAC and CKS. The statistical measure and for each of the algorithms is shown in Table I below. In addition, we have compared the performance of all the proposed models and determine the best suitable model that can be used in real-life decision-making or selecting the most suitable mode of childbirth.

From Table I, we can see that the decision tree classifier has predicted the best accuracy of 0.918307, and the F1 score is 0.918198 from the branch of the Tree. Secondly, the hist gradient boosting classifier has gained the best accuracy of 0.959158 with an F1 score is 0.959071 from the section of Ensemble's algorithm. Thirdly, the KNN classifier has acquired better accuracy, which is 0.961015, along with an F1 score of 0.960853 from the area of neighbor's classifiers. Also, from the section of naive Bayes algorithms, we can figure out that Gaussian naive Bayes has shown the best accuracy of 0.874381 and its F1 score is 0.872635 among all naive Bayes classifiers. Next, calibration also has placed the best accuracy of 0.877063, and its F1 score is 0.875664 from the branch of naive Bayes. After that, we can see from the semi-supervised classifiers, the label propagation has gained the best accuracy of 0.906972, and the F1 score is 0.906223. Besides, it can also be seen from the discriminant analysis section that the quadratic discriminant analysis has proved the best position of accuracy 0.979992 with an F1 score of 0.979962. Moreover, SVC is the best for predicting childbirth mode with an accuracy of 0.956477 and an F1 score of 0.956302 from all algorithms of SVM. Furthermore, we also can find out that the Gaussian process classifier placed the accuracy of 0.891708 and the F1 score is 0.890333. In the neural network, the multilayer perceptron classifier has acquired a good performance with an accuracy of 0.954404, and the F1 score is 0.954299.

Overall, by considering all the sections of algorithms for the prediction of childbirth mode, we can observe that the quadratic discriminant analysis is the winner with an accuracy of 0.979992 and the F1 score is 0.979962. The neighbors' classifier also comes up with the second-best with an accuracy of 0.961015, and the F1 score is 0.960853.

VI. Conclusion and Future Work

Selection of the best baby delivery methods is crucial for protecting both the mother and the newborn baby. But it still remains to explore the best sets of features when making this decision in a computerized way. That's why we try to leverage AI to recognize the best mode of baby delivery. Nowadays, machine learning, deep learning, and other computerized computation models are ubiquitously being used in medical decision-making. Here, we have used machine learning-based binary classification algorithms for decision-making between two methods of childbirth. This model will assist the doctor in making a more accurate decision within a very short time. This machine-learning-aided decision will not replace the necessity of the doctors for decision-making. Instead, it will help the physician to gain a deeper insight into the patient's information available. The way of decision-making using this model is very computerized and less likely to have an error.

The dataset we have used in this project is not very robust. In the future, we want to add much more observation to our dataset and make this model much more general. We believe a large set of data will produce better accuracy and less overfitting. Besides, we will implement a more in-depth learning-based classification to expand the investigation and make the top choice for record-breaking performance. After childbirth, we plan to implement this system to predict other real-life biomedical factors in advance. In addition, the data can be collected during the whole nine months of the mother's pregnancy. In the future, we plan to make a GUI of this model available to physicians, who can use it as like medical device for decision making.

Faculty of Sciences of Monastir, Electronics and MicroElectronics Laboratory (LEME)
Monastir 5019, Tunisia

***Abstract*—Over the last years, physical attacks have been massively researched due to their capability to extract secret information from cryptographic engine. These hacking techniques are based on exploiting information from physical implementations instead of cryptographic algorithm flaws. Fault-injection attacks (FA) and Side-channel analysis (SCA) are the most popular techniques of implementation attacks. Aiming to secure cryptographic devices against such attacks, many studies have proposed a variety of developed and sophisticated countermeasures. Hence, the majority of these secured approaches are used for precise and single attack and it is difficult to thwart hybrid attack, such as combined power and fault attacks. In this work, the Advanced Encryption Standard is used as a case study in order to analyse the most well-known physical-based Hacking techniques: Differential Fault Analysis (DFA) and Correlation Power Analysis (CPA). Consequently, with the knowledge of such contemporary hacking technique, we proposed a low overhead countermeasure for the AES implementation that combines the concept of correlated power noise generating with a combined-approach based fault detection scheme.**

Keywords—Advanced encryption standard; fault attack; power attacks; combined countermeasure; hardware implementation

I. Introduction

From a data security viewpoint, securing secret information requires using algorithms that resist theoretical hacking techniques. Though, treating an algorithm in a purely mathematical way or, in other words, shying away from its physical implementation opens the door to numerous threats in the real-world security. In the modern age of electronics, cryptanalysis attempts to reveal sensitive data based on physical property of a cryptographic device rather than making use of the theoretical flaws in the implemented cryptographic algorithm. Indeed, as the cryptographic algorithms are implemented on a physical platform, they are susceptible to well-known physical attacks, namely Fault Attacks (FA) and Side-Channel Analysis (SCA). These two classes of attacks exploit the physical interactions with cryptographic systems to break their security and extract secret information. These attacks are practical due to their methods to reveal the secret information from most cryptosystems which supposed to be cryptanalytically secure.

In SCA hacking technique, a passive adversary observes platform side-channel information to reveal the sensitive information. Indeed, these devices leak sensitive correlated information in the form of electromagnetic emissions (EM), time execution, power consumption, allowing a hacker to reveal the secret key from the cryptographic device [1]–[4].

On the other hand, FA hacking technique is an active cryptanalysis based on perturbing the cryptographic device processing in order to obtain an abnormal behaviour. The hacker then exploits the erroneous of the cryptographic device result to retrieve the secret key [5], [6]. Many studies combine SCA and FA in order to form even more sophisticated attacks [7], [8].

Aiming to secure cryptographic devices against such real-world attacks, countermeasures must be thus designed to harden cryptographic implementations before they are used in the wild. Many studies have proposed a variety of developed and sophisticated countermeasures. In particular, countermeasure for the AES crypto-core has been massively researched for many years against both fault injection Attack and power analysis attacks.

For SCA, most implemented countermeasures aim to decreasing the signal-to-noise ratio (SNR) by using two key approaches; the noise insertion or the leaked sensitive correlated information destruction. These countermeasures are categorized as logical [9], architectural [10], [11], and circuit-level countermeasures [12]–[14]. For the logical and architectural countermeasures, the used approach is specific to the crypto-core and design. On the other hand, physical countermeasures are nonspecific and can be used to protect any crypto-core by providing cover around it [2].

Error detection schemes against FAs are, generally, based on some redundancy approaches. Either using the temporal redundancy, where a given operation is computed twice, or using hardware redundancy by executing the same transformation at the same time to compare the obtained results and check whether a fault was induced. Adding correction and error detection codes to intermediate values is another option to protect the considered cryptographic system named information redundancy [15], [24].

Although the secured approaches have been widely studied for each kind of physical attack, the study of combined countermeasures has not been well explored in the existing literature. In this paper, we perform an in-depth study of Differential fault attack (DFA) and Correlation power analysis

(CPA) and we propose a dual complementary AES cryptographic circuit to defend against both fault and power SCA attacks.

The main contributions of this paper are as follows:

1) We firstly present a fault based Hacking technique to indicate how a fault injection can be useful to extract the sensitive data of the AES crypt core. In the suggested case study, we clarify the main procedures that can threat the security of the considered AES design basing on DFA attack.

2) We study the power based Hacking technique and we perform a successful CPA on the FPGA based AES implementation using the Side-channel Attack Standard Evaluation Board (SASEBO).

3) We develop a combined fault detection scheme to secure the AES cryptocore based on an error detection code for linear AES transformation and temporal redundancy for the nonlinear SubByte transformation. This proposed scheme can be applied for both LUT and GF SubByte transformation implementations.

4) To avoid information leakage, the proposed fault detection scheme is enhanced using a correlated power noise generator. This enhanced countermeasure eliminates the AES cryptocore power correlation with the secret key by adding an interfering power signal which depends on the manipulated data and a nosey key.

5) Finally, we implement our AES cryptocore with the proposed countermeasure on a Virtex V Xilinx field-programmable gate array (FPGA) device. Moreover, to investigate the practicality and effectiveness of the proposed architecture, we compare our implementation results to similar secured AES implementations presented in literature.

The paper is organized as follows. Section 2 introduces the proposed AES Faults-based Hacking technique using the DFA attack. Section 3 studies the AES power Side-Channel analysis using the CPA attack. Section 4 presents the proposed fault-resilient AES implementation. The proposed power based SCA-Countermeasure for AES implementation is presented in Section 5. The experimental results and comparison with previous works reported in the literature is given in Section 6. Section 7 concludes the paper.

II. The Faults-based Hacking Technique using the DFA Analysis against AES Implementation

A. Related Works

Fault attacks exploit the possibility to inject a fault into cryptographic devices in order to reveal the secret key. The fault injection is done by means of Electromagnetic field, supply voltage variation, laser beam, or temperature control. In particular, Differential Fault Attacks on AES has become a widely research topic using different fault-models; single-bit, single-byte fault and multibyte fault.

In [16], two DFA attacks on AES are proposed, the first attack inject a theoretical single-bit fault into an intermediate result allowing hacker to extract the AES-128 secret key with 50 faulty ciphertexts. While the second attack inject a byte-fault and reveal the key with less than 250 faulty ciphertexts.

Reference [17] presents an improved DFA attack approach on AES using unknown and random multi-byte faults. The authors focused on combined fault model that inject single-byte and multi-byte faults. Their attack showed that about 97.3% of the attacks can be completed within 3 pairs of correct and faulty ciphertexts.

In [18], authors presented a DFA combined fault model combining a single-byte random faults model in encryption process with a single-byte faults model in the key schedule process. Their experimental results showed that 6 pairs of correct and faulty ciphertexts could reveal the AES-128 secret key. Reference [19] shows that a FA can break the advanced encryption standard (AES) by exploiting the existing target devices Input/Output signals instead of the artificial triggering implementation. Indeed, authors identify fault injection time by employing target devices electromagnetic emission. Using one-byte fault model, the attack was successfully executed 55 times out of the 1000 conducted fault injection attacks overall.

In this paper, we aim to propose a low-cost fault-resilient AES architecture that resists side-channel attack. So, as a first step, we must study how a fault injection can be used to extract the cryptographic key. In this step, the Giraud's Single-Bit Differential Fault Analysis [16] is adopted as a case study to give details of the main procedure that can menace the security of the considered AES implementation. Consequently, with the knowledge of the considered Fault-hacking technique, we will propose the adequate DFA countermeasure for AES cryptocore.

B. The Fault Injection Step

In this step, we have adapted the single-bit fault model to simulate the physical real defects. This model assumed that only one bit in the considered circuit is faulty and supposed that one line in the circuit behaved as if it is at logic 0 or logic 1. For the multiple-bit fault model it is assumed that the same basic assumptions as the single-bit fault models, except allowing two or more lines in the circuit to be faulty at the same time.

For our considered DFA attack, the Single-Bit model is adopted, where only one bit was injected at the beginning of the final round (see Fig. 1).

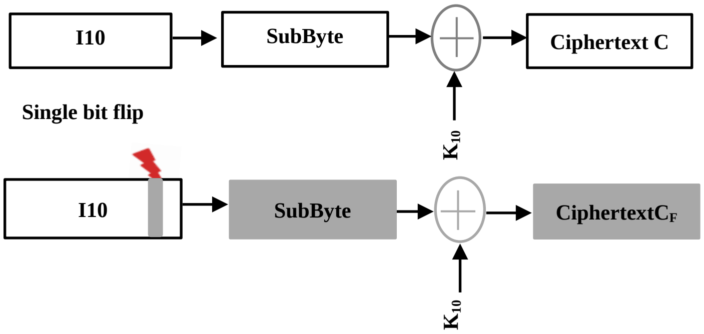

Fig. 1. The Single-Bit Fault Injection into the Input of the 10th Round.

C. The Fault Propagation Step

Using the DFA Single-Bit model, only a faulty one-bit *'e'* was injected in the output of the 9th AES round (I_{10}). When flipping a single bit between the MixColumns of the ninth round and the SubBytes of the tenth round, the changed bit spreads in the last round and generates a faulty Ciphertext (CF) with single faulty byte.

As presented in Fig. 2, the injected fault into the AES-128 bloc modifies 8-bit through the SubBytes operation. Indeed, this non-linear operation is a byte substitution and executes each 8-bit input separately. The affected byte is Xor-ed with another round key byte of the tenth round and produces one differential fault.

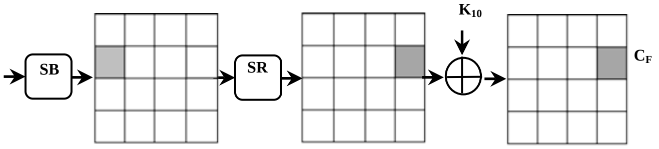

Fig. 2. Propagation of Injected Fault in $I_{10.}$

D. The Fault Exploitation Step

In order to reveal the AES secret key, the hacker exploits the observable fault by exploiting some relation between the two obtained ciphertexts. Indeed the hacker must repeat the experiment with the same plaintext and same key but without inducing fault. As a result, two ciphertexts derived from the same plaintext and key are obtained, where one of the ciphertext is fault-free (C) and the other is faulty (CF).

As a first step, the hacker tries to solve these equations.

$$C = SB\,(I_{10}) \oplus k_{10} \tag{1}$$

$$C_F = SB\,(I_{10} \oplus e) \oplus k_{10} \tag{2}$$

$$\Delta = C \oplus C_F \tag{3}$$

where $SB(I_{10})$ is the result of the SubByte transformation applied on one byte of the 9th round inputs (I_{10}) and k_{10} is the 10th round key corresponding byte (k_{10}). While Δ is the injected fault differential. As the single bit flip on I_{10} is the adapted fault model, the Δ Hamming weight (HW) must equal 1. In order to reveal the *k10* value, the hacker must ensure a full exploration of all possible key values. Therefore, the hacker first computes for each key-assumption ($\tilde{k}$) of the real-key byte (k), the corresponding hypothesized fault differential $\tilde{\Delta}$ as follows:

$$\widetilde{I_{10}} = SB^{-1}(C \oplus k\widetilde{10}) \tag{4}$$

$$\widetilde{I_{10F}} = SB^{-1}(C_F \oplus k\widetilde{10}) \tag{5}$$

$$\tilde{\Delta} = \widetilde{I_{10}} \oplus \widetilde{I_{10F}} \tag{6}$$

where $\widetilde{k_{10}}$ denotes the hypothetical key and $\widetilde{\mathrm{I}_{10}}$ is the input of the corresponding tenth round. Finally, the hacker must verify if the calculated $\tilde{\Delta}$ is identical to Δ. Indeed, the hypothetical key $\widetilde{k_{10}}$ may be a correct assumption for the real key k_{10} if the $\tilde{\Delta}$ Hamming weight is equal to 1. Otherwise, the hypothetical key $\tilde{k}$ is rejected. This process is recomputed for each k_{10} byte to reveal the overall round key k_{10}.

Fig. 3 present the number of injected fault needed to retrieve the whole 16-byte last-round key of AES-128. As shown in Fig. 2 the considered hacking technique needs only 32 fault injections to extract the whole 128-bit tenth round key. Finally, since the AES key expansion is invertible, the hacker can compute the original key (k_0) going backwards.

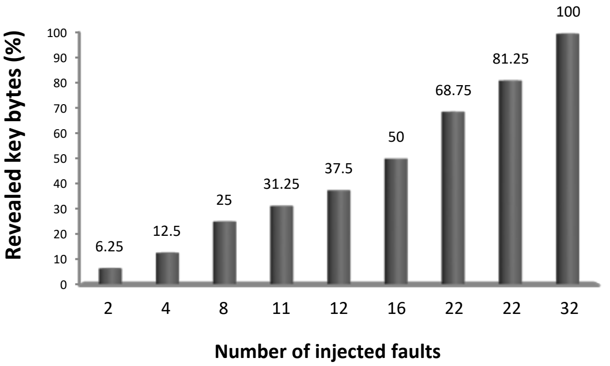

Fig. 3. The DFA Attack Results.

III. The Power Analysis-based Hacking Technique using the CPA Attack Against AES Implementation

Power-based side-channel attacks assume that there is a correlation between the level of power consumption and cryptographic operations manipulated by the cryptocore.

Simple power analysis (SPA) [20], differential power analysis (DPA) [21], and correlation power analysis (CPA) [22] are three fundamental techniques of power-based SCA attacks. The CPA hacking technique requires the least power traces to extract the secret-key and it has been considered as the most powerful power-based SCA. In this paper, the CPA-based Hacking technique was adopted as a case study in order to indicate the main procedure that can threat the AES cryptocore security.

A. CPA based Hacking Theory

The goal of CPA-based hacking technique is to accurately model the power consumption of the cryptographic circuit under attack in order to find correlation between characteristics of real power consumption traces and a predicted power trace. Therefore, choosing the accurately power model enable hackers to predict correctly the secret key by obtaining highest level of correlation.

1) The CMOS device power consumption model: For the cryptographic platforms based on the SOC design, the CMOS technology still the principal hardware solution due to its various advantages. The total power consumption of a CMOS device (P_{total}) is composed of two components: the static power (P_{static}) and the dynamic power ($P_{dynamic}$) [21]. P_{static} is the result of the transistors leakage current and depends on the circuit design. Hence, $P_{dynamic}$ is consumed when switching occurs. Indeed, if a CMOS cell changes from 0 to 1 or from 1 to 0, switching happens in transistors and Pdynamic is consumed. Therefore it depends on the manipulated data and the operation being done.

$$P_{dynamic} = P_{0\rightarrow 1}.C_{L.}\ f.\ V_{dd} \quad (7)$$

where C_L denotes the gate load capacitance, f denotes the clock frequency, VDD is the supply voltage and P0→1 the probability of a 0→1 output transition. As shown in (7), at a given time, the dynamic power dissipation depends upon the number of bit switching from one position to another [23][22]. Power consumption-based SCA uses a leakage model in order to define a relationship between the device power consumption and the secret information employed.

Various power models are proposed to estimate the power consumption of device under attack when processing the target data. The most well-known models are the Hamming distance and Hamming weight models.

a) The Hamming Weight Model

The Hamming weight model (HW) is the most basic power consumption model [21]. This model computes, in a data word, the number of bits set to 1. Considering multiple bits at a time, it is important to understand that the power consumption is, exclusively, based on the numbers of bits that are at logical 1 and not the number those bits are meant to represent. [25]. So, the predicted power consumption PW in an n-bit microprocessor is computed simply by:

$$PW= a*HW(D)+b= a * \sum_{j=0}^{n-1} d_{j} +b \quad (8)$$

where dj = 0 or 1 is the bit values of the binary data D ($D=\sum$) handled by the cryptographic device under attack. is a scaling factor between the power consumed and the Hamming weight. and b is a term for everything like static power dissipation, the variation from one clock cycle to another, and time dependent components.

b) The Hamming Distance Model

The Hamming Distance model (HD) was proposed by Brier et al in [22], where the leakage is assumed to depend on switching activity in CMOS device. This model supposes that the power consumption in the target circuit correlates to the bits number changing from one state to another. Indeed, to estimate the device power consumption, the hacker uses the HD model and count number of 1→0 and 0→1 transitions that occur in a register or bus of a cryptographic device when it changes from one state to the next state. The consumptions for a bit switching from 0 to 1 or from 1 to 0 are further assumed to be same. Let R the reference state for a data word from which the bits are switched and D the current state manipulated by the target device. The power consumed PW is described by the mathematical equation for the hamming distance model as follows:

$$PW=a*HD(D)+b = a*HW(R \oplus D) + b \quad (9)$$

where $HW(R \oplus D)$ is the number of flipping bits from binary data *R* to *D*.

2) Pearson correlation coefficient: To evaluate the correlation between the estimated power consumption and the real power trace, the Pearson coefficient, $\rho_{W,PW}$ is considered as an efficient way. This correlation coefficient calculates the correlation between estimated power consumption PW of target data D and the equivalent real power traces measured W during processing the target cryptographic operation. $\rho_{W,PW}$ is described as follows:

$$\rho_{W,PW} = \frac{Cov(PW,W)}{\sigma_{PW}*\sigma_{W}} \quad (10)$$

where Cov denotes the covariance between PW and W, and and are standard deviation for PW and W respectively. When manipulated, the selected data D must depend on the desired secret key and the correlation coefficient is adopted as a distinguisher. Therefore the hacker predicts the unknown key and calculates the correlation coefficient $\rho_{W,HD}$ for every key candidate. The values will respect the inequality $0 \leq |\rho_{W,HD}| \leq 1$ and the right key assumption is supposed to indicate the biggest value.

B. CPA based Hacking Practice

In this section, we demonstrate the efficiency of the power analysis-based side-channel attacks on AES-128 engine implemented on FPGA (see Fig. 4). The steps involved in a successful CPA-hacking technique are:

1) Attack point selection step: In this step, a hacker chooses the attack point which can be a register or some function manipulating an intermediate result of the algorithm. This point must depend on both the known variable (e.g. the output of S-box) and secret keys K. In this case, the 10th round encryption is attack because the latter has been isolated from the other rounds and have relatively clear power signals [26]. Then, we calculate the original secret key, K0, going backwards since the AES Key Schedule is invertible. Fig. 5 shows the selected intermediate node D denoted as the output of Subbytes transformation and the reference point R defined as the corresponding Ciphertext. The AES-128 is used as a case study but this power-hacking technique can be applied to AES-192 and AES-256.

2) Power Assumption step: This step consists of predicting the target device power consumption with certain leakage model to estimate the dynamic power consumption reflecting secret-data moving and manipulated operations. As explained in previous section, power models present the correlation between the power consumed of the cryptographic CMOS device and data processed by this device at the same time. Indeed, bus value switching or registers value switching from 0 to1 or from 1 to 0 consumes some energy amount to achieve the transition. Hence, by counting the bits transition number at a given time, the hacker may predict the device under attack power consumption.

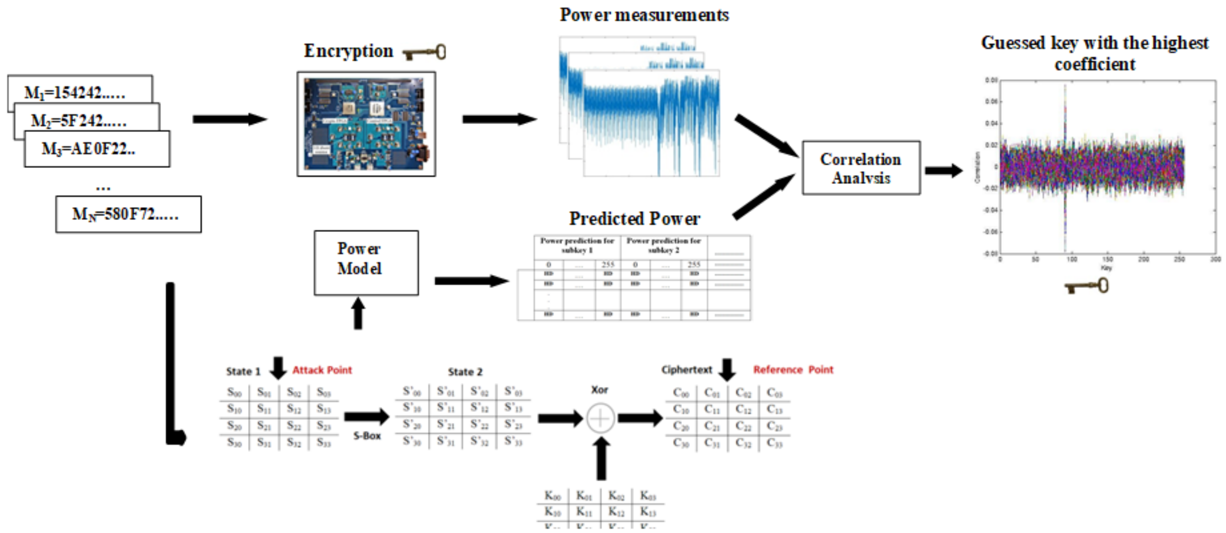

Fig. 4. Power Side-Channel Attack on 128-AES.

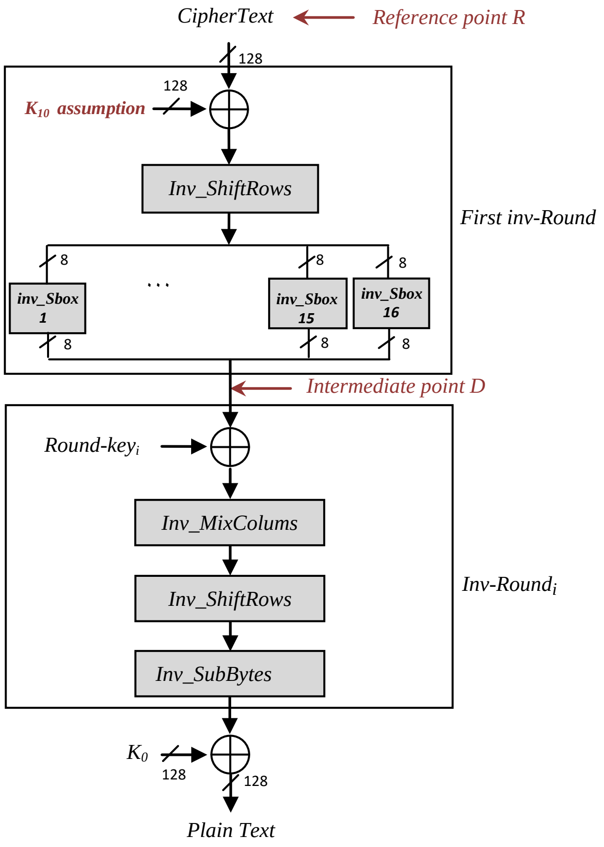

Fig. 5. The Selected Node for CPA Attack.

In this step, we have adapted the hamming distance model to predict the power consumption of the last AES-128 round encryption. The AES-128 decryption is an inv_round based encryption algorithm that process 128-bits data blocks as 16 bytes using 128-bits cipher keys. Each inv_rounds manipulates 128-bits round keys (K1 to K10) calculated from the original AES key, K_0 [27]. Indeed, this secret round-key is Xor-ed with the previous inv_round output, followed by an Inverse-ShiftRows transformation and Inverse-SubBytes transformation. The Inverse SubBytes operation divides the resulting 128-bits into 16 bytes and passing each through a Substitution S-Box. The S-box block takes 8-bit as input and produces 8 bite as output. Therefore, predicting one byte of the considered key is simple to calculate. For N Ciphertexts (N=20 000 in our case study) we predicts a subkey (The number of sub-key guess is limited to 28 assumptions: 256) and we calculate *HD(D)* predicted power consumption of the selected point *D* by the hamming distance model.

This step is repeated for 16 S-box outputs. So, we obtain a predicted power matrix P of size N x 256 x 16 as shown in Table I. *HD* value can be 1,2,3 or 8.

3) Measuring Power consumption step: The common setup for all Power-based side-channel attacks uses a PC in order to send known plaintexts to the target cryptographic circuit, trigger a device and save its power measurements traces. Therefore the hacker must obtain a matrix with a data pair of same Ciphertext used in the Power assumption step and their corresponding power measurements. The power measurements traces are normalized using pre-amplifier and gathered by oscilloscope during the AES encryption process. In this work, power measurements were performed by the "DPA contest v2" competition from the COMELEC Telecom department. The platform used to perform the power measurements acquisition is the Xilinx FPGA based Side-channel Attack Standard Evaluation Board (SASEBO)[28].

4) Correlation analysis step: This step evaluates the correlation between the predicted power and the power measurements using the Pearson coefficient. In this CPA statistical step, the measured power traces, denoted W, are compared to the predicted power consumption, denoted PW, for each 256 sub-key guesses. The correlation coefficient ρ_{WPw} is applied as follows:

TABLE I. PREDICTED POWER MATRIX P

Power prediction for subkey 1			**Power prediction for subkey 2**			**……………**	**Power prediction for subkey 16**		
0	…	255	0	…	255	……………	0	…	255
HD	…	**HD**	**HD**	…	**HD**	**……………**	**HD**	…	**HD**
HD	…	**HD**	**HD**	…	**HD**	**……………**	**HD**	…	**HD**
. . .									
HD	…	**HD**	**HD**	…	**HD**	**……………**	**HD**	…	**HD**

$$\rho_{W,Pw} = \frac{E(W,Pw)-E(W)*E(Pw)}{\sqrt{V(W)V(Pw)}}, \qquad (11)$$

If the sub-key assumption is correct, we expect that only one value, corresponding to the correct sub-key prediction, leads to a high correlation coefficient. The experimental result with only 3000 power measurements is shown in Fig. 6. As illustrated, the correlation power traces do not reveal the correct secret-key. Indeed there is no high correlation value in the obtained trace. The same correlation coefficient is calculated for the 256 sub-key assumption using 20000 power measurements. As indicated in Fig. 7, a unique correlation value, corresponding to the correct sub-key assumption, have high correlation value. Besides, the correct key assumption regularly stands out with a notable difference leading to a sure verdict of a successful attack. Fig. 9 corresponds to the correlation coefficient of correct sub-key assumption of. Hence, Fig. 8 presents the correlation value when the key guess is incorrect. This trace proves that there is no correlation between the predicted trace P and the corresponding measured trace W.

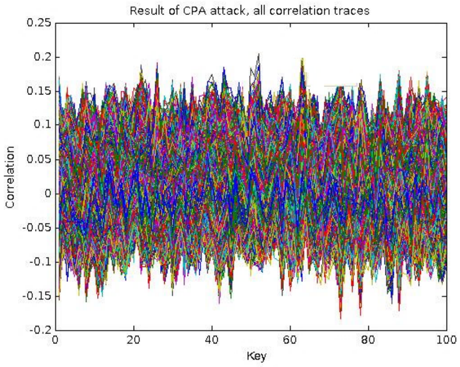

Fig. 6. Failed CPA using 3000 Inputs.

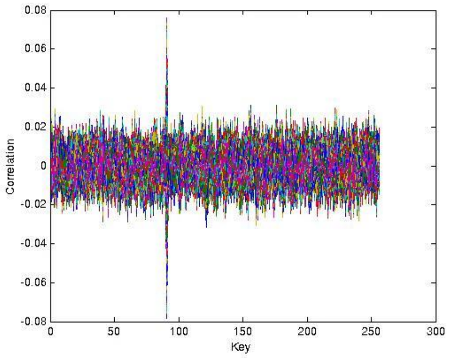

Fig. 7. Successful CPA using 20000 Inputs.

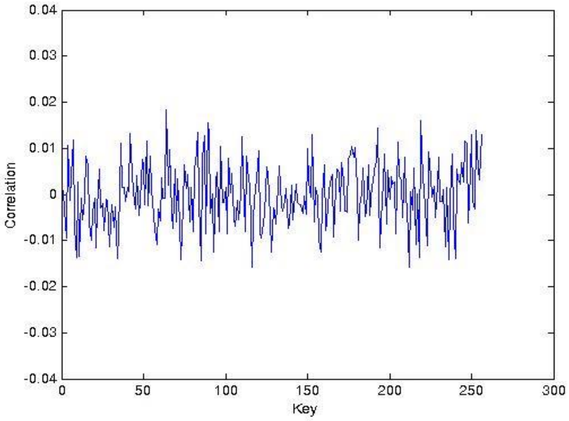

Fig. 8. Correlation Coefficient of an in Correct Sub-Key Assumption.

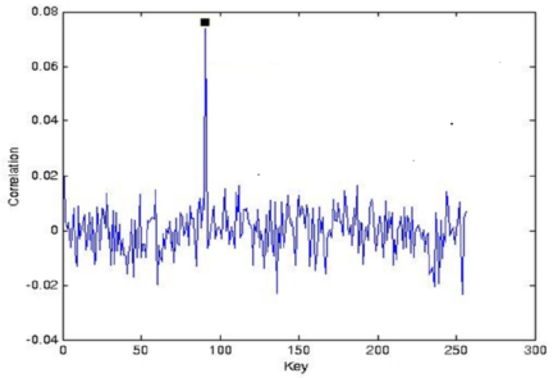

Fig. 9. Correlation Coefficient of a Correct Sub-Key Assumption.

In Fig. 10 the correlation coefficient for all the sub-key assumption, in terms of the number of power measurement was presented. This correlation trace presents the correlation coefficient between the measured power consumption and the predicted power consumption for various numbers of traces.

In fact, we remark that the correct sub-key assumption (plotted in black) can be distinguished by approximately 6000 power traces. This obtained result proves that CPA attack is an efficient power side-channel attack technique to extract the secret key.

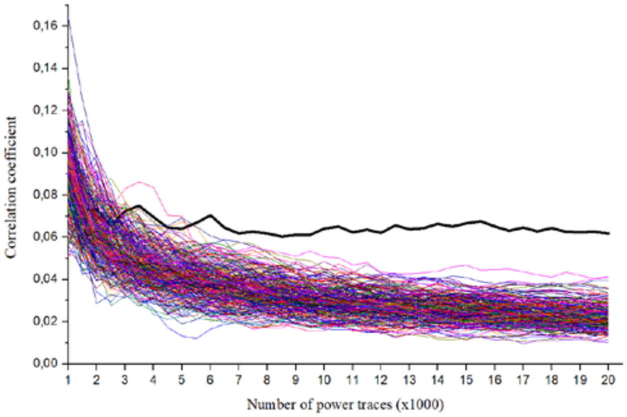

Fig. 10. Correlation Coefficient for all the Sub-Key Assumption.

IV. The Proposed Fault and Side-Channel Resistant 32-Bit AES

Power-Channel Analysis and Fault Attacks have seen a rise in popularity these last years, due to their practical methods to reveal the sensitive data from most cryptosystems which supposed to be cryptanalytically secure.

Our goal is to protect the cryptographic application against such attacks by detecting injected faults in the cryptocore and artificially introducing a noise in order to enhance the attack difficulty and reduce the probability of successful attacks. This section presents the proposed AES hardwarebased countermeasure to resist both Fault injection and Power sidechannel attacks. Fig. 11 shows the 32-bits AES block used as a case study.

The proposed design takes four 32-bit columns for the input data, one by one, executes them independently, and at the end, produces four 32-bit output columns.

A. Proposed Fault Detection Scheme for the AES

To secure the AES implementation against fault injection attacks, we incorporate fault-resilient techniques into the considered cryptographic hardware. Various DFA countermeasure schemes have been proposed to secure AES implementations, which are based on some sort of redundancy: information redundancy, hardware redundancy, or time redundancy in order to detect injected faults.

In this section we present an efficient combined fault detection based countermeasure that applies time and information redundancy to secure the considered AES cryptocore.

In this section we present an efficient combined fault detection based countermeasure that applies time and information redundancy to secure the considered AES cryptocore. The proposed Fault resilient AES implementation uses error detection code based on the (5, 4) CRC [29] to protect linear transformations and temporal redundancy approach for the Subbyte nonlinear transformation.

In fact, the information and hardware redundancy techniques induce more hardware overhead which can degrade cryptographic devices performances [30]. On the other hand The SubBytes operation is the most important non-linear operation in the AES, it occupies 70% of the AES Round area and 60% of the Key_Generator area.

Fig. 12 shows the temporal redundancy-based countermeasure to protect the Subbyte implementation.

As shown in Fig. 11, using same inputs, the Subbytes transformation is calculated twice with the same S-box hardware block and at the end, the result of the main calculation is compared with the result of the recalculation.

The fault detection scheme checks whether the indicator Sbox_FLAG equals zero or not. This Sbox_flag is calculated using a parity tree of exclusive-or gates.

Fig. 13 shows the information redundancy based countermeasure for linear transformations (ShiftRow, Mixcolum and AddRoundKey) with concurrent error detection. The ShiftRow shifts the bytes in each state row by a certain position without changing the parity from its input to its output. Correspondingly, there is no parity modification from the inputs of MixColumn to its outputs.

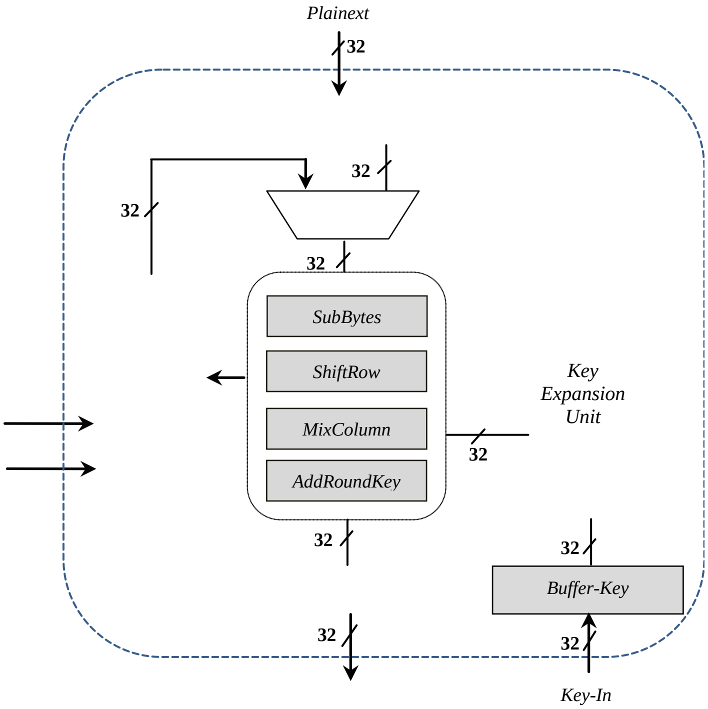

Fig. 11. Proposed 32-Bit Data-Path.

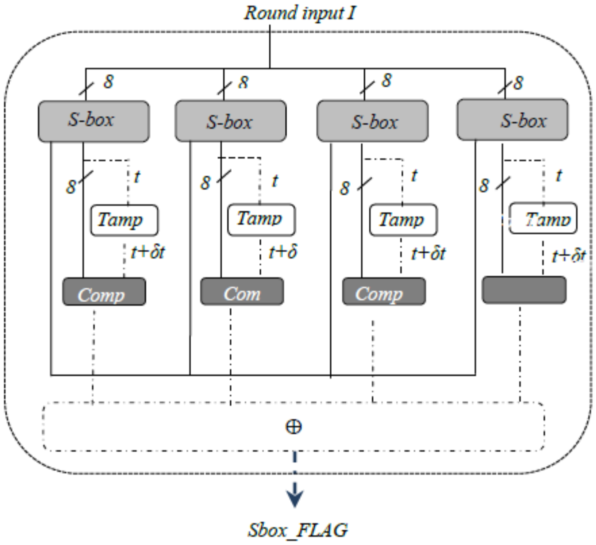

Fig. 12. SubByte Block with Error Check.

To detect injected fault in the Shiftrow and the Mixcolumn operations, we apply the information redundancy technique by using redundant information to protect these transformation.

Let SB(x) the Subbytes output and SR(x) the Shiftrow output as shown in Fig.13, where SB(x) = sb_0+sb_1x +sb_2 x^2 +sb_3 x^3 and SR(x) = sr_0 +sr_1 x +sr_2 x^2 +sr_3 x^3, {sb$i$, sr_i} ∈ GF(2^8). P_{SB} is the Shiftrow's input parity obtained by (12).

$$P_{SB}=P(SB)= \sum_{i=0}^{3} sb_i \tag{12}$$

where sb_i ∈ GF (2^8) is fault detection approach checks whether the flag Shiftrow_fg , obtained by (13), equals zero or not.

$$Shiftrow\_fg = P_{SB} \oplus \sum_{i=0}^{3} sr_i \tag{13}$$

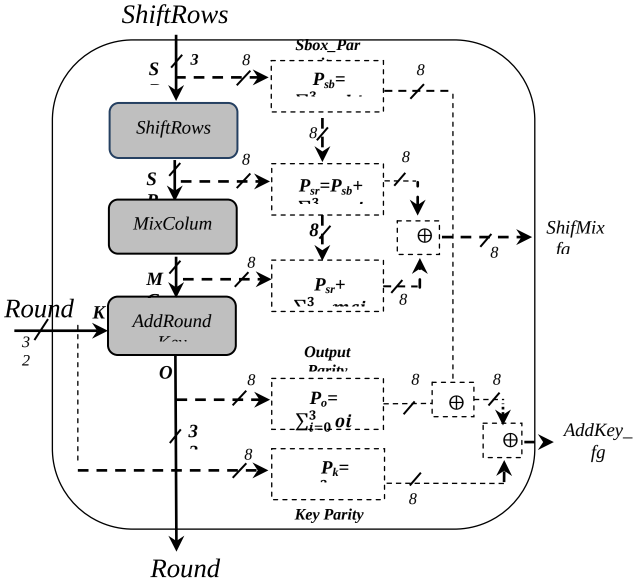

Fig. 13. Concurrent Error Detection Bloc for Linear Operations.

To protect Mixcolum operation, we use the same information redundancy based technique and we compute the flag mixcolumn_fg. The produced Flag will be XOR-red with the ShiftRow_fg in order to produce (ShifMix_fg).

At the Round output, the Shiftrow‗s input parity Psb will not be modified by the Mixcolum and the ShiftRow operations. But it will be changed by the AddRoundkey operation. So, to secure the AddRoundKey operation against fault injection, the key‗s parity PK must be calculated and xor-ed with the parity Psb. The obtained result will be XOR-ed with PO, the output‗s parity round, to produce the *AddKey_fg* flag. This DFA-countermeasure can be used to detect injected faults during the encryption process and produces Flags in order to interrupt the AES process. (see Fig.13).

B. Proposed SCA-Countermeasure for AES Cryptocore

The threats from Power attacks and Fault attacks challenge the integrity and security of cryptosystems. Various countermeasures for these attacks have been extensively studied in the existing literatures.

The author in [31] shows the impact of the countermeasure for one type of attack on the efficiency of another type of attack has been well explored.

Their experimental results show that the parity check code based fault detection technique makes CPA attack more difficult to retrieve the key than the original AES implementation. Based on this study, our Fault attack-resistant AES will affect the key retrieve speed of the CPA attack.

To more improve our fault resilient AES implementation, the hiding technique aims at lowering the Signal Noise Ratio (SNR) during the cryptographic operation by either adding more sources of noise or lessening the strength of the signal power trace that relates to the cryptocore operations. This makes CPA attack much harder as the data leaked has also to be correlated with external interfered key used inside the secured core.

Fig. 14 shows the Power analysis countermeasure for the AES cryptocore. This technique will be applied to the combined Fault resistant architecture presented in previous section. As shown in this figure, a parallel noise was incorporated into the AES cryptocore. The noise generating circuit obfuscates the AES cryptocore power traces by a power trace signal correlated with the plaintext and an interfering random key K_{interf}.

The AES cryptocore execute the AddRoundKey operation using the plaintext and the secret key K. Simultaneously, the noise generating circuit performs the same operation with the same plaintext but with the interfering keyK_{interf}. Two similar Subbytes transformation will takes the two AddRoundKey outputs as input and produces two signals S and S_{interf}.

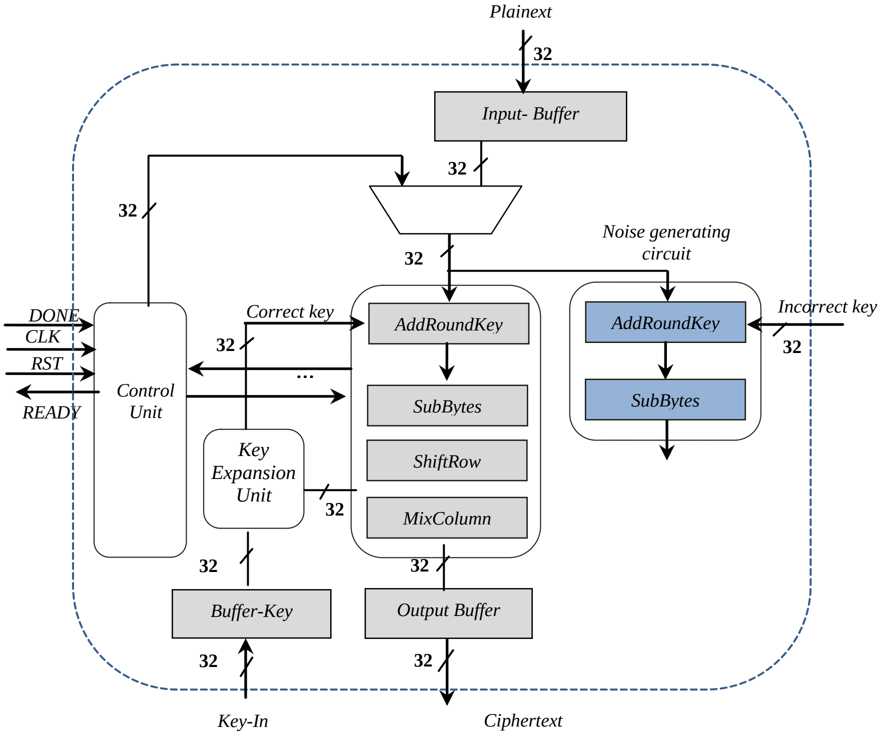

Fig. 14. Power Countermeasure for 32-Bits AES.

This proposed noise injection technique obfuscates the global AES cryptocore power trace by decreasing the correlation and bond between the secret values and the leaked information. In fact, the AES cryptocore power consumption correlates to plaintext and the secret keys couple (K, Kinterf). Furthermore, this added noise cannot be removed by statistical differential method; therefore, even if the power consumption curves was moved precisely and the Sboxes corresponding key successfully recovered, the hacker will still end up in failure because of the interference of the generated noise. This noise injection based countermeasure technique was experimentally proved in [32].

V. Implementation Results and Comparison

The proposed SCA/DFA Countermeasures for the AES design is practically examined using a Xilinx FPGA device, while the FI resistance is evaluated using the extensive fault simulations.We synthesized our implementation with the Xilinx ISE using the XC5VFX70t FPGA platform. The results and comparison with similar reported works are presented in Table II.

The AES-encryption implementation without the proposed countermeasure takes 445 slices for 296.43 MHz. The FPGA implementation result shows that our secured AES-encryption design occupies 14 % more area and 13% less throughputs compared to the original AES-cryptocore.

It can be seen from Table II, our proposed design has the minimum area overhead compared to [33], [34], [35] and [37].

TABLE II. FPGA Implementation of the Fault Resilient AES: Result and Comparison

	Area Overhead (%)	**Time Overhead (%)**	**FC (%) Single-bit**	**FC (%) Random-bit**
Our secured AES	**14**	**-13.5**	**100**	**100**
[33]	**43.33**	**-7.91**	**67.70**	**-**
[34]	**26.9**	**≈ 0**	**100**	**99.996**
[35]	**81**	**≈ - 0.17**	**100**	**93.75**
[36]	**2.3**	**-50**	**100**	**75**
[37]	**14.45**	**-18.71**	**85.958**	**98.54**

The temporal redundancy countermeasure presented in [36] add 2.3% overhead in terms of added hardware overhead and presents, approximately, four times degradation in terms of throughput overhead compared to our proposed countermeasures. Compared to [37] and [33], our secured AES design has the minimum area overhead and time overhead. These results prove that our proposed circuit is relevant to be arranged in many security domains such as embedded services routers, smartcards and emerging technologies using IoTs.

In order to evaluate the fault coverage of our protected AES cryptocore, fault-simulations are performed using the VHDL language. Two type of fault are used in the considered fault coverage simulation: Single-bit faults and Random-bit fault. For the single bit-fault type, we consider that a single-bit fault is inserted into 1-bit in random locations at random clock cycles of random rounds. On the other hand, random-bit fault type considers that faults are injected with random faulty bit number at random locations of random rounds. Fault simulations are performed over 1 000 000 times. As shown in the Table II, our fault simulations show that for single bit and random-bit faults, our protected AES-cryptocore have error coverage of 100 %.

Comparing our design to other similar countermeasures, our obtained fault coverage has the highest protection. Although our secured AES needs more resource overhead compared to some designs, it allows an excellent trade-off between fault-attack coverage, implementation area and throughput, which are relevant to secure embedded systems with resource constraint. In our future work, our power-baser cannel attack must be enhanced using new approaches based on deep-learning models.

VI. Conclusion

Recently, cryptographic embedded platforms used for trusted execution environment have been proven to be vulnerable to the power SCA and fault attacks. In this paper, we present a detailed fault and power based Hacking techniques to demonstrate how the fault injection or power analysis can be exploited to reveal the AES secret key. In the proposed case study, we explain the principal techniques that can threat the security of the AES design by using DFA and CPA attacks. This study was conducted in order to propose an adequate low-overhead hardware countermeasure that secures critical 32-bit AES cypto-core against both fault injection and power-based side-channel attacks. The proposed countermeasure gathers a combined fault resistance approach using parity testing for linear operations and time redundancy for the non-linear SubBytes operation with an artificially introduced noise provided by a correlated power noise block. The proposed countermeasure can be used for the encryption and decryption designs in order to enhance attack difficulty and reduce the probability of successful attacks. The proposed combined countermeasure has low overhead and achieves a 100% fault coverage during the considered AES process.

***Abstract*—Recent advancements in drone technology are opening new opportunities and applications in various fields of life especially in the form of small drones. However, these advancements are also causing new challenges in terms of security, adaptability, and consistency. This research discusses the drone technology, area of usages, citizen multi-objective uses, drones security, protection, and secrecy apprehensions, drone current intimidations and susceptibilities, existing approaches for drone cyber-security methods, security threats to drones and data sources for current literature review. Small drones are proving to be a new opportunity for the civil and military industries. The small drones are suffering from architectural issues and the definition of security and safety issues. The rapid growth of the Internet of Things (IoT) opens new dimensions for drone technology but posing new threats as well. The tiny flying intelligent devices are challenging for the security and privacy of data. The design of these small drones is yet not matured to fulfill the domain requirements. The basic design issues also need security mechanisms, privacy mechanisms and data transformations.**

Keywords—Drone technology; security; internet of things; threats; privacy

I. Introduction

In this modern atomic world, drone technology is mainly used for military purposes and defensive areas. Drone technology is rapidly growing for defense purposes. These microdevices are flying in the air 200 feet above the ground. This range of height varies from device to device and purpose to purpose. This range can be in feet, meters, and kilometers. Flight time of these intelligent devices also varies from device to device [1][2]. The frequency variations and their properties are discussed in Table I.

TABLE I. Frequency Variations and their Properties

Parameters	**2GHz**	**5GHz**
Frequency band	Low speed	High Speed
Cost	Cheap	Costly
Range	Extended range	Undersized range
Effect of noise	Noisy	Less noisy
interference	Prone to interference	Less prone to interference
Physical barriers	Overcome physical barriers	Unable to overcome physical barriers.
Performances	Disturb Wi-Fi speed	Don't disturb Wi-Fi speed

A. Rules and Guidelines

Many countries have strict rules and regulations for drone usage in civilian areas [16-18]. The rules and regulations issued advice for drone owners to use drones under government license. Drones must not enter private legacies without the permission of the owner. In Lebanon, strict rules are followed for drone usage. No person can fly drones in private areas, without the permission of the owner. To fly drones in private areas, the owner of the drone must get the permission certification for this act. Without this, one can face serious prosecutions. Following are some rules which must be followed by each drone owner in the USA.

- A drone must not reach 400 feet in height.
- A drone must not enter sensitive areas i.e. aircraft and airfields.
- A drone must be operated with safety and care to prevent face examination.
- A drone must not enter civilian areas.
- A drone must not be operated in gatherings and functions

Such rules are strictly followed by drone owners for safe drone flights. Heavy fines and punishments can be faced by the owners of the drone if such rules are violated.

B. Drone Structural Design

A UAV structure comprises three components. These components include Unmanned Aircraft, Ground Controller, and Communication link [3,19]. An explanation of these components is given below.

- The Flight Controller is the CPU of a drone.
- Ground station controller provides communication between the craft and controller.
- Data communication link provides information communication between ground controller and drone.

In [3] drones are categorized depending on their distance from the ground controller. These categories are given below.

- Line of sight distance drones use radio waves for communication.

- Beyond line of sight distance, drones use satellite communications.

C. Drone Communications Categories

Drones are classified into different categories based on their communication styles. These categories are D2D, D2G, and D2N. This communication is described in Fig. 2.

1) Drone-to-drone: Drone to Drone communication is not yet legalized. Machine learning approaches can be used in such communication in a wireless environment. This is also known as peer-to-peer communication. Such communication is more prone to jamming and DoS attacks [20 – 23].

2) Drone-to-ground location: This type of communication is mainly standardized and based on specific protocols with 2 and 5 GHz frequencies. It can also be operated on Bluetooth and Wi-Fi. Many of such communications are not available in the public sector because of security and authentication issues. Such communication is more prone to eavesdropping and man-in-the-middle attacks as shown in Fig. 1.

3) Drone-to-network: Such communication allows network selection for control and transfer of information. Several Wi-Fi networks can be used at different frequencies in such types of communication.

4) Drone-to-satellite: GPS devices are involved to provide real-time communication in such types of drone communication. Drone communicates with the satellites for location measurement. This communication is more secure and safe as compared to other categories and is used in the military.

D. Unmanned Aerial Vehicles Types

All Unmanned Aerial Vehicles can be called drones. In this section, differences between drones, UAVs and UAS are described in detail. Fig. 7 explains this classification difference in detail.

1) Drones: Drones are remote-based air devices that can be used on earth and in ships for different purposes. Different types of drone categories are described below based on their technology.

a) Multi-Blade Drones: Such drones are based on vertical landing and flying mechanisms. Such drones usually based on fixed operations and are easier to be attacked by external devices. This communication is very accurate but has less mobility because of the huge consumption of energy.

b) Fixed-Blade Drones: These drones consume less energy and are most suitable as compared to multi-blade drones [33,34]. These drones are faster and can handle heavy payloads.

c) Hybrid-Blade Drones: These drones have fixed as well as moving wings. These drone devices are speedy as compared to other types.

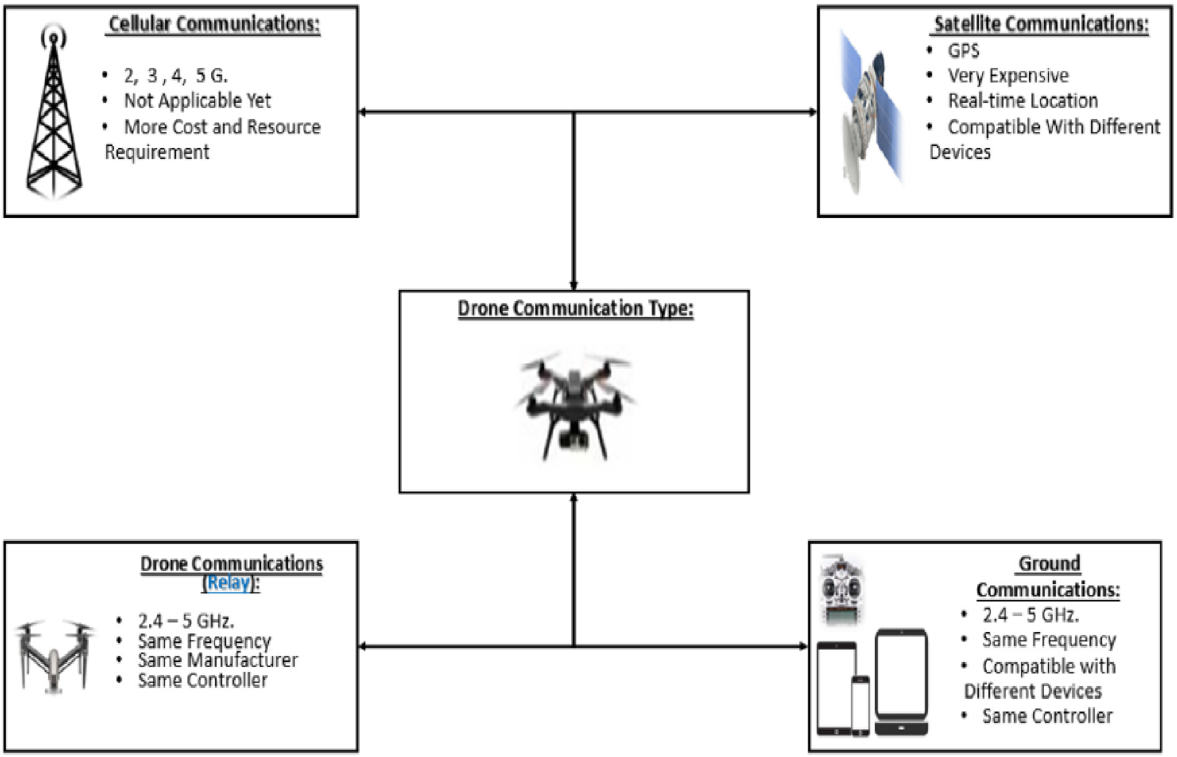

Fig. 1. Drone Communication.

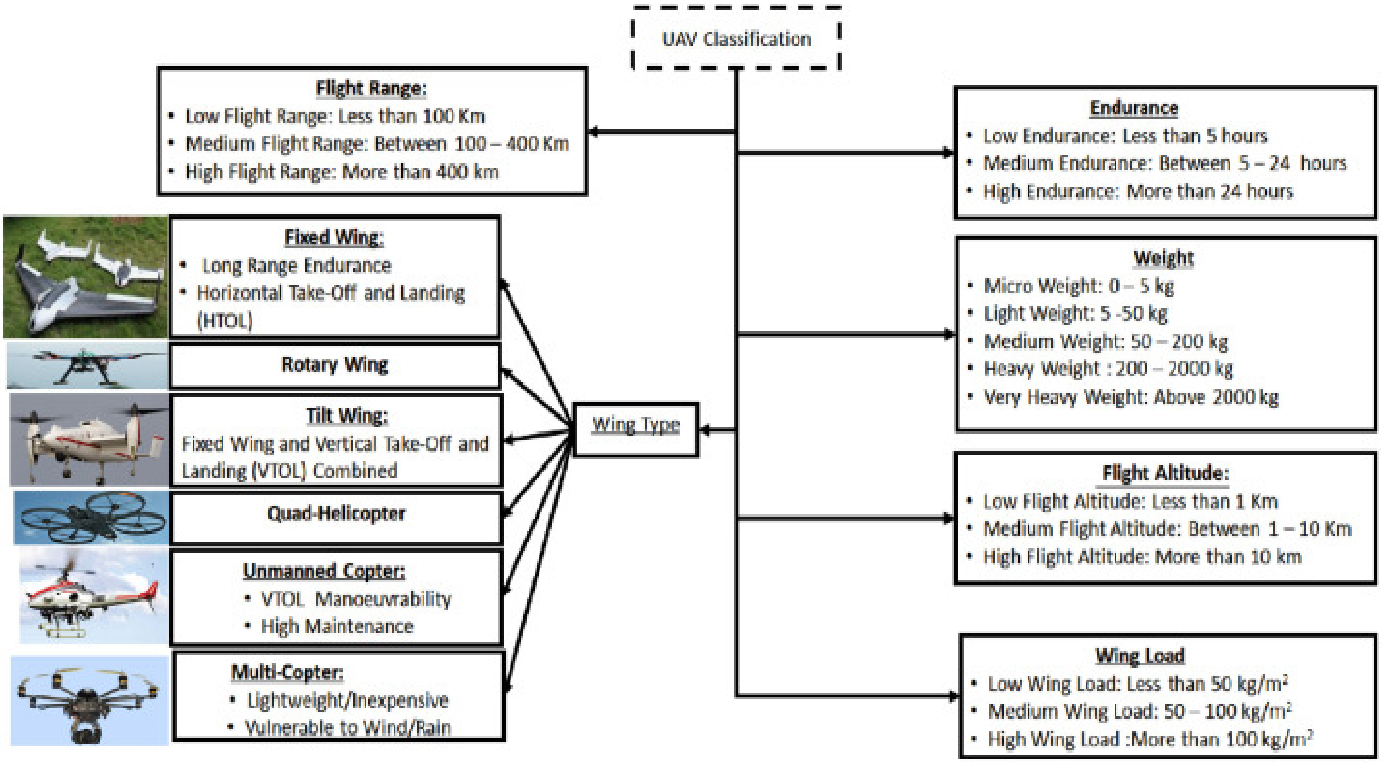

UAV Classification
Flight Range:
• Low Flight Range: Less than 100 Km
• Medium Flight Range: Between 100 – 400 Km
• High Flight Range: More than 400 km
Endurance
• Low Endurance: Less than 5 hours
• Medium Endurance: Between 5 – 24 hours
• High Endurance: More than 24 hours
Fixed Wing:
• Long Range Endurance
• Horizontal Take-Off and Landing (HTOL)
Rotary Wing
Tilt Wing:
Fixed Wing and Vertical Take-Off and Landing (VTOL) Combined
Quad-Helicopter
Unmanned Copter:
• VTOL Manoeuvrability
• High Maintenance
Multi-Copter:
• Lightweight/Inexpensive
• Vulnerable to Wind/Rain
Wing Type
Weight
• Micro Weight: 0 – 5 kg
• Light Weight: 5 -50 kg
• Medium Weight: 50 – 200 kg
• Heavy Weight : 200 – 2000 kg
• Very Heavy Weight: Above 2000 kg
Flight Altitude:
• Low Flight Altitude: Less than 1 Km
• Medium Flight Altitude: Between 1 – 10 Km
• High Flight Altitude: More than 10 km
Wing Load
• Low Wing Load: Less than 50 kg/m²
• Medium Wing Load: 50 – 100 kg/m²
• High Wing Load :More than 100 kg/m²

Fig. 2. UAV Classification.

2) UAVs: These devices consist of a controller which can be a mobile or a computer. These devices can be operated independently and are classified into the following categories. A UAV can fly remotely/autonomously using a controller, mobile phone, computer, or even a tablet [24]. They are characterized into the following types [25]:

- Remote Pilot Control UAVs are based on the controller which is handled by a human on the ground.
- Remote Supervised Control UAVs works independently and can be handled by a human if needed.
- Full Autonomous Control drones work independently without any human intervention.

3) UAS: UAS is a combination of UAV and drone. A UAV is also a UAS that is controlled by a controller [38].

4) RPA: Remotely Piloted Aircraft works independently for a long time without any intervention. It is used in complex missions and flights [37].

II. Areas of Usage

In the current era of technology, drone demand is increasing day by day. Drones help in delivering foods, items, and goods. Drones are also called flying riders. The main objective of using drones is to reach those areas where human access is limited. Drones usage is present in many areas of life [13][33]. This usage is discussed below in Fig. 3.

A. Citizen Multi-Objective Uses

Drone technology is used by civilians in many areas of daily life. These domains consist of life-saving, disaster management, etc. main uses of drones are discussed below.

a) Camerawork: Drones use is increasing in photography and video shooting in those areas where the human approach is difficult [34].

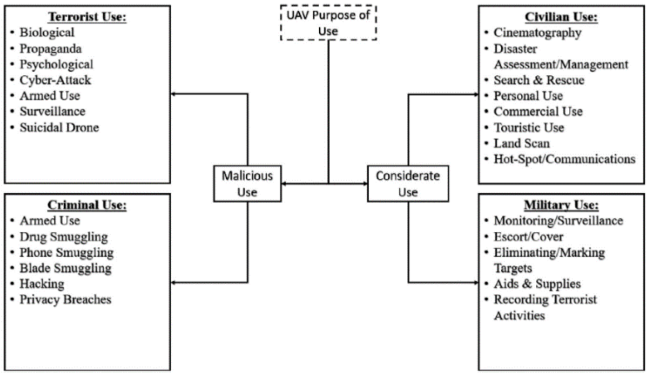

Fig. 3. Drone Uses in different Areas of Life.

b) Disaster Management: Disaster monitoring and controlling is also possible using UAVs and UAS since the 2005 major disaster. It helps in evaluating the situation of destruction and damage.

c) Exploration and Rescue: UAVs are also used to explore and save the lives of people and other livings beings.

d) Tourism: UAVs help in exploring different areas in tourism and traveling trips [35], which improves tourism revenue.

e) Commercials: Drones and UAVs are used to shoot commercials and Ads with HD cameras in minimum time. This saves time and cost for overall shooting.

f) Emergency Supervision: Extremist attacks and disasters can be handled and monitored using UAVs and drones [36].

g) Quick Reaction: Drones and UAVs as a first aid kit in many situations [37]. Drones were also used in the Covid-19 pandemic to provide disinfectant spray. Drones help in delivering foods and other items in this situation [38, 39 and 40].

h) Ecological Management: Drones provide different ecological measurement tasks including population calculation etc. it can also be used to calculate environmental parameters. It is also used to monitor crop parameters, air quality analysis, and weather measurement.

i) Subsurface/Oceanic Devotions: Underwater drones help in monitoring the underwater environment and operations [41]. Drones can provide live recording and monitoring.

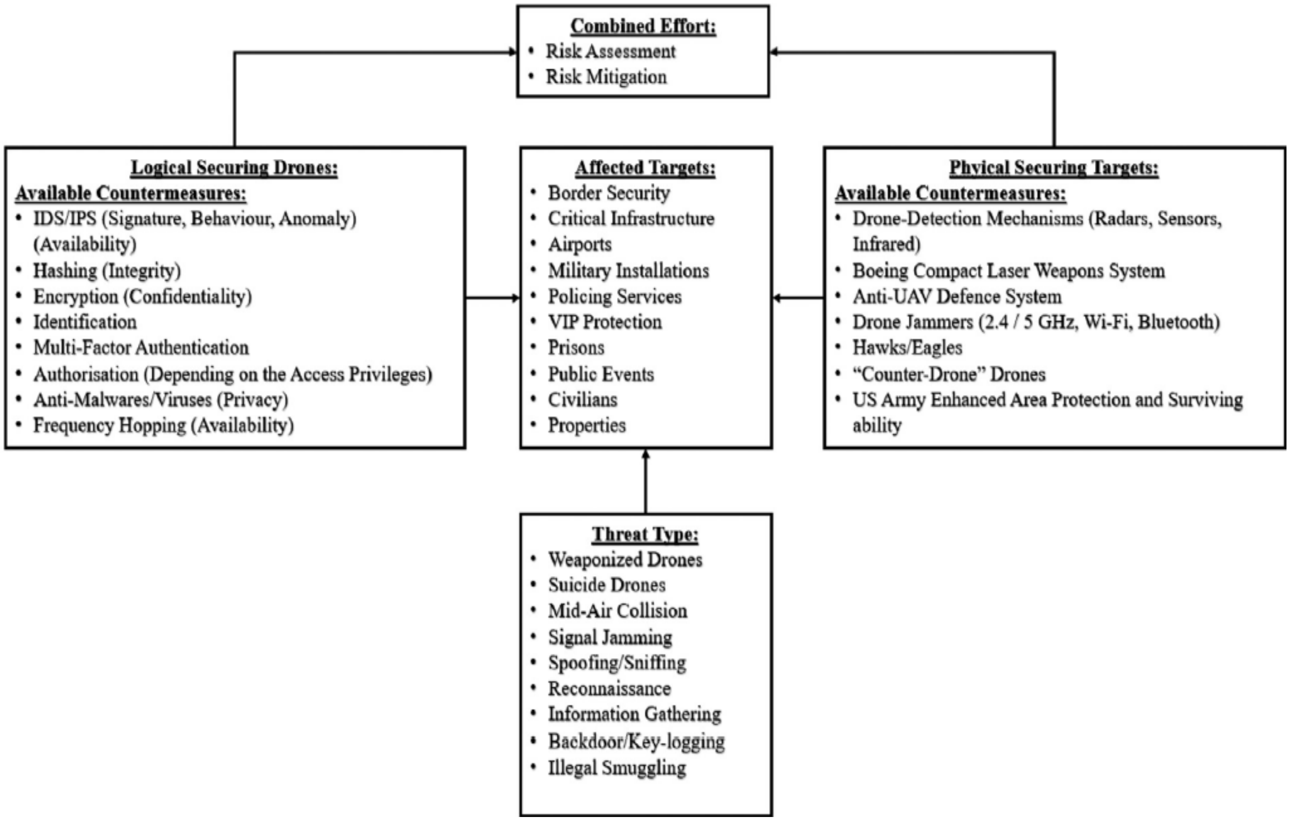
III. Drones Security, Protection, and Secrecy Apprehensions

Drone technology provides several advantages and benefits for human beings. It helps in day-to-day activities as well as the military and monitoring of weather. However, several privacy and safety concerns are associated with their advantages. Security and privacy breaches should be addressed properly. Recording and image capturing by drones must be done keeping in mind the privacy and confidentiality of people's concerns [42]. For sanctuary and risk examination of drones, several studies are present in which risk associated with it is considered and discussed.

It is important to maintain secrecy, reliability, obtainability, verification, and non-denial possessions above message-passing networks are fulfilled. This can be achieved through AAA procedures and progressions:

- Authorization is achieved by providing access to the control unit of the drone/UAV.
- Verification can be obtained by using multi-level authentication using knowledge {specific key), identity verification and biometric verification.

Security threats are associated with drones which can be physical or cyber-attacks. It is important to limit drone usage in civilian areas and properties. The negative use of drones is also increasing day by day. This usage also creates problems for the citizens and civilians. Drone owners use Bluetooth or Wi-Fi channels to control their drones in restricted areas. This can leads to financial loss. Drones are used to breach Wi-Fi connections and Bluetooth signals. Such breach causes so many privacy and security concerns for peoples. Fig. 4 shows the important security threats to drones. Solutions to prevent these threats are also discussed. A summary of present and upcoming safety apprehensions is given below.



Combined Effort:
• Risk Assessment
• Risk Mitigation
Logical Securing Drones:
Available Countermeasures:
• IDS/IPS (Signature, Behaviour, Anomaly) (Availability)
• Hashing (Integrity)
• Encryption (Confidentiality)
• Identification
• Multi-Factor Authentication
• Authorisation (Depending on the Access Privileges)
• Anti-Malwares/Viruses (Privacy)
• Frequency Hopping (Availability)
Affected Targets:
• Border Security
• Critical Infrastructure
• Airports
• Military Installations
• Policing Services
• VIP Protection
• Prisons
• Public Events
• Civilians
• Properties
Phyical Securing Targets:
Available Countermeasures:
• Drone-Detection Mechanisms (Radars, Sensors, Infrared)
• Boeing Compact Laser Weapons System
• Anti-UAV Defence System
• Drone Jammers (2.4 / 5 GHz, Wi-Fi, Bluetooth)
• Hawks/Eagles
• "Counter-Drone" Drones
• US Army Enhanced Area Protection and Surviving ability
Threat Type:
• Weaponized Drones
• Suicide Drones
• Mid-Air Collision
• Signal Jamming
• Spoofing/Sniffing
• Reconnaissance
• Information Gathering
• Backdoor/Key-logging
• Illegal Smuggling

Fig. 4. Drone Threats Taxonomy.

A. Safety Apprehensions

A drone is tiny, lightweight, and has high mobility characteristics. It can be used to monitor criminal activities which are done at a high level of privacy. It can also be used by criminals to perform their illegal activities.

Drones can be equipped with dangerous objects to perform criminal acts. Such acts can create damage to civilians. It is a matter of concern to overcome such extremist activities for the wellbeing of peoples. Several terrorist groups can associate armed objects with a drone to perform their illegals activities.

Security doesn't constantly deliver protection. There are chances of damage done by the civilians in civilian areas which can result in financial loss [43]. The following list provides the safety concerns in detail.

- Minimum safety features in architecture can lead to control drone usage. This can result in damage and loss [44].
- Minimum mechanical and operative ethics include smashing avoidance techniques which can lead to drone's incapability to identify airliners [45].
- Absence of Administrative knowledge: especially it mainly occurs when people have less knowledge of safety features [46].

B. Confidentiality Apprehensions

Privacy is also the main factor to be considered for people. Drones must be kept out of those areas which are private. One must know the level of privacy of people before capturing or entering a private legacy. Three types of privacy threats are discussed below.

- Flying drones over someone's property is considered a major issue because of the risks associated with this act. Because such data can be used by scammers for negative purposes.
- Monitoring somebody's location must be avoided without their permission [47].
- Monitoring someone's acts and doings is also another unethical act which is also a matter of concern [48].

IV. Drones Current Intimidations & Susceptibilities

Several security threats are associated with drones and UAVs. Many design and architecture issues of drones cause such threats and vulnerabilities. Data and information protection must be addressed in drones to overcome these issues [49].

- Susceptible to Spoofing: several weak points are present which are related to architecture and control of UAVs and drones which may result in spoofing of information shared by the drone. Spoofing can be of several types [50, 51, 52, 53] . GPS spoofing is the easiest way to capture information and do modifications to it.
- Susceptible to Viruses: there are chances of malware and virus threats in the information shared by drones via a communication device which can be a mobile or a computer. This communication is also insecure because of poor wireless connection.
- Susceptible to data interruption: drones are more susceptible to data interruption and interception. Which may result in various threats associated with data vulnerability [54]. Such type of data interruption also causes malicious data insertion from drone to controller device [55].
- Susceptible to handling: drone devices are tiny objects which have building programming and control instructions, these instructions are more prone to manipulation which may change their operation and cause serious destructions [56].
- Susceptible to machine-driven problems:
- Many technical problems may occur during flight operations which may result in damage and destruction of data. Such failures may include unstable control connection [57,58].
- Susceptible to functioning problems: such issues include poor knowledge of control and command of a drone. Such lack of functioning information causes accidents and damage [59]. Many times, the drone also gets crushed in such incidents [60].
- Susceptible to environmental problems: Environmental factors include, wind speed, rain, heat, humidity result in problems for drone flight [61, 62].
- Susceptible to signal congestion: drones can also be spoofed using a signal loss mechanism which may transfer the control to a third party. Such situations also cause problems. This problem occurs by using device microcontrollers i.e. Arduino and raspberry-pi [63].

V. Existing Approaches for Drone Cyber-Security Methods

Major security methods for drone cybersecurity are categorized into the following types. Such classification is based on the attacker's aim and purpose. The following section discusses the existing approaches to prevent drone security issues.

A. Drone Network Security

Several security problems occur during drone flights and communication with a base station. To overcome such problems, and intrusion detection method was identified which can recognize illegal activities. Intrusion detection methods capture network flow and detect abnormal activities. Several intrusion detection methods are present which are used to analyze anomalies. These methods include rule-based, signature-based, and anomaly-based intrusion detection methods.

B. Drone Information Safety

Drone communication must be transformed into packet data to prevent load on the communication network. Such packaging allows safe communication to some extent. However such packaging also produces many problems. In one study [64], cipher security is discussed which can protect data from attackers.

C. Scientific Resolutions

Scientific methods are present in the drone domain which works by analyzing the network flow using forensic methods of monitoring. Such monitoring provides identification and detection of illegal access and capturing.

VI. Security Threats to Drones

Drone security has many layers and types according to its size, use, and controlling mechanism. The drone control in many cases using Wi-Fi with IEEE 802.11 communication protocol [65]. The typical designs of drones using the communication network are Wi-Fi networks with its ground stations. These networks are vulnerable to security breaches. Professional drones may be hijacked due to no proper encryption on their chips [66]. The second hijacking mechanism known to the research community was the man-in-middle attacks which is possible up to 2 KM only. The bottleneck so far emerged was with no encryption drones may be hijacked by individuals [67].

The novice trend in drone security is the Internet of Drones (IoD). The concept is equally popular in defense and industry drones [68]. The wide range of applications of IoD is in civilian and military drones simultaneously. The basic problem with drones was that they will design without security mechanisms in mind. There were fundamental security and privacy issues in drone technology regarding its design. The major issues identified in the domain of IoD security are privacy leakage, data confidentiality, data protection, data flexibility, data accessibility, and data encryption and decryption strategies [69].

In many studies in the last few years, various security and data privacy threats are identified by various researchers. The identified cybersecurity attacks are divided into four categories such as protocol-based attacks, sensors-based attacks, compromised components attacks, and jammers attacks. An account of such identified possible threats under these four cybersecurity attacks, found in the literature review, is given in Table II.

Table II shows that the majority of the available work in cybersecurity and data privacy of industrial drones is just the identification of possible threats. The solution to these threats does not exist. An attempt was made to use encryption to secure data transmission of a drone to a base station by using a Key Encryption algorithm for secure packet delivery [11].

Small drones and their usage are gaining the attention of the research community in recent years. These drones are popular because they have fewer wingspan and lightweight as well. The security and privacy of individuals and governments under threat due to these small drones as well [74]. Some other studies are also highlighting common challenges and threats to drone security [14-19].

Tian presented an efficient privacy-preserving authentication framework for edge-assisted internet of drones that was capable of ensuring the privacy of the drones Network [20]. Similarly, Hell presented a drone system for the security and surveillance purpose of a factory [21]. This system was capable of monitoring a defined area of a factory for security purposes. A similar application was also presented by Tosato in 2019, where he introduced an autonomous application of a swarm of drones for sensing industrial gas [22]. These types of drones are getting popular these days to monitor and surveillance the industrial area or an agriculture farm for the sake of security management.

TABLE II. Typical Cybersecurity and Data Privacy Threat to Smart Drones

	Common Cybersecurity Threats	**Threats Identified Citations**	**Countermeasures Citations**
Protocol-based Attacks	Security of Communication Link	[70], [71], [72], [73]	[72]
	Data Confidentiality Protection	[1]	
	Replay Arrack	[34], [35]	[36]
	Privacy Leakage	[1], [23]	
	De-authentication Attack	[8], [10],	
Sensors based Attacked	GPS Spoofing/Jamming Attack	[4], [37], [38]	[39], [40]
	Motion Sensors Spoofing	[41]	[42]
	UAV Spoofing/Jamming Attack	[4]	
Compromised Component	IoT Security Threats	[4], [5], [18]	
	Control/Data Interception	[4], [6],	
Jammers	Denial of Service	[4], [8], [10],	
	Stop Packet Delivery	[11]	[11]

The contributions to the identification of cybersecurity threats to drones are the healthy research area in the recent past. In 2016, Vattapparamban discussed a study on the application of drones for smart cities where he also discussed basic issues of Cybersecurity and privacy [23]. A few of these issues are also highlighted in Table I. A similar study to identify the possible security attacks along with the limitations of drone systems with a set of recommendations was also presented in 2020 by Yaacoub [24]. There are various studies [25], [26], and [27] that closely study the problems and challenges in drone security and its applications in business, commerce, etc. A few of them also proposes the use of blockchain for secure data delivery using 5G and IoT enables drones [27]. However, this system heavily relies on manual identification of threats type and intensity. There is a need for a smart and intelligent system for drone security that can analyze data of security breach attempts and attacks and adopt a proactive measure to ensure the security of the drones.

There are a few other survey-based studies [28], [29], [30], and [31] to identify common challenges and solutions to security threats and issues to drones used for industrial and commercial purposes. A few tried to address the problem of device authentication with lightweight authentication using key agreement [28] and key-enabling technique [30] for safe drones. The application of IoT drones in agriculture is also getting very common and recent contributions are discussed [9][32-33].

The problem of hacking and hijacking of drones and UAVs is a common threat to commercial drones that are specifically studied in [34], [35], [36], and [37]. The countermeasures problem of hacking and hijacking of drones and other UAV machines is proposed in [36] and [37]. Another common issue of drones is capturing of the drones [38] and UAV machines are GPS spoofing that also needs a secure and authentic solution. A few other studies on the hijacking of drones and intercepting control of a drone are also discussed in [39], [40], [41], and [42].

A. Gap Analysis of Drone Security using Machine Learning

There are a few basic types of machine learning techniques such as supervised learning, unsupervised learning, semi-supervised learning and reinforcement learning, deep learning, etc. During the literature survey, it was found in the recent past that, various attempts have been made to use machine learning solutions to handle cybersecurity attacks for mobile networks [45], wireless sensor networks [46], cloud computing [48], IoT systems [53][7][12], etc. An account of previous attempts to use machine learning for the security of various types of wireless networks is given in Table III.

However, there is no previous work is found to use machine-learning-based cybersecurity solutions for drone security threats. Additionally, we propose to use a machine-learning-based security solution with Blockchain to improve authentication and access control mechanisms in drone security.

In the detailed survey of literature from 2010 to 2020 in the area of drone and UAVs security, safety, and privacy concerns, more than 30 contributions were found in the form of research papers mainly published in IEEE and ACM journals. Majority of these papers highlight challenges and problems in the area of cybersecurity, device interception, data privacy, GPS spoofing, IoT spoofing, hijacking drones, and many similar cybersecurity threats in recent times. However, the majority of the literature is just highlighting identified key threats and issues to the security of drones but a majority of them are not giving solutions and countermeasures to handle security threats to drones. Only, in [27], blockchain is proposed for secure data delivery using 5G and IoT enables drones. However, this system heavily relies on manual identification of threats type and intensity. Other attempts are also relying on key-based authentication of devices that are not authentic of security specifically in the domain of IoT based drones. There is a clear research gap to make drones secure and safe from major cybersecurity threats to make drones useful for commercial and industrial purposes.

TABLE III. APPLICATION OF MACHINE LEARNING-BASED SOLUTION FOR CYBERSECURITY

Sr. No	Attacks	Security Technique	Machine Learning Solution
1	Jamming	Secure Offloading	Q-learning [45], [46] DQN [47]
2	Denial of Service	Secure Offloading	Neural Networks [48] Multivariate correlation analysis [49] Q-learning [50]
3	Malware	Access Control	Q/Dyna-Q/PDS [51] K-nearest neighbors [52] Random Forest [52]
4	Intrusion	Access Control	Naive Bayes [53] Support vector machine [53] Neural network [54] K-NN [55]
5	Spoofing	Authentication	SVM [56] DNN [57] Dyna-Q [58] Q-learning [58]
6	Traffic blockage	Authentication	Q-learning [59]

There is a need for a smart and intelligent system for drone security that can analyze data of security breach attempts and attacks and adopt a proactive measure to ensure the security of the drones. Previously, machine learning-based cybersecurity solutions are proposed for mobile networks, wireless sensor networks but not proposed for drone security. Additionally, we propose to use a machine-learning-based security solution with Blockchain to improve authentication and access control mechanisms in drone security.

VII. Data Source for Current Literature Review

Major data sources are explored for literature study of proposed system. Instead of searching through internets, direct databases are accessed to get relevant studies. However some other sources are also searched to get all possible relevant papers. These papers are filtered and only relevant papers are studied for this review. Manual selection is performed to exclude irrelevant papers. Table IV shows the data sources for current study.

A. Workflow of Current Literature Study

Literature study is carried out indifferent steps. Different actions are performed at each stage to get accurate and relevant proposed solutions. In the first step, literature review is performed with IoT, smart devices and security challenges for these devices. These security challenges are categorized and discussed accordingly. In next step, solutions for these threats are discussed and security issues are identified. Limitations for existing solutions are identified in these papers. A new solution is proposed to overcome these limitations. Fig. 5 shows the workflow of current literature study.

B. Year-Wise Publications

The following graph shows the year-wise publications list. In 2011 relevant studies were 9 which are considered in the proposed study shown in Fig. 6. This number increases each year. In 2020, relevant studies are increased which include IoT and drone security and solutions. Fig. 7 shows the graph in which drone security issues, solutions, threats, uses, frameworks, and algorithms are described for the current selection of papers.

TABLE IV. FOUNDATION OF DATA FOR CURRENT STUDY

VIII. Conclusion and Future Work

Now-a-days, IoT is the most widely used network among all networks. It is a network of communicating devices, which are interacting with each other. It is widely used for home automation, health care, and remote devices. Among all these applications, IoT is wonderfully used in civilian departments. It is widely utilized to interconnect medical and industrial devices. These devices provide easy and effective facilities to people. The machine learning based solutions for drone security is also used to handle cybersecurity attacks for mobile networks, wireless sensor networks, cloud computing, IoT systems, etc. IoT devices provide far-off fitness, manufacturing, and emergency alert method. This research can be further enhance using machine learning based security solution with Blockchain to improve authentication and access control mechanisms in drone security.

Blockchain Technology in Education System

A Survey Examining Potential Uses of Blockchain in Saudi Arabia Education

Afnan H. Alsaadi[1], Doaa M. Bamasoud[2]
Dept. of IS, College of Computing and Information Technology
University of Bisha, Bisha
Saudi Arabia

***Abstract*—The aim of this paper is to review the blockchain technology and its benefits in relations to education system. Blockchain technology is widely researched and highly evaluated and appraised for its unique infrastructure. In general, blockchain researched for its association with Bitcoin and cryptocurrency advantages. In this survey the plan is to conduct a full review of previous literatures focused on blockchain in education systems. Provide overall reviews of blockchain concepts and architecture behind the technology and to examine verification software that used by the technology to improve security and immutability. Brief discussion on the consensus algorithms and hashing function and how these operate and difference type of blockchain will be discussed. In this survey, the existing technology used in Saudi Arabia will be reviewed. In-depth research conducted for over 70 papers, of which 35 noted in this survey. Blockchain emerging promise a real time democracy and justice to all users over the world. Educational Industries said to revolutionize its communication system and accessibility and extend their market globally by widening their admissions and providing secure cost-effective, transparent and immutable communications across their educational platforms.**

Keywords*—Blockchain; certifications; authentication; decentralized-education; transparency; immutability; smart contracts; learning accessibility; fraud prevention; sustainability; ledger; consensus

I. Introduction

Electronic peer- to - peer without any third party is the solution to end double spending [1]. A digital signature is the part of the solution [1]. The authors in [1] invoked hashing by timestamped proof, “the network timestamps transactions by chain them into an ongoing chain of hashing-based proof forming a record cannot be changed”. Additionally, added “the longest chain not only serves as proof of the sequence of events witnessed, but proof that it came from the largest pool-of CPU power; keeping long chains to outpace attackers. Blockchain technology first emerged as cryptocurrency technology only, but its popularity increased as the technology addressed other classical problems for the centralized system.

Mainly described as a ledger for digital currency and used for cryptocurrency. This decentralized cryptographic system provided a platform for users to transfers money without necessarily relying on any centralized trusted establishment such as payment services or banks [2].

Blockchain technology becomes popular among researchers and technology developers and cooperation e.g., IBM, Sony and Samsung, immediately after disappearance of its creator [1]. The attention, however, advanced the research of blockchain and brings more critical analysis and examination. Blockchain is not a ledger, it is a journal. Carlson in [3] considered blockchain idea only buried into bitcoin currency and not addressed technology in-depth. Added that “the author has weighed the costs and benefits of transacting with virtual currencies, considered the sustainability of the virtual currency, and contemplated the application of existing regulatory schemes to virtual currency” [3].

This suggesting that blockchain structure is misunderstood and not clearly defined by the authors. However, this is also followed by another Blockchain critics, the authors in [4] suggesting that blockchain technology has a potential to diminish government’s authorities by end their role of supervising people’s money and subverting critical regulation by cutting out middleman such as large operations and corporations. A full analysis conducted by [5] analyzed the code of law as valuable contribution to blockchain. A critical analysis improves the quality of the research into blockchain technology. On another hand, the strong arguments indicted the usefulness of the technology to be taking seriously by researchers. In [4] the authors added the architectural features of blockchain are the center of the attentions. Blockchain designed in such a way is that it evades the effectiveness of regulation and enforcement [5]. The suggestion made by [4] quoted by [5] mainly focused on the novelty of blockchain as the main point of revolution, rather than using all characteristic structures of blockchain which are not revolution. The points below quoted directly from researcher [5] summarized the basis of blockchain structure suggested to underline both opportunities and threats in the discussion and the reviews:

1) *Blockchains are disintermediated* and transnational networks, often relying on open-source software protocols.

2) *Resilient and tamper-resistant*, due to their distributed nature, the consensus mechanisms employed, and the use of hashing.

3) *Blockchains are transparent*—in the sense that transaction data is authenticated and visible—and the data they contain is non-repudiable (due to the use of public-private key cryptography).

4) *Characterized by pseudonymity*—as they allow transacting parties to participate in the system without disclosing their identity.

5) Blockchains have incentives and cost structures, e.g., block rewards and mining fees that incentivize and compensate parties maintaining a blockchain-based network.

6) Blockchain are unique, and characteristic is the deployment of consensus mechanisms to coordinate social activity towards an agreement on the situation within the system.

7) Blockchains enable a specific type of "autonomy": they facilitate the execution of software code that is entirely independent of any one party.

(Global Survey for blockchain carried by Deloitte 2020).

Moving forward with blockchain, this technology despite its young age, it has been the center of attention among researchers, analysts, law assimilators and centralized system beneficiaries (middleman). A survey conducted by [6] linked the attention is due to the features presented by blockchain, such as decentralized nature, persistency, anonymity, and auditability properties. To be fully conversant with blockchain concept the followings must be clearly defined and understood [7]:

- Asymmetric key cryptography.
- Consensus algorithms.
- Hashing.
- Consensus.

Blockchain is part of the solution to critical problems of ownership, transparency and can be used in many digital communications as solution to our everyday arising challenges [8].

Existing technology provided education system with numerous advancements of learning environment and productivity, however the authors in [9] cited further area of improvements such smart learning track, where the blockchain technology predicted to play significant role.

A block is an entity (data structure) hold information that present past record and current transactions and keep permanent records of transactions. Each block created through process called mining and each new block connected with its predecessor with cryptographically secured reference shown in Fig. 1. The validation process called the hash function.

How hash function design in blockchain is rather critical process to the success of secured blockchain procedure. For a cryptographic hash function to be considered secure; it must represent a certain characteristics or properties, these features determined the hash function suitability for cryptocurrencies such as Bitcoin and other secured transactions. Thus, the cryptographic hash function is an integral part of the blockchain innovation. It is the main characteristic that gives security capabilities to the processed transactions and making it immutable. Hash function designed to protect data stored in the block [10] and then data in a blockchain distributed across the network of multiple nodes or computers. Thus, blocks data becomes very secure and impossible to be altered retroactively without having to alter the entire chain.

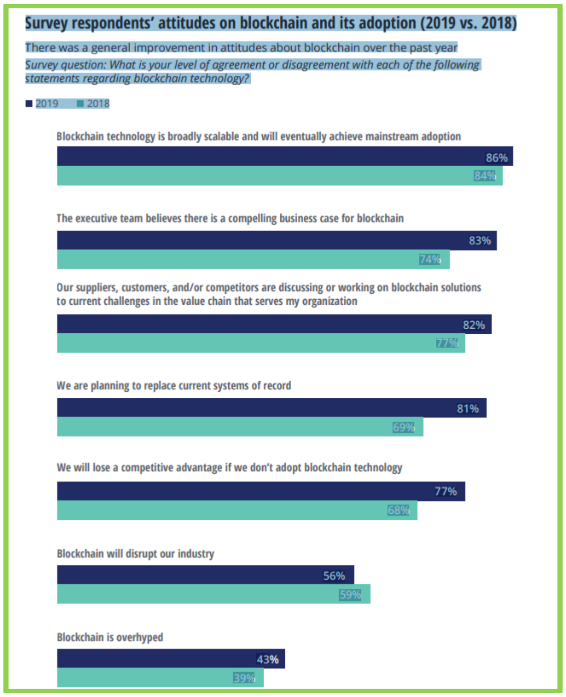

Fig. 1. Blockchain Adoption.

These authentications proofed by mathematical algorithms [11] which deem secure and protected from others. These can be achieved in many ways, but most commonly the use of encryptions and can only be decrypted by legitimate person.

Passing this process, the system integrity can be guaranteed [12] that information has not been modified by unauthorized party. Through this process, system recognizes manipulation and detects it and prevents data corruption. This is how the use of cryptographic hash functions in blockchain works.

There are two significant properties make hash function satisfying [8]:

- Should be fast to compute and strong, and.
- Minimize duplication and data cannot be extracted from its original hash.

The authors stated that: "There are three requirements for practical applications of a hash function for message authentication and digital signatures", the fourth requirement also known as pre-image resistance or one-way property.

A. Blockchain Types

As shown in Fig. 15, there are three different forms of Blockchain [6].

- Public: Everyone can check the transaction and verify it.
- Consortium: It refers to a node with authority that can be selected in advance, typically has business-to-business relationships, the data in blockchain can be open or private, and can be classified as partially decentralized like Hyperledger.

- Private: This applies to the fact that not every node in the blockchain will participate, with one or more restrictions. The interpretation of firm authority for data management access.

B. How Transaction Complete in Blockchain

The transaction complete securely between two parties without exchange of identification or third party using public key. Communications are transparent among all networks. Nodes validate transactions and group them in Block [10].

The created block identified by its hash: “a cryptographically unique value calculated on the contents of the block and includes a reference to the hash from the previous block, so that, blocks are linked” [10]. This chain of blocks is thus a record of transactions or a public accounting book (ledger), shared by all the nodes in the network.

Mining is one of the key concepts behind the Bitcoin protocol said [11]. All transaction collected and grouped into block that ready to be linked to its predecessors.

In order to add new block to blockchains, a signature linking the transaction to previous block must be elected [12]. This process involved finding nonce value which is required to satisfy the secure hashing algorithm SHA256. In this surveyor we only briefly explained the functions rather than diving into equations or calculation.

Blockchain technology provides a structural ledger database for storing transactional records known as blocks and links them with numerous databases known as the chain [13]. These immutable records are then signed cryptographically using a distributed consensus or validation protocol [14]. The following processing staging are essential tools to secure blockchain transaction:

1) Education system: technology strength and transformation: Its evidently education system has been evolving and transforming over the past centuries. Institutions and universities provide diverse methods of learning to reach out learners. One of these methods is the distance learning, which dated back since 1873 where first initiated by Professor Ana Eliot Ticknor and then followed by the University of Queensland in Australia in 1911 and the University of South Africa 1946. These humble initiations shaped the distance learning of today. The only difference between now and then was the methods of delivery. Traditionally, learning delivered on campus, certifications received in persons or by post, transcription and copy of credential kept with registrars, but this paradigm have been shifting gradually to online educations and communications: All communications currently handled online. From entry applications, payment system, and learning, handling coursework, and submitting assignment and communicating with tutors all completed through universities platforms.

The paradigm shifting in educations often appraised for its efficiency, increased productivity and improved learning outcomes. A research conducted by Bill& Melinda Foundation on positive distance learning and how technology advanced learned outcome.

The report conducted by [15] expressed positive outcome for learner at the time, it was a revolution concept to create such “learning environment that student in rural areas had expanded learning opportunities in a variety of subject.” [15]. The Impact of digital technology is countless and how this technology improves learning outcomes is incalculable.

A research conducted in relation to digitalization. “In terms of education this means we should create Knowledge that is accessible virtually with the focus on the student”. This means students are build and developed from all areas and these facilities aid their learning.

Rather those days where students she/he travel distances or encountering lock of access to documents or physical visit to library and time restrictions to information.

The authors in [16] added virtual access is achieved through Internet or Intranets, facilities such as “e-mail, web notices, discussion forums and video conferencing allow a student to access information without visiting the physical location of delivery”. A typical interactive e-learning system will have these characteristics and thus demonstrates the paradigm shift” [16].

2) Education system: technology weakness and volatility: Despite the enormous benefits of technology in education and the positive contribution achieved, technology comes with some downside risks and must be appropriately evaluate [17]. In relation to how technology apprised, and debates the author, highlighted that the impact of technology in education should appropriately addressed both strength and weakness. Unforeseen its potential risks will hinder the quality of the any review [17].

A recent public awareness publishing; highlighted these facts: Data published by [18] highlighted critical information into how criminal may damage universities infrastructure-based knowledge and steal significant data that can be harmful to countries’ economy.

“In 2018 researcher discovered logging pages for 300 fake websites and login pages for 76 universities across 14 countries”. “And between 2013 and 2017, accounts of more than 100,000 professors worldwide stolen, and led to the loss of more than 30 terabytes of academic data and intellectual property”. [18]. As we moving to cloud space and more online present via working groups or communicating online, there is urgency to seek more security and proof systems to convey information and communication through.

3) Education: system venerability (centralized cloud space): Cyberspace attacks can be permanently damaging to system and can be irreversible. The authors in [18] Highlighted reasons behind such attacks that could be and not limited to the followings:

- For financial gain, criminals can sale critical data and research information and breakthrough to hostile enemies or competitors to publish dedicated researcher findings and claim ownerships.

- Steal critical information on national infrastructures research for knowledge advancement, substage strategic planning and future projects.
- Malicious attackers can damage important files and documents and can navigate through to gain full access to intellectual properties.
- Talents at universities can be targeted and their activities monitories by infiltrator.
- Undermine national security and economic prosperity.

4) Education: blockchain the transformation promise: Blockchain Technology its innovative disruptive system with prominent potentials, fully authenticated and transparent, economically viable and with direct and indirect benefits to support sustainable educational system for all.

Recent survey carried by [19] on usability and impact of blockchain adoption including positive impact and barriers of use. Lack of knowledge of the technology and comparison with the existing system showed impactful results. The following Fig. 1 to 6 shows Survey results:

(Global Survey for blockchain Deloitte 2020).

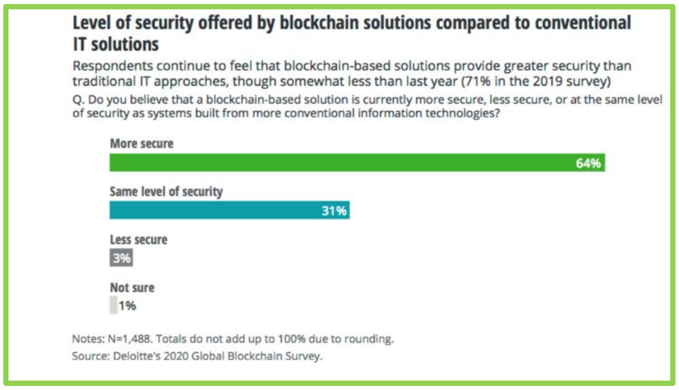

Fig. 2. The Level of Security vs IT Solution.

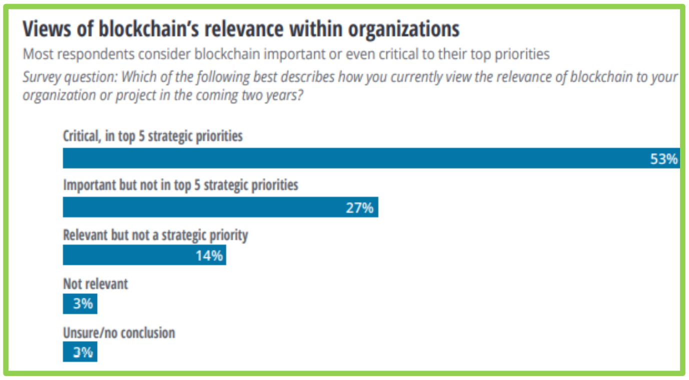

Fig. 3. Blockchain Significant Advantages over Existing System.

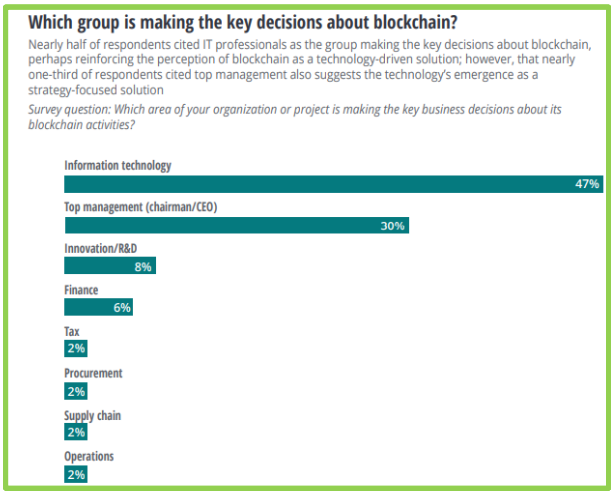

Fig. 4. Global Survey for Blockchain Carried by Deloitte 2020.

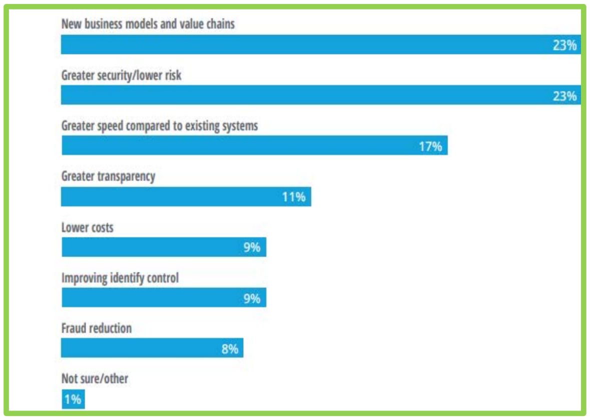

Fig. 5. Decision Maker on Organization.

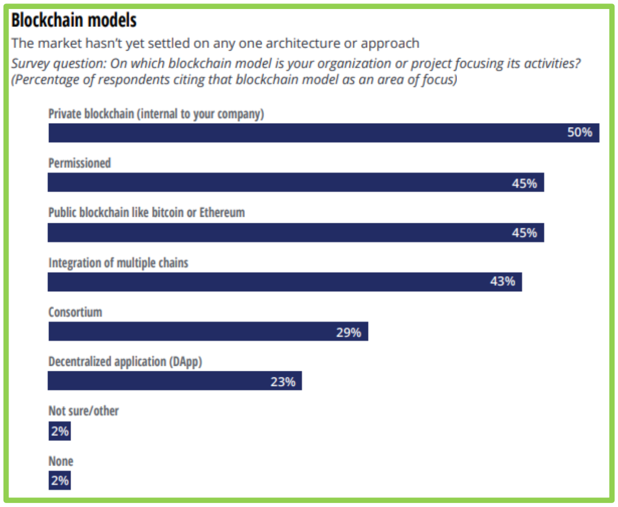

Fig. 6. FBlockchain Model.

5) Education: blockchain technology: The first case reviewed is a Cambridge, Massachusetts education model: “MIT has formed the Digital Credentials Consortium an international network of universities to develop a shared system for digital academic credentials [20]. Public ledger technology enables us to develop new tools, standards, and strategies to store and manage digital academic credentials. Certificates can be cryptographically signed and tamper-proof. They can represent or recognize many different types of achievements [21]. DCC was founded in 2018 by leading universities with expertise in the design and verification system.

Academia of DCC raised questions about the overall system of trusted verification and authentication of learning and credentials; and there was a clear concern about the way credential issuing and transcription managed, after consultation, consortium strongly agreed that there is an urgency to renew system. Benefits for learners:

- Maintain a compelling verifiable record of student lifelong learning achievements to share with employers in a trusted manner.
- A safe and secure digitally transferred credential with no extra fees.

Available secure stored data from multiple educational institutions and credential. A team from learning machine and MIT media lab creates “blockers” an open standard platform to issuing and verifying blockchain certificates. DCC highlighted future project planning [21], “we are exploring how recent advances in public key infrastructures, public ledgers, and blockchains can be used to rethink the way we recognize and transact with academic achievements”.

Digital Credential Consortium is a powerful organization with unique strength of intellectual talents. “The infrastructure for design and governance of academic credentials has been set a sight and credentials now transformed into tokens of social and human capital that can create new opportunities for participation in educational industry” [21].

“Real-life use case: More than 600 of 2018 MIT graduates chose to receive a digital version of their diplomas on Blockcerts’ blockchain. Consequently, the students' academic records will be stored forever, and future employers can immediately verify them” [20].

Organization and world’s fined universities and institutions are benefiting from blockchain technology and building searcher on how to completely adopt this technology. In this survey, several universities will be reviewed:

a) Curriculum: Smart curriculum design is one of the most researched subjects these days. Mainly associated with blockchain technology and the usefulness of its features. In [22], the QualiChain platform that will offer blockchain-enabled verification of education and other credentials as well as data analytics and decision support for process optimization [22].

Permanence of blockchain record, smart contracts these features seen as attractive tool for education commissioners [23]. These features make blockchain technology-based products or services significantly different from previous internet-based commercial developments [23]. The authors in [23] addressed the lack of knowledge about the social advantages and potential for blockchain in education by stakeholders. The authors highlighted the benefits blockchain in comparison with existing system: shown in Fig. 7.

- Self-sovereignty, i.e. for users to identify themselves while at the same time maintaining control over the storage and management of their personal data.
- Trust, i.e. for a technical infrastructure that gives people enough confidence in its operations to carry through with transactions such as payments or the issue of certificates.
- Transparency & Provenance, i.e., for users to conduct transactions in knowledge that each party has the capacity to enter that transaction.
- Immutability, i.e. for records to be written and stored permanently, without the possibility of modification.
- Disintermediation, i.e. the removal of the need for a central controlling authority to manage transactions or keep records.
- Collaboration, i.e. the ability of parties to transact directly with each other without the need for mediating third parties.

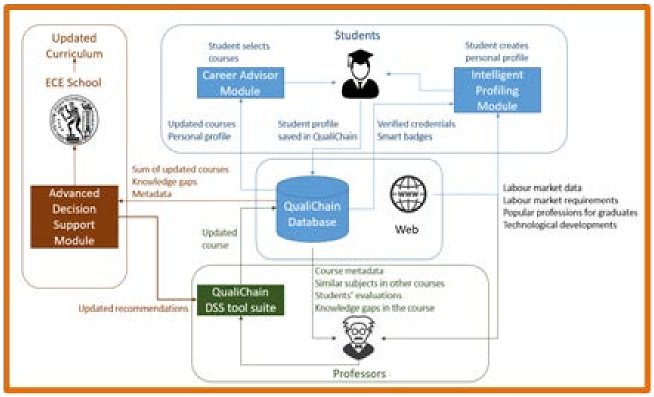

Fig. 7. Education Curriculum.

b) Certification: The Hyperledger Fabric is an open source blockchain platform (refer to Fig. 8 and 9).

Hyperledger Fabric Architecture and permits for faster blockchain network. The application connects with blackchin via REST web, APIs and by using HTTP and JSON data format [25].

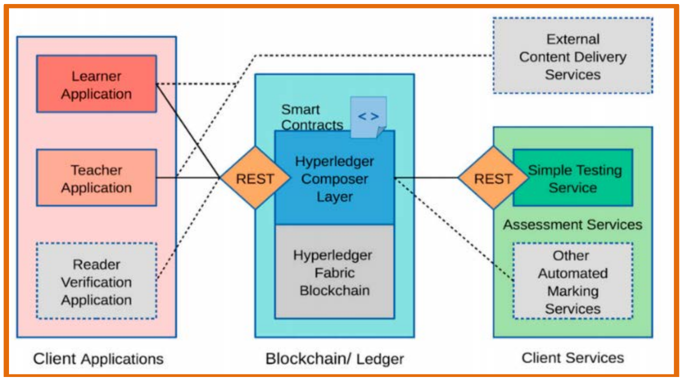

Fig. 8. Hyperledger Structure.

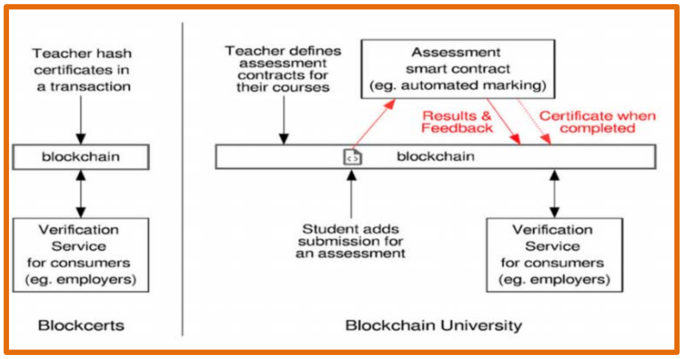

Teacher hash certificates in a transaction

Teacher defines assessment contracts for their courses
Assessment smart contract (eg. automated marking)
Results & Feedback
Certificate when completed
blockchain
Student adds submission for an assessment
Verification Service for consumers (eg. employers)
Blockchain University

Fig. 9. Blockcert (Blockchain Certificates) for University.

c) Smart Contract: Smart contract covers ranges of facilities in crypto-educations system, from enrolling into course to coursework evidenced based, timeline tracking, helps both tutors and learners' opportunities to manage datelines, fast enquiry and verifications, track of students' learning progress etc.

Transaction processed in transparent and scalable manner to insure full transparent [24].

- Summarized five Timestamped logs.
- Cryptographic &Timestamped Logs.
- Cryptographic hash function.
- Timestamped append-only Logs.
- Block headers & Merkle Trees.

d) Immutability: Technology profoundly changed educational system but "the way we issue and managed academic credentials, which represent learning outcomes and achievements, has not yet taken advantage of the possibilities of digital technology". The blockchain can resolve these issues and provides data access to universities in permissions-less or permissioned (private permissioned -loop) such as peers control access described by [25]. Peers control access model discussed and adopted worldwide by large organization and private consortiums. Is less complex to use and tailored to specific application.

"The adoption of cloud computing is in line with the objective of saving resources/saving costs and improving the interaction between students and the educators. "The future of How Blockchain deliver its activities in absent of administrators and how tasks, sequences and process occurred in a simple structured and intelligent way and protect itself without external forces.

Although blockchain structured as database or system platforms blockchain is also machine learning, deep learning and autonomous systems simply does everything and can do everything. Large corporation making the utmost benefits of blockchain, Sony, IBM, IEEE, etc.

e) Cybersecurity: Security is one of essential unique feature of blockchain, hence each step carried with security in mind. These three-encryption control mechanisms are indispensable for blocks encryptions:

- The system randomly generates a 32-bit whole number known as (nonce) this number only use once, which is then added to a hashed to encrypt. These steps are essential to protect data from cypher attached.
- A block header hash is then generated.
- Hash is a 256-bit cipher merged with the nonce. Data kept within the block.

The hash function key is one of the most important elements in blockchain structure and Merkle tree. These sets of structure's differentiate blockchain uniqueness [14], shown in Fig. 14.

f) Sustainability: Sustainability is the future business. The subject of digitalization and blockchain adoption is not completed without in depth instigation into sustainability, and business continued and its efficiency and consumption. Given the governing authorities and strategies taken by a given government, compliance is needed to carefully address incompatible innovation and instigate threats to digital sustainability and assessment, in particular the role of politics. [26]. Shown in Fig. 10, adaptive governance can be defined as the adjustment of regulatory rules and practices to incorporate new data and to balance the risks and benefits of a given activity.

g) Consensus: It is important part of validation by all participants in this mechanism Blockchain enhances trust across a business network". With blockchain trust comes natural within the network community because it provides cryptographic proof over a set of transactions.

"Because the transaction can't be tampered with and are signed by the relevant counterparties, any corruption is readily apparent". Blockchain is sustainable and its existence will be continued since it's an independent and not own by any vendor.

Organizations like the IEEE developing courses in many areas of education to sell to corporate and other societies. Blockchain strengthen existing standards. "As a record-keeping strategy, blockchains pose a novel way to track whether participants are complying with standards that they publicly claim". [4]. IEEE taking full advantageous of blockchain smart processing tools and tight security.

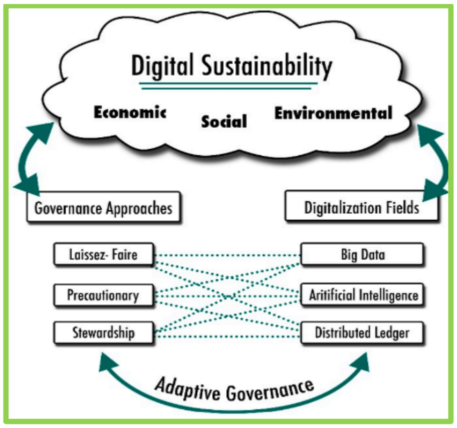

Fig. 10. Digital Sustainability.

h) Consensus process: Blockchain and our smart credential platform in the education sector will explore areas of automatic recognition and attribution or transfer of credits, verifying accreditors lifelong records of learning, student grants and funding also can leverage sovereign identities for verifying students and even educators" [27]. Sony creating trusted platform using blockchain. "We will be demonstrating how blockchain will become the future of maintaining and managing transcripts and high security data in education" [27].

IBM [14] and Linux Foundation also in partnership with Sony developed 'Hyperledger'. These initiatives enables multiple institutions to add transcription and student's achievement on a ledger records for a lifetime. "Blockchain technology makes it possible to associate these types of data with individuals" [20]. The authors added "This will enable people to handle their own academic progress record, and to have control over how to improve their learning cycle, for example. I believe this will change education as we know it and make it substantially more efficient," [20]. As a global leader in this field there is no doubt his input will shape the world of digital education. IBM hyper ledger offer both public and private tailored access to its end-users.

Blockchain technology spreading fast and among large and reputable universities and institutions, this not to underestimates the challenges emerging from researchers challenging blockchain, efficient and scalability of the system, [28]. In a permission-based system, decision taking to for an example, how to ignore malicious nodes and mining processing executions computation. There also concern about designing of smart contract based blockchain application.

Many enterprises integrate blockchain with their systems for the benefits of the blockchain. Despite its strength, blockchain has some challenges in security, privacy, scalability, and other issues [28]. Although blockchain breakthrough solves major issues, certain areas within blockchain deserve further attention and scrutiny. There should be more critical analysis and evaluations, to ensure earl rectification of upcoming problems. Blockchain is a transformation that changed the world for better, despite the slow progress of these technologies beside educational system.

Other technologies emerging from blockchain can bring some social justices to humanity. The past decades technology is controlled by only half of the world and the rest are poor, deprived and disfranchised. Half of the world still does not connect to basic elements of technology for example electricity, education and healthcare, the main reason for these is those intermediaries' systems of greed.

Promotes transparency, "You build peer-to-peer self-sustaining applications that can stand its ground. From destabilized governments to supply chain vendors, use cases of blockchain are endless. Control over personal information is vital and can be successfully addressed using blockchain" [29]. Blockchain story is not going away, and its strength and capability is growing fast, "A billion dollars in venture capital has flowed to more than 120 blockchain-related start-ups, thirty of the world's largest banks have joined a consortium to design and build blockchain solutions, Nasdaq is piloting a blockchain-powered private market exchange and Microsoft has launched cloud-based blockchain-as-a-service" [30].

6) Digital education system: Saudi Government boosted its digital Education system and made enormous transformation by implementing a set of EdTech infrastructure 2017. Future Gate is a country-wide, large-scale initiative of Tatweer education and part of KSA vision for 2030 developments is to focus on digital literacy skills of 21st century.

7) Current education system in Saudi Arabia: Saudi Arabia student's outbound policy decreases and now reverses the equation by investing in their educational system and opening new opportunities of international student studying in the Saudi Arabia. Recent reports by WENR [32] showed slow on Saudi's outbounds students decreases and inbound increases both by national and international students' seeking education in Saudi Arabia. "The expansion of Saudi Arabia's higher education system and the construction of more universities in recent years has helped accommodate a rising inflow of students from other countries, resulting in a high inbound student mobility ratio of 4.6 percent between 2008 and 2017" [33].

Since 2019 Saudi Arabia open new venues of shared researchers and collaborations with international foreign universities to stimulate students' exchange. This is seen as positive steps forward to Saudi openness and commitment to educations. Fig. 11 and 12 show statistic carried by WENR.

Now Saudi Arabia authorized foreign universities to set up Campuses and there is strategy to slow outbound students' mobility. This certainly reduces outbound costs and strengthens inbound prosperity. This is also an opportunity for Saudi to adopt blockchain technology for its international exchange and by slowing outbounds students and bring in international universities can provide cost effectives digital education at home and make double win saving and attracting inbounds students by using Blockchain Technology to facilitate and improve education system [32].

Blockchain Potential Benefits and Impact on Saudi Arabia Education, as shown in Fig. 13:

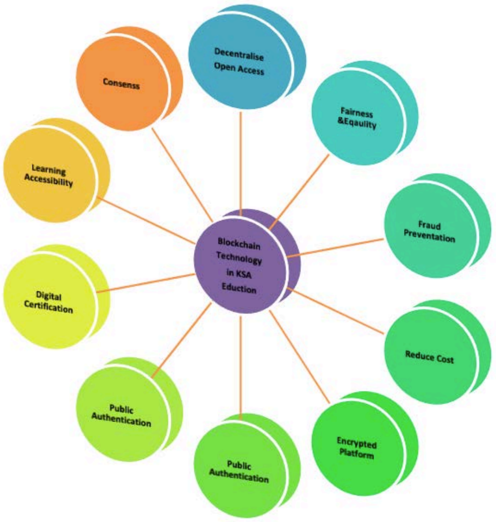

Fig. 13. Proposal Blockchain Potential Benefits to Saudi Education.

II. SWOT Analysis of Using Blockchain Technology

A. Strength of using Blockchain Technology

1) Blockchain is decentralized data setting is incorruptible and consistently reliable online database registry of various digital transactions where participants can modify the data by following a process of approval procedures: this called consensus and, in this process, all nodes in the network or majority must agree to transactions.

*2) Blockch*ain is an encrypted system that uses different styles of encryption and hash to store data in protected databases. The system distributes these data records over various nodes and forms a consensus on the position of the data they contain that makes difficult to corrupt.

*3) Blockch*ain data and information not stored in local system or cloud space but in multiple nodes tight secured. Main principle of decentralization, information not kept in one space and data is transparent [21].

4) Smart contracts are computer protocol that facilitated and enforce negotiation. Can be partially or fully and self-executed and self-enforced. In Ethereum these contracts have the ability to communicate within their internal storage and analyses, evaluate and send message to trigger execution. Smart contracts offer valuable advantages: such as enforcement, management, and payment, and performance, these aspects must be satisfied in fast and effective manners without third party authorization [21].

B. Weaknesses associated with the use of Blockchain Technology

1) Existing centralized vendor managed system both traditional and cloud-based structures offer services at sum costs and provides in return, computing services that includes software, storage, servers, database, networking, analytics reports, intelligence reports and flexible utilization of resources [18]. Thus, makes competition to newly emerged blockchain harder or less favorable to businesses comfortable with these facilities.

2) Blockchain has some challenges in security, privacy, scalability [33].

3) Blockchain is here and to stay and to influence major actors globally, it has been recognized and gradual implementation across industry spreading fast [35] (refer to Fig. 16 blockchain mind map).

4) Old system offers history of services and builds trusts among users and vendors common interests. Offer transformation and rapid innovation to its end-users.

5) Traditional and newly formed cloud space, structure of database stored locally and on cloud storage with simple procedures access. In centralized system (data stored in a company's data centers). Offer tailored and optional transparency and stored data can be visible to public or private as requested.

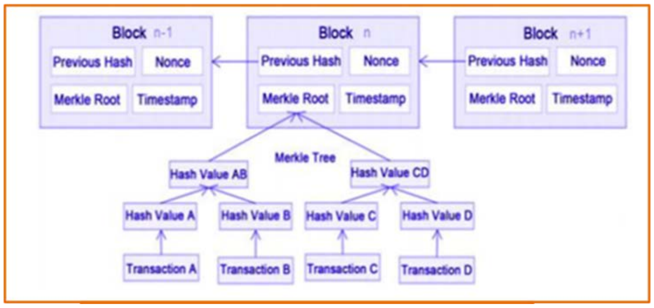

Fig. 14. Hash Function.

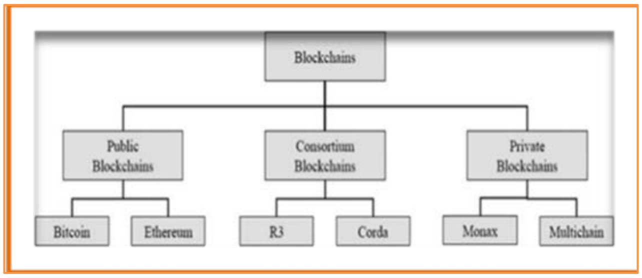

Fig. 15. Types of Blockchain.

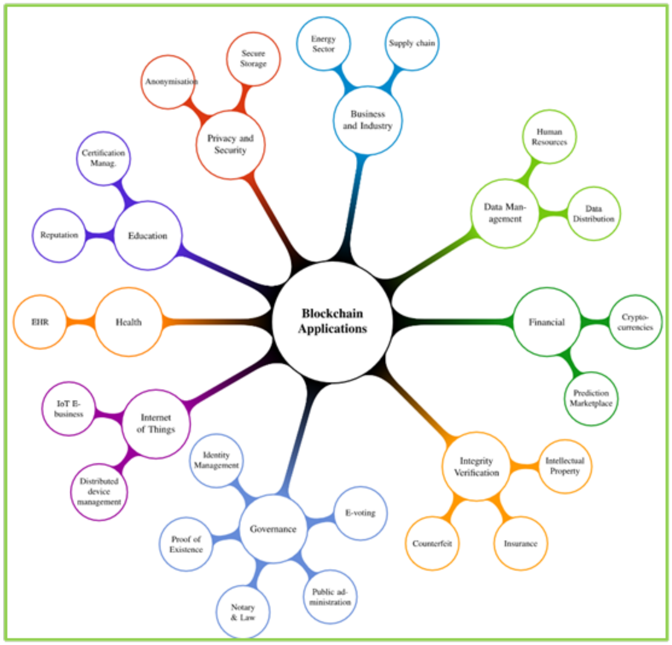

Fig. 16. Mind Map Abstraction of different Types of Blockchain Applications.

C. *Opportunity Associated with Blockchain Technology*

1) Recoded ledger and immutability.

2) Tight cryptography (using hash function).

3) Decentralizes and open access.

4) Availability.

5) Strength distributed resilience and control.

6) Decentralized network and open source.

7) Asset's provenance.

8) Dynamic environment.

9) By removing intermediaries and delivering a dependable shared view of permissioned data, blockchain could:

*10)*Reduce costs effectively: (e.g. Administrations, university running costs, Third party and students).

*11)*Speed up settlement (e.g. faster validation, digital enrolment verifications, and certification).

*12)*Increase resilience (e.g. no single point of failure).

*13)*Improve transparency (e.g. easier to monitor).

D. *Threat*

Threats and risks by [31] analysts seem glomming but effective as well. Ledger conflicts competition, Lack of ledger interoperability Lack of inter-ledger governance and limitation of smart contract coding programming.

III. Conclusion

To conclude this study, blockchain has reached its maturity in education system globally, despite the speed at which educational establishments are moving towards complete change of system and full blockchain technology adaptation. The fact Blockchain still available for adaptations, those who start first will benefit more. The scale of emerging educational platform using blockchain Technology growing fast and making use of all benefits ranging from smart contracts system of payments to Id identification and token and students learning authentications, thus the story of blockchain is growing and staying.

World Class education Institutes are using the technology to their advantageous, for instance the powerful educational Institutes such as Cambridge, MIT, are teaming up to create Blockcerts, an open standard platform for creating and issuing verifying certificate's. In 2018 MIT 600 graduates accepted digital version of their diplomas on Blockcerts blockchain, other universities and educational. A consortium consisted of top world university called (DCC) Digital Credential Consortium issuing both credential and transcripts already in place. During this study research encounter several papers discussing the weakness of this technology and focus was on the scalability issues and shortage of skills rather than major structural issue with blockchain frameworks. These voices raised concerns in relation to scalability and proof-work, others focus on privacy and closed loop system. Blockchain has fruitful future and benefits to all industry including major benefits to education system. This study has its limitation; however a better review in future will cover most areas in more prices and systemic approach. Blockchain offers real promise to all industries without exceptional. This surveyor focused on blockchain functionality and potential for its education system. Most research focused on the main issues blockchain differentiates itself from the reset of the other technology, which is the decentralization and immutability and transparency and more advancement into certification platform such as Hyperledger's. There should be further in-depth research mainly focused in how these platform developed and functionality i.e. prototyping, product testing and survey on privacy vs openness of decentralization. Majority of research developed built on previous literatures and limited further opinions or new development which seems closed loops as if all researchers working from one point of view. There is no underestimation of the prefund efforts made by the blockchain community of research. New development need and research guidance and direction also missing.

Supporting Multi-interface Entities in Software-Defined Wireless Networks

Jun-Hyuk Park[1], Wonyong Yoon[2]
Department of Electronics Engineering
Dong-A University, Busan
South Korea

***Abstract*—Software-Defined Networking (SDN) has gained growing momentum from its earlier application for wired networks (e.g., data center networks) to its application for wireless and mobile networks. In addition, state-of-the-art wireless and mobile networks (cellular networks and mesh networks) have been enhanced through the integration of multiple radio access technologies or multiple interfaces. This paper considers how to evolve multi-interface wireless mobile networks according to a future SDN-based paradigm, and deals with the technical problems therein. It presents the design and implementation of mechanisms that support SDN-based control of two types of multi-interface wireless mobile networks: one with multi-interface user devices and the other with multi-interface switching entities. As a methodology of demonstrating the feasibility of the proposed solution, a novel testing suite incorporating a real SDN controller and a standardized network simulator is designed and built. The functional verification and performance of the proposed solution is demonstrated in a virtual network topology but with the orchestration of the real SDN controller. The results show the multi-interface wireless entities can exploit the multi-radio and multi-channel wireless resources with the help of SDN approach.**

Keywords*—*Software-defined networking; multi-interface; multi-interface switch; flow-precision mobility; flow-precision routing

I. Introduction

Software-Defined Networking (SDN) has recently drawn significant attention from the networking communities owing to its potential to introduce innovative networking mechanisms by decoupling the control plane from the data plane of networks and centrally controlling the resulting networks [1]. The recent high interest in SDN is greatly attributed to Google's B4, which has nicely applied the SDN principle to real operating wide-area networks connecting Google data centers globally [2]. B4 enables near 100% link utilization between data centers using SDN-based centralized traffic engineering and OpenFlow-based switch management [1]. In addition to works on SDN-based data center networks, other SDN applications to wired networks include applying SDN for inter-domain routing [3], and adopting multiple controllers for wide-area wired network orchestration [4]. Gupta and co-workers proposed an SDN-based Internet Exchange Point (IXP) and solved various challenges in building real deployable software defined exchange points [3].

The application of SDN to wireless networks has been recently and extensively studied, for example, wireless local area networks (WLANs), wireless mesh networks, and cellular networks like Long Term Evolution (LTE) [5], [6]. SDN-based approaches to WLANs, both enterprise WLANs [7]-[9] and community WLANs [10], have been proposed for various purposes of network virtualization, radio resource management, flow-based quality of service (QoS), and mobility support. The SDN-based control of wireless mesh networks has been examined from the perspective of load balancing and mobility management [11], [12]. LTE cellular networks have been recently examined for an SDN rebase from the perspective of both the core network part [13]-[20] and radio access network part [21]- [23].

Apart from SDN-driven research, it is noticed that multi-RAT(Radio Access Technology) wireless networks have been a promising approach to resolve the ever-increasing bandwidth demand as various radio access technologies become available with different communication ranges, and radio interfaces become more and more affordable in terms of the unit price [24]-[26]. In multi-RAT wireless networks, either devices (e.g., smartphones) or switching entities (e.g., routers) can be equipped with multiple radio interfaces to provide and utilize an enhanced network capacity. A typical example of the former case is multi-RAT LTE/WLAN heterogeneous networks where user equipment (UE) such as smartphones have LTE and WLAN radio interfaces available for radio access. A typical example of the latter case is multi-RAT, multi-channel wireless mesh networks where wireless routers are equipped with multiple WLAN radio interfaces simultaneously operating on different WLAN channels for capacity enlargement [25]. It is envisaged that these multi-radio wireless mobile networks can be orchestrated based on the SDN paradigm with a centralized holistic view on multi-radio resources more effectively than traditional distributed local control. For example, congestion on LTE access networks can be alleviated by offloading LTE/WLAN multi-radio devices to WLAN access points (APs) based on the centralized decision of the SDN controller, thereby leading to more enhanced multi-radio resource utilization and load balancing.

This trend toward softwarizing networks and enhancing multi-interface availability motivates the authors to examine, to the best of the authors' knowledge, the first in-depth investigation into the feasibility of SDN-based centralized control of multi-RAT wireless mobile networks as a next-generation evolution. In so doing, technical issues induced by multi-radio inherency are studied, which can be further classified into handling (i) multi-RAT devices and (ii) multi-

This work was supported by the Dong-A University research fund. W. Yoon is the corresponding author. The authors thank S. G. Lee.

RAT switching entities in the SDN paradigm. Mechanisms are proposed to resolve the issues of these two categories and implement them into an integrated suite of a real SDN controller and standard-compliant software switches in a simulation space. The first issue is considered in the context of emerging LTE/WLAN heterogeneous multi-radio networks, and thus, how to support LTE/WLAN multi-radio devices using an SDN controller and what benefits an SDN-based approach will bring. The second issue is considered in the context of multi-radio, multi-channel wireless mesh networks, and thus, how to support multi-radio routers using an SDN controller and its effectiveness. Although a case for SDN-based heterogeneous networked environments has been made [27] [42] [43], our investigation tackles detailed technical issues of resolving the limitation of the current open SDN standard in supporting multi-interface wireless network entities and incorporates procedural mechanisms.

The rest of the paper is organized as follows. Section II summarizes previous related works. Section III discusses the problem of supporting devices with multi-RAT interfaces in SDN-based wireless networks and proposes a novel solution to enable it. Section IV discusses the problem of supporting switching entities with multi-RAT interfaces in SDN-based wireless networks and proposes a novel solution to support it. Section V demonstrates the performance evaluation of the proposed solutions. Section VI provides some concluding remarks regarding this research.

II. Related Work

There are previous works applying SDN approaches to WLANs, both enterprise WLANs [7]-[9] and community WLANs [10]. Suresh and co-workers proposed Odin as an open SDN framework for an enterprise WLAN, where the Odin master on an SDN controller communicates with Odin agents at the access points to support seamless mobility, load balancing, hidden terminal mitigation, and other management functions [8]. Schulz-Zander and others proposed a two-tiered control architecture, called AeroFlux, where global control servers deal with global mobility management and load balancing, and near-sighted control servers manage the per-client or per-flow Wi-Fi transmission settings [9]. Yiakoumis and co-workers studied SDN-based home WLANs and proposed a mechanism called BeHop for virtual slicing of a physical WLAN, a personal AP abstraction, and infrastructure management such as for the channel and power [10]. Lee and others proposed an extension of SDN to mobile phones called meSDN [7]. By incorporating an OpenFlow-based local controller in a mobile device, they enabled application-aware uplink flow QoS, a network fault diagnosis, and WLAN virtualization.

Applying the SDN paradigm to multi-hop wireless mesh networks with Wi-Fi radio interfaces has also been studied [11], [12], [32]. Detti and co-workers proposed wmSDN, which is an SDN-based multi-hop wireless mesh network, mainly for the purpose of load balancing between multiple WMN gateways [12]. Dely and others proposed an OpenFlow-based architecture for flexible routing in wireless mesh networks [11] [32]. They demonstrated that the simplification of client mobility between mesh access points is feasible in conformance to OpenFlow messaging triggered by the handover decision of a monitoring server. Although both works introduced an SDN implementation of wireless mesh networks, they did not consider multi-radio capable routers in terms of topology management and routing. Peng et al. proposed Access Point handoff in SDN-based wireless networks by exploiting dual network interfaces [40].

Cellular networks, particularly LTE networks, have recently drawn significant interest from the research community and industries. Some works have studied the issues and solutions for an SDN-based core network (wired part) [13]-[20], and others have focused more on the issues and directions for an SDN-based radio access network (wireless part) [6], [22]. Nagaraj and co-workers propose offloading flows from the evolved packet core (EPC) to other IP transport networks based on flow classification [13]. Mahoodi and others considered SDN-based EPC and studied the case of an intra-LTE handover procedure [14]. Heinonen and co-workers proposed a mechanism for dynamically switching the user plane tunnels in SDN-based cellular core networks [15]. Moradi and others looked into the scalability issue of SDN-based cellular WANs and proposed a three-level control of the switch regions and a recursive topology discovery mechanism [16]. Jin and co-workers proposed a scalable and flexible LTE core network architecture that can program forwarding to middle boxes based on service policies [17]. Pentikousis and others studied applying SDN to mobile core networks, and proposed a flow-based forwarding architecture for the benefit of the operators [18]. Basta and co-workers examined possible scenarios for the placement of EPC functions with a consideration of network function virtualization (NFV) [19]. Hampel and others proposed using SDN to program the encapsulation and decapsulation on top of IP to enable flow-based policy enforcement and mobility [20]. Gudipati and co-workers considered applying the SDN concept to LTE radio access networks, and proposed abstracting multiple eNBs as a single big base station and centrally managing radio resources together for load balancing and utility optimization [21], [22]. There are works that seek joint coordination of radio access networks and transport core networks [33], [34]. Bernardos and co-workers considered accommodating various wireless mobile networks in the SDN realm, and proposed a high-level architecture and the required northbound and southbound interfaces [33]. Tan and others proposed a wireless SDN architecture with a distributed user plane and a centralized function-oriented control plane, and demonstrated end-to-end QoS management and a content-aware data broadcast in converged LTE and Wi-Fi networks [34]. Most recently, Abdulghaffar [39] proposed SDN-based 5G core networks.

Most relevant to our work, some works have considered SDN-based control of heterogeneous wireless mobile networks, including works by Mendonca and co-workers [27], CROWD [35] [36], OpenRoads [37], and SoftMobile [23]. Mendonca and others first examined the possibility of applying an SDN approach in heterogeneous networks consisting of wired networks, infrastructure-based wireless networks, and infrastructure-less wireless networks (e.g., mobile ad hoc networks) [27]. They considered typical use cases such as an SDN-based gateway assignment and data offloading. Ali-

Ahmad and co-workers dealt with very dense networks of multiple radio technologies, and proposed a two-tier controller architecture for scalability in the control of dense networks [35], [36]. Yap and others proposed an OpenFlow-based wireless architecture for orchestrating and virtualizing heterogeneous wireless networks, and demonstrated a case study of WiMAX to/from a Wi-Fi handover [37]. Chen and co-workers considered complex control plane issues in multi-RAT heterogeneous mobile networks, and proposed a holistic control framework for providing a global network view (spectrum, connection, and interference map, among others) and abstraction along with coordination algorithms (for example, joint scheduling and interference cancellation) [23]. Mafakheri and co-workers took software-defined radio access network approach for LTE and WLAN coordination [38]. Alshaer et al. considered the problem of providing application QoS in SDN-based heterogeneous dense wireless networks [41].

III. Supporting Multi-Interface Device

As the first type of multi-radio wireless mobile networks, the authors consider the LTE/WLAN multi-RAT wireless network illustrated in Fig. 1, where user devices (e.g., smartphones) are equipped with both an LTE radio interface and a WLAN radio interface. In 3GPP terminology, these are called UE. An entire LTE network in the data plane consists of an access network part, i.e., evolved node B (eNB), and core network parts, i.e., the serving gateway (S-GW) and packet data network gateway (P-GW). Although 3GPP has specified a tight integration of an LTE network and WLAN networks with P-GW as an anchor, most mobile network operators resist deploying it owing to the high cost of backhauling WLAN networks to an LTE core network part [26], [28]. Thus, the current norm is a loose integration or non-seamless integration of both networks, as depicted in Fig. 1. In this network, multi-radio devices typically make a radio access technology (RAT) selection using their connection manager software with only local logic. Furthermore, once selected initially for a flow, a RAT cannot be changed to another RAT dynamically. For these reasons, the current network has difficulties in achieving an optimal multi-radio resource utilization and providing quality of experience (QoE) dynamically [26]. It is envisaged that the SDN-based integration of LTE and WLAN networks can resolve the above issues without causing a severe backhaul cost.

Tailoring multi-radio wireless mobile networks to the SDN rebase basically involves making OpenFlow channels between an SDN controller and each switching entity, as indicated by the dotted lines in Fig. 1 and 2. Note that we assume OpenFlow to be used as an SDN standard [29]. Issues in the design of such SDN-based multi-radio networks arise in two facets: supporting multi-radio devices and supporting multi-radio switching entities.

In Fig. 1, as per the current SDN standard, each interface of a multi-radio device is separately known to attach a port of a corresponding switching entity to an SDN controller. For this reason, the SDN controller cannot distinguish a LTE/WLAN multi-RAT device from two single-radio devices with LTE and Wi-Fi, respectively. Identifying a multi-radio device and serving it with a combination of adequate radios with the help of the SDN controller is not possible in the current SDN standard, and hence, some new enhancements are needed to resolve this issue.

An SDN controller’s awareness of multi-radio devices is a key enabler to the effective utilization of multi-radio access technology (RAT) resources. For example, flow-precision inter-RAT mobility for a multi-radio device can be supported in the SDN context to ensure load balancing for a holistic network perspective. For this purpose, the authors propose mechanisms for integrated device identification and inter-RAT flow mobility control.

Fig. 2 illustrates the mechanisms in the form of a message sequence chart and explains each step. SDN controllers should incorporate device management module with multi-RAT device support: When a device attaches to a RAT base station through a radio interface, the controller keeps track of an interface mapping from the radio interface (with a unique MAC address) to a {switch, port} tuple. When a device has multi-RAT attachments concurrently, the controller keeps track of a list of multiple interface mappings per device.

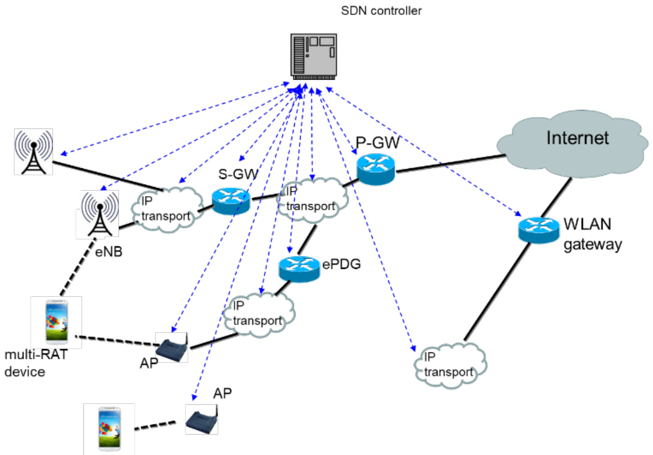

Fig. 1. An LTE/WLAN Network with Multi-RAT Devices. Its SDN Rebase is indicated by the Dotted Lines.

(5) WLAN radio turn-on
attachment
(6) Device attachment message (identity)
(7) Multi-RAT device detection
(8) Inter-RAT mobility decision
(9) Mobility command message
(10) Flow 2 modification

Fig. 2. A Message Sequence Chart for Handling a Multi-RAT Device.

(Step 1) A multi-radio device attaches to RAT 1, which is LTE, and a switching entity corresponding to eNB then notifies the SDN controller of the attachment and identification of the device. For the purpose of identification, an international mobile equipment identity (IMEI) can be used. (Step 2) The controller becomes aware of the device through LTE. (Steps 3 and 4) Two flows are set up based on the OpenFlow standard. (Step 5) The multi-radio device turns on its RAT 2 interface, which is a Wi-Fi interface, and discovers a WLAN AP. (Step 6) The device attaches to a WLAN AP and the AP in turn notifies the SDN controller of the attachment and identification of the device on WLAN. For the purpose of identification, the same IMEI can be used. (Step 7) Through the identification, the controllers handle the device as multi-radio capable. (Step 8) The controller makes a decision on the mobility of flow 2 from RAT 1 to RAT 2. (Step 9) A mobility command is sent out to the RAT 1 base station and device. (Step 10) A new flow table entry for flow 2 on RAT 2 is configured using an OpenFlow Flow Modify message.

IV. Supporting Multi-Interface Switch

As the second type of multi-interface wireless networks, the authors consider the multi-radio multi-channel wireless mesh network illustrated in Fig. 3, where mesh routers are equipped with multiple IEEE 802.11-based radio interfaces operating on separate physical channels in parallel. In the figure, three different colors are used to indicate three non-overlapping WLAN channels. How to map each interface to a channel is a key concern for resource utilization, and static, dynamic, and hybrid channel assignments have been extensively studied. The current state-of-the-art method is a distributed approach that can rely only on local information for a channel assignment [25]. The authors believe that an SDN-based holistic coordination of multiple (homogeneous) radio interfaces of each wireless mesh router and their operating channels can result in better utilization throughout the entire network.

In Fig. 3, each interface of a multi-radio switch (mesh router) should operate on different channels to fully exploit the available Wi-Fi channels. However, as per the current SDN standard, information regarding on which physical channel a port (i.e., a wireless interface) operates is lacking, and thus, the optimization of multi-RAT resource utilization is hard to achieve. Furthermore, a port for a wireless interface of a wireless switch should actually be used for both incoming packets and outgoing packets because it uses the wireless broadcast medium. However, the SDN standard only specifies that an incoming port should be different from an outgoing port, and thus, we need some mechanisms for supporting wireless ports in the SDN paradigm.

For a multi-interface switch, a radio port is first configured for each RAT interface (e.g., IEEE 802.11 radio interface) and its operating channel is initially configured. Because a radio interface uses the wireless broadcast medium, forwarding rules can be properly specified only by distinguishing which neighbor is the intended receiver. For this purpose, for a radio port, virtual radio ports should be defined for each neighbor relation. A wireless interference and channel reconfiguration may impact wireless neighbor links and hence trigger the creation or deletion of virtual radio ports. The neighbor switches of each switch can be discovered using the peer management protocol (PMP) of the IEEE 802.11s mesh standard. Thus, the switches themselves can determine whether a virtual radio port should be set for each discovered neighbor.

Fig. 4 illustrates mechanisms for handling multi-radio switches and multi-radio multi-channel aware routing in the form of a message sequence chart, and explain each step. (Step 1) A wireless port is set up, and a radio port status message including its operating channel is sent to the controller. (Step 2) Depending on how many neighbors the wireless port has, virtual radio ports are set up and known to the controller. (Step 3) Another wireless port is set up, and a radio port status message is transmitted. (Step 4) virtual radio ports for this port are set up and known to the controller. (Step 5) The controller is aware of a multi-radio switch, as well as its radio and virtual radio ports. (Step 6) A new flow 1 is created. (Step 7) The controller sets up a route for flow 1 from switch 1 to switch 2 and switch 4. (Step 8) Another flow 2 is created. (Step 9) The controller's multi-radio, multi-channel aware routing module determines whether to support the new flow 2 on a route from switch 1 to switch 3 and switch 4. (Step 10) The interfaces on the route use channel 2, which is less utilized than channel 1, and hence, can benefit from the multi-channel enhanced network capacity.

Fig. 4. A Message Sequence Chart for Handling a Multi-radio Switch (Mesh router). A Routing Procedure Exploiting Multi-channel Diversity is also included.

Switch management module with multi-radio switch support: The controller keeps track of each switch's radio ports and the mappings from each radio port to a list of virtual radio ports. The data structure for the radio ports and virtual radio ports includes operating physical channels for multi-channel awareness.

Forwarding module: When a new flow arises on multiple radio switches, a route for the flow can be determined based on a multi-radio, multi-channel aware algorithm to exploit channel diversity. Without multi-radio, multi-channel awareness, traditional shortest-path routing algorithms such as the well-known Dijkstra algorithm will only consider the link costs. For a multi-radio device, an existing flow on one radio can be examined to move to another radio based on an inter-RAT mobility algorithm with a holistic view of the entire multi-radio network.

V. Performance Evaluation

The authors built an integrated testing suite for SDN controller implementation [30] [31] and software switch implementation using a network emulation scheme. It is verified that the controller and switches interoperate with each other in conformance with the OpenFlow specifications. For the implementation of the proposed mechanisms for multi-radio wireless mobile networks, we use Vendor messages to carry the additional proposed information on multi-radio devices and multi-radio switches. In this way, legacy single-radio devices and switches can still be supported without modification. The modules in the switch software are coded in C/C++ languages. The authors designed and implemented the proposed mechanisms using a multi-radio switch and device support in a widely used network simulator space (ns-3), and made them interoperate with a real SDN controller. Hence, the inherent benefits of ns-3 (e.g., module reusability and extensibility) can be exploited. Our experience in this paper shows that researchers and developers can prototype and test new ideas and mechanisms for OpenFlow switches used in software in a timely and flexible manner.

The authors present two exemplary performance results to demonstrate the benefits of the proposed mechanisms. The tests were conducted using simple but effective topologies to highlight the benefits. We first examine the performance of the proposed SDN-based LTE/WLAN flow mobility procedure for a multi-radio device. We use a small topology in Fig. 5 for the ease of analysis. Initially, two flows (flows 1 and 3) exist over the LTE radio access technologies for a multi-radio device, and later, another flow (flow 2) over LTE is created. At time 24, the multi-radio device turns on its Wi-Fi radio interface, and according to the proposed mechanisms, the SDN controller instructs inter-RAT flow mobility for flow 3. The topology in Fig. 5(a) shows the flows after the flow mobility is performed. The traffic load on LTE is distributed to Wi-Fi, and hence, the network utilization is improved and individual flows can enjoy higher rates. This result highlights the strength of SDN-based holistic orchestration of heterogeneous multi-radio resources and flows.

Next, we examine the performance of the proposed WMN flow-precision multi-channel routing. In Fig. 6(a), a wireless mesh network topology is illustrated. Each node is equipped with two Wi-Fi radio interfaces, and flow 1 (blue) and flow 2 (red) are considered for the simulation. First, Fig. 6(b) shows the throughput for when both flow 1 and flow 2 use the same channel, i.e., the SDN controller does not have a notion of multi-channel routing. Initially, flow 2 monopolizes the channel, and at time 30, flow 1 is created and uses the same channel. We observed that the channel is shared between the two flows. Next, Fig. 6(c) shows the throughput for multi-channel aware routing. The scenario is the same, but when flow 1 is created, the SDN controller can conduct multi-channel aware routing, and thus two orthogonal channels can be utilized by the two flows, respectively. We observed that the throughput is significantly better for multi-channel aware routing by the SDN controller. Although we use a simple multi-channel aware routing algorithm in this evaluation, we anticipate that more sophisticated algorithms can solve a very complex channel assignment and routing problems more effectively.

VI. Conclusion

As the emergence of multi-radio (heterogeneous or homogeneous radio) wireless mobile networks increases, the mechanism of centrally coordinating all available multi-radio network capabilities in a holistic manner has become essential. This paper presented the first in-depth study on how to incorporate multi-radio devices and multi-radio switches within the SDN paradigm. We examined the possibility of SDN-based control of two promising multi-interface wireless mobile networks, i.e., LTE/WLAN heterogeneous networks and multi-radio multi-channel wireless mesh networks, and proposed their control mechanisms. Through the integration of a real SDN controller and standard-compliant simulated switching entities, it is demonstrated the functional verification and performance of the proposed mechanisms. Future work may include the implementation and experimentation of the proposed solution in real network settings.

A Machine Learning based Analytical Approach for Envisaging Bugs

Dr. Anjali Munde
Amity College of Commerce and Finance
Amity University Uttar Pradesh
Noida, India

***Abstract*—A software imperfection is a shortcoming, virus, defect, mistake, breakdown or glitch in software that initiates it to establish an unsuitable or unanticipated result. The foremost hazardous components connected with a software imperfection that is not identified at an initial stage of software expansion are time, characteristic, expenditure, determination and wastage of resources. Faults appear in any stage of software expansion. Thriving software businesses emphasize on software excellence, predominantly in the early stage of the software advancement. In succession to disable this setback, investigators have formulated various bug estimation methodologies till now. Though, emerging vigorous bug estimation prototype is a demanding assignment and several practices have been anticipated in the text. This paper exhibits a software fault estimation prototype grounded on Machine Learning (ML) Algorithms. The simulation in the paper directs to envisage the existence or non-existence of a fault, employing machine learning classification models. Five supervised ML algorithms are utilized to envisage upcoming software defects established on historical information. The classifiers are Naïve Bayes (NB), Support Vector Machine (SVM), K- Nearest Neighbors (KNN), Decision Tree (DT) and Random Forest (RF). The assessment procedure indicated that ML algorithms can be manipulated efficiently with high accuracy rate. Moreover, an association measure is employed to evaluate the propositioned extrapolation model with other methods. The accumulated conclusions indicated that the ML methodology has an improved functioning.**

I. Introduction

From the time of establishment of software expansion, defect restoration is studied as the most monotonous tasks, primarily for its in-built vagueness. Furthermore, the procedure of repairing bugs is gradual. The procedure of bug-restoration has a chief involvement in the software advancement. In order to lessen the concern of fault correction, bug estimation is examined significantly by the investigators. Numerous machine learning directed estimation prototypes are constructed and verified on several arguments.

The continuation of software faults influences considerably on software consistency, feature and upholding expense. Attaining errorless software is laborious, when the software utilized meticulously as largely there are unknown defects. Furthermore, extending software fault estimation prototype which can estimate the imperfect components in an initial stage is an actual test.

Contemporary developments rotate about the information that defects can be envisaged, widely beforehand they are identified. Significant corpuses of preceding fault information are fundamental to be proficient to envisage defects with sufficient precision. Software analytics has initiated continuous opportunities for tapping data analytics and rationalizing to enhance the feature of software. Functional analytics applies the outcomes of the software evaluation as real time data, to create valuable extrapolations.

Software defect estimation is an indispensable action in software expansion as envisaging the defects components earlier to software implementation attains the operator contentment and corrects the complete software functioning. Besides, envisaging the software fault initially increases software alteration to distinctive situations and enlarges the resource consumption.

Several methods are recommended to undertake Software fault estimation obstruction. The utmost comprehended procedures are Machine Learning procedures. Machine learning is effectively employed to build extrapolations in numerous database. Provided the enormous amount of fault database accessible currently, envisaging the occurrence of faults can be completed employing several machine learning procedures.

The application of machine learning to establish an exclusively mechanised technique of determining the act to be acquired by a business when a fault is testified was initially propositioned through Cubranic and Murphy [1]. The technique implemented helps text classification to envisage defect rigorousness. This technique functions accurately on 30% of the defects testified to creators. Sharma, Sharma and Gujral [2] apply feature selection to enhance the precision of the fault estimation prototype.

In this communication, supervised Machine Learning (ML) classifiers are employed to assess the ML potentials in Software fault estimation. The analysis examined Naïve Bayes (NB), Support Vector Machine (SVM), K- Nearest Neighbors (KNN), Decision Tree (DT) and Random Forest (RF) classifier. The considered ML classifiers are directed to three distinctive database acquired from [3] and [4] mechanisms.

Further, the manuscript evaluated among Naïve Bayes (NB) classifier, Support Vector Machine (SVM) classifier, K-

Nearest Neighbors (KNN) classifier, Decision Tree (DT) classifier and Random Forest (RF) classifier and compared then on the basis of distinct assessment quantities for instance accuracy, precision, recall, F-measures and the ROC curves of the classifiers.

The manuscript is structured as per the following sequence. An examination of the associated work in Software fault estimation is exhibited in the Literature Review. An outline of the designated ML algorithms is exhibited in the Proposed Model. The database and the assessment technique is explained in the Evaluation Methodology. Investigational outcomes are depicted in Results accompanied by inferences and future works.

II. Literature Review

Formerly, various efforts in the subjects of fault estimation have been achieved. Peng He et al. performed a practical analysis on software fault estimation with a basic metric set [5]. Investigation has been performed on 34 announcements of 10 open source assignments accessible at PROMISE repository. The outcome signifies the outcome of uppermost-k metrics or minimum metric subset gives satisfactory result in comparison with standard forecasters.

Anuradha Chug et al. [6] employed three supervised and unsupervised learning algorithms for envisaging faults in software. NASA MDP database were administered by utilizing Weka tool. Various quantities such as recall and f-measure were applied to estimate the functioning of classification and clustering algorithms. Through examining distinct classification algorithms Random Forest has the maximum accuracy of MC1 database and gives maximum rate in recall, f-measure and receiver operating characteristic [ROC] curve and it specifies least amount of root mean square errors in all conditions. In an unsupervised algorithm k-means gave the smallest amount of inaccurate clustered examples and it considers least period for envisaging defects. Hammouri, A. et al [7] proposed software defect estimation prototype established on Machine Learning Techniques to envisage impending software defects created on past database and exhibited that Machine Learning techniques can be applied successfully with high precision.

Logan Perreault et al. [8] employed classification algorithm for instance naïve bayes, neural networks, support vector machine, linear regression, K-nearest neighbor to discover and envisage faults. The investigators manipulated NASA and tera PROMISE database. To compute the accomplishment, they tapped accuracy and f1 measure with noticeably distinct metrics.

R. Malhotra in [9] exhibited a valuable methodical evaluation for software fault estimation procedures applying Machine Learning. The article encompassed an evaluation of all the findings concerning the interval of 1991 and 2013, examined the Machine Learning methods for software fault estimation prototypes, and evaluated their functioning, matched among Machine Learning and statistic methods, evaluated among distinct Machine Learning methods and reviewed the power and the limitation of the Machine Learning methods.

Singh and Chug [10] examined widespread Machine Learning algorithms tapped for software fault estimation. The analysis exhibited significant outcomes comprising that the Artificial Neural Network has least inaccuracy amount, but the linear classifier is advanced than auxiliary algorithms in term of fault estimation precision.

Malhotra and Singh [11] indicated that the Area Under Curve is constructive metric and utilised to envisage the defects in initial stages of software expansion and to increase the validity of Machine Learning methods.

This article examines established machine learning techniques Naïve Bayes (NB), Support Vector Machine (SVM), K- Nearest Neighbors (KNN), Decision Tree (DT) and Random Forest (RF). The communication estimates the Machine Learning classifiers by means of different performance quantities. Three known database are employed to assess the Machine Learning classifiers.

Alternatively, maximum cited assignments examined new Machine Learning techniques and distinct database. Few of the earlier investigations primarily concentrated on the metrics that generate the Software fault estimation as feasible as imaginable, though earlier investigations suggested distinctive approaches to estimate software faults in place of Machine Learning methods.

III. Proposed Model

The research directs to examine and assess supervised Machine Learning algorithms. The investigation exhibits the performance correctness and competency of the Machine Learning algorithms in software fault estimation and postulates a comparative study of the designated Machine Learning algorithms.

The supervised machine learning algorithms attempt to create an extrapolating function through deducing associations and needs among the identified feed in and outturn of the categorized training data, thus we can envisage the outturn amounts for recent feed in data created on the resulting extrapolating function. Subsequently are encapsulated explanations of the designated supervised Machine Learning algorithms:

- Naïve Bayes (NB): Naïve Bayes classifier functions on the theory of probability. The notion of naïve bayes classifier is established on the effort of Thomas Bayes (1702-1761) of Bayes Theorem for conditional probability. Naïve Baye's Classifier performs on the notion of baye's theorem through a naïve theory that an existence of a specific feature in a class is entirely discrete to the existence of additional features.

- Support Vector Machine (SVM): SVM is most widespread supervised machine learning technique which is equivalently tapped for classification and regression, however SVM is typically utilised for classification. The notion of SVM is to obtain a hyperplane that categorizes the training data points in order to obtain marked classes. The feed in of SVM is the training data and it functions the training sample feature to envisage category of test feature.

- K Nearest Neighbour (KNN): KNN algorithm well -known by K-Nearest Neighbours Algorithm is tapped to elucidate the difficulties of classification together with regression. The theory of algorithm is primarily established upon feature comparison in two of them, classification and regression. KNN classifier is distinct from previous probabilistic classifiers as the simulation encompasses a discovering phase of calculating probabilities from a training experiment and employ them for impending estimation of a test experiment. In probability established prototype when the prototype is proficient the training experiment could be dropped and classification is completed by means of the calculated probabilities.

- Decision Tree (DT): DT is a familiar investigation technique utilised in data mining. Decision Tree signifies a hierarchal and extrapolative prototype that utilises the elements examination as branches to access the elements target amount in the leaf. Decision Tree is a tree with decision nodes, that have several branches and leaf nodes that characterise the conclusion.

- Random Forest (RF): Random Forest comprises of a substantial quantity of distinct decision trees that function as an ensemble. Individual tree in the random forest separate out a class estimation. The class that has the highest votes turns out to be prototypes estimation. A big quantity of comparatively disjointed prototypes (trees) functioning as a group will outshine any of the specific prototypes.

IV. Evaluation Methodology

The database used in the study are three different databases, specifically DB1, DB2 and DB3. All databases comprise of two measures; the amount of defects (Bi) and the amount of test workers (Wi) for respective day (Ti) in a section of software launches period. The DB1 database has 46 quantities that were included in the examining procedure exhibited in [4]. DB2, captured from [4], computed a technique where defects for the period of 111 consecutive days of examining the software technique. DB3 includes 109 quantities. DB3 is established in [3], that comprises actual calculated records for a restoration plan of a real time control utilization exhibited in [12]. Tables I to III show DB1, DB2 and DB3, respectively.

The database was subjected to pre-treatment through a recommended clustering method. The recommended clustering method indicates the data with class labels. The labels are fixed to categorize the amount of defects into six distinct classes; A, B, C, D, E and F (Table IV).

TABLE IV. AMOUNT OF EVERY CLASS AND QUANTITY OF OCCURENCES

Amount of Every Class and Quantity of Occurrences				
Fault Class	***Number of Faults***	***DB1***	***DB2***	***DB3***

F	More than 25	2	2	0

To estimate the functioning of utilising Machine Learning algorithms in software fault extrapolation, we tapped an array of prominent quantities [13] established on the created confusion matrices. The subsequent subdivisions explain the confusion matrix and the tapped estimation quantities.

a) Confusion Matrix: The confusion matrix is an explicit table employed to determine the functioning of Machine Learning algorithms. Fig. 1 to 6 exhibits an illustration of a standard confusion matrix. Every row of the matrix signifies the occurrences in an actual class, although every column signifies the occurrences in a forecasted class. Confusion matrix recapitulates the outcomes of the examining algorithm and specifies a description of the amount of True Positive (TP), False Positives (FP), True Negatives (TN), and False Negatives (FN).

Confusion Matrix for the Training Data - Decision Tree.

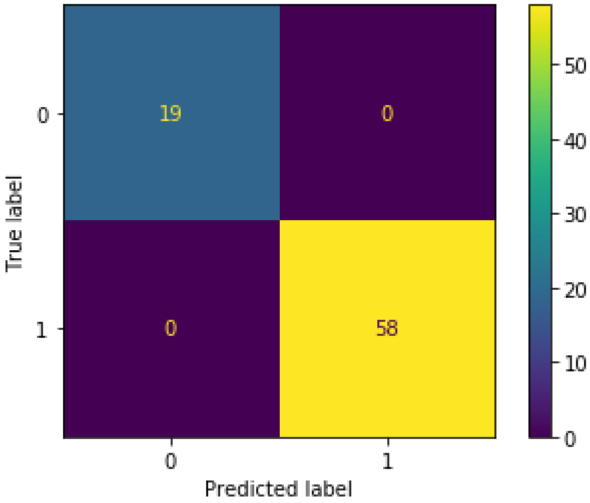

Fig. 2. Confusion Matrix of Training Data for DB2.

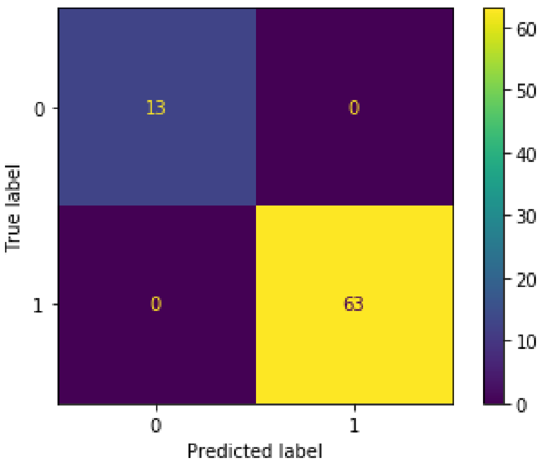

Fig. 3. Confusion Matrix of Training Data for DB3.

Confusion Matrix for the Testing Data - Decision Tree.

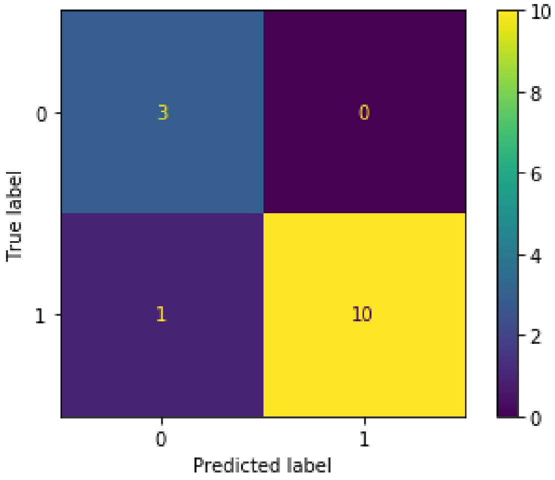

Fig. 4. Confusion Matrix of Testing Data for DB1.

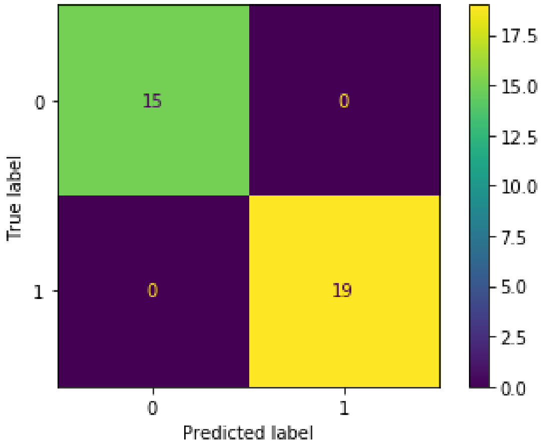

Fig. 5. Confusion Matrix of Testing Data for DB2.

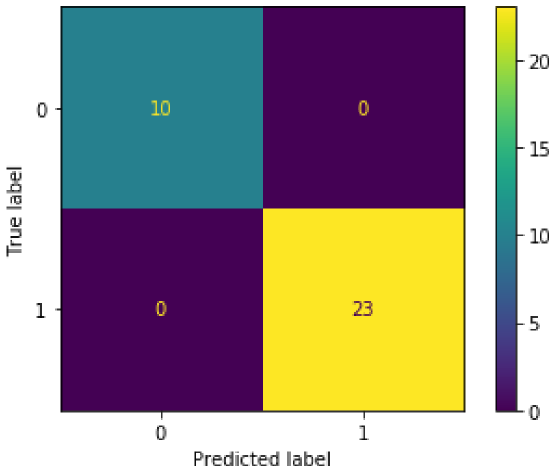

Fig. 6. Confusion Matrix of Testing Data for DB3.

b) Accuracy: Accuracy is the quantity of accurate outcomes between the total amount of inspected occurrences. The highest accuracy is one, while the poorest accuracy is zero. Accuracy could be calculated through the subsequent rule (Table V):

ACC = (TP + TN) / (TP + TN+ FP + FN)

TABLE V. ACCURACY FOR THE DATABASES

Accuracy for the Databases					
Database	***NB***	***SVM***	***KNN***	***DT***	***RF***
DB1	1	0.71	0.79	0.93	0.93
DB2	1	0.85	0.79	1	1
DB3	1	0.70	0.70	1	1
Average	1	0.75	0.76	0.98	0.98

c) Precision: Precision is computed as the amount of true positive extrapolations divided with the total amount of positive extrapolations. The highest precision is one, while the poorest is zero and could be computed through (Table VI):

Precision = TP / (TP + FP)

d) Recall: Recall is computed as the amount of positive extrapolations divided with the total amount of positives. The highest recall is one, while the poorest is zero. Recall is evaluated through the subsequent rule (Table VII):

Recall = TP / (TP + FN)

TABLE VI. PRECISION FOR THE DATABASES

Precision for the Databases					
Database	***NB***	***SVM***	***KNN***	***DT***	***RF***
DB1	1	1	1	1	1
DB2	1	0.85	0.77	1	1
DB3	1	0.70	0.78	1	1
Average	1	0.85	0.85	1	1

TABLE VII. RECALL FOR THE DATABASES

Recall for the Databases					
Database	***NB***	***SVM***	***KNN***	***DT***	***RF***
DB1	1	0.64	0.73	0.91	0.91
DB2	1	0.89	0.89	1	1
DB3	1	1	0.78	1	1
Average	1	0.84	0.80	0.97	0.97

e) F-measure: F-measure is described by way of the weighted harmonic mean of precision and recall. Generally, it is tapped to join the Recall and Precision quantities in one quantity so as to evaluate distinct Machine Learning algorithms among each other. F-measure rule is evaluated through the subsequent rule (Table VIII):

F- measure= (2* Recall * Precision)/(Recall + Precision)

TABLE VIII. F-MEASURE FOR THE DATABASES

F-Measure for the Databases					
Database	***NB***	***SVM***	***KNN***	***DT***	***RF***
DB1	1	0.78	0.84	0.95	0.95
DB2	1	0.87	0.83	1	1
DB3	1	0.82	0.78	1	1
Average	1	0.82	0.82	0.98	0.98

f) Root-Mean-Square Error (RMSE): RMSE is a quantity for assessing the functioning of an extrapolation prototype. The perception is to compute the variation among the envisaged and the definite estimates. If the definite estimate is X and the envisaged estimate is XP then RMSE is computed by the subsequent formula:

$$RMSE = \sqrt{\frac{1}{n} * \sum_{i=1}^{n} (Xi - XPi)^2}$$

g) Area Under Curve(AUC): AUC exemplifies the probability that the classifier would rank an arbitrarily selected positive instance greater than an arbitrarily selected negative instance. The AUC is established on a chart of the false positive value with the true positive value. The highest value is one signifies that 100% estimation of the model is accurate, while the poorest is zero signifies that 100% estimation of the model is inaccurate. Fig. 7 to 12 exhibits an illustration of the Area Under Curve.

h) Receiver Operating Characteristic (ROC): ROC Curve is an outstanding technique of calculating the functioning of a Classification prototype. The True Positive value is plot with False Positive value for the probabilities of a classifier estimations.

AUC and ROC for the Training Data - Decision Tree

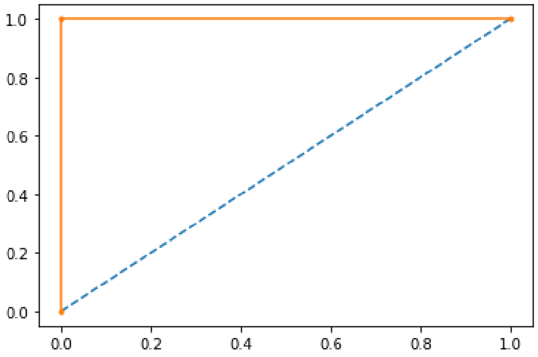

Fig. 7. AUC of Training Data for DB1.

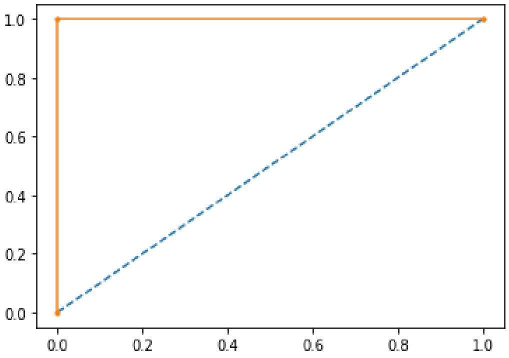

Fig. 8. AUC of Training Data for DB2.

AUC and ROC for the Testing Data - Decision Tree.

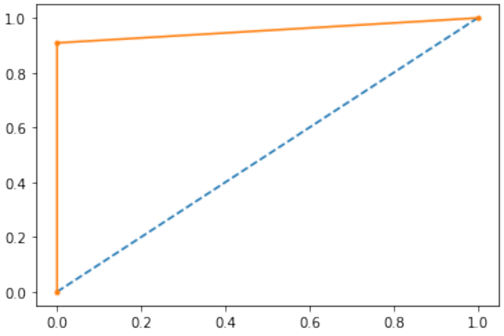

Fig. 10. AUC of Testing Data for DB1.

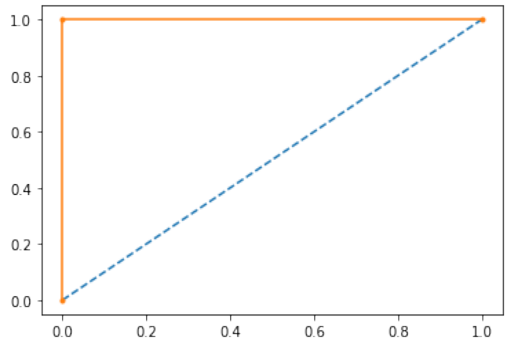

Fig. 11. AUC of Testing Data for DB2.

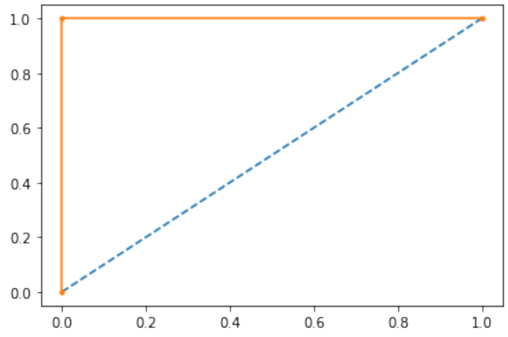

Fig. 12. AUC of Testing Data for DB3.

Conclusively, to assess the Machine Learning algorithms with additional methods, the RMSE value is estimated. The composition in [2] anticipated a Linear Regression (LR) prototype to envisage the increasing amount of software defects utilising past calculated defects. The assessment procedure was performed on the similar database that is used in this investigation. The lesser the RMSE amount, the reliable the model. Table IX exhibits the RMSE values for all the ML Algorithms and LR models.

TABLE IX. RMSE VALUES FOR THE ML ALGORITHMS AND LR MODELS

RMSE Values for the ML Algorithms and LR Models						
Database	***NB***	***SVM***	***KNN***	***DT***	***RF***	***LR***
DB1	0.0	0.53	0.53	0.26	0.26	0.43
DB2	0.0	0.38	0.38	0.0	0.0	0.38
DB3	0.0	0.55	0.55	0.0	0.0	0.36

V. Results

This inquiry utilised Jupyter Notebook, Python as Machine Learning tool, to assess five Machine Learning Algorithms Naïve Bayes (NB), Support Vector Machine (SVM), K-Nearest Neighbors (KNN), Decision Tree (DT) and Random Forest (RF)) in software default estimation.

The accuracy of Naïve Bayes (NB), Support Vector Machine (SVM), K- Nearest Neighbors (KNN), Decision Tree (DT) and Random Forest (RF) classifiers for the three database are presented in Table VI. As exhibited in Table VI, the five Machine Learning algorithms attained a high accuracy value.

The typical estimate for the accuracy value in all database for the five classifiers is over 75% on average. Though, the lowermost estimate emerges for SVM and KNN algorithm in the DS3 database. This is for the reason that the database does not have greater than 20 defects and SVM and KNN algorithm requires a significant quantity of defects so as to attain a better accuracy rate. Thus, SVM and KNN got a greater accuracy value in DS2 database that are comparatively larger than the DS1 and DS3 database.

The precision measures for employing NB, SVM, KNN, DT and RFs classifiers on DS1, DS2 and DS3 database are exhibited in Table VII. Outcomes indicate that the five Machine Learning algorithms can be utilised for defect extrapolation successfully with a right precision value. The typical precision rates for every classifier in the three database are greater than 85%.

The next assessment quantity is the amount of recall. Table VIII exhibits the recall rates for the five classifiers on the three database. Correspondingly, the Machine Learning algorithms attained a suitable recall rate. The highest recall rate was attained by NB classifier that is 100% in all database. Whereas, the typical recall rates for SVM, KNN, DT and RM algorithms are 84%, 80%, 97% and 97%, correspondingly.

Further, to evaluate the five classifiers concerning recall and precision quantities, we employed the F-measure rate. Table exhibits the F-measure rates for the utilised Machine Learning algorithms in the three database. As presented in the table, NB has the maximum F-measure rate in all database trailed by DT and RF then SVM and KNN classifiers.

The outcomes represent that NB, DT and RF classifiers have improved rates than LR models. The typical RMSE amount for all Machine Learning classifiers in the three database is 0.28, whereas the typical RMSE estimates for LR model is 0.39.

VI. Conclusions and Future Work

Software fault estimation is a procedure in which an extrapolation prototype is generated so as to envisage the anticipated software defects created on past data. Numerous methodologies have been propositioned utilising distinct database, distinct metrics and distinct functioning quantities. This article assessed the application of Machine Learning Algorithms in software defect estimation. Five machine learning methods have been employed, Naïve Bayes (NB), Support Vector Machine (SVM), K- Nearest Neighbors (KNN), Decision Tree (DT) and Random Forest (RF). The assessment procedure is applied utilising three database. Investigational outcomes are accumulated built on accuracy, precision, recall, F-measure, and RMSE quantities. Outcomes showed that the Machine Learning procedures are effective methods to envisage the impending software faults. The evaluation outcomes exhibited that the NB classifier has the greatest outcomes in comparison to others. Furthermore, investigational outcomes presented that employing Machine Learning method imparts an improved functioning for the estimation prototype in comparison to other methods, such as LR model. For future scope, new Machine Learning procedures can be adopted and an extensive assessment between them can be performed. Moreover, inserting additional software metrics in the study procedure is a feasible method to foster the correctness of the estimation model.

***Abstract*—Online and offline newspaper articles have become an integral phenomenon to our society. News articles have a significant impact on our personal and social activities but picking a piece of an appropriate news article is a challenging task for users from the ocean of sources. Recommending the appropriate news category helps find desired articles for the readers but categorizing news article manually is laborious, sluggish and expensive. Moreover, it gets more difficult when considering a resource-insufficient language like Bengali which is the fourth most spoken language of the world. However, very few approaches have been proposed for categorizing Bangla news articles where few machine learning algorithms were applied with limited resources. In this paper, we accentuate multiple machine learning approaches including a neural network to categorize Bangla news articles for two different datasets. News articles have been collected from the popular Bengali newspaper Prothom Alo to build Dataset I and dataset II has been gathered from the famous machine learning competition platform Kaggle. We develop a modified stop-word set and apply it in the preprocessing stage which leads to significant improvement in the performance. Our result shows that the Multi-layer Neural network, Naïve Bayes and support vector machine provide better performance. Accuracy of 94.99%, 94.60%, 95.50% has been achieved for SVM, Logistic regression and Multi-layer dense neural network, respectively.**

Keywords*—Bangla news classification; supervised learning; feature extraction; category prediction; machine learning; neural network

I. Introduction

A newspaper is known as a powerhouse of information. People get the latest information about their desired content through online or offline newspapers. Thousands of newspapers are published in different languages all over the world. Whatever happens around the world may be a thousand miles away but reaches us within a second through online news content. In the recent years, the importance of online articles has also increased rapidly due to the rapid rise and availability of smart devices. Bangla is the fourth most spoken language and vast amounts of Bangla news articles are produced every hour worldwide. Choosing the appropriate information from the sea of web is difficult as the news has no categorization based on its content. Online news websites provide subject categories and sub-categories [1] which significantly vary newspaper to newspaper. So, these might not be sufficient for fulfilling users' choice of interest. Readers like to explore news from various news sources rather than one source and recommending suitable news to the readers based on its contents can improve the readers' experience.

The paper's main motivation is to help in recommending relevant news to the Bengali online news readers using multi-category classification. Readers are only attracted to the news articles of their interest [2]. For this purpose, the readers have to explore all the news articles of different news sites to get the desired items. For example, a user interested in entertainment-related news has to go through all the news articles from various news sites and analyze information from multiple tiresome sources. A user would prefer such a system or framework that would gather news articles of interest from various news sites and access the system anywhere on any electronic device. Although frameworks are available to notify the readers about news' on their desire categories, manually categorizing thousands of online Bangla news articles is challenging. Moreover, appropriate categorization of Bangla news articles considering their content is essential for the readers and designing an automated system for this purpose is a crying need.

Several approaches have been proposed for news categorization for different languages, i.e. Indonesian [4], Hindi[5], Arabic[6][11], Spanish [7], and these approaches mainly based on traditional machine learning algorithms such as Naïve Bayes, decision tree, K-Nearest Neighbors etc. Since Bengali is morphologically rich and complex considering the large scale of alphabets, grapheme and dialects, it needs special consideration of its features in the training phase for classification on Bangla news based on its context. However, some approaches are available in Bangla language [13-16], but these researches were limited to some traditional methods and dealt with small datasets. Due to the scarcity of resources and the complex structure of Bangla text, it's been a challenging task to classify the Bangla news.

In this paper several popular machine learning models and a multi-layer dense neural network are implemented on two different datasets. Dataset I has been built of five categories called Economics, Entertainment, International, Science and Technology and, Sports containing 1425 documents from

*Corresponding Author

popular Bangla newspaper Prothom Alo available on [20] and collected a dataset named dataset II from the Kaggle website [17] which has a total of 532509 records with nineteen categories. But, 169791 records of five categories are used from that dataset in this paper. A list of Bangla stop words are built containing 875 words [21] to remove from the newspaper contents for preprocessing purpose. Similar preprocessing steps are applied for both datasets separately and achieved better accuracy for multiple machine learning models. The accuracy of 92.63% and 95.50% for dataset I and dataset II was achieved for the multi-layer dense neural network, respectively.

The remaining part of the paper is organized as follows - Section II reviews several related works on different types of news classification both for Bangla and other languages. Section III presents research methodology which describes datasets and proposed methods. Section IV depicts result analysis. Finally, this work is concluded and provides future direction in Section V.

II. Related Work

Text classification is the process of assigning labels to text according to its content. It is one of the most fundamental tasks in Natural Language Processing (NLP) with broad application such as sentiment analysis, topic labeling, spam detection, intent detection etc. Nowadays, many tasks have been conducted on this field. Especially it is done for English language as there are enough resources for English language [3]. On the other hand, there are not enough resources except English for the task because very few works have been carried out for the task. However, working on this field is also increasing day by day in recent times. Some works of text classification on non-English languages are overviewed in the following:

Naïve Bayes and Two-Phase Feature Selection Model were used to predict the test sample category for Indonesian news classification. Naive Bayes classifier is quicker and efficient than the other discriminative models. In text classification applications and experiments, Naive Bayes (Naïve Bayes) probabilistic classifier is often used because of its simplicity and effectiveness using the joint probabilities of words and categories given a document [4]. M. Ali Fauzi et al. [4] used Naïve Bayes for Indonesian news classification. Abu Nowshed Chy et al. [10] used Naïve Bayes for Bangla news classification.

Machine learning approach was used for the classification of indirect anaphora in Hindi corpus [5]. The direct anaphora has the ability to find the noun phrase antecedent within a sentence or across few sentences. But, indirect anaphora does not have explicit referent in the discourse. They suggested looking for certain patterns following the indirect anaphora and marking demonstrative pronoun as directly or indirectly anaphoric accordingly. Their focus of study was pronouns without noun phrase antecedent.

A method was designed for classification of Arabic news, the classification system that best fits data given a certain representation [6]. A new method was presented for Arabic news classification using field association words (FA words). The document preprocessing system generated the meaningful terms based on Arabic corpus and Arabic language dictionary. Then, the field association terms were classified according to FA word classification algorithm. It is customary for people to identify the field of document when they notice peculiar words. These peculiar words are referred to as Field Associating words (FA words); specifically, they are words that allow us to recognize intuitively a field of text or field-coherent passage. Therefore, to identify the field of a passage FA terms can be used, and to classify various fields among passages FA terms can be also used.

Cervino U et al. applied machine learning techniques to the automatic classification of news articles from the local newspaper La Capitaolf Rosario, Argentina [7]. The corpus (LCC) is an archive of approximately 75,000 manually categorized articles in Spanish published in 1991. They benchmarked on LCC using three widely used supervised learning methods: k-Nearest Neighbors, Naive Bayes and Artificial Neural Networks, illustrating the corpus properties.

This paper delineates the Bangla Document Categorization using Stochastic Gradient Descent (SGD) classifier [8]. Here, document categorization is the task in which text documents are classified into one or more of predefined classes based on their contents using Support Vector Machines and Logistic Regression. Even though SGD has been around in the machine learning community for a long time, it has received a considerable amount of attention just recently in the context of large-scale learning. In text classification and natural language processing, SGD has been successfully applied to large-scale and sparse machine learning problems often encountered.

Fouzi Harrag, Eyas EI Qawasmah [11] used ANN for the classification of Arabic language document. In this paper Singular Value Decomposition (SVD) had been used to select the most relevant features for the classification.

Neural network was used for web page classification based on augmented PCA [12]. In this paper, each news web page was represented by term weighting schema. The principal component analysis (PCA) had been used to select the most relevant features for the classification. Then, the final output of the PCA is augmented with the feature vectors from the class-profile which contains the most regular words in each class before feeding them to the neural networks. According to this paper it's evident that, in case of Sports news, WPCM provides most acceptable classification accuracy based on their datasets. Their experiment evaluation also demonstrates the same.

A research group of Shahjalal University of Science & Technology used different machine learning based approaches of baseline and deep learning models for Bengali news categorization [13]. They used baseline models such as: Naïve Bayes, Logistic Regression, Random Forest and Linear SVM and deep learning models like BiLSTM, CNN. They found out that the highest result comes from the Support Vector Machine in the base model and CNN in deep learning where CNN gave the best performance for their Dataset.

In paper [14] authors used multi-layer dense neural network for Bangla document categorization. As feature selection technique they used TF-IDF method. They used three dense layers and 2 dropout layers. They got 85.208% accuracy.

Authors on [15] used four supervised learning methods namely Decision Tree, K-Nearest Neighbor, Naïve Bayes, and Support Vector Machine for categorization of Bangla web documents. They also build their own dataset corpus but they didn't publish it. Their corpus included 1000 documents with a total number of words being 22,218. Their Dataset included five categories such as business, health, technology, sports and education. As feature selection they used TF-IDF method and they got 85.22% f-measure for Naïve Bayes, 74.24% for K-Nearest Neighbor, 80.65% for Decision Tree and 89.14% for Support Vector Machine.

An exploration group used Bidirectional Long Short Term Memory (BiLSTM) for classification of Bangla news articles [16]. They used Gensim and fastText model for vectorization of their text. Their Dataset contained around 1 million articles and 8 different categories. They got 85.14% accuracy for BiLSTM for their Dataset.

III. Methodology

The goal of this proposed model is to categorize Bangla news automatically based on the content of the document. In order to meet this up, some steps are performed such as 1) Data collection, 2) Data preprocessing, 3) Feature selection and extraction, 4) Dividing Dataset into training and testing set, 5) Building and fitting models, 6) Category prediction. Fig. 1 depicts an overview of the approach. The details of the steps are explained in following paragraphs.

A. *Data Collection*

Data is crucial in machine learning which required a lot of data to come up with somewhat generalizable models. The Bangla dataset corpus is built for this research task & the news articles have been collected from the popular news portal Prothom Alo online newspaper. News articles of five categories such as 'International', 'Economics', 'Entertainment', 'Sports', 'Science and Technology' has been used for the dataset. This dataset corpus consists of 1425 documents. Each category contains 285 documents, which can be found at [20]. Details of the dataset are represented in Table I.

Another dataset is also downloaded from the Kaggle website [17]. This Dataset contains newspaper articles from 2013 to 2019 from Prothom Alo. The newspaper articles have already been classified into different categories such as International, State, Economy, etc. Only five categories, namely, Entertainment, International, Economic, Sports, and Technology. In the Table II, the details and statistical analysis of the whole Dataset are given.

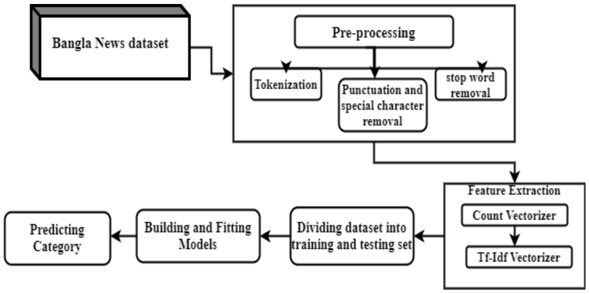

Fig. 1. Overview of Bangla News Classification System.

Total	169791	250

B. *Data Pre-processing*

Data Preprocessing is a technique that is used to convert the raw data into a clean data set. Preprocessing the data is an important task and it is essential for getting better accuracy. In the experiment, the data was processed by several techniques such as removing empty data from document, tokenization, punctuation removal and stop word removal, white space removal, number removal.

1) Tokenization: Splitting a text into sentences, then words, and then characters. Based on spaces, texts are broken down into words and using the list function; words are broken down into characters.

2) Punctuation, special character and number removal: Punctuation like ; : । ' " ' , ? !, etc. and special character like @, #, $, %, ^, &, (, *,), etc. and number that is not important for classification are removed from the whole Dataset.

3) Stop word removal: High-frequency words common in every document and have not much influence in the text are called stop words. Stop words are collected from two different sources [18]&[19], and combined unique stop words and increased the number of stopwords. The stop words list that was build contains 875 stop words, and it can be found at [21]. The list of 361 bangali stop words like "অবশ্য, অনেকে, এ, এবং, ইত্যাদি, করেছিলেন, নিতে, হয়, etc." All the stop words are removed from the Dataset for getting better accuracy.

4) Categorical encoding: There are two types of categorical encoding entitled label encoding and one-hot encoding. In label encoding, each label is assigned a unique integer based on alphabetical ordering. On the other hand, each category is represented as a one-hot vector in one hot encoding. That means only one bit is hot or true at a time. An example of a one-hot encoding of a dataset with two categories is given in Table III. Label encoding technique has been used for encoding category in machine learning algorithms and one-hot encoding for multi-layer dense neural network.

TABLE III. EXAMPLE OF ONE HOT ENCODING

	Label 1	Label 2	Label 3
Doc 1	0	0	1
Doc 2	1	0	0

After the data preprocessing step, statistical analysis step is performed on both Dataset to see if data preprocessing step is successfully performed and how words are related to each category. Fig. 2 illustrates the flow chart of the data preprocessing system. Fig. 3 and Fig. 4 illustrate the 14 most frequent words of each category of Dataset I and Dataset II. It is seen that these words are strongly related to corresponding categories that help the model successfully predict a document category. After pre-processing step, structure and number of word is changed on datasets. The detailing after pre-processing step of the two dataset is given in Table IV and Table V.

C. *Feature Selection and Extraction*

In this step, string features are converted into numerical features. Bag of words and TF-IDF model are used for converting string features into numerical features for performing the mathematical operation. Dataset I consists of 43404 unique words, and Dataset II that is downloaded from the Kaggle website [17] consists of 915428 unique words after data preprocessing. All the words do not have impact on the classification. So, the most frequent words have been used as features that have importance to classification. For selecting features, a Count vectorizer was utilized, which works based on the frequencies of words. Both datasets' model accuracy are observed in the Count vectorizer approach by considering different minimum document frequencies and maximum document frequencies. And for Dataset I, the best result is found by considering minimum document frequency 10, which means the words are excluded that are only on 10 or less than 10 documents and maximum document frequency 0.6, which means the words that are on the 60% document or more than that. For Dataset II, the highest accuracy is got by considering minimum frequency 10 and maximum document frequency 0.6 because those words have no significance in determining the class. In this paper 1320 most frequent words are used as a feature vector for Dataset I, and the rest of the words are excluded. For Dataset II, 10,000 most frequent words are used as a feature vector.

After selecting features, the TF-IDF vectorizer has been used for feature extraction because count vectorizer doesn't return the proper value. As it is known, count vectorizer only returns 0 or 1 as the value of a different word which does not states the transparent frequency of different words from a document.

1) Bag of words: It is a basic model used in natural language processing. A bag-of-words is a representation of text that describes the occurrence of words within a document.

2) TF-IDF: TF-IDF stands for Term Frequency-Inverse Document Frequency which says the word's importance in the corpus or Dataset. TF-IDF contain two concept Term Frequency (TF) and Inverse Document Frequency (IDF).

Term Frequency is defined as how frequently the word appears in the document or corpus. Term frequency can be defined as:

TF = No. of time word appear in the doc. / Total no. of word in the doc.

Inverse document frequency is another concept that is used for finding out the importance of the word. It is based on the fact that less frequent words are more informative and essential. IDF is represented by the formula:

IDF = No of Docs / No of Docs in which the word appears

TF-IDF is a multiplication between TF and IDF value. It reduces the importance of the common word that is used in a different document. And only take important words that are used in classification. TF-IDF matrix of first 10 docs and first six words of dataset I is given in Table VI.

E. Splitting Dataset into Training and Testing Set

After Successful feature extraction, Datasets are split into train and test datasets. Both datasets are divided into 4:1. Four portions of dataset are used for the training set, and the rest portion is for testing. That means 80% of data from the datasets are used for training, and the rest 20% is considered as the testing. This step is done using the sklearn library, which is very simple.

F. Building and Fitting Models

In this stage, the datasets are fitted into different machine learning classifier algorithms and neural network.

1) Using machine learning classifier algorithm: Here several machine learning classifiers used such as Naïve Bayes, K-Nearest Neighbor, Support Vector Machine, Random Forest, Decision Tree for the classification of Bangla news & import sklearn built-in classifier for this.

2) Using multi-layer dense neural network: Here the data preprocessing technique and feature extraction technique is the same as machine learning algorithms. However, one hot encoder is used for encoding the encoding category. For categorizing task, feed forward neural network is used as classification algorithm. It is organized in the form of multiple layers. In the proposed model, dense layer has been used. Feed forward neural network consists of the input layer, the hidden layers and the output layer. Dataset generated Input patterns are transmitted from input layer to next layer which is also called by first hidden layer. Later output from the first hidden layer is being used as the input of the second hidden layer. The same process continueing untill reach the last hidden layer. Finally, the output of the last hidden layer is being used as the input of output layer or last layer. For building such model, Sequential model has been used. This model uses a linear stack of layers. The most common layer is a dense layer which is a regular densely connected neural network layer with all the weights and biases. In the first layer input shape is determined since the following layers can make automatic shape inference. To build the Sequential model, layers one by one are added in order. Total three dense layers used. After each dense layer, one dropout layer added with a 20% dropout rate.

For the layers between the input and output layer, relu activation function is used, and in the output layer, the softmax function is used as an activation function. Before training the model, the learning process is configured using optimizer and loss function. Here adam optimizer and categorical_crossentropy is used as optimizer and loss function respectively to train the model. Different numbers of dense layers, different numbers of nodes between layers, and different epochs are used for checking the accuracy of the model. Finally, the model is built by adding three dense layers. On the first layer, 750 nodes are added, on the second layer 450 nodes, and on the third layer, 5 nodes are added as the dataset is of five categories. The multi-layer dense neural network model for the two datasets is depicted in Fig. 5. The model is trained in 200 epochs. By doing so, the highest accuracy is got for both Datasets. Step by step procedure that is done for building a multilayer dense neural network model for getting the highest accuracy Bangla news classification is represented in Fig. 6. How the training loss and accuracy changes in both Dataset is represented in Fig. 7 and Fig. 8, respectively.

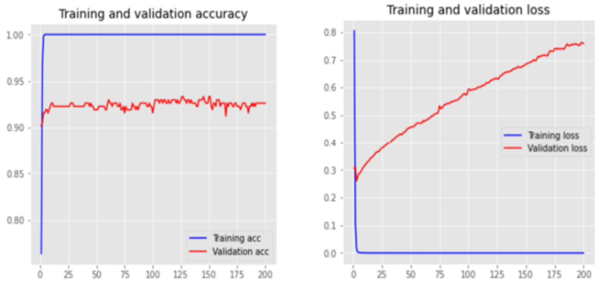

Fig. 7. Training and Validation Accuracy and Loss for Dataset I.

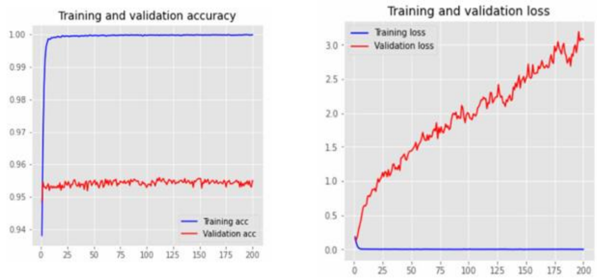

Fig. 8. Training and Validation Accuracy and Loss for Dataset II.

G. Category Prediction

After fitting Dataset to classifier, the main job is to predict category. In this stage, the model is trained to predict the test data that are unseen to the machine. If any vectorized sample of Bangla news is given to the model, it can predict the category of the sample data. Here for training, as different classifiers are used such as Naïve Byes, Decision Tree, K-Nearest Neighbors, Support Vector Machine, Random Forest, and also the model which is made by neural network can predict the category of vectorized sample data.

The model and vectorizer are saved as a pickle file and then it is used to classify. A random sample is given to the model and it successfully classifies the random sample. A screenshot of the random testing is given in Fig. 9.

IV. Result and Discussion

In this section, the performances of the model are analyzed on different machine learning algorithms and neural network for both Datasets.

A. Accuracy of Model

Onfusion matrix is a presentation for summarizing the performance of a classification algorithm. The confusion matrix for all classifier algorithms is given in Fig. 10 and Fig. 11 for Dataset I and Dataset II, respectively. By judging the confusion matrix the best model can be decided. From this matrix, the accuracy, precision, recall, and f1-score of the built model can be calculated. For different classifiers, different confusion matrices are built and from those confusion matrices, the accuracy, precision, recall, and f1-score of different classifiers is calculated. The performances of the different models are represented in Tables VII and VIII for dataset I and dataset II respectively and the highest precision, recall and accuracy category wise for all the classifiers are shown as bold font. Overall performance of different classifier model is shown in Tables IX and X for both dataset respectively. Here, highest accuracy, precision and recall, and f1-score of algorithms are shown also as bold font. Fig. 12 is a plot of the accuracy of different classifiers for both datasets. F1-score of classifiers according to news type is shown on Fig. 13 and Fig. 14 for Dataset I and Dataset II respectively.

1) Naïve bayes: Both dataset have five categories. From Tables VII and VIII it is clear that there are variations in different performance rate for different types of news. For dataset I Entertainment has the lowest f1-score and for dataset II sports has the lowest f1-score when Naïve Bayes classifier is used. If all the categories are combined the accuracy for Naïve Bayes model is 91.23% and 92.76% for dataset I and dataset II, respectively.

2) K-Nearest neighbor: The accuracy of this model is 84.81 % for dataset I and 70.4% for dataset II. The lowest performance rate is found for entertainment category in dataset I and the same is international category in dataset II.

3) Support vector machine: Support Vector Machine can be defined over a vector space where the problem is for finding a decision surface that “best” separates the data points in two classes [9]. Support Vector Machine has different types of kernels. The linear kernel is used for the purpose. Overall accuracy of this model is 89.12% for dataset I and 94.99% for dataset II. Here science and technology category shows the lowest performance rate for dataset I and for dataset II sports category shows the lowest performance.

4) Random forest: For building Random Forest classifier model entropy criterion and 50 n_estimators are used here and got accuracy 87.01% for dataset I and 91.4% for dataset II. In the prediction model the lowest rate of performance is found in science and technology category for dataset I and sports for dataset II.

5) Decision tree: The overall accuracy of this model is 62.45% for dataset I and for dataset II accuracy is 79.87%. Again for dataset I science and technology has the lowest rate of performance and for dataset II sports has the lowest rate of performance in this prediction model. On the other hand the highest rate of performance is found in sports category for dataset I and science and technology is for dataset II.

6) Logistic regression: Again, the lowest accuracy is found for science and technology category in dataset I and sports category in dataset II in this model.. The highest rate of performance in the prediction model is sports for dataset I and science and technology for dataset II. The overall accuracy of this model is 90.52 % for dataset I and 94.6% for dataset II.

7) SGD classifier: If all the categories are combined to get the accuracy of the SGD classifier, the accuracy is 88.77% and 93.78% for dataset I and dataset II, respectively. The SGD confusion matrix is shown in Fig. 10(g) and 11(g) for both dataset which shows which category has high performance. For dataset I sports has the highest f1-score and science and technology category has the lowest f1-score and for dataset II science and technology has the highest f1-score and sports has the lowest f1-score.

a) Accuracy of different classifier for Dataset I

b) Accuracy of different classifier for Dataset II

Fig. 12. Accuracy of different Classifier for both Dataset.

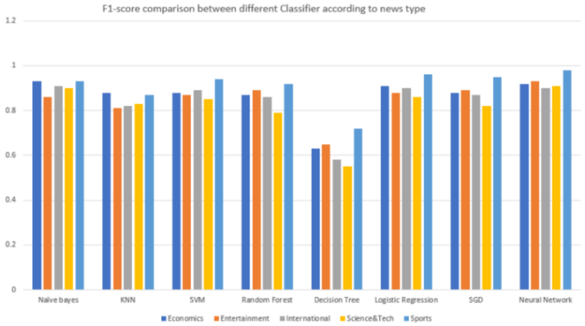

Fig. 13. Comparison of f1-score of Dataset I of different Classifier according to the News Types.

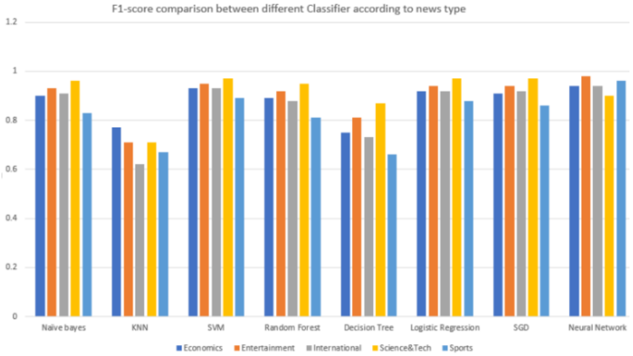

Fig. 14. Comparison of f1-score of Dataset II of different Classifier according to the News Types.

8) Multi-layer dense neural network: In this case, international news for dataset I and science and technology news for dataset II have the lowest rate of performance. In Machine learning model it can be seen that, In dataset I, all classifiers returned lowest performance in science & Technology category, except Naive Bayes and K-Nearest Neighbor. Where in dataset II, all classifiers gives lowest performance in sports category where only K-nearest neighbour gives lowest performance on other category. But ,it doesn't happen in multi-layer dense neural network model. The accuracy of this model is also quite impressive. For dataset I sports and for dataset II, entertainment has the highest rate of performance. This model has the highest accuracy comparing the other traditional machine learning models. The overall accuracy of this model is 92.63% for dataset I and 95.50% for dataset II.

B. *Comparison of Algorithms*

Table IX shows that in the traditional machine learning algorithms for dataset I the highest result comes from the Naïve Bayes classifier model and Table X shows for dataset II Support Vector Machine has the highest result. But for both dataset the highest accuracy comes from multi-layer dense neural network. That means multi-layer dense neural network gives the best performance for both dataset. In Table IX it is also shown that decision tree classifier gives the worst result for dataset I. On the other hand from Table X, it is shown that k-nearest neighbor classifier gives the worst result. If the confusion matrix of Fig. 11(b) is observed it is seen that the highest false classification is found for k-nearest neighbor. From Tables IX and X of overall performance, it is shown that most of the classifiers have low variance and low bias which indicates the proposed model doesn't have underfitting and overfitting.

V. Conclusion and Future Work

The main focus of this research is to build an automatic classification system for Bangla News documents. This system provides users an efficient and reliable access to classified news from different sources. Different as well as most widely used machine learning classifiers and multi-layer dense neural network are used for categorization and a comparison has been conducted between them. Among the classifier algorithms, Support Vector machine Classifier provides the best result. In the model, TF-IDF technique is used for vectorization to fit data to the classifier.

In future, word2vec model will be used for better result and for preventing the limitation of TF-IDF model. In TF-IDF model, more importance is put on the uncommon words. But, semantic information of the words is not stored in TF-IDF model.

In this research, multi-layer dense neural network and some built in classifier like Naïve Bayes classifier, k-nearest neighbor classifier, random forest classifier, support vector machine classifier and decision tree classifier were used. In future, CNN, RNN and other neural network model will be examined to build the model for better performance.

***Abstract*—Arabic is one of the Semitic languages in antiquity and one of the six official languages of the UN. Also, Arabic classification plays a significant and essential role in modern applications. There is a big difference between handling English text and Arabic text classification; preprocessing is also challenging for Arabic text. This paper presents the implementation of a Naïve Bayes classifier for Arabic text with and without stemmer. A set of four categories and 800 documents were used from the Text Retrieval Conference (TREC) 2001 dataset. The results showed that Naïve Bayes with light stemmer achieves better results than Naïve Bayes without stemmer. The findings of the classifier accuracy by employing stemmer and without stemmer are as preprocessing. It reveals that the accuracy resulted from the light stemmer was better than the classifier without stemmer detection, which Naïve Bayes Classification with light stemmer got 35.0745 higher than the Naïve Bayes Classification 33.831% without stemmer. After contrasting them, the stemmer got better accuracy than the classifier.**

Keywords—Arabic language; light stemming; information retrieval; Naïve Bayes classification

I. Introduction

Machine-readable information is available in large and increasing quantities that complicate comprehension and use. Machine learning (ML) provides tools that help organize vast numbers of texts and detect them automatically [1]. Feature selection is the most significant application in ML. Feature selection, by identifying the most salient features for learning, the interest of the learning algorithm sheds the lights on the most valuable data for analysis and future prediction [1-4]. The ideas were adopted from test theory to develop a technique for correlation-based feature selection and estimate a group of ML algorithms that taught a different group of natural and artificial problems. The feature selection is easy and fast to implement; it removes irrelevant and repetitive data and its ability to enhance the learning algorithms' performance in many cases. The results of this technology can be contrasted with a modern feature selector elicited from the literature but require much less computation. In the current research, the domain of Arabic documents will be used to decrease features number and promote the performance detection of the Arabic document.

There is no comprehensive definition of the Arabic language. Some Arabic language documents or emails may have some unwanted words or samples; this email detects spam due to unwanted email messages; not all Arabic emails are spam. And the commercial email that is spam [5], spam as the name suggests, is unwanted emails, but there is a general question, what are junk emails? Although Arabic is known to many users, it is difficult to see the definition of both the Arabic language and unwanted messages.

This paper is organized as the following. Section 2 provides a review of previous related studies. The background of the study on Arabic classifiers is tackled by Section 3. The steps followed during the experiment present in Section 4. Section 5 shows the experimental setup and results. Finally, Section 6 discusses the conclusion and future work.

II. Literature Review

Text Classification (TC) is considered as a form of supervised learning task which involves assigning documents with predefined category labels depending on the suggested likelihood by a set of labeled training documents. Before the ML approach emerged in TC, knowledge engineering was the most common way in which the expertise of those working in the field was utilized. A set of rules was manually created into document classification within predefined categories [6] explained that ML recruitment in TC presented several advantages as it lower cost and time in terms of the expert workforce only without any effect on precision. TC problems often present as a group of D documents and a group of S predefined categories with the significant purpose of assigning each (d_i, c_j) pair with a Boolean value (d_i = ∈ D and c_j = ∈ S). An indeed given (d_i, c_j) value represents the decision of allocating document d_i to class c_j; however, a falsely assigned (d_i, c_j) value represents otherwise. Formally speaking, the primary task is the approximation of the obscure objective function f: D × S → {True, False} [4], which clarifies an actual method of classifying the documents through the classification function f': D × S → {True, False} in a manner there will be a minimal number of decisions off and f' that do not correspond.

Several learning algorithms have been developed and applied to TC. Among them includes k-Nearest Neighbor (KNN), Decision Tree (DT), Neural Networks, and Naive Bayesian (NB) [7-10].

The author in [11] compared these learning techniques and concluded that they all perform equally when there are more than 300 documents in each category. However, DT, KNN, and LLSF performed better than neural networks and Naïve Bayes Classification (NB) when there are fewer than ten positive training documents in each category.

Although several supervised ML approaches have been applied to TC, the task still demands the extra effort to predefine the categories and assign category labels to the training set documents. In large and dynamic text databases, this can be a complicated task. According to [6], inter-indexer inconsistency is another phenomenon that makes TC complicated. Accordingly, two experts may disagree on the category to designate a document. For example, a story about Bill Clinton and Monika Lewinsky could be classified under politics, gossip, both types, or neither category based on the subjective decision of human indexer [6]. The first synthesis that motivates us to discuss this is as follows:

- A large number of classification text.
- A large feature space.

TC's applications include document organization, hierarchical web page categorization, and text filtering. Document organization indicates the task of structuring documents into folders (maybe flat or hierarchical). For example, the incoming adverts to an editorial office may be grouped into categorized like Cars, Real Estate, Computers, etc., before publication. Conversely, text filtering indicates to the classification of a dynamic group of documents to relevant and irrelevant groups. This is illustrated in a news system in which articles in a newspaper are filtered from a news agency [6]. For instance, the delivery of news unrelated to sports in a sports newspaper will be blocked. Likewise, incoming messages may be classified as Arabic or not Arabic by a document filter in a bid to block Arabic message delivery [12]. The hierarchical classification process is one of the most flexible processes in the web browsing process due to the ease of navigating the hierarchical form of the categories and directing the search to a specific type instead of putting a general query on a search engine for general purposes. The hierarchical classification of documents generally requires the subdivision of the classification problem into smaller classification tasks. Some of the previous studies that addressed hierarchical document classification are [13-16].

TC using ML techniques entails a preprocessing of the texts, which require the transformation of the document into suitable forms for applying the learning algorithms. [17] introduced the commonly used vector space model called document representation. This model represents each document as a vector with each separate dimension corresponding to the word distinct occurring for all the words in the document. Text classifiers are applied for crime detection and weather prediction. In addition, they are also used to detect and track Arabic over documents. Table I showed the Arabic classification process is both detailed and benchmarked with previous works.

III. BACKGROUND OF STUDY

A. Document Preprocessing

As indicated earlier, the scheme of document grouping in which intra-group similarities are high and low [18]. The essential process is preprocessing due to its significant role in improving and developing these schemes for any classifiers. The text analyst should take into account the relationship between preprocessing and similar measures on Document Classification. Performing preprocessing of documents is an essential process for classifying documents that are implemented by applying ML techniques.

Reference [18] pointed out that the significance of such stage in Document Classification is attributed to the presence of large numbers of unnecessary words present in the documents, many of which negatively influence classification rather than help in that. Using documents as a whole with unnecessary words is complicated. There are many of these words. The researchers themselves presented some non-essential utterances that may be found in the documents. The terms are classified into conjunctions, other grammatically based categories, particles, and that are typically employed without providing any assistance to the researcher in the classification of the document. In addition to some of the words presented by researchers like these words in the English language "ate, eaten, eat" and "أكلت , يؤكل , الاكل "in Arabic language, it is possible to decrease the number of the unique document words. Hence, we conclude that documents free of unnecessary words are applied to them with appropriate prior treatment, and this would improve and increase the performance of the Document Classification approach.

After applying this step, the documents must be converted into a form appropriate for the representation process. Thus, the learning algorithms application is conducted. Then work will be done to remove unnecessary words like special markers and punctuation marks. To perform this process, many commonly used tasks, namely normalization, tokenization, stop-word removal, and mainly stemming, needed to be done. These tasks will be illustrated below, according to the review of previous studies.

B. *Classification Algorithm*

In the supervised algorithms, it is assumed that the categorical structure of a given database is already known. The supervised algorithms require a set of labeled documents to map documents into the predefined labels. As mentioned previously, it is challenging to determine the category and correct label of the training sets, particularly in large databases. Hence, this section will focus on the commonest supervised algorithm, NB.

NB is one of the common ML techniques. It depends on the Bayes' theorem, which claims to have strong (naive) and cumulative independence assumptions. A thorough description of the fundamental probability model theorem serves as the independent feature for the NB. A proper NB classifier could simply presume that there is no relationship between the existence or absence of a given class feature with that of any other feature. Also, and considers a simple probabilistic-based classifier. This assumption is expressed as follows:

$$\mathrm{P}(C_i|d) = \frac{P(C_i)P(d|C_i)}{P(d)} \qquad (1)$$

Where $P(\mathrm{C_i}\,|d)$ it indicates a previous possibility of category C_i in the presence of another instanced, $P(\mathrm{C_i})$ represents the possibility of category C_i which might be calculated through:

$$P(C_i) = \frac{N_i}{N} \qquad (2)$$

where N_i = the number of documents belonging to the category C_i, and N represents categories number, $P(d|\mathrm{C_i})$ represent the possibility of d document belongs to the given categoryC_i, as well as P(d) is the possibility of instance d. clarifies the complete NB pseudocode.

- BEGIN: about all the available values.
- Follow the rules for every individual value as:
  - Calculate and count the values of the classes appearing.
  - Obtain the class, which is frequently occurring.
  - Make the rule, which connects this particular class with instance values.
  - Find out the rate at which the error occurred for the rule.
  - Choose the rules with the minor error rate END.

IV. Experiment Process

A. *DataSet*

The dataset includes a set specifically designed to assess the extraction of the Arabic text for Arabic classifiers created as part of TREC 2001. The group has 383,872 Arabic documents, mostly newswire dispatches issued by Agence France Press (AFP) between 1994 and 2000 [19]. Ground truth and standard TREC queries have been created for such collection: 25 queries were considered part of TREC 2001 (Technology, 2001). The collection of queries has matching relevance judgments produced utilizing the pooling technique. Based on that, part of TREC 2001 is defined for classifiers as in Table II, which include four classes along with a group of documents (a gross of 800 documents).

B. *Normalization*

The steps of normalization ensure a specific characters' order that allows multiple variants. The reason behind the importance of data normalization for Arabic experiments is attributed to the fact that different encoding guidelines might either be used or not used at all by newspaper article and sometimes occurs in the same language. The following steps pinpoint the normalization of corpus and quires employed by [20]:

- Punctuation Removal.
- The removal of diacritics. Some entries consisted of weak vowels. Such elimination enabled text to become compatible.
- The removal special characters and numbers.
- Substituting آ, أ , and إ with ا.
- Substituting the end of ى with ي.
- Substituting the end of ة with ه.

C. *The Removal of Stop-Words*

Terms that usually frequently appeared in every document are so-called stop-words. These terms give no hint of their core document contents. Stop-words are determined so that a stop-words list could be established [21] . For that, an important thing in the Arabic system to omit stopping words from documents during preprocessing. Consequently, it is omitted from the group of indexed terms. Since there is no unified stop-words list of Arabic systems that can be used in classification systems. In this study, Khoja stop-words list tested with light10 stemmer [22].

TABLE II. Summary Description of Arabic Data Set

Categories	# of document
1	200
2	200
3	200
4	200

D. Tokenization

Converting a word into a distinctive word in text processing is a highly significant step. The tokenization process bears the responsibility of splitting the text into tokens, defining boundaries, words, numbers, and abbreviations. Arabic text tokenization is an important initial step as part of pre-processing phase. To define the complete word, in such a paper, the word was considered bound by white space marks to tokenize the Arabic text. Most importantly, the stemming process is regarded as the follow-up step after tokenization and the removal of stop-words.

E. Stemming

The term stemming indicates an approach of conflation that seeks to locate a common stem for a group of words in a text [23, 24]. For the conflation process, we used light10 stemmer by following the same process used by Larkey's [25]:

- They are deleting "و" ("and") if the rest of the word has greater than or equal to three letters. Regardless of the importance of deleting"و ," it considers also problematic due to the fact that many popular Arabic words begin with this letter. Therefore, the length standard is more stringent here than the specific definite articles.
- Omitting every definite article, as this omission leaves word length greater than or equal to two letters.
- Dwelling into the list of suffixes once in the order (right to left) as shown in Table III, omitting every one of them that were at the end of the word if these omitting leaves word length greater than or equal to two letters.
- Table III shows the eliminated strings. Both conjunctions and definite articles are considered 'prefixes'. Light10 stemmer does not omit any character that can be considered an Arabic prefix.

TABLE III. PREFIXES AND SUFFIXES THAT ARE ELIMINATED THROUGHOUT LIGHT 10

Prefixes	Suffixes
ال، وال، بال، كال، فال، لل، و	ها، ان، ات، ون، ين، يه، ية، ه، ة، ي

F. Estimation

To complete estimation, Term Frequency (TF) x Inverse Document Frequency (IDF)) (TF x IDF) weighting was used for the weighting calculated as.

$$w_i = tf_i . log\left(\frac{N}{df}\right) \quad (3)$$

In classification problems, the estimation measures are generally determined from a matrix by employing a group of incorrectly and correctly categorized for each class (called the confusion matrix). Table IV revealed the confusion matrix for a binary categorization problem with classes that are merely positive and negative.

Here, FP, FN, TP, and TN are described thus:

- False Positives (FP): The negative examples are wrongly projected as positive.
- False Negatives (FN): positive instances which are wrongly predicted as negative.
- True Positives (TP): The positive examples that are correctly projected as positive.
- True Negatives (TN): The negative instances which are correctly predicted as negative.

The accuracy rate (ACC) is the commonly used estimation measure on the ground that estimates the classifier efficiency depends on its proportion of correct projections. The ACC of a classifier is calculated as follows:

$$ACC = ((TP + TN)/(TP + TN + FP + FN)) * 100 \quad (4)$$

TABLE IV. CONFUSION MATRIX

Projected Class		
True Class	***Positive***	***Negative***
Positive	TP	FN
Negative	FP	TN

V. EXPERIMENTAL SETUP AND RESULTS

As soon as the documents of the text are processed, they go through the classification tasks that occur by both stemming and converting them to an appropriate format. The collection of the document is classified twice for evaluation objectives. The first categorization is without stemmer, in which document collection occurs before stemming and applies to documents, whereas the second categorization is referred to as light stemmer that is used for the document collection. In respect of the available classifier approach, the overall dataset is classified for cross-validation. In conclusion, the cross-validations are classified as well as those in [26] for estimation. The remaining folds are employed for testing objectives, whereas K-fold cross-validation, K - 5 folds are used for validation and training.

Table V reveals the findings of the classifier accuracy by employing stemmer and without stemmer as preprocessing. It reveals that the accuracy resulted from the light stemmer was better than the classifier without stemmer detection, which the NB with light stemmer got 35.0745 higher than the NB 33.831% without stemmer. After contrasting them, the stemmer got better accuracy than the classifier. The last evaluation by employing the number of features revealed that without stemmer worse in decreasing the number of features, whereas stemmer was better, as shown in Table V.

TABLE V. EFFECT OF THE LIGHT STEMMER AND WITHOUT STEMMER USING NB AS A CLASSIFIER

Stemmer	Without Stemmer	Light Stemmer
Accuracy	33.830846	35.074627
#features	91756	46167

VI. Conclusion and Future Work

The experiments revealed that applied stemmer as preprocessing on our data set considers significant. Therefore, it has a substantial impact on the NB classifier on side accuracy and features number. Without stemmer, it does not significantly impact our dataset, as illustrated in Fig. 1 and 2. Major weakness concerning the without stemmer in preprocessing pertains to the dimensionality of terms requiring the second contribution to fill the huge term called feature selection. The critical concepts to be taken from the web to improve Arabic preprocessing are indicated. Therefore, the real datasets are employed in the experiments of this study. The primary finding regarding stemmer is essential for categorization. As stated earlier, it is better than with stemmer. In general, the finding is inconclusive due to the effect of classification or the chosen features revealed.

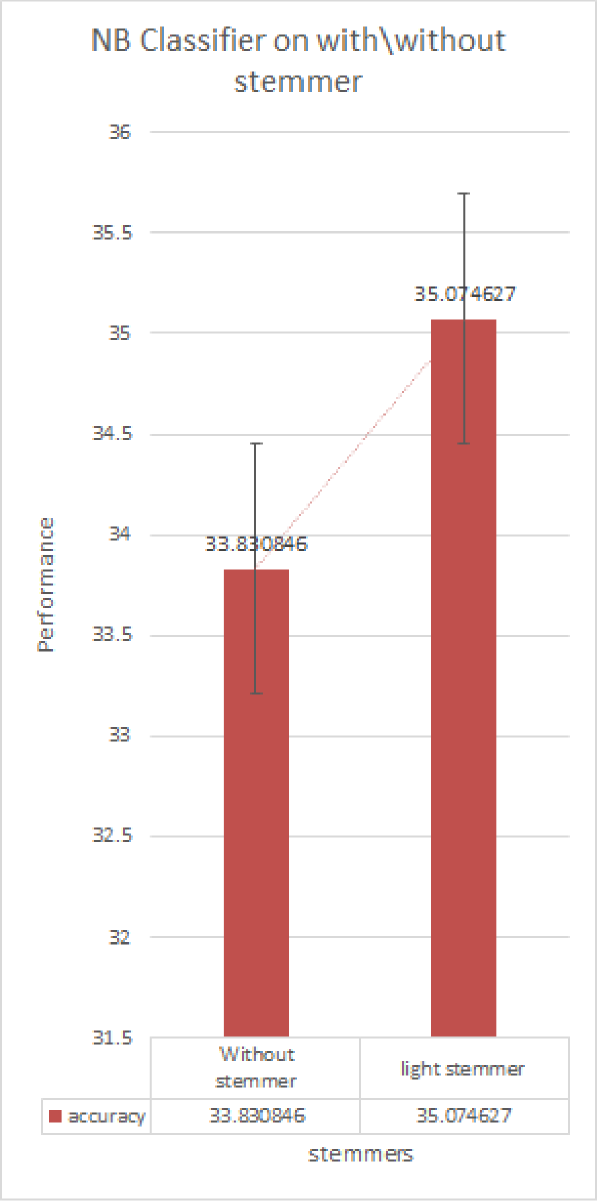

Fig. 1. Performance of Arabic Classifier using with/without Stemmer.

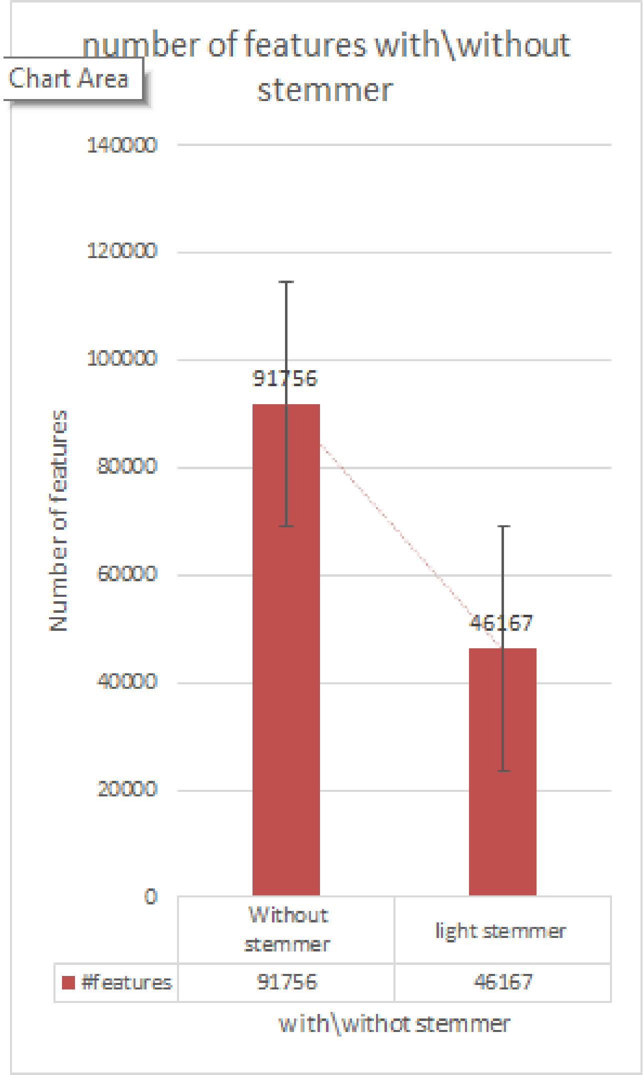

Fig. 2. Effect of Number of Features using with/without Stemmer.

Nevertheless, the central related weakness without stemmer in preprocessing is the dimensionality of terms revealed, which requires future work to bridge the gap concerning huge terms number called feature selection. This study answers the question regarding the effects of classifiers algorithms on Arabic classifiers with/without employing stemming of words and the purpose of investigating the performance of the used NB as Arabic classifiers on the classification performance with/without the employment stemming of terms.

A lot of open questions of the study are unanswered. Content classification considers a significant research area that provides various directions for additional studies. As a result, this section presents some suggestions for future research. Future studies conducted in this field are recommended to read this paper to try different classifiers and contrast their performance by employing various stemmer's algorithms. Also, using feature selection strategies for reducing the dimensionality of terms in the datasets as well as choosing the best features depending on their relevancy and significance to the subject class.

ACKNOWLEDGMENT

The researchers wish to thank (LDC) the Linguistic Data Consortium for their supplement of LDC2001T55 Arabic Newswire Part 1 at no cost, as one of the students of the Fall 2012 LDC Data Scholarship program.

***Abstract*—Personal daily movement patterns have a longitudinal impact on the individual's decision-making in traveling. Recent observation on human travel raises concerns on the impact of travel behavior changes on many aspects. Many travel-related aspects like traffic congestion management and effective land-use were significantly affected by travel behavior changes. Existing travel behavior modeling (TBM) were focusing on assessing traffic trends and generate improvement insights for urban planning, infrastructure investment, and policymaking. However, literature indicates limited discussions on recent TBM adaptation towards future technological advances like the integration of autonomous vehicles and intelligent traveling. This survey paper aims to provide overview insights on recent advances of TBM including notable classifications, emerging challenges, and rising opportunities. In this survey, we reviewed and analyzed recently published works on TBM from high-quality publication sources. A taxonomy was devised based on notable characteristics of TBM to guide the classification and analysis of these works. The taxonomy classifies recent advances in TBM based on type of algorithms, applications, data sources, technologies, behavior analysis, and datasets. Furthermore, emerging research challenges and limitations encountered by recent TBM studies were characterized and discussed. Subsequently, this survey identified and highlights open issues and research opportunities arise from recent TBM advances for the future undertaking.**

***Keywords*—Travel behavior; travel behavior modeling; prediction modeling; intelligent traveling**

I. Introduction

Personal daily movement habit cumulatively influences the decision-making approach of the individual when traveling. Recent observation on human travels raises concerns on the impact of recent travel behavior changes towards many aspects including traffic management, transport planning, and decision-making. Researchers carried out travel behavior studies with the goal of understanding human travel behavior via analytical approach. The main goal of travel behavior studies is to generate translational travel behavior model for facilitating prediction analysis for travel planning insights. Therefore, Travel Behavior Modeling (TBM) is introduced as cost-efficient and timesaving approach for supporting that goal. Traffic management are severely affected by increasing traffic congestion occurrence due to human travel behavior. Recent observation pointed out the increases of inferior travel habit like slow driving style that further amplified by faulty road condition and crowded area. These behaviors and external factors eventually cause indirect losses on many aspects. Massive transport congestion in the US costed the economy with average wasted 5.5B work hours, more than 2.9B gallons of fuel, and more $100 billion per year. China also faced similar problem with consequences of increasing annual travel cost that currently priced at $1,126 per person [1]. Victoria Transport Policy Institute highlighted that traffic congestion is the leading cause of critical delay, high fuel consumption and economic wastage in the US. This issue has considerably contributed towards decline in trade and growth. This expense is expected to rise by 2020 to the extent of $121B [2].

Future travel behavior is expected to change drastically soon due to mainstream popularity of autonomous vehicles and smart travel technologies. Increasing adaptation of autonomous vehicles eventually change how human travel, consequently impacting travel behavior norms and environment [3]. The use of autonomous vehicles increases travel mileage with reduced share of slowing traffics with other slow-mode public transports. These changes are already reflected in growth pattern in many dispersed urban cities. Eventually, autonomous vehicles reduce the need for private vehicles and provide extraneous conveniences for user despite its minor contribution towards parking congestion. A recent study reported the implications of substituting all private motor vehicles with shared autonomous vehicles (SAV) in Berlin, Germany [4]. Their findings indicates that the substitution is likely to decrease the number of cars that accommodates private travel demand by 91%. In addition, the number of vehicles that accommodates travel demand in Lisbon are expected to decrease by 95% with the introduction of SAV [5]. Moreover, travel demand involving family-sharing private vehicles are also expected to significantly decrease due to redundant purpose [6]. However, such substitution in Atlantis, US only observe minor decrease of only 9.5% due to lower priority on accommodating individual travel demand. In addition, the association of travel behavior with socio-economic (income, household composition) indicates land-use patterns that is leveraged to assess the mobility of individual traveler [7]. TBM is expected to play significant roles in realizing these future endeavors due to its direct role towards predicting traveler choices.

Many studies were conducted over the years in developing methods, algorithms, and models for TBM. Such examples of modeling are Short-term Travel Behavior Prediction [8], Intra-Household TBM [9], Sense Place TBM [10], Markov Travel Model [11], and Inferring Structural Models [12]. These modeling were built for facilitating prediction on travel demand and travel decision. Many TBM studies analyzes and diagnoses travel behavior pattern at individual level [13], [14], [15], [16]. Eventually, specific modeling for this scale were developed like Individual TBM [14], Regret-based Choice

Model [13], Rethinking TBM [16] and Heterogeneous TBM [15]. With the upcoming changes from autonomous vehicles adaptation, land-use transposition, we can anticipate that TBM holds many potentials with lasting impact towards improving this aspect.

This survey aims to provide overview insights on recent advances of travel behavior modeling including emerging trends, challenges, and opportunities. Gaining latest insights on travel behavior modeling eventually contribute towards driving forward many sectors like transportation, tourism, and urban development. In this survey, recent published works on TBM from quality journals and established conferences indexed by Web of Science (WoS) were reviewed. A taxonomy was devised based on the survey to classify recent TBM advances based on many notable aspects. Furthermore, the problems and issues addressed by recent work were reviewed to derive the existing research challenges in TBM. Moreover, this survey analyzed the reported limitations and future works to highlight any persistent issues or opportunities in TBM for future studies. The main contributions of this survey paper are:

1) A taxonomy of travel behavior modeling that classifies TBM based on algorithms, applications, data collection techniques, technologies, travel behaviors, models, and datasets.
2) A summarization of emerging trends on research challenges and limitations in implementing TBM in present applications.
3) A summarization of open issues and opportunities from recent advances in TBM for future undertaking.

The content of this paper is organized as follows. Section 2 explains the fundamentals of travel behavior modeling including definitions, process, and terminologies. Section 3 introduces the devised taxonomy of travel behavior modeling based on the conducted survey including characterizations and instances of each classification. Section 4 then presents the summarization of identified research challenges and limitations from existing TBM. Section 5 then highlights the open issues and opportunities arises from recent TBM advances for future studies. Finally, Section 6 presents the conclusions for this paper.

II. Travel Behavior Modeling

This section introduces the fundamentals of travel behavior modeling including the underlying concepts, definitions, and working terminologies. The presented fundamentals offer general information on travel behavior modeling for understanding the remaining contents in this paper.

The origin of travel behavior modeling started by the introduction of behavioral modeling to systems theory and control theory in 1970s [17]. Behavior modeling addresses the conventional approaches' inconsistencies on state-space, transfers, and convolution representations. Eventually, behavior modeling is adapted in many event or activity analysis over the years including travel behavior analysis. Travel behavior analysis is important in supporting sustainable development in parallel with society growth and technological advances. Travel behavior studies are carried out to explore human travel behavior's impacts towards fuel consumption, environment, urban development, and citizen upbringing.

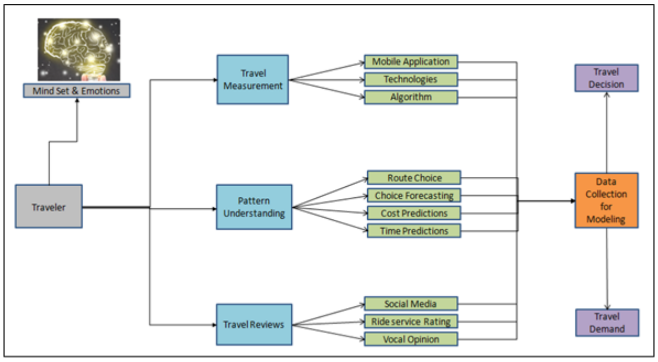

Fig. 1. Functional Model of Travel Behavior Modeling.

Travel behavior analysis starts by anticipating the mindset of traveler associated with travel measurement, pattern understating, and travel reviews. In general, TBM is utilized to process these variables to generate prediction on travel decision and travel demand. TBM learns user activities based on recorded travel experiences information like time, place, and mode of transportation. TBM then diagnose, understand, and response to the change of activities and subsequently predict future travel decision. Eventually, the generated prediction should accommodate travel habits and transportation in future travel based on the preferences and lifestyle of the user. Fig. 1 summarizes the framework of overall processes and related attributes in travel behavior modeling.

To help readers in understanding the remaining contents in this paper, we specify the working terminologies that are commonly used as follows:

- Algorithms: Processing operations or rule sets of the analysis models created by travel behavior modeling.
- Applications: Computer programs or software that implemented travel behavior modeling as core function with the purpose of facilitating travel behavior analysis.
- Models: Machine learning models created based on statistical or mathematical approach to extract and learn behavior patterns from travel datasets.
- Industries: Industrial domains, sectors, or fields of the applied travel behavior modeling.

III. Taxonomy of Travel Behavior Modeling

This section introduces the taxonomy on travel behavior modeling based on the conducted survey as illustrated in Fig. 2. This taxonomy classifies travel behavior modeling based on algorithms, applications, data sources, technologies, analysis, models, and testing datasets. Characterizations of each travel behavior modeling classification are presented as follows.

A. Travel Behavior Modeling Algorithms

Our taxonomy classifies the algorithms of recent TBM advances based on the algorithm objectives and approaches. The algorithms of recent TBM advances are classified and characterized as follows.

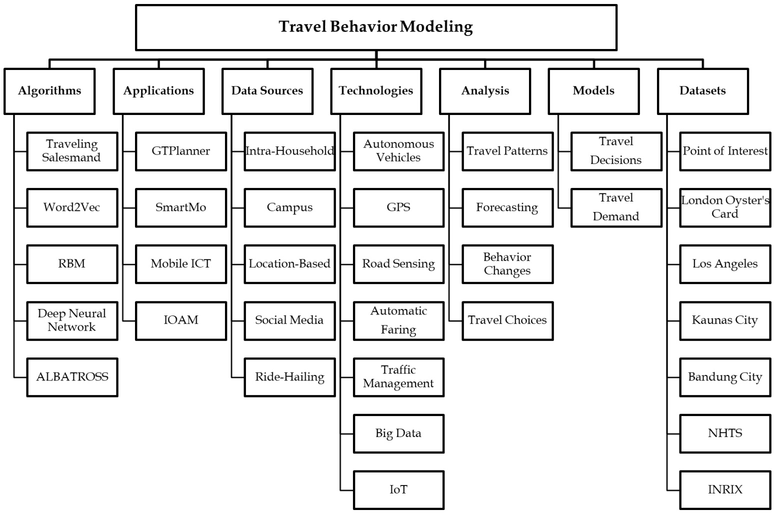

Fig. 2. Taxonomy of Travel Behavior Modeling.

1) Traveling Salesman: The crucial aspect in travel behavior modeling is the efficiency of behavior modeling optimization. Optimizing algorithm like Traveling Salesman are used in several instances such as benchmarking, performance comparison, algorithm selection, algorithm analysis, and algorithm comparison. Optimizing algorithm model is achieved using two ways: (1) fitting nonlinear curves with fixed semantics and (2) training artificial neural networks on benchmark results. A study demonstrated effective travel behavior modeling based on Traveling Salesman algorithm by using model optimization approach [18].

2) Word2Vec: Albeit the various methods available for analyzing travel demand prediction, automatic translation and word prediction are crucial in facilitating the analysis. The Word2vec algorithm allows the recalibration of PyTre packages on supporting automated translation and prediction via natural language processing (NLP). By leveraging natural language processing, performance measurement on testing or training dataset is carried out swiftly. Despite the swift advantages, the algorithm is limited by its stochastic nature that eventually requires implementation via deliberate experimental design. In addition, integrating model like Rethinking Travel Behavior (RTB) is viable in the algorithm development to support performance measurement. RTB model predicts the travel demand based on mode, trip purpose, education level, family type, and occupation. Furthermore, the model utilizes the same datasets throughout processing for consistency [16].

3) Restricted Boltzmann Machine: This algorithm enables consideration of information heterogeneity and variable correlations in processing that commonly occurs on large scale datasets. A recent study investigated on generative machine learning approaches by analyzing multiple discrete-continuous (MDC) travel behavior event from 293,330 travel data [19]. RBM-based algorithm performs significantly better in modeling behavior with larger datasets due to increased modeling accuracy and future forecasting. The study proposed a framework that recommends RGM-based algorithm implementation based on different instances of route choice, dynamic road pricing, and traffic simulation application.

4) Deep Neural Network: Taking advantages of the prowess of deep learning, researchers start to implement deep neural network model to predict travel choices pattern. A recent study proposed a deep neural network structure model that allows many additional structural settings like hidden layer structure, activation functions, number of training epochs, dropout ratio, and learning set ratio [20]. The proposed approach leverages deep learning capabilities to models traveler behavior using deep neural network structure.

5) ALBATROSS: Machine learning identifies that versatile application which is related to the ALBATROSS model using decision trees. Through this model, researchers can focus more on freight transport research, feature engineering, driver behavior, data extraction from digital media and the GPS trajectories that are focusing on transport research [21].

B. Travel Behavior Modeling Applications

In general, travel behavior modeling applications aim to support event pattern analysis on travel demand and planning. However, the applications comprise of different features depending on the travel sectors or the scale of users it covers. Instances of application and its distinct features are presented as follows.

1) GTPlanner: GTPlanner uses TBM for facilitating transportation system planning by generating travel insights based on user preferences and duration [22]. GTPlanner is an exemplary educational travel advisor by promoting the impact of individual traveling modes which consequently fostering quality travel behaviors. GTPlanner also features rudimentary trip planner that allows en route behavior changes tracking and generates latest insight prospects.

2) SmartMo: SmartMo is a mobile-based application for gathering traveler real-time information and generate real-time travel insights. SmartMo gathers and assess event information like pre-trip (mode of transportation and trip purpose), on-trip (start trip, route tracking and end trip), and post-trip(upload). Taking advantages of traveler event information, SmartMo enables real-time route checking, insights update, data autonomy, data security, and time efficiency for monitoring traveler behavior [23].

3) Mobile ICT: Nowadays, mobile devices like smartphone and tablets plays significant role in facilitating travel activities with travel planning and social networking features. Travel planning is simpler than ever before, when smart devices and applications have become mainstream in human culture. Planning tasks like browsing travel date, mode of travel, destination, and coordinating trip decisions are easily carried out via mobile devices. With mobile devices, travelers can fully utilize any online advantages to maximize the travel outcomes throughout the trip duration. Such instances of outcomes including increased count of places visited, social gatherings attended, and trips planned in groups [24]. Empowered by mobile computing, travel behavior and tourist business also change drastically over the years [25]. Travel behavior comprises 5 core phases: dreaming (reviews, blogs, travelers' experiences), planning (information and travel guidance), booking (flight, accommodation, bus, car, and tours), experiencing (on demand booking and maps) and sharing (friends, relatives, and social network) [26].

4) Interactive Online Accessbility Mapping (IOAM): Interactive web usability mapping facilitates many traveling purposes like commuting, school, healthcare, lodging, social activities, and entertainment. IOAM features four transportation modes: walking, biking, vehicle transit, and selected destination requirements. A recent study investigated the role of IOAM in facilitating users on understanding travel behavior. The study reported that participants with access to IOAM valued the tool in understanding residential location and travel-related decision-making process [27].

C. Travel Behavior Modeling Data Sources

Working data for TBM are originated from various sources like social media, crowdsourcing, or service providers. Many TBM studies work with data generated using survey-based approach that utilizes user interviews and online questionnaires. Such instances of data sources that were found in the survey are related with intra-household, campus, location-based tool, social media, and ride-hailing services. The characterizations of each related data sources are discussed as follows.

1) Intra-Household: Modeling and forecasting traveler's time preference takes account on several individual aspects into consideration like demographics, situational, psychological, and sociological. For instance, predicting bus travel time preferences largely dependent on parameters of different modes and actors like bus drivers, other bus users, and other metro users [11]. Another instance is the modeling of individual travel behavior based on intra-household interactions via datasets of 67K trips made by 3.5K individuals [9]. In general, suitable data collection techniques for this type of TBM relies heavily on the individual familiar sense of the location. Another instance is the modeling of travel decision among users between two shopping centers in California via 719 survey data [10]. The utilized TBM assess movement patterns between two traveler vehicles based on two factors: energy conservation and environmental protection. Another instance of intra-household consideration in TBM is travel activity assessment for addressing fuel consumption, car uses, and gas emission in South India [28].

2) Campus: The goal of using TBM for modeling individual travel behavior in campus is to generate mapping on daily transport travel demand. For instance, Dalhousie University, Canada carried out a travel survey among its campus residents pertaining travel activities and environmental awareness. The survey gathered information from campus residents like resident's work, entertainment activities, social activities, formal education activities, and shopping activities [29]. In addition, many travel projects especially from European countries often generated their travel behavior datasets using GPS with volunteer participants from urban cities.

3) Location-Based Tool & Services: The rapid advances of location-based services have turned location-based tool into a powerful data gathering and communication methods. For instance, a study observed travel check-in behavior from social media data by analyzing its location-based social network (LBSN) features [30]. Their findings reveal contrasting pattern of check-in behavior between weekday and weekend activities, with emergences of unique patterns exhibited by different gender. Their study demonstrated on how spatial pattern of check-in mapping surface density and smoothness are ascertained using kernel density estimation (KDE) associated ArcGIS.

4) Social Media: Social media has become the mainstream online interaction platform for discussing or sharing opinions and experiences on traveling. Social media usage on traveling topics holds myriads of information like patterns and reviews of past traveling events recorded by many travelers. Social media network like Facebook, Twitter, and Yelp can generate enriched travel movement behavior data via location-based sharing features [31]. In their study, Rashidi et al. reviewed many possible methods for analyzing travel-related social media data effectively [32]. They highlighted that the geo-tagging features are leveraged by city planners and business premises to understand the urban dynamic of their areas. Gaining insights on recent urban dynamic can help these entities to adapt instead of relying on outdated information from old records. Featuring services like check-in logs and hotspot, social media data helps researchers to understand the travel demand of visited locations. Location-based information from these services allows TBM to predict individual travel behavior with better accuracy and efficiency. However, limited access towards those social media data remains to be the main issue for data mining and natural language processing. Restricted data fetching indirectly reduces the quality of insights on travel behavior that are obtained from social media [33], [34]. Another instance is how a study implemented logistic regression model for analyzing Facebook check-in logs to predict future check-in patterns [35]. Their findings indicate how majority of Singaporeans adapted and modified their leisure travel behavior via social media influences. Another study highlighted the significant impacts of social media in travel itinerary planning and social sharing norm [36].

The advances of social media platform also amplify social media data usage generation, resulting massive collection of user interaction. There are several technical challenges in analyzing social media big data for understanding travel behavior like incompatible text parsing, data format inconsistencies, and hidden sentiments. For instance, Twitter social media data contains check-in logs enabled by geo-tagging features along with text posting information [37]. Travel studies can leverage the geo-tagged information to identify the relationship between conventional model of travel demands [38], [39]. The prospect of traffic incidents identification and verification via Twitter opens the possibilities for efficient and real-time data management. Moreover, Instagram allows location sharing and posting of travel experiences via pictorial, posts, and videos [40]. Other social media platform like Foursquare also records individual travel behavior information based on check-in logs, number of visits, and activity patterns [41]. A movement behavior study on bike-sharing services in Washington used probabilistic models and analysis to understand bike user behaviors [42]. The study explores the relationship between bike-sharing user activities in different event throughout using the services. The employed probabilistic model allows for information fetching on weekly activity patterns from check-in logs via Foursquare.

5) Ride-Hailing Services: Ride-hailing services has turned into mainstream methods for public to access transportation thanks to the advances of mobile computing and smart devices. The services facilitate many advantageous features including quick availability, on-demand, timesaving, flexible payment methods, privacy, and security. Previous travel behavior studies often work with datasets associated with Uber services due to its reputation in ride-hailing services. A transportation analysis study explored the rising popularity of Uber as mainstream method of transportation in the Greater Toronto and Hamilton Areas (GTHA) [43]. The study investigated the behavioral process of combined probabilistic decisions with consideration of process of formation and conditional semi-compensatory decision. However, the developed model does not indicate intricate comparison between Uber and private cars, public transport, and motorless vehicles. They also pointed that most young adults prefer Uber services due to its compatibility and flexibility for accommodating the trip. Nowadays, most ride-hailing services embedded their facilities on smart devices and online platforms, providing users with quick access to transportation. TBM is used for supporting these facilities by facilitating timely demand availability, ride sharing organization, and travel punctuality. The current increasing preferences towards ride-hailing services indicates the increases of demand for automated vehicles in the future. Consequently, public adaptation towards mainstream ride-sourcing norm also triggers changes in transportation aspect like carpooling, biking, ride-hailing (Lyft, Uber), and micro-transit (Bridj, Chariot). Such instance of changes was recorded in a dataset comprising attributes like times, distance, and earning from rides, and travel behavior via social demographic interviews with 311 passengers [44].

D. Travel Behavior Modeling Data Embedded Technologies

Based on the survey, TBM are commonly embedded in many transportation technologies like autonomous vehicles, road sensing, GPS analytics, automatic fare, real-time traffic monitoring, big data, and smart vehicles. The role of TBM on empowering these technologies are discussed as follows.

1) Autonomous Vehicles: The premise of innovating autonomous vehicles (AV) is to allow drivers to perform other en-route tasks or activities apart from piloting the vehicle. Powered by the integration of diffusion model and spatial travel demand model ingenuity, AV poses significant impact on future travel behavior. With mainstream adaptation especially in Germany and USA, AV are gaining attraction due to long-term travel duration and cost efficiency with least mobility impairment. TBM is essential in anticipating the travel behavior changes prompted by this adaptation and predicting its impact on travel demand. Consequently, policy recommendations to support the adaptation of AV and mitigating its negative consequences are crucial [45].

2) Global Positioning System (GPS): The travel pattern generated from GPS logs effectively reflects the daily movement of an individual and their travel behavior. A recent study observed and compared individual movement activities when inside and outside of their home using TBM, specifically C-Means (FCM) clustering algorithm [46]. The use of GPS also contributes towards generating many travel behavior data, that eventually leveraged for strategic urban planning. For instance, Dar es Salaam travel behavior data is generated using citizen GPS to help Tanzanian government in improving public transport policies and infrastructure [47]. TBM help processing these GPS data to generate insights on effective planning for street infrastructures, landmarks, and land use [48].

3) Road Sensing: In their study, Su et al. explores the utilization of road events to enhance the quality of road sensing system [49]. Road events like traffic jams, road accidents, potholes, bumps, and road signs further enrich the compatibility comparison of the suggested route. Subsequently, they proposed a low-cost crowd-sourcing data collection and integration system for detecting en-route risks and generating alternative routes. Safety risks and complications like slippery roads, pavement roughness, and travel regulation are considered based extracted information from crowd-sourced big data.

4) Automated Faring: In his work, Kang implemented scalable inference methods for analyzing the relationship between public transit system route and travel behavior [50]. The study focuses on the association between traveler's origin-destination choices with multi-modal travel environment. Two preference vectors and true OP-pairs were investigated using Automatic Fare Collection (AFC) system-type data (stop-level ODs). The investigation was possible after gathering and analyzing data for route choice with stochastic travel environment specifically for paying travel fare.

5) Real-Time Traffic Management: Such instance of TBM usage in real-time traffic management technologies is the transport model algorithm development by Wen and Chunming. The presented algorithm tracks and predicts real-time traffic dynamics based on agent-based transport model and independent observations of the trajectory of several hundred vehicles [51]. The study involves arrays of TBM technologies including big data, machine learning, and sensor networks for generating efficient travel time and fuel consumption.

6) Big Data Infrastructure: When working with big data, TBM is crucial to facilitate large scale spatial analysis on human mobility via movement monitoring. The analysis itself comprised of processing on many variables including preliminary analysis, path, trip purpose, origin-destination matrices, mode, path choices, and unresolved travel errors. Nevertheless, utilizing TBM with big data requires adaptation depending on the technique and methodologies used to process the data. Future TBM studies should work with larger data sample sizes to explore its scalability on facilitating accurate movement analysis [52].

7) Internet of Things (IoT): With mainstream use of travel route system, travel behavior data is generated in real-time using smart devices and IoT technologies. The data generated via this method often utilized to map travel routes of many travelers based on their point of interest. Using automated event detection, the system gathers and process information like visit duration and activities to generate the next best travel routes. Future TBM studies can develop algorithms that maps frequent tangible travel routes and personalize suggested route ranking.

E. Travel Behavior Modeling Analysis

In general, travel behavior studies examine and analyze human daily travel behavior and its impact to society development. This taxonomy classifies the spectrum of related behavior analysis into 4 classes: travel patterns, forecasting, behavior changes, and travel choices. Summarization of work examples on each type of behavior analysis are presented as follows.

1) Travel Patterns: Behavior analysis on travel patterns focuses on analyzing instances and patterns of travel activities over a period or duration. For example, Krueger et al. proposed an integrated model that facilitates travel pattern assessment with consideration of moral values, norms, modalities, and travel behavior [53]. The model enables rapid identification on any travel pattern modification with concurrent shifts in normative beliefs. However, further refinement of the model is crucial such as including latent parameter constructs like values, aims, and personal identity. In addition, the study plans refining the model to generate travel decisions in a comprehensive representation of social context. Another study highlighted the implications of recent travel behavior of working adults by observing their weekly travel movement. The observation involves working adults without young children in California districts, with the goal of increasing auto use and reducing active transit use. A recent study investigated on travel patterns and its relationship with household compositions in major cities for sustainable urban development [54]. Their findings reveal that insights from urban travel patterns helps city planners and policymakers in addressing societal barriers and sustainable traveling.

2) Travel Forecasting: Travel forecasting predicts predetermined outcomes based on existing event records to helps encounters future travel difficulties. A user can plan their travel accordingly based on the insights generated by travel forecasting system. In this context, the forecast of travel demand via user travel planning helps transportation scheduling and policy making. To generate simulated user travel planning, random forecast is utilized to generate ensembles of random decisions. A robust random forecast can predict and classify user travel preferences to further measure the model capacities and interpretability. Prediction of user travel preferences eventually contributes towards facilitating behavioral interpretation and pattern discovery in complex datasets.

3) Behavior Changes: The changes of dynamic between travel behavior and residential point revolves around three major changing conditions: relocation of travel purpose, residential location choice, and modification of residential environment [55]. Behavior changes in travel activities often characterized by factors or traits like travel satisfaction, travel attitudes, and travel behavior. Behavior changes also influenced by point of travel origin that is commonly home location, reflected towards the entirety of the travel plan. Maneuvering alternatives but unfamiliar routes during travel also triggers behavior changes depending on the travel locations.

4) Travel Choices: Predicting traveler's choice of destination based on emerging trends from previous travel behavior record is challenging. Researchers started to develop specific behavior modeling for assessing destination travel choices to allow predictions on multi-instances of destination choices. Inclusion of real market subdivision with regards to attitudinal parameters is crucial for model plausibility and statistical testing. The destination choice behavior modeling eventually leads towards enabling cross-function classification of other supporting parameters like estimation, goodness, and fitness. The entire process consists of two-stages: starting with common choice of functional destination, then adjustment based on rules allocation [56].

F. Travel Behavior Modeling Models

TBM observes travel demand conditions that are based on a variety of factors including location, place, and time. Travel demand and travel decision are interlinked due to travel decision dependency on variables like cost and transport mode. However, the true common factors between travel demand and travel decisions are typically the location, place, and destination. TBM models enables early prediction on travel demands but heavily reliant on given input like transport mode and precise location or destination. Such instances of TBM models are Individual TBM, Regret-based TBM, and Rethinking TBM, Short-term TBM. Derived from the survey, our taxonomy classifies TBM models into two major categories: facilitating travel decisions and facilitating travel demand.

1) Travel Decision: Travel decision is influenced by traveler's choices with cost, mode of transportation, time, weather, location, and route. The need for understanding traveler's choice bring forth the development of many variation of travel decision-based model. Generating ideal destination choices based on previous travel patterns are challenging especially with consideration of multitude of instances [56].

With increasing traffic congestion occurrence in many metropolitan cities, real-time traffic prediction and routing generation now becomes essential. Using provided information like ongoing routes, traffic density, and incident vicinity, TBM helps by generating optimal routes to destination. Such instance of TBM uses is in GPS routing that monitor trips via rapid route identification using probabilistic modeling. However, TBM implementation in GPS routing can still be improved in terms of accuracy with latest hardware fitting and en-route approach [8].

The goal of intra-household TBM is to facilitate accurate and effective travel decision-making based on daily intra-household interactions. Individual travel decisions often influ-

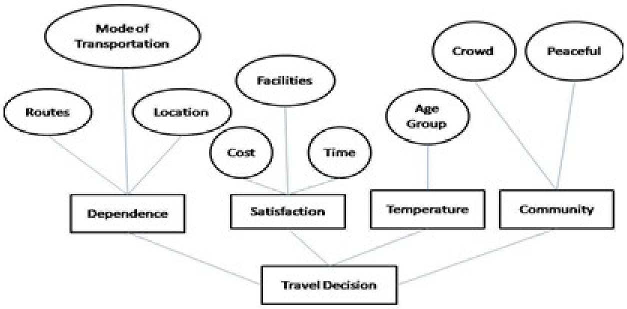

Fig. 3. Relational Variables in Travel Decisions Analysis.

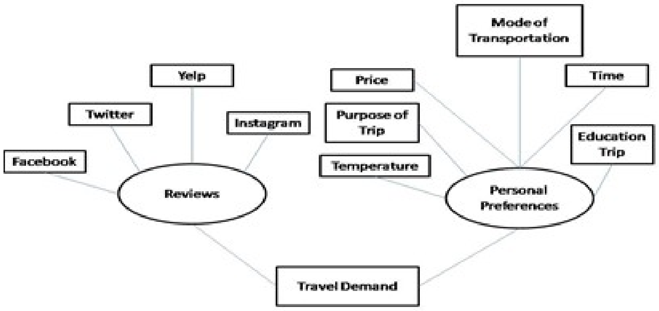

Fig. 4. Functional Model of Travel Behavior Modeling.

enced by opinions, prior experience, and needs of household members or acquaintances. A study developed a method using this model for eliminating decision bias that restrained viable outcomes in accommodating intra-household travel necessity effectively. Bayesian-based multivariate spatial specification is implemented to allow individuals to take household readiness into account during generating travel decision.

Sense Place TBM was built to help identifying relations among the derives of six different variables representing a site. SPTBM is facing many problems with regards to data collection, planning practice, and modeling. A study used SPTBM with the aim to inspect the sense of a location's structure and measurement using survey data. There are three factors in sense of places that are fetched using the three-tiered structural equation model, which parallels estimated sense analysis factors. Sense analysis factors are mostly related to environment [10]. The integrated model of the system involves moral values, norms, modalities, and traveling behavior. This model can identify travel pattern modification during the time of travel in response to concurrent shifts in normative beliefs and behavior. The drawbacks of this model were addressed by bringing improvement in the framework in terms of more latent construct parameters like values, aims, and personal identity. Such approach allows for more comprehensive representation for travel decisions in a social context [53].

Markov Travel Model (MTM) focuses on travel decision concerning travel time, future foresting and individual preferences and behavior. Such TBMs that utilizes MTM concept are Class-Specific Mode Choice Model, Initialization Model, and Transition Model. These models would identify the evolution of preferences or modality styles. Possible enhancements to this study are based on preference dependencies for the individuals based on habits and framework improvements [11].

Another instance of travel decision model is Inferring Structural TBM that obtains socially optimal feedbacks on the utilization of a public-funded transportation infrastructure. This model leads to understanding the dynamics for governing the adoption of sustainable alternatives to driving with primary commute mode. Thus, a realistic decision-making approach is generated to improve the accuracy of travel decisions [12].

Fig. 3 summarizes the relational factors considered in travel decision analysis. Prime factors like dependence, satisfaction, temperature, and community possess additional sub-components. For instance, dependence has routes, mode of transportation and location. Routes may have different choices including clear route, rush route, less polluted route, or proper space for the vehicles. Mode of transportation has many options such as public transport, private vehicles, or bicycle walk, and location may have different choices like natural attraction, vacation planning, and business trip. Satisfaction factor depends on three parameters namely cost, facilities and time. Temperature has different effects on individuals depending on their age, young adults usually endure better compared to elders during winter. The community factor is dependent on whether the surrounding community emanating crowd or peaceful environment.

2) Travel Demand: Travel demand relies on the travel forecasting which depends upon varying parameters such as the most visited place, convenient hours, and seasons. There are several notable models that were developed to facilitate travel demand prediction analysis as discussed as follows.

Liang et al. developed Individual Travel Behavior (ITB) model focusing on identifying travel demand from public transport passengers travel activities. This model was built to analyze travel behavior individually for supporting feasible public transport implementation. Also known as the travel behavior graph-based model, ITB predicts individual graphs for passengers based on different public transport choices and demand, and provides an analysis of travel features with the help of customized public transport. There are several drawbacks of travel behavior graph-based models like fetching and scheduling the demand of research is higher with the optimization of the transport operating network justifiable on a large scale [14].

Regret-based choice models estimate travel demand on many levels and relate to various travel choice contexts. The models show outcomes for different traditional utility-based models in comparison with behavioral interpretations. The objective of this type of model is to present regret based decision-making process to provide more quality and behavioral insights. Regret-based choice models are enhanced in terms of the framework by better disentanglement in various sources of heterogeneity [13].

Heterogeneous Travel Behavior (HTB) aims to facilitate trip generation and simulation. The HTB model skips the entire path to an activity-based model and can predict the

TABLE I. CHARACTERISTICS COMPARISON BETWEEN VARIOUS TBM MODELS.

Reference	Model	Data Type	Data Size	Future Work
[8]	Travel Decision	GPS	260 individuals.	En-route prediction before and beginning of trip.
[9]	Travel Decision	Survey	67,000 trips, 3,500 individuals.	More accurate and effective travel decision.
[10]	Travel Decision	Survey	719 individuals.	Enhancement using socio-demographic indicators.
[9]	Travel Decision	Survey, mobile data	Not reported.	Transportation planning applications.
[53]	Travel Decision	Survey	170 individuals.	Enhancement of framework.
[11]	Travel Decision	Interviews	1st wave (303), 2nd wave (286), 3rd wave (258) individuals.	Enhancement of framework.
[12]	Travel Decision	Survey, Open Street map data	Not reported.	Realistic decision-making approach.
[14]	Travel Demand	Smart card data	6 passengers.	Automatic graph generation with larger scale computing.
[13]	Travel Demand	Survey	242 individuals.	Significantly improves the performance of the random regret minimization model to enhance the framework.
[16]	Travel Demand	Glove embedding vectors	6 billion input word vectors from 37 million texts.	Stochastic nature of the algorithm that requires careful experimental design.
[15]	Travel Demand	Survey	Trips range from 0 to 5, cross-classification model with 1.24 trips.	Inclusion of additional variables for better accuracy rate.

development of travel demand with least computer processing time. HTB possess many advantages such as prediction of true travel speeds, mode-defined constants, and improved assignment results. Another model is Microscopic Trip Generation Module that maintain an operating model while improving the research and its design. However, there are some limitations in the model such as lack of accuracy, auto-ownership, and microscopic tour generation [15].

Fig. 4 summarizes the relational factors considered in travel demand analysis like reviews and personal references. Reviews are collected through social media. Personal preferences are more dependent to each traveler. Comparison of models in the term of data type, size, and future improvement suggestion is summarized in Table I.

The survey findings indicates that travel decision-based TBM future direction eventually leads towards precise en-route prediction. Precising the prediction requires investigation on crucial factors like pre-planning, transportation accommodation planning, and effective travel decision framework. The prospect of precise en-route prediction is viable and have lasting impact towards adapting TBM with realistic decision-making capabilities. Furthermore, existing travel demand based TBMs were largely constrained or limited by technical components and scalability aspects. These TBMs often hindered by computing limitation or handling large-scale data for automatic graph generation. Improving these components can increase the performance of applied random regret minimization model and framework enhancement. The inclusion of additional variables from datasets with greater size are recommended to enrich or enhance the model prediction accuracy.

G. Travel Behavior Modeling Common Datasets

Existing travel behavior studies have worked with many travel datasets from various sources ranging from open data, crowdsourcing, and conventional surveys. In the following discussions, we present the summarization of several notable travel behavior datasets based on our conducted survey.

1) Point of Interest Dataset: This dataset was shared to help researchers in finalizing trip purpose parameter for developing destination prediction algorithm with higher accuracy [8]. This dataset is generated via crowdsourcing Open Street Map with 260 participants, allowing their vehicle's location to be recorded for every 70 minutes. The dataset comprises attributes including trip time, weekdays, origin, purpose, user, trip number and most common destination visited. The original XML data was drawn via Geographic Information Systems (GIS) in the form of layers of files linked with GPS data. This dataset features relational travel information of roughly estimated 26,000,000 points of interest in American states of Maryland, Washington D.C., and Virginia.

2) London's Oyster Smart Card & Survey Dataset: Since 2012, data generated by smart cards usage in London's transportation system has been used to create the dataset. There are two different smart cards and two different modes of transportation: tube and bus. 2.18 million journeys of 9708 passengers were recorded in the dataset. Furthermore, the smart cards dataset often paired with the London Travel Demand Survey dataset. The survey contains collected household information including household demographics, socio-economic information, and travel-related information. The survey inquires common information like ID, age, manager, total number of owned vehicles, household income, working status, occupation, weekly work frequency, daily commuting distance, frequency of becoming driver or passengers [57].

3) Los Angeles Dataset: Using survey with 352 participants from 219 households over 2395 days, this dataset is generated to map individual daily travel activities. The dataset contains variables including information on total number of daily trips distributed by types of transport, demographic, employment status, household, owned vehicle, and annual income. Daily individual travel activities were recorded in weekly basis with exclusion of repetitive activities in daily basis [58].

4) Neighborhoods for Active Kids Dataset: This dataset is generated to help management to build and implement active school travel planning. The dataset includes communities

TABLE II. Recommendations for Optimizing uses on Common TBM Datasets.

Datasets	Descriptions	Suggestion
Point of Interests [8]	Destination prediction	Develop more efficient algorithm and use age factor parameter in the datasets for understating about age group destination prediction.
London's Oyster Card and Survey [57]	Passenger's movement and travel demand forecasting	Develop an advisory system to be used during travel time.
Los Angeles [58]	Transportation professionals and policy makers consider shifting from the conventional one-day approach toward a multi-day approach.	Collaboration with IT industry and transportation industry for making bridge between them.
Neighborhoods for active kids [59]	Independent mobility by providing child friendly social and safe environment, traffic safety, and policies that promote local schools and safe vehicle-free zones around schools.	Development and enhancement of the ideas in terms of algorithm and software.
Kaunas City [60]	Travel time data collection	Develop a method for data security.
Bandung City [61]	Measurement of transport demand	Develop a strong policy for sustainable transportation in developing countries.
National Household Travel Survey (NHTS) - City of Long Beach [62]	Trip destination prediction	Develop an algorithm for trip designation prediction.
INRIX [63]	Traffic management	Development of traffic management algorithm with increased accuracy and efficiency.

to support independent mobility by providing traffic safety, social environment, local promotion school policy and safe vehicle areas around the children schools. Dataset variables consists of school travel mode and child characteristics such as age, gender, ethnicity, physical activity, child beliefs regarding traffic safety, neighborhood, independent mobility, and household characteristics. The household characteristics are education, employment, number of adults, number of children, car ownership, household beliefs, distance to the school, traffic safety, stranger danger, convenience, and social interaction. Social environment covers neighborhood, safety, neighborhood cohesion, neighborhood connection and other related factors such as residential density, street connectivity, high traffic exposure and low traffic exposure [59].

5) Kaunas City Dataset: This dataset original use is for facilitating state government to analyze car travel time pattern around the city. Developed using Python, a Geographic Information System (GIS) was created with the purpose of extracting, analyzing, and visualizing car travel data. The extracted data constitutes the dataset with information like coordinates of origin, coordinates of destination, mode of travel, date, and departure time [60].

6) Bandung Metropolitan City Dataset: Bandung Metropolitan City dataset recorded traveler's check-in behavior, comprising enriched insights on understand traveler's preferences. Personal verification is required including user ID, gender, date, time, and geo-location (longitude and latitude), and address. The attributes contained in this dataset is closely similar to Shanghai dataset including total number of check-ins, total number of processed check-ins, and total number of users distributed by gender [61].

7) National Household Travel Survey (NTHS) - City of Long Beach Dataset: The NHTS dataset is generated via conventional survey conducted in the city of Long Beach, California. The survey was conducted to gather consensus on environmental factors at trip destinations that affect non-motorized travel behavior in the area. The national household travel survey was conducted between 2008 to 2009 comprising information on motorized users, area density, diversity, and design at destinations that significantly affect mode choice decisions [62].

8) INRIX Dataset: The Floating Car Data (FCD) of Netherlands focuses on traffic information, traffic management and automated vehicles. The INRIX dataset recorded travel time of persons and goods from place of origin to destination (O-D) and hours of delay [63].

Based on the condition of presented datasets, several recommendations are suggested to help future TBM studies in optimizing uses of these datasets. The suggested recommendations for each dataset are summarized in Table II.

IV. Research Challenges in Travel Behavior Modeling Applications

TBM acts as simulator and generate decision-making insights and trends for travel decision and travel demand analysis. The output insights are used to strategize effective land use, vehicle sales, infrastructure investment and planning, and service improvement. Despite the many advantages, leveraging TBM optimally are challenging in many aspects including limitation of enabler technologies, data sources, and collection methods. The classifications based on our taxonomy reveals several emerging trends and challenges in utilizing TBM. We derived these challenges by analyzing available common parameters in recent TBM works and classified them based on elements in our TBM framework in Fig. 1. The research challenges are deliberately discussed as follows.

A. Technological Limitation

Many studies on TBM methods and technologies have been carried out over the years. However, these studies also encounter limitations like model inaccuracy or inefficiency, partial framework, transport-dependent planning, unrealistic decision manner, and inconstant socio-demographic. The survey results indicates that future work on TBM eventually heading towards the application of generalized probabilistic models. Future TBM possibly requires intricate programming development of behavior models for processing massive mobile apps data with increased efficiency and accuracy.

TABLE III. SUMMARIZATION ON CHALLENGES, RECOMMENDATIONS, AND FUTURE DIRECTIONS FOR TBM.

Challenges	Objectives	Recommendations	Future Directions
Behavior Modeling	- Predicting individual travel behavior - Individual TBM Graph	- Develop methods for suspicious behavior prediction - Advanced case detection on sudden behavior change	- Travel demand prediction - Automatic behavior graph generation
Destination Prediction	- Trip prediction purpose - Predicting destination location - Advanced pre-input route generation	- Long-term behavior prediction - Integrating emergency alert service - Remote prediction without internet dependencies	- En-route prediction of destination - Increasing prediction accuracy rate
Policy	- Feedback investigation - Travel planning environment - Schedule composition and activity duration	- False feedback prediction - Smart cities development support - Policy proposals	- Decision-making to match real-world behavior
Expensive Autonomous Vehicles	- Reducing public transportation - Ride sharing network promotion	- Public adaptation - Low-cost maintenance	- Low-cost development of autonomous vehicles

TBM is used in many instances including travel management, traffic management, medical access, healthcare planning, and sustainable urban planning. TBM can generate timely decision-making insights in case of additional input like dietary preferences, emergency events, or destination changes. Despite the many usage instances, TBM is in fact heavily used in many processes of traffic management and planning. Several methods employ TBM to facilitate traffic management like spatiotemporal monitoring [64], closed-circuit TV camera [65], smart vehicle technology [66], traffic control [67], and movement behavior [68].

B. *Quality of Generated Data for Modeling*

TBM output relies on the dataset quality it works with, depending on the reliability of its data source and collection method. Albeit the dataset quality often reduced due to data privacy measures, these measures are necessary to protect data sources and users from external threat. The prospect of combining TBM with effective user mobile data access control and monitoring are considered viable for future TBM. Accurate direct access can further enrich generated insights for user travel planning, preferences, routes, and safety using real-time information. Moreover, data quality from conventional surveys like questionnaire and interview are diminished by high inaccuracy rate due to invalid feedback and lack of verification.

Nowadays, social media usage serves as the prime data sources for analyzing travel behavior and experiences. Social media data holds rich information like user posts, opinions, or discussions on their travel experiences. However, real-time social media datasets are not available for the public due to provider's policies [31]. For instance, users can retrieve data generated by Google Maps via application programming, however, certain personal information like travel speed, gender, vehicles, and cost may be redacted. Therefore, mutual collaborations between researchers and social media providers in research should be intensified productively to fully utilize the potential of TBM.

Apart from social media, the mainstream use of ride-hailing services also generates many useful datasets for travel behavior studies. Travel datasets generated by ride-hailing services features unique perspectives on travel behavior like on-demand services, quick booking, and time-critical traveling. However, similar to policies restriction of social media, ride services like Uber and Grab does not share their data to the public [44]. Due to the nature of the business, corporate reputation is of utmost important that any allegation of misconduct or misuse are devastatingly damaging. Albeit the unique characteristics of the ride services datasets, its data quality is also affected by many external factors and dependencies. External factors like internet connectivity, unavailability of drivers during holidays, and apps usability eventually determines the quality of the generated datasets.

V. OPEN ISSUES AND OPPORTUNITIES FOR TRAVEL BEHAVIOR MODELING

This section discusses and summarize the identified open issues emerging from the research challenges found in the survey. Despite the recent advances that attempted to address the challenges, TBM itself revolves around human user which is a complex system. Considering the complexities and difficulties in understanding human behavior, future TBM research should focuses on personalization aspect to address the remaining issues. The remaining open issues are summarized in Table III and discussed as follows.

1) *Quality Behavior Modeling:* Modeling travel behavior duration is crucial in facilitating individual travel behavior prediction and model graph generation for supporting analysis on travel decisions and demands. The modeling procedure generates automatic travel behavior graph using computing [14] and models the behavior prediction [13]. The constant need for accurate rapid event prediction in person travelling activity, particularly if the behavior has become routine, is a persistent problem in behavior modelling. Therefore, methods for understanding sudden behavior changes in the middle of traveling trip is necessary to anticipate risks and maneuver. Future studies also can concentrate on enhancing travel activity data collection approaches and channels for generating insights on encouraging quality personal travel behavior.

2) *Real-Time Destination Prediction:* Destination prediction remains as one of the major issues in TBM that is influenced by many goal variables like en-route trip, destination location, and advance travel route information. Modeling destination prediction often constrained by dependencies on high accuracy rate of en-route prediction of destination [8]. In addition, the accuracy rate is often affected by internet connectivity especially for facilitating long-term travels or remote locations. To address this issue, travel application should provide comprehensive planning mode that generate insights by taking account trip preparation. This mode also should actively

identify mapping point with available communication access and store the coordinates for offline viewing. Furthermore, future studies should focus on the scope of facilitating real-time route changes with consideration of cost, duration, and safety.

3) Intelligent Travel Policies: Existing policies focuses on intelligent travel decisions including feedback investigation, environmental impact, schedule composition planning, activity duration, and emergency readiness. However, there are limited policy guidelines for encouraging quality travel decision-making that matches real-world travel behavior [12]. The increased possibility of faulty travel decision-making increases the likelihood of ensuing problem and its negative impact. Therefore, methods to differentiate between valid feedback and invalid feedback is critical to eliminate any change outlier during behavior modeling.

4) Cost-Efficient Autonomous Vehicles: Adaptation and usability of autonomous vehicles remains the main issue for anticipating future travel behavior and building ride-sharing practices. This issue stemmed from the persisting high cost of adopting or implementing autonomous vehicles in transportation ecosystem. Therefore, the development of low-cost autonomous vehicles is paramount for large-scale public adaptation into mainstream transportation [4], [5], [6].

VI. Conclusions and Future Work

In this paper, we presented overview insights on recent advances in TBM encompassing modeling classifications, emerging challenges, and arising opportunities. Leveraging insights from travel demand and travel decision analysis, TBM enables the prediction of future possibilities of travel scenarios. A taxonomy of travel behavior modeling along with the characterization and summarization of works on each classification were presented. Based on the survey, recent advances in TBM are distinctly classified based on algorithms, data sources, technologies, travel behavior, models, and datasets. Despite its heavy uses in facilitating transportation sectors, TBM also indirectly supports other sectors like tourism, marketing, and urban planning. Based on the reported challenges in recent TBM advances, we learn that model inaccuracy and inefficiency issues persist and largely constrained by current technological limitation and dataset qualities. The prospect of improving TBM via large scale integration and crowdsourcing are considered viable due to increased likelihood for better accuracy and efficiency. Based on the survey, we identified several notable issues and opportunities arising from recent TBM advances revolving aspects like behavior modeling, destination prediction, policy, and expensive autonomous vehicles. Our findings envision that future travel behavior are expected to change drastically due to many substantial aspect evolutions. Therefore, TBM is expected to play significant roles in realizing these visions. Researchers and industry analysts can investigate the TBM open issues and research opportunities highlighted in this survey for future undertaking. Future studies can also leverage the proposed taxonomy and identified challenges to enrich understanding on TBM for improvement purposes.

***Abstract*—With the increasing amount of pornography being uploaded on the Internet today, arises the need to detect and block such pornographic websites, especially in Eastern cultural countries. Studying pornographic images and videos, show that explicit sensitive objects are typically one of the main characteristics portraying the unique aspect of pornography content. This paper proposed a classification method on pornographic visual content, which involved detecting sensitive objects using object detection algorithms. Initially, an object detection model is used to identify sensitive objects on visual content. The detection results are then used as high-level features combined with two other high-level features including skin body and human presence information. These high-level features finally are fed into a fusion Support Vector Machine (SVM) model, thus draw the eventual decision. Based on 800 videos from the NDPI-800 dataset and the 50.000 manually collected images, the evaluation results show that our proposed approach achieved 94.06% and 94.88% in Accuracy respectively, which can be compared with the cutting-edge pornographic classification methods. In addition, a pornographic alerting and blocking extension is developed for Google Chrome to prove the proposed architecture's effectiveness and capability. Working with 200 websites, the extension achieved an outstanding result, which is 99.50% Accuracy in classification.**

Keywords*—Computer vision; image proccessing; object detection; pornographic recognition and classification; blocking extension; machine learning; deep learning; CNN

I. Introduction

In the digital era, information has become a powerful weapon to manipulate the development of a society. People nowadays are easy to find and upload any information they want on the Internet. On the one hand, these pieces of information sometimes are good and bring positive value to the human race. On the other hand, many harmful kinds of negative information can also be found with only some keywords by anybody, even children. Pornography content is one of them. Many women worldwide are victims of sexual cybercrimes because their private videos are spread on the social network. Furthermore, pornographic content is even restricted in many countries. From the above problems, the need for an effective pornographic visual content detector is necessary.

Many efforts have been made recently to classify pornographic images among normal ones. In the early stages, the skin-based method has been applied. These approaches check whether images have nude people or not based on the ratio of the exposed skin. Another approach is handcrafted features-based, which uses various descriptors to extract key point low-level features in an image. A visual codebook may be learned by applying the k-means algorithm on a training set. After that, the trained codebook could represent any images, and a classifier may detect pornographic ones. Applying low-level features to identify obscene images, it achieved significantly higher performance than skin-based methods. However, representing images by visual words still suffers a severe problem since it ignores the spatial relationship, which is very important to represent the image's content. The state of the art approaches for this classifying problem are based on deep learning methods. These approaches build models with neural networks that let it learns features from the image's contents itself.

Previous studies [1], [2] [3], have implemented the above approaches and achieved some particular success, especially the deep-learning-based approach has proposed a potential development for this problem. However, the context in images is very complicated, and there are many similarities between a pornographic image and a normal one. The normal image that contains a large region of exposed skin (e.g., swimming, wrestling, people wearing bikinis) or contains people with sexy poses may be misclassified as pornography. Misclassification may seriously affect the user experience while using the internet. To avoid this problem, we have to clarify what is pornography. According to Oxford Advanced Learner Dictionary, "Pornography is magazines, DVDs, websites, etc., that describe or show naked people and sexual acts to make people feel sexually excited, especially in a way that many other people find offensive."[1] From the definition, an image can be determined as pornographic if it contains naked people. In other words, pornographic images are images that consist of human's sensitive objects and organs such as breasts, anus and genitals. We called this method is the sensitive object-based approach.

Based on that insight, this paper presents a novel approach for pornographic content detection and classification, which not only leverages the advantages of previous approaches but also compensates for these methods' weaknesses. Our main approaching strategy is using the effectiveness of object detection to identify pornographic elements in visual content with steady prediction. Additionally, skin and human recognition are also integrated into our method to distinguish between images with humans from images without humans, but with human like skin colors such as sand or wood. These two modules not only capable to augment the classification's decision but also can be served as the counterweight to prevent the potential bias that comes from object detection. Ultimately, a linear classification

[1] https://www.oxfordlearnersdictionaries.com/definition/english/pornography

model SVM is adapted to make the eventual prediction using features from these three modules, eliminate the limitations during the process while keeping their advantages.

In summary, our main contributions are as follows:

- A method is proposed to detect sensitive objects on the human body. Then, these objects were combined with skin and human features feeding to SVM model to conclude if an image is pornographic or not.
- Based on the pornographic textual and visual detection, a pornographic alerting and blocking extension is developed as an initial gate warning user before accessing inappropriate websites.

The rest of the paper is organized as follows. Section II describes details of some relevant approaches included skin-based approaches, handcrafted features-based approaches, and deep learning-based approaches. Section III presents theoretical background with four main models that we used to detect sensitive objects: Mask R-CNN, YOLO, SSD, and Cascade Mask R-CNN. The detail of our proposed method will be presented in Section IV. In order to demonstrate the applicability of the proposed model, a web-based extension will be introduced in section V. After that, Section VI provides the details of our dataset, experiments, and the achieved results. Finally, we give conclusions and suggest some future works in Section VII.

II. Related Work

Pornographic recognition and classification have been a long-lasting problem with many existing studies. In this paper, previous studies are grouped into four primary categories according to their main approach, which are: skin-based approach, handcrafted features-based approach, deep learning-based approach and object-based approach.

The skin-based approach is considered the earliest and most basic method of recognizing visual pornography, as it focuses on estimating the exposed skin area within an image. Several low-level or high-level features such as shape, color, facial, or belly can be utilized in order to achieved higher estimation. The final decision of this method mostly depended on mathematic or statistic thresholds based on the predicted skin ratio and the image's ground-truth. Previous studies with skin-based approach can be determinating seperate skin ratios on different body areas [4], combining facial recognition and skin recognition [1], or utilizing a pre-train discrimination neural network following a skin extractor [5]. Although the effectiveness of recognizing most cases of pornographic visual content, as [6] pointed out, the skin-based approach comes with vital weakness as its performance can be affected highly by the quality and resolution of the input image. Additionally, the strong resemblance between athletic or sporting images with a vast amount of exposed skin and pornographic images under the skin-ratio threshold can be a serious problem of recognizing the right one, which certainly affects the performance of skin-based methods.

The handcrafted feature-based approach, mostly applying the Bag-of-Visual-Word technique, extracts key-point features inside visual data using feature descriptors and maps it into vectors. To obtain features, various feature descriptors can be adapted such as: SIFT and Hue-SIFT [2]; BossaNova [7], which is an image representation based on histogram of distance; or Temporal Robust Features [8], a spatial-temporal interest point descriptor that adapts Fisher Vector intermediate representation. When these representative vectors are formed, a visual codebook can be constructed and concatenated with discrimination algorithm likes SVM to determine the pornographic of input visual content. However, the diversity and discrepancy of pornographic visual content along with the omission of spatial relationship make it difficult to determine the appropriate features to describe visual pornography comprehensively.

The robustness of deep learning-based methods in recent years has brought a significant result in visual pornography identification. Rather than adapting descriptors to obtain representative features manually, the advantage of neural network architecture helps model extract features and refine learning parameters themselves, thus improve the performance of predicting pornographic visual content. Previous studies with pornography detection [9], [10] utilize pre-trained neural network models and fine-tune on a custom pornography dataset instead of training the architecture from scratch. However, training strategies and network customization must be made to optimize architectural's parameters and prevent the model suffer from over-fitting.

Lastest studies about visual pornography [11], [12], [13] identify that sensitive objects, organs or body parts, likes vulva, dildo, female breast or anus, have been known to carry rich information of describing a major part of pornographic content. By recognizing these organs or objects with object detection models, it is possible to draw the conclusion about the pornographic of input visual content with high accuracy. Normally, studies under the object-based method often adapted exist object detector and fine-tuned it on a custom annotated dataset. However, the selection of appropriate pornographic organs or objects as well as the method of annotating depended heavily on the study scale and perspective. Noticeably, Tabone et al. [14] proposed seven sexual organs and objects for pornography classification included buttocks, female breast, female genital (which are divided into two sub-classes: female genital posing and female genital active), male genital, sex toy and benign object. Eventually, they annotated those classes with a five-set labeled point: one center point and four perpendicularly offset for each. Additionally, some common sexual poses or intercourses can be learned in pattern to improve the performance of prediction. Although methods under object-based approach can ensure the high performance of prediction on most pornographic visual data, in some special cases, the strong resemblance of some everyday object with sexual organs under certain conditional (light, viewpoint, or shape) such as sausage and male genital make it difficult to make the right decision.

In our previous studies with sensitive objects and organs on object-based approach in [15] [16], not only we developed a pornographic object detector with Mask R-CNN to identify the most four common sensitive objects includes women breast, male/female genitals and anus, but also we utilized the training strategy of object detection model with two-step learning to overcome the false positive prediction of pornographic objects, thus improve the overall performance of prediction.

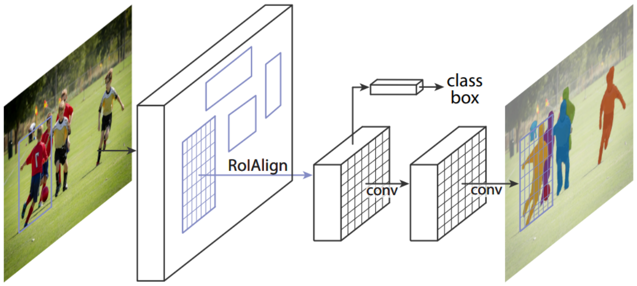

Fig. 1. Mask R-CNN Main Architecture [17].

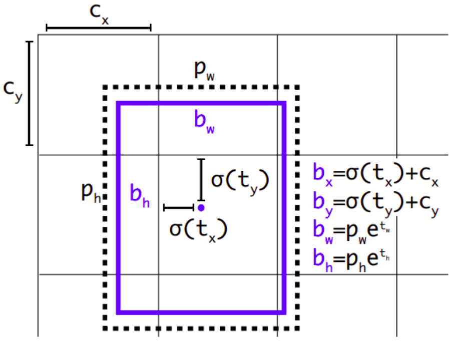

Fig. 2. YOLO Bounding Box with Location Prediction [21].

III. Theoretical Background

A. Mask R-CNN

Mask R-CNN [17] is a robust object detection and instance segmentation framework that draws bounding boxes for object detection and generates a high detail segmentation mask for instance segmentation. In this paper, the Matterport's version of Mask R-CNN [18] is adapted, which uses ResNet101 [19] and Feature Pyramid Network (FPN) [20] as main backbone.

The Mask R-CNN model included multiple stages and branches from the original Faster R-CNN framework, whith the main architecture can be seen in Fig. 1. Tts network hierarchy included the Region Proposal Network branch for object bounding boxes identification and Box Regression Network branch for bounding box regression. Furthermore, a simple FCN is added to predict the segmentation masks on each Region of Interest (RoI) in a pixel-to-pixel manner. Furthermore, for the core operation of feature extraction, Mask R-CNN applies pooling algorithm RoIAlign to extract small feature maps called Region of Interest (RoI) features to be well aligned and preserved with the corresponded object in the pixel level. Hence, RoIAlign helps Mask R-CNN achieves pixel-to-pixel alignment and high accuracy in prediction and mask segmentation. On each RoI, the new multi-task loss function of Mask R-CNN has been introduced, which combines the loss of classification, localization, and segmentation mask by Eq. 1.

$$\mathcal{L}_{\text{Mask R-CNN}} = \mathcal{L}_{\text{class}} + \mathcal{L}_{\text{box}} + \mathcal{L}_{\text{mask}} \tag{1}$$

The loss function $\mathcal{L}_{\text{class}}$ and $\mathcal{L}_{\text{box}}$, which is adapted in Mask R-CNN, are defined by Eq. 2 and Eq. 3 respectively, with p_i, p_i^*, t_i, t_i^* are the predict class, ground truth label, predicted bounding box coordinates and ground truth bounding box coordiniates.

$$\mathcal{L}_{\text{class}} = \frac{1}{N_{\text{cls}}} \sum_i -p_i^* \log p_i - (1 - p_i^*) \log(1 - p_i) \tag{2}$$

$$\mathcal{L}_{\text{box}} = \frac{\lambda}{N_{\text{box}}} \sum_i p_i^* \cdot L_1^{\text{smooth}}(t_i - t_i^*) \tag{3}$$

On the other hand, the loss function of instance segmentation mask $\mathcal{L}_{\text{mask}}$ is defined as the average binary cross-entropy loss between the ground-truth mask y_{ij} and the predicted mask y_{ij}^k, only in terms of class k-th in Eq. 4:

$$\mathcal{L}_{\text{mask}} = -\frac{1}{m^2} \sum_{1 \le i,j \le m} [y_{ij} \log y_{ij}^k + (1 - y_{ij}) log(1 - y_{ij}^k)] \tag{4}$$

B. Yolo

You Only Look Once (YOLO) is the state-of-the-art, real-time object detection system proposed by Joseph Redmon. YOLO [22] uses a single neural network to predict bounding boxes and class probabilities directly from full images in one evaluation. In YOLOv2 [21], they remove the fully connected layers from YOLO and use anchor boxes to predict bounding boxes. This research applied YOLOv3 [23], the latest version of YOLO using Darknet53 network architecture that helps the model achieves the outstanding benchmark comparing to others. Fig. 2 illustrates how YOLO model predicts the bounding box location on the image. Network model identifies 4 coordinates of the bounding boxes t_x, t_y, t_w, t_h, then the bounding box predictions is calculated by Eq. 5:

$$\begin{cases} b_x = \sigma(t_x) + c_x \\ b_y = \sigma(t_y) + c_y \\ b_w = p_w e^{t_w} \\ b_h = p_h e^{t_h} \end{cases} \tag{5}$$

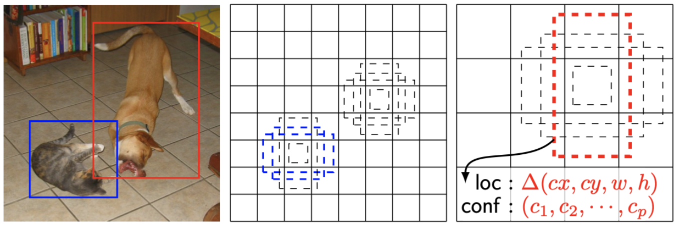
with the the top left corner point of the predicted box(c_x, c_y) as well as the width and height p_w, p_w, respectively. To optimized training parameters, YOLO adapted the loss function as shown in Eq. 6

$$\mathcal{L}_{\text{YOLO}} = \mathcal{L}_{\text{conf}} + \mathcal{L}_{\text{loc}} \tag{6}$$

in terms of

$$\begin{aligned} \mathcal{L}_{\text{loc}} = \lambda_{\text{coord}} \sum_{i=0}^{S^2} \sum_{j=0}^{B} 1_{ij}^{\text{obj}} \Big[(x_i - \hat{x}_i)^2 + (y_i - \hat{y}_i)^2 \\ + (\sqrt{w_i} - \sqrt{\hat{w}_i})^2 + (\sqrt{h_i} - \sqrt{\hat{h}_i})^2 \Big] \end{aligned} \tag{7}$$

and



loc : $\Delta(cx, cy, w, h)$
conf : $(c_1, c_2, \cdots, c_p)$

(a) Image with GT boxes (b) 8 × 8 feature map (c) 4 × 4 feature map

Fig. 3. SSD Framework. [24] (a) SSD only needs an Input Image and Ground Truth Boxes for Each Object During Training. In a Convolutional Fashion, SSD Evaluates a Small Set (e.g. 4) of Default Boxes of Different Aspect Ratios at Each Location in Several Feature Maps with Different Scales (e.g. 8 x 8 and 4 x 4 in (b) and (c)).

$$\mathcal{L}_{\text{cls}} = \sum_{i=0}^{S^2}\sum_{j=0}^{B}\left[1_{ij}^{\text{obj}} + \lambda_{\text{noobj}}(1 - 1_{ij}^{\text{obj}})\right](C_{ij} - \hat{C}_{ij})^2 + \sum_{i=0}^{S^2}\sum_{c\in\mathcal{C}} 1_i^{\text{obj}}\left[p_i(c) - \hat{p}_i(c)\right]^2 \quad (8)$$

C. SSD

Single Shot Multibox Detector (SSD) is proposed by Wei Liu et al. [24] which is known as the object detection model with high accuracy and speed. Unlike the other models, which need to hypothesize bounding boxes, followed by some complicated steps to handle them, SSD uses a fixed set of default boxes, then predicts scores and box offsets by using small convolutional filters to feature maps as illustrate in Fig. 3. One of the advantages of SSD is that it can detect objects of mixtures of scales with high accuracy. To achieve that, SSD produces predictions of different scales from feature maps, which are also in various scales and explicitly separates predictions by aspect ratio. For the balance between swiftness and precision, SSD runs a convolution network on the input image only once and then computes the feature map. SSD framework can be summarized as follows:

- The training phase inputs images with ground truth boxes for each object.
- With different scales of images, SSD evaluates a small set of default boxes in different aspect ratios at each location in several feature maps.
- For each default box, the framework predicts both offsets and confidences of shape for all object categories. At the training phase, SSD tries to match these default boxes to the ground truth boxes.

During the training process, SSD adapts the multi-task loss function described in Eq. 9:

$$\mathcal{L}_{\text{SSD}} = \frac{1}{N}(\mathcal{L}_{\text{conf}} + \alpha\mathcal{L}_{\text{loc}}) \quad (9)$$

in terms of:

$$\mathcal{L}_{\text{loc}} = \sum_{i,j}\sum_{m\in\{x,y,w,h\}} 1_{ij}^{\text{match}} L_1^{\text{smooth}}(d_m^i - t_m^j)^2 \quad (10)$$

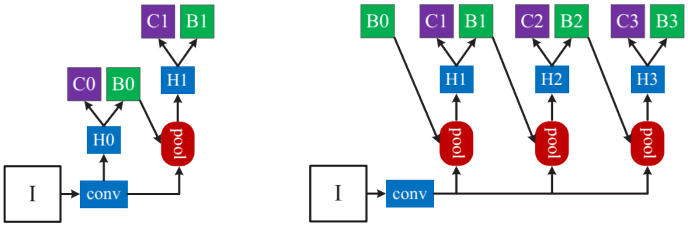


Fig. 4. Architecture of Faster-RCNN (left) and Cascade-RCNN (right) [25].

and

$$\mathcal{L}_{\text{cls}} = -\sum_{i\in\text{pos}} 1_{ij}^k \log(\hat{c}_i^k) - \sum_{i\in\text{neg}} \log(\hat{c}_i^0), \text{ where } \hat{c}_i^k = \text{softmax}(c_i^k) \quad (11)$$

D. Cascade Mask R-CNN

Cascade R-CNN [25] is a multi-stage object detection based on Faster R-CNN. It adds two extra stages to the standard two-stage Faster R-CNN architecture, as can be seen in Fig. 4. Besides, the data of each stage is trained with increasing IoU thresholds, which aims to reduce the overfitting problem between the training and testing processes.

The Cascade R-CNN architecture can be integrated with other models to improve the performance. For experiments, we use Cascade Mask R-CNN [26], a combination of Cascade R-CNN and Mask R-CNN, on Detectron2 [27]. As being the extended version of Mask R-CNN, Cascade Mask R-CNN shares a similar loss function with Mask R-CNN, as shown in Eq. 12.

$$\mathcal{L}_{\text{Cascade Mask R-CNN}} = \mathcal{L}_{\text{class}} + \mathcal{L}_{\text{box}} + \mathcal{L}_{\text{mask}} \quad (12)$$

IV. Methodology

In this article, instead of using low-level image features, a novel model for extracting high-level features, which can be used for classification afterward is proposed. The proposed method consists of two stages as shown in Fig. 5. The first stage is the high-level feature extraction which combines 10 high-level features from 3 blocks: sensitive objects detection (8 features), Human presence (1 feature) and Skin color extraction (1 feature). The second stage of the model is an SVM classifier for making the final decision of discriminating pornographic or non-pornographic content. The details of each block are described below.

A. First Stage - High-level Feature Extraction

1) Sensitive object detection module: When examining pornographic visual contents, including images and videos, we realize that the sensitive objects in the human body appear frequently, so that these objects can be used for detecting pornographic content effectively. In other words, we can apply object detection models to detect these objects and use it as high-level features. Throughout the image, four sensitive

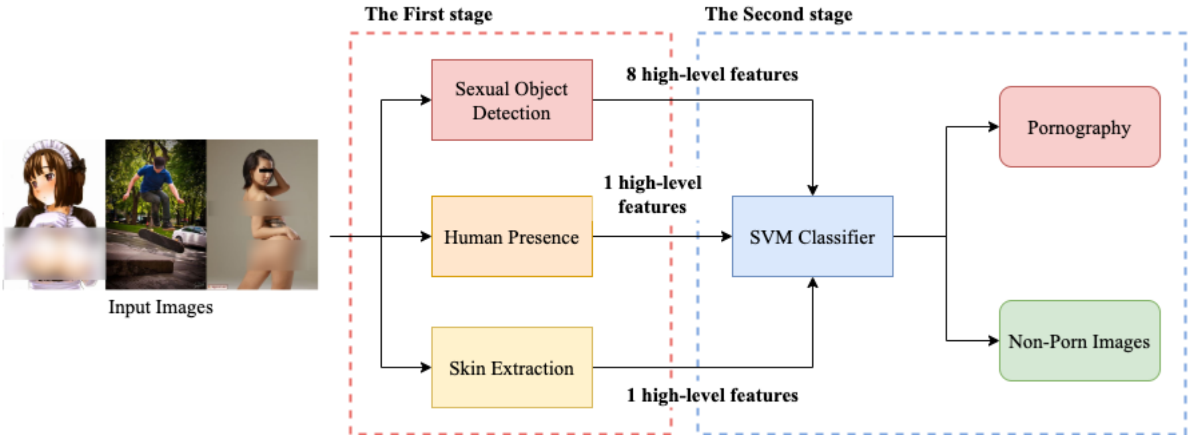

Fig. 5. Block Diagram of the Proposed Pornography Classifier.

objects and organs included female breasts, male/female genitals, and anus, are identified along with bounding boxes and corresponding confidence scores. Two high-level features are extracted for each type of sensitive object, including the number of detected objects and each type's highest confidence score, thus making eight high-level features for feeding to the main fusion model.

2) *Human presence module:* Images or videos are considered sexual if and only if it contains people or parts of people, therefore the second information can be used to solve the task in this paper is human presence. In other words, human detection is a sub-task of the object detection problem, thus the object detection model can be adapted to identify humans' presence on visual content. The existing human in images detected is another high-level feature we proposed to improve our model.

In this module, a human detector on Detectron 2, which used the pre-trained model on COCO dataset, is adapted to identify humans' existence from the input image. The segment mask of detected people was then used to recognize these people's presence on the image and adapted as the input for the skin extraction module. Thus the feature of human presence, in terms of a binary value, is adapted to the main fusion model.

3) *Skin extraction module:* For the skin extraction, we adapted two color spaces, HSV and YCbCr, to recognize skin areas from the image. While HSV is being used for its advantage in describing a high-quality color as well as reducing the problem of illuminating color identification, YCbCr is adapted for its advantage to describe skin on various races with significant results. Moreover, YCbCr is one of the most popular color spaces applied to skin extraction methods.

The color spaces thresholds that we applied for skin extraction in our proposed approach is described in Eq. 13. Based on these boundaries, we decided whether the pixel is describing skin or not by combining two extracted results from HSV and YCbCr range.The ratio of the total body skin areas on the image, which value varies between 0 and 1, as another high-level feature along nine upper describing features.

$$\begin{cases} 0 \leq H \leq 17 \\ 15 \leq S \leq 170 \\ 0 \leq V \leq 255 \end{cases} \text{and} \begin{cases} 0 \leq Y \leq 255 \\ 85 \leq Cb \leq 135 \\ 13 \leq Cr \leq 180 \end{cases} \tag{13}$$

The skin extraction task is performed on the human segmentation areas, which we get from the Human Presence module described above. We calculated the skin ratio only on human segments, not on the entire original image. This gives a better view of the human body's skin ratio, where the higher exposed skin, the higher pornographic probabilities.

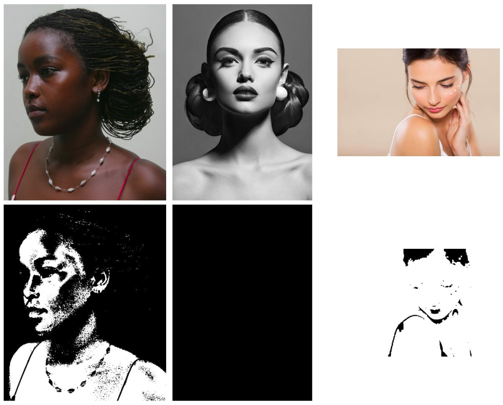

Fig. 6. Skin Extraction Algorithms Results.

However, we must admit that the skin extraction algorithm has a certain weakness when it deals with gray-scale or black/white images as well as images with skin-liked color, such as sand, wood, etc. Under these cases, the skin extraction neither working nor achieving great results, as described in Fig. 6. Thus, that will be one of the problems we have to overcome in the future.

B. *The Second Stage - SVM Classifier*

Ten high-level features from the three modules above then feed into a discriminative SVM model, which works as a fusion mechanism, to become the proposed approaching method. Generally, the overview of the fusion model is illustrated in

Fig. 5 where the sensitive object detection module can be replaced by Mask R-CNN, YOLO, SSD, and Cascade Mask R-CNN model, respectively. For the SVM model, kernel Radial Basis Function (RBF) is adapted as it comes with our proposed method's highest performance.

In the proposed model, sensitive object information plays the most crucial part in determining the sexuality of input visual content as it accounts for 80% of input features feeding to the fusion module. Moreover, the presence of humans from input images and the ratio of explicit body skin on these human segments play an additional role in ensuring the effectiveness of the method's performance. Ten high-level features feeding to the SVM model can leverage their effectiveness in prediction as well as eliminate the limitations from their own modules.

V. Pornographic Blocking Extension for Website

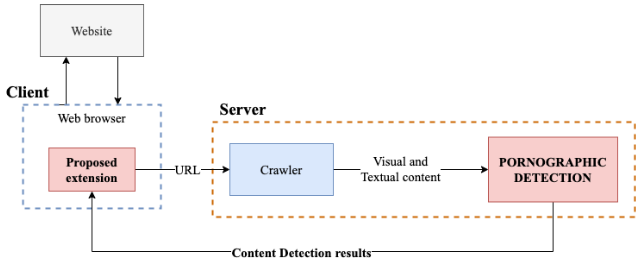

Fig. 7. Procedure of Pornographic Blocking Extension.

From our previous work in [28], [29] and [15], we developed an extension on Google Chrome for pornographic website recognition works as an initial gate alerting and blocking people before accessing the unappropriated website. The extension involves pornographic textual content identification using the NaiveBayes classifier and visual content identification based on YOLO sexual object detection to determine the pornography of the input website.

A. Procedure Flow

The main procedure of this extension can be observed in Fig. 7. Initially, visual and textual contents are crawled from the input website on the crawler module. Then, pornographic visual and textual identification modules are adapted to identify how pornography the website is.

In the visual identification module, a sensitive object detection was adapted to determined if website images are pornography or not. Due to the fast execution and great performance, YOLOv3 was chosen for the extension. On the other hand, the Vietnamese/English pornographic textual classifier was adapted from [29] for the textual identification module. This classifier uses the NaiveBayes algorithm to discriminate whether the sensitiveness of textual contents from the website.

Based on the predicted results of these contents, the extension alerting three safety levels to the user, which are: (1) Safety: textual and visual contents are both recognized as safety; (2) Porn-Type-1: one of the textual or visual content is recognized as pornography; (3) Porn-Type-2: textual and visual contents are both recognized as pornography.

TABLE I. The Website Dataset

	Safety	Porn-Type-1	Porn-Type-2	**Total**
Vienamese	65	5	11	81
English	35	15	69	119
Total	100	20	80	200

TABLE II. Result on the Manual Dataset

Object detection model	**Object-based method (object detection)**	**Proposed method (Skin + Human + object detection)**
Mask R-CNN	81.64%	**85.63%**
YOLO	93.87%	**94.06%**
SSD	88.93%	**89.32%**
Cascade Mask R-CNN	**93.43%**	93.39%

B. Pornographic Website Dataset

To evaluate the performance of the pornographic alerting and blocking extension, we collected a website dataset including 100 pornographic websites and 100 safety websites with Vietnamese and English languages. The websites are divided into three categories: Safety, Porn-Type-1, and Porn-Type-2 corresponded with the definitions of extension outcome notifications. The distribution of the pornographic website dataset by category is described in Table I.

VI. Experimental Results

A. Results and Evaluation

On the experiment, we evaluated our method with a manual image dataset along with the public dataset NPDI-800 [7]. The manual image dataset includes 25.000 normal and 25.000 pornographic images, while the NPDI-800 dataset contains 400 pornographic videos and 400 normal (non-porn) videos.

For video evaluation, one frame per second is extracted to determine the pornography of input video. The evaluating strategy of pornographic video is modelized as shown in Fig. 8. As can be seen, extracted frames are classified into two groups, namely pornographic frames, and normal frames, by a classifier. Based on the ratio of porn frames on total frames, the input video is classified as pornographic or normal.

Fig. 9 and Fig. 10 show our experiments on NPDI-800 dataset with a various "porn rate" threshold from 1% to 15%. With that strategy, we achieved the best result when we considered pornographic video contain 1% or more frames detected as pornographic. To assess the effectiveness of our proposed approach, we have done two experiments on the same testing set: (i) using object detection's outputs directly to distinguish pornography from normal images, (ii) feeding the SVM with object detection's output information combining with extracted skin and human segmentation features.

TABLE III. Result on NPDI-800 Dataset

Object detection model	**Object-based method (object detection)**	**Proposed method (Skin + Human + object detection)**

Porn	100	100	100.0%
Total	200	199	**99.50%**

The first experiment was done by using the results from sensitive object detection directly to judge an image is pornographic or not. If the model detects at least one of four sensitive objects in an image, this image will be concluded as pornography and vice versa. From the results on the manual dataset, which showed in Table II, the YOLO model achieved the best Accuracy score with 93.87%. While evaluating videos, this approach gives us the highest accuracy of 94.88% when the YOLO model is used to detect sensitive objects on the NPDI-800 dataset. Detail result at 1% of porn rate ratio has been shown in Table III. As shown in Fig. 9, both YOLO and SSD models had the best result at 1% porn frame ratio while Mask R-CNN achieved its best at 15% and this number was 3% of porn frame ratio on Cascade Mask R-CNN.

The second experiment was conducted by adapting our proposed approach, which used an SVM with ten high-level features inputs from sensitive object detection, human presence, and skin extraction modules. Generally, we achieved better results in comparison with the method using sexual object detection algorithms only, which can be observed on Table II and Table III. On the NPDI-800 dataset, Mask R-CNN and Cascade Mask R-CNN's results improved significantly when adapting the proposed approach, from 54.38% to 74.13% and 76.63% to 82.75%, respectively. However, the highest results still are achieved by the YOLO model with 94.06% accuracy on our manual dataset and 94.88% on the NPDI-800 dataset. The comparison with other methods on the NPDI-800 dataset can be observed in Table IV. As can be seen, the performance of our method in the NPDI-800 dataset is quite impressive.

B. Website Extension Experiment

In the experiment with pornography blocking extension, our manual website dataset is adapted to evaluate the effectiveness of recognizing not-safe-for-work websites. The results in prediction on three types of website can be observed on Table V and Table VI.

As can be observed, the extension achieved the outstanding results with 99.00% Accuracy in recognizing Safety websites, 100.0% and 77.50% Accuracy on Porn-Type-1 and Porn-Type-2 websites, respectively. However, the extension recognizes Porn-Type-2 websites with only 77.50% Accuracy as some certain websites are identified into Porn-Type-1. Thus, all the pornographic websites during the experiment are identified by the extension with the absolute 100% Accuracy in recognition, leading to the total result of 99.50% Accuracy in porn/non-porn website classification. Still, we have to notice that there might be some confusing cases, which are websites containing sensitive contents. These kinds of websites might be civil intent, such as sex education lecture/advice or nude photographs for medical purposes. This makes the model quite difficult to determine the suitable decision, which might reduce our extension's performance in the real practical implementation.

VII. Conclusion

This paper proposed a new approach to identify pornographic visual content based on sensitive object detection and skin color. The proposed approach detects four sensitive objects including female breast, male or female genital and anus. Then these sensitive object information are used as high-level features along with human precense and skin extraction information as input of the fusion SVM model. Eventually, the SVM model decides whether the input visual content is pornography or not. Applying the four most notable object detection algorithms, which are Mask R-CNN, YOLO, SSD, and Cascade Mask R-CNN, sensitive object features are identified. We achieved the best results on our custom dataset and the public NPDI-800 dataset, which are 94.06% and 94.88% Accuracy respectively, when the YOLOv3 is adapted as the sensitive object detector and RBF is used as the SVM kernel.

In addition, to prove the effectiveness of our proposed method in practical application, an extension for alerting and blocking pornographic website is built. Measuring the accuracy by surfing 200 websites, the extension has shown impressive results: 99.00% of normal websites and 100% of pornographic websites was identified correctly.

Abstract—**Due to TIC development in the last years, users have managed to satisfy many social experiences through several digital media like blogs, web and especially social networks. However, not all social media users have had good experiences with these media. Since there are malicious users that are able to cause negative psychological effects over people, this is called cyberbullying. For this reason, social networks such as Twitter are looking to implement models based on deep learning or machine learning capable of recognizing harassing comments on their platforms. However, most of these models are focused on the use of English language and there are very few models adapted for Spanish language. This is why, in this paper we propose the evaluation of an RNN+LSTM neural network, as well as a BERT model through sentiment analysis, to perform the detection of cyberbullying based on Spanish language for Ecuadorian accounts of the social network Twitter. The results obtained show a balance between execution time and accuracy obtained for the RNN + LSTM model. In addition, evaluations of comments that are not explicitly offensive show a better performance for the BERT model, which outperforms its counterpart by 20%.**

I. Introduction

Nowadays, the constant information and communication technologies (ICTs) development has enabled interpersonal interaction, allowing real experiences to be transferred to a virtualized medium such as social networks (SSNs) [1]. Within this environment, SSNs users can establish real time conversations to exchange ideas [2]. This satisfies the need for affection and integration through positive reinforcers and facilitates socialization among its users [3].

However, there are not only positive reinforcements for the use of social networks, but there are also risks such as, emotional distancing, loss of limits in communication, sexting, cyber addiction, or cyberbullying [4]. In cyberbullying, malicious users take advantage of situations of vulnerability to attack others through offensive comments using digital media. Although cyberbullying does not produce physical injuries, it causes negative psychological effects and disorders in users who are victims of these practices [5]. For this reason, social platforms such as Twitter offer methodologies based on social systems for cyberbullying recognition, such as Social Filter or the Theory of Planned Behavior, have become increasingly popular [6]. These methodologies are able to identify stalkers based on the allegations in their messages and the behavior of the account. However, these techniques tend to be ineffective in the face of occasional or unidentifiable comments.

Similarly, different countries take preventive measures through campaigns or laws that limit and sanction this type of practice. In the case of Ecuador, the Ministry of Education agreed on an operational definition for this type of practices within educational environments, described as violent acts that are frequently carried out intentionally between students of an educational institution, in a relationship of imbalance of power. Through it, a bully seeks to assert superiority in a group. [7]. For its part, the National Agency for Intergenerational Equality establishes that the competent authorities and entities must create an inter-institutional strategy to prevent, detect and address all forms of harassment within educational institutions (*bullying*, *ciberbullying*, sexual harassment) [8]. One of the most common forms of harassment in Ecuador, is cyberbullying which has a 7.46% share of the total, which puts it ahead of the total number of cases where victims were beaten in the same period with 7.02% [7]. It is worth mentioning that these statistics are limited to cyberbullying in educational environments.

II. Background

Following the ideas on [9], [10], [11] they carry out campaigns through images, talks, marches and trends in SSNs on tolerance and social respect to prevent cyberbullying. Despite this, the campaigns carried out, being a preventive method, are not able to act on a perpetuated act or event of cyberbullying. For this reason, there are methodologies based on deep learning and machine learning capable of identifying comments with potential cyberbullying [12]. Based on this resource, it is possible to take the necessary measures against the users involved. In this regard, deep learning offers cyberbullying prediction models based on Support Vector Machine (SVM), Linear Regression (LR) and Naive Bayes (NB) [13], [14], [15], [16].

However, the studies carried out are limited to work in the English language, which results in greater vulnerability for Spanish-speaking user groups in SSNs.

For this reason, works such as [17] and [18] test SVM, LR and NB models to perform sentiment analysis based on Spanish language. Antagonistically, these evaluations are focused on traditional methods for sentiment analysis tasks with NLP. In this sense, traditional methodologies show a good level of accuracy when performing sentimental analysis.

However, methods based on Recurrent Neural Networks (RNN), Convolutional Neural Networks (CNN), Memory Networks (MemNNN), Long Short-Term Memory (LSTM) and Recursive Neural Network (RecNN) it present a more robust and efficient result in the area of Natural Language Processing (NLP) [19], that represent an area of study for cyberbullying cases in Spanish language.

For this reason, in recent years, neural networks are dedicated for sentimental analysis tasks in SSNs; becoming a focus of research interest, offering models capable of classifying various sentimental topics from texts of limited length [20]. At the same time, these works are focused on empirical experiments whose adjustment seeks to avoid overfitting, to allow the implementation of the models in SSNs.

One such model is found within [21], where a sentimental analysis based on a convolutional recursive neural network (RvNN) coupled to pretrained word vectors in the upper layer for English language is proposed. Thus, it uses the RvNN as an alternative to the CNN clustering layer, thus reducing the loss of local information and allowing the model to efficiently capture long-term dependencies based on its tree structure. Consequently, a classification accuracy of 89.1%, as it extracts sentimental representations at word level considering syntactic and semantic relations, similar to what was achieved with techniques such as Latent semantic analysis (LSA) proposed in [22], [23].

On the other hand, [24] proposes a CNN-based text classification model for a dataset of verbal aggression in English language. The experiment combines the LSTM and a CNN to a 2-dimensional embedding Term Frequency Inverse Document Frequency (TF-IDF) layer. The obtained result reaches 91—% accuracy for the LSTM+2D TF-IDF and 92% accuracy for the CNN+2D TF-IDF model. Thus, it increases the accuracy achieved by the LSTM with 72% and CNN with 83% when using a preprocessed embedding layer such as Word2Vec [25].

In 2018, [26] proposes a pre-training method based the deep bidirectionality of BERT. Thus, his model is trained using the ”masked language model” (MLM) but without the ”next sentence prediction” (NSP) task and a left context model that is trained using a standard left-to-right LM (LTR), instead of an MLM. Then, it manages to improve the accuracy of traditional BERT by 2.5%. In this context, [27] proposes a model that uses a single linear neural network layer for classification. In its experimentation, it achieves an accuracy of 81% when using the Wikipedia Corpus.

Also, [20] conducts an evaluation of BERT for the detection of cyberbullying on social media: Twitter, Wikipedia, and FormSpring. The purpose of their evaluation is to refine the parameters of BERT when using the [26] Corpus to achieve better results. Therefore, in evaluating the model, it achieves an accuracy of 90% when using the Wikipedia Corpus. However, its best performance was achieved with a Twitter Corpus with which it obtains 94% detection accuracy. While, an RNN+LSTM model evaluated with the same Corpus only achieves 85% accuracy.

As a Spanish language case, we found that [17] performs the detection of violence against women in SSNs, based on Opinion mining techniques, Document Term Matrix (DTM), such as *bolsa de palabras* (bag of words), together with NB, Decision Trees (DT) and SVM algorithms for the social network Twitter. It´s most relevant result shows an accuracy of 90.35% when using the DT algorithm.

Thus, [18] presents a semi-automatic and presumptive detection system of cyberbullying; based on NB, SVM and LG techniques for the social network Twitter in Spanish language, called Spanish Cyberbullying Prevention (SPC). Thus, [18] uses sentiment analysis, machine learning and NLP to analyze phrases in Spanish from a group of trends and specific users from Ecuador, in order to identify the existence of a semantic set related to cyberbullying with up to 91% of precision, when using SVM.

In this context, we continue the work presented in [18], where a comparison is made between two models of deep learning; the first one based on RNN+LSTM and the second one on BERT for the presumptive detection of cyberbullying in Spanish language. Our goal is to obtain accurate and efficient models in terms of execution time, using bidirectional models with memory capabilities to train the models with a Spanish language Corpus.

The rest of the document is presented as follows: Section III describes the methodology used for the proposed method. Section IV analyze the results obtained. Finally, section V presents the conclusions of this paper.

III. Methodology

After reviewing several proposals of deep learning works for sentimental analysis focused on cyberbullying, we propose the implementation represented in Fig 1, composed of 3 stages: Dataset extraction, deep learning training and testing the trained models.

A. Dataset Extraction

Prior to training deep learning models, it´s important establish a dataset according to the subject matter. Therefore, it is necessary to generate a customized Corpus that fits the needs of the research. For this purpose, Twitter´s API and its advantages were used to form a Corpus through the extraction, processing and analysis of tweets through several implemented scripts; which were subsequently used for the proper training of the proposed models. Scripts with NLP algorithms are used to semi-automatically identify the sentiments of each tweet since its content is related to cyberbullying situations and a correct labeling of the data depends on it.

Main Corpus elaboration starts establishing a set of phrases and keywords that suggest some kind of insult or harassment; as well as others that show a more pleasant type of feeling, as shown in Table I. Thus, a set of weightings is established to determine the choice of an appropriate label for a comment. The label can be between 0 and 1, where the first value indicates that a comment is negative or has harassment and the second one when it is a positive or clean one. In turn, the Corpus used here has been implemented and developed by [18].

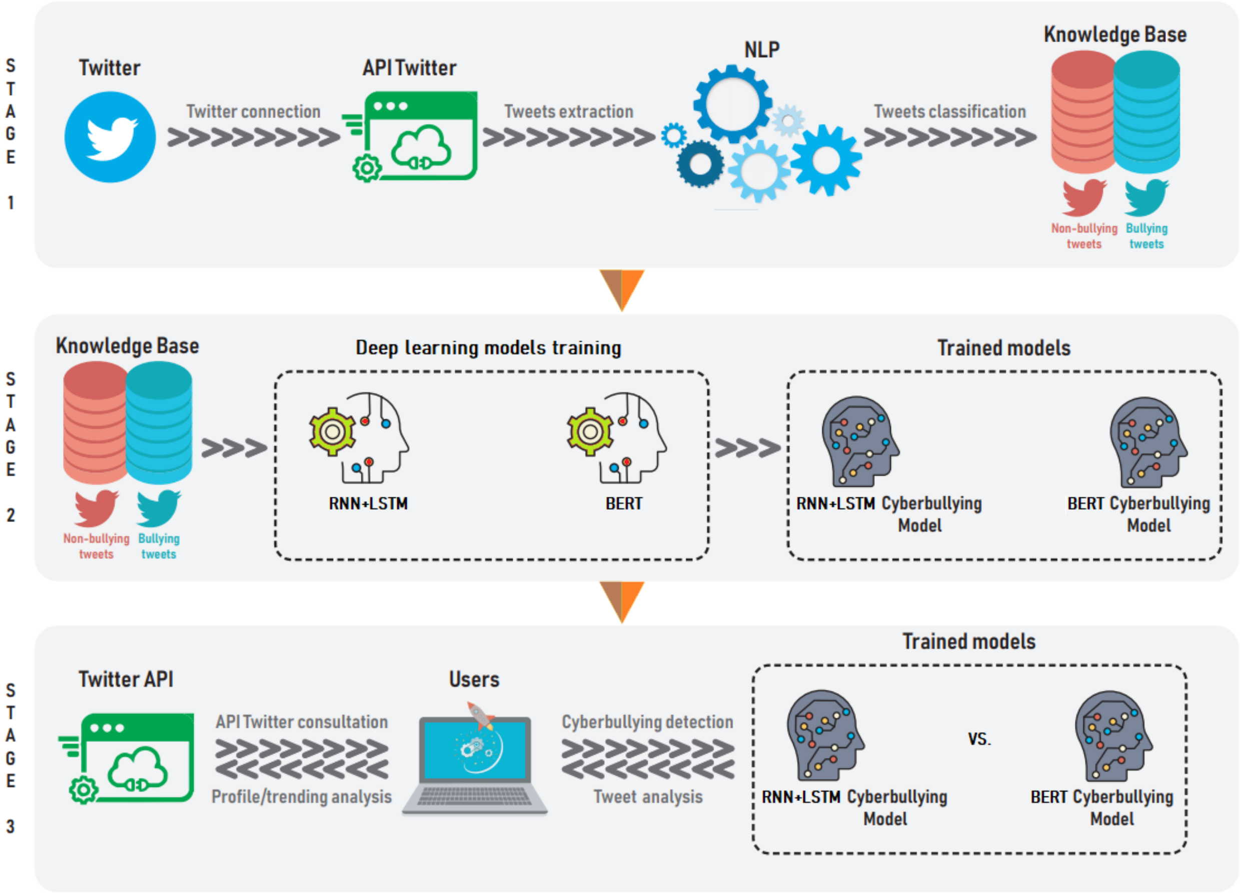

Fig. 1. Implementation Stages of Deep Learning Models.

TABLE I. Sample Corresponding to 6.25% of Phrases used for Tweets´s Automatic Classification According to a Positive or Negative Intent Focus

Frases Positivas	Frases Negativas
amar	desgraciado
eres increíble	gay
genial	hija de put*
gracias	indio
muy amable	vales verg*

However, to establish a margin of error, we have developed a second manually classified corpus. This is how a comparison is established between the effectiveness of an automatic classification method and one with personal criteria. The second Corpus represents 1.36% of information respect to automated version Corpus. The result is a difference of 20% less in the interpretation of the data considered as ”harassment” by the automatic model compared to the manual model. Subsequently, a data cleaning process was applied to remove mentions, emoticons and retweets because they affect the content of the comments and, consequently, could generate false negatives or positives in the system. As a result, a Corpus was formed with 881503 tweets, where 471432 of them correspond to comments with some type of harassment.

It should be noted that, as described in [18], a limitation of the Corpus is the impossibility of analyzing irony, since both verbs and contextual structures are not taken into consideration.

B. Deep Learning Training

To detect comments with presumed cyberbullying, our designed system uses a training corpus composed of 53.48% of comments or phrases with bullying. From this, the use of two models of deep learning is considered to detect and classify negative sentiments in Spanish language.

The proposed system has been developed from two methods: RNN + LSTM and BERT, because they are currently the deep learning models with the highest level of accuracy and development in prediction and classification tasks in the area of sentiment analysis.

1) RNN+LSTM Model: Sequence classification is defined as a predictive modeling problem where we have an input sequence over space or time and our goal is to predict a category where to assign that sequence [28]. Hence, a classification model development starts with the implementation of a block that allows text preprocessing, so that a deep cleaning is applied to the content of the original comments.

The stipulated cleaning includes special characters, punctuation symbols and repeated words elimination.

Also, it is necessary to apply *”Stemming”* or *”Lemmatization”* techniques that allow delete word endings to obtain their base structure, all that to avoid an excessive amount of identifiers, which may result in an inefficient classification system.

On the other hand, word representations are a fundamental component of many NLP systems, so it is common to represent words as indexes in a vocabulary [29]. However, this fails to capture the corresponding lexical structure. Hence, the importance of text preprocessing and the use of techniques that allow a mathematical fitting of a one-dimensional word space to a continuous vector space with fewer dimensions.

For the case of RNN, there is *Word Embedding*, known as a set of techniques for language modeling and NLP learning techniques. Its use represents an efficient way to clean, coding and vectorize words.

Thereby, the technique allows us know the spatial position of a word when it´s part of a vector, its characteristics and surrounding words. Here, a Word Embedding technique *"Word2Vec"* was proposed by [25] to delimit the number of most common words in a dataset, as well as their length provided by this technique. For this reason, with a greater features number defined, a better level of interpretation will be reached during training stage. Also, it should be considered that the system will take as reference only the words defined as the most common ones, since the rest of the words are labeled with a 0. This process is carried out automatically during the Tokenization process, where the larger text strings are divided into smaller parts or Tokens; in this way the larger text samples can be converted into sentences and these in turn can be tokenized into words. From Tokenization, it is possible to analyze the number of times each word appears in the dataset, as shown in Table 2.

TABLE II. Dataset´s Most used Words Sample

Top	Word	Top	Word
1	hac	**11**	grac
2	buen	**12**	amar
3	quer	**13**	sol
4	dec	**14**	mejor
5	put	**15**	dia
6	ir	**16**	pas
7	pod	**17**	verg
8	amig	**18**	tan
9	ser	**19**	gust
10	ver	**20**	hol

Based on the most used words, a dictionary was defined to match the variety of words in the comments with the tokenization of the vocabulary. After that, the comments were transformed into integer sequences. These sequences are truncated or filled in so that they all have the same length, prior to assigning the data to Train and Test blocks. Subsequently, the Train and Test blocks were defined in portions of 25% and 75% respectively. After padding the sequences, two matrices were obtained; the first one corresponding to X-Train of (220375x500) and the second one assigned to X-Test of (661126x 500), where 500 corresponds to the maximum length sequences. On the other hand, the labels in Y-Train and Y-Test are directly extracted from the original data set.

On the other hand, our RNN+LSTM model main feature is to use of a Bidirectional LSTM layer. Its use implies a remarkable improvement compared to a standard LSTM layer. A single LSTM layer is only capable of retaining information from a past state because it only considers one input related to past state. In contrast, a bidirectional LSTM layer can handle past and future states combined and thus give a better understanding context to the model to be trained.

Our RNN+LSTM model is composed as follows: an input layer, followed by an Embedding layer, commonly used in models with text. Next, a Batch normalization layer is placed, to adjust the dimensions of the data in the Embedding layer to the rest of the layers. Subsequently, a Bidirectional layer is applied, to provides our RNN model with a two-way LSTM memory; this adds the BERT´s main feature to the RNN+LSTM, bidirectionality.

2) BERT Model: Preprocessing of the dataset for the BERT model was performed using*stopwords* as a technique for removing special characters and punctuation symbols not relevant to the meaning of a sentence. [30]. Subsequently, as in RNN+LSTM, a tokenization process was applied. However, BERT has it´s own library to perform preprocessing and tokenization tasks called *BERT Tokenizer*. The library, by itself, splits text into tokens and at the same time converts those tokens into tokenizing vocabulary indexes. In addition, it allows to limit or equalize the sentences to equal length and to create an attention mask; where the last parameter is a necessary component for the training of the model. Through this, sentences were constrained into vectors with a maximum length of 64 identifiers of tokens each. Thus, as in the RNN+LSTM model, the dataset was divided into Train and Test blocks in portions of 25% and 75%, respectively.

By using a pre-trained model, BERT presents an efficient prediction accuracy when compared to other methods of deep learning. However, it´s possible increase the model´s accuracy level through Fine-Tunning techniques. This thanks to the *Transformers by Hugging Face* option in the *PyTorch* class. This do a settings, tokenization and architecture optimizing since base model; all thanks because Transformers provide a general-purpose architectures for natural language understanding with about 32 pre-trained models in more than 100 languages.

In addition, BERT is a robust model that consumes a large amount of system resources on which it will be run. One way to optimize its performance during a training and save memory is the use *PyTorch DataLoader* class. On the other hand, *PyTorch*, is a deep learning project development library whose main feature is the use of GPU acceleration. Thanks to this, *PyTorch* allows a dynamic behavior change of a neural network on the go. Finally, for our BERT model, the *BERT base* configuration was chosen for its trade-off between number of parameters vs. execution time. The base BERT model differs from the *BERT large* model by 2.8% and its runtime increases substantially; for this reason it will not be considered in this study.

Base BERT is configured by 768 hidden layers and 12 headers. However, it´s possible set a number of improvements to the model through AdamW optimizers, including a learning rate between $5e^{-5}$, $3e^{-5}$, $2e^{-5}$.

TABLE III. SEVERAL STUDIE-CASES HARASSMENT AND NON-HARASSMENT COMMENTS EXAMPLES

Harassment free Tweets	Harassment Tweets
si te toca estar en mesa. si sólo tienes que ir a votar y desaparecer.	Todos se cagaron, porque empezaron a decir, ”ahí viene la mujer de ese man”, nos escuchó gritar ”cachudo”,
Que viva Guayaquil de mis amores!	jajajaja cerraran las bien puertas y ventanas que pasa el lelo y su mafia.

C. Testing the Trained Models

Once the models are trained, we use different datasets to establish two case studies with which to corroborate their classification accuracy. For this paper, we used two accounts belonging to Ecuadorian users whose contents have different focuses: the first account specializes in hurtful comments (Study Case 1) and the other is focused on political issues (Study Case 2).

Based on this, the operating characteristics are evaluated through accuracy parameters of the trained models.

Thereby, an analysis is made of the phrases or words that, according to the models, suggest some type of harassment or insult.

In addition, the models make it possible determine the percentage of harassment on each analyzed account has in relation to extracted information.

Table III shows one example of a comment with harassment and one without harassment, from which the Study Cases Corpus are composed.

IV. ANALYSIS OF RESULTS

To validate our proposed models, we used the Table IV parameters for RNN+LSTM model and Table V parameters for BERT model.

Both models were trained and evaluated on a computer with 12 processing threads at 3.9GHz coupled with 48GB of RAM. In addition, since the models allow the use of vector graphics processing for their execution, a GPU with 1920 CUDA cores and 6GB of VRAM was used.

Batch size	32
Dense layer	1, with “Sigmoid” activation

A. Operating Characteristics Analysis

Fig. 2 shows the curves with operating characteristics (ROC) of RNN+LSTM and BERT models.

TABLE V. BERT MODEL STRUCTURING

Settings	BERT
Epochs	4
Hidden layers	768
Heads	12
Batch size	32
Parameters	768
Learning rate	$5e^{-5}$
Epsilon value	$1e^{-8}$

The curve corresponding to RNN+LSTM model, in blue, shows an area under the curve (AUC) with a value of 0.97. On the other hand, BERT´s curve model, in red, shows an AUC with a value of 0.98.

Thereby, AUC is the probability that a negative random comment is considered as negative and a positive one as positive. Therefore, the value of the AUC ranges from 0 to 1.

Our implemented models provide optimal performance overall, where BERT model outperforms the RNN+LSTM model by 1%.

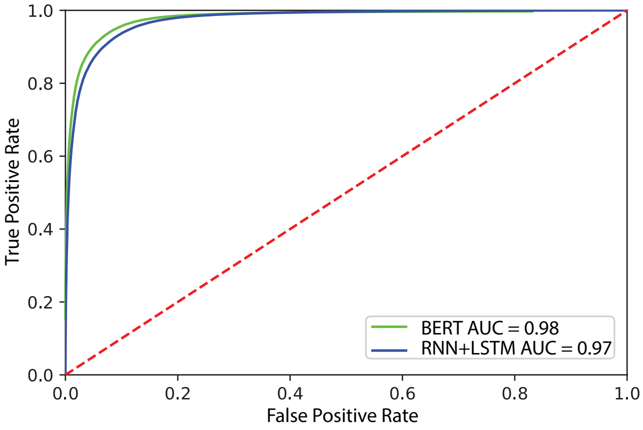

Fig. 2. RNN+LSTM & BERT Model´s Operating Characteristics.

B. Performance Analysis

As shown in Table VI, the BERT model reflects the highest accuracy with respect to its counterpart with RNN+LSTM and even surpasses by far the result obtained with SVM. In [18]. However, the RNN+LSTM model offers very close performance to that of BERT, with only a fraction of its run time.

TABLE VI. RESULTS FROM TRAINED MODELS

Parameter	RNN+LSTM	BERT	SVM	NB	LR
Accuracy [%]	91.82	92.82	87	83	85
Execution time [min]	78	270	-	-	-
AUC	0.97	0.98	-	-	-
Number of Tweets	220000	220000	230000	230000	230000

In terms of Epoch, RNN+LSTM model shows a decreasing trend with respect to the precision value, as shown in Fig. 3. Thus, the higher the number of Epochs the accuracy tends to

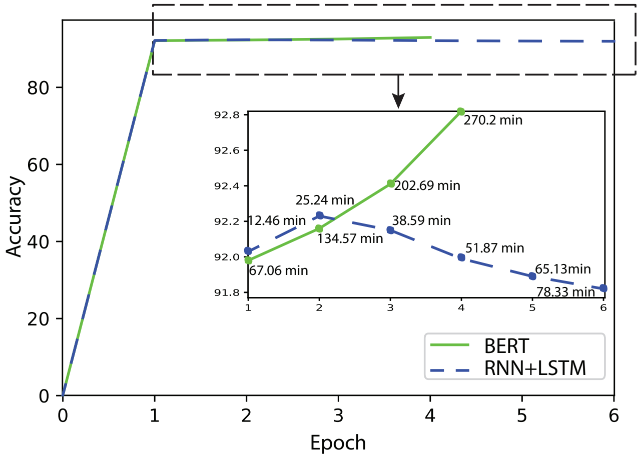

Fig. 3. Execution Time and Accuracy by Epoch.

stabilize at a lower value with respect to its starting point; being the number of Epochs chosen the appropriate one to achieve a stable value close to the one achieved by the BERT model.

On the other hand, BERT model shows an increasing behavior; suggesting that the model can achieve even higher levels of accuracy. However, a higher level of accuracy may represent a model´s overfitting.

At the same time, Fig. 3 evidences a convergence point with an accuracy´s approximate value between the two models at Epoch number 2.

However, this sample shows the difference in the execution time required by each model to achieve this accuracy value; where RNN+LSTM uses only 18% of time used by BERT.

C. Validation Analysis of Acertation

In order to evaluate the trained models, we have used data from two Twitter accounts whose users will be described as @USER_1 (Study Case 1) and @USER_2 (Study Case 2); in order to maintain these accounts anonymous. In turn, the accounts have different content approaches. The analysis are shown in Table VII. At the same time, we use the portion of the dataset intended for Test tasks.

TABLE VII. STUDY CASES ACCOUNTS CYBERBULLYING AVERAGE

Account	Account´s Harassment percentage [%]
@USER_1	86,3
@USER_2	19,27

The model´s results using non-explicitly offensive comments were satisfactory, especially with BERT model. With the dataset test portion, we generate a list of 20 random comments with alleged cyberbullying, BERT was able to identify 85% of them correctly. While, under the same parameters, RNN+LSTM identified 75% of comments correctly.

In Study Case 1, 20 random comments are evaluated by RNN+LSTM and BERT they were able to predict 85% of comments correctly; part of these results are shown in Table VIII and Table IX respectively.

However, for Study case 2, BERT demonstrated a higher level of prediction than RNN+LSTM. When generating a list of 20 comments with suspected cyberbullying, BERT got 30% of them right, as seen in Table XI; while RNN+LSTM barely managed to identify 10%, from Table X.

This is due to the comments in Study case 2, which have no insults or hurtful comments as such, unlike Study Case 1. Which don´t contain any insults or hurtful comments as such, unlike Study Case 1. This is where the advantages of using a pre-trained model over a relatively inexperienced one become evident.

In addition, upon visual inspection of the classification results, it can be determined that BERT suggests a better approach to harassment, since it does not take any sentence as harassment even if it shows a potential insult. Likewise, this phenomenon can be better appreciated in the comments of Study Case 2, where RNN+LSTM model generates more false-positive cases.

On the other hand, results show a 16% of comments whose terms suggest some kind of insult without actually being harassment.

This is where implemented models tend to show bad results with respect to a real state of interpretation; taking into account that it can be a subjective parameter depending on the user who interprets it.

V. Conclusions

In this paper, we continue the work presented in [18], evaluating two models of deep learning in NLP tasks for the detection of cyberbullying in Twitter social network. The proposed models achieve at least a 5% improvement in accuracy over the best model of the previous work corresponding to SVM.

Our first model, RNN+LSTM, shows as the most balanced option between execution time with 78 [min] and an accuracy of 91.82%; which means a difference of 1% compared to 92.82% of BERT´s accuracy, but using 82% more run time.

However, RNN+LSTM doesn´t represent the most efficient cyberbulling classification option, due to BERT has a better criterion when detecting harassment, just like Study case 2, where BERT outperforms RNN+LSTM by 20%. Thanks to the fact that BERT is a pre-trained model and that the analyzed account does not contain explicitly offensive comments, which presents a challenge for both models in predicting harassment.

At the same time, RNN+LSTM model requires 33.33% more Epochs to approach the accuracy value of the BERT model. Nevertheless, RNN+LSTM is shown to be a robust option for presumptive detection tasks of cyberbullying in SSNs. For this reason, it is recommended that the model be redesigned to include a more robust Bidirectional layer with a larger number of neurons.

On the other hand, BERT model offers different model architectures with a greater or lesser number of parameters, depending on the desired implementation approach. Thus, there is potential improvement for accuracy if we evaluate the *bert-large-uncased* or *bert-base-multilingual-uncased* models. However, a different BERT model requires higher computational capabilities, which can be limiting factor for its implementation.

Finally, through the case studies, it was determined that the trained models are robust enough to predict whether an account includes cyberbullying comments in its content and at the same time its percentages.

***Abstract*—Driving in an unfamiliar traffic regulation using an unfamiliar vehicle configuration contributes to increase number of traffic accidents. In these circumstances, a driver needs to have what is referred to as 'situation awareness' (SA). SA is divided into (level 1) perception of environmental cues, (level 2) comprehension of the perceived cues in relation to the current situation and (level 3) projection of the status of the situation in the near future. On the other hand, augmented feedback (AF) is used to enhance the performance of a certain task. In Driving, AF can be provided to drivers via in-vehicle information systems. In this paper, we hypothesize that considering the SA levels when designing AF can reduce the driving errors and thus enhance road safety. To evaluate this hypothesis, we conducted a quantitative study to test the usability of a certain set of feedback and an empirical study using a driving simulator to test the effectiveness of that feedback in terms of improving driving performance, particularly at roundabouts and intersections in an unfamiliar traffic system. The results of the first study enhanced the ability of the in-vehicle information system to provide feedback considering SA levels. This information was incorporated into a driving simulator and provided to drivers. The results of the second study revealed that considering SA levels when designing augmented feedback significantly reduces the driving errors at roundabouts and intersections in an unfamiliar traffic regulation.**

***Keywords*—Situation awareness; unfamiliar traffic regulation; augmented feedback; in-vehicle information systems**

I. Introduction

International drivers, especially from an opposite, unfamiliar traffic regulation (UFTR), are involved in a large number of traffic accidents [1], [2]. In this paper, a UFTR represents driving a right-hand drive vehicle in a keep-left traffic regulation for drivers who are only familiar with driving a left-hand drive vehicle in a keep-right traffic regulation. The minority of countries (75 countries), such as Australia and Japan [3] are following a UFTR in their traffic system. In the case of UFTR, and especially for international drivers, driving can be more demanding, resulting in an increased number of vehicle accidents, especially at roundabouts and intersections [4].

Overall, satisfactory driving in these conditions requires drivers to be aware of the environment as well as the configurations of the vehicle. This is known as situational awareness (SA). In general, SA refers to the perception of surroundings with respect to time and space, the comprehension of their meaning, and the projection of their status in the future [5]. Accordingly, SA can be divided into three levels [5]: level 1 perception, level 2 comprehension and level 3 projection.

In-vehicle information systems aim to enhance the road safety by providing the drivers with some feedback that help them to make the proper reactions [6]. However, most of existing works ignore designing the provided feedback based on the SA levels, particularly for information required when driving at roundabouts and intersections in a UFTR. The aim of this paper is to consider the SA levels when designing the feedback provided to drivers by in-vehicle information systems. That is, the feedback is provided in perceptual, comprehensible and projectable manner. We hypothesize that considering the SA levels when designing the target feedback can reduce the driving errors and thus improve the road safety. To evaluate this hypothesis, we firstly conducted a quantitative study to test the usability of a certain set of feedback (i.e., travelling path, turning, signalling and speeding at roundabouts and intersections). The results of the first study enhanced the ability of the in-vehicle information system to provide feedback considering SA levels. Then, we conducted an empirical study using a driving simulator to test the effectiveness of that feedback in terms of improving driving performance, particularly at roundabouts and intersections in an unfamiliar traffic system.

The rest of the paper is organized as follows. Section 2 introduces the situation awareness and its levels in driving domain, the rules of driving at roundabouts and intersections in a UFTR and how these rules differ between familiar and unfamiliar traffic regulation, and some in-vehicle information systems that provide visual feedback at roundabouts and intersections. Section 3 tests the usability of presenting the visual feedback in accordance with SA levels. Section 4 evaluates the effectiveness of that feedback in terms of improving the road safety. Section 5 concludes the paper.

II. Background

A. Situation Awareness in Driving

SA in the driving refers to the perception of the elements in the traffic system within a volume of time and space, the comprehension of their meaning, and the projection of their

status in the near future [7]. Traffic system includes three main components: vehicles on the road, users of the road and road environment. Accordingly, the levels of SA in this domain are:
Level 1: Perception of the relevant elements in the traffic system.
Level 2: Comprehension of the meaning of the perceived elements.
Level 3: Projection of near-future status of traffic system.

In relation to driving in a UFTR, the study [8] discovered the drivers' SA when driving at a UFTR by testing the lane changing performance at straight and curved roads in addition to roundabouts and intersections. The findings of [8] showed that international drivers are likely to have low SA when driving at roundabouts and intersections. Accordingly, the current study focuses on driving at roundabouts and intersections in a UFTR.

B. Driving at Roundabouts and Intersections in a UFTR

Australia is a keep-left country whose traffic system follows a UFTR in this research. In case of no traffic presents in the dual-lane roads, Australian traffic rules are as follows [9]:
1) Approach a roundabout/intersection (a) using the correct approaching lane according to the target direction (i.e. the right, left, and right or left lane when turning right, turning left, and going straight-ahead, respectively), (b) signalling prior to turning left or right and (c) slowing down or completely stopping the vehicle.
2) Enter a roundabout/intersection in the correct direction of traffic flow.
3) Exit a roundabout/intersection using the correct lane.

International drivers who come from keep-right countries must consider the main differences in traffic rules and vehicle configuration when driving at a roundabout/intersection in their home countries and in a UFTR. The differences are as follows:

- In the right-hand drive vehicle (the driver is not familiar with) has its direction indicator stalk on the right of the steering wheel whereas in the left-hand drive vehicle (the driver is familiar with) has its direction indicator stalk on the left of the steering wheel.
- The correct direction when entering a roundabout in a UFTR is clock-wise, not as it is on the keep-right traffic system (i.e. counter clock-wise).
- The correct direction of the traffic flow in a UFTR is the opposite of traffic flow in a keep-right traffic system.

In general, drivers become more aware of the driving environment when they manage to identify the information relevant to the task in rapid patterns to prepare themselves to make appropriate decisions and reactions. This helps the driver understand the relationship between the driving goal and other components of the traffic system at any moment in time [10]. Hence the driver will make fewer errors and avoid vehicle accidents. The information the drivers need can be provided to the drivers by In-vehicle Information Systems (IVISs).

C. Augmented Feedback in Driving

Augmented feedback is a form of technology that enhances the performance of a certain task by integrating computer-generated objects with the virtual or real environment [11]. It can be described as a set of stimuli whereby learners receive information from external sources in order to reinforce their behaviour and learning process [12]. The augmented feedback usually targets a task the operator is performing or going to perform in the future. Augmented feedback can be provided in different modalities, such as video, auditory or haptic in order to enrich the user's experience. In general, augmented feedback shows promising results with applications in various human situation, including driving [13], to enhance a number of related physical tasks. In driving, augmented feedback can be provided to drivers via in-vehicle information systems (IVISs).

IVISs are a form of technology that can support drivers by providing real-time feedback returned to drivers telling them what is going. The driver perceives the feedback from the system and understands it to make a decision, and refine or correct his/her driving reactions [14]. That keeps the drivers in the loop and thereby improving the drivers' SA and safety [15]. However, there is growing concern that IVIS might distract drivers from the primary driving task and thus compromise driving safety, as looking at the provided feedback consumes the driver's visual demand. The drivers are required to move their eyes back and forth between the road and the system. Additionally, there is a potential safety issue if the system provides drivers with unnecessary information, as it reduces driving performance [16], [17].

To reach the potential goal of IVISs, the system should provide only the important information. The driver does not need to capture the information that is irrelevant to the current or upcoming driving task. Additionally, the system should provide perceivable information (represents level 1). That is, the driver should not have to take his or her eyes off the road while glancing at the provided information. Also, the system must provide quick comprehensible information [18] (represents level 2). Unclear information might confuse the driver and affect his or her ability to make the correct reaction within the appropriate time. Moreover, the system should provide the information in a projectable manner (represents level 3). That is, the information helps the driver make a correct decision in relation to the upcoming situation. Understanding the drivers' needs of provided information are necessary to design the most useful system.

In relation to driving in a UFTR, the study [8] extracted the required information to drive safe at roundabouts and intersections. The information included upcoming area of the road to inform the driver about the upcoming roundabout and intersection, travelling path to inform the driver about the correct travelling lane when approaching, entering and exiting a roundabout/intersection, direction indicator to remind the driver of the correct position of direction indicator stalk, and speed to inform the driver about the speed limit of the travelling road. Visual feedback is selected by overseas drivers as the most preferable feedback modality to present that information when driving in a UFTR [19]. Therefore, in this research, we only focus on visual feedback provided by IVISs.

D. Visual Feedback in Roundabouts/Intersections In-Vehicle Information Systems

Becic et al., [20] investigated the effectiveness of an IVIS in reducing the number of crashes at a rural stop-controlled intersection in a keep-right traffic regulation. The system displays the upcoming intersection as arrows cross each others on either right or left display based on the traffic flow in the upcoming intersection. The arrows show the traffic direction without showing the required travelling lane the driver should travel within. Also, the information regarding direction indicator and speed limit is not provided to the drivers.

Zhang et al., [21] designed an IVIS that assists the driver when approaching a cross, "arch-shaped" intersection in a keep-left traffic regulation. The system provides visual feedback in a head-up-display (HUP) on the central-lower part of the windshield. The system shows the traffic status of upcoming intersection, leaving the drivers to slow down or make another proper reaction.

Tran et al., [22] studied driving performance at signalised turn-left intersections in a keep-right traffic regulation. In such a driving scenario, the driver does not have priority to turn left. He/she must cross the traffic flow coming from the opposite direction. Using a 3D HUP, the IVIS system visualises a three second projected path of the vehicle coming from the opposite side of the road. The path is presented in the driver's main field of view. As long as no vehicle is approaching the intersection, the system presents nothing to the driver. In other words, the system does not describe the situation until traffic exists in the upcoming area.

Caird et al. [23] designed a sign IVIS that visually provides two road signs "prepare to stop" and "signals ahead" on a HUD. These two signs inform the driver of an upcoming change in the road, but they do not provide a complete picture of what is coming next, leaving drivers to guess about whether the traffic light might be at an intersection, roundabout, or T-junction.

Alyamani et al., 2019 [24] extended the feedback designed in [19] and provided it to the international drivers when driving at a UFTR (see Figure 1). The feedback is presented on a HUD. The feedback includes up-coming section of road, either intersection or roundabout, the correct travelling path, direction indicator and speed limit to help drivers make proper decision and reaction when driving at a roundabout/intersection.

Table I compares different roundabout/intersection in-vehicle information systems according to feedback the system provides. Two of the works reviewed above support the drivers when driving in a keep-left traffic regulation. All the works reviewed above provide the drivers with feedback related to the upcoming section of the road either prior approaching all upcoming roundabout/intersection or only when traffic exists in the upcoming area. Feedback regarding travelling path is only supported totally in [24] and partially in [22]. None of the above works take into account presenting the direction indicator and speed except [24]. Accordingly, this research focuses on evaluating the usability of the feedback designed by [24] as will be described in the following section.

III. Testing the Usability of Required Feedback

A short questionnaire was developed to collect overseas drivers' opinions about the design of the feedback proposed by [24]. We particularly focused on presenting the feedback in a perceivable (level 1), comprehensible (level 2) and projectable (level 3) way. The proposed location of the target feedback was in the lower-central part of the windshield, using a HUD (level 1), the content included well-known symbols, icons and road signs (level 2) to help the driver make decisions about the required driving performance and behaviour (level 3).

A. Questionnaire Design and Procedure

An open recruitment process was adopted. Participants were recruited via an email that included the survey link. At the beginning of the questionnaire, information and instructions regarding driving at roundabouts and intersections in NSW, Australia, were presented. The questionnaire started by collecting demographic information, such as gender, age and driving experience in both keep-right and keep-left traffic regulations. Then, a GIF image of a vehicle driving in a simulated keep-left road was presented to give participants a better sense of driving in a keep-left traffic regulation, especially for those who were only familiar with a keep-right traffic regulation. Then, the participants were asked to answer the usability questions. Table II shows the list of questions, the target feedback and the rating scale. Each question included an image (see Fig. 2); participants were asked to observe the image and answer the question. The participants could add any comments after answering the question. Questions QA, QBs and QCs addressed the usability of the information in relation to its perceivability (level 1), comprehensibility (level 2) and projectability (level 3), respectively.

B. Participants

We distributed the online surveys to 65 participants, aged 19-52 with mean of 31.7 (SD: 1.1). The participants were only familiar with a keep-right regulation. All had a driver's license issued in their home keep-right country with a mean driving experience of 13.5 years (SD = 1.3) and drove in familiar regulations for an average of 19.7 hours/week (SD = 1.9).

C. Data Analysis

The usability questions were grouped into two categorical variables. Responses of the first question were categorised as 'easy', (including 'easy' and 'very easy') and 'difficult' (including 'very difficult' and 'difficult'). Responses to the second question were categorised as 'clear' (which included 'very clear' and 'clear') and 'not clear' (including 'not very clear' and 'not clear at all'). Responses to the third question were grouped into 'useful', (including 'very useful' and 'useful') and 'not useful' (including 'not very useful' and 'not useful at all'). Undecided responses were excluded. As we had one sample and categorical variables, we conducted a non-parametric test (i.e. one sample chi-square goodness-of-fit test) [25] to determine usability in relation to each question.

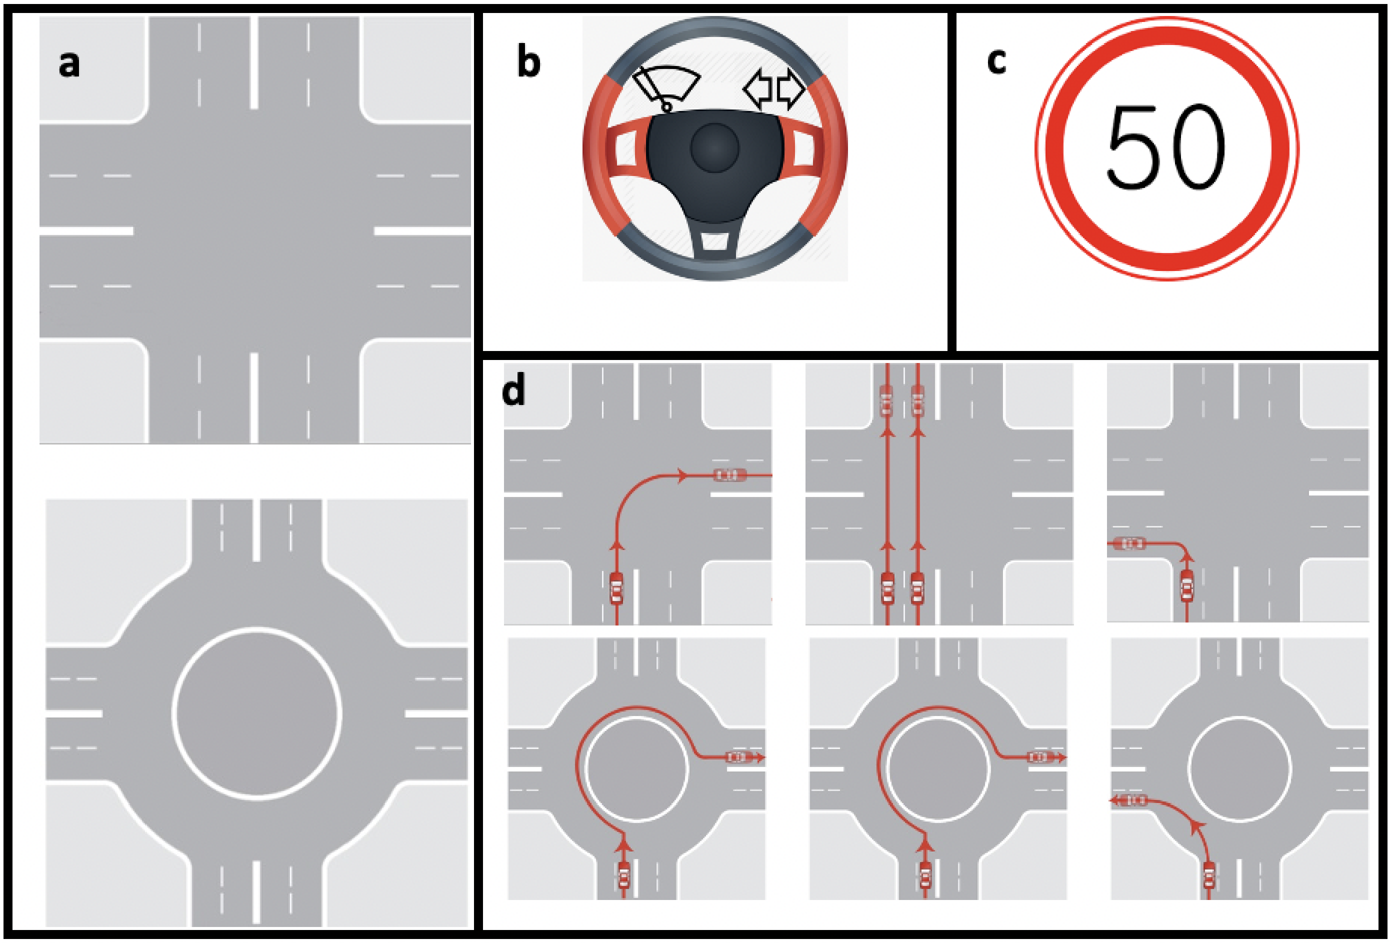

Fig. 1. Extended Design of Required Feedback to Support Overseas Drivers when Driving in Roundabouts and Intersections [24]. The Feedback Include a) the Upcoming Section of the Road, b) using the Direction Indicator,c) Speed Limit and d) Travelling Path).

D. Results

In relation to the first question, 44 participants thought feedback presented on the lower-central part of the windshield using a HUD was easy to perceive whereas 10 participants thought it was difficult (see Table III). The minimum expected frequency was 27.0. The difference was statistically significant $(\chi^2(1) = 21.407, \rho < .001)$.

The majority of participants (55) thought the upcoming area feedback clearly described the conditions of the upcoming area; only 2 participants did not think it was clearly described. The minimum expected frequency was 25.5. The difference was statistically significant, $\chi^2(1) = 49.281, \rho < .001$. On the other hand, 27 participants thought the upcoming area feedback could help them make a decision regarding the required reaction or performance at the upcoming roundabout or intersection, while 24 participants thought this feedback could not help them do so. The minimum expected frequency was 25.5. The difference was not statistical significant $(\chi^2(1) = .176, \rho = .674)$.

Most participants (56) thought that the combination of upcoming area and travelling path feedback clearly described the situation; only 3 participants found that this combination did not clearly describe the situation. The minimum expected frequency was 29.5. The difference was statistically significant$(\chi^2(1) = 47.610, \rho < .001)$. Similarly, 59 participants thought that presenting upcoming area and travelling path feedback was useful for planning the required reaction at the upcoming section of road; only 2 participants thought it was not useful. The minimum expected frequency was 30.5. The difference was statistically significant $(\chi^2(1) = 53.262, \rho <$

TABLE II. QUESTIONS TO EVALUATE THE USABILITY OF NECESSARY FEEDBACK

Q#	Question	Target feedback	Rating scale
QA	How easy is it to perceive the feedback in the image below?	All	'very difficult', 'difficult', 'normal', 'easy' and 'very easy'
QB1	How well does the feedback describe the situation shown in the clip above?	Upcoming area	'not clear at all', 'not very clear', 'normal', 'clear', 'very clear'
QB2	How well does the feedback describe the situation shown in the clip above?	Upcoming area + travelling path	
QB3	How well does the feedback describe the situation shown in the clip above?	Upcoming area + direction indicator	
QB4	How well does the feedback describe the situation shown in the clip above?	Upcoming area + speeding	
QC1	How useful is the feedback helping you make decisions about the required performance at the upcoming roundabout/intersection?	Upcoming area	'not useful at all', 'not very useful', 'normal', 'useful', 'very useful'
QC2	How useful is the feedback helping you make decisions about the required performance at the upcoming roundabout/intersection?	Upcoming area + travelling path	
QC3	How useful is the feedback helping you make decisions about the required performance at the upcoming roundabout/intersection?	Upcoming area + direction indicator	
QC4	How useful is the feedback helping you make decisions about the required performance at the upcoming roundabout/intersection?	Upcoming area + speeding	

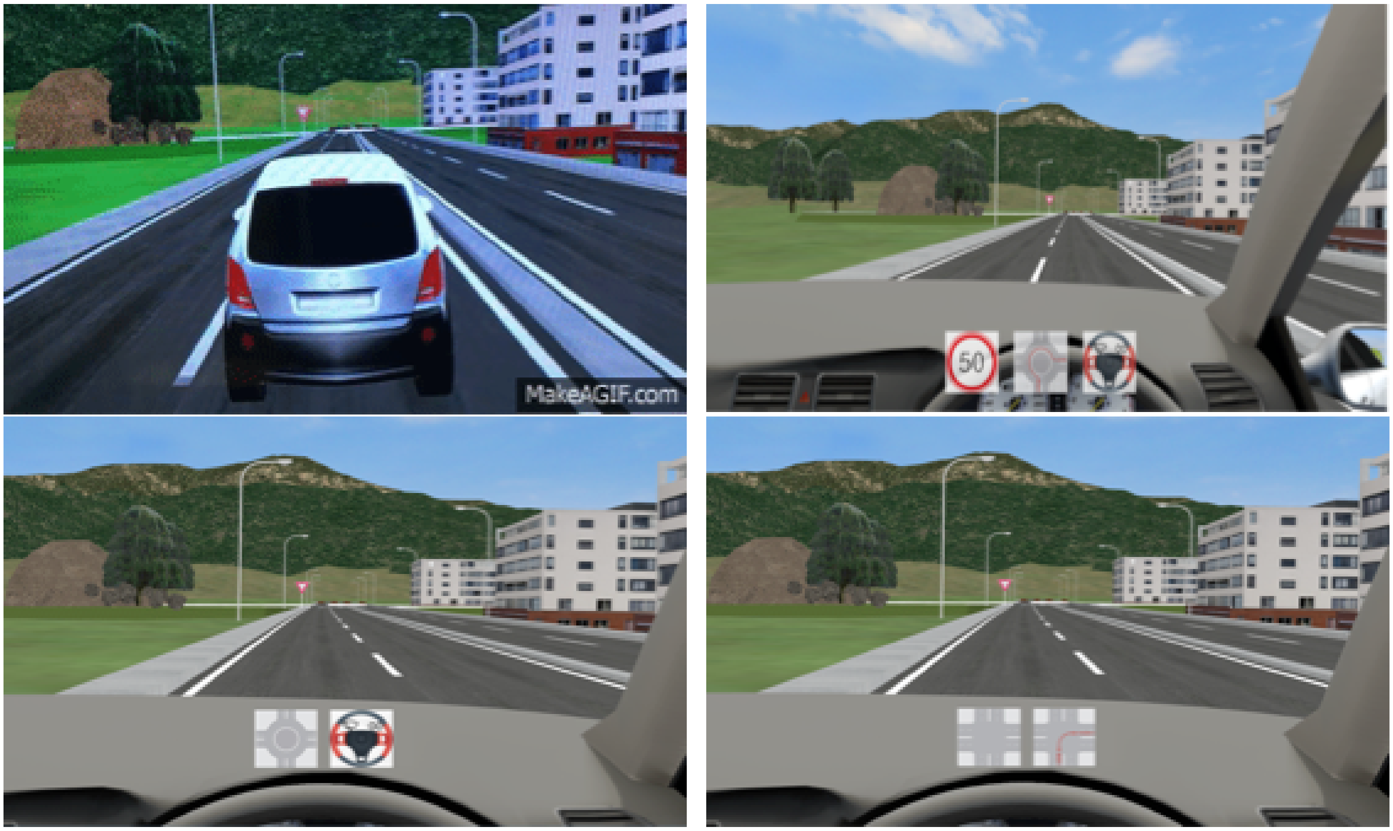

Fig. 2. Some Images used in the Usability Questionnaire.

TABLE III. POSITIVE AND NEGATIVE RATINGS FOR EACH QUESTION

Question	# of 'easy' responses	# of 'difficult' responses	$\chi^2(1)$	p
QA	44	10	21.407	$<$ .001*

Question	# of 'clear' responses	# of 'not clear' responses	$\chi^2(1)$	p
QB1	55	2	49.281	$<$ .001*
QB2	56	3	47.610	$<$ .001*
QB3	47	10	24.018	$<$ .001*
QB4	57	5	43.613	$<$ .001*

Question	# of 'useful' responses	# of 'not useful'	$\chi^2(1)$	p
QC1	27	24	.176	=.674
QC2	59	2	53.262	$<$ .001*
QC3	39	12	14.294	$<$ .001*
QC4	62	0	-	-

* Statistically significant.

.001).

In relation to upcoming area and direction indicator feedback, 47 participants thought this combination clearly described the situation, whereas 10 participants thought it did not. The minimum expected frequency was 28.5. The difference was statistically significant, $\chi^2(1) = 24.018, \rho < .001$. In addition 39 participants thought it was useful to plan the required reaction using both upcoming area and direction indicator feedback together, whereas 12 participants thought it was not useful to do so. The minimum expected frequency was 25.5. The difference was statistically significant ($\chi^2(1) = 14.294, \rho < .001$).

In relation to a combination of upcoming area and speeding feedback, 57 participants thought presenting upcoming area and speeding feedback together clearly described the situation, while 5 participants thought it did not. The minimum expected frequency was 31.0. The difference was statistically significant ($\chi^2(1) = 43.613, \rho < .001$). 62 participants thought it was useful to plan the required reaction using that combination of feedback; no participant thought it was not useful to do so. The chi-square goodness-of-fit test could not be performed as the variable was constant (there was no value for the 'not useful' group).

E. Discussion

A significant percentage of participants (67.7%) reported that feedback displayed on a HUD was easy to perceive. Therefore, we should present the target feedback on a HUD. A significant percentage of participants (84.6%) also thought that providing only upcoming area feedback (i.e. static feedback) clearly described the upcoming situation. However, there was insignificant difference between the percentage of participants (41.5%) who reported that upcoming area feedback was useful for directing the driver to make the proper decisions at the upcoming section of road and those who did not (36.9%).

Participants were confused about the required reaction due to their unfamiliarity with the keep-left traffic regulation, even the driving rules at roundabouts and intersections were explained at the beginning of the questionnaire. On the other hand, a significant percentage of participants thought that combining upcoming area information with any of the other forms of dynamic feedback (i.e. travelling path, direction indicator and speed) clearly described the situation and was useful for making appropriate decisions at an upcoming section of road. In fact, 86.2%, 72.3% and 87.7% of participants found that the combination of upcoming area and travelling path, upcoming area and direction indicator, upcoming area and speed, respectively, clearly described the situation of the upcoming section of road. Also, 90.8%, 60.0% and 95.4% of participants found the combination of upcoming area and travelling path, upcoming area and direction indicator, upcoming area and speed, respectively, was useful for making appropriate decisions at an upcoming section of road. Hence, we recommend providing static feedback supported by dynamic feedback. The static feedback functioned to describe provided the upcoming situation while dynamic feedback supported decision making.

In relation to a combination of upcoming area and travelling path feedback, four participants (6.2%) who responded that this combination was clear and useful recommended that we use only travelling path instead, as travelling path was shown on the roundabout and intersection. Two participants (3.1%) who were undecided about the clarity and usefulness of this combination found the simultaneous presentation confusing. One participant (1.5%) who had a negative response regarding the clarity and usefulness of that combination commented: "I do not know if I will drive through one or two roundabouts" and "should I follow the line at first and second roundabout?" As a result of the wider potential for such confusion, we would follow the recommendations we received from participants and only provide travelling path feedback when it was necessary.

IV. EFFECTIVENESS EVALUATION

The study evaluates the effectiveness of the feedback mentioned above for improving the road safety, particularly for drivers who are not familiar with driving in a UFTR.

A. Method

1) Participants: The study involved twenty international participants. The participant age range was 20-35 years with a mean age of 24.2 years ($SD = 2.7$). All participants were unfamiliar with a keep-left traffic regulation and right-hand drive vehicle. They each had a driving license of their home country with a mean driving experience of 5.9 years ($SD = 3.3$). They drove in average 14.7 hours/week ($SD = 9.0$).

2) Apparatus: The experiment was conducted on the Forum8 drive simulator, which is a fixed-based simulator. It represents a right-hand drive vehicle with three 42-inch monitors, creating a 150 degree horizontal and 30 degree vertical field of view. The monitors display the central and peripheral visual fields to the driver. UC-win/Road was used as software to model the traffic system in addition to locating the visual feedback on of the monitors. The driving data (e.g., speed, brake and steering wheel angel) was recorded for future analysis.

3) Driving Track, Scenario and Tasks: Using Forum8, the participants drove in a simulated keep-left traffic system (see Fig. 3- (a)). The driving track was similar to the track designed in [24]. The track included dual-lane roads crossed each other in three roundabouts and intersections. Participants were asked to drive in a certain direction, which forced them to drive through all roundabouts and intersections, each time with a different direction (left, right, and forward). Participants were asked to drive appropriately at those roundabouts and intersections following the Australian rules (see Section II-B).

4) Procedure: The experiment had three sessions - pre-experiment, preparation and two driving tests. In the pre-experiment session, participants were asked to complete an initial computer-based questionnaire. It was used to collect demographic information and driving experience data. In the preparation session, the driving simulator, Forum8, was introduced. Participants were verbally informed about the upcoming session and the Australian traffic rules, focusing on the rules for driving at roundabouts and intersections. In addition, they received a quick explanation of differences in vehicle configuration, such as the position of the wiper and direction indicator stalk, whereas the direction indicator stalk of a right-hand drive vehicle is placed the other way around. Then, participants were driving in a built-in test scenario for 10 minutes in order to familiarise themselves with the driving simulator. This scenario was supported by Forum8 and represented a keep-left driving environment. The scenario followed a route that differed from the test route to minimise the learning effect. During the familiarisation test, the researcher answered any questions participants might have. Participants had a 5-minute break after the familiarisation test while the researcher prepared the simulation for the driving test.

The third session (i.e. driving tests) had two driving trials - “Control” (no feedback offered) and “Experimental”, (providing feedback). The researcher randomly divided the 20 participants into two similar sized groups (10 participants each). Both groups participated in both trials. However, the order of the two trials was randomised between them in order to reduce the learning effect. Whereas the first group started with the control trial, the second group started with the experimental trial. There was a one-hour break between the two trials. Each driving test took around seven minutes to complete. The session started with providing the participants with a map of the driving track that indicated the direction the driver should follow (see Fig. 3- (b)). Participants took approximately three minutes to study the map. Then, they were asked to complete the driving tasks of each trial without making driving errors. In the experimental trial, participants did not receive any information regarding the feedback they would receive.

5) Data Collection and Analysis: Two log files (video and CSV) were generated by the simulator for each participant and for each trial. Both log files had data on driving performance. For each trial, we observed the following driving errors:

Error 1 Driving in an incorrect lane when approaching the roundabout and the intersection.
Error 2 Not indicating the target direction when approaching the roundabout and the intersection.
Error 3 Speeding while approaching the roundabout and the intersection.
Error 4 Driving in the incorrect direction of traffic flow inside the roundabout/intersection.
Error 5 Driving in an incorrect lane when exiting the roundabout and the intersection.

The number of the above errors that occurred at all roundabouts and intersections was calculated. The Wilcoxon signed-rank test was run to compare the number of each error in the experimental trial versus the control trial.

B. Results

Overall, the total number of errors among participant of each error type decreased when the feedback was provided. The difference in number of each driving error with and without providing feedback among participants was not normally distributed (see Table IV). For instance, the difference of driving in an incorrect lane when exiting the roundabout/intersection (Error 3) had a skewness of 1.032 (0.512) and a kurtosis of -0.230 (0.992). Thus, a non-parametric test (i.e. Wilcoxon signed-rank test) was employed to investigate differences between the driving errors before and after providing feedback.

Wilcoxon signed rank test (see Table V) showed that the numbers of Error 1, Error 2, Error 3 and Error 4 when providing augmented feedback were statically significantly fewer than than the numbers of those errors when augmented feedback was not provided ($Z = -2.648$, $p = .008$), ($Z = -1.998$, $p = .046$), ($Z = -2.167$, $p = .030$), and ($Z = -2.266$, $p = .023$), respectively. On the other hand, Wilcoxon signed rank test indicated that the number of Error 5 when providing augmented feedback was insignificant fewer than the number of Error 5 when the augmented feedback was not provided to participants ($Z = -1.642$, $p = .101$.).

C. Discussion

In general, presenting perceivable, comprehensible and projectable feedback significantly assisted the drivers who are not familiar with driving in a keep-left regelation to approach and enter roundabouts and intersections in a UFTR.

One participant mentioned indicating the target direction was very difficult as the direction indicator stalk is located on the right side of the steering wheel not on the left as it is on the vehicle that he used to drive in my home country. However, presenting perceivable, comprehensible and projectable direction indicator feedback significantly reduced the number of using improver direction indicators when approaching roundabouts and intersections ($Z = -1.998$, $p = .046$). One participant commented: ”it was easier for me to look at the indicator feedback instead of looking at the real stalks to find out which is the correct stalk to use, the right or the left”. Another participant mentioned that direction indicator feedback corrected him when he used the wiper indicator instead of direction indicator.

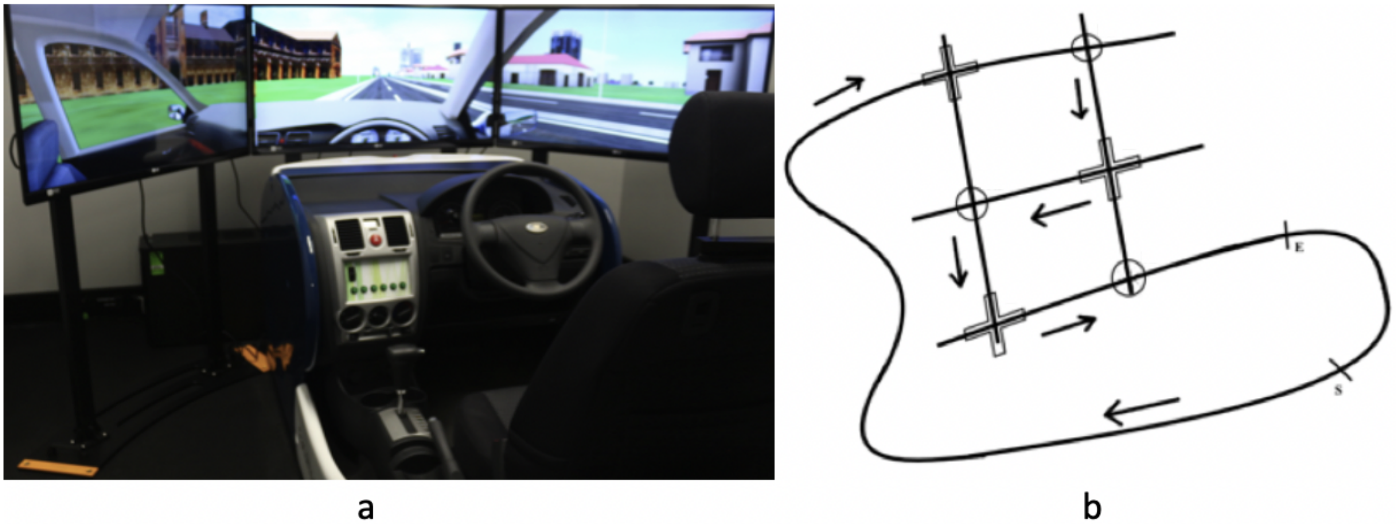

Fig. 3. (a) Forum8 (b) The Start and End Points and Required Direction on the Driving Track. Adapted from [24].

TABLE IV. Results of Normality Tests for the Difference in Number of Each Error Type with and without Feedback

Error	Shows (SE)	Kurtosis (SE)	Error	Shows (SE)	Kurtosis (SE)
Error 1	-2.573(0.512)	9.386(0.992)	Error 4	1.032(0.512)	-0.230(0.992)
Error 2	0.992(0.512)	1.712(0.992)	Error 5	-0.120(0.512)	-0.088(0.992)
Error 3	0.991(0.512)	0.263(0.992)			

TABLE V. Number of Driving Errors Grouped by Error Type with and without Feedback Support

Error	Number of errors (Control trial)	Number of errors (Experimental trial)	Difference	Z	p
Error 1	20	5	-15	-2.648	.008*
Error 2	17	11	-6	-1.998	.046*
Error 3	34	18	-16	-2.167	.030*
Error 4	15	1	-14	-2.266	.023*
Error 5	39	28	-11	-1.642	.101

* Statistically significant.

The correct direction when entering a roundabout in a UFTR is clock-wise, not as it is on the keep-right traffic system. In addition, the correct direction when entering an intersection in a UFTR is the opposite side of the road that the driver is familiar to use when driving in a keep-right traffic system. That might lead the drivers to make improper decision when approaching roundabouts and intersections in a UFTR. For instance, in case of approaching a roundabout, if the driver does not realise those changes in traffic rules, the driver might approach the roundabout using improper travelling lane. Also, the driver might enter the roundabout from the wrong direction. However, presenting perceivable, comprehensible and projectable travelling path significantly reduced the cases of approaching the roundabouts and intersections from incorrect lane ($Z = -2.648$, $p = .008$) and entering roundabouts and intersections from the incorrect direction ($Z = -2.266$, $p = .023$). One participant mentioned that travelling path feedback was very clear and understandable and that helped him to recognize the correct travelling path.

On the other hand, controlling the speed of the vehicle is a task that is not changed when driving in a familiar and unfamiliar traffic regulation. That is, the driver does not require to adapt his or her speeding behaviour when driving in a UFTR. However, presenting perceivable, well-known and projectable speeding feedback helped the drivers to significantly reduce their speed when approaching the roundabouts and intersections ($Z = -2.167$, $p = .030$). This result might be influenced by providing other information next to speed feedback. Other studies [20], [21], [22], [23] managed to reduce the drivers' speed without presenting speed feedback. More research is needed to explore the exact feedback that assisted the drivers to slowdown.

V. Conclusion

In this paper, we presented the results of a quantitative study that subjectively investigated the usability of augmented visual feedback that designed to help the drivers when driving at roundabouts and intersections in an unfamiliar traffic regulation (i.e. a keep-left traffic regulation using a keep-right drive vehicle). The usability was evaluated based on the situation awareness levels. That is, the information should be designed in a perceivable, comprehensible and projectable manner. Sixty-five participants who were not familiar with an Australian traffic regulation answered the online survey. The results enhanced the ability of the driver to capture the provided information, understand it and plan appropriately for the required driving reaction.

Then, another twenty participants who were not familiar with an Australian traffic regulation participated in an empirical study. The participants drove with and without providing the feedback in a simulated keep-left traffic environment using a driving simulator (i.e. Forum8). The study aimed to evaluate the effectiveness of the perceivable, comprehensible and projectable feedback in reducing the driving errors and thus improving the road safety. The results confirmed our hypothesis that considering the SA levels when designing the feedback can significantly reduce the driving errors when reaching and entering roundabouts and intersections and thus enhance road safety in a UFTR.

The current work focused mainly on driving at roundabouts and intersections in a UFTR. Thus, the work was limited by feedback that provided for a particular driving task. Another limitation was that presenting the visual feedback in accordance with SA levels was evaluated in a specific driving condition (a fine weather with no traffic movement).

The current work can be extended to cover the following points:

- Evaluate the usability of further feedback that designed to assist the drivers in different driving tasks, such as lane-changing and parking.
- Evaluate the effectiveness of the feedback in other driving conditions, such as rainy and traffic jam.

An Interactive Tool for Teaching the Central Limit Theorem to Engineering Students

Anas Basalamah
Department of Computer Engineering
Umm Al-Qura University
Makkah, Saudi Arabia

***Abstract*—The sole purpose of this paper is to guide students in learning the introductory statistical concepts, such as, probability distribution and the central limit theorem (CLT) in an intuitive approach through an interactive tool. When a used data has different probability distributions, this paper intends to clarify the notions of the CLT and the use of samples in the hypothesis testing of a population by demonstrating step-by-step procedures and hands-on simulation approach. This paper discusses the relationship between the sample size and the nature of the sampling distribution, which is a vital element of the CLT, in different population distribution using the developed interactive tool. Finally, the impact of the developed interactive tool is measured via a survey experiment that illustrated the success of the developed tool in teaching the CLT.**

***Keywords*—Probability distribution; CLT; population; interactive tool; sampling distribution**

I. Introduction

The fundamental concept of statistics field in which students more often face difficulties to understand is the central limit theorem (CLT). The CLT provides an overview of using random sampling method for making an inference about any population. Therefore, it is considered as a vital concept in inferential statistics, a critical knowledge for any statistician, and one of the foundation concepts of any statistics course. In [1], authors highlighted to focus on developing the ideas of central statistics before moving on to the set of tools and procedures. The CLT is one of the central ideas of statistics. While learning it, students get puzzled more often to interpret the theory and implication of this important concept. This paper aims to create an engaging way of teaching and learning the theory and implication of the CLT for both teachers and students through explanation, simulation, and visualization. We built an web application (interactive tool) using html, css, and javascript for generating and visualizing the uniform, normal, positively skewed, and negatively skewed distribution with corresponding sampling distribution.

Students can collaborate by selecting their desired distribution, sample size, and number of samples during the simulation process in the class for giving them a part of the simulation process and creating an engaging environment in the class. Students can select different sample size and number of samples for a particular distribution that enables them observing the changes of sampling distribution more closely with the changes of these parameters. It helps the student to understand the impact of sample size on the sampling distribution. The sampling distribution is the probability distribution obtained from a large number of samples, which are drawn from a particular population. It is the distribution of frequencies of all possible outcomes that could occur for a statistics of that particular population.

The pedagogical approach taken in this paper for teaching CLT is different comparing to the other approaches because of the features of the developed interactive tool, which creates an engaging environment for the students and ensures students participation alongside to make the understanding of the CLT clear to the students.

The remaining part of this paper is organised as the following: Section II discusses the background and motivation of this research topic along with the literature review, Section III studies the concept of the central limit theorem and different probability distributions, Section IV describes the importance of the central limit theorem, Section V shows the empirical demonstration of the CLT with the help of visualization using the interactive web-application tool, Section VI investigates the impact of the developed tool in teaching the CLT in the classroom, and Section VII concludes the paper.

II. Background

To make valid statistical interference about the concept of the CLT and sampling distribution, students must get the opportunity to draw multiple samples [2]. This paper is highly motivated by the recommendation given in [2], hence it incorporates multiple samples in simulation to clear the logic of the CLT to the students. The simulation provides a realistic scenario to the students for intuitively understanding these concepts. Although, simulation is not exempt of issues [3], but it is the best way of teaching the CLT to the students.

In [4], [5], the authors investigated that the concept of CLT is not only difficult for the non-math major students, but also for math major students. They added that the central limit theorem is the most vital result conveyed theorem in the introductory statistic course since it includes many of the statistical inferences that are required for the later part of the course. Although, students are lost more often in understanding the logic behind the CLT. Therefore, it becomes a necessity presenting the concept in a intuitive way through simulation such that it can be easily understandable to the students.

Interactive learning experience has always been considered as the most effective pedagogical tools [6], [7], [8], [9], [10], [11] and the use of interactive environment is considered as the effective way of learning and visualizing a complex theory. There are a large number of simulation tools and online applets for learning the CLT as well [12], [6]. Most of these simulated environments has complex interface, requires knowledge of programming, and has complex procedures, which makes students less attractive to these simulation applets. The time spent to these applets for understanding different distributions and the CLT is comparatively higher and less engaging. The sampling distribution of any given population always follows normal distribution. To clear this concept, this paper brings all the distributions along with various sample sizes together in a single interface without showing the background codes that helps students get the idea easily in the shortest time. This paper intends to bring a simulated interactive teaching applet, which can be used both online and offline by the students and can meet all the above criteria.

In sum, the above stated context motivates us working on the same problem and providing a more interactive method of teaching CLT to the students. The interactive tool designed for the students has an interactive interface that allows the students to take different size and different number of samples iteratively for plotting their respective sampling distribution. As a result, students get an overview on how the estimated means of different samples with a particular sample size get centralized and form a bell-shaped curve, which is the principle of the CLT. The following section investigates different probability distribution and the concept of the CLT along with its properties.

III. Population Distributions, Sampling Distribution, and the CLT

A. Population Distribution

The central limit theorem states that the sampling distribution of a given population forms a bell-shaped curve or follows normal distribution regardless the variable's distribution in the population. The distribution of a variable can follow different probability distributions, i.e. uniform distribution, normal distribution, positively skewed distribution, and negatively skewed distributions (see in Fig. 1).

The distribution of a variable is the distribution of the random sample that is drawn from the population. The CLT acts on all the probability distribution that have a finite variance. Therefore, the CLT cannot be applied on Cauchy distribution because of having infinite variance. In addition, the CLT acts on independent and identically distributed variables, where the value of a particular variable does not depend on the values of other variables. But the distribution of all these variables must remain constant throughout the measurement process.

B. Sampling Distribution

The sampling distribution is the mean of the randomly drawn samples from the population. For example- lets assume that someone draws a sample with a fixed sample size from a given population, then calculates its mean and plots it on a histogram. If this process in repeated many times, the produced histogram displays the distribution of the sample mean. This mean distribution is considered as the sampling distribution in statistics.

The shape of the sampling distribution depends on the sample size and number of samples. For different sample size the shape of the sampling distribution differs. Similar observation found with the number of samples. The following sections discusses these phenomena in detail.

C. The Central Limit Theorem

The central limit theorem states that the sampling distribution of sufficiently large size of samples drawn with replacement from a given population that has the mean μ and standard deviation σ, will form an approximated normal distribution curve. This statement is true regardless the distribution of the population. Usually, a sufficiently large sample size is the samples having size of 30 or more ($n \geq 30$). If the population distribution is normal, the CLT is true for smaller size of samples as well. If the population distribution is strongly skewed, it may require larger size and number of samples. The relationship between the sample size and the shape of the sampling distribution is clarified in section V.

Also, the CLT statement holds correct for the binomial population distribution, provided that $min(np, n(1-p)) > 5$, where p is the probability of success and n is the sample size. As a result, normal probability distribution can be used to quantify uncertainty for making inferences about a population mean.

1) Properties of CLT: There are two attribute of any distribution, namely- the mean (μ) and the standard deviation (σ). The sampling distribution converges the normal distribution, when its mean is equal to the population mean and the standard deviation is $\sigma/\sqrt{n}$. The standard deviation σ decreases by $\sqrt{n}$ with the increment of the sample size n.

In sum, the sampling distribution approximates the normal distribution with the increment of sample size and the spread of the distribution suppressed. These properties have significant implications, which will be discussed in the later sections of this paper.

IV. Importance of the CLT

The central limit theorem is important because of the following to reasons, namely- normality assumption and precision estimates.

A. CLT and the Normality Assumption

The normality assumption is very essential in statistics for parametric hypothesis testing of the mean, i.e. t-test. The CLT supports the assumption as it states that the sampling distribution of any population can approximate a normal distribution. This critical implication of the CLT allows the hypothesis testing even if the data is non-normally distributed. However, the testing is allowed if and only if the sample size is large enough. Because, a non-normally distributed data also behaves like a normal distribution for larger sample size.

Moreover, parametric tests of the mean are robust from the normality assumption when the sample size is sufficiently large. This is also a contribution of the central limit theorem.

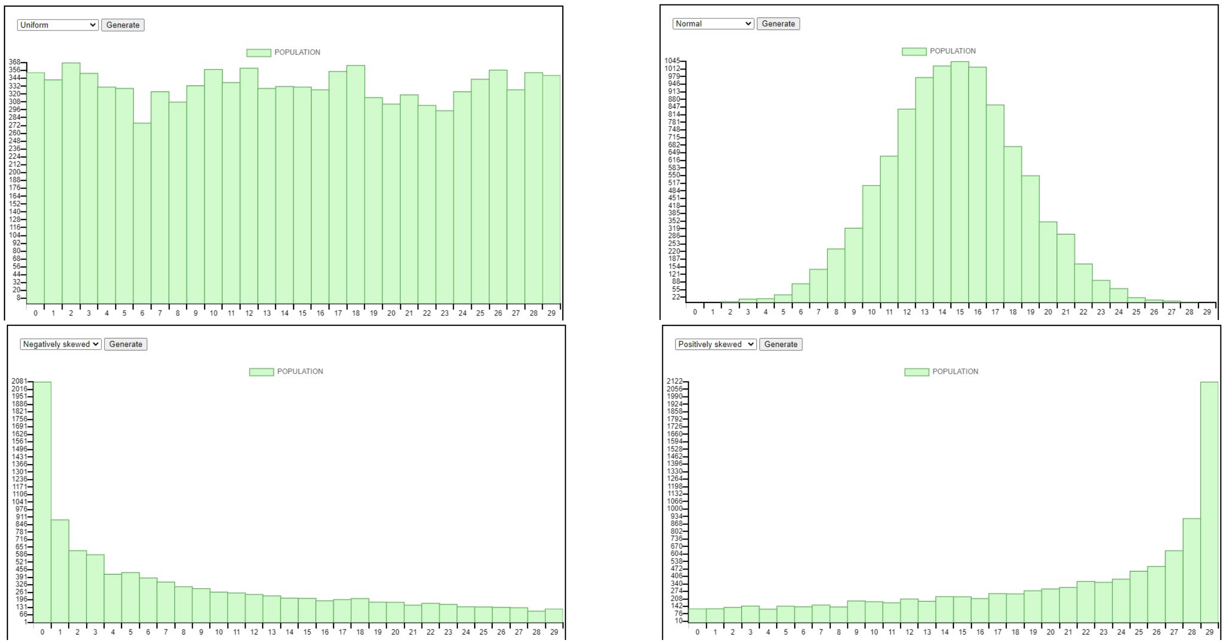

Fig. 1. Different Population Distributions, Namely- uniform, Normal, Negatively Skewed, and Positively Skewed Distribution.

B. Precision of Estimates

In all the figures, the sampling distribution of the mean clusters around the population and becomes denser as the sample size increases (see in Fig. 2, 3, and 4). This property of the Central Limit Theorem is relevant when using samples to estimate the mean for the entire population. The larger the sample size, it is more likely that the sample mean will be closer to the actual population mean. In other words, the estimate is more accurate.

On the other hand, the sampling distribution of the mean is much wider for smaller sample sizes. When the sample size is small, it is not uncommon for the sample mean to be away from the actual population mean. In this case, the estimate will be less accurate. Finally, understanding the Central Limit Theorem is important when relying on the validity of the results and assessing the accuracy of the estimation. We should use a large sample size to meet the normality assumptions and get more accurate estimates even if the data is non-normally distributed.

V. Empirical Demonstration of CLT

This section demonstrates the central limit theorem with respect three different different population distribution, namely- uniform distribution, normal distribution, and severely skewed distribution. For illustrating the impact of CLT on severely skewed distribution, we consider the negatively skewed distribution. All the population distributions taken for the demonstration are shown in Fig. 1.

A. The CLT with Uniform Distribution

At first, we consider the uniform distribution shown in Fig. 1. We take the sampling frequency distribution for the sample size less than 30 and greater than 30 in Fig. 2, respectively. We observe that the obtained sampling distribution for the sample size of 10 is ranging from 6.9 to 22.7, whereas the sampling distribution for the sample size of 30 ranges from 6.9 to 22.7. Besides, the shape of the sampling distribution is more normal using the sample size 50 comparing to the sample size 10.

Therefore, we can conclude that if we increase the sample size, the sampling distribution gets more tighten and centralized in uniform distribution.

B. The CLT with Normal Distribution

Similarly, we check the behaviour of sampling distribution using a normal distribution that is depicted in Fig. 1. We consider sample size of 10 and 50, respectively, and observed the similar conclusion as uniform distribution. The demonstration of CLT using normal distribution is depicted in Fig. 3. We observe that the obtained sampling distribution for the sample size of 10 is ranging from 11.1 to 17.9, whereas the sampling distribution for the sample size of 30 ranges from 12.68 to 16.48.

Hence, it is clear that the sampling distribution for larger sample size is more centralized comparing to the smaller sample size. We further observe that sampling distribution for the normal population using sample size of 10 is more tighten and centralized comparing to the sampling distribution of uniform population using sample size of 50 (see in Fig. 2 and Fig. 3).

C. The CLT with Skewed Distribution

Finally, we take a highly skewed population distribution, i.e. negatively skewed distribution depicted in Fig. 1, for testing the sampling distribution behaviour and investigating the CLT. The same process is followed for the skewed population analysis as before. Two sample size of 10 and 50 are considered. The obtained sampling distribution figures for both the sizes

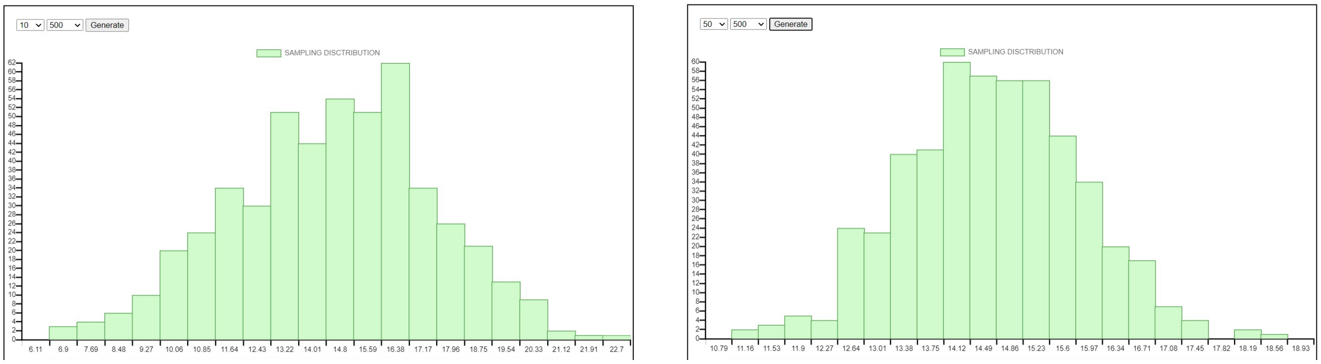

Fig. 2. The Central Limit Theorem Explained with Uniform Distribution.

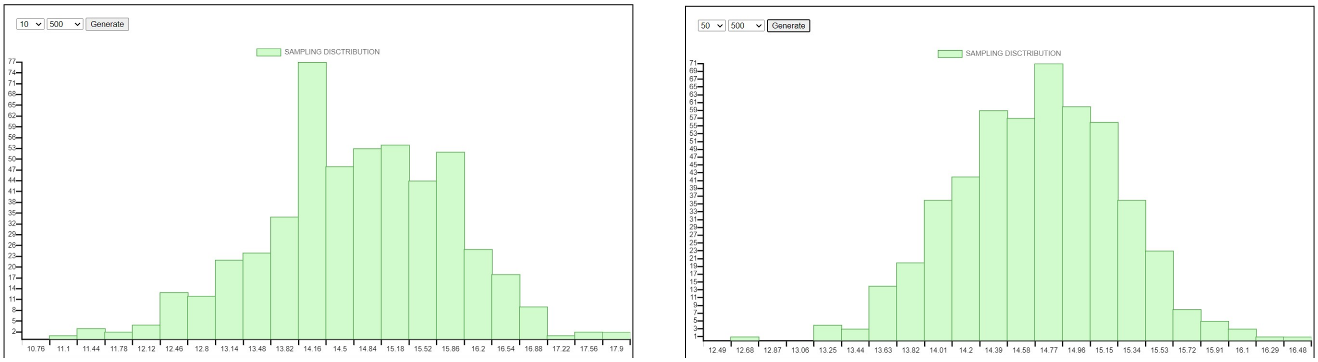

Fig. 3. The Central Limit Theorem Explained with Normal Distribution.

are depicted in Fig. 4. Similar observation is found, i.e. if the sample size increases the obtained distribution gets tightened and the shape approximates a normal bell-shape.

The range of sample mean obtained for the size 10 is from 1.6 to 16.6 and for the size 50 is from 4.92 to 11.92, which supports the previous statement and justifies the central limit theorem.

VI. Impact

We have developed an interactive teaching applet using HTML5, CSS, and Java-script. The interactive tool is a dynamic, responsive, and device independent web-application that can be opened by double clicking on the index html file. Students only need to have a web-browser installed in their device. The teaching applet has a attractive and simple user interface, where user can generate different population distributions, can select random samples of different sizes, and can plot their sample mean. Student can add a single sample to the sampling distribution iteratively or can add large number of samples at a time, which enables them to visualize the changes occurred in the sampling distribution after adding each sample to the sampling distribution. Students can easily absorb the motto of the CLT by watching how the sampling distribution becomes tightened after the addition of new sample means to the distribution.

We observed that all the students got the gist of the CLT easily after taking the class with the help of the developed interactive teaching applet. Therefore, we can claim that the interactive tool developed by us can successfully be used during the teaching/learning process of the CLT.

VII. Conclusion

This paper intends to provide a simulation based overview of the central limit theorem, which intuitively helps the students for cracking the concept. The relationship of the sample size and the sampling distribution is well illustrated throughout the empirical analysis section, which is an essential concept for the students as they go deep into their statistics course. The last section shows the impact of this study and the developed interactive tool about how well the students were able to absorb the concept after using the developed tool.

Improving the Effectiveness of e-Learning Processes through Dynamic Programming: A Survey

Norah Alqahtani[1], Farrukh Nadeem[2]
Department of Information Systems,
Faculty of Computing and Information Technology
King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—E-learning has been widely adopted as an important tool for distance education, especially in these days of pandemic Covid-19. However, several problems/challenges have been reported in different processes of e-learning that need to be addressed for effective use of e-learning. These problems/challenges include development of student focused contents, giving learner partial control, addressing different learning styles, etc. Recently, several efforts have been made to solve e-learning process problems using dynamic programming techniques. Dynamic programming techniques divide a problem situation into several subproblems and dynamically solves each sub-problem based on student needs. Thus it allows student focused customization at each step and provides adaptive e-learning to support students with different capabilities. The objective of this study is to review different e-learning problems and challenges and how those can be addressed using dynamic programming techniques. We conclude by highlighting the importance of different dynamic programming techniques for different processes of e-learning.**

Keywords*—*e-learning; e-learning challenge; dynamic programming

I. Introduction

Developments in information and communication technology (ICT) have introduced E-learning programs which can be employed efficiently as an alternative to allow users to learn and teach new technologies and courses. E-learning refers to knowledge that uses electronic technology beyond the traditional classroom to access curricula. It can be applied to a course, program, or diploma that is entirely online [1]. E-Learning online courses are available 24/7, regardless of the time of day, accessible and reliable educational resources to students in geographically spread regions and time zones. This type of delivery enables the portability of training (i.e., tablet/iPad, laptop, cell phone for files or video assessments and links to webinars, etc.), allowing for easy learning on the go, particularly with the growth of networks, mobile use, and learning via computers or laptops [2]. There are numerous e-learning systems and methods (known as learning management systems) that can be used to conduct online courses. Given the right tools, various processes can be automated, such as scoring or viewing reading materials. E-learning is often the most efficient way to adapt the learning to people's busy lifestyles, allowing individuals to gain new skills and develop their careers. In recent days, the importance of e-learning has been recognized, as the COVID-19 pandemic crisis has made e-learning mandatory in all institutions of learning such as schools, colleges and universities throughout the world [3]. In fact, The problems of e-learning can be summarized in five major issues such as: struggle for adaptability, technical problems, computer literacy, time management, and self-motivation. Therefore, Many methods have been used to improve the e-learning process that has helped to improve this area and increase its level of effectiveness; one of these methods is Dynamic Programming (DP). Dynamic programming techniques which are ideal for embedded systems are increasingly comparable to adaptive control techniques for dynamic systems. A growing number of researchers are inspecting and studying dynamic programming (DP) algorithm-based learning systems to solve and fix stochastic ideal control problems, arguing that DP provides the proper basis for combining planning results into real-time reactive dominance techniques, as well as for learning these techniques when the managed system is incompletely understood. This paper reviews how the DP is contributing to solving some of the problems in the field of e-learning through various studies. This paper's structure is as follows: as an introduction, we first present the definition of the DP and then provide a description of the DP. Next, the role of the DP in improving learning is discussed. The fifth section is a comparative analysis that concludes the studies presented in this paper, and the final section concludes the article.

II. Dynamic Programming

Dynamic programming allows to overcome an optimization problem (e.g. optimizing, decreasing, or finding the total number of ways to do something). It is defined as a quantitative technical analysis that has been used for fundamental and sophisticated problems that require a series of decisions to be made [4]. In [4], the authors defined DP as one of the algorithms used to find the ideal value of a problem. This problem's solution is decomposed into several steps (subproblems) until the solution of a required problem can be considered a succession of interdependent decisions.

A. Steps of Dynamic Programming

DP problems require four phases [4]:

- Break the basic problem into subproblems known as phases.
- Accomplish the last problem stage for all potential states.
- Returning from the last phase, resolve every middle phase. This is completed by defining ideal policies from that point to the terminus (final stage) of the problem.

- Get the ideal solution to the original problem by sequentially solving all the stages.

Using the DP, sub-problem results are stored. Therefore there is no need to recalculate these results the next time they are requested. This is an alternative to simple recursion, which requires repeating the solution operation each time the sub-problem is encountered. In (Programming n.d.) address these phases as following: description,definition, computation and construction. knabsack problems and shortest paths are two problems that predominate in studies and research on computer algorithms [5]. The issue of knapsacks goes back more than a century, i.e., we need to calculate the amount of each item to be included in a collection for a set of objects, each with a weight and a value whereby the overall weight should be smaller or equal to a specific limit. The overall value is set as high as possible [5]. The shortest path's problem consists of obtaining a path between two vertices in a diagram or such that the total of the weights of its edges decreases, described in [6]. In this paper also we introduce the longest common subsequence problem and illustrate how to enhance learning area.

III. The Role of Dynamic Programming in e-learning

DP is a useful technique for optimizing problems, which pursue the maximum or minimum solution since it allows to browse all possible sub-problems without defining a specific answer. It ensures that the methods used to solve or approximate algorithms are accurate and efficient. Futhermore, it provides a general means of modeling and solving such consecutive learning problems. This formulation offers value in three respects. First, the formulation of the DP allows the optimal solution to be calculated. This is usually only true for small problems [7]. Second, the formulation of the DP sometimes allows structural results to be shown in a theoretical way, which either provides insight into the problem and the behavior of the optimal policy or provides a characterization of the optimal system that can be directly exploited to find an optimal approach, as in sequential hypothesis testing. Third and finally, the DP sometimes provides heuristics that are beneficial for large-scale and complex learning problems.

DP approved his role to enhance and optimize problems in learning during the following studies:

A. Shortest Path

Shortest path is the problem of getting the lowest rout in a graph from one vertex to other. In e-learning systems, a course is considered as a graph where each node represents a unit of knowledge. The shortest path's challenge is to find a routing between the peaks of the graph mentioned above so that the overall total of the edge weights is minimal. The Bellman-Ford algorithm (BFS) is one of the algorithms that may be used to solve this problem.

In [8] a DP approach is employed to choose the shortest and the optimale path in virtual learning environments (VLEs). This environment catches a large number of students to allow them to learn and study everywhere. The intention is that the location of the student is considered to be no longer a band [9]. In [8], the author applied an analytical hierarchy process (AHP) method for transforming parameters from qualitative to quantitative ones. The system of VLE is suggested on the basis of an in-depth personal learner profile. The objective is to select the best route compatible with a learner's attention and qualitative properties like attitude, motivational capacity, learning style, and knowledge level. The user in the system, is confronted with service providers who prop VLEs. Every provider of service provides learning subject and internships that are educated by different teachers. The layers are presented in Fig. 1. [8]

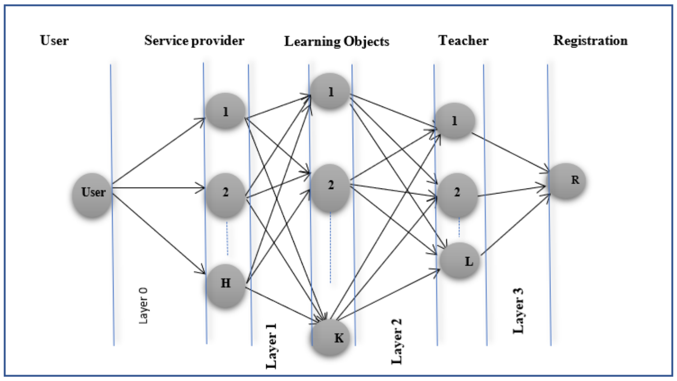

Fig. 1. The Suggested Network [8].

In the above figure, a network has been presented in which a dynamic process is implemented to choose the shortest route for each learner. The selection of the user depends on the qualitative criteria of every route. These paths must have a quantitative value to implement the DP. To achieve this, the qualitative criteria are converted into numerical values according to the user's preferences (the numerical values are shown in the table in the study paper). Then, the path preferences are related with numeral values. Three matrices are constructed in this study to calculate the ratio of the numerical values of pathways, which are estimated by the learning styles, attitudes, abilities, motivations, and knowledge levels of users based on the numbers of preferences. In this manner, the weights are calculated, and the ideal pathway for learners will be specified.

In [10], the author notes that they aim to estimate the prosperity and/or validation of education systems with a specific pipeline, unlike successful e-learning architectures. He suggests an evaluation procedure that consists of applying the DP process to model the user profile's ideal path problem and applying reliability to measurement the interconnections between users in a network of e-learning. This study has endorsed the effectiveness of DP through a comprehensive example. It is identical to the previous study, resulting from this example presented in Fig. 2 below [10]. In below Fig. 2, we can see the service providers number are five, the number of presented course are five and there are five teachers

According to the calculation of numeric values, the ideal path as presented in Fig. 2 is 0-3-9-12-16 that means the group included of the 3rd provider of service, the 4th learning object, and the 2nd educator is identified to become the shortest and the optimal. DP contributes to solving Markov decision process to enhance the learning path of learns in [11]. The atmosphere for adaptive learning is random. Therefore, to establish an

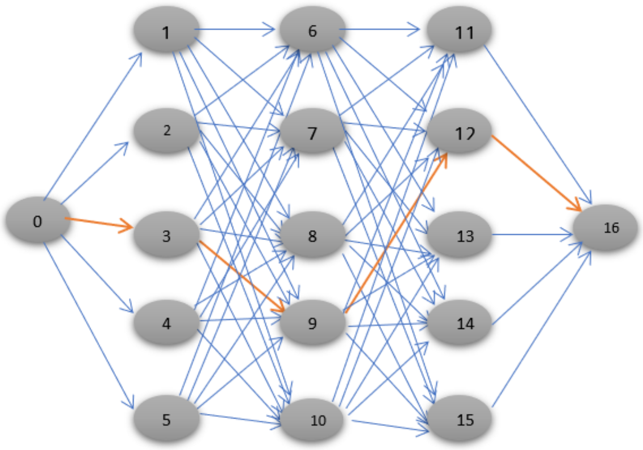

Fig. 2. Finding the Best Path [10].

effective learning path, the Markov Decision Process (MDP) model is suitable. Besides, the best activity in a sample space [12] is observed. Therefore, the MDP is recommended to provide a structured format to describe a multi-stage decision-making process in a probabilistic context. DP approach utilized to resolve the MDP. The issue in this study, selecting the bestead learning path with the highest reward, this problem an optimal substructure it can be split into subproblems, for that DP is the most proper way of solving it [13]. It is almost similar to that of a traveling salesman problem who wants to find the shortest way to increase his bonus. The learning objects it will consider as nodes, and learners' learning style as routes between nodes (in this study, used the Felder-Silverman Learning Style). According to Markov's process, the selected path will offer the highest cumulative remuneration [14]. After constructing the DP code by MATLAB program, the shortest path among two learning materials (learning objects) are computed for all successive LO. Fig. 3 illustrates the result of this study [10].

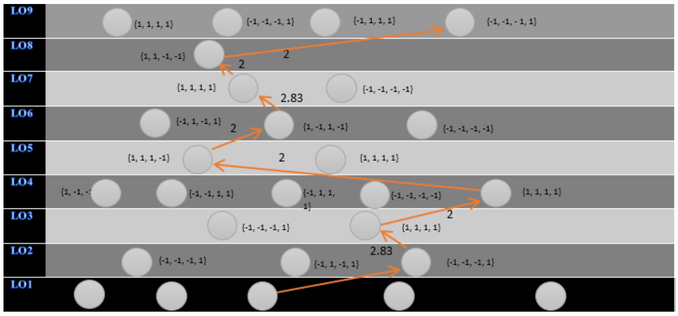

Fig. 3. Optimal Learning Path for Learner with Style 1, 1, -1, 1[11].

B. 0/1 Knapsack

Knapsack problem is considered as a combinatorial improvement problem in which each item is related with a profit and a weight. This problem aims at maximizing the number of items in a knapsack by matching capacity of knapsack.
The 0/1 knapsack problem can be declared as: offered a limited number of items and a knapsack, find the total revenue under the constraint that the overall weight of all selected items at maximum the weight boundary. However, present learning material is uniform and constant during each grade without concentrating on individual trait's or group differences. This problem makes materials of educational not attractive to some students. Establishing a progressive direction in compiling student books is a playful way of meeting students' demands and enhancing education efficiency. The study [15] In 2012 discussed the problem when the learner meets with a vast amount of content through the process of learning while he/she has a fixed time, and for this, he/she may sense disappointed and frustrated. The study proposed a novel procedure to aid learners get learning content more personalized to their characteristics and background in a playful manner; it used the 0/1 knapsack problem to choose the most suitable adaptive learning materials in a limited amount of time specified by the learner. There are various content categories in learners' books, like texts, exercises, examples, etc. These are known as elements. For each of these items or components, a specific part of the time allotted for teaching a book is set aside.

Students take the regular exam first, and their learning rate is evaluated. Then, the outcome of this test is converted into a coefficient. The time required for each of the upper elements to be taught determined by multiplying the original time allocated by each element's coefficient. For all the features, we can also measure time [10]. To provide the most appropriate learning objects to the learner in a restricted period, the 0/1 Knapsack problem has been applied. This problem is one of the most known combinatorial improvement problems. It is known as a classical NP-hard, which has an excellent search space.

The 0/1 knapsack problem (KP) is appropriately known as follows: We are given n items and a knapsack. Item i weights wi, and the knapsack has a weight boundary C. If object i is put into the knapsack, we will gain a profit p. The issue is to increase the overall profit under the constraint p that the sum weights of all selected objects are at most C. For that, the knapsack problem can be formulated as:

$$\begin{array}{ll} \text{maximize} & z = \sum_{j=1}^{n} p_j x_j \\ \text{subject to} & \sum_{j=1}^{n} w_j x_j \leqslant c \\ & x_j \in \{0,1\}, \quad j \in \{1,\ldots,n\} \end{array} \tag{1}$$

Where p denot to the profit ,w refer to the weight and x is a binary variable indicating whether object i is selected or not, in the above Equation, p the constraint that requires to be convinced and realizes the profit of a feasible n-tuple, the following Fig. 4 illustrates this problem [10]. Each student has his/her account and personal profile. When coming to the application for the first time, many questions were faced by each learner to reach the personalities of learner, characteristics, and learning styles. This application, which is established in the suggested way, showed a significant effect on adaptive learning.

Dynamic programming has proven its role in universities through scholarship programs. Bursaries serve as an important motivation and play a vital role in inspiring students to work hard at the universities, exemplify, and strive in their academic career in higher education [16]. It is often viewed from the teaching perspective as an essential factor. Many research findings have shown that bursaries positively impact college

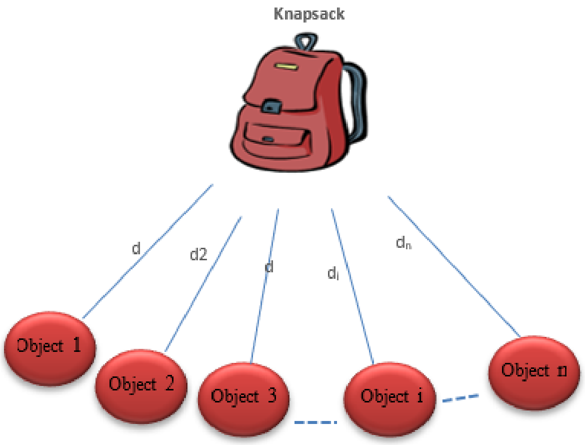

Fig. 4. The Description of Knapsack Problems [10].

performance and inspire students to pursue further education [17]. Various scholarships are sponsored by multiple donors, such as entrepreneurs, companies, citizens, etc. responsible for deciding the number of awarded persons and the cost allocated to any individual beneficiary. The university is involved for awarding the scholarships to applicants by the rate on departmental results. Yet university administrators are not allowed to split the current scholarships further into new scholarships with lower rewards.

In [16], they proposed a challenging DP approach to change the conventional process of decision-making for awarding scholarships. The aim is to figure out the ideal scholarship allocation with the greatest justice while taking into account practical channels and the requirement for fairness. This study explores a department's scholarship allocation process. A variety of scholarships are available to graduate students from a department who have done exceptional work in the course of their university studies. In two ways, multiple types of scholarships are different the number of the offered ones and the money allocated for these scholarships. For various scholarships, students can apply free of charge. The outcomes of the scholarship assessment depend on the scores received by the students in the previous year. A student's total score consists a score named basic, which is calculated based on coursework and some additional study findings provided by the academic accomplishments, such as journal papers. The score mentioned above is calculated in a scale to simplify student work assessment, whereas various forms of achievements are estimated. Also, to turn a particular work into standard ratings, a standardization procedure is implemented. For example, the score of a published paper can be measured in two components: Rating the impact factors of journals and the order of the authors. The study assumed that the department was responsible for the allocation of scholarships and the scholarship was distributed according to the rank of the applicants' final scores. To prevent unfairness in distributing scholarships, we add the limitation that at least no less scholarship should be given to students with a higher score.

Otherwise, the research takes into account other realistic constraints. For example, multiple students cannot share a single scholarship; they can only be rewarded no more than once for a specific form of scholarship, various grants; students should be assigned all the grants. The ideal assignment is the method that guarantees that the sum of a student's scholarship is corresponding to the scale of the overall score.

TABLE I. SCHOLARSHIP DETAILS (HUANG ET AL. 2018)

ID	1	2	3
Scholarship value	8000	5000	10000
Number of awardees	2	3	1

TABLE II. CANDIDATES DATA (HUANG ET AL. 2018)

ID	1	2	3	4	5
Score	25	20	30	35	15

The scholarship assignment problem was viewed as a join of two sub-problems. One is seeking the available assignments schemes that pass the constraints and the primary justice demand together [16]. The second, lies on the quantification of each sensible scheme's justice, then, choose the ideal strategy with the top justice. To handle the first subproblem, a way formed of knapsack sub-problems is advanced to allocate in sequence students to scholarships. In the knapsack sub-problem, every student's overall mark is considered the knapsack, and the valent mark of every scholarship is considered as the element placed in the knapsack [16]. The Gini coefficient to calculate unfairness of each feasible solution is added to resolve the second sub-problem. The equity of welfare distribution can be quantified by the Gini coefficient (variation among the real and ideal sum of scholarship earned by every single student) [16]. This study explained the proposed method through a small case: three scholarship kinds and five candidates as an example, as we see in the below Tables I, II and III.

Then, we can calculate the coefficient of Gini of the individual plans, as mentioned in Table IV which is indicated in the schedule IV: As the Scheme 1 Gini coefficient is the smallest, Schema 1 is the one with the highest equity as shown in the Table V. In this numerical example, scheme 1 is therefore selected as the last scheme of scholarship assignment. Dynamic programming helps universities in its strategic management for whole university or departments

TABLE III. RESULTS OF THE IDEAL(HUANG ET AL. 2018)

inside it through multiple knapsacks. It popularizes the basic knapsack problem (KP) from a singular knapsack to many knapsacks with (probably) various capacities. The goal is to allocate each element to at most one of the knapsacks so that none of the capacity restrictions are assaulted and to maximize the overall profit of the elements placed in the backpacks [18]. When the university develops her strategic administration to plan and apply optimization procedures, this enables the university to be ranked in the education list [19]. In 2019, Dorota et al. in [19] proposed a model which is quantitative for university managing strategy as an entire or university section. This study's methodology is gathering qualitative methods utilized in the administration strategy and the quantitative multiple knapsacks.

This study covers only the building model and decision-making operation related to administration in small Polish universities but not yet implemented. This gives us the attraction standards of the department chosen by students.

C. The Longest Common Subsequence (LCS)

Finding the longest subsequence in the same order in the two sequences given,is consider the goal of LCS. This means determining the most extended sequence obtained by removing some items from the first original sequence and removing other items from the second original sequence. This Problem also has a different application in text editing and data compression [20].

Among the main tasks of e-learning is the customization of learning. As mentioned earlier, the interest of numerous researchers has been drawn to the customization of learning objects (LOs) due to the immense significance of the LO in the learning process [21]. LCS contributed to the adaption of learning through personalizes LOs for learners. Mahdi and Fattaneh in [21] see Students and educational resources are the two key learning entities, so educational programs should give both these two entities high priority. They have developed a robust algorithm which is genetic for educational slides, thus adapting as a particular material in the e-learning resources. This algorithm potentially implemented in each type of LO. Initially, a default LO series will be assigned to the learners. This series is diagram of LOs as node or vertex and relationship among them as an edge. This hypothetical sequence is defined with the aid of a skilled and then required from the learners to rearrange these materials, and reasons will be presented for each change.

Below, the action is taken to determine the rearranging of the sequence of LOs and create a new series of them.

- Insert a new LO or deleting from the LOs sequence default (stretched to add or remove a sequence of LOs).
- To interchange the two LOs with each other.

TABLE VI. RESULT OF FIRST CASE(DUNN ET AL. 2011)

Groups	The sequence of commonly used learning objects						
Group 1	1	2	3	4	5	6	7
Group 2	1	2	3	4	5	6	7

TABLE VII. RESULT OF SECOND CASE(DUNN ET AL. 2011)

Groups	The Frequently Occurring Sequence of Learning Objects						
Group	1	3	2	4	5	6	7

This study introduced a diversity of relationships among LOs in the following.

First Case: (independent relationship): Since the LCS considers a sequence in the default sequence that is not necessarily sequential; the sequences suggested by students can be placed in groups with a specific order. For instance, as we see in Fig. 5, the LOs default sequence is displayed, and independent relationship and prerequisite are indicated in it; two LOs (4 and 5) are not linked, and for of them can be educated after LO 3 and if finished from 4 and 5, LO 6 can be taught [21] If we assume that the sequences are as follows for two sets of students (Table VI): As shown in Table VI, a general pattern is found in both groups with a hypothetical LO sequence, and the variance is on the independents (LO 4 and LO 5); therefore, it is possible to examine the reactions of the groups on their LO sequences, and after the educational experts, the endorsement chooses a better sequence. It might alternatively be conveyed that both sequences are right, and any of the sequences can be used in developing the preferred method. For instance, the best sequence may be chosen (a more similar group) after evaluating the new individual's similarity with each group. Then it sequence suggested to the person. Any calculation employed to determine the sum of similarity between entities and the groups can be a measure of similarity [21].

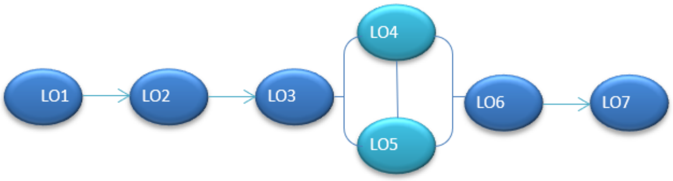

Fig. 5. The Green Line Shows the Independent Relation and the Blue Line Shows the Precedence Relation [21].

Second Case (Precedence relationship): Let's assume the above example and that one group has determined the prevalent sequence as follows (Table VII): Fig. 5 shows that LO 2 is a precondition for the LO3, but the group in Table VII does not reveal this prerequisite relationship. This may be because the group has been unable to find the group has established the prerequisite relationship among LOs or the fake prerequisite relationship among LOs [21].

Third Case (Container relationship): if there are some LOs, everyone has much smaller LOs. The largest LOs have the required connection, but the interior ones are independent. In Fig. 6, For instance, the First and last LOs are selected. As shown in Fig. 6, the lesson's three primary topics are (Part 1, Part 2, and Part 3). Many sequences of LOs in each

TABLE VIII. RESULT OF THIRD CASE (DUNN ET AL. 2011)

Groups	Proposed sequence							
Group 1	S 11	S 12	S 14	S 13	S 31	S 33	S 34	S 32

subject are not linked to each other, but the following part is expected to be articulated before starting. Both classes did not completely recognize the sequences in the following table. We were unable to find any LCS from 21, 22, 23, and 24 in the first category, for example, due to the fact that its members are suggested sequences which are sufficiently different [21]. The proposed sequence groups are shown in Table VIII and the final result of case 3 displayed in Table IX. Case 4 (relationship unknown): The effect of dissimilar granularity levels of LOs is investigated. Most popular strategies teachers apply to prepare instructional material is to choose many sections from distinct marital learning such as leaflets, handbooks, or books. Because each of these various tools explores the topic from different viewpoints, there are often no standard sections between selected parts; it is a crucial and time-consuming job to design a series of these instructional materials [21] as shown in Fig. 7. To overcome this problem, we suggest to the student to be able to offer or suggest a sequence for these sections (chapters), next we created the sets based on this proposition. For each set, we need another sequence for each chapter's parts to be suggested by its member (such as case 3), and novel groups are created in ones that already in the past stage [21].

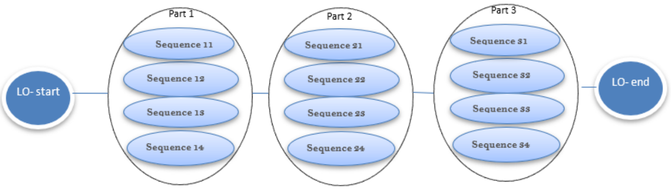

Fig. 6. The Relationship to the Container is Indicated by the Grey Circle [21].

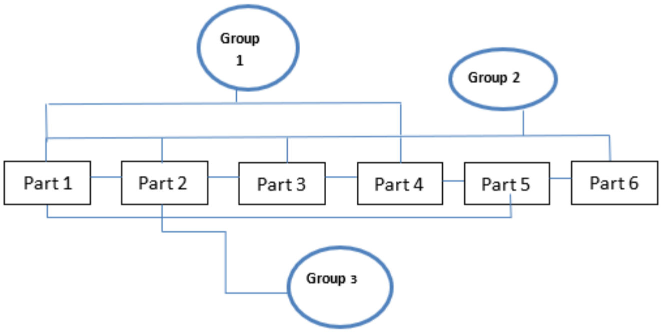

Fig. 7. Extended third Case[21].

In this study, LCS helps define the fitness function; this function for each set is equal to how much the organ is similar to others in that set. This propinquity gains from computing the LCS of student suggested sequence for LOs with other groups' organs. The findings suggest that this algorithm is efficient, and its findings could be used in different learning activities [21].

Another application of the dynamic programming using the LCS is to detect the plagiarism from a specific text or document, this method was proposed by Mahalakshmi S. et al. [22] in which they presented a system based on a symbolic execution next to the reasoning of the weakest requirement in order to find the distinction of paths and to grasp the semantics of execution paths. Indeed, the proposed method uses the LCS to provide a line-by-line comparison between the text-based search and the string by passing the file that is the object of this comparison through the following steps, starting with reading and converting the file, and then finding the shortest path between the data in the file and the data in the repository. Finally, extract the similarity report using the LCS algorithm based on recursivity. The proposed method proved to be very efficient compared to the existing methods.

Alexey Sorokin in [23] has applied the LCS method differently to predict the word forms. In fact, LCS is used to extract summary paradigms from input pairs, inflected word forms and suffix/prefix characteristics to automatically predict the paradigm. The proposed algorithm is based on a mixture of affix characteristics and ngram character models, which significantly improves performance, especially for language processing. In [23], A. Sorokin has employed several tasks to perform his method starting by the encoding stage which is consist in encode the input sequence with some label and trying to predict these labels using machine learning algorithms to convert the input into paradigm abstract. Then, a finite automata is used to extract the LCS. Furthermore, they perform the automatic inflection since the proposed method includes in the feature set the lemma suffixes and the prefixes. Finally, they use the ngram score enhancement the model score.

The LSC was also used to identify the sentence parallelism in student essays, W.Song et al. [24] proposed a robust method to automatically detect and identify the sentence parallelism using machine learning algorithms with the help of LSC. In their work, they build an annotated essay dataset. Furthermore, they construct a feature vector by using the strategies of the combination of generalized word alignment and the alignment measures between word sequences. W.Song et al. [24] started by collecting a dataset of 500 essays made by students, then they annotated the dataset to make the classification and to generate the classification report. The features extracted from the annotated dataset will be fed to a machine-learning algorithm to generate a prediction model. They made a study on various alignment measures, because the parallelism is quite similar to the alignment, to assess the alignment of sentences. They employed a several strategies to generalize the word alignment based on two features which are the semantic and the syntactic properties. Interactions of alignment metrics with word alignment strategies produce the features to show the alignment between sentences. Furthermore, The LCS is used to solve the problem of the parallel sentences by the use of dynamic programming. To assess the efficiency of the suggested method, they tested several algorithms on the basis of dynamic programming, and they reported that they achieve an f-score up to 82% in the best cases.

An interesting application of the LCS was proposed in [25] by A.Flores-Mendez et al. [25], they proposed a new method to verify the dynamic signature by the use of LCS and genetic algorithm. In their approach, they based in two major steps :

TABLE IX. FINAL RESULT OF THIRD CASE(DUNN ET AL. 2011)

Effective groups	1	1	1	1	2	2	2	2	1,2	1,2	1,2	1,2
Result	S 31	S 33	S 34	S 32	S 22	S 21	S 24	S 23	S 11	S 12	S 13 / S 14	S 14 / S 13

learning and verification by the use of the LCS. The learning process is made by solving a polynomial equation and by measuring the distance between the current signature and a set of data to verify if they are similar or not. In the other hand, the verification process was about calculating the shortest path to be assigned with a very similar signature based on the learning stage. Furthermore, the genetic algorithm was used to build a knowledge model to make the process inspired by the natural mechanism. The authors reported that the accuracy of the proposed method was outstanding, and it achieves more than 90%.

Multiobjective Dynamic Programming (MODP), which based basically on traditional DP, is advanced as a mechanism for resolving issues (problems) that involve incompatible goals that obey to features of DP. Significant progress in multiobjective dynamic optimization has been made in the last two decades. MODP considers One of the most provocative topics, is A normal expansion of DP is its utilized in conjunction with sets of fuzzy [26]. one of the applications of mode is resource allocation, this also can help e-learning systems to allocate its resource [26].

IV. COMPARATIVE ANALYSIS

DP is considered one of the methods that contribute to improve e-learning through different problems. The DP technics are used in many fields to solve several issues in different case of studies. In the present paper, we discuss three major issues (shortest path, knapsack and LCS) that help improve the learning sector. Based on the studies that we have discussed before, we find that the LCS is used generally to perform a classification process. Indeed, the LCS technique allows finding the nearest samples by finding the shortest paths based on the semantic, which is different from the shortest path, which is based only on the distance. In the other way, the knapsack is used to optimize the choice of the sample; thus, it employed always to maximize the gain. Table X summarizes the studies introduced above.

V. CONCLUSION

Dynamic programming is a method of optimization depends on the precept of optimality realize by Richard Bellman. It is considered one of the solutions and methods that have contributed to solving many problems in various fields, especially in e-learning. This survey explained how DP contributed to supporting education through three types of problems (shortest path, knapsack, and long common sequence), where during the shortest path problems DP supports adaptive e-learning through generating the suitable path of different learners with different learning style and provide the appropriate learning materials as we shown in first three studies. knapsack problems contribute in supporting higher education through the scholarship assignments and assist to select the suitable learners to gain scholarship in a fair way as introduced in fourth study and knapsack problems aid universities in strategic plan and administration like in fifth study. Last studies illustrates the role of LSC problem to detect the most suitable sequence of Learning Objects from the ones introduced by the learners to personalized the learning materials in effective way and this enhancing adaptivity in e-learning. Also, LCS contribute in some application that help learners such as plagiarism detection and verifying the dynamic signature. All studies have proven how DP has contributed to improving and supporting e-learning.

1	HAMED FAZLOLLAHTABAR 2008	E-Learning has mainly been embraced as a favorable resolution by multiple communities to provide opportunities of learning to personal learners to reduce training time and cost.	Applying DP to detect the shortest route in the education environment for learners and use the approach of analytical hierarchy process to transfer the parameters of qualitative to quantitative ones	An ideal learning path was generated with the help of dynamic programming and parameters quantitative conversion of qualitative parameters
2	Hamed Fazlollahtabar 2012	From the reliability of each direction, choose the best path aligned with the concern of the student. Of course, depending on the decision maker's preference, other requirements may also be introduced.	It proposes an evaluation technique that uses a DP approach to model an ideal user profile route and use reliability to calculate user interconnections in an e-learning network.	The system helped the user find the optimum course and approved that during the illustrated example.
3	Norah Alqahtani , Mahmod Kamel, Mostafa Saleh 2018	There are individual differences for learners, and each learner needs to get educational materials appropriate to his learning style.	Develop adaptivity in the education process by using the Markov Decision Process (MDP) with dynamic programming (shortest path problem).	With the help of DP, MDP contributes to generating the appropriate e-learning path for different learners with different learning styles.
4	Hans Wang Yu Gu ,Jun Chen , Zhiyuan Liu , and Di Huang 2018	The traditional way to scholarship assignments consumes much time and effort in application operations conducted by students to gain university scholarship.	The repeatedly solving a chain of knapsack subproblems and altering the monetary a unit scores value. The ideal deployment plan can then be eliminated by performing the coefficient of Gini for quantifying the equity of each proper schema.	To clarify the applicability of the suggested procedure, an illustrative example is acknowledged in this study, and the result shows the proposed method addresses the fairness demand that pupils who do better should receive awards higher than those who do worse.
5	Dorota Kuchta Radoslaw Rynca 2019	Several approaches in the literature may be beneficial in university strategic administration. Some of them are linked to the sustainability element in balancing the grade of complishment of multiple, often overlapping, goals that need to be taken into account when constructing strategies. Such approaches include portfolio product/service ones. Their utilized, however, is mostly axiomatic and disconnected from management's quantitative sides. This study want to provide a proposal to alter the portfolio methods.	Gathering among non-quantitative portfolio approaches with the quantitative multiple knapsack dilemma used in strategic management.	For the first time in the literature, a connection among portfolio procedures and a quantitative improvement approach for university administration objectives was introduced in this study. For all manner of educational institutions, portfolio approaches seem to be theoretically useful. The chosen criteria make it possible to identify different items (departments, colleges, services, topics, etc.) and imagine the present status and plan enhancement. The entire strategy makes it potential to simulate different methods for the learning institution's growth, and take the ideal decision.
6	M. Mahdi Barati, Fattaneh Taghiyareh 2013	finding the most suitable sequence of LOs from the ones proposed by the students to personalized the learning materials in effective way	genetic-based algorithm with help LCS for adapting the learning slides as a significant learning material in e-learning environments	The needed data has been gathered with questionnaires from thirty-six learners that register in the course of Bio Computing. The results analysis displays that the suggested model has been so effective in adapting the slides of educational.
7	Mahalakshmi S, and Kavitha S. 2016	The suggested model aims to discover the similarity and the plagiarism between the input document/text and the data in the repository	The authors apply an LCS method to find the high similar text by using five steps process to the input document,in which they employ the LCS as a recursive function.	The proposed method outperformed the existing algorithm in the literature, which are based on a simple distance calculation.
8	Alexey Sorokin 2016	The proposed method aims to predict the words form by transforming the input data into labels and extracting the lemma suffixes and the prefixes to construct a feature set. Finally, a classifier is performed to predict the form.	The authors apply a finite automata is used to extract the LCS. Then, they perform the automatic inflection to construct the final feature set to be subject for a classifier to find and foretell the words form	The method has been proposed shows a high accuracy since it uses additional information which is the ngram score enhancement the model score.
9	Song et al. 2016	Automatically detect and identify the sentence parallelism using machine learning algorithms with the help of LSC	They employed a several strategies to generalize the word alignment based on two features which are the semantic and the syntactic properties. Furthermore, The LCS is used to solve the problem of the parallel sentences by the use of dynamic programming.	they tested several algorithms based on dynamic programming, and they reported that they achieve an f-score up to 82% in the best cases.
10	Flores-Mendez and Bernal-Urbina 2010	An automatic way to verify the dynamic signature by the use of LCS and genetic algorithm	They use the LCS combined with the genetic algorithm to verify and classify the dynamic signatures	The authors reported that the accuracy of the proposed method was outstanding, and it achieves more than 90%.

University of Tabuk
Faculty of Computers and Information Technology
Saudi Arabia, Tabouk

***Abstract*—The continuous development of social media and online commerce, which permeates all aspects of our lives, leads to the need for a similar mechanism similar to the financial credit score in traditional business. Also, a realistic classification of users through social media to be used in all aspects of the relationships between users and some of them or between them and organizations is needed. In this article a new metrics to classify users according to their creditworthiness of the transactions that take place through the Internet is established. The object from this aricle design a social credit system model (SCSM) based on these new metrics. How to deal on the Internet, attacking people on social media, violating the privacy of people and others. Also Buying and selling operations, executing purchase and sale orders, paying amounts of money easily and quickly, and so on. These data and their degree of importance were determined according to several questionnaires directed to several segments of society. This creditworthiness can be used in banks, Uber, Online transactions and so on.**

***Keywords*—Social media; online commerce; social credit system; creditworthiness**

I. Introduction

The increase in credit fraud in the information age has disrupted economic market activities and could cause significant damage to global economic systems. This lead researcher to study a social credit and assess credit risk by scoring each user based on objective measures.

This study is mainly done to build a SCSM model which gains importance from the need to facilitate all operations that take place over the Internet.

Social media can be defined as a Web based information system that allows users to create profiles, support communication between users, and create relationships [1]. Loans, financial transactions and credit cards need certain conditions to approve these transactions. These conditions are known nowadays as people's creditworthiness. Companies and banks rely on home address, income, job data and so on to determine the creditworthiness of people. Also, the way to pay its past payments will greatly affect its creditworthiness, which allows or does not allow it to take a loan or get a credit card. Traditional data in our time is insufficient to build creditworthiness, Using social data is one such option [2]. It is needed in all online transactions. The individual's profile data on social networks such as Facebook, largely reflects the real data of the person who can be used to build creditworthiness [3]. Building a social credit system based on these ideas can improve all Traditional and online financial transactions. This system will add confidence to all online processes. There is various example that may benefit from social credit scoring, for instances you can accept a friend on Facebook based on his social credit. There are multi ways people interact with the consumer credit system, more specifically, the way they access credit and the way they are held accountable for their debt [4]. Microfinance has been taken care of and how to ensure credit evaluation. In addition to traditional credit rating methods such as sociodemographic and credit data, other data from Facebook (like group, friends, and so on) has been extracted and used in a new model to automate the credit scoring process for microfinance [5]. The impact of using metrics based on social networks has been analyzed to give a score to customers is illustrated in [6]. Goel and Gold stein in [7], discussed using the available data through social media to show people's trends in purchasing, clicking on ads and registering in different events. They rely on friend-to-friend relations to make the decision and categorize people. This relationship on social media predicts a user's behavior by tracking a friend's behavior in purchases, clicking and any online transaction. The Chinese system of social credit has been designed to target many fields [8], [9]. The social credit scores are routinely incorporated to include most information about the people, so it's affect on get job, even dating or marriage, it become active to structure the people's life [10], [11]. These are aimed at judicial and other credibility in the fight against fraud. There is also another goal of building social community loyalty to increase trust among individuals. Social credit information is collected by specific parties, ranging from administrative sanctions, payments, volunteering, web searches, social media comments, GPS tracking data and most online transaction data. This system expands the information collected and the goals in which this system is used. This data is comprehensive and not important to our primary goal of building creditworthiness for online transactions. Researchers in [12], relied on a collection of social media data collected through the most popular Chinese website Weibo. This data mainly includes demographics, tweets, and people-to-people relationships. They apply some machine learning techniques to predict the credit score of a person. In [13], how to rely on people-to-people relationships on social networks in the distribution of new products has been studied. The point was also made that with more information on social networks, the marketing process would be accurate. Infer the degree of credit for people from their online social data studied at [14]. A model for learning about online user behavior, especially via Twitter, has been suggested as illustrated in Fig. 1. In it, the tweets are analyzed and the words discovered to classify people credit. For example, as described in the figure, the same drunken habits and watching football matches are associated with sending late-night tweets. Accordingly, the system can predict certain behavioral habits of users, and on the basis of these habits can be credited through social media. In Research [15], [16], work is done to identify the most influential social media users in the activities of others in order to draw greater advertising and administrative attention to them. In 2014-2020 the Chinese government intend to build social credit system (SCS) to better collect and evaluate citizens' creditworthiness, and grant rewards and punishments based on one's social credit. They built the SCS depend on collect information from national development and perform commission, Supreme People's Court, other Central Governmental Agencies, and the other Government Agencies Bank of China and others benefit from this information to judgment on the people from are this people in redlist or discredited judgment debtor [17]. China's Internet market was examined in [18], [19], where social-media data were used to describe borrowers' behavior and how credit rating systems can influence social behavior in china's social credit systems, it's research in concepts of an ideal citizen, the state and associated private enterprises can reinforce trust within society by issuing social credit scores to everyone, so everyone will likely aim to achieve a high social credit score, but the government state need to consider the implications of their policies and consider avenues that individual for low social credit scores could turn towards for assistance.

This article was based on the development of multiple models to compare the accuracy of customer scores obtained based on social networks or without. It relied on the efforts of lawyers and data scientists who extract credit worthiness from the big data available online in most social network sites. Legal problems have also been analyzed and solutions are found for all these problems to ensure transparency and trust. From the previous, we noted a lack of processing some concepts that must be dealt with to produce a robust system that can reflect an individual's true creditworthiness. Violating the privacy of people and other social media events and linking social media to e-commerce sites to assess people's transactions is our goal. In addition, a model will be built in which the type of data is determined and how it is collected, analyzed, and used to build the creditworthiness. Also, this article different from others, specific data will not be analyzed for creditworthiness, but will be designed a model adjust what data can be collected or added and how it will be used to accurately grant people credit. This model collect data from multi sources such as social networks, online sales and purchases data about the individual, in order to classify individuals in terms of creditworthiness.

This article organizes as follows: In section introduction, we talked about the literature review and display the difference between this article and others and the features this article has. The methodology used in collect the data are discussed in section Methodology. The analysis the questionnaire content and get the results are explained in results and discussion section. In section design SCSM, talked about the design the model. In section conclusion, displayed the conclusion we got from this article.

Good Credit

Fig. 1. Credit Score Based on Social Data.

II. Methodology

This article depend on the questionnaire. So, in order to gather needed information from the society, two-part questionnaire is designed using Google Docs and URL. The questionnaire was distributed online by WhatsApp, Instagram, and Telegram social media users. The questionnaire distributed to a number of specialists on banking, service providers and other peoples. It will be taken into consideration that the subscribers familiar with regulations, laws and banks and a fair distribution in terms of age and gender. The questionnaires designed to three groups:

1) The first for ordinary internet and social users.
2) The second for companies and service providers via the Internet or in traditional ways.
3) Finally, for those familiar with the work of banks.

By using Likert questionnaires, the data can be collected quickly and this data can also be interpreted and relied on it [20]. Here this type of measure will be used to collect the exact respondent's opinion on specific points. It allows us to build our model accurately. The advantages of the Likert scale questions in surveys is that:

- It is an accurate way to collect data, through which you can analyze and understand data well.
- It can be used with quantitative data.
- It is easy to conduct it as it does not take time.
- Multiple options, allowing accurate answers from respondents.

In this article a 6-point measures will be used as illustrated in table I, as they increase the accuracy of the answer. The scale combines answers that vary from weaker (Strongly disagree) to strongly agree support. To increase the accuracy of the questionnaire results, this scale does not have a neutral answer

to obtain weighted answers from all participants. Another type of question (yes / no) is used in this article to specifically measure the participants' opinion on some issues related to financial transactions over the Internet and the legality of tracking users' information over the Internet. The volunteers were requested to answer the question are listed in Appendix A.
total of 600 respondents answered the survey questions. In this dataset, rows represent different type of events and column different criteria for analysis. Each data record represents the value of a particular analysis criterion for a type of event. Based on the data obtained from the survey, a dataset are organized using excel tool. The next step was sampling the data in order to prepare them for further analysis. Based on the results of this questionnaires and the previous literature review, a SCSM will be designed.

TABLE I. A Sample 6-point Likert Scale

	likert scale	
Srtongly Disagree	Disagree	Slightly Disagree
Slightly Agree	Agree	Strongly Agree

III. Results and Discussion

This section contains the results and discussion of all questionnaire.

1) Results and discussion of the first questionnaire: Table II, explains responses obtained from respondents; the percentage response was calculated in line with the 6-likert scale.

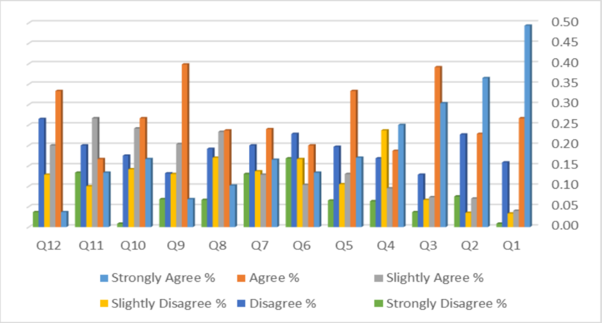

Fig. 2. Percentage Results of Internet and Social Users Questionnaire Likert Part.

As shown in fig. 2, for the first question, a large percentage of people agreed that they use the Internet a lot, where the percentage of Strongly Agree was 49% for this question. The overall approval rate was approximately 80%, which supports us in providing the proposed model for classify internet users. Also, even if it was less, the respondents agreed in the second question that they use social media frequently a lot, which will support our proposed model based on social media for extracting data on individuals. The results for the third question are Strongly Agree 30%, Agree 39%, Slightly Agree 7%, Slightly Disagree 7%, Disagree 13%, Strongly Disagree 4%. Regarding this question, the high approval rate indicates the future of Internet commerce and that it will expand rapidly and continuously. Participants have been responding to the fourth question with percentage Strongly Agree 25%, Agree 19%, Slightly Agree 10%. These ratios make us predict that the information available from users' interactions through the Internet will be rich and sufficient to build our model. The approval rate (63%) for the fifth question opens up different methods for us to obtain accurate data on individuals to be accurately evaluated through our proposed model. Since the use of such applications as the Uber application provides us with more information on the behavior of individuals. The sixth and seventh questions are concerned with studying the degree of problems that individuals face in buying and selling through the Internet. The percentage of problems encountered when selling transaction by individuals on the Internet is higher than in purchasing transaction, and this mainly results from the lack of experience of individuals in selling via the Internet. Generally, these questions indicate the existence of actual problems when applying transaction via the Internet: Strongly Agree 13%, Agree 20%, Slightly Agree 10% for question six and Strongly Agree 17%, Agree 24%, Slightly Agree 13% for the seventh question.

Questions from 8 to 10 are concerned with studying the existence of verbal and psychological attacks, privacy violation, and data theft. The rate of expectation of a privacy violation problem is higher than the other two problems, where the overall approval rate is 61%. Respondents' answers for these three questions support the need for the model presented in this article.

The eleventh question measure the prevalence of banking transactions that take place over the Internet. Of course, there is a percentage that has a weight that does not use these services, due to fear of problems with online transactions. Finally, the twelfth question is one of the most important questions, as it measures the opinions of the participants regarding the possibility of using the transactions that take place through the Internet and social media in building a creditworthiness system similar to that found in banks.

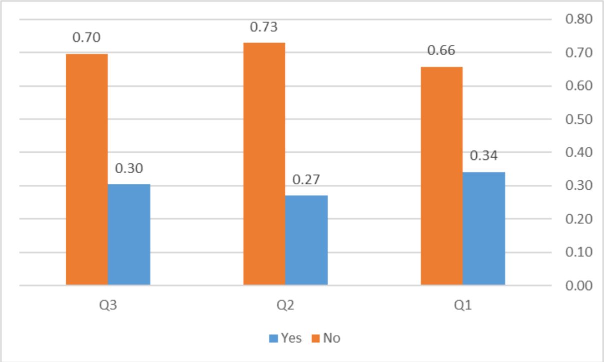

Fig. 3. Percentage Results of Internet and Social Users Questionnaire Yes/No Part.

Fig. 3, illustrate the three (Yes / No) questions that display Internet users in general. Table III, contains the respondent's answers. it given to users to measuring their opinion specifically about the problems they face when selling (such as eBay) or buying. It is noticeable in Fig. 3, that the product quality problems were approved by a number of subscribers, close to 34%. Also, the problems of buying and selling via the

TABLE II. RESULTS OF INTERNET AND SOCIAL USERS QUESTIONNAIRE LIKERT PART

Questions	Strongly Agree	Agree	Slightly Agree	Slightly Disagree	Disagree	Strongly Disagree	Total Response	Results
Using Internet	296	160	24	20	95	5	600	Accepted
Using Social Media	219	137	42	21	136	45	600	accepted
Buying Product	182	235	44	40	77	22	600	accepted
Purchases and Sales	150	112	57	142	101	38	600	Accepted
Using Uber	102	200	78	63	118	39	600	Accepted
Problem During Sales	80	120	62	100	137	101	600	Not Accepted

TABLE III. INTERNET AND SOCIAL USERS QUESTIONNAIRE – YES/NO PART

Questions	Yes	No	Total Response
Quality Problem	205	395	600
Financial Problems at Selling	162	438	600
Financial Problems at Buying	182	418	600

Internet had support, but less than the quality problems. These problems are mainly found because there is no real evaluation that reflects users' behavior online.

An important question was asked to Participants about how to pay the value of goods purchased over the Internet. The classification of the answers is shown in Table IV, Also, Fig. 4, shows the percentage of each choice. As shown, payment on receipt is the predominant feature with a good percentage that uses the visa in its online purchasing transactions. This result is due to the fear of a large percentage of participants from using their credit card over the Internet. Also, this supports our need for the proposed model in our article.

TABLE IV. RESULTS OF INTERNET AND SOCIAL USERS QUESTIONNAIRE CHOOSE PART

Question ID	Visa	when receiving	Total Response
Payment Method	12	18	30

2) Results and discussion of the second questionnaire: The questions directed to companies, that apply their transaction through the Internet, measure the extent of the difficulties they face, whether there is a need to make rating of Internet users and what are the basic data that can be used in this rating process. Table V, contains the answers of 30 participants in this questionnaire.

As shown in Fig. 4, the first question measures the extent to which the company uses the Internet to apply their commercial transactions. Answers show that approval responses slightly outweigh disagreement. This is a result of the fear of conducting these transactions, as there is no accurate rating of the person you are dealing with. The answer to the third question may be related to the first question. As is the case with a number of participants who are not using online business transactions, they are likely to see no income from the Internet.

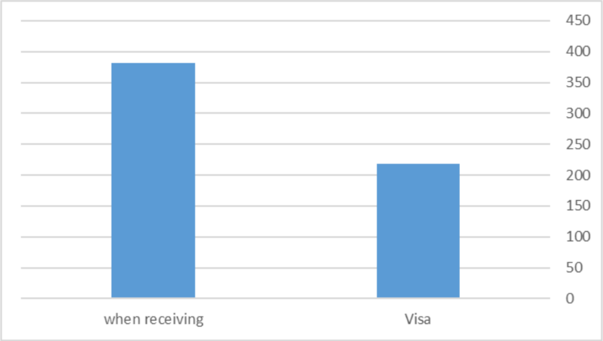

Fig. 4. Percentage Results of Internet and Social Users Questionnaire Choose Part.

Returning to the second question, the respondents 'answers fluctuate between approval and disapproval (Agree 30%, Slightly Agree 20%, Slightly Disagree 20%, Disagree 30%) Equally. This indicates that there are multiple problems in dealing with suppliers via the Internet for companies. This encourages us the importance of having a model that manages the rating process for all users over the Internet.

Questions 4 to 6 are concerned with measuring the extent of problems caused by online buyers. Such as users not completing their orders, refusing to receive product, and using the product return process a lot. The percentage of those who agree to the fourth question is high, and this is due to a large number of individuals who do not complete their requests for various reasons. This behavior does not significantly affect the design of our model, but put a little weight on it in the rating of individuals. As for the fifth and sixth question (refusal to receive, return of products), even with a low percentage in approval of them, it indicates its importance within the proposed model. As these two process represent a major inconvenience to companies.

For questions 7 to 9, it measures the percentage of respondents' approval or disapproval, gradually from Strongly Agree% to Strongly Disagree%. These questions measure the quality of data exchanged over the Internet and its relevance in building a model that represents a user's creditworthiness.

The high approval rate for the ninth question indicates that the majority of respondents agree that the user's credit worthiness based on the study of his behavior over the Internet increases individuals' confidence in completing their electronic transaction.

with respect to the yes/no questions, as explained in Fig. 5, the first and second questions are related to the companies' dealings with suppliers. The responses of the participants confirmed that there are problems with the quality of the products received, as well as financial problems with the suppliers, but in a not large way as it is equal to 27% of the total percentage. Also, the third question is related to financial problems with corporate buyers, and the percentage has risen slightly to 30%. I think even with low percentages that support the existence of actual problems for companies, the existence of a rating for users through internet will contribute to reducing this percentage significantly while providing protection for these companies.

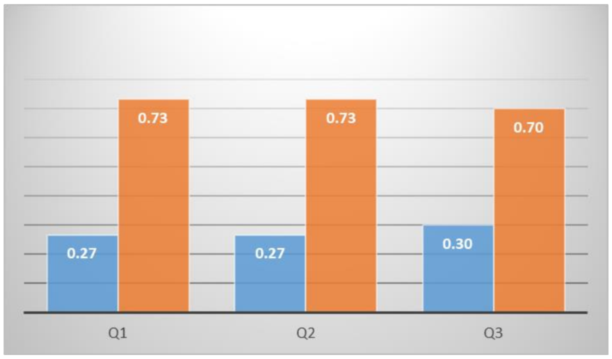

Fig. 5. Percentage Results of Companies and Online Service Providers' Questionnaire Yes/No Part.

3) Results and discussion of the third questionnaire: The third questionnaire related to banking workers or specialists in the field of regulations and laws was applied by 30 of the participants. Table VI, shows the results obtained, also Fig. 6, shows the percentages of these results for each question. As shown in the Fig. 6, the percentages of the answers to the first question are slightly tilted to refuse to track individuals 'transactions through the Internet. I believe that the percentage of approval also has weight because of the need to track individuals' transactions to prevent crimes. Using of this data was rejected more strongly in the answers to the second question from the participants, due to the sensitivity of not using this data institutionally. From observing the results, the use of this data can be permitted based on strict restrictions on its use. Finally, the answers to the third question tend to deny permission to use this data in the absence of a legal umbrella for this use.

with respect to yes/no questions, Table VII, illustrates the answers of 30 participants. Fig. 7, explain clearly the large percentages of the answer were yes. Where the three questions focus on the importance of the existence of laws and legislation to allow tracking, use and publication of individual transactions over the Internet. Naturally, this segment of the participants was encouraged to issue regulations and legislation that regulate these operations.

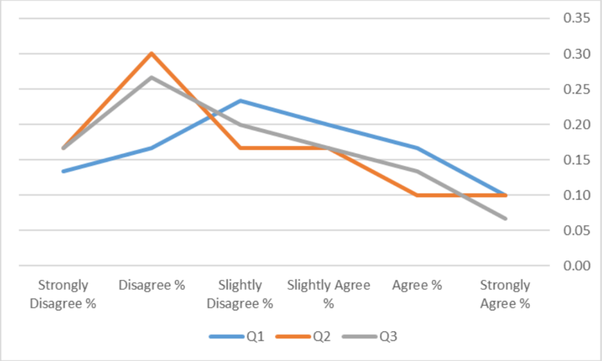

Fig. 6. Percentage Measure for Participants that are familiar with Regulations, Laws and Banking.

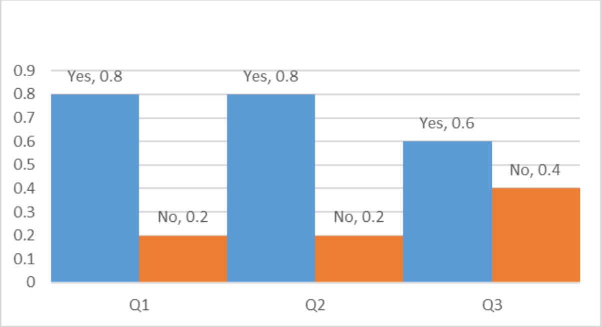

Fig. 7. Percentage Results of Those Are Familiar with Regulations, Laws and Banking Questionnaire Yes/No part.

Based on the results of the third questionnaire, it is clear that it is possible to benefit from individuals' transactions on the Internet to design the proposed model that gives a score for each individual, provided that there are legislations that support and protect the existence of this model.

Based on the results of the third questionnaire, it is possible to benefit from individuals' transactions on the Internet to design the proposed model that gives a score for each individual, provided that there are legislations that support and protect the existence of this model.

IV. Design SCSM

This model was designed based on the results and discussion of previous questionnaires. Most of the survey results support the existence of the proposed SCSM model, as the results see electronic commerce expanding at increasing rates in the future. The proposed model (SCSM) is illustrated in Fig. 8. First, with regard to our need for regulations and laws, the results of the questionnaire propose that it is better to have controls for tracking, using and disseminating individuals 'data on the Internet. Therefore, a module was added in proposed model that is responsible for monitoring and controlling the use of this data in terms of its size or who is authorized to use it. This module offers the business community a great opportunity to complete its operations with confidence and under a legal umbrella.

Based on the results of the questionnaire, there are problems in buying and selling between individuals and some

Law to Publishing Users' Information	18	12	30

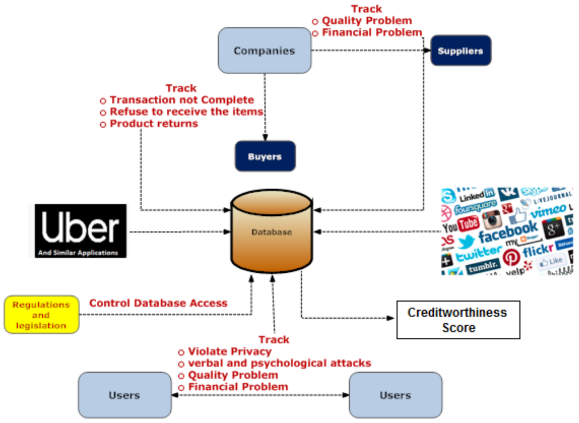

Fig. 8. Designed Model.

of them, which lose the credibility of the transaction that take place over the Internet. Therefore, this data was tracked and added to the model database in order to be used in the creditworthiness of individuals because of its weight according to the analysis of the questionnaires.

There are Another important data that needed to track and add to the model database. For example, verbal and psychological attacks, privacy violation, and data theft. This data has great weight because of its impact on accurately describing the behavior of individuals. Its presence also reduces or eliminates the fear of individuals from online transactions because it adds safety and reliability for the individuals available for transactions.

Today's social media data is very informative. Most people of different ages have multiple social media accounts. With the multiplicity and diversity of this data, our model can rely on it to give an accurate assessment of creditworthiness.

On the other hand, the use of such applications as the Uber application gives important information that reflects the behavior of individuals, whether the individual is the service provider or the beneficiary of it. Tracking this data and recording it in the form database (from discussing the survey results) is very helpful for the final decision describing the creditworthiness of each individual. Therefore, the data for these applications were added to the model as shown in Fig. 8.

V. CONCLUSION

a new concept was introduced to classify individuals in terms of creditworthiness and confidence in dealing with the Internet. This concept was developed to introduce SCSM model in order to be used to increase the reliability of transactions that take place over the Internet. The design of this model relied on collecting multiple data such as social media data, online sales and purchases data, and so on. These data and their degree of importance were determined according to several questionnaires directed to several segments of society.

The first was directed at regular users of the Internet and social media to study the extent of their confidence in transactions that take place over the Internet and what problems they face. As for the second, it was directed at the business community from companies that carry out transactions over the Internet. In this questionnaire, companies' problems with customers and suppliers are studied. Finally, there was a questionnaire directed to banking workers or specialists in the field of regulations and laws. This questionnaire was directed to study the extent of our need for laws regulating the tracking and circulation of information.

These questionnaires were analyzed and the results of the analysis were used to determine the data that is important to incorporate into the model. Finally, the SCSM was introduced.

A. Future Work

Developing the SCSM model to make it compatible with the huge development in communications and data transmission will be the focus of our attention in the future. It will be made more flexible to accept and rely on new data that arise from social media and other new services on the Internet.

Extended Graph Convolutional Networks for 3D Object Classification in Point Clouds

Sajan Kumar[1], Sai Rishvanth Katragadda[2], Ashu Abdul[3], V. Dinesh Reddy[4]
School of Engineering and Sciences
Department of CSE, SRM University,
Amaravati, AP, India

***Abstract*—Point clouds are a popular way to represent 3D data. Due to the sparsity and irregularity of the point cloud data, learning features directly from point clouds become complex and thus huge importance to methods that directly consume points. This paper focuses on interpreting the point cloud inputs using the graph convolutional networks (GCN). Further, we extend this model to detect the objects found in the autonomous driving datasets and the miscellaneous objects found in the non-autonomous driving datasets. We proposed to reduce the runtime of a GCN by allowing the GCN to stochastically sample fewer input points from point clouds to infer their larger structure while preserving its accuracy. Our proposed model offer improved accuracy while drastically decreasing graph building and prediction runtime.**

Keywords*—Object classification; graph convolution networks; non-autonomous driving

I. Introduction

Autonomous vehicles are becoming the future of mobility, supported by advances in deep learning techniques. Point cloud learning has lately attracted increasing attention due to its wide applications in many areas, such as computer vision, autonomous driving, and robotics. Recent advances in graph convolution networks suggest that graph representations could provide better features for point cloud processing. Graphs are one of the most common data structures in the analysis and storage of the real-world data-modeling of social networks, roads, etc. However, the amount of work devoted for developing the neural network models to process graphs has not been proportional to the amount of data available for such analysis. In the past couple of years, some researchers have looked at generalizing current neural network models to process arbitrary graphs, some of which we will briefly summarize later in this section. Thomas et al. [1] offers a brief overview of GCNs and the architecture is shown in Fig. 1. In essence, most GCNs have a universal architecture and their convolutional nature arises from sharing filter parameters over all graph locations.

The objective of a GCN is to learn a function of features for a given graph G, which takes the inputs:

- X, an $N \times D$ feature matrix which summarizes a feature description x_i for every node i (where N is the number of nodes, and D the number of input features),
- A descriptor of the graph's structure in matrix form, usually as an adjacency matrix A.

This produces an output Z, which is a node-level $N \times D$ feature matrix (F is the number of output features per node).

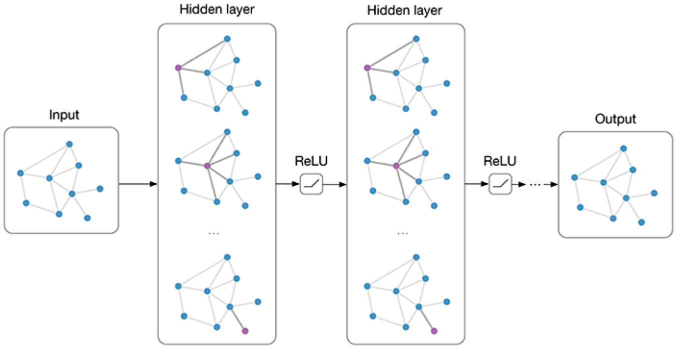

Fig. 1. Overview of a Graph Convolutional Network (GCN) and its Associated Layers [1].

Each layer H^l out of the total layers L in the GCN can then be modeled as a nonlinear function:

$$H^{(l+1)} = f(H^{(l)}, A)$$

, where

$$H^{(0)} = X \text{ and } H^{(L)} = Z. \quad (1)$$

Most GCNs only differ in how the nonlinear function f is parametrized and chosen.

The rest of this paper is organized as follows. Section II presents motivation as well as related works. Limitations and contributions are presented in Section III. Section IV elaborates the pointGCN model and the proposed work is presented in Section V. Experimental studies are then presented in Section VI, followed by a discussion on the results in Section VII. Finally, conclusions are provided in Section VIII.

II. Related Works

Existing research on processing the arbitrary graphs proposed the usage of the neural networks for extracting the information from the arbitrary graphs. Bruna et al. [2] used the graph-based analogs with the convolutional neural networks (CNN) to obtain an efficient architecture by reducing the number of parameters, relying on hierarchical clustering of the graph and by analyzing the spectrum of the graph's Laplacian matrix. David et al. [3] introduced a CNN approach with an end-to-end pipeline that could operate directly on arbitrarily sized graphs to generalize molecular feature extraction. Jain et al. [4] used the high-level modeling ability of spatio-temporal graphs to improve a recurrent neural network architecture to model the sequential computer vision tasks (like human or object interactions) more effectively. Mich et al. [5] proposed a true generalization of CNNs to work on any graph structure by developing a model based in spectral graph theory, which affords the same linear computational and learning complexity as traditional CNNs. This work constitutes a big jump forward in the field in terms of modeling GCNs. Moreover, Kipf et al. [1], created a GCN model based on spectral graph convolutions that scale linearly in the total number of graph edges. The model layer representations encoded the specific features of nodes as well as the local structure of the graph around a given region. Hence it is clear that GCNs offer a better scheme for the analysis of data that is generally arbitrarily grouped or sparse in nature, such as the structure seen in point clouds. In terms of the application of CNNs to the processing of 3D point clouds, PointNet [6] is the first major DL method for 3D classification and segmentation. The network directly takes point clouds as input and allows for efficient and effective classification, segmentation and scene semantic parsing. The model proposed by kiran et al. [7] uses 3D prior maps to reduce the computational requirements on 3D point clouds. Zar zar t al. [8] proposed the PointRGCN for using the point cloud inputs for vehicle tracking. The model uses a residual GCN and a contextual GCN for refining a 3D object from a point cloud using a graph representation of the object.

We propose to extend the PointGCN model developed by zang et al. [9]. We down sample the graph with localized convolutions to obtain the latent features for describing the local structures of the input point cloud. Our approach attempts to leverage the flexibility of GCNs in dealing with unstructured input with the inherent nature of point clouds. From our experiments, we see that proposed model reduces the computational requirements on 3D point clouds and improves the performance.

III. Current Limitation of GCN Models

Most of the research in the field of point cloud computation involves converting of 2D image to a point cloud to extract information. The existing research focusses on utilizing the depth information collected via a LiDAR for classification or segmentation (as done in PointNet). We know that such methods are accurate individually, but do not necessarily make the best use of the data at hand. The GCN models which we reviewed are effective but not necessarily specialized for real-world object classification tasks. PointGCN [9] does not appear to target any specific application and hence is not specifically optimized for any purpose. Likewise, PointRGCN [8] mainly works on bird's-eye view detection and classification tasks rather than typical views from a camera on the ground. It also uses a variety of different models to obtain its final result. Through our work, we would like to extend [9] and [8] to fit other kinds of point cloud datasets without restricting to autonomous driving. We will be looking into using some of the datasets at [10] to train on and will attempt to generalize the model to gain good predictive performance on these varied datasets.

The main contributions of the paper are:

- Extending and generalizing a GCN model to work on other kinds of LiDAR point clouds such as objects in urban environments or the interiors and exterior of buildings, without suffering a significant performance loss.
- Optimizing and generalizing current GCN model such that it can run on small computing processors such as arm cortex A7.

Our work will attempt to combine useful features from the current state of the art (for 3D object classification) into an innovative approach that will hopefully match current performance in the field at a reduced time cost. The models currently used in research (processing on a point cloud with PointNet and RGB feature/depth extraction) have their own merits and demerits. 2D RGB images are better for feature extraction and segmentation at a reduced time cost. However, the 2D RGB images lack the depth information, which leads to poor capturing of the relationship between the subject and the objects. In our approach we use the point clouds to bridge this gap for extracting the relationship between the objects and the subject. We note that we can generalize the current methods in the field to adapt with different types of data. In our approach, we adapt a method without suffering the feature loss. This method will be important for the researchers working on autonomous driving, cave mapping, home modeling, and video game designers, to name a few.

IV. Architecture of the PointGCN Model

The PointGCN appears to have the potential for flexibility in inputs and did not require the processing of its data through multiple models [9]. It was also extremely lightweight in terms of the code involved, and so would be easier to modify.The following is a brief overview of the model architecture for a Graph Convolutional Network for the purpose of 3D object classification as used in [9]. Similar to most simple CNNs, the GCN consists of a convolution layer, a pooling layer, and a fully connected layer. The graph convolutional layer allows the GCN to encompass the structural information of the object to be able to discriminate between them. Graph Laplacians of the input point cloud data are generated. The graphs are normalized to keep them to a uniform spectrum range. As described in [11], the ChebyNet Graph-CNN performs better on homogenous graphs for prediction tasks such as image classification. Hence, a similar transformation is applied to the heterogeneous graphs generated from point clouds. To obtain a single level of a feature transformation, the model applies Chebyshev polynomial filters, which keep the learned feature maps localized.

A Rectified Linear unit (ReLu) nonlinear activation function is applied at the output of each graph convolutional layer. Furthermore, global max pooling is performed after these activations are applied. This allows for the computation of the global statistics of all the output points. When multiple graph convolutional layers are used, the statistics of each layer are used together for the final probability computations.

The version of the model we used two graph convolutional layers, and the Chebyshev polynomials are of order = 4 and order = 3 for the two layers respectively. The rest is similar to as used in [9], with a 40-nearest neighbor graph for each point cloud object for graph convolution and global pooling. The intermediate outputs of the graph convolution layers are passed through a final fully-connected linear layer with softmax activation as a flattened vector. The number of output nodes in the output layer corresponds to the number of labels in the dataset, which in our case, we kept at 40 labels. Hence, the output is a vector where each index corresponds to the probability of the input belonging to that label.

V. Proposed Approach - Modified PointGCN

PointGCN was geared to be used with the ModelNet40 dataset. Therefore, in order to use the model with different datasets and different labels, we had to make the model label-agnostic, and make sure the data format we wanted to use worked everywhere in the model.

We also approached the problem from another angle. The initial implementation in [9] used 2048 point cloud examples per test/train set, and each point cloud consisted of 2048 points. This amounted to an extremely large amount of input data and meant the creation of the nearest-neighbor graphs from the point cloud data was computationally expensive and extremely memory-intensive. It often formed a bulk of the actual runtime of the network where data was fed into it. Therefore, we tried running the model and testing its accuracy with fewer training examples and points per cloud instead, which would significantly reduce runtime if successful.

We then also attempted to make some changes in the PointGCN model itself, by introducing link prediction and an entity classification layer, which helps in the recovery of missing points or facts from the dataset, and recovery of attributes corresponding to the missing entity, which was motivated by work in [12]. Hidden representation of GCN of ith layer is computed by:

$$h_i^{l+1} = \sigma\left(\sum_{jN_i} \frac{1}{c_i} W^l h_j^{(l)}\right)$$

If we introduce the link prediction and entity layer in the above function to utilize this hidden representation we can compute the edges more freely by:

$$h_i^{l+1} = \sigma\left(W_0^l h_i^l + \sum_{rR} \sum_{jN_i} \frac{1}{c_{i,r}} W_r^l h_j^{(l)}\right)$$

where $N_{r,i}$ denotes the set of neighbor indices of node i under relation rR and ci,r is a normalization constant. In the entity classification layer the GCN uses $c_{i,r} = |N - ri|$. This method helps determine a node's relational encoding, aids in nearest-neighbor finding, and helps reduce the computation cost. Though the there is an increase in the number of hyperparameter's the paper [13]

We decided to try and generalize the PointGCN model to achieve a good accuracy over two different datasets:

- Princeton ModelNet40 Dataset [14]: A volumetric representation of 3D objects across 40 categories, generated in a highly controlled environment using CAD models.
- CMU Oakland Dataset [15]: Contains 44 labels as shown in Fig. 2. This is generated using a SICK LMS laser scanners and used in push-broom, collected around the CMU campus in the neighborhood of Oakland, Pittsburgh, and contains X, Y, and Z point coordinates, corresponding labels, and confidence as properties.

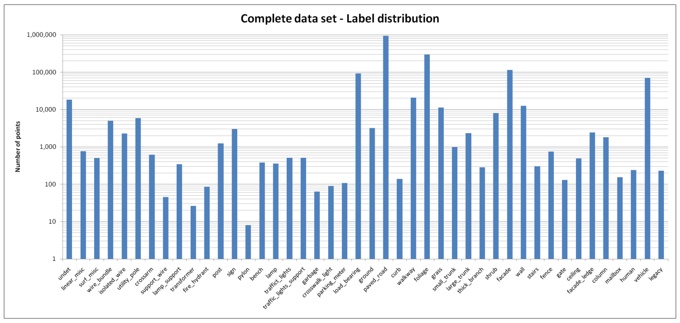

Fig. 2. A Log-scale Plot of the Distribution of the 44 Different Labels in the CMU Oakland dataset. The Four Labels with the Lowest Frequencies were Dropped out to Maintain Consistency with the 40 Outputs in the ModelNet40 Dataset.

A. Preparing Input Datasets

We faced some challenges in deciding how to generalize the input datasets to the model. The biggest is the representation of the data points in point clouds. Each prepared dataset uses a different representation of 3D point clouds, which is specific to a single model's architecture. Furthermore, the collection methods and reference frame of the collecting device also vary across datasets. Some datasets contain far more information (such as semantic annotations or segmentations) that cannot be found in other datasets. Each dataset also has a different density and distribution of points for every object in the set. The CMU Oakland dataset has labels for objects that occur so infrequently in the set that the data is unusable on a larger scale (mainly power cables or wires in the background). The PointGCN model constructs its initial graph data from two arrays found in an HDF5 file. The first, the 'data' array, is an N-by-M array with N point cloud examples and M points per point cloud. Each point in the point cloud is a 3-by-1 array consisting of the X, Y, and Z coordinates of the point. The second array is the 'label' array, an N-element array, with each index corresponding to a point cloud in the 'data' array. This meant there must be a generalized method of preparing or feeding the respective data into the model. As such, for object classification, we decided to use the bare minimum. A preprocessed dataset to the model should contain the X, Y, and Z coordinates per point, along with the object label to which that point belongs.

B. Dataset Creation

To overcome the issues we faced with point sparsity and the parsing of datasets, we wrote a script to process and 'mass-create' datasets that we could test on. This script was tested and used on the CMU Oakland dataset [15] which is shown in Fig. 3. It requires the point cloud x, y, and z coordinates, along with the corresponding label for the point, in four columns in a formatted text file as the input. This required some manual processing, including dropping points with the four least frequent labels (essentially unusable data). Dropping four labels from the 44-label Oakland dataset also allowed us

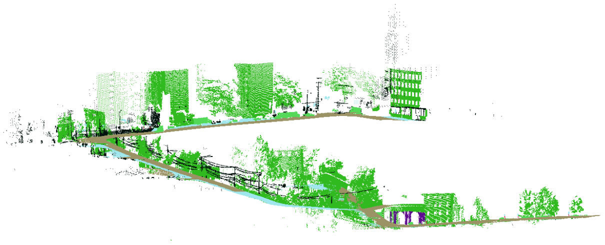

Fig. 3. A Visualization of the Complete, Preprocessed CMU Oakland Point Cloud Dataset, with the Lowest Frequency Labels Dropped from the Set.

to keep the model consistent with the total data labels in the ModelNet40 set. This would allow us to cross-test graphs made with one dataset on another dataset. A maximum number of point clouds per data file is set as well. These data points were later split into test and train datasets using a random distribution.

Once the data is read in and sorted, the creation process can begin. A label is randomly selected on a uniform distribution, and the required number of points from the corresponding data is picked to form a point cloud. In order to overcome the problem where a labeled object has too few points to create a substantially-sized point cloud for training, we add noise, or jitter, to the ground truth points, in order to create new points for the object.

The jitter fulfilled two purposes at once. First, since these points are only jittered with a value between 0.25 and 0.5 in Cartesian space, the created points would “fill in the blanks” in a sparsely-sampled object while remaining close enough in physical space to the object in question, as illustrated in Fig. 4. Secondly, the addition of random noise, and the randomized nature of label selection, allows every created dataset to be different. This would allow us to test the robustness of the model to small perturbations as well. Finally, the datasets were split into test and training datasets, of which five datasets were used for training, and two for testing.

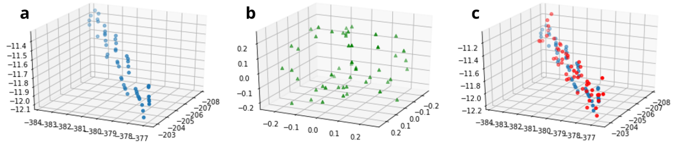

Fig. 4. A Visualization of the Jittering Process: (a) the Set of Points from the Point Cloud for the Label ‘curb’; (b) Randomly Generated Jitter Values Corresponding to Each of the Points; (c) the Original Points (blue) Along with the Jittered Original Points (red) are Added to the Point Cloud

VI. Results

The modified model was run using Tensorflow with GPU acceleration. The learning rate was set to between $12and24 \times 10^4$, and was halved every 20 epochs or so.Our first experiment simply involved training the PointGCN model on the Oakland dataset and the ModelNet40 dataset separately, and comparing the results. With the ModelNet40, after 260 epochs of testing and training, we received an average test accuracy of 86% among the 40 input classes. For the Oakland set, four of the least frequent data labels were dropped, to ensure consistency between the total number of PointGCN outputs. After 260 epochs of testing and training, we received an average test accuracy of 91%.

For the smaller point cloud tests, sets of 64 and 128 points per point cloud were used, with only 1000 training and test examples per set (5000 training examples and 2000 test examples in total). The maximum number of epochs were set at a 100. The graph batches used by the network were first built using the Oakland dataset, and then cross-tested with the ModelNet40 dataset, in order to test the flexibility of the nodes created by the model. The final results after a 100 epochs can be seen in Table I and Table II below.

TABLE I. Final Training and Test Accuracy of CMU Oakland and Princeton ModelNet40 Datasets with a Reduced Number of Points Per Cloud. With the Base Graph for the GCN Model Built using the Oakland Dataset

	64 Points per Cloud		128 Points per Cloud	
Accuracy (%)	Oakland	ModelNet40	Oakland	ModelNet40
Training Data	95.82	90.31	96.06	90.37
Test Data	91.30	87.67	92.00	88.80
Overall	**93.56**	**88.99**	**94.03**	**89.59**

TABLE II. Final Training and Test Accuracy of CMU Oakland and Princeton ModelNet40 Datasets with a Reduced Number of Points Per Cloud, with the Base Graph for the GCN Model Built using the ModelNet40 Dataset

	64 Points per Cloud		128 Points per Cloud	
Accuracy (%)	Oakland	ModelNet40	Oakland	ModelNet40
Training Data	94.65	87.72	94.23	93.73
Test Data	83.66	84.59	85.18	87.45
Overall	**89.15**	**86.15**	**89.71**	**90.59**

The results were quite surprising. Even with a significantly reduced number of points per point cloud, both the test and training accuracies of the model on both input datasets were extremely high. When a dataset is used to construct the graph batch used by the GCN model, it demonstrates a significantly higher training and test set accuracy. Nonetheless, given that both ModelNet40 and Oakland achieve 90% accuracy and 89% accuracy respectively, on graphs not even constructed from their data, shows the flexibility and robust nature of the model. Furthermore, the runtime is also drastically decreased, especially on a GPU setup. For 7000 input point clouds with 64 points per cloud, the graph build runtime was a mere 8 minutes, and the runtime for a 100 epochs was approximately 9 minutes and 40 seconds. For the same number of input clouds at 128 points per cloud, the graph build runtime was around 13 minutes and 38 seconds, with the runtime for a 100 epochs at 12 minutes and 34 seconds. This is quite remarkable given that the runtime with over 14,000 input clouds at 2048 points per cloud has a total runtime of over a day for similar levels of accuracy, even when GPU-accelerated.

VII. Discussion

From the results of the GCN’s prediction on the ModelNet40 and Oakland datasets, it is clear that the model has been extended to run with more than a single, specialized dataset. An approach using a GCN offers an adaptability that a CNN would not offer if trained on a single dataset. This would reduce the need to have to train a model on a different dataset for a different use case every time. From cross-testing one dataset on a graph built from another dataset, it is clear that the GCN has the ability to learn and refine graphs such that it can reflect the overall structure of an input point cloud. It is also a model that has the potential to be robust to changes in the input dataset. However, on comparison with a variety of other models on the ModelNet leaderboard at [16], this model falls some ways short of the state-of-the-art methods. Nonetheless, it is still better than a lot of other models on the list and so is an approach that shows promise.

TABLE III. COMPARISON WITH STATE-OF-ART METHODS ON MODELNET40 & OAKLAND DATA SET

Method	ModelNet40	Oakland
MV3D [17]	62.94	57.31
AVOD [18]	77.90	62.03
PointPillars [19]	78.39	67.39
PointRCNN [20]	85.94	73.210
RGCN [13]	83.42	74.05
PointRGCN [13]	85.97	76.73
Extended PointRGCN(Ours)	90.59	89.71

We implemented the MV3D, AVOD, PointPillars, PointRCNN, RGCN, PointRGCN, and compared with the proposed approach. All the results reported above are the average results of 10 trials for each dataset for our proposed method taking 128 points per cloud and the results are presented in Table III. The high accuracy achieved by the model on the reduced-size point clouds was also a very curious result. As such, we looked closer at how the nature of the input data to the GCN could affect its performance. The GCN model we adapted could use one of two methods for sampling from the larger point cloud set - immediate sampling or uniform sampling. Immediate sampling just takes the first 64 or 128 points in the array from the entire point cloud. Uniform sampling attempts to take 64 or 128 samples from a uniform random probability distribution across the point cloud. If the points are unsorted, both sampling methods are equivalent. However, if the points are sorted before they are passed in, using immediate sampling shows very different effects. We attempted to sort the Oakland dataset point clouds before passing them into the GCN. We found that the accuracy on the Oakland set itself dropped to a meager 33% on the training set and 24% on the test set, while the ModelNet data achieved a 41% on the training set and 37% on the test set.

This poor performance could be attributed to the GCN receiving a poor understanding of the general structure of the point cloud from the input data. In other words, with the data sorted and sampled from the front, the GCN can essentially “visualize” only a very small fraction of the entire cloud. This does not allow it to truly infer any larger-scale features, and any features it were to infer would be grossly incorrect, given that it only has access to a small physical portion of the cloud. When the data was left unsorted, it allows the GCN to sample parts of the point cloud stochastically, thus giving it enough points to infer larger features in the cloud and encode it in the graph. We can conclude from this smaller investigation that allowing uniform, randomized sampling of the entire point cloud, even with a small number of points, can offer the same levels of accuracy while drastically decreasing graph building and prediction runtime.

VIII. CONCLUSION AND FUTURE WORK

In this paper a novel approach for extending and generalizing a GCN model to work on different point clouds such as objects in urban environments or the interiors and exterior of buildings, without suffering a significant performance loss. Further, we worked on Optimizing and generalizing current GCN model such that it can run on small computing processors such as arm cortex A7. Through our experimentation on a modified version of PointGCN, we conclude that it is possible to generalize a graph convolutional network across datasets. The proposed model seems to be able to learn and preserve underlying patterns that appear in point clouds regardless of the object represented by the point cloud, and thus make for powerful processors of the data type. Additionally, our model do not appear to lose accuracy significantly when the number of points in the point cloud input is reduced, as long as the points remain representative of the larger structure of the object at hand.

In future, we would like to extend our work by looking at how exactly the graph generated by the GCN seems to preserve the global statistics of features, and how it can effectively exploit those same statistics across datasets. We can improve the performance of our current model by adding deeper layers, where they can compute the interrelation between points to generate a feature map across the datasets. As part of future work, we also plan to see if we could combine LiDAR information with RGB images for better recognition.

***Abstract*—Lattice-based crypto systems are regarded as secure and believed to be secure even against quantum computers. lattice-based cryptography relies upon problems like the Shortest Vector Problem. Shortest Vector Problem is an instance of lattice problems that are used as a basis for secure cryptographic schemes. For more than 30 years now, the Shortest Vector Problem has been at the heart of a thriving research field and finding a new efficient algorithm turned out to be out of reach. This problem has a great many applications such as optimization, communication theory, cryptography, etc. This paper introduces the Shortest Vector Problem and other related problems such as the Closest Vector Problem. We present the average case and worst case hardness results for the Shortest Vector Problem. Further this work explore efficient algorithms solving the Shortest Vector Problem and present their efficiency. More precisely, this paper presents four algorithms: the Lenstra-Lenstra-Lovasz (LLL) algorithm, the Block Korkine-Zolotarev (BKZ) algorithm, a Metropolis algorithm, and a convex relaxation of SVP. The experimental results on various lattices show that the Metropolis algorithm works better than other algorithms with varying sizes of lattices.**

Keywords*—*Lattice; SVP; CVP; post quantum cryptography

I. Introduction

A lattice an abstract structure defined as the set of all integer linear combinations of some independent vectors in R_n. Over the last two centuries, mathematicians have explored the fascinating combinatorial structure of lattices, and it has also been studied from an asymptotic algorithmic viewpoint for at least three decades. Most fundamental problems are not considered to be effectively solvable on lattices. In addition, hardness results suggest that such problems can not be solved by polynomial-time algorithms unless the hierarchy of polynomial-time collapses. Cryptographic constructions based on lattice hold a clear promise for cryptography with strong security proof, as was demonstrated by Ajtai [1], who came up with a construction of cryptographic primitives based on worst-case hardness of certain lattice problems.

Two main important and very closely related hard computational problems used by cryptographers are the Shortest Vector Problem (SVP) and the Closest Vector Problem (CVP). In the former, for a lattice specified by some basis we are supposed to find nontrivial and small nonzero vector (length of vector) in the lattice. The problem CVP is an inhomogeneous variant of SVP, in which given a lattice (specified by some basis) and a vector v, one has to find the vector in L closest to v. The hardness of these problems is partially due to the fact that multiple bases can generate the same lattice. This work presents the best hardness result known for SVP, compares different algorithms solving SVP with respect to their efficiency and optimal solution.

II. Preliminaries

A. Definitions and Related Problems

Let $(b_1,\ldots,b_n)$ be a basis in $\mathbb{R}^n$ and N a norm on $\mathbb{R}^n$. Let L denote $\bigoplus_{i=1}^{n}\mathbb{Z}b_i, L$ is called a lattice. Set

$$\lambda(L)=\min_{v\in L\backslash\{0\}} N(v)$$

We are now able to define SVP. For L a lattice, the exact form Shortest Vector Problem, denoted by $SVP(L)$ is as follows.

$$SVP(L):\ \text{Find } v\in L \text{ such that } N(v)=\lambda(L)$$

As it is often the case, we will actually be interested in algorithms solving an approximation of SVP. For $\gamma\geqslant 1$ the approximated form of $SVP(L)$, denoted by $SVP_\gamma(L)$ is

$$SVP_\gamma(L):\ \text{Find } v\in L\backslash\{0\} \text{ such that } N(v)\leqslant\gamma\lambda(L)$$

Now, a closely related problem is the Closest Vector Problem $CVP(L,x)$, defined for a lattice $L\subset\mathbb{R}^n$ and $x\in\mathbb{R}^n$ as

$$CVP(L):\ Find\ v\ \in L \text{ such that } N(v-x)=\lambda(L)$$

In its exact form. As in the above we can define an approximated problem CVP_γ

$$CVP_\gamma(L):\ Find\ v\in\ L\ such\ that\ N(v-x)\leqslant\gamma\lambda(L)$$

In fact, CVP_γ solves SVP_γ. Indeed, for $i=1,\ldots,n$ set $L^i=\mathbb{Z}b_1\oplus\ldots\oplus 2b_i\oplus\ldots\oplus b_n$ and x_i a solution to $CVP_\gamma\left(L^i,b_i\right)$, then one of the vectors in $\{x_i-b_i\}_{i=1\ldots n}$ is a solution to $SVP_\gamma(L)$. For we have the following claim:

Claim 1. Let x_i be a solution to $CVP\left(L^i,b_i\right)$ then $\{x_i-b_i\}_{i=1,\ldots,n}$ contains a solution to $SVP(L)$
Proof. Indeed, let $x=\sum n_ib_i$ be any solution to $SVP(L)$, as $N\left(\frac{x}{2}\right)<N(x)$ we get that $\frac{x}{2}\notin L$ and there is $i\in\{1,\ldots,n\}$ such that n_i is odd. Then, $x+b_i\in L^i$ Therefore, the set $\{x_i-b_i\}_{i=1,\ldots,n}$ contains a element of norm less than or equal to $N(x)$.

When N is the l^2 norm on $\mathbb{R}^n, CVP$ has another formulation that allows us to use convex optimization techniques. To this end, let B be the matrix given by the basis $(b_1,\ldots,b_n)$ and c a vector in $\mathbb{R}^n$. Then, $CVP(L,c)$ is equivalent to

$$\begin{aligned}&\text{minimize} && x^TB^TBx-2c^Tx\\ &\text{subject to} && x\in\mathbb{Z}^n\end{aligned}$$

This is readily seen by expanding out the quantity $\|Bx-c\|_2$. Following (ref), we will apply a convex relaxation to this problem to get an efficient randomized algorithm solving CVP_γ.

Finally, a last related problem is the Hermite Shortest Vector problem denoted by $HSVP$. Again, let $B \in \mathbb{R}^{n\times n}$ be the matrix given by $(b_1,\dots,b_n)$, for $\gamma \geqslant 1$, $HSVP_\gamma(L)$ is the following problem.

$$HSVP_\gamma(L): \text{ Find } v \in L \text{ such that } N(v) \leqslant \gamma|\det(B)|$$

According to a theorem of Minkowski's, HSVP and SVP are in fact closely related. The LLL algorithm described in Section III-A actually solves $HSVP_\gamma$.

B. Hardness: Average and Worst Case

An interesting feature of lattice problem is there hardness. M.Ajtai in his seminal papers [1], [2] showed in particular that worst-case hardness is related to average-case hardness and that SVP is NP-hard for randomized reductions. This makes lattice problems particularly interesting as basis for crypto systems. Example of such systems are systems of Ajtai and Dwork [3], Goldreich, Goldwasser and Halevi [4], the NTRU cryptosystem [5], and the first fully homomorphic encryption scheme by Gentry [6]. In this section we state a number of hardness results without proofs. For a more precise treatment see also [7]. The main result of worst-case to average case NP-hardness is as follows.

Theorem 1 Suppose there is a randomized polynomial time algorithm $\mathcal{A}$ such that for all $n, \mathcal{A}$ returns a vector of $\Lambda(X)$ of length $\leqslant n$ with probability $\frac{1}{n^{O(1)}}$ for $\Lambda(X)$ chosen at random in $\Lambda_{n,m,q}$ where $m = \alpha n \log(n)$ and $q = n^\beta$ for appropriate α, β. Then, there exist a randomized polynomial time algorithm $\mathcal{B}$ and constants c_1, c_2, c_3 such that for all $n, (b_1,\dots,b_n)$ basis of $\mathbb{R}^n$ and $L := \oplus\mathbb{Z}b_i, \mathcal{B}$ performs the following with high probability [3]:
1) Finds a basis $\{\beta_1,\dots,\beta_n\}$ for L such that

$$\max\|\beta_i\| \leqslant n^{c_1} \min_{(c_i)\ basis\ of\ L} \max\|c_i\|\,;$$

2) finds an estimate $\bar{\lambda}$ of $\lambda(L)$ such that,

$$\frac{\lambda_1(L)}{n^{c_2}} \leqslant \tilde{\lambda} \leqslant \lambda(L)$$

3) If moreover, L has a n^{c_3} unique shortest vector, finds this vector.

We are now oing to explain the content of this theorem. First of all, we must explain a number of concepts and notation.

Here, $\|.\|$ refers to the l^2 -norm.

A randomized algorithm is an algorithm that uses a degree of randomness as part of its process. As such, it does not guarantee success, but the probability of success for a given input size can be computed. A randomized algorithm is said to perform an event with high probability if the probability of this event goes to 1 as the input size goes to $+\infty$

We turn now to the definition of $\Lambda(X)$. Let $n, m, q \in \mathbb{N}, (\mathbb{Z}/q\mathbb{Z})^{n\times m}$ the space of matrices with entries in $(Z/q\mathbb{Z})$, and $\Omega_{n,m,q}$ the uniform distribution on $(\mathbb{Z}/q\mathbb{Z})^{n\times m}$ Now, for any $X \in (\mathbb{Z}/q\mathbb{Z})^{n\times m}$, set $\Lambda(X)$ as the lattice $\{y \in \mathbb{Z}^m \mid Xy \equiv 0[q]\}$ and $\Lambda_{n,m,q}$ the space of such lattices. We see $\Lambda_{n,m,q}$ as a probability space by choosing X according to $\Omega_{n,m,q}$ and computing $\Lambda(X)$. For any $X, \Lambda(X)$ is indeed a lattice, as $q\left(\mathbb{Z}^m\right) \subset \Lambda(X)$.

Finally, for $c \geqslant 1$ a lattice L endowed with a norm N is said to have a c-unique shortest vector v if the following holds

$$\{v \in L \mid N(v) \leqslant c\lambda(L)\} = \{v, -v\}$$

This result is called a worst-case to average case hardness because it links the lack of a polynomial ranodmized algorithm over 'all' lattices to the lack of such algorithm for a small class of lattices, namely $\Lambda_{n,m,q}$. We also note that similar results exist for related problems such as CVP. In the following, we list further hardness results.

Theorem 2 SVP is NP -hard under the l_∞ -norm. Moreover, CVP is NP-hard under the l_p -norm for all $p \geqslant 1$ [8]..

Theorem 3 For all γ, CVP_γ is NP-hard under any l_p -norm [9].

Building on results by Ajtai [2], Micciancio proved the following.

Theorem 4 For all $\epsilon > 0, SVP_{\sqrt{2}-\epsilon}$ is NP -hard under randomized polynomial time reductions [10].

Finally:

Theorem 5 There is $c > 0$ such that CVP is NP-hard to approximate within a factor $n^{\frac{c}{log(log(n))}}$, where n is the dimension of the lattice [11].

Many other results related to hardness exist. We only decided to mention some of the most fundamental ones.

III. Solving SVP

This section presents solving SVP and related results. Even though many hardness results have been found, we can still solve approximate SVP within some reasonable constant depending on the input size. Usually, the 'reasonable constant' is not known theoretically to be 'reasonable' but only empirically. For instance, the first algorithm on this list, LLL, is only known to solve SVP within a factor exponential in the input size. However, results with LLL are in practice much better than the bound.

A. Lenstra-Lenstra-Lováz Algorithm

This section presents the Lenstra-Lenstra-Lovász reduction basis algorithm, by Lenstra, Lenstra and Lovász, see [12]. Originally, the purpose of this algorithm is to factor polynomials, we will not consider this problem here.

Moreover, it is important to note that the techniques used were developed by Hermite, Minkowksy and others to study Siegel sets and lattices in algebraic groups. This is why LLL is in fact an algorithm solving $HSVP$. $HSVP$ and SVP are related thanks to the following results due to Minkowski.

Theorem 6 (Minkowski). Let $n \in \mathbb{N}$ and L be any lattice in $\mathbb{R}^n$, then

$$\lambda(L) \leqslant \gamma_n(\det(L))^{\frac{1}{n}}$$

where γ_n is some constant depending only on n. More precisely, γ_n is known to satisfy

$$\sqrt{\frac{n}{2\pi e}} \leqslant \gamma_n \leqslant \sqrt{\frac{n}{\pi e}}$$

This theorem admits a short and elementary proof but can also be seen as a consequence of Minkowski's convex body theorem. For proofs and further details see [13] and [14]. In particular, we get the following important fact.

Claim 2. For $\gamma \geqslant 1, HSVP_{\gamma_n\gamma}(L) \Rightarrow SVP_{\gamma}(L)$

The Gram-Schmidt orthogonalization method is critical in the LLL algorithm, we briefly recall what this method entails. Let $(V, \langle\cdot,\cdot\rangle)$ be a vector space endowed with a scalar product and $\|\cdot\|$ the l_2 -norm on V given by this scalar product. For any basis $(b_1, \ldots, b_n)$ we define inductively its orthogonalization $(b_1^*, \ldots, b_n^*)$ as

$$b_i^* = b_i - \sum_{j<i} \left\langle b_i, b_j^* \right\rangle b_j^*$$

This new basis $(b_1^*, \ldots, b_n^*)$ is orthogonal i.e. $\left\langle b_i^*, b_j^* \right\rangle = 0$ whenever $i \neq j$. More-over, $\operatorname{span}(b_1, \ldots, b_r) = \operatorname{span}(b_1^*, \ldots, b_r^*)$ for all $1 \leqslant r \leqslant n$. In the following, we will pay particular attention to the Gram-schmidt coefficients $\mu_{i,j} := \frac{\langle b_i, b_j \rangle}{\|b_j^*\|^2}$ for $i > j$. Moreover, let B^* be the matrix with columns the vectors $(b_1^*, \ldots, b_n^*)$ and L the lattice generated by $(b_1, \ldots, b_n)$. Then, it is readily seen that vol $(L) = \|b_1^*\| \cdot \ldots \cdot \|b_n^*\|$. (For vol $(L) = |\det(B^*)|$ as for all i we have $\operatorname{span}(b_1, \ldots, b_r) = \operatorname{span}(b_1^*, \ldots, b_r^*)$, but $\operatorname{diag}\left(\|b_1^*\|^{-1}, \ldots, \|b_n^*\|^{-1}\right) B^* \in O_n(\mathrm{R})$ so $\det(B^*) = \|b_1^*\| \cdot \ldots \cdot \|b_n^*\|$.) Now, assume that $\frac{\|b_i\|}{\|b_{i-1}\|}$ is bounded below by some constant $c > 0$. As $b_1 = b_1^*$, we get that

$$\|b_1\|^n \leqslant c^{-n(n-1)/2} \|b_1^*\| \cdot \ldots \cdot \|b_n^*\| = c^{-n(n-1)/2} \operatorname{vol}(L)$$

So b_1 is a solution to $HSVP_{c-(n-1)/2}(L)$.
In order to make use of this observation, we define the following condition.

Definition 1 (Lovász' condition). A basis $(b_1, \ldots, b_n)$ satisfies Lovasz' condition if there is $\delta \in \left(\frac{1}{4}, 1\right]$ such that for all $2 \leqslant i \leqslant n$

$$\frac{\|b_i\|^2}{\|b_{i-1}\|^2} \leqslant \delta - \mu(i, i-1)^2$$

Where $(b_1^*, \ldots, b_n^*)$ is the Gram-Schmidt orthogonalization of $(b_1, \ldots, b_n)$.

```
initialization;
Require: a basis $(b_1, \ldots, b_n)$ of $L$ and $\delta \in \left(\frac{1}{4}; 1\right]$
Ensure: the output basis $(b_1, \ldots, b_n)$ of $L$ satisfies
  Lovász' condition
$i \leftarrow 2$
while $i \leqslant n$ do
    $b_i \leftarrow b_i - \sum_{j<i} \mid \mu_{i,j} \rceil b_j^*$
    if $\|b_i^*\|^2 \geqslant \left(\delta - \mu_{i,i-1}^2\right) \|b_{i-1}\|^2$ then
        $i \leftarrow i + 1$
    else
        $swap\ b_i,\ b_{i-1};$
        $i \leftarrow \max(2, i-1);$
    end
end
```

Algorithm 1: LLL basis reduction algorithm

For the sake of simplicity, we removed the necessary parts that consist in updating the Gram-Schmidt orthogonalization and Gram-Schmidt coefficients. Therefore, the previous algorithm is only a sketch of the Lenstra-Lenstra-Lovász reduction algorithm. Let us now state the main result about this algorithm, namely its complexity and the properties of the output basis.

Theorem 7 Let $(b_1, ..., b_n)$ be a basis generating a lattice L and $\delta \in \left(\frac{1}{4}, 1\right]$. Given these as input, the LLL algorithm terminates in poly $\left(d, (1-\delta)^{-1}, \log(\max\|b_i\|)\right)$ and the output is a basis $(\beta_1, \ldots, \beta_n)$ generating L such that:

$$\frac{\|\beta_1\|}{\operatorname{vol}(L)^{1/n}} \leqslant \left(\frac{1}{\delta - \frac{1}{4}}\right)^{(d-1)/4}$$

In particular, for $\delta = 1 - \epsilon$ with e small, the LLL algorithm terminates in $poly\left(d, \frac{1}{\epsilon}, \log(\max\|b_i\|)\right)$ time and the output satisfies:

$$\frac{\|\beta_1\|}{\operatorname{vol}(L)^{1/n}} \leqslant \left(\frac{4}{3} + O(\epsilon)\right)^{(d-1)/4} \simeq 1.07^{d-1}$$

Empirically, it has been observed that for large n, that $\frac{\|\beta_1\|}{\operatorname{vol}(L)^{1/6}}$ is around 1.02^n which is a considerable improvement [15].

This result is about how well LLL solves the Hermite Shortest Vector Problem [12]. According to a remark made earlier, we obtain the following result concerning our main interest, the Shortest Vector Problem.

Corollary 1. With the same input as above, the output $(\beta_1, \ldots, \beta_n)$ satisfies:

$$\frac{\|\beta_1\|}{\operatorname{vol}(L)^{1/n}} \leqslant \left(\frac{1}{\delta - \frac{1}{4}}\right)^{(d-1)/2}$$

Or for $\epsilon > 0$ small and $\delta = 1 - \epsilon$ we get that:

$$\frac{\|\beta_1\|}{\operatorname{vol}(L)^{1/n}} \leqslant \left(\frac{4}{3} + O(\epsilon)\right)^{(d-1)/2} \approx 1.15^{d-1}$$

More precisely, we can get the following complexity.

Theorem 8 (Lenstra-Lenstra-Lovaisz, 1982,[L.LL 82]). The LLL algorithm has complexity $O\left(n^6 \log\max\|b_i\|\right)$.

Now, we briefly mention an improvement of LLL due to Schnorr and Euchner, see [16]. In the previous algorithm, when the swap function is applied, instead of swapping b_i and b_{i-1} we apply what Schnorr and Euchner call deep insertions. This entails to inserting b_i at the index j where j is the smallest index satisfying:

$$\delta \left\|b_j^*\right\| \geqslant \|b_i\|$$

The result of this change is shorter outputs but longer running time.

B. Block Korkine-Zolotarev Algorithm

The Block korkine-Zootarev (BKZ) algorithm is another algorithm solving SVP_γ. Even though it also runs in polynomial time, its purpose is to achieve better accuracy than LLL, therefore has longer running time. After breaking down how LLL algorithm works, we could see that it uses an SVP-oracle for lattices in dimension 2 called Gauss's reduction. Given more efficient oracles or higher dimensional SVP -oracles we could hope for a more efficient algorithm. This algorithm was proposed by Schnorr and Euchner in their paper [17].

Along this line of thought, given an SVP-oracle for all dimensions up to some integer k the BKZ algorithm finds a shorter vector than LLL does. Unsurprisingly, running BKZ takes more time than running LLL. Here, there is a clear tradeoff between the shortness of the output and the complexity of the algorithm. Moreover, as of today it is not known theoretically if BKZ terminates in polynomial time, only empirical results are known.

Here, an SVP-oracle is a mean by which we are able to solve the exact SVP. Many techniques were developed to solve SVP, but as one could guess from NP-hardness results, all these methods have at least exponential time complexity. Therefore, it is not deemed feasible to run these algorithms in high dimension. Among such oracles are enumeration algorihtms which are some kind of greedy algorithms that dates back to Pohst [18], sieving techniques which are applications of Monte-carlo methods (just as the next section is) due to Micciancio and Voulgaris in [19], and a method based on Voronoi cells due to the same authors in [20]. Even though these methods have exponential complexity, they can still be used for lattices in reasonably large dimension.

Let us now turn to the exposition of BKZ algorithm. To this end, we first need to define the notion of Korkine-Zolotarev reduced basis and a KZ-reduction algorithm. Suppose we have a SVP -oracle $\mathcal{O}$ up to dimension k and, for any basis $(b_1, \ldots, b_k)$ generating a lattice L define $\pi_i : \mathbb{R}^k \to \operatorname{span}(b_1, \ldots, v_i)^\perp$ as the orthogonal projection and $L_i = \pi_{i-1}(L)$. A basis $(b_1, \ldots, b_n)$ is called KZ-reduced if

$$||b_i^*|| = \lambda(L_i)$$

where $(b_1^*, \ldots, b_n^*)$ is the Gram-Schmidt reduction of $(b_1, \ldots, b_n)$. (Note that $\pi_i(b_i) = b_i^*$.) As for all i there is $\alpha_i \in [-1/2; 1/2]$ such that $\alpha_i b_i^\infty + b_{i+1}^* \in L_i$ we get by an induction argument the following theorem.

Theorem 9. Let $(b_1, \ldots, b_n)$ be a KZ -reduced basis. Then,

$$\|b_1\| = \lambda(L) \text{ and } \frac{\|b_1\|}{\|b_k\|} \leqslant k^{(1+\log(k))/2}$$

Moreover, we have the following KZ-reduction algorithm.

```
Result: Write here the result
initialization;
Require: a basis $B = (b_1, \ldots, b_n)$ for $L$ and a $SVP$
  -oracle $\mathcal{O}$ for up to $k$ dimensions.
Ensure: The output basis is KZ-reduced.
$m \leftarrow c(R)$
for $i = 1$ to $k$ do
    call $\mathcal{O}$ to find $b_i^* \in \pi_i(L)$ of length $\lambda(\pi_i(L))$
    lift $b_i^*$ into $b_i \in L$ such that $\|b_i^* - b_i\|$ is minimal;
    change $(b_{i+1}, \ldots, b_k)$ such that $(b_1, \ldots, b_k)$
      generates $L$
end
```

Algorithm 2: KZ-reduction algorithm

Note that step 4 may look as hard as solving CVP but is actually a lot easier thanks to the properties of orthogonal projections. Now, BKZ is as follows.

Algorithm 3 Schnorr and Euchner's BKZ-reduction algorithm
Require: a basis $B = (b_1, \ldots, b_n)$ for $L, \text{ak} \in \mathbb{N}, \delta \in \left(\frac{1}{4}, 1\right)$ and a SVP -oracle $\mathcal{O}$ for up to k dimensions.
Ensure: The output basis satisfies Lovisz' conditon with factor δ and $\|b_i^*\| = \lambda\left(\pi_{i-1}\left(\bigoplus_{j=1}^k b_{i+j-1}\right)\right)$ for i from 1 to $d-k+1$

```
initialization;
Require: a basis $B = (b_1, \ldots, b_n)$ for
  $L, \text{ak} \in \mathbb{N}, \delta \in \left(\frac{1}{4}, 1\right)$ and a $SVP$ -oracle $\mathcal{O}$ for up
  to $k$ dimensions.
Ensure: The output basis satisfies Lovisz' conditon
  with factor $\delta$ and $\|b_i^*\| = \lambda\left(\pi_{i-1}\left(\bigoplus_{j=1}^k b_{i+j-1}\right)\right)$
  for $i$ from 1 to $d-k+1$
repeat
    for $i = 1$ to $d-k+1$ do
        KZ-reduce the basis $\pi_{i-1}(b_i, \ldots, b_{i+k-1})$;
        Lift up to the closest vectors in $L$ and
          complete the basis.
    end
until no changes occur;
```

Algorithm 3: Schnorr and Euchner's BKZ-reduction algorithm

The theoretical complexity computation of this algorithm is not computed, but the following can be proved.

Theorem 10 Given a basis $(b_1, \ldots, b_n)$ generating L and an SVP oracle $\mathcal{O}$ for up to k dimensions, the BKZ algorithm outputs a basis $(\beta_1, \ldots, \beta_n)$ generating L that satisfies:

$$\frac{\|b_1\|}{\lambda(L)} \leqslant \left(k^{\frac{1+\log(k)}{2k-2}}\right)^{n-1} \text{ and } \frac{\|b_1\|}{\operatorname{vol}(L)^{1/d}} \leqslant \sqrt{\gamma_k}\left(k^{\frac{1+\log(\omega)}{2k-2}}\right)^{n-1}$$

C. Metropolis-Hasting's Algorithm

The next algorithm is a randomized algorithm applying the well-known Metropolis algorithm, a kind of Monte-Carlo method, to lattice problems. For a precise account on this method see for instance [21]. The following Metropolis algorithm is due to Ajitha, Biswas, and Kurur in [22]. This algorithm returns an approximate solution with respect to the euclidean norm, denoted by $\|\cdot\|$.

The search space is defined as follows.

Once again let $(b_1,\ldots,b_n)$ be a matrix of R^n, L the lattice it generates and B the matrix given by $(b_1,\ldots,b_n)$.

The main idea behind this Metropolis-Hastings is to work on a bounded set of vectors with integer entries and pair each of these vectors v to a cost $c(v) := \|Bv\|$. If $w \in L$ has norm less than or equal to k then $w = Bv$ where v has integer entries bounded above by $M = (\alpha n)^n$, where $\alpha = \max_{i,j}\left(|b_{ij}|, k\right)$. Thus, it is enough to look at vectors bounded above by M. As we want to modify the vector step by step, it is interesting to work with more than one vector at a time. Let us now define the Markov chain we will be working on.

Fix parameters $k \in \mathbb{R}, m \in \mathbb{N}$ and set M as above. The search space S consists of matrices $A' := [A \mid I]$ with integer entries bounded above by M where A is a $n \times m$ matrix and I is the $n \times n$ identity matrix. It remains only to describe the transition probability of the Markov chain. We first describe the neighbourhood of a given the state, the actual transition matrix will be described later on in the pseudo-code of the Metropolis-Hastings algorithm.

A matrix $S' = [S \mid I]$ is in the neighbourhood $N(R')$ of $R' = [R \mid I]$ if

(i) S is equal to R up to swapping two columns;
(ii) S is equal to R up to multiplying a column by -1
(iii) we can get from R' to S' by $r_i \leftarrow r_i \pm 2^l r_j$ for any $1 \leqslant i \leqslant m, 1 \leqslant j \leqslant n+m, i \neq j$

Two interesting features of S are:

- For any $R' \in S, \#N(R') = O\left(m^2 \log(M)\right)$
- For any $R', S' \in S$, there is a path between R' and S' of length $O(mn\log(M))$

Let us now turn to the pseudo-code and the actual description of the transition probability.

Here, (p_i) is a probability distribution on $\mathbb{N}$ such that there is $n_0 \in \mathbb{N}$ satisfying $p_i = 0$ for all $i \geqslant n_0$. This algorithm seems to give better results than LLL for lattices in low dimensional vector spaces. However, in higher dimension such methods will have to deal with the following geometric issue, the so-called *curse of dimensionality*. Let $R > \epsilon > 0$ then

$$\frac{\mathrm{vol}\left(B_{\mathbb{R}^n}(R)\right)}{\mathrm{vol}\left(B_{\mathbb{R}^n}(R-\epsilon)\right)} \rightarrow_{n\rightarrow+\infty} 0$$

Therefore, as n goes to $+\infty$ 'most' of the states of the markov chain built in the Metropolis algorithm will lie in the annulus $B_{\mathbb{R}^n}(R) \backslash B_{\mathbb{R}^n}(R-\epsilon)$ and the markov chain might take more and more time before hitting any point inside $B_{\mathbb{R}^n}(R-\epsilon)$. For more on related heuristics see [23].

```
initialization;
Require: a basis $B = (b_1,\ldots,b_n)$ for $L$ and $K \in \mathbb{Q}$
Ensure: Matrix $R$ with integer entries such that $BR$
  has a column $c$ with $\|c\| \leqslant K$.
$m \leftarrow c(R)$
while  $m > K$ do
    Select $S$ a neighbour of $R$ by performing one of
      the following operations.
        • Swap two columns with probability $\frac{C_2^m}{\#N(R)}$;
        • Multiply a column by -1 with probability $\frac{m}{d}$
        • Add $2^i$ times a column of $R$ to another column of $R$
          with probability $\frac{d-C_3^m-m}{d} \cdot p_i$
    if *if* $m > c(R)$ then
        $m \leftarrow c(R)$;
    end
    if $S \in S$ then
        $R \leftarrow S$ with probability $\min\left(\frac{e^{-c(S)/T}}{e^{-c(R)/T}}, 1\right)$;
    end
end
```

Algorithm 4: Metropolis-Hasting's algorithm for SVP

Finally, note that a similar method is widely used to solve exact instances of SVP. The version of this algorithm used to solve SVP is called a sieve method and is often used as an SVP -oracle in the BKZ algorithm, see for instance the following paper by Micciancio and Voulgaris [19].

D. Convex Relaxation

This section presents the convex relaxation (see [24] for definitions and results on convex relaxation) to obtain another randomized algorithm to solve CVP_γ (thus, SVP_γ as well). As mentioned in the first part of this report, CVP_γ admits another formulation, more precisely $\mathrm{CVP}(L,c)$ is equivalent to

(1)
$$\begin{gathered} \text{minimize} \quad x^T B^T B x - 2c^T x \\ subject\ to\ x \in \mathbb{Z}^n \end{gathered}$$

.
Where B be the matrix given by the basis $(b_1,\ldots,b_n)$ and c a vector in $\mathbb{R}^n$. A convex relaxation consists in relaxing the hard condition $x \in \mathbb{Z}^n$ to a looser condition so that the problem considered is now a convex optimization problem. Here, the method is due to Park and Boyd in [25]. The convex relaxation is in this particular case an instance of semidefinite programming, for more on this topic see [26]. We first relax Problem 1 into a non-convex problem

(2)
$$\begin{gathered} \text{minimize} \quad x^T B^T B x - 2c^T x \\ \text{subject to } x_i(x_i - 1) \geqslant 0, \forall i \end{gathered}$$

Now, set $P := B^T B$ we can reformulate Problem 2

$$minimize Tr(PX) - 2c^T x$$

(3) subject to $\operatorname{diag}(X) \geqslant x$

$$X = xx^T$$

Finally, relax condition $X = xx^T$ of Problem 3 to $X \geq xx^T$ which means that $X - xx^T$ is semidefinite positive. But $X \geq xx^T$ is equivalent to $\begin{bmatrix} X & x \\ x^T & 1 \end{bmatrix} \geq 0$. So we get the following relaxation.

(4)

$$\begin{array}{ll} \text{minimize} & \operatorname{Tr}(PX) - 2c^T x \\ \text{subject to} & \operatorname{diag}(X) \geqslant x \end{array}$$

$$\begin{bmatrix} X & x \\ x^T & 1 \end{bmatrix} \geq 0$$

Now, this is a semi definite relaxation that can be solved in polynomial time.

```
initialization;
Require: $P = B^T B, c \in \mathbb{R}^n, K \in \mathbb{N}$
Solve (4) to get $X^*$ and $x^*$
$\Sigma \leftarrow X^* - x^* x^{4T}$
Find Cholesky factorisation $LL^T = \Sigma$;
$x^{\text{best}} \leftarrow 0$;
$f^{\text{best}} \leftarrow 0$
for k=1,2, ..., K do
    $z^{(k)} \leftarrow x^* + Lw$ where $w \sim \mathcal{N}(0, I)$
    $x^{(k)} \leftarrow \text{round}\left(z^{(k)}\right)$
    if $f^{best} > f\left(x^{(k)}\right)$ then
        $x^{best} \leftarrow x^{(k)}$;
            $f^{best} \leftarrow f\left(x^{(k)}\right)$
    end
end
```

Algorithm 5: Randomized algorithm for suboptimal solution

Where the Cholesky factorisation is an algorithm computing the square root of a positive semidefinite matrix in $O\left(n^3\right)$ [27].

```
initialization;
Require: $x \in \mathbb{Z}^n, P = B^T B, c \in \mathbb{R}^n$.
$g \leftarrow 2(Px + c)$
repeat
    Find index $i$ and integer $a$ minimizing $a^2 P_{ii} + cg_i$;
    $x_i \leftarrow x_i + c_3$
    $g \leftarrow g + 2cP_i$
until $\operatorname{diag}(P) \geqslant |g|$;
```

Algorithm 6: Greedy descent algorithm

This last algorithm runs in polynomial time as well. Combining these two algorithms we get a approximate solution such that for all integer $a \in \mathbb{Z}$ and all index i, x is a better solution than $x + ae_i$

IV. Experimental Results

This section describes how the said approaches perform on benchmark instances. We see that the output of the LLL algorithm is near to the shortest vector which is $2^{\frac{n-1}{2}}$ of the shortest vector for the given lattice, it can be used for polynomial factoring etc. LLL algorithm complexity is $O\left(n^6 \cdot \log^3 \beta\right)$, where β is $\max_{1 \leq i \leq n} ||b_i||$. We ran tests to compare LLL algorithm and BKZ algorithm on data from [22], [21] and [24].

For experimental analysis a class of SVP instances are generated using the techniques developed by Richard Lindner and Michael Schneider [28]. They have given sample bases for Modular, Random, ntru, SWIFT and Dual Modular lattices of dimension 10. We have tested our code for all these instances and found that our algorithm works faster and gives shorter lattice vector when compared to LLL. The tested results are given in the Table I.

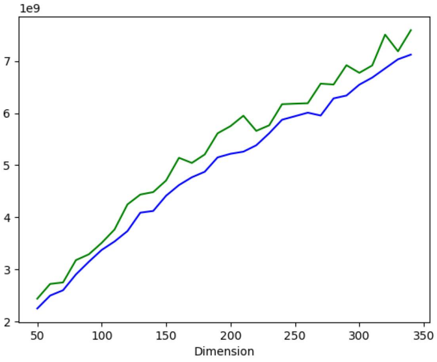

Fig. 1. Norm of the Output/ Dimension; Blue: BKZ / Green: LLL.

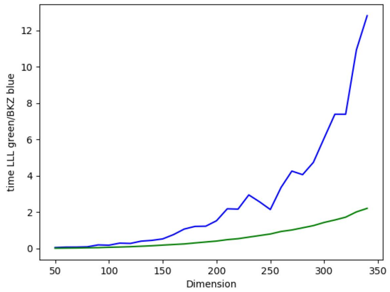

Fig. 2. Running time/ Dimension; Blue: BKZ / Green: LLL.

A. LLL/BKZ

Fig. 1 and Fig. 2 compare the basis reduction algorithms LLL and BKZ for a given family of Lattices parametrized by their dimension. Moreover, BKZ given an enumeration oracle for blocks of size 30. In particular, we see that with these parameters, the BKZ algorithm needs considerably more time to get a slightly shorter vector. To some extent, the LLL algorithm already seems to be efficient. A comparative results for running time of BKZ and LLL algorithms for varying dimension of lattice is given in Fig. 2.

TABLE I. RESULTS OF LLL AND MH FOR VARIOUS LATTICES

n	Input size	t (LLL: MH algo)	Norm (LLL: MH algo)
15	150	1234.58: 1147.2279	0.016: 201.651
20	8	3: 2.8284	0.2680: 0.052
25	8	1.73: 1.73	0.008: 0.004
30	8	4.123: 3.8729	0.008: 0.008
50	100	20.49: 8.66	0.108: 291.892

B. Metropolis-Hasting's Method

For a specific class of lattices [21], we have tested LLL and MH algorithms and the results are shown in Table I. Moreover, these data seem to support the curse of dimensionality heuristic as we can see the times needed to solve cases with large input size is high compared to small input size.

C. Convex Relaxation

The algorithm from [24] returns an approximate solution to CVP shown in Table II. To test their method, they computed solutions for instances randomly generated : all entries ar $\sim \mathcal{N}(0,1)$ then normalized so that the solution to problem (1) without the integer constraint has value -1. In what follows, n will denote the dimension, opt the percentage of outputs that were optimal solutions and t the time it took to get this output. All values are averages.

TABLE II. RESULTS FOR CVP FOR RANDOM INSTANCES

n	t	opt
50	0.397	90%
60	0.336	94%
70	0.402	89%

Because of the NP -hardness of CVP it is hard to compute the quantity opt in higher dimensions. However, the break down of running times of the method for larger $n's$ presented in Table III.

TABLE III. RUNNING TIMES OF THE CONVEX RELAXATION

n	t_{total}	SDP	Random sampling	Greeedy 1-opt
50	0.397	0.296	0.065	0.036
60	0.336	0.201	0.084	0.051
70	0.402	0.249	0.094	0.058
100	0.690	0.380	0.193	0.117
500	20.99	12.24	4.709	4.045
1000	135.1	82.38	28.64	24.07

In spite of the theoretical running time being $O\left(n^3\right)$ we can note that the total running time seems to grow subcubically.

V. CONCLUSION

In this paper we have discussed Shortest Vector Problem, Closest Vector Problem and their average case and worst case hardness results. Further, this work presented solving SVP using the LLL algorithm, BKZ algorithm, a Metropolis algorithm and a convex relaxation. We have compared the performance of these algorithms on various lattices by varying input sizes and the results we have obtained are fairly encouraging. The experimental results on various lattices shows that Metropolis algorithm works better than other algorithms.

ACKNOWLEDGMENT

The authors would like to thank the reviewers for their valuable comments.

Black-box Fuzzing Approaches to Secure Web Applications: Survey

Aseel Alsaedi[1], Abeer Alhuzali[2], Omaimah Bamasag[3]
Computer Science Department, Faculty of Computing and Information Technology
King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—Web applications are increasingly important tools in our modern daily lives, such as in education, business transactions, and social media. Because of their prevalence, they are becoming more susceptible to different types of attacks that exploit security vulnerabilities. Exploiting these vulnerabilities may cause damage to the web applications as well as the end-users. Thus, web apps' developers should identify vulnerabilities and fix them before an attacker exploits them. Using black-box fuzzing techniques for vulnerability identification is very popular during the web apps' development life cycle. These techniques pledge to find vulnerabilities in web applications by constructing attacks without accessing their source codes. This survey explores the research that has been done in the black-box vulnerability finding and exploits construction in web applications and proposes future directions.**

***Keywords*—Black-box fuzzing; web application security; vulnerability scanning; automatic web app testing; vulnerability detection; survey**

I. Introduction

Web applications are significant components in various fields: commercial, banking, entertainment, education, healthcare, and social networking. To reach international markets, organizations have utilized web applications to promote their products/goals and provide end-user services. In recent years, web applications have evolved rapidly. This rapid development has led to the use of different technologies and libraries, which results in more complex and feature-full applications. Many application developers do not have the necessary security skills that prevent them from writing buggy code. That, in turn, allows attackers to exploit those vulnerabilities and may cause damage. Thus, the security of web applications is of paramount concern.

Verizon's 2019 report [1] stated that most data breaches occurred due to attacks on web applications. Two out of three of all the examined data breaches were in web applications. Another report on web application vulnerability [2] analyzed nearly 5,000 different web apps from March 2019 until February 2020 and found that 26% of these applications have critical vulnerabilities. The remaining apps had medium-level vulnerabilities. All these studies indicate that vulnerabilities are prevalent in web applications.

Typically, security staffs use manual analysis to identify vulnerabilities to fix. This process is time-consuming and error-prone, as it depends on the expertise level of the analyst, and it is challenging because of the increasing complexities of web applications. Additionally, manual analysis is difficult to perform in each new update on applications that can lead an attacker to exploit vulnerabilities.

Many automated techniques for vulnerability analysis and exploit constructions have been proposed. These approaches aim to reduce the cost, time, effort, and precision during testing. Due to these benefits, these types of approaches have become a hot topic in recent years, especially when applications tend to be complex. Broadly, these approaches can be categorized into white-box, and black-box fuzzing approaches. The white-box testing is based on examining the source code and the behavior of a web application to find security vulnerabilities. Several studies utilized this technique to identify critical vulnerabilities in web applications such as [3], [4], [5], [6], [7], [8], and [9]. Unfortunately, this type of approach cannot apply to a wide range of web apps; many times, it is specialized for a particular programming language. Additionally, the source code of the web app is not available at each time. On the other hand, the black-box fuzzing is a vulnerability-analysis and exploits construction approach that automatically discovers vulnerabilities and generates exploits without accessing the source code. Compared with white-box, the major benefit of using black-box fuzzing is that it is fast and efficient, and it can find security bugs in any web application, regardless of its implementation details. Thus, this technique applies to a wide range of web applications. Additionally, the black-box fuzzing approach is helpful for developers who have little or no experience in writing secure source code.

As a result of the pressing need to protect web applications without accessing the source code, a significant research effort has been geared towards developing many techniques for detecting web applications using the black-box fuzzing approach. Much of this research addresses a specific class of vulnerabilities or delivers fewer false positives, such as [10] and [11].

As such, the primary goal for this survey is to analyze the last ten years of existing bug-finding techniques in web applications , focusing on the black-box fuzzing approach. Further, this survey contributes towards identifying the challenges of the black-box fuzzing approaches, which aids the research community in determining where further research can be performed and provides valuable insights for improving the crawling module. Because of our goal, this survey intends to answer the following questions:

1) What are the techniques utilized by the approach?
2) Is the approach applicable to be used in modern web applications?
3) How does the approach construct benign inputs needed by web applications to explore further and test the application?

This paper is organized as follows. Section 2 provides an overview of the web application and its common vulnerabilities. Section 2 describes a black-box fuzzing approach, and Section 4 analyzes and compares existing approaches. Section 5 discusses the results by identifying current techniques' main weaknesses and then identifying potential research areas. Finally, Section 6 concludes our review.

II. Web Applications' Architecture and Common Vulnerabilities

A. Web Application Architecture and Characteristics

The traditional web applications have a three-tier architecture: client-side, server-side, and back-end databases that provide and store the web application data. The client-side part is executed on the user's web browser, allowing the user to interact and communicate with the web application via user inputs, links, etc. The client-side code is written using different technologies such as HTML, JavaScript, and CSS. On the other hand, the server-side is executed on the web server, responding to the client messages and managing the business logic. Server-side code is commonly written in PHP, Java, and so on. The client-side and server-side communicate with each other through messages, which are HTTP requests and responses. To demonstrate how a web application works, Fig. 1 shows a high-level view of how a typical web application works when communicating with the server-side to register a new user. It can be summarized as follows:

1) The user opens the web page, which its browser can render, and fills out all the necessary inputs to complete the registration. Filling out inputs on web forms provides interactions between users and browsers that enable users to deal with different input types, such as numeric and text. Once the user has completed the fill-in and submitted the form (usually by clicking the submit button), the inputs are encapsulated into an HTTP request and sent to the server.
2) The server-side receives the client request and then processes it.
3) The server-side sends the web form data to the database as a query to add the user to the web application list.
4) The server-side replies to the user as an HTTP response to the present result.

Today, web applications are getting more complex and dynamic because of the adaptation of different technologies such as AJAX (**A**synchronous **J**avaScript **A**nd **X**ML). The web form in our example, as shown in Fig. 2 can dynamically update part of the page to prevent unwanted requests when the data involves errors. It can also change the page's display contents dynamically without waiting for the server-side to deliver a new HTML page.

B. Web Applications' Vulnerabilities

Web applications play critical roles in our lives and are used in various activities and services. Typically, web applications deal with private or sensitive data, which becomes a valuable target for attackers. As shown in Fig. 2, a web application accepts potentiality dangerous inputs since the entered user inputs may include malicious code that harms the application. There are many types of vulnerabilities; in the following, we will focus solely on the most common vulnerabilities.

1) Cross-Site Scripting: XSS is a vulnerability executed on the client-side of the web application. The XSS is a code injection that enables the attacker to execute a malicious script (e.g., JavaScript code) in the victim's browser. The exploitation of XSS vulnerability is very dangerous, according to OWASP [12], because the XSS enables the attacker to modify web pages and steal sensitive information such as cookies, session tokens, and users' credentials. There are two classes of XSS attacks: reflected and stored.

- **Reflected XSS** occurs when the attacker successfully injects a malicious script into an HTTP request. The victim browser receives an HTTP response, including a malicious script, and executes it.
- **Stored XSS** occurs when an attacker injects a malicious script in content such as post comments and store permanently, often on the database. Suppose that malicious content is retrieved from the database without filtering. In that case, the malicious code will be executed on the victim's browser at all times when any user visits the infected page.

2) SQL Injection: SQLI is ranked as the most common injection vulnerability on web applications according to OWASP [12]. It occurs when an attacker manipulates the original logic, semantic, or syntax of an SQL query by using specially designed inputs such as SQL keywords or operators into original queries, which aims to control the back-end databases of the web application. There are two types of SQLI attacks: first-order SQLI and second-order SQLI.

- **First-order SQLI** The malicious queries are loaded and executed directly on the database.
- **Second-order SQLI** The crafted input is inserted into the database without sensitization. After that, that malicious content is retrieved without sanitization, which will allow the execution of malicious content.

III. Black-Box Fuzzing Approach as Defensive Technique for Protecting Web Applications

A. Typical Scenario

The black-box scanner consists of three primary modules: the crawling module, attack module, and analysis module. Crawling is a fundamental component in web application scanners which explores the applications that determine the scanner's capability to identify vulnerabilities. If a vulnerability scanner can discover subtle vulnerabilities on the application's deep locations, this indicates that the scanner has an effective crawling component. To understand how black-box fuzzing works, we will use the following example.

Envision a simple web application with a home page, registration page, and course-view page. As shown in Fig. 3, the user can access the course-view page only after completing the registration process. The crawler starts with a seed URL and extracts all reachable pages. The crawler identifies entry points and analyzes web forms to assign input values

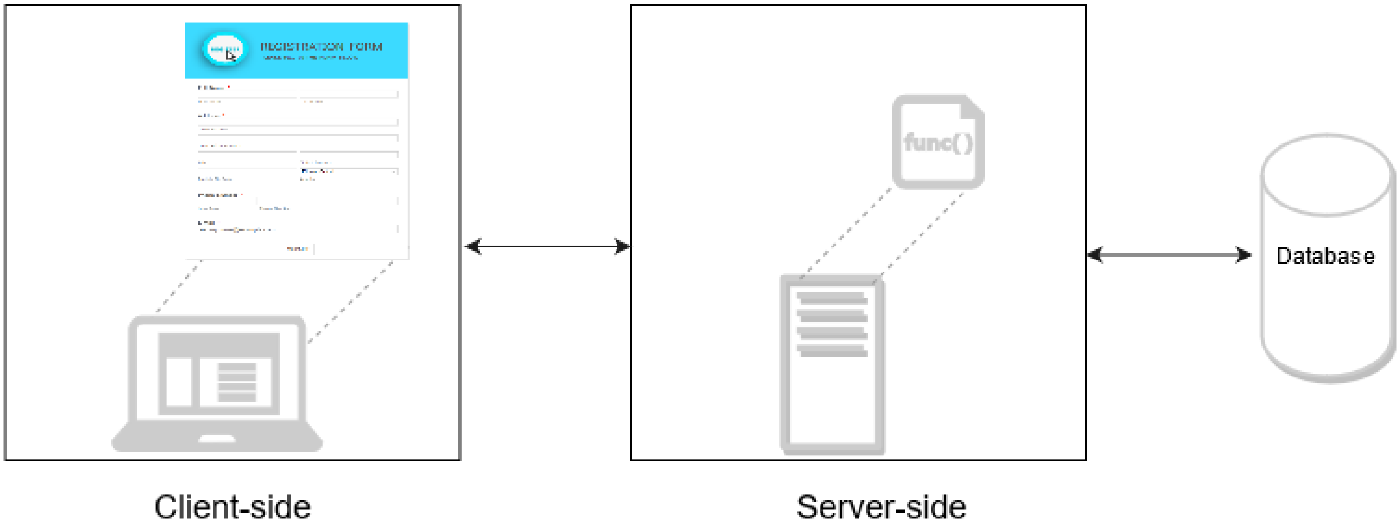

Fig. 1. Web Applications Architecture.

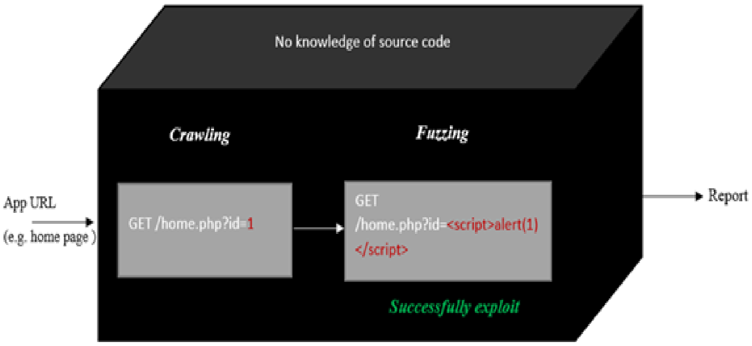

Fig. 4. Black-box Fuzzing Approach.

to discover several links on the application [13]. Then, the attack module fuzzes the application using information learned from the crawler. In other words, the attack module produces attack strings for each input or entry points to fuzz the web application. Finally, the analysis module analyzes the response page after launching the attack to determine where the attack string is reflected in the web application and reports the vulnerabilities [13]. In Fig. 4, the analysis module checks if the script code of the XSS attack is executed.

B. Automated Tools

Many black-box vulnerability scanners, commercial and open-source, are available, all of which have unique characteristics. Here, we review some black-box scanners.

Acunetix [14] is a commercial tool for automatic scanning web applications. It crawls web applications, even the AJAX-heavy ones. It provides different technologies, such as AcuSensor, to increase coverage and obtain higher accuracy for some vulnerabilities, such as accessing the application's source code. It discovers a wide range of vulnerabilities, such as XSS, SQLI, and so on.

AppSpider [15] is a commercial tool to find security bugs automatically. It complies with sophisticated technologies of modern web applications such as AJAX. It has discovered more than 95 attacks, including the OWASP Top 10 vulnerabilities [12]. It can construct values for web forms based on test cases and modify them to belong to different languages and more values.

Burp Suite Professional [16] is a commercial tool that web application scanners provide as part of their features. The scanner covers the most vulnerabilities on OWASP [12], such as XSS, SQLI, XPath, and so on. It has an advanced crawler that discovers vulnerabilities behind advanced JavaScript and dynamic features. It also constructs inputs for forms randomly and uses an intelligent manner to determine what fields are encountered on the page. It provides the ability to tune the configuration of the security test.

Nessus Professional [17] is a commercial vulnerabilities scanner. It can identify vulnerabilities accurately because of its high crawling coverage adapting different technologies to support modern web applications, including Ajax. Additionally, it scans at high speed and has very low false positives.

Netsparker [18] is a commercial web-vulnerability scanner that aims to identify different types of vulnerabilities such as XSS, SQLI, and so on. The crawler can handle different technologies, regardless of their complexity, platform, or architecture. Hence, it can be used for scanning modern web applications. The power of the tool is developed to identify vulnerabilities and gain nearly zero false positives precisely.

Grabber [19] is a free and open-source web-application-vulnerability scanner. It discovers security bugs involving XSS, SQLI, file inclusion, backup files, simple Ajax, and JS source-code analyzer. It scans the web application automatically by identifying the application's entry points into which the data can be injected. It is suitable to use for scanning small web applications.

Vega [20] is a free and open-source web-application scanner. It discovers many vulnerabilities, including SQLI, XSS, remote file inclusion, shell injection, and so on. The Vega crawler can extract URLs and forms and automatically constructs inputs for web applications. Further, it gives the user an additional feature to work as a proxy and be semi-automated to maximize the crawling coverage of web applications.

W3AF (**W**eb **A**pplication **A**ttack and **A**udit **F**ramework) [21] is a free and open-source vulnerability scanner. It discovers different types of vulnerabilities, including XSS and SQLI. Further, the crawler module extracts URLs and forms, and it uses an intelligent manner to give a fake value based on developers' knowledge of the tool.

Wapiti [22] is a free and open-source web-vulnerability scanner. It identifies various vulnerabilities, such as XSS, XXE, XPath, SQLI, and so on. The tool works in this way: the crawler extracts the URLs and forms from HTML, Flash, and basic JavaScript. After that, it launches a payload of attacks on the scripts and forms gained from the crawler to determine vulnerable locations. Finally, it generates reports to show the vulnerabilities and their locations. The crawler support fills form through some placeholder values that are consistent with most policies for web applications.

WFuzz (the **W**eb **Fuzz**er) [23] is a free and open-source web-application-vulnerability scanner. It is designed to perform brute-force attacks against web applications. It can find the essential web pages that are difficult to reach through normal browsing. It also discovers XSS, SQLI, and XXE attacks on GET and POST parameters. Table I shows an overview of the existing web application scanners in the black-box fashion.

IV. BLACK-BOX FUZZING RESEARCH APPROACHES

To develop an effective black-box fuzzing approach, the increase in crawling coverage has become significant. Thus, this section analyzes the existing primary research in this domain and answers the previously mentioned questions.

Question 1: What are the techniques utilized by the approach?

Many approaches have been used to improve the coverage of the crawler to detect web applications in a black-box fashion. By answering this question, it will be possible to identify the approach and determine if there are any contributions or limitations of these approaches, as the following:

Bisht et al. [24] proposed an approach to detect server-side parameter tampering vulnerabilities in web applications. It is based on extracting constraints from the web forms (i.e., client-side) and uses constraint solving technology to generate test cases that expose the parameter tampering opportunities.

Doupé *et al.* [25], these authors proposed an approach that aimed to enhance the crawling of black-box scanners to discover a wide range of vulnerabilities. Their approach is based on capturing the changes in the application states and using the changes discovered to enhance the crawling coverage. However, their approach does not handle dynamic contents implemented by AJAX. Additionally, it does not support enhanced form submission.

Djuric [26] developed a tool called SQLIVDT to generate SQLI against web applications. His approach uses two types of crawling, which are automated and manual, to identify all the gateways to web applications and can be used to execute SQLI. However, this approach handles dynamic features manually via proxy.

Li and Xue [27] capture web applications' behavior as a finite state machine (FSM) and discover logic-flow vulnerabilities from the difference between the FSM of the expected behavior of an application without bugs and the actual FSM. However, their approach cannot handle dynamic contents.

Pellegrino *et al.* [28] proposed a semi-automated scanner that aims to expand the code coverage of web applications. It uses dynamic analysis on the client-side code to handle JavaScript-based web applications. As a result of this work, the author improved the crawling coverage by more than 86% compared to other tools. However, this research's primary goal is to analyze the client-side of dynamic web applications without adept form submission. Moreover, this approach is limited to finding XSS vulnerabilities.

Muñoz *et al.* [29] proposed a novel approach to maximize the crawler's code coverage. Their approach is based on analyzing web forms to extract fields that fill with appropriate values from external sources. In general, this approach cannot guarantee that the application's server-side will accept the constructed input values.

Deepa *et al.* [30] proposed *DetLogic* to improve the crawler by discovering the logic vulnerabilities in web applications. *DetLogic* acts as a proxy between the client-side and server-side of the applications that utilizes the information coming from the server to model web application behavior as a finite state machine (FSM). Logical constraints are then constructed from the FSMs to launch attacks. However, their approach is more applicable to static web applications rather than modern web applications. Additionally, this approach does not handle modern web forms that include certain restrictions on the form inputs.

Deepa *et al.* [31] proposed an approach to detect XQuery and parameter-tampering vulnerabilities in XML-database-based applications. Their approach aims to reduce false alarms and expand the coverage of crawlers. To achieve more web exploration, it analyzes the client-side code to handle the constraints of the web forms. However, their approach is limited to find few types of vulnerabilities.

Koswara *et al.* [32] developed *W3AF+* that extends their basic functionality from *W3AF*[21]. The authors developed a traditional crawler to adapt their method to handle dynamic web applications (e.g., Ajax applications). Their method depends on recording changes of the inner states on the applications. They handle the dynamic application by extending their crawler via capturing the changes caused by the event generator and saving the new state of the resulting DOM in the original state machine when it differs from the current state. However, their method is restricted to *on-click* event.

Liu *et al.* [33] developed a tool to increase the crawler coverage of the scanner via filling the required information, such as login forms, through giving correct values by the user when the crawler gives the user an instruction to complete. However, this approach cannot guarantee that the application's server-side code will accept the constructed input values.

Aliero *et al.* [34] proposed an SQLIVS tool that aims to maximize the coverage of crawlers to find subtle vulnerabilities and minimizes false alarms. Their approach is based on analyzing different HTTP responses to determine the presence of SQLI vulnerabilities.

Eriksson *et al.* [35] proposed a tool, *Black Widow*, to maximize the code coverage of black-box-vulnerability scanners in web applications. Their approach is based on capturing the application's inner state to identify the sinks and sources and enhancing the navigation model to navigate more dynamic workflows. However, their approach is limited to finding XSS vulnerability and construct inputs on forms randomly.

Question 2: Is the approach applicable to be used in modern web applications?

Generally, modern web applications have many dynamic features that appear when rendering applications at runtime. These features can generate a change in the pages' DOM, which includes generating contents dynamically, such as forms, links, and so on. Consequently, these DOM changes can affect the navigation graph of the web application, which may impact finding the vulnerable path and, therefore, lead to miss vulnerabilities. Table II shows a comparison of the approaches regarding the adaptation of dynamic features on their crawling.

TABLE II. Comparison of the Approaches Regarding Adaptation Dynamic Features

Approach	Dynamic features
[24]	×
[25]	×

[27]	×
[28]	✓
[29]	✓
[30]	×
[31]	×
[32]	✓
[33]	✓
[34]	×
[35]	✓

Question 3: How does the approach construct benign inputs needed by web applications to explore further and test the application?

Traditionally, constructing inputs for web forms that mimic user interaction with web applications has been done mostly manually or randomly. Filling forms enable users to deal with different types of inputs, such as numeric, text, etc. This variety of input restrictions makes the automatic construction of the correct inputs challenging. Thus, web application analyses infer the required inputs to be generated to explore the application's workflow and find more vulnerabilities. Table III shows a comparison of the approaches regarding constructing inputs on their crawling.

TABLE III. Comparison of the Approaches Regarding Construct Inputs on their Crawling

Approach	Input generation

V. Discussion

Many researchers focus their efforts on discovering security bugs on the web app before attackers exploit them. In Section IV, we discussed several research efforts tackling the challenge of code coverage on the black-box fuzzing approach. We found that the crawling module of the black-box fuzzing approach is a significant challenge in modern web applications. The first limitation is that many existing research systems still suffer from shallow coverage of the black-box fuzzing approach due to difficulties in handling the dynamic features of modern web apps. Unless the crawling module of the black-box fuzzing approach can support dynamic features such as JavaScript, it is difficult for that fuzzer to analyze most modern web applications that may include critical vulnerabilities behind elements generated on the fly. As shown in Table II, the results indicate that there are no significant differences between studies on supporting dynamic features. In fact, most of the previous studies that handle contents generated dynamically are limited to specific types of events. The second limitation that has hampered crawling involves the design of web forms. Input validation with its restrictions makes it difficult for an automatic generation to fill inputs correctly and submit them to the server-side code. Due to this limitation, the scanners fail to find vulnerabilities in deep locations in web application structures. As shown in Table III, several techniques used to construct input on forms, which do not guarantee that the values will be accepted by the server code, for all previous techniques except [24], [30] and [31]. To precisely infer valid inputs, the study [24], [30], [31], [8], and [9] use constraint solver to construct inputs on the forms by deriving constraints of HTML form inputs.

As a result, the black-box fuzzing approach can achieve better performance when considering the inner state of applications, dynamic features, and input generation. An intriguing research direction is exploring how to combine existing techniques to overcome these limitations and produce a fully automatic scanner in a black-box fashion.

VI. Conclusion

This paper reviews recent and existing techniques regarding black-box fuzzing to discover vulnerabilities. Our survey shows that new technologies and programming capabilities have accelerated the evolution and the complexity of web applications. As a result, automatically analyzing web apps for security purposes becomes more challenging. Additionally, we found that the crawling module of black-box fuzzing approaches still suffers from shallow coverage, which affects identify vulnerabilities on dynamic web applications. Improved crawling module of the black-box fuzzing approach to include dynamic features is necessary to assist the crawler in discovering more links and, therefore, find more vulnerabilities. Further, it is necessary to consider the practical approaches for input generation that can analyze web forms and infer their restrictions to generate correct input values automatically.

As far as these issues, the central problem of the black-box fuzzing approaches is how to deal with these challenges to enhance performance, which leads us to propose another area where black-box scanners should be improved.

***Abstract*—In the process of cloud service selection, it is difficult for users to choose trusted, available, and reliable cloud services. A trust model is a perfect solution for this service selection problem. In cloud computing, data availability and reliability have always been major concerns. According to research, around $285 million is lost per year due to cloud service failures, with a 99.91 percent availability rate. Replication has long been used to improve the data availability of large-scale cloud storage systems where errors are anticipated. As compared to a small-scale environment, where each data node can have different capabilities and can only accept a limited number of requests, replica placement in cloud storage systems becomes more complicated. As a result, deciding where to keep replicas in the system to meet the availability criteria is an issue. To address above issue this paper proposes a trust model which helps in selecting appropriate node for replica placement. This trust model generates comprehensive trust value of the data center node based on dynamic trust value combined with QoS parameters. Simulation experiments show that the model can reflect the dynamic change of data center node subject trust, enhance the predictability of node selection, and effectively decreases the failure rate of node.**

Keywords*—Trust; trust model; cloud; availability; reliability

I. Introduction

Cloud computing provides usable, convenient, and on-demand cloud services in the form of shared computing resource sharing pools. It includes three levels of services: Infrastructure as a service (IaaS), Platform as a service (PaaS), and Software as a service (SaaS), where IaaS provides consumers with comprehensive computer infrastructure services, such as hardware server rental, PaaS is to provide software development platform as a service to consumers, SaaS is to provide software to consumers through the network mode. It is a general practice to choose cloud service providers based on a comprehensive evaluation of QoS metrics [1]. The same is considered here in this work to evaluate the trust value of data center nodes. High availability and high-performance are essential features user expects from cloud service providers[3]. Replication plays an important role for any system to improve availability, throughput and response time for user [24].

In fact, replication is an essential corner stone in data storage not only for cloud computing but also for traditional storage systems [12], [13], [14], [15], because it can relatively impact the performance of cloud storage in terms of storage cost, network usage, response time, etc. [22], [23], [24], [25]. Therefore, maintaining static number of replicas in cloud storage for every data file would be inefficient for storage cost and data availability [16], [17], [18]. As a consequence, the determination of the optimum number of replicas and the suitable nodes for replicas has become a key issue in the cloud computing [19], [20], [21].

To address the above issue this paper proposes a node selection model based on the dynamic trust. The trust value is calculated by direct and recommended trust. In order to reflect trust value more comprehensively the concept of Dynamic Trust Value (DTV) is introduced in this model. Further the concept of information entropy is introduced to solve the problem of weighting of trusted parameters, so that the comprehensive trust value and QoS value are weighted to obtain the optimal node selection for replica placement.

II. Related Works

For the study of cloud service selection, many scholars at home and abroad have done a lot of work. For example works such as multi-objective genetic algorithm, particle swarm optimization PSO [1], artificial neural network algorithm [2].The application of these methods are generally aimed at a relatively static scenarios. The generation and disappearance of network services in a cloud computing environment are often dynamic, so it is necessary to solve the authenticity judgment of services in a cloud computing environment. Further it is important to solve the problem of degree of understanding of service quality when selecting a service algorithm [3], the trust of cloud services and other problems.

In response to the above problems, at the same time, in order to ensure the success of the service selection algorithm, the research based on the trust degree of the service subject is particularly important. Ma You et al. [4] proposed a new ESOW algorithm for QoS measurement. The ESOW algorithm is based on the user's subjective trust. The two parts of preference weight and objective weight are synthesized. The calculation of user's subjective weight is based on the adaptive SWDM algorithm, and the objective weight is calculated according to the OWDM algorithm. Sarbjeet [5] proposed a method based on the past experience and third-party service recommendation trust evaluation mechanism.

DASA et al. [6] proposed a dynamic trust calculation model that can effectively evaluate the behavior of malicious agent strategies. It mainly analyzes and evaluates all relevant elements to make correct decision. Zhouao et al. [7] proposed a dynamic virtual resource lease method from the perspective of service provider's benefit maximization, from the perspective of price allocation and request urgency. Cao Jie et al. [8] based on the interpersonal relationship in sociology relationship combined with user satisfaction evaluation, recommendation evaluation and third-party supervision feedback, a new credible measurement model was proposed. Zhang Lin et al. [9] combined relevant ranking factors, attribute factors, and intervals according to the behavior and dynamics of information services factor, penalty factor, and other four factors, a new dynamic trust monitoring model is proposed. Abawajy [10] proposes a distributed trust management framework based on reputation, which can pass the past experience, trust level and first level of honesty to determine the trust value of cloud computing entities.

III. Proposed Methodology

A. Basic Definitions

The service feedback results of the system described in this paper can be expressed by the two values namely positives and negatives. Therefore, the trust value of the data center node can be defined as the probability P of providing a good service, that is, using the evaluation information to reflect the probability P of providing a good service as accurately as possible. The process of cloud computing includes three main entities:

Service Provider: Represented as pro_j, representing the $j-th$ node, this node can provide users with the resources required by the user's cloud service request.

Service Consumer: Represented as $user_i$, i represents the $i-th$ service request user, the node can send service request information to the service intermediary, and can provide service history and service results to the service intermediary. As an evaluation of pro_j, user $user_i$ vs. pro_j is defined as a binary.

Service Broker: Represented as a broker, responsible for processing request response and management, and responsible for processing $user_i$ feedback information, providing $user_i$ with pro_j node evaluation information.

B. Direct Trust and Recommended Trust

The direct trust value is calculated using the past historical transactions and feedback information of two trading entities[16]. In the process of calculating the trust value, the Bayesian theory [11] is introduced to calculate the trust value of the node.

Suppose that the probability of good service provided by pro_j is P_j. After several transactions between the nodes and $user_i$. The evaluated binary "$Positives_{ij}$, $Negatives_{ij}$" is obtained, and the probability density function of P_j is obtained as:

$$\begin{gathered} f(p|\alpha,\beta)=\tfrac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)}p^{\alpha-1}(1-p)^{\beta-1} \\ 0\leqslant p\leqslant 1,\alpha\geqslant 0,\beta\geqslant 0 \end{gathered} \tag{1}$$

In the formula:$\alpha=$ positives $_{ij}+1,\beta=$ negatives $_{ij}+1$

The Gama function is represented by:

$$\Gamma(z)=\int_0^{+\infty}\mathrm{e}^{-t}t^{z-1}\mathrm{d}t \tag{2}$$

Then there is a probability density function that can obtain the Bayesian estimate of P_j as:

$$P_{ij}=\int_{P_j=0}f\left(P_j|\alpha_{ij},\beta_{ij}\right)P_j\mathrm{d}P_j=\tfrac{\alpha_{ij}}{\alpha_{ij}+\beta_{ij}}= \\ \tfrac{\text{positives }_{ij}+1}{\text{negatives }_{ij}+\text{ positives }_{ij}+2} \tag{3}$$

Then get the direct trust value : $T^{\mathrm{dt}}=P_{ij}$

The recommended trust value refers to the user $user_i$'s trust value for the service provider pro_j is obtained through the recommendation between other related entities, and the related entities are synthesized based on empirical evaluation. During the evaluation, the set of recommended entities is assumed to be R. The associated user-recommended user R in R recommends the two-tuple to $user_k$:

$$\left\{\begin{array}{l} \mathrm{Re}_{-}^{\text{postives}}\ \sum_{k\in R}\ \text{postives }_{kj} \\ \mathrm{Re}_{=}^{\text{negatives}}\ \sum_{k\in R}\ \text{negatives }_{kj} \end{array}\right. \tag{4}$$

Similarly, through the Bayes principle, the recommended trust value can be obtained:

$$T^{rt}=\frac{\mathrm{Re}_{\text{possives}}^{ik}\ +1}{\mathrm{Re}_{\text{negatives}}^{k}\ +\mathrm{Re}_{\text{postives}}^{ik}\ +2} \tag{5}$$

C. Time Decay Function

Not all user feedback can truly reflect the trust status between entities. Because over time, old user feedback may not accurately reflect the current trust value. For example, it may be evaluated that the service behavior of the entity has been modified or improved. So at this time set the weight according to the time of feedback to accurately reflect the user's feedback. This can be achieved by setting the time decay function mechanism. Assume that at time τ, after the unit time t, the user feedback trust formula for the attenuation of the value over time is shown in equation (6).

$$f_{ij}(\tau+t)=\left\{\begin{array}{ll} f_{ij}(\tau), & f_{ij}(\tau)\geqslant\theta_1,t\leqslant\theta_2 \\ f_{ij}(\tau)\mathrm{e}^{-\lambda(t-\theta_2)}, & f_{ij}(\tau)\geqslant\theta_1,t>\theta_2 \\ b, & \quad\text{other} \end{array}\right. \tag{6}$$

In the formula: λ is the decay constant, which is used to control the decay rate of the trust value. The value of λ can be set according to different service types. At the same time, the user's true intention of evaluating the entity and reducing trust are considered for the update frequency. A start attenuation threshold θ_2 and a stop attenuation threshold θ_1 are set here. When the elapsed time t is greater than θ_2, the trust value decreases gradually according to the attenuation constant, and when the trust value is less than or equal to the stop attenuation threshold at θ_1, the trust value is set to a fixed value b, and the trust value will not change with time.

D. Calculation of Comprehensive Trust

The calculation of comprehensive trust includes two aspects: the direct trust value T^{dt} and the recommended trust value T^{rt}, and the weight between the two can be set according to different service types. Set them to α, β and $\alpha + \beta = 1$, in this paper, they are set to 0.5, 0.5 respectively, then the calculation formula of the comprehensive trust $\mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right)$ of the data center node r_k is:

$$\begin{gathered}\mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right)=\alpha * \frac{\text{positives}_{ij}+1}{\text{negatives}_{ij}+\text{positives}_{ij}+2}+ \\ \beta * \frac{\mathrm{Re}_{\text{positives}}^{ik}+1}{\mathrm{Re}_{\text{negatives}}^{k}+\mathrm{Re}_{\text{positives}}^{k}+2}\end{gathered} \tag{7}$$

E. Dynamic Trust Value

Dynamic Trust Value (DTV), which represents the trend of trust value with respect to change with time. It can reflect the historical change of trust value, and has a pre-judgment indicator for the next node selection, thus improve the efficiency of node selection.

In order to be able to quantify the value of DTV, the least squares data fitting method is introduced. The least squares fitting method is a method to approximate or compare the functional relationship between the coordinates represented by discrete point groups on the plane with a straight line. Assume that the trust degree of pro_j changes with time as $\left\{\left(t_k, \text{trust}_k^j\right): k \in [1, n]\right\}$, where the node $\left(t_k, \mathrm{tr}\, ust_k^j\right)$ represents the trust value P_k of pro_j at time t_k. According to the least squares method, the fitted straight line equation is assumed to be:

$$y_j = \mathrm{DTV}_j * t_k + b \tag{8}$$

The slope of the straight line DTV_j is the Dynamic Trust Value of the defined data center node, b represents the intercept. In order to determine the value of DTV_j, b, according to the principle of the least square method, all data nodes $(t_k, y_k)\,(k = 1, 2 \ldots n)$. The square sum of the deviation values of all data nodes is minimized, that is:

$$\begin{gathered}M=\sum_{k=1}^{n}\left(\text{ trust }_k-y_k\right)^2= \\ \sum_{k=1}^{n}\left(\text{ trust }_k-\mathrm{DTV}_j * t_k-b\right)^2 subjectto \min(M)\end{gathered} \tag{9}$$

The condition for obtaining the minimum value is that the corresponding binary function takes the extreme value of 0, that is:

$$\frac{\partial M}{\partial \mathrm{DTV}_j}=\frac{\partial M}{\partial b}=0 \tag{10}$$

After finishing, the normal equations are obtained:

$$\left\{\begin{array}{l}\sum_{k=1}^{n} \text{trust}_k - \mathrm{DTV}_j \sum_{k=1}^{n} t_k - nb = 0 \\ \sum_{k=1}^{n} \text{trust}_k * t_i - \mathrm{DTV}_j \sum_{k=1}^{n} t_k^2 - b \sum_{k=1}^{n} t_k = 0\end{array}\right. \tag{11}$$

The linear parameter values DTV_j and b can be obtained by solving the normal equations, namely:

$$\begin{gathered}\mathrm{DTV}_j=\left(n \sum_{k=1}^{n} t_k * \operatorname{trus} t_k-\sum_{k=1}^{n} \text{trust}_k \sum_{k=1}^{n} t_k\right) / \\ \left(n \sum_{k=1}^{n} t_k^2-\left(\sum_{k=1}^{n} t_k\right)^2\right)\end{gathered} \tag{12}$$

$$\begin{gathered}b=\left(\sum_{k=1}^{n} t_k^2 \sum_{k=1}^{n} \operatorname{trus} t_k-\sum_{k=1}^{n} t_k \sum_{k=1}^{n} t_k * \operatorname{trus} t_k\right) \\ \left(n \sum_{k=1}^{n} t_k^2-\left(\sum_{k=1}^{n} t_k\right)^2\right)\end{gathered} \tag{13}$$

Then you can get the Dynamic Trust Value DTV_j of pro_j's trust change.

For the research needs of this paper, after the calculation of the Dynamic Trust Value DTV_j, it is normalized and converted into the following formula:

$$\mathrm{TCV}_i=\frac{\mathrm{TCV}_i-\min \left\{\mathrm{TCV}_k\right\}}{\max \left\{\mathrm{TCV}_k\right\}-\min \left\{\mathrm{TCV}_k\right\}} \tag{14}$$

The trust value can be converted to the range of [0, 1]. Since the Dynamic Trust Value of trust degree (DTV) reflects the change trend of trust degree, the level of DTV reflects the change of trust degree, so it can be based on the value of DTV. It is used to predict the value of future trust. The higher the DTV, the higher the trust value of the data center node. On the contrary, it indicates that the node provides false information, so that the trust is in a downward trend.

At the same time, when choosing the range of Dynamic Trust Values, the range of different trust change trend values will be normalized to the interval of [0, 1]. Choosing different intervals will not have much impact on the experimental results. However, in order to reflect the user's true trust feedback behavior, this paper selects the range of Dynamic Trust Values pertaining to e-commerce platforms such as eBay and Amazon [-0.875, 0.875].

F. Quality of Service (QoS)

QoS describes the ability of a product or service to meet consumer demand. To achieve better availability of cloud the following aspects, such as processing time, storage capacity, link capacity and type of operating system are considered as QoS parameters. They reflect service availability from different perspectives. This paper considers the QoS attributes of data center nodes from four aspects: Processing Capacity, Storage Capacity, Link Capacity and Operating System. The calculation of service performance can be calculated through user feedback or a third-party monitoring mechanism.

Assuming that there are a group of n services that meet the functional requirements, the vector of each group corresponding to the QoS attribute is set as: $Q_j = (q_p, q_s, q_l, q_o)$

$j = 1, 2, 3 \cdots, n, q_p, q_s, q_l, q_o$, respectively represent the processing capacity, storage capacity, link capacity and type of operating system of the j data center node. Because the value span between these attributes is relatively large, all QoS attributes need to be converted to normalization. q^{+}, q^{-}, respectively represents the value after the positive and negative QoS attributes are normalized, and their normal conversion methods are:

$$q^{-} = \begin{cases} \frac{q^{\max} - q}{q^{\max} - q^{\min}}, q^{\max} - q^{\min} \neq 0 \\ 1, q^{\max} - q^{\min} = 0 \end{cases} \tag{15}$$

$$\mathrm{q}^{+} = \begin{cases} \frac{q - q^{\min}}{q^{\max} - q^{\min}}, q^{\max} - q^{\min} \neq 0 \\ 1, q^{\max} - q^{\min} = 0 \end{cases} \tag{16}$$

Equation (15) shows that the attribute is negatively correlated with performance, that is, the larger the attribute value, the worse the performance, such as processing capacity and storage capacity; Equation (16) indicates that the attribute is positively correlated with performance, that is, the larger the attribute value, the better the performance and reliability. $q^{\max}$ and $q^{\min}$ respectively represent the maximum and minimum values in the attribute group. Then the QoS value can be obtained by linearly weighting each attribute:

$$Q = w_1 * q_p + w_2 * q_{\mathrm{s}} + w_3 * q_l + w_4 * q_o \tag{17}$$

G. Optimal Node Selection Strategy based on Information Entropy

The optimal node selection in the cloud computing environment is not only related to the QoS value, but also closely related to the trust value and the value of feedback by the user. It is a comprehensive reflection of the user's service quality. In previous studies, the analysis was only from the perspective of pure QoS. Some of them considered the trust value, but only considered the trust of the interaction process, and quantified the trust value as a single QoS value. This lacks in-depth study of service credibility. This paper believes that the optimal node selection should be considered in combination with both trust and QoS. Only considering any single aspect is unreasonable. At the same time, it is aimed at existing research where it only quantifies trust into a single value to evaluate the trust degree, which does not reflect the problem of trust degree changing with time. This paper integrates the Dynamic Trust Value (DTV) into the calculation process of node selection, and combines the concept of information entropy to determine the parameter weight between trust and QoS, so as to obtain the optimal node selection strategy.

Information entropy is a concept used to measure the amount of information. It is often used to give a rough measure of the uncertainty of information. Information entropy is a measure of the uncertainty of the result before the event. After the event, It is a measure of information obtained from the event. Therefore, the information entropy of an event is not only a measure of the amount of information of an event, but also can be included as relevant information in the event itself [12].

TABLE I. INFORMATION ENTROPY AND WEIGHT CALCULATION

Index	Service Quality	Trust Value
Value	0.6	0.8
Initial Value	0.4	0.2
Information Entropy	0.9708	0.7205
Weights	0.426	0.574

According to the calculation principle of information entropy, the information entropy determined by the quality of service QoS_j is:

$$\begin{gathered} H\left(\mathrm{QoS}_j\right) = -\mathrm{QoS}_j \log \mathrm{QoS}_j - (1 - \mathrm{QoS}_j) \log \\ \left(1 - \mathrm{QoS}_j\right) \end{gathered} \tag{18}$$

The information entropy determined by the trust value is:

$$\begin{aligned} & H\left(\mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right)\right) = -\mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right) \log \mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right) \\ & -\left(1 - \mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right)\right) \log\left(1 - \mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right)\right) \end{aligned} \tag{19}$$

Then the weight of the quality of service QoS_i can be determined:

$$\delta_1 = H\left(\mathrm{QoS}_j\right) / \left(H\left(\mathrm{QoS}_j\right) + H\left(\mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right)\right)\right) \tag{20}$$

And the weight of trust value $\delta_2 = 1 - \delta_1$

Among them, $\mathrm{CT}\left(\mathrm{pro}_{\mathrm{r}}^{\mathrm{j}}\right)$ means the degree of reliability of the subject j, and 1-$\mathrm{CT}\left(\mathrm{pro}_{\mathrm{r}}^{\mathrm{j}}\right)$ indicates the undeterminable component; QoS_j is the evaluation of the service quality of the subject j, and $1 - QoS_i$ is the uncertain component of its service quality.

For example, a service subject's (service quality, trust value) is (0.6, 0.8), then their information entropy is (0.970, 0.720), then the weight indicators of the two are: 0.4, 0.5, see Table I for details.

After the weights are calculated, the calculated trustworthiness value is trend-corrected according to the DTV_j value, so that the trustworthiness value can more accurately reflect the trustworthiness of the node. According to the dynamic trust value of trustworthiness, the correction formula is as follows (21).

$$\overline{\mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right)} = \begin{cases} \mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right) + \left(1 - \mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right)\right) \times \\ \mathrm{DTV}_j \mathrm{DTV}_j > 0.5 \\ \mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right) \mathrm{DTV}_j = 0.5 \\ \mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right) * e^{DTV_j - 0.5} \mathrm{DTV}_j < 0.5 \end{cases} \tag{21}$$

When the normalized Dynamic Trust value of trust degree DTV_j is equal to 5, we know that the change of trust value is in a relatively stable state at this time, so we do not change the trust value, and make a difference when the value of DTV_j is greater than or less than 5. The treatment is to punish some of the service providers' false information caused a decline in the trend of the change in trust, while the increase in the value of the trend of the change in the degree of trust changes the value of the trust appropriately. According to the revised trustworthiness value,QoS value and information entropy, the calculation weight is determined to obtain the comprehensive value of optimal node selection:

$$\Delta = \delta_1 * \mathrm{QoS}_j + \delta_2 * \overline{\mathrm{CT}\left(\mathrm{pro}_{r_k}^{j}\right)} \tag{22}$$

The following is a data center node selection strategy process based on the dynamic trust value:

1) The service broker receives the node selection request from the service user ($user_i$).
2) The service intermediary selects the data center node provider (pro_j) that meets the user's functional requirements by analyzing the service request.
3) According to formula (7), the service consumer obtains the comprehensive trust value through the direct trust value and the indirect trust value.
4) According to equation (8), the Dynamic Trust Value DTV of the node provider is obtained.
5) According to formula (17) to obtain the quantified QoS value of the overall service quality and formula (21) to modify the trust value, and through the information entropy calculation to obtain the corresponding weight.
6) According to equation (22), the overall evaluation value of the optimal node selection can be obtained.
7) Choose the node with the largest overall evaluation value as the best choice for replica placement.

IV. Results and Discussions

For this work simulation method is opted to verify the effectiveness of the node selection model proposed in this paper based on Dynamic Trust. The experiments were run on the cloud simulation software CloudSim3.0 [13]. CloudSim is a new universal and extensible simulation framework that supports seamless modeling and simulation, based on a specific environment and configuration, by extending its basic functions, can conduct experiments on cloud computing infrastructure and management services.

When CloudSim starts the simulation, you first need to create a data center (Datacenter), create resources such as CPU and memory in the data center, you can map user requests to the appropriate service provider (DatacenterBroker) through CIS (CloudInformationService), according to service selection Strategy for resource allocation. The operating environment is the Eclipse integrated development platform based on java development, and the CloudSim simulation program runs on the Intel Pentium dual-core G630, 2.7GHz, 2GB memory, Ubuntu18.04 64 bit Operation System on the desktop.

In this experiment, according to the different trend values of the trust degree of the node provider SP, the SP is divided into three categories:

1) Class A: The Dynamic Trust Value of SP is monotonously increasing. For example, due to the improvement of technical quality, the value of trust gradually increases.
2) Type B: The Dynamic Trust Value of SP's trust degree is relatively stable, that is to say, this type of SP provides stable cloud service functions and has good trust.
3) Type C: The Dynamic Trust Value of the SP is monotonously decreasing. For example, the SP provides a cloud service product with a false function description, which leads to the decrease of the trust value.

TABLE II. Simulation Parameters

Parameter		Default Value	Description
Operating Parameters	CloudletNum	100	Total number of tasks
	VmNum	500	Total number of SP
Algorithm Parameters	Num_luser	100	Total number of SC
Weights	α,β	0.5	Trust Weight
	w_i	0.25	QoS weight parameters

In order to conduct metric comparison, two test indicators are set: success rate and predicted success rate.

Within a certain time interval T, the CIS (CloudInformationService) in the CloudSim simulator provides the number N of service providers to all SCs according to the selection strategy, where the number of SPs that successfully interact with the SC is S (here, there is no fraud Behavior), the success rate is:

$$\theta = \frac{S}{N} \times 100\% \tag{23}$$

Where: θ is the average degree of cooperation between network nodes.

Within a certain time interval T, the CIS in the CloudSim emulator provides the number of service providers N to all SCs according to the selection strategy, encountered a situation where the node happened to be in the blacklist, or encountered during the interaction deception, the total number of times in both cases is M, then the model's predicted success rate is:

$$\varphi = \frac{N - M}{N} \times 100\% \tag{24}$$

In the formula: φ can reflect the model's ability to predict the next step.

In the verification test, it is assumed that the number of SP subjects is 500 and the number of SC subjects is 100 in a cloud environment. The trust value of each virtual machine starts to be randomly generated. The node selection policy input parameters, namely, CloudletNum, vmNum, num_user, α, β, w_i are shown in Table II.

In the table, CloudletNum represents the total number of tasks requested by users in the CloudSim simulation environment, and the tasks from different users are relatively independent; vmNum is the number of virtual machines; num_user represents the number of users; α and β are the direct trust weights and recommendation Trust weights, respectively. The data results of each group are averaged after 10 times.

Case Study 1: In a cloud environment, the nature of data center node is highly dynamic. It is assumed that a service node rj is malicious, but the resource may be used to cover its important service transactions. Good service quality establishes good trust. After a period of time, the service provider lowers the standard of service quality in order to reduce costs, but due to the establishment of early trust, the poor post-service has a higher trust value. So, it is necessary to introduce the trust time decay mechanism. When there is no transaction in the middle of a period of time, the trust value will decrease with time. Also set a decay constant, you can set the credibility decay speed according to different service types. The service occurs in a malicious time period, and a larger attenuation constant can be set. Fig. 1 shows the attenuation of the trust value under different attenuation constants, namely, type1(λ=y1=exp(-0.025x)), type2(λ=y2=exp(-0.05x)) and type3(λ=y3=exp(-0.1x)). Simulation results show that the larger the attenuation parameter, the faster the attenuation rate.

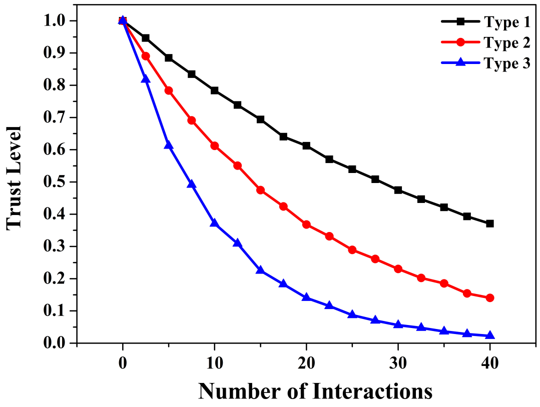

Fig. 1. Change of Trust under Different λ Values.

Case Study 2: Fig. 2 shows the change of the trust value of the three types of service providers during the interaction of the service subjects. From the figure, it can be seen that the class A SP is in the increasing trend as the number of interactions are increasing and its credibility has been maintained with a growing trend. The Trust value of the B-type SP increases with the number of interactions, but when it reaches a certain level, it will be in a relatively stable state. The Trust value of C-type SP begins to increase with the number of interactions. The trust value also increases. Although the C-type SP maintains a high trust value in the early stage, due to the provision of false services, the trust level in the later stage decreases, which ultimately leads to a lower level of trust value.

Case Study 3: Fig. 3 shows the comparison of the three different strategies namely the node selection method based on the Dynamic Trust Value, the node selection method based on trust degree, and the node selection method based on non-trust degree. It is an indicator of success, so its success rate has a greater advantage than the latter. But at the same time, the node selection method based on the dynamic trust has always maintained a better growth trend, because its DTV which effectively reflected the change trend of trust. This method has the ability to predict, to a certain extent can filter out false information, thereby improving the success rate of node selection in a better way.

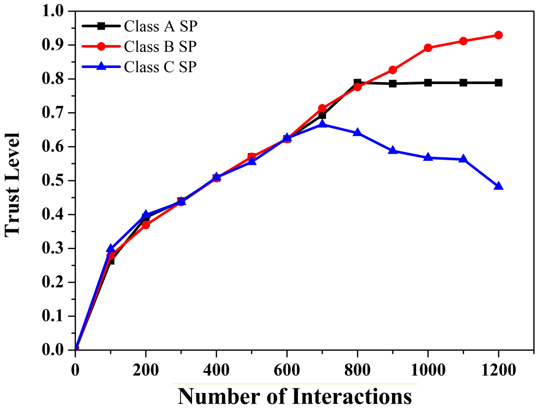

Fig. 2. Comparison of Different SP's under Dynamic Trust.

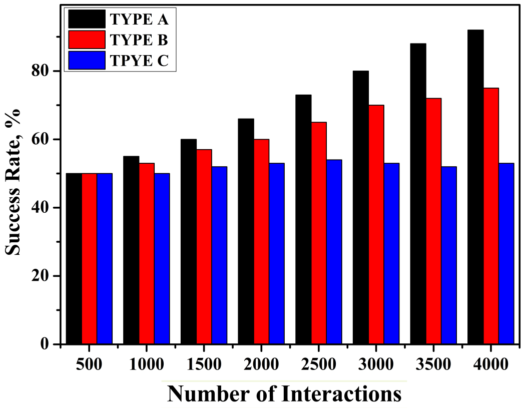

Fig. 3. Comparison of Node Selection Rate of Different SP's.

Case Study 4: Fig. 4 shows the comparison of the prediction success rate among the three methods namely the node selection method based on the Dynamic Trust Value, the node selection method based on trust degree, and the node selection method based on non-trust degree. The proposed method DTV has a certain predictive ability for node selection, so the prediction success rate has always shown a relatively stable growth state, while the node selection method based on trust does not predict the success rate after reaching a certain level. Again, this is because the trust-based node selection method does not contain the Dynamic trust evaluation and lacks continuous predictive ability. The trust-based node selection method has no consideration of trust factors, so it has the great blindness that led to the development of the prediction success rate in molar shape. The experimental results show that the model based on the DTV proposed in this paper effectively improves the prediction ability of node selection for replication.

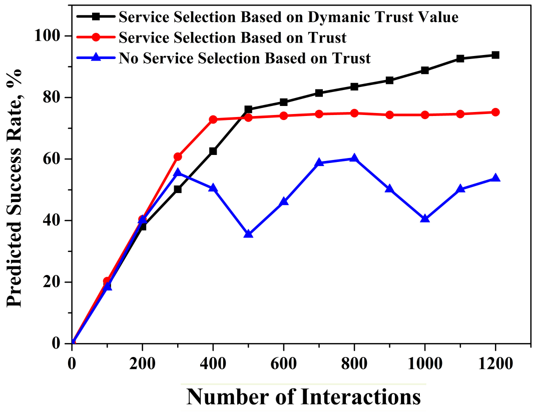

Fig. 4. Comparison of Predicted Success Rate of Proposed Model with Others.

V. Conclusion

In the cloud computing environment, this paper aims at the problem of replica placement in data center nodes for enhanced availability. The node selection for replica placement is a difficult process. Based on the proposed trust model it improves the ability to predict service quality of data center node and increases the accuracy of data center node selection for replication. The concept of Information Entropy is introduced to avoid the shortcomings that only perform simple weighted analysis of trusted parameters, and effectively improves the success rate of node selection. Experimental analysis shows that this method can better meet users' service quality and trust in node selection. Further the data center node which gets selected for replication using this model exhibits less failure rate, there by enhances availability in cloud.

Rangamati Science and Technology University
Rangamati, Bangladesh

***Abstract*—The segmentation, detection and extraction of the infected tumor from Magnetic Resonance Imaging (MRI) images are the key concerns for radiologists or clinical experts. But it is tedious and time consuming and its accuracy depends on their experience only. This paper suggest a new methodology segmentation, recognition, classification and detection of different types of cancer cells from both MRI and RGB (Red, Green, Blue) images are performed using supervised learning, Convolutional Neural Network (CNN) and morphological operations. In this methodology, CNN is used to classify cancer types and semantic segmentation to segment cancer cells. The system trained using the pixel labeled the ground truth where every image labeled as cancerous and non-cancerous. The system trained with 70% images and validated and tested with the rest 30%. Finally, the segmented cancer region is extracted and its percentage area is calculated. The research examined on the MATLAB platform on MRI and RGB images of the infected cell of BreCaHAD dataset for breast cancer, SN-AM Dataset for leukemia, Lung and Colon Cancer Histopathological Images dataset for lung cancer and Brain MRI Images for Brain Tumor Detection dataset for brain cancer.**

***Keywords*—Semantic segmentation; CNN; brain; breast; leukemia; lung**

I. Introduction

Muscles, bones, the liver and the lungs are forming rapidly from trillions of cells produced by the human body. Lung cancer starts its journey from the lung. Secondary type cancer spreads to the lung from another part of the body. Cancer which cannot compete against infection spreads in the bone marrow and also a cancer that happens in white blood cells is known as Leukemia. The brain tumor is a collection or a combination of unnatural tissue in the brain. MRI, computerized tomography (CT) scan and the Biopsy technique used to detect the brain tumor. MRI images are safer than CT scan images, because MRI can produce higher contrast compared with CT scan and MRI images also do not harm the body. As the MRI images produce a pure resolution of brain tissues, they are used in detection and classification techniques. The lymph vessels and blood vessels help breast cancer to propagate outside the breast.

Nowadays, it is common to see that deep learning-based segmentation is a more useful segmentation technique in the present world which introduces deep learning in every sphere of the digital world. Semantic segmentation is one of the best deep learning-based segmentation techniques that introduces the machine's knowledge to human beings. A good example is supervised learning that includes labeled the ground truth dataset of learning object categories. This outstanding supervised methodology used SegNet architecture for the segmentation purpose of cancer cells that are of different types. Classification of objects is more useful and necessary for the recognition of testing objects like cancer cells in this study. This research used Convolutional Neural Network(CNN) for classification purposes. It takes the help of the resnet50 architecture that uses fc1000 layers for this deep classification of the testing image [1]. The authors implement an idea that turns the machine into a human brain. To test this study, different types of cancer datasets for segment and detect cancer cells of heterogeneous have been used. The system split all dataset images of the different format into different classes, categorized them into Breast, Leukemia, Lung and Brain where every category of the dataset is labeled using the pixel label named Cancerous and Non_Cancerous class. During performance as a human being, test image is classified using CNN classifier and based on the classified predict label, classified category along with its labeling are passed into the SegNet architecture to build a SegNet semantic segmentation procedure using VGG16 layers. Creating semantic segmentation procedure, a test image is segmented and segmented cancer cell is detected using morphological operations and detected cancer area is calculated. Many researchers have only worked with specific types of cancer cell detection with different methods, but in this research we focused on many types of cancer cell detection using the proposed system. In brief, we develop a system to segment, detect and classify the cancer cells more especially Brain, Breast, Leukemia, and Lung using semantic segmentation and classification using the CNN classifier which is more convenient than traditional existing method.

The structure of this research has been designed as follows. The next Section II contains a review of some recent related research works. The proposed methodology is described in brief in Section III. Results and discussion sections are described in Section IV and conclusions and future research plans are discussed in Section V.

II. Literature Review

There have been many works done to detect and analyze cancer cells. Some of the existing works are described below.

Fahad Lateef and Yassine Ruichek [2] have completed a survey. According to the shared conceptions underlying their structure, they categorized different methods among ten different classes in their survey. They also provided a brief description of the publicly available datasets. Besides, to measure their accuracy, they used an evaluation matrix. Furthermore, they paid attention to different methodologies and examined to achieve their desired performances. Finally, they ended the research by describing discrete amounts of open questions and their probable solutions.

Alqazzaz, Salma, et al. [3] have proposed a methodology where they applied a CNN e.g. SegNet to 3D datasets for automation of the brain tumor and sub tumor portions segmentation, as well as enhancing tumor, edema and necrosis. They applied a process to further advance tumor segmentation. In this process, to produce four maximum feature maps, they integrated the four distinctly trained SegNet architecture. To encrypt fascinating info into a feature presentation, they combined both the intensity of the pixels of the primary MRI modalities and the large feature maps. To classify the MRI voxels, the combined features are taken as input and applied to a tree that can make decisions. The authors used the BraTS 2017 challenge dataset to evaluate their methodology.

Ahmed Ghoneim, Ghulam Muhammad, M. Shamim Hossain [4] have proposed a method to classify and detect Cervical cancer. They used CNN and extreme learning machines to classify. Images of the cells are passed into a CNNs frame so that deep-learned features can be extracted. Then, extracted features have been used to classify the test images. They claimed that the classifier gives 91.2% accuracy.

Konstantinos Kamnitsas, Christian Ledig, Virginia F. J. Newcombe, Joanna P. Simpson, Andrew D. Kane, David K. Menon, Daniel Rueckert, Ben Glocker [5] have applied effective multi-scale 3D CNN with complete associated CRF for segmentation of the brain lesion. They projected a double route i.e. three-dimensional CNN and 11-layers deep to segment brain lesions. The authors used BRATS 2015 and ISLES 2015 dataset to examine their architecture.

Almajalid, Rania, Juan Shan, Yaodong Du, and Ming Zhang [6] have modified the u-net model for breast ultrasound imaging (BUS) segmentation. They applied a post processing after the segmentation stage. The authors claimed that the method achieved 82.52% accuracy in the term of average DICE.

Al-jaboriy, Saif S., Nilam Nur Amir Sjarif, Suriayati Chuprat, and Wafaa Mustafa Abduallah [7] have introduced a machine learning-based autonomic leukocyte cell segmentation procedure. Using artificial neural networks (ANNs) and 4-moment statistical features, the features were extracted from blast cells.

Kamal, Uday, Abdul Muntakim Rafi, Rakibul Hoque, Jonathan Wu, and Md Kamrul Hasan [8] have proposed a deep learning model for the segmentation of lung tumors from CT scans called Recurrent 3D-DenseUNet. To differentiate between tumorous and non-tumorous image-slices, they applied morphological operations and selective thresholding. They claimed that the system gained an average dice score of 0.7228.

III. Methodology

The proposed system divided into the following three steps:

- Classification stage.
- Semantic segmentation and detection stage.
- Calculate cancer area.

”Fig. 1” illustrates the proposed methodology.

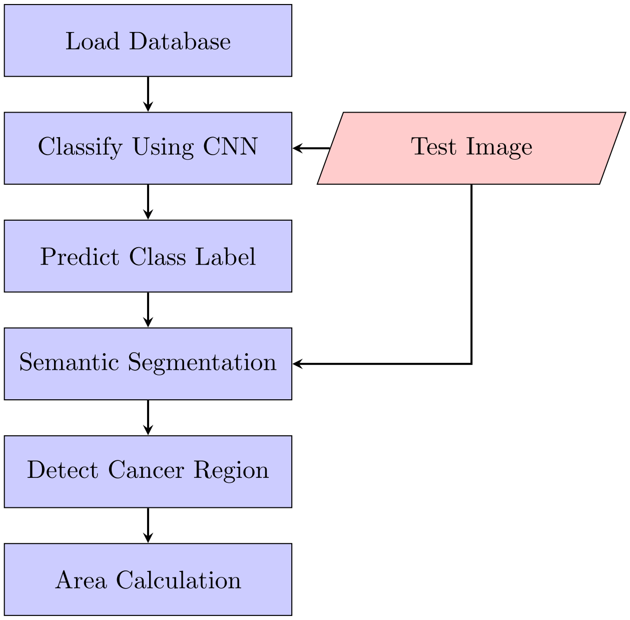

Fig. 1. Block Diagram of the Proposed System.

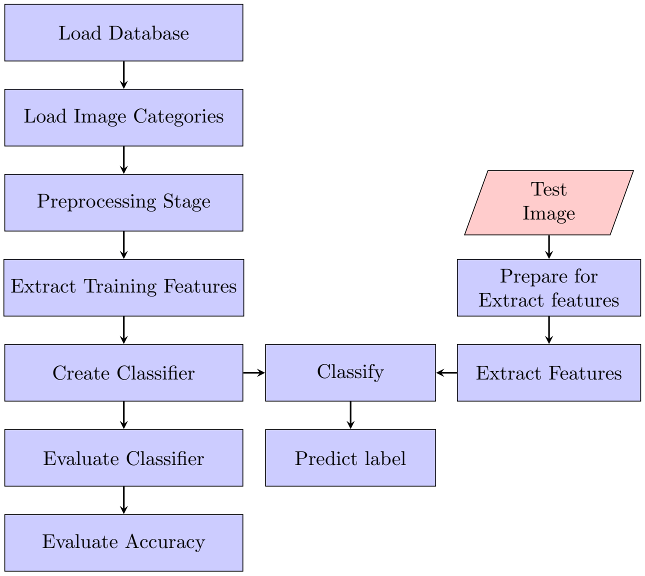

Fig. 2. Block Diagram of the CNN Classifier.

A. Classification Stage

To classify a dataset into user-defined classes, a supervised learning classification method is used [9]. It is the procedure that predicts the class of given data. The task of resembling a mapping procedure from input to output is known as classification predictive modeling. ”Fig. 2” illustrates the block diagram of the CNN classifier.

For training a classifier, a pre-trained CNN is used as a feature extractor in the proposed system. CNNs are trained to gather a large set of varied images. From these vast collections of data, CNNs can extract important features viz. SURF, LBP and HOG [11].

1) Load Data Base: To test the classification approach of cancer cells, the system used Brain, Breast, Leukemia and Lung category here. The data sets loaded to the system for creating the CNN classifier.

2) Load image category: The system constructed an image data store (imageDatastore) function based on the following categories ‘Brain’, ‘Breast’, ‘Leukemia’ and ‘Lung’. The system used the image data store (image Datastore) function to help manage the data. As an image data store (imageDatastore) function operates on image file locations, all the images don’t load into memory.

3) Preprocessing Stage:

a) Apply CNN using ResNet-50: ‘ResNet-50’ net can be loaded from neural network toolbox^{TM}. The system needs to initialize ‘ResNet-50’ applying resnet50. The first layer shows the input dimensions. CNN required 224-by-224-by-3 image size. A package of convolutional layers interspersed with rectified linear units (ReLU) and max-pooling layers exist in this architecture.

b) Prepare Training and Testing Image Sets: The system fragments the dataset into training and validation data. The system picked 60% of cancer cells for training and the remaining, 40%, for the testing. It randomized the dividing process to remove any biasing. The CNN architecture processed training and testing datasets. A supervised procedure and the training data trained the model [10]. The parameters of the model are accustomed depending on the judgement results. Both the parameter estimation and variable selection can be taken by the model fitting. Using some performance metrics the accuracy of the model is evaluated using the test set. Besides the training and testing set, a validation dataset is used to validate the trained model [11]. It is a very general way to assign more than 50% images for the training set, 25% for the test set, and the remainder for the validation set.

c) Pre-process Images For CNN: Resnet-50 uses 224-by-224-3 dimension images to perform. So, the system converts grayscale images into RGB and resizes them according to the requirement of resnet50. During network training, additional data augmentation processes use that resized image. The system resized both the training and testing images.

4) Extract Training Features: To extract features, the CNN model has few layers. The features are extracted from edges and blobs at the beginning of the networks. The second convolutional layer weights are required to visualize first convolutional layer weights [12]. Then the system resized and scaled the weights for visualization. In the first layer, there are about 96 discrete groups of weights. The first convolutional layer weight is given in “Fig. 3”. The activation method is used to extract the deep learning features. ’fc1000’ layers are used to extract features using activation functions. Either a graphics processing unit (GPU) or a central processing unit (CPU) is used by the activation function automatically.

5) Create Classifier using extracted features: A multiclass support vector machine(SVM) classifier uses extracted features to train a classifier. The fitcecoc function is used primarily by a fast-stochastic Gradient Descent solver. To create the classifier firstly, the system collects training labels from the training dataset. After that multiclass SVM classifiers are trained by the system using the fastest-linear solver [13][14].

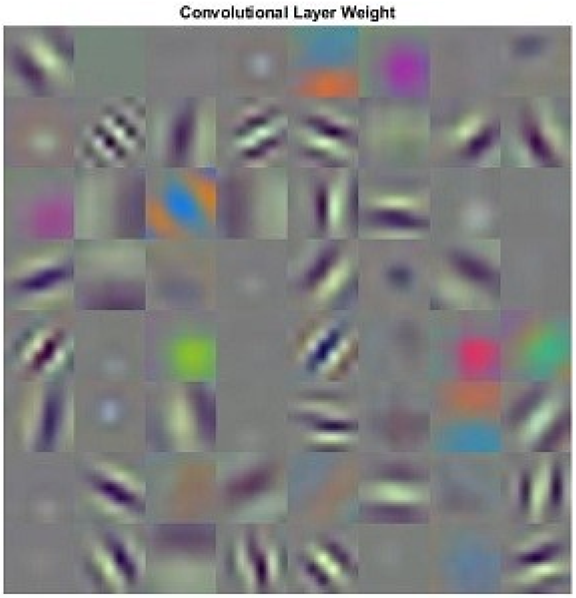

Fig. 3. First Convolutional Layer Weight.

6) Evaluate Classifier: In this step, the system tests extracted features using the trained CNN classifier. To evaluate the classifier, extracted features fed to the classifier, then the system identified class labels and tabulated the outcomes via a confusion matrix. Finally, the confusion matrix is converted into percentage form.

7) Classification of the test cancer cell: To classify the test cancer cell, the system needs to pre-process the test image or test the cancer cell. For this purpose, the system has to apply pre-processing stages before applying classification. When image features are extracted using an activation function, then extracted image features passed to the classifier and the previously created classifier classifies the test image [1].

8) Predict class label: When the classifier classifies the test image, the classifier predicts a label that represents which class the test image belongs to. Based on this predicted class label, the next segmentation stage starts to process. This predicted class label helps the next process to minimize its dataset and its processing time or execution time also.

B. Semantic Segmentation and Detection Stage

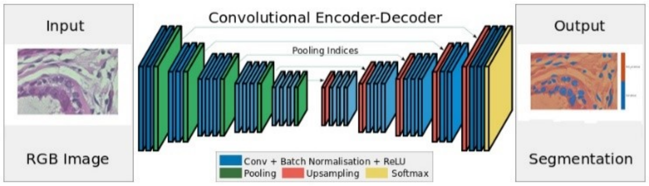

Fig. 4. Architecture of Semantic Segmentation.

“Fig. 4” illustrates the architecture of semantic segmentation. The encoders (i.e., a sequence of non-linear processing layers) are contained by the SegNet architecture. A pixel-wise classifier also follows the decoders (i.e., an equivalent group of decoders). Characteristically, one or more convolutional layers are contained by each encoder. Applying max-pooling directories in the encoding order, the decoder up-samples the light encoding because of the max-pooling [2].

To execute up-sampling of the low-resolution feature model in the decoders, max-pooling indices are used as one major component of the SegNet. This procedure bears some significant merits of holding the highest frequency niceties in segmented images. In the decoders, this procedure also helps to diminish trainable constraints. Using the stochastic gradient descent, the complete system can be accomplished end-to-end. The block diagram of semantic segmentation is given in “Fig. 5”.

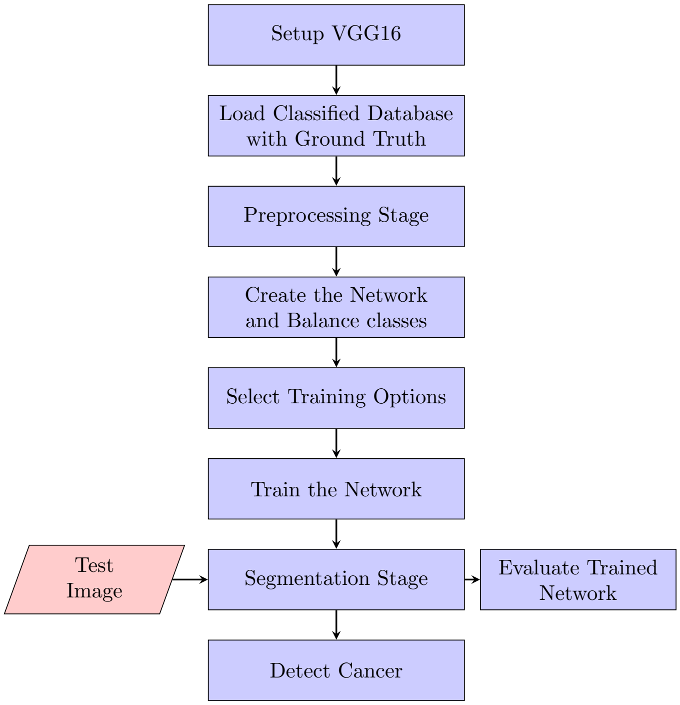

Fig. 5. Proposed block Diagram of Semantic Segmentation.

1) Setup VGG16: VGG-16 net is a 16 layers deep CNN net. The system loads a pre-trained network trained.To classify pictures into 1000 object classes (such as Brain, Breast, Leukemia, Lung and many other cancer types),the pretrained network is used. The system loaded a pretrained VGG-16 CNN net and examined the layers and categories. The pretrained VGG-16 network loaded using the vgg16 function. A sequence of the network object is used to produce output. The network has 41 layers. There are 16 layers with learnable weights: 3 fully connected layers and 13 convolutional layers exist in the net and all those 16 layers are learnable [3].

2) Load Classified Database with Ground Truth: After setting up the neural network, the system loaded the database with its ground truth. For this reason, the system classified the class of the test image. Based on the classified class the system loaded the only classified class database with its ground truth. Some labeled image with its original image is given in “Fig. 6”.

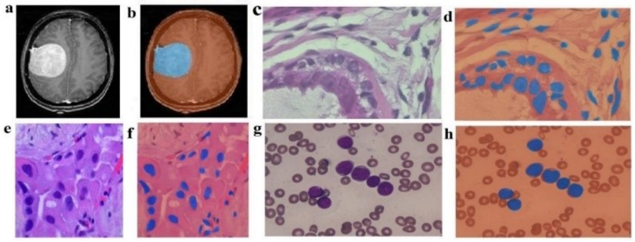

Fig. 6. Original images (a. Brain, c. Breast, e. Lung, g. Leukemia) and Labeling Images (b. Brain, d. Breast, f. Lung, h. Leukemia).

3) Preprocessing Stage:

a) Identify class and PixelLabelId: The system identified all class names and their corresponding pixel label id based on the classified loaded database. A large set of images and its counter set of labeled data are required to train a semantic segmentation network. To state the mapping between class names and label IDs, the pixel label data used. In the used dataset, the labels are “Cancerous” and “Non-cancerous” having 1, 2 label IDs respectively.

b) Analyze Dataset Statistics: In this study count pixels of Each Label used to observe the circulation of class labels in the database. The system can count the number of pixels in each label of a class and also can count the total pixels of each class in the used database. Using those pixel values, the percentage of cancer area and the non-cancer area are calculated. Those can be calculated using the following formula:

$$Frequency\ of\ each\ labels = \frac{Sum\ of\ label\ pixels}{Sum\ of\ image\ pixels} \quad (1)$$

c) Resize both Database Images and Labeled Images: In this research SegNet used the only process RGB images that are 300-by-300. To avoid re-saving all database images to this setup, the system used a converted and resized RGB image. The resized procedure has been applied not only for extra data augmentation, but also for training the network. Both the dataset image and labeled images are resized by the system.

d) Prepare both Training and Test Set: The system has described in the previous CNN section. The system needs to split the total dataset images and their pixel labels for training and testing sets. The system split the dataset 60% for the training set and 40% for the testing set.

4) Create the Network and Balance Classes: The system used the ‘segnetLayers’ procedure to make a neural network depending on VGG-16. The system specified the network image size. Then the number of categories is specified. Finally, the system created the SegNet layer network using image size, the number of categories and VGG-16. The classes are not balanced in an earlier dataset. To improve training, the system used class weight to equilibrium the classes. The pixel label computed earlier with a count each of label to compute the average frequency class weights, the pixel label measured past with the count of each label. The system identified class weights using a pixel classification layer. Then the system needs to update the pixel classification Layer of SegNet and delete the current pixel classification Layer and add the newly defined layer.

5) Select Training Options: The gradient method used Stochastic gradient descent momentum (SGDM). The system also needs to adjust the mini-batch size according to the memory size installed in the GPU to be used. The system applied training options to regulate the hyper-constraints used for SGDM. A factor of 0.3 every 10 epochs has been used to diminish the learning rate. Setting the 'ValidationData' parameter against the validation data every epoch, the system has tested the network. When the validation accuracy joins, stopping the criteria of the training has been set to 4 by the 'ValidationPatience'. To diminish memory procedure while training, a mini-batch size of 8 has been used. Depending on the quantity of GPU on the system, this mini-batch size can increase or decrease. In addition, At the end of every training epoch, the saving of network checkpoints is enabled by this name-value pair. The system can continue training from the kept checkpoint, if training is hindered because of a system deduction or power outage.

6) Train the Network: Data augmentation has been used during training to progress the accuracy of the network. Data augmentation has been completed using randomized X/Y translation and left/right reflection. The system used the image data augmenter to regulate these data augmentation constraints. Image data augmenter assists different other categories of data augmentation. During start training, the system combined data augmentation selections and the training data using pixel label image datastore. Batches of training data are read by the pixel label image datastore. To pass the resultant data of the augmentation process to the training process, data augmentation is applied. Pixel label image source is used to define the final data used for learning. Augmentation is also done here. After completing training, the system can segment the test image of the cancer cell using the created semantic segmentation network. For this reason, the system has to load the test image to the semantic segmentation network.

7) Semantic Segmentation: The field of computer vision has been empowered by deep learning. Semantic segmentation is one part of computer vision. Labeling each pixel is the purpose of semantic segmentation. Because the system is predicting for each pixel in the image, the dense prediction is referred to as the system. As the system created the SegNet network and trained it successfully, the system can now segment the loaded test image to the network. Using the trained net, the system can segment the test image and overlap the pixel label in it. It can be seen that the regions have been relatively neatly divided. Some test images are given in "Fig. 7".

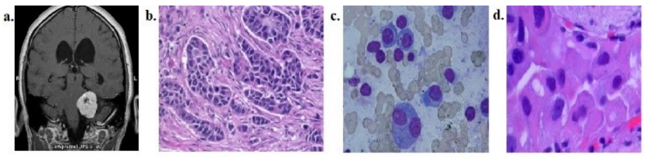

Fig. 7. Input Images (a. Brain, b. Breast, c. Leukeima, d. Lung).

The system can compare the segmentation result with the ground truth. As a result of overwriting, the green and magenta areas are different from the true values. For each class segmented by SegNet, the system can evaluate how much the ground truth region is included. This is an index called IoU and can be measured using the jaccard function. In addition to jaccard, the dice coefficient and BF coefficient are often used as the coefficient for expressing the similarity to the true value. The system uses the dice function and the bfscore function on MATLAB respectively. Segmented result of the test images given in "Fig. 8".

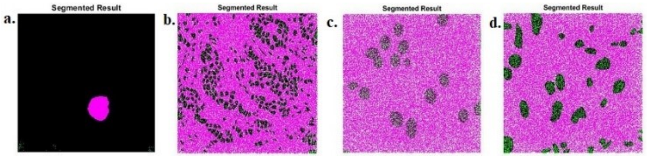

Fig. 8. Segmented Results (a. Brain, b. Breast, c. Leukemia, d. Lung).

8) Evaluate Trained Network: Semanticseg function has been run on the complete test set, to calculate the accuracy. Semanticseg returns the outcomes as a pixel label datastore object. The 'WriteLocation' parameter is used to write the location of the actual pixel label data. The system used the evaluate semantic segmentation function to calculate semantic segmentation metrics. For individual classes and for each input image, the semantic segmentation process returns various metrics for the complete dataset. The dataset metrics used to identify the network performance.

9) Detect Cancer: After segmentation, the system can detect any object from the segmentation output. Based on the cancer cell labeled, the system can separate the cancer cell from another labeling object. To get a meaningful segmentation output, the system applies different morphological operations and finally converts it into a binary form so that it can separate the cancer cell and others. Cancer cells represented in white e.g. 1 and non-cancerous are represented as black e.g. 0 [15]. The binary representation of segmented cancer cells given in "Fig. 9".

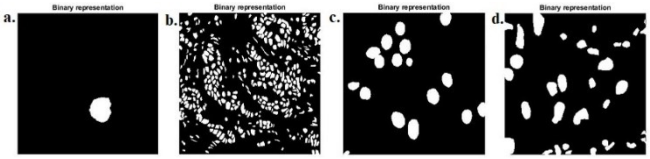

Fig. 9. Binary Representation (a. Brain, b. Breast, c. Leukemia, d. Lung).

After detecting cancer cells, the boundary of the cancer cells is identified by applying boundary detection algorithms and the boundary is represented by the red color. Detected cancer output is given in "Fig. 10".

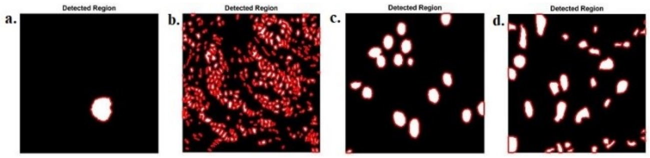

Fig. 10. Detected Region (a. Brain, b. Breast, c. Leukemia, d. Lung).

C. Area Calculation

Traced and detected cancerous outcomes are in the binary form. So, to calculate the percentage area of the cancerous region, the intensity (i.e., 1) of each pixel is summed and the total number of pixels of the test image is counted. The following equation is used to count both the area of the detected cancerous area and the total area of the test image [3].

$$Area = \sum_{i=1,j=1}^{n,m} P(i,j) \tag{2}$$

In the system, the cancerous area is identified with the pixel intensity having ones and the non-cancerous area identified with the pixel intensity zeros [1]. The percentage of the cancerous area is calculated with the ratio of the cancerous area and the total test image are as follows:

$$The\, percentage\; area = \frac{The\ area\ of\ Cancerous\ Cell}{The\ area\ of\ tested\ image} \times 100\% \tag{3}$$

IV. Result and Discussion

This paper developed a system to experiment on different databases of different types of cancerous cells. For brain cancer or brain tumor dataset purpose, the authors used Brain MRI Images for Brain Tumor Detection dataset. It consists of 154 brain images. For breast cancer histopathological annotation and diagnosis (BreCaHAD) dataset contains required files for Breast Cancer Histopathological Annotation and Diagnosis. It contains three folders named groundTruth_display (ground truth used on actual images), groundTruth (json files), images (original images). From those folders, the authors used only original images. This dataset contains 162 test images. For leukemia, the authors used SN-AM Dataset [16][17][18][19][20], which has three subsets. They used subset-2, and subset-3 where each of the subset contained 30 images. Lung and Colon Cancer Histopathological Images dataset [21], which consists of 25000 histopathological images and five categories, is used for Lung Cancer. Each image's size is 768 x 768 pixels, and each of them is in a jpeg file format. The authors created new polygonal ground truth for all datasets.

For evaluation of the proposed methodology Intersection over Union (IoU) is used. To evaluate IoU, detected cancerous areas and another area counted from ground truth are required. More formally, the hand-labeled ground truth that can form a polygon in the cancerous region and another polygon created with detection from the system methodology is required to estimate the proposed system accuracy using IoU. As the system used by the hand labeled ground-truth of different datasets and applied Intersection over Union (IoU) evaluation metric [22].

$$IoU = \frac{Region\ of\ the\ Overlap}{Region\ of\ the\ Union} \tag{4}$$

Table I. illustrates the IoU measuring raw values calculated from the total database and individual IoU. Calculating the average IoU from the above table, the system produces 93% accuracy.

TABLE I. Evaluation of the System

Cancer Type	Area of Overlap	Area of Union	IoU
Brain	93,195	94,529	0.9859
Breast	2,724,105	2,988,369	0.9116
Leukemia	597,690	642,560	0.9302
Lung	72,695,210	80,560,420	0.9024

Again, in the classification, the confusion matrix is applied to evaluate the exactness of CNN. It is used to identify the accuracy of the classifier. By observing how the classifier predicts a correct one as a truly positive and also observing a relationship of each category it can predict a class. The main job of a confusion matrix is to predict the results of a classifier and identify how correctly the classifier predicts a known class. Using true negative (x), true positive (w), false negative (z) and false positive (y) of the confusion matrix, the system can calculate the following performance.

$$Accuracy(Ac) = \frac{w+x}{w+x+y+z} \times 100 \tag{5}$$

$$Misclassification\ Rate = 1 - Accuracy \tag{6}$$

$$Specificity = \frac{x}{x+y} \times 100 \tag{7}$$

$$Precision(Ps) = \frac{w}{w+y} \times 100 \tag{8}$$

$$Recall(Re) = \frac{w}{w+z} \times 100 \tag{9}$$

$$F - measure(F-m) = \frac{2 \times Recall \times Precision}{Recall + Precision} \times 100 \tag{10}$$

TABLE II. Performance Calculation of CNN Classifier

Cancer Type	w	x	y	z	Ac(%)	Ps(%)	Re(%)	F-m(%)
Brain	18	54	0	0	100	100	100	100
Breast	18	54	0	0	100	100	100	100
Leukemia	18	54	0	0	100	100	100	100
Lung	18	54	0	0	100	100	100	100

Table II shows that the CNN classifier gave a 100% accuracy rate.

V. Conclusion

This research overcame the limitation of using individual methods for the cancer detection system for both MRI and Histopathology images. The results obtained in this research notify that the author's strategy is practical and can also pointedly support precise, can automatically detect cancerous cells and the proposed combination gives better accuracy after applying the machine learning algorithm.The authors reduced the training time and increased the segmentation accuracy using a CNN classifier and SegNet model with a morphological operation which is better than the common SegNet architecture. The experimental result achieves detection of cancer cells from various cancer databases that represent proper accuracy rates of an average of 93%.

Future research will be focused on using the more accurate, advanced deep learning algorithms to reduce the time complexity for large datasets and improve the accuracy rate. We will use more types of cancer cells and their categories. This research will open many opportunities for further research in image segmentation and cancer cell detection.

Analysis of the Use of Videoconferencing in the Learning Process During the Pandemic at a University in Lima

Angie Del Rio-Chillcce[1], Luis Jara-Monge[2], Laberiano Andrade-Arenas[3]
Faculty of Science and Engineering
University of Sciences and Humanities
Lima, Perú

***Abstract*—Due to the health emergency situation, which forced universities to stop using their centers as a means of teaching, many of them opted for virtual education. Affecting the learning process of students, which has predisposed many of them to become familiar with this new learning process, making the use of virtual platforms more common. Many educational centers have come to rely on digital tools such as: Discord, Google Meet, Microsoft Team, Skype and Zoom. The objective of the research is to report on the impact of student learning through the use of the aforementioned videoconferencing tools. Surveys were conducted with teachers and students who stated that 66% were not affected in their educational development. Most of them became familiar with the platforms; however, less than 24% qualified that their academic performance has improved, some teachers still have difficulties at a psychological level due to this new teaching modality. In conclusion, teachers and students agree that these tools are a great help for virtual classes.**

Keywords—Digital tools; health emergency; universities; video conferencing; virtual education

I. Introduction

Globally, due to the new pandemic SARS-CoV-2 or known as COVID-19, the use of different softwares for student education is increasing. Less than a decade ago, videoconferencing was only used to avoid unnecessary expenses on business trips, thus reducing savings on lodging and time.

There was an abrupt change with the arrival of this new virus. This has led to a growing need for all students (from kindergarten to university level) to establish and become familiar with this new teaching and learning process, making the frequent use of these platforms more common.

Online class imbalance learning is a new problem that is happening in the real world [1]. In Indonesia, there are two problems that inhibit its education system, namely, transportation and distance. As a first solution, they applied the use of information and communication technologies (ICT). To reach a large mass of students, they created the Virtual Class Box (VCB) 5.0 device to support digital distance learning between teachers and students [2].

On the other hand, China rushed and experimented for a two-month trial period by forcing its universities to work remotely [3], obtaining as a result of their ICT, acceptable academic performance. However, he also stated that online platforms are not explicitly for student purposes.

Latin American countries such as Uruguay, created a digital program designed exclusively for the quality of teaching and learning in students due to the shortage of teachers [4].

One of the ways of interactivity is the so-called Discord application [5], normally used for video games. In their latest updates they added the trend of video calls, based on this, the student-teacher activities improved, consolidating the educational synergy.

In this day and age, conventional education is having gaps when it comes to teaching. Because, due to factors beyond their control, the immobilization of people decreed by many governments worldwide has left them alone at home, unable to go out, much less to places where there is a conglomeration of people. Education at any level has been affected in the delivery of classes [6].

Currently, the need for Peruvian students has increased by 80% the use of online classes. Because virtually the entire 100% of their houses of study will be disabled in person to prevent the spread of the virus from March 16, 2020 to date. By carrying out virtual meeting platforms such as Zoom or Google meet.

Today, they are the most innovative and adaptable means of telecommunication to our new national lifestyle. Since, it allows to establish a more real and visual connection between teachers and students. Helping also not to delay education. A study in 2019 [7], demonstrates that online learning helps university students improve their academic performance.

As it is in one of the Peruvian professional study houses, Universidad de Ciencias y Humanidades, in which the pandemic forced all its teachers to use videoconferencing without having previous knowledge of these, making a sudden change in the teaching methodology, since the virtual meeting platforms such as zoom and google meet had a time limit. Therefore, by having unique videoconferencing platforms, students will be able to receive instructions as if they were in person, and maintain the synergy of real-time intercommunication. However, these habits are not well received by some courses that require mandatory explanations by the physical presence of a teacher; discarding the disadvantages that some may have due to the quality of the network in their homes.

By carrying out this work we will make a research contribution and, above all, we will see that each person has a different learning pace, which leads us to question, with the excellent quality of the platforms, are videoconferences really effective for university teaching and learning?

The objective of this article is to know the impact of different videoconferencing tools that have been used in the teaching and learning process at a University in northern Lima in times of pandemic.

The structure of the article is as follows: Section II, Literature Review, the antecedents will be explained; in Section III, Methodology, the steps to be followed will be detailed; in Section IV Results are discussed; in Section V, Discussions and in Section VI Conclusions and Future Work are discussed.

II. Literature Review

Currently, in times of pandemic, teaching is at a distance where the use of different means of videoconferencing is relevant in education. Since, it has a very significant role in the learning experience of the students [8].

The author [9], indicates that ICT has contributed to the new educational reforms. Google meet was mostly used by students in work meetings as opposed to teachers who preferred to zoom in on class meetings.

The use of the Zoom Videoconferencing platform helps both teachers and students in their work, teaching and learning, which allows both parties to interact and learn about the benefits of the platform, in addition to creating a socially positive learning environment [10]. The author [9], [10] coincide in their methodologies, since both apply a quantitative approach, having as statistical results, where a good percentage of Zoom videoconferences are accepted by students and teachers.

On the other hand, the author [11] mentions in the results of his studies that students do not have problems related to virtual education using videoconferencing platforms, however, there is a latent concern about issues related to the laboratory since, in it, they needed instruments that only the University could provide and that the vast majority of students do not have the possibility of acquiring.

In similar instances, a university student group, in their article [12], emphasized that it is not only in the professional field that institutions use videoconferencing for teaching.

In a study of e-learning, the modern form of online learning, the following benefits were found [13], such as cost-effectiveness, learning flexibility and, above all, the independent part.

In an investigation [14], explains that students have learning effectiveness during their online classes using Discord, as it allows access to requested activities and availability. However, what is detrimental to its reinforcement is the low quality of its network speed and the self-conscious behavior on the part of the students when they do not contribute opinions by activating their microphones.

Students in Indonesia, however, refuted that answer [15], he mentioned that when his students use videoconferencing tools in their classes, the behavior of the students is different, assuring that many of them have managed to overcome the shyness of speech, in which, virtually, they have more courage to contribute their opinions.

III. Methodology

The following will describe the most influential points of Videoconferencing platforms that contribute to virtual education, such as: Discord, Google Meet, Microsoft Teams, Skype, Zoom.

A. Survey

In this work 2 surveys were applied to: 25 university students and 10 teachers of the University of Sciences and Humanities of the career of Systems and Computer Engineering, using the Google Form tool to carry out these surveys. These surveys will help us to collect data from both students and teachers.

-Link to the survey for teachers:

$docs.google.com/forms/d/1T6ZFX6Forz4$
$U_QhLKxHAILyA1ITYQ698i0uq8oAY0Vc$

Table I, lists the questions on the form for teachers.

TABLE I. Teacher Survey Table

N°	Teacher Survey
1	¿At what level do you consider you are psychologically and pedagogically qualified to work with virtual videoconferencing tools?
2	¿How many hours have you increased your workload to develop your online classes?
3	From your perspective, do you feel that stress has built up during the new teaching methodology?
4	¿Do you think you need to improve your digital skills to face the new teaching and learning processes in virtual environments?
5	Nowadays, the use of different videoconferencing platforms has diversified. On a scale of 1 to 5, indicate your knowledge of each of them, where 1 is none and 5 is total.
6	Rate the following tools, indicating the level of use in your online classes.
7	From your point of view, do you feel comfortable with the new teaching modality?
8	Based on the academic performance of your students, consider:

-Link to student survey:

$docs.google.com/forms/d/1o7cqxYVTB_zJd - EoRSS - 8W9LnyAIco5ll8IgiQQ2xJU$

In Table II, we will mention the questions in the survey focused on students.

B. Zoom

Zoom is a tool used for synchronous online teaching, which allows you to work efficiently. It includes several functions such as: annotation tools, polls, meeting rooms and video and screen sharing. These functions facilitate learning [16].Below in Table III, the most important tools of the Zoom platform will be detailed.

It offers innovative learning opportunities and tools, integrating video conferencing and teacher-student communication.

TABLE II. Student Survey Questions

N°	Student Survey
1	¿Do you consider that your level of learning has increased in the new virtual learning environment?
2	¿Does teaching teachers via videoconferencing help you learn?
3	According to the aforementioned. Give a brief explanation of your answer.
4	¿Do you think you need to strengthen your digital skills to adapt to new learning processes in virtual environments?
5	Currently, the use of the different Videoconferencing platforms has diversified. On a scale of 1 to 5, mention the knowledge of each of them, where 1 is nil and 5 is total.
6	Please rate the following tools, indicating the level of use in your online classes
7	¿From your point of view, do you feel comfortable with the new learning modality?
8	¿How often do you have trouble concentrating during your online classes?
9	Based on your academic performance, consider:

TABLE III. Main Zoom Tools

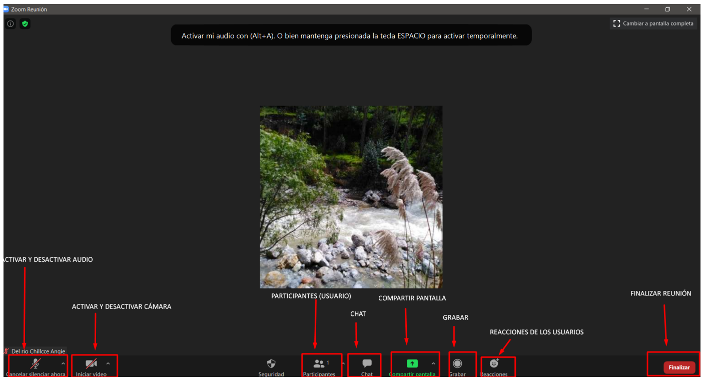
TOOLS	USAGE
Start a meeting	Create a videoconference.
Schedule a meeting	Allows you to schedule a specific day and time for the meeting.
Use of the calendar	Gives the option to use Google calendar, to receive notifications of meetings already scheduled.
Screen sharing	Allows all participants to have the option to choose what to share with other meeting participants
Screen Recorder	It is useful to replay the meeting as many times as you want, it is very helpful to take notes and remember some details.
Virtual whiteboard	Allows you to draw, write or carry out explanations in an easier way.
Chat	Participants have the option to interact both directly and privately.
Live Broadcasting	It is used to make live broadcasts using applications such as Facebook or Youtube.
User management	You have the option to enable and disable the audio and video of the participants, as well as manage which user enters the meeting.

In Table IV, some advantages and disadvantages of the platform are mentioned.

TABLE IV. Table Advantages and Disadvantages of Zoom

Advantages	Disadvantages
The pc version and mobile application has a relatively easy, comfortable and intuitive interface.	Despite being an easy to use tool, it can be confusing for some people who are not adapted to this new technology.
It has a free version	It has a 40 minutes limit for the free version.
Allows screen sharing in real time	As it is a synchronous application the use of internet or a stable connection is important.
No need to be registered to join a meeting, nor download the application	It collects data and emails from all connected devices exposing the user.
A permanent ID will be assigned to the user	It is no necessary to download and install the application to use it.

In Fig. 1, the main and basic Zoom tools are shown.



Activar mi audio con (Alt+A). O bien mantenga presionada la tecla ESPACIO para activar temporalmente.

Fig. 1. Zoom Interface.

C. Google Meet

Google Meet is a relatively recent application [17], was launched in April 2020 to all users, free of charge. It was previously known as Hangouts. It is mainly focused on companies and educational centers.

Below in Table V, the most important tools of the Meet platform will be detailed.

TABLE V. Main Meet tools

TOOL	USE
Create a video call	Allows you to create the video call, by logging in with your Google account.
Invite other users to join a meeting	Gives you a meeting link or code that you can send to other users.
Screen sharing	Allows you to show your screen or the window of an application.
Screen Recording	Allows you to record the sessions so that the student has all the information at hand.
Chat	Users can interact by sharing files and views.
Controls for hosts	The host can mute, set or delete a user.

In Table VI, some advantages and disadvantages of the Meet platform are mentioned.

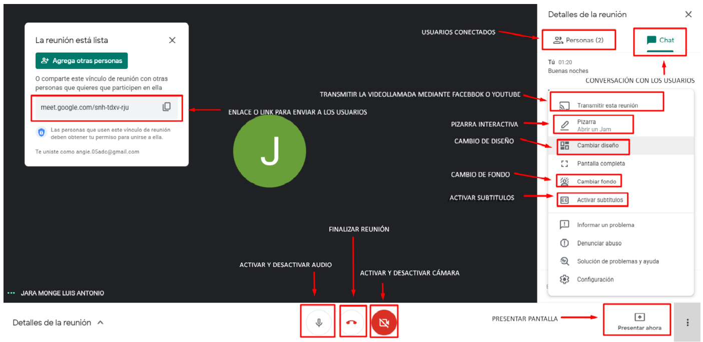
TABLE VI. Advantages and Disadvantages of Meet

Advantages	Disadvantages
Allows you to create meetings with more than 200 participants	60 minutes limit for the free version.
Facilitates real-time captioning during conversation	Has few mechanisms to control user audio.
It has a simple and deductible interface	Each participant must be registered or have a Google account.
The security of the videoconference is guaranteed due to the encryption of the transmissions	it is a synchronous application, this means that the internet connection is indispensable.

Google Meet is closely connected to Google Suite, this makes it possible to add meetings through Event Calender.

In Fig. 2, the main Meet tools are shown.

D. Skype



La reunión está lista

O comparte este vínculo de reunión con otras personas que quieres que participen en ella

meet.google.com/snh-tdxv-rju

Las personas que usen este vínculo de reunión deben obtener tu permiso para unirse a ella.

Te uniste como angie.05adc@gmail.com

Tú 01:20
Buenas noches

Detalles de la reunión

Fig. 2. Meet Interface.

Like the other virtual meeting platforms, this one offers its services at zero prices, i.e. free of charge, so that people can meet at a distance. Despite being an offshoot of Microsoft's own [18]. Table VII shows the features that Skype has.

TABLE VII. Skype Application Features

HERRAMIENTA	USO
Speed per calls	24kbps / 128kbps.
Courier writing	Unlimited for ongoing call.
Call recording	If in case the guests want to see the show again.
Shared screen	It has the ability to transmit live presentations from the phone or computer.
Multi platform	phone, pc, laptops, tablets, has accessibility to Skype.

We continue with Table VIII, the advantages and disadvantages of this virtual meeting platform will be detailed.

TABLE VIII. Advantages and Disadvantages of Skype

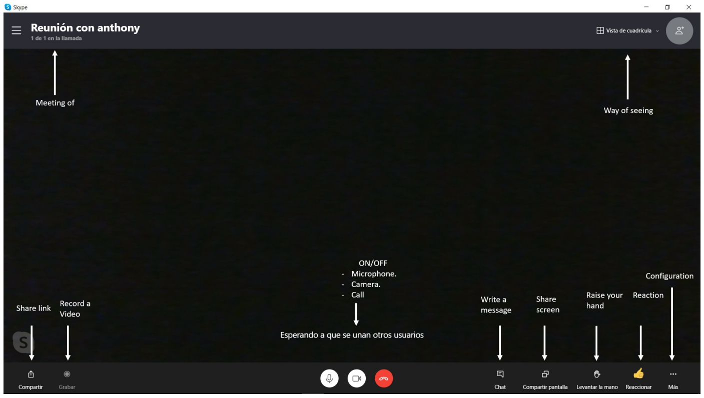
Advantages	Disadvantages
Skype has accessibility for the different Operating Systems such as: Windows, Mac, Linux, Android, iOS.	It is not used mainly for academic meetings, both university and school.
Advanced Encryption Standard Security.	Sometimes during video call, video and audio quality tends to drop, which is annoying for users.
It has the capacity of 50 people connected in real time.	If the time limit exceeds, the video transmission is cut off, however, the call continues as audio.

In the Fig. 3, the tools of said platform are indicated by arrows.

E. Microsoft Teams

This virtual meeting platform is also used by hundreds of students nationwide, launched since 2017 becoming better known by the education sector since the year 2019, as well as providing a good integrated teaching and learning space [19].

Next, it is detailed in Table IX, the characteristics that the platform carries within a videoconference on-line.



Esperando a que se unan otros usuarios

Fig. 3. Skype Platform.

TABLE IX. App Features Microsoft Teams

TOOL	USE
Messenger service	Ability to communicate personally with one of the members.
Time limit	The platform can be used between users for 24 hours at a time.
Time	Shows the time spent inside the room..
Setting	Shows other options available to the application, such as: audio distribution.
Leave	By pressing that option, the member can exit the live session.
Reactions	Interaction of members, such as: raising your hand to give your opinion, then the host will respond to your request.

To achieve a distinction between the aforementioned platforms, it will be detailed in Table X, the advantages and disadvantages of the Microsoft Teams video conferencing platform.

TABLE X. Advantages and Disadvantages of Microsoft Teams

Advantages	Disadvantages
PKI security Protect data used to encrypt transport layer connections.	It has a paid version for the full use of its services.
Has resources at the time of live meetings	It does not allow more than 300 users working simultaneously.
It has a free plan, however, it restricts some tools	A large percentage of users do not feel conformism with the tools, that is, difficult adaptability without prior training.
Your files are stored in the cloud. (Drive)	Requires the mandatory use of the internet.

In Fig. 4, each of the parts that Microsoft Teams has during a live meeting are noted.

F. Discord

The Discord platform is a means of creating a quality remote environment during emergency training. [20]. It is used

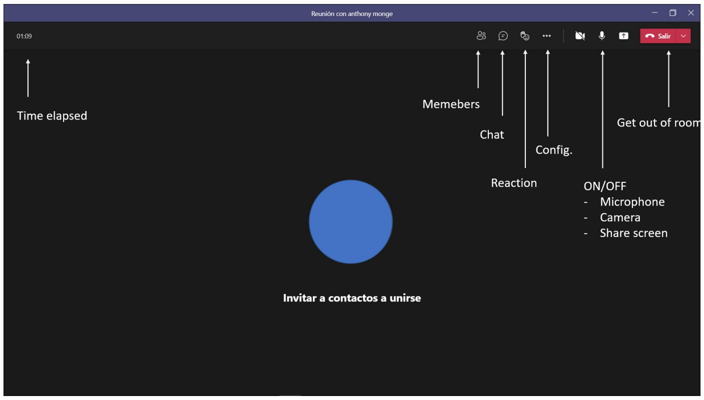


Fig. 4. Microsoft Teams Platform.

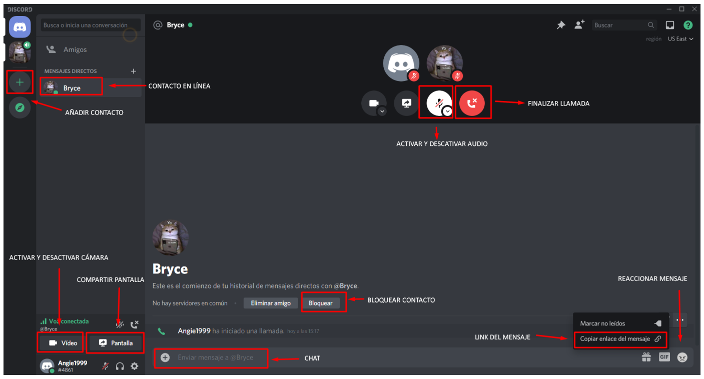

Este es el comienzo de tu historial de mensajes directos con @Bryce.

No hay servidores en común

Angie1999 ha iniciado una llamada. hoy a las 15:17

Fig. 5. Discord Conference.

to convert a traditional class to a virtual class, a monotonous listening class into an engaging listening class. In Table XI, we will proceed to list some of its tools.

TABLE XI. Discord App Features

TOOL	USE
Add contact	Be able to add a user to make the video call.
Create video call	Lets create the video call.
Share screen	Allows video call participants to choose what to share.
Chat	It serves to have a more direct communication.

The following is detailed in Table XII, some advantages and relevant disadvantages of the videoconferencing platform Discord.

TABLE XII. Advantages and Disadvantages of the Discord Application

Advantages	Disadvantages
Due to the optimized performance, you can communicate without losing call quality.	After the launch of the paid version (Discord Nitro), limited some features in version (Discord Classic), and much more in its free version.
The tool is cross-platform.	Requires previous training for its use.
The platform is free.	The video calling option is not optimized, so there is a chance it will fail.
It is customizable for a better user interface.	You do not have the option to record video calls.
Ability to provide class with up to a maximum of 50 people.	Discord is not available for the Linux Operating System.
Technical support available to your users.	He had complaints from scammers.

In Fig. 5, the main interface of the Discord tool is shown, in addition to having a good educational and group environment, with a knowledge of the application there will be no deficiencies in its use. Multiple options are displayed within the interface that can be performed during a call in progress, either by transmission or just aural.

Through the comparisons made, it can be clearly concluded that the platforms have similar characteristics as: Time in which the class takes place, interaction option, screen sharing, writing internal messages to a user as well as in public. Except for Discord, for not having the option of video recording.

Then, the videoconferences differ between them by one or another option of use, therefore, the student's learning and the teacher's teaching still remains to be analyzed, Therefore, the results of the survey carried out will be explained by means of graphics.

IV. Results

A. Regarding the teachers surveyed:

- The 66.6% considers that he is highly trained physically and psychologically to work with videoconferencing tools, as well as the 33.4% consider it to be at an intermediate level. As shown in Fig. 6.

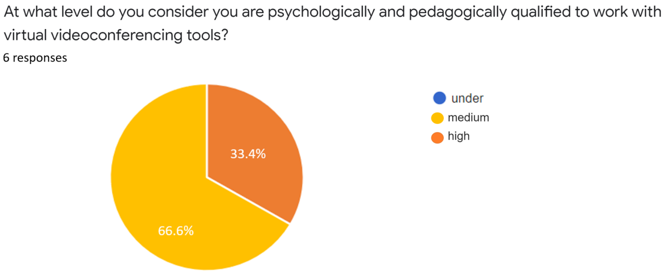

Fig. 6. Questions about Teacher Training.

- The 50% dedicates more than 3 hours (than normal) a day to develop his class, meanwhile the 33.3% dedicate 3 hours a day and 16.7% he claims he only spends 2 hours. As shown in Fig. 7.
- The 66.4% of teachers assess that they have accumulated a medium stress with the new teaching methodology, while the 16.8% considers that he accumulated high stress, in the same way the 16.8% accumulated low stress. As shown in Fig. 8.
- The 100% consider that you need to keep learning the new digital tools. As shown in Fig. 9.

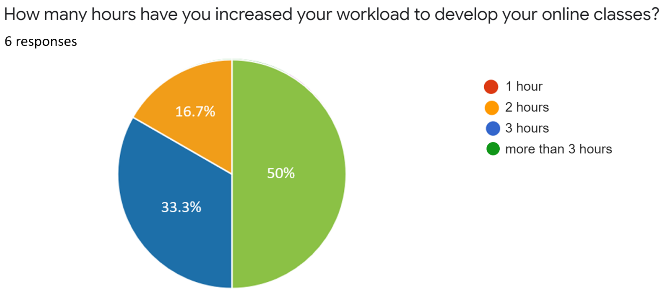

Fig. 7. Ask about the Hours Dedicated to Developing the Class.

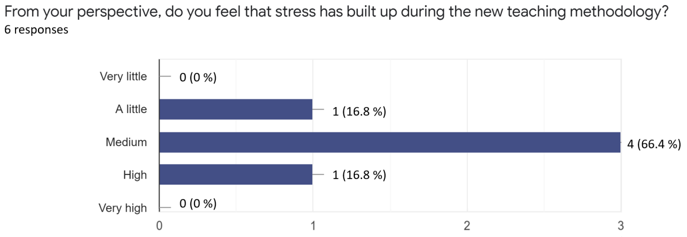

Fig. 8. Question about Accumulated Stress in Teachers.

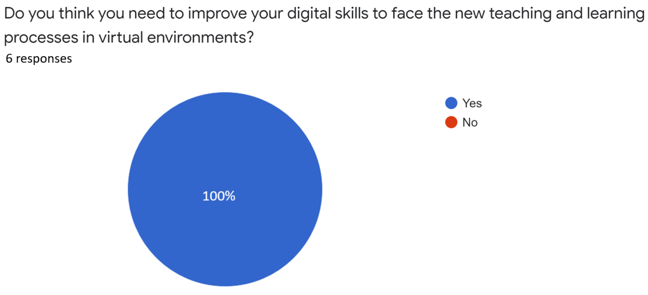

Fig. 9. Ask about the New Digital Tools.

- The vast majority of teachers have a very high knowledge of the Zoom and Meet platforms, however they have a medium-low knowledge of the Skype, Microsoft Teams and Discord tools. As shown in Fig. 10.
- Almost all teachers confirmed that they use the Zoom and Google Meet tools more frequently to teach their classes, as shown in Fig. 11.
- Only 16.7% considers that he feels very comfortable with this teaching modality; however, the 83.3% consider that you are comfortable with this mode of teaching. As shown in Fig. 12.

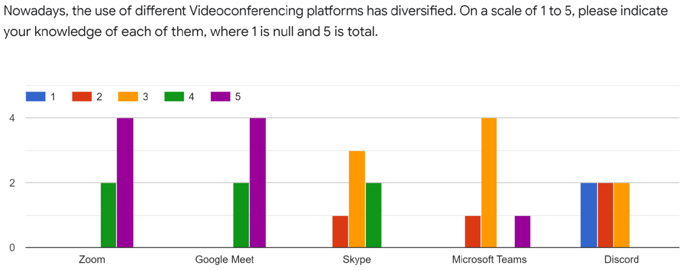

Fig. 10. Question about the Knowledge of Videoconferencing Tools.

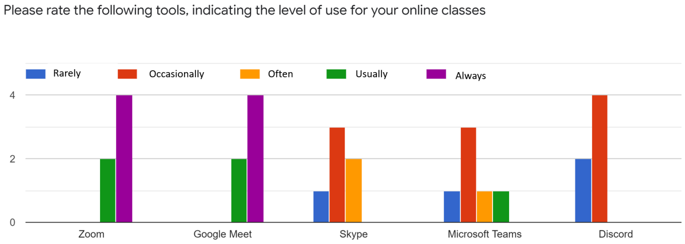

Fig. 11. Question about the use of Videoconferencing Tools.

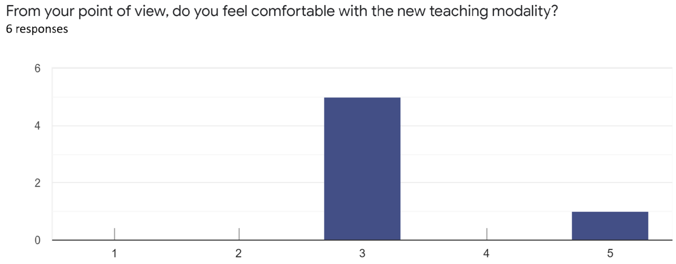

Fig. 12. Ask the Teacher about this New Teaching Method.

- An 83.4% of teachers consider that students' academic performance has remained on the sidelines and only 16.7% indicates that it has improved. As shown in Fig. 13.

B. Regarding the Surveyed Students:

- The 60% of students rate that their learning level has remained in a normal state, the 20% estimates that it has improved, and 8% qualifies that he has learned little; however, the 8% he considers that he has learned very little. As shown in Fig. 14.

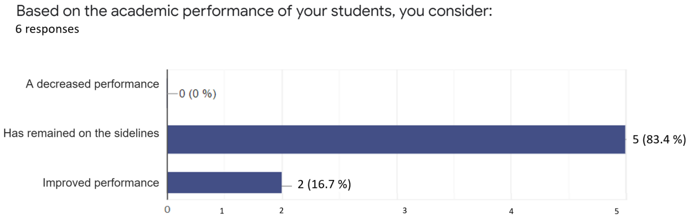

Fig. 13. Question about the Student's Academic Performance.

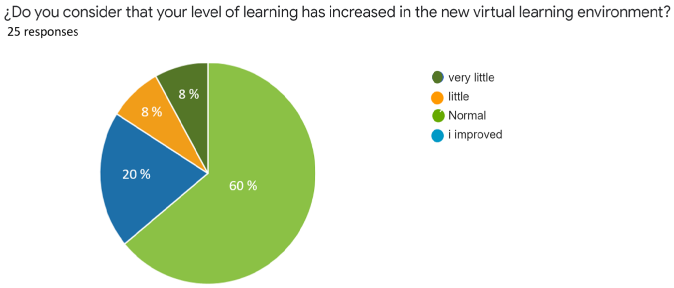

Fig. 14. Ask about the Student about their Level of Learning in New Virtual Learning Environment.

- The 68% of the surveyed students rate that they agree that video conferencing tools help them learn; however, the 32% considers that they do not agree. As shown in Fig. 15.

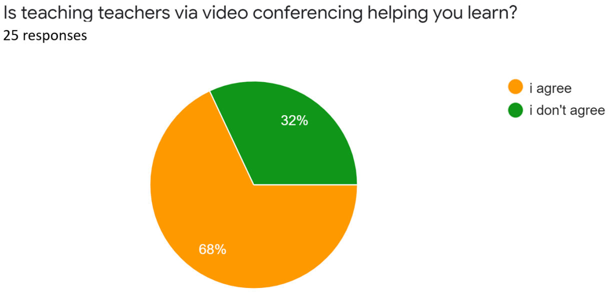

Fig. 15. Ask about the Student about their Level of Learning via Video Conferencing.

- The 72% of respondents believe that they need to continue strengthening their digital knowledge, although, 28% consider not.

- The vast majority of students have a medium-high knowledge of the Zoom and Meet platforms, however, they have low-zero knowledge of the Skype, Microsoft Teams and Discord tools. As shown in Fig. 16.

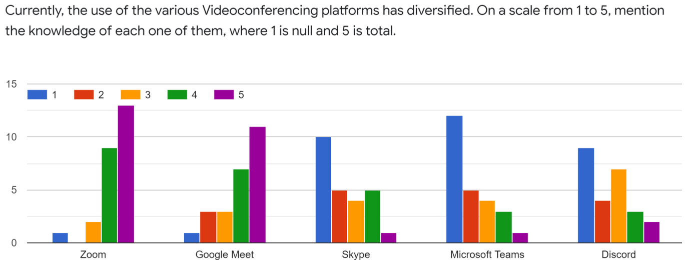

Fig. 16. Ask the Student about Knowledge of Videoconferencing Tools.

- Almost all students confirmed that they most frequently use the Zoom and Google Meet tools for their online classes. As shown in Fig. 17.

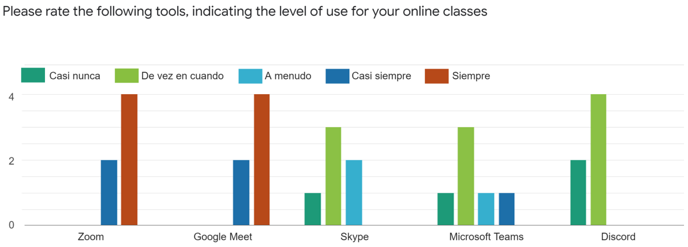

Fig. 17. Ask the Student about the use of Videoconferencing Tools.

- The 16% considers that he feels very comfortable regarding the new learning modality, a 20% rate that you feel comfortable, the 44% considers that it is normal, the 16% estimates that he feels uncomfortable, in the same way a 4% He rated that he is not comfortable. As shown in Fig. 18.

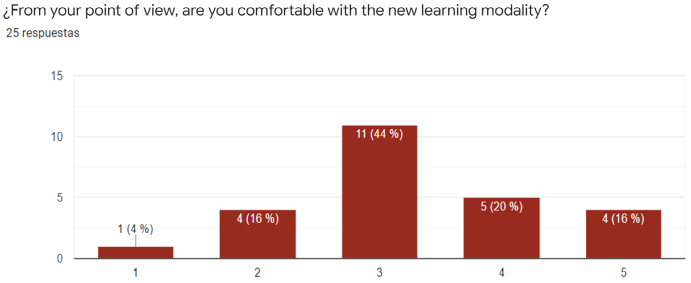

Fig. 18. Ask the Student about their Learning Comfort.

- The 52% indicated that he very seldom has concentration problems during classes, only on the 32% who has problems often, and the 16% indicates constantly has problems. As shown in Fig. 19.

- The 24% rated that their performance has improved considerably, the 60% considers that his performance has remained on the sidelines, and only the 16% indicates that its performance has decreased. As shown in Fig. 20.

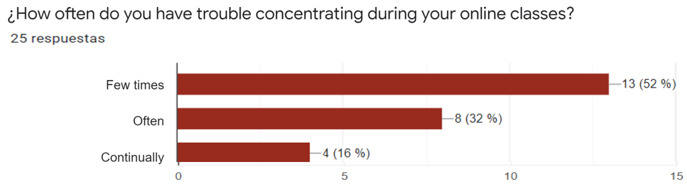

Fig. 19. Ask the Student about his Concentration During Class.

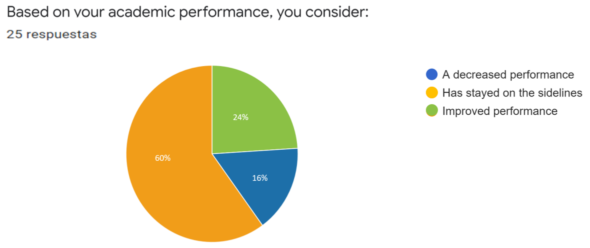

Fig. 20. Ask the Student about their Academic Performance.

V. Discussions

During the points mentioned and analyzed for the use of these different virtual platforms, the financing aspect is essential due to various factors. Both by the student entity (University or college), as well as by the students for the usability of the conference applications [21].

According to the author [22], mentions that Zoom features are optimal for conducting video conferencing in an intuitive way. Another Study Reveals About Improving Scores During Online Exams [23]. That is, in 2020 there were higher grades in its average. Which means that students' grades have risen significantly since e-learning was introduced at the beginning of the pandemic. In the results of [24], Through their survey, they detailed that the majority of students in a 56.3 % They assured that the most used and / or known platform is Zoom. Obtaining a result similar to our work as the most used videoconferencing application for this new mode of education. He also added, and we agree, that the solution of practical exercises such as: mathematics; require more than distance learning.

The results obtained in comparison with the author [10] they coincide, as, video conferencing platforms help teachers and students in teaching and learning work.

VI. Conclusions and Future Work

In conclusion, regarding the results obtained from the surveys, the vast majority of teachers and students perform at an advanced level in the platforms for the virtual teaching and learning environment. Likewise, teachers have constant and fluid communication with their students during class partitions. However, some teachers still have difficulties at a psychological level due to this new teaching modality. The teachers mentioned that they are in constant training to learn the new digital tools. Students feel comfortable and motivated during their virtual classes.

The contribution of this research work is aimed at the educational environment, making the results known through online learning surveys. The academic community of the University, made up of students, teachers and authorities, benefit from this work.

Further research is expected later, adding the other departments and comparing little-known video conferencing platforms.

***Abstract*—With the evolution and popularity of computer networks, a tremendous amount of devices are increasingly being added to the global internet connectivity. Additionally, more sophisticated tools, methodologies, and techniques are being used to enhance global internet connectivity. It is also worth mentioning that individuals, enterprises, and corporate organizations are quickly appreciating the need for computer networking. However, the popularity of computer and mobile networking brings various drawbacks mostly associated with security and data breaches. Each day, cyber-related criminals explore and devise complicated means of infiltrating and exploiting individual and corporate networks' security. This means cyber or network forensic investigators must be equipped with the necessary mechanisms of identifying the nature of security vulnerabilities and the ability to identify and apprehend the respective cyber-related offenders correctly. Therefore, this research's primary focus is to provide a comprehensive analysis of the concept of network forensic investigation and describing the methodologies and tools employed in network forensic investigations by emphasizing on the study and analysis of the OSCAR methodology. Finally, this research provides an evaluative analysis of the relevant literature review in a network forensics investigation.**

Keywords*—Network forensics; Tshark; Dumpcap; Wireshark; OSCAR; network security

I. Introduction

The evolution of computer networks and the internet has created many opportunities for the perpetration of cyber-related crimes. Numerous computing devices are connected to a complex mesh of computer networks all over the globe. Cyber attackers are continuously adapting complicated strategies to perpetuate cyber-related crimes. The nature and the type of crimes are costly to the affected victims [1]. In some instances, the committed cybercrimes not only cause significant financial losses but might also render the affected organization inoperable. Thus, it is essential to have a mechanism of performing necessary investigation and audit to establish the course and the perpetrators of the associated cybercrimes. In the context of cyber-criminal investigations, the mechanism is referred to as network forensics.

Network forensics is a digital forensic process that involves the investigation, Analysis, and monitoring of computer networks to discover essential information that helps in the apprehension of cybercriminals [2]. Network forensics also helps in gathering necessary and legal information, evidence, and traces of intrusion detection. In essence, network forensics helps a cyber-forensic investigator monitor network traffic and identify any malicious content within network traffic. Network forensics is data-centric, and thus it is not primarily restricted to the Analysis of network traffic. Instead, it is also associated with related concepts, notably mobile forensics, memory forensics, and host-based forensics [1].

Primarily recent Internet technology advances drive the evolution of network security and its associated forensic processes and related toolsets. When more facets of our everyday lives move to electronic networks and databases where they are vulnerable to illegal activity, there is a growing need for advanced analytical resources. Some widely mentioned explanations for the use of network forensics are based on

- Analysis of computer systems belonging to victims or authorities.
- Collection of facts for use in court; Recovery of lost data in the event of software and hardware failure.
- Analysis for a computer system after a break-in.
- Collection of information about how the computer systems function for debugging purposes, optimization of their computer systems The list only scratches the surface of what network forensics can do in the sense of risk management and data recovery;

The following example illustrates the critical role that this technology can play in an investigation process. The companies usually use different items when it comes to network security. Such devices typically approach protection from two main perspectives; detection and monitoring, in other words. Types of items for protection include firewalls and systems for access controls. Likewise, the intrusion detection systems and antivirus software are examples of detection products. Although the used products foil several attacks, novel attacks often bypass protection products without being detected. Investigating the attacks in these cases is a challenging job. Serious attackers are, in many cases, skilled at removing evidence. Consequently, firewall logs and intrusion detection warnings that miss such attacks entirely or may prove insufficient for a thorough investigation, mainly when the goal is to apprehend the attacker.

Network forensics has been suggested in information security literature to incorporate investigative capabilities in existing networks. This refers to a dedicated research infrastructure that enables network packets and events to be captured and evaluated for research purposes. Complementation of the above Network Security optimization is performed. The forensic network is of significant importance to companies worldwide. On the one hand, it helps learn the specifics of recent threats, ensuring that potential attacks are thwarted. Furthermore, network forensics is essential to investigate the abuses of insiders that constitute the second most costly model of corporate assault. Lastly, law enforcement refers to network forensics for cases in which a device or digital machine is either the object of a crime or used to carry a criminal offense.

Network forensics is a complex phenomenon that needs the utilization of a variety of tools and methodologies. It is thus essential to have a good understanding of how these tools and techniques can aid in the process of network forensics and the discovery of malicious activity and intrusion attempts. This paper aims to provide a comprehensive description of network forensics' concept to understand the tools and methodologies used. Emphasis is based on giving a vivid portrait of the OSCAR methodology as used in network forensics. An analysis and review of critical related works that illustrate the practical implementation of the network forensics concept are extensively discussed.

II. Related Work

The field of network forensics attracts diverse interests that ultimately have led to the publication of various research works aimed at bridging the knowledge gap within the topic domain. In particular, much of the related works in the field of network forensics is related to security. It is essential to note that any network provided that is connected to the internet is prone to a variety of cyber-attacks. The attacks are generally designed in such a way that they exploit ay vulnerabilities within the network. A forensic investigator is thus tasked with the responsibility of coming up with essential strategies to perform a comprehensive network forensic process to identify potential cases of network intrusion [3]. In addition to the fact that the legislature has borne some of the cost of crime prevention, company secrets are compelled to utilise the most dynamic security measures available to secure their essential information [4].The advent of information and communication technologies has ushered in a new era of human existence known as the information society. As the most well-known product of this community, cyberspace has provided people with enormous opportunity to search for and store large volumes of data. This has not only improved the visibility of information, particularly scientific and economic conclusions, but it has also resulted in an increase in targeted cyber-attacks aiming at gaining unauthorised access to such sensitive data. Meanwhile, the concept of safeguarding trade secrets has taken on new significance as information with independent economic or competitive worth [5]. One of the numerous issues that trade secrets have produced as valuable and sensitive knowledge as a result of the expanding space of information and communication interchange is the widespread response of governments to the use of coercive instruments with powerful deterrent effects, such as Terry's case [6]. This research comprehensively discusses it as discussed in the related domain [7], [8], [9], [10], [11].

A. Network Security and Network Forensic

Apart from assisting in identifying and apprehending cyberterrorists and attackers, network forensics also plays a significant role in extending the security model within a network. As noted by Almulhem, network forensics helps network administrators to enhance the prevention and detection of network and cyber-related attacks. In essence, network forensics makes it possible to perform a comprehensive vulnerability analysis process to identify potential threats facing a network [12]. Almulhem adds that network forensics is more associated with a security model than a product or service aimed at enforcing security or network prevention. Instead, network or digital forensics emphasizes the design and implementation of methodologies, tools, and concepts that aim to enhance the process of forensic investigation [12].

Kilpatrick et al. suggest the implementation of SCADA (supervisory control and data acquisition systems that form a vital infrastructure for network forensics [13]. SCADA networks are essential for forensic investigations in that the underlying architecture makes it possible to analyze, monitor, and monitor network behavior [13]. In particular, the SCADA network forensics makes it possible to design and build robust SCADA networks. This is because traffic analysis is an essential constituent of the architecture of a SCADA network.

Network forensics also plays a significant role in the implementation of security mechanisms in the machine to machine networks (M2M) [14]. M2M networks utilize artificial intelligence and machine learning to improve the communication process. Network forensics is used to identify security issues in M2M networks by implementing two distinct modules; forensic and attack detection module. Further, a forensics strategy that uses anti-distributed honeypot is used to aid in detecting and preventing DDoS attacks [14].

To illustrate and reiterate the importance of network forensics investigations, it is paramount to review several case studies whereby the concept has been adequately implemented. Particularly, Kurniawan and Riadi [15] managed to explore and device a unique framework upon which it was made possible to utilize the concept of network forensics to analyze and identify the behavior of the notorious Cerber Ransomware. The approach is aimed explicitly at establishing an attempt to reconstruct the timestamp of an attack [15]. Focus is placed on the need to exact malware deemed to have infected a particular network host. The eventual results indicate that analysis of network forensics behavior can identify patterns of infections, exploits channels, and the ultimate payload associated with the Cerber Ransomware.

1) Network Security Forensic Mechanisms: A firewall within a network environment provides a network forensic investigator with a perfect opportunity to conduct a comprehensive analysis of all the previous network intrusion attempts. As noted by Messier, the majority of firewall systems are equipped with the ability to either implement the software capability in UNIX or Windows [16]. Consequently, a forensic network investigator can either analyze Syslog or Event Logs files to identify and analyze the nature of intrusion activities within and targeted towards a network. An analysis of firewall logs is also essential. It greatly assists in identifying the existing security vulnerabilities and eventually enables the security administrator to develop essential security enhancements.

Bensefia and Ghoualmi reiterate the importance of having a unique branch of network forensics primarily dedicated to analyzing firewall logs [17]. Firewall forensics is a dedicated effort aimed at analyzing firewall logs with the specific objective of gaining useful insights regarding the nature of attacks identified and blocked by the network firewall. While the contents of a firewall log file might be difficult to decode, it is noteworthy to provide essential information that will eventually help a cyber-forensics investigator apprehend a suspected cybercrime offender.

2) Honeypot Forensics: A honeypot is a specialized part of a computer or network system that is designed is such a way that it appears and seems to have critical and sensitive information. At the same time, in a real sense, it is mainly isolated from the main network. An elaborate illustration of how a honeypot device(s) is placed in a network is indicated in Fig. 1. It is worth noting that most of Honeypot's services are secret though it is difficult to assert their suspicious nature [18]. Honeypots are considered to be essential components that help to enhance the security of an organization [19]. Having a honey port within a network makes it possible for a forensic investigator to conduct a comprehensive analysis of all the possible network-related activities and logs carried throughout the honeypot device. Additionally, network forensic investigators are in a good position to perform a comparative analysis of the data obtained from the Honeypot with similar data extracted from other network devices. A network forensic investigator must perform a comprehensive analysis of the existing honeypots in a network whereby the interaction level can be categorized as low, medium, or high level.

Network forensics is restricted to the analysis of firewalls and honeypots systems, but instead, it is widely applicable among most popular network devices. IDS and IPS are perhaps some of the most common types of devices and systems that are commonly targeted by a network forensic investigator to obtain essential cyber forensic evidence that will culminate with the apprehension of a cyber-forensic offender [19]. Routers and switches also provide essential value in that it is possible to obtain essential intrusion information from MAC address tables, ports, and routing tables, among others. Web proxies, as well as, special types of servers such as DCHP, name, and application servers also provide a network forensic investigator with rich information aimed at obtaining crucial cyber forensics evidence [19].

III. Network Forensics

Network forensics is a scientific method used to discover and retrieve information with evidential value and is used to solve a cyber-crime or apprehend a cyber-criminal. The evidence is retrieved from network and computing devices such as hard disks, routers, switches, memory devices, wireless devices, and mobile devices. Table I provides additional information related to possible viewpoints based on potential areas where the forensic investigation could be performed. Network forensics differs from intrusion detection in that the gathered evidence should be admissible in a court of law and thus should satisfy both legal and technical requirements [20]. Consequently, for forensic evidence to be accepted in a court of law, it must be authentic, relevant, complete, reliable, and believable. It is also noteworthy that the tools and techniques used to perform network forensics should also meet a court of law's legal and technical requirements.

While intrusion detection helps strengthen and improve a computer network's security, network forensics is primarily associated with the need to identify the evidence related to a security breach. In most cases, network forensics helps to solve matters related to cyber-terrorism, child pornography, narcotics, homeland security, online fraud, and corporate espionage, among others [21]. Public police mostly use the evidence obtained from network forensics and private investigators working for individuals, businesses, law enforcement agencies, and even the military [20]. It is also essential to note that business organizations and the military might also use network forensics to ensure continuity and availability of core services. In this context, network forensics help to identify vulnerabilities in corporate networks that make it convenient to implement the necessary security enhancements.

The context of the discussion offered in the paper is to explore the investigative purposes of network forensics. The investigation process starts with identifying a malicious activity upon which the evidence is then collected and preserved. The forensic activity proceeds to examine and analyze the evidence to establish the source and the nature of the malicious activity. Finally, the evidence is reported and presented to the relevant stakeholders and eventually used to make the required decision. All the essential processes involved in network forensic investigation are strategically executed using OSCAR principles that are explained in the next section.

IV. Network Forensics Methodology (OSCAR)

To ensure that forensic evidence is both accurate and reproducible, the OSCAR methodology of Network Forensics Investigation is applied. OSCAR [22] is an acronym that stats for,

- O for Obtaining Information
- S for Strategizing
- C for Collecting Evidence
- A for Analyzing Evidence
- R for Reporting

Fig. 2 illustrates the flow chart model for the OSCAR methodology.

A. Obtaining Information

This stage is associated with obtaining information regarding the incident itself and the environment in which the event took place. It is essential to collect as much information about an event to know exactly what took place. Usually, it is advisable to collect information on the description of the incident, time, date, and how it was discovered [15]. Other entities related to the event include the systems, persons, and devices involved and the summary of actions taken after the incidence discovery. It is also essential to note details about the review of discussions made, any legal issues, and the identity of the incident manager. The environment helps the forensic investigator have a good understanding of the organization's response towards an incident and the stakeholders who should be involved in the investigation process [23]. It is thus vital to collect as much information related to the organization as

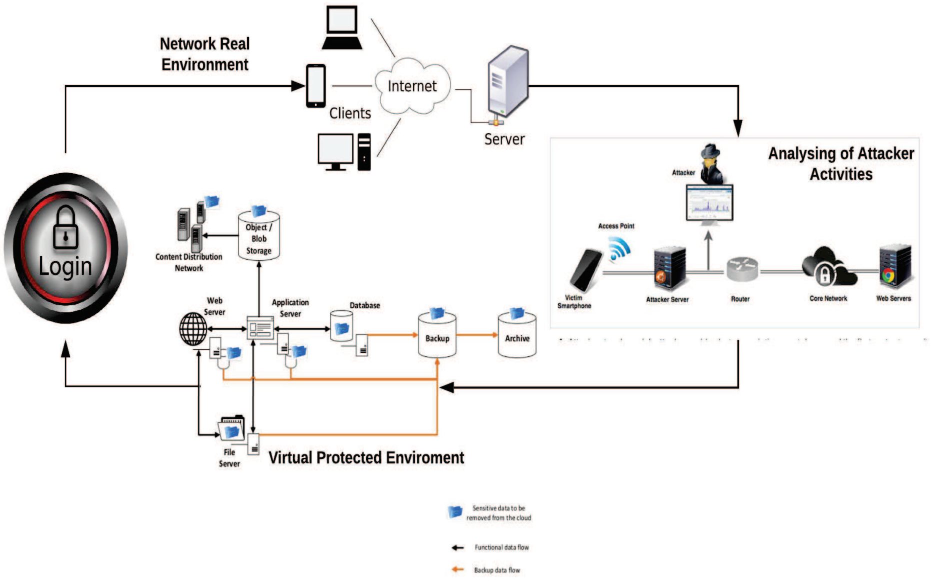

Fig. 1. Logical Placement of a Honeypot within a Network.

TABLE I. Presents Additional Information Related to Possible Viewpoints based on Possible Areas where Forensic Investigation Could be Performed

View Point	Nature of Forensics
Application	Internet browser, email, register files, application software, virus, worm, Trojans, and files (slack, erased, and swap)
System	UNIX, Windows, log system, and audit system
Hardware	PC, PDA, printer, router, switches, firewall, and IDS
Processing	Victim's, intermediate's, and attacker's side

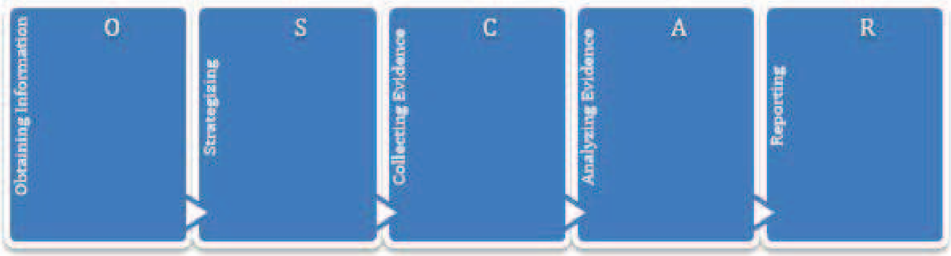

Fig. 2. Network Forensics Investigation Methodology (OSCAR).

possible. Relevant information includes the business model, any legal issues, available resources, communication systems, network topologies, and the procedures and processes used for incidence response management.

B. Strategy

Strategy requires the formulation of a detailed plan on how to carry out the investigation. Strategizing also details how evidence will be acquired [15]. This should be done using various criteria, mainly because pieces of evidence from different sources have varying levels of volatility. As indicated in Table II, the acquisition of proof should be based on several parameters such as source, the effort required, volatility, and the expected value. Evidence prioritization is vital because it helps the forensic to establish the priority of assigning personnel and resources required in network forensics. An important aspect worth noting is that each organization has different policies associated with data retention, access, and configurations [22]. Consequently, the evidence prioritization should be based on specific organizational policies. When formulating an evidence acquisition strategy, it is paramount to consider the following tips.

- Understand the goal of investigation and time frame
- List of your recourses
- Prioritize your evidence acquisition
- Estimate the value and cost of obtaining evidence
- Identify sources of evidence
- Plan to initial analysis
- Keep in mind that network forensics is a process that can be performed reiteratively

C. Collecting Evidence

The strategizing step requires the formulation of an acquisition plan and prioritization of evidence sources. Evidence used in network forensics can be obtained either from the end or intermediate devices [22]. In the former, the evidence can be gathered from the attacker's or the victim's devices, while in the latter, evidence can be obtained from third-party devices and networks. A summary of the probable sources of evidence is provided in Table III.

The next step is to collect evidence from the identified sources using the established priority. Consequently, three vital components must be considered, notably documentation capture, and store or transport.

Documentation: This means that all actions, including a list of all systems, files, and resources, should be carefully logged. It is also essential to maintain self-descriptive notes that make it easy to identify the collected evidence. The descriptive content should contain the date, time source, investigating officer, and the method used to acquire the evidence. Ensure that all devices accessed and all actions were taken during the gathering of evidence are kept to a careful log. Your notes must be kept appropriately and can be cited in court. If the case is not going to court, the notes will also be very helpful during the review. Make sure to document the date, time, source, acquisition process, investigator name(s), and custody chain.

Capturing: evidence involves ensuring that the data or network traffic packets, as well as logs, are written to a hard, CD, or removable hard drive. Network forensics tools such as Wireshark and tcpdump are used to capture data packets [15].

Store/Transport: implies that the evidence should be stored in a secure place to maintain the chain of custody. It is essential to keep updated and signed log containing the details of all the parties who have obtained access to the evidence. Care should also be exerted when handling and disposing of evidence to maintain its integrity, reliability, and admissibility before a court of law.

TABLE II. PRESENTS EXAMPLE OF PRIORITIZATION OF EVIDENCE THAT LIST POSSIBLE SOURCES OF PROOF IN THE CASES, THE PROBABLE VALUE, LIKELY EFFORT OF OBTAINING AND THE EXPECTED VOLATILITY. FOR EVERY INVESTIGATION THESE PRINCIPLES WERE SELECT DISTINCT

Source of Evidence	Likely value	Effort	Volatility	Priority
Web Proxy Cache	High	Low	Medium	1
Firewall logs	High	Medium	Low	2
ARP tables	Low	Low	High	3

In summary, the following tips are crucial during the process of evidence collection.

- Obtaining evidence as soon as possible.
- Make verifiable steganography copies of collected evidence.
- Use reliable and reputable tools
- Document everything, which helps you later.
- Keep secure your notes and hide the original under restricted custody and access.

D. Analyze

The strategizing step requires the formulation of an acquisition plan and prioritization of evidence sources. Evidence used in network forensics can be obtained either from the end or intermediate devices [22]. In the former, the evidence can be gathered from the attacker's or the victim's devices, while in the latter, evidence can be obtained from third-party devices and networks. A summary of the probable sources of evidence is provided in Table III.

The next step is to collect evidence from the identified sources using the established priority. Consequently, three vital components must be considered, notably documentation capture, and store or transport.

Documentation: This means that all actions, including a list of all systems, files, and resources, should be carefully logged. It is also essential to maintain self-descriptive notes that make it easy to identify the collected evidence. The descriptive content should contain the date, time source, investigating officer, and the method used to acquire the evidence. Ensure that all devices accessed and all actions were taken during the gathering of evidence are kept to a careful log. Your notes must be kept appropriately and can be cited in court. If the case is not going to court, the notes will also be very helpful during the review. Make sure to document the date, time, source, acquisition process, investigator name(s), and custody chain.

Capturing: evidence involves ensuring that the data or network traffic packets, as well as logs, are written to a hard, CD, or removable hard drive. Network forensics tools such as Wireshark and tcpdump are used to capture data packets [15].

Store/Transport: implies that the evidence should be stored in a secure place to maintain the chain of custody. It is essential to keep an updated and signed log containing the details of all the parties who have obtained access to the evidence. Care should also be exerted when handling and disposing of evidence to maintain its integrity, reliability, and admissibility before a court of law.

In summary, the following tips are crucial during the process of evidence collection.

E. Report

This is perhaps the most crucial aspect of forensic investigation primarily because it helps to convey the results to the concerned parties. Thus, it is vital to present the report in a manner that can be understood by a lay and non-technical

TABLE III. Provides Evidence used in Network Forensics that can be Obtained Either from the End or Intermediate Devices

Affiliation	Source
End side (attacker and/or victim side)	Operation system audit trail, system event log, application event log, alert log, recovered data, and swap files
Intermediate	Traffic data packets, firewall log, IDS log, router log, and access control log

TABLE IV. Tools & Devices Use for Various Testing Applications

Device/Tool	Usage	Software/OS Version	Company/Developed
Mac-Book Air	Create a test network, host proxies	macOS Siera (10.12.6)	Apple
iPad	Test device connected to test network	iOS 11.2.6	Apple
Charles Proxy	Capture/save live network traffic	4.2.5	Karl von Randow
Wireshark	Capture/save live network trafficv	2.6.0	Wireshark
Burp Suite	Capture live network traffic	1.7.33	PortSwigger Security
Windows Laptop	Network forensics of iOS apps	Windows 10	Windows
NetworkMiner	Analyze network traffic	2.3.1	NETRESEC Erik Hjelmvik

audience. Additionally, the report should be not only factual but also contains defensible details. The report's technical information and results should be explained thoroughly to aid in the decision-making process.

V. Network Forensic Tools

Network forensic tools help in network investigation to gather essential information about an intrusion activity. These tools are used to analyze network traffic to identify the nature and type of activities within the network over a specific duration [45]. The forensic tools are designed so that they are compatible with network hardware devices such as firewalls, thereby making it possible to collect and preserve network traffic.

Additionally, these tools are equipped with the ability to perform a quick analysis of network traffic. Network forensics tools can be categorized based on either host-based or network-wide-based. Additional categories include general-purpose tools, specific tasks tools, or libraries/framework tools [46]. A review of the most frequently used network forensic tools is summarized in Table IV. The following subsections discuss them comprehensively.

A. Wireshark

Wireshark is an open-source graphical user interface application software tool designed to capture, filter, and analyze network traffic. It is easy to use, and thus it is helpful in the analysis of network forensics data. Wireshark has more packet filtering capabilities, decoding protocol features, and packets detail markup language (PDML). In Wireshark, it is possible to view network packets as they are captured in real-time. Wireshark also shows the results of lost pockets due to CPU power [47]. Wireshark can be used as several instruments in one Anwendung. Program. You will use it to evaluate the structure of Network traffic checking for potential security flaws And assaults on health. This can detect other types of Encapsulation, isolation, and show of all fields in the Packet network. You have all those powerful capabilities. Do you think Wireshark's hard to know? For specific instances, Respect it, but you can quickly learn how to use it, the filters with the app, and how to use them Packets unique to the network. Filters in WireShark refer to Berkeley Packet Filters. That is simply a language for microprogramming Compiled against packets and executed at run time Taken off by software like tcpdump and Wireshark. Primarily, filters are used to separate a Quite small parcel set among a large number of Packets focused on search criteria. The filter is compiled to run as best Quality, significant when you are doing a quality Real-time grab. Filtering is for others WireShark's most essential features since it makes Achieving two purposes: selectively collecting the packets From the network, and to locate interested parties Packages [47][48] [49].

B. Tshark

Tshrak is a command-line tool used for data network protocol analysis. It helps to capture traffic from a live data network and read traffic information from saved packet data files. It can also print a decoded form of network packets to a quality output or writes the packet to a pcap file. For instance, tshark can capture data traffic on the network interface "eth1" filtering out all traffic from port 22 and sorting the results in the file "test1.pcap. # tshark I eth1 w test1.pcap" not port 22. Capture on eth1 235. Tshark is a packet capture application that can potent-sensing and explain pcap scrutiny functionality. It captures packet-data from an alive network or inspects packets from an earlier trapped file and decodes those packets' form into the standard output file. The default capture file format built into TShark is pcap. Weka consists of data pre-processing, classification, regression, clustering, correlation and visualization methods that are well-suited to the creation of new schemes [22] [50] [51].

C. Dumpcap

The dumpcap is a network traffic analysis tool, which is designed to capture data packets. It is a Wireshark distribution tool, which comes in command-line. The tool captures traffic from a live network and is equipped to write the output in a pcapng file format. Dumpcap has the added advantage of using fewer system resources, making it possible to boost the capture capabilities. Table V provides a summative analysis of popular tools used for network forensics [47].

D. Network Forensic Analysis Tools (NFATs)

Network Forensic Analysis Tools (aka NFATs) allow network investigators and system administrators to track networks and gather any anomalous or malicious traffic information. Such tools synergize with network infrastructure and network

TABLE V. MOST COMMONLY USED TOOLS TO SUPPORT VARIETY OF NETWORK FORENSIC INVESTIGATIONS

Tools	Open Sourece/ Proprietary software	Plateform	Website	Attributes

appliances, such as firewalls and IDS, to make it possible to maintain long-term network traffic records. NFATs allow for rapid analyzes of patterns detected by network security tools.

VI. SYSTEM TYPES ARE USED TO GATHER DATA / TRAFFIC FROM THE NETWORK

Two types of Network traffic collecting data systems can be “stop, look and listen” or “catch-it-as-you-can.”

“Catch-it-as-you-can”: All packets are sent to the database through a traffic point where they are stored in. The analysis is then conducted on stored data. Data from the analysis is also stored in the database. The data saved can be preserved for future review. Nevertheless, it should be noted that this type of device demands a considerable storage capacity.

The “stop, look and listen” method is different from the “catch-it-as-you-can” approach because only data is stored in the database needed for analysis. The incoming traffic in memory is filtered and processed in real-time, meaning this device needs less storage and a much faster processor.

Since the two systems need ample storage space, it is necessary to weigh and address privacy issues with the “catch-it-as-you-can” system. This program also collects user data; however, ISPs are prohibited from receiving or revealing information without user permission.

VII. CHALLENGES RELATING TO NETWORK EVIDENCE

Network-based evidence faces specific challenges in many fields, including collection, storage, content, privacy, confiscation, and admissibility. Below we’ll cover some of the significant issues Below.

Collection : Within a network environment, clear proof can be hard to locate. Networks include as many bits of data as possible; from wireless devices to web proxies to big log servers; which often makes it difficult to determine the proof’s correct position. Even if you know where a specific piece of evidence exists, it can be difficult for political or technological purposes to access it.

Storage: Commonly, the network of computers can not use permanent or secondary data. As a result, the data they hold can be so fragile they won’t survive a computer reset.

Content: Unlike files, management to contain all file contents and their metadata, network devices with the desired degree of granularity may or may not store information. Network computers also have minimal storage capacity, instead of full data records that have crossed the network, only selected transaction or data transfer metadata are typically retained.

Privacy: Legal problems related to personal privacy occur unique to computer network-based retrieval techniques, depending on the jurisdiction.

Sezure: Seizing a hard disk may disturb a person or an organization. Nonetheless, it is also possible to design and implement a replica of the original, so that critical operations can continue with minimal disruption. Seizing a networked device can be even more damaging. A whole part of the network can be downgraded indefinitely for more extreme situations. Investigators can, however, minimize the impact on computer network operations in such circumstances.

Admissibility: For criminal and civil cases, evidence-based on file systems is now widely acknowledged. So long as the evidence stored on the file system is legitimate collected, adequately interpreted, and relevant to the case, there are clear precedents for the processing and presenting the evidence in court. In comparison, network forensics is a modern approach to automated investigations. There are often contradictory or even non-existent legal precedents for accepting different kinds of facts based on the digital network. With time, digital network-based testimony becomes more prevalent, setting precedents for the case and standardizing them.

VIII. Conclusion

Network forensic investigation is an essential process that helps a cyber-forensics investigator to obtain, analyze, evaluate, categorize, and identify crucial evidence. It ultimately makes it possible to apprehend a cyber-criminal or any person suspected of committing a cyber-criminal offense. Consequently, it is paramount for a network forensic investigator to consider adopting and utilizing an efficient and robust forensic network investigation methodologies that ultimately help improve the investigation process. As intimated in this research, the OSCAR methodology provides a forensic investigator with essential tools and guidelines that determines the approach, methods, and strategies used to obtain, strategize, collect, analyze, and report the findings of a network forensics investigations. It is also paramount for the network forensic investigation process to follow and be executed using essential tools such as Wireshark, tshark, Burpe Suite, and tcpdump that tends to help in simplifying and improving the forensics investigation process. Future work: To developed a tool-kits that parse various network protocols commonly used in various sorts of different networks are required. And, because most data in networks is volatile, it may be necessary to preserve or document it selectively in advance to speed up the forensic process.

***Abstract*—With the rapid development of remote sensing technology, our ability to obtain remote sensing data has been improved to an unprecedented level. We have entered an era of big data. Remote sensing data clear showing the characteristics of Big Data such as hyper spectral, high spatial resolution, and high time resolution, thus, resulting in a significant increase in the volume, variety, velocity and veracity of data. This paper proposes a feature supporting, salable, and efficient data cube for time-series analysis application, and used the spatial feature data and remote sensing data for comparative study of the water cover and vegetation change.The spatial-feature remote sensing data cube (SRSDC) is described in this paper. It is a data cube whose goal is to provide a spatial-feature-supported, efficient, and scalable multidimensional data analysis system to handle large-scale RS data. It provides a high-level architectural overview of the SRSDC.The SRSDC offers spatial feature repositories for storing and managing vector feature data, as well as feature translation for converting spatial feature information to query operations.The paper describes the design and implementation of a feature data cube and distributed execution engine in the SRSDC. It uses the long time-series remote sensing production process and analysis as examples to evaluate the performance of a feature data cube and distributed execution engine. Big data has become a strategic highland in the knowledge economy as a new strategic resource for humans. The core knowledge discovery methods include supervised learning methods data analysis supervised learning, unsupervised learning methods data analysis unsupervised learning, and their combinations and variants.**

I. Introduction

In recent decades, the remarkable developments in Earth observing(EO) technology provided a significant amount of remote sensing(RS) data openly available [1]. This large observation dataset characterized the information about the earth surface in space, time, and spectral dimensions [2][3]. Apart form these dimensions, these data also contain many geographic features, such as forests, cities, lakes and so on, and these features could help researchers to locate their interested study areas rapidly. Now these multidimensional RS data with features have been widely used for global change detection research such as monitoring deforestation [4] and detecting temporal changes in floods [35]. However, the conventional geographic information system (GIS) tools are inconvenient for scientists to process the multidimensional RS data, because they lack appropriate methods to express multidimensional data models for analysis. And researchers have to do additional data organization work to conduct change detection analysis. For a more convenient analysis, they need a multidimensional data model which could support seamless analysis in space, time, spectral and feature [5].

Recently, many researchers have proposed using a multidimensional array model to organize the RS raster data [6][7]. Subsequently, they achieved the spatio-temporal aggregations capacity used in spatial on-line analytical processing (SOLAP) systems [8][9], as a data cube. Using this model, researchers can conveniently extract the desired data from the large dataset for analysis, and it reduces the burdens of data preparation for researchers in time-series analysis. However, in addition to extracting data with simple three-dimensional (3D) space-time coordinates, researchers occasionally need to extract data with some geographic features [10][11][12], which are often used to locate or mark the target regions of interest. For example, flood monitoring often needs to process multidimensional RS data which have the characteristics of large covered range, long time series and multi bands [13]. If we built all the analysis data as a whole data cube which has the lakes or river features, we could rapidly find the target study area we need by feature and analyse the multi bands image data to detect the flood situation with the time series. That makes researchers focus on their analysis work without being troubled by the data organization. This study aims to develop the spatial-feature remote sensing data cube(SRSDC), a data cube whose goal is to deliver a spatial feature-supported, efficient, and scalable multidimensional data analysis system to handle the large-scale RS data. The SRSDC provides spatial feature repositories to store and manage the vector feature data, and a feature translation to transform the spatial feature information to a query operation. To support large-scale data analysis, the SRSDC provides a work-scheduler architecture to process the sliced multidimensional arrays with dask [14].

The remainder of this paper is organized as follows. Section 2 describes some preliminaries and related works. Section 3 presents an architectural overview of the SRSDC. Section 4 presents the design and implementation of a feature data cube and distributed execution engine in the SRSDC. Section 5 uses the long time-series remote sensing production process and analysis as examples to evaluate the performance of a feature data cube and distributed execution engine. Section 6 concludes this paper and describes the future work prospects.

II. Preliminaries and Related Work

A. Knowledge Discovery Categories

In the following, we discuss four broad categories of applications in geosciences where knowledge discovery methods have been widely used and have aroused impressive attention. For each application, a brief description of the problem from a knowledge discovery perspective is presented.

Detecting objects and events in geoscience data is important for a number of reasons. For example, detecting spatial and temporal patterns in climate data can help in tracking the formation and movement of objects such as cyclones, weather fronts, and atmosphere rivers, which are responsible for the transfer of precipitation, energy, and nutrients in the atmosphere and ocean. Many novel pattern mining approaches have been developed to analyze the spatial and temporal properties of objects and events, e.g., spatial coherence and temporal persistence that can work with amorphous boundaries. One such approach has been successfully used for finding spatio-temporal patterns in sea surface height data, resulting in the creation of a global catalogue of Mesoscale Ocean eddies. The use of topic models has been explored for finding extreme events from climate time series data. Given the growing success of deep learning methods in mainstream machine learning applications, it is promising to develop and apply deep learning methods for a number of problems encountered in geosciences. Recently, deep learning methods, including convolutional neural networks (CNNs) and recurrent neural networks (RNNs) have been used to detect geoscience objects and events, such as detecting extreme weather events from a climate model.

Knowledge discovery methods can contribute to estimating physical variables that are difficult to monitor directly, e.g., methane concentrations in air or groundwater seepage in soil, using information about other observed or simulated variables. To address the combined effects of heterogeneity and small sample size, multi-task learning frameworks have been explored, where the learning of a model at every homogeneous partition of the data is considered as a separate task, and the models are shared across similar tasks.

The sharing of learning is able to help in regularizing the models across all tasks and avoid the problem of over fitting. Focusing on the heterogeneity of climate data, online learning algorithms have been developed to combine the ensemble outputs of expert predictors and conduct robust estimates of climate variables such as temperature. To address the paucity of labeled data, novel learning frameworks such as semi-supervised learning, active learning, have huge potential to improving the state-of-the-art in estimation problems encountered in geoscience applications. Forecasting long-term trends of geoscience variables such as temperature and greenhouse gas concentrations ahead of time can help in modeling future scenarios and devising early resource planning and adaptation policies. Some of the existing approaches in knowledge discovery for time-series forecasting include exponential smoothing techniques, the auto regressive integrated moving average model and probabilistic models, such as hidden Markov models and Kalman filters. In addition, RNN-based frameworks such as long-short-term-memory (LSTM) have been used for long-term forecasting geoscience variables.

An important problem in geoscience application is to understand the relationships in geoscience data, such as periodic changes in the sea surface temperature over the eastern Pacific Ocean and their impact on several terrestrial events such as floods, droughts and forest fires. One of the first knowledge discovery methods in discovering relationships from climate data is a seminal work, where graph-based representations of global climate data were constructed. In the work, each node represents a location on the Earth and an edge represents the similarity between the eliminated time series observed at a pair of locations. The high-order relationships could been discovered from the climate graphs. Another kind of method for mining relationships in climate science is based on representing climate graphs as complex networks, including approaches for examining the structure of the climate system, studying hurricane activity. Recently, some works have developed novel approaches to directly discover the relationships as well as integrating objects in geoscience data. For example, one work has been implemented to discover previously unknown climate phenomena. For causality analysis, the most common tool in the geosciences is bivariate Grange analysis, followed by multi-variate Granger analysis using vector auto regression (VAR) models.

B. Knowledge Discovery Methods

As a new strategic resource for human beings, big data has become a strategic highland in the era of knowledge economy. It is a typical representative of the data-intensive scientific paradigm following experience, theory and computational models, since this new paradigm mainly depends on data correlation to discover knowledge, rather than traditional causality. It is bringing about changes in scientific methodology, and will become a new engine for scientific discovery.

Knowledge discovery of remote sensing big data lies at the intersection of earth science, computer science, and statistics, and is a very important part of artificial intelligence and data science. Its aims at dealing with the problem of finding a predictive function or valuable data structure entirely based on data and will not be bothered by the various data types and, is suitable for comprehensively analyzing the Earth's big data.

The core knowledge discovery methods include supervised learning methods, unsupervised learning methods, and their combinations and variants. The most widely used supervised learning methods use the training data taking the form of a collection of (x, y) pairs, and aims to produce a prediction y' in response to a new input x' by a learned mapping f(x), which produces an output y for each input x (or a probability distribution over y given x). There are different supervised learning methods based on different mapping functions, such as decision forests, logistic regression, support vector machines, neural networks, kernel machines, and Bayesian classifiers. In recent years, deep networks have received extensive attention in supervised learning. Deep networks are composed of multiple processing layers to learn representations of data with multiple levels of abstraction, and discover intricate structures of the big earth data by learning its internal parameters to compute the representation in each layer. Deep networks have brought about breakthroughs in processing satellite image data, forecasting long-term trends of geoscience.

Unlike supervised learning methods, unsupervised learning involves the analysis of unlabeled data under assumptions about structural properties of the data. For example, the dimension reduction methods make some specific assumptions that the earth data lie on a low-dimensional manifold and aim to identify that manifold explicitly from data, such as principal components analysis, manifold learning, and auto encoders. Clustering is another very typical unsupervised learning algorithm, which aims to find a partition of the observed data, and mine the inherent aggregation and regularity of data. In recent years, much current research involves blends across supervised learning methods and unsupervised learning. Semi supervised learning is a very typical one, which makes use of unlabeled data to augment labeled data in a supervised learning context considering the difficulty of obtaining some geoscience supervision data. Overall, knowledge discovery of the big earth data needs to leverage the development of artificial intelligence, machine learning, statistical theory, and data science.

C. Related Work

With the growing numbers of archived RS images for Earth observation, an increasing number of scientists are interested in the spatiotemporal analysis of RS data. Many researchers proposed combining online analytical processing (OLAP) [15] technology with the GIS [16] to build a data cube. They built the multidimensional database paradigm to manage several dimension tables, periodically extracting the dimension information from the data in GIS, and achieved the ability to explore spatiotemporal data using the OLAP spacetime dimension aggregation operation. Sonia Rivest et al. deployed a spatial data warehouse based on GIS and spatial database to acquire, visualize, and analyze the multidimensional RS data [17]. Matthew Scotch et al. developed the SOVAT tool [18], using OLAP and GIS to perform the public health theme analysis with the data composed of spatiotemporal dimensions. These tools can facilitate researchers extracting data with spatiotemporal dimensions; however, their multidimensional data model is unsuitable for complicated scientific computing. Further, they did not adopt an appropriate architecture for large data processing [19][20]. Therefore, their ability to handle large-scale data is limited.

Owing to natural raster data structure of Earth observation images, the time-series imagery set can be easily transformed to multidimensional array. For example, a 3D array can represent the data with spatiotemporal dimensions. This data type is suitable for parallel processes, because a large array can be easily partitioned into several chunks for distributed storing and processing. In addition, the multidimensional array model enables a spatiotemporal auto-correlated data analysis; therefore, researchers need not be concerned about the organization of discrete image files. Thus, much research is focused on developing new analysis tools to process the large RS data based on the multidimensional array model; e.g., Gamara et al.[21] tested the performance of spatiotemporal analysis algorithms on array database architectures - SCIDB [22], which described the efficiency of spatiotemporal analysis based on the multidimensional array model, Assis et al.[23] built a parallel RS data analysis system based on the MapReduce framework of Hadoop [24], describing the 3D array with key/value pairs. Although these tools have significantly improved the computation performance of RS data analysis, they also contain some deficiencies. First, many of them focused only on analyzing the RS raster image data located by geographic coordinates, and did not provide the support of spatial feature, thereby limiting their ability to use these geographic objects in the analysis application. Next, some of these tools require analysers to fit their algorithms into specialised environments, such as Hadoop MapReduce framework [25]. This will be user unfriendly to researchers who only desire to focus on their analysis application.

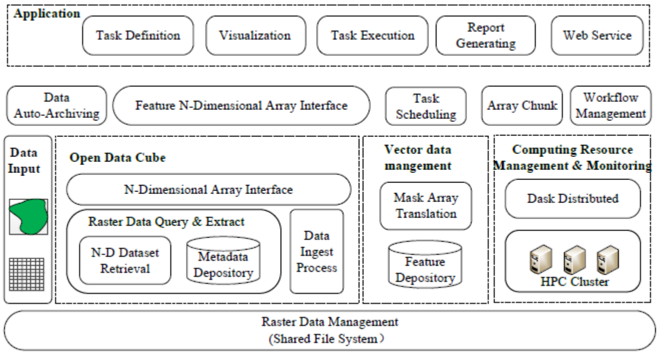

Fig. 1. The Architecture of the SRSDC.

III. Architecture Overview

A. Target Data and Environment

The SRSDC system is designed for providing the services of large RS data time-series analysis with spatial features, and it aims to manage and process the large-scale spatial feature data and satellite images seamlessly. Based on the open data cube (ODC) [26], which is a popular data cube system used for spatial raster data management and analysis, we archived large amounts of satellite data within China. These data came from different satellites including Landsat, MODIS, GaoFen(GF) and HuanJing(HJ). In addition, the SRSDC also contains many features data within China, such as lakes, forests and cities. These spatial vector data were downloaded from the official web site of OpenStreetMap [27]. Before obtaining these satellite images in the SRSDC, the geometric correction and radiometric correction for these images must be ensured. This can ensure the comparability between the images in different time, space and measurements; subsequently, the global subdivision grid can be used to partition the data into many tiles(grid files). These tiles were stored as the NetCDF format [28], which supports many analysis libraries and scientific toolkits.

B. FRSDC Architecture Overview

The SRSDC system adopted the relational database and file system to manage the spatial data. It is designed to be scalable and efficient and provide feature support for time-series analysis. Compared with the ODC system [29], which only supports spatial raster data management and analysis as a data cube, the SRSDC supports the extraction of target satellite data as a multidimensional array with the geographic object. It could perform the spatial query operation with geographic objects, instead of locating data with only geographic coordinates. Therefore, the dataset built for analysis has geographic meaning. Thus, if researchers desire to obtain the target dataset, they only need to query data with the geographic meaning of the analysis themes, without knowing specific geographic coordinates. As shown in Fig. 1, the system is primarily composed of the data management and distributed execution engine (DEE). Data management consists of two parts, raster data management and vector data management. For the raster data, the SRSDC will archive it into a shared network file system and extract its metadata information automatically; these metadata will be stored into the metadata depository managed by ODC. For the vector data, the SRSDC stores them as geographic objects in the spatial database. After the data management, an N-Dimensional array interface is responsible for transforming the raster data and vector data to an N-Dimensional array that has the spatial feature information. Xarray [28] is used for array handing and computing. DEE is responsible for providing the computing environment and resources on high performance computing(HPC) clusters. The SRSDC use dask [24], which is a parallel computation library with blocked algorithms, for the task scheduling, distributed computing, and resource monitoring. It could help researchers to execute the analysis tasks in parallel.

IV. Design and Implementation

A. Feature Data Cube

1) Spatial feature object in FRSDC: Spatial feature is a geographic object that has special geographic meaning. It is often important for RS application, because researchers occasionally need to process the RS image dataset with geographic objects, such as the classification of an RS image with spatial features [30][31][32]. However, many RS data cube systems only provide the multidimensional dataset without features. Hence, researchers are required to perform additional work to prepare the data for analysis. For example, the ODC system [24] and the data cube based on SCIDB [22] could only query and locate the study area by simple geographic coordinates, so researchers must transform their interested spatial features to coordinate ranges one by one if they want to prepare the analysis ready data. To solve this problem, the SRSDC combined the basic N-Dimensional array with geographic objects to provide the feature N-Dimensional array for researchers, and researchers could easily organise the analysis ready N-Dimensional dataset by their interested features. Within the SRSDC, now we primarily archive the forest and lake features of China, and store them as geographic objects in a PostGIS database [33][34]. The unified modeling language(UML) class diagram in the SRSDC is shown in Fig. 2, and the description of these classes is as follows:

1) The feature class is provided for users to define their spatial feature of interest with a geographic object. It contains the feature type and the geographic object.
2) The feature type class represents the type of geographic object, such as lakes, forests, cities and so on. It contains the description of the feature type and analysis algorithm names that are suitable for the feature type.
3) The geographic object class describes the concrete vector data with geographic meaning, such as Poyang lake (a lake in China). It contains the vector data type to illustrate its geometry type.
4) The raster data type class is used to describe the type of satellite data. It contains the satellite platform, product type, and bands information.
5) The feature operation class is used to extract the feature data-cube dataset from the SRSDC. It contains the feature object, raster data type, and time horizon to build the target feature N-Dimensional array. It also provides some operation functions for users.

2) Data management: As mentioned above, data management consists of raster data management and vector data management. Because of satellite data's large volume and variety, the SRSDC uses the file system to store the raster data and manage the metadata by a relation database that contains NoSQL fields.

In the metadata depository, the SRSDC uses NoSQL fields to describe the metadata information instead of a full relation model. This is because the number of satellite sensors is increasing rapidly, and if the full relation model is used, the database schema must be expanded frequently to meet the new data sources. In contrast, NoSQL fields are more flexible in describing the metadata of satellite data that originate from different data sources. The NoSQL fields contain the time, coordinate, band, data URL, data type, and projection. Among these fields, some are used for data query, such as the time, band, coordinates, and data type. Some other fields are used for loading the data and building the multidimensional array in memory, such as data URL and projection. In addition, comparing the vector data volume (GB level) we download from the OpenStreetMap [26] with the raster data volume (TB level) we archived from several satellite data centers [32], we found that most spatial features that are represented by the vector data are not as large as the raster images; therefore we established a feature depository instead of file system to store and manage them as geographic objects. These objects may contain different geographic meanings, and we defined them as feature types.

The runtime implementation of feature data cube building and processing is shown in Fig. 3. First, the SRSDC receives the user's data request from the web portal and obtains the target geographic object by querying the feature depository. Next, it conducts a feature translation to transform the geographic object into a mask array and obtains the minimum bounding rectangle(MBR) of the feature. Subsequently, with the vertex coordinates of MBR and time horizon, the SRSDC searches for the required raster data's metadata to locate physical URLs of the raster data. Next, ODC's N-Dimensional array interface will load the raster data set from the file system and build a multidimensional array in memory. Subsequently, the mask array will be applied to masking the multidimensional array, and a new multidimensional array with features for analyzing and processing will be obtained. Finally, the SRSDC will

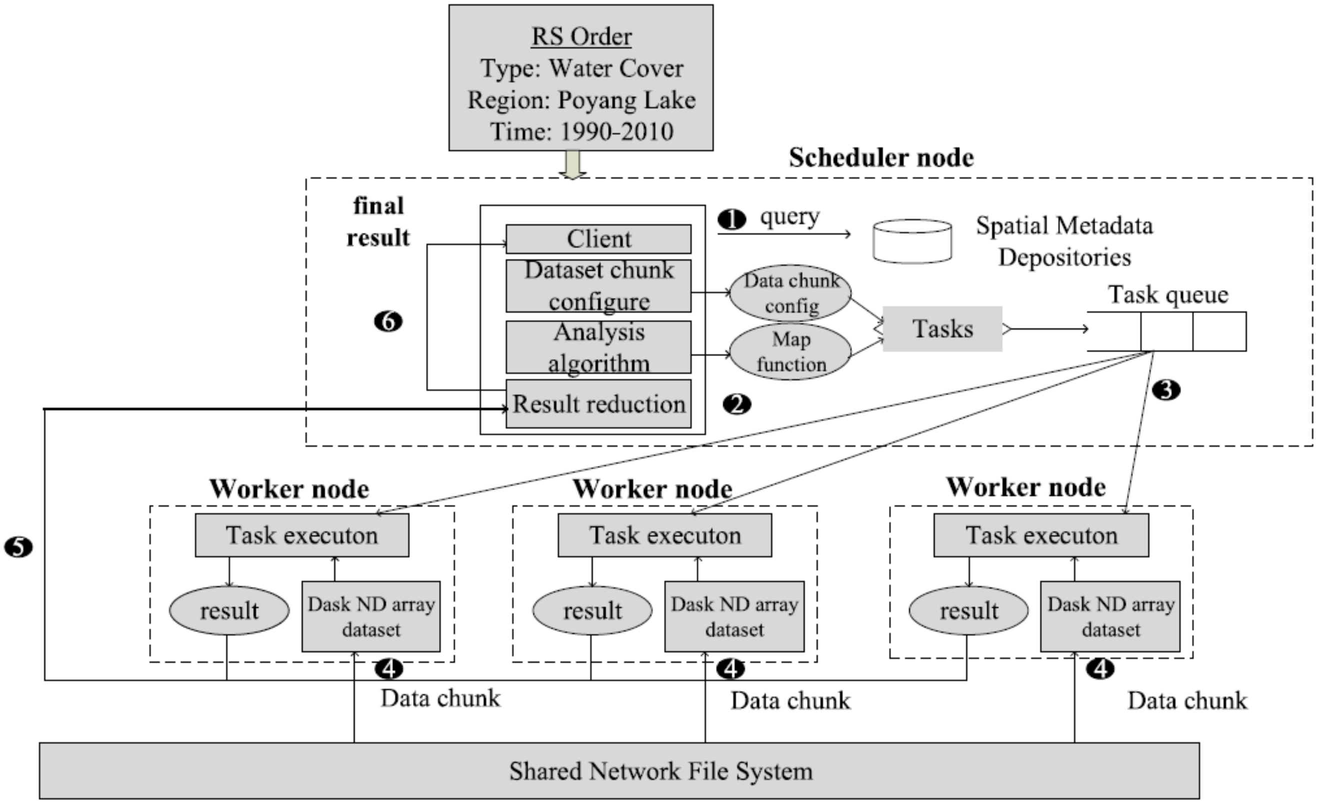

Fig. 2. Large-scale RS Analysis Processing with Distributed Executed Engine.

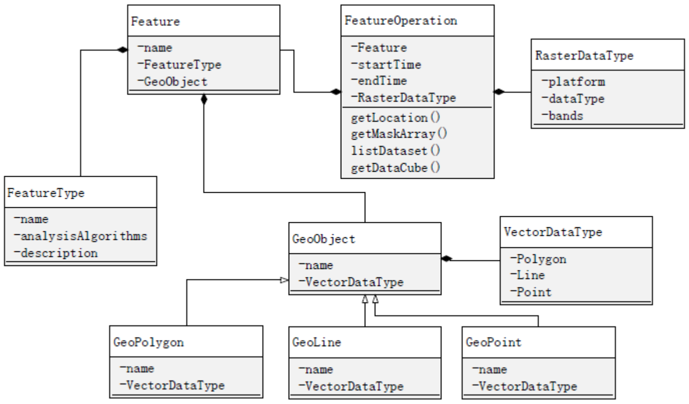

Fig. 3. The UML Class Diagram in the SRSDC.

process the data with the relevant algorithm and return the analysis results to the user.

B. Distributed Executed Engine

As an increasing number of RS applications need to process or analyze the massive volume of RS data collections, the stand-alone mode processing can not satisfy the computation requirement. To process the large-scale RS data efficiently, we built a distributed executed engine using the dask a distributed computing framework focusing on scientific data analysis. Compared with the popular distributed computing tools such as Apache Spark, dask supports the multidimensional data model natively and has a similar API with pandas and numpy. Therefore, it is more suitable for computing an N-Dimensional array. Similar to Spark, dask is also a master-slave system framework that consists of one schedule node and several work nodes. The schedule node is responsible for scheduling the tasks, while the work nodes are responsible for executing tasks. If all the tasks have being performed, these workers' computation results would be reduced to the scheduler and the final result would be obtained.

In the SRSDC, we could index the satellite image scenes by adding their metadata information to the database, and then obtain the data cube dataset (N-Dimensional arrays) from the memory for computing. However, to compute the large global dataset, we should slice the large array into the fixed-size sub-arrays called chunks for computing in the distributed environment. The SRSDC partitions these native images into seamless and massive tiles based on a latitude/longitude grid. The tile size is determined by the resolution of satellite images. For example, in the SRSDC, the Landsat data (each pixel 0.00025°) was partitioned into tiles of size 1°x 1°, and the tiles (4000x4000 pixels array) can be easily organized as a data chunk, which is suitable for the memory in the worker node. By configuring the grid number and time horizon, the chunk could be built. Further, with these data chunks, the SRSDC can transform the big dataset (N-Dimensional arrays) to several sub-arrays loaded by different worker nodes. After all the data chunks have been organized, the scheduler will assign the chunks to the workers and map the functions for

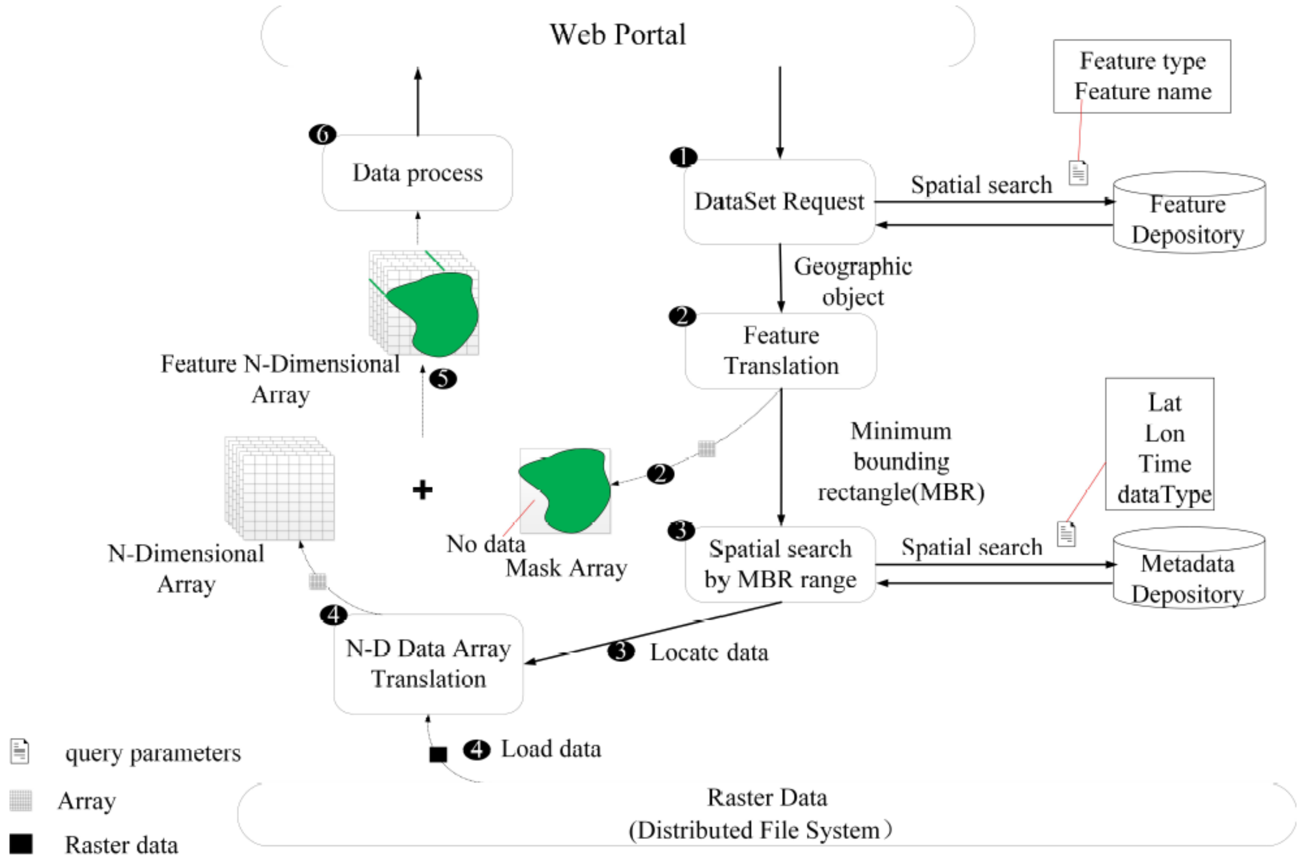

Fig. 4. Runtime Implementation of Feature Data Cube Building.

computing.

As shown in Fig. 4, the processing of large-scale time series analysis by the distributed executed engine is as follows:

1) Organize the data cube dataset by multidimensional spatial query.
2) Configure the appropriate parameters (grid number or time horizon) to organized the data chunks for workers, manage the chunks' ids with a queue.
3) Select the analysis algorithm and data chunks to compose the tasks, and assign these tasks to the worker node.
4) Check the executing state of each task in the workers; if failure occurs, recalculate the result.
5) Reduce all the results to the scheduler and return the analysis result to the client.

V. Experiments

To verify the ability of multidimensional data management and large-scale data analysis in the SRSDC, we conducted the following time-series analysis experiments focusing on spatial feature regions and compared the performance of GEE and stand-alone mode processes on the target dataset.

In this experiment, two RS application algorithms for time-series change detection have been used: NDVI for vegetation change detection and water observation from space (WOfs) for the water change detection. We built the distributed executed engine with four nodes connected by a 20 GB Infiniband network; one node for the scheduler and tree nodes for the workers. Each node was configured with Inter(R) Xeon(R)E5-2460 CPU(2.0GHz) and 32GB memory. The operating system is CentOS 6.5, and the python version is 3.6. To test the performance of the feature data cube, we selected two study regions with the special features as examples. One region for the NDVI is Mulan hunting ground, Hebei Province, China(40.7°-43.1°N, 115.8°-119.1°E), and another region for WOfs is Poyang Lake, Jiangxi Province, China. We built two feature data cube datasets for 20 years(1990-2009) with Landsat L2 data and the geographic objects. The data volume for Mulan hunting ground is approximately 138 GB and the data volume for Poyang Lake is about 96 GB. Figure 5 shows the percentage of observations detected as water for Poyang Lake over the 20-year time series. The red area represents the frequent or permanent water, and the purple area represents the infrequent water. From the result, the shape area of Poyang Lake can be observed clearly. Fig. 6 shows the annual average NDVI production on the Mulan hunting ground; Fig. 7 shows the NDVI time series result of the sampling site(41.5620°N, 117.4520°E) over 20 years. As shown, the values during 2007-2008 were abnormally below the average. This is because the average annual rainfall during this time is lower than that in normal years.

To test the processing performance of the DEE for different amounts of data, we tested time consumed by processing 6.3 GB, 12.8 GB, 49.6 GB, 109.8 GB, 138.6GB input data for NDVI production. These data have been partitioned into 4000x4000 pixels tiles mentioned above, with which we compared the performances of the stand-alone model and DEE models:

1) stand-alone model: organize the dataset as data chunks, and process these data chunks serially with a single server.
2) DEE model: organize the large dataset as data chunks, and assign different workers to read these data chunks to process them in parallel with the distributed executed engine, which consists of one schedule node and three work nodes. As shown from the experimental results in Fig. 8, the DEE mode is much faster than the stand-alone mode because it can use the shared memory of clusters nodes and process the large dataset in parallel. As the process data amount increases, we also observed that the time consumed will grow nonlinearly.

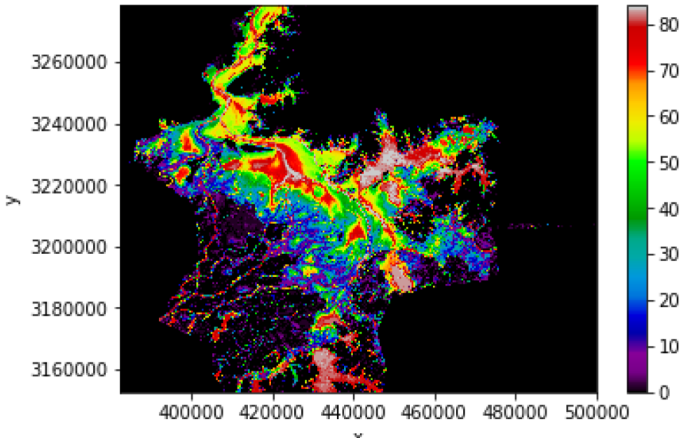

Fig. 5. Water Area of Poyang Lake over 20-year Time Series.

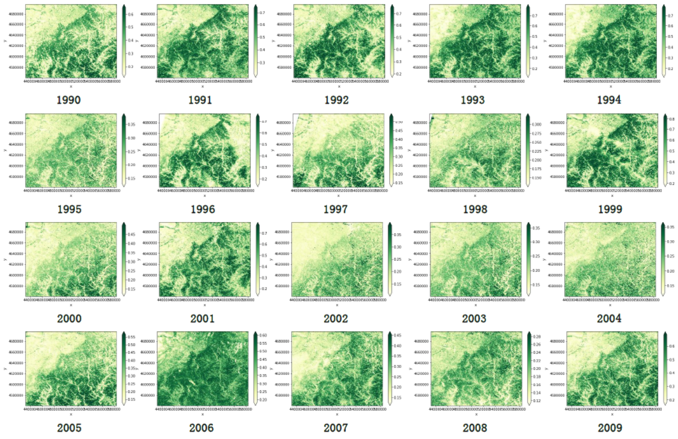

Fig. 6. The Annual Average NDVI of Mulan Hunting Ground for 20 Years.

This is due to the IO limit of the shared network file system and scheduling overhead. The speedup performance when generating the NDVI production with increasing numbers of work nodes also proved this point, as shown in Fig. 9. Therefore, we conclude that the SRSDC has a certain capacity to process the massive data, which is unsuitable for the memory.

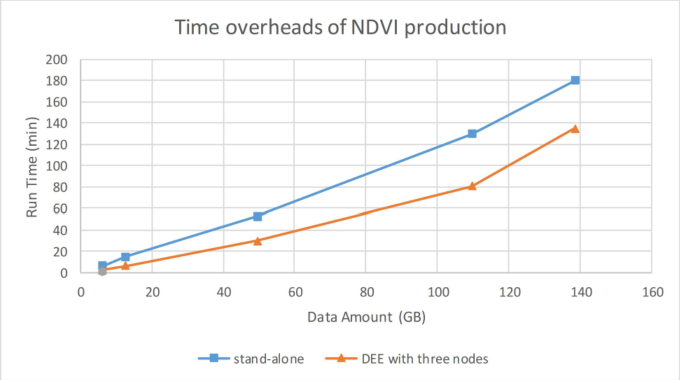

Fig. 8. Runtime of NDVI with the Increase of Data Volume.

VI. Conclusions

We have designed and tested a feature supporting, scalable, and efficient data cube for time-series analysis application, and used the spatial feature data and remote sensing data for comparative study of the water cover and vegetation change. In this system, the feature data cube building and distributed executor engine are critical in supporting large spatiotemporal RS data analysis with spatial features. The feature translation ensures that the geographic object can be combined with satellite data to build a feature data cube for analysis. Constructing a distributed executed engine based on dask ensures the efficient analysis of large-scale RS data. This work could provide a convenient and efficient multidimensional data services for many remote sensing applications [33][34]. However, it also has some limitations; for example, the image data is stored in the shared file system, and its IO performance is limited by the network.

In the future, more work will be performed to optimize the system architecture of the SRSDC, such as improving the performance of the distributed executed engine, selecting other storage methods which could ensure the process data locality, adding more remote sensing application algorithms, etc.
