Structurally, speech recognition consists of four stages: (1) speech analysis, (2) feature extraction, (3) modeling, and (4) testing techniques or matching process. The block diagram of feature matching, which includes all stages of speech recognition, is shown in Fig. 1.

Fig. 1. Block Diagram of Feature Matching.

The first stage is speech analysis, which contains different types of information that shows a human voice identity. After the pronunciation has been detected, this work needs to extract the speech feature on each frame in the second stage. The feature extraction involves calculation of Mel Frequency Cepstral Coefficients (MFCC) for each frame. By using the MFCC, it is able to develop the features from the speech signal which can be used for speech recognition system [25]. The MFCC consist of the following steps: Windowing, Fast Fourier Transform (FFT), power spectrum calculation, Mel Frequency warping, and Discrete Cosine Transform (DCT). The block diagram of the feature extraction process of MFCC is shown in Fig. 2.

Since the effect of frame blocking the speech signal becomes discontinuity, windowing is required in the first process of second stage. Then, FFT is applied to transform speech signal to frequency domain in each frame. Furthermore, the power spectrum for each frame is calculated. However, it is having a lot information which is not needed for feature matching process. Thus, Mel Frequency Warping is used for filtering in the form of a filter bank to determine the size of the power spectrum of a certain frequency band and convert the frequency into mel. Finally, DCT is used for producing a mel spectrum to improve recognition quality [25], [26].

In the third stage, the feature extraction process was done on a set of words and then stored the feature vector sequences [27] as the dictionary. The dictionary function performs feature extraction, which will be stored and used as a reference. The dictionary will be used as a matching reference with the recorded voice speech features. Thus, in the early stages, this work needs to save the voice that will be used as a dictionary dataset. The data were stored in the dictionary and formatted as an array. There were 25 feature vector data sets in the dictionary, which consisted of voice left (5 sets), right (5 sets), up (5 sets), down (5 sets) and stop (5 sets).

Fig. 2. The Flowchart of Feature Extraction Process of MFCC.

Typically, people have different speaking speeds and characteristics [28]. Dynamic Time Warping (DTW) is used to normalize these differences. Moreover, feature vectors of the voice test sequence were also compared with each word in the dictionary set using the DTW algorithm and the best match in each set was outputted in the final stage. DTW is an algorithm used to measure similarity between two sequences which may vary in time or speed. Thus, it can find the best alignment between two different sequences of signals. Fig. 3 shows the flowchart to implement the DTW algorithm.

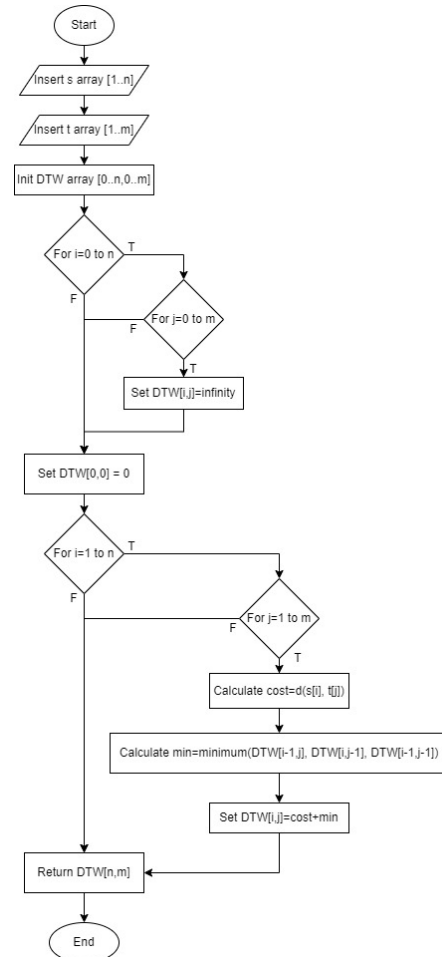

Fig. 3. The Flowchart of DTW Algorithm.

The DTW algorithm works mainly by calculating the Euclidean distance between two points [8], which is the point of the test and reference points for recognizing or authenticating each frame [29]. The threshold was set so that the random noise signal is not generated by the matching speech. Therefore, the DTW algorithm can also be used to find the best matching between voice data test and dictionary data. Then the Euclidean distance function is called when calculating the DTW. After that the matching process between the dictionary voice features with the voice data that has been recorded is performed. Fig. 4 shows the flowchart for calculating Euclidean distance. Finally, this distance will use for comparing voice and reference voice to recognize or authentication process. The detail process of recognize or authentication is described in Section IV below.

Fig. 4. The Flowchart of Euclidean Distance Calculation.

#### IV. MATERIAL AND SYSTEM DESIGN

This work used the TIMIT Acoustic-Phonetic Continuous Speech Corpus dataset. This is a standard dataset used for evaluation of automatic speech recognition systems. It consists of recordings of 630 speakers of 8 dialects of American English each reading 10 phonetically-rich sentences. It also comes with the word and phone-level transcriptions of the speech. Furthermore, to obtain the work’s objective, the five sets of voice dictionaries (such as left, right, up, down, and stop) is used for matching processes by making changes in articulation.

The system design consists of three parts: Dictionary, DTW, and Euclidean Distance. The Dictionary was used to store five words: left, right, up, down and stop. Each word was repeated 5 times. The voice test sequence will be matched to all words in the first dictionary set and then the word with the least distance will be extracted. Then, the voice test sequence will be matched to all words in the second dictionary set and the matched word will be extracted. The same will be done for the next three sets. Thus, the dictionary will give 5 matched outputs from the dictionary set. The most repeated word in the output will be regarded as the best match.

The DTW can normalize the speed difference of speaking [30]. It can find best-alignment between two different signals. This function will call the Euclidean distance function to calculate the distance between the test signals with reference signals. After that, the results of feature extraction were matched with the dictionary that has been recorded as the reference. This function will do the matching features by calling DTW to find the best alignment between the two sets of sequences.

The voice received by the system compared to reference voice that has been stored in the dictionary. The distance of both speeches was calculated using the Euclidean Distance algorithm. The closest distance to the set reference speech is output for recognizing or authentication process.

#### V. RESULT AND DISCUSSION

In this section, the block diagram and flowchart in the previous section have been implemented in the programming language using Lab-VIEW and MATLAB on a desktop of Intel i7 4-core CPU and 8 GB RAM. Furthermore, this work describes the performance comparison results in the speech recognition system.

##### A. Experimental Result

The testing phase was performed by connecting a microphone to a computer that had installed Lab-VIEW and MATLAB program code. Then, while the speaker speaks a voice, the signals were acquired by the Lab-VIEW for 2 seconds duration at 11025 Hz sampling rate. This work tested the system using 5 different voice speeches consisting of “Left”, “Right”, “Up”, “Down”, and “Stop”. Each of these words was repeated 100 times with different articulations. The detailed information about the amount of data for the matching process can be seen in Table I.

The recognized outputs were observed to calculate the system performance. The first test is the success level of the system in identifying what is spoken. The details of the first testing result of accuracy rate can be seen in Table II.

The average accuracy rate for Lab-VIEW and MATLAB are: 85,6 % and 89,6 %. The accuracy results are obtained by ratio between true positive (TP) and true negative (TN) to TP, TN, false positive (FP), and false-negative (FN) as shown in (1) [31]. TP presents the number of voices that are labeled correctly and TN for the number of voices that are correctly identified as not corresponding to the words spoken. FP indicates the number of voices that are incorrectly labeled. FN denotes the number of voices that are unidentified in words spoken.

TABLE I. DETAILED INFORMATION ABOUT DATA FOR MATCHING PROCESS

| Word         | The number of data |
|--------------|--------------------|
| Left         | 100                |
| Right        | 100                |
| Up           | 100                |
| Down         | 100                |
| Stop         | 100                |
| <b>Total</b> | <b>500</b>         |

TABLE II. THE TESTING RESULT OF ACCURACY RATE IN THE SPEECH RECOGNITION SYSTEM

| Word           | Lab-VIEW Accuracy Rate (%) | MATLAB Accuracy Rate (%) |
|----------------|----------------------------|--------------------------|
| Left           | 81                         | 91                       |
| Right          | 85                         | 85                       |
| Up             | 88                         | 87                       |
| Down           | 85                         | 92                       |
| Stop           | 89                         | 93                       |
| <b>Average</b> | <b>85,6</b>                | <b>89,6</b>              |

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

The second test is to test the running time required to execute the program. The execution time is calculated from the voice received by the system until the system finishes identifying the voice. The testing is done 100 times on each word. The second test result of execution time can be seen in Table III, which shows that the average execution time for Lab-VIEW and MATLAB are: 723 ms and 969,4 ms.

TABLE III. THE EXECUTION TIME RESULT OF SPEECH RECOGNITION SYSTEM

| Word           | Lab-VIEW Execution Time (ms) | MATLAB Execution Time (ms) |
|----------------|------------------------------|----------------------------|
| Left           | 752                          | 1044                       |
| Right          | 883                          | 1091                       |
| Up             | 617                          | 953                        |
| Down           | 698                          | 847                        |
| Stop           | 665                          | 912                        |
| <b>Average</b> | <b>723</b>                   | <b>969,4</b>               |

The third test is CPU usage. This test is quite important in building the system so that resources can be used optimally. The testing is done 100 times on each word. The third test result of CPU usage can be seen in Table IV, which shows that the average of CPU usage for Lab-VIEW and MATLAB are: 1,55 % and 1,57 %.

TABLE IV. THE CPU USAGE RESULTS OF SPEECH RECOGNITION SYSTEM

| Word           | Lab-VIEW CPU Usage (%) | MATLAB CPU Usage (%) |
|----------------|------------------------|----------------------|
| Left           | 1,56                   | 1,41                 |
| Right          | 1,84                   | 1,42                 |
| Up             | 1,41                   | 1,74                 |
| Down           | 1,63                   | 1,67                 |
| Stop           | 1,29                   | 1,62                 |
| <b>Average</b> | <b>1,55</b>            | <b>1,57</b>          |

### B. Discussion

Based on experimental results, the average accuracy rate of MATLAB is better than Lab-VIEW since the value of TP and TN in the MATLAB results is higher than Lab-VIEW. On the other hand, Lab-VIEW has a shorter execution time than MATLAB since Lab-VIEW has simple code that is assessed according to the number of elements or lines used. The faster the code can be updated or debugged the better surveyable the program is [32].

In order to verify the performance comparison results, a box-plot method or also called Box-and-Whisker plot method was conducted as presented in Fig. 5. From the figures, this work can find that average accuracy rate and execution time are significantly different between Lab-VIEW and MATLAB using t-test at the level of significance ( $\rho$ ) of 0.05. This result indicates that the average accuracy rate of MATLAB is actually better than Lab-VIEW. Then, Lab-VIEW actually has a shorter execution time than MATLAB since both of them

are significantly different. It is also in accordance with the experimental results.

CPU usage becomes an essential metric to determine how well an application is using the cores. CPU usage refers to a program's usage of processing resources, or the amount of work handled by a CPU. Since the amount and type of managed computing tasks are the same, Lab-VIEW and MATLAB have almost the same CPU usage. Based on the statistical analysis, the CPU usage is not significantly different between Lab-VIEW and MATLAB using t-test at the level of significance ( $\rho$ ) of 0.05. This result indicates that the Lab-VIEW and MATLAB have the same CPU usage since both of them are not significantly different and in accordance with the experimental result.

Fig. 5. Box-and-Whisker Plots of Average (a) Accuracy Rate, (b) Execution Time and (c) CPU usage.

## VI. CONCLUSION

This work has designed a speech recognition system using feature matching on Lab-VIEW and MATLAB. The feature was extracted using MFCC and calculating distance using DTW from the speech. Before performing the speech, this work saved a set of the features from speech voice as a training set in a dictionary. The matching process was performed between the feature of the voice and the feature which had been saved in the dictionary. In the testing phase, this work tested five speech words and each word was repeated 100 times. The system experimented using the most common performance in the speech recognition system i.e., accuracy rate, execution time, and CPU usage. The performance comparison results show that the average accuracy rate of Lab-VIEW is 85.6% and MATLAB is 89.6%. The execution time testing of Lab-VIEW is 723 ms and MATLAB is 969.4 ms. While, the Lab-VIEW and MATLAB have almost the same CPU usage which is around 1.5%.

Speech recognition has wide smart applications and includes voice-controlled appliances fully featured speech-to-text software, automation of operator-assisted services and voice recognition aids. This work's result indicates that the performance comparison is able to be used according to the requirements of smart application-based speech recognition systems. Hence, the performance comparison results in improving many speech recognition system applications can be further extended, which can make the process more robust and effective.

**Abstract**—Scheduling in a permutation flowshop refers to processing of jobs in a set of available machines in the same order. Among the several possible performance characteristics of a flowshop, makespan remains one of the highest preferred metrics by researchers in the past six decades. The constructive heuristic proposed by Nawaz-Enscore-Ham (NEH) is one of the best for makespan minimization. The performance essentially depends on the initial ordering jobs according to a particular priority rule (PR). The popular priority rules are non-increasing order of the jobs' total processing time, the sum of average processing time and standard deviation and, the sum of average processing time, standard deviation and absolute skewness among others. The objective of this paper is to propose and analyse a new job priority rule for the permutation flowshop. The popular priority rules available in the literature are studied and, one of the best priority rules; the sum of average processing time and standard deviation is slightly modified, by replacing the standard deviation by mean absolute deviation (MAD). To assess the performance of the new rule, four benchmark datasets are used. The computational results and statistical analyses demonstrate the better performance of the new rule.

**Keywords**—Priority rule; flowshop scheduling; makespan; NEH algorithm

## I. INTRODUCTION

Permutation flowshop scheduling problems (PFSSP) remain one of the most studied domains in operations research in the past six decades. PFSSP refers to scheduling ' $n$ ' number of jobs for processing in ' $m$ ' number of machines in the same order. According to Rinnooy Kan [1], PFSSP is proved to be NP-hard when the number of machines is greater than three. Since the PFSSP is np-hard, the computation time grows exponentially for larger problems and hence, exact solution becomes impossible or expensive. As a result, several dispatching rules, heuristics and metaheuristics have been proposed over the decades. Efficient heuristics report solutions with acceptable accuracy levels in a reasonable time. Priority rules or dispatching rules are some form of heuristics and have been studied in both academia and industry domains extensively for decades (Tay and Ho 2008)[2]. A few simple dispatching rules that are being extensively used in jobs' scheduling are: Shortest Processing Time (SPT) rule, Longest Processing Time (LPT) rule, Earliest Due Date (EDD) rule, First Come First Serve (FCFS) rule.

The optimization parameters for the PFSSP are generally; flow time, idle time or makespan (Liu et al., 2016) [3] to satisfy different production line requirements. They find

numerous real-time applications and could be combined with Internet of Things (IOT) for specific applications (Salis, 2021) [4]. Among the many parameters that are being optimised, makespan minimization is widely considered by researchers over the years. Johnson's [5] algorithm proposed in 1954 yields an optimum solution for two machines and ' $n$ ' jobs PFSSPs which was extended to three machines cases.

As the problem is NP-hard, the exact solution becomes impossible for larger problems and the computation time grows exponentially with the problem size. Earlier approximate heuristics could not yield the expected accuracy and the breakthrough came in 1983 when Nawaz-Enscore-Ham (NEH) [6] algorithm was proposed. NEH algorithm which has a complexity of  $O(n^3.m)$  uses the largest processing time (LPT) dispatching rule and is considered as one of the best constructive heuristics for makespan minimization even today. Many improvements and extensions have been proposed by many authors over the years. NEH essentially consists of three phases:

- Pre-arranging the jobs according to the non-increasing order of their total processing times (Priority Rule).
- Selecting the first two jobs from the processed sequence as the initial partial sequence (Initial Sequence).
- Inserting other jobs one by one at a suitable place that minimises the partial makespan (Insertion Phase).

Ribas et al. (2010) [7] tested four priority rules combined with the powerful insertion technique of NEH including rules from NEHKK1 (Kalczyński and Kamburowski 2008) [8], N&M (Nagano and Moccellini 2002) [9], LPT, and a random job sequence. Baskar and Xavier (2015) [10] analysed the job insertion technique for different initial sequences.

The authors improved the solution quality of NEH by suitably modifying the first and third phases. Several priority rules for NEH are proposed and available in the literature and the ones proposed by Dong et al. [11] and Liu et al. [12] yield better results.

Framinan et al. [13] analysed 177 initial sequences for the NEH heuristic and concluded that SUM PIJ / DECR (i.e. original NEH) is ranked 1 among all for the makespan minimisation.

During the insertion phase, we come across several occasions when the partial makespan remains the same for

more than one partial sequence. NEH breaks such ties randomly. Several effective tie-breaking rules are proposed and analysed for the solution quality. The tie-breaking rules proposed by Fernandez and Framinan [14], Lie et al. [12], Benavides [15] and the ones recently by Baskar and Xavior [16] are a few to mention.

This paper considers the sum of the average processing times and means absolute deviation (MAD) for the initial ordering of jobs (Priority Rule) and analyses its impact using well-known benchmark datasets.

The structure of this paper is as follows: the new priority rule is presented in Section 2 followed by the benchmark and performance metrics used for the assessment in Section 3. The results and statistical analyses are detailed in Section 4 and Section 5 discusses about the conclusion, limitations and future work.

## II. NEW PRIORITY RULE

The initial ordering of jobs or priority rule does affect the solution quality of the NEH heuristic. The priority rule considered by the original NEH is non-increasing order of the jobs' total processing times. Total processing time (TPT) for a particular job,  $j$  can be represented as,

$$TPT_j = \sum_{i=1}^m p_{ij} \quad (1)$$

$m$  – Number of machines in the schedule.  $p_{ij}$  denotes the processing time of job ' $j$ ' in the machine ' $i$ '.

Dong et al. [11] added the standard deviation of the processing times with the average total processing time,  $AVG_j$  for a job and reported improved results. Mathematically, standard deviation,

$$SD_j = \sqrt{\frac{1}{(m-1)} \sum_{i=1}^m (p_{ij} - AVG_j)^2} \quad (2)$$

Another priority rule proposed recently by Liu et al. [12] adds the absolute skewness with the priority rule of Dong et al. [11] and the rule improves the solution further. Skewness (SKE) for a job,  $j$  is defined as,

$$SKE_j = \frac{\frac{1}{m} \sum_{i=1}^m (p_{ij} - AVG_j)^3}{\left[ \sqrt{\frac{1}{(m-1)} \sum_{i=1}^m (p_{ij} - AVG_j)^2} \right]^3} \quad (3)$$

In this paper, the standard deviation is replaced by another similar metric, the Mean Absolute Deviation (MAD) which is the average of the absolute deviations from the mean value.

For a job ' $j$ ',

$$MAD_j = \frac{1}{m} \sum_{i=1}^m |(p_{ij} - AVG_j)| \quad (4)$$

MAD was used as the variation measure in the tie-breaking rule of Liu et al. [12]. Another metric, the median absolute deviation (MAD1) is also used instead of mean absolute deviation during the process; that is, descending order of average processing time + median absolute deviation as a priority rule. However, the results are not encouraging in this case.

For a job ' $j$ ',

$$MAD1_j = \text{Median} (|(p_{ij} - AVG_j)|) \quad (5)$$

The benchmarks and analyses results using different combinations are presented and discussed in the coming sections.

## III. BENCHMARK AND PERFORMANCE MATRIC USED

For comparing the performance of similar heuristic algorithms in flowshop scheduling, several benchmark problem sets are available in the literature. One of the earlier benchmarks proposed for permutation flowshop is the one proposed by Carlier in 1978 [17] with varying jobs and machines combination. The instances have high processing times, up to 999-time units. DUM dataset proposed in 1998 by Demirkol et al. [18] has a combination of jobs {20, 30, 40, 50} and machines {15, 20} resulting in 40 instances of 5 in each set. The processing time is randomly fixed between {0, 200} time units. The Taillard [19] instances proposed in 1993 are available under 12 groups of 10 instances each. The processing times in 5, 10 and 20 machines vary from 0 to 99 for 20, 50, 100, 200 and 500 numbers of jobs. The known upper bounds for all the 120 problems are available online [20] and are accessible for researchers.

Recently, Vallada et al. [21] proposed new hard benchmarks which are 480 in numbers. They are categorized into small and large problem sets. The small instances, termed as VFR (Small) are 240 in numbers with a combination of {10, 20, 30, 40, 50, 60} jobs and {5, 10, 15, 20} machines. Similarly, the larger instances have a combination of {100, 200, 300, 400, 500, 600, 700, 800} jobs and {20, 40, 60} machines, totaling 240 in numbers. The instances are grouped under 48 sets of 10 instances each. In line with Taillard's, these benchmarks do have processing times from 0 to 99. The known upper bounds are provided by the authors themselves.

The parameter used for the comparison of the performance of different heuristics is the Percentage Relative Deviation (PRD) which is defined as:

$$\text{Percentage Relative Deviation, PRD} = \frac{(\text{Makespan} - \text{KnownUpperBound}) \times 100}{\text{KnownUpperBound}} \quad (6)$$

## IV. COMPUTATIONAL RESULTS AND DISCUSSION

Different priority rules (initial ordering of jobs) considered are summarized below:

- PR-NEH: Descending order of their total processing times.
- PR-D: Descending order of the sum of their average processing time and standard deviation.
- PR-LJP: Descending order of the sum of their average processing time, standard deviation and absolute (skewness).
- PR-DB: Descending order of the sum of their average processing time and mean absolute deviation.

- “No PR” refers to no initial ordering of jobs; raw data are used as received.

Codes are generated for all priority rules in MATLAB R2012b and run in an i5 desktop PC with 4 GB RAM. Many heuristics initially order the jobs according to a priority rule and then refine the solution further using some strategy. The initial priority ordering may have significant impact on the final result. To start with, Taillard instances are initially ordered as per the priority rule (PR) considered and the makespans computed without any further processing. The average PRDs (APRDs) are presented in Table I. The bold digits indicate the best result for a particular problem set. There is not much difference in the results among the PRs considered. The best APRD of 21.40% is reported by PR-DB and the worst one by PR-D (21.64%); the difference being 1.12%. Even no “no priority rule” reports a better mean value of 21.61% and accounts for best results in 4/12 sets. Though PR-DB reports the lowest deviation, it reports best results in one case only, 10 machines and 100 jobs.

Subsequently, the impact of different initial sequences has been investigated. NEH considers the first two jobs of the processed sequence as the initial sequence. Baskar et al. [22] considered a few other sets of jobs as initial sequences and analysed (Table II) the impact using Taillard dataset. The performance was analysed by randomly selecting two jobs also from the processed sequence. The results show that the APRDs vary slightly with respect to the initial partial sequence. According to them, randomly selecting two jobs also results in a reasonably good APRD with 3.43% which may be due to the job insertion strategy that was originally used by the NEH algorithm. It is to be noted that many heuristics could not even better this mean value of 3.43% for the Taillard benchmark.

Now, to assess the performance; the PR is applied to the classic NEH algorithm and the results are tabulated in Table III to Table VI. The benchmark used are; Carlier’s [17] proposed in 1978, Taillard’s [19], in 1993, Demirkol’s [18] in 1998 and the latest VFR benchmark proposed in 2015 by Vallada et al.[21]. The better APRDs are shown in bold and italics in all the tables.

For the Carlier 8 instances (Table III); Dong et al. priority rule, PR-D reports an APRD of 1.44%, an increase of 3.60% in the APRD over PR-NEH which is taken as the reference for the analysis in this paper. That is, for this dataset, the solution quality deteriorates when PR-D is used for initial ordering the jobs. The APRD of the new priority rule, PR-DB is 1.21%, a significant 12.95% improvement over the rule used by NEH.

For the comparatively larger dataset of Demirkol’s which are 40 in numbers also, the proposed priority rule, PR-DB reports better APRD than the priority rules, PR-NEH and PR-D with an improvement of 4.70% over the reference PR-NEH. The improvement of the rule, PR-D over PR-NEH being 1.61%. Here, the lower bounds (LB) are considered instead of upper bounds (UB) for better comparison as the makespans better the UBs provided by Demirkol et al. in many cases. While using Taillard’s dataset; three more priority rules are considered as detailed below:

- PR-LJP1: Descending order of the sum of their average processing time, mean absolute deviation and absolute (skewness).
- PR-LJP2: Descending order of the sum of their average processing time, mean absolute deviation and skewness.
- PR-DB1: Descending order of the sum of their average processing time and median absolute deviation.

| %Improvement | Ref.        | 0.78        | -2.35       | %Improvement | Ref.        | 2.99        | 3.89        |

The PR-LJP proposed by Liu et al. [12] is proved to yield better results for the Taillard dataset. PR-LJP adds a third metric, absolute (skewness) to the priority rule, PR-D. However, when this absolute (skewness) is added to the sum of average processing time and mean absolute deviation (PR-LJP1); the APRD comes down to 3.16% from 3.06%. The APRD slightly improves to 3.12% when the absolute (skewness) is replaced by skewness (PR-LJP2). For this dataset, PR-D reports an APRD of 3.22% and PR-DB, 3.17%. The improvement of PR-DB is 4.52% over PR-NEH which is better than PR-D (3.01% improvement). When the median absolute deviation (MAD1) replaces the mean absolute deviation (PR-DB1), we get an APRD of 3.29% (Table V) for the Taillard instances.

The results of VFR (Small) and VFR (Large) datasets are given in Table VI. The performance is different here. For the VFR (Small) dataset, the performance of PR-DB worsens by 2.35% whereas; PR-D reports 0.78% improvement over the reference priority rule, PR-NEH. For the smaller problems, the priority rule, PR-D reports the best results. However, when the number of problem sets are considered, the reference rule, PR-NEH accounts for better results in 11/24 sets followed by PR-

D, 8/24 sets and the new rule, PR-DB does well in only 5/24 cases.

However, for the VFR (Large) dataset, the performance of the newly proposed rule, PR-DB is better than PR-D and PR-NEH. The improvement over PR-NEH is 3.89% for this larger dataset. The new rule also reports best results in 13/24 problem sets. PR-D comes next with better results in 8/24 cases. The priority rule, PR-NEH which performs extremely well in smaller problems of VFR, could not match that performance and accounts for only 3/24 problem sets.

The summary of the results is presented in Table VII.

TABLE VII. SUMMARY OF RESULTS (APRDs)

| Benchmark          | PR-NEH | PR-D        | PR-DB        |
|--------------------|--------|-------------|--------------|
| Carrier            | 1.39   | 1.44        | <b>1.21</b>  |
| Demrikol (over LB) | 17.43  | 17.15       | <b>16.61</b> |
| Taillard           | 3.32   | 3.22        | <b>3.17</b>  |
| VFR (Small)        | 3.83   | <b>3.80</b> | 3.92         |
| VFR (Large)        | 3.34   | 3.24        | <b>3.21</b>  |

For all the datasets except VFR (Small), the newly proposed priority rule, PR-DB outperforms PR-D and PR-NEH.

Paired t-tests are carried out at 95% confidence level using MINITAB17 and the results are presented in Table VIII.

TABLE VIII. PAIRED T-TEST ON DIFFERENT BENCHMARKS

| Pairs              | T-Value | P-Value      |
|--------------------|---------|--------------|
| <b>Carlier</b>     |         |              |
| PR-NEH vs PR-D     | -0.18   | 0.862        |
| PR-NEH vs PR-DB    | 0.55    | 0.597        |
| <b>Demirkol</b>    |         |              |
| PR-NEH vs PR-D     | 1.30    | 0.202        |
| PR-NEH vs PR-DB    | 3.75    | <b>0.001</b> |
| <b>Taillard</b>    |         |              |
| PR-NEH vs PR-D     | 1.16    | 0.270        |
| PR-NEH vs PR-DB    | 1.46    | 0.172        |
| <b>VFR (Small)</b> |         |              |
| PR-NEH vs PR-D     | 0.38    | 0.710        |
| PR-NEH vs PR-DB    | -0.85   | 0.403        |
| <b>VFR (Large)</b> |         |              |
| PR-NEH vs PR-D     | 3.86    | <b>0.001</b> |
| PR-NEH vs PR-DB    | 4.54    | <b>0.000</b> |

Since only PR-D and PR-DB are similar priority rules, they are compared with PR-NEH and listed in Table VII and Table VIII. The analyses could prove the statistical significance in three cases with probability values of 0.001, 0.001 and 0.000 for the pairs; PR-NEH vs PR-DB (Demirkol), PR-NEH vs PR-D (VFR-Large) and PR-NEH vs PR-DB (VFR-Large) respectively.

## V. CONCLUSION AND FUTURE WORK

This paper proposes a new priority rule, PR-DB for the permutation flowshop scheduling problems. The popular NEH algorithm considers the jobs according to the non-increasing order of their total processing times. Dong et al. added another metric, the standard deviation of the processing times of a particular job for initial ordering. In this work, the standard deviation used in the priority rule of Dong et al., PR-D is replaced by Mean Absolute Deviation. The PR is applied to the classic NEH heuristic for makespan minimisation. Computational results show that the performance is better than PR-D for the Carlier, Demirkol, Taillard and VFR (Large) datasets. The results do not improve in the case of VFR (Small) instances. The paired t-tests are carried out to assess the statistical significance. The main advantage of the new rule is that it is simple yet powerful. It can be easily applied in scheduling the jobs in any engineering industry. Similarly, it can be combined with any popular tie-breaking rule to improve the solution quality further. Also, the results obtained could be used as the seed solution for any metaheuristic for better solution and schedules. Future work includes the assessment of PR-DB for other potential benchmarks also.

## ACKNOWLEDGMENT

The authors are sincerely thankful to the anonymous referees and editors, who provide constructive comments to improve the technical content and presentation of the paper. We also thank Professors Michele Lanzetta, Andrea Rossi and Reha Uzsoy for providing Demirkol dataset and other required information in writing this paper.

**Abstract**—Location-based services (LBSs) have received a significant amount of recent attention from the research community due to their valuable benefits in various aspects of society. In addition, the dependency on LBS in the performance of daily tasks has increased dramatically, especially after the spread of the COVID-19 pandemic. LBS users use their real location to build LBS queries to take benefits. This makes location privacy vulnerable to attacks. The privacy issue is accentuated if the attacker is an LBS provider since all information about users is accessible. Moreover, the attacker can apply advanced attacks, such as map matching and semantic location attacks. In response to these issues, this work employs artificial intelligence to build a robust defense against advanced location privacy attacks. The key idea behind protecting the location privacy of LBS users is to generate smart dummy locations. Smart dummy locations are false locations with the same query probability as the real location, but they are far from both the real location and each other. Relying on the previous two conditions, the deep-learning-based intelligent finder ensures a high level of location privacy protection against advanced attacks. The attacker cannot recognize the dummies from the real location and cannot isolate the real location by a filtering process. In terms of entropy (the privacy protection metric), accuracy (the deep learning metric), and total execution time (the performance metric) and compared to the well-known DDA and BDA systems, the proposed system shows better results, where entropy = 15.9, accuracy = 9.9, and total execution time = 17 sec.

**Keywords**—LBS; dummy; deep-learning; attacks; accuracy; resistance; performance

## I. INTRODUCTION

The Internet of Things (IoT) can be defined as a network of devices that are connected through the Internet to facilitate performing tasks remotely. The IoT is involved in all aspects of people's lives, and it can be used in a wide range of applications in industry, transportation, and medicine [1]. In smart cities, the IoT forms the backbone for performing several missions, as shown in Fig. 1.

Among the IoTs, location-based services (LBSs) are considered the most important services that serve people daily. LBSs can be seen as commercial location applications that utilize the geographical location information of smart devices and mainly smartphones, enabling users to search for Points of Interest (PoIs), such as nearest restaurants, hospitals, libraries, and sports clubs [3]. In other words, LBSs employ a Global

Positioning System (GPS) to perform queries issued from the user side. In addition, smartphone users can easily obtain the benefits of LBS applications by downloading them from various sites, such as the Apple Store or Google Play Store. From an intersection of technologies point of view, LBS can be illustrated as shown in Fig. 2.

### A. The Importance of Location-based Services

In general, the importance of LBSs comes from their provided benefits, which make our lives easier and more enjoyable. In detail, three main sectors of daily life highlight the importance of LBS-enabled applications:

1) *Medical sector.* In the e-health field, LBSs play a significant role in monitoring patient health conditions (e.g. pulse rates and blood pressure levels), avoiding disasters [4, 5]. This, in turn, means that LBSs contribute to limiting the spread of illnesses such as COVID-19 by enabling medical staff and patients to avoid meeting and consequently maintaining a safe social distance.

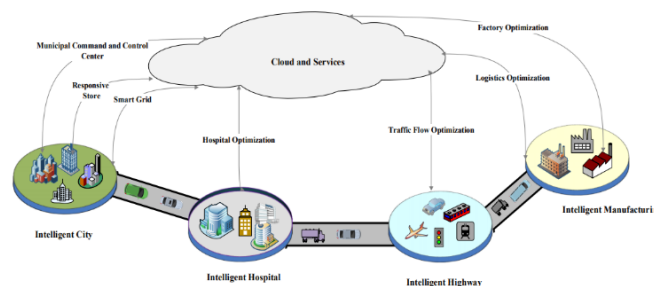

Fig. 1. IoT in Smart Cities [2].

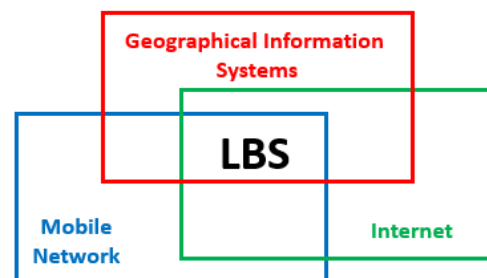

Fig. 2. LBS from an Intersection of Technologies Point of View.

\*Corresponding Author.

2) *Entertainment sector.* A further advantage of LBSs is enabling users to search for PIOs, such as nearby restaurants and music clubs, or enjoying games online [6, 7].

3) *Social sector.* Integrating LBS applications with wireless communication technologies have enabled the creation of location-based social networking services, such as Foursquare, Twinkle, and GeoLife [8]. This integration bridges the gap between the physical world and digital online social networking services.

**B. Statement of Problem**

The valuable benefits of the LBS applications mentioned above are not without risk. The key problem behind the extensive utilization of LBS applications is that the privacy of LBS users may be attacked. In the cybersecurity research field, privacy is a term that refers to sensitive information about users' interests, habits, or personal lives [9, 10]. Obtaining such information harms users and can even threaten their lives in cases of blackmailing or stealing valuable personal information, including the nature of their business, the details of their business trips, or their religious affiliation.

To gain a deep look at the privacy issue in LBS applications, the mechanism used for serving users should be analyzed. Using LBS applications requires constructing and sending queries relying on the real geographical locations of LBS users, who obtain their real locations through GPS. After manipulating these queries by the LBS provider, the results are returned to the users. Fig. 3 illustrates the general mechanism followed by LBS applications.

As shown in Fig. 3, there are three main steps, as follows.

- 1) The LBS user establishes a query using their real location. This query is then sent to the LBS provider.
- 2) The LBS provider processes the received query to answer the user. The result of the query (the retrieved POI) is packaged for resending.
- 3) The result is sent back to the LBS user and seen on the smartphone screen.

The scenario described in Fig. 3 is insecure against an attacker targeting the privacy of the LBS user. To define the problem accurately, modelling is required. Let  $\langle \alpha, \beta \rangle$  denote the coordinates of the real location of a given LBS user. Based on this representation, the query that is sent to the LBS provider is defined as:

$$Q_{LBS} = \{ \langle \alpha, \beta \rangle, S_{POI}, D, ID \}$$

Where:  $S_{POI}$ : set of points of interest that represent the result of the sent query.  $D$ : diameter of the search region (measured by Kilometres).  $ID$ : identity of the LBS user.

The privacy problem starts when an attacker tracks the real location of the LBS user or analyzes the sent query, as shown in Fig. 4.

In both cases (i.e., tracking the real location or analyzing the sent query), personal information about the LBS user is obtained. Malicious activities can be performed by a man-in-the-middle (MITM) attack. However, the privacy problem is

accentuated if the attacker is the LBS provider since all information is accessible. Upon this, the attacker (the LBS provider) can track the real location of the LBS user or analyze the received query. A malicious profile is then constructed on the attacker side, containing personal information that will be employed to attack the victim physically. Fig. 5 illustrates this dangerous scenario.

Formally, let  $VP$  denote the victim profile. Then,

$$VP = Track(\langle \alpha, \beta \rangle) \cup (Analyze Q_{LBS})$$

In terms of data flow and trust boundaries (attack surface), the security gap is represented by obtaining the query illustrated in Fig. 6.

It is worth mentioning that tracking the real location of LBS users leads to location privacy issues, and analyzing the sent query leads to query privacy issues [11]. In this work, we are concerned about location privacy only.

Fig. 6. Security Gap from the Attack Surface Perspective.

### C. Motivation and Research Questions

In light of the dangerous spread of the COVID-19 pandemic, dependence on mobile applications and the Internet has increased. This is because this dependency keeps people healthy in terms of achieving social distancing requirements. Increasing dependency on mobile applications is tightly coupled with an increasing level of privacy threats [12]. Moreover, existing advanced methods that could be used to track users, such as those that gather private information [13, 14], make privacy concerns more relevant. The capabilities of attackers are growing daily, with advanced attacks used to collect personal information from LBS users being applied. The attacker in a Map Matching Attack (MMA) employs the side information to gather sensitive data about the LBS user. In other words, the attacker can discover the kinds of activities the user is involved in by knowing the geographical map from which the LBS query is issued (i.e., without tracking the real location of the LBS user) [15, 16]. Fig. 7 illustrates the basic concept of an MMA.

Another advanced attack used for penetrating protection methods is the Semantic Location Attack (SLA) [18]. In an SLA, the attacker can infer semantic meanings related to the user's behavior, relying on both the time and place of where a user stays, as shown in Fig. 8.

Fig. 7. Concept of MMA [17].

Fig. 8. Concept of SLA [19].

Motivated by these advanced attacks, two main research questions must be answered:

1) How do we ensure high resistance against both MMA and SLA?

2) How can privacy protection be quantified in terms of preventing attackers from penetrating privacy protection approaches?

### D. Contribution

The contributions of this work are listed as follows:

- In response to the first research question, a deep learning technique is proposed to generate strong dummy locations that protect the real location of the LBS user.
- In response to the second research question (second quality requirement), the entropy metric is employed to measure the resistance of the proposed deep learning based privacy protection system.

### E. Structure of the Work

The rest of this work is organized as follows. Related work is reviewed in Section II. Section III presents the methodology of designing and constructing the proposed system in detail. Security analysis is discussed in Section IV, followed by the results in Section V. Finally, the conclusion and suggestions for future work are provided in Section VI.

## II. RELATED WORK

In response to privacy concerns, researchers have proposed several approaches. The approaches were addressed from different perspectives, namely, server-based approaches, user-based approaches, and Trusted Third Party (TTP) approaches. Fig. 9 is a classification of LBS privacy protection approaches, where each category has its drawbacks.

The authors of work [20] proposed a Dummy Data Array (DDA) algorithm for generating dummy locations to protect the location privacy of LBS users. For a given region, which is divided into a grid of cells, the key idea of the DDA algorithm is to calculate both the vertices and the edges of each cell in the grid. Then, the DDA algorithm randomly selects some of the cells as dummy locations. To select strong dummy locations and achieve k-anonymity, the DDA algorithm selects k cells of equal area. The authors of the work [22] provided a survey of privacy protection approaches and they focused on dummies. Similarly, [21] uses dummies to protect the location privacy of LBS users, but with a different dummy generation method. The authors proposed two algorithms. The first is called CirDummy, which generates dummies based on a virtual circle that contains the real location of the LBS user. The second is called GridDummy, which generates dummies based on a virtual grid that covers the real location of the LBS user.

Fig. 9. Classification of Privacy Protection Approaches for LBS Applications.

Mix zones are defined in which all users' locations are hidden within these zones with some conditions to strengthen the protection method. In the work [23], the authors present the (DSC-LPP) approach to protect location privacy in the wireless channels. It is based on the idea of spatial cloaking-location privacy preserving. In the wireless channels, access points are essential elements in the structure of the network. Distance between the user and AP is the primary key for transforming and retrieving the location of users. Relying on this fact, the authors proposed to include the distance information in exchanged messages. The distance information can be exploited to confuse the attacker by manipulating it through mathematical transforming. The transformation leads to calculate a new location information, which in turn forms a clocking region. The clocking region reflects a security area of the location privacy. To enhance the performance, normalization is employed in the process of transformation for the purpose of building clocking regions. The advantage of this approach is that it can protect location privacy in a fixable way depending on increasing or decreasing the area of the clocking regions. However, if attackers have side information about the geographical map where the LBS user is located, the mechanism of protection becomes weak. In other words, this approach is not robust against MMA.

Pseudonym method [24] is used for protection of the user identity. The key idea is confusing the relationship between the position information and user identity information. This method is based on TTP model, TTP is the simplest intermediary entity between the user and the LBS provider. If the request is accepted, the request will be sent to the LBS provider; at the same time, the real ID will be changed to a pseudo-ID.

Information Retrieval (PIR) [25] was used to achieve full privacy protection. The key idea of the PIR technique depends on mathematical principle. It says that if it is impossible to compute a certain number or perform a certain mathematical task, then the information that form the task is protected. When the query is represented by a task, and PIR technique is applied, then, the LBS server can process and answer the query without knowing any sensitive information about the query.

### III. PROPOSED SYSTEM

This section is structured so that the threat model is defined first. The proposed system design is then described in detail. Next, security analyzes are discussed. Finally, the mechanism of evaluation of the proposed system is presented with the corresponding metrics.

#### A. Threat Model

The objective of the threat model is to draw the environment within which the proposed system is running and is expected to be robust against attackers. The threat model consists of four blocks as shown in Fig. 10.

- Attacker. The attacker is the LBS provider itself (or its maintainer), where all LBS queries are sent to it, and connecting with this malicious party is mandatory.
- Malicious goal. The goal of the attacker is to build a malicious profile about the LBS user. This is done by

gathering personal data about the victim through tracking the real locations used to establish LBS queries.

- Capabilities. The attacker's ability is supported by launching attacks on the victim, including MMA and SLA attacks.
- Type of attack. The type of each attack launched on the victim is active. This is because the LBS provider (attacker) can access all information received while serving the LBS user.

#### B. System Design

This section provides the architecture of the proposed system with its main components and the role of each component.

1) *Architecture of the proposed system:* The system decomposes three main components: the intelligent finder, query builder, and sender. The system is decentralized one because it is installed on each mobile device of LBS user. Table I summarizes the three components in terms of the assigned task, technique used, and installation.

Graphically, Fig. 11 shows the architecture of the proposed system with interconnections among the three components.

Fig. 10. Blocks of the Threat Model.

TABLE I. COMPONENTS OF THE SYSTEM

| Name               | Task                         | Technique                                                        | Installation          |
|--------------------|------------------------------|------------------------------------------------------------------|-----------------------|
| Intelligent finder | Generating dummy locations   | Convolutional Neural Network (CNN), Support Vector Machine (SVM) | LBS user (Smartphone) |
| Query builder      | Building the protected query | Anonymity of identity                                            | LBS user (Smartphone) |
| Sender             | Sending the protected query  | Wireless communication                                           | LBS user (Smartphone) |

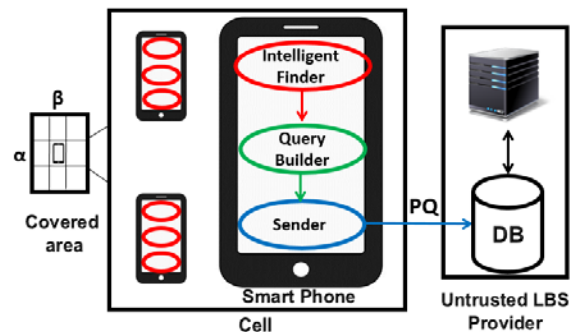

Fig. 11. Architecture of the Proposed System.

As shown in Fig. 11, the smartphone (which represents an LBS user) is located in a certain location (cell) within the covered area that consists of  $(\alpha \times \beta)$  cells. The rest of the cells are spread on different regions that contain various PoIs. The cells that form the covered area can be exploited as dummy locations to protect the location privacy of LBS users. In other words, using fake locations instead of the real location cuts the tracking series that is performed on the attacker's side to complete the malicious profile. This is because the attacker (LBS provider) cannot recognize the real location among dummies. However, the attacker attempts to compromise the protection method by applying advanced attacks such as MMA and SLA. This requires that the process of generating (or finding) dummy locations be accurate to provide strong dummies that can protect location privacy against advanced attacks. In this work, artificial intelligence is employed to generate strong dummies based on Convolutional Neural Networks (CNNs) and Support Vector Machines (SVMs). Upon this, the intelligent finder selects (generates, or searches) strong dummy locations and then provides them to the query builder to establish a query with multiple locations (one of them is the real one). Then, the sender sends the protected query (PQ) to the LBS provider (attacker). The attacker is confused about determining the real location among dummies. Below is a detailed description of the role of each component.

2) *Role of an intelligent finder*: The main task of this component is ensuring the location privacy of the LBS user. This is performed by protecting the location information used to form the sent query. Based on a novel location privacy protection approach, namely, Vectors of Protection (VoP), this component ends its assigned task. VoP fills a vector of locations by dummies, and the real location in the LBS query is replaced by this vector. The key idea of the VoP approach is illustrated in Fig. 12.

As shown in Fig. 12, the real location of the LBS user ( $LBS_L^r$ ) is represented by the left side. The role of the intelligent finder component is to fill the vector by dummy locations by executing the VoP approach. The rest of the query units remain constant.

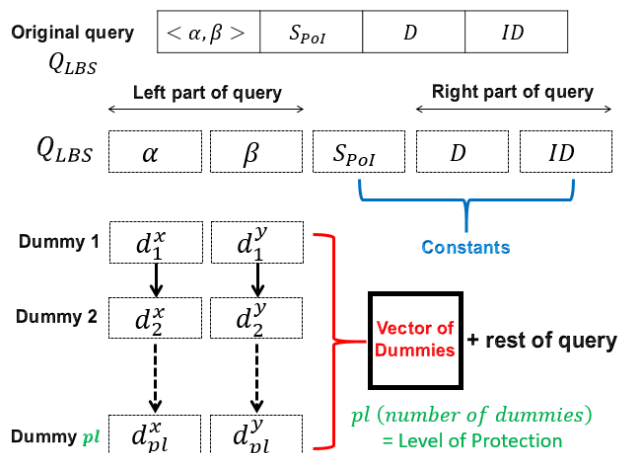

Fig. 12. Key idea of the VoP Approach.

In detail, for a region divided into  $\alpha \times \beta$  cells, the real location of the LBS user  $LBS_L^r$  is located in a certain cell. Each cell has a query probability  $CELL_p^q$ . The query probability is a term that refers to the number of queries sent from a specific location in the past (i.e., number of queries built based on the cell divided by the total number of queries built based on the whole cells). Each cell has a certain value of query probability, as shown in Fig. 13.

The VoP approach selects dummies randomly. From the real location of the LBS user, some vectors are issued to the selected dummies. Then, the selected dummies are stored in the vector of dummies. The number of dummies determines the level of protection. This means that the LBS user has full control over the desired level of privacy protection. For instance, if the LBS user selects 3 dummy locations, the level of privacy protection is 4. This is because the real location is surrounded by three dummies, as shown in Fig. 14.

The process of selecting dummies randomly without any constraint is a poor tactic. This is because the query probability of each dummy location differs from the query probability of the real location of the LBS user. This increases the ability of the attacker to determine the real location among dummies. Therefore, it is better to select dummy locations with the same query probabilities as the real location of the LBS user. Fig. 15 illustrates the selection process under the same query probability condition.

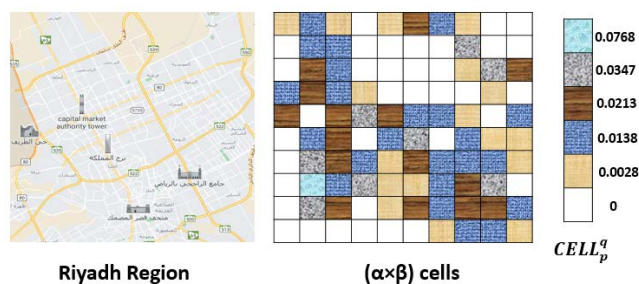

Fig. 13. Query Probabilities of Cells.

Fig. 14. Achieving Privacy Protection of 4 Levels.

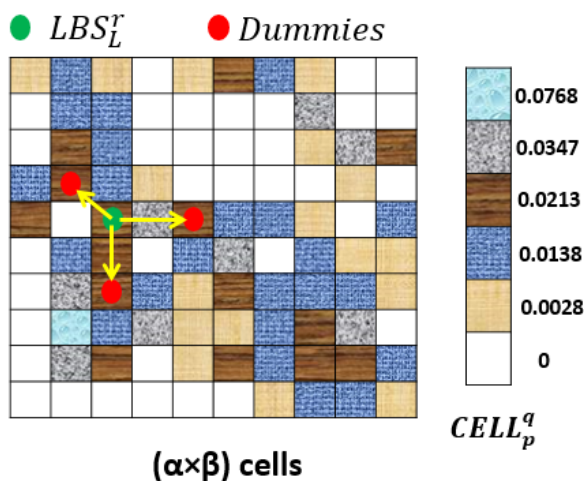

Fig. 15. Selecting Dummies Depending on the Same Query Probability Condition.

This method guarantees that the uncertainty (at the attacker's side) in determining the real location among the dummies is maximal. Mathematically, this uncertainty is represented by entropy. Entropy is a term that refers to the inability to determine an object among others based on the same features [26]. The entropy of identifying the real location out of the dummy vector  $ENT_{dv}^r$  is defined as:

$$ENT_{dv}^r = - \sum_{i=1}^{pl} CELL_{p_i}^q \times \log_2 \times CELL_{p_i}^q \quad (3)$$

where  $pl$  denotes the protection level of privacy.

Despite selecting dummies based on the query probabilities condition, the privacy threat remains. Selecting weak dummy locations creates a vulnerability where the attacker can apply MMA and SLA successfully. Weak dummies mean that the dummy locations are near the real location of the LBS user. This allows the attacker to filter dummies easily. This requires additional conditions in the process of selecting dummy locations. This condition states that the selected dummies must be far away from the real location of the LBS user, as shown in Fig. 16.

Fig. 16. Selecting dummies Depending on both the same Query Probabilities and Far away Conditions.

The actual selection process is performed by the intelligent finder component. Electing suitable dummies (i.e., strong dummies) requires an intelligent method. This intelligent method depends on scanning the covered region and then determining strong dummies. In this work, a deep learning method (the CNN network) with the help of SVM is employed to elect strong dummies to fill the vector of dummies.

The task of the CNN is extracting the features of a given geographic region (map). This is performed by scanning the map through two kinds of layers: convolutional layers and pooling layers. Fig. 17 illustrates the mechanism used by the CNN for extracting features of a given region.

As shown in Fig. 17, the CNN goes through the map in a convolutional manner (depending on a filter or kernel) to extract the first level of features. Then, the extracted features are grouped through a pooling layer to draw a deep look at the locations included in the map. This procedure (i.e., convolution and pooling) is repeated frequently for the series of extractions. The final pooling layer includes the final features. Among the extracted features, some locations are suitable to be strong dummies, while some are weak dummies. The SVM is linked to the fully connected layer to classify the locations into two main groups: strong dummies and weak dummies. SVM is an intelligent technique that separates a given set of data into two major classes. SVM relies on margin, which can be seen as a restricted area between the two classes. Fig. 18 shows the basic concept of SVM.

SVM is represented mathematically by the sigmoid function, which forms the (S) curve from a graphical perspective, as shown in Fig. 19.

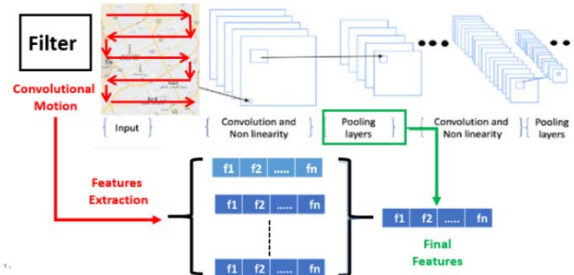

Fig. 17. Extracting Features of Map using CNN.

Fig. 18. Basic Concept of SVM.

Fig. 19. Sigmoid Function.

According to the sigmoid function, the complete CNN network will be seen as a classifier, where all values above (+) or lower than (0) represent strong dummies, and the area between the range [0, +1] represents the margin. Fig. 20 shows the complete CNN.

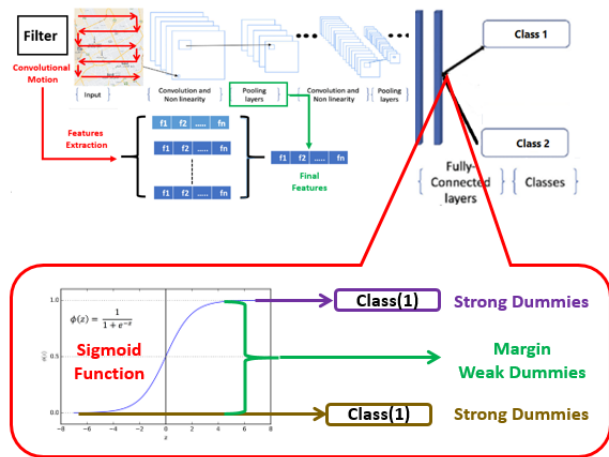

Fig. 20. Complete CNN Network.

Regarding the VoP approach, the complete CNN feeds it with a set of strong dummies. Let  $final_{CNN}^{dummies}$  denotes the final set of strong dummies. The vector of dummies is then filled by a random selection of dummies since they all satisfy the two conditions. The size of the VoP (or the number of selected dummies) is based on the privacy protection level that is desired. Mathematically,

$$VoP = random \{ final_{CNN}^{dummies} \} \quad (4)$$

The intelligent finder represented by the CNN is trained on the Brightkite dataset [27]. It consists of 7.3 million rows and five columns (user ID, check-in time, latitude, longitude, and location id). To involve query probabilities, we add a new column QP to the database. The values of the QP are generated randomly. Additionally, the Brightkite dataset is used for the testing stage. Therefore, the dataset is divided into two parts, as shown in Fig. 21.

Fig. 21. Dividing the Brightkite Dataset.

3) *Role of the query builder:* This component is responsible for building the protected query. It receives the vector of dummies generated by executing the VoP approach (the task of the intelligent finder) and then constructs the query. To add a second layer of privacy protection, another task is assigned to this component, which blurs the ID of the LBS user. To end this, the query builder components use an anonymity technique. The key idea behind the anonymity technique is to hide the ID of the LBS user by replacing it with a fake ID. Upon this, the query generated by the query builder component is constructed as shown in Fig. 22.

As shown in Fig. 22, the ID of the LBS user in the original query is replaced by a fake identity ( $\overline{ID}$ ). This adds additional protection to location privacy since the attacker (LBS provider) can recognize neither the real location among dummies nor the identity of the LBS user. Thus, the whole units of the protected query are given by:

$$Protected[Q_{LBS}] = \{ \langle \begin{matrix} \alpha & \beta \\ d_1^x & d_1^y \\ d_2^x & d_2^y \\ \vdots & \vdots \\ d_{pl}^x & d_{pl}^y \end{matrix} \rangle, S_{Pol}, D, \overline{ID} \} \quad (5)$$

4) *Role of the sender:* This component is responsible for sending the protected LBS query to the LBS provider for manipulation. Fig. 23 illustrates the task of the sender component.

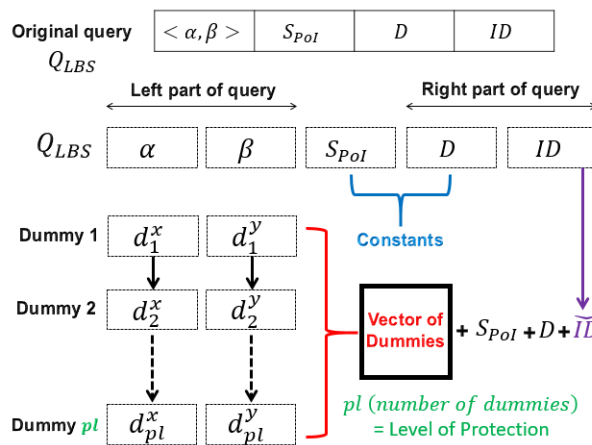

Fig. 22. The Query Builder Constructing a Protected Query.

Fig. 23. Sending a Protected Query to the LBS Provider (Attacker).

Manipulating the protected LBS query at the LBS provider-side leads to confusion. This is because the victim profile will be full of conflicting data that is not beneficial. Thus, the location privacy of the LBS user is protected against the LBS provider if it acts maliciously.

#### IV. SECURITY ANALYSIS

This section discusses the security analyses, where the issues are taken from the attacker's perspective. In this context, two main issues are involved, as shown in Fig. 24.

In regard to knowing the proposed approach by the attacker, a reversing trial is expected to be performed to filter dummies. Here, the power of the randomization process is employed. As mentioned in formula 4 above, the final set of dummies is selected randomly. This means that if 20 dummies are strong and can be used as actual dummies, 5 dummies can be selected randomly to be utilized as actual dummies to achieve a protection level of 6 degrees. Randomization ensures complete doubt about determining which of the 5 dummies are elected among the 20 dummies. This reflects uncertainty in the process of selecting dummies on the attacker side. As a result, the attacker can only randomly guess the real location among dummies. Thus, reversing the VoP approach fails to achieve the malicious goal of the attacker.

In regard to discussing the success of the MMA and SLA attacks from the perspective of the attacker, these attacks fail. The reason is that the VoP approach takes into account the  $CELL_p^q$ , where it is the same for all locations (the real and dummies). In addition, the dummies selected by the CNN are far from both each other and the real location. Therefore, attempting to collect the dummies in one region is inapplicable at the attacker side. This means that the success of the attacks will not be achieved.

Fig. 24. Issues of Security Analysis.

#### V. RESULT AND DISCUSSION

This section provides the results in the context of comparison with two approaches. The first approach is the classical one. A classical approach is an approach inspired by the proposed VoP approach, where the dummies are selected randomly without taking any optimization into account (i.e.,  $CELL_p^q$  and distance-relation between the  $LBS_L^r$  and the other dummies). The classical approach is referred to as the basic dummy approach (BDA). The second approach involved in the comparison is the one that is proposed in ref [20], which is DDA.

##### A. Evaluation Metrics

In this work, three types of metrics are used for evaluation, as shown in Fig. 25.

The privacy-based metric, entropy, which is defined above (by formula 3), is employed to measure the privacy protection level that is achieved. Entropy is a metric addressed by many authors who conducted surveys, such as [28- 32], and by others who made technical research papers, such as [33-36]. The mechanism of an evaluation relying on the entropy metric is adjusted by the following rules:

Fig. 25. Types of Evaluation Metrics.

- 1) There is no upper limit to the value of entropy.
- 2) There is no lower limit to the value of entropy.
- 3) A higher entropy value means a higher privacy protection degree.
- 4) A lower entropy value means a lower privacy protection degree.

For the deep-learning-based metric, an accuracy metric is utilized. Accuracy is a term that refers to the ratio of records (dummies) that are correctly classified (i.e., selected as strong dummies) [37]. The accuracy metric is inspired by a confusion matrix, a common term in the data mining research field [38]. Table II shows the confusion matrix (COFMX).

TABLE II. COFMX AND ITS COMPONENTS

| Actual dummy (Predicted dummy) | Confusion matrix          |                           |                 |
|--------------------------------|---------------------------|---------------------------|-----------------|
|                                | DM                        | $\neg$ DM                 | Sum             |
| DM                             | True positives DM (TPDM)  | False negatives DM (FNDM) | TPDM + FNDM = P |
| $\neg$ DM                      | False positives DM (FPDM) | True negatives DM (TNDM)  | FPDM + TNDM = N |

Where:

- 1) TPDM is a positive dummy that is correctly labelled by the CNN classifier.
- 2) TNDM is a negative dummy that is correctly labelled by the CNN classifier.
- 3) FPDM is a negative dummy that is incorrectly labelled positive.
- 4) FNDM is a positive dummy that is mislabelled negative.

Accuracy is given by the following formula:

$$Accuracy = \frac{(TPDM+TNDM)}{\text{number of all records/dummies in the testing set}} \quad (6)$$

The mechanism of evaluation relying on the accuracy metric is adjusted by the following rules:

- 1) There is an upper limit to the value of accuracy (1 or 100%).
- 2) There is a lower limit to the value of accuracy (0).
- 3) A higher accuracy value means a higher prediction degree.
- 4) Lower accuracy value means a lower prediction degree.

For the performance-based metric, time dominates the case. Thus, the total execution time ( $TexeT$ ) required to execute the approach is used. The  $TexeT$  is defined by:

$$TexeT = T_{VoP}^{exe} + 2 \times T_{query}^{send} + T_{query}^{processing} \quad (7)$$

where  $T_{VoP}^{exe}$  refers to the time of executing the proposed VoP approach at the smartphone of the user,  $T_{query}^{send}$  refers to the sending time of the query (assuming that the return takes the same time), and  $T_{query}^{processing}$  refers to the processing time at the server-side to answer the send query. The mechanism of evaluation relying on the  $TexeT$  metric is adjusted by the following rules:

- 1) There is no upper limit to the value of  $TexeT$ .
- 2) There is no lower limit to the value of  $TexeT$ .
- 3) A higher  $TexeT$  value means a lower performance degree.
- 4) A lower  $TexeT$  value means a higher performance degree.

### B. Entropy-Based Evaluation without Threats

Without applying any threat, the value of entropy is calculated to increase the protection level from 3 to 21 (i.e., from three dummies to 21 dummies). Fig. 26 shows the results.

Discussion and justifications: As shown in Fig. 26, the CNN-VoP and BDA approach experiences increased entropy values as the protection level increases. The reason is related to mathematical justification, where increasing the number of dummies involved in the protection level leads to an increase in the entropy value. However, the CNN-VoP approach achieves better scores than the BDA approach. This is due to selecting dummy locations under the control of  $CELL_p^q$  in the CNN-VoP approach. In contrast, no constraints are used in the BDA approach. For the DDA approach, its curve can be divided into three parts. The first part behaves the same as the

CNN-VoP and BDA approaches to increase the values of entropy. In the first part, the DDA sometimes overcomes the BDA depending on the tree that combines similar dummies, which in turn means that some dummies have  $CELL_p^q$  that are similar to the  $CELL_p^q$  of the real location or approximately close to it. In the second part, where PL=12, the DDA performs the worst. This is because there are no available candidates that can be used as actual dummies, and in this case, the DDA repeats the dummies, which negatively affects the entropy value. In the third part, the DDA enhances slightly, but the BDA outperforms it due to the broad set of dummies available compared to a limited set controlled by the DDA.

Fig. 26. Value of Entropy Metric vs. Increasing PL without any Threat.

### C. Entropy-Based Evaluation under Threats

After applying the MMA threat, the value of entropy experiences a decreasing trend compared to the normal situation; the attacker has no information about the geographic map from which LBS queries are sent. This is shown in Fig. 27.

Fig. 27. Value of Entropy Metric vs. Increasing PL under MMA Threat.

Discussion and justifications: As shown in Fig. 27, despite the negative impact of the MMA threat, the CNN-VoP approach maintained its peak position. This is because of the factors taken into account in the procedure for selecting the dummies, where (1) the  $CELL_p^q$  of each dummy is the same as the real location (which contributes to destroying the benefits that may be gained at the attacker side by analyzing the dummies if they are located in well-known areas) and (2) the dummies are spread over a wide space that cannot be collected in one area for malicious filtering by the attacker. The BDA scheme overcomes the DDA scheme since DDA is vulnerable to selecting the dummies based on area similarities. This gap can be exploited by the attacker to filter some dummies,

weakening the defense that is created by the DDA. In contrast, the BDA scheme ignores the similarities since it selects dummies randomly, avoiding the drawback of the DDA scheme. Table III shows the numerical results of the entropy metric.

The results summarized in Table III show that the BDA scheme experiences slight weaknesses against MMA attacks compared to a significant weakness in the DDA scheme.

For robustness against the SLA attack, Fig. 28 shows the documented results, where a severe negative impact is clearly seen in the DDA approach compared to the normal situation.

Discussion and justifications: As shown in Fig. 28, the common fact that "the value of entropy increases as the PL increases" is still working in all schemes involved in comparison. However, the entropy values are less when compared to the values under MMA threat, which reflects that the SLA is more dangerous than the MMA threat. Despite this change, the CNN-VoP scheme is still ranked at the top, followed by the BDA scheme. At the last position, the DDA scheme is coming. This scenario can be justified by the positive contribution of using CNN to scan and elect strong dummies for membership in the final set of dummies used for privacy protection. The BDA scheme ignores the factor related to elect dummies that achieve the condition of distance (i.e., long distances between the elected dummies and the real location). The DDA scheme employs none of the factors, and therefore, it performs the worst as a protection method. Table IV shows the entropy values after applying the SLA threat.

To address the difference between the MMA and SLA threats, Fig. 29 shows a visual representation of the entropy values documented in Table III and Table IV.

Table V shows the transformation of the visual representation of Fig. 29 into numeric values.

TABLE III. RESULTS OF ENTROPY IN THE THREE SCHEMES UNDER MMA THREAT

| Approach \ PL |                | 3     | 6     | 9     | 12    | 15    | 18     | 21     |
|---------------|----------------|-------|-------|-------|-------|-------|--------|--------|
| CNN-VoP       | Entropy Values | 1.658 | 3.046 | 4.208 | 6.046 | 9.987 | 11.587 | 13.508 |
| BDA           |                | 0.854 | 2.196 | 2.809 | 3.906 | 4.501 | 6.946  | 7.609  |
| DDA           |                | 0.427 | 1.078 | 2.145 | 2.578 | 3.150 | 5.347  | 6.005  |

Fig. 28. Value of Entropy Metric vs. Increasing PL under SLA Threat.

TABLE IV. RESULTS OF ENTROPY IN THE THREE SCHEMES UNDER SLA THREAT

| Approach \ PL |                | 3     | 6     | 9     | 12    | 15    | 18    | 21     |
|---------------|----------------|-------|-------|-------|-------|-------|-------|--------|
| CNN-VoP       | Entropy Values | 1.007 | 2.113 | 3.666 | 5.711 | 7.999 | 9.720 | 11.994 |
| BDA           |                | 0.700 | 1.539 | 1.999 | 2.878 | 3.332 | 4.448 | 5.996  |
| DDA           |                | 0.364 | 0.886 | 1.589 | 1.988 | 2.997 | 4.123 | 5.231  |

Fig. 29. Visual Representation of the Entropy values under MMA and SLA Threats.

TABLE V. DIFFERENCE IN ENTROPY VALUES AMONG THE THREE SCHEMES AFTER APPLYING MMA AND SLA THREATS

| Approach \ PL |                              | 3     | 6     | 9     | 12    | 15    | 18    | 21    |
|---------------|------------------------------|-------|-------|-------|-------|-------|-------|-------|
| CNN-VoP       | Difference of Entropy Values | 0.651 | 0.933 | 0.542 | 0.335 | 1.988 | 1.867 | 1.514 |
| BDA           |                              | 0.154 | 0.657 | 0.81  | 1.028 | 1.169 | 2.498 | 1.613 |
| DDA           |                              | 0.063 | 0.192 | 0.556 | 0.579 | 0.153 | 1.224 | 0.774 |

Table V shows that the SLA threat has a more negative impact on the privacy of LBS users than the MMA threat. This is because the attacker employs time usage and knowledge about the geographic map to attack privacy (or filter some dummies). Thus, it is recommended to pay more attention to the semantic location threat in the location privacy research arena.

#### D. Accuracy-Based Evaluation

For the accuracy of electing suitable (or strong dummy locations), Fig. 30 illustrates the output of the three schemes.

Discussion and justifications: As shown in Fig. 30, the CNN-VoP scheme performs the best, followed by the BDA and DDA schemes. The root reason for this is related to using SVM as a classifier in the structure of the CNN used to scan and discover the dummy locations. Due to the series of convolutional and pooling layers used in the CNN, effective features of the region that includes the real location of the LBS user are generated. Based on the extracted features, strong dummies that satisfy the two conditions are elected. This means that some strong base criteria are used in the CNN-VoP scheme compared to poor ones in the other two schemes. This helps to add another strong justification about the strength of the CNN-VoP scheme in deep learning. This, in turn, provides proof of why entropy values are higher in both cases (i.e., without a threat and under the threat of attack) discussed above.

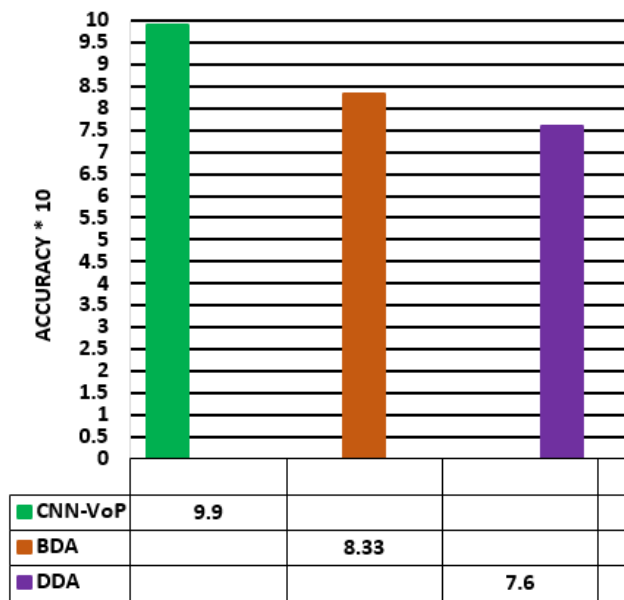

Fig. 30. Accuracy of Three Schemes

### E. Performance-Based Evaluation

According to the increased number of sent  $Q_{LBS}$ , the total execution time is calculated for the three schemes, as shown in Fig. 31.

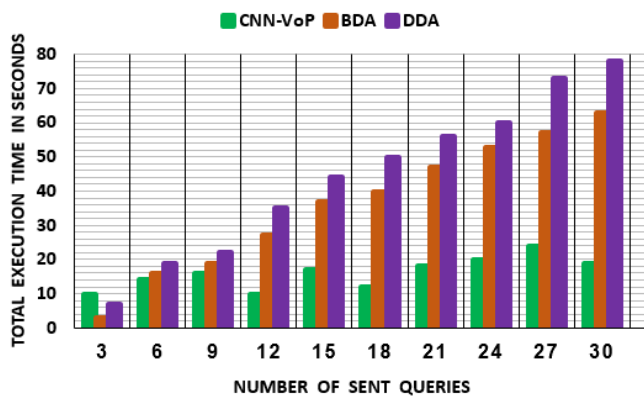

Fig. 31. Performance of Three Schemes in Terms of  $TexeT$ .

Discussion and justifications: As shown in Fig. 31, the CNN-VoP scheme performs the best compared to the BDA and DDA schemes, except at the beginning, where it is the worst. The reason that the CNN-VoP scheme performs the worst at the beginning is related to the training stage, where it still has no knowledge and requires much more time. During this period, the BDA scheme selects the dummies randomly, which is a fast method and leads to the shortest time. The DDA scheme consumes some time to construct the tree of dummies and thus comes after the BDA. After that, when increasing the number of sent queries,  $TexeT$  increases in all schemes. However, the CNN-VoP scheme achieves the best performance since, after the training completes, it can select dummies directly based on a knowledge database. The BDA scheme returns to the second-order, while the DDA performs the worst (the longest time). This is related to a common problem when using a decision tree, which is an overfitting problem. This

means that the process of constructing the decision tree requires manipulating all branches without ignoring any branches. This consumes substantial time and leads to poor performance by the DDA scheme. In terms of average,  $TexeT = 17 \text{ sec}$  for the CNN-VoP scheme,  $TexeT = 47 \text{ sec}$  for the BDA scheme, and  $TexeT = 67 \text{ sec}$  for the DDA scheme.

### VI. CONCLUSION AND FUTURE WORK

Recently, the world witnessed a widespread COVID-19 pandemic which changed the way people performed daily tasks. In this context, and to avoid infection, people tended to use location-based services (LBSs), which have received great attention from companies and research groups. Relying on an LBS opens the door for attackers to attack the privacy of LBS users since performing tasks requires sending the user's real location. The problem is accentuated concerning advanced methods that attackers can use, such as Map Matching Attacks (MMAs) and Semantic Location Attacks (SLAs). The privacy of LBS users will be under great threat if the LBS provider acts as an attacker and can apply MMA and SLA attacks. In responding to this challenge, this work presents a location privacy protection system. The system consists of three main components. The first component is the intelligent finder. The role of the intelligent finder is to find (or select) strong dummy locations for privacy protection against the malicious party (the LBS provider), such that the attacker will be confused about determining the real location of the LBS user among the dummies. The intelligent finder uses a deep learning technique, which is the Convolutional Neural Network (CNN). The CNN is employed to create a classifier that classifies locations found in the region where the LBS user is located into the categories of weak and strong dummies. After creating the strong dummy category, a Vector of Protection (VoP) approach is performed. Strong dummies satisfy two main constraints: (1) the query probability of each selected dummy is the same as the real location, and (2) they are spread away from each other and the real location. The previous two constraints ensure high resistance against advanced MMA and SLA threats. The second component is the query builder, which is responsible for (1) constructing the protected query based on the selected strong dummies and (2) hiding the identity of the LBS user. The third component is the sender, which is responsible for sending the protected query to the LBS provider. The proposed location privacy protection system is evaluated according to entropy (the privacy protection metric), accuracy (the deep learning metric), and total execution time (the performance metric). Compared to well-known systems, which are the DDA and the BDA, the proposed system shows better results, where entropy = 15.9, accuracy = 9.9, and total execution time = 17 sec.

Limitation: Privacy protection for an LBS considers location privacy and query privacy; the sent query can be analyzed depending on the query sampling attack. In attacking query privacy, the attacker relies on the PoI as well as its link with the locations. In this work, query privacy was not taken into consideration.

Future work: In future work, we will enhance the proposed system to ensure comprehensive privacy protection in LBS

applications (i.e., ensuring both location privacy and query privacy). In addition, we will test the system using different databases for training the intelligent finder and use another advanced intelligent method, such as advanced clustering.

# A Conceptual User Experience Evaluation Model on Online Systems

Norhanisha Yusof<sup>1</sup>, Nor Laily Hashim<sup>2</sup>, Azham Hussain<sup>3</sup>

Department of Information Technology and Communication, Politeknik Balik Pulau, Penang, Malaysia<sup>1</sup>  
School of Computing, Universiti Utara Malaysia, Kedah, Malaysia<sup>2,3</sup>

**Abstract**—An online system has become a priority for organisations or companies in many countries, as it allows many processes to be conducted via online platforms, which contributes to profit gain. There are different types of user experience (UX) evaluation models that have been proposed to guide the measurement and development process. However, most of these models only have dimensions, and there is no guidance for UX measurement on online systems. The lack of evaluation models for online system measurement requires further investigation. This paper aims to identify the gaps in UX evaluation models, and develop a conceptual UX evaluation model for online systems. The method used in this study includes reviewing several literatures and shortlisting the relevant publications on UX and online systems. After that, the gaps were identified from the existing UX evaluation model in the relevant publications based on the ISO standard. Then, the study identified the important components of UX, and proposed a new conceptual UX evaluation model for online systems. The results of the study are the identification of the gaps in existing UX evaluation models, and the development of a new conceptual UX evaluation model that is specifically for online systems. Therefore, the results help in considering UX dimensions, criteria, and metrics and potential UX components for evaluation and measurement. The paper contributes to system developers, designers, and also researchers for future UX evaluation model development for online systems. Future studies could use the reviewed UX evaluation models to identify relevant dimensions of online systems, and hence improve the model that they will develop. The findings may also be beneficial to organisations that own online systems by providing guidelines on important dimensions involved in their UX-based evaluations.

**Keywords**—User experience; UX evaluation; UX model; online system; conceptual model

## I. INTRODUCTION

Since the beginning of the millennium, computers have been widely utilised in various countries, resulting in a revolution in information and communication technology (ICT), known as the digital revolution. The digital revolution has rapidly grown in developed countries, where there are various applications or electronic systems in use. Nowadays, an online system is one of the most important applications of ICT that has become a priority in all systems around the world. An online system is a platform used by any individual or organisation to perform their work through the Internet, whereby it is flexible and accessible to users [1]. Online systems might be totally secure, or could allow third-party programmes to join via programming platforms. Online systems are useful tools for storing, organising, utilising, and

gathering data. Nowadays, online platforms have been modernised, whereby the users can have access to all information at their fingertips. The users use the Internet in their daily lives to get information, shop, and communicate with chosen online systems. This priority is quickly expanding in emerging countries because it can help manage any transaction easily. Many governments and businesses support the delivery of online systems, which allows them to leverage existing technology transactions and interactions with higher efficiency and easy access [2]. There are many online systems; for example, eBay, Craigslist, Amazon Marketplace, Airbnb, and Uber [3], [4]. An online system is not only for business purposes, but it is also for government systems, such as e-government [5] and e-procurement system, because it can integrate the use of ICT to improve customer, supplier, and other relationships [6].

The study of online systems is a significant part of today's economy. For example, the potential of an online system to contribute total profitability to governments and companies is enormous. It is important to remember that every dollar saved in terms of cost because of using an online system can directly contribute to the productivity of the country. The study of online systems is significant for a variety of reasons, including the fact that many industrialised countries and business companies use them to manage relationships with their users [4]. The benefits of online systems are as follows: easy to use, quick response time, automatically processed via technology, and faster in terms of accessing information because it is online worldwide.

User experience (UX) is the perception and reaction of real-world users towards real products and services. UX, as defined by ISO 9241-11 (2018), which is the perceptions and responses of a person as a result of the use or anticipated use of a product, system, or service [7]. Besides that, UX is also related to users' emotions, beliefs, and physical and psychological responses. It also incorporates brand image, presentation, system performance, and physical state as a result of earlier experiences, attitudes, skills, and personality, among other things [8]. The term UX is most commonly associated with the design and presentation of online software solutions such as websites and applications [9]. Thus, UX is an important factor in creating quality products, systems, and services, especially for online systems because many users use online platforms in their daily lives and the impact needs to be known through an evaluation. UX evaluation is one way of analysing individuals' experiences [10]. UX evaluation is a burgeoning field with a wide range of approaches [11]. One of the most important

aspects of studying UX is evaluation, which refers to the use of a set of procedures and tools with the goal of determining how people feel about using a system or product [8].

However, there is a lack of investigation of the user experience related to an online system in literature as explored by the authors. For example, the study by [12] explored the emotions of online learning systems among college teachers, and proposed an integrated model of Technology Acceptance Model (TAM); however, they emphasised on identification of technology usage intentions among the teachers, and the study did not involve UX dimensions except emotion only. There are also some researchers who focus more on factors influencing UX [13] but overlooked UX evaluation, including coming up with a conceptual UX evaluation model for an online system with important measurements. Besides that, the study by [14] proposed a conceptual model for UX whereby it is related to the process of UX practices in organisations. The model does not focus on evaluating UX of online systems and does not discuss the model in terms of UX components from instrumental and non-instrumental qualities perspectives. UX components can be defined as important aspects of human-technology interaction [15]. For example, instrumental and non-instrumental qualities are important in a UX model measurement because they are core components of experiences related to the user perception including emotion while users are using the system [16]. On the other hand, [17] have developed a new conceptual UX model for evaluation that focuses on workers' performance evaluation, and not on the online system. Furthermore, the need to conduct this study is motivated by the lack of existing models that were more focused on specific systems such as e-commerce [18], e-banking [19], and mobile [20]. Furthermore, these studies do not provide clear and comprehensive measurement for general online systems.

The gaps discussed above have motivated the authors to study UX that is related to online systems by identifying the required dimensions and main components of the conceptual model that can be referenced for UX measurement on online systems. Therefore, the gaps in existing UX evaluation models need to be identified with a conceptual UX evaluation model development for a better measurement.

The objective of this current research is to identify the gaps in the existing UX evaluation models and develop a conceptual UX evaluation model for online systems. The research questions (RQ) addressed in this paper is as follows:

RQ 1: What are the gaps in UX evaluation model for online systems?

RQ 2: What are dimensions of a conceptual UX evaluation model for online systems?

This paper is organised as follows: Section 2 presents the background of online systems and relates to a user UX; Section 3 discusses the methodology of the study; Section 4 discusses the results and discussion regarding existing UX evaluation model including conceptual model development; and Section 5 provides the concluding remarks and future work for this paper.

## II. BACKGROUND

This section presents the research studies in the literature related to UX evaluation, which covers the content. The gaps in the existing UX evaluation models discovered in the literature review are considered in the newly developed conceptual UX evaluation model for online systems.

### A. Evaluation

UX has become a more prominent part of system development, following the growth of business and process models. UX is influenced by the user's internal state, for example, individual motivations, expectations, needs, and mood; the characteristics of the system being used, such as complexity, usability, and functionality; and it is also associated with interactions of the context or environment with the system [21]. The analysis of user interaction related to web systems is crucial for satisfaction, and it may even encourage changes to improve UX level [22]. There are five points in UX concepts, which are understanding of research, sketch, design, implement, and evaluation [1]. One of the pillars of academic UX research has been identified as evaluation [11]. The experience evaluation is crucial for UX practitioners in the workplace [11]. UX evaluation depends on the components or factors that exist in the models [23]. Thus, UX encompasses product aspects and individual aspects, whereby these consist of users' perception such as pragmatic and hedonic quality, aesthetics, user's emotional experiences, expectations, and needs [21].

In the literature review, many UX evaluation studies of online systems only have dimensions and criteria [15], [18]–[20], [24]. However, they are lacking the UX dimensions, criteria, and metrics in the UX evaluation models. Having the dimension, criteria, and metric of the model for measurement is important because the organisation or stakeholder can have a clear understanding of how to conduct an evaluation of the product or system usage more specifically. Furthermore, there is a need for conceptual UX evaluation models for online systems because this model fills the gap in the literature of UX and online systems, including providing important dimensions; and it is also due to the studies on UX evaluation that did not define additional concrete UX dimensions [11]. Moreover, the conceptual UX evaluation model was developed since there was a lack of user experience studies on online systems after the publication review was conducted by the researcher. From the reviews conducted on this domain and to the best of the authors' knowledge, there is no work focused on the UX evaluation model for online systems yet. Furthermore, UX is still a blurred conceptualisation, causing the need for this study to be conducted [9]. Therefore, this study has developed a conceptual UX evaluation model for online systems.

### B. UX of Online Systems

With the growth of Information and Communication Technology (ICT) nowadays, information can be obtained through an online system, social media, chat, and others [25]. Through the circulation of technology nowadays, many organisations or companies use online system platforms for various processes and transactions. It is publicly accessible, open, and more convenient. Thus, the user experience should be designed for human use as well, with easy access and

assistance for user limitations such as reading small texts [1]. However, there is still a lack of research conducted related to UX and evaluation for online systems. From a conceptual standpoint, different researchers have varying interpretations of what UX is to suit their studies and application needs. Some studies argue that UX is holistic; others suggest that the complexity of experience should be broken down into evaluative components.

Based on the analysis of the existing models, it has been noted that the field of UX research should also be given attention in terms of measurement models [13]. UX can be associated with users' affective, cognitive views such as hedonic quality, attractiveness, and the subjective perception made by the users of a product, system, or services [9]. However, additional research is needed into how these qualities with UX dimensions can be represented in a more precise manner. Moreover, certain important dimensions that have a significant impact on user experience remain implicit in certain models [13]. Thus, a conceptual model for UX modelling should be established to comprehend, explore, and analyse interactions between users and products [13]. Defining a conceptual UX evaluation model can be considered by incorporating UX dimensions, criteria, and metrics in modelling and reflecting elements that have a direct impact on the user experience and online systems. The author in [17] developed a new conceptual UX model for evaluation called the TAMUX model, but it is for workers' performance evaluation and not for online systems. TAMUX is the combination of the Technology Acceptance Model (TAM) and the Components of user experience (CUE) model. The weaknesses of the conceptual model by [17] is it is lacking in terms of dimensions with criteria because it only has components such as task characteristic, individual characteristic, system characteristic, and performance effect.

Meanwhile, the current study by [25] conducted an evaluation of an online learning programme to investigate user experience improvement. However, the evaluation in Chow's research is more concerned about usability with the five dimensions of learnability, efficiency, memorability, errors, and satisfaction. There is no conceptual UX model that can be used or referred to for online system measurement. Therefore, these studies show the need for a conceptual model that consists of UX dimensions, criteria, and metrics because the measurement can be conducted in a more clearly and directed manner. Moreover, the development of conceptual the UX evaluation model also helps or enables organisation or business stakeholders to define and redefine the metrics in order to improve their user interface and users' experience [26]. The next section will discuss further on methodology and analysis of findings to answer the RQ as stated in the earlier section.

### III. METHODOLOGY

This study used online databases such as 'Scopus' and 'Elsevier Science Direct' to search for previous literature. The searching technique in this study is referring to [27] study as a guidance. The review considers publications on user experience, UX, models, and systems for nine years from January 2013 to 15 October 2021. Only articles written in English and final published journals were considered for this

study. Keywords such as 'user experience', 'UX', 'model', and 'online system' were used to search for articles in databases. 'Paper title' or 'abstract' or 'paper keywords' were the search criteria. The researcher found an entire list of all relevant publications by using multiple keyword combinations. From all these databases, the initial search yielded roughly 503 research publications.

Then, 503 of these papers were screened based on title and abstract. The screening method eliminated articles such as reports, book reviews, and review papers. The papers that passed the screening were subsequently scrutinised for appropriateness for online systems by evaluating a manuscript. Approximately 227 papers were screened through manuscript review and selection criteria. Then, only six papers were shortlisted and further investigated after reading the entire text. After completing the reading, irrelevant publications were filtered out based on the scholarly judgement. The result of final papers shows that there is a lack of UX model evaluation for online systems. Table I shows the results of the final review from databases, which resulted in a final shortlist of six relevant publications by the authors. While Fig. 1 shows the flow of literature review method.

TABLE I. REVIEW PAPERS FROM DATABASES

| Databases               | Keyword used                                      | Result based on keyword | Result based on title and abstract | Final shortlist |
|-------------------------|---------------------------------------------------|-------------------------|------------------------------------|-----------------|
| Scopus                  | 'user experience' AND 'model' AND 'online system' | 105                     | 24                                 | 4               |
|                         | 'UX' AND 'model' AND 'online system'              | 3                       | 0                                  | 0               |
| Elsevier Science Direct | 'user experience' AND 'model' AND 'online system' | 337                     | 192                                | 2               |
|                         | 'UX' AND 'model' AND 'online system'              | 60                      | 11                                 | 0               |
| Total                   |                                                   | 503                     | 227                                | 6               |

After conducting a final review of relevant publications related to online systems, the authors analysed the papers in terms of domain of UX Model, instrument used, number of participants, and dimensional measurement, which are based on System and software Quality Requirements and Evaluation (SQuARE) such as Measurement of quality in use (ISO 25022:2016) and Measurement of system and software product quality (ISO 25023:2016). These two ISOs were used as a guidance to determine the dimensions that have similar descriptions in the various existing UX evaluation models, and to ensure consistency of the terms used in the identification of common dimensions in this domain. ISO standards are widely used in the field of Human-Computer Interaction (HCI) [28]. The current study has reviewed six papers that were shortlisted in order to identify the gaps in the existing UX evaluation models and to answer research question 1 (RQ 1). Meanwhile, the components of a conceptual UX evaluation model for

online systems have been developed based on the gaps identified and included the important dimensions from the literature in order to answer the RQ 2. Therefore, the study answered the RQ by conducting the paper review, identified the gaps, and then developed a new conceptual UX evaluation model.

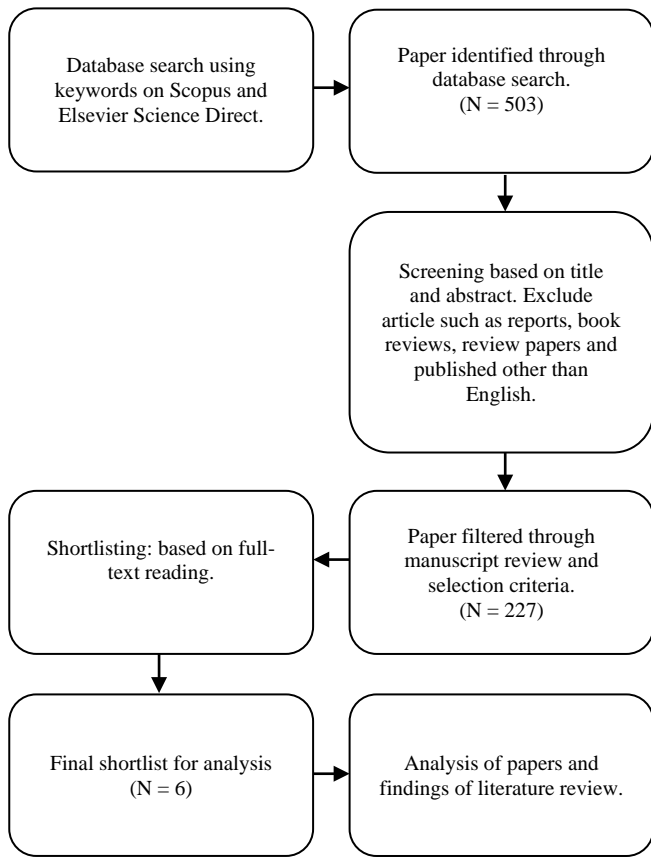

Fig. 1. Flow of Literature Review Methodology.

#### IV. RESULT AND DISCUSSION

There are various UX evaluation models or frameworks in the literature that have been introduced. However, these models are inadequate for online system measurement because these models are lacking in terms of important dimensions, criteria, and metrics. This study used ISO 25022:2016 and ISO 25023:2016 as guidance by referring to their description and categorisation of the dimensions in the UX evaluation model since there are various dimensional measurements in the literature. This section discusses existing UX evaluation models in the literature that have been identified in Section 3, and a summary of these models is presented in Table I by extracting important aspects such as domain of UX Model, instrument used, number of participants, dimensional measurement, other dimensions used (Based on ISO 25022:2016 and ISO 25023:2016), and the identified remarks or gaps.

##### A. E-commerce’s UX Evaluation Model

In the work by [18], it is mentioned that improved user experience can attract new users, increase visitor numbers, and transaction volume of the system. The model was developed to

evaluate e-commerce websites. The study’s strength is that it employs the Fuzzy Comprehensive Evaluation Method, which improves the model by implementing specific steps to enable systematic evaluation, including the use of triangular fuzzy number theory, methods of psychological stratification, and weighting factors. Six experts in the field of e-commerce evaluated the model. The model developed by [18] consists of three dimensions: Visceral, behavioural, and reflective, and has verification. Based on ISO 25022:2016 and ISO 25023:2016, this model has emotional and functionality dimensions. However, this model does not provide dimension with criteria, and no metric is provided for online system measurement. Besides that, among the weaknesses of the model is that information can be lost by criteria’s aggregation as it is based on probability and possibility measurement [through Analytic Hierarchy Process (AHP)] [29], [30]. Therefore, there is a need to provide dimensions, criteria, and metrics of the proposed model for online systems because these three components will provide clear measurement for evaluation. Fig. 2 shows the model developed.

##### B. Testing of UX Model with News Sites

The study by [15] has established a model that constitutes a fundamental theory for evaluating news websites, and is theoretically applicable to all UX studies. The model is expanded to estimate how satisfied users are with news websites. Instrumental qualities, non-instrumental qualities, and emotional responses are among the UX components that exist in this model. The strength of the model is determined by the measurement of instrumental qualities and non-instrumental qualities using AttrakDiff2 [31]. Meanwhile, emotional responses are measured through the Positive and Negative Affect Schedule (PANAS) elements [32]. Based on the ISO standard, this model consists of usefulness, emotional (ISO 25022:2016), and trust dimensions (ISO 25023:2016). However, the weaknesses of this model are broad measurements. For instance, pragmatic and hedonic qualities do not have criteria and metrics that are specifically for evaluation measurement. The model is also only for testing news sites and online news. Therefore, there is a need to provide dimensions, criteria, and metrics of the proposed model for online systems. Fig. 3 shows the developed model for testing news sites.

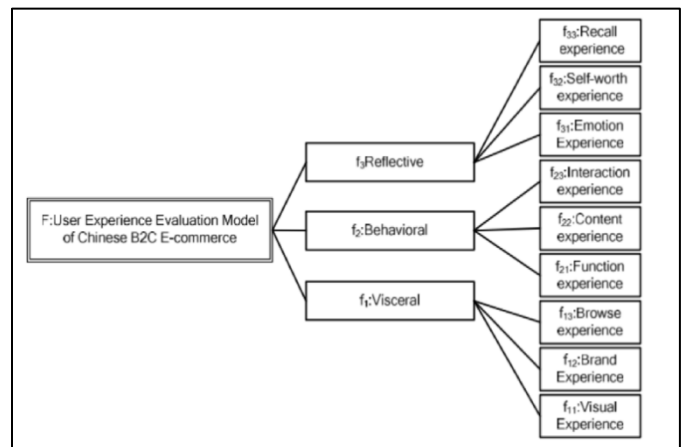

Fig. 2. Improved Hierarchical Model of p E-commerce’s [18].

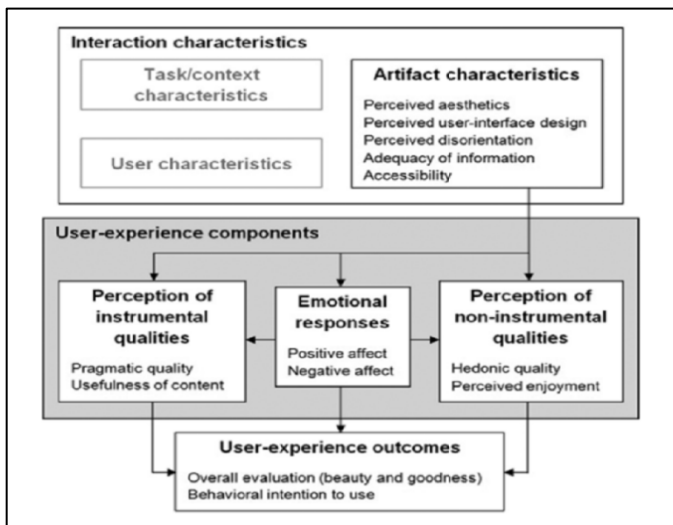

Fig. 3. High-Level Representation of the Model of UX with News Sites [15].

### C. Security and Usability Evaluation Model for e-Banking

The work by [19] investigated frameworks or models, including approaches for evaluating e-banking security and usability. Their study combines a collection of frameworks that were related to security and usability properties such as the following: (1) interface; (2) navigation; (3) content; (4) offered services; (5) registration and transaction procedure; and (6) multi-factor authentication methods. This combination is called the hybrid security and usability evaluation model. Based on the ISO 25023:2016 standard, this model consists of usability and security dimensions. The strength of this model is it is able to evaluate e-bank assets that are accessible to the public, and it covers 13 different security and usability categories with more than 160 metrics. Finally, this model comprises the security evaluation part of the framework with 72 metrics, and usability evaluation part with 97 metrics. However, the weakness of this model is the unclear presentation of dimensions in the model with criteria and metrics. Moreover, security and usability evaluations are required to be considered in the quality improvement process; thus, these dimensions need to be designed and tested as part of the quality improvement process in order to ensure their coherence with other parts of the process [19]. Therefore, it can be concluded that the presentation of this model can be improved for evaluation and online system measurement. Fig. 4 shows the proposed security and usability evaluation model.

for the edutainment field. Moreover, the model can be used in a variety of disciplines, including industrial and collaborative settings. Based on the ISO standard, this model consists of emotional (ISO 25022:2016) and usability dimensions (ISO 25023:2016). However, the weaknesses of this model are this model is general due to the lack of criteria and metrics that link to the dimensions. The measurement for the online system should be clear in order to get better results for evaluation. Therefore, the dimensions, criteria, and metrics of the proposed model for online systems are required. The UXIVE model is depicted in Fig. 5.

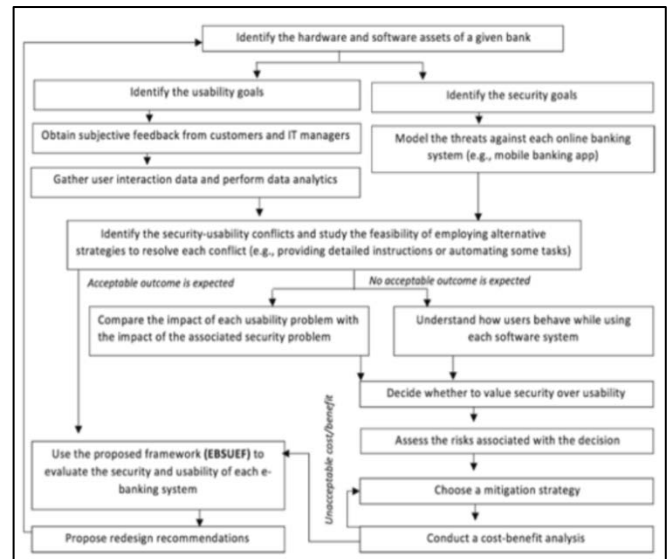

Fig. 4. The Proposed Security and usability Evaluation Model [19].

### D. Evaluation of the Modified Immersive Virtual Environment (UXIVE) Model

The UXIVE model has been introduced by [24], in which the constructed model components are derived from existing models. The method used was quantitative (questionnaire), and the findings were analysed for model validation using Structural Equation Modelling (SEM). The sample size is large (152 respondents); thus, SEM has been employed for statistical analysis. The strength of this model is validated, which comprises ten new UX dimensions, namely presence, immersion, engagement, skill, emotion, flow, usability, technology adoption, judgement, and experience consequence

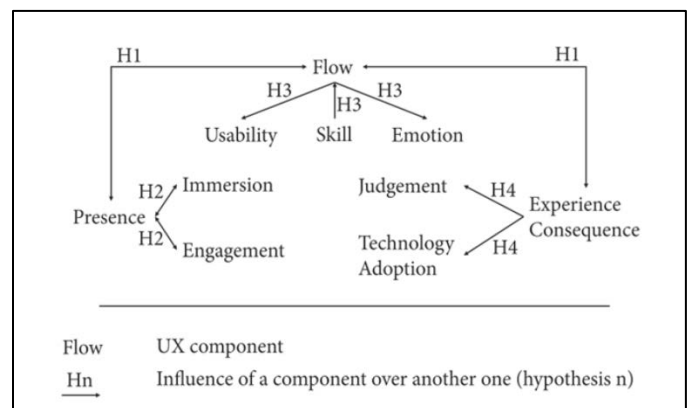

Fig. 5. The Hypothesised UXIVE Model [24].

### E. UX Evaluation Model on Mobile Terminal Products

The Content Interaction Vision Model (CIV Model) was developed by [20]. Content, interaction, and vision are the three UX dimensions of the CIV model. Their study examines the important dimensions by using the Heuristic evaluation approach and Nielsen's ten (10) usability principles. The strength of the model is that the results of the dimensions are displayed in the form of a radar chart, which uses a set of questionnaires from the System Usability Scale (SUS) for the evaluation. Based on ISO 25023:2016, this model consists of functionality and usability dimensions. In the same vein, the

study by [33] also used SUS and proposed the UX Maturity Model for e-commerce websites, which focused on the three cores of user experience, namely user research, visual design, and user testing. This shows that the UX evaluation conducted with other instruments could strengthen the findings of the study. However, Huang *et al.*'s [20] model evaluation focused more on the usability principle in order to construct the CIV evaluation method and it has a subjective metric. Moreover, this model has no verification for the feasibility of the evaluation model. Therefore, it is necessary to identify the appropriate dimension, criteria, and metrics for online systems to get clear measurement of evaluation regarding user experience (UX). Fig. 6 shows the CIV Evaluation Model of User Experience.

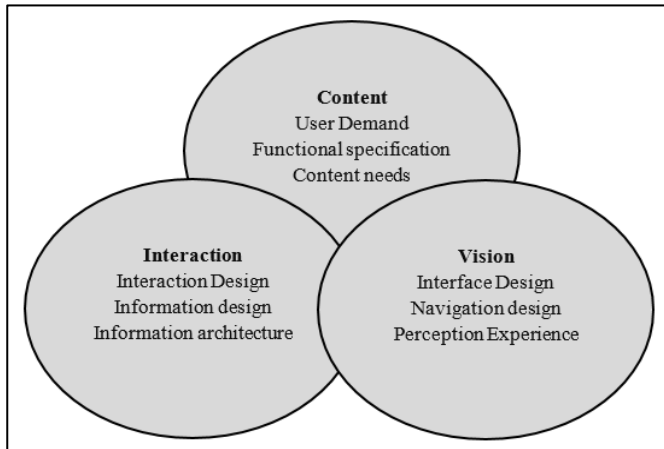

Fig. 6. CIV Evaluation Model of user Experience [20].

#### F. Loyalty Model for E-commerce Recommender Systems

The study by [34] about the use of an e-commerce recommender agent explores the major determinants in the establishment of female online shopper loyalty. Then, a new model is introduced, developed, and analysed in order to improve e-commerce consumer loyalty via the recommender systems. The strength of the model is the use of SEM to analyse the relationships between independent and dependent variables for quantitative research. Their study used the SEM tool because it combines factor analysis, path analysis, and multiple regression analysis to evaluate construct relationships [34]. Moreover, based on ISO 25023:2016, the dimensions in this model that were measured are usability, transparency, satisfaction, and trust. However, this model did not provide clear criteria and metrics for evaluation, which consists of dimensions and relationships for each construct. Their research also has some limitations in terms of data dissemination and collection because the evaluation only involved one e-commerce platform, whereby it could not be generalised to the population studied. In addition, the proposed model requires two items: Experience and search-characteristic products for

future research [34]. Therefore, there is a need for dimensions with criteria, and metrics of the model as well as a need to consider the experience element of the model in future research. Fig. 7 shows the Loyalty Model for E-commerce Recommender Systems. Meanwhile, Table II shows the summary comparison of existing UX evaluation models or frameworks identified.

Based on the model analysis in Table II above, the models were purposely developed for e-commerce [18], testing a news site [15], e-banking system [19], edutainment [24], mobile terminal products [20], and an e-commerce recommender system [34]. Thus, there is no generic online system measurement that can be used as each one is tailored to a specific system. This means that existing UX models are more focused on systems such as e-commerce, e-news, e-banking, and mobile product but there is no guided measurement for online system as overall such as for online reservation, online booking including e-government, e-procurement.

The model by [15] has provided subjective metrics, but it is for news websites. Meanwhile, Huang *et al.* [20] did not present how they performed verification for the feasibility of the evaluation model. In addition, the [34] model does not have criteria for the measurement. Moreover, the model by Liu *et al.* [18], Alarifi *et al.* [19], and Tcha-Tokey *et al.* [24] also did not provide metrics for UX evaluation. The dimensions with criteria and metrics in the existing model are lacking in order to give clear description to the users about the measurement and conducting evaluation. Thus, these studies show that there is a lack in terms of dimensions with criteria and metrics in the existing models that are specifically for online system measurement. Hence, this current study motivates the researchers to develop a new conceptual UX evaluation model for online systems by identifying the important dimensions for better measurement.

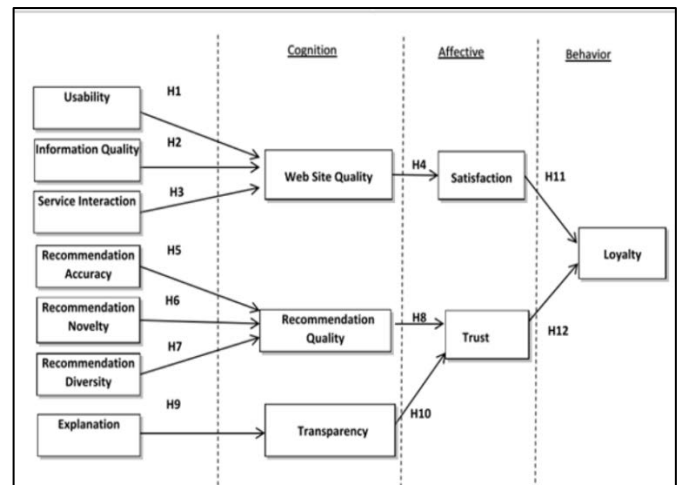

Fig. 7. Loyalty Model for E-commerce Recommender Systems [34].

TABLE II. THE SUMMARY COMPARISON OF EXISTING UX EVALUATION MODELS OR FRAMEWORKS

| Authors                       | Instrument and Number of Participants       | Dimensions that measured                                                                                  | Other Dimensions (Based on ISO 25022: 2016 and ISO 25023: 2016) | Remarks/ Gaps                                                                                                                    |
|-------------------------------|---------------------------------------------|-----------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Liu <i>et al.</i> [18]        | Questionnaire (6 experts)                   | Visceral, Behavioural, Reflective.                                                                        | Functionality, Emotional.                                       | No UX metric provided in the model.<br>Model for e-commerce site.                                                                |
| Aranyi and van Schaik [15]    | Questionnaire AttrakDiff2, PANAS (85)       | Ease of use, Perceived Enjoyment, Beauty and Goodness, Behavioural intention.                             | Usefulness, Trust, Emotional, Satisfaction.                     | Has subjective metrics but it is for news websites.<br>Model for designer (online news or interactive product)                   |
| Alarifi <i>et al.</i> [19]    | Users using web portals from the five banks | -                                                                                                         | Usability, Security                                             | Do not provide criteria and metrics of model.<br>Does not provide any prioritisation of metrics.<br>Model for e-banking systems. |
| Tcha-Tokey <i>et al.</i> [24] | Questionnaire (152)                         | Presence, engagement, immersion, flow, skill, experience consequence, judgement, and technology adoption. | Usability, Emotional                                            | Only have UX dimensions.<br>No metrics provided in the model.<br>Model for edutainment field.                                    |
| Huang <i>et al.</i> [20]      | Experiment (10)                             | Content Interaction Vision                                                                                | Functionality, Usability                                        | No verification for the feasibility of the evaluation model.<br>For mobile and design of online product only                     |
| Ali <i>et al.</i> [34]        | Survey questionnaire (300)                  | Web Site Quality, Recommendation Quality, Loyalty                                                         | Usability, Transparency, Satisfaction, Trust                    | Has dimensions whereby it is a construct, but do not have criteria.<br>Model for e-Commerce Recommender Systems.                 |

Moreover, it also shows that there are various dimensions measured by the existing models, and the researcher used the ISO standard such as System and Software Quality Requirements and Evaluation (SQuaRE) which Measurement of quality in use (ISO 25022:2016) and Measurement of system and software product quality (ISO 25023:2016) as a guidance in order to identify and categorise appropriate UX dimensions that are similar to each model. Thus, the models by Alarifi *et al.* [19], Tcha-Tokey *et al.* [24], Huang *et al.* [20], and Ali *et al.* [34] have similar descriptions of dimensions, for example, usability. Meanwhile, the model by Liu *et al.* [18] and Huang *et al.* [20] have the functionality dimension. Besides that, the emotional dimension has been measured by the model by Liu *et al.* [18], Aranyi and van Schaik [15], and Tcha-Tokey *et al.* [24]. Furthermore, the model by Aranyi and van Schaik [15] and Ali *et al.* [34] have the trust and satisfaction dimension in their measurement. Therefore, this argument shows that the common UX dimensions for evaluation for online system measurement are usability, functionality, emotional, trust, and satisfaction. These dimensions can be considered in measurement for online systems.

On the other hand, based on ISO 25022:2016, the usability characteristic comprises efficiency, effectiveness, and satisfaction, whereby these dimensions can be considered in the model for online system measurement. However, from the analysis that has been done, the measurement of these

dimensions requires UX components, so that the evaluation of users can be conducted more accurately and correctly, for example, considering the pragmatic and hedonic qualities with UX metrics. Based on Fig. 8 below, it shows the gaps flow from existing UX evaluation models that were derived from Table II. The purpose of this figure is to provide an overview of the models that have been identified from the literature, including the gaps and the requirements of the developed conceptual UX evaluation model. As mentioned earlier, this study identified six existing evaluation models related to user experience and online systems. The flow in Fig. 8 shows that the UX evaluation model requires UX dimensions, criteria, and metrics for the model of online systems in order to get a clear measurement illustration.

Besides that, the findings also revealed that any development of the UX evaluation model for online systems should consider prioritisation for the metrics because it will determine which dimensions need to be prioritised for the evaluation measurement [19]. Furthermore, there is a need for the verification for the feasibility of the model to be concerned in any UX evaluation model development. The existing UX model is also still not focus on measuring emotions. Therefore, it can be concluded that there is a need for dimensions with criteria and metrics for online system measurement. Among the dimensions that can be considered in the measurement are efficiency, effectiveness, satisfaction, functionality, emotional, and trust. Thus, these findings addressed important components with justification for an online system measurement.

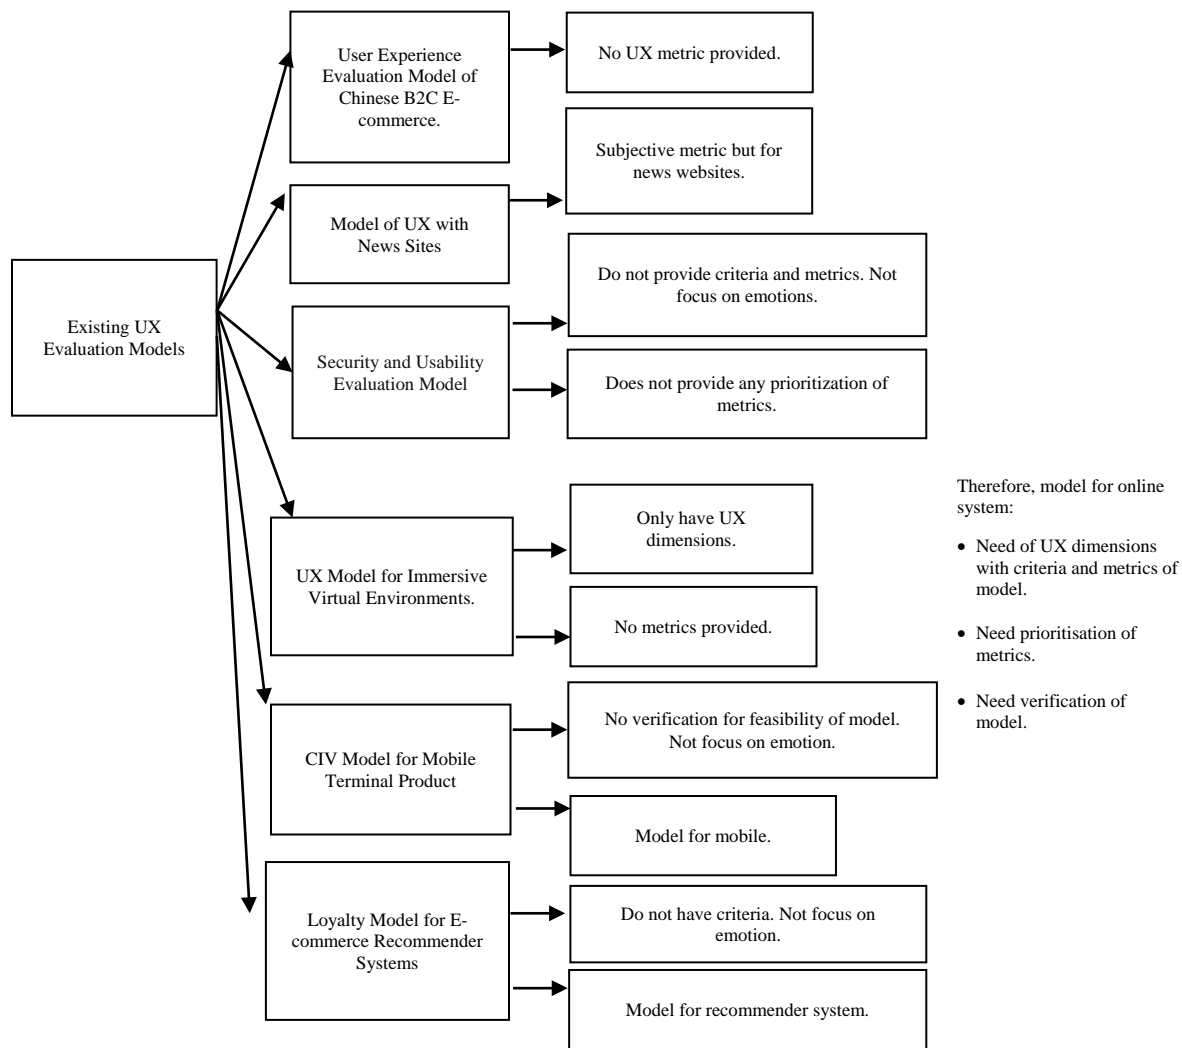

Fig. 8. Gaps of Existing UX Evaluation Models.

### G. Development of Conceptual UX Evaluation Model for Online Systems

Fig. 9 shows the conceptual UX evaluation model for online systems. This conceptual model was proposed to fill the gaps in the literature that has been identified and discussed in Section 4. The conceptual model in this study is adapted from the Aranyi and van Schaik model [15] because this model consists of interaction characteristics such as user characteristic, task characteristic, and artifact characteristic; and user experience components such as perception of instrumental qualities, perception of non-instrumental qualities, and emotional responses. As mentioned earlier, all these components are important and needed because they are core components of experience whereby users' perception, including emotions, are evaluated during the interaction with the system [16]. User characteristic refers to user knowledge or skill such as education, system experience, personality or role, and language proficiency [35]. While task characteristic refers to business workflow in the study by Seffah *et al.* [36], another study refers to complexity and involvement in primary tasks [35]. Besides that, artifact characteristic refers to the online system used by the user.

There are many examples of online systems such as online ticketing systems, online management systems, online billing systems and so on. Online systems are also implemented by the e-government, e-procurement systems, and others. Thus, the findings are significant for these type of online systems to be considered because they can refer to this conceptual UX evaluation model that will be developed for system measurement and enhance their positive user experiences. Meanwhile, instrumental qualities can be related to technical features, for example, task suitability, self-descriptiveness, and controllability [16]. Non-instrumental qualities can be related to design features, for example, material, form, and combinations of colour [16]. The perception of non-instrumental qualities, emotions, and the perception of instrumental qualities are influenced by interaction characteristics, which consist of system function, user, and context, whereby it has experiential consequences such as overall experience, acceptance, intention to use, and alternative choice [37]. Thus, these core UX components of experience are important for measurement by the organisation, especially those that use online systems.

Based on the findings in Table II which have been discussed, a conceptual model needs to have dimensions with criteria and metrics of model, prioritization of metrics, and model verification. Moreover, based on the discussion earlier (Table II), the dimensions that can be considered in the measurement are efficiency, effectiveness, satisfaction, functionality, emotional, and trust. However, the conceptual model development is designed by including appropriate dimensions and linking with criteria and metrics in order to provide clear measurement for online systems. Another study has provided UX dimensions with metrics, but it is for mobile learning [38].

According to [39], instrumental qualities are related to efficiency, effectiveness, navigation, system visibility, and others. Meanwhile, [40] discussed that non-instrumental qualities are related to aesthetics, innovativeness, and originality. There has been research that places satisfaction under the category of instrumental qualities [39]. However, attractiveness and satisfaction could be placed under non-instrumental qualities or hedonic qualities based on literature support and data from systematic literature review (SLR) as conducted by [41] study. Based on this argument, satisfaction can be measured as a hedonic quality, whereby it considers the overall experiences of the system by the users [39]. Therefore, based on these arguments, efficiency and effectiveness can be placed in the instrumental qualities, while attractiveness and satisfaction can be placed in the non-instrumental qualities as shown in Fig. 9. These dimensions also show that the proposed conceptual UX evaluation model for online system has been extended from [15] terms of dimensions as shown in Fig. 9.

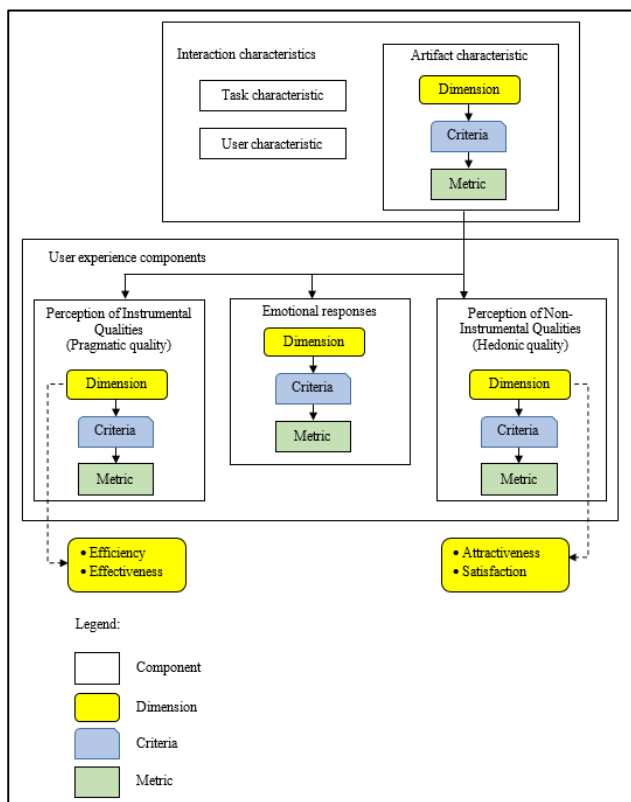

Fig. 9. A Conceptual UX Evaluation Model for Online Systems.

Based on Fig. 9, a conceptual UX evaluation model for online systems has two parts, which are interaction characteristic and user experience components. Interaction characteristics consist of components such as task characteristic, user characteristic, and artifact characteristic. The conceptual model that has artifact characteristic links to user experience components, which has perception of instrumental qualities (pragmatic quality), emotional responses, and perception of non-Instrumental qualities (hedonic quality) whereby it is adapted from Aranyi and van Schaik's model [15]. The new conceptual UX evaluation model is extended by including the dimensions, criteria, and metrics in the user experience components. This conceptual model also revealed the important dimension for online systems, namely efficiency and effectiveness for pragmatic quality; and attractiveness and satisfaction for hedonic quality. On the contrary, the study by [7] stated that the sub-category of emotion relates to attractiveness, enjoyment, and fulfilment. However, this study placed attractiveness under hedonic as investigated by [41] study. Besides, instrumental and non-instrumental qualities could influence the reactions of users emotionally in the use of the system [42].

By applying this conceptual UX evaluation model for online system measurement, the organisation can provide a positive experience for their users with the system. Therefore, this conceptual UX evaluation model for online systems can contribute to system developers and designers as a guidance in order to measure users' experiences because the model representation is flexible, simple, and easy to understand. In addition, the novelty of this model development consists of the UX dimensions, criteria, and metrics whereby it will give a clearer structure of the model for evaluation measurement not only to the system developer and designers, but also benefits researchers for future studies.

## V. CONCLUSION AND FUTURE WORK

Online systems are becoming more important sources of services for many people; research on the model of online systems is a necessity because it is important for any quality improvement process. This paper conducted a literature review from online databases such as Scopus and Elsevier Science Direct about the current state of UX evaluation for online systems, and the researchers have identified relevant papers that were finally selected for full review and critically analysed. It seems that the existing UX evaluation models do provide dimensions, however, they do not have criteria and metrics in supporting for more detailed and guided the measurement. It is found that many of the developed UX evaluation models have weak links between dimensions, criteria, and metrics in the evaluation measurement. The analysis of papers was based on System and Software Quality Requirements and Evaluation (SQuARE) such as Measurement of quality in use (ISO 25022:2016) and Measurement of system and software product quality (ISO 25023:2016). After identifying gaps in the previous literature on existing UX evaluation models, then this study proposed a new conceptual UX evaluation model for online systems and extended the model by adding important dimensions needed for measurement such as efficiency, effectiveness, attractiveness and satisfaction. Moreover, the user experience component

such as pragmatic quality, emotional responses and hedonic quality also are needed for measurement. The newly developed conceptual UX evaluation model is expected to aid decision makers in resolving any evaluation issues, for instance, the early stages in the development process of the model for online systems. Thus, the goal of this study has been achieved by analysed the UX evaluation models and proposed a conceptual UX evaluation model for online systems that can benefit system developers, designers, and also researchers. It believes that a developed model consisting of dimensions, criteria, and metrics is necessary to ensure the comprehensiveness of the online system measurement in the future.

Future research can be conducted to explore more UX dimensions for online systems in order to get more understanding for evaluation. For future studies, further identification of general criteria and metrics for online systems will be conducted. Therefore, this paper provides a new conceptual UX evaluation model for online systems whereby it is significant to the system developers and designers because they can use the findings of this study in the system development phase and researchers can use it as a guide for future studies. Findings from this paper are also important for system developers and designers to gain an in-depth understanding of the important dimensions of online system measurement such as for e-commerce and it can be used as a basis or guide to redesign existing systems to enhance positive user experience.

#### ACKNOWLEDGMENT

This research was supported by Ministry of Higher Education (MoHE) of Malaysia through Fundamental Research Grant Scheme (FRGS/1/2019/ICT01/UUM/02/4). The authors also want to thank Department of Polytechnic and Community Colleges Education (Hadiah Latihan Persekutuan) for their support.

# Applying Artificial Intelligence in Retrieving Design Solution

Y. Moubachir, B. Hamri, S. Taibi

Q.S.M. Lab, Mohammed V University in Rabat, EMI, Morocco

**Abstract**—Design is a very important step in the product life cycle, because it is generally the key for the success or the failure of the product. The field of design theories and methodologies is full with theories and methods that have been taught and developed throughout the years. Most of them rely on subdividing the design process into phases, where the transition between each two phases rely on using some design tools. One of the main challenges of nowadays is to find a way for the integration of artificial intelligence (AI) in the design process. This integration could be very benefic, due to the fact that AI can learn quickly the relationship between input and output of any phenomena, and it can also give us a prediction of the behavior, if the inputs parameters vary. In our previous work we shaded the light, on how we can improve the transition between design phase by storing and retrieving design solutions using morphological analysis and design tools like DFX. In this work, we present a deferent methodology to perform this transition which rely on using an artificial intelligence tool called Artificial Neural Networks (ANN) instead of morphological analysis to retrieve the right design solution. To illustrate this method, we will take the same example from our previous work and will show how we can use ANN to learn and predict the right design solution.

**Keywords**—Artificial intelligence; ANN; design methodologies; DFX; morphological analysis

## I. INTRODUCTION

The design phase is a very important step in the product life cycle [1], even if it is generally costing for approximately 5% of the global cost of the project. But the decisions made in this step influence 70% of the global cost of the project [2]. Nowadays, product design is becoming a very challenging task due to the fact that a design team need to have a deep understanding of a variety of fields of knowledge (technological, social, cultural...) to ensure the success of their products once it's putted in the market [3]. In this scope the field of design theory and methodologies is rich of research and result that have been used and taught in industry and education [4], which are used as guidelines to help identifying right steps to take, for the purpose of identify the shape of the product that will succeed. Those facts lead to the growing complexity of products [5] which make the design process a very difficult step. This complexity is related to the fact that the number of parameters that we need to take in consideration in our product are increasing exponentially.

The application of Artificial neural network (ANN) in the design phase of the product life cycle is still in the earlier stage of development [6] [7]. And it's integration in the design process is systematically growing in many field of design [8]. This is due to the fact that ANN has a big potential to help

reducing complexity in the design process, and leading the designers to converge quickly to the wright design solution [9].

The goal of this work is to present a new methodology that will help in the integration of artificial neural network (ANN) in the design process. To achieve this goal, we will start from our previous work which had as purpose, to store and retrieve design solution based on morphological analyses and design tools [10], in that work the idea was to improve the transition between design phases, by relaying on storing technical solution based on some criterions that are already predefined, and then retrieving the right one based on the selected criterions, using morphological analysis method. In this work, the main contribution relay on using artificial neural network for retrieving design solution instead of morphological analysis. This can be achieved based on a deferent modelization of the problem. To illustrate this new method, two type of modelization of the problem will be proposed and compered.

In this scope our work is built up as bellows. In Section II, a short presentation of the main idea for the previous work, and the illustrative example that will be used. Section III, depicts the functioning and the sizing of the artificial neural network are presented. Section IV, is devoted to show the two types of possible modelization of the ANN that can be used to retrieve design solution works. Section V sums up our contributions and outlines some possible upcoming work.

## II. PREVIOUS WORK

The main idea of the previous work was to show how we can identify a suitable design solution based on the desired values of set of inputs criterions (Fig .1).

The illustrative example was the “mounting of spur gear in a shaft”, as a design problem where we have different possible solutions regarding the inputs criteria. For that example, eight design solutions were proposed as shown in Fig. 2 and each design solution has different characteristics:

Fig. 1. Configuration of the Problem.

Fig. 2. Design Solutions for Mounting Spur Gear in a Shaft.

- S1: the spur gear is directly mounted in the shaft.
- S2, S4, S5, S6 and S7: A key is mounted between the shaft and the gear. The shaft and the spur gear hole have a cylindrical shape, with different axial blocking solutions.
- S3: An interference fit is used between the gear inner hole and the shaft.
- S8: A key is mounted between the shaft and the gear, and the shaft and the spur gear hole have a tapered shape.

For this illustrative example the developed criteria are Manufacturability index [11] (MI), Number of commercial part, Total number of part, manual assembly time [12] and Reparation cost index. For each solution we calculate the possible value regarding each preselected criterion. The results of calculations are given in Table I.

TABLE I. RESULT FOR EACH SOLUTION

| Solutions | MI   | Commercial parts | N° of parts | $(\alpha+\beta)/720$ | Reparation index |
|-----------|------|------------------|-------------|----------------------|------------------|
| S1        | 0.31 | 0                | 1           | 0                    | 1.00             |
| S2        | 0.30 | 3                | 5           | 0.5                  | 0.36             |
| S3        | 0.49 | 1                | 3           | 0.25                 | 0.41             |
| S4        | 0.55 | 3                | 5           | 0.5                  | 0.34             |
| S5        | 0.28 | 2                | 5           | 0.5                  | 0.35             |
| S6        | 0.32 | 2                | 5           | 0.5                  | 0.34             |
| S7        | 0.30 | 1                | 4           | 0.5                  | 0.41             |
| S8        | 0.14 | 3                | 5           | 1                    | 0.48             |

### III. ARTIFICIAL NEURAL NETWORK

The artificial neural network is a mathematical tool that was developed based on the functioning model of the human brain. This mathematical tool is used in many fields of artificial intelligence, like image recognition, machine learning, prediction and classification. In this work ANN will be used as machine learning tool, where the aim is to learn the obtained values of each solution, in order to build a mathematical model

which will give us for each set of criteria, the most suitable possible solutions.

#### A. Functioning of the Neural Network

An artificial neural network is a model that generally consists of three types of layers. An input layer, several hidden layers and an output layer (Fig. 3). For each neuron in the network (Fig. 4), the output value is calculated as follow (1):

$$x_j = \sigma\left(\sum_{i=1}^n w_{ij} \cdot O_i\right) \quad (1)$$

Where :

$x_j$  : The neuron output value.

$w_{ij}$  : Value of the weight which links two neurons.

$O_i$ : Neuron output value of the preceding layer with ( $O_n=1$  bias).

$\sigma$  : Transfer function.

There are several type of transfer function that can be used in the neural network, like the Gaussian function (2), tangent hyperbolic (3), linear (4) or the sigmoid function (5). This last one is generally the mostly used transfer function [13].

$$\sigma(t) = \exp(-t^2) \quad (2)$$

$$\sigma(t) = \frac{e^t - e^{-t}}{e^t + e^{-t}} \quad (3)$$

$$\sigma(t) = t \quad (4)$$

$$\sigma(t) = \frac{1}{1 + e^{-t}} \quad (5)$$

Fig. 3. Neural Network Model.

Fig. 4. The Model of the Activation of each Neuron.

### B. Sizing the Neural Network

The purpose of sizing the neural network is to identify the most suitable neural network for our case of study. This operation begins by identifying the number of neurons in each layer and the number of hidden layers. In other words, the goal is to find the smallest size of the network that has an equation that generalizes the best the relationship between inputs and outputs (Fig.5 (a)) to do so two things must be avoided:

- The overfitting: which means that the network used is too large, so that the equation obtained has integrated the errors in the training set of the model (Fig. 5(b)).
- The underfitting: which means that the network used is too small, so that the equation obtained is not adequate with the actual model (Fig. 5(c)).

Thus, to properly size the network, we will start with the smallest possible network. We will then calculate the error obtained. If this error is too large, we will continue to increase the size of the network until the error becomes too small.

### C. The used Neural Network Model

The use of a neural network begins with the learning process. The learning process begins by a set of input and output data are given to the network for learning purpose. In our case we will give the network, for each set of output values  $S_k$  (solution S) a set of input values corresponding to it  $I_m$  (criterion) where « m » is the number of inputs and « k » is the number output. The goal of this model is to identify from the training data the values of the  $w_{ij}$  of the mathematical equation which links the input values to output values. The learning of the network is done according to the following steps :

- 1) The identification of the input values and the corresponding output values (training set).
- 2) Initialization of the values of  $w_{ij}$ .
- 3) Calculating the error E : which is the square of the difference between the results of the neuron values and real the output (6).
- 4) Using the Gradient Descent Method (Several variants of the gradient decent are possible, in our example we will use the delta-bar-delta method [5] ) to modify the values of  $w_{ij}$ .
- 5) Return to step 3 until the error becomes small.

$$E = 1/2(\sum_i^k (S_i - x_i)^2) \quad (6)$$

With :

k : is the number of outputs.

$S_i$  : the value of the output of the training set.

$x_i$  : the value of the output obtained by the neural network.

Fig. 5. (a) Proper Result, (b) Overfitting, (c) Underfitting.

## IV. LEARNING MODEL

In this section we present the two learning models for the studied problem “mounting a pinion in a shaft”. The first model consist of using a network of five inputs and three outputs, and the second one consist of using a network of five inputs and eight outputs. Then we will compare the obtained results of the two models.

In our case we will refer to the output values of the network by  $S_k$ , which refer to one of the eight design solutions presented in Fig. 2. For the set of input values related to the  $S_k$  solution, we will refer to them by  $I_k$ , this set is composed of 5 values which are corresponding to the values obtained by each of the  $S_k$  solution in regard to the five criterions  $I_k$ . For example,  $I_1$  related to the  $S_1$  solution is {0.3 ;1 ;0 ;1 ;0 ;1 }.

### A. First Model

For this first learning model, a neural network composed of 5 inputs and 3 outputs will be used. In this case the five inputs are corresponding to the 5 values of the criterions. The input values for each criterion should be standardized (there values should be between -1 and 1) [5], this step is very important so the network can give us reliable results. For this, we will divide the values of the number of commercial parts and the total number of parts by 10, and for the other criterions they are already standardized.

The output values are three neurons so each solution will be encoded as follow:

S1 corresponds to the value (0,0,0).

S2 = (0.0,1)

S3 = (0.1,0)

S4 = (0.1,1)

S5 = (1.0,0)

S6 = (1.0,1)

S7 = (1.1,0)

S8 = (1.1,1)

The python programming language and Tcl as graphical user interface (Fig. 6) were used to do the learning with a developed backpropagation algorithm. The weights values of our network were calculated using the Delta-Bar-Delta method [5].

To size the network, two possible networks were evaluated. the first network “5.2.3” consists of two neuron in the hidden layer and the second one “5.3.3” is composed of three neuron in the Hidden layer ( Fig. 7).

The details of the obtained results are for each network are:

1) For neural network “5.2.3”:

- Learning parameter: Learning rate: 0.1; Momentum: 0.7; Delta-bar-delta parameter: ;  $\kappa=0.05$ ;  $\theta=0.3$ ;  $\phi=0.2$
- Global error = 0.073.
- Weights: [array([[ -6.9558979, -10.7009645, 17.15070722, 9.81960633, -12.31982889, -

1.65349976],[ 1.7778629, -8.79354065, 17.27106976, -3.2645242 , 16.7249306 , -13.02356945]], array([[ 35.5968495 , 34.0311664 , -37.00298035],[ -5.08638478, -8.1145575 , 5.80673535],[5.01774992, -49.84129666, 4.49115069]]).

From this study it is noted that the network "5.3.3" provides a global error around 5.96 E-10 (Fig. 8) while the network "5. 2 .3" gives a global error (Fig. 9) of 0.073. So we can say that the network " 5.3.3 " is the most suitable for our example, because it is the smallest network that provides good results.

Fig. 9. The Evolution of the Error after each Iteration using a “5.2.3” Network.

B. Second Model

This second learning model is a neural network with 5 inputs and 8 outputs. The five inputs correspond to the values of the chosen criteria and the eight neurons were chosen for the output values. In this case, each output neuron corresponds to a given solution, if an output neuron obtains the value of 1, then this solution is the most suitable in regards to the given values of the inputs criteria.

To size this network, two networks were evaluated the first one is with one neuron in the hidden layer, and the second one with two neurons in the hidden layer (Fig. 10). Details of the obtained results are:

1) For Neural network“5.1.8”:

- Learning parameter: Learning rate: 0.1 ; Momentum: 0.7 ; Delta-bar-delta parameter:  $\kappa=0.05$ ;  $\theta=0.3$ ;  $\phi=0.2$ .
- Global error: 0.06801684134122636.

Fig. 10. A (5.2.8) Net used for the Learning of the Technical Solution.

According to this study, we notice that the network “5.2.8” gives a total error of about 2.16E-08 (Fig. 11) while the network “5. 1. 8” (Fig. 12) gives a total error of 0.068. So we can say that the network “5. 2. 8” is the most suitable for our example.

C. Synthesis

As a summary, we can see that the first network “5.3.3” is a network that was able to record the relationship between the elements of input and outputs, with a network that contains fewer parameters (13 neurons). But the downside of this model is that we are unable to identify the nearest solution if we deviate the values of the inputs criteria. On the other hand, the network “5.2.8” is a network which contains more parameters. But in the other hand, it has the advantage of giving the nearest solution if we deviate the values of the inputs criteria.

Fig. 11. The Evolution of the Error after each Iteration using a “5.2.8” Network.

Fig. 12. The Evolution of the Error after each Iteration using a “5.1.8” Network.

## V. DISCUSSION AND CONCLUSION

The use of neural network method in the retrieval of the wright design solution has a great practical value to industry, because it has the potential of saving time and cost in the design processes [14].

In comparison to our previous work [6], where we used morphological analysis to retrieve design solution, we can see that the use of ANN has the advantage of predicting possible solutions if we change the values of the inputs criteria. Where in our previous work, the values of the criteria were fixed and cannot be changed. In this case, if our design problem had different values for at least one of the criteria the method cannot be used, but in the other hand the use of ANN help us to overcome this issue.

The purpose of this work is to present a method to improve the identification of technical solutions that will meet a set of design parameters that were pre-identified in the previous phase of the design. The proposed method is an idea that can be applied in several other problems like, selection of bearing type, Material selection or the choice of the machining process. The advantage of this method is that, it allows us to make a quick and visual choice of the suitable solution by using the power of ANN. But the drawback is that this method requires a huge work in advance to include all kinds of possible solutions in regards to the developed criteria.

**Abstract**—Amid the worldwide wave of pandemic lockdowns, there has been a remarkable growth in E-learning. Online learning has become a challenge for students. It has become difficult for students to find the content they need. The mounting accessibility of textual content has necessitated comprehensive study in the areas of automatic text summarization and question generation. Multiple Choice Questions is very smooth for evaluations, and its assessment is implemented through computerized applications in order that results may be declared within some hours, and the evaluation system is 100% pure. The system proposes an interactive reading platform where the user can upload an E-Book and get textual summary and generates questions like MCQs, fill in the blanks and one word. The user can also evaluate the questions answered. The proposed system is an all-in-one interactive reading platform.

**Keywords**—Machine intelligence; natural language processing; neural networks; predictive models; text processing

## I. INTRODUCTION

The “Live with Covid” era has notably modified the manner we live. The field of education can't isolate itself from the drastic adjustments, resulting in the near-total closures of schools, early childhood education and care (ECEC) services, colleges, and universities [1]. It has compelled us to follow the online mode of learning. As transferring to online learning has introduced us to flexibility and self-paced mastering. But there are few cons to this. The new format of classes for students has left them with a lack of motivation and creates a sense of isolation from the classrooms which may affect their academic performance throughout the term. Also, with the development of information technology, more and more information appears on the internet, retrieving the needed information and making sense out of huge data becomes difficult for users. Hence, there comes a need for a system which can provide us with summarization and question generation for easier and quicker retrieving of relevant information from huge chunks of data and to test the understanding of the subject through assessments.

In Section II, Review and Planning of the paper is discussed. In Section III, various text processing algorithms like LSTMs, T5, BERT, WordNet, ConceptNet, Sense2Vec, etc. are discussed and the best suited ones are elaborated. In

Section IV, Literature Survey was carried out wherein, technical research papers and some existing systems were studied. The gaps in the theory and applications are also addressed. In Section V, Inferences from the literature survey are mentioned. In Section VI, the Proposed System is described in detail along with its workflow and features. In Section VII, the implementation part of the system is discussed in detail. In Section VIII, the results are presented along with various comparisons between the findings. In Section IX, conclusions are stated and possible topics for future research are mentioned.

## II. REVIEW AND PLANNING

Text Processing is one of the most common tasks in many ML applications. The review considered following queries.

Q1- What are the different techniques for performing the NLP tasks like Text Summarization, Question Generation and Question Answering?

Q2- What are the different distractor generator algorithms used to generate three distractor options in MCQs?

Q3- What challenges were faced while using these algorithms? And which one was the best suited for the use case?

For the survey, databases of IEEEEXPlore, Google Scholar, and Articles were searched manually, by using various keywords like “Text Summarization”, “Question Generation”, “Question Answering”, “Distractor Generation”, etc. The search was narrowed down to research that only perform Abstractive Text Processing [2] which includes the tasks like text summarization, Question generation and question answering. The approaches to generate distractors for incorrect options of MCQs were also studied. Research papers of various Text Processing Approaches were studied from the mentioned repositories like Journals, Conferences and Articles. While trying to select the literature for the system, time duration was limited from 1997 to 2021. Along with Research Papers certain existing system were also reviewed. The research papers that satisfy the above conditions were studied and a few comparisons were made based on certain parameters. The notable points are highlighted in this paper. These remarks helped in identifying solutions to the review questions.

### III. TEXT PROCESSING ALGORITHMS

Text Processing is one of the most common tasks in many NLP applications [3]. These algorithms help the computers to analyze, understand and derive meaning from human language in a smart and useful way. For this system, out of all the Text Processing Algorithms, RNN based Sequence model like LSTM and Transformer based models like T5 and BERT were studied. The highlights from research papers are mentioned below.

#### A. LSTM versus Transformers

LSTM were one of the most popular choices for performing Natural Language processing tasks [4], but were replaced after the introduction of current state of the art transformer which surpass LSTM over the accuracy and convenience of performing the NLP tasks [5]. Limitations of LSTM are- it is difficult to train (takes very long time), transfer learning never really worked, and it must be computed in serial per token [6].

#### B. T5 Transformer

The text-to-text framework introduced in the paper [7], allows NLP tasks, like document summarization, machine translation, question answering regression tasks to be trained to predict the string representation of a number instead of the number itself using the same model for loss function, and hyperparameters. The input and output of the T5 model is always purely text to text format i.e., text string as shown in Fig. 1.

#### C. BERT Transformer

The BERT model in [8], being inspired by the Cloze task (Taylor, 1953) alleviates the unidirectionality constraint by using a “Masked Language Model” (MLM) pre-training objective. Few of the input tokens are arbitrarily masked by the MLM and their original vocabulary id is predicted solely based on the context. It also makes use of “next sentence prediction” task in addition to mask language model to jointly pretrain text-pair representations as shown in Fig. 2.

#### D. BART Model

BART is a denoising autoencoder used for pre-training sequence-to-sequence models. It is trained by corrupting text with random noise function thus, model learns to restructure the original text as shown in Fig. 3. A standard Transformer with simple neural machine translation architecture is used in BART. It evaluates several noising approaches. It finds the optimum performance by arbitrarily shuffling the sequence of original sentences and thereby uses a novel in-filling scheme, where a single mask token is placed in spans of text.

#### E. Distractor Generator for Incorrect Options

For distractor generation mainly WordNet, ConceptNet, Sense2Vec were studied.

WordNet is a large lexical knowledgebase of English. Every word (i.e., Adjectives, nouns, verbs) is grouped into sets of logical synonyms (synsets), expressing a unique concept. Every Synset is interlinked to another by lexical relations and conceptual-semantic [10]. A hypernym is a higher-level category for a given word. Considering an example as shown

in Fig. 4, color is hypernym for red. Hyponyms are the sub-categories of an entity. A hyponym is a type-of relationship with its hypernyms [11]. A Co-Hyponym are words that shares the same hypernym as another word. To generate distractors the main goal is to extract co-hyponyms [12].

ConceptNet is a semantic network that is used to help computers understand the meaning of words that people use. It generates distractors for locations, items, etc. which have a “Part of” relationship [13]. ConceptNet Number batch is a set of semantic vectors, also known as word embeddings which can be used as direct representation of word definitions or an initial state for further machine learning [14]. Fig. 5 depicts an example of Generation of distractors using ConceptNet.

Fig. 1. T5 Text-to-Text Framework. [7].

Fig. 2. BERT Fine-Tuning Procedure. [8].

Fig. 3. A Schematic Diagram of BART. [9].

Fig. 4. An Example of Relationship between Hyponyms and Hypernyms.

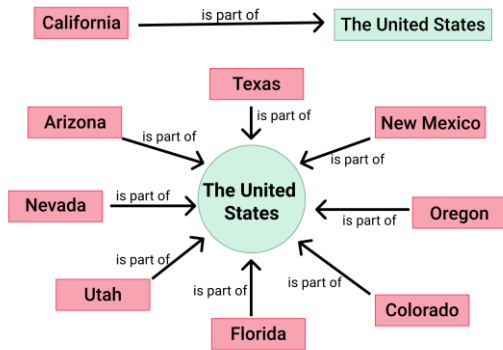

Fig. 5. An Example of Generating Distractors using ConceptNet.

Sense2Vec automatically generates relations among words from a text corpus in contrast to being human-curated. To predict a focus word given other words or to predict surrounding words of a given focus word a neural network algorithm is trained with millions of sentences as its dataset. Thus, resulting word vectors which are fixed size vectors or array representation of every word. The associations between different kind of words are represented by these word vectors, thus preserving the relationship among various words. The system uses 2015 Reddit vectors instead of the 2019 as the output obtained was slightly better.

#### IV. LITERATURE SURVEY

For the system, literature survey was conducted into two parts. For the first part of literature survey, several research papers related to text summarization, question generation and question answering were studied. The inferences from paper reading are tabulated in Table III. Later, study of existing systems was carried out that aid in the process of interactive reading experience and self-assessment. The observations from existing systems' review are tabulated in Table IV.

#### V. SURVEY INFERENCE

In the mentioned reviews, out of all the Text Processing Algorithms, RNN based Sequence model like LSTM and Transformer based models like T5 and BERT were studied. T5 is an integrated text-to-text model with text strings as its input and output, whereas BERT-style models generate outputs as a class label or a span of the input.

The issue of understanding each word based on the understanding of previous words couldn't be handled by traditional neural networks. Thus, Recurrent Neural Networks were introduced to handle the same. These networks have loops in them, allowing information to persist. The limitations of traditional RNN are that computation is slow because of the concurrent nature. If relu or tanh are used as activation functions, it becomes very difficult to process longer sequences. It is vulnerable to issues such as exploding and gradient vanishing. Further LSTMs came into picture. LSTMs are a special kind of RNN, capable of learning long-term dependencies and work well on a large variety of problems. Transformer became a huge achievement over the RNN based seq2seq models. Using transformer All to All comparison can be done fully parallel, it has multi-headed attention and

positional encoding and Transfer Learning worked well on it. But its limitations include attention can solely deal with text sequences whose size is pre-defined. The sequence must be split into fixed-sized segments or chunks before being given as input into the system. Fig. 7 depicts evolution of text processing algorithms.

Hence, due to its advantages in terms of speed and compatibility to the task, the different transformer models like T5, Distil BERT, Distil BART were decided to be used in the system for performing text summarization, question answering and question generation tasks as shown in Fig. 6.

Fig. 6. Categories of Text Processing Tasks.

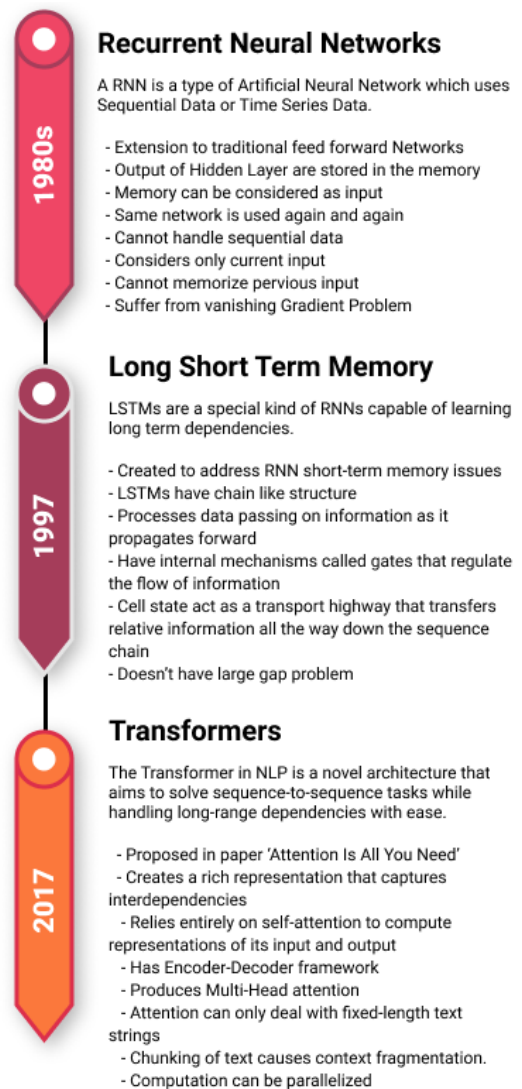

Fig. 7. Evolution of Text Processing Algorithms.

## VI. PROPOSED SYSTEM

Firstly, the user needs to sign up to the system and using credentials, log in to the home page. They can reset their passwords and edit their profiles as per their wish. The users will be categorized into guests and authors.

When a user (guest) authenticates into the system, an application tutorial will be displayed to make them familiar on how to use various features of the system. The user will either choose an E-Book (pdf) from the system library or upload one of their own. Then, the user will be able to read the E-Book in an E-reader, also have access to page wise summary and a self-assessment of the E-Book. The assessment will have three categories of questions – MCQ's, Fill in the blanks and One-word type questions. Additionally, the user can generate summarization from series of pages and get solution to a question they ask in context to a specific page. The system will display a collection of top-rated E-Books scraped from an E-Book rating and cataloguing website.

When authenticated authors logs into the system, they will be allowed to publish their E-Book (pdf), auto-generated page wise summary and a self-assessment of the E-Book to the library. The author will be able to search for their published E-Book from the library and get a preview of the generated summary and self-assessment. Furthermore, if they wish they can modify the same. Fig. 12 depicts proposed system.

## VII. IMPLEMENTATION

The systems' frontend designing is done using React.JS and in the backend, node.js express is used to host the web server and mongo DB Atlas is used for the database [15].

In the Mongo DB Atlas, a FLIP database is created in which there are three collections.

- User's E-Books: It stores all the data of the E-Book uploaded by the user.
- FLIP library: It stores all the data of the E-Books available in system's library.
- Authorized Authors: It stores the user's IDs of all the users that are categorized as authors.

MongoDB was chosen for its flexibility, scalability and cloud storage services. Also, it eases the restriction of a schema for of DB.

In the node server, APIs are available for uploading the E-Book to the server, performing CURD operations on the Mongo DB. It also runs three Python Scripts to perform mainly three tasks which are-

### A. Summary Generation and Self-Assesment Script

Firstly, for summary generation, T5 for Conditional Generation and T5Tokenizer from T5 base is used. This model was chosen over its other competitors like BERT, because it's pretrained on the much large and cleaner C4 dataset and in comparison, (base version), it contains nearly twice the number of parameters as BERT (T5: 220M & BERT: 110M) [7]. Additionally, it was also pre-trained specific for the text summarization task so no further fine tuning was required [8].

The content is then Pre-processed for removing all white spaces and is passed through the T5Tokenizer to get it tokenized. Its limitation is that there is a maximum limit of 509 tokens (excluding special tokens) for generation of summary. It was overcome by extracting the first chunk of 509 tokens from the tokenized content and then special tokens were added to them. Further, they are passed to the T5ForConditionalGeneration model to generate the summary whose length must be between 100 to 508 tokens. This generated summary is then added back to the front of the tokenized content. Now, the above process is repeated till tokenized content has less than 509 tokens. What this essentially does is retains the context of the previously generated summary with addition to the context provided by the additional tokens added in current iteration. Repeating this process will shorten down the size of the tokenized content to 509 tokens or less so that they can be fed to the T5 model at once without losing much context of the previous iteration.

An alternative approach to this, would be using the pre-trained DistilBART model. The process would majorly remain unchanged except for the limit for the length of the token chunk would be increased from 509 to 1022.

Next, Extraction of keywords is done using NER (Name Entity Recognition). Basic advantage of this method over other keyword extraction algorithms like Multipartite Rank, Tfidf, TextRank, etc is that it is able to identify Named Entities (NEs) which are real-life objects that are proper names and quantities of interest. And heuristically, when selecting answers for MCQ or other type of question in non-language related subjects these Named Entities have shown to provide more relevant and correct questions.

The name entities are extracted using SpaCy library from the content to get a list of keywords to be used as answers to the questions generated [16]. Using Maximal Marginal Relevance (MMR), the top five most relevant name entities can be procured out of the extracted ones. In MMR, the keywords that are most analogous to the text are selected. Then, iteratively new candidates are selected such that they both are analogous to the text and not analogous to the previously selected keywords. The similarities are measures based on Cosine similarity [17].

An alternative to MMR is Max Sum Similarity (MSS), The maximum sum distance of a pairs of data is calculated as the maximized distance which exists in between the two data points. In this case, candidate similarity was expected to be maximum to the document while minimizing the similarity between candidates. But a drawback in this is that, to get more diverse options there is a need to provide larger number of keywords to filter from, which is not possible for this system every time.

Then, for Generation of the question pre-trained T5ForConditionalGeneration base model is taken and it is fine-tuned on the question generation task using the SQuAD-The Stanford Question Answering Dataset [18]. The construction of fine-tuning dataset is done in the form of 3 columns the context, the answer and the question. The input is provided in the format of

context : (-context-) answer : (-answer-) </s>

and provide the target in the following format-

question : (-question-) </s>

In this way, nearly 80,000 rows are trained as a part of training dataset and 10,000 rows are used for validation of the trained model. For training the model batch size of 4 is used and for 1 epoch (which nearly takes about 4 hours to complete on the google collab notebook). Now, iteration over the keyword list is carried out and this fine-tuned model is used to generate questions for each keyword as output given the input as “context: (--summary--) answer: (--keyword--) </s>”.

To generate the distractors for the keywords the Sense2Vec Reddit 2015 is used. As Sense2Vec performs better with Named Entities compared to other algorithms like Wordnet, ConceptNet, etc.

The list of keywords is iterated and then- the best sense for selected keyword is generated and then the top thirty most similar words to it are found based on the best sense it gets. Then, the list of these words is filtered using Normalized Levenshtein Distance with a threshold of 0.7. Further, to select the top three distractors the MMR is used, by comparing the selected keywords and the distractors that are found. If any distractors for the keywords are not found, then those question-Keywords pair are used for one-word type questions.

Now, for generating fill in the blank's questions, the top three keywords to be used as answers to the questions are found using the Multipartite Rank algorithm in the Python keyword extraction library as it seems to work best for these types of tasks [19]. Using the keyword processor in the FlashText library, the keywords are mapped with the sentences of which they're a part of and then this Sentence-Keyword pair are used as Fill in the Blanks questions.

### B. Summary Generation for Collection of Pages Script

This script takes concatenated content of series of pages as input and then summarizes them using procedure same as that of the Summary Generation part mentioned in the Summary generation and self-assessment script.

### C. Question Answering for a Question asked in Context of a Specific Page Script

In this, pre-trained T5ForConditionalGeneration base model is taken and fine-tuned on the question answering task using the SQuAD- The Stanford Question Answering Dataset.[18] The fine-tuning dataset is constructed in the form of 3 columns- the context, the answer and the question. The input is provided in the format of “context: (-context-) question: (-question-) </s>” and provide the target in the following format of “answer: (-answer-) </s>” In this way nearly 80,000 rows are trained as the part of training dataset and 10,000 rows are used for validation of the trained model. For training the model batch size of 4 is used and for 1 epoch (which nearly takes about 4 hours to complete on the Google collab notebook). Now, this fine-tuned model is used to generate answers for the input questions, context which are fed to the model in the following format of “context: (--page\_content--) question (--input\_question--) </s>”.

An alternative approach to this would be using the pre-trained DistilBERT model. The process of fine tuning would majorly remain unchanged except for the input format would become “CLS (--question--) SEP (--context--) SEP” and for target is “CLS (--answer--) SEP”.

In the frontend, for sign up and sign in, Google Firebase Authentication Services are used. Thus, enabling the users to register using an email ID, password. And then signing in using the credentials provided to them. Further they are also provided with user support like resetting the password and updating the profile [20].

To upload an E-Book to the server, an upload API is used which in turn uses the node.js express- fileupload package and triggers the Summary generation and self-assessment Script where the summary and self-assessment for each page of the E-Book is generated and then the Inserting API of the CURD APIs is used to upload the generated content to the Mongo DB's user's E-Book collection. To retrieve the generated content of the E-Book uploaded by the user, the Retrieving API of the CURD APIs is used which uses E-Book name and user ID as a query in the Mongo DB user E-Book collection. To generate the summary for series of pages, the Summary Generation API is used which requires the content (concatenation of the content of series of pages) as request parameters. The API triggers Summary generation for Collection of pages Script and gives the script received content as an input. To generate answers to the questions in context to a specific page, the Question Answering API is used which requires the content (content of the specific page), question as request parameters. The API triggers Question Answering Script and provides the script with received content and question as input. For authors to upload an E-Book to the FLIP library, the library upload API is used which is same as upload API but the difference being that it uploads the E-Book to the FLIP library collection instead of the user's E-Book collection. For authors to modify the content of the selected E-Book, the Modification API is used which uses the update API of the CURD APIs to update the data of the E-Book in the FLIP library collection.

## VIII. RESULTS

### A. Text Summarization

This task was performed using two approaches namely Pre-trained T5 model and Pre-trained DistilBART model. The performance of the two was evaluated based on the evaluation benchmarks like CNN/DM-ROUGE-1, CNN/DM-ROUGE-2 and CNN/DM-ROUGE-L which are recorded in the Table I.

1) *WMT 2016*: It is a group of datasets which can be used in the shared tasks - IT domain translation, an automatic post-editing, news translation, biomedical translation, etc. [21]. The score for WMT English to Romanian and Romanian to English are referred to as En-Ro and RO-EN [22].

2) *CNN/ daily mail*: It is a text summarization dataset. From CNN and Daily Mail Websites news stories, human generated abstractive summary bullets were generated as questions (with one of the entities hidden), and news stories as the corresponding passages which are used by the system to

answer the fill in the blank question as expected. The websites were crawled, using scripts released by authors and these scripts also extracted and generated pairs of passages and questions [23].

3) *ROUGE*: Recall-Oriented Understudy for Gisting Evaluation (ROUGE) is a collection of metrics used for evaluating natural language processing tasks like text summarization, machine translation software. An auto-produced summary or translation is compared against a reference or set of references (human-produced) summary or translation by the metrics.

- Rouge-N: Overlying of N-grams among the reference summaries and the system.
- Rouge-L: Longest Common Subsequence primarily totally based statistics. It takes into consideration sentence level structure similarity clearly and identifies longest co-occurring in collection N-grams automatically [24].

### B. Question Answering

This task was performed using two approaches namely Pre-trained T5 model and Pre-trained DistilBERT model. The performance of the two was evaluated based on the evaluation benchmarks like GLUE and SQuAD which are recorded in the Table II.

1) *GLUE*: The General Language Understanding Evaluation (GLUE) benchmark is a set of resources used to train, evaluate, and analyze Natural Language Understanding systems. It is of the model-agonistic format and hence, any system that is capable to process sentence and sentence pairs or outputting corresponding predictions is eligible to participate. Its' final goal is to drive analysis within the development of general and robust NLU systems [25].

2) *SQuAD*: The Question Answering Datasets use two major metrics called SQuAD Exact Match (EM) and SQuAD

F1 Scores. SQuAD EM is a simple yet strict all-or-nothing metric wherein every question-answer pair, if the characters of the model's prediction exactly match the characters of (one of) the True Answer(s), EM = 1, otherwise EM = 0. SQuAD F1 score is metric used for classification problems, and QA. It is ideally used when precision and recall are of equal importance It is calculated over individual words within the prediction against those in the True Answer. The premise of F1 score is that the number of shared words between the truth and prediction: precision is the ratio of the quantity of shared words to the overall number of words in the prediction, and recall is the ratio of the count of shared words to the total count of words in ground truth [26].

$$F_1 = \frac{2}{\text{recall}^{-1} + \text{precision}^{-1}} = 2 \cdot \frac{\text{precision} \cdot \text{recall}}{\text{precision} + \text{recall}} \quad (1)$$

### C. Question Generation

For gaining knowledge about the accuracy of the system trials were carried out on 5, 10, 15 and 20 samples of E-Books each five pages long. The results of this approach on the system are recorded in the Table V and Table VI.

TABLE I. PERFORMANCE BASED ON EVALUATION BENCHMARKS FOR TEXT SUMMARIZATION

|                   | WMT EnRo / RO-EN | CNN/DM-ROUGE-1 | CNN/DM-ROUGE-2 | CNN/DM-ROUGE-L |
|-------------------|------------------|----------------|----------------|----------------|
| <b>T5</b>         | 28.0             | 42.05          | 20.34          | 39.40          |
| <b>DistilBERT</b> | 37.96            | 44.16          | 21.28          | 40.90          |

TABLE II. PERFORMANCE BASED ON EVALUATION BENCHMARKS FOR QUESTION ANSWERING

|                   | GLUE | SQuAD-EM | SQuAD-F1 |
|-------------------|------|----------|----------|
| <b>T5</b>         | 82.7 | 85.44    | 92.08    |
| <b>DistilBERT</b> | 77.0 | 77.7     | 85.8     |

| 10              | 246                         | 187                      | 39                         | 76.02                          | 23.98                            |
| 15              | 408                         | 319                      | 65                         | 78.19                          | 21.81                            |
| 20              | 537                         | 436                      | 77                         | 81.20                          | 18.81                            |

A collection of 20 sample E-Books were tested on the basis of above-mentioned sampling procedure on the system. The algorithms were trained to generate 8 questions per page. The Fig. 8 compares number of E-Books with time required to generate total questions. Questions generated by the system were considered to be relevant or irrelevant in accordance to grammatical and logical correctness in English language. For evaluation of the questions generated, it was found out that when 20 samples were tested, maximum accuracy of 79.435% is achieved. Otherwise for 5, 10 and 15 samples, accuracy of 79.245%, 78.614% and 79.317% is recorded respectively. The Fig. 9 compares ideal number of questions to be generated with the actual number of questions generated. The Fig. 10 depicts percentage relevancy of questions generated. For evaluation of the MCQs' options generated, it was observed that when 20 samples were tested, maximum accuracy of 81.199% is achieved. Otherwise for 5, 10 and 15 samples, accuracy of 73.873%, 76.016% and 78.186% is recorded, respectively. The Fig. 11 shows percentage relevancy of accurate options generated.

From the above data it can be summarized that with increased number of pages and question the accuracy of the

system went on increasing slightly. Also, the lower bound of the accuracy for relevant question generation was 78.614% and the same for relevant MCQ's option generation was 73.873%. Hence, we can conclude that the performance of the T5 transformer for question generation and question answering task, Distil BART for text summarization task and Sense2Vec for the distractor generation task was optimal and much better than the realm of mere guessing (50%).

### IX. CONCLUSION

The boost in the amount of text data generated with time and development of technology has demanded research in automatic text summarization and question generation. Because of lockdown, E-reading and online examinations have turn out to be very popular, which includes many important examinations. No all-in-one system existed which provided both text summarization, question generation and question answering all at once. Hence, using NLP Transformers models like T5, Distil BERT, Distil BART this project creates such system resulting in reduced reading time and providing concise summary along with a questionnaire by implementing the existing algorithms with optimal accuracy. On implementing the fine-tuned transformers, efficient results are found out. Thus, the objectives for creating a system that provides a one stop destination solution to text summarization and question generation tasks were achieved.

For future work, the system can be elevated by scoring the readers on the basis of number of correct questions answered. This system can be used to evaluate the student’s capability and skills efficiently. Also, for upgradation of the system, focus will be on creating challenging questions for better learning

process. The system can be integrated with educational platforms like Moodle. A subscription model can also be created along with basic one. The paid version will have a feature that will enable users to communicate with the authors to solve queries. And authors will be updating the auto generated questions that they feel are semantically incorrect.

# A Regression Model to Predict Key Performance Indicators in Higher Education Enrollments

Ashraf Abdelhadi, Suhaila Zainudin, Nor Samsiah Sani  
Center for Artificial Intelligence Technology (CAIT)  
Faculty of Information Science and Technology  
Universiti Kebangsaan Malaysia  
Bangi, Selangor, Malaysia

**Abstract**—Key Performance Indicators (KPIs) are essential factors for the success of an organization. KPIs measure the current performance and identify the ongoing progress for specified business objectives. The Ministry of Higher Education (MoHE) in Palestine used established formulas to predict the KPI. These KPIs are vital for charting the organization aims. This study applies regression models for student enrollment data sets to predict accurate KPIs that can be used and adapted for any higher education system. The predictive engine will determine the KPI based on linear regression techniques such as Lasso, Elastic Net, and non-linear regression such as Support Vector Regression (SVR), and K-Nearest Neighbor (KNN). The Ministry of Higher Education (MoHE) in Palestine provided the datasets related to enrollments and graduations data for different Higher Education Institutions (HEIs). The regression algorithms were evaluated by mean absolute error, mean square error (MSE), root mean square error (RMSE) and the R Squared. The experiment demonstrates that the 40% training with 60% testing splitting using linear regression shows the best result.

**Keywords**—Data mining; KPI; regression; higher education; prediction model

## I. INTRODUCTION

Key Performance Indicators (KPIs) are the critical signs of development in the direction of a meant result. KPIs afford a focal point for strategic and operational improvement, create an analytical foundation for decision-making, and assist awareness interest on most topics. KPI performs a critical element given that it is given fast and specific data through evaluating present-day overall performance in opposition to a goal required to fulfil commercial enterprise desires and objectives [1].

Businesses adopted frameworks such as the balanced scorecard (BSC) [2] as a strategic performance metric to improve internal business functions and their outcomes. Correspondingly, education centers, knowledge creation and worker centers such as ministries or learning institutions also benefited from utilizing BSC to chart the KPIs for Higher Education Institutions [3]. On a global scale, the United Nations Educational, Scientific, and Cultural Organization (UNESCO) published a practical guide for educational planners who wish to construct an indicator system [4]. The author in [4] included examples of HEIs, notably the University of Edinburgh and University Technology Malaysia, that planned their strategic development plans alongside a monitoring system, such as BSC.

The structure and content of education systems around the world vary greatly. As a result, they compare national education systems with other countries or benchmark progress toward national and international goals. Hence, UNESCO designed the International Standard Classification of Education (ISCED) to serve as a framework to classify educational activities as defined in programs and the resulting qualifications into internationally agreed categories. The basic concepts and definitions of ISCED are internationally valid and comprehensive of the full range of education systems [5].

However, there is no solid data mining framework and model to predict the higher education (HE) KPI across the world and at MoHE Palestine in particular. For instance, the current MoHE practice to extract and predict KPI is manual. The staff collect the data from different resources by phone and emails, then record it into an excel sheet, as shown in Fig. 1. The formula miscalculated will lead to a wrong decision.

| Indicator definition                                                                                                                        | Indicator formula (calculation)                                                                                                            |
|---------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| All students enrolled in post-secondary educational institutions in relation to the to the age category of tertiary education in Palestine. | $\frac{\text{Number of enrolled students for the academic year}}{\text{Number of population age category 18 - 22 in the same year}}$       |
| All enrolled students in post-secondary educational institutions, distributed according to level of study (ISCED5-8)                        | $\frac{\text{Number of enrolled students in a specific level}}{\text{The overall number of enrolled students}}$                            |
| All enrolled students in post-secondary educational institutions, distributed according to level of study (ISCED9)in Jordan                 | $\frac{\text{Number of students in short - cycle tertiary education (level 5)}}{\text{Number of students in tertiary education}}$          |
| All enrolled students in post-secondary educational institutions, distributed according to level of study (ISCED9)in India                  | $\frac{\text{Number of students in Bachelor or equivalent tertiary education (level 6)}}{\text{Number of students in tertiary education}}$ |
| All enrolled students in post-secondary educational institutions, distributed according to level of study (ISCED7)in Mexico                 | $\frac{\text{Number of students in master or equivalent tertiary education (level 7)}}{\text{Number of students in tertiary education}}$   |

Fig. 1. Example of KPIs Formulation.

## II. PROBLEM STATEMENT

Although the MoHE has computerized most of its services and automated most operations, the ministry is still facing some issues in the reporting system and predication, which affects the strategic plan for the upcoming years, for instance, predicting wrong enrollment students' number for the forthcoming academic year in government Tertiary Education Institutes (TEIs) can cause in improper budget allocation which means wasting of resources. Also, extracting knowledge from complex data sets takes a long time and a human effort to drill deeply into the big data sets. Therefore, the main worthwhile problem that needs to be addressed is to discover a new fast, efficient, and incredibly accurate

computerized approach or data mining algorithm to resolve the KPI extraction and prediction problem primarily for our case study (MoHE) based on the database for the benefit of the higher education management.

Data availability, especially for the education sector, has spurred interest in data-driven decision making [6]. The process of making organizational decisions based on actual data rather than intuition or observation alone is known as data-driven decision making (or DDDM). Therefore, DDDM offers the opportunity to discover a new fast, efficient, and incredibly accurate computerized approach or data mining algorithm to resolve KPI extraction and prediction for the MoHE case study.

### III. RELATED WORK

Data mining includes many techniques from other domains such as statistics, machine learning, pattern recognition, database, data warehouse systems and visualization [7]. Most organizations monitor their operation performance and achievement through dashboards and Business Intelligence (BI) [8]. However, in many institutes, this is limited to standard reports which cannot measure the unknown KPIs and in most cases, it is difficult to predict future performance. Most top managers rely on their intuition in order to select their potential KPIs that will lead to redundant KPIs. Managers also focus on the results rather than on the actual indicators that can be used [1].

The author in [1] built a model to predict key performance indicators for Massive Online Open Courses (MOOC) that is very similar to the Cross-Industry Standard Process for Data Mining (CRISP-DM). The model consisted of six stages from defining the business strategy model, definition of KPIs and the multidimensional model. The multidimensional model is composed of two analysis cubes: Enrollment and Activity. The enrollment analyzes the students' features such as country, interests and expectations and whether these features represent specific patterns. Data mining techniques are used to extract and predict KPIs. These techniques analyze the KPIs to mine the relationships identified during the business strategy modelling. The author in [1] used different algorithms such as Support Vector Machines (SVM), a Random Forest of Decision Trees (DT) and Neural Networks.

In 2015, [9] proposed a framework for predicting students' academic performance. The primary purpose is to discover hidden information and knowledge from the students' data so that the model can predict the student grades in a specific subject based on independent parameters such as GPA, race, gender, family income, university entry mode. The model proposed in [9] used three different classifications algorithms: Decision Tree (DT), Naïve Bayes (NB), and Rule-Based (RB) through the WEKA software tool. The model allows users to categorize the students under two or three categories; good, poor, and average. If this framework and model can be modified to use a regression algorithm, the output can be numbers or percentages, which is more accurate.

The author in [10] built a model to classify attrition among B40 students in bachelor's degree programs in Malaysia's public universities. The machine learning model indicates that

the Random Forest algorithm is the best model in predicting student attrition compared to Neural Network and Decision Tree.

The author in [11] applied different machine learning techniques to qualitatively predict the whole project KPIs in critical construction project stages. Artificial neural network (ANN) and the neuro-fuzzy method using fuzzy C-means (FCM) and subtractive clustering to predict project KPIs. The models map the KPIs of three critical project stages to the whole project KPIs. Validation used the data of actual projects to confirm models' effectiveness and compare the results of the employed machine learning techniques.

The author in [12] created a model to predict and identify factors that influence graduates' employability. Seven years of data (from 2011 to 2017) from Malaysia's Ministry of Education were used to test and evaluate the model. They applied three different algorithms; Decision Tree, Support Vector Machines and Artificial Neural Networks. The results show the decision tree (J48) produces higher accuracy compared to other techniques. Also, according to this study, three factors, attribute age, industrial internship, and faculty, contain the most information and affect the final class, which is employability.

TABLE I. SUMMARY OF RELATED WORK

| Reference | Theme (concept)                                | Findings/Conclusions                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [1]       | Data mining framework and KPI Predictive model | It is a good model but without a clear framework that can cover the whole KPIs prediction process.                                                                                                                                                                                                                                                                                   |
| [9]       | Data mining framework and KPI Predictive model | The model can predict the student grades (dependent parameter) in a specific subject based on independent parameters such as GPA, race, gender, family income, university entry mode. The study focused on being more comparative between three algorithms. The result is a lack of graphs and charts that clearly show the output and the output discrete, not a continuous number. |
| [11]      | KPI Predictive model                           | All KPIs were measured qualitatively by designing a questionnaire, and there is no database containing accurate records. Also, The research measures project performance from the owner's point of view.                                                                                                                                                                             |
| [12]      | Predictive model                               | Created a model to predict and identify factors that influence graduates' employability.                                                                                                                                                                                                                                                                                             |
| [10]      | Predictive model                               | Built a model to classify attrition among B40 students in bachelor's degree programs in Malaysia's public universities.                                                                                                                                                                                                                                                              |

### IV. MATERIALS AND METHODS

The Cross-Industry Standard Process for Data Mining (CRISP-DM) is a methodology model with six stages describing the information technology existence cycle. It will help plan, organize, and enforce data science (or machine learning) tasks Fig. 2. It standardizes data mining techniques throughout industries, analytics, and data science projects.

Fig. 2. CRISP-DM Diagram.

The six CRISP-DM Phases are Business Understanding, Data Understanding, Data Preparation, Modeling, Evaluation and Deployment.

The research experiment will apply the six CRISP-DM Phases on the Ministry of Higher Education and Scientific Research (MoHE) in Palestine [13] focus on the KPIs related to students' enrollments according to INTERNATIONAL STANDARD CLASSIFICATION OF EDUCATION (ISCED) [14] such as enrolled students in post-secondary educational institutions, distributed according to each field of study:

- 1) According to Education Program.
- 2) Arts and Humanities.
- 3) Social Science, Journalism and information.
- 4) Business, Administration and law.
- 5) Natural Science, Math and Science.
- 6) Information and communication technology.
- 7) Engineering Manufacturing and Constructions.
- 8) Agriculture, Forestry, Fisheries and Veterinary.
- 9) Health and Welfare.
- 10) Services.

UNESCO designs ISCED to serve as a framework to classify educational activities as defined in programs and the resulting qualifications into internationally agreed categories. Therefore, the basic concepts and definitions of ISCED are intended to be internationally valid and comprehensive of the full range of education systems [14].

The details of the methodology followed in this study is explained below.

#### Phase 1: Business Understanding

This phase concerns determining the business goals which is to predict a set of KPIs that has been defined in higher education and the best practice to measure those KPIs.

#### Phase 2: Data Understanding and Data Resources Analysis

At this phase, the data resources have been prepared for modelling, including several activities such as data selection, data cleaning, data construction, data integration, combining data from multiple sources, and re-formatting data as necessary. Data Source identification (databases, schema names, tables, view, spreadsheets), SQL scripts performed to create specific views in the staging database, combine data from multiple sources to one repository pre-processing data stage, including data selection, cleaning and integration.

The enrollment and graduation data form the core sources [13] for our data mining experiments. For instance, the original enrollment table consists of 50 attributes and 3,895,158 instances as it contains the historical data since the MoHE establishment. The enrollment attributes (fields) were identified to contain 34 features and 3862763 instances as some fields duplicated for both English and Arabic values. The graduation data sets have 461,598 instances and 24 attributes.

#### Building Database Repository using SQL server:

The database repository is built based on main tables such as enrollment, graduations, ISCED levels, programs, and degrees, in addition to many lookup tables such as high schools' lists, districts, nationalities, universities lists. Data views were created to focus on the data from 2014 to 2018, including 25 attributes and other attributes from other tables containing the ISCED data, which is essential for data mining. Some repeated features (fields) such as the Arabic values have been eliminated because it's considered duplicate values, other values replaced with null values excluded.

#### Data Cleaning and Transformation:

Any noisy and inconsistent data were removed to handle the missing data fields, transform data into forms appropriate for the mining task, for instance, the area code to numbers from 1 to 16, the high school types coded from 1 to 5 and the high school stream coded to numbers as well (Tables II, III and IV) The data is split into 60% training and 40% testing sets.

TABLE II. AREA CODE DATA TRANSFORMATION

### Phase 3: Modeling

Regression predicts a range of numeric values or continuous values. For example, a regression model that predicts KPI values could be developed based on observed data for many other factors such as enrolled students, specific programs, number of graduates throughout history.

Numerous models were constructed and assessed primarily based on numerous techniques. In this study employed Linear Algorithms: Linear Regression (LR), Lasso Regression (LASSO) and Elastic Net. The study also applied nonlinear algorithms such as Support Vector Regression (SVR), and K-Nearest Neighbors (KNN) using Python. In terms of parametrization, the variable "ISCED\_Level1\_Id" is assigned as a target to be predicted. To generate the training, the random\_state variable is assigned to 1 to replicate results with frac=0.6. Then select any data, not in the training set and include it in the testing set based on the index, test = df.loc [~df.index.isin(train.index)].

### Predicting ISCED KPIs:

In this study, the first experiment is to predict the KPIs for enrolled students in post-secondary educational institutions, distributed according to every ten fields of study based on the first level of (ISCED) and the general studies. So, the model will predict KPIs according to the 10 identified field of study. The second experiment is to predicts find the ratio between enrollment and graduation based on the graduates data sets.

### Phase 4: Evaluation

There are three metrics for evaluating predictions in regression; Mean Absolute Error, Mean Squared Error, and R2. The Mean Absolute Error (or MAE) is the sum of the absolute differences between predictions and actual values. It gives an idea of how wrong the predictions were. The measure provides a picture of the magnitude of the error but no idea of the direction (e.g., over or under predicting). A value of 0 indicates no error or perfect predictions.

The Mean Squared Error (or MSE) is just like the implied absolute mistakes in that it affords a gross concept of the significance of the mistakes. Taking the rectangular root of the implied squared mistakes converts the units lower back to the unique units of the output variable and may be significant for description and presentation. This is referred to as the Root Mean Squared Error (or RMSE). So, for instance, if MSE= -34.705 and SD =45.574, this metric is inverted to increase the outcomes.

The R2 (or R Squared) metric illustrates the goodness in the shape of a fixed of predictions to the actual values. In statistical literature, this degree is referred to as the coefficient of determination. This is a value among zero and 1 for no-match and best match, respectively. For example, if R2 = 0.2, the predictions have a negative match to the real values with a value toward 0 and much less than 0.5. The last stage is the deployment with the task of plan deployment and tracking, produce the final report, and review tasks by conducting an assignment retrospective approximately what went well, what might have been better, and a way to enhance it [1].

## V. EXPERIMENTAL RESULTS AND DISCUSSION

Before applying different algorithms for different datasets based on the academic years, the three linear regression algorithms were tested with varying percentages of splitting of training and testing data (10% to 90%) (Table V).

According to [15] (scikit-learn, 2021), Linear Regression fits a linear model with coefficients  $w = (w_1, \dots, w_p)$  to minimize the residual sum of squares between the observed targets in the dataset and the targets predicted by the linear approximation. Mathematically it solves a problem of the form;

$$\min_w ||Xw - y||_2^2$$

TABLE V. SHOWS LINEAR REGRESSION RESULTS FOR DIFFERENT SPLIT

Lasso Regression:

The Lasso is a linear model that estimates sparse coefficients. It is helpful to prefer solutions with fewer non-zero coefficients, effectively reducing the number of features the given answer depends on. For this reason, Lasso and its variants are fundamental to the field of compressed sensing. Under certain conditions, it can recover the exact set of non-zero coefficients.

$$\min_w \frac{1}{2n_{\text{samples}}} \|Xw - y\|_2^2 + \alpha \|w\|_1$$

The Lasso estimate thus solves the minimization of the least-squares penalty with  $\alpha \|w\|_1$  is the  $l_1$  The implementation in the class Lasso uses coordinate descent as the algorithm to fit the coefficients [15] (scikit-learn, 2021). Table VI shows the experimental results for lasso regression when applying different splitting.

Elastic Net is a linear regression model trained with both  $l_1$  and  $l_2$ -norm regularization of the coefficients. This combination allows for learning a sparse model where few of the weights are non-zero, like Lasso Elastic-net, which is beneficial for multiple features correlated with each other, such as high school average and high school stream. Lasso is likely to pick one of these at random, while elastic-net is likely to determine both [15] (scikit-learn, 2021).

$$\min_w \frac{1}{2n_{\text{samples}}} \|Xw - y\|_2^2 + \alpha \rho \|w\|_1 + \frac{\alpha(1 - \rho)}{2} \|w\|_2^2$$

Table VII shows the experimental results for Elastic Net regression when applying different splitting.

When comparing the three linear algorithms (Fig. 3), the Linear algorithm score the lowest error compared to the Lasso and Elastic Net.

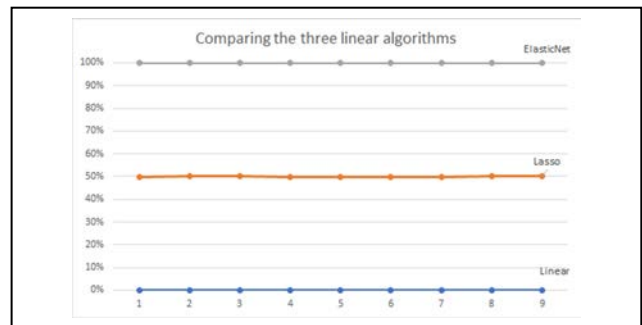

Fig. 3. Comparison between the three different Linear Algorithms.

Moreover, the slightest error margin was 40% training and 60% testing data sets (Fig. 4). Therefore, the rest of the algorithms tested for the exact sampling percentages (40% training and 60% testing) for the same academic year. Then, we look at the different iterations for three algorithms with varying percentages of data sampling (training and testing). There is no significant difference using the same algorithm for further selection, but there is a difference when it comes to the non-linear algorithms.

The experiment conducted for the same academic year, the enrollment KPI was based on ISCED level one for five different algorithms, as shown in Table VIII.

The ISCED KPIs predicted values for enrolled students in post-secondary educational institutions, distributed according to the 10 fields of study. Fig. 5 shows that the values are very close to the actual values.

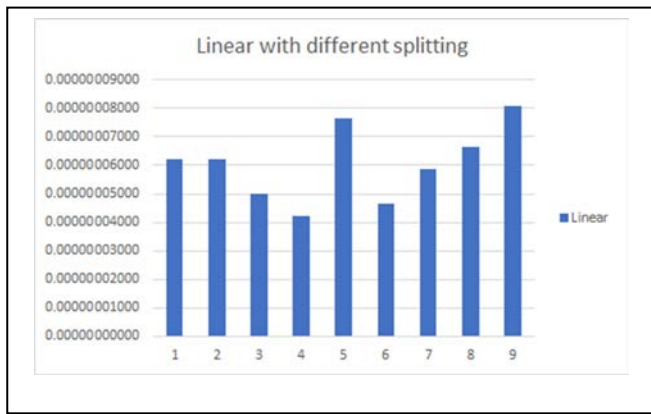

Fig. 4. Margin Error based on % Splitting Sampling.

TABLE VIII. KPI PREDICTION ERROR

| Algorithm                       | Time(M.S.MS) | MAE        | MSE               | RMSE         | R2           |

## VI. CONCLUSION

In conclusion, with clear and coherent strategies, figuring out the present-day situations, operation sector, unique varieties of competencies that generate, performance will lead to success. To create this kind of situation calls for the provision of strategic records to confirm the current situations, to outline the strategy [16]. Also, applying Cross-Industry Standard Process for Data Mining (CRISP-DM) process model as a research methodology to develop a data mining model that could help be adapted by individuals and HEIs, using machine learning algorithms can lead to good results and accuracy [17]. However, without clear KPIs, it's challenging to have a clear strategy for the upcoming years. It is crucial to create an analytical model to act as the basis for decision making and help focus attention on HE enrollment. This study provides a practical solution for such a problem by proposing a KPIs predicting model from available data at MoHE and integrating the data from different resources into a database repository from which KPIs will be predicted. This model tested different regression algorithms such as linear regression, Lasso, Elastic Net; non-linear Support Vector Regression (SVR) and K-Nearest Neighbors (KNN). However, the most successful predictive model and particularly in performance indicators used was Linear regression. The training and splitting data were tested from 10% to 90%, the targets values were compared from the historical data in the last few years. The regression algorithms were evaluated by mean absolute error, mean square error (MSE), root mean square error (RMSE) and the R Squared. The 40% training

with 60% testing splitting using linear regression shows the best result. In the future, this model can be part of a complete HE Framework to predict the KPIs and act as the main engine for that Framework.

#### ACKNOWLEDGMENT

The authors would like to thank Universiti Kebangsaan Malaysia (UKM) and DTK Grant (TT-2020-015) for supporting this research and the General Directorate of Research and Development at Ministry of Higher Education and Scientific research-Palestine for providing the data.

# A Novel Stance based Sampling for Imbalanced Data

## A Case Study on COVID-19 Healthcare News

Isha Agarwal, Dipti Rana, Aemie Jariwala, Sahil Bondre  
Department of Computer Engineering, SVNIT, Surat, India

**Abstract**—While the world is suffering from coronavirus pandemic (COVID-19), a parallel battle with Infodemic, the proliferation of fake news online is also taking place. The spread of fake news during this global pandemic COVID-19 has dangerous consequences. This is the driving force behind this study. Relying on incorrect information obtained from the internet or social media can be fatal. According to a World Health Organization survey, at least 800 people have lost their lives because of COVID-19 misinformation during this time, highlighting the accurate automated classification of fake news. However, the data at disposal for classification is imbalanced. The Internet has a vast repository of authentic healthcare news, whereas Fake News on COVID-19 healthcare is not abundant. This imbalance leads to incorrect classification. The paper studies alternative approaches to text sampling. In this paper, we propose a stance based sampling method for balancing news data. The disparity between the title and content of news items is utilized to sample data points selectively and rectify the imbalance. The key findings are that the proposed stance-based sampling strategies enhance categorisation task performance consistently for varying degrees of imbalance. The proposed techniques can better detect misleading news in the health care sector.

**Keywords**—Fake news; healthcare; sampling; stance; COVID-19; imbalance

### I. INTRODUCTION

More than half of the global population now owns a smartphone, has internet access, and uses social media. There has been a 13.2 per cent rise in social media users by 2020. During the COVID19 outbreak, there was a tremendous spread of fake news and misinformation on a multitude of

health-related topics. The World Health Organization (WHO) coined the term "Infodemic" to characterize the spread of false information. This information apocalypse has deadly implications, which is why a system to identify misleading news is urgently needed. JS Brennen et al. identified the types of misinformation on COVID-19 [1].

Real news articles about health issues outweighed those that had been validated and labeled as fake, causing an imbalance in the news dataset. The most common solution to this problem is sampling to restore data balance. The two-class sampling problem for non-textual numeric data was explored and summarized by Japkowicz and Stephen in 2002 [2]. However, not much contribution has been made to textual data. This research uses stance to present a novel data sampling strategy for rebalancing the classes of news content in the healthcare sector (Fig. 1). In contrast to standard sampling strategies used to improve classification performance, the implications of stance-based classification for false news detection are examined.

The study begins by reviewing the necessary theoretical foundation and academic work in text preprocessing, feature extraction, stance identification, and textual sampling (Section II). Section III introduces a curated dataset for assessing the performance of the proposed algorithms. The training of a stance classifier, which is required for stance-based algorithms, is described in Section IV. The stance-based approaches are discussed in detail in Sections V and VI. The results of the algorithms are presented in Section VII, along with a comparative study of traditional approaches. Finally, a brief conclusion of the paper, along with the future scope of research, is laid out in the concluding section.

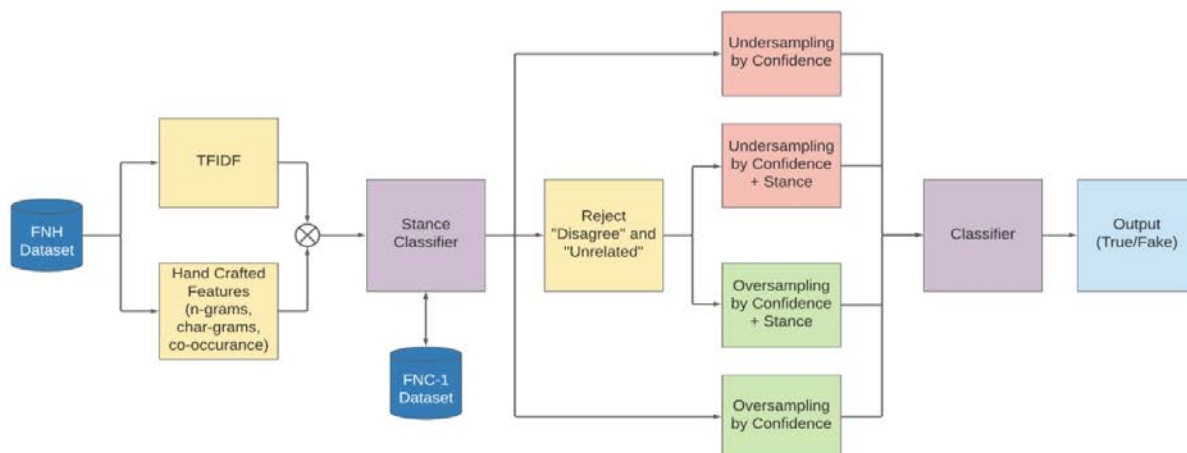

Fig. 1. Block Diagram for Sampling using Stance.

## II. BACKGROUND AND RELATED WORK

During the COVID-19 epidemic, various traditional and deep learning techniques for fake news detection are being studied. For training the textual data, important features need to be extracted, and thus, the textual data needs to be first preprocessed, followed by feature extraction.

### A. Textual Data Preprocessing

Within various studies and research, apart from tokenisation and stopword removal, authors have performed removal of HTTP URLs special characters [3][4][5]. In the study [6], the authors, in addition to the traditional preprocessing techniques, data augmentation using the back translation technique to increase the existing data is performed. The back-translation technique is the process in which the text is translated to its original language by converting it first into an intermediate language.

### B. Feature Extraction

Along with preprocessing, the main task involves feature extraction, after which the model is trained using traditional or deep learning classifiers. Within feature extraction, various methods have been used, to name the popularly used include TF-IDF, GLoVe, and Pre-trained BERT. For TF-IDF, different kinds of features are tested, including uni-gram, bi-gram, character level, etc. The studies [7][8] used these different TF-IDF representations at word-level, n-grams, etc., before feeding them to the classifier and obtained excellent results. Various studies [6][9][10][11][12] applied TF-IDF to convert the textual data into vector space and extract the important features. These studies showed a significant detection of fake news with an accuracy of 80-95%.

The limitation associated with TF-IDF is that it takes into account the occurrence of a particular word and not its grammatical meaning. This is where word-representation such as GLoVe and BERT shine. Stanford developed a global vector for word representation, termed GLoVe [13]. Each word is represented in a meaningful vector space where the cosine distance between two words depicts their similarity. In the studies [14][15], the authors applied an embedding layer using 300-dimensional pre-trained glove vectors. This layer could convert the tweet texts into a meaningful vector space. Dharawat et al. [11] utilised a 100-dimensional pre-trained glove vector along with various classifiers, and similarly, other studies [16][4] employ the same dimension vector for the feature extraction process.

Google developed a pre-training NLP technique, termed BERT [17]. It is based on an understanding of the context and relationship by learning text representation in both directions. There are two main models of BERT - BERT Base and BERT Large and mBERT is the BERT representation for multilingual representation. In the study [18], pre-trained BERT embeddings and mBERT have been utilized to extract features from tweets. Hossain et al. [19] have utilized pre-trained BERT embedding for understanding the similarity between misconceptions and tweets. Cheng et al. [20] used the BERT embedding for converting rumor texts into vector form. After BERT, the LSTM-based variational autoencoder [21] is

utilized to extract the important features. With this approach, a sufficient performance score was obtained. Various methods are utilized. However, these three embeddings are commonly used and help with providing efficient performance.

### C. Stance Detection

Stance detection is the process of identifying the stance (related, unrelated, etc.) from the textual data. It is identified through understanding the similarity of the headline and body of news content or article [22]. Common approaches involve training a labeled dataset with their stances, but a challenging task in this area includes stance detection without having the target values or no training data.

Lillie et al. investigated the topic of false news identification and stance classification and published their findings [23]. Echo chambers and model organism issues are two examples of difficulties that make collecting high-quality data challenging. Several methods for stance classification and fake news detection have been explored, but it has been difficult to compare their results because of different data and measures. One specific approach is very appropriate and interesting for the thesis project, which is the use of a Hidden Markov Model (HMM) in analysing rumours in microblog data, achieving very promising results. Augenstein et al. experiment with conditional LSTM encoding to build a representation of tweet dependent on target [24]. An additional change includes augmenting the conditional encoding along with bidirectional encoding for stance detection.

### D. Sampling Textual Data

Japkowicz et al. studied and unified all the previous approaches for solving the class imbalance problem using sampling and explained the nature of the problem by comparing the performance of the learning concept on parameters like complexity, training set size, and degree of imbalance [2]. A critical insight from the study was that class imbalance is not a problem because of the relative size of the small and large class, but it is only a problem when the size of its small class is too little for the complexity of the concept, i.e. when it contains minimal examples per subcluster. When each subcluster of the minority class contains many examples, accuracy remains high no matter the amount of imbalance or complexity of the concept. Textual data is a complex concept to learn, and the data distribution is sparse.

An active learning heuristic and representative sampling strategy is to read through the clustering structure of "uncertain" documents, reducing human effort in text classification tasks [25]. It also provides typical samples from which users can be polled to speed up SVM classifier convergence. This random sample includes more than one unlabelled document. Representative sampling was also compared to SVM active learning and random sampling by Zhao Xu et al. [25].

## III. DATASET

For training the model, a curated dataset for fake news in the healthcare domain is required. Within this paper, the FNN dataset has been used. It consists of the following features -

Title, Content, URL, and Publishing Date. This hand-curated dataset has been created using web scraping techniques from various fake/satire and true labeled websites. The statistics for the dataset are presented in the table (Table I), where true news instances supersede the fake news instances, thus creating a high imbalance in the news ecosystem.

TABLE I. FNH DATASET DISTRIBUTION

|       | Fake | True |
|-------|------|------|
| Count | 2424 | 7069 |

#### IV. TRAINING THE STANCE CLASSIFIER

For correcting the imbalance existing in the dataset, the stance approach has been chosen. Stance takes into account the textual similarity between the title and body content. Based on the similarity, we can gather its stance value and decide which instances of the particular class need to undergo sampling. This approach provides better insights on choosing instances to undergo sampling than the random traditional approach.

However, the FNH dataset has no stance labelled attribute. Introduction of the stance and its confidence for each instance of the dataset, a stance-labelled dataset is trained. In this paper, the FNC-1 dataset is used as the stance-labelled dataset. The training set is the entire FNC-1 dataset, and the testing set is the FNH dataset. A classifier works with the numerical data, and thus the textual data is represented in vector form.

##### Algorithm 1: Training Stance Classifier on FNC-1

**Input:** An annotated list of documents from FNC-1 dataset

**Output:** Classifier trained to identify stance between title and content of news article

**Begin:**

1. Create a vocabulary of words  $V$  from all text data
2.  $X := \{ \}$
3.  $N = \text{size}(\text{FNC-1})$
4. For every document  $d_i$  in FNC-1,  $i := [1,2,3,\dots,N]$ :
  - a.  $t_i := d_i.\text{title}$ ,  $c_i := d_i.\text{content}$
  - b.  $V_{t_i} := \text{TF-IDF}(V, t_i)$ ,  $V_{c_i} := \text{TF-IDF}(V, c_i)$
  - c.  $P_i := \text{co\_occurrence}(t_i, c_i)$
  - d.  $Q_i := \text{n\_grams}(t_i, c_i, n)$
  - e.  $R_i := \text{char\_grams}(t_i, c_i, n)$
  - f.  $S_i := \text{word\_overlap}(t_i, c_i)$
  - g.  $w_{t_i} := \text{word\_embedding}(t_i)$ ,  $w_{c_i} := \text{word\_embedding}(c_i)$
  - h.  $T_i := \text{cosine\_similarity}(w_{t_i}, w_{c_i})$
  - i.  $X_i := [V_{t_i}, V_{c_i}, P_i, Q_i, R_i, S_i, T_i]$
  - j.  $\text{append}(X, X_i)$
5.  $Y := \text{FNC1.stance\_labels}$
6. Create Instance of Multinomial Naive Bayes Classifier: MNB
7.  $\text{MNB.train}(X, y)$
8. Return MNB

**End**

Along with using TF-IDF (or word vectorization method), a hand-crafted vector space is created to emphasize the correlation between the headline and body of each document in a vectorized format. The hand-crafted vector space is a 28-dimensional vector space, and the distribution is explained in the table (Table II).

TABLE II. DISTRIBUTION OF VECTOR SPACE IN HAND-CRAFTED FEATURES

| Feature                                  | No. of vectors |
|------------------------------------------|----------------|
| Binary co-occurrence                     | 2              |
| Binary co-occurrence (stopwords removal) | 2              |
| N-grams                                  | 3              |
| Char-grams                               | 3              |
| Count-grams                              | 22             |
| Word-overlap                             | 1              |
| Word-embedding                           | 1              |

The TF-IDF vectors of the headline and the body, each 100 size vector are concatenated along with the handcrafted vectors is concatenated to give a 228 vector space for each document.

Within the FNC-1 dataset, there are five classes, and thus, Multinomial Naive Bayes takes into account of Bayes Theorem and provides the probability for the different classes for a single instance. Thus, the 228 vector space is subjected to a Multinomial Naive Bayes classifier to create the final trained model. The final trained model is then used for predicting the stance and confidence for the FNH dataset.

##### Algorithm 2: Generating Stance Values for FNH

**Input:** List of documents from FNH Dataset and an instance of MNB classifier from Algorithm 2

**Output:** Stance values for each document in the dataset

**Begin:**

1.  $X := \{ \}$
2.  $N := \text{size}(\text{FNH})$
3. For every document  $d_i$  in FNH,  $i := [1,2,3,\dots,N]$ :
  - a.  $t_i := d_i.\text{title}$ ,  $c_i := d_i.\text{content}$
  - b.  $V_{t_i} := \text{TF-IDF}(V, t_i)$ ,  $V_{c_i} := \text{TF-IDF}(V, c_i)$
  - c.  $P_i := \text{co\_occurrence}(t_i, c_i)$
  - d.  $Q_i := \text{n\_grams}(t_i, c_i, n)$
  - e.  $R_i := \text{char\_grams}(t_i, c_i, n)$
  - f.  $S_i := \text{word\_overlap}(t_i, c_i)$
  - g.  $w_{t_i} := \text{word\_embedding}(t_i)$ ,  $w_{c_i} := \text{word\_embedding}(c_i)$
  - h.  $T_i := \text{cosine\_similarity}(w_{t_i}, w_{c_i})$
  - i.  $X_i := [V_{t_i}, V_{c_i}, P_i, Q_i, R_i, S_i, T_i]$
  - j.  $\text{append}(X, X_i)$
4.  $\text{Stance\_Labels} := \text{MNB.predict}(X)$
5. return  $\text{Stance\_Labels}$

**End**

#### V. UNDERSAMPLING USING STANCE

For balancing the classes in undersampling, the instances of the majority classes are deleted till it is equal to the instances of minority classes. The deletion of the instances can be random, which is a traditional yet inefficient approach. Deleting the instances based on a systematic algorithm is an efficient approach.

In the previous section, the algorithm to acquire the stance label and confidence for each document is presented. The principle followed for undersampling is that the documents associated with low confidence should be subjected to deletion, which further resolves the imbalance.

In algorithm 3, the majority (true) class is sorted in descending order based on the confidence attribute, and the first N attributes are taken into consideration where N is equal to the number of instances belonging to the minority (fake) class.

---

**Algorithm 3: Undersampling based on Confidence**

---

**Input:** List of documents from FNH Dataset labeled with stance

**Output:** Undersampled data for classification task

**Begin**

1.  $D := \{FNH, Stance\_Labels\}$
2.  $True\_News := D.filter(d \text{ where } d.label = "True")$
3.  $Fake\_News := D.filter(d \text{ where } d.label = "Fake")$
4.  $True\_News := sort(True\_News, True\_News.stance.confidence, reverse=true)$
5.  $N := size(Fake\_News)$
6.  $Sampled\_True\_News := pick\_n(True\_News, N)$
7.  $Sampled\_Data := \{Sampled\_True\_News, Fake\_News\}$
8. return  $Sampled\_Data$

**End**

---

Along with the confidence attribute, the stance attribute has also been introduced within the FNH dataset. As the undersampling has been performed on the majority (true) class, the removal of stance attributes that are labeled as “disagree” or “unrelated” needs to be performed. The reason being that if a particular document is labeled true, then the headline and body needs to belong to the “agree” or “discuss” stance.

In Algorithm 4, after the deletion based on the stance values, sorting has been performed on the majority (true) class based on the confidence in the descending order. The first N instances are chosen where N is equal to the number of instances of the minority (fake) class.

---

**Algorithm 4: Undersampling based on Stance and Confidence**

---

**Input:** List of documents from Fake News Dataset labeled with stance

**Output:** Undersampled data for classification task

**Begin**

1.  $D := \{FNH, Stance\_Labels\}$
2.  $True\_News := FNH.filter(d \text{ where } d.label = "True" \text{ and } d.stance.label != ("Disagree" \text{ or } "Unrelated"))$
3.  $Fake\_News := FNH.filter(d \text{ where } d.label = "Fake")$
4.  $True\_News := sort(True\_News, True\_News.stance.confidence, reverse=true)$
5.  $N := size(Fake\_News)$
6.  $Sampled\_True\_News := pick\_n(True\_News, N)$
7.  $Sampled\_Data := \{Sampled\_True\_News, Fake\_News\}$
8. return  $Sampled\_Data$

**End**

---

The accuracy of the minority class is heavily weighted in evaluating performance since, in an unbalanced dataset, the minority class accuracy must improve. Thus, undersampling with stance variations is compared to the baseline, which was the original imbalance data, as well as the traditional undersampling approach.

From the graph (Fig. 2), it can be concluded that both approaches utilizing undersampling using stance supersede the traditional undersampling method and the baseline in performance as seen. Undersampling using stance and confidence performs the best as the imbalance ratio increases. This showcases that randomly choosing instances to undergo undersampling is an inefficient approach compared to utilizing the stance and confidence associated with each document.

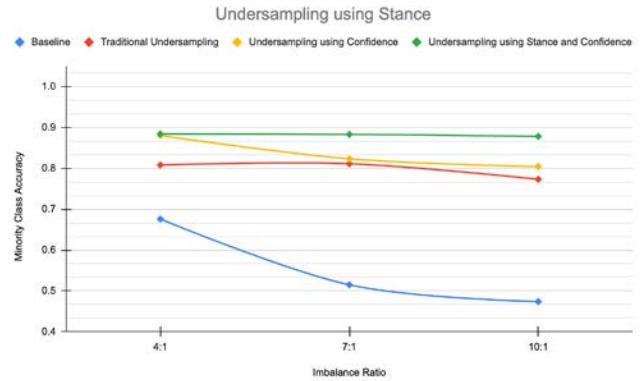

Fig. 2. Evaluation of Undersampling using Stance.

## VI. OVERSAMPLING USING STANCE

To balance the classes in oversampling, the minority class instances are oversampled until they are equal to the majority class instances. The oversampling method involves selecting a subset of minority class instances. These subsets are duplicated in a method that when these oversampled instances are added to the original minority instances, they equal instances of the majority class. The direct duplication could lead to overfitting, and hence it is important to choose an optimal number of subsets that undergo duplication to avoid overfitting.

Oversampling using stance uses the same base principle utilized in undersampling using stance. In Algorithm 5, first, sorting the minority (fake) class instances in descending order based on the confidence is performed.

The k integer which decides the subsets which will undergo oversampling is chosen in a way to avoid overfitting. In the case of the FNH dataset, the k chosen is 100 to keep the direct duplication of the subjects under 100. Choosing k within the range of [10, 50] requires the direct duplication of the subset to be done more than 150 times to resolve the imbalance. This leads to the overfitting of the data. However, choosing the k value to be greater than 100 will increase the time taken as larger subsets are chosen to undergo oversampling.

Once the top k instances are chosen from the minority class, they are subjected to oversampling such that the number of instances of both majority and minority classes is equal.

**Algorithm 5: Oversampling based on Confidence**

**Input:** List of documents from FNH Dataset labelled with stance and integer k

**Output:** Oversampled data for classification task

**Begin**

1. D := {FNH, Stance\_Labels}
2. True\_News := D.filter(d where d.label = "True")
3. Fake\_News := D.filter(d where d.label = "Fake")
4. Fake\_News := sort(Fake\_News, True\_News.stance.confidence, reverse=true)
5. Sampling\_Examples := pick\_n(Fake\_News, k)
6. Sampled\_Fake\_News := Fake\_News + oversample(Sampling\_Examples)
7. Sample\_data := {True\_News, Sampled\_Fake\_News }
8. return Sample\_data

**End**

For oversampling using stance and confidence, the same principle utilized for undersampling using stance and confidence has been used. After rejecting based on the stance value and sorting the minority class instances in the descending order based on their confidence, the first k subsets are chosen, which undergo oversampling (Algorithm 6). The method to choose the value of k has been explained in oversampling using stance.

**Algorithm 6: Oversampling based on Stance and Confidence**

**Input:** List of documents from FNH Dataset labeled with stance and integer k

**Output:** Oversampled data for classification task

**Begin**

1. D := {FNH, Stance\_Labels}
2. True\_News := D.filter(d where d.label = "True")
3. True\_News := FNH.filter(d where d.label = "Fake" and d.stance.label != ("Disagree" or "Unrelated"))
4. Fake\_News := sort(Fake\_News, True\_News.stance.confidence, reverse=true)
5. Sampling\_Examples := pick\_n(Fake\_News, k)
6. Sampled\_Fake\_News := Fake\_News + oversample(Sampling\_Examples)
7. Sample\_data := {True\_News, Sampled\_Fake\_News }
8. return Sample\_data

**End**

Oversampling with stance variations is compared to the baseline, which was the original imbalance data, as well as the traditional oversampling approach, and the priority is provided to the accuracy of the minority class. The reason is that within imbalanced data, the model tends to overfit, and the performance of the minority class is low.

Oversampling using stance supersedes the traditional oversampling method and the baseline in performance, as seen in Fig. 3. Oversampling using stance and confidence increases its performance and has a steady increase in the accuracy of the minority class across all imbalance ratios, while the traditional oversampling method scores reduce as it reaches a high imbalance ratio.

Fig. 3. Evaluation of Oversampling using Stance.

**VII. RESULTS**

For the evaluation purpose, the MCC score is taken into account. MCC is the only evaluation metric that considers all four quadrants of a confusion matrix, whereas Accuracy and Precision skew toward the positive class. To understand whether the model is overfitting by having high accuracy for the majority and low accuracy for the minority class or the model is balanced effectively, the accuracy of majority and minority class is both taken into account.

The evaluation metric is based on the confusion matrix and the MCC score. This has been done by averaging five trials for each method. The tables (Tables III to V) provide the performance of sampling using stances against the traditional sampling methods for the imbalance ratios 4:1, 7:1, 10:1.

For 4:1 imbalance ratio, it can be observed that oversampling methods supersede the undersampling methods in performance. Within the undersampling methods, the stance methods exceed in performance compared to the traditional method by a huge margin.

TABLE III. SIMULATION OF RESULT FOR RATIO 4:1

| Stance                             | Accuracy Majority Class | Accuracy Minority Class | MCC   |
|------------------------------------|-------------------------|-------------------------|-------|
| Baseline                           | 0.949                   | 0.677                   | 0.659 |
| Traditional Random Undersampling   | 0.884                   | 0.801                   | 0.685 |
| Traditional Random Oversampling    | 0.908                   | 0.932                   | 0.841 |
| Undersampling: Confidence          | 0.785                   | 0.876                   | 0.665 |
| Undersampling: Stance & Confidence | 0.872                   | 0.889                   | 0.76  |
| Oversampling: Confidence           | 0.921                   | 0.919                   | 0.84  |
| Oversampling: Stance & Confidence  | 0.925                   | 0.918                   | 0.843 |

Within the oversampling methods, the traditional oversampling method shows a minor improvement in performance compared to the oversampling using stance methods.

TABLE IV. SIMULATION OF RESULT FOR RATIO 7:1

| Stance                             | Accuracy Majority Class | Accuracy Minority Class | MCC   |
|------------------------------------|-------------------------|-------------------------|-------|
| Baseline                           | 0.978                   | 0.495                   | 0.569 |
| Traditional Random Undersampling   | 0.842                   | 0.814                   | 0.655 |
| Traditional Random Oversampling    | 0.935                   | 0.953                   | 0.889 |
| Undersampling: Confidence          | 0.835                   | 0.817                   | 0.653 |
| Undersampling: Stance & Confidence | 0.883                   | 0.894                   | 0.777 |
| Oversampling: Confidence           | 0.947                   | 0.959                   | 0.907 |
| Oversampling: Stance & Confidence  | 0.948                   | 0.955                   | 0.905 |

For 7:1 ratio, it follows the similar pattern as 4:1 ratio where oversampling methods supersede the undersampling methods in performance. Within undersampling methods, the undersampling using confidence showed a significant drop while undersampling using stance and confidence supersede in performance by a huge margin.

Within oversampling methods, the difference in performance for oversampling using stance and traditional method is very less. This showcases that with an increase in imbalance ratio, the oversampling using stance shows improvement in their performance.

For 10:1 ratio, both of the oversampling using stance variants supersedes in performance while the performance of traditional oversampling method reduces significantly. Within the undersampling methods, the undersampling using stance and confidence showcases steady improvement in performance with an increase in the imbalance ratio.

TABLE V. SIMULATION OF RESULT FOR RATIO 10:1

| Stance                             | Accuracy Majority Class | Accuracy Minority Class | MCC   |
|------------------------------------|-------------------------|-------------------------|-------|
| Baseline                           | 0.983                   | 0.466                   | 0.558 |
| Traditional Random Undersampling   | 0.833                   | 0.793                   | 0.625 |
| Traditional Random Oversampling    | 0.955                   | 0.863                   | 0.840 |
| Undersampling: Confidence          | 0.798                   | 0.818                   | 0.616 |
| Undersampling: Stance & Confidence | 0.872                   | 0.886                   | 0.758 |
| Oversampling: Confidence           | 0.949                   | 0.958                   | 0.908 |
| Oversampling: Stance & Confidence  | 0.953                   | 0.959                   | 0.914 |

## VIII. CONCLUSION AND FUTURE WORK

People are led to believe false facts about various health advice and medical treatments as a result of fake news. This creates a pressing need for accurate detection of fake news in healthcare. The proposed framework focuses on improving the performance of fake news detection in order to address these issues. Because the number of true articles in this work outnumbers the number of fake articles, stance has been used for the text sampling method, both undersampling and oversampling.

Understanding the relationship between the headline and the article's content is essential in stance classification. The FNH dataset has been trained to obtain their respective stance labels and confidence. Two approaches have been proposed. Stance-based undersampling and stance-based oversampling were carried out using these variations. These proposed approaches demonstrated a significant improvement in overall detection performance when implemented with various imbalance ratios compared to traditional methods.

Apart from increasing the performance using stance by resolving balance, the broader implications of the paper also highlight the unique method of converting the textual data into vector space highlighting the similarity between the title and body content of the document which further was utilized grabbing the stance and confidence attribute for each document.

Future work can be extended by training different classifiers for stance detection. Experiments can also be further carried out considering the tuning of configuration parameters for the rate of sampling, etc.

**Abstract**—In current years, there has been an increasing attention in Underwater wireless sensor networks (UWSNs). Underwater sensor networks (USNs) can be applied for many various purposes. To address the routing issue, the Cuckoo Search Optimization Algorithm with Energy Efficient and QoS Aware (CSOA-EQ) based routing methods have been proposed in this chapter. Every application is important in its own right, but some of them can help improve sea investigation to meet a variety of underwater applications, such as a catastrophic event alert system (such as torrent and seismic monitoring), supported navigation, oceanographic data collection, and underwater surveillance, ecological applications (such as the nature of organic water and contamination monitoring), modern applications (such as marine investigation), and so on. For example, sensors can assess specific metrics, such as base intensity and securing pressure, to monitor the auxiliary nature of the securing environment in offshore engineering applications. UASNs have also improved our understanding of underwater environments, such as climate change, underwater creature life, and the number of inhabitants in coral reefs.

**Keywords**—Underwater wireless sensor networks (UWSNs); QoS aware (CSOA-EQ); underwater environments

## I. INTRODUCTION

Sensor Networks have emerged as a potential examination topic this year. In these types of networks, the routing issue is a critical component that must be handled in order to extend the life of the organisation. Because of the number of sensor nodes in the organisation, routing becomes increasingly unpredictable as the size of the organisation grows [1]. Sensor nodes in Wireless Sensor Networks are highly reliant on memory, processing power, and battery life.

Surface buoys operational with GPS can acquire their regions, as seen in Fig. 1. The numeral of beacon nodes be far lower than the amount of obscure nodes. Because beacon nodes have more energy and a communication range of roughly 200 metres, they can legitimately communicate with buoys and have more neighbours. Furthermore, compared to hidden nodes, beacon nodes have more equipment assets and superior figuring capacity, allowing them to do more. The obscure nodes are slightly less expensive, and they aren't required to waste energy [2]. An obscure hub's communication radius is roughly 100 metres, and it is unable to officially communicate with the buoys. It can normally only associate with its immediate (usually one-jump) neighbors [3]. The obscure nodes can achieve nearby positioning to successfully participate in the organization exercises thanks to local data exchange among themselves and nearby beacon nodes.

Optimization is everywhere, so there are many applications for this paradigm [4]. In practically all technical and industrial applications, we are continually looking for ways to improve anything, whether it is to minimize cost and energy consumption or to boost benefit, yield, execution, and effectiveness [5]. Because resources, time, and money are all limited in practice, optimization is undoubtedly more important. Because most real-world applications have clearly more complex variables and parameters influencing how the framework functions, making the greatest use of any given assets needs a paradigm shift in logical reasoning. The essential components of the optimization cycle for each optimization challenge are the optimization algorithm, an effective numerical test system, and a realistic-portrayal of the physical cycles we want to illustrate and optimize [6]. After we have a good model, the general computation costs are dictated by the optimization strategies used for search and the numerical solver utilized for simulation. To address the routing issue, Cuckoo Search Optimization Algorithm with Energy Efficient and QoS Aware (CSOA-EQ) based routing methods have been proposed [7]. A wireless sensor network (WSN) is made up of self-contained sensor nodes. These sensors are extremely small. They are widely disseminated in large numbers [8]. These sensor nodes are intelligent and successful, providing a very wonderful and adaptive network where regular wired and wireless networks are unable to deliver. WSN is used in a variety of engineering applications, including monitoring unfenced far margins, terrorist development in high-altitude backwoods territories, and LPG pipe lines put in deep water. The sensor node detects or monitors movement or functions in a network region or area and delivers information to the base station.

A QoS aware routing provides optimality when sensor nodes are transmitted in underwater sensing applications, such as monitoring LPG pipelines [9]. As a result, this research also focuses on QoS-aware routing. The compromise between network QoS assurance and network lifetime is a fundamental issue in QoS aware routing, i.e., the presentation of QoS aware routing and the implementation of Energy efficient routing are diametrically opposed. The main goal is to maintain the energy-efficient and QoS-aware routing running smoothly. This chapter describes WSN execution and compares it to ACO and PSO's suggested CSOA-EQ execution in terms of normal number of ways, energy consumption, and normal parcel delay [10]. The proposed CSOA-execution EQ's is considerably enhanced when compared to ACO and PSO.

Fig. 1. Schematic Diagram of UWSN.

## II. LITERATURE REVIEW

Sudip Misra, Anudipa Mondal, and Ayan Mondal (2019) introduced DATUM, a game theory-based dynamic topology control approach for enhancing throughput and network lifetime in UWMSNs within the sight of interactive media sensor nodes with the least network latency [1]. This author uses a cooperation game theoretic approach to select the best combination of methods for limiting postponement and amplifying throughput, as well as the best transmission power for extending network lifetime. Luis M. Pessoa, Cândido Duarte, Henrique M. Salgado, Vasco Correia, Bruno Ferreira, Nuno A. Cruz, and Anibal Matos (2019) evaluate the long-term deployment feasibility of a large-scale network of abandoned underwater sensors, with power provided by autonomous underwater vehicles (AUVs) in periodic visits [2]. They conduct a versatile analysis to determine the size of network that can be supported by a single AUV, both in terms of total number of sensors and partition separation between sensors.

## III. EXISTING METHODOLOGIES

### A. Ant Colony Optimization Algorithm

The field of "Ant Algorithm" investigates how models derived from observations of real ants' behavior stimulate the development of novel algorithms for solving distributed control problems via optimization [11]. The basic idea is that self-organizing standards, which take into account the profoundly co-ordinate behavior of actual ants, may be utilized to co-ordinate populations of artificial agents working together to solve computing problems. Various forms of ant algorithms, including as seeking, division of labour, brood arranging, and co-employable vehicle, have been enlivened by a few distinct aspects of ant province behavior. "One of the better examples of ant algorithms is "Ant Colony Optimization (ACO)"[12]. Because the forward ants in the ACO strategy are sent to no specific destination node in the essential algorithm, sensor nodes must communicate with one another and every node's routing tables must contain the IDs of all sensor nodes in the neighbourhood as well as the journalist levels of the pheromone trail, making the ACO

strategy more energy efficient. In big networks, this can be an issue because nodes would require a lot of memory to save all of the data about the neighbourhood.

### B. Particle Swarm Optimization

Molecule Swarm Optimization (PSO) was developed by Kennedy and Eberhart in 1995, based on a range of natural behaviours such as fish and flying creature learning. PSO has since sparked a plethora of new interests and structures an exhilarating, ever-expanding study topic known as swarm insight. This method searches the spaces of a target work by changing the trajectories of individual agents, termed particles, in a quasi-stochastic manner as piecewise ways determined by positional vectors [13]. Particle swarm optimization (PSO) mathematical expression is followed[14]. Assuming a Dimensional search space,  $m$  particles form a group. The position of the particle  $I$  in the search space is  $x_i$  and Vector is  $x_i = (x_{i1}, x_{i2}, L, x_{iD})^T$  and the flying speed is  $V_i = (v_{i1}, v_{i2}, L, v_{iD})^T$ . The individual extremum of particle  $I$  is  $P_i = (P_{g1}, P_{g2}, L, P_{gD})^T$ . In the formula  $g$  is the number of fitness optimum in the group [13]. The particles are iterative operation according to the following formula (3) and (4) and schematic diagram is shown in Fig. 4.

$$v_{id}^{k+1} = \omega v_{id}^k + c_1 \cdot r_1 \cdot (p_{id}^k - x_{id}^k) + c_2 \cdot r_2 \cdot (g_{id}^k - x_{id}^k)$$

$$x_{id}^{k+1} = x_{id}^k + v_{id}^{k+1}$$

$\omega$  is non-unconstructive number, called the inertia weight (inertia weight), Its role is not to adjust the algorithm of global and local search ability of balance.  $I=1, 2, \dots, m$   $d=1, 2, \dots, D$ . Acceleration constant  $c_1$  and  $c_2$  (acceleration constant) is a non negative;  $r_1$  and  $r_2$  is a random number between.  $v_{id} \in [-v_{max}, v_{max}]$ ;  $v_{max}$  is a constant, setting by the user;  $k=1, 2, \dots$  is the number of iterations [15].

## IV. PROPOSED METHOD

### A. Network Architecture

First, we'll go through the network architecture employed in this chapter. The sensor network in this scenario is a Big Network (BN), with the water's surface as the top surface and the seabed as the bottom surface. This underwater sensor network is organized into miniature crow nests, as seen in Fig. 2 (CNs). Fig. 1 shows the network architecture of the suggested model.

Fig. 2. Network Architecture of the Proposed Model.

A source node should be at the lower left corner of the BN, whereas a sink node should be in the upper right corner. Allow  $N_a$  sensor nodes equipped with audio modems to communicate with sonobuoys positioned at arbitrary depths. These nodes are all stagnant and do not have any water flowing through them. Each node in the network has the same main energy, transmission power, and range, as well as symmetric interactions between nodes. The sink node is assumed to also be equipped with an offshore level sonobuoy, and that each node is aware of both its own and the sink node's location. Furthermore, as seen in Fig. 2, there are several nodes within a CN. Furthermore, as seen in Fig. 2, there are many nodes within a CN that store the CN that they have a place with. The length of the CN is commonly referred to as  $d$ , and it is entirely dependent on  $r$ , which is the sensor node exchange radius. Similarly, the duty cycle technique assumes that each nodes condition varies independently of the state of the others. Because each node is awake for a short period of time before going to sleep for the remainder of the time, this is the simplest type of obligation cycle. There is no need for global synchronization because each sensor node can maintain track of its own and the sink node's locations.

### B. CSOA-EQ Algorithm

Similarly, because the routing database does not exist, no RAM is utilized to save the path. Additionally, the multiple-routing method will be combined with geo-routing to improve the reliability of packets being received efficiently, and packets will be dispatched from many routes at the same time. Furthermore, the duty cycle instrument allows the nodes to rest occasionally to conserve energy while no data is being transmitted. The network is said to be a Big Network separated into little crow homes. In the proposed technique; each sensor node can communicate directly with all of its vertex, edge, and surface adjacent nodes. A CN within a BN, as seen in Fig. 3, node  $u$ , is an outstanding illustration of this type of CN.

In Fig. 4, a flowchart of the proposed method is exposed.

Fig. 3. Relation between  $r$  and  $d$  in the Network.

### C. Proposed CSOA-EQ Algorithm

Similarly, the routing database does not exist, so no memory is used in the process of storing the path. Furthermore, the multiple-routing process will be used with geo-routing to increase the reliability of packets being received effectively, and packets will be dispatched off the destination at the same time from numerous routes. In addition, the duty cycle instrument allows the nodes to occasionally rest in order to save energy while no data is being delivered. It's thought that the network is a Big Network divided into small crow homes. To prevent packet flooding, each node's diffusion radius is defined, and every node can only transfer data within this radius. Furthermore, in the suggested algorithm, node selection is settled in a later step depending on the node's reasonableness.

Every sensor node in the proposed algorithm can communicate directly with all of its vertex-adjacent, edge-adjacent, and surface-adjacent nodes. It should be noted that a CN within the BN, as shown in Fig. 2, is an excellent example of such a CN. Similarly, node  $m$  is the farthest node with whom  $u$  can have a direct conversation. As a result, the Base Exchange radius of node  $u$  is determined by the Euclidean distance between  $u$  and  $m$ .

As a result, the following equation determines the relationship between the length of the CN edge ( $d$ ) and the transfer radius of the sensor nodes ( $r$ )

$$(2d)^2 + (2d)^2 + (2d)^2 = r^2 d = \frac{r}{\sqrt{12}} \quad (1)$$

- First, as shown in Fig. 1,  $N_a$  nodes are haphazardly spread at various depths of  $H$  in BN space to depict the suggested technique. Based on the measure of  $d$ , the BN is then partitioned into various CNs. Using range-based or without range localization techniques; each node should also know its own location and the location of the sink node. Fig. 5 illustrates this. Furthermore, each node must be aware of which CN it belongs to. The fact that each of these nodes has the same fundamental energy is crucial. The routing cycle begins in two steps after the fundamental design of the nodes:
- Stage 1: The initial phase of the routing for the source node  $u$  is discovering all of the node's nearby Crow Nest (CN) subunits. A CN can have vertex-adjacent, edge-adjacent, and surface-adjacent neighbours, as previously stated. We select CNs that are closer to the sink than the current Crow Nest (CN) and have at least one awake node from all nearby CNs. This is to prevent the course from being bypassed in vain and the sink way from being escaped. The nodes in these CNs are then recorded and assessed as possibilities for the next stage. Following the shaping of a large number of applicant nodes, the second routing stage begins with the CSOA-EQ algorithm, as shown below.

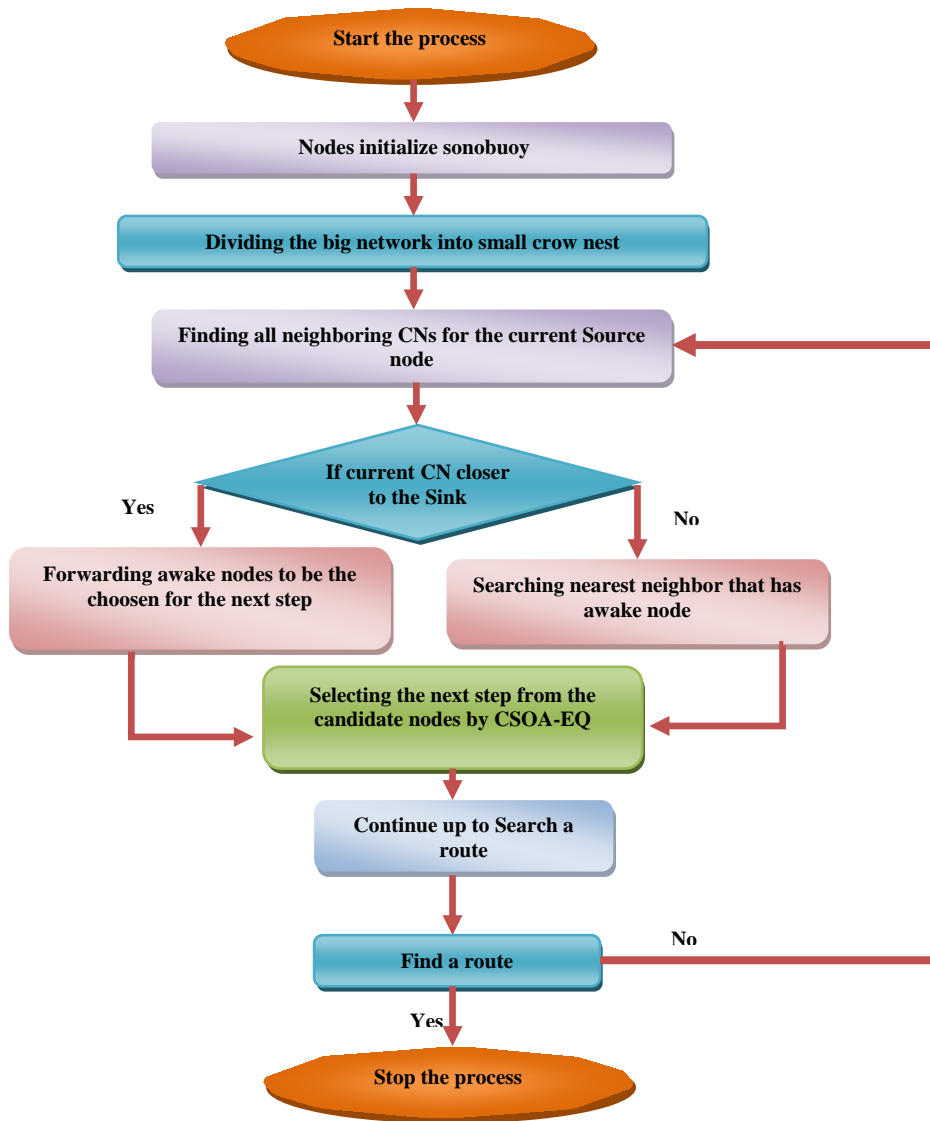

Fig. 4. Flowchart of the Proposed Method.

Fig. 5. Relation between  $r$  and  $d$  in the Network.

- Stage 2: First, mother cuckoos are horizontally distributed across the search field using the Cuckoo Search Optimization Algorithm. The following advancements are then carried out in order to achieve the optimal precision in optimization.
- Step 1: A random number of eggs is allotted to each mother cuckoo. The equation then determines the Egg Laying Radius (ELR) of each bird in relation to this number.

$$ELR = \beta \times \frac{\text{Number of current cuckoo's eggs}}{\text{Total number of eggs}} \times (\text{var}_{hi} - \text{var}_{low}) \quad (2)$$

Where  $\beta$  is a positive integer that represents the maximum ELR value. It's that each bird can only lay eggs within a certain radius.

- Step 2: Mother cuckoos lay their eggs in this area. After the laying process, the profit value of all mother cuckoos and egg is calculated using the cost function (described below). Then, in order to keep the cuckoo population under control, we destroy eggs with a lower yield. The laying process is completed at this point, and the eggs are grown and matured over time.
- Stage 2: This is where mother cuckoos lay their eggs. The benefit estimation of all mother cuckoos and eggs is calculated after the laying cycle using the cost work given below. To regulate the most extreme population of cuckoos, we kill eggs with a lower yield at that time. Near the end of this stage, the laying cycle is completed and the eggs are formed and developed.
- Stage 3: The presence of young cuckoos creates a new population of cuckoos. The algorithm's current mothers are young cuckoos. The cuckoos' dwelling areas are then grouped using the K-mean grouping technique. Because the search field and number of optimization are not large in this chapter, K is assumed to be 1.
- Stage 4: Following bunching, the benefit of each group is calculated, and the bunch with the highest benefit is presented as the best place for cuckoo relocation. In the same way, the cuckoo with the highest profit in this group is chosen as the worldwide ideal.
- Stage 5: If the algorithm arrives at the ideal combination, it stops; in any case, these means are reshaped. The issue in the CSOA-EQ algorithm is the closeness of the cuckoo's populace to one another. In the event that the cuckoo populace is near the greatness of the intermingling coefficient indicated in the algorithm, the algorithm has arrived at its assembly.

It ought to be noticed that CSOA-EQ yield is the global optimal arrangement which is accomplished by adjusting it to the neighboring node with the most elevated net revenue. The above advances proceed until there are no different nodes or CNs that gives routing conditions.

The following bounce node is best picked by the CSOA-EQ algorithm in this chapter based on the node with the maximum energy() in the objective CN. The distance between the current node and the chosen node, the method misfortune

based on the propagation delay, and the measure of the current node's residual energy are all factors that influence this decision. Regardless of the standards, the energy required to send, rest of the node's energy when data is shipped off this node, and the node's underlying energy are all taken into account in this cost calculation. Similarly, because exponential-sine capabilities are ones in which minor changes in parameters can result in dramatic changes in the capacity's implications, the cost work for selecting the next bounce node is as follows:

$$\dot{v}_{ij} = \frac{\mu}{D} + \frac{\kappa}{L} + \tau C_{ij} + \zeta E_{resi} \quad (3)$$

In Eq. (3),  $\mu$ ,  $\kappa$ ,  $\tau$ ,  $\zeta$ , they're constant coefficients with a sum of 1 that's utilized to manage the weight in the cost function.  $C_{ij}$  is also defined by.

$$C = E_{ij}^{rem} \exp\left[1/\sin\left(\pi - \frac{\pi E_{ij}^{rem}}{E_0}\right)\right] \quad (4)$$

In the above relation  $E_{ij}^{rem}$  is the remaining energy of node I if sent to node j,  $E_{ij}^{rem}$  is the current remaining energy of node i and  $E_0$  is the initial energy of node i. Accordingly, based on the relation, the optimal selection of the next step for node I through CSOA-EQ algorithm based on the node with the highest energy in the crow nest is in the crow nest is made by.

$$J = \text{Arg max}_{j \in \{S, N_d\}} (\omega_{ij}) \quad (5)$$

Here,  $N_d = \alpha N_a$  is a set of all awake nodes in the network according to the duty-cycle mechanism, Where nodes and  $0 < \alpha \leq 1$  is the duty-cycle parameter. It is worth nothing that the larger  $\alpha$  becomes, the more paths there are for the next selection, and so the network can route information from the source to the sink through different paths.

#### D. Time Complexity

As shown in Algorithm 2, CSOA-EQ for temporal complexity is made up of five key phases. Here's a quick rundown of each stage and its associated time complexity:

- Step 1: The first stage, according to Equation, is to calculate the dependability constraint score (6). The temporal complexity of this step can be estimated as follows:  $O(|T||AC|)$ .

$$\sum_{\forall C_j \in A_C} Y_{i,j} X_j \geq K; \forall v_i \in T \quad (6)$$

- Step 2: The second step is to calculate the time constraint score using Equation (7). This step takes a long time:  $O(|T||AC|)$ .

$$\sum_{\forall C_j \in T} Y_{i,j} X_j \frac{\omega_i}{\sum_{\forall C_j \in A_C} Y_{i,t} X_t} \leq \frac{w}{(k-1)}; \forall C_j \in A_C \quad (7)$$

- Step 3: The third step is to calculate the maximum distance between sensors and controllers using Equation (8). the time complexity of this step is:  $O(|T||AC|)$ .

$$L_{v_i}^* = \max_{\forall C_j \in A_C} \{Y_{i,j} X_j l^*(v_i, C_j)\} \quad (8)$$

- Step 4: The fourth phase entails sorting all of the eggs into fitness categories. The temporal complexity of this phase can be represented as  $O(\text{no of eggs}) \times N_{\text{pop}} \log N_{\text{pop}}$ .
- Step 5: The fifth stage entails sorting mature cuckoos based on their fitness values, which is a lengthy process:  $O(N_{\text{pop}} \log N_{\text{pop}})$ .

Hence, the time complexity can be written as  $O(N_{\text{pop}} \log N_{\text{pop}} + |T||AC|)$ . Furthermore, while increasing network size does not result in a significant change in  $N_{\text{pop}}$ , it can be concluded that  $|T||AC|$  has upper hand on  $N_{\text{pop}} \log N_{\text{pop}}$ . As a result, Cuckoo-overall PC's time complexity is:  $O(|T||AC|)$ .

### V. EXPERIMENTAL RESULTS

#### A. Number of Sensor Nodes on Average Number of Paths Found

Table I compares the number of sensor nodes to the average number of pathways discovered, which explains the ACO, PSO, and CSOA-EQ results. When the existing approaches and the new CSOA-EQ are compared, the proposed method produces better results (Fig. 6).

TABLE I. NUMBER OF SENSOR NODES ON AVERAGE NUMBER OF PATHS FOUND

| Number of sensor nodes | ACO   | PSO   | Proposed CSOA-EQ |
|------------------------|-------|-------|------------------|
| 200                    | 1.255 | 1.468 | 1.861            |
| 400                    | 2.216 | 2.365 | 2.632            |
| 600                    | 2.945 | 3.014 | 3.265            |
| 800                    | 3.465 | 3.984 | 4.147            |
| 1000                   | 4.875 | 4.971 | 5.852            |

Fig. 6. Sensor Nodes on Average Number of Paths Found.

The evaluation table of Number of sensor nodes on average number of paths detected explains the ACO, PSO, and recommended CSOA-EQ values. When the results of existing approaches and the proposed method are compared, the

suggested CSOA-EQ method comes out on top. We can also observe that as the number of nodes grows, so does the number of paths detected, resulting in enhanced network dependability and speed in identifying the path within the network.

#### B. Number of Sensor Nodes on Energy Consumption

Table II shows a comparison table of the number of sensor nodes on the average number of pathways identified, which explains the ACO, PSO, and CSOA-EQ results. When comparing existing approaches to the proposed CSOA-EQ, Fig. 7 shows that the proposed CSOA-EQ uses less energy.

The comparison table of number of sensor nodes on average number of paths detected explains the ACO, PSO, and proposed CSOA-EQ values. When comparing the existing and suggested approaches, the proposed CSOA uses the least amount of energy.

#### C. Average Packet Delay

Table III provides the Average Packet Delay Comparison Table, which illustrates the differences in ACO, PSO, and CSOA-EQ values. Fig. 8 shows that when existing approaches are compared to the proposed CSOA-EQ, the suggested method produces better results.

The ACO, PSO, and suggested CSOA-EQ values are explained in the Comparison chart of Number of sensor nodes on average packet latency. When comparing the outcomes of the existing approaches and the proposed method, the suggested CSOA-EQ provides better results.

TABLE II. NUMBER OF SENSOR NODES ON ENERGY CONSUMPTION

| Number of sensor nodes | ACO   | PSO   | Proposed CSOA-EQ |
|------------------------|-------|-------|------------------|
| 200                    | 9.024 | 8.802 | 6.789            |
| 400                    | 8.632 | 7.744 | 5.065            |
| 600                    | 8.125 | 7.062 | 4.732            |

## VI. CONCLUSION

Cuckoo Search Optimization Algorithm with Energy Efficient and QOS Aware (CSOA-EQ) based routing methods have been proposed in this research to address the routing issue while attempting to handle these constraints. The proposed approach is also utilized to boost the likelihood of items being delivered successfully. By using duty cycle approach, nodes are also placed to sleep on a regular basis to save energy while no data is delivered. By introducing a differential equation in the CSOA-EQ algorithm, path selecting in the proposed technique is performed based on energy utilization and residual energy of the current node. When designing a network path for a WSN, fuel efficiency is a crucial consideration. The effectiveness of CSOA-EQ is appropriate in many application areas, as evidenced by its use in WSN routing issues. In this paper, we present a routing technique just on Cuckoo Search Optimization Algorithm with Energy Efficient and QOS Aware (CSOA-EQ), and also a probability of route selection based on pheromone and residual energy. We established that the proposed strategy is more energy efficient through simulated results. As part of future research, the CSOA-EQ algorithm will be used to increase network longevity, energy usage, and average packet latency.

**Abstract**—The paper is a comprehensive study of existing research trends in the sector of Arabic language, with a focus on state-of-the-art methods to illustrate the existing condition of various theory in that sector, with the goal of facilitating the adaptation and extension of prior ones into new systems and applications. In the Arabic alphabet, there are 28 letters. Depending on its place in the word, every Arabic letter has over one shape; a single character may have from one to four shapes. The Touching between character and the Overlapping occurred in the handwritten. Historical documents contained a massive knowledge and culture. There are many old books that need to be converted into readable format. Which would take a long time if humans converted it. However, the main problem is the lack of research in Arabic Handwritten especially for segmentation of touching characters. Thus, current trends of the segmentation techniques are investigated to identify the current state-of-the-art of segmenting touching characters in other domains for constructing enhance techniques for Arabic touching characters. In this paper, it reviewed approaches for the segmentation of the touching characters. This paper presents the trend of approaches for the recognition process and segmentation of Arabic handwritten touching characters. In this paper, it highlighted the strength of each technique, the method used, and the drawback of the techniques. Based on the outcome, this will provide a good foundation for constructing a better technique for segmentation of Arabic touching characters, especially from the degraded documents.

**Keywords**—Component; character segmentation; Arabic handwritten; character touching; recognition

## I. INTRODUCTION

Arabic is now the official language of nearly 26 nations, with a population of 280 million people globally. It is among the six official languages of the United Nations (UN) (Chinese, Arabic, English, French, Russian, and Spanish). Furthermore, several of its vocabulary and forms are used in Persian (Farsi), Jawi, Kurdish, Urdu, and Pashto.

Some individuals here nowadays mostly use pen and paper to write notes (for instance). That strategy has a number of flaws. Handwritten text is difficult to retain and access in an efficient and appropriate manner. Searching through them and sharing them with others is a time-consuming process. A lot of critical knowledge may be lost and not utilized efficiently if that content was not available in electronic form.

The segmentation might confront various difficulties. In addition, character should not be too tinny and neatly segmented to better identify the recognition process [1]. The Arabic word is often a line that draws this intricacy of segmentation [2]. Because it used computers in almost every aspect of life, it also known the modern era as the information technology era. The computer is a necessary component of human life. Although, compared to humans, computers do not have nearly as much intelligence. Humans can recognize any sort of text picture from old and deteriorated texts in libraries, but computers cannot comprehend these text images directly [3]. Offline handwritten touching Arabic characters segmentation is a popular topic in study, however it's fraught with difficulties because to differences in writing, overlapping, and touching letters. The segmentation becomes tough when two characters are related to each other [4]. Mostly, all libraries and national archives throughout the world hold large volumes of historical and deteriorating documentation as a book. To convert these important resources to a machine-readable file, special care must be taken [5]. The Arabic language comprises 28 letters, each of which has a distinct form. Because letters in writings are combined to create words, these connections affect the appearance of the letters, thus the shape of an isolated character differs from the shape of a character in the middle and end of the word [6]. Segmentation is closely connected to recognition since it is a highly significant and key phase that splits a picture into sub-units such as lines, words, and letters [7].

OCR (Optical Character Recognition) is a technique that converts scanned or other kinds of pictures into editable format [8]. But even though picture segmentation is not strongly associated with image recognition, the two are inextricably linked. Segmentation process is a critical foundation for image recognition [4]. Picture segmentation, a critical process, splits the picture into tiny pieces.

Even though handwriting is common and varies from person to person, segmentation, which is used to break the text into lines, words, and characters of handwritten text, is still a difficult task. As a result, many observers are going to investigate answers to solve the problem, and some of them have made notable achievements; however, more research is needed to improve the performance of already developed systems. Although it is impossible to explain all the established approaches in this work, the study conducted by addressing the difficulties of touching Arabic handwritten letters [9].

However, this paper aims to show the results and specifications of each segmentation method to assist researchers in determining the best technique for their work.

The rest of the paper is arranged as follows. Section II explains the fundamentals of the Arabic language's characteristics Section III describes the works that are related. Results and discussion details are in Section IV. Section V discusses the conclusion and next work for further study.

## II. RELATED WORK

According to a review of the published literature on the segmentation of touching characters, there is a lack of research effort for handwritten and typed Arabic characters when compared to the number of techniques proposed for other languages such as Chinese and English.

In [13], for printed Arabic text, propose a segmentation based on Omni typeface and open-vocabulary OCR. The APTID-MF dataset was chosen as the basis for the suggested approach. This method does not need an explicit font type identification stage. The method used in this work requires cautious management, since picture samples produced by conventional image augmentation algorithms might lose important features and can be linked.

According to [14], to segment Arabic handwritten text, a region-based approach is used to extract the diacritic. After grayscale the picture, they binarize it, then use the region-based method, and finally extract the diacritic from the image. The researcher utilized the Al Quran as a dataset and added 10 handwritten Arabic pictures. This study also addresses diacritics, which are crucial to the syntax and semantics of a word. While it is part of the alphabet, the points and hamza "ء" are considered as diacritics.

Meanwhile [15] the researcher identifies fork points on handwritten Chinese character skeletons. The primary goal of this study is to increase the proportion of segmentation and recognition. The method identifies the feature point in the binary picture, then thins and smooths the character image to identify the fork and endpoints. Following that, they make some changes to eliminate the erroneous branches. They make use of the DHCCRL database. The rectification of form distortion and the selection of 6,000 handwritten Chinese character pictures are two of the work's highlights.

In addition, [16] method for developing a junction detecting algorithm the researcher omitted a database in this study. This study is just for the Printed Uppercase Alphabet and only between two characters. In this study, just one segmentation instance was investigated. The case presented in this study is neither trustworthy nor practical. In fact, the touching in the writing is more difficult.

Fig. 1 illustrates an instance in which they tested the two characters created by the researcher and placed a straight line between them; normally, it is not touched in this manner during natural handwriting compared to the case shown in the figure below, which is quite significant.

Fig. 1. Example Two Touched Characters [16].

Moreover [17] a technique based on junctions was used to create a handwritten Devanagari character by using a combination of feature to extract the character. Beginning with Handwritten Character Transformation to Bit-mapped Binary Images, the binary image was scaled, and then The Extraction was performed. They get the data from the CVPR Unit, ISI, and Kolkata. One benefit of this research is the collection of 4900 handwritten Devanagari characters. There are five options in this research. On the other side, it might be claimed that there is an advantage to having a lot of options. If, for example, two characters cannot be effectively segmented, the other option can be used.

Furthermore, in [18] Inam Ullah used the junction method while handling Arabic handwritten text. The picture is transformed to binary, and just one point of thickness is kept, making it easier to discern endpoints. However, the intersection set theory is then applied to determine the junction point and broken character. The major goal of this research is to use the algorithm to convert a handwritten, unreadable old Arabic book into a readable one. One advantage of this study is that identifying the endpoints aids in the discovery of the broken character. The researcher chooses the contact point by hand from one of four datasets: IFN/ENIT, CEDAR, and IFN/ENIT, Arabic Dataset, AHDB, and Arabic Handwritten 1.0.

In [19], segmentation of Arabic handwritten text has been performed using contour analysis. In this research, the page is divided into lines initially. Second, the line is divided into sub-words, and last, the sub-words are divided into characters. This method makes use of the database IFN/ENIT. Instead of identifying the baseline or intersecting points, this study replicates the human analogue in Arabic text writing.

Likewise, in Inam Ullah [9], the touching Arabic handwritten characters were segmented using contour tracing. Remove unnecessary noise from a binary picture. Identifying the End, Touching, and Neighboring Points Direction should be written. In the end, they are divided into characters. Many databases were considered, including AHDB, IFN/ENIT, Arabic handwritten 1.0, IBN SINA, IAM, and NIST. Because of proper segmentation, this study could achieve 97.27 percent.

Referring to [20] Corner detection in pictures is a fundamental computer vision problem.

In Lamia Berriche (2020) [24] the technique used is Seam carving-based and Datasets are IESK-ArDB and IFN/ENIT this method leads to Result of 95.67% clear remark for this research is that small characters could be considered secondary components.

Finally, according to [5], the researcher ran one set of 100 words without overlapping and another set of 100 words with overlapping from the benchmark database. And next apply the Method on the handwritten words and report the results for only the second batch. As it stated, it is a simple method that is straightforward to use and quick. Slant correction approaches do not give good results when writing characters with severely slanted and horizontally overlapping characters. Few letters, such as u, v, w, m, and n, are over-segmented or skipped segmented. In Core-zone detection, the researcher advised to count the white pixel until the first major change happens. But how can determine if this one is significant or not? This is a fluid word, and anyone may argue for or against it. Because science only speaks the language of numbers. Their method is straightforward; however, they cannot provide the results of segmentation before and after using the Core-zone detection. As a result, it can be determined if it is essential or not. The researcher simply stated that the first set of words is excellent, with no percentage showing how much is good, so that may compare the overlapping and non-overlapping sets. Also, make it more dependable.

### III. ARABIC LANGUAGE CHARACTERISTICS

#### A. Location/Direction in Writing

In both handwritten papers and machine printed materials, Arabic text is written from right to left, but numerals are written in the same way as numbers in other languages, for example, from left to right [10], [11].

Fig. 2 shows one example.

Fig. 2. Direction for Arabic Writing.

Fig. 3 shows an Arabic numeral example.

Fig. 3. Arabic Number Direction.

#### B. Shape of Arabic Characters

Because Arabic writing letters are interconnected with each other, virtually every character in the Arabic language changes its shape in writing in word according to its placement in the word.

Fig. 4 depicts Arabic letters that change shape depending on their location in an Arabic word, as well as instances of how these characters are linked to form words. The picture illustrates four Arabic letters as an example. However, not much different in the rest of the Arabic language letters regarding the shape forms of the letters compared to the selected four alphabets [12].

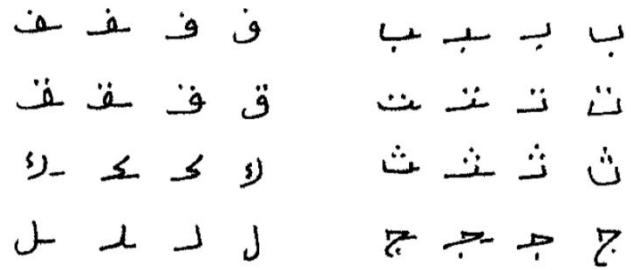

Fig. 4. Example of Shape Alphabet [12].

### IV. CHALLENGES AND LIMITATIONS

There are several obstacles for academics to address in this field, and there is a desire for new ways to develop as computer technology improves and resource constraints diminish [26].

Based on Ouwayed and Belaid's study [23], Kang [22], Aouadi [21], and Saber et al. developed a method for segmenting touching Arabic letters in the same word or other words on the same line or other lines. These existing approaches are template-based segmentation techniques, in which a glossary file is created for all potential touching graphics, that is not only time-consuming due to the variation in Arabic writing and similarities in Arabic characters, but it also fails to address the issue of touching Arabic handwritten characters. Whereas these approaches employed self-defined criteria to govern segmentation accuracy, the segmentation process of touching character pictures suffered as a result.

Over or under segmentation happens because of datasets utilized, languages type (since Arabic has more issues than other languages), type of data (printed or written by hand), and suggested segmentation technique.

By referring to [25] there were some of the challenges such as: Datasets of Arabic handwritten characters, preprocessing noise, Techniques that are cutting-edge, Documents of low resolution and quality, Segmentation, Systems that operate in real time.

The factor that considered as the main factor which is the segmentation. Certain earlier efforts relied on manually dataset segmentation, while others relied on segmented databases. A few of the accessible datasets are not segmented, while others relied on segmented datasets. It's crucial to find a scalable approach to automatically divide documents into lines and subsequently into words (or characters), particularly for big and ancient datasets. Another difficulty in segmentation is dealing with ligatures and the large quantity of Arabic characters.

The multiple sub-words could affect the segmentation process some of the words with single sub-word such as: "محمد" and it could reach to five sub-words for example: "أوروبا" which could increase the difficulties to recognize it as one word during the segmentation process.

Fig. 5 illustrates the challenges of the existing approaches for Arabic Handwritten touched characters segmentation.

Fig. 5. Challenges of the Existing Approches.

### V. RESULT AND DISCUSSION

After the research method is to find the most successful approach for Arabic handwritten touching character segmentation, but because of the many factors that need to be considered, such as paper quality, number of touching characters that have been tested, database selected, methods used, algorithm applied, and time taken to segment character. Because of all of that, it is difficult to give certain results, especially if some of these factors are not mentioned in the study. However, the author has reviewed ten of the approaches. Table I shows the sample of comparison for each method with its database selected and the result. Author has found a serious need for a specific database which could improve the future research and ease the way for the research to become more reliable, which has a logical result to be compared among the other studies.

TABLE I. METHOD COMPARISON

| Method                          | Methods Comparison                                          |        |
|---------------------------------|-------------------------------------------------------------|--------|
|                                 | Dataset                                                     | Result |
| Seam carving-based              | IESK-ArDB and IFN/ENIT                                      | 95.66% |
| segmentation-based on Omni font | APTID-MF                                                    | 95%    |
| region-based technique          | Al Quran                                                    | 80%    |
| Fork Points on the Skeletons    | DHCCCRL                                                     | 99.41% |
| junction detection algorithm    | -                                                           | 100%   |
| Junction based approach         | CVPR Unit, ISI, and Kolkata                                 | 92.8%  |
| junction approach in Arabic     | IFN/ENIT, CEDAR, AHDB, Arabic Handwritten 1.0.              | 93.3%  |
| contour analysis segmentation   | IFN/ENIT                                                    | 89.4%  |
| Contour Tracing                 | AHDB, IFN/ENIT, Arabic handwritten 1.0, IBN SINA, IAM, NIST | 97.27% |
| Core-Zone                       | CEDAR                                                       | 92.6%  |

The author discovered that the junction algorithm developed by InamUllah yields the highest percentage of segmentation accuracy while being a simple process consisting of three main steps: binary process, thinning process that allows tracing the boundary of the character and if there are more than two binary points, it means there is a junction point to be segmented, and segmentation. However, this study has limitations for future work, such as: during the thinning process, some of the elements may be missing or counted as secondary objects; additionally, the alphabet may be triggered due to its tail. Furthermore, the method could not segment more than one junction point at the same time.

### VI. CONCLUSION

The results of this study revealed current research trends in the field of Arabic. It emphasized the present state of several research elements in that field. This can encourage and make it easier to adapt and extend existing systems to new applications and systems. Arabic has a vast and undiscovered reach; nevertheless, little research has been done in that field previously.

We exhibited some of their prior work that was similar to contemporary state-of-the-art methodologies, with fewer mistakes and a high degree of abstraction. As demonstrated in the difficulties section, this identification is meant to give recommendations for future advancements in the field.

Because of the quality of screening, touching handwritten characters is present in old manuscripts. The Author therefore found that touching characters occurs widely in English, Chinese, Devnagari, Numbers and Arabic handwritten historical materials by exploring the literature for the review. This paper is scanning several approaches to help the researchers in this field to find the advantage and disadvantage of these approaches. For future research, the researcher encourages develop a database for touching characters in Arabic language to give more attention to multiple overlapping.

### ACKNOWLEDGMENT

The author would like to thank his brothers Abdulrahman Algaradi and Abdullah Algaradi for sponsoring him during this research.

**Abstract**—Customer trust has been recognized as an essential part of the rising trend of social commerce. Lack of trust facilitates the hesitation of customers to shop online or to avoid them completely. Therefore, it is essential to implement and analyze a way of buyer-seller relationship establishment that will improve customers' trust. This paper aims to develop a trust model of Social Network Sites (SNSs) sellers, and to assess the dimensions and criteria that affects customer's trust on Online Social Network Sites (SNSs) sellers by using Analytic Hierarchy Process (AHP) approach. The study was carried out among those who have transactions with Malaysian online SNSs sellers at least every three months. The findings have indicated the top three influencing criteria: recommendation, transaction safety, and rating. This study provides insight into the customers' thoughts about placing trust on online SNSs sellers for selling and purchasing activities.

**Keywords**—Online commerce; trust; social commerce; multi-criteria decision-making

## I. INTRODUCTION

The emergence of social commerce on Social Network Sites (SNSs) has changed the near-constant connectivity that enables online sellers to connect with customers. Its 24/7 connectivity allows online SNSs sellers to produce their content and exchange products or services with other users. On the other side, the customer may connect with other online SNSs sellers for current information on products or services [1]. Various platforms are used to share information about products and services to increase sales volume [2] to build customer's trust in buying and purchasing activities.

Although social commerce has become widespread, certain challenges lead to the lack of trust among customers on online SNSs sellers. In social commerce, trust is referred to a customer's belief to trust a seller's ability, generosity, integrity, and predictableness [3]. The uncertainty of the level of content provided by users and the lack of face-to-face interactions make trust a crucial component of social commerce [4]. Social interactions between customers are believed to increase customer trust in sellers [5]. Many customers avoid making online purchases due to a lack of trust in online platforms [6]. For example, customers' concerns regarding the quality of the information provided by online SNSs sellers make them trust the information provided by other customers more than they trust the online SNSs sellers. This demonstrates the significance of trust in motivating people to purchase online.

Various studies were carried out to identify different criteria that influence customer's trust on purchase intention in social commerce. In [3], various characteristics influencing customers' trust in social commerce include reputation, size, information quality, transaction safety, communication, economic feasibility, and electronic word-of-mouth (E-WoM) referrals. Another study adopted some constructs from the technology acceptance model (TAM) to describe social commerce constructs [4], and show trust positively affects the purchase intention, consistent with many other TAM researches.

Trust and informativeness are suggested in [7] as social network characteristics that affect trust in social commerce. Analysis among Indonesia backpackers discovered that attitude and compatibility are significantly influenced purchase intention [8]. According to the research findings of young people's trust in tourism sites, trust and satisfaction are more important than site design and E-WoM [9]. A recent study in [10] indicates that trust and satisfaction influence repurchase and E-WoM intentions.

Several studies also examine the influencing criteria by concentrating on particular SNSs as the medium of social commerce. A study in [11] discovered that propensity to trust and testimonial were two factors that influence trust in the online purchase through SNSs. Results from a study conducted in Thailand, users of social commerce are more likely to trust social commerce if it provides adequate online environments that include recommendation and referrals, rating and reviews, communication, security issues and E-WoM [12].

An empirical study on Instagram users discovered that perceived benevolence, perceived integrity of online store and key opinion leader endorsement are significant factors explaining customer trust and later influencing purchase intention [13]. In a recent study examining the relationship between social presence and customer relationship quality as measured by customer commitment and loyalty, it was found that in social commerce, social commerce trust mediates the effect of social presence on both commitment and loyalty of customers [14]. A survey among individuals using social commerce services in Korea revealed four factors that influence purchase intention related to social commerce: economy, necessity, reliability and sales promotion [15]. A quantitative method depending upon the sample size is employed in most of the existing studies. On the other hand,

one study finds the criteria through statistical methods and uses BP Neural Network approach to construct a social commerce trust evaluation model [16].

The trust element in purchasing-related decision-making can be seen as a multi-criteria decision-making (MCDM) problem. Problems are formulated and solved in MCDM with the criteria taken into consideration to assess an alternative's performance [17]. Analytic Hierarchy Process (AHP) is an MCDM approach that integrates quantitative and qualitative techniques [18] for handling measurable and intangible criteria. AHP enables subjective evaluation by using experts' judgement to decide the importance of criteria. Based on its importance, AHP determines the criteria that dominate the decision-making process and prioritize them. In decision-making, AHP reflects the analytical thinking of humans, where the assessment is performed in a hierarchical structure. In addition, all criteria to be taken into account will not be viewed as equal but by relative weight in the decision-making process. AHP decreases bias in the decision-making process by consistently reviewing the experts' evaluations.

This paper presents a study that aims to capture additional aspects of social commerce that supplement customers' insight and also encourage them to evaluate online SNSs sellers relatively. The rationale behind this study is to explore in-depth the factors that influence customers' trust. A sample of customers who have transactions with the identified Malaysian online SNSs sellers at least every three months is selected for experimental evaluation. This study also examined the potential of applying the AHP technique achieve two objectives:

1) to rank the criteria based on expert evaluation under multiple criteria relevant to this field.

2) to obtain the criteria weights by performing pairwise comparisons of importance between the criteria that influence customers' trust on online SNSs sellers and prioritize the influencing criteria prior to purchasing.

## II. DATA AND METHODOLOGY

We proposed a research model for analyzing customers' trust focused on Malaysian society to evaluate online SNSs prior to buying-selling activities. The model is designed to analyze the relevant factors that influence Malaysian customers' trust in order to validate the buyer-seller relationships, especially in the field of SNSs. The primary goal of this empirical research was to determine whether and how customers' trust on online SNSs sellers is obtained before deciding to purchase. The AHP method used in this study is illustrated in Fig. 1 to investigate the criteria that affect the customers' trust in online SNSs sellers.

In this first step, the decision problem should be defined since it drives the whole process on why AHP has to be used. As the traditional rating method is unable to filter out the responses' inconsistency, the AHP methodology employs the consistency test that screen out inconsistent responses. This study identified criteria based on the previous literature, as shown in Table I [19]. These criteria would be expected to collect the necessary information regarding their buying decision for evaluations and comparisons.

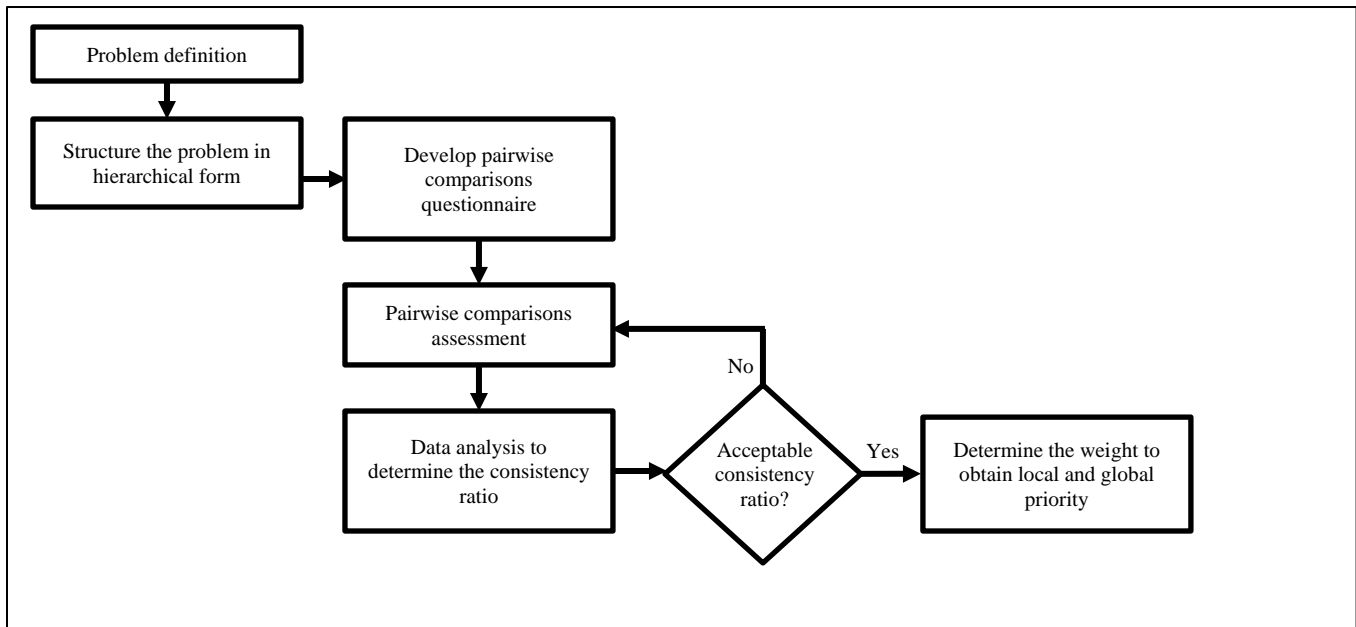

Fig. 1. Overview of AHP Methodology.

TABLE I. PROBLEM IDENTIFICATION

| Dimension                  | Criteria              | References          |
|----------------------------|-----------------------|---------------------|
| E-WoM                      | - Positive Valence    | [3], [4], [20]–[25] |
|                            | - Negative Valence    |                     |

|                            | - Propensity to Trust | [22], [34]          |

### III. RESULTS

A schematic representation in a hierarchical structure was formed to structure the problem, as illustrated in Fig. 2. The hierarchy consists of two levels and starts from Level 1 represents the goal, i.e. prioritizing the criteria to evaluate trust on online SNSs sellers. It is then broken up into four dimensions relevant to the goal are represented in Level 2: E-WoM, information quality, social commerce constructs, and people. The sub-criteria associated with each of the dimensions form Level 3.

Once the hierarchical structure has been developed, the relative contribution of each criterion must be obtained through a paired comparison from each expert. In the AHP procedure, the selection of expertise is crucial in establishing the significance of factors in pair comparisons. It is thus vital to identify before a decision has been reached which criteria an expert has to satisfy [35]. Wrong expert selection may lead to a discrepancy in judgement. Furthermore, the qualities required by an expert are varied according to the field of study.

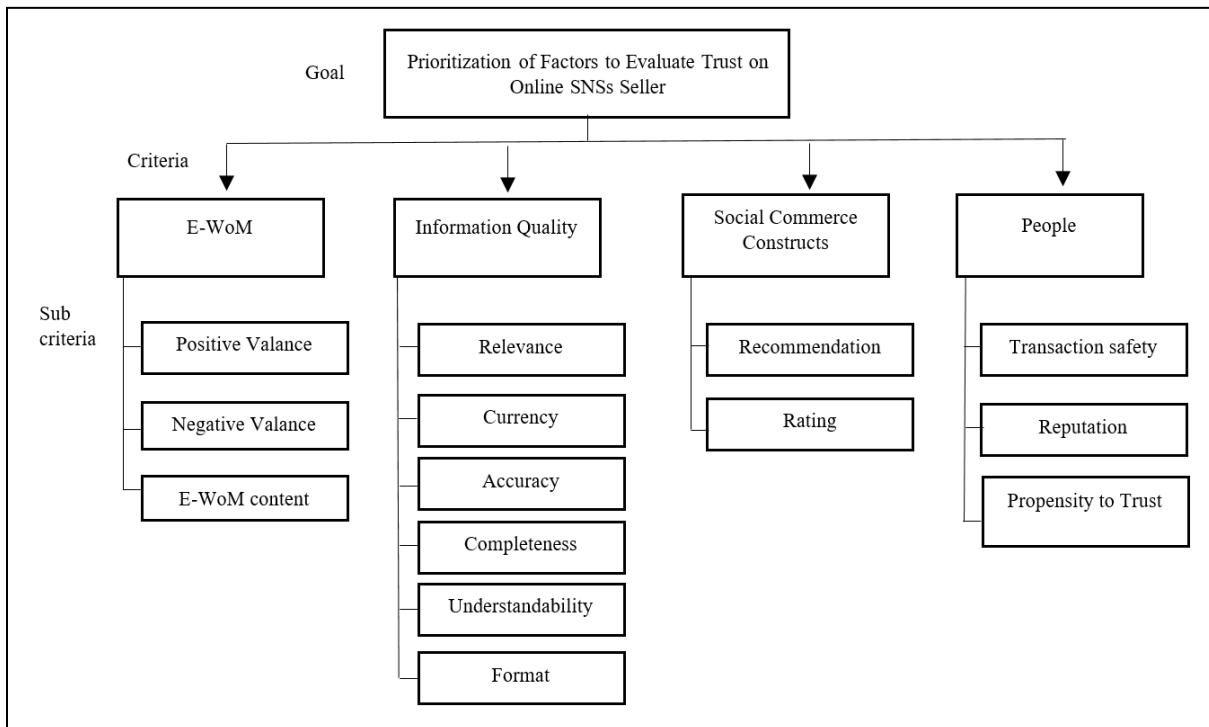

Fig. 2. Hierarchical Structure.

The experts' input plays a significant role in getting the comparison pairwise. In the AHP technique, a single expert is usually assumed to be appropriate to offer a decision. However, a single expert can provide an uncertain judgment. To reduce the uncertain judgment, group decision-making can be employed. The judgment of each member is combined to reach a consensus in group decision-making.

According to Forman and Peniwati [36], two common approaches to aggregate the individual judgments are Aggregation of Individual Judgments (AIJ) and Aggregation of Individual Priorities (AIP). The AIJ combines all individual judgements to act as a 'new' decision by employing geometric mean. The AIP judgment, meanwhile, is based on a number of consensus groups, which may use either arithmetic or geometric mean. All other group decisions are added to the calculated group decisions.

In this study, experts are categorized as people who shop at least once every three months. The definition of experts is based on previously completed similar studies [3], [37]-[42]. 15 respondents took part in making a paired comparison based on the definition of experts, and this can be an excellent contribution to producing a less biased decision.

In order to identify the ranking among factors according to their importance, the information acquired from the questionnaire has been evaluated. The judgement was then consolidated to determine the weight of each criterion by each expert. Criterion ranking was based on the weight determined using the normalized principal Eigen criteria.

The results of this study were based on the evaluations made by the 15 respondents, which were then aggregated using the geometric mean as the AIJ approach was employed. Table II shows a sample of individual evaluations in the form of a pairwise comparison matrix.

The aggregate comparison matrix for criteria for the hierarchical structure level 2 is shown in Table III. An aggregate comparison matrix for sub-criteria in Level 3 to show the relative priorities of the sub-criteria with respect to the Criteria in Level 2 is shown in Table IV (sub-criteria E-WoM), Table V (sub-criteria People), Table VI (sub-criteria Information Quality), and Table VII (sub-criteria Social Commerce Constructs).

TABLE II. SAMPLE INDIVIDUAL JUDGMENT IN THE PAIR-WISE COMPARISON MATRIX

|                   | Accuracy | Relevance | Completeness | Currency | Understandability | Format |
|-------------------|----------|-----------|--------------|----------|-------------------|--------|

TABLE VII. AGGREGATED COMPARISON MATRIX FOR SUB-CRITERIA SOCIAL COMMERCE CONSTRUCTS

|                | Recommendation | Rating |
|----------------|----------------|--------|
| Recommendation | 1              | 1.79   |
| Rating         | 0.56           | 1      |

The pairwise comparisons were established for the criteria based on the judgements provided by each expert. The assessment will identify the importance of criteria and sub-

criteria based on the hierarchy structure from step 2. The comparisons are made using a scale of absolute judgements that represents how much one element dominates another with respect to a given attribute.

In determining weights for criteria and sub-criteria, the following procedures are applied to each of the aggregated comparison matrices:

- 1) Calculate the sum values in each matrix column.
- 2) Divide each value in each column by the column sum to normalize the matrix.
- 3) Determine the weight by calculating the average value of each row of the normalized matrix.

The data is analyzed at this point in order to calculate the consistency ratio. If the consistency ratio is not acceptable, the pairwise comparison assessment will be reviewed by experts.

When it comes to making decisions, humans are notoriously inconsistent. The Consistency Ratio (CR) measures the consistency of judgments in order to validate the results. The acceptable CR values (Table VIII) depend on the size of matrices as proposed in [43]. The judgments are consistent and valid if the value is within the range. In this scenario, the experts will be requested to review their judgement. Because of the equation's constraint, the CR value is not relevant to 2X2 matrices [42]. In addition, the two-element matrix has a perfect consistency.

The following four steps are used to compute the CR:

- 1) Multiply each column total by its respective weight for each criteria.
- 2) Get the  $\lambda_{max}$  value by adding values calculated in Step 1.
- 3) Get the Consistency Index (CI) value using Equation (1).

$$CI = (\lambda_{max} - n) / (n - 1) \quad (1)$$

where n is the number of the criteria being compared in the matrix.

- 4) Get the CR value using Equation (2).

$$CR = CI / RI \quad (2)$$

where RI is the Random Index. RI value is determined from a lookup table (Table IX) depends on the n value.

TABLE VIII. ACCEPTABLE CR VALUE

| Size of matrices | Acceptable CR values |
|------------------|----------------------|
| 2x2              | Not applicable       |
| 3x3              | ≤5%                  |
| 4x4              | ≤8%                  |
| Larger           | ≤10%                 |

TABLE IX. RANDOM INDEX

## IV. DISCUSSION

This section discusses the data analysis for the criteria and each sub-criteria, as well as the determination of weight to obtain local and global priority.

### A. Criteria

People are the most significant criteria, as demonstrated in Table X, with a weight of 28%. Individuals, small or large groups of people, or communities who play a key role in social commerce are referred to as individual consumers and sellers [44].

With a weight of 27%, Social Commerce Constructs is ranked second. Customers can create their own content and share their experiences with online SNSs vendors, products, or services using features offered on social platforms. At the same time, they are permitted to exchange information with others and to offer online social support to other customers. According to [45], social commerce constructs have an impact on customers' trust as well as purchase intention.

In the ranking, E-WoM comes in third. Customers rely on information offered by others to assist them in making purchasing decisions in a virtual world of social commerce. Customers must share any information written by them in order to build confidence with online SNSs sellers.

The Information Quality is ranked last. The customer's absence of direct product experience necessitates adequate, reliable, and high-quality information offered by online SNSs sellers. In addition, the transaction takes place in a non-face-to-face setting.

### B. Sub-Criteria for E-WoM

The ranking of sub-criteria under E-WoM criteria is shown in Table XI. With a weight of 38%, negative valence takes first rank. This is reinforced by a study conducted by [46] which found that negative valence e-WoM had a greater impact on client decision-making than positive valence e-WoM. Positive valence, on the other hand, comes in second rank with a weight of 33%. With a weight of 29 percent, e-WoM material is ranked last. Customers who are heavily involved in online purchases are influenced by the quality of e-WoM, whereas those who are less involved are influenced by the volume of e-WoM [47].

### C. Sub-Criteria for People

The ranking of sub-criteria evaluated under the People criteria is shown in Table XII. With a weight of 40%, Transaction Safety is at the top of the list. Account transfers or bank deposits are the most prevalent payment methods used by customers and online SNSs sellers in social commerce. It is critical for a customer to believe that the seller is protecting their personal and transaction information through this process.

With weights of 30%, Reputation is ranked second. Customers assume that the seller of online SNSs is skilled and trustworthy based on their reputation. Customers will trust online SNSs sellers that have a strong reputation in their buying and selling activities.

TABLE X. NORMALIZED MATRIX AND RANKING WEIGHTS OF CRITERIA

| Criteria                   | E-WoM | Social Commerce Constructs | Information Quality | People | Weights | $\lambda_{max}$ , CI,RI                        | CR     | Ranking |
|----------------------------|-------|----------------------------|---------------------|--------|---------|------------------------------------------------|--------|---------|
| E-WoM                      | 0.243 | 0.237                      | 0.229               | 0.260  | 0.242   | $\lambda_{max}=4.0028$<br>CI= 0.0009<br>RI=0.9 | 0.0010 | 3       |
| Social Commerce Constructs | 0.273 | 0.266                      | 0.268               | 0.260  | 0.267   |                                                |        | 2       |
| Information Quality        | 0.227 | 0.213                      | 0.214               | 0.204  | 0.215   |                                                |        | 4       |
| People                     | 0.258 | 0.283                      | 0.289               | 0.276  | 0.277   |                                                |        | 1       |

TABLE XI. NORMALIZED MATRIX AND RANKING WEIGHTS OF SUB-CRITERIA E-WoM

| Sub-criteria     | Positive Valence | Negative Valence | E-WoM Content | Weights | $\lambda_{max}$ , CI,RI                         | CR     | Ranking |
|------------------|------------------|------------------|---------------|---------|-------------------------------------------------|--------|---------|
| Positive Valence | 0.331            | 0.338            | 0.323         | 0.331   | $\lambda_{max}=3.000$<br>CI = 0.0002<br>RI=0.58 | 0.0004 | 2       |
| Negative Valence | 0.368            | 0.375            | 0.384         | 0.376   |                                                 |        | 1       |
| E-WoM Content    | 0.301            | 0.287            | 0.293         | 0.294   |                                                 |        | 3       |

TABLE XII. NORMALIZED MATRIX AND RANKING WEIGHTS OF SUB-CRITERIA PEOPLE

| Sub-criteria        | Transaction Safety | Reputation | Propensity to Trust | Weights | $\lambda_{max}$ , CI,RI                           | CR       | Ranking |
|---------------------|--------------------|------------|---------------------|---------|---------------------------------------------------|----------|---------|
| Transaction Safety  | 0.399              | 0.398      | 0.401               | 0.399   | $\lambda_{max}=3.000$<br>CI = 5.72E-06<br>RI=0.58 | 9.86E-06 | 1       |

| Propensity to Trust | 0.300              | 0.302      | 0.301               | 0.301   |                                                   |          | 2       |

TABLE XIII. NORMALIZED MATRIX AND RANKING WEIGHTS OF SUB-CRITERIA INFORMATION QUALITY

| Sub-criteria      | Accuracy | Relevance | Completeness | Currency | Understandability | Format | Weights | $\lambda_{max}$ , CI,RI                          | CR     | Ranking |
|-------------------|----------|-----------|--------------|----------|-------------------|--------|---------|--------------------------------------------------|--------|---------|
| Accuracy          | 0.190    | 0.233     | 0.242        | 0.181    | 0.161             | 0.161  | 0.195   | $\lambda_{max}=6.0444$<br>CI = 0.0088<br>RI=1.24 | 0.0071 | 1       |
| Relevance         | 0.113    | 0.139     | 0.118        | 0.168    | 0.161             | 0.147  | 0.141   |                                                  |        | 5       |
| Completeness      | 0.128    | 0.192     | 0.163        | 0.172    | 0.171             | 0.171  | 0.167   |                                                  |        | 4       |
| Currency          | 0.186    | 0.146     | 0.169        | 0.177    | 0.186             | 0.195  | 0.177   |                                                  |        | 2       |
| Understandability | 0.214    | 0.156     | 0.172        | 0.172    | 0.180             | 0.183  | 0.179   |                                                  |        | 3       |
| Format            | 0.168    | 0.135     | 0.136        | 0.129    | 0.141             | 0.143  | 0.142   |                                                  |        | 6       |

TABLE XIV. NORMALIZED MATRIX AND RANKING WEIGHTS OF SUB-CRITERIA SOCIAL COMMERCE CONSTRUCTS

|                | Recommendation | Rating | Weights | $\lambda_{max}$ , CI,RI     | CR | Ranking |
|----------------|----------------|--------|---------|-----------------------------|----|---------|
| Recommendation | 0.642          | 0.642  | 0.642   | $\lambda=2$<br>CI=0<br>RI=0 | NA | 1       |
| Rating         | 0.358          | 0.358  | 0.358   | 0.168                       |    | 2       |

Propensity is ranked last, with a weight value of the same as Reputation. Since customers and sellers may or may not know each other, trust plays a vital part in social commerce. As a result, each person's level of trust may vary depending on the information available.

#### D. Sub-Criteria for Information Quality

In social commerce, information quality has been identified as a significant criterion in influencing customers' online purchase decisions [48]. The ranking of sub-criteria evaluated under the Information Quality criteria is shown in Table XIII. With a weight of 19 percent, Accuracy is ranked top. Customers may be forced to rely on the information provided

by the seller if they are unable to test the product or services prior to making a purchase. As a result, sellers must be able to deliver information that is accurate, unambiguous, meaningful, believable, and consistent.

With the same weight of 18 percent, Currency and Understandability are ranked second and third. Sellers must present up-to-date information that customers can grasp in order to gain their trust. With a weight of 17 percent, Completeness is ranked fourth. Relevance and Format, meanwhile, are ranked fifth and sixth, respectively, with a 14 percent weighting. The seller's information should represent all conceivable states that are relevant and required by the user when making a purchase choice.

E. Sub-Criteria for Social Commerce Constructs

The ranking of sub-criteria studied under Social Commerce Constructs criteria is shown in Table XIV. Recommendation is ranked first, with a 64 percent weighting. With a weight of 36%, a Rating that represents a measurement scale on a product, service, or seller is ranked second. Customers must rely on other customers' experiences represented through ratings and recommendations because they cannot personally experience the product or services.

F. Determination of Local and Global Weights

The weights for each primary criteria are multiplied by the weights of each relevant sub-criteria to arrive at the global weights. Local weights are the weights assigned to each main and sub-criteria. Table XV reveals that the sub-criteria Social Commerce Constructs' (0.1728) is the most important, followed by Transaction Safety (0.1120) under sub-criteria People. The least important sub-criteria, Relevance and Format of Information Quality, are both weighted at 0.0294.

This study identified new criteria and sub-criteria for evaluating the trustworthiness of online SNSs sellers from a theoretical standpoint. To depict the priority of characteristics that influence customers' trust in those sellers, a hierarchy structural model is built as illustrated in Fig. 3.

Online SNSs sellers can use the identified influencing criteria to improve their business activity in the real world. One

of the most important findings is that online SNSs sellers should pay more attention to customer recommendations, which could lead to increased client trust. Existing customers' positive recommendations may entice new consumers to engage in buying-selling activities. Furthermore, if a known friend recommends an online SNSs sellers, potential clients will have more confidence in the business.

Second, throughout the selling-buying activities, online SNSs sellers must verify that the transaction and its linked information are secure. For transaction payment, the majority of online SNSs sellers employ bank transfers. As a result, it is critical to ensure that the personal information of associated customers is kept secure and not shared with third parties. Customers should also be constantly updated about transaction status and payment confirmation because the transaction does not take place face-to-face.

Finally, customers can use ratings to help them decide whether or not to purchase something. Existing customers rate online SNSs sellers based on their transaction experience. Because a positive rating will help potential clients trust online SNSs sellers, online SNSs sellers must maintain a positive rating in order to expand their business. In addition, customers' trust in online SNS sellers should be based on the People dimension and Social Commerce Constructs as discussed in the analysis results.

TABLE XV. FINAL WEIGHTS AND OVERALL RANKING - GRAPH

| Criteria                   | Local Weights | Sub-criteria        | Local Weights | Global Weights | Overall Ranks |
|----------------------------|---------------|---------------------|---------------|----------------|---------------|
| E-WoM                      | 0.240         | Positive Valence    | 33%           | 7.92%          | 7             |
|                            |               | Negative Valence    | 38%           | 9.12%          | 4             |
|                            |               | E-WoM Content       | 29%           | 6.96%          | 8             |
| Social Commerce Constructs | 27%           | Recommendation      | 64%           | 17.28%         | 1             |
|                            |               | Rating              | 36%           | 9.72%          | 3             |
| Information Quality        | 21%           | Accuracy            | 19%           | 3.99%          | 9             |
|                            |               | Relevance           | 14%           | 2.94%          | 13            |
|                            |               | Completeness        | 17%           | 3.57%          | 12            |
|                            |               | Currency            | 18%           | 3.78%          | 10            |
|                            |               | Understandability   | 18%           | 3.78%          | 11            |
|                            |               | Format              | 14%           | 2.94%          | 14            |
| People                     | 28%           | Transaction Safety  | 40%           | 11.20%         | 2             |
|                            |               | Reputation          | 30%           | 8.40%          | 6             |
|                            |               | Propensity to Trust | 30%           | 8.40%          | 5             |

Fig. 3. Hierarchy Structure Model

## V. CONCLUSION

Customers lack direct product experience in social commerce since activities take place in a non-face-to-face environment. A lot of research has been undertaken to investigate the factors that influence customers' trust in online commerce. However, there are few studies that look at the criteria and their significance in the context of online sellers who utilize social media sites as their marketing platforms. This study addresses the gap by examining the factors for boosting customers' trust in online SNSs sellers from many angles.

This study has successfully achieved the objective by using the AHP technique to discover and rank the criteria that influence a customer's trust in online SNSs sellers prior to making a purchase intention. The following criteria are prioritized based on the ranking: (1) Recommendation, (2) Transaction Safety, (3) Rating, (4) Negative Valence, and (5) Propensity to Trust, according to this study. To highlight the priority as well as the interaction between criteria and sub-criteria, a hierarchy structural model is created.

The findings of this study show which criteria the customers should consider according to its importance when

evaluating the reliability of online SNSs sellers prior to making a purchase. The identified criteria, on the other hand, will serve as a guideline for online SNSs sellers to establish customer trust in their buying and selling activities.

The identified criteria and sub-criteria can be investigated further in future research to quantitatively assess the trustworthiness of online SNSs sellers. There may be interrelationships between some of the specified criteria and sub-criteria. In that instance, Analytical Network Process (ANP) might be used to do more research because it ignores interaction between criteria and sub-criteria. The results of this study can be integrated or compared with those from other multi-criteria approaches like TOPSIS, ELECTRE, and SWOT.

**Abstract**—Using textual passwords suffer from the balance between security and usability. Password policies are usually adopted by system administrators to force users to choose strong passwords. However, users often use a simple password to make it easy to remember, which reduces the password strength and make it vulnerable to information security threats. When users enter their passwords in public places like airports or cafes, they become exposed to shoulder surfing attacks which are considered as a kind of social engineering. With a little effort, an attacker can capture a password by recording the individual's authentication session or by direct observation. To overcome this vulnerability, we propose a new textual-password approach that uses camouflage characters and a virtual keyboard which leads to generating strong and easy to remember passwords. The perspective of usability and security was evaluated by experimental studies conducted with 65 users and then compared with recent studies. The results showed that the proposed technique has the lowest shoulder surfing success rate with just 3.63% with reasonable usability.

**Keywords**—Shoulder surfing; caesar cipher; virtual keyboard; graphical password; social engineering

## I. INTRODUCTION

Current authentication systems have a lot of weaknesses even if the system is secured, an individual's behaviour may cause a security breach. Users usually pick a short or easy password to remember, which makes their accounts vulnerable to attack and easily guessable. On the other hand, longer passwords are harder to memorise and to type correctly [1][2]. To consider a password as strong it must have eight characters or more, contain numbers, special characters mixed with small and capitalize alphabets [3].

By adding the human factor to the equation of security and how easily social engineering can manipulate the user, textual passwords become vulnerable to spyware attacks, keyloggers, dictionary attacks, and shoulder surfing attacks [4]. Most individuals are aware of security threats but they insist to avoid them. A survey reported that 90% of 152 computer users leaked their passwords. In this situation, forcing the user to create a password according to strict policies will not solve this issue [5]. To overcome the limitations of text-based passwords, many techniques such as two-factor authentication and graphical passwords are used [6]. Moreover, using input devices such as the mouse and touch-screen makes graphical authentication techniques possible. Unfortunately, they are unsecured to many attacks such as shoulder-surfing, spyware, Social Engineering and Dictionary attacks.

Shoulder surfing attack is a type of identity theft, it occurs when the attacker looks over someone's shoulder to get passwords, login PINs or other sensitive personal data. This attack can also be done by a small wireless camera that is easy to install. To overcome this problem, a wide range of research efforts have been done on eye-tracking algorithms. Systems login that is based on gazing to select a character from an on-screen keyboard is one of the solutions for shoulder-surfing but it may take a long entry time and lack of input accuracy [7]. Another approach to solve this problem is using a graphical password or integrating both graphical and textual passwords [8][9].

Graphical password has been widely used, especially on smartphones. An Individual can unlock his smartphone after the correct pattern is mapped out on a three-by-three rectangle, as in Fig. 1. As shown in Fig. 2 all the authentication Graphical methods can be grouped into three categories:

1) *Recognition-based system*: in this method users can login by choosing the correct photo from a list at the signup time [10].

2) *Hybrid system*: this method combines more than one schema to eliminate their issues and produces a more stable and useful system [11].

3) *Recall-Based system*: this method asks the user to draw or write something to use it as the Authentication code. There are two types of Recall base systems:

a) The Pure Recall method is relayed on the user to give the right authentication code at the login time [12].

b) Cued Recall method is based on helping the users to login by giving them a hint to remember their passwords [12].

However, most login graphical techniques may suffer from a complicated algorithm or need a special device, which increases the need to develop a new secure login method.

In this paper, we first discuss the shoulder surfing attack as a part of social engineering, then propose a defensive model that can resist shoulder surfing attacks. The defensive model is designed on the concept that the user can enter random camouflage characters by using a virtual keyboard. The character of the virtual keyboard is shifted by using Caesar cipher which is used to encrypt and decrypt the user input. After applying an experimental study to test the defensive model with 65 participants and analyzing the data, the conclusion is presented to summarize the primary outcomes and to determine model usability and efficiency against shoulder surfing attacks.

Fig. 2. Categorization of Authentication Methods for the Graphical Password.

## II. RELATED WORK

Graphical password authentication systems that depend on recognition based and recall based schema has been adopted in many research to fight against shoulder surfing attacks. In [13], Jiya Gloria Kaka et al. compared 10 graphical authentication methods based on three common attacks and the usability features. Although, most of the authentication systems have acceptable usability only three methods were effective against shoulder surfing attacks.

In [14], Jianwei Lai et al. introduce a unique authentication scheme that resists shoulder-surfing attacks. The scheme is based on textual passwords, so to login, the user will enter part of the password and skip the password character that is marked with 'x'.

Aakansha S. Gokhale et al. developed a new graphical password authentication technique that resists shoulder surfing, brute force and guessing attacks [15]. The authentication technique is based on three questions related to 25 pictures. In the login phase, the user must click on the correct location in the image for every question. The system has a very large password space equal to  $8.367939e+34$  which can provide a strong secure password.

In [16], Dongmin Choi et al. discussed five model's authentication schemes against shoulder surfing and social engineering attacks. The paper compared defensive types; QWERTY based Secure Keypad, ABC based Secure Keypad,

Touch and Slide Secure Keypad, colour-based Secure Keypad and Random Secure Keypad. As a result, the five techniques were weak against shoulder surfing attacks.

Aravinda Thejas Chandra et al. developed an authentication system based on eye-tracking and a smart camera [17]. The gaze-based PIN identification application was tested on a nine-digits keypad by using real-time eye-tracking to login. Although it can be used as a defensive mechanism against shoulder surfing, the paper did not study the medical effect of the system on the user's eyes for a long period of using special if the password is more than 6 characters.

In [18], Anindya Maiti et al. proposed a defensive model based on a random alignment keyboard with twenty-six alphabets created by an augmented reality wearable device. The model involves three different randomization strategies, each one of them can shift the 26 characters to produce a new virtual keyboard. Although the system is effective as a defensive mechanism against side-channel and shoulder surfing attacks, it requires a secured wireless channel and special hardware.

Eiji Hayashi et al. designed a novel secure mechanism for user authentication that can be used with any screen size [19]. In the proposed model the user chooses a set of images as a graphical password. To login, he must choose his distorted images from the set of images. This authentication technique relies on the fact that human perception is influenced by his information. Despite the simplicity of the method used, it is effective against social engineering and shoulder surfing attacks.

Vishal Kolhe et al. introduced an authentication system based on a 3D password [20]. The 3D password is a multi-passwords system that combines a textual password with a graphical password in a virtual environment. Users can move in a virtual environment to create their passwords. Although the model provides secure authentication and user friendly, it has many disadvantages like time, memory requirement and cost. The system provides immunity against brute force attacks and key loggers but is still vulnerable to shoulder surfing attacks.

Hung-Min Sun et al. introduced a graphical authentication system for smartphones called PassMatrix [21]. The system consists of many components:

- Password verification module.
- vertical and Horizontal axis control module.
- Login indicator generator module.
- Image discretization module.
- Communication module.
- Database.

The images which are used to login are divided into horizontal (1-11) and vertical axis (A-G) grids. To login, the user must circle his hand on the screen to get the generated key or listen to an audio that contains the generated key by using earbuds or a Bluetooth headset. The audio is sent from the

server using a secure channel, then the user must shift the character to match the key. This procedure is repeated until the login is finished. The total accuracy of all login trials is 93:33% which means it can be used to defend against smudge attacks and shoulder surfing attacks.

### III. SOCIAL ENGINEERING AND SHOULDER SURFING ATTACKS

Social engineering is an attack that depends on the human factor. It's classified as a non-technical attack in general. However, it can be combined with technical types of attacks like Trojan and spyware, which makes it more effective [22]. Cyence, a cyber security analyst company reported In 2016, that the United States was the most targeted country with social engineering attacks and had the highest attack cost, followed by Japan and Germany. The total cost of these attacks in the US alone was \$121.22 billion [23].

Shoulder surfing is a kind of social engineering. It can be performed by using technical and non-technical ways. Although shoulder surfing attack can be noticed by the victim, it could be combined with other types of attacks like spear-phishing and dumpster diving which makes it a powerful attack. A survey was done in the US, Germany, and Egypt concluded that 67.4% of Shoulder surfing occur in public places and 74.1% of the observer were strangers [24]. Depending on the Humans nature people act like that for different reasons such as curiosity, boredom or to get private data. Some companies produce special screens that make it difficult to see the smartphone or computer screen from an angle to keep the privacy [25]. This screen can be useless when the attacker uses a small hidden camera that can capture video and send it directly to the attacker. Although there are multi-solutions to solve the shoulder surfing problem, they are suffering from common issues such as:

- 1) The most common software and operating system use alphanumeric usernames and passwords for authentication, which makes it difficult to apply random security algorithms.
- 2) Some graphical password Algorithms used in systems are vulnerable to shoulder surfing and other types of attacks [26].
- 3) Adding layers of security or complex authentication systems decreases the usability and functionality of the system.
- 4) The common careless behaviours like writing down a password or using the data autofill technique make security solutions worthless.

### IV. PROPOSED DEFENSE MODEL

In this study, two different models were designed, a shoulder surfing defensive model and a traditional login system that contains just a password with eight characters and a username. The proposed defensive model is based on camouflage characters and a virtual keyboard with shifted alphabetic as shown in Fig. 3.

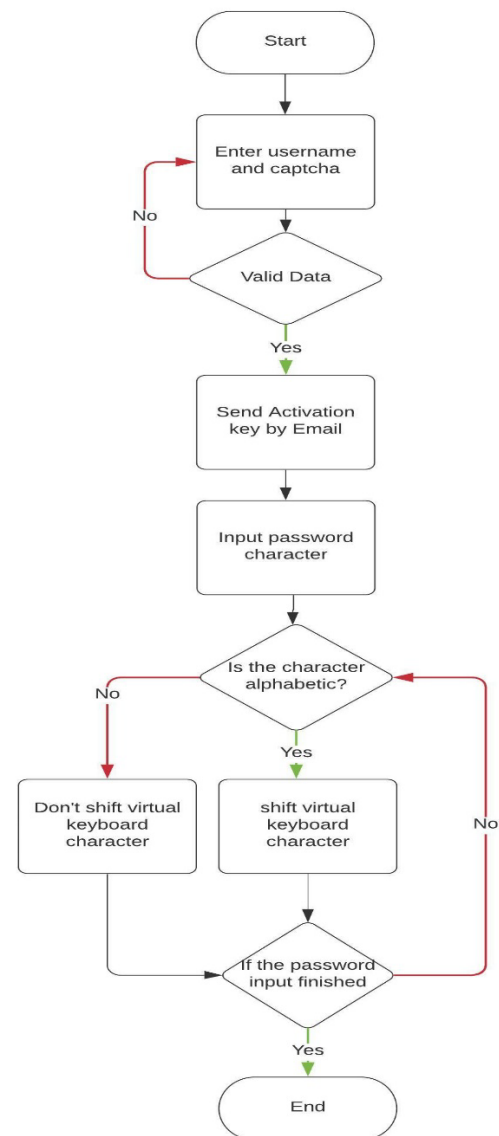

Fig. 3. The General Authentication Mechanism.

The virtual keyboard uses Caesar cipher to shift the 26 alphabetic, while the rest of the keyboard keys which are coloured with blue will be static and will act as normal keys as in Fig. 4. Caesar cipher is a simple substitution cipher that uses the same key for encryption and decryption [27]. Depending on the symmetric key letters are shifted a certain number of places down the alphabet. If the shift exceeds the number of the alphabet, the alphabet will just be rotated to the front. The alphabet in the proposed model is arranged in horizontal lines according to the QWERTY keyboard, so the first alphabet is q and the last is m. The result of Caesar cipher will be according to the QWERTY keyboard not to the normal alphabetic sequence. This system also applies another layer of protection by adding camouflage characters to the real password. The user authentication process is divided into two phases as follows.

Fig. 4. The Virtual QWERTY Keyboard.

**A. Registration Phase**

1) The user must enter eight characters password, username, and email to register an account as in Fig. 5.

2) The traditional system will just use the password and the username to login as in Fig. 6.

**B. Login Phase**

1) For authentication, the user must enter his username and captcha character as in Fig. 7. After that, the server will send the activation key to the users' email. The activation key (AK) will be random from 1 to 9 and it mustn't be in the password that has already been entered by the user in the registration phase.

2) In the Caesar encryption algorithm, the encryption key (k) will be chosen randomly from 1 to 10 to shift the character in the virtual keyboard. In the encyusting process, x is the character number in the virtual keyboard and k will be fixed in each authentication session as in Eq (1).

$$En(x) = (x-k) \text{ mod } 26 \quad (1)$$

3) Every time the user enters an alphabetic character, the virtual keyboard will shift only the alphabetic character's position according to the Caesar cipher. Note that the virtual keyboard will shift after pressing alphabetic keys and will not shift, if the user enters a number, special symbols or press any other button. The user password must be written by the physical keyboard, but according to the virtual keyboard character. For example, if the first password character is 'x', the user will press 'k' on the physical keyboard as shown in Fig. 8.

4) The user will combine his real password with a camouflage character by using the activation key followed by a character equal to the value of the activation key. For example, if the activation key was 5 and the user password was xAvd4\$141 the user could enter 5t!C3wxAvd4\$141, xAvd4\$1415t!C3w or xAv5t!C3wd4\$141 as his password. The sequence 5t!C3w will be used as a camouflage for the password and can be added at any position to the real password.

5) After entering the password the decryption key will equal the number of entered alphabetic multiplied by the encryption key. For example, if the encryption key was 3 and the user entered 5 alphabetic the decryption key would be 15.

6) Finally, when the user submits the system will Decrypt the password by using Caesar decrypt equation as in Eq (2). Note that the password will be decrypted from right to left and the decryption key will be subtracted from the encryption key after decrypting each alphabetic. For example, if the decrypt key is 33 and the password is 'tupert24wertq', the letter 'q' will be decrypted with k equal 33 and 't' with k equal to 30. Then the system will omit the camouflaged character from the password to get the real password.

$$Dn(x) = (x-k) \text{ mod } 26 \quad (2)$$

As a result of this approach, if a person tries to comment shoulder surfing attack, he will not succeed; because the arrangements of the alphabet change after every click and the password is protected by the camouflaged character. Also, this technique is powerful against the keylogger that takes screenshots after each input.

## V. EXPERIMENTAL STUDY

The experimental study aims to evaluate the model against shoulder surfing attacks and to measure the usability of the proposed techniques. The following explains the experimental details:

1) Design two applications; the first, with a traditional login system, and the second, is based on the virtual keyboard; to be able to evaluate the proposed defensive techniques against shoulder surfing.

2) The experiment was done in a controlled environment in the lab and all participants entered 8-character passwords in both systems.

3) Experimental study with 65 participants divided into 20 PhD holders and 45 students. fifty-five of the participants will act as ordinary users, and 10 will act as shoulder surfing attackers. The experiment began with a brief explanation of the proposed defensive techniques. To become familiar with the system, the 55 participants are allowed to create their passwords and then login to the system approximately 3 times. Also, the 55 participants were informed that they are just allowed three attempts to login each time with each a count. If the three attempts failed, the account would be locked and the user has to try to login with a new account.

4) Measuring the success rate of the attack will clarify the models' susceptibility to shoulder surfing. To accomplish that, the 55 participants acted as victims, with 5 random students and 5 PhD holders acting as shoulder surfer attackers. The efficiency of the model is determined by analyzing and comparing the shoulder surfing success rate of the experiment with other studies.

## VI. RESULTS

To determine the model's usability two factors must be measured, entering time and login success rate. The success rate of the shoulder surfing attack will evaluate the model defensive technique. The result of these factors is used to compare four systems: The suggested traditional system which depends on static username and password memorized by the user, the defence proposed model and two models from other studies. For simplicity, the traditional login system will be represented with M1 and the defensive model with M2. While

the M1 password has a fixed number of characters which is 8, the M2 password is between 10 and 18 characters.

### A. Entering Time

The average time of the M1 model was 22.78, while M2 was 32.62 seconds as shown in Table I. The min and max time of the M1 system was 19.8 and 27.2 seconds, while in M2 was 30.1 and 36.6 seconds. The standard deviation (SD) in the entering time test of the two models was almost equal. By comparing the result it's clear that the M1 system is easier to use than the M2 model. Although the M1 test was better it has a fixed number of characters which is 8, while M2 has more characters even if the AK equals one. In general, the test result is affected by two factors:

- 1) The user typing speed.
- 2) The number of characters of the password.

### B. The Success Rate of Login

The login success rate is calculated by dividing the overall success login attempts over the total of all attempts of one participant. All 55 participants have given 3 attempts for login and they repeated this process for 5 different accounts. Table II shows the SD and mean values for M1 and M2 models. By comparing the mean value, M1 is better than M2 by 0.015. However, all participants have used the M1 model before in their life which makes it the most familiar model to them.

### C. Success Rate of Shoulder Surfing Attack

The experiment of shoulder-surfing attack was performed by 10 attackers and 55 users represent the victims. To keep the experiment real just 25 of the users were told that they will be watched to capture the login data. The attacker has to get the exact password and guessing is not allowed. The M1 model value was very high with 80.1%, while the defensive model M2 was 3.63% as shown in Table III.

The conducted result compared to the most related studies in terms of resisting shoulder surfing attacks and usability, support the M2 model technique in defending against shoulder surfing attacks as shown in Table IV.

TABLE I. THE RESULTS OF ENTERING TIME IN SECONDS

| Model | Min  | Max  | Mean  | SD   |
|-------|------|------|-------|------|
| M1    | 17.8 | 25.2 | 22.78 | 3.76 |
| M2    | 30.1 | 36.6 | 32.62 | 3.25 |

TABLE II. THE RESULTS OF THE LOGIN SUCCESS RATE

| Model | Mean  | SD   |
|-------|-------|------|
| M1    | 0.961 | 0.39 |
| M2    | 0.946 | 0.44 |

TABLE III. THE RESULTS OF THE SHOULDER-SURFING SUCCESS RATE

| Model | shoulder-surfing success rate |
|-------|-------------------------------|
| M1    | 80.1%                         |
| M2    | 3.63%                         |

TABLE IV. PROPOSED MODELS RESULT COMPARE TO OTHER STUDIES

| Study                  | Entry Time | Success Rate of login | The success rate of shoulder surfing |
|------------------------|------------|-----------------------|--------------------------------------|
| <b>Proposed models</b> |            |                       |                                      |
| M1                     | 22.78      | 96.1%                 | 80.1%                                |

## VII. DISCUSSION

In this section, we analysed the data collected from the 65 participants, 55 acted as normal users and 10 as attackers. The M1 model has a faster entry time and a higher log in success rate than the M2 model; which makes the M1 a more friendly system. However, the M1 system is vulnerable to shoulder-surfing threats by 80.1% while M2 scores just 3.63%. The outcome obtained from the experiment indicates that using a visual keyboard with camouflage characters is a good defensive mechanism against the shoulder-surfing attack. It might be worth mentioning that the delay in M2 entry time is happening because the user must first check his email to get the AK key, then he must enter the password according to the dynamic virtual keyboard. This result is not enough to conclude that the M2 model is the best approach against shoulder-surfing, so it should be evaluated with other models [28][29] that are designed to fight against shoulder surfing. By comparing all models, it's obvious that the defence model M2 is the best defensive model with a success rate of shoulder surfing attack equal to 3.36%. However, it's the worst in entry time As shown in Fig. 9. Note that in the M2 model, the user must enter the password every time and can't use the autofill technique. Also, the model M2 aims to improve protection against shoulder surfing attacks, if it is done with human eyes or electronic devices like cameras. Furthermore, regardless of the defensive technique used users' behaviour is considered as the first line of defence against shoulder surfing attacks.

Fig. 9. The Proposed Model Result Compared to other Studies.

## VIII. CONCLUSION

In this paper, a new model that relies on camouflage characters and a virtual keyboard combined with the Caesar cipher is proposed as a defence method against shoulder

surfing attacks. An experiment with 65 users was conducted to evaluate the proposed defence model against a traditional login model. The evaluation depends on two factors: usability and the shoulder-surfing success rate. The results of the developed model were compared with two other studies that focus on shoulder surfing defence and use the same factors to measure their models. The obtained usability test indicates that the proposed defence model has the highest entry time compared to the other system, but it has the best result in preventing shoulder surfing. Depending on the results, the proposed defence model is recommended as the best solution for shoulder surfing attacks.

**Abstract**—COVID-19 epidemic continues to threaten public health with the appearance of new, more severe mutations, and given the delay in the vaccination process, the situation becomes more complex. Thus, the implementation of rapid solutions for the early detection of this virus is an immediate priority. To this end, we provide a deep learning method called CovSeg-Unet to diagnose COVID-19 from chest CT images. The CovSeg-Unet method consists in the first time of preprocessing the CT images to eliminate the noise and make all images in the same standard. Then, CovSeg-Unet uses an end-to-end architecture to form the network. Since CT images are not balanced, we propose a loss function to balance the pixel distribution of infected/uninfected regions. CovSeg-Unet achieved high performances in localizing COVID-19 lung infections compared to others methods. We performed qualitative and quantitative assessments on two public datasets (Dataset-1 and Dataset-2) annotated by expert radiologists. The experimental results prove that our method is a real solution that can better help in the COVID-19 diagnosis process.

**Keywords**—Deep learning; COVID-19; loss function; balanced data

## I. INTRODUCTION

In December 2019, a viral pneumonia epidemic of unknown etiology emerged in Wuhan city, Hubei province, China [1]. On January 9, 2020, the World Health Organization (WHO) and Chinese Health Authorities officially announced the discovery of a new coronavirus. This pneumonia is an infectious disease caused by a virus identified under the name SARS-CoV-2 (Severe Acute Respiratory Syndrome CoronaVirus-2) by the ICTV (International Committee on Taxonomy of Viruses) [2], and causing a disease called COVID-19 (COroNaVIrus Disease 2019). SARS-CoV-2 belongs to the coronavirus family. The reservoir of this virus is probably animal. Although SARS-CoV-2 closely resembles a virus detected in a bat, the animal that transmits it to humans has yet to be identified with certainty. Several research studies suggest that the pangolin, a small mammal eaten in southern China, could be involved as an intermediate host between bats and humans.

The new coronavirus has been confirmed to be transmitted between humans [3], and this is done mainly by air or by close

contact with a contagious subject. Smaller particles can also be emitted in the form of aerosols during speech or during coughing efforts, which would explain that the virus could persist suspended in the air in an unventilated room. Finally, the virus can retain infectivity for a few hours on inert surfaces from where it can be transported by the hands. According to data from the World Health Organization, updated up to 24 hours on June 18, 2021, COVID-19 has affected 220 countries and territories, causing 178,584,744 people to be infected and 3,866,607 deaths worldwide. The overall number of people recovered is 163,102,134. Currently, the active cases are 11,616,003 of which 99.3% in mild condition and 0.7% in serious or critical condition, which poses a great threat to international human health.

Due to the vaccination process slowness, the high rate of virus contamination, and the appearance of new dangerous COVID-19 mutations, it is essential to detect and identify the disease at an early stage so that suspected patients do not infect the healthy population. As a result, new requirements for the prevention and control strategy must be put in place. Reverse Transcription Polymerase Chain Reaction (RT-PCR), gene sequencing for respiratory, or blood samples confirm the diagnosis of COVID-19. However, the false negatives of the RT-PCR [4], the delay in obtaining the results, and the tests carried out on people not strongly suspected of being infected with COVID-19 imply that numerous COVID-19 patients would not be identified quickly to isolate them from others. In addition, given the rapid and contagious spread of the virus, they present a real threat to infect a larger population, especially in areas with high epidemics. On the other hand, chest examinations quickly established themselves as an interesting diagnostic tool, given the characteristic presentation of COVID-19 lesions [5]. These tests can identify lesions, underlying conditions and complications associated with acute airway conditions. Consequently, the use of CT in particular High Resolution Computed Tomography (HRCT) could provide enormous help to radiologists [7] for the diagnosis, follow-up or investigation of pulmonary complications in patients suspected or confirmed of COVID-19. Thus, the development of an artificial intelligence (AI) method based on deep learning could help them enormously to assess the degree of lung damage caused by COVID-19.

According to [6], the authors indicated that CT images can be used to detect COVID-19 even before certain clinical symptoms are observed. Typical signs of COVID-19 appear in CT images as unilateral, multifocal, and terminal Ground Glass Opacity (GGO). This is a hazy cloud above the lungs that indicates a variety of problems, and may mean that the lungs are partially filled with inflamed material, and there is thickening in lung tissue or partial breakdown of the alveoli and tiny air sacs of the lungs. Pleural effusion, lymphadenopathy, and condensation [3], which are air spaces in the lungs filled with a substance, usually pus, blood or water, surrounded by an opaque edge of frosted glass, and although this is a common feature of lung disease, it may be more characteristic of COVID-19. To detect COVID-19 disease at an early stage, it is necessary to detect and locate these pathological changes in a short time. The growing number of patients and the limited number of well-trained expert radiologists in most hospitals prevent and slow down the process of early detection. Indeed, the use of deep learning methods for the automatic segmentation of the COVID-19 CT model has become paramount, and may offer an effective solution to identify and locate signs of COVID-19 in CT images [8].

In this paper, a new efficient method of COVID-19 diagnostic using Deep Learning network is proposed. Section II presents the related works, Section III shows problem statement, and Section IV explains in detail the proposed method. Section V describes simulations experiments. Section VI discusses the obtained results. Finally, the summary and future works are delineated in Section VII.

## II. RELATED WORK

In the literature, numerous methods of segmentation based on deep learning networks have been used to process and analyze chest X-ray or CT images for the COVID-19 diagnosis [9]. These methods mainly consist of delineating the regions of interest in these images, such as lobes, bronchopulmonary segments, lung, and infected regions or lesions for further quantification and evaluation.

CT provides detailed and high definition three dimensional images to detect COVID-19. Among the segmentation methods used for the diagnosis of COVID-19 we cite, U-Net [10], UNet++ [11], V-Net [12]. The authors of [9] have proposed a 3D architecture of U-Net using inter-slice information; this method consists in replacing the conventional layers of U-Net by a 3D version. In [12], the authors proposed the V-Net architecture, in which they used the residual blocks as the basic convolutional block, and optimized the network by a loss of dice. In [13], the authors proposed the Attention U-Net method, which captures fine structures to locate lesions and pulmonary nodules in medical images. Generally, the large number of well-labeled images is the key to forming an efficient and robust segmentation network. In the case of COVID-19 image segmentation, the data used during the training phase is limited and often unavailable because manual lesion delineation is a difficult operation and requires a lot of time.

Several other research works obtaining reasonable segmentation results have been proposed in this context. The lung segmentation field is experiencing a lack of labeled medical images, as a result, semi supervised and unsupervised methods are very favorable and recommended in studies on COVID-19, as in [10], the authors used an unsupervised method to generate pseudo-segmentation masks for the images. In [14], the authors proposed a new COVID-19 lung infection segmentation network called Inf-Net to detect infected regions from chest CT images. This method uses a parallel decoder for aggregating high-level features and generating a global map. Then, it uses a semi-supervised segmentation framework based on a propagation strategy chosen at random to overcome the lack of labeled data. In [15], the authors proposed a computer-assisted diagnosis (CAD) system based on the YOLO predictor to detect and diagnose COVID-19. The CAD method calls the data balancing regularizations, transfer learning, and augmentation to improve the overall diagnostic performance for COVID-19. The authors of [16] proposed a synergistic approach based on deep meta-learning to accelerate the detection of COVID-19 cases. This approach uses contrastive learning with a pre-trained ConvNet encoder for the classification of COVID-19 cases. In [17], the authors proposed a computer-aided detection (CAD) method to assist radiologists to automatically detect COVID-19 on the chest X-ray images. The proposed method uses the DLs: the Discrimination-DL to extract lung features from chest X-ray images, and the Localization-DL to localize and assign the infected lung region. In [18], the authors built prognosis models to predict the patients' severity outcomes. The proposed method is based on deep learning in the CT image segmentation process for COVID-19 pneumonia, and it uses datasets from multiple institutions worldwide to validate the proposed models. In [19], the authors propose a CovFrameNet framework to detect COVID-19 cases using CT images, which incorporates an image preprocessing mechanism and a deep learning model for smoothing, denoising, feature extraction, classification, and performance measurement.

## III. PROBLEM STATEMENT

Our main goal through this paper is to diagnose COVID-19 lung infection in chest CT images. In this regard, we use an architecture similar to that of the U-Net [10] approach called CovSeg-Unet method, U-Net is considered as the most commonly used algorithm in medical image segmentation. U-Net is a symmetrical encoder/decoder architecture consisting of several stages. Each stage of the encoder performs a set of operations such as, convolution, normalization, max pooling, activation, concatenation etc. In parallel, each stage of the decoder performs deconvolution operations. U-Net method uses jump connections allowing the exploitation of local and global information. These connections concatenate the subsampling characteristics of the contraction path with those of the up-sampling of the expanding path.

The general idea of the CovSeg-Unet approach is described as follows. Let  $S$  be a learning space which contains a set of  $n$  images  $X = X_1 \dots X_n$ , and  $n$  corresponding ground-truth masks  $Y = Y_1 \dots Y_n$ . From the  $Y$  ground-truth masks, the network learns the lung infections distribution of the  $X$

learning images to establish an image-to-image mapping relationship between  $X$  and  $Y$ , this map is defined as follows:  $\Phi = f_{dec} \circ f_{enc}$ .

$f_{enc}$  is the encoder function that learns the characteristic vectors of infected lung regions to establish a functional space. While  $f_{dec}$  is the decoder function, which learns the spatial localization of features to better locate the infected/uninfected region. And  $\Phi$  is the set of probabilities extracted from an input biomedical image, and is represented by  $\Phi(f) = P_1, P_2, \dots, P_n$ , where  $P_i = \{0,1\}$  are the probabilities given to the last convolutional layer of classification by the nonlinear function SoftMax. The key idea here focuses on the spatiotemporal modeling of characteristic points that can represent lung infections.

#### IV. PROPOSED METHOD

In this section, we present the CovSeg-UNet approach that we propose to diagnose COVID-19 from CT images. The CovSeg-UNet approach architecture is shown in Fig. 1. Generally, the CovSeg-UNet approach architecture's is made up of two blocks; the first one consists of preprocessing the CT images. While the second one performs all encoder/decoder operations to learn high level features from training sets, and locate the spatial information. The CovSeg-UNet network details are shown.

##### A. Preprocessing

One of the major problems encountered in the deep learning is processing of biomedical images that coming from several machines with different acquisition parameters. To deal with this problem, we apply a preprocessing step on these images to improve the learning of the COVID-19 suspect recognition model despite of the data heterogeneity. This step of preprocessing consists of two steps; the first one concerns the normalization of the signal that processes the intensity of each scanner CT voxel. In this step, we chose the pulmonary window value from Table I to separate the lungs from the other organs. Since each CT scanner has its own Hounsfield (HU) units, consequently, the data collected in different hospitals will have different HUs. For this reason, we are

using a multi-valued window, ( $W_L$  is the window center value, and  $W_W$  is the window width), the  $W_L$  value is randomly assigned from -600 to -500, while the  $W_W$  value is fixed at 1200. In the second preprocess step, we normalizing the CT images to be in [0, 255]. Through this process we normalize multiple images of different scanners to the same standard, by separating the lungs from other organs, removing unnecessary information (CT features, etc.) or/and noise, increasing images, and improved accuracy.

##### B. CovSeg-UNet Architecture

In order to detect COVID-19 lung infections using CT images, we propose the CovSeg-UNet approach, which characterized by an end-to-end architecture based on one of the most robust approaches in biomedical image segmentation that is U-Net. The network of the CovSeg-UNet approach is supplied as input by pre-processed CT images and their ground-truth masks. Our proposed method relies on an encoder to extract contextual feature maps from pre-processed images to reduce the dimensions of CT images, and a decoder to locate feature map information in the image. Table II shows the detailed architecture of our encoder/decoder.

Generally, the encoder is made up of four residual blocks (ResBlock), already pre-formed on the ImageNet database, the use of these blocks allows us to avoid the disappearance/explosion gradient, to preserve the local information, to improve precision by increasing the depth of the network, and to optimize the formation of layers. Each residual block is made up of two blocks (conv\_bloc and identity\_bloc), and is expressed by  $R(I) + I$ , where  $I$  is the input vector, and  $R(\cdot)$  represents the mapping from input  $I$  to the output of the residual unit. However, the decoder has two inputs, one input from the parallel layer of the encoder and a second from the previous layer of the decoder. Finally, the decoder output is sent to the SoftMax activation function (see equation (1)) for the prediction of the region infected with COVID-19. Algorithm 1 describes the training steps of the proposed model.

$$\sigma(\vec{z})_i = \frac{e^{x_i}}{\sum_{j=1}^k e^{z_j}} \quad (1)$$

| Initial | Conv2d(7 x 7), stride = 2<br>BatchNormalisation<br>ReLu<br>MaxPoling                                                                                             | (64 x 64 x 64)                                                            |
| Encoder | Stage 1 : x2 ResBlock(64 x 64 x 256)<br>Stage 2 : x3 ResBlock(128 x 128 x 512)<br>Stage 3 : x5 ResBlock(256x256 x 1024)<br>Stage 4 : x2 ResBlock(512x512 x 2048) | (64 x 64 x 256)<br>(32 x 32 x 512)<br>(16 x 16 x 1024)<br>(8 x 8 x 2048)  |
| Decoder | Stage 1 : UpSampling(16 x 16 x 256)<br>Stage 2 : UpSampling(32 x 32 x 128)<br>Stage 3 : UpSampling(64 x 64 x 64)<br>Stage 4 : UpSampling(128 x 128 x 32)         | (32 x 32 x 128)<br>(64 x 64 x 64)<br>(128 x 128 x 32)<br>(256 x 256 x 16) |
| Final   | Conv2d(256 x 256 x 16)<br>Softmax Activation(256 x 256 x 1)                                                                                                      | (256 x 256 x 1)<br>(256 x 256 x 1)                                        |

Where  $\vec{z}$  is the input vector of the softmax function ( $z_0, \dots, z_k$ ), all  $z_i$  values can take any real value.  $e^{z_j}$  is applied to have a positive value for each element of the input vector. The term at the formula bottom is the normalization term, which makes it possible to have a  $Sum = 1$  of all the output values (are each in the range (0, 1)) of the function, thus constituting a valid probability distribution,  $k$  represents the number of classes in the multiclass classifier.

**Algorithm 1:** Training procedure for CovSeg-UNet method

```

C. Loss

The imbalanced class problem is considered as the major challenge in the detection process of lung infections because the distribution of infected/uninfected regions is highly skewed (the infected regions vary between 0% and 20% of the pixels of the lung image). So, if the loss function does not consider this problem, the model will classify the majority of pixels as uninfected regions, and become overfit. For this reason, we use a class-balanced cross-loss function and the penalty factor  $\lambda$ .

The loss function is defined as a weighted sum of two loss functions; the balanced cross loss  $L_{BCE}$  and the inverse cross loss  $L_{ICE}$ :

$$L_B = \lambda_1 \cdot L_{BCE} + \lambda_2 \cdot L_{ICE} \quad (2)$$

Respecting to the cross-loss, we use the balanced cross-entropy to overcome noise in biomedical images, we also use the balance parameter  $W$  to balance the pixel distribution of infected/uninfected regions in  $L_{BCE}$ :

$$L_{BCE} = -w_c \sum_{i \in y_c} q(y_i = 1 | s) \log(p(y_i = 1 | s)) - w_{cn} \sum_{i \in y_{nc}} q(y_i = 0 | s) \log(p(y_i = 0 | s)) \quad (3)$$

Where  $q(y_i = i | s)$  is the ground-truth mask of the sample  $S$ .  $Y_i = 0, 1$ ,  $p(y | s)$  is the probability map produced by the function softmax,  $w$  represents the balancing parameter  $w(k) = S/KS(k)$ .  $S$  is the samples number in the training set, and  $S(K)$  represents the samples number in the class  $K$ . However, cross-entropy relies heavily on the accuracy of the annotation. When the data is mislabeled,  $q(k | s)$  will not be able to represent the true class distribution, which will lead the cross-entropy  $p(k | x)$  to learn this incorrect distribution type. To deal with this problem, we use reverse learning to know which classes the input  $x$  does not belong to. Inverse cross-entropy is defined as follows:

$$L_{ICE} = \sum_{i=1}^k p(y_i = 1 | s) \log q(y_i = 1 | s) \quad (4)$$

The weighted combination of entropies ( $L_{ICE}$  and  $L_{BCE}$ ) in the loss function allowed a good convergence of the gradient and relevant learning. The  $L_{BCE}$  term efficiency exhibits in the distribution balance of infected and uninfected classes, while the  $L_{ICE}$  term strength appears in the resistance against noise caused by scanner settings. As a result, the balanced symmetric entropy function obtained high performance in the COVID-19 lung infections localization on the test data set.

V. EXPERIMENT

In this section, we explain the different experiments carried out to evaluate the performance of our proposed approach under different simulation scenarios. We start by describing the used dataset and experimental environment of the simulation. Subsequently, we perform quantitative study of the hyper-parameters to show their effects on the model learning. Finally, we present the different performance metrics used to assess the efficiency and robustness of our approach.

A. Datasets

In this work, we have applied our method on two Datasets.

Dataset-1: this dataset contains two versions [21]. The first version is published on April 2, 2020, comprising 100 CT images (of 40 COVID-19 patients) of size  $512 \times 512$  labeled by radiologists, these radiologists have defined three tags: pleural effusion in frosted glass (= 3), consolidation (= 2), and mask value (= 1). The second version is released on April 14, 2020, comprising 829 CT images (of 9 COVID-19 patients) sized  $630 \times 630$ . Radiologists have tagged 373 images with COVID-19 pulmonary symptoms and the rest of the images as normal cases.

Dataset-2: this dataset is publicly available, contains 20 CT volumes with more than 1800 slices collected from 40 different COVID patients [22]. Each CT slice is of size  $512 \times 512$  labeled by expert radiologists to mark regions for infections.

The first column images of Fig. 2 represent the original images, while the second column images represent their corresponding ground-truth masks. Two examples of images of normal people are shown in the third and fourth rows. The first and second rows include two COVID-19 images, where the COVID-19 regions are the white and gray regions of the ground-truth masks, while the healthy regions are the black pixels (note that if a person is in good health his ground-truth mask will be completely black).

Fig. 2. Example of Images belong to Dataset-1 and Dataset-2.

In our simulations, we merged the two versions of dataset-1 to form a new dataset, while keeping 60% of these images for the training, 20% for the validation, and 20% for the test. We implemented our method in the Keras simulation environment with the TensorFlow back-end using the Python 2.7 programming language. Simulations were run on an infrastructure equipped with a Tesla P-100 GPU card, and 16 GB RAM memory.

### B. Hyper-parameters Setting

In deep learning, hyper-parameters of the deep neural network crucially influence the performance of the network. In this part, we carried out several experiments to choose the best values of the Hyper-parameters allowing improving the performances of our method. In this regard, we fixed the number of epochs and the batch size respectively at 100 and 64. We simulated and compared the different precision obtained values with different optimizers, different learning rates, and different values of  $\lambda_1, \lambda_2$  of the  $L_B$  loss function.

TABLE III. THE CHOICE OF THE BEST COMBINATION FOR INPUT HYPERPARAMETERS, BEST ACCURACY SHOWN IN BOLD FONT

| Optimizer               | Learning- rate                                     | Loss (LB)                                                                                                                        | Accuracy                          |
|-------------------------|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|
| ADAM<br>SGD<br>Adadelta | Lr = 0.0001                                        | $\lambda_1 = 0.5, \lambda_2 = 0.5$                                                                                               | <b>0.9445</b><br>0.8921<br>0.9032 |
| ADAM                    | Lr = 0.001<br>Lr = 0.00001<br><b>Lr = 0.000001</b> | $\lambda_1 = 0.5, \lambda_2 = 0.5$                                                                                               | 0.944<br>0.924<br><b>0.964</b>    |
| ADAM                    | Lr=0.000001                                        | $\lambda_1 = 0.4, \lambda_2 = 0.2$<br>$\lambda_1 = 0.5, \lambda_2 = 0.5$<br><b><math>\lambda_1 = 0.3, \lambda_2 = 0.5</math></b> | 0.957<br>0.964<br><b>0.991</b>    |

From Table III, we observe that the values of the hyper-parameters  $\lambda_1 = 0.3, \lambda_2 = 0.5$ , and the use of the ADAM [23] optimizer with a learning rate equal to 0.000001 showed the best performance in term of accuracy.

### C. Performance Metrics Evaluation

To assess the efficiency and robustness of our proposed approach, we use the following performance metrics: Accuracy [24], Sensitivity [25], Matthews Correlation Coefficient [25], and Dice [26]. By definition, higher values of these metrics imply a better segmentation quality. The mathematical formulas of these metrics are respectively expressed below:

$$Accuracy = \frac{TP + TN}{TP + TN + FN + FP} \quad (5)$$

$$Sensitivity = \frac{TP}{TP + FN} \quad (6)$$

$$MCC = \frac{TP * TN - FP * FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}} \quad (7)$$

$$Dice = \frac{2 * TP}{2 * (TP + FN + FP)} \quad (8)$$

## VI. RESULTS

In this section, we evaluate the effectiveness of the proposed method by performing qualitative and quantitative studies on an open-source benchmark. The obtained results of our method are compared with those of existing methods in the state of the art.

### A. Ablation Study

To show the importance of each component of our approach, we did an ablation study on the dataset-1 by evaluating the following performance metrics; Accuracy, Dice, Sensitivity, and Precision. The study of ablations was subdivided into three possible cases. In the first case, we added the preprocessing block without using the loss function ( $L_B$ ) during the learning phase, whereas in the second case, in the learning phase we introduced the loss function without using the preprocessing block. In the latter case, we used the preprocessing block and the loss function ( $L_B$ ) (see Fig. 3). From these simulation cases, we notice that the data preprocessing step has a remarkable effect on the model performances. The first case shows the overfitting phenomenon that occurred when it exceeds epoch 40, and which led to a degradation in the performance of the model (see Fig. 4). The results of this study are illustrated in Table IV.

On the other hand, the result of the third case shows that the use of the loss function with the preprocessing block helps to avoid the overfitting problem, and consequently, to improve the performances of the model and to have good results. Fig. 5 and Fig. 6 show the qualitative results of our method on different test samples, the first column (1) represents the lung images, the second column (2) shows the ground-truth mask, and the last column (3) corresponds to the predicted lung infection mask of COVID-19. These qualitative results prove the robustness and the efficiency of our diagnostic method of the region infected by COVID-19.

TABLE IV. ABLATION STUDY ON THE DATASET-1

| Cases                                  | Accuracy     | Dice         | MCC          | Sensitivity  |
|----------------------------------------|--------------|--------------|--------------|--------------|
| Preprocessing, BinaryCrossEntropy      | 0.890        | 0.514        | 0.432        | 0.741        |
| $L_B$ , without Preprocessing,         | 0.934        | 0.632        | 0.590        | 0.842        |

### B. Comparison with Baseline Methods

In this part, we compare our segmentation method of CT images with the reference segmentation methods such as U-Net basic [10], DenseUNet [27], Attention U-Net [13], and UNet++ [11]. Table V represents obtained results by the different methods on dataset-1 and dataset-2. As results, the proposed method outperforms other methods in terms of performance measures. Dice, Sensitivity, and Accuracy metrics reach 83.3%, 98.2% and 99.1% respectively on dataset-1, and 83.4% 89.1% 98.3% on dataset-2.

TABLE V. PERFORMANCES COMPARISON AGAINST BASELINE ARCHITECTURES ON DATASET-1 AND DATASET-2

|           | Methods              | Dice         | Sensitivity  | Accuracy     |
|-----------|----------------------|--------------|--------------|--------------|
| Dataset-1 | U-Net [10]           | 0.708        | 0.678        | 0.865        |
|           | DenseUNet [27]       | 0.660        | 0.607        | 0.651        |
|           | Attention U-Net [13] | 0.560        | 0.623        | 0.632        |
|           | UNet++ [11]          | 0.815        | 0.857        | 0.903        |
|           | <b>CovSeg-Unet</b>   | <b>0.833</b> | <b>0.982</b> | <b>0.991</b> |
| Dataset-2 | UNet [10]            | 0.712        | 0.665        | 0.747        |
|           | DenseUNet [27]       | 0.610        | 0.607        | 0.715        |
|           | Attention U-Net [13] | 0.631        | 0.723        | 0.890        |
|           | UNet++ [11]          | 0.815        | 0.887        | 0.968        |
|           | <b>CovSeg-Unet</b>   | <b>0.834</b> | <b>0.891</b> | <b>0.983</b> |

### C. Comparison with other Methods

Many studies have been done to diagnose COVID-19. To prove the robustness of our method, we carried out a comparative study with different approaches such as Inf-Net [14] and Automatic [17]. We simulated these approaches using their open-source implementation. The quantitative results obtained by the different methods are shown in Table VI. Dice, Sensitivity, and Accuracy are the performance metrics to be evaluated in this benchmarking study. From Table VI we notice that the CovSeg-Unet method reaches an Accuracy = 0.991 on Datasets-1, and an Accuracy = 0.983 on Datasets-2. The obtained values in these simulations prove that the CovSeg-Unet method outperforms other approaches in terms of Dice, Sensitivity, and Accuracy.

TABLE VI. PERFORMANCES COMPARISON AGAINST EXISTING APPROACHES ON DATASETS-2.

| Methods            | Dice         | Sensitivity  | Accuracy     |
|--------------------|--------------|--------------|--------------|
| Inf-Net [14]       | 0.579        | 0.877        | —            |
| Automatic [17]     | 0.714        | 0.733        | 0.739        |
| <b>CovSeg-Unet</b> | <b>0.834</b> | <b>0.891</b> | <b>0.983</b> |

## VII. CONCLUSION

In this work, we address a more difficult task in the segmentation of limited and unbalanced biomedical images. To cope with this task, we have proposed an end-to-end architecture similar to U-Net, the proposed method network learns the discriminating features of lung infections from CT images to establish an image-to-image mapping relationship. We used the ResNet50 architecture to preserve local information and avoid the issue of fading gradients. To improve the learning of the discriminating features of the network, we introduced a preprocessing block to remove noise and unnecessary information which blows up the performance of the network. In order to strengthen the model to be learned

from non-equilibrium data, we have proposed a loss function  $L_B$ . Experimental results on two datasets demonstrated the effectiveness of the CovSeg-Unet method in locating COVID-19 infected regions. The quantitative and qualitative results obtained by comparing CovSeg-Unet method with the others methods prove the efficiency of our method, which can be a real solution to detect, diagnose and locate regions infected with COVID-19.

# Elevint: A Cloud-based Internet of Elevators

Sarah Mohammed Aljadani, Shahd Mohammed Almutairi, Saja Saeed Ghaleb, Lama Al Khuzayem

Department of Computer Science  
King Abdulaziz University  
Jeddah, Saudi Arabia

**Abstract**—With the significant growth of the number of high-rise buildings nowadays, the dependence on elevators has also increased. The issue that faces elevator passengers in case of breakdowns is the long waiting time for the arrival of the maintenance engineers to perform the repair, as the process of reporting is done manually. The safety concern increases when people are trapped. Most state-of-the-art approaches detect faults without providing means to facilitate the communication between elevator owners, maintenance companies, and engineers or notify them in case of breakdowns. Moreover, none of the proposed fault detection solutions rely on rules specified by experts in the field. This paper aims at addressing these issues by proposing a system that manages, monitors, detects faults and informs users of any faults instantly by sending notifications. Specifically, the paper proposes a mobile application, Elevint, that is, cloud-based and exploits the Internet of Things (IoT) technology. Elevint provides real-time monitoring of elevator operating conditions collected from sensors. The data is then transferred to the cloud, where faults are detected by applying rules that compare the current conditions with severity levels determined by experts. In the case that a fault is detected, elevator owners and maintenance companies are automatically notified. Moreover, through Elevint, maintenance companies can assign engineers to repair the fault and elevator owners can view and re-schedule the engineer's visit if needed. Testing our system on an elevator model shows 98% accuracy. In future, we intend to test it on real elevators to verify its applicability in practice.

**Keywords**—Internet of things; elevator; fault detection; monitoring; notification; real-time

## I. INTRODUCTION

The use of elevators has increased dramatically throughout the world, due to the congestion of population in main cities. Thus, cities have tended to increase the number of skyscrapers to accommodate the high number of populations. Successively, the reliance on elevators around the world has increased. Safety remains a critical issue in the design of elevators, since its failure may endanger people, disrupt their schedule, and threaten their lives.

Presently, when an elevator breaks down or people are trapped, there is an extensive waiting time before the relevant people are notified. This is because the process of informing the maintenance technicians is done manually. If this process is somehow automated, the maintenance team will arrive faster, and the breakdown time will be reduced significantly.

Therefore, to ensure the safety of elevator passengers, it is necessary to speed up the process of notifying the elevator owners and maintenance companies about failures. Developing notice of the breakdown in a timely manner will

not only reduce the downtime and save money, but will also allow preventive maintenance of the elevator [1].

With the advancement of technology in the 21st century, researchers in academia have considered investigating the safety control system of elevators through the Internet of Things (IoT) with the aim of moving the industry from preventative maintenance to predictive maintenance [2]. Most state-of-the-art research in this area proposes a monitoring elevator system that exploits IoT techniques to achieve the supervisory functions of early warning to reduce elevator accidents [3] while using smart sensors and cloud services [4]. Monitoring will help do analysis research to identify the main factors that cause accidents; thus, it will eventually help reduce accidents and injury rates [5].

On the other hand, elevator companies have also started to make smart elevators and are investing billions of dollars in this new technology [6]. However, it is not possible for all elevator owners to replace their old elevators with new smart ones, since there would be significant costs. This research aims at filling the gap by elevating current conventional elevators to smart elevators, through installing safety control systems that reduce downtime by analyzing the elevators' data and notifying the right people in a timely manner. Specifically, this paper proposes an IoT cloud-based elevator monitoring and fault detection mobile application which includes the following features:

- 1) Enable elevator owners and maintenance companies to monitor their elevators' operating conditions from anywhere in real-time.
- 2) Facilitate the communication between elevator owners, maintenance companies, and technicians through instant messaging services.
- 3) Detect major underlying factors for elevator faults based on some expert-defined heuristic rules.
- 4) Notify elevator owners and maintenance companies instantly about detected faults.

The remainder of this paper is organized as follows: in Section II, we review related work in this area and in Section III, we explain our proposed solution. We present our results in Section IV, followed by Section V which concludes the paper.

## II. RELATED WORK

Wang et al. [7] developed a system called EleSense, which is a framework for high-rise building structure monitoring. They used two kinds of sensing devices, the sensors are two

sets of vibrating wire strain gauge sensors attached at the inner tube and outer tube in each floor, and temperature sensors in most of the floors. A cluster head installed on each floor sends the data gathered from sensors to the base station. The base station is attached in the top of the elevator and while the elevator is moving, the base station moves with it and collects data from sensors. The results show that EleSense can significantly reduce communication costs, while providing reliable data.

Jiang et al. [8] proposed a system that provides fault detection based on real-time data from sensors that collect various parameters of running elevators, such as the weight of the lift car, the signal of portal crane, the signal of the layer precision of the elevator and the signal of safety gear. The system also enabled trapped people to communicate with maintenance staff. Moreover, the system has video and audio monitoring with Wimax (Worldwide Interoperability for Microwave Access) technology, which provides video and audio transmission based on the Internet Protocol version 4.

Zarikas and Tursynbek [9] described a system for an intelligent elevator, integrated with a smart building. The system's aim is to build a decision engine that can control the elevator's actions through AI techniques.

Salim and Akin [10] proposed an IoT-based elevator system that predicts and diagnoses errors from elevators. In this system, after troubleshooting, the data is collected from the elevators via sensors. This data is then transferred from the elevator to the control system, over the Internet to be sent to the data maintenance company to solve the problems. The system used fire sensors, low electricity and door status to detect faults. The advantage of this system is that it has a website to monitor the status of elevators, in addition to saving all elevator data and extracting reports.

Zhang et al. [11] measured the level of comfort during the elevator ride by measuring the acceleration on three directions axes x, y and z using sensors embedded in a smartphone. The elevator ride comfort level is evaluated based on the collected data, and the assessment results are uploaded to a structural health monitoring site. The results of the experiment show that their method has met the engineering requirements. Using the sensors inside the mobile device to monitor the elevator vibration may be easier and saves the time and effort of installing these sensors into a device on the elevator.

Suárez et al. [12] proposed an application that informs the maintenance company of the elevators' failures and trapped people. The application, which is developed using Microsoft Azure, implements on a cloud that is responsible for receiving data from elevators and processing it, then sending notifications accordingly. The disadvantage of this system is that it only deals with elevator faults as opposed to other systems which can also cater for management and monitoring in real-time.

Oalere et al. [13] developed a system to reduce elevators breakdowns, by early reporting of faults and diagnosis from historical data gathered from monitoring the vibration and noise using sensors. The system is divided into three layers. The first layer is the sensors layer that includes two kinds of

sensors for vibration and audio. The second layer contains the Yun microcontroller, which is an Arduino development board that analyses the signals from the sensors and helps to achieve the IoT communication. The third layer includes the web application server. They measured the results over a month, and the results showed that the elevator stops were noticeably reduced, due to notification of breakdowns. This system is very close to our proposed system but lacks some extra sensors and a monitoring camera.

Ming et al. [14] proposed an elevator safety monitoring system based on IoT technology and included audio and video monitoring. The research used sensors for vibration, acceleration, speed, diving noise, direction, floor station, elevator car door switch, voltage, temperature, and all these sensors were used to analyze data and increase safety.

Li [15] proposed a framework for an elevator security monitoring system based on cloud computing to monitor the running status of the elevator in real time. The system can provide reminders of faults, show alarm information and can classify the alarm information according to the severity.

Zhou et al. [16] introduced a remote elevator monitoring system based on IoT through real-time monitoring, fault diagnosis, alarm, and maintenance, without mentioning any details of the proposed system and results.

Huang et al. [17] proposed a warning system, which can monitor elevators failures through sensors and send the data to the remote monitoring platform. The system can send the information and remind the maintenance personnel to deal with it as soon as possible.

An et al. (a) [18] proposed an elevator monitoring system with the aim of helping managers in elevator maintenance companies to detect elevator faults early and to ensure the safety of passengers. Several sensors such as, temperature, vibration, speed, and load were exploited to capture elevators' data in real-time. This data is then sent through an industrial gateway to an InterProcess Communication (IPC) server before being sent to a SQL server through a General Packet Radio Service (GPRS) network. The web application also includes real-time video-monitoring, and a fault prediction model based on a Prognostics and Health Management (PHM) technology. The disadvantage of the system, however, is that it is a web-based application rather than a mobile application and does not provide notifications in case a fault is being detected.

An et al. (b) [19] proposed an intelligent elevator management system based on Building Information Modeling (BIM) and IoT technologies. Specifically, sensors such as temperature, humidity, speed, vibration, and load are employed to collect input data, then this data is sent through a RS485/CAN communication to the cloud for processing. The desktop application also includes real-time video monitoring as well as some functions such as, voice assistance and emergency assessment. The disadvantage of the system, however, is that it is a desktop application rather than a mobile application and does not provide means for detecting faults.

Shen et al. [20] proposed a predictive maintenance system using IoT and Machine Learning (ML) for a Permanent

Magnet Synchronous Motor (PMSM) traction elevator. First, raw data from the temperature and encoder sensors are captured then processed by Arduino. Data analysis using MATLAB is then performed on the digital data to compile it into a 30-minute data file. The data file then gets analyzed to determine which data requires predictive maintenance. The data is then classified into four categories: long, medium, short, and urgent according to predefined thresholds. Finally, this data is used for training the K-nearest Neighbor (KNN) ML model, so new data can be predicted accordingly. The accuracy of the system is 95.5%. The disadvantage of the system, however, is that it relies on two sensors' data only, and it is not a mobile application and does not provide notifications.

Guo et al. [21] described a system to monitor elevators in real-time based on multi-sensor fusion to ensure detecting common elevators faults then present the results on a website. The sensors consisted of magnetic switches, network camera, barometer, and accelerometer. The system was installed on a real elevator to test it.

Bai et al. [22] proposed a fault-prediction model based on improved PSO-BP which is optimized by an improved particle swarm optimization algorithm to enhance elevators safety using real-time data collected from the SCADA of the elevator. The convergence rate of the improved PSO-BP model is increased by 35.47%, and the prediction accuracy is improved by 49.12%

Gupta et al. [23] proposed a solution to use the elevators during COVID-19, without touching any surface to maintain sterilization and safety by deploying facial recognition software that uses pattern recognition, voice command using speech analysis method, and the body temperature to notify the people around them if someone has more than the suggested temperature. All these sensors are embedded in one device.

Table I shows a comparison between the related work according to the aim and criteria that we have developed. The first criterion (A) indicates whether the system is cloud-based or not. Secondly, (B) specifies if the system includes a fault detection model or not. Thirdly, (C) specifies if the system have video monitoring. Subsequently, (D) indicates whether the system has a mobile application or not. Finally, we determine if the system is implemented (E), available (F) or provide notifications (G). Out of the 18 methods, seven are cloud-based, fourteen systems include fault detection (some of them were predictions), nine systems include video monitoring, only three systems are mobile applications, twelve are implemented, three systems are available, and only five systems provide notifications. As can be seen from the table, all approaches include at most four features, except for Guo et al. which includes five.

As far as we know, there isn't a system that provides all features. Therefore, we aim to build an IoT cloud-based fault detection mobile application, called Elevint, where data is collected from several sensors, combining related elevators worldwide. Data will then be analyzed in the cloud to be monitored and faults can be detected using rules determined by experts. Once a fault is detected, the system will alert the

maintenance company, which in return will repair it. Thus, Elevint will include all features except for video monitoring, which we leave as future work.

### III. PROPOSED SOLUTION

In this section, we explain our system, Elevint, which is a cloud-based remote elevator condition monitoring system that comprises a mobile application. Elevint's system architecture is depicted in Fig. 1 Elevint aims at enabling faster repairs, preventing catastrophic breakdowns, and assisting in fault diagnosis. Specifically, Elevint provides real-time monitoring of elevator operating conditions, such as vibration, temperature, weight, light, and movement including others, through fixed sensors connected to an Arduino microcontroller. The data collected from sensors is then transferred via Wi-Fi to the cloud, where faults are detected by applying rules that compare the current conditions with severity levels determined by an expert. For example, if the temperature exceeds 60 degrees Celsius in the engine room, this indicates a possible failure in the elevator engine. Therefore, notifications are sent to elevator owners and maintenance companies to speed up the process of reporting a breakdown and to reduce the downtime of elevators.

The Android-based mobile application connects elevator owners with maintenance companies and technicians, in which messages can be exchanged between them, as well as other tasks can be performed, such as scheduling periodic maintenance and viewing maintenance history. The main feature of the mobile application is that it enables all three users, to monitor the status of the elevator in real-time i.e., the elevator's current floor, the temperature, the vibration, among others. The data gathered from the sensors is sent to the FireBase real-time cloud-hosted database, through which it gets sent to the mobile application. The mobile application is set up to show updated sensor data at 25-second intervals (changeable). Using a cloud-based architecture provides a quicker maintenance service, as the maintenance team can access the elevator data online and analyze it to find out the likely nature of the fault. For the hardware platform, our system uses a computer with Windows operating system and uses Arduino to create the circuit in which the sensors get connected. As for the software platform, the system uses Basic4Android and Visual Studio to create the application.

#### A. Hardware Components

Many hardware devices were used to produce an electric circuit connected to an Arduino Mega using the Wi-Fi to collect the real data of the elevator and send it to the application. Following is a description of some sensors that were used.

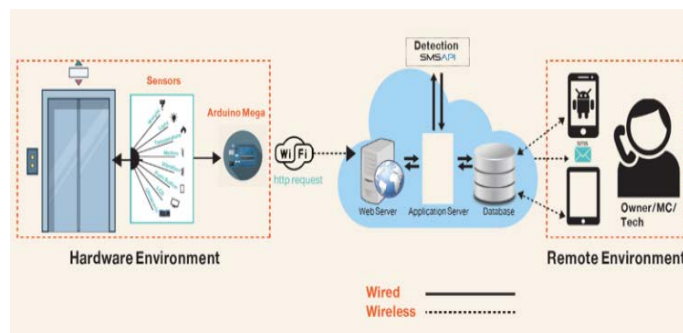

Fig. 1. Elevint System Architecture.

1) *Temperature sensor*: DS18B20 Temperature Sensor uses MAXIM's 1-wire bus protocol, which requires only 1 wire for receiving and transmitting data. The Temperature Sensor detects the temperature of the object it is attached on.

2) *Passive infraRed (PIR) sensor*: An electronic sensor that measures infrared (IR) light radiating from objects in its field of view. If the digital pulse is high (3V), it means a motion is detected, while if the digital pulse is low, it means it is idle or no motion is detected.

3) *Photo resistor light sensor*: When the value read from the photoresistor sensor module goes below a certain threshold value (determined by the developer), it means that it is dark, or the light is OFF. When the analog value from the sensor goes above the threshold value, it means the light is ON.

4) *HC-SR04 ultrasonic sensor*: The ultrasonic sensor emits an ultrasound that travels through the air. If there is an object or obstacle on its path, it will return to the module. Considering the travel time and the speed of the sound, you can calculate the distance.

5) *Vibration sensor*: Vibration is a sign of the state of the machine - no matter how accurate and unnoticed by the human senses -. Non-normal vibration of problems in the industrial machine can be detected early and repaired before machine failure occurs. Therefore, vibration analysis is used to determine the state of the equipment, location, and type of problems. Vibration sensors are sensors for measuring, displaying, and analyzing linear velocity, displacement, proximity, or acceleration.

6) *Load cell and HX711 weight sensor*: The Load cell senses the weight and provides an analog value to the HX711 Load Amplifier Module, which is an Analog to Digital Converter (ADC) that digitally converts the Load cell output.

7) *LCD display*: are used in electronic projects, as they are good for displaying information, such as the data that are collected from the sensors.

#### B. Connecting the System's Circuit

To connect the system's sensors, the circuit was made by connecting the module and sensors to the Arduino board, then the Arduino was connected to the computer using a USB cable. Fig. 2 shows the circuit connected, including the sensors and the Arduino.

Fig. 2. The Circuit.

Table II shows the pins that are connected from the module to the pins on the Arduino of the circuit.

TABLE II. THE CIRCUIT OF ARDUINO

| Module                             |      | Arduino |
|------------------------------------|------|---------|
| <i>Temperature &amp; Vibration</i> | VCC  | + 5 V   |
|                                    | DO   | D4      |
|                                    | GND  | GND     |
| <i>Passive InfraRed</i>            | VCC  | + 5 V   |
|                                    | OUT  | PIN2    |
|                                    | GND  | GND     |
| <i>Ultrasonic</i>                  | VCC  | + 5 V   |
|                                    | Echo | 10~     |
|                                    | Trig | 11~     |
| <i>LCD Display</i>                 | VCC  | + 5 V   |
|                                    | Echo | 10~     |
|                                    | Trig | 11~     |
|                                    | GND  | GND     |

C. Elevint Application

Fig. 3 and 4 show some pages from the Elevint application. Fig. 3 (A) shows the screen where a new user is registered, and after registering, the user can view screen (B) which shows the list of functions that suits the user of the application; whether they are an elevator owner, a maintenance company, or a technician. The functions provided for an elevator owner are: adding a new elevator, monitoring elevator data in real-time, sending messages to a maintenance company and scheduling a maintenance visit. Screen (C) shows adding a new elevator, Screen (D) provides a view of the elevator’s real data, Screens (E-F) shows how to schedule a maintenance visit. In Fig. 4, screens (G-K) show how the user can view the maintenance history in detail. Screen (L) shows the message function which allows easy communication between the user and the maintenance company.

D. Detection Rules

The rules for detecting the various faults are of the form:

if condition then action(s) {else action(s)}

Note that the part between curly brackets indicates that it can be excluded. If more than one action is included, then actions will be numbered. Tables III to VI shows our rules for detecting a number of faults. The first row in each table indicates the goal of the detection rule, the second row specifies the used sensors, and the third row shows the detection rule. Note that these detection rules are not fixed rules, but rather heuristic gathered from experts in the field.

The threshold values used in the rules were determined through the performed tests on the elevator model.

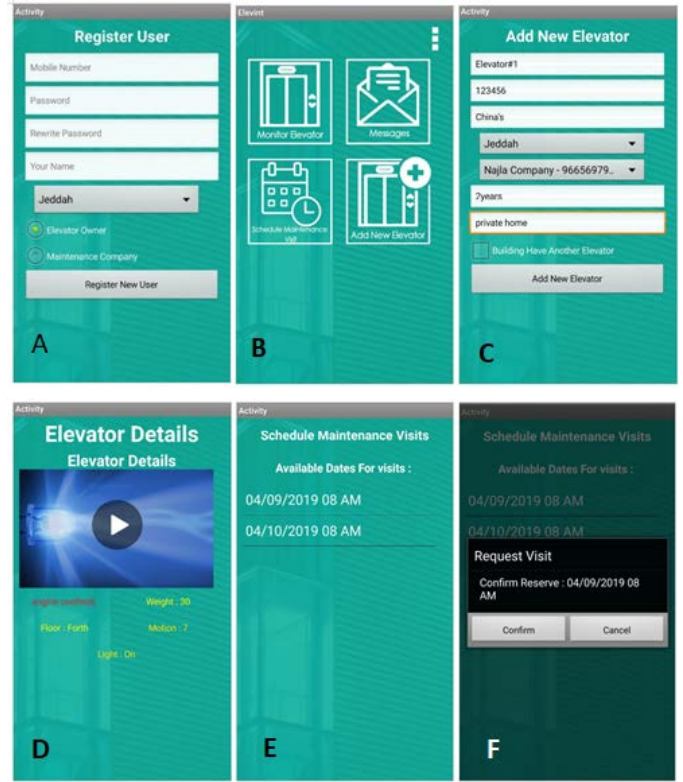

Fig. 3. App Pages for Maintenance Company Users - Part 1.

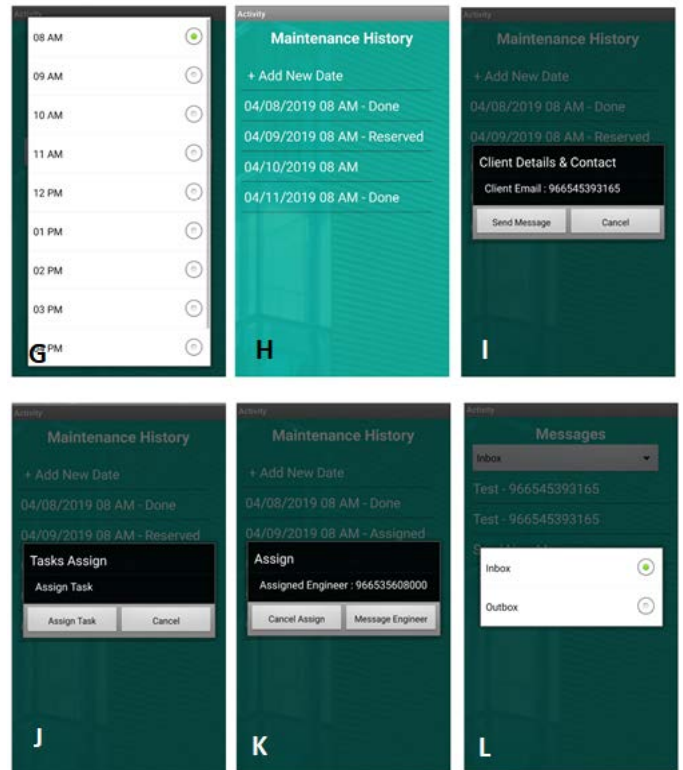

Fig. 4. App Pages for Maintenance Company Users - Part 2.

Table III demonstrates rule #1, which detects if the elevator's engine is overheated. For instance, when the temperature exceeds 60 degrees Celsius in the engine room, it indicates the possibility of a fault in the elevator engine and therefore, the LCD screen and the Monitor Elevator screen on the Elevint application will show the exact temperature, and an SMS will be sent to the owner of the elevator indicating that an overheat engine fault is possibly detected in an elevator, giving its serial number. Note that notification\_rule#6 is demonstrated in Table VII and will be explained in the next section. Otherwise, if the temperature of the engine is a normal value, it will appear on the LCD screen and will be displayed in the Elevint application. We have tested "overheated engine" faults by directing a lighter on the temperature sensor and the result was an SMS message sent to the mobile number of the owner registered on Elevint.

TABLE III. DETECTION RULE #1

| <i>detection_rule#1: Overheat Engine</i> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Goal</b>                              | Detect a possible fault in the elevator's engine (e.g., fire)                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Sensors</b>                           | Temperature                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Table IV shows rule #2, which detects if there are people trapped in an elevator. For instance, if Motion = High and Light = Off, that means there are people trapped in the elevator. Thus, the LCD screen and in the Elevint application will show: "Last Motion: 3 seconds ago", and Lighting: On. An SMS will also be sent to the elevator owner indicating that people may be trapped in the elevator with its serial number. Otherwise, the data will be displayed on the LCD screen and in the Elevint application. We have tested faults from type "Trapped People" by turning off the light and doing movements in front of the motion sensor and the result was an SMS message sent to the mobile number of the owner registered on Elevint.

Table V demonstrates rule #3, which detects if the elevator is stuck between floors. For instance, if the distance between floors is detected to be 15.5 cm and the vibration is 0, then the LCD screen and the Monitor Elevator screen on the Elevint application will show the message: "Floor: elevator is stuck", and an SMS will be sent to the owner of the elevator indicating that the elevator, giving its serial number, may be stuck. Otherwise, the data will be displayed on the LCD screen and on the Elevator Monitor in the Elevint application. We have tested "elevator stuck" faults by moving the elevator and stopping it between two floors and the result was an SMS message being sent to the mobile number of the owner registered on Elevint.

TABLE IV. DETECTION RULE #2

Table VI demonstrates rule #4, which detects if the elevator is overloaded. For instance, if the weight is 1200 g, then the LCD screen that is attached on the elevator and the Monitor Elevator screen on the Elevint application will show the message: "Weight: elevator overloaded", and an SMS will be sent to the owner of the elevator indicating that the elevator, giving its serial number, is overloaded. Otherwise, the data will be displayed on the LCD and on the Elevator Monitor in the Elevint application. We have tested faults from type "overloaded elevator" by putting a weight on the weight sensor and the result was an SMS message sent to the mobile number of the owner registered on Elevint.

E. System Notification Rules

In our application, we send SMS notifications to users when certain events take place according to the rules of the form:

when event then action(s)

TABLE VI. DETECTION RULE #4

| <b>detection_rule#4: Overloaded Elevator</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Goal</b>                              | Informing a maintenance company and an elevator owner about a detected fault.                                                                                                                                                                                                                                                                                                  |
| <b>Event</b>                             | <i>a fault is detected</i>                                                                                                                                                                                                                                                                                                                                                     |
| <b>Action</b>                            | 1) <i>sendSMS</i> (elevator owner, "Hi <i>owner_name</i> , a fault has been detected in the elevator with the serial number: <i>serial_no</i> , possible fault: <i>fault</i> ."<br>2) <i>sendSMS</i> (maintenance company, "Hi <i>mainComp_name</i> , a fault has been detected in the elevator with the serial number: <i>serial_no</i> , possible fault: <i>fault</i> ."<br> |

#### IV. EXPERIMENTAL RESULTS

We tested our fault detection rules by creating manually 10 faults for each of the 5 rules and calculating the results using the classification metrics from the information retrieval using the formulas below:

$$\text{precision} = \frac{TP}{TP+FP} \quad (1)$$

$$\text{recall} = \frac{TP}{TP+FN} \quad (2)$$

$$F1 = 2 * \frac{\text{precision} * \text{recall}}{\text{precision} + \text{recall}} \quad (3)$$

$$\text{accuracy} = \frac{TP+TN}{TP+FP+TN+FN} \quad (4)$$

where *TP* is the number of correctly detected real faults, *FP* is the number of detected faults which were wrong (i.e., not fault), *FN* is the number of undetected faults which were true (i.e., failed to detect) and *TN* is the number of undetected faults which were not fault (i.e., normal case).

Fig. 5 shows the results for all five detection rules, in which, the precision, calculated from (1), was 1 for all rules, while the recall, calculated from (2), was 1 in two rules only. For rules 1, 4 and 5 the recall scores were 0.86, 0.8, 0.9 respectively. The average precision for all rules is 1 and the average recall is 0.91. The F1 measure from (3) was also calculated and the result is 0.95. Finally, the accuracy from (4) was calculated and the result is 0.98.

Fig. 6 shows the testing of Detection Rule #4 and Fig. 7 shows the elevator model that was used to evaluate Elevint.

## V. CONCLUSION

Undoubtedly, elevator failures can cause significant delays and threats to humans' lives if not handled quickly and efficiently. A main cause of the delay is the manual approach taken to report elevator breakdowns. The problem with most state-of-the-art approaches is that they concentrate on monitoring and detecting faults without providing automatic means for notifying users when these faults happen. Moreover, their fault detection mechanisms do not rely on rules specified by experts in the field. Furthermore, none of the previous approaches offered means for managing elevators and facilitating the communication between elevator owners, maintenance companies and engineers. As opposed to previous approaches, this paper has proposed Elevint, an IoT, cloud-based mobile application that provides managing, monitoring, fault detection and notification services. Specifically, through Elevint, elevator owners can request a maintenance visit and monitor their elevators' data in real-time, while maintenance companies can assign engineers to specific faults or scheduled visits, and view elevators' data and maintenance history. Moreover, all users can communicate with each other through Elevint via messaging. Furthermore, faults are detected by applying heuristic rules that compare the current conditions with severity levels determined by experts. Finally, when a fault is detected, elevator owners and maintenance companies are automatically notified. Testing Elevint on an elevator model showed promising results. In the future, we aim to increase the number of detected faults by adding more detection rules, and to test our system on real elevators. We also intend to improve the

system further by offering fault prediction rather than fault detection using AI techniques.

**Abstract**—Wireless Visual Sensor Networks (WVSN) play an essential role in tracking moving objects. WVSN's key drawbacks are storage, power, and bandwidth. Background subtraction is used in the early stages of target tracking to extract moving targets from video images. Many standard methods of subtracting backgrounds are no longer suitable for embedded devices because they use complex statistical models to manage small changes in lighting. This paper introduces a system based on the Partial Discrete Cosine Transform (PDCT), reducing the vast dimensions of processed data while retaining most of the important information, thereby reducing processing and transmission energy. It also uses a dual-mode single Gaussian model (SGM) for accurate detection of moving objects. The proposed system's performance is to be assessed using the standard CDnet 2014 benchmark dataset in terms of detection accuracy and time complexity. Furthermore, the suggested method is compared to previous WVSN background subtraction methods. Simulation results show that the proposed method consistently has 15% better accuracy and is up to 3 times faster than the state-of-the-art object detection methods for WVSN. Finally, we showed the practicality of the suggested method by simulating it in a sensor network environment using the Contiki OS Cooja Simulator and implementing it in a real testbed using Cortex M3 open nodes of IOT-LAB.

**Keywords**—Background subtraction; discrete cosine transform; embedded camera networks; Gaussian mixture models; wireless visual sensor networks

## I. INTRODUCTION

Wireless sensor networks (WSNs), which are made up of thousands of scalar sensors nodes that are spatially distributed and wirelessly communicated, have attracted researchers' interest [1]. Small and low-power CMOS cameras and microphones are used in Wireless Visual Sensor Networks (WVSNs), which can collect visual cues from the environment. The WSN's capabilities are being expanded to include sophisticated environmental monitoring, advanced health care delivery, traffic avoidance, fire prevention, and monitoring, as well as object tracking, and modern surveillance systems [2]. WVSN has focused on military, commercial traffic management, and precision agriculture surveillance applications [3]. Three major problems make WVSNs lack vision processing capability. First, sensor nodes' visual

processing capability, second, memory storage constraints for sensor nodes and Finlay; communication of large volumes of image data. However, maximising network lifespan while processing huge volumes of multimedia data while following application-specific QoS requirements such as latency, packet loss, bandwidth, and throughput is a challenge. In addition to developing energy-sensitive multimedia processing algorithms and infrastructures, it is also necessary to establish efficient communication strategies [3].

Object detection is the first and most critical step in target tracking [4]. Robust object detection is typically the dominant consumer of processing and resources, where the moving targets are extracted from the video frames to perform further high-level processing. Lighting changes, shifting backgrounds, artificial or fast motion, and occlusion make accurate foreground object segmentation challenging [5]. The major methodologies for completing the object detection task include optical flow [6], frame differencing [7], and background subtraction [8].

Background subtraction is a standard and consistent method for detecting moving foreground that involves subtracting the background model from the current frame and changing the background model on a regular basis to remove the effects of illumination and inappropriate events. This method is extensively used for motion detection tasks in dynamic scenarios. In practice, basic techniques like mixture of Gaussians (MOG) [9], KDE [10], codebook [11], and ViBe [12] are employed for real applications. Despite the accuracy and efficiency of the MoG [9], the evaluation in [13] demonstrates that MoG can only handle three frames per second on the Blackfin DSP camera nodes with a low image resolution frame size of  $320 \times 240$ . The need to update the MoG probability distribution parameters accounts for the long computation time of MoG.

This work aims to investigate the development of moving object detection over WVSN. The Discrete Cosine Transform (DCT) [14] is a frequently utilised image compression technique over WVSN [15, 16]. The DCT algorithm converts signals from the spatial domain to a frequency domain representation. We apply the DCT to minimise the dimensionality of the background subtraction problem while

\*Corresponding Author.

maintaining accuracy. The following are the contributions made by this paper:

- A new compression-based background subtraction called Spectral Dual Mode Background Subtraction (SDMBS) uses Partial Discrete Cosine Transform (PDCT) [15] (for dimensionality reduction) and Dual mode SGM [17] (for accuracy) to model the background and distinguish the foreground from the background.
- We implement our approach and compare it to MoG and other compressed-based MoG methods to demonstrate the computational efficiency of our suggested methods. According to the results, our method is up to 10 times faster than the original MoG and three times faster than the compressed-based MoG.
- To demonstrate the algorithm's ability to work in wireless sensor network environments, we simulated and realised the proposed SDMBS in a Cooja network simulator and on the IOT-LAB M3 board.

The rest of the paper is organized as follows. We first present the related work in Section II. We then present a detailed account of the proposed SDMBS approach in Section III. Section IV discusses the simulation results and performance evaluation in detail. Section V draws the paper's conclusion.

## II. RELATED WORK

### A. Object Detection in WVSN

In visual sensor networks, the cost of data communication is usually far higher than the cost of image processing. As a result, traditional object detection methodologies are ineffective for monitoring and surveillance applications; instead, the image raw data is sent to the sink node, where detection methods are used to determine the moving object. Alternative approaches are to either compress the image at the sensor node and apply object detection at the sink node after decompression, or process the frame before transmission and transmit the useful information or features for further analysis at the sink node. Compression can be applied using Compressed Sensing (CS), wavelet, or DCT. In the second approach; frame processing is applied either on raw image data or compressed domain to further reduce processing complexity at the sensor node. The compressed data is already computed and has less storage space than the raw image frame. The two approaches are briefly reviewed in this section.

1) *Compressed data*: According to Robust Primary Component Analysis (RPCA) [18], DECOLOR [19], the basic concept of low-order factorization structures and sparse factorization is to divide a given matrix of acquired frames into background and sparse foreground by outliers. The goal of Compressed Sensing CS (low-rank BS) [20] is to send a compressed image to the base station using Compressed Sensing (CS) [13] and then use Orthogonal Matching Pursuit (OMP) [21] to rebuild the image at the receiver end. The authors of [22] proposed a CS-based detection approach that

uses CS measurements of a moving object to reconstruct the foreground in a video.

2) *Processed data*: Because the video to be sent in surveillance applications is generally static, a resource-constrained environment like WVSN does not require the transmission of the entire video. The video can be processed using a compression-based background removal technique to recognise moving objects and send only the foreground data to the monitoring location to save energy and bandwidth. A method for sending image portions instead of the whole image as described in [23]. It ensures that the sink node receives the bare minimum of image content, as assessed by in-node energy consumption and reconstructed picture peak signal-to-noise ratio (PSNR). The image processing block (Running Gaussian Average technique for object extraction and DWT for ROI transmission) operates at a high frequency to facilitate rapid processing and is only engaged by a separate network processor when images need to be analysed [24]. Because it runs continually, the network processor block is designed to operate at a low frequency. The suggested approach for image processing and communication requires relatively little energy, as evidenced by practical test and simulation results. To save transmission energy, Nandhini et al. [25] propose a method for detecting objects with fewer measures that combines a mean measurement differencing approach with an adaptive threshold strategy.

CS-based background subtraction is measured based on the node before object information is sent, reducing complexity in terms of power, storage, and bandwidth. CSMOG [26] applies MOG [9] to low-rate CS measurements. CSMOG [26] is based on the idea of reducing the number of dimensions in data while still capturing the majority of the information via a random projection matrix. The CSMOG method is consistently superior, up to 6x faster, and uses significantly fewer resources than the standard method, according to real-time requirements. The DWT-based CS object identification framework [27] uses a simple measurement matrix termed the deadweight tonnage block diagonal matrix to refine the pixel-based foreground following the block-based foreground recognition phase in the first stage. The averaging approach using the Adaptive Threshold Technology (MMDATS) in [25] is based on the framework for robust subspace learning. The OMP approach is used to reconstruct the object from foreground measurements. Due to its excellent directional selectivity and shift-invariance, [28] uses a motion segmentation algorithm based on interframe differentiation using the complex Daubechies wavelet transform in the wavelet compression domain.

To reduce the storage space and time required, a background statistical subtraction approach [29] based on motion segmentation in the compression transform domain using Wavelet has been proposed. A good observation was made in 8x8 blocks using the DCT coefficients of the pre-coded JPEG image [22]. They developed a background subtraction strategy that properly depicts the background model over time using competing Hidden Markov Models (HMM). Three techniques for modelling the background directly from the compressed video are presented in [30].

Moving average, median, Gauss blending. These methods use the DCT coefficient (including the AC coefficient) to characterise the background at the block level, and then update the DCT coefficient to match the background. Popa et al. [31] use low DCT compressed area processing to simulate the background. Processing at the block level instead of the pixel level reduces the number of simulation parameters by almost one-third. They also reduce the number of coefficients per block from 64 to 16 while retaining segmentation quality. In the DCT domain, Ye et al. [32] evaluated the background stability and separability of objects. The suggested method restores the target by suppressing the background coefficients by modelling the background as a single Gaussian model for each frequency point. A quaternion-DCT for infrared target recognition is presented by [33]. This approach shows how to create a quaternion with two-directional features (motion feature and kurtosis feature). The QDCT drawing feature acts as a unique signature that helps solve problems when finding small targets. To reduce complexity and simplify hardware implementation, Manimozhi et al. [34] employed a diagonal matrix of binary substitution blocks as the measurement matrix for both DCT-based and DWT-based CS procedures.

According to related research, a large volume of video is required, as well as a significant amount of storage space and processing time for the segmentation method. Compression-based processing is recommended for restricted WVSNs to address the above issues. As a result, we'll describe a motion segmentation method using the DCT in the compression transform domain based on statistical background subtraction. The dual-mode SGM-based background subtraction technique recognises just the foreground blocks of the discrete cosine transform's detailed component to reduce processing complexity. Then, adjust the foreground block to recognise the foreground object. The foreground block is moved to the sink side for rebuilding and tracking. In Fig. 1, the proposed SDMBs (page size = 4) is compared to the original MOG [9] and with block measurements based on compressed sensing (CSMOG) [26].

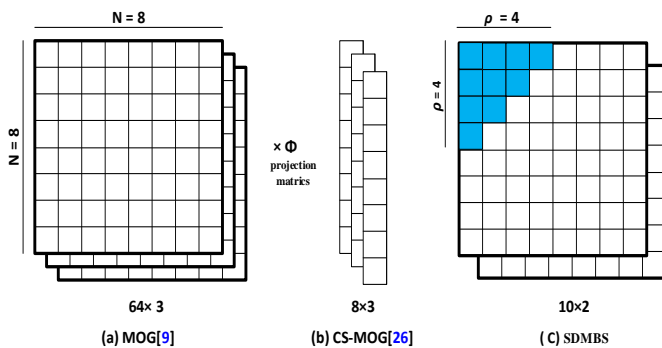

Fig. 1. Block Computation for (a) MOG, (b) CS-MOG and (c) SDMBs.

### III. PROPOSED SYSTEM MODEL

We first describe the steps of Spectral Dual-Mode Background Subtraction (SDMBs), then justify the use of dual-mode SGM (D-SGM) on top of the reduced dimension data PDCT. Fig. 2 depicts the proposed SDMBs algorithm's block diagram as well as the network topology.

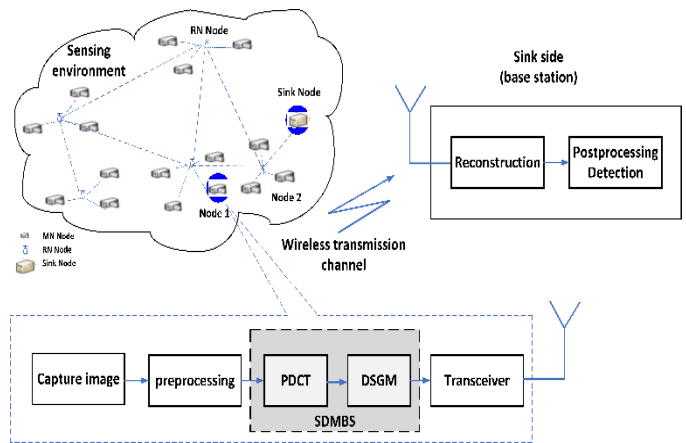

Fig. 2. The Proposed Block Diagram for WWSN-based Object Detection.

#### A. Network Model

We are considering randomly deploying WWSN nodes in the surveillance field. Each WWSN node is constrained in terms of process and memory resources. The WWSN system model is composed of  $N$  visual sensor nodes, Relaying Nodes (RNs), one or more Monitoring Node or Sensor node (MNs), and a Sink Node (SN) [23]. Each sensor node  $i$  is thought to be in a 'wakeup' state according to a unique duty cycle  $\beta_s \in [0, 1]$  during a period  $t_s$  to successfully send an image via the network. Thus, it avoids any conflicts induced by two or more nodes simultaneously broadcasting image data. Thus, each sensor is awake for a length of time  $\beta_s t_s$  and sleeps for a length of time  $(1 - \beta_s) t_s$ . The frame count is set to zero when a sensor node enters a 'wake up' condition.

#### B. Pre-Processing

Simple spatial Gaussian filtering and median filtering are used to suppress salt and pepper and Gaussian noise in images captured during the preprocessing step [27]. The filtered frame is then divided into equal-sized blocks, with the SDMBs algorithm applied to each block separately. This can be done in parallel, further reducing computation time.

#### C. Discrete Cosine Transform (PDCT)

As seen in Fig. 2, each video frame is subsequently divided into  $8 \times 8$  blocks. After that, each block is subjected to DCT. Each  $8 \times 8$  DCT block is represented by the first ten low-frequency DCT components. The partial DCT has the advantage of compressing an  $8 \times 8$  block into 10 samples, which is useful for WSNs with limited resources. Although the rest of the data is sparse, the DCT DC-coefficient stays concentrated in the series' upper left corner. Compressed sensing CS [25] requires a sparse value.

#### D. Dual Mode Signal Gaussian Model (DM-SGM)

To deal with the inaccuracies that come from modelling the scene using SGMs [35], a dual-mode SGM with age [17] is utilised. While still learning the background reliably, this model safeguards the background model from foreground and noise contamination. The compressed domain PDCT low frequency components are subjected to DM-SGM to identify whether or not the image block contains a moving target. Here, the Gaussian parameter for each grid is computed. Mean,

variance, and age are then used to model the background, determining and updating the foreground blocks. There are two models for each block; appearance background models and candidate background models. The candidate background model is ineffective until its age exceeds that of the apparent background model. This dual-mode SGM differs from two-version Gaussian combination models (GMM) [9] in that, with a bi-modal GMM, the foreground facts could still contaminate the history. However, with the dual-mode SGM approach, this is no longer the case.

The two models are switched at this point. At the end, the foreground blocks are determined and applied to the pixel refining stage to detect the pixels containing the target within the foreground block, according to the flowchart in Fig. 3.

The group of pixels in grid  $i$  at time  $t$  is denoted as  $\mathcal{G}_i^{(t)}$ , the number of pixels in  $\mathcal{G}_i^{(t)}$  as  $|\mathcal{G}_i^{(t)}|$ , and the observed pixel intensity of a pixel  $j$  at time  $t$  as  $I_j^{(t)}$ , and the mean  $\mu_i^{(t)}$ , the variance  $\sigma_i^{(t)}$ , and the age  $\alpha_i^{(t)}$  of the SGM model applied to  $\mathcal{G}_i^{(t)}$  is updated as

$$\mu_i^{(t)} = \frac{\tilde{\alpha}_i^{(t-1)}}{\tilde{\alpha}_i^{(t-1)}+1} \tilde{\mu}_i^{(t-1)} + \frac{1}{\tilde{\alpha}_i^{(t-1)}+1} M_i^{(t)} \quad (1)$$

$$\sigma_i^{(t)} = \frac{\tilde{\alpha}_i^{(t-1)}}{\tilde{\alpha}_i^{(t-1)}+1} \tilde{\sigma}_i^{(t-1)} + \frac{1}{\tilde{\alpha}_i^{(t-1)}+1} V_i^{(t)} \quad (2)$$

$$\alpha_i^{(t)} = \tilde{\alpha}_i^{(t-1)} + 1 \quad (3)$$

$$M_i^{(t)} = \frac{1}{|\mathcal{G}_i|} \sum_{j \in \mathcal{G}_i} I_j^{(t)} \quad (4)$$

$$V_i^{(t)} = \max_{j \in \mathcal{G}_i} (\mu_i^{(t)} - I_j^{(t)})^2 \quad (5)$$

$$V_i^{(t)} = (\mu_i^{(t)} - M_i^{(t)})^2 \quad (6)$$

DM-SGM [17] uses another SGM as a prospective background model. At this point, the candidate background model is rendered ineffectual until it reaches the same age as the apparent background model, at which point the two models are exchanged. We update the mean, variance, and age of the candidate background model and the apparent background model at time  $t$  for grid  $i$ ,  $\mu_{C,i}^{(t)}$ ,  $\sigma_{C,i}^{(t)}$ , and  $\alpha_{C,i}^{(t)}$  and  $\mu_{A,i}^{(t)}$ ,  $\sigma_{A,i}^{(t)}$ , and  $\alpha_{A,i}^{(t)}$ , respectively, according to (1), (2), and (3), if

$$(M_i^{(t)} - \mu_{A,i}^{(t)})^2 < \theta_s \sigma_{A,i}^{(t)} \quad (7)$$

Where  $M_i^{(t)}$  is the observed mean and  $\theta_s$  is a threshold parameter. Also, we update  $\mu_{C,i}^{(t)}$ ,  $\sigma_{C,i}^{(t)}$ , and  $\alpha_{C,i}^{(t)}$ , according to (1), (2), and (3).

If condition (7) is violated, and if the observed mean matches the candidate background model, then

$$(M_i^{(t)} - \mu_{C,i}^{(t)})^2 < \theta_s \sigma_{C,i}^{(t)} \quad (8)$$

If none of the conditions hold, we start the candidate background model with the current observation. Only one of the two models is altered when this process is used, while the other is left alone. If the candidate's age exceeds the apparent meaning, the two backdrop models for the grid are swapped after updating.

$$\alpha_{C,i}^{(t)} > \alpha_{A,i}^{(t)} \quad (9)$$

Once the candidate is exchanged, the background model is initialised. Finally, an apparent background model is solely employed to determine foreground pixels, as stated in Section E. preventing the background model from being distorted by the foreground data that represents the object.

The candidate background model, rather than the apparent background model, learns the foreground data in the dual-mode SGM, preventing the background model from being distorted by the foreground data that represents the moving object in the frame. So, the models are changed and the correct background model is chosen if the candidate background model's age is greater than the apparent background models.

### E. Pixels Refining

A foreground block contains both foreground and background pixels. Each video frame contains a large number of background blocks. As a result, we just need to focus on the small number of foreground blocks. To detect which pixels in a foreground block are indeed foreground, a basic background learning technique for each block is created. If we classify a pixel  $j$  in a group  $i$  as a foreground pixel,

Fig. 3. A Flowchart for the DSGM Process.

$$(I_j^{(t)} - \mu_{A,i}^{(t)})^2 < \theta_d \sigma_{A,i}^{(t)} \quad (10)$$

where  $\theta_d$  is a threshold parameter. So, instead of the apparent background model learning the foreground data, the candidate background model learns it. Additionally, the correct background model will be chosen if the candidate background model's age is greater than the apparent background model's, where the models will be swapped. As a result, we don't have to be concerned about the model learning inaccurate foregrounds.

#### F. Computation Complexity

The quantity of elements processed in every frame determines the difficulty of the computation. We can only evaluate the computing complexity of one block because each frame is divided into equal-sized blocks of size  $8 \times 8$  pixels. Because each frame is broken into blocks of  $8 \times 8$  pixels of similar size, we may calculate the computing cost of a single block.

- For the CS process, we consider the original MoG [9], where each pixel is modelled by 3 Gaussians, which means that we need  $64 \times 3$  Gaussians per block.
- For CS-MoG [26], where each projection value requires three Gaussians, the number of Gaussians required per block is  $8 \times 3$  (a factor of 8 reduction).
- For our proposed method, each block is modelled by 2 Gaussian DM-SGM and we proceed over the 10 low-frequency DCT components, which require  $10 \times 2$  number of Gaussians for each block, a reduction by a factor of 9.6 and 1.2 per block w.r.t. the original MoG and CS-MoG, respectively. Experiments show that it is 2.5 times faster than CS-MOG in processing time.

#### G. Scene Reconstruction

When an image arrives at the sink node, it is superimposed on the previously received reference frame. Because the suggested technique only communicates a fraction of the entire image, the pixel coordinates at the MN node stay unchanged. This allows a portion of the transmitted image to be used to replace pixels in the reference image at the sink node more efficiently. The pixel values are, however, subject to channel distortion due to the transmission environment.

### IV. EXPERIMENTAL RESULTS AND ANALYSIS

In this section, experimentation and performance evaluation are done to determine the relevance of our proposed method. The experimental dataset and setup are explained, then the qualitative analysis is shown to illustrate the performance of our system, and evaluation for quantitative and execution performance is done to test the accuracy and running time. In addition, the algorithm is also simulated in a sensor network environment using the Cooja Simulator of Contiki OS [36, 37] and realised in a real testbed using IOT-LAB [38].

#### A. Dataset and Setup

We will present the results of our compressed domain-based moving object detection technique on a standard

benchmark dataset, CDnet 2014<sup>1</sup> [39], to demonstrate its effectiveness. The CDnet 2014 data set is divided into 11 categories with different challenges, each of which contains four to six video sequences. Each video sequence consists of 600 to 7999 frames, with resolutions ranging from  $320 \times 240$  to  $720 \times 576$ . The simulations were run on an Intel Dual Core i7 3.6GHz processor with 8GB of RAM. The code is written in the C++ language. The total number of frame sequences in each dataset was averaged during the experiments.

#### B. Qualitative Analysis

Fig. 4 and 5 show the results of our moving object detection technique, Spectral Dual-Mode Background Subtraction (SDMBS). Fig. 4 exhibits performance for some of the representative frames from CDnet 's different categories to show performance against all the CDnet 2014 challenges. Fig. 4 and 5 demonstrate the ground truth and detected object discoveries from the original video frames. Comparing the resulting foreground mask to the relevant ground truth demonstrates the robustness of our suggested strategy for detecting moving objects across different categories.

Most of the CDnet 2014 challenges have excellent qualitative performance; nevertheless, the PTZ and camera jitter categories, as shown in Fig. 4, have poor qualitative performance. The worst performance Due to the zooming and moving features of this category, a compensation stage is required before the object detection stage to compensate for the frame movement. Because of the ghosting artefacts created in the videos in this category, the Intermittent Object Motion category is noisy. Background items moving away, abandoned objects, and objects stopping for a brief moment before moving away are the key features of this category. Shadow appearance in the shadow category affects the performance and the foregrounds are not detected completely.

Fig. 4. Foreground Results of CDnet 2014 Dataset [39].

<sup>1</sup> <http://www.changedetection.net/>

When we compared our results to different existing methods published on the CDnet website [39], we identified MOG [9], KNN [40], ViBe [12], and SubS [41] as candidates. Thus, we compared our proposed compressed-based background subtraction SDMBS with recent and state-of-the-art methods [26,42], classical methods like [9,40], and fast methods like the ViBe [12] Background Subtraction Algorithm.

In [26], a block-based MOG is designed to be processed using the compressed sensing CS elements of the frame-blocks CS-MOG and is targeted at WVSN applications, whereas [42] is a background model update algorithm that uses an intermittent technique along with an adaptive block-learning algorithm.

The results of three video sequences, Highway (baseline), Fountain2 (dynamic background), and Snowfall (bad weather), are illustrated in Fig. 5. The original video frame for the three datasets and its corresponding groundtruth are shown in the top two rows. The results of MOG [9], Vibe [12], two current state-of-the-art techniques [26, 42], and SDMBS are shown in the next five rows (from top to bottom). In the last row of Fig. 5, we demonstrate a qualitative comparison of our proposed technique with other current methods, revealing that our method outperforms several of the existing systems. From the results, it is observed that our system accurately recognises foreground objects and has a considerably high resemblance to the ground truth when compared to other examined systems.

Fig. 5. Results with Highway (Baseline), Fountain2 (Dynamic Background), and Snowfall (Bad Weather) Videos Frames.

### C. Quantitative Analysis

In the quantitative evaluation, our method is compared to widely popular and state-of-the-art object detection algorithms for WVSN by conducting experimentation on the benchmark (CDnet 2014) dataset [39]. Several evaluation metrics are utilised to provide a credible measure of the outcome. Average recall (Re), precision (Pr), and F-measure (Fm) for all the video sequences in each category are listed in Table I. True positive (TP), false positive (FP), true negative (TN), and false-negative (FN) are the four types of pixel-based count metrics that can be created using the available ground truth data [39].

As the frequency of false negatives decreases, the value of Recall (Re) increases, which is used to measure the degree of completeness of the recognised foreground. Precision (Pr) is a metric measuring how accurate the identified foreground is, with a lower value when there are a lot of false positives. F-measure (Fm) is a metric for determining the balance of recall and precision with equal weights, implying that it is high only when both recall and precision are high. The three evaluation metrics, recall (Re), precision (Pr), and F-measure (Fm), are only considered to avoid redundancy.

TABLE I. EVALUATION METRICS

| Metrics                   | Description                 |
|---------------------------|-----------------------------|
| Recall (Re)               | $\frac{TP}{TP + FN}$        |
| Precision (Pr)            | $\frac{TP}{TP + FP}$        |
| F-Measure (Fm)            | $\frac{2(Pr, Re)}{Pr + Re}$ |
| Specificity (SP)          | $\frac{TN}{TN + FP}$        |
| False Positive Rate (FPR) | $\frac{FP}{FP + TN}$        |
| False Negative Rate (FNR) | $\frac{FN}{TN + FP}$        |

The best and second-best performing approaches for each category, based on the average Fm for all the video sequences, are noted in red and bold in Tables II and III. When compared to classical methods, SDMBS may only be competitive in some areas, such as dynamic background, low frame rate, and bad weather. While there are approximate results for most categories with Subs [41] when SDMBS is ranked (2nd), this can be explained in terms of the design trade-off. While; when compared to state-of-the-art methods [26], we achieve a 15% increase in accuracy than CS-MOG [26] which is a compressed-based background subtraction applied for WVSN. In Fig. 7, the execution speed of SDMBS is compared to that of other methods at two resolution scales (320240 and 640480). For the two resolution scales, SDMBS excels in terms of speed. As seen in Fig. 7, SDMBS provides equivalent results to FBS-ABL [42], although it is more accurate, as seen in Fig. 6. When compared to other block-based techniques, this demonstrates SDMBS's effective design strategy.

Fig. 6 and 7 highlight the trade-off between detection performance and execution speed, and as can be seen, extensively adaptable approaches have fast/practical execution at the cost of diminished performance. We achieve a 2.3x

improvement in frame rate (FPS) over CS-MOG [26], a compressed-based background subtraction method used for WVSAN. This shows an efficient decrease in processing time.

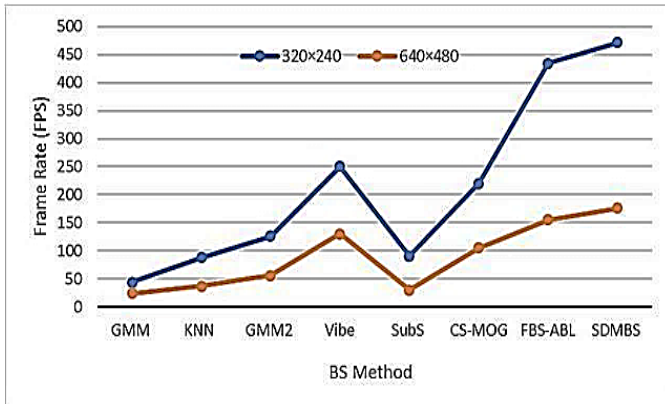

Fig. 7. Frame Rate for Different Techniques.

#### D. Sensor Network Simulation

This section illustrates the capability of the proposed system to work in WSN environments: first, simulation is carried out over Cooja of the Contiki OS Network Simulator [36], [37] to add the effect of lost packets and throughput. Second; the system is released on a real testbed using IOT-LAB [38]. Traffic trace files are used in the real testbed and simulated environment [15].

1) *Cooja simulation*: Four sensor nodes are installed. The sink is located at the left upper node (node 1) of the network area of  $100\text{ m} \times 100\text{ m}$  square grid. The destination node is located at (node 4). The simulation uses two datasets: pedestrians and PETS2006 (baseline) videos. The detection of moving objects is carried out at the host to select the blocks containing moving objects, and the blocks are then sent and routed through intermediate nodes to the base station. The received blocks at the destination are reconstructed to show the moving target, Fig. 8.

Fig. 9 shows the received image PSNR for two approaches: First, the full transmission of the image frame (Full Tx), while the second is our approach to transmitting the important portion of the image containing the moving object (Partial Tx). Although the proposed approach has a lower PSNR ratio than the full transmission approach, however, the average value is 27db. PSNR and energy are calculated using [15].

The proposed approach was compared to the direct approach for the energy consumption analysis. In the direct technique, a multi-hop transfer of an entire image to the sink node is used. On the aforementioned datasets, Fig. 10 depicts the energy using both methodologies. As can be observed, the node's energy usage has been significantly reduced. The two datasets show that the suggested approach can be employed in real-time moving object detection systems since a portion of the image data, including object information, is received at the sink node with an appropriate range of PSNR values and less energy.

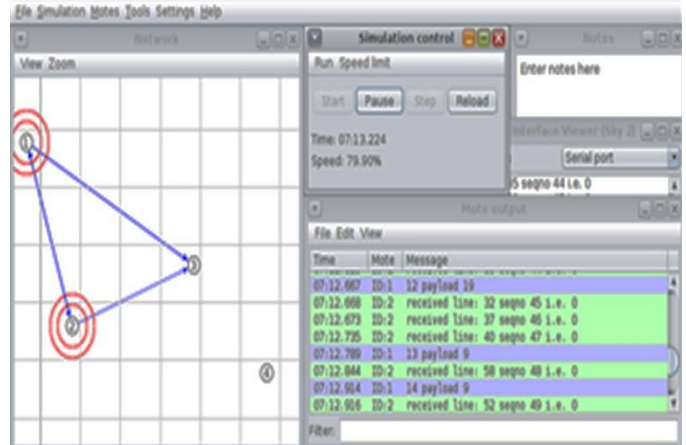

Fig. 8. Cooja Snapshot.

Fig. 9. PSNR for the Two Datasets.

Fig. 10. Energy Consumption.

2) *IOT-LAB realization*: IoT-LAB<sup>2</sup> [38] is a large-scale WSN testbed that includes over 2000 wireless sensor nodes and a variety of processor architectures and wireless chips. IoT-LAB can be accessed through a web portal or by using the command-line tools. It allows users to retrieve experiment results and access serial ports on devices. Based on trace files as presented in [15], the IoT-LAB testbed M3 open nodes illustrated in Fig. 11(b) was employed in our experiments to replicate the intended object detection of the two datasets: pedestrians and PETS2006 (baseline). As shown in Fig. 11(a), the nodes m3-1, m3-10, m3-15, and m3-16 are used as senders, and m3-24 (blue circles) is used as a receiver to acquire varied loss rates as shown in Fig. 11(a). The sender (sender node) sends data packets according to the sender's trace file specifications (st-packet). The receiver (receiver node) maintains track of the packets it receives in a receiver trace file (rt-packet) as shown in Fig. 11. The sequence numbers of correctly received packets are received on the user's computer, which is used to reconstruct the video and calculate experiment metrics.

Fig. 12 shows the results of applying the proposed moving object detection technique in IOT-LAB to the two datasets: pedestrians on the first row and PETS2006 on the second row. The foreground blocks are transmitted and routed to the sink node. The sink node decompresses the received block and determines the moving object's location. For surveillance applications, object location is the most important piece of information that requires further analysis. The object ROI is transmitted to the sink node correctly with minimum network resources, memory, and bandwidth. The energy is minimised with an accepted PSNR.

## V. CONCLUSION

A background subtraction method that is both computationally efficient and accurate has been developed for object tracking across the limited resources of Wireless Visual Sensor Networks (WVSNs). To address the computation bottleneck of processing for constrained sensor networks, we use partial DCT to reduce the data dimensions while preserving the information content. In addition, energy-efficient block-based dual-mode SGM is utilised for foreground block detection, where the image frame is divided into blocks and only blocks containing foreground pixels are further processed for the refining stage. The foreground pixels are determined and the moving object is located. In contrast to standard Compress Sensing CS, which compresses the entire frame, the target region of interest ROI in our proposed method is compressed, communicated, and routed toward the sink node for further analysis. Our experimental results show that our method is as efficient as traditional algorithms. Moreover, it is up to three times faster than the state-of-the-art WVSN object detection methods, and 15% more accurate. For embedded camera networks, we demonstrate that our suggested technique can accurately detect a moving object in real-time. We applied the proposed detection method in a WSN environment using Cooja of the Contiki OS Network Simulator. We verified that

the energy required for transmitting the detected object to the sink node in our proposed detection method is lower than that of comparable methods at acceptable PSNRs. Finally; the system is released on a real testbed using IOT-LAB using testbed M3 open nodes.

**Abstract**—This paper describes a new efficient cryptosystem for the color image encryption technique, based on a combination of multidimensional proposed chaos systems. This chaos system consists of six bisections:  $T_1(x)$ ,  $T_2(x)$ ,  $T_2(y)$ ,  $T_3(x)$ ,  $T_3(y)$ , and  $T_3(z)$ . They induce three chaotic matrix keys and three chaotic vector keys. We use a multidimensional chaotic system together with an encryption algorithm to provide better security and wide key spaces. The proposed cryptosystem uses four levels of random pixel diffusions and permutations simultaneously and  $\omega$  - times interchange between rows and columns. The correlations between the RGB components of the plain image are reduced. The level of security, the computational complexity, the quality of decoding a decrypted image under closure threat is improved. The simulation results showed that the algorithm shows a high level of security, and the assurance that the image recovered at the receiving point is identified as the image at the transmission point.

**Keywords**—Chaotic system; encryption; decryption; image; algorithms; cryptosystem

## I. INTRODUCTION

The world is moving towards digitizing all types of data. The digital use of data is hourly increasing. Digital images are at the forefront of the most used data on the internet. With the increase in the technology of the World Wide Web and the growth of its uses, the sharing of data over the internet has diversified, and among this data is the exchange of digital images. In many cases, the images are sensitive, and they contain information that is not publishable, such as images related to the health conditions of individuals, as well as secret military locations related to the national security of countries. Since the areas of communication via the Internet are open and vulnerable to attacks on data, the use of encryption for such images has become very important and necessary. A color image holds many rows and columns of pixels; these pixels contain quantized values that represent the degree of the color at any point in the image. Thus, the color image defined as a matrix of value pixels, each containing three numerical RGB components to describe the color of a tiny area. Since sensitive images may invite attacks from anywhere around the world, image security is an important issue. The aim of image encryption is to transform a plain image to different cipher one that is difficult to read [1]. Chaos theory is one of the most

important security approaches used in encrypting images due to its capacity for mixing, sensitivity to initial conditions, control parameters, and completely random behavior. In 1989 [2], Matthews developed the first chaotic encryption technique. Many researchers are interested in presenting various algorithms to create a strong and robust encryption system for digital images, and some of them depend on the chaos system to induce random secret keys to maintain the confidentiality of images. In this paper, we used a multi-dimensional chaos system with many parameters to increase the key space. Since the proposed chaos system is developed and new, the chaotic and bifurcation behavior of it have been made and the values that enter the system into a chaos state have been determined. This paper presents a cryptosystem based on the proposed multi-dimensional chaotic maps and multiplexing frequent levels of shuffling, scramble, and pixel diffusion for the digital image component RGB. The practical results showed the intensity and resistance of the proposed algorithm compared to many related ones. The analysis proved a significant increase in the size of the encryption keys, which makes our algorithm outperform others against the brute-force attacks. His work introduced a low complexity algorithm for image cryptography using a multiple definition function for linear chaotic map denoted NPWLCM. Since then, many scientific papers have described image encryption based on chaotic systems. In this work, we describe a multi-chaotic system to encrypt the RGB components of color images simultaneously such that, the RGB components affect one another. The proposed six maps; ;  $T_1(x)$ ,  $T_2(x)$ ,  $T_2(y)$ ,  $T_3(x)$ ,  $T_3(y)$ , and  $T_3(z)$  increase conjugation of the items  $x_i^3$ ,  $x_i^2$ ,  $y_i^2$ ,  $x_i y_i$ ,  $y_i^3$ ,  $z_i^2 x_i$ , ...  $z_i^3$ . Pixel Transform Table (PTT) procedure input these maps to output three  $M \times N$  matrix keys ( $M_r$ ,  $M_b$ ,  $M_g$ ) and three vector keys ( $V_r$ ,  $V_b$ ,  $V_g$ ) of length  $MN$ . The image's rows and columns are shuffled and scrambled using the vector keys. While the matrix keys are used to change the values of pixels four times to increase the complexity and thus the security of the cryptosystem. The remainder of this paper presents the related work in Section 2. Section 3 and section 4 explain in detail the proposed chaotic system and its chaotic behavior and bifurcation. In Section 5, we describe the encryption and decryption cryptosystem. Finally, in Section 6, we show the practical results and comparisons with another research.

## II. RELATED WORK

The encryption algorithms based on the chaos theory have been arisen as a power approach to increase the security over the last few decades. The vast majority image encryption algorithms have been introduced based on one- and two-dimensional chaotic maps. In 2017, Pak and Huang [3] described a new chaotic system created by composing the output of two existing one-dimensional chaotic maps. Their algorithm achieved a total shuffling based on a linear-nonlinear-linear structure. In 2007, Chong Fu et al. [4] used a three-dimensional Lorenz chaotic system to increase security and performance of image cryptography. In 2008, Xiangdong et al. [5] presented a chaotic shuffling algorithm using a sorting transformation of a chaotic sequence to obtain address codes for image transposition. Their algorithm avoided the drawbacks of image scrambling ways like rising of complexity and requiring understanding of probability distribution. In 2009, Juan et al. [6] described a three-dimensional image cryptography approach based on a discrete chaotic system with a security key induced from the initial conditions and parameters of the logistic system. In 2011 [7], researchers introduced an image encryption scheme using a Lorenz and Rossler chaotic system to obtain a large key space, improving security and complexity. In 2005, Zhang et al. [8] presented an algorithm based on a chaotic map and big size encryption key to encrypt the given image followed by a pixel shuffling process using an induced chaotic permutation matrix. In 2011, Keshari and Modani [9] presented an image cryptosystem based on two random maps; a chaotic map lattice to change pixel values by iterating the chaotic map for given initial conditions and Arnold's cat map to rearrange the pixel's position. The same year, Zhang, and Liu [10] introduced a novel image encryption algorithm using a skew tent chaotic system. In their work, they shuffle the order of the positions of all the pixels in the image. Their algorithm was based on permutation-diffusion architecture. In 2012, Khade and Narnaware [6] presented another method to encrypt a color image depending on 3D Logistic and Chebyshev maps. The proposed chaotic maps substituted the RGB components, generated a key, and scrambled the image pixels. The used technique depending on a logistic map used to depict a grey-scale image. A digital matrix approach is used where the three-dimensional matrix value is replaced according to the generated chaotic sequences, whereby the pixel replacement and mixing are achieved at the same time.

Color images are rich with information and have attracted wide attention. Each pixel contains numerical values of RGB components that determine density of RGB components in the color image. Many encryption algorithms have been described [11, 12, 13, 14, 15, 16, 17]. These algorithms are more vulnerable to attack because they neglect the correlations between RGB components. In 2012, Wang et al. [18] proposed a new algorithm using a three-dimensional matrix of the color image and a two-dimensional Lorenz and tent chaotic system at the same time to encrypt RGB components. Their algorithm has four phases. First, the three-dimensional matrix is converted to a two-dimensional matrix and the low-frequency wavelet coefficient is divided into overlapping blocks. Then, encryption is achieved by scrambling the pixel value diffusion based on a completely random chaotic sequence. In 2016,

Younes [19] published a useful survey of different techniques of image encryption, discussing several image encryption techniques from 2013 to 2015. In 2021, El Shafai et al. [20] introduced an encryption method to encrypt medical images depending on a piecewise linear chaotic map, and DNA encoding techniques. In 2018, Wu and Yang [21] introduced an algorithm depending on pixel diffusion and a DNA approach, which exploited the two-dimensional Hénon-Sine map to create a pixel permutation. In 2019, Wu et al. [22] used a nonlinear operation in cylindrical diffraction domain and compressed sensing to encrypt a multi-image based on an asymmetric approach. In 2013, Song et al. [23] defined a neighborhood nonlinear map and Coupled Map Lattices (CML) to describe a novel framework based on the Nonlinear Chaotic Algorithm (NCA) chaos and its spatiotemporal merits. In 2020, Yasser, et al. [13], induced an image encryption algorithm using a combination between Discrete Wavelet Transform (DWT) and a chaotic system to shuffle pixels and substitution operations.

## III. PROPOSED CHAOS SYSTEM

The proposed chaotic system consists of new 1D, 2D, and 3D equations derived from logistic map and cubic maps. The proposed system is a bijection and increases the quadratic and cubic coupling of the items  $y_i^2, x_i^2, x_i y_i, x_i^3, z_i^3$ , and it provides more security to the system. Six chaotic key maps will be derived within a limited range in (0,1).

$$\left\{ \begin{array}{l} \text{1D chaotic system} \\ x_{n+1} = r * x_n * (1 - x_n)(1 - \sin(x_n)) \\ \text{2D chaotic system} \\ x_{n+1} = r' * x_n * (1 - x_n)(1 - \sin(x_n)) + \gamma_1 y_n^2 \\ y_{n+1} = \mu y_n (y_n + 2)(1 - \sin(x_n)) + \gamma_2 (x_n y_n + x_n^2) \\ \text{3D chaotic system} \\ x_{n+1} = \lambda x_n (2 + x_n)(1 - \sin(x_n)) + \beta y_n^2 x_n + \alpha z_n^3 \\ y_{n+1} = \lambda y_n (2 + y_n)(1 - \sin(y_n)) + \beta z_n^2 y_n + \alpha z_n^3 \\ z_{n+1} = \lambda z_n (2 + z_n)(1 - \sin(z_n)) + \beta x_n^2 z_n + \alpha y_n^3 \end{array} \right\} \quad (1)$$

The control parameters beyond the range have no chaotic behavior. Fig. 1 shows that the 1D and 2D systems enter a chaotic condition and outputs a chaotic series in the region (0,1) subject to:  $5.77 < r', r < 12.97$ ,  $2.68 < \mu < 3.6$ ,  $0.039 < \gamma_1, \gamma_2 < 0.25$ . Fig. 2 shows that, the 3D system enters a chaotic condition in the region (0,1) subject to:  $3.49 < \lambda < 3.83$  and  $0.039 < \beta, \alpha < 0.043$ . The Bifurcation diagram of 1D, 2D, and 3D are shown in Fig. 3 and Fig. 4, respectively.

Fig. 1. The Behavior of the (1,2)-D chaotic Map in First 300 Iteration at  $r = 6.27$  in  $x$ - $y$  Plane.

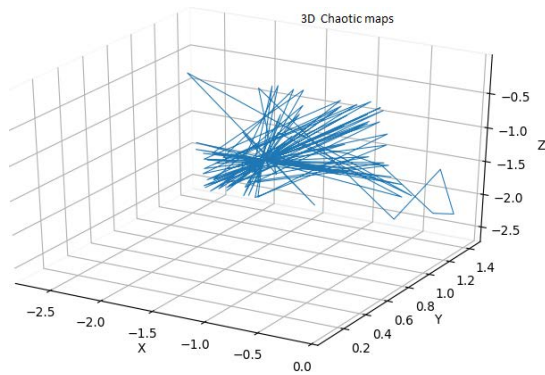

Fig. 2. The Behavior of the 3D Chaotic Map in First 1000 Iteration at  $\lambda = 3.81$ ,  $\beta = 0.41$ , and  $\alpha = 0.046$  in x-y-z- Space.

Fig. 3. Bifurcation Diagram of Sequences in 1D (2D) Chaotic System.

Fig. 4. Bifurcation Diagram of Sequences in 3D Chaotic System.

#### IV. DIAGONALIZING OF THE PROPOSED CHAOTIC MAP

For a given prime number,  $n$ , the proposed system in (1) can be represented as the set  $T$  of bijections as follows:

$$T = (T_1(x), T_2(x), T_3(x), T_2(y), T_3(y), T_3(z)), \quad (2)$$

where each bijection  $T_i(\dots) \in T$  can be defined as:

$$T_i \begin{bmatrix} x_{n+1} \\ y_{n+1} \\ z_{n+1} \end{bmatrix} = \begin{pmatrix} a & b & c \\ d & e & f \\ g & h & i \end{pmatrix} \times \begin{bmatrix} x_n \\ y_n \\ z_n \end{bmatrix} \text{ mod } n \quad (3)$$

$$T_i \begin{bmatrix} x_{n+1} \\ y_{n+1} \\ z_{n+1} \end{bmatrix} = A \times \begin{bmatrix} x_n \\ y_n \\ z_n \end{bmatrix} \text{ mod } n. \quad (4)$$

If the determinant  $|A|$  is not equal to zero and  $\gcd(|A|, n) = 1$  is satisfied, then the matrix  $A$  is invertible. The inverse of system (1) is:  $x_{n+1} = (A^{-1} \times x_n) \text{ mod } n$ . Diagonalizing equations in (1) means finding a new  $x', y', z'$  system with no cross terms. Based on the Principal Axes theorem every quadratic form can be diagonalized. The diagonalization of the quadratic form 2D is  $(x'_{n+1})^T D x'_{n+1}$ ,  $(y'_{n+1})^T Q y'_{n+1}$ , where  $D$  and  $Q$  are  $2 \times 2$  matrices within four parameters for each. On the other side, diagonalization of the

3D form of the three variables  $x, y$ , and  $z$  increases the number of parameters up to nine [12].

#### V. PROPOSED SCHEME

##### A. Chaotic Key Generation

A color image  $P$  decomposes to three components  $RGB$ : red, blue, and gray with  $M \times N$  matrices each component with  $M$  rows and  $N$  columns of pixels. The proposed algorithm uses a novel scheme called Pixel Transform Table (PTT) to generate three  $M \times N$  matrix keys  $(M_r, M_b, M_g)$ , and three vector keys  $(V_x, V_y, V_z)$  of length  $MN$ . The chaotic maps  $T_1(x)$ ,  $T_2(x)$ , and  $T_2(y)$  generate three sequences of real numbers, they are converted to  $(M_r, M_b, M_g)$ , and the chaotic maps  $T_3(x)$ ,  $T_3(y)$ , and  $T_3(z)$  generate three other sequences which are transformed into  $(V_x, V_y, V_z)$ . The Pixel Transform Table (PTT) approach is shown below.

##### PTT ( $\rho \geq MN$ , jD map)

Input: The chaotic system (1)

Output: Random map  $T_j$

1. Initialize the chaotic parameters in the maps (1).
2. Iterate the system (1) to generate the sequences  $S_j(i)$  using jD map, where  $j = 1 \rightarrow 6$ , and  $i = 1, 2, \dots, \rho$ .
3.  $S_j(i) = \{S_1(i), S_2(i), \dots, S_6(i)\}$ .
4. For each  $j$ , generate the set of integer sequences  $S_j^l(\rho)$

from the set sequences  $S_j(i)$  as:

$$S_j^l(\rho) = \left[ (S_j(i) \times 10^{14}) \right] \text{ mod } \rho$$

5. For each  $j = 1 \rightarrow 6$   
 $S^j(\rho) = \text{Sort}(S_j^l(\rho))$   
 find out the position of values  $S^j(\cdot)$  in  $S_j^l(\cdot)$ , then construct set of transfer  $T^j = \{t_1(i), t_2(i), \dots, t_6(i)\}$ , where the value  $S_j^l(t_j(i)) = S^j[i]$ ,  $i = 1, 2, \dots, \rho$ .
6. The sequences  $(t_1(i), t_2(i), t_3(i))$  are moved to three  $M \times N$  matrix keys  $(M_r, M_b, M_g)$ , and the sequences  $(t_4(i), t_5(i), t_6(i))$  are converted to the three vector keys  $(V_x, V_y, V_z)$  of length  $MN$ , respectively.

##### B. Image Encryption Algorithm (IEA)

The encryption is an operator that transforms the plain image  $P$  to an unknown cipher image  $P_5$ . IEA algorithm involves three phases as follows:

$$\text{IEA: Plain Image } (P) \rightarrow \text{Cipher Image } P_5$$

**Phase One:** We describe a new and double secure block shuffling mechanism together with pixels values change. The primary effect of PPT in this process is initially changing randomly the pixel values of  $RGB$  called 1<sup>st</sup> diffusion level as follows:

$$R^r = M_r R (M_r)^T \text{ mod } 256$$

$$B^b = M_b B (M_b)^T \text{ mod } 256$$

$$G^g = M_g G (M_g)^T \text{ mod } 256$$

where  $R^r$ ,  $B^b$ , and  $G^g$  are the producing matrices that contains the chaotic values. In each matrix ( $R^r, B^b, G^g$ ), we swap randomly the rows with an odd index ( $2k + 1$ ) with the rows that have an even index ( $2k$ ), and randomly interchange the columns with an odd index ( $2l + 1$ ) with the columns of an even index ( $2l$ ), as shown in Fig. 5. We repeat the swap process  $\omega$ -times and get ( $R^r(\omega), B^b(\omega), G^g(\omega)$ ).

Fig. 5. One-Time Swapping Rows and Columns of the Matrix ( $R^r, B^b, G^g$ ).

Phase Two: In this phase, the pixel positions were scrambled in columns and rows by using two vector keys ( $V_x, V_y$ ). We apply 2<sup>nd</sup> diffusion level by dividing the components  $R^r(\omega), B^b(\omega),$  and  $G^g(\omega)$  values by their size  $MN$  to result the pixels values, i.e.

$$R'(\omega) = \left\lfloor \frac{B^r(\omega)}{MN} \right\rfloor \text{ mod } 256$$

$$B'(\omega) = \left\lfloor \frac{B^b(\omega)}{MN} \right\rfloor \text{ mod } 256$$

$$G'(\omega) = \left\lfloor \frac{G^g(\omega)}{MN} \right\rfloor \text{ mod } 256$$

Combine the matrices  $R'(\omega), B'(\omega),$  and  $G'(\omega)$  horizontally to obtain the  $M \times 3N$  matrix  $P_1$ , and generate a sequence of  $3MN$  numbers  $Y_1 = y_1, \dots, y_{3NM}$  from the rows of  $P_1$ . Permute the row  $Y_1 = y_1, \dots, y_{3NM}$  by the vector key  $V_x$ . We get the scramble vector  $Y'_1 = y'_1, \dots, y'_{3NM}$ . Reshape the vector  $Y'_1$  into three  $M \times N$  matrices;  $Ry(\omega), By(\omega),$  and  $Gy(\omega)$ . This process is repeated again as follows: Combine the matrices  $Ry(\omega), By(\omega),$  and  $Gy(\omega)$  vertically to obtain the  $3M \times N$  matrix  $P_2$ , and generate a sequence of  $3MN$  numbers  $Z_1 = z_1, \dots, z_{3NM}$  from the columns of  $P_2$ . Permute the sequence  $Z_1 = z_1, \dots, z_{3NM}$  by the vector key  $V_y$ . We get the scramble vector  $Z'_1 = z_1, \dots, z_{3NM}$ . Reshape the vector  $Z'_1$  into three  $M \times N$  matrices;  $Rz(\omega), Bz(\omega),$  and  $Gz(\omega)$ . Combine these matrices horizontally, we get a new  $M \times 3N$  denoted  $P_3$ .

Phase Three: Let  $D_{now}$  be the current ciphered pixel value after the current diffusion,  $P_{now}$  the present plain pixel value,  $D_{pre}$  the old cipher pixel value after the previous diffusion,

and  $P_{pre}$  the old plain value. Their initial values in  $Rz(\omega), Bz(\omega),$  and  $Gz(\omega)$  are equal to zero. Keep track of rows in  $P_3$  to set three vectors  $V(Rz(\omega)), V(Bz(\omega)),$  and  $V(Gz(\omega))$  each with length  $MN$ . We apply 3<sup>rd</sup> level of pixel diffusion on these vectors using the vector product with the key vector  $V_z$  as in the following:

$$\begin{cases} Zz^r = (V(Rz(\omega)) \times V_g) \text{ mod } 256 \\ Zz^b = (V(Bz(\omega)) \times V_g) \text{ mod } 256 \\ Zz^g = (V(Gz(\omega)) \times V_g) \text{ mod } 256 \end{cases} \quad (5)$$

where  $Zz^r, Zz^b,$  and  $Zz^g$  are the producing vectors that contains the chaotic values of  $V_z$ . We apply 4<sup>th</sup> and final level of pixel diffusion as shown in the next procedure where  $[(:)]$  refers to the components  $Zz^r, Zz^b,$  and  $Zz^g$  while  $[:]$  refers to a random value.

| <b>4<sup>th</sup> random Diffusion</b> ( $[(:)], [:]$ ) |                                                                                                                                   |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| Input:                                                  | $V_z = (Zz^r, Zz^b, Zz^g)$                                                                                                        |
| Output:                                                 | Vector ( $D_{now}(Zz^r), D_{now}(Zz^b), D_{now}(Zz^g)$ )                                                                          |
| 1. Generate three random values follows:                |                                                                                                                                   |
|                                                         | $\epsilon_{1l} = \text{rand}() \% 3$                                                                                              |
|                                                         | $\epsilon_{2l} = \text{choice a random value from } \{V_z\} \text{ mod } 256$                                                     |
|                                                         | $\epsilon_{3l} = \text{choice a random value from } \{V_z\} \text{ mod } 256$                                                     |
| 2. For $\omega$ in range $MN$ do                        |                                                                                                                                   |
| 3. If $\epsilon_{1l}=0$ then                            |                                                                                                                                   |
|                                                         | $D_{now}(Zz^r) = (\epsilon_{2l} \cdot P_{now}(Zz^r) + \epsilon_{3l} \cdot (D_{pre}Zz^r \times P_{pre}Zz^r)) \text{ mo } 256.$ (6) |
| 4. Else If $\epsilon_{1l}=1$                            |                                                                                                                                   |
|                                                         | $D_{now}(Zz^b) = (\epsilon_{2l} \cdot P_{now}(Zz^b) + \epsilon_{3l} \cdot (D_{pre}Zz^b \times P_{pre}Zz^b)) \text{ mo } 256.$ (7) |
| 5. Else If $\epsilon_{1l}=2$                            |                                                                                                                                   |
|                                                         | $D_{now}(Zz^g) = (\epsilon_{2l} \cdot P_{now}(Zz^g) + \epsilon_{3l} \cdot (D_{pre}Zz^g \times P_{pre}Zz^g)) \text{ mo } 256.$ (8) |
| 6. End For.                                             |                                                                                                                                   |

Reshape  $D_{now}(Zz^r), D_{now}(Zz^b),$  and  $D_{now}(Zz^g)$  into three  $M \times N$  matrices;  $Rz(\omega), Bz(\omega),$  and  $Gz(\omega)$ . We get the components of encrypted image  $P_5$  of size  $M \times N$ .

The flowchart of the encryption process with the induced 6 keys is shown in Fig. 6. The flowchart of the decryption algorithm and the 6 keys is shown in Fig. 7.

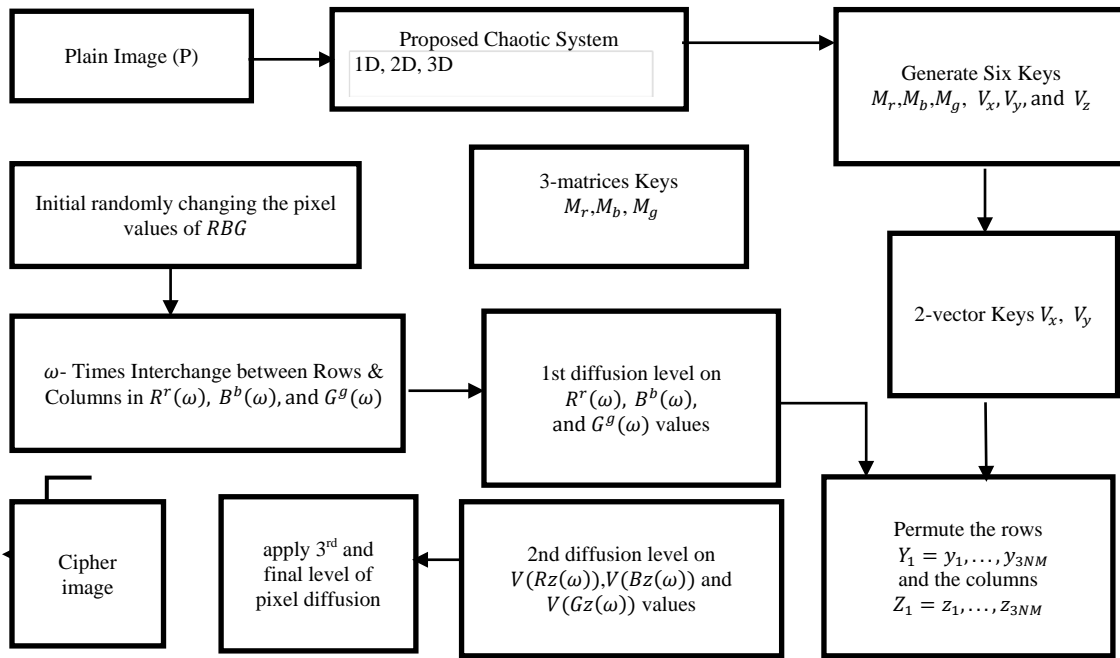

Fig. 6. The Outline of Image Encryption Algorithm IEA.

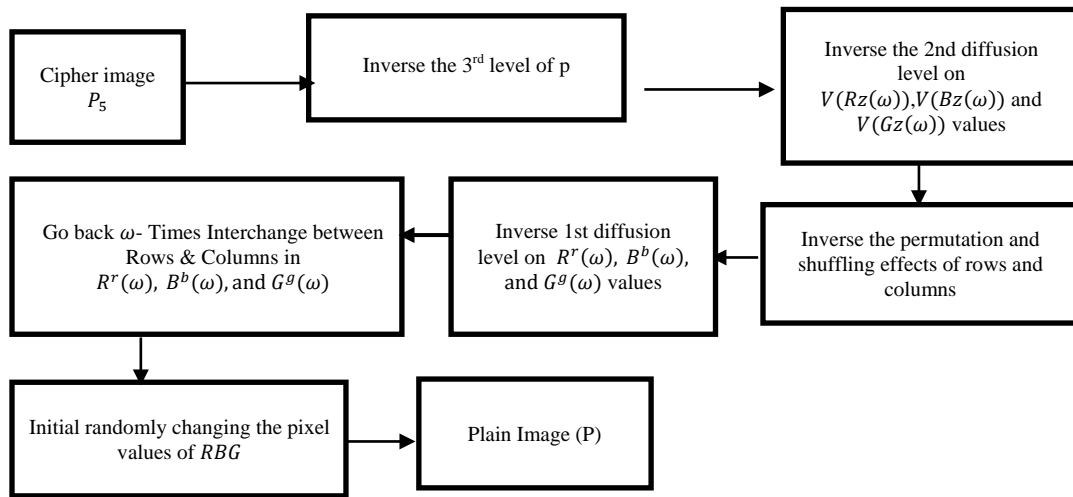

Fig. 7. The Outline of Image Decryption Algorithm IDA.

### C. Image Decryption Algorithm (IDA)

The image decryption algorithm (IDA) is like that of the image encryption pseudocode but in the inverse direction.

Step 1: All random values used in IEA are used in IDA.  
Step 2: Inverse 4<sup>th</sup> random Diffusion ( $[\cdot]$ ,  $[\cdot]$ ). Obtain  $Zz^r$ ,  $Zz^b$ , and  $Zz^g$  from  $D_{now}(Zz^r)$ ,  $D_{now}(Zz^b)$ , and  $D_{now}(Zz^g)$ . The inverse of the equations (6), (7), and (8) are the equations (9), (10), and (11) respectively.

$$Zz^r = \left( \frac{D_{now}(Zz^r) - \varepsilon_{3l}(D_{pre}Zz^r \times P_{pre}Zz^r)}{\varepsilon_{2l}} \right) \bmod 256 \quad (9)$$

$$Zz^b = \left( \frac{D_{now}(Zz^b) - \varepsilon_{3l}(D_{pre}Zz^b \times P_{pre}Zz^b)}{\varepsilon_{2l}} \right) \bmod 256 \quad (10)$$

$$Zz^g = \left( \frac{D_{now}(Zz^g) - \varepsilon_{3l}(D_{pre}Zz^g \times P_{pre}Zz^g)}{\varepsilon_{2l}} \right) \bmod 256 \quad (11)$$

Step 3: Inverse 3<sup>rd</sup> level of pixel diffusion. Obtain  $V(Rz(\omega))$ ,  $V(Bz(\omega))$  and  $V(Gz(\omega))$  from  $Zz^r$ ,  $Zz^b$ , and  $Zz^g$ , respectively. The inverse of the equations in (5) are the equations in (12).

$$\begin{cases} V(Rz(\omega)) = \left( \frac{Zz^r \times Vg}{Vg \cdot Vg} \right) \bmod 256 + \tau Vg \\ V(Bz(\omega)) = \left( \frac{Zz^b \times Vg}{Vg \cdot Vg} \right) \bmod 256 + \tau Vg \\ V(Gz(\omega)) = \left( \frac{Zz^g \times Vg}{Vg \cdot Vg} \right) \bmod 256 + \tau Vg \end{cases} \quad (12)$$

Step 4: Delete the effect of rows and columns scramble by using the inverse vectors  $(V_x^{-1}, V_y^{-1})$ .

Step 5: Inverse 2<sup>nd</sup> random Diffusion as follows:

$$B^r(\omega) = [MN \cdot R^l(\omega)] \bmod 256$$

$$B^b(\omega) = [MN \cdot B'(\omega)] \bmod 256 \quad (13)$$

$$G^g(\omega) = [MN \cdot G'(\omega)] \bmod 256$$

Step 6: Come back to the reverse paths to delete the effect of randomly interchange the columns rows.

Step 7: Inverse 1<sup>st</sup> random Diffusion as follows:

$$R = (M_r)^{-1} R^r ((M_r)^T)^{-1} \bmod 256$$

$$B = (M_b)^{-1} B^b ((M_b)^T)^{-1} \bmod 256 \quad (14)$$

$$G = (M_g)^{-1} G^g ((M_g)^T)^{-1} \bmod 256$$

These seven steps recover the plain image  $P$ . Mathematically, the image decryption algorithm is represented as in the next formula:

IDA: Cipher Image  $P_5 \rightarrow$  Plain Image ( $P$ )

#### D. The Computational Complicity

In this section, we discuss the running time of the steps in IEA. The running time of the PPT subroutine is  $O(\rho = MN + \epsilon)$  for small constant  $\epsilon$ , and the running time of the steps 1-7 is a linear function of the size of the image, i.e., the running time is  $O(MN)$ . The experimental process demonstrates that the consumption time of our approach IEA/IDA is practicable. The processor Intel(R) Core (TM) i7-8550U CPU @ 1.80 GHz 2.00 GHz and 8GB RAM is used in IEA/IDA is practicable. The processor Intel(R) Core (TM) i7-8550U CPU @ 1.80 GHz 2.00 GHz and 8GB RAM is used in encryption/decryption on 256 image  $P/P_5$  of size  $256 \times 256$ . The average consumption time is less than 4.01ms. Our running time is close to the running time in [24].

## VI. EXPERIMENTAL RESULTS AND HISTOGRAM ANALYSIS

The system is implemented by anaconda 4.8.3. Python is the programming language that we have picked for development. The implementation is examined in Windows 10 64-bit O.S. with an Intel(R) Core (TM) i7-8550U CPU @ 1.80GHz 2.00 GHz and 8GB RAM. Take the initial parameters and values: 1D ( $r = 5.78, x_0 = 1.2 \times 10^{18}$ ), 2D ( $r' = 6.37, \mu = 3.33, \gamma_1 = 0.17, \gamma_2 = 0.14, x_0 = 2.3 \times 10^{18}, y_0 = 1.2 \times 10^{18}$ ), 3D ( $\lambda = 3.66, \beta = 0.041, \alpha = 0.039, x_0 = 3.4 \times 10^{18}, y_0 = 4.5 \times 10^{18}, z_0 = 5.6 \times 10^{18}$ ), to encrypt "Baboon" and "Lena" images of size  $256 \times 256$  and their RGB components as shown in Fig. 8(a-d). The histograms of the "baboon", "Lena" and their RGB components before encryption are shown in Fig. 9(a-c); the histograms illustrate how pixels in the plain images "baboon" or "Lena" are correlated to the pixels at each color density level.

Fig. 8. (a-d) shows "Baboon" and "Lena" Color Images and the RGB Components of their Respective Color Images before the Encryption Process.

Fig. 9. Histograms of the RGB Components of "Baboon" and "Lena" before Encryption respectively.

Fig. 10 (a-d) shows the "baboon" and "Lena" encrypted images and their respective encrypted RGB components. The histograms of the RGB components of "baboon", and "Lena" after the encryption are shown below in Fig. 11 (a-c). The histograms illustrate how pixels in the ciphered RGB are uniformly correlated to the pixels at each color density level.

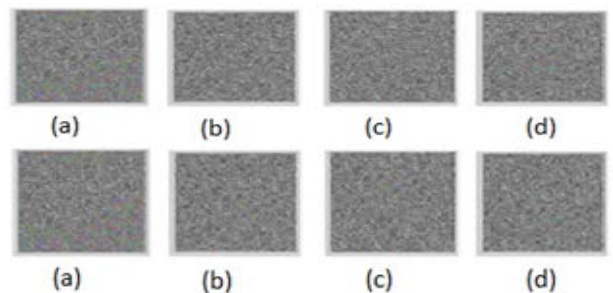

Fig. 10. (a-d) Shows "Baboon" and "Lena" Cipher images and their Ciphered RGB Components.

Fig. 11. (a-c): Histograms of RGB Component of "Baboon" and "Lena" after Encryption.

## VII. SECURITY ANALYSIS

### A. The Key Size

The total number of unique keys used in the encryption must be big enough to make brute-force attacks ineffective. Our algorithm employs six values;  $x_0^{1D}, x_0^{2D}, y_0^{2D}, x_0^{3D}, y_0^{3D}, z_0^{3D}$  and the eight parameters of  $\mu, r, r', \gamma_1, \gamma_2, \lambda, \beta, \alpha$ , as secret keys. Wang and Teng [25] proved that if the precision is  $10^{-17}$ , the keys  $K_{x_0^{1D}} = K_{x_0^{2D}} = K_{y_0^{2D}} = K_{x_0^{3D}} = K_{y_0^{3D}} = K_{z_0^{3D}} = 10^{17}$ ,  $K_\mu = K_r = K_{r'}, K_{\gamma_1} = K_{\gamma_2} = K_\lambda = K_\beta = K_\alpha = 0.5 \times 10^{17}$ . Let the plain color images have size  $256 \times 256$ . The number of iterations over six maps  $I_0$  is  $6 \times (3 \times M \times N) = 6 \times (3 \times 256 \times 256) \approx 2^{20} \approx 10^7$ . The total key space reaches to  $\approx 1.953 \times 10^7 \times 10^{235} = 1.953 \times 10^{242}$ . Our key space is larger than  $2^{138}, 2^{58}, 10^{140}, 2^{256}, 10^{79}, 4.2 \times 10^{122}, 10^{60}$ , and  $10^{112}$  [4, 13, 6, 9, 18, 26, 27, 28] respectively. It is greater than  $2^{448} = 7.8 \times 10^{134}$ , the maximum key space mentioned in the survey paper [14]. The total numbers of keys within the diagonalization form (1) reach 24 initial values and parameters. Our key increases it up to  $10^{415}$ . The proposed algorithms describe a sufficiently enough key space to withstand brute-force assaults.

### B. The Sensitivity Analysis of the Secret Keys

Little differences between keys yield different cipher images. When the image is decrypted, using a wrong key induces another image. Fig. 12 displays the decrypted image of the Baboon with the proper key of  $\lambda=3.66$ . On the other side, Fig. 13 illustrates the decryption of the Baboon image with the incorrect encryption key  $\lambda=3.660000000000000001$ . It was successful in making the algorithm sensitive to the key. A small modification in the key will result in an entirely different decryption result, and the attacker won't be able to get to the right plain image.

Fig. 12. Result of Correct Parameters used to Decrypt the Baboon Image and its R, G and B Components.

Fig. 13. Result of Wrong Parameters used to Decrypt the Baboon Image and its R, G and B Components.

### C. Adjacent Pixels Correlation Analysis

The correlation between pixels is assessed by the degree of pixel association. In general, the stronger the correlation between nearby pixels in the ciphered image, the poorer the encryption algorithm's performance will be, and vice versa. The correlation in vertical, horizontal, and diagonal directions

between 3000 randomly selected nearby pixels is calculated as follows:

$$E(x) = \frac{1}{N} \sum_{i=1}^N (x_i) \quad (15)$$

$$E(y) = \frac{1}{N} \sum_{i=1}^N (y_i) \quad (16)$$

$$D(x) = \sum_{i=1}^N (x_i - E(x))^2 \quad (17)$$

$$D(y) = \sum_{i=1}^N (y_i - E(y))^2 \quad (18)$$

$$cov(x, y) = \frac{1}{N} \sum_{i=1}^N (x_i - E(x))(y_i - E(y)) \quad (19)$$

$$r_{xy} = \frac{cov(x, y)}{\sqrt{D(x)}\sqrt{D(y)}} \quad (20)$$

The values of two neighboring pixels,  $x$  and  $y$ , in the Horizontal direction H/D, Vertical Direction V/D and Diagonal direction D/D are shown in Tables I to III and Fig. 14. They exhibit a high level of concentration and a tendency of one in two neighboring pixels in the plain image and a correlation extremely near to 0 in the ciphered image, which means that adjacent pixels in the ciphered image are random, and the encryption impacts resist statistical attack.

TABLE I. TWO ADJACENT PIXEL CORRELATION VALUES FOR PLAIN AND CIPHERED IMAGES (V/D)

| Image  | V/D | Plain image | Cipher Image  |          |
|--------|-----|-------------|---------------|----------|
|        |     |             | New Algorithm | Ref [28] |

Fig. 14. Correlation Test of the RGB Components of the Plain Image and Ciphered Image. The Figure Displays the Distribution Coefficient of nearby Pixels in Three Directions (H/D, V/D, and D/D) for the Plain Image (up) and the Ciphered Image (down).

#### D. Discovery of Differential Attack

To evaluate the capacity to withstand a differential attack, the Pixel Change Rate Number, and the Unified Average Change Intensity (UACI) tests are applied. The NPCR test measures the number of different pixels between plain and encrypted images, and the UACI test measures the average intensity of these two images [29]. A gentle pixel change generates a softly modified cipher image. Analyzing the relationship between the cipher image created and the plain image using NPCR and UACI becomes essential. The definition of UACI and NPCR is as follows:

$$UACI_{R,G,B} = \left( \frac{\sum_{ij} |c_{R,G,B}(i,j) - c'_{R,G,B}(i,j)|}{255} \right) \times 100 \quad (21)$$

$$NPCR_{R,G,B} = \left( \frac{\sum_{ij} D_{R,G,B}(i,j)}{M \times N} \right) \times 100 \quad (22)$$

$$D_{R,G,B}(i,j) = \begin{cases} 0 & \text{if } C_{R,G,B}(i,j) = C'_{R,G,B}(i,j) \\ 1 & \text{Otherwise} \end{cases} \quad (23)$$

Respectively, the width and height of the image are M and N, and the pixel values in the *i*-th row and *j*-th column are  $C_{R,G,B}(i,j)$  and  $C'_{R,G,B}(i,j)$  for the two ciphered images before and after one pixel of the original plain image is altered. Table IV shows the values of  $NPCR_{R,G,B}$  over 99.55% and values of  $UACI_{R,G,B}$  above 33.44%. The studies illustrate that our technique is highly sensitive to minor changes in the original image, even if the two original images are only one-bit different, the decrypted images are somewhat different.

TABLE IV. RESULTS OF NPCR AND UACI (PERCENT)

| Image  | The Proposed Algorithm |         |         | Ref [10] |         |
|--------|------------------------|---------|---------|----------|---------|
|        |                        | NPCR%   | UACI %  | NPCR%    | UACI %  |
| Lena   | R                      | 99.5117 | 33.4218 | 99.6052  | 33.4132 |
|        | G                      | 99.4751 | 33.4411 |          |         |
|        | B                      | 99.5132 | 33.4887 |          |         |
| Baboon | R                      | 99.5895 | 33.6405 | 99.6227  | 33.4865 |
|        | G                      | 99.5728 | 33.3403 |          |         |
|        | B                      | 99.6368 | 33.4706 |          |         |

### E. Peak Signal-to-Noise Ratio (PSNR) Analysis

In image reconstruction, PSNR is used primarily as a quality metric. The following equation is calculated:

$$PSNR_{R,G,B} = 20 * \log_{10} \left( \frac{255}{\sqrt{MSE_{R,G,B}}} \right) \quad (24)$$

$$MSE_{R,G,B} = \sum_i \sum_j \frac{C_{R,G,B}(i,j) - C'_{R,G,B}(i,j)}{M \times N} \quad (25)$$

The mean square error (MSE) describes the difference in the values from 0 to 255 between the plain and the ciphered image. The variations between the original and the encrypted image in the PSNR values also are shown in Table V. Our approach shows higher resistance to statistical attacks.

TABLE V. RESULTS OF PSNR

| Image  | New algorithm |        |        | Ref [27] |        |        |
|--------|---------------|--------|--------|----------|--------|--------|
|        | R             | G      | B      | R        | G      | B      |
| Lena   | 7.9687        | 8.8887 | 9.7595 | 7.8992   | 8.5765 | 9.6785 |
| Baboon | 8.3985        | 9.4578 | 8.9701 | 8.9581   | 9.4143 | 8.4156 |

## VIII. CONFLICT OF INTEREST

The authors declare that there is no conflict of interest and there is no competition in the financial interest.

## IX. CONCLUSION

We proposed a large enough key space algorithm to resist brute-force attacks for image security. The proposed cryptosystem generates three keys in the form of a square matrix  $M \times N$ , and three keys in the form of a vector matrix of length  $MN$ . Our cryptosystem for image encryption technique is based on a combination of multidimensional chaos systems and the diversity between shuffling and scrambling of rows and columns in the RGB components of the plain image, as well as multi-level diffusion of pixel values. The computational study between the proposed algorithm and other cryptosystem showed that the proposed algorithm has high level of security and wide key spaces. The advantage of the current algorithm is using multi-level encryption based on big key space.

#### AUTHORS' PROFILE

**Mahmoud I. Moussa** is an associate professor of computer science at the faculty of computers & artificial intelligence, Benha University in Egypt. He received his Ph.D. in Parallel Algorithms (mainly in parallel graph algorithms) from faculty of informatics at Karlsruhe Institute of Technology-KIT, Germany. His research interests span both theoretical computer science and information security. Much of his work has been on improving the understanding, design, and performance of algorithms and analysis, mainly through the application of graph algorithms, bioinformatics, as well as Steganography and Cryptography. Moussa's work includes a prediction method for biological activity using random forests and kernel functions in Support Vector Machine (SVM), image encryption using chaotic maps, a method for using smartphone devices efficiently and offloading only when necessary.

**Eman I. Abd El-Latif** received the M.Sc. degree and Ph.D. in computer science, at Faculty of Science, Benha University, Egypt, 2016 and 2020, respectively. She is currently working as lecturer at mathematics department, Benha University, Egypt. Her areas of research include Digital Forensics, Security (Encryption – Steganography), and image processing.

**Nawaz Majid** is an assistant professor of computer science at Department computer science, Faculty of science, Northern Border University (NBU), KSA. His research interests span both theoretical computer science and information security. Adding more to that, he worked on research including Data mining and knowledge discovery.

# A Visual-Range Cloud Cover Image Dataset for Deep Learning Models

**Abstract**—Coastal and offshore oil and gas structures and operations are subject to continuous exposure to environmental conditions (ECs) such as varying air and water temperatures, rough sea conditions, strong winds, high humidity, rain, and varying cloud cover. To monitor ECs, weather and wave sensors are installed on these facilities. However, the capital expenditure (CAPEX) and operational expenses (OPEX) of these sensors are high, especially for offshore structures. For observable ECs, such as cloud cover, a cost-effective deep learning (DL) classification model can be employed as an alternative solution. However, to train and test a DL model, a cloud cover image dataset is required. In this paper, we present a novel visual-range cloud cover image dataset for cloud cover classification using a deep learning model. Various visual-range sky images are captured on nine different occasions, covering six cloud cover conditions. For each cloud cover condition, 100 images are manually classified. To increase the size and quality of images, multiple label-preserving data augmentation techniques are applied. As a result, the dataset is expanded to 9,600 images. Moreover, to evaluate the usefulness of the proposed dataset, three DL classification models, i.e., GoogLeNet, ResNet-50, and EfficientNet-B0, are trained, tested, and their results are presented. Even though EfficientNet-B0 had better generalization ability and marginally higher classification accuracy, it was discovered that ResNet-50 is the best choice for cloud cover classification due to its lower computational cost and competitive classification accuracy. Based on these results, it is concluded that the proposed dataset can be used in further research in DL-based cloud cover classification model development.

**Keywords**—Cloud cover; dataset; classification; GoogLeNet; ResNet-50; EfficientNet-B0

## I. INTRODUCTION

Cloud cover is an important observation for weather monitoring. It is classified as a percentage cloud cover of the visible sky. Changes in cloud cover percentage affect the global mean surface temperature and pressure systems [1], the amount of solar UV radiation reaching the earth's surface [2], the melting rate of ice shields [3], and the radiation-energy-carbon balance of tropical rain forests [4]. It also plays a crucial part in the selection of sites for observational astronomy [5, 6]. From the clean power generation perspective, cloud cover percentage has an instantaneous effect on the power generation capability of solar panels [7]. For safety reasons, offshore oil and gas excavation and production activities are

also subject to weather conditions [8], which may be associated with cloud cover.

Since cloud cover is an important parameter of prevailing weather conditions, its classification plays an important role in weather monitoring at offshore oil and gas platforms. Currently, these platforms rely on various sensors to monitor weather conditions. The procurement cost of these sensors is usually high. Additionally, any subsequent maintenance activity is also costly due to the remoteness of the offshore site. As a low-cost alternative, deep learning (DL)-based technologies can be applied to monitor, forecast, and predict climate and weather conditions [9], and postprocess cloud cover [10]. A DL-based cloud cover monitoring system requires the installation of a less expensive visual-range sensor, a single-board computer, and a pre-trained DL classification model. This solution can be applied as support to the existing sensor-based system or deployed as a module for a larger DL-based weather monitoring system at remote oil and gas platforms.

The deep learning classification models depend upon a large collection of images for training and testing purposes. Publicly available weather image datasets do not distinguish between different cloud cover conditions [11-13]. As a result, they are not suitable for a multi-class cloud cover classification problems. The objective of this study is to fill this gap by proposing a novel visual-range cloud cover image dataset, named Manzoor-Umair: Cloud Cover Dataset (MU-CCD), for deep learning classification models. The proposed study classifies cloud cover conditions into six classes. For every cloud cover condition, 100 source images are manually identified. Various augmentation techniques are applied to the source images to improve the quality and quantity of each cloud cover condition. As a result, the dataset consists of 9,600 RGB images at 1920x1080 pixel dimensions.

The dataset is aimed at a DL-based classification module of cloud cover for a larger DL-based weather classification system to be deployed at remote oil and gas facility. Thus, to access its suitability, the MU-CCD is evaluated on three well-known deep learning image classification models, namely GoogLeNet, ResNet-50, and EfficientNet-B0. The presented results indicate that the proposed dataset is well suited for training and testing of deep learning-based cloud cover classification models and, as a result, can be used for the

This research work is a part of an ongoing research project funded by Yayasan Universiti Teknologi PETRONAS – Fundamental Research Grant (YUTP-FRG-2019, grant number 015LC0-158).

development of cloud cover classification modules of a larger DL-based weather monitoring system.

The rest of the paper is divided in the following manner: The literature review section describes the related literature on cloud cover classification and publicly available weather image datasets. The methodology section explains the steps taken to create MU-CCD. The proposed dataset section discusses the different features and statistics of MU-CCD. The dataset effectiveness experiment section presents the classification performance of well-known DL-based image classification models on MU-CCD, and finally, the conclusion and future work section sums up the work and identifies the future directions.

## II. LITERATURE REVIEW

### A. Cloud Cover Classification

The most common way to classify cloud cover is by visual observation of the sky by an experienced meteorologist [14]. This method divides the sky into eight segments, called octas (C). For every segment, the percentage presence of cloud cover is noted. The cumulative percentage cover of clouds then identifies the present cloud cover conditions. The method has been used in studies conducted by Robaa [15] and Werkmeister et al. [16]. Other methods of identifying cloud cover include the processing of images from all-sky cameras and satellite data. However, based on its simplicity and practicability, classifying cloud cover conditions by observing sky images for cloud cover percentage is found to be more suitable and relevant for the presented work.

### B. Visual-Range Weather Image Datasets

In this section, recently published image weather datasets are selected to assess their suitability for cloud cover classification problems. Since the presented study focuses on visual-range cloud cover image classification, thus the selected datasets consist of visual-range weather images under various geographical and weather conditions.

The RFS Weather Dataset is a visual-range image dataset aimed at computer vision applications [11]. The dataset is a collection of images acquired from various online resources such as Creative Commons, Flickr, Pixabay, and Wikimedia Commons. The images in the data are divided into three categories, namely, rain, fog, and snow. Additionally, the dataset borrowed images of sunny and cloudy categories from a dataset proposed by Lu et al. [17]. For each category, there are 1,100 images. Thus, in total, the RFS Weather Dataset consists of 5,500 images. However, the cloudy images in the dataset are not categorized by the percentage of cloud cover. Thus, to classify different cloud cover conditions, this dataset is found to be unsuitable for training and testing of a deep learning classification model.

The 4Seasons is a multi-weather visual-range video dataset aimed at autonomous vehicle driving applications [12]. The dataset covers three weather conditions, namely, sunny, overcast, and snowy, as well as two illumination conditions, namely, day and night. Due to its application nature, the dataset does not further bifurcate the overcast conditions into various cloud cover classes. The absence of such bifurcation makes it

unsuitable for cloud cover classification using deep learning models.

The Image2Weather dataset is a large-scale visual-range image dataset aimed at weather conditions and temperature estimations [13]. The dataset consists of 180,000 images and covers five weather types, namely, sunny, cloudy, foggy, rainy, and snowy. The dataset was created using existing images from an online resource. Based on the image metadata, its geographical location and image capture time were identified. This information is then used to retrieve corresponding weather information from an online weather center. However, the cloudy weather in the presented dataset is not further categorized into different cloud cover conditions, which makes it unsuitable for training and testing of deep learning classification models.

Based on the presented evidence, it is deduced that, at present stage, the reviewed weather image datasets are unsuitable for machine classification of cloud cover conditions. For example, all three datasets, i.e., the RFS Weather Dataset [11], 4Seasons dataset [12], and Image2Weather dataset [13], do not categorize cloud cover images as a percentage of sky cover. Thus, classification of various cloud cover conditions is not possible using these datasets. Thus, in this paper, to address the need for training and testing dataset for deep learning cloud cover classification models, we propose a visual-range cloud cover image dataset that presents six cloud cover conditions based on percentage of sky cover.

## III. METHODOLOGY

This section discusses the optical sensor and methodology of MU-CCD development.

### A. Optical Sensor

In this experiment, a visual-range 24 mega-pixel NIKON D3400 camera is utilized to capture images in JPEG format at 6000 x 4000 pixels in sRGB color space. The camera was set to auto mode and various zoom levels were applied throughout the data collection process.

### B. Data Collection and Preprocessing

In the first phase of Manzoor-Umair: Cloud Cover Dataset (MU-CCD) development, sky images were captured on nine different occasions across five geographically separated locations in West Malaysia. The images are taken across the year to capture different seasonal attributes. In addition to this, to record varying levels of illumination, the images are taken at different times of the day. These images are visually analyzed and sub-images containing sky conditions are extracted at a resolution of 1920x1080 pixels. Images having undesired artefacts or sensor noise are then removed. The highest visual quality images are selected for the second phase.

### C. Image Classification

The second phase of MU-CCD creation is the manual classification of selected images. We have classified cloud cover conditions into six categories. These classes are clear sky, few clouds, isolated clouds, scattered clouds, broken clouds, and overcast. Table I describes the empirical methodology adopted for CC classification based on cloud

cover percentage in an image. For each class, 100 images are manually classified.

**D. Data Augmentation**

Data augmentation is an effective technique to increase the quality and size of image datasets. It not only provides a solution for limited data but also addresses the issue of overfitting in DL models [18]. In the third phase, a data augmentation policy (DAP) is designed to augment the image data. The policy makes sure that label-preserving augmentation techniques such as flipping, down sampling, color space transformation, noise injection, grid shuffle, weather-related augmentation, and kernel filtering are applied to images. Based on the DAP, an image augmentation pipeline (IAP) is developed using a Python-based library, Albumentations [19],

and applied to all six source image pools. This results in 1,600 images per class. The flow of IAP is illustrated in Fig. 1.

TABLE I. CLOUD COVER CLASSIFICATION

| Class ID | Class Name       | Visible Cloud Cover (%) |
|----------|------------------|-------------------------|
| 1        | Clear Sky        | 0                       |
| 2        | Few Clouds       | 1-10                    |
| 3        | Isolated Clouds  | 11-25                   |
| 4        | Scattered Clouds | 26-50                   |
| 5        | Broken Clouds    | 51-90                   |
| 6        | Overcast         | 91-100                  |

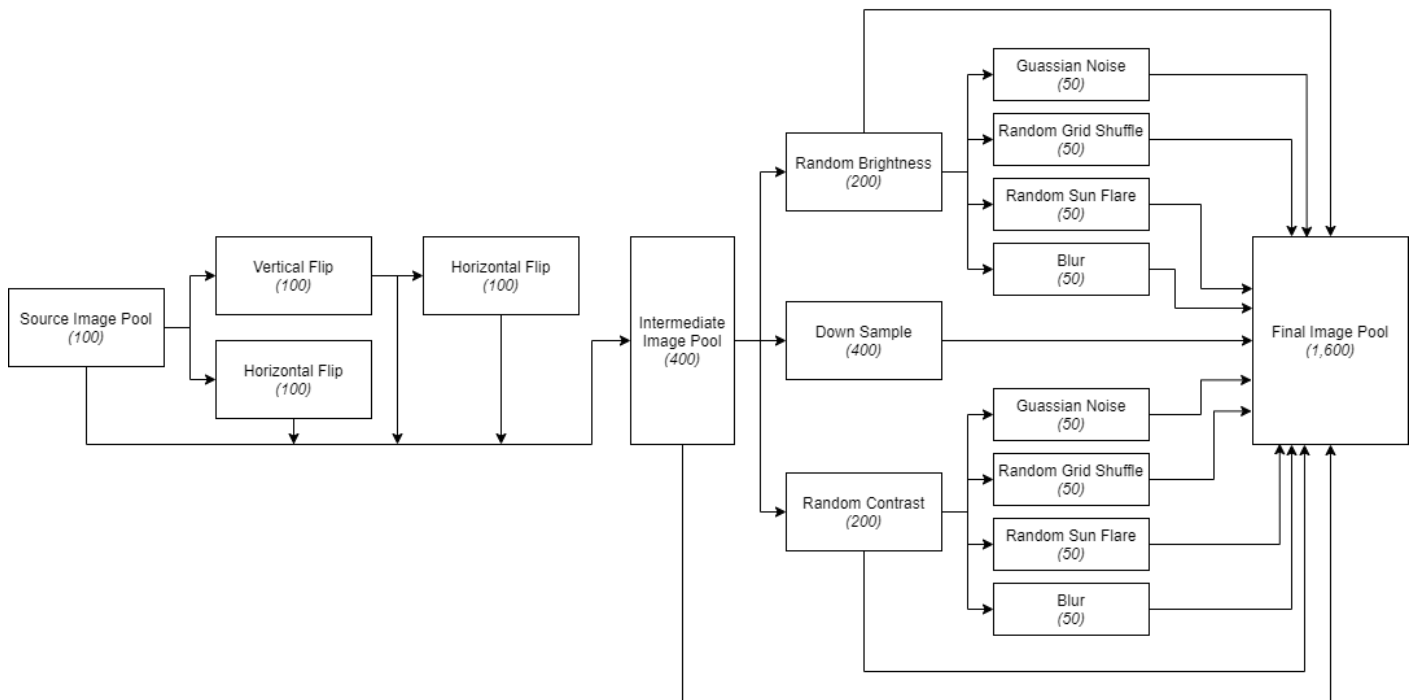

Fig. 1. Image Augmentation Pipeline (IAP).

E. Image Naming Convention

After each stage of IAP, a suffix is added to the output image's file name. The list of used suffixes and their corresponding augmentation methods is given in Table II.

TABLE II. AUGMENTATION SETS AND CORRESPONDING FILE NAME SUFFIXES

| Serial No. | Augmentation Set | Augmentation Method | Suffix |
|------------|------------------|---------------------|--------|
| 1          | AS1              | Horizontal Flip     | HF     |
| 2          |                  | Vertical Flip       | VF     |
| 3          | AS2              | Down Sample         | DS     |
| 4          | AS3              | Random Brightness   | RB     |
| 5          |                  | Random Contrast     | RC     |
| 6          | AS4              | Gaussian Noise      | GN     |
| 7          |                  | Random Grid Shuffle | GS     |
| 8          |                  | Solar Flare         | SL     |
| 9          |                  | Blur                | BL     |

A sample file called "DSC\_0183\_7\_VF\_RC\_BL.JPG" indicates that the source image is "DSC\_0183\_7.JPG" and that it has been vertically flipped (VF), randomly contrasted (RC), and blurred (BL).

IV. PROPOSED DATASET

MU-CCD is a visual-range image dataset of six cloud cover classes. The dataset is designed for training and testing of DL-

based cloud cover classification problems. The presented image format is JPG in RGB color space, and the dimensions are 1920x1080 pixels. By applying nine different augmentation methods, the number of image instances per class is increased from 100 to 1,600, resulting in a total of 9,600 images in the dataset. The images in final dataset are then randomly divided into training and testing sets at a ratio of 80:20. The summary of MU-CCD is presented in Table III.

TABLE III. SUMMARY OF MU-CCD

| Source Images per Class | Augmentation Methods Applied | Final Images per Class | Total Images in Dataset | Training Images | Testing Images |
|-------------------------|------------------------------|------------------------|-------------------------|-----------------|----------------|
| 100                     | 9                            | 1,600                  | 9,600                   | 7,680           | 1,920          |

The dataset takes advantage of various data augmentation techniques to increase its dataspace. As a result of the carefully designed DAP, it represents a balanced proportion of image augmentation sets. For example, the dataset can be divided into four image augmentation sets. A tabular description is presented in Table II. The first augmentation set (AS1) consists of the original image and its flipped versions. The second set (AS2) contains down-scaled images. The third augmentation set (AS3) pool has images with color space variations. Finally, the fourth augmentation set (AS4) has a mix of noise injection, grid shuffle, weather-related augmentation, and kernel filtering applied to the images. Each set has an equal proportion of 25% in the dataset.

For the interest of the reader, in Fig. 2, class-wise original and augmented image samples from MU-CCD are presented.

Fig. 2. MU-CCD Class-Wise Original and Augmented Image Samples.

## V. DATASET EFFECTIVENESS EXPERIMENT

To validate the effectiveness of MU-CCD in DL-based cloud cover classification problems and to provide reference measures, we have trained and tested three selected DL models on the proposed dataset. In the following subsections, the hardware and software setup, selection of deep learning models, experimental configurations, training and validation results, and discussion are presented.

### A. Hardware and Software Setup

The experiment was conducted on an Intel (R) Core (TM) i7-9750H CPU running at 2.60GHz. The machine has a 16 GB main memory and runs the Windows 10 Pro operating system. An NVIDIA GeForce RTX 2070 with a Max-Q Design GPU is used for DL model training and testing. The GPU has 8 GB of memory. All the simulations are conducted on MATLAB version R2021a.

### B. Deep Learning Classification Models' Selection

For the proposed experiments, three DL models are selected based on their ability to improve computational accuracy, ease of training, and effective convolutional neural networks (CNNs) network scaling ability. The selected models are GoogLeNet [20], ResNet-50 [21], and EfficientNet-B0 [22].

The GoogLeNet network was developed by Google [20]. It is the winner of the ILSVRC 2014 competition. The network is based on the Inception architecture, and its receptive field size is 224x224 pixels in RGB color space. GoogLeNet is a 22-layer deep network that focuses on improving computational accuracy.

Deep residual nets, or ResNet, was the winner of the ILSVRC 2014 competition [21]. The plain network architecture is inspired by the VGG nets. There are different variants of ResNet based on the depth of its layers. The 50-layer deep variant is known as ResNet-50. The network has a receptive field size of 224x224 pixels in RGB color space. The network is based on a residual learning framework that eases the training of deeper neural networks.

The EfficientNet-B0 model is developed by Google. The baseline network is built using neural architecture search, which optimizes the accuracy and efficiency of the network [22]. The EfficientNet-B0 has 290 layers, and its receptive field size is 224x224 pixels in RGB color space. The model has various variants and has shown improvement in the top-1 accuracy for ResNet-50 on the ImageNet dataset.

### C. Experimental Configurations

Three separate cloud cover classification experiments are designed and performed on MU-CCD. For all three experiments, Stochastic Gradient Descent with momentum (SGDM) was selected as an optimization algorithm as it is known for its faster convergence. The initial learning rate for SGDM is set at 0.01. The validation frequency and maximum epoch number are fixed at 50 and 10, respectively. Due to the relatively increased layer depth of the ResNet-50 and EfficientNet-B0 models and GPU memory constraints, an image batch size of 64 is selected for these models. The GoogLeNet, however, is trained using an image batch size of

128. For all three experiments, the validation patience is set at 5.

### D. Training, Validation Results and Discussion

All three models are trained and validated on a training-validation set (TVS) of MU-CCD. The TVS has 7,680 images, which are split into 70% and 30% for training and validation purposes. The training accuracy and loss graphs for all three models are presented in Fig. 4, 5, and 6. In each figure, the top graph depicts training accuracy performance, while the bottom graph represents the corresponding loss. The legends for Fig. 4, 5, and 6 are presented in Fig. 3.

The GoogLeNet took the least amount of time (i.e., 415 seconds) to train the network, and attained the highest training accuracy of 98.4%. However, its validation accuracy remains the lowest in the group. Fig. 4 illustrates the training accuracy and loss for GoogLeNet.

As depicted in Fig. 5 and 6, the ResNet-50 and EfficientNet-B0 models' validation accuracies were almost similar and slightly higher than GoogLeNet. However, when compared for training time, ResNet-50 was trained 27% faster than EfficientNet-B0.

For all three models, overfitting is observed, as their validation loss remains higher than their training loss. Moreover, it was observed that the EfficientNet-B0 generalized well, as it yielded the lowest difference between its training and validation loss. Table IV presents the training and validation statistics of the evaluated models.

Fig. 3. Legends for Fig. 4, 5 and 6.

Fig. 4. Training (Top), Validation (Bottom) Graphs for GoogLeNet.

Fig. 5. Training (Top), Validation (Bottom) Graphs for ResNet-50.

Fig. 6. Training (Top), Validation (Bottom) Graphs for EfficientNet-B0.

**E. Testing Results and Discussion**

All three models are tested on the testing set (TS) of MU-CCD, which consists of 1,920 images.

During the training-validation phase, it was found that EfficientNet-B0 generalized well as compared to ResNet-50 and GoogLeNet. By analyzing the confusion matrix for GoogLeNet, ResNet-50, and EfficientNet-B0 in Fig. 7, 8, and 9, respectively, a similar observation is made. EfficientNet-

B0’s overall classification accuracy of 87.2% remains the highest among all three models. However, it was marginally higher than ResNet-50’s classification accuracy. For 3 classes (few clouds, isolated clouds, and overcast), EfficientNet-B0 resulted in the highest classification accuracy. The scaled-up network dimensions of EfficientNet-B0 can be attributed to a higher processing time per image during the testing phase. It was 3 times higher than the next best model, i.e., ResNet-50. The confusion matrix for EfficientNet-B0 is presented in Fig. 7.

The ResNet-50 showed very competitive results among all the deep learning models in question. The model not only took less time to process an image, but it also classified the cloud cover with high accuracy. Despite the poor performance of GoogLeNet and EfficientNet-B0 for class 4 (Scattered Clouds) instances’ classification, ResNet-50 yielded relatively better results. As presented in Table V, across all six classes, the model’s classification performance remains highly competitive with the other two models. The confusion matrix for ResNet-50 is presented in Fig. 8 which shows an overall accuracy of 87.0%.

Due to its simple architecture, the GoogLeNet took the least amount of time to process an image during the testing phase. However, this performance is marginally better than ResNet-50. Similarly, in classifying class 1 and 6 instances, the model slightly surpassed ResNet-50, but the model’s over-all classification performance remains the lowest among all models. The model’s overall accuracy was 83.5%, and it is illustrated in Fig. 9.

TABLE IV. TRAINING AND VALIDATION RESULTS OF DEEP LEARNING MODELS

| Model           | Training Time (sec) | Training Accuracy | Validation Accuracy | Training Loss | Validation Loss |
|-----------------|---------------------|-------------------|---------------------|---------------|-----------------|
| GoogLeNet       | 415                 | 98.43%            | 63.63%              | 0.06          | 2.65            |
| ResNet-50       | 655                 | 95.31%            | 66.75%              | 0.10          | 1.09            |
| EfficientNet-B0 | 895                 | 96.87%            | 66.62%              | 0.04          | 0.89            |

TABLE V. CLASSIFICATION RESULTS OF DEEP LEARNING MODELS

| Model           | Classification Accuracy |         |         |         |         |         |         | Per Image Processing Time (sec) |
|-----------------|-------------------------|---------|---------|---------|---------|---------|---------|---------------------------------|
|                 | Class 1                 | Class 2 | Class 3 | Class 4 | Class 5 | Class 6 | Overall |                                 |

## VI. CONCLUSION AND FUTURE WORK

Installation and maintenance of weather sensors at remote oil and gas platforms entails high CAPEX and OPEX. As an alternative, a low-cost deep learning-based weather monitoring system can be used. One of the components of such a system can be a cloud cover classification model. To train and test this model, in this paper, we have proposed a novel visual-range cloud cover image dataset named MU-CCD. Across West Malaysia, at various occasions and time of the day, sky images were captured and preprocessed. The images were then manually classified into six cloud cover classes. Various label-preserving augmentation techniques were applied on manually classified images to increase the size and quality of the dataset.

As a result, the final dataset consists of 9,600 images covering six cloud cover states. The dataset can be downloaded from <https://www.kaggle.com/umairatwork/manzoorumair-cloud-cover-dataset-muccd>.

The suitability of the proposed dataset for training and testing of the DL classification model was evaluated on three selected DL models. The classification results of these models were also presented. It was found that the dataset is well suited for DL-based cloud cover classification model training and testing. However, it was observed that for clear sky and overcast conditions, the dataset can be further improved for more visually distinct features in the source images. Additionally, it was observed that EfficientNet-b0 generalized well on the presented dataset and effectively classified the images. However, because of its increased number of layers, the model took the longest time to process an image. While considering the classification accuracy and computational cost factors in combination, ResNet-50 emerges as an ideal candidate for the cloud cover classification problem. However, improvement in its generalization capability and classification accuracy can be further investigated as a future work.

# Blockchain in the Quantum World

Arman Rasoodl Faridi, Faraz Masood, Ali Haider Thabet Shamsan, Mohammad Luqman, Monir Yahya Salmony

Department of Computer Science  
Aligarh Muslim University  
Aligarh, India

**Abstract**—Blockchain is one of the most discussed and highly accepted technologies, primarily due to its application in almost every field where third parties are needed for trust. Blockchain technology relies on distributed consensus for trust, which is accomplished using hash functions and public-key cryptography. Most of the cryptographic algorithms in use today are vulnerable to quantum attacks. In this work, a systematic literature review is done so that it can be repeated, starting with identifying the research questions. Focusing on these research questions, literature is analysed to find the answers to these questions. The survey is completed by answering the research questions and identification of the research gaps. It is found in the literature that 30% of the research solutions are applicable for the data layer, 24% for the application and presentation layer, 23% for the network layer, 16% for the consensus layer and only 1% for hardware and infrastructure layer. We also found that 6% of the solutions are not blockchain-based but present different distributed ledger technology.

**Keywords**—Blockchain; quantum computers; distributed ledger technology; security; systematic literature review; quantum attacks

## I. INTRODUCTION

Quantum computing is one of the latest technologies that has exploded in popularity in recent years. While the foundation of quantum mechanics has been more theoretical than practical for over 100 years, now the time has arrived when practically all firms are delving into it. In the late 1970s and early 1980s, research defining the fundamentals of quantum computing surfaced. Paul Benioff, an Argonne National Labs scientist, wrote a paper in 1979 that showed the theoretical foundation for quantum computing [1] and suggested that a quantum computer might be developed. Numerous businesses claim to be developing quantum computers, such as IBM, which is currently providing its clients with the first solutions in the form of a Quantum Gate Model. Google, Microsoft and many other companies are exploring similar machines.

Satoshi Nakamoto introduced the decentralised transfer and maintenance of digital assets that cannot be duplicated [2]. Distributed ledger technology (DLT) was initially used in finance, but it was subsequently discovered that it could be used whenever we desire to eradicate centralisation or intermediaries. The most widely used DLT is blockchain. There are other types of DLTs like IOTA [3], Hashgraph [4] etc., which are based on Directed Acyclic Graphs. Radix is also a DLT that uses a distributed database to store transactions [5]. Blockchain may be conceived as a sequence of interconnected blocks containing transactions. Every block stores the hash of the previous block, which results in a chain that is very difficult

to modify since modifying every transaction necessitates modifying the block, and modifying the block necessitates modifying the entire chain. Blockchain is the foundation of cryptocurrencies such as Bitcoin [2], Ethereum [6], Litecoin, etc.

Quantum computers cannot solve optimisation issues in a substantially scalable manner. In a universal infrastructure, there will be classical computers and quantum computers, with the quantum computer having a significant edge in terms of optimisation. Several quantum algorithms, such as Grover's algorithm [7], Shor's algorithm [8], and others, can solve some problems far quicker than conventional algorithms. Problems that have previously been almost insolvable will now be resolved in a reasonable period. In this regard, advancement in the quantum computing sector has piqued the curiosity of many researchers in both academia and industry.

Blockchain technology started to proliferate because of its nature to provide unbreakable data security, but once practical quantum computers are developed, they cannot provide such security [9]. Smart contracts can be hampered, and the whole technology will go down. The security of the blockchain is built on mathematical challenges that are extremely difficult for even the most powerful conventional computers to solve.

Public key cryptography protects cryptocurrencies. To breach public key encryption, quantum computers might possibly threaten the crypto industry, where some currencies are worth trillion of dollars. Encryption can be bypassed, allowing attackers to mimic legal owners of digital assets. All security assurances will be meaningless if quantum computing gets strong enough. To decrypt data, quantum computers will need thousands of qubits, compared to today's hundreds. Machines will also require persistent qubits that can do calculations for much longer than currently achievable.

NIST (National Institute of Standards and Technology) has already started finding, evaluating, and standardising public-key cryptography algorithms that are quantum-resistant [10]. However, it is necessary for the research community to primarily focus on blockchain technology. A lot of work is going on to create a quantum secure blockchain. To systematically analyse them following research questions are set:

RQ1: What challenges and security issues could occur due to the rise of quantum computers in blockchain technology?

RQ2: What are the various strategies and approaches used by researchers to make blockchain quantum resistant?

To answer these research questions, a systematic literature review has been undertaken. In Section 2, the research method is discussed in detail. Section 3 explores the basics of blockchain and quantum computing and the related challenges and solutions associated with these technologies. The survey results and answers to the research questions are discussed in Section 4, and the work is then concluded in Section 5 with future directions.

II. RESEARCH METHOD

This research utilised the SLR (Systematic Literature Review) method, as it helps to conduct the secondary research using a well-defined method. This approach gives us a framework to follow in order to discover, analyse, and evaluate relevant literature to find unbiased and reproducible answers to our research questions [11]. The parts of the process include planning, conducting and reporting on the review. Section 1 deals with the planning phase. Reporting is handled in Sections 3 and 4. This section goes through the phases of the review process, which includes:

A. Research Identification

This preliminary search aims to discover existing systematic reviews and determine the volume of studies that would be appropriate. A single search string is utilised instead of many search strings. Only databases related to the issue and widely accepted in the scholarly community are included. For this study, only IEEE Xplore, Elsevier, ACM Digital library, Springer Nature and Taylor & Francis is used.

The search string is formed to search throughout the metadata using the Boolean operator "AND," and the simple search term is ("Blockchain" AND "Quantum").

B. Inclusion and Exclusion Criteria

Inclusion and exclusion criteria should be based on the research questions to guarantee that the research questions can be effectively interpreted and that the studies are properly classified. Because the wide usage of blockchain grew in prominence after 2015, we chose all papers published after January 2016. We also limited the results to journal and conference articles, excluding online material, books, and magazines. If duplicate articles or corrections are found in any of these articles, they were removed. Finally, only articles written entirely in the English language are chosen.

C. Study Selection Process

We found 126 items in IEEE Xplore, 395 in Elsevier, 187 in the ACM digital library, 272 in Springer Nature, and 96 in Taylor & Francis Online using the specified search term and inclusion-exclusion criteria. A three-stage selection technique was implemented to guarantee that only relevant research articles were evaluated. Following the search, the results are extracted using keywords and titles. Following that, the abstracts of the papers were read, and the number of articles was decreased. Only high-quality studies that answered the research questions were picked in the last step, which involved reading whole articles and ranking them based on content. For efficient monitoring and control during the selection process, a separate folder was created for each evaluation stage, along with a new Excel sheet. The research is entirely transparent and

traceable as a result of this. Table I shows the step-by-step selection criteria, and Fig. 1 shows the count of publications that were included.

TABLE I. CRITERIA FOR ACCEPTANCE AT EACH STAGE

| Review Stage | Method                                                                | Criteria for acceptance                                                                                                         |
|--------------|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| First        | Filter the articles using keywords and titles.                        | The title or keyword should be related to the research objective. Select the document for the next stage if there is any doubt. |
| Second       | Exclude articles based on abstracts                                   | Check if the abstract relates to the research question. In case of doubt, move the paper to the subsequent stage.               |
| Third        | Articles are excluded based on their entire text and article quality. | Papers that correspond to the research subject and proper experiments or mathematical proof is provided are selected.           |

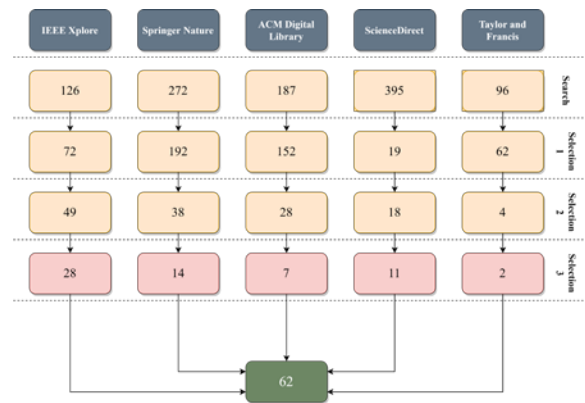

Fig. 1. Number of Papers Selected at each Stage.

D. Data Extraction

Once the analysis of the selected articles was completed, an excel file was created to record the data extracted from each publication. Table II shows the fields that were taken from each publication.

TABLE II. FIELDS USED FOR DATA EXTRACTION

| S. No | Field                            | Description                                                 |
|-------|----------------------------------|-------------------------------------------------------------|
| S1    | Title                            | The paper's title                                           |
| S2    | Database                         | Where an article is published                               |
| S3    | Rating                           | According to the content                                    |
| S4    | Experiment                       | Whether or not proper experimentation is carried out        |
| S5    | Mathematical Proof               | Whether or not mathematical proof is provided               |
| S6    | Architecture/Framework/Algorithm | Whether the architecture, framework, or algorithm is given. |
| S7    | Code                             | Whether source code is given to duplicate the results       |
| S8    | Survey                           | Is it a survey paper                                        |
| S9    | Problem identified               | Which type of issue is discussed in the paper               |
| S10   | Category of Solution             | What type of solution is provided                           |

### E. Data Synthesis

According to the research questions, all data taken from the selected publications was synthesised. This makes it simple to understand the challenges and different kinds of solutions provided.

As shown in Tables III and IV, a systematic data analysis assisted in the formalisation of specific categories related to the description of problems and solutions.

TABLE III. CHALLENGES BASED ON LAYERS

| S. No. | Layers                             | Articles                         |
|--------|------------------------------------|----------------------------------|
| 1      | Application and Presentation Layer | [17], [18], [27], [19]–[26]      |
| 2      | Consensus Layer                    | [28]–[36]                        |
| 3      | Network Layer                      | [37], [38], [47], [39]–[46]      |
| 4      | Data Layer                         | [48], [49], [58]–[65], [50]–[57] |
| 5      | Hardware and infrastructure layer  | [48]                             |
| 6      | Not based on Layers                | [66], [67]                       |

TABLE IV. SUMMARY OF SOLUTIONS FOUND IN THE LITERATURE

| S.No. | Solution                               | Article                                                                                 |

| 16    | New Consensus                          | [21], [28]–[30], [32]–[36]                                                              |
| 17    | Review                                 | [9], [91]–[94]                                                                          |

Furthermore, as shown in Fig. 3 and 4, a frequency analysis is performed for the problems and solutions under study.

### III. SLR FINDINGS

We synthesised the data from the selected papers depending on the research questions. The problems are not clearly defined but presented as an overall solution to blockchain problems with quantum computing. In order to categorise them properly, the solutions provided are split based on different layers of blockchain. Every layer has different security requirements, so based on these layers, research articles are grouped. Also, some solutions are working of more than one layer, so these solutions are identified separately for each layer. First, we explain the problems in each layer and then different types of solutions studied in the literature.

#### A. Challenges and Issues

After the analysis, it is decided to represent blockchain in layers as shown in Fig. 2 and then understand the issues according to each layer. Dividing into layers make it easy to understand where research is still required. These layers, along with problems, are explained below:

1) *Hardware and infrastructure layer*: Internet users (peers) can now connect with other peers and share data as distributed systems are becoming more prevalent. This layer is responsible for creating virtual resources such as storage, networks, and servers. Nodes are the essential part of this layer because nodes are hardware devices that connect to the network and help make consensus in the blockchain. Infrastructure security frequently necessitates either limiting or prohibiting access to the node. So, improvement is needed at the infrastructure level to implement quantum blockchain properly.

2) *Data layer*: Data stored in blockchain depends on the type of blockchain-like Hyperledger Fabric [12] that contains channel information, whereas a Bitcoin blockchain needs to store the information about the sender, receiver, and amount. Blockchain network data is added only when consensus is reached among the nodes. Hash functions help in the easy identification of blocks and the detection of any changes made to the blocks. To ensure the confidentiality and integrity of the data stored on the blockchain, transactions are digitally signed. Blockchain uses asymmetric cryptography to secure information about the block, transactions, and transacting parties, among other things.

To sign a transaction, private keys are used, and anyone with the public key is used, and anyone with the public key can verify the signer. Because the encrypted data is also signed, digital signatures ensure data integrity. Every transaction in a block is hashed and organised in the form of a Merkle tree. In the Merkle tree hash of transactions are organised in the form of a binary tree. If any transaction is changed, then the whole Merkle tree is changed, which changes the whole block as the block contains the hash of the Merkle tree.

Fig. 2. Different Layers of the Blockchain.

As a result, any manipulation will render the signature invalid. Most blockchain systems depend significantly on a digital signature to improve security. These signatures rely on the difficulty of solving a mathematical problem, such as determining the factors of large integers. The data layer is highly dependent on these algorithms, and once practical quantum computers are developed, breaking these algorithms will be easy. As a result, this layer is too much vulnerable to quantum attacks.

3) *Network layer:* The network layer is in charge of inter-node communication and handles block propagation, transactions, and discovery. It is also called the propagation layer or peer to peer layer. In a peer-to-peer network, nodes share the workload to achieve a common goal in a distributed network. This layer ensures that nodes can discover other nodes in the network to interact, propagate, and synchronise information with other nodes. This layer also handles the propagation of the world state. A node can be a light node or a full node. Light nodes can merely retain the blockchain's header and send transactions. Full nodes are responsible for transaction verification and validation, mining, and consensus rule enforcement. They are in charge of ensuring the network's trustworthiness. So, it is needed that this layer uses quantum network in the future.

The term "Quantum Internet" [13]–[15] refers to the entire system, which comprises both quantum and classical packet switching networks. A traditional network in which hosts and routers can handle quantum information in the network graph structure is known as a quantum network. Between these nodes, there are classical channel for transferring classical data and quantum channel connections for transmitting quantum data.

4) *Consensus layer:* The rules that nodes follow to ensure that transactions are validated within those rules, and that blocks respect those rules is known as consensus. There is a consensus algorithm behind every blockchain as the trusted

third party is missing to validate transactions in case of conflict. The consensus layer is the most significant layer for any blockchain. Consensus protocols provide a set of irrefutable agreements between nodes in a distributed peer-to-peer network. Consensus keeps all of the nodes in sync. Consensus is in charge of validating the blocks, ordering them, and guaranteeing that everyone agrees. It is easy to attack this layer with the help of quantum computers. Attackers can search hash collisions, which can subsequently be used to change blocks in a network without impacting the integrity of the blockchain. Also, for mining, it is required to search a nonce, and with quantum computers, it will be very fast. This can enable an attacker to reconstruct the whole blockchain without getting detected by the network.

5) *Application layer:* The application layer includes smart contracts[16], chaincode[12], and decentralised apps (dApps). Smart contracts are digital contracts built on the blockchain that is automatically executed when particular events occur, or any external criterion are met. Chaincode is a collection of related smart contracts used to do a certain purpose. dApps are software applications that run on a blockchain network of computers rather than on a single device. Because they are decentralised, decentralised apps are free of the control and influence of a single authority.

dApps provide several advantages, including user privacy, developer independence and lack of censorship. The application layer comprises two layers: the application layer and the execution layer. The application layer is where end-users interact with the blockchain network, including scripts, APIs, user interfaces, and frameworks.

The execution layer, which includes smart contracts, underlying rules, and chaincode, is a sublayer. This sublayer contains the code and rules that are actually executed. A transaction is propagated from the application to the execution layer, but it is validated and executed by the semantic layer. The execution layer processes transactions and preserves the blockchain's deterministic nature. It receives instructions from the application layer. A smart contract code should not be pulled down or changed after being deployed on a blockchain, but it may be possible with quantum computers. Similarly, instead of making the smart contract more complex within the same technology, it is necessary that from now on, those researchers should start moving towards quantum-resistant smart contracts.

## B. Solutions

First, the basic concepts of quantum computing and some of the properties are discussed in this section. After that, the explanation of the solutions and methods that are found in the literature are discussed.

Quantum computing focuses on developing computer systems using quantum theory and quantum bits, or qubits. Quantum computers use subatomic particles' ability to exist in many states, i.e., it can be 0 or 1 simultaneously. Algorithms work by manipulating bits with gates, which change their states. The NAND gate is a universal gate, but the NAND gate's behaviour is not reversible because it accepts two inputs

and returns outputs that are not unique. In quantum computing, working with reversible gates is typically convenient since every reversible gate may be implemented on a quantum computer. The Toffoli gate is a reversible gate that takes three bits as input, can imitate the NAND gate.

Toffoli's gate converts  $(\alpha, \beta, \gamma)$  to  $(\alpha, \beta, (\gamma + \alpha * \beta) \bmod 2)$ . The Toffoli gate maps  $(\alpha, \beta, 1)$  to  $(\alpha, \beta, \alpha \text{ NAND } \beta)$  when  $\gamma = 1$ . Quantum computers are classically computationally ubiquitous because they can implement the Toffoli gate, even if the Toffoli gate alone is insufficient to implement any function on quantum states. The electron, which can have a spin pointing up or down, provides a simple physical prototype for this two-state system. These states are usually written as  $|0\rangle$  and  $|1\rangle$  in quantum mechanics as a convention. Quantum computers, unlike conventional computers, are not limited to manipulating only these two states. State superpositions, such as  $\frac{|0\rangle + |1\rangle}{\sqrt{2}}$  are also feasible. These two-state systems are known as quantum bits or qubits. Qubit states can alternatively be represented as two-dimensional vectors, for example.

$$|0\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, |1\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \quad (1)$$

This is significant because multiplying the corresponding vectors allows gates to be represented mathematically as  $2 \times 2$  matrices acting on qubits.

A linear combination of  $|0\rangle$  and  $|1\rangle$  with complex coefficients can be used to describe the state  $|\psi\rangle$  of any given qubit, i.e.

$$|\psi\rangle = p|0\rangle + q|1\rangle, p, q \in \mathbb{C}. \quad (2)$$

A classical computer requires two complex numbers to describe an arbitrary quantum state; similarly, modelling  $n$  arbitrary quantum states on a classical computer requires  $2^n$  complex numbers and so a minimum of  $2^n$  Bits. By definition, a quantum computer requires just  $n$  qubits to describe  $n$  states. Modelling quantum systems on the classical computer will thus take the time that grows exponentially with the number of states  $n$ , whereas modelling the same system on a quantum computer only requires time that grows linearly with  $n$ . In other words, the classical computer takes  $O(2^n)$  time and the quantum computer takes  $O(n)$  time for this example.

The Hadamard gate is important in quantum computing. This gate, represented by  $H$ , has the following representations in matrix form and state notation:

$$H = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} = \frac{1}{\sqrt{2}} \sum_{a,b \in \{0,1\}} (-1)^{ab} |a\rangle \langle b| \quad (3)$$

The Hadamard gate is a crucial component of quantum algorithms like Shor's algorithm, Grover's, and Simons algorithm as the Hadamard gate translates  $n$  qubits that are all in the same state to an equal superposition of the  $n$  qubits' potential states. Shor's algorithm, on the one hand, argues that, due to quantum mechanics, factorisation may be done in polynomial time rather than the exponential time, which is the basis of many public-key algorithms. Grover's algorithm, on the other hand, can cut the sufficient security strength of algorithms like the AES (Advanced Encryption Standard) in

half for a given key length, rendering infrastructures secured by them open to attack [7].

Shor's algorithm is noteworthy because it solves the complex problems of integer factorisation. The best extant algorithm for this problem is known as the generic number field sieve, and it operates in  $O(e^{(\log(N)^{1/3} \text{poly}(\log \log N))})$ , where  $\text{poly}$  is a complex polynomial. Shor's algorithm outperforms  $O((\log N)^3)$  in terms of speed.

Shor's approach employs the well-known Euclidean algorithm to compute the greatest common divisor (GCD) and then Simon's algorithm to gain the exponential speedup. Given an integer  $Z$ , one can compute  $\text{gcd}(f, Z)$  by selecting a random number  $f < Z$ . The problem is solved if  $f$  is a factor of  $Z$ ; otherwise,  $\text{gcd}(f, Z)$  must equal one. Assume  $M$  is the order of  $f$ , i.e., the lowest positive integer is  $M$  such that  $f^M \bmod N = 1$ . Then, as long as  $M$  is even and  $f^{M/2} + 1$  is not a multiple of  $Z$  (which is very likely), both  $\text{gcd}(f^{M/2} + 1, Z)$  and  $\text{gcd}(f^{M/2} - 1, Z)$  are factors of  $Z$ .

The problem is solved as long as the  $M$  matching to a particular  $f$  can be found. Consider the function  $g(x) = f^x \bmod Z$  to compute  $M$ . The task of computing  $M$  is thus reduced to period-finding for this function  $g$  since:

$$g(x + M) = f^{x+M} \bmod Z = f^M f^x \bmod Z = f^x \bmod Z = g(x) \quad (4)$$

The problem is solved by using Simon's algorithm. Simon's approach solves the period-finding problem, that is, calculating the period  $M$  of a function  $g$  that satisfies  $g(x) = g(x + M)$  for any  $x$ . This was a significant subproblem in Shor's method that provided an exponential speedup: Simon's algorithm runs in  $O(n)$  on a quantum computer and  $O(2^{n/2})$  on a classical computer [68].

With a uniform superposition of states over  $n$  qubits, Simon's algorithm computes the function  $g$  on the superposition, measures the answer, and applies the Hadamard gate to the  $n$  resultant qubit states. If the period  $M$  is represented as a  $n$ -bit vector  $\vec{M}$ , measuring the state after applying the Hadamard gate returns a vector orthogonal to  $\vec{M}$  with a high probability. After  $O(n)$  iterations of this process, one receives  $n - 1$  orthogonal vectors to  $\vec{M}$ . Because  $\vec{M}$  exists in an  $n$ -dimensional vector space, this is enough to determine the period  $M$ .

Grover's algorithm[69] is intended to tackle the problem of unstructured search. This problem can be described formally: given a function that transforms  $N$ -digit binary values to either 0 or 1, find  $x$ . Grover's algorithm is relatively straightforward to implement. To begin, use the Hadamard gate on a set of  $n$  qubits to generate a uniform superposition of states, where  $N = 2^n$ . Following that, a gate is built that rotates the uniform superposition towards the state  $|a\rangle$  corresponding to  $a$ . With a high probability, measuring the state after  $O(\sqrt{N})$  applications of this gate will yield  $|a\rangle$ . This is an improvement over the  $O(N)$  steps a random classical algorithm would take to find a best-case situation.

1) *Quantum properties*: A quantum state is a mathematical object that offers a probability distribution for each potential measurement of a system's outcomes. When we combine quantum states, we get another quantum state. Pure quantum states cannot be expressed as a mixture of other states, whereas mixed quantum states can be described as a combination of other states. Quantum computing performs computations by utilising the collective characteristics of quantum states, such as superposition, collapse, and entanglement.

A superposition of quantum states may be thought of as a linear combination of many quantum states, resulting in the development of a new valid quantum state. The basic states are  $|0\rangle$  and  $|1\rangle$ . All the Qubits are superposition on these basic states. Quantum superposition differs substantially from classical wave superposition. A superposition of  $2^m$  states, ranging from  $|0000\dots 0\rangle$  to  $|1111\dots 1\rangle$  will exist for a quantum computer with  $m$  qubits. The probability of a quantum state  $|\psi\rangle$  is  $|A_v|^2$  for any set of values  $v$  with probability amplitudes  $A_k \in \mathbb{C}^5$  in such a way that  $|\psi\rangle := \sum_v A_v |\psi_v\rangle$  for the measurement of  $|\psi\rangle$  resulting in  $\psi_v$ . Authors in [28] discussed the new consensus algorithm using quantum entanglement.

When one particle's quantum state cannot be characterised independently of the other particle's quantum state, they are said to be entangled. Even if the individual components are not in a defined state, the system's quantum state as a whole may be characterised. When two qubits become entangled, a one-of-a-kind relationship is established. The entanglement will be demonstrated by measurements, which may produce a value of 0 or 1 for individual qubits where the measurement of both the qubits will be the same. Even if the particles are separated by a significant distance, this is always true. For a quantum state  $|\psi\rangle$  with  $|\psi\rangle := \sum_v A_v |\psi_k^x, \psi_k^y\rangle$ , then on measurement of  $|\psi\rangle$  then probability X sees  $\psi_k^x$  and Y sees  $\psi_k^y$  is equal to 1.

While interacting with the outside environment, any wave function is reduced to a single eigenstate from the superposition of many eigenstates, and then it is called wave function collapse. In this case, the probability is 1 for all measurements of quantum state  $|\psi\rangle$  resulting in  $\psi_v$  where  $|\psi\rangle := \sum_v A_v |\psi_v\rangle$ , for some  $v$ .

A quantum channel can transfer both quantum and classical information. Quantum channels are trace-preserving mappings between spaces of fully positive operators. In other words, a quantum channel is just a quantum operation considered as a pipeline meant to transmit quantum information rather than simply the reduced dynamics of a system. Some solutions, as discussed in [18], [65] are based on quantum channels.

The idea of quantum key distribution (QKD) was initially presented in the 1970s, but it was not fully realised until the 1980s. QKD allows to sharing and distribute secret keys for cryptographic protocols. The essential thing is to keep them private, just between the communicating parties. Quantum superpositions or quantum entanglement and conveying information in quantum states may be used to develop a communication system that detects eavesdropping. If the extent of eavesdropping is less than a certain threshold, only then a

secure key can be generated otherwise, the communication is terminated. This is the general concept of Quantum cryptography that is why it is added as a property. Authors in [18], [19], [21], [26], [31], [41], [46], [70] discussed the usage of QKD for quantum blockchain.

2) *Hash-based signature*: The hash-based signature is used to utilise the cryptographic safe hash function properties. These properties include pre-image resistance, one-wayness and collision resistance. Hash-based signature systems rely entirely on the underlying safe cryptographic hash function, limiting the attack surface and cryptanalysis possibilities. By removing the need for several security components, hash-based signature systems substantially minimise implementation complexity. Any hash function that meets the security criteria of cryptographic hash functions can be employed to build hash-based signature algorithms. Because of this inherent flexibility, several underlying hash functions may be used to meet the required performance requirements based on the application-specific environment. Any difficult-to-invert function may be converted into a secure public-key signature system using hash-based cryptography. As a result, this might be a solution for post-quantum blockchains as discussed in [24], [32], [50], [71].

3) *Code-based cryptography*: All cryptosystems, symmetric or asymmetric, whose security is based, in part or entirely, on the difficulties of decoding a linear error-correcting code, perhaps chosen with some particular structure or in a particular family (for instance, quasi-cyclic codes, or Goppa codes) is code-based cryptography [72]. The ciphertext is a codeword with flaws that can only be corrected by the owner's private key (the Goppa code). Grover's algorithm does not significantly outperform earlier code-based cryptosystem attacks in terms of speed.

4) *Lattice-based cryptography*: A lattice is a collection of points having a periodic structure in  $n$ -dimensional space. Given  $n$ -linearly independent vectors  $v_1, v_2, v_3, \dots, v_n \in \mathbb{R}^m$  the set of vectors created by them is the lattice  $\mathcal{L}$

$$\mathcal{L}(v_1, v_2, v_3, \dots, v_n) = \{\sum x_i v_i \mid x_i \in \mathbb{Z}\} \quad (5)$$

A basis of the lattice is made up of the vectors  $v_1, v_2, v_3, \dots, v_n$ .

Because of its strong security proofs based on worst-case hardness, reasonably efficient implementations, and considerable simplicity, lattice-based cryptography [73] appears to promise post-quantum cryptography. In two ways, the worst-case security guarantee is critical. It helps us determine the cryptosystem's concrete parameters by ensuring that the cryptographic framework is free of fundamental flaws.

5) *Multivariate cryptography*: A set of (usually) quadratic polynomials over a finite field is a public map for a multivariate public-key cryptosystem (MPKC) [74]. In general, finding a solution to such structures is an NP-complete/-hard problem [75]. One of the intriguing instances is Patarin's Secret Fields [76], which generalises a suggestion by Matsumoto and Imai [77]. The NP-hardness of solving

nonlinear equations over a finite field underpins its fundamental security assumption. This is one of the most influential families of PKCs (public-key cryptography), as it can withstand even the most powerful quantum computers in the future. The MQPKC, unlike many other forms of PKC, cannot be solved quickly using Shor's algorithm with a conventional computer because it does not rely on any of the difficulties that Shor's algorithms can resolve.

6) *Directed acyclic graph*: A distributed ledger technology, a DAG [66], is an alternative to regular blockchain that seeks to solve blockchain technology's speed, scalability, and cost concerns. DAG is also a system that uses a digital ledger to keep track of transactions. DAG (Directed Acyclic Graph) is a more expressive outline than an entirely linear model. A DAG is a data or information structure that may be used to show a variety of difficulties. It is a topologically ordered acyclic graph. The node follows a specific sequence for each directed edge. Every DAG begins with a node with no parents and ends without children. There are no cyclic graphs on this page. A DAG is made up of nodes and arrows that connect them. By allowing many chains to exist on the system simultaneously, DAG can solve the single-chain problem of blockchain. IOTA is a DAG currency that is quite well-known. DAG Tangle is what they call it. It eliminates the need for miners in the verification process entirely. The white paper published by IOTA claims that Tangle is quantum-proof [3].

7) *Quantum blind signature*: A blind signature is a digital signature that blinds the message before it is signed. As a result, the message will go undetected by the signer. After that, the signed message will be unblinded. It functions as a standard digital signature and can be publicly verified. Blind signatures that can survive quantum attacks are referred to as "post-quantum blind signatures." Blind signatures have been widely used in the applications like the creation of e-cash and voting agreements. As a result, new quantum blind signature technologies will be necessary for the future. This solution works with other solutions like lattice-based or multivariate cryptography in order to provide quantum-resistant blockchain [18], [19], [39], [42], [54], [55].

8) *Quantum walks*: A random walk is a random process in mathematical space that defines a path consisting of a series of random steps, as defined by Pearson in 1905 [78]. Random walks are essential in solving practical issues since they can be used to evaluate and mimic the unpredictability of items and determine the correlation between them. Quantum walks were introduced in 1993 [79]. The polar opposite of traditional random walks is quantum walks. Quantum walks differ from regular random walks in that they do not converge to any limiting distributions and are much faster because of Quantum interference [79]–[81]. Quantum walks can outperform any traditional algorithm by order of magnitude. The two types of quantum walk-based algorithms are continuous time-based and discrete time-based algorithms [82].

9) *Hardware and software based blockchain*: As shown, blockchain implementation may be implemented into many different technology stack layers. So, hardware-based security is also essential. It may involve hardware-based secure key storage or hardware replacement for quantum channels. Hardware-based key storage is already being developed as cold wallets, but it must also be quantum secure. The authors in [48] develop a quantum computing device as a multi-input multi-output quantum channel.

10) *Quantum cloud computing*: In a cloud computing environment, a cloud quantum computer is a computer that can be accessed over the internet. Users may now make use of a variety of cloud quantum computing services to solve complicated issues that demand a lot of computational power. The design and performance of different cloud quantum computing systems vary. Solutions discussed in [17], [48] used quantum cloud computing.

11) *Post-quantum threshold signature*: Threshold signature [83] is a unique digital signature that can be used to identify a group of users. It is generated by an authorised subset of the private keys. The public keys are already generated with these private keys. It is very easy to verify these signatures as only a single public key and a single signature is enough. If at least  $n$  users out of  $m$  users efficiently sign the message, then the system is known as  $(n, m)$  threshold. The solution discussed in [29] is based on solving quadratic equations in a finite field, an NP-hard problem. This system is a threshold signature system and is considered safe even after developing a powerful quantum computer.

12) *Quantum random oracle model*: In a random oracle [84], anyone may give it an input and output of fixed length. If someone has already requested the input, the oracle will provide the identical result. If the oracle receives an input that it has not seen before, it generates a random output. To make the whole system secure, it is needed to replace all the hash functions used in the system with random oracles. Traditional oracle models can be easily attacked by using quantum superposition. This may result in the failure of many classical security proofs and must be rewritten. Quantum random oracle along with lattice-based solutions are discussed in [43].

13) *One way function*: A one-way function is easy to compute on all inputs but complex to invert given the image of a random input. In many cryptographic systems, one-way functions have proven useful primitive. Extensive work on one-way quantum functions has also been done in the post-quantum period. These one-way functions accept outputs of the quantum states by taking classical bit strings as input. Many information-theoretically secured digital signature techniques rely on the one-wayness characteristic of these functions [85], [86] have been proposed. To authenticate both classical bit strings and quantum states, these one-way functions should be both quantum-classical and classical-quantum in design. As a result, [60] developed quantum

money systems based exclusively on the security of one-way functions that are resistant to quantum attacks.

14)Zero-knowledge proof: Zero-Knowledge Proofs (ZKPs) enable data to be validated without disclosing the data itself. As a result, they have the potential to transform the way data is gathered, used, and transacted. Each transaction is assigned a 'verifier' and a 'prover'. In a ZKPs transaction, the prover tries to prove something to the verifier without revealing anything about it. The authors of [47] suggest employing two indistinguishable hash functions combined with ZKPs protocols to ensure security against quantum attacks.

#### IV. RESULT AND DISCUSSION

Blockchain is an up-and-coming technology, and it is assumed that it is the foundation of web 3.0. Quantum computing is not just theoretical now, as can be seen with the development of quantum computers by google (72 qubits), Xanadu (24 qubits), IBM (127 qubits), Intel (49 qubits) etc. Quantum Computers are real threats to blockchain technology, as discussed in the article. Our literature review found that to make blockchain stable even with quantum computers, work must be done at all the layers of blockchain, not just one layer. By that, we can genuinely make a quantum-resistant blockchain.

The focus was mainly on the research questions in the survey, and both the research questions were answered. The security threats on the blockchain are divided based on the layers of the blockchain and based on that we analysed the papers. As shown in Fig 3, most of the work (i.e., 30%) mainly focused on the data layer, which seems likely because mainly encryption and transactions are handled in this layer. The next area of focus was the application and presentation layer, with 24% of articles has shown the work on that. This layer includes applications based on blockchain, which may include smart contracts or chain codes. Therefore, the security of this layer is essential; however, the focus of the articles found concerning specific applications, so the focus should be on general solutions as well. For the network layer, it is found that 23% of papers work to find secure quantum networking and 16% of the articles found work on either changing the consensus algorithm or proposing the new algorithm in itself. Only 1% of articles discussed infrastructure and 6% about working with distributed ledger other than blockchain like IOTA, which is based on the directed acyclic graph.

Fig. 3. Security Challenges Identified based on Blockchain Layers.

Next, we aimed to categorise solutions based on four categories only, i.e. Hash-based signatures, Code-based cryptography, lattice-based cryptography and Multivariate cryptography . However, instead of sticking to these four, we decided to make it more transparent and focus on the essential solutions. As shown in Fig. 4, around 25% of papers focused on lattice-based cryptography.

Consensus is necessary for blockchain for the settlement of the transaction. 14% of the papers proposed a new or modified consensus algorithm using either a new hash function, digital signature, or quantum properties. As hash functions and digital signatures are the backbones of blockchain technology, it is necessary to create new or modified signature schemes, and it has been found that 11% of research papers focused on hash-based signatures and 11% of the paper focused on quantum blind signatures. So these are the key areas where research is going on. Analysing the problems and solutions, it is clear that some layers still need some work, like the infrastructure and consensus layers. These layers are also necessary. Findings also suggest that some authors give a solution for one layer and claim that the blockchain will be posted quantum blockchain To make blockchain safe from quantum attacks, it is necessary to create the solution keeping in mind all the layers and find a solution that covers the problems of each layer.

This paper mainly focused on the research found in the literature to increase blockchain security in the post-quantum era. Some literature having reviews based on different focus areas are also found, like authors in [95] focused on proof of stake only, authors in [91] discuss the survival of DLTs after quantum computing. However, it was not thorough, focus on bridging quantum, and classical computing is done in [9], authors in [10] has done a good survey on post-quantum blockchain and compared the significant features of the post-quantum encryption cryptosystems that advanced to the second round of NIST call. This study is restricted for database and year selection to make the review process repeatable and free from any bias.

Even after that, many articles are obtained, evaluated, read, classified, and summarised, and answers to the research questions are presented. The findings suggest that it is needed to see blockchain systems in layers, and researchers should provide solutions to the quantum attacks based on these layers.

Fig. 4. Frequency Analysis of Solution for the Discussed Challenges.

## V. CONCLUSION

This study starts with the development of the research questions. To appropriately answer these questions, the systematic literature review is done, and the process is explained in-depth, including the database selection, search process, inclusion and exclusion criterion, creating and extraction of fields and summarising the results. During this process, we found and classified threats based on blockchain layers. Some of the threats were spread over different layers, so these threats are discussed individually for a proper explanation. Many different solutions are also found regarding these threats. The mapping between these threats and solutions has been presented, keeping in mind the full proof solution of post-quantum blockchain.

We discovered that blockchain could operate after quantum computers, but it must work on every layer of the blockchain network, or the solution will not be feasible. Even after developing solutions, they must be thoroughly tested in the real world. If a new application, whether decentralised or not, is being created on the blockchain, quantum attacks should be considered from the planning phase. It has been discovered that blockchain in its current form is unsuitable and must be modified. In the future, researchers will need to create similar solutions and test them for all such issues that have yet to be solved or discussed.

**Abstract**—High efficiency video (HEVC) coding made its mark as a codec which compress with low bit rate than its preceding codec that is H.264, but the factor that stop HEVC from many applications is its complex encoding procedure. The rate distortion optimisation (RDO) cost calculation in HEVC consume complex calculations. In this paper, we propose a method to cross out the issue of complex calculations by replacing the traditional inter-prediction procedure of brute force search for RDO by a deep convolutional neural network to predict and perform this process. In the first step, the modelling of the deep depth decision algorithm is done with optimum specifications using convolutional neural network (CNN). In the next step, the model is designed and trained with dataset and validated. The trained model is tested by pipelining it to the original HEVC encoder to check its performance. We also evaluate the efficiency of the model by comparing the average time of encoding for various resolution video input. The testing is done with mutually independent input to maintain the accuracy of the system. The system shows a substantial saving in encoding time that proves the complexity reduction in HEVC.

**Keywords**—CNN; HEVC; deep learning; RDO; encoding time; complexity reduction

## I. INTRODUCTION

Video compression is an area to explore while considering the flourish of video acquisition devices, social media, live transfer of videos etc. The high efficiency video encoding HEVC system possess a better compression compared to its previous system advanced video coding AVC. However, the computational complexity of HEVC is a matter of discussion because of its Rate distortion optimisation [1] (RDO) cost calculation for coding tree unit [2] (CTU). There for this computational complexity in HEVC is a matter of research interest, the focus will be to reduce the computational complexity[3] with better efficiency. Before going into the details let's review the evolution of HEVC its drawback and goodness compared to its ancestral system.

ITU-T video compression standard introduced H.261 is the year November 1988. In the H.26x family, first member, H.261 in video coding standards in the domain of the VCEG (ITU-T Video Coding Experts Group) then Specialists Group on Coding for Visual Telephony [4]. H.261 was originally

designed to transmit data over ISDN lines with data rates as multiples of 64 Kbit/s. The coding algorithm was designed in such a way to work at video bit rates in 40 Kbit/s to 2 Mbit/s [5]. MPEG-2 consists of “three different kinds of coded frames: I-frame /intra-coded frames, P -frame/predictive-coded frames, and B-frame/ bidirectionally-predictive-coded frames” [3]. The I-frame is a single uncompressed or raw frame that is a separately-compressed version. “The I-frame coding takes the advantage of spatial redundancy and the persistence of vision of human eye ie the inability of human eye to detect several changes in the image. I-frames do not depend on data in the previous or the next frames,”[6] Unlike in P-frames and B-frames, and because of that its coding matches with the still photography. The raw frame is spitted into 8X8-pixel blocks. The data in all block is transformed using discrete cosine transform (DCT)[6]and results is a matrix of size 8x8 of coefficients that have real number values. The DCT transform converts spatial domain into frequency domain, but it does not change the information in the block; if the DCT is calculated with perfect precision, the original block can be recovered clearly by applying the inverse discreet cosine transform [5] “H.263 [7]is a popular video compression standard for low-bit-rate compressed format focusing on videoconferencing. It was standardized by the organisation ITU-T, Video Coding Experts Group (VCEG) in 1995/1996”[4] . H.263 is the member of the H.26x family of video coding standards in the domain, ITU-T. Like other H.26x standards, H.263 is also based on (DCT) discrete cosine transform video compression. It was later advanced to add different additional enhanced features in the year 1998 and 2000. “H.264 is one of the popularly used codec on the planet, with significant note in optical disc, broadcast process, and streaming in video markets etc.[5] The applications are noted in Table I. Still, many uses of H.264 are subject to royalties, something that should is taken into considered before Google's WebM, as well as the general availability of decoding abilities on target platforms and devices” [8]. H. 264 mostly called as AVC (Advanced video coding), its block segmentation based, motion compensated with DCT technique. The aim behind AVC was to transfer video in low bit rate with better efficiency for UHD videos to its adaption of it.

Fig. 1. (a) Rate Distortion Cost Calculation of CU Procedure. (b) The Representation of CU Classification as Layers to Analyze Depth.

“High Efficiency Video Coding, is also known as HEVC or H.265, is the step in this evolution. It builds off a lot of the techniques used in AVC/H.264 to make video compression even more efficient. When AVC looks at multiple frames for change those macroblock chunks can be a few different shapes and sizes, up to a maximum of 16 pixels by 16 pixels. With HEVC, those chunks can be up to 64x64 in size much larger than 16x16, which means the algorithm can remember fewer chunks, thus decreasing the size of the overall video” [9]. HEVC’s quad tree [10] partitioning uses the brute force search for RDO (rate distortion optimisation) cost calculation. The complexity of the procedure is more when used with normal signal processing steps that makes the HEVC [11] complex. Fig. 1(a) shows the procedure of rate distortion optimisation as a flowchart. It is divided into check procedure and comparison procedure. It initially checks for the rate distortion cost of the parent CTU [12] and the total cost of splitting it till end. Once this procedure is done comparison is done. In comparison it will the checking the RD [11] cost of parent and the cost after splitting. if the RD cost after split is more than the system will not split further and if the RD cost of parent is more then it will proceed with the split. This calculation procedure in HEVC is tedious that make the system complex. This issue was addressed by many algorithms, some provides

enhancement to the existing HEVC system while other set provides a totally new algorithm [3] providing a new architecture [13] to perform the procedure of compression. Deep learning based algorithms [13] [14] started working on this in recent years. So a depth decision algorithm with deep CNN [15][16] is modelled to solve this issue. Fig. 1(b) shows the level and depth of CTU. Understanding this depth concept [6] helps in designing deep CNN [13] algorithm to predict depth and thus to make intra prediction less complex.

The paper aims in complexity reduction in video compression (HEVC) by reducing encoding time. It is achieved by designing a deep learning-based system that predicts the depth of the CTU by making the intraprediction procedure less complex. The design is evaluated by pipelining it with the original HEVC and evaluates the complexity of the system. The overall design idea is shown in Fig. 2. The paper is divided mainly into two halves, 1) design of the deep depth decision algorithm, here the deep depth decision algorithm is designed tested and validated for datasets and 2) evaluation and experimental results of the model pipelined with original HEVC, were the model is pipelined with the original HEVC and the performance is evaluated for various resolution videos. The paper is concluded with the results showing encoding time reduction and future scopes.

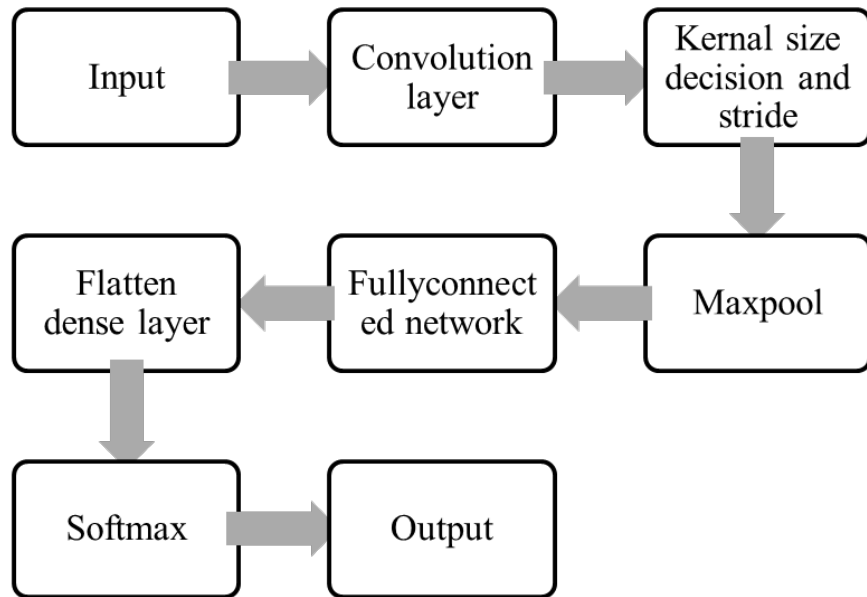

Fig. 2. Illustration of Steps in Order for the Modelling of Deep Depth Decision Algorithm with CNN.

## II. DESIGN OF DEEP CNN DEPTH DECISION ALGORITHM FOR INTER PREDICTION

The inter prediction and its computational complexity was the issue took for analysis to model a new network. The design of this network should possess less computational complexity compared to the existing system and should be

compatible to the existing codec. The design chosen should be compatible for faster transmission of frames while coding, so scalability and compatibility will also be the focus while designing, considering all this convolutional neural network (CNN) is chosen for this purpose so that all features are extracted correctly from the frames to produce better prediction as shown in Fig. 3.

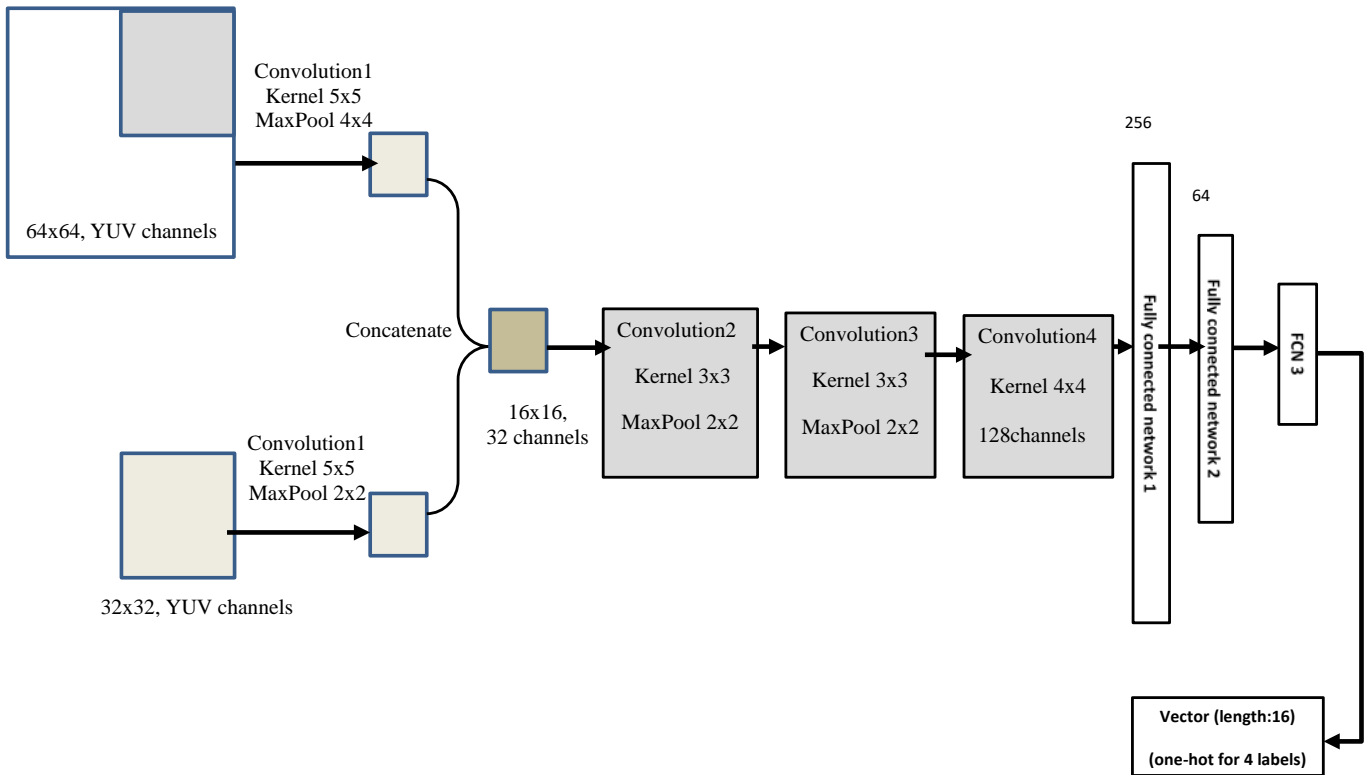

Fig. 3. The Representation of Deep Depth Decision Algorithm Model, with Input as 64X64 Patch followed by Convolution, MaxPool, Fully Connected Network followed by the 16 Length Output.

The CNN[17] used here is having multiple layer, the initial layer is the input layer. The input used here is video frames. The video frame can be of various properties, the YUV is the format chosen for this evaluation, other formats are also compatible in this model. The next layer in CNN model is convolutional layer, this is the layer that extracts the features of the frame based on the kernel used. The kernel size can be chosen based on the features that need to be extracted, if the kernel size is big it collects the global features or information from the frame whereas the small kernel [12] extracts the local features. Based on the need of the feature kernel can be chosen. In the design 5X5, 3X3 along with the 16X16, 4X4 [18] are also used, so model clearly extracts the global and local features from the frame. To cover all the inputs zero padding is used in this model. The stride used is same as the width of the kernel used in each case in the design. After extracting the feature its max pooled to reduce the size and converge the multiple values to a single value or less values. The activation function helps to decide the neuron is fired or not, so activation function is the node is kept in between and in the end of neural network. Here the activation function [19] used is ReLU rectified linear unit. ReLU maintains a value between (0-  $\infty$ ) zero and infinity by avoiding negative values. It's a simple function that returns if input is negative else returns the same value in other cases. Both forward and backward propagation exist in CNN [20] network. Here in the model training uses backward propagation while validation uses forward propagation.

The model designed takes the input as YUV CTU of 64X 64, the first convolution layer users its kernel and converts as 32X32 coding unit. The both CU of 32x32 are concatenated to extract more features and its pooled to 16X16 patch. The next stage of convolution with 3x3 kernel extracts its fine features, and a 4x4 for global features. After feature extraction in each stage the data are pooled by 2x2. In final stage the fully connected later flatten the information and compress it using SoftMax to 256 to 64 to a 16-length vector holding all the information of the CTU depth. The model is trained with various resolution input varying from 240p to 4k. After training the model will be having a training loss factor of 3.1049. the loss function estimated in this model is the cross entropy. Cross-Entropy Loss can be evaluated for separate images and independently and finally added together to obtain the final cross entropy as each path are mutually independent. A 66.12% of accuracy is obtained by the trained model.

#### A. Dataset

The dataset is the collection of sample video frames used for testing training and validation of the design proposed. Multiple and verity in dataset helps in the improvement of accuracy in the model. Here the dataset contains the Coding Unit image file extracted from the YUV video files as set of input and their corresponding depths for HEVC intra-prediction as output to train the proposed system. The dataset chosen here has multiple resolution and are not of same pattern videos to maintain the quality and efficiency of the model.

In HEVC intra-prediction, each I-frame is divided into 64x64 (CTU). For each 64x64 CTU, there's a depth prediction

represented by a 16x16 matrix. The elements in the matrix are 0, 1, 2 or 3, indicating depth 0/1/2/3 for a 4x4 block in the CT. The dataset contains images and corresponding labels. There're three folders: train, validation, test Image files: Each image may have different size based on the resolution of the video, and it is one frame extracted from a video. While using in the system, split the image into several 64x64 images or 32x32 and so on.

Labels: The labels are in separate folder called pkl folder. For one CTU, which is a 64x64 image file, the label will be a Python list with a length of 16. The length is 16 vectors instead of a 16x16 matrix, because there's redundant information for a 16x16 matrix, and it can be reduced to a 16x1 vector. So, for a 64x64 CTU, it has 16 labels, each label corresponds to a 16x16 image block in the CTU. If the frame is split into 64x64 CTUs, the size of the train dataset is around 110K images. The size of the validation dataset is around 40K images. The name of the image file will be like: v\_0\_42\_104\_.jpg, where v represents Video Number, followed by FrameNumber, CTU number and image extension. The Video Number is to find the corresponding .pkl file, like v\_0.pkl. To get the label for a certain 64x64 CTU, index the dict by:

label\_vector = video\_dict [FrameNumber][CtuNumber],  
for example: label\_vector = video\_dict ["42"] ["104"]. The label\_vector will be a length 16 Python list. Dataset loading in deep learning projects implemented in PyTorch can be done by in load\_example.py.

In the final stage for evaluation and comparison CPIH data set is also used to know the performance of the proposed system verses the existing models. The CPIH data set is not used in any of the testing or training for proper quality check.

#### B. Input and Pre-Processing Layer

The input used here is the YUV image patch derived from video frames. Each of this will be saved in a folder with separate labels in a python dictionary. The raw inputs need to be pre-processed by down sampling and splitting into 64x64, 32x32 and so on.

#### C. Convolution Layer

This layer performs convolution operation between the input and the kernel. If  $i$  is the pre-processed input and  $k$  is the kernel of size varying from 5X5 ,4x4,3x3 etc the convolution block output can be formulated as equation 1 and  $*$  represent the convolution operation. The size of the kernel decides the nature of the feature extracted.

In the design both global and fine features are extracted with variant kernels.

$$output = i * k \quad (1)$$

#### D. Fully Connected Layer

The fully connected layer initially flattens the output of convolution layer to a large single dimensional vector. The SoftMax operation helps to compress it further to required size without losing the information in it. The FCN1, FCN2 and FC3 along with averaging help it to shrink to 16 length vectors changing from 256 to 64 to 16.

E. Other Layers

The system is having a loss of feature dropping as the stages are crossing so the activation function ReLU[21][22], rectified linear unit shown in equation 2 where z is the input and R(z) is the output of ReLu . It should be noted that the output is activated by sigmoid function represented by S(z) in equation 3.

$$R(z) = \begin{cases} z, & z > 0 \\ 0, & z \leq 0 \end{cases} \quad (2)$$

$$S(z) = \frac{1}{1+e^{-z}} \quad (3)$$

In original HEVC the prediction process is complex and time consuming as it should predict the RDO cost, so here the CNN network [23],[24]with depth decision [25][26] helps to predict the depth of each patch of 64X64 to a 16-length vector whereas original HEVC needs a matrix of size 64X64 to store it. The model converts the input patch to a 16 vector which can predict all the characteristics of that CTU with depth information as 0/1/2/3. The model is designed to take the input as 64x64 but while processing its split into 32x 32. Predicting for 64x64 patch directly doesn't make sense so the actual input is 32x32. The depth is 0 when the patch is not split and encoded as it is. The 64x 64 patch represent 16 length vectors.

So, for representing 32x32 the vector required is 4x4. So, in the output blocks of four 4x4 patches will be available as output for a CTU of 64x64. Each value in the vector indicate the depth of the CTU. if the first vector is 0 it says that It is a 64x64 patch and if depth is 1 means the 64x64 CTU is split once into four 32x32 CTUs and so on.

III. EVALUATION AND EXPERIMENTAL RESULT ANALYSIS OF DEEP CNN DEPTH DECISION ALGORITHM FOR INTER PREDICTION

The designed model is allowed to work with the HEVC codec as shown in Fig. 4. To simulate the original HEVC, HM software is used. The evaluation is done between the original HEVC and proposed model for intraprediction, pipelined to HEVC using CPIH dataset. Integrating neural network models in HEVC encoder helps to test the complexity reduction using deep-learning-based method in HEVC intraprediction. Using neural networks, the system can directly predict the Coding Unit (CU) depths for each frame. The intention is to speed up the encoding process of HEVC encoder. Thus, after we have a trained model, another thing that needs to be done is to integrate the deep learning prediction process into the HEVC encoder.

Fig. 4. Pipelining Structure with Deep Depth Decision Algorithm Model Added to the Original HEVC Model. It shows the Overall Steps for the Evaluation of the Designed Model.

This is to check the compatibility of the model with existing HEVC and also it makes the evaluation of the performance of our neural network model easier. This pipeline is used for evaluating the performance of a neural network model in HEVC intra-prediction process. Comparing the difference in encoding time, Y-PSNR, U-PSNR, V-PSNR, YUV-PSNR with the original HEVC encoder helps to know the efficiency of the model. FFmpeg, Python3, PyTorch are the requirements to perform this.

The frames are send for encoding to HM software for original HEVC encoding and calculates encoding time, Y-PSNR, U-PSNR, V-PSNR, YUV-PSNR and the same set is send to the pipelined model or the proposed model and calculates the encoding time, Y-PSNR, U-PSNR, V-PSNR, YUV-PSNR. Both are evaluated and made as graphical representation to check the performance comparison.

The results show that the time of encoding with and without pipelining the deep CNN network is shown in the Table I for some sample input. The input chosen for the test is mutually independent from the training set to maintain the accuracy and the wide range of resolution is also considered to check the performance of the system foe different resolution video frames. The results clearly show that there is a change in encoding time and thus the system proves it can reduce the and bit rate in each case, it supports the encoder with a better performance. Computational complexity of the original HEVC is high due to the RDO cost calculation. The experimental results show the time of encoding is drastically changed to low values for the proposed method. The PSNR curve is slightly

low here compared to original model but the system performance is not affected by this. The total process is done in python environment, when it's done, it will output with all information on the command line, like the encoding time, YUV-PSNR and so on. A sample output is shown in Fig. 5 and the comparison graphs are shown in Fig. 6. The proof of reduction in complexity is shown in Fig. 7 with the change in encoding time.

TABLE I. ENCODING TIME COMPARISON

| Image source                     | Resolution | Time of encoding with HEVC pipelined with Deep CNN network(T1) | Time of encoding with original HEVC(T2) | T1-T2     | $\Delta T$ proposed |

#### IV. CONCLUSION

In this paper, a deep learning based inter-prediction is proposed to avoid the computational complexity issue in HEVC which predict the depth of the CTU in a 16-length vector than calculating the RDO cost by traditional signal processing method. The modelling adopted CNN network to perform this model with deep layers to predict the depth. The data set used for training was YUV and its tested on CPIH dataset to maintain the accuracy of the system and to avoid transfer or copied learning. The trained model is converted to

system and pipelined to the original HEVC system to check the performance. The system evaluated the time of encoding with and without pipelining and calculated  $\Delta T$ . The results and simulation clearly show that the design suits for the HEVC to work with less encoding time thus by reducing the complexity of the HEVC. The results prove it, the future enhancement on this can focus on the extension of this to inter prediction that improve the HEVC more.

# The Pragmatics of Function Words in Fiction: A Computer-aided Text Analysis

Ayman Farid Khafaga

College of Science and Humanities, Prince Sattam Bin Abdulaziz University, Saudi Arabia  
Faculty of Arts and Humanities, Suez Canal University, Egypt

**Abstract**—This paper uses a computer-aided text analysis (CATA) to decipher the ideologies pertaining to function words in fictional discourse represented by Edward Bond's *Lear*. In literary texts, function words, such as pronouns and modal verbs display a very high frequency of occurrence. Despite the fact that these linguistic units are often employed to channel a mere grammatical function pertaining to their semantic nature, they, sometimes, exceed their grammatical and semantic functionality towards further ideological and pragmatic purposes, such as persuasion and manipulation. This study investigates the extent to which function words, linguistically manifested in two personal pronouns (I, we) and two modal verbs (will, must) are utilized in Bond's *Lear* to convey both persuasive and/or manipulative ideologies. This paper sets three main objectives: (i) to explore the persuasive and/or manipulative ideologies the four function words under investigation communicate in the selected text, (ii) to highlight the extent to which CATA software helps in deciphering the ideological weight of function words in Bond's *Lear*, and (iii) to clarify the integrative relationship between discourse studies and computer-aided text analysis. Two findings are reported in this paper: first, function words do not only carry semantic functions, but also go beyond their semantic functionality towards pragmatic purposes that serve to achieve specific ideologies in discourse. Second, the application of CATA software proves useful in extracting ideologies from language and helps better understand the power of function words, which, in turn, accentuates the analytical integration between discourse studies and computer, particularly in the linguistic analysis of large data texts.

**Keywords**—Computer-aided text analysis (CATA); concordance; function words; persuasion; manipulation; ideology; Bond's *Lear*

## I. INTRODUCTION

Starting from the assumption that language is a means of communication that often reflects the ideologies of its users, it can be claimed that there is a reciprocal relationship between language and ideology [1]. This relationship has been approached within the field of fictional discourse [2], and in other discourse genres [3]. The different linguistic units expressing language can also be said to be ideology carriers. In the realm of critical discourse analysis (CDA), ideology is one cornerstone of its analytical umbrella to the extent that it is uncommon to conduct a CDA for any text without a reference to ideology; CDA takes as one of its core concerns the task of decoding the hidden ideologies in discourse, either spoken or written. According to van Dijk [4], ideology refers to such set of specific rules, beliefs, and attitudes that are commonly shared between individuals of the same group,

institution and/or party. For him, ideologies are individualized - and institutionalized-based notions that not only demarcate the process of communication within the in-group, but also determine specific communicative guidelines to contact with the out-group. These shared-beliefs often serve to discursively distinguish between the 'We' and 'They' relationship in discourse. The communal relationship between language and ideology is clearly evident in discourse, particularly where notions of power, dominance, and control are addressed [5]. Ideology can be discussed from different linguistic angles, including the semantic, the pragmatic, the lexical, or the grammatical, and it can also be communicated at the different levels of discourse: the word, the sentence, and the utterance. Even function words, such as pronouns and modal verbs, whose main purpose in discourse is to convey a grammatical function, can also be perceived as ideology carriers.

This paper attempts to decipher the ideological significance of function words in Edward Bond's *Lear*. The reason why a drama text is selected for the analysis lies in the fact that literary genres always witness numerous number of function words that are recurrently repeated in these texts. In many cases of their usage in texts, these words carry their naturally semantic function of grammaticality. So, for instance, the different personal pronouns are employed to conduct their semantic function of just referring to deictic concepts, and also the modal verbs can be discursively used to indicate obligation (must, should), high level of certitude (will), possibility (can), etc. In light of this paper, these function words are linguistically investigated by means of a computer-aided text analysis (CATA) and CDA to decode the ideologies these words convey beyond their ordinary semantic functions.

As a result of the incessant technological development, computer software have come to occupy substantial significance in numerous studies within the scope of linguistic studies, as they are used to draw both theoretical and empirical results that contribute to the field of linguistics in general and to textual analysis in particular [6], [7], [8], [9]. These studies highlighted the indispensable role of computer software as digital tools that serve to support and facilitate a comprehensive and enhanced analytical milieu, wherein analysts and linguists can easily manage their analyses by providing adequate, credible and ample results. According to [10], adopting a computational approach to the analysis of fictional texts not only facilitates the whole process of text analysis, but also emphasizes the integration between modern technologies and other social and human disciplines.

The paper is theoretically framed upon three concepts. The first is critical discourse analysis, which is approached in terms of Fairclough's [11] model of analyzing grammatical concepts in discourse, including pronouns and modality, the core concern of this study; the second is ideology, which is addressed in light of van Dijk's [12] perspective concerning the concept; and the third is a computer-aided text analysis, which is represented by a frequency distribution analysis (FDA) to the four function words under investigation. Crucially, the analysis seeks to highlight the analytical integration between CDA and CATA, as well as to shed light on the way these two analytical tools are interwoven within the discourse of Bond's *Lear* to decipher the hidden ideologies of persuasion and/or manipulation encoded in the conversational turns of characters in the selected play, and channeled by the function words employed throughout dialogicity.

Approaching pronouns and modality as carriers of ideology in discourse by the application of CATA via concordance reflects the significance of the grammatical aspects and function words as linguistic tools in the communication process [13], and the significance of utilizing and applying computer software to the analysis of large data texts [14], [15]. There is no discourse that does not carry ideological significance; such an ideological significance serves to open the gate of research towards recurrent discussions that function to discover further meanings pertaining to texts, or to challenge and refute the existing meanings of such texts. Literature is a fertile soil wherein discourse analysts and linguists find so many linguistic phenomena worthy of linguistic research [16], [17]. Despite the fictional nature of communication in literary texts, they are still considered as mirrors of what is going on reality, and, therefore, are perceived as parallel to naturally occurring conversations.

#### A. Research Questions

The current study tries to offer answers to the following research questions:

- 1) To what extent does a computer-aided text analysis contribute to the analysis of fictional texts?
- 2) What are the ideologies communicated by function words in the selected play?
- 3) To what extent does Key Word in Context (KEWIC) offered by concordance contribute significantly to the understanding of the power of function words in fictional discourse?

#### B. Research Objectives

The answer of the abovementioned research questions constitutes the main objectives of the study as follows:

- 1) To highlight the extent to which computer-aided text analysis helps in deciphering the ideological weight of function words in Bond's *Lear*.
- 2) To clarify the complementary relation between critical discourse analysis and computer-aided text analysis.
- 3) To explore the persuasive and/or manipulative ideologies function words communicate in the text at hand.

In what follows, the paper provides the theoretical background as well as the review of literature relevant to the study of function words as carriers of ideologies in discourse in Section II. Section III provides the methodology adopted in this paper by offering the analytical procedures, the rationale, and the description of the selected data. Section IV is dedicated to the analysis of the selected data. Section V presents the discussion of the results reported in this study, and Section VI is the conclusion of the article, which also provides recommendations for further research.

## II. LITERATURE REVIEW

### A. Computer-Aided Text Analysis (CATA)

The employment of a computer-aided text analysis (hereafter, CATA) proves useful for the understanding of the thematic and ideological message of texts in corpus linguistics [18]. Applying the different computer software to the analysis of texts serves to facilitate the process of interpretation pertaining to these texts, which in turn, helps decode the ideological significance encoded in the linguistic expressions, either at the word level or the sentence one. Such ideological significance carried by words and/or sentences is difficult to be deciphered if it is approached manually; that is, without the work of computer [19]. Nowadays, computer software occupies an integral part in the field of linguistics. The importance of computer software is not only confined to the computational linguistics studies, but they have their contributive part in the other fields of linguistics, including pragmatics, semantics, morphology, and discourse studies [20]. This is because computer software such as concordance can efficiently foster the analytical process in large data texts in a way human performance alone proves to be inadequate [21].

It is worth mentioning that CATA offers various analytical tools and options. One of these analytical options is the Frequency Distribution Analysis (FDA), which entirely functions to provide the number of occurrences a searched item occurs in a text. According to [22], the frequency analysis that can be generated by concordance makes it available for analysts to have a general look about the textual nature of a specific lexis in a text. This further serves to direct the analytical wheel towards the significant precedence of one occurrence over another, which is computationally enabled by the second variable offered by CATA, that is, the variable of Key Word in Context (KWIC). The variable of KWIC provides the contextual picture in which a specific searched word occurs. In other words, KWIC clarifies the contextual environment of the searched items, which, in turn, helps arrive at the ideological significance pertaining to words and/or phrases [23]. A further analytical option realized by CATA is Content Analysis (CA). For Weber [24], content analysis serves to categorize the different words into classes according to their semantic features. This content or semantic categorization is very contributive to the thematic intelligibility of texts, as it classifies words into semantic groups that ultimately function to achieve a comprehensive understanding of the thematization of texts, particularly large data texts such as the literary ones, as is the case with the play under investigation.

In light of this paper, CATA is enabled by the program of Concordance to provide the analytical options listed above. Concordance is a computer software that enables analysts and users to collect, access, classify and analyze the different types of texts, specifically those that abound in large amount of data [25], [26]. Concordance, therefore, can retrieve all occurrences of a searched lexis in a text, can display the contextual environment of any word, and can categorize all words according to their semantic content [27]. By deriving the frequency distribution of the four function words under investigation, which is accompanied by both the use of KWIC and content analysis, the ideologies the four function words carry will be revealed.

### B. Ideology and Discourse

Ideology has been a main area of concern for discourse and ideological discourse analysts within linguistic studies adopting critical discourse analysis as their theoretical framework [28], [29], [30], [31]. These studies have emphasized the connection between language, power and ideology. They point out that ideology is enacted through language and helps to legitimate domination. They argue that any aspect of structure could be ideologically significant; that is, all linguistic expressions can communicate ideological significance, which can also be manifested phonologically, syntactically, semantically, pragmatically, etc. Highlighting the significant role of institutionalized ideology, van Dijk [32] postulates that ideologies are specific types of ideas that form what he terms 'belief systems' or 'social representations'. He maintains that such beliefs cannot only perceived as belonging to individuals, but they also form the general cognitive and background shared by groups.

According to van Dijk [33], ideology is a mediator element between society and discourse. Such a relationship serves to facilitate and activate the linguistic intelligibility among the different members of the group. Forming and agreeing upon a unified ideological background within the in-group is a prerequisite that helps to establish a successful act of communication produced by the different representations of discourse. By means of ideology, relations of power and dominance are motivated in discourse; power relations are produced and practiced. Ideology is employed also to persuade and/or manipulate; in both cases, it is a medium through which the powerful exercise their power and the powerless resist. Consequently, one can find different discursive practices that tend to manipulate and others to persuade. The targets sought beyond each type determine the type of ideology practiced in the process of communication, that is, whether or not the benefit is both speaker and hearer-oriented (persuasion), or only speaker-oriented (manipulation). Van Dijk maintains that ideology intelligibility among the members of the group leads to a successful participation of the individual member towards the ideological principles shared by the group as a whole. This ideological participation tends to create a discursive cohesion among discourse participants, which, for Khafaga [34], accentuates the idea that individually-based ideology affects and is affected by the institutionalized ones; it is an unremitting process of influence that emphasizes ideology-discourse reciprocity.

### C. Fairclough's Grammatical Approach to Critical Discourse Analysis

In discussing the role of function words and their ideological significance in discourse studies, Fairclough [11] proposes four sets of items that can be used for the linguistic analysis of function words in texts and discourse. The first set requires the investigation of the experiential values of texts, which necessitates the analysis of pronouns and modality. The second set involves the analysis of the relational values of texts, and entails a focus on the grammatical features, such as the type of sentence used, i.e. declarative, interrogative, or imperative; the type of modality: truth, obligation, or possibility modality; and the type of pronouns used in discourse. The third set of items constitutes the study of the expressive values grammatical features have, including expressive modality. The fourth set comprises the analysis of the different types of sentences used; for example, simple, compound, or complex, as well as the relationship between the various structures of sentences. Fairclough's sets of items abound in grammatical aspects relevant to produce an ideology-loaded type of discourse. Pronouns and modality are discursively employed to express, produce and maintain agency, particularly in the field of ideological/critical discourse studies [35], [36], [37]. These studies clarified that the reason lies in the fact that agency is closely related to notions of power and domination, and it is difficult to find any ideological discourse that does not address issues of power, dominance, persuasion, and manipulation.

### D. Pronouns

Using pronouns in discourse is perceived as one way of communicating agency, which, in turn, operates as conduits of ideologies in discourse [38], [39]. The use of the pronoun 'I' serves to communicate the competency, authority and responsibility of the speaker, whereas the pronoun 'you' conveys domination among discourse participants. Concerning the pronoun 'we', Fairclough [11] argues that it is divided into two types: "inclusive 'we' and exclusive 'we'". The inclusive 'we' includes both the reader and the writer (speaker and hearer), whereas the exclusive 'we' refers to the writer (speaker) only without any reference to the other participants in discourse. Pinto [40] further affirms that the use of the inclusive 'we' indicates that the goals and benefits of the whole group is more important than the benefits of the individual, whereas the exclusive 'we' establish a border between the benefits of the individuals and those of the group. Pinto maintains that in the case of manipulative discourse, the inclusive 'we', once employed, masks imposition under the guise of cooperation, as it manipulatively shows that the benefits of the group is inferior than those of the individual. Therefore, the inclusive 'we' is discursively used to show unity, solidarity and competency, whereas the exclusive 'we' indicates distance and separateness between the speaker and his/her addressees.

### E. Modality

According to [11], modality is classified into "relational modality" and "expressive modality." Such categorization, for him, is based on the type of authority exercised by the speaker over his/her addressees. In relational modality, the authority is

practiced by one participant over another, while in expressive modality; the focus is on the speaker's authority in terms of the truth of the propositional content of the linguistic expression. He maintains that it is not only through modal verbs that modality can linguistically be communicated, but it can also be expressed by other grammatical tools, including adverbs and tense. For Fowler [41], modality has four types: truth, obligation, permission and desirability. Truth modality can be expressed by modal auxiliaries represented in 'will', adverbs of certitude such as 'certainly'. This type of modality shows that the speaker's assumption is completely true. Truth modals are used to express a high level of certitude. Obligation modality can be realized by the use of some modal auxiliaries, such as 'must', 'should' or 'ought to'. Obligation modality draws the recipient's attention to the necessity of carrying out the speaker's proposition. Permission modality can be presented by the modal auxiliaries, such as 'can' and is used to give their participants permission to carry out their propositions. As for desirability modality, it concerns itself to clarify the speaker's status of accepting or refusing what is communicated by his/ her proposition.

#### F. Previous Studies

The use and application of computer software in general and concordance in particular to the analysis of large data texts such as the fictional ones has been the focus of many studies within the field of linguistics. [42], for example, used data mining to investigate the semantics, rhythm and pace in narrative writing. They clarified the extent to which input data can significantly contribute to the final interpretation of fictional texts, and concluded that data mining via visualization can mirror the semantic categorization a fictional text carry. Another study conducted by [43] explored the extent to which concordance is effective in the analysis of fictional discourse. This study demonstrated that concordance can be applied to large data texts in order to generate authentic and credible results that contribute to the interpretation of texts. This study focused on two analytical variables generated by concordance: frequency distribution analysis and key word in context. The study concluded that the application of concordance to the study of literary genres contribute to the thematic and ideological understanding of texts.

Within the scope of translation studies, [44] showed the significance of using modern technological software in producing credible versions of translations. The study recommended the incorporation of computer software into the process of teaching and learning university courses of translation in the different academic institutions in Saudi Arabia. Furthermore, [45] conducted a research in which they explored the impact of CALL software (computer assisted language learning) on the performance of students who major English as a foreign language (EFL) in Saudi university. This study clarified that the application of CALL to EFL settings influences the various learning outcomes of EFL students positively. The study is based on testing the effectiveness of using the two computer programs of Snagit<sup>TM</sup> and Screencast on acquiring the skill of reading. The study revealed that the application of the two computer software serves to improve the academic level of students, by fostering the linguistic skills pertinent to the acquisition of the skill of reading. The study

also reported that such technological incorporation into EFL course functions to develop not only the linguistic competence of EFL students, but also their communicative skills. This study concluded by recommending the application of the different CALL software to the different EFL courses in the context of Saudi universities.

Within courtroom settings and legal discourse studies, [46] conducted a research in which they explored the extent to which concordance helps investigate the linguistics of opening statements, by decoding the various ideologies beyond the semantic proposition of the linguistic expressions. This study employed a frequency distribution analysis to arrive at the hidden meanings and the pragmatic purposes targeted as a result of the recurrent employment of particular lexical items in the analyzed texts. The aforementioned studies show the effective and contributive role computer software play in the field of linguistic studies, either on fictional texts or outside the scope of fiction, i.e., in EFL and courtroom settings. Such contributive significance is anticipated to be extended in this study to present a further dimension of the application of CATA to decipher the ideologies of function words in fiction.

It is perspicuously evident that all previous studies have employed CATA software into the linguistic analysis of texts. Some of these studies focused on fictional texts, whereas other studies have presented discussions on legal texts, EFL settings, etc. One observation concerning related literature is that it did not use CATA software within the scope of pragmatics; that is, none of the previous studies has employed CATA software to explore the different pragmatic purposes in discourse. This last point is the core concern of the current study, which constitutes the research gape attempted to be addressed in this article.

### III. METHODOLOGY

#### A. Data and Rationale

The data in this study encompasses Edward Bond's *Lear* [47]. The play is structured around 4 acts that constitute eighteen scenes forming the whole production of the dramatic work. The rationale beyond the selection of this play in particular is due to the fact that it witnesses a significant usage of some grammatical aspects that prove indicative in communicating different ideologies, varying from the persuasive to the manipulative. This has been marked by the frequency analysis added in this article, which displays an ideological weight for such grammatical aspects; they are not employed chaotically in the dramatic dialogue of the play, but are vessels of ideology. Significantly, Bond's *Lear* exhibits a remarkable ideological discourse that requires a concise linguistic analysis, specifically with regard to the dexterous employment of pronouns and modality to communicate ideologies.

#### B. Research Procedures

Three procedural steps were followed in the analysis of the selected play. The three stages revolved around the use of three variables of CATA: frequency distribution analysis (FDA), key word in context (KWIC), and content analysis (CA). The first stage constituted preparing the text of the selected play, by uploading it electronically so as to be ready

for analysis. This stage offered a general idea of the way the discursive atmosphere of the play is communicated via the conversational turns of its characters. In the second stage the four function words (I, we, will, must) were electronically highlighted to mark their occurrence in the play. This was conducted by using a frequency distribution analysis to the whole play-text, wherein occurrences of each searched item were monitored. The third stage presented an interpretative task in which all highlighted items were discussed in terms of their indicative occurrences within the particular contextual environment in which they occur. After the three analytical stages, findings were firstly reported, and then interpreted in terms of the extent to which the searched items were contributive to conveying specific persuasive and/or manipulative ideologies. Significantly, all emphases (italicized) in the selected extracts in the analysis part are made by the author for analytical reasons.

C. The Frequency Analysis

During the process of analysis, the work of concordance was confined to reflecting a frequency distribution analysis for the searched lexical items that marked as indicative in the study of pronouns and modality as ideology carriers. This frequency analysis is conducted by concordance. Concordance facilitates the process of accessing and examining large data texts in order to arrive at credible and concise results that could be difficult to be realized if the analysis is conducted without the help of computer software [48], [49]. The options provided in concordance here were only to mark the word in its contextual environment. This context was determined by only five words before and other five words after the searched item. This functions to give a brief about the nature of the linguistic context in which the word occurred in text. Kennedy [50] argues that concordance is a software that serves to generate all occurrences of a given word or lexis in a corpus. Further, Hockey [51] points out that a concordance or a frequency analysis is produced by virtue of the searched item and the contextual environment in which it occurs. Concordance, for him, offers what is called KWIC (Key Word in Context), that gives much information about the searched word in its different contexts in text. This, in turn, serves to extend the interpretative process, opening new horizons that help better interpret the linguistic expression.

IV. DATA ANALYSIS AND RESULTS

This part constitutes two analytical strands: pronouns and modality, both of which reflect the extent to which pronouns and modality are carriers of specific ideologies, persuasive and/or manipulative in the discourse of the selected play.

A. Pronouns

This part of the analysis presents two pronouns that are used in the discourse of Bond's Lear to communicate specific ideologies varying from persuasion to manipulation: the pronoun 'I' and the pronoun 'we'.

1) *The pronoun I*: The pronoun 'I' is used in Bond's play to communicate specific ideologies, whose core concern varies from persuasive ideology to manipulative one. The former aims to get the addressees persuaded of some particular idea, whereas the latter constitutes the realization of

the speaker's desire even if it runs counter to the recipients' attitudes. Thus, one can say that the first type is addresser-/addressees-benefit oriented, while the second type is only an addresser-benefit oriented. Consider the following extract:

Lear. I knew it would come to this! I knew you were malicious! I built my wall against you as well as my enemies! (Lear (henceforth, L)., p. 7)

Lear manipulates the first-person pronoun 'I' to persuade his participants of the legitimacy of building his wall. He employs the deictic 'I' to show that he was right when he decided to build the wall. Lear's use of the past tense in *knew* and *built* also serves to prove his competency, and to clarify that he was far-sighted when he started to build the wall. Lear puts himself in the position of the agent and puts his two daughters in the position of the patient. Through using agency, Lear tries to communicate that it is he who has the competency to foresee the future and to give judgment. In this way he tries to make them accept everything he is going to allege. The following tables present a frequency analysis of the thematic use of the pronoun 'I', through which the different types of ideologies communicated by the first person singular 'I' can be caught by the context in which it occurs.

TABLE I. A FREQUENCY DISTRIBUTION ANALYSIS OF THE MANIPULATIVE 'I'

| I.....TF (555)            |      |                          |      |
|---------------------------|------|--------------------------|------|
| context                   | word | context                  | line |
| when I was young.         | I    | stopped my enemies       | 103  |
| my sworn enemies.         | I    | killed the fathers       | 176  |
| me. And when              | I    | killed the fathers I     | 178  |
| when I killed the fathers | I    | stood on the field among | 178  |
| This is not possible!     | I    | must be obeyed!.         | 238  |
| two bodies with them.     | I    | Knew it would come       | 289  |
| It would come to this     | I    | Knew you were malicious! | 289  |
| you were malicious!       | I    | Built my wall against    | 290  |
| That's how                | I    | crushed the fathers      | 341  |
| O why did                 | I    | cut his tongue out?      | 625  |

Note: TF means total frequency of the searched word

TABLE II. A FREQUENCY ANALYSIS OF THE PERSUASIVE 'I'

| I.....TF (555)      |      |                           |      |
|---------------------|------|---------------------------|------|
| Context             | word | context                   | line |
| So stay. LEAR .     | I    | could have a new life     | 1048 |
| wall down, and      | I    | had to stop that          | 2001 |
| hand.) And now      | I    | must move them            | 2003 |
| Murderer. And now   | I    | must begin again.         | 2518 |
| must begin again.   | I    | must walk through my life | 2519 |
| shivering in blood, | I    | must open my eyes         | 2522 |
| hurry on. LEAR.     | I    | am the King! I kneel      | 2765 |
| what she's doing!   | I    | must tell her             | 2798 |
| eyes, my eyes!      | I    | must stop her             | 2805 |
| all my mistakes,    | I    | understand all that       | 3255 |
| As fit as I Was.    | I    | can still make my mark    | 3662 |

As indicated from the two tables above, Table I shows that only 10 occurrences out of 555 are employed to convey manipulative ideologies. Table II clarifies that 11 occurrences are used to indicate persuasion. The contextual environment in which the deictic 'I' occurs reflects the extent to which it is employed to achieve persuasion and/or persuasion, which is clarified by the thematic and content analysis of the KWIC pertaining to the pronoun 'I'.

2) *The pronoun 'we'*: The pronouns 'we', 'us', and 'our' are used inclusively in Bond's play to establish relations of agreement, solidarity, and inclusion; and exclusively to show power, distinction and authority. These pronouns are among the main rhetorical strategies speakers used to communicate ideology, or as [52] puts it pronouns are "one of the major tools of persuasion used by politicians" (P. 37). Consider the following extract:

Cordelia. You were here when they killed my husband. I watched them kill him. I watched and I said we won't be at the mercy of brutes anymore, we'll live a new life you must stop speaking against us. (L., p. 83).

Cordelia tries to convince Lear to stop talking against the new government. She starts her persuasive ideology with clarifying a number of irrationalities committed against her on the hands of Bodice and Fontanelle. She involves Lear in her speech as a witness you were her when they killed my husband. Cordelia then uses the pronouns 'we' and 'us' both inclusively in we won't be at the mercy of brutes anymore and 'we'll live a new life; and, exclusively, in you must stop speaking against us to show intimacy and solidarity with the old king in the first two utterances, and to threaten the him in the third utterance so as to stop him talking against her. Cordelia's use of the first-person plural pronoun also indicates that she is authoritative enough to speak on behalf of others in the government, which reflects her power and domination. Cordelia's first utterance we won't be at the mercy of brutes anymore emphasizes her power and determination that she will never allow herself to be at the mercy of brutes again. Her second utterance we'll live a new life is an attempt to manipulate Lear's mind through a seductive promise of a new life in the future in which he will live in peace under her rule. The connection between the truth modal 'will' and the pronoun 'we' emphasizes her ability to carry out what she promises to do. Cordelia's exclusive 'us' in against us serves to show her power and domination over the situation. She establishes herself as a leader who has the complete access to speak on behalf of others in the government. Tables III and IV offer a frequency distribution analysis and a KWIC of both the inclusive and exclusive 'we'.

TABLE III. A FREQUENCY ANALYSIS OF THE INCLUSIVE 'WE'

| WE.....TF (104)    |      |                       |      |
|--------------------|------|-----------------------|------|
| Context            | Word | Context               | Line |
| How could          | we   | ever be free?         | 105  |
| and I said         | we   | Won't be at the mercy | 3478 |
| brutes any more,   | we   | will live a new life  | 3479 |
| much suffering But | we   | made the world        | 3531 |
| and fragile and    | we   | have only one thing   | 3532 |

TABLE IV. A FREQUENCY ANALYSIS OF THE MANIPULATIVE 'WE'

| WE.....TF (104)                |      |                               |      |
|--------------------------------|------|-------------------------------|------|
| Context                        | Word | Context                       | Line |
| CORDELIA. When                 | we   | have power these things won't | 1867 |
| don't build the wall. Cordelia | we   | must. Lear.                   | 3499 |
| Tell her . CARPENTER.          | We   | came to talk to you           | 3508 |
| There are things               | We   | have other opponents          | 3539 |
| and tell you this before       | we   | put you on trial              | 3542 |

The two tables show that the pronoun 'we' is used inclusively 5 times (Table III), and exclusively 5 times (Table IV) out of 104 occurrences. In both cases the pronoun 'we' is employed to carry manipulative ideology. Again, this manipulative usage of the pronoun 'we' is demonstrated through the variable of KWIC. That is, by looking at the contextual environment in which this pronoun occurs in text.

*B. Modality*

Two types of modality are discussed in this section: obligation modality and truth modality. Both types expresses agency and are carriers of ideology.

1) *Obligation modality*: The obligation modals 'must' and 'should' are dexterously employed in Bond's Lear to reflect the power of the speaker over his participants. Speakers use these modals to impose their own ideology over their recipients and to direct their behavior towards a complete obedience and submission to their own purposes [53]. The use of obligation modality dominates the discourse of oppression in which powerful characters use these modals to practice their domination over those who are powerless. Notice the following extract:

Bodice. We must go to our husbands tonight. We must attack before the wall's finished. We must help each other. (L., p. 8).

Bodice is talking to her sister, Fontanelle, with regard to their plan to attack Lear's army and to wrest him from his kingdom. Bodice uses the obligation modal 'must' three times to convey the necessity of doing what they decide to do, and to emphasize that attacking their father becomes urgent so as to stop the acts of building on the wall. Bodice's use of the obligation modals in we must go to our husband, we must attack before the wall's finished, and we must help each other is to emphasize her power and domination over her sister. She directs her even in her relation with her husband. The first-person plural pronoun 'we' which precedes the modals emphasizes solidarity, which Bodice tries to communicate to Fontanelle in order to make her sure that she seeks her interest; this in turn functions to push Fontanelle to carry out what her sister demands quite willingly. The obligation modal 'must', thus, is manipulated to channel manipulative ideology. The following frequency analysis adds more clarification for the manipulative use of the obligation modal 'must', both in the affirmative and negative forms.

TABLE V. A FREQUENCY ANALYSIS OF 'MUST'

| MUST.....TF (100)                |      |                                      |      |
|----------------------------------|------|--------------------------------------|------|
| Context                          | Word | Context                              | Line |
| (To WARRINGTON.)<br>You          | must | deal with this fever.                | 64   |
| the FIRING SQUAD).<br>They       | must | work on the wall                     | 123  |
| to help me, but you              | must | let me deal with the                 | 129  |
| But the work's slow. I           | must | do something to make                 | 136  |
| kind or merciful. I              | must | build the fortress.<br>Bodice        | 165  |
| and now you                      | must | understand ! BODICE.                 | 168  |
| Wall , wall, wall this wall      | must | be pulled down<br>Fontanelle.        | 227  |
| This is not possible! I          | must | be obeyed!<br>WARRINGTON.            | 238  |
| Fontanelle are left alone.<br>We | must | go to our husbands<br>tonight        | 322  |
| terrified of him. Bodice.<br>We  | must | attack before the wall's<br>finished | 324  |
| the Council of war. We           | must | help each other.<br>Goodbye          | 327  |
| know what she's doing! I         | must | tell her - write to                  | 2798 |
| My eyes, my eyes! I              | must | stop her before I die                | 2805 |

TABLE VI. A FREQUENCY ANALYSIS OF "MUSTN'T"

| MUSTN'T.....TF (9)    |         |                         |      |
|-----------------------|---------|-------------------------|------|
| Context               | Word    | Context                 | Line |
| this act. Bodice. You | Mustn't | talk like that in front | 151  |

Tables V and VI demonstrate that 13 occurrences of the affirmative 'must' and 1 occurrence of the negative 'mustn't' are used as carriers of manipulative ideology in the discourse of the novel. Despite its very low frequency, the negative obligation modal is highly indicative in communicating manipulative ideologies. The indication here lies in the fact that the high frequency of one word is not an indicator that this word is thematically indicative. However, low frequency words are also very indicative in many cases.

2) *Truth modality*: Many characters in Bond's play use the truth modal 'will' to reassert their trustworthiness, and to prove the validity of their speech. In Lear, the modal 'will' is used to communicate both persuasive and manipulative ideology. Here are some extract:

Fontanelle. I know you will get on with my husband. He's very understanding; he knows how to deal with old people.

Bodice. You will soon learn to respect them like your sons. (L., pp. 5-6).

Both Fontanelle and Bodice try to convince their father to bless their secret marriage from his hereditary enemies; the duke of North and the duke of Cornwall. Both of them know for sure that their father refuses their marriage, so they uses

the truth modal 'will' to influence their father's opinion towards their husbands. Fontanelle's utterance I know you'll get on with my husband signifies to state her determination to marry Cornwall. Bodice's utterance you'll soon learn to respect them like your sons is another trial to make her father bless her marriage from North. Bodice's use of the pronoun 'you' shows her power in delivering her message to her father. The two daughters try to remove the feeling of fear that occupies Lear's mind against the two husbands so as to accept their marriage without any objection. Tables VII and VIII present a frequency distribution analysis of the manipulative and persuasive 'will'.

TABLE VII. A FREQUENCY ANALYSIS OF MANIPULATIVE 'WILL'

| WILL.....TF (77)                |      |                           |      |
|---------------------------------|------|---------------------------|------|
| Context                         | Word | Context                   | Line |
| keep our enemies out.<br>People | will | live behind this wall     | 107  |
| live in peace. My wall          | will | make you free             | 109  |
| you can be -because you         | will | have my wall.             | 158  |
| LEAR. My enemies                | will | not destroy my work       | 264  |
| When I'm dead my people         | will | live in freedom and peace | 271  |

TABLE VIII. A FREQUENCY ANALYSIS OF PERSUASIVE 'WILL'

| Will.....TF (77)       |      |                            |      |
|------------------------|------|----------------------------|------|
| Context                | Word | Context                    | Line |
| Fontanelle. I know you | will | Get on with my husband     | 206  |
| Straighter! Bodice you | will | Soon learn to respect them | 213  |
| look after you. You    | will | live in decent quietness   | 3235 |
| LEAR. The wall         | will | destroy you                | 3505 |

Tables VII and VIII show that the total frequency of the truth modal 'will' is 77; only 9 occurrences are indicative in expressing particular ideologies, 5 of which are employed to convey manipulative ideology (Table VII), whereas 4 occurrences are used to communicate persuasive ideology (Table VIII). These two tables further emphasize the complementary relationship between the two variables of CATA used here: the FDA and the KWIC variables. To clarify this point, one can obviously notice that despite its ability to offer us the total frequency of a specific word, FDA still inadequate to help us better understand the indicative occurrence of a given word. Only through the variable of KWIC one can identify what is indicative and what is non-indicative among occurrences. This complementary nature of the two variables further strengthens the whole interpretative process of the analyzed text.

## V. DISCUSSION

The analysis demonstrates that pronouns and modals, sometimes, and within particular contexts, go beyond their grammatical and semantic functions to communicate and maintain particular pragmatic purposes and ideological meanings, including persuasion and manipulation. The four function words under investigation convey a specific type of ideology in the discourse of Bond's Lear. The following table adds more clarification.

TABLE IX. PRAGMATIC IDEOLOGIES OF FUNCTION WORDS IN BOND'S LEAR

| Type of function words | Linguistic manifestation | Type of ideology           |
|------------------------|--------------------------|----------------------------|
| Pronouns               | Pronoun 'I'              | persuasive<br>manipulative |
|                        | Pronoun 'we'             | manipulative               |
| Modality               | Obligation modality      | persuasive<br>manipulative |
|                        | Truth modality           | persuasive<br>manipulative |

As indicated from Table IX, communicating persuasive and manipulative ideologies is realized in Bond's Lear through pronouns, which manifest themselves in the pronouns 'I' and 'we'; each pronoun is employed to achieve a specific ideological and pragmatic purpose. The table also demonstrates that truth and obligation modalities are very indicative in communicating both persuasive and manipulative ideologies in the discourse of the play.

Other findings are also demonstrated in this study as follows:

First, the application of CATA software proves useful in extracting ideologies from language and helps better understand the power of function words, which, in turn, accentuates the analytical integration between discourse studies and computer, particularly in the linguistic analysis of large data texts. It is analytically evidenced that the two variables of FDA and KWIC are complementary in nature in the sense that the latter is a context-oriented that target the identification of indicative words generated by the total frequency analysis of the former. Significantly, both FDA and KWIC contribute to the linguistic analysis of literary texts, particularly to decipher the hidden ideologies beyond the semantic propositions of the mere linguistic expressions.

Second, the analysis demonstrated that function words, manifested here by pronouns and modality, have ideological significance in discourse. This goes in conformity with Fowler's [54] argument that there is a reciprocal relationship between language and ideology in the sense that each single linguistic unit can communicate specific ideology of its user. Ideology is usually there in language and the employment of particular linguistic expressions rather than others is ideological in nature, that is, it is produced in this particular way and in such a specific linguistic expression to communicate particular ideological meanings of the speaker/writer. Consequently, every single word can mirror the ideology of its user. In the context of this study, it is not only content words that communicate and maintain ideologies in discourse. However, function words contribute significantly in communicating and maintaining ideologies. In particular discourse contexts, function words cease to maintain their common semantic meaning to convey further ideological purposes.

Third, manipulative ideology is presented by personal pronouns ('I' and 'we'), and modality (obligation 'must' and truth 'will'). The pronouns 'I' and 'we' are used to show the

speaker's power and domination over his participants which facilitate his persuasive task. Obligation and truth modals are also used to express necessity and certitude. All these strategies are more representative in the discourse of oppression. This correlates with previous studies, such as [11], [20], and [46], which emphasize the ideological weight of pronouns and modality.

Fourth, persuasive ideology is presented in Lear through agency (pronoun I) and modality (must, will). Using agency through the pronoun 'I' reflects the desire of the speaker to express competency. Obligation and truth modals are used to express necessity and certitude, while negation is employed to expose the daughters' violence, disobedience and cruelty. These linguistic strategies serve to convey a persuasive ideology that can be said to be based on facts and past experiences. This also goes in the same direction with Sornig's [55] argument that persuasion can be realized by means of the different linguistic levels, including the grammatical one which constitutes the employment of grammatical aspects, such as the use of modality, deixis, negation, and passive structures.

## VI. CONCLUSION

This study offered a computer-aided text analysis to decode the ideological significance of function words represented by the pronouns (I, we) and the modal verbs (must, will) in the discourse of Edward Bond's Lear. The study used three analytical strands: van Dijk's ideological discourse analysis, Fairclough's model of the grammatical aspects in the analysis of discourse, and a computer-aided text analysis, which is analytically enabled by the three variables offered by CATA: frequency distribution analysis (FDA), key word in context (KWIC), and content analysis (CA). The three approaches are analytically incorporated to explore the extent to which pronouns and modality contribute to the communication of specific ideologies that vary from persuasion to manipulation in the selected text. The analysis of the selected play has evidenced the employment of pronouns and modality for ideological purposes. In terms of the use of pronouns, the analysis identified their linguistic weight as carriers of ideological agency. Sometimes, these pronouns are used inclusively, as is the case for the inclusive 'we', and in other discursive cases they are used exclusively, as is the case for the exclusive 'we'. Also, the first person singular pronoun 'I' is analytically used to communicate competency. With regard to the use of modality, the analysis showed that truth modals are used to communicate the ideological agency of certitude on the part of the user, whereas obligation modals are employed to exercise agency via expressing a high level of commitment, both on the part of speakers/writers and the hearers/readers alike. The analysis further demonstrated that pronouns and modality in the current study are employed to achieve two types of ideology: manipulative and persuasive; the former always targets the benefits of speakers/writer, while the latter often serves the benefits of all discourse participants.

This paper recommends further applications of other variables of CATA, such as LWIC (Linguistic Inquiry and Word Count) and DICTION (software package that contains

31 predefined Dictionaries) to the textual and thematic analysis of other types of function words, such as prepositions, conjunctions, and demonstratives. This might reveal different and/or similar findings than what is approached in this paper.

#### ACKNOWLEDGMENT

The researcher would like to thank Prince Sattam bin Abdulaziz University in Saudi Arabia alongside its Scientific Research Deanship for all technical support it has provided to complete this study.

**Abstract**—Road traffic injuries and deaths cause considerable economic losses to individuals, families, and nations as a whole. One of the strategies needed to curtail these fatalities is the surveillance of helmetless motorcyclists, which is carried out by developing an automatic detection system based on computer vision. Generally, this system consists of three subsystems, namely, moving object segmentation, motorcycle classification, and helmetless head detection. HOPG-LDB (Histogram of Oriented Phase and Gradient - Local Difference Binary) descriptor for this system produced good accuracy; however, it still has a drawback related to a large number of features. Based on these observations, this paper proposed an Adaptive Two-phase Mutation Binary Improved Fruit Fly Optimization Algorithm (ATMBIFFOA) to reduce the features. The ATMBIFFOA is a new feature selection algorithm that improved BIFFOA (Binary Improved Fruit Fly Optimization Algorithm) with an adaptive two-phase mutation algorithm. The BIFFOA produced good accuracy; however, weak in reducing feature dimension. The adaptive two-phase mutation algorithm was used to cover this weakness. The experiment results show that the proposed method can reduce the number of features and computation time effectively from BIFFOA. The proposed method produced motorcycle classification accuracy of 96.06% for the JSC1 dataset and 96.85% for the JSC2 dataset. As for helmetless head detection, the proposed method produced an average precision of 66.29% for the JSC1 dataset and 63.95% for the JSC2 dataset.

**Keywords**—Motorcycle classification; helmetless head detection; BIFFOA; two-phase mutation algorithm

## I. INTRODUCTION

Road traffic injuries and deaths cause considerable economic losses to individuals, families, and nations as a whole. Based on the current trends, these problems are predicted to continually occur for a long period. Furthermore, World Health Organization (WHO) published that traffic accidents were the 7th leading cause of death in the world, with 1.35 million mortality cases being recorded yearly [1]. In Indonesia, the number of deaths caused by two and three-wheel motorcyclists was approximately 74% among other traffic accidents [1]. The main cause of this type of accident is the head injury sustained due to the unyieldingness of the use of helmets. WHO reported that the use of helmets reduces the risk of 69% of head injuries [1]. Most countries mandated the use of helmets; however, many motorcyclists still violate the regulation and escape the consequences, because of the difficulty of direct surveillance on the highway, which is not

monitored for a full day. Meanwhile, research in automatic detection based on computer vision has been growing rapidly, to curtail these problems.

In general, the study of detection of motorcyclists not wearing helmets was divided into two subsystems, namely motorcycle detection and helmetless head detection [2]. The feature extraction process gives an impact on the performance of both subsystems. Previous studies have used hand-crafted features and a convolutional neural network (CNN). The Histogram of Oriented Gradient (HOG) descriptor is a hand-crafted feature that results in relatively high accuracy. The author in [3] used HOG to classify vehicles in various environments and views. The author in [4] used HOG in both subsystems which resulted in good accuracy, but it still incorrectly detects distant objects. The author in [5] reported that HOG produces higher accuracy than Wavelet Transform (WT), Local Binary Pattern (LBP), and their combination in helmetless head detection. The author in [6] reported that HOG produces higher accuracy than Scale-Invariant Feature Transform (SIFT) and LBP in both subsystems.

Currently, the CNN method is popular for classification and detection in various domains. The author in [7] used CNN for motorcycle detection to overcome the problem of changing lighting and poor video quality. CNN was also used for helmetless head detection with various models, for example, AlexNet [8], VGG16 [9], VGG19, Inception V3, and MobileNets [10]. The author in [11] combined HOG and LBP for vehicle classification, and compared hand-crafted features (combination of HOG, LBP, and Haralick) and Custom CNN for helmetless head detection. The result showed that the method produces higher accuracy than HOG and LBP for motorcycle classification. For helmetless head detection, Custom CNN is superior in terms of accuracy and hand-crafted features are superior in terms of prediction time with relatively good accuracy. In addition, [12] compared several hand-crafted features (HOG, LBP, and Gabor) and CNN for vehicle classification. The result showed that the HOG produces better accuracy than other descriptors and CNN.

However, several authors stated that the HOG lacks to deal effectively with images of varying lighting [13], and different local patterns [14]. This ineffectiveness can be solved by combining HOG, Histogram of Oriented Phase (HOP), and Local Difference Binary (LDB) descriptors called Histogram of Oriented Phase and Gradient - Local Difference Binary (HOPG-LDB) [15]. The result of the experiment showed that

\*Corresponding Author

the HOPG-LDB descriptor increases the accuracy of the HOG, however, it still has a drawback related to a large number of features. The author in [16] stated that one of the preprocessing techniques that reduce these numbers is feature selection. The author in [17] stated that feature selection techniques are divided into 2, namely filters and wrappers. The author in [18] reported that the wrapper method tends to provide better performance than the filter. This technique can significantly improve the selection of relevant features [19].

The author in [20] reported that Binary Improved Fruit Fly Optimization Algorithm (BIFFOA) feature selection produces a good performance. Based on the experiment of this method compared with other algorithms, namely binary Gray Wolf Optimization (bGWO), Binary Gravitational Search Algorithm (BGSA), Binary Bat Algorithm (BBA), Binary Salp Swarm Algorithm (BSSA), Binary Grasshopper Optimization Algorithm (BGOA), Genetic Algorithm (GA), Particle Swarm Optimization (PSO), Correlation-based Feature Selection (CFS), Fast Correlation-Based Filter (FCBF), F-Score, Information Gain (IG), and spectrum. The results showed that the BIFFOA has the best accuracy, however, weak in reducing feature dimensions.

A solution for reducing feature dimensions was proposed in [21], which integrated the Gray Wolf Optimizer algorithm (GWO) and two-phase mutation (TMGWO). The first phase mutation is used to reduce feature dimensions and the second attempt to increase accuracy. The experiments of this method were compared with other algorithms, namely BBA, Binary Crow Search Algorithm (BCSA), binary Gray Wolf Optimization Algorithm (bGWOA), binary Whale Optimization Algorithm (bWOA), Discrete Particle Swarm Optimization (DPSO), Flower Algorithm (FA), Multi-Verse Optimization (MVO), PSO, and Non-Linear Particle Swarm Optimization (NLPSO). The results showed that the TMGWO produces the best accuracy and second-best feature reduction compared to other methods.

Detection of motorcyclists not wearing helmets in real-time is required the high accuracy and speed. The addition of a feature selection process can improve this performance. BIFFOA feature selection produced a good performance; however, weak in reducing feature dimension [20]. This weakness can be solved by adding a two-phase mutation algorithm. This study aims to add a feature selection process to detect motorcyclists not wearing helmets. The addition of the proposed feature selection is to reduce the number of features so the computation time of motorcycle classification and helmetless head detection can be reduced. The main contributions of this paper are:

- Adaptive Two-phase Mutation Binary Improved Fruit Fly Optimization Algorithm (ATMBIFFOA) is proposed. This algorithm is a fusion of BIFFOA and an adaptive two-phase mutation algorithm.
- An algorithm of adaptive two-phase mutation that is modified from a two-phase mutation is proposed.
- The ATMBIFFOA feature selection is added after the feature extraction process to reduce features in the motorcycle classification and helmetless head detection.

This paper is organized as follows. Related work is presented in Section II that is divided into two parts: motorcycle detection and helmetless head detection. Section III explains the dataset used, the proposed algorithm, and the evaluation methods. In Section IV, we present the experimental result and discussion. Finally, the main conclusion is introduced and future work is suggested in Section V.

## II. RELATED WORK

In general, this study is divided into two subsystems: motorcycle detection and helmetless head detection.

### A. Motorcycle Detection

Motorcycle detection has concerned three processes: vehicle segmentation, feature extraction, and classification. The author in [22] used three shape features: length, width, and their ratios to categorize vehicles into five groups. The result received from the usage of the decision tree (DT) classifier confirmed high accuracy, however, the features had been now no longer able to differentiate bicycles, motorcycles, and tricycles. The author in [23] used the features of length, width, area, diameter, and the ratio of distance to decide the object's center of mass and its main axis length. The classification method used a multilayer perceptron (MLP) to categorize the vehicles into three categories: heavy and mild duties, and motorcycles.

The author in [24] used the area feature to categorize motorcycles and others. Meanwhile, the author in [25] proposed a way that specializes in calculating the number of motorcycles on the street in real-time. The features used are area, height, and width to categorize motorcycles and non-motorcycles.

The author in [6] compared a few descriptors: HOG, SIFT, and LBP in classifying motorcycles and non-motorcycles. The effects confirmed that the HOG descriptor has exceptional accuracy. The author in [26] compared HOG, Speeded Up Robust Features (SURF), SIFT, and LBP in motorcycles detection. It has a look at extensively utilized information of images taken from in front, besides, and at the back of motorcycles. The result confirmed that the HOG descriptor has better accuracy.

A observe through as in [27] proposed a system that categorized vehicles into four categories: cars, vans, buses, and motorcycles. The system used Intensity Pyramid-based HOG (IPHOG) descriptor and support vector machine (SVM) classifier. The outcomes confirmed that the situations of climate and light converting have decreased accuracy than the normal condition.

The author in [28] used the LBP descriptor and SVM classifier to locate motorcycles. This descriptor became as compared with SURF, HOG, and Haar Wavelet. The outcomes confirmed that the proposed method has higher accuracy than the others. The author in [5] proposed a WT descriptor that became as compared with LBP, HOG, and SURF. The outcomes confirmed that the WT descriptor has higher accuracy than the others.

The author in [29] proposed a combination of shape and color features comprising of area, the ratio of width and height,

and color deviation standard. These features served as entering for the k-nearest neighbors (KNN) classifier to decide the motorcycles and non-motorcycles. The proposed approach becomes capable of calculating the wide variety of passengers on a motorcycle. The outcomes confirmed mistakes in type due to the fact the data had been taken from afar, overlapping vehicles, and the passenger sitting too near the rider. The author in [11] concatenated HOG and LBP with sequential minimum optimization (SMO) for training the SVM classifier. The outcomes display that the combination of those descriptors produced higher accuracy than the HOG and LBP descriptors. The author in [15] concatenated HOG, HOP, and LDB descriptors with MLP classifier. The results show that the proposed descriptor has higher accuracy than HOG, HOP, LDB, HOG-HOP, HOG-LDB, and HOP-LDB descriptors. Moreover, the proposed method has higher accuracy than in [5], [6], and [11].

CNN has additionally been used for motorcycle detection. The author in [30] used CNN which specializes in jam situations. The CNN is also used in [7] to address numerous lights and bad video quality. The take a look at outcomes displays that the accuracy generated is better than hand-crafted features, however, the computation time is much longer.

### B. Helmetless Head Detection

Helmetless head detection has involved three stages: ROI (region of interest) determination, feature extraction, and classification. The ROI determination pursuits to check the region round a rider's head. The heads of the rider and passenger are above the motorcycle image; therefore, the studies focused at the top a part of the object. Once the head region is known, the following steps are feature extraction and classification.

The author in [24] used the circular hough transform (CHT) descriptor for helmetless head detection. The result confirmed that it error still occurs for the detection of two or extra passengers. The author in [5] proposed the HOG descriptor, and the dataset was taken in a static environment. The assessment was performed by comparing HOG, WT, LBP, WT+LBP, WT+HOG, LBP+HOG, and WT+HOG+LBP descriptors. The result confirmed that the HOG descriptor has the best accuracy. The author in [6] compared HOG, SIFT, and LBP descriptors. The outcomes confirmed that HOG has the best accuracy. However, the data were taken on a quiet road.

Some researchers have combined shape, texture, and color features to enhance accuracy. The author in [29] used features of arc circularity, average intensity, and hue. Data were taken from three recording conditions, which include near, far, and medium. It turned into located that the greatest mistakes had been from the data recording acquired from afar.

The author in [26] used the features of arc circularity, average intensity and hue, and Center Symmetric-Local Binary Pattern (CS-LBP). These features served as entering the KNN classifier for the classification of heads with and without helmets. The technique focused on troubles with data recording

taken from special angles withinside the front, besides, and back. However, the head images were cropped manually. The author in [31] extensively utilized arc circularity, average intensity and color, and HOG.

The author in [28] used geometric, shape, and texture characteristics. The study used a combination of CHT, LBP, and HOG descriptors. CHT is used to decide the geometric form of an image. This technique has a weak point that the incapability of detecting images of low resolution. The author in [15] used the HOPG-LDB descriptor that concatenated HOG, HOP, and LDB descriptors. The results show that the HOPG-LDB descriptor has higher accuracy than HOG, HOP, LDB, HOG-HOP, HOG-LDB, and HOP-LDB descriptors. Moreover, the proposed method has higher accuracy than in [5] and [6].

The author in [32] used CNN with the YOLOv2 model to detect riders without helmets. The author in [7] used the AlexNet model on each light and heavy traffic. The author in [8] extensively utilized the AlexNet model and inaccurate detections have been made for riders placing on hats. The author in [33] used the iter\_45, Inception-V3 network, and full ImageNet network models. The author in [34] proposed Faster Regions with Convolution Neural Network (R-CNN) for decreasing the computing time. However, inaccurate detections have been nevertheless made for bicycle riders. The author in [11] compared hand-crafted features (a combination of HOG, LBP, and Haralick) and Custom CNN. Custom CNN is advanced in terms of accuracy and hand-crafted features are advanced in terms of prediction time with pretty proper accuracy.

## III. MATERIALS AND METHODS

### A. Dataset

This study used two datasets, namely JSC1 and JSC2 taken from the rear and front of an object, respectively. Both datasets contain motorcycle and non-motorcycle images used for the input of motorcycle classification. The input of helmetless head detection used the motorcycle images. Fig. 1 shows some samples of both datasets.

The datasets were generated from the segmentation process of the video. This process consists of several stages, namely histogram equalization of video frames that have been converted to grayscale, Gaussian Mixture Model (GMM) to determine foreground, and morphological operations (opening and dilation) to remove noise. The author in [35] stated that GMM is robust to lighting changes. The first video for the JSC1 dataset was recorded on Cipinang Baru Timur Street at East Jakarta, Indonesia with a frame speed of 19.49 fps. The second video for the JSC2 dataset was recorded on Budi Raya Street at West Jakarta with a frame speed of 20 fps. Both videos have a resolution of 1280 x 720 pixels and a duration of 3 hours. Training data was generated from the first 2 hours and testing data was generated from the rest. This data division technique was also used in [6]. The number of the training and testing data are shown in Table I and Table II, respectively.

Fig. 1. Samples of Datasets.

TABLE I. THE NUMBER OF TRAINING DATA

| Dataset | Motorcycle Classification Subsystem |                | Helmetless Head Detection Subsystem |                     |
|---------|-------------------------------------|----------------|-------------------------------------|---------------------|
|         | Motorcycle                          | Non-motorcycle | Head with helmet                    | Head without helmet |

### B. Developed System

In general, the system for detecting helmetless motorcyclists is divided into 3 subsystems, namely moving object segmentation, motorcycle classification, and helmetless head detection. This study focuses on developing motorcycle classification and helmetless head detection, as shown in Fig. 2. The stage of the head detection in the helmetless head detection subsystem is begun the determination process of the

ROI of the head from the motorcycle image. The ROI limits are determined based on the minimum and maximum positions of the upper 1/3 of the blob image generated from the segmentation process. The resulting image was converted to a grayscale image and was enhanced by its contrast using CLAHE (contrast-limited adaptive histogram equalization). Fig. 3(a) is an example of a motorcycle image. Fig. 3(b) is the result of this process. The next step was to create two binary images with opposite intensities using thresholding and inverse thresholding, but some blobs still need to be filtered and fixed. Fig. 3(c) shows the result of this process. The filtering was carried out by morphological operations (opening and filling holes), removing blobs on the side and top edges, and removing too big blobs. Moreover, overly tall blobs were fixed by removing the bottom. Fig. 3(d) shows the result of this process. Edge detection of Laplace of Gaussian (LoG) is used for the next step with the results as in Fig. 3(e). After that, CHT is applied to both images, and then the results are combined on an ROI head image. An example of this result is as in Fig. 3(f). The classification in the head detection is used to classify the objects bounding box on the circular into the head and non-head. Classification in helmetless head detection is used to classify head objects into heads wearing a helmet and not wearing a helmet. Fig. 3(g) is an example of the classification of head detection. The author in [5] reported that the MLP classifier produces a good performance so this paper used it. The feature extraction process used the HOPG-LDB descriptor [15].

### C. Binary Improved Fruit Fly Optimization Algorithm (BIFFOA)

The author in [20] explained that BIFFOA is developed from the Improved Fruit Fly Optimization (IFFO) algorithm for the feature selection, by converting it from continuous to binary version. The author in [36] explained that the IFFO algorithm is improved from the Fruit Fly Optimization (FFO) algorithm that is used to determine global optimization. The weakness of the FFO algorithm is that the search radius on all iterations is the same. In the IFFO Algorithm, the search radius ( $r$ ) for each iteration is calculated using (1).

$$r = r_{max} \cdot \exp\left(\log\left(\frac{r_{min}}{r_{max}}\right) \cdot \frac{Iter}{Iter_{max}}\right) \quad (1)$$

where  $r_{max}$  and  $r_{min}$  are the radii of maximum and minimum, respectively.  $Iter$  represents the iteration, and  $Iter_{max}$  represents the maximum number of iterations. The author in [37] explained that  $r_{min} = (UB-LB)/2$  and  $r_{max} = 10^{-5}$ , where  $UB$  (upper bound) and  $LB$  (lower bound) value 1 and 0, respectively.

The initialization parameters in the BIFFOA algorithm are  $PS$ ,  $r_{max}$ ,  $r_{min}$ , and  $Iter_{max}$ . In addition, the initial swarm location is initialized by selecting the best solution, which is determined by the agent with the smallest fitness value. The fitness function is designed as shown in (2).

$$Fitness = \alpha \gamma_R(D) + \beta \frac{|R|}{|C|} \quad (2)$$

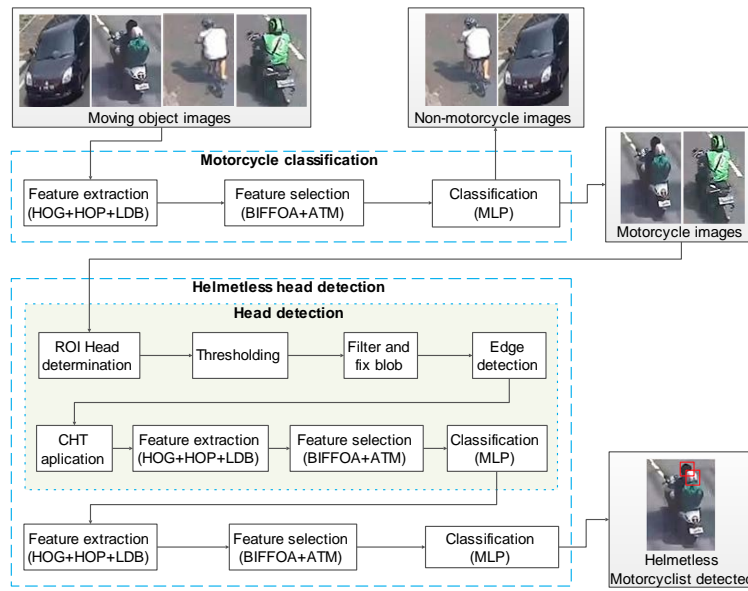

Fig. 2. A Developed System of Motorcycle Classification and Helmetless Head Detection.

Fig. 3. Image Sample of Results from each Step: (a) Motorcycle Input (b) ROI Head Determination (c) Thresholding (d) Filter and Fix Blob (e) Edge Detection (f) CHT Application (g) Classification.

where  $\gamma_R(D)$  represents the classification error rate of a given classifier.  $|R|$  and  $|C|$  denote the length of the selected feature subset and the total number of features, respectively.  $\alpha$  and  $\beta$  represent the weight of classification accuracy and selected feature subset, respectively. The values of  $\alpha$  and  $\beta$  for this study are 0.99 and 0.01, respectively. The agents used are a swarm of fruit fly positions. The initial positions of this fruit fly are binary numbers randomly generated. The position of fruit flies is updated using (3).

$$x_{i,j} = \begin{cases} 1 - \delta_j & \text{if } S(\Delta x_{i,j}) \geq \text{rand}() \\ \delta_j & \text{otherwise, } j = 1, 2, \dots, n \end{cases} \quad (3)$$

where  $n$  is the dimension length and  $\text{rand}()$  is the generation of random numbers between  $[0, 1]$ .  $\delta_j$  is the  $j^{\text{th}}$  dimension of the optimal solution.  $S(\Delta x_{i,j})$  is the sigmoidal transfer function (S-shaped), as in (4).

$$S(\Delta x_{i,j}) = \frac{1}{1 + e^{-\Delta x_{i,j}}} \quad (4)$$

where  $\Delta x_{i,j}$  is calculated using (5).

$$\Delta x_{i,j} = \begin{cases} \delta_j \pm r \cdot \text{rand}() & \text{if } j = d \\ \delta_j & \text{otherwise, } j = 1, 2, \dots, n \end{cases} \quad (5)$$

where  $r$  is the search radius for every iteration that is calculated using equation (1).  $d$  is a dimension index that is chosen randomly. The pseudocode of the BIFFOA is shown in Algorithm 1 [20].

#### D. Two-Phase Mutation Algorithm

A two-phase mutation algorithm was proposed in [21] to improve the GWO algorithm. Algorithm 2 shows the

pseudocode of the two-phase mutation [21]. The input of this algorithm is the best grey wolf ( $X_\alpha$ ) in each iteration. The  $X_\alpha$  is mutated in two phases, the first is used to reduce features and the second is utilized in improving accuracy. The mutation is executed when the  $r$  is less than the Mutation Probability ( $M_p$ ). The value of  $r$  is between 0 and 1, which is generated randomly and the  $M_p$  value is 0.5.

---

**Algorithm 2.** The standard two-phase mutation

---

1. **Input:** the best grey wolf  $X_\alpha$  from each iteration
  2.  $Fitness =$  calculate the fitness of  $X_\alpha$   
//start the first phase
  3. Define vector *one\_positions* to store the locations of the selected features in  $X_\alpha$
  4. Define  $X_{mutated1} = X_\alpha$
  5. **For**  $i=1$  to length of *one\_positions* //for each selected feature in  $X_\alpha$
  6.     Generate a random number  $r$
  7.     **If** ( $r < M_p$ )
  8.          $X_{mutated1}[one\_positions[i]] = 0$  while keeping the other features
  9.          $Fitness\_mutated =$  the fitness of  $X_{mutated1}$
  10.        **If** ( $Fitness\_mutated < Fitness$ )
  11.             $Fitness = Fitness\_mutated$
  12.             $X_\alpha = X_{mutated1}$
  13.        **End if**
  14.     **End if**
  15. **End for**  
//start the second phase
  16. Define vector *zero\_positions* to store the locations of the unselected features in  $X_\alpha$
  17. Define  $X_{mutated2} = X_\alpha$
  18. **For**  $j=1$  to length of *zero\_positions* //for each unselected feature in  $X_\alpha$
  19.     Generate a random number  $r$

**E. Proposed Algorithm: Fusion of BIFFOA with Adaptive Two-Phase Mutation Algorithm**

ATMBIFFOA is a new feature selection algorithm that is proposed in this paper. It improved the BIFFOA by adding an adaptive two-phase mutation algorithm that aims to reduce feature dimensions. The pseudocode of the ATMBIFFOA is found in Algorithm 3, while that of the adaptive two-phase mutation algorithm is found in Algorithm 4.

The input of the adaptive two-phase mutation algorithm is the best solution for each iteration ( $X^*$ ) that is defined as shown in (6).

$$X^* = (x_1, x_2, \dots, x_n) \quad (6)$$

where  $x_j$  is the  $j^{\text{th}}$  dimension of  $X^*$ , and  $n$  is the dimension length of  $X^*$ . When each  $x_j$  values= 0, then the corresponding feature is unselected. And when each  $x_j$  values= 1, then the corresponding feature is selected. The  $M_p$  is defined as the vector as shown in (7).

$$M_p = (mp_1, mp_2, \dots, mp_n) \quad (7)$$

where  $mp_j$  is the mutation probability of the  $j^{\text{th}}$  dimension. The  $mp_j$  values are constant at the beginning of iteration ( $mp_j$  in the study is 0.5). However, when the iteration is greater than or equal to the weight iteration ( $I_w$ ), then  $M_p$  is equal to the dimension weights of the best agents. The  $I_w$  is calculated using (8).

$$I_w = t_w \times Iter_{max} \quad (8)$$

where  $t_w$  is a weight threshold that values a range of [0, 1].

The dimension weights of the best agents are represented in the vector ( $W_i$ ), as in (9).

$$W_i = (w_{i,1}, w_{i,2}, \dots, w_{i,n}) \quad (9)$$

where  $w_{i,j}$  is the weight of the best agent in the  $i^{\text{th}}$  iteration and  $j^{\text{th}}$  dimension that is calculated using (10).

$$w_{i,j} = \frac{w_{(i-1),j} \times (i-1) + x_{i,j}}{i} \quad (10)$$

where  $x_{i,j}$  is the value of the best solution in the  $i^{\text{th}}$  iteration and  $j^{\text{th}}$  dimension.

---

**Algorithm 3.** The proposed ATMBIFFOA

---

1. **Input:**  $PS, r_{max}, r_{min}, Iter_{max}$   
//Initialize the ATMBIFFOA parameter:
  2. Set  $PS, r_{max}, r_{min}, Iter_{max}$
  3. Set  $W_0, M_p, I_w$
  4. Calculate the fitness of all agents using (2)
  5. Set the best solution as swarm location
  6.  $Iter = 0$
  7.  $X^* = \Delta$
  8. **Repeat**
  9. Calculate the search radius  $r$  using (1)
  10. Calculate  $\Delta x_{ij}$  using (5)  
//Ospres is foraging phase
  11.     **For**  $i=1, 2, \dots, PS$
  12.         Calculate  $S(\Delta x_{ij})$  using (4)
  13.         Using (3) to generate food source,  $X_i = (x_{i,1}, x_{i,2}, \dots, x_{i,n})$
  14.     **End for**  
// Vision foraging phase
  15. Calculate the fitness of all agents using (2)
  16. Update the swarm location when there is a better solution in the population
  17. Update  $W_i$  using (9)
  18.     **If**  $Iter \geq I_w$
  19.          $M_p = W$
  20.     **End if**  
//Mutation process
  21. Process of the adaptive two-phase mutation
  22. **Until**  $Iter = Iter_{max}$
  23. **Output:** Solution  $X^*$
-

The mutation process in the two-phase mutation algorithm is executed in all dimensions of one\_position and zero\_position vector. Therefore, this algorithm takes a long time when used in a large number of features. The adaptive two-phase mutation algorithm limited the number of mutated dimensions with the 1<sup>st</sup> Mutation Candidate Probability ( $P_{mc1}$ ) and the 2<sup>nd</sup> Mutation Candidate Probability ( $P_{mc2}$ ), therefore, its computation time can be reduced. The mutation position of both vectors is selected through random permutation.

**Algorithm 4.** The proposed adaptive two-phase mutation

1. **Input:** the best solution  $X^*$  from each iteration  
//start the first phase
2. Define vector *one\_positions* to store the locations of the selected features in  $X^*$
3. Define  $X_{mutated1} = X^*$
4. Define the number of mutation candidate  $n_{mc} = P_{mc1} \times$  length of *one\_position*
5. Define vector *one\_mutation\_candidate* to store the location of the mutated candidate by selecting  $n_{mc}$  random permutations in *one\_position*.
6. **For**  $i=1$  to length of *one\_mutation\_candidate*
7.     Generate a random number  $r$
8.     **If** ( $r < M_p[\text{one\_mutation\_candidate}[i]]$ )
9.          $X_{mutated1}[\text{one\_mutation\_candidate}[i]] = 0$   
while keeping the other features
10.         *Fitness\_mutated* = the fitness of  $X_{mutated1}$
11.         **If** (*Fitness\_mutated* < *Fitness*)
12.             *Fitness* = *Fitness\_mutated*
13.              $X^* = X_{mutated1}$
14.     **End if**
15.     **End if**
16. **End for**  
//start the second phase
17. Define vector *zero\_positions* to store the locations of the unselected features in  $X^*$
18. Define  $X_{mutated2} = X^*$
19. Define the number of mutation candidate  $n_{mc} = P_{mc2} \times$  length of *zero\_position*
20. Define vector *zero\_mutation\_candidate* to store the location of the mutated candidate, by selecting the  $n_{mc}$  random permutations in the *zero\_position*
21. **For**  $j=1$  to the length of *zero\_mutation\_candidate*
22.     Generate a random number  $r$
23.     **If** ( $r < M_p[\text{zero\_mutation\_candidate}[j]]$ )
24.          $X_{mutated2}[\text{zero\_mutation\_candidate}[j]] = 1$   
while keeping other features
25.         *Fitness\_mutated* = the fitness of  $X_{mutated2}$
26.         **If** (*Fitness\_mutated* < *Fitness*)
27.             *Fitness* = *Fitness\_mutated*
28.              $X^* = X_{mutated2}$
29.     **End if**
30.     **End if**
31. **End for**
32. **Output:** the improved  $X^*$

**F. Evaluation Methods**

The parameters for measuring performance were feature number (NF), time of average classification (Time), accuracy (Acc), precision (Pre), and recall (Rec). Especially for helmetless head detection, we used average precision (AP) to measure accuracy. Equations (11), (12), and (13) are used in calculating accuracy, precision, and recall, respectively.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (11)$$

$$Precision = \frac{TP}{TP+FP} \quad (12)$$

$$Recall = \frac{TP}{TP+FN} \quad (13)$$

where TP, TN, FP, and FN represent true positive, true negative, false positive, and false negative, respectively. The TP is the true detection of the ground-truth bounding box. The correct detection was measured using the intersection over union (IOU) as in (14).

$$IOU = \frac{area(B_p \cap B_{gt})}{area(B_p \cup B_{gt})} \quad (14)$$

where  $B_p$  and  $B_{gt}$  represent the predicted and ground-truth bounding box, respectively. The detection is considered correct when the IOU is greater than or equal to the threshold. In this study, the threshold value was 0.5.

AP is the area under the precision-recall curve which has a range of [0, 1] and it is calculated as in (15) [38].

$$AP = \sum_n (R_{n+1} - R_n) P_i(R_{n+1}), \quad (15)$$

where  $P_i(R_{n+1})$  is calculated using (16).

$$P_i(R_{n+1}) = \max_{\tilde{R}: \tilde{R} \geq R_{n+1}} P(\tilde{R}) \quad (16)$$

where  $P(\tilde{R})$  is the precision measured at the time of recall  $\tilde{R}$ .

The experiment was carried out by selecting the best result on each process, namely a combination of cell and block sizes on the HOPG-LDB descriptor, variation of  $t_w$  value on the ATMBIFFOA, and a combination of hidden layer number, neuron number, and training algorithm on the MLP. The block size variations were 2x2 and 3x3 cells. The cell size variations in the 2x2 blocks were 4x4, 6x6, 8x8, and 12x12 pixels and the 3x3 block sizes were 4x4 and 8x8 pixels. The variations of  $t_w$  values were 0.25, 0.5, and 0.75. The variations of the number of hidden layers used are 1, 2, and 3. The number of neurons in the hidden layers ( $n_H$ ) was determined by using (17) [39].

$$n_H = \sqrt{n_i + n_o} + l \quad (17)$$

where  $n_i$  is the number of neurons in the input layer,  $n_o$  is the number of neurons in the output layer, and  $l$  is an integer constant of 1 to 10. The  $l$  variation of this study was 1, 5, and 10. Finally, we used 8 variations of the training algorithm, namely the gradient descent with adaptive learning rate backpropagation (traingda), scaled conjugate gradient backpropagation (trainscg), conjugate gradient backpropagation with Powell-Beale restarts (traincgb), conjugate gradient backpropagation with Fletcher-Reeves update (traincgf), conjugate gradient backpropagation with Polak-Ribière update (traincgp), one step secant backpropagation (trainoss), gradient descent with momentum and adaptive learning rate backpropagation (traingdx), and gradient descent backpropagation (traingd). This paper used the learning rate of 0.05, the epoch maximum number of 1000, and the limit for error of 0.001 for the training. The author in [40] reported that these parameters result in a good performance.

For the ATMBIFFOA, the parameters of PS and  $Iter_{max}$  are 24 and 100, respectively. The values of  $P_{mc1}$  and  $P_{mc2}$  are 0.25 and 0.01, respectively. The K-fold cross-validation (K=5) was used to separate the training and validation data in the feature selection process. Each experiment is run 5 times and the average results are used. All the experiments were carried out in Windows 10 Ultimate 64-bit operating system, with processor Intel Core (TM) i7-9750HQ CPU and 16 GB of RAM. All the algorithms were implemented in the MATLAB R2019a Software.

#### IV. RESULTS AND DISCUSSION

This section shows the experiment results of the proposed method for motorcycle classification and helmetless head detection.

##### A. Motorcycle Classification

The first experiment is to determine the best accuracy of the proposed method (ATMBIFFOA) with variations of  $t_w$ . Table III shows the results of this experiment for the motorcycle classification. From this table, we can be seen that the best accuracy reaches 96.06% for the JSC1 dataset and 96.85% for the JSC2 dataset.

Furthermore, the proposed method is compared with the previous study, namely in Table IV. Here, [20] used BIFFOA feature selection. From this table, it can be seen that the proposed method is superior in terms of the number of features and classification time. Meanwhile, in terms of accuracy, the proposed method is superior for the JSC1 dataset, and [20] is superior for the JSC2 dataset. For this reason, we conclude that the addition of an adaptive two-phase mutation algorithm in BIFFOA can effectively reduce the number of features.

TABLE III. EXPERIMENTAL RESULTS WITH VARIATION OF  $t_w$  FOR MOTORCYCLE CLASSIFICATION

| Dataset | $t_w$ | Acc (%)      | Pre (%)      | Rec (%)      | NF           | Time ( $\times 10^{-3}$ s) |
|---------|-------|--------------|--------------|--------------|--------------|----------------------------|
| JSC1    | 0.25  | 95.90        | 95.38        | 96.05        | 899.0        | 46.4321                    |

(a) JSC1 Dataset.

(b) JSC2 Dataset.

Fig. 4. Convergence Curve of the Proposed Method and the Previous Study for Motorcycle Classification.

Fig. 4 displays the convergence curve of the proposed method and the previous study in [20]. The proposed method produces a better optimal solution than the BIFFOA.

##### B. Helmetless Head Detection

Table V shows the experimental results of helmetless head detection with variations in the value of  $t_w$ . From this table, it can be seen that the highest AP reaches 66.29% for the JSC1 dataset and 63.95% for the JSC2 dataset. Furthermore, the proposed method is compared with previous studies.

Table VI shows a comparison of the proposed feature selection method and previous study. Here, [20] used the BIFFOA feature selection. From this table, it can be seen that the proposed method is superior in terms of the number of features and classification time. In addition, the AP of the proposed method is superior for the JSC2 dataset, although it is slightly lower for the JSC1 dataset. Fig. 5 shows the comparison of the convergence curve between the proposed method and the previous study. The proposed method produces a better optimal solution than [20]. Therefore, we can conclude that the addition of an adaptive two-phase mutation algorithm to BIFFOA can reduce features effectively.

## V. CONCLUSION

This paper proposed a new feature selection algorithm called ATMBIFFOA for motorcycle classification and helmetless head detection. The experiment used two datasets with different recording angles, namely the rear and front of an object. The motorcycle classification accuracy of the proposed method reaches 96.06% for the JSC1 dataset and 96.85% for the JSC2 dataset. Meanwhile, the AP of helmetless head detection reaches 66.29% for the JSC1 dataset and 63.95% for the JSC2 dataset. The proposed algorithm is more effective than BIFFOA in terms of the number of features and the time of classification. For this reason, the proposed method is more suitable for the detection of motorcyclists who do not wear helmets in real-time. However, the addition of an adaptive two-phase mutation algorithm to BIFFOA can significantly increase the feature selection time. In the future, ATMBIFFOA can be used with faster classifiers such as KNN, SVM, and DT to reduce the time consumption of feature selection.

## ACKNOWLEDGMENT

The authors would like to thank the Research Directorate of Universitas Gadjah Mada in the Recognisi Tugas Akhir (RTA) 2021 schema for funding this research.

**Abstract**—The COVID-19 pandemic has had catastrophic consequences all over the world since the detection of the first case in December 2019. Currently, exponential growth is expected. In order to stop the spread of this pandemic, it is necessary to respect sanitary protocols such as the mandatory wearing of masks. In this research paper, we present an affordable artificial intelligence-based solution to increase the protection against COVID-19, covering several relevant aspects to facilitate the detection and prevention of this pandemic: non-contact temperature measurement, mask detection, automatic gel-dispensing, and automatic sterilization. Our main contribution is to provide high-quality, real-time learning and analysis. To achieve this goal, we used a deep convolutional neural network (CNN) based on MobileNetV2 architecture as the learning algorithm and Advanced Encryption Standard (AES) as an encryption protocol for sending secure data to notify hospital staff. The experimental results show the effectiveness of our model by providing 99.7% accuracy in detecting masks with a runtime of 1.54 s.

**Keywords**—Face mask detection; coronavirus; COVID-19; deep learning; MobileNetV2; AES

## I. INTRODUCTION

The world faces a serious pandemic named COVID-19 as a result of the new SARS-CoV-2 virus, which began in China in late December 2019. This epidemic spread quickly beyond China on February 25, 2020 for the first time [1]. By January 20, 2022, the total number of identified cases was 338 807 207 while 5 581 841 individuals had passed away worldwide [2]. The most common symptoms of COVID-19 are fever, headache and loss of smell, muscle pains, and dry cough. In the most severe forms, the onset of acute respiratory distress syndrome leads to death, especially in people who are more fragile because of their age or comorbidities [3]. Coronavirus infections are frequent in humans and in most cases, they are transmitted directly (from one person to another) by respiratory droplets. However, they are also transmitted indirectly by surfaces [4]. To reduce the spread of this disease, many protective and safety measures have been taken by the authorities such as mandatory wearing of an indoor mask, physical distancing, self-isolation, limitation of citizen movement within a country's borders and abroad, closure of non-essential workplaces and educational institutions, and finally reduction of public transport and restriction of domestic and international travel [5]. Overall, the sanitary protocols of

preventing COVID-19 have shown positive results in reducing the spread of the virus [6].

Consequently, we propose a new system of access control in compliance with health protocols. In this article, we present an intelligent system to help organizations comply with COVID-19 security rules and reduce the spread of the pandemic. We focus on the most common internal measures, such as the distance between people, which should be at least 1.5 to 2 meters. Equally crucial is wearing a mask and washing hands with hydro alcoholic gel. Finally, people with a temperature above 38°C should stay at home and receive health care, and should not go to work or school or interact with others outside the home.

Our system is designed to help the fight against this pandemic by monitoring the wearing of masks to reduce the spread of viruses [7]. Moreover, this system detects the fever of people without making contact. The room is sterilized daily and automatically when an abnormal temperature is detected. Gel is distributed without the need to touch the dispenser since COVID-19 could be transmitted by a plastic surface. Finally, the algorithm used in this work detects mask-wearing at 99.7% efficiency.

The remainder of this paper is organized as follows: The second section explores some related works and similar approaches to COVID-19 detection. In the third section, we outline our suggested method for COVID-19 detection and prevention. Then, in the fourth section, we describe the materials and methods used in the experiment, including the results of the evaluation. In the fifth section, we offer the conclusion.

## II. RELATED WORK

It has become increasingly important to consider some methods of COVID-19 prevention and detection to limit and restrict the rapid spread of the epidemic virus. In their works, several researchers have proposed numerous approaches to detect COVID-19 and protect persons from this virus.

The authors in [8] have proposed a portable non-contact method to screen the health status of people wearing masks through analysis of respiratory characteristics. In their work, they proposed the use of a device which consists of a thermal camera FLIR ONE and an Android phone. This work is based on face detection in a video stream to capture technical breathing data. Then, the deep learning algorithm Gated

Recurrent Unit (GRU) is applied to the respiratory data to obtain the result of medical screening. While this method can help to combat the current epidemic of COVID-19, the proposed algorithm is not stable in the respiratory status measurement because of the effects of different types of masks.

In another work [9], the authors focus on the workflow based on the detection of COVID-19 from image classification using the deep learning model's convolutional neural network (CNN), they provided a pre-processing pipeline aimed at removing the sampling bias and improving the image quality. The results show that the CNN algorithm based on a Visual Geometry Group (VGG19) model provides better COVID-19 detection results against pneumonia for the ultrasound images. This work enables quick, accessible, affordable, and reliable identification of COVID-19 and helps to slow the transmission of COVID-19 infection. However, the used database requires a large number of images for better identification.

Jordi Laguarda and all, in [10] built a data collection pipeline of COVID-19 cough recordings between April and May 2020. They created the largest balanced COVID-19 audio cough to develop an intelligent speech-processing framework that leverages acoustic biomarker feature extractors to pre-screen COVID-19 from cough recordings.

In [11], the authors proposed a mask-wearing detection system. This system recognizes whether or not a person is wearing a mask based on the transfer learning technique. The ResNet-50 model is based on YOLO v2 (deep learning algorithm), which gives an accuracy of 81% of mask detection. The major drawback of this work is that the authors did not give details about the confusion matrix of the proposed algorithm.

Regarding temperature detection, there are several variant Arduino-based solutions. For instance, in [12], IoT systems for security monitoring based on temperature detection were presented. However, the used sensor does not give accurate results. In this context, in [13], the authors present a comparison between three types of sensors to measure temperature without making contact. According to the obtained results, the thermal camera Lepton gives the most accurate value with a minimum error rate.

To summarize, the previously cited works were carried out to design and deploy COVID prevention and detection systems. However, we deduce that these systems perform poorly for small and unvaried datasets because of the great variety of masks and the differing of symptoms from one person to another.

To remedy the problems mentioned above, our main objective is to offer a COVID-19 detection and prevention system based on deep learning for the detection of mask-wearing. We provide an effective and intelligent solution with a secure monitoring process based on the MobileNetV2. Moreover, because of the sensitivity of transmitted results to doctors, we need to ensure confidentiality. In fact, to provide secure end-to-end service, data are encrypted based on symmetric cryptography using AES (advanced encryption algorithm).

### III. OVERVIEW OF THE PROPOSED SCHEME

The pandemic of COVID-19 is spreading rapidly every day. This disease has become a major threat to people's lives as it often causes death. Therefore, we base our research on the prevention and detection of this disease in the field of work and the health sector.

In this section, we provide an overview of our proposal to achieve the previously presented goals. We start by defining the system model containing the elements of our solution, where we implement specific algorithms. Indeed, we present an intelligent solution for the detection of and prevention from coronavirus. Our proposed model consists of the following subsystems, illustrated in Fig. 1.

Our model is useful in buildings such as hospitals, clinics, and company headquarters. Indeed, we contribute the design of an intelligent system to detect and prevent COVID-19 based on the use of deep learning algorithms to classify people with and without mask, and an algorithm for non-contact temperature detection. Our solution is based on the extraction of significant face parameters such as eyes and nose, followed by the application of the CNN algorithm based on MobileNetV2 architecture. Then, to detect the temperature, we apply an algorithm that generates a thermal image and measures the temperature. After detecting an abnormal temperature value, we use an encryption algorithm to send the result to the hospital. These results are decrypted using an open-source application. Furthermore, to clean hands when entering the building, we use a system that allows the automatic contactless distribution of alcohol gel.

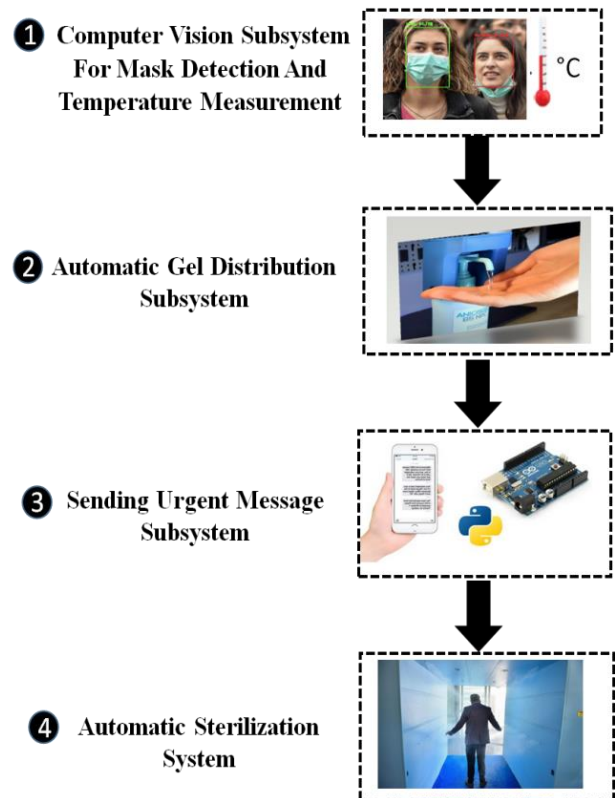

Fig. 1. COVID-19 Detection and Prevention Model.

Finally, for the automatic sterilization phase, we ensure our system is equipped with high quality cleaning products to sterilize the room every day and following the detection of abnormal temperature.

Fig. 2 presents a flowchart of the COVID-19 detection and prevention process, beginning with the presence of a person. First, he/she must practice social distancing, which at minimum is equal to 1.5 meters. After that, she/he moves on to the next step of mask detection.

If the person is not wearing a mask or not covering their nose, an audible signal is sent to warn him to wear the mask correctly and repeat the test. Otherwise, he/she must leave. If the mask is worn correctly, the second step is processed to measure the temperature without contact. For this task, the thermal sensor will be triggered using an infrared sensor to measure the temperature.

In the event that this person has a body temperature above normal, the door remains closed and an audible signal informs this person to go to the waiting room for five minutes and then repeat a second temperature measurement test. For this duration of waiting, we used a timer which is triggered by a sensor after entering the waiting room. After the second test, if the person's temperature remains high, a signal is displayed informing them to exit and wait for the ambulance service. As soon as the sensor detects the exit of a person, an audible message informs the other persons to leave. After three minutes, the sterilization is triggered automatically using a cleaning product against the virus. However, if the person is wearing the mask correctly and the temperature does not exceed the normal degree, then the door opens and it goes to the gel-dispensing stage. For this step, if the sensor detects the presence of a hand at a distance of less than 7 cm, the gel is dispensed automatically. Otherwise, if the distance is greater than 7 cm, the system remains closed.

Fig. 2. The Proposed Detection and Prevention Model.

### A. Mask Detection Algorithm

For our mask detection algorithm, we rely on MobileNetV2, which is a convolution optimization for convolutional neural networks. This small, low latency, low power model is adjusted to meet the resource constraints of a variety of use cases. MobileNetV2 is a highly efficient architecture that can be applied to embedded devices with limited computing capacity. Used for feature extraction, facial recognition, and object detection, it is based on separable in-depth convolution as the base unit. This convolution has two layers: deep convolution and point convolution (1 \* 1 convolution) [14].

An inverted residual structure is used to allow the network to calculate the activations (ReLU) more efficiently, and to retain more information after activation. These connections are between the bottleneck layers.

MobileNetV2 architecture contains the fully convolutional initial layer with 32 filters, followed by 19 bottleneck residual layers [15]. Algorithm 1 presents the steps of the proposed system.

---

#### Algorithm 1: mask port detection

---

**Inputs:** database containing different images with and without masks

**Outputs:** categorized images showing the presence of a face mask

For the images in the database of two categories,

1. Convert RGB (red, green, blue) images into grayscale images
2. Resize the images to 224\*224
3. Normalize the image and convert it to a four-dimensional array

**End**

#### To build the MobileNetV2 model,

1. Add a convolution layer of 32 filters
2. Add a convolution layer 1\*1
3. Insert a flattening layer in the network classifier
4. Add a dense layer to activate ReLU
5. Add AveragePooling2D
6. Add the final dense layer with two outputs for two categories

**End**

#### Train the model

---

We use OpenCV (Open Source Computer Vision Library) to detect faces in an image [16]. This software is a very popular algorithm that is used to detect one or more faces in the image (Fig. 3).

Fig. 3. Mask Detection Chain.

### B. Fever Detection Module

For the detection of fever, we propose the temperature detection process following Algorithm 2.

---

#### Algorithm 2: Fever detection algorithm

---

**Input:** Amount of infrared energy emitted by an object

**Output:** Read the temperature of the sensor

1. Measure the amount of infrared energy
2. Calculate the signal using DSP (calculation unit)
3. Convert to a temperature value using an ADC
4. Generate data via the I2C communication protocol
5. Read the temperature

If  $t > 38^{\circ}\text{C}$ , the door remains closed and the person enters the waiting room

Otherwise, if  $t < 38^{\circ}\text{C}$ , the door is opened automatically

**End**

---

The flowchart illustrated by Fig. 4 summarizes the mask and temperature detection. When the person wears the mask properly and his temperature does not exceed  $38^{\circ}\text{C}$ , the door opens automatically followed by the automatic alcohol gel-dispensing step to clean hands from viruses. Alternatively, if the sensor detects an abnormal temperature with a false mask port, then the door remains closed.

Fig. 4. Flowchart for Mask and Temperature Detection.

### C. Automatic Gel Dispenser

For the gel dispenser, we use a specific sensor that measures the distance between a body and the used component. As presented above, if a person places their hand less than 7 cm in front of the sensor, the gel will be automatically dispensed without touching it. We use this contactless system to clean the person's hands from viruses before entering the building to reduce the transmission of this epidemic.

### D. Message-Sending System

For this task, after detecting the temperature using the thermal sensor and verifying that it exceeds normal temperature, a message is sent quickly to the hospital. This message contains the location of the company headquarters and the degree of detected abnormal temperature. To secure the sending of the message against malicious attacks, our system is based on the AES-CBC-256 algorithm. AES guarantees that sensitive data is only accessible for authorized users to read.

### E. Automatic Sterilization System

To curb the spread of this epidemic, our system is based on high quality cleaning products. Therefore, the automatic sterilization system uses a water pump to dispense the cleaning products against the virus. The purpose of sterilization is to reduce the population of microorganisms, facilitate cleaning, protect personnel when handling instruments, and avoid contamination of the environment.

## IV. EXPERIMENTS AND RESULTS

We describe in this section the detailed realization of our proposed system. Fig. 5 introduces the architecture of the detection and prevention system, subdivided into four subsystems. For the mask port and temperature detection system, we chose a Raspberry Pi 4 model b card. This card is equipped with a 1.5 GHz processor and 8 Go RAM. We chose a USB-type camera to allow better resolution of 8 megapixels for mask detection against a 5 megapixel camera. For

contactless fever detection, we chose MLX90614 thermal sensor for its advantages of low cost and small size. As previously described, when the system has checked that the person is wearing the mask correctly and his temperature does not exceed the normal degree, then the door opens, and an SG 90 servo motor is used to switch to the automatic gel distribution system. To this end, we have chosen the SG 90 servo motor as an ultrasonic sensor and an Arduino Nano board equipped with a microprocessor. For the detection of the body, we propose using ATMega328, and for the message-sending phase, we chose an Arduino mega 2560 card equipped with a microprocessor: ATMega2560 and a GSM SIM 800L V2 module. The GSM module SIM800L V2 starts and searches the network automatically, and has low energy consumption. It can be directly connected to Arduino which has 5V level [17]. If the module receives a signal via serial communication from the USB port with the Raspberry Pi, it sends directly to the hospital an encrypted message containing the location of the company headquarters and the abnormal temperature of the person. This encryption is determined by the AES algorithm. For the automatic sterilization system, we used a speaker, a mini water pump, an ultrasonic sensor, and an Arduino Nano board.

The experiments are conducted in the Anaconda environment (version 5.2.0) using Python language. The experimental configuration computer is an Intel i5-3317U processor at 1.70 GHz with 6 GB of RAM. We present in the following section the results of each module.

#### A. Mask Detection Camera

1) *MobileNetV2 implementation:* To develop the model, we must first import the required functions from the Keras ML library. Keras is a deep learning API written in Python. Keras enables rapid experimentation which is able to move from

idea to result as quickly as possible. The basic data structures of Keras are layers and models [18]. All layers used in the MobileNetV2 model are implemented using Keras.

2) *Database description:* The dataset [19] consists of 3833 images in which 1915 images are people who are wearing face masks and the remaining 1918 images are people who are not wearing face masks. This large number of images is used to train and test our algorithm to improve the performance of the model. Fig. 6 contains mainly a front face pose with different mask colors.

First, each image is converted from RGB (red, green, blue) to a grayscale image that contains a single-color channel (the “grayscale” of each pixel). The images are then resized to reduce the complexity and computational power of the MobileNetV2 model.

In this algorithm, we used the cv2.cvtColor function to convert the RGB image to grayscale, and the cv2.resize function to resize our image to the dimensions (img\_size, img\_size). Our img\_size parameter was set to 224, so that each image becomes a 224\*224 square image. The prepared image is added to the ‘data’ list and the class label is added to the ‘labels’ list. To optimize the training time and reduce the complexity of the model, we convert the ‘data’ list into a more efficient NumPy array, and then we divide the array by 255, which normalizes the pixel range between 0 and 1. In the proposed model, we used TensorFlow to reshape the data (image) in data processing.

TensorFlow is an open-source interface developed by Google researchers to perform deep learning and other statistical and predictive analysis workloads. It is designed for running advanced analytics applications for users such as predictive modelers and data scientists [20, 21].

Fig. 5. Proposed Evaluation Scheme.

Fig. 6. Image Data Set with Two Classes of “with Mask” and “without Mask”.

3) *Simulation results:* The evaluation of our proposal is based on different metrics, where the confusion matrix, the false positive (FP), the true positive (VP), and the true negative (TN) rates are calculated. Fig. 7 presents the confusion matrix. This matrix is in the form of a table which is often used to describe the performance of our classification model on the set of images with and without masks. Our algorithm detects with a true positive 1569 out of 1574 images with masks, and detects with a true negative 1462 out of 1574 images without masks.

Fig. 7. Confusion Matrix.

The first intuitive indicator of success is precision. It is the quantitative relationship between correctly predicted positive observations and total predicted positive observations [22].

The formula (1) is used to calculate the precision of our algorithm, where our method achieves an accuracy of up to 99.7%.

$$\text{Accuracy} = \frac{TP + TN}{TP + FP + FN + TN} * 100 \quad (1)$$

Moreover, Recall or Sensitivity is the quantitative relationship of positive observations correctly predicted, or all observations within the actual class-yes [23]. It is calculated following Equation (2). Our model reaches a Recall equal to 99.68%.

$$\text{Recall} = \frac{TP}{TP + FN} * 100 \quad (2)$$

The F1 score (Equation (3)) is used to assess a two-class system. It is a method which combines the precision of the model and the recall rate. It is defined as the harmonic mean of the model accuracy and the recall rate, where the result retrieved from our model is. F1 score = 99.69%.

$$\text{F1 Score} = \frac{2 * (\text{Recall} * \text{Accuracy})}{(\text{Recall} + \text{Accuracy})} \quad (3)$$

Fig. 8 illustrates the contrast between loss of training and corresponding validation to the dataset. One of the main reasons for obtaining this precision resides in Average Pooling [24].

A much higher number of neurons and filters can cause a decrease in performance. The optimized values of the filters and the size of the pool allow the main part (face) of the image to be filtered in order to detect the presence of a face.

The system is able to effectively detect faces which are partially obscured either with a mask, hair, or a hand. It considers the degree of occlusion over four regions –nose, mouth, chin, and eyes – to differentiate an annotated mask from a face covered by a hand.

Fig. 8. Training Loss and Accuracy of the Model.

MobileNetV2 works best for all types of masks, thereby introducing the effectiveness of the proposed model in detecting masked faces. We improve our model using the Adam optimizer. Table I illustrates the results of comparing different related work methods in terms of precision. The work presented in [12] used the Medical Masks Dataset (MMD). The authors of [11] obtained an average test precision equal to 81% using YOLO v2 with ResNet-50, where in [25] the authors use the CNN model, which achieves a validation precision of 96% for the detection of facial mask. In [26], the authors use Real-World Masked Face Recognition Dataset (RMFRD) in their work. They obtained a test accuracy equal to 97% using ResNet-50.

By analyzing the performance of MobileNetV2 in the management of all types of masks, we find that our model is the most efficient and fast, where it achieves a mask detection accuracy of 99.7% thanks to its optimized architecture that contains inverted residuals and linear bottlenecks.

TABLE I. COMPARISON OF RESULTS

| References | Algorithms             | Precision in classifying images |
|------------|------------------------|---------------------------------|
| [11]       | YOLO v2 with ResNet-50 | 81%                             |
| [25]       | CNN                    | 96%                             |
| [26]       | ResNet50               | 97%                             |
| Our work   | MobileNetV2            | 99,7%                           |

On the webcam stream (as shown in Fig. 9) of using the MobileNetV2, the classification results are displayed on a label above the visual rectangle.

Fig. 9. Results obtained without Masks and with Masks.

### B. Fever Detection Module

For fever detection, we used MLX90614 non-contact sensor [27]. This infrared (IR) temperature sensor can be used to measure the temperature of particular objects ranging from -70°C to 380°C. It includes two built-in devices: one is infrared thermopile detector (detection unit) and the other is DSP signal conditioning device (computing unit). The sensor uses IR rays to measure the temperature of the object without making any physical contact, and it communicates with the microcontroller using the I2C protocol. The sensor measures both the object temperature and the ambient temperature to calibrate the object temperature value. The detection results are shown in Fig. 10. As evident in this figure, if the infrared sensor detects the presence of the hand, then the MLX90614 will automatically measure the temperature and the result obtained below the visual rectangle.

Fig. 10. Simulation Result for Non-Contact Temperature Measurement.

We conducted the test on 130 students from our school by using an IR thermometer with the MLX90614. Table II summarizes our assessment. The results show that there is an average difference between the two sensors of 2.5°C for measuring a person's temperature. Our system only has two errors of incorrect temperature measurement. To conclude, our system helps us to reduce the spread of this pandemic.

TABLE II. EVALUATION OF OUR PROTOTYPE

|                                                       |                           |
|-------------------------------------------------------|---------------------------|
| Number of students tested                             | 130                       |
| Test result for MLX90614                              | Between 32.6°C and 34.3°C |
| IR thermometer test result                            | Between 35.1°C and 36.8°C |
| Temperature degree difference between mlx90614 and IR | 2.5°C                     |
| Number of errors                                      | 2                         |
| Test duration for each student                        | 2.6 seconds               |
| CPU temperature for the Raspberry board               | Between 42°C and 59°C     |
| Detection distance for two sensors                    | 2cm                       |

Fig. 11 illustrates the functional prototype for the detection of mask wear and fever.

Fig. 11. Functional Prototype for the Detection of Mask Wear and Fever.

### C. Automatic Gel Dispenser

For this module, we used the ultrasonic sensor. We send a high pulse of  $10\mu\text{s}$  to the trigger pin of the sensor. Then, this sensor sends a series of eight ultrasonic pulses at 40 KHz (inaudible to the human ear). The ultrasounds propagate in the air until touching an obstacle and then return in the other direction towards the sensor. After that the sensor detects the echo and triggers the measurement. Finally, the signal on the echo pin of the sensor remains high. This allows for the duration of the round trip of the ultrasound to be measured and thus the distance to be determined [28]. The Equation (4) calculates the distance.

$$\text{Distance} = (\text{pulse duration (in } \mu\text{s)} / 2) / 29.1 \quad (4)$$

Using Proteus 8 Professional software, we obtained the results presented in Fig. 12. In fact, if the ultrasonic sensor detects the presence of a body, then the servo motor turns to distribute the alcohol gel.

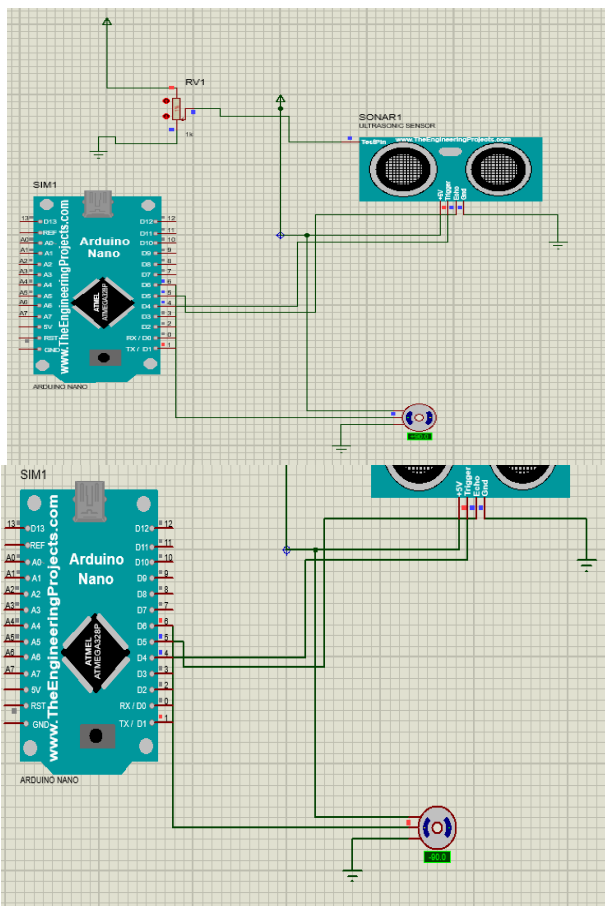

Fig. 12. Functional Schemefor the Automatic Gel Distribution.

Fig. 13 shows the experimental result for the automatic dispensing of gel. The sensor detects the presence of a human hand to dispense the gel automatically.

Fig. 13. Experimental Scheme for the Automatic Gel Distribution.

### D. Message-Sending System

After an abnormal temperature detection, the system sends a signal to the message-sending system via USB communication. This message is based on Arduino Mega 2560 board and GSM SIM 800LV2 module. If this signal is received, then the module has to send an encrypted message quickly to the hospital from the SIM card. This message contains the location of the company headquarters and the abnormal temperature level of the person.

For the decryption phase, we used an open-source application called CrypTool [29]. Its use is simple: when receiving the encrypted message, the receiver must put it in the field message encrypt with the secret code of 24 bit. Then, the message will be decrypted automatically after 1s.

### E. Automatic Sterilization System

To reduce the transmission of COVID-19 [30], we have built a smart contactless system to automatically sterilize the room. In this regard, our system is based on ultrasonic sensor, water pump, speaker, push button, and Arduino Nano. Fig. 14 show the experimental results.

In fact, after that the ultrasonic sensor detects the exit of the person, the sound message will be triggered to inform other people to exit. After three minutes, the Arduino board will send a signal to the water pump to automatically dispense the cleaning product. For the sterilization phase each day, we have provided our system with a push button to control the start of cleaning product dispensing.

Fig. 14. Experimental Scheme of the Automatic Sterilization System.

## V. CONCLUSION

In this article, we present an intelligent temperature and mask detection system. The main objective is to improve internal security against COVID-19 by ensuring a detection and prevention method.

To achieve this goal, we applied a deep convolutional neural network based on the MobileNetV2 architecture. We used a real database composed of masked and unmasked images. Moreover, we use AES-CBC- 256 as the encryption protocol to ensure security and privacy information users. The MLX90614 is implemented as a contactless temperature detection sensor. The results show that by using OpenCV, Keras, and TensorFlow, our MobileNetV2 architecture operates with a maximum accuracy of 99.7% and a runtime of 1.53s. The maximum contactless temperature detection distance must not exceed 2cm.

For future work, we will improve our algorithm to detect false mask-wearing, to identify building personnel wearing their masks, and record their temperature every day.

# Human Emotion Recognition by Integrating Facial and Speech Features: An Implementation of Multimodal Framework using CNN

P V V S Srinivas, Pragnyaban Mishra

Department of Computer Science and Engineering  
Koneru Lakshmaiah Education Foundation (KLEF)  
Guntur, India

**Abstract**—This Emotion recognition plays a prominent role in today's intelligent system applications. Human computer interface, health care, law, and entertainment are a few of the applications where emotion recognition is used. Humans convey their emotions in the form of text, voice, and facial expressions, thus developing a multimodal emotional recognition system playing a crucial role in human-computer or intelligent system communication. The majority of established emotional recognition algorithms only identify emotions in unique data, such as text, audio, or image data. A multimodal system uses information from a variety of sources and fuses the information by using fusion techniques and categories to improve recognition accuracy. In this paper, a multimodal system to recognise emotions was presented that fuses the features from information obtained from heterogenous modalities like audio and video. For audio feature extraction energy, zero crossing rate and Mel-Frequency Cepstral Coefficients (MFCC) techniques are considered. Of these, MFCC produced promising results. For video feature extraction, first the videos are converted to frames and stored in a linear scale space by using a spatial temporal Gaussian Kernel. The features from the images are further extracted by applying a Gaussian weighted function to the second momentum matrix of linear scale space data. The Marginal Fisher Analysis (MFA) fusion method is used to fuse both the audio and video features, and the resulted features are given to the FERCNN model for evaluation. For experimentation, the RAVDESS and CREMAD datasets, which contain audio and video data, are used. Accuracy levels of 95.56, 96.28, and 95.07 on the RAVDESS dataset and accuracies of 80.50, 97.88, and 69.66 on the CREMAD dataset in audio, video, and multimodal modalities are achieved, whose performance is better than the existing multimodal systems.

**Keywords**—Emotion recognition; multimodal; fusion; MFCC; MFA; FERCNN; CREMAD; RAVDESS

## I. INTRODUCTION

Emotion recognition is the process of determining a person's emotional state. Affective computing and human-computer interaction (HCI) applications rely heavily on it [1]. In recent studies, emotion identification has sparked increased attention in academics and the commercial sector [2]. It is used in a variety of applications, including analysis of Twitter, tutoring systems, playing video games, prediction of consumer satisfaction, and military healthcare [3-5].

Speech or audio emotion recognition has been employed in medical studies to examine the changes in the emotions of depressed patients and in children who are having communication difficulties. It can also be used to warn the drivers during driving when the condition of the driver is fatigued to avoid accidents. Low level information from the speech or audio signals is extracted by the speech or audio emotion recognition system to comprehend the emotion status. Compilation of databases related to emotions, extraction of emotional features from the speech or audio signal, reduction of features by using dimensionality reduction techniques, and classification of emotions into respective classes are all part of this classification problem based on speech or audio signal sequences. K nearest neighbour, Gaussian mixture model, Support vector machines, and artificial neural networks are some of the traditional techniques that are used for speech or audio emotional recognition and are not that efficient because human emotions have high complexity and uncertainty [6].

About 93% of communication with humans is done through nonverbal means such as voice tone, facial expressions, and body language [7]. Identifying emotions through facial expressions which has been extensively studied [8][9] resulted in higher accuracies by making the changes at the pre-processing stage. To reduce overfitting during the training stage, adding dropout to the CNN model plays a prominent role in reducing overfitting during training [10]. Extracting of faces from the chain of video sequences and extracting the features from the resulted images are the steps followed in general to detect the emotions of the faces in the video sequences [11]. The robust face detection algorithm [12], the AdaBoost learning algorithm [13], and the spatial template tracker [14] are some of the techniques used in detecting the faces in the video. Fisher vectors, Active Shape model, Active Appearance model, local binary patterns, principal component analysis [15] and Gaussian mixture model [16] are some of the methods that are used for feature extraction in facial images. Occlusions and light changes may also lead the identification technique to be misled. If the emotion is to be identified through speech, ambient noise and differences in the voices of different participants are major factors that might affect the final recognition result. According to both physiological and psychological research, humans need both audio and visual signals to correctly understand emotions for which multimodal systems that fuse audio and video signals can be used.

Thanks to recent research interest in multimodal systems, the limitations of monomodal systems [17] [18] have been overcome. The information obtained from different modalities at different levels of fusion was fused by multimodal systems. The different fusion levels are classified into two different categories, namely: matching prior to fusion and matching after fusion. Feature level and sensor level fusion techniques [19] come under the first category, and decision, rank, and score level fusion techniques come under the second category. To combine the audio and video features of the multimodal, a fusion method that takes advantage of both decision and feature-level fusion was developed. Latent space fusion methods preserve analytical or numerical correlation between the different modalities and store them in a common latent space.

## II. RELATED STUDIES AND MOTIVATIONS

Many attempts have been made by researchers to enhance emotion identification using a combination of audio and visual information [20]. According to [21], audio-visual emotion detection may be categorized as kernel-based, feature level, model-level, decision-level, score-level, and hybrid level fusion techniques. In this paper, we focus on latent-space fusion methods and multimodal recognition to detect emotions. Multimodal emotion recognition systems consistently outperform unimodal systems [22], [23], and [24]. Although there are certain benefits to using multimodal affective systems, they also face some important challenges [24]. Selecting the modalities that result in the best combinations is the area that has been focused on in recent studies [25]. CREMA-D [26], RAVDESS [27], and SAVEE [28] are some of the existing multimodal datasets that have been considered for research in recent times. A multimodal method by Cid et al. [29] used tempo, pitch, and energy feature extraction techniques to extract the audio features and a Bayesian classification method to classify the emotions. Edge-based characteristics are obtained from visual images to classify them in the SAVEE database.

Gharavian et al. [30] evaluated the performance of a neural network called FAMNN. MFCC, Zero Crossing Rate, and pitch are some of the audio feature extraction techniques used to extract the audio features. Visual information is obtained by using marker positions on the face concept, and the resulted features are given to a feature selection algorithm (FCBF). For audio features, Huang et al. [31] used prosodic and frequency domains, while for facial expression description, they used geometry and appearance-based features. Using a back-propagation neural network, each feature vector was utilised to train a single-modal classifier. They suggested a genetic learning-based collaborative decision-making model, which was compared to concatenated equal weighted choice fusion, BPN learning-based weighted decision fusion, and feature fusion methods. The audio spectrum features are obtained from BERT and CNN and are combined in parallel to form a multimodal [32].

A HGFM method was proposed by Xu [33], which fuses the hand-crafted features and the features extracted from the gated recurrent unit. The key frame videos are summarized by

the method proposed by Noroozi [34] which uses a CNN model and the concept of stack fashion or late fusion for detecting the emotions. Xu et al. [35] proposed a multi-hop memorized network that describes the single-modality and cross-modality interactions among the three different feature domains in aspect-level sentimental analysis of a multimodal system. Zadeh et al. [36] introduced a tensor fusion network that uses the product of audio, visual and image elements to represent multimodal fusion information.

RMFN, a multistage recurrent network for fusion described by Liang et al. [37], divides the multimodal fusion into various stages that utilize LSTM to record multimodal interactions in both synchronous and asynchronous modes. Liu et al. [38] lowered the computational complexity of the parameters by using a low-rank multimodal fusion approach that employs a low-rank tensor to relieve the increased computational cost of considering all three modalities. Poria et al. [39] used LSTM to isolate audio, video and text elements before combining them in a multi-level architecture. Ghosal et al. [40] developed a multi-attention recurrent network architecture for multimodal representation that learns features through attention. Tsai et al. [41] suggested learning interactions between modalities by employing multimodal transformers to construct an attention-based cross-modal architecture.

By using the RAVDESS dataset Fu Z et al. [47], R. Chatterjee et al. [48], Chang X et al. [49], Wang W et al. [50] achieved test accuracies of 75.76, 90.48, 91.4, and 89.8 on their respective multimodal systems. Ghaleb E et al. [52], He G et al. [53] proposed multimodal systems which resulted in test accuracies of 66.5 and 64 on the CREMAD dataset. Rory Beard et al. [51] proposed a multimodal where CREMAD and RAVDSR datasets are used for experimentation and resulted in test accuracies of 65.0 and 58.3, respectively.

## III. RESEARCH METHOD

### A. Dataset Description

CREMAD and RAVDESS datasets are used for experimentation and evaluation purposes. Both datasets consist of data related to the emotions of actors in both audio and video modes. Angry, disgust, fear, happy, neutral, and sad are the common emotions present in both datasets in both modes, whereas RAVDESS audio data consists of two more emotions, calm, and surprise. CREMAD consists of 22326 and 60359 emotions related to audio and video. RAVDESS consists of 4321 and 45225 emotions related to audio and video. A detailed overview of the datasets is given in Table I below.

### B. Image Feature Extraction

From the given set of video sequences of the multimodal dataset the videos should be converted into images and then facial features should be extracted from the images. The detailed description of the features is extracted from the videos is given below.

From the given set of facial emotion videos  $f_{vid}$  of a multimodal dataset, the images are represented in linear scale space  $L_{ss}$  which is obtained by convoluting  $f_{vid}$  with 3 dimensional Gaussian Kernel.

TABLE I. DESCRIPTION OF CREMAD AND RAVDESS DATASETS

| Name of The Dataset | Emotion Type | Data mode and Number of Emotions |                  |
|---------------------|--------------|----------------------------------|------------------|
|                     |              | Audio Mode                       | Video/Image Mode |
| CREMAD Dataset      | Angry        | 3510                             | 10472            |
|                     | Disgust      | 4116                             | 10098            |
|                     | Fear         | 3918                             | 10626            |
|                     | Happy        | 3709                             | 9661             |
|                     | Neutral      | 3666                             | 10867            |

|                     | Sad          | 559                              | 7140             |
|                     | Surprise     | 596                              | NA               |

$$L_{ss}(\cdot; \sigma_{L_{ss}}^2, \tau_{L_{ss}}^2) = \text{Gau}_k(\cdot; \sigma_{L_{ss}}^2, \tau_{L_{ss}}^2) * f_{\text{vid}}(\cdot) \quad (1)$$

linear scale space,  $f_{\text{vid}}$  is video sequence,  $\sigma_{L_{ss}}^2$  is Spatial variance,  $\tau_{L_{ss}}^2$  is Temporal variance,  $\text{Gau}_k$  is Spatial Temporal Gaussian Kernel.

$$\text{Gau}_k(x, y, t_d; \sigma_{L_{ss}}^2, \tau_{L_{ss}}^2) = \exp(-(x^2 + y^2)/2\sigma_{L_{ss}}^2 - t_d^2 / 2 \tau_{L_{ss}}^2) \quad (2)$$

Whereas  $x$  and  $y$  represents the axis of the frames that are obtained from the facial input video sequence  $f_{\text{vid}}$ ,  $t_d$  denotes the axis if time in the temporal domain

A method proposed by Forstner and Harris [42] [43] considers a Gaussian window to identify distinct points of the image which in turn determines the locations in  $f_{\text{vid}}$  when there are significant changes in the intensity of image in the given space and time domains when sliding the Gaussian window in various directions. The distinct points can be detected by convoluting Spatial-Temporal Second Momentum matrix with the given Gaussian weighted function  $\text{Gau}_k(\cdot; \sigma_i^2, \tau_i^2)$ .

The Spatial-Temporal Second Momentum matrix is  $3 \times 3$  dimensional matrix and is given as

$$\begin{bmatrix} L_{ssx}^2 & L_{ssx}L_{ssy} & L_{ssx}L_{sst} \\ L_{ssx}L_{ssy} & L_{ssy}^2 & L_{ssy}L_{sst} \\ L_{ssx}L_{sst} & L_{ssy}L_{sst} & L_{ssz}^2 \end{bmatrix} \quad (3)$$

And the distinct points identification is given by

$$\mu_{\text{ch}} = \text{Gau}_k(\cdot, \sigma_i^2, \tau_i^2) * \left( \begin{bmatrix} L_{ssx}^2 & L_{ssx}L_{ssy} & L_{ssx}L_{ssz} \\ L_{ssx}L_{ssy} & L_{ssy}^2 & L_{ssy}L_{ssz} \\ L_{ssx}L_{ssz} & L_{ssy}L_{ssz} & L_{ssz}^2 \end{bmatrix} \right) \quad (4)$$

Where  $L_{ssx}$ ,  $L_{ssy}$  &  $L_{ssz}$  are first order derivatives that are defined as follows

$$L_{ssx}(\cdot, \sigma_{L_{ss}}^2, \tau_{L_{ss}}^2) = \partial_x(\text{Gau}_k * f_{\text{vid}}) \quad (5)$$

$$L_{ssy}(\cdot, \sigma_{L_{ss}}^2, \tau_{L_{ss}}^2) = \partial_y(\text{Gau}_k * f_{\text{vid}}) \quad (6)$$

$$L_{ssz}(\cdot, \sigma_{L_{ss}}^2, \tau_{L_{ss}}^2) = \partial_z(\text{Gau}_k * f_{\text{vid}}) \quad (7)$$

Where  $\sigma_i^2 = S_{\text{ssk}} * \sigma_{L_{ss}}^2$ ,  $\tau_i^2 = S_{\text{ssk}} * \tau_{L_{ss}}^2$  and  $S_{\text{ssk}}$  is a constant

The existence of distinct points in the  $f_{\text{vid}}$  is indicated by the eigen values  $\lambda_1, \lambda_2, \lambda_3$  that can hold larger values. In the Spatial-Temporal domain the variations that are existing in the intensity of image are obtained by concatenating the  $\text{trace}_{L_{ss}}$  and determinant of  $\mu_{\text{ch}}$  which is given as

$$H_{fn} = |(\mu_{\text{ch}})| - K * \text{trace}_{L_{ss}}^3(\mu_{\text{ch}}) = \lambda_1 * \lambda_2 * \lambda_3 - k(\lambda_1 + \lambda_2 + \lambda_3) \quad (8)$$

$K$  is a constant and the function  $H_{fn}$  is normalized such that the effect of variations in the images due to illumination can be removed

### C. Audio Feature Extraction

Zero crossing rate (ZCR), Mel Frequency Spectrum Coefficient (MFCC), pitch and energy are some of the feature extraction techniques used to extract the features of the emotions from the given audio signal.

1) *Zero crossing rate*: The number of times the audio signal crosses the zero-line, x-axis, is referred to as the zero-crossing rate, and it is stated as follows.

$$Z_{t_n} = \frac{1}{2N} * \sum_{n=1}^N \left| \text{Sign}_{\text{Aud}}(x_{\text{Audt}}(n)) - \text{Sign}_{\text{Aud}}(x_{\text{Audt}}(n-1)) \right| \quad (9)$$

$$\text{Sign}_{\text{Aud}}(x_{\text{Audt}}) = \begin{cases} 1 & \text{if } x_{\text{Audt}} > 0 \\ 0 & \text{Otherwise} \end{cases} \quad (10)$$

Where,  $t_n \in [t_{n1}, t_{n2}]$ ,  $x_{\text{Audt}(t_n)}$  is the respective audio signal that was divided into segments by using a sliding window that was having a length of  $T$ ,  $n \in [0, N]$  and  $x_{\text{Audt}}(n)$  is the  $t_n^{\text{th}}$  Segments time sequence

2) *MFCC (Mel frequency cestrum coefficient)*: The coefficients of the corresponding spectral form of the audio stream are represented using a nonlinear Mel scale. The Mel frequency was used to analyse cepstral coefficients, and the steps below were followed.

*Step 1: Audio Signals are splitted into frames by using fixed shift and window sizes.*

*Step 2: Fast Fourier Transform (FFT)*

*for each frame is calculated.*

*Step 3: Frequencies are based on the Mel Scale used.*

*Step 4: Logarithm of the resulted output of Step 3 is calculated.*

*Step 5: Discrete Cosine Transform (DCT) for each frame is calculated.*

Acoustic tube characteristics pitch and energy are exhibited by MFCC that contains great amount of emotional information which plays a key role in emotion recognition.

3) *Pitch*: It depicts the signal's fundamental frequency [44]. The valence of an audio stream is connected to its rhythm and average pitch from an emotional standpoint. For example, higher amount of pitch may be associated to discomfort, lower standard deviation to sadness and usually happiness and discomfort are having higher talk and pitch rates whereas sadness can be represented by lower talk and pitch rates [45]. Autocorrelation is used to calculate the pitch of the audio signal and is given as follows.

$$x_{Aud}[n] \text{ be Stochastic Process Sinusoidal function}$$

$$x_{Aud}[n] = \text{Cos}(w_0 n + \varnothing) \text{ and the autocorrelation of } x_{Aud}[n] \text{ is given as}$$

$$R_{Aud}[t] = E\{x_{Aud}^*[n] * x_{Aud}^*[n+t]\} \quad (11)$$

$$= \frac{1}{2} \cos(w_0 t)$$

Maximum of the autocorrelation value is used to calculate the pitch,  $S_{Aud}$  Samples are used to calculate the estimate of  $R_{Aud}[t]$

$$R_{Aud}^{\wedge}[t] = \frac{1}{S_{Aud}} * \sum_{S_{Aud}=0}^{S_{Aud}-|t|} (W_{Aud}[S_{Aud}] * x_{S_{Aud}} * W_{Aud}[S_{Aud} + |t|]) \quad (12)$$

$W_{Aud}[S_{Aud}]$  is window length of  $S_{Aud}$  the Expected value of

$$R_{Aud}^{\wedge}[t] \text{ is given as}$$

$$E_{Aud}\{R_{Aud}^{\wedge}[t]\} = \left(1 - \frac{|t|}{S_{Aud}}\right) * \frac{\text{Cos}(w_{Aud0} * S_{Aud})}{2}, |t| < S_{Aud} \quad (13)$$

4) *Energy*: It represents the signal's intensity or total energy. From an emotional standpoint, an audio signal having exciting emotions (e.g., pain or happiness) has more energy than an audio signal containing sadness or fatigued feelings [46]. The energy of the audio signal  $x_{Audt}(n)$  is given as

$$\text{Energy}_{Aud} = \sqrt{\frac{1}{N} * \sum_{n=1}^N (x_{Audt}(n)^2)} \quad (14)$$

#### D. Feature Level Fusion

From the features obtained from audio and video signals, only a few portions of the features are related to emotions. Personality, age, gender, and many other features are obtained from audio and video signals, which may impact the quality of recognition of the emotions that are used in the model for training. Feature Level Latent Space methods are one of the existing categories of methods that are used to find the common features related to emotions and map them into the required latent space. By maximizing the cross correlation of the respective features and by minimizing the feature distance or by taking the normalization of the features, they can be used in feature level fusion. Marginal Fisher Analysis (MFA) is a supervised method that is used for audio video feature level for fusion by extracting the required features from the respective modalities. The process of  $MFA^s$  feature level fusion is given as below.

Information related to class labels is used in latent space generation. The compactness in the intra class is given as

$$S_{compact} = \sum_i \sum_{i \in N_{k1}^+} \|W_{AV}^T x_i - W_{AV}^T x_i\|^2$$

$$= 2 W_{AV}^T X_{AV} (D^{AV} - S^{AV}) * X_{AV}^T W_{AV} \quad (15)$$

$X_{AV} = \{x_1, x_2, \dots, x_n\}$  is the frame set,  $N$  is the total samples and  $N_{k1}^+$  is  $k_1$  in the same class.

$$S_{ij}^{AV} = \begin{cases} 1 & \text{if } i \in N_{k1}^+(j) \\ 0 & \text{Otherwise} \end{cases} \quad (16)$$

$$D_{ij}^{AV} = \sum_j S_{ij}^{AV} \quad (17)$$

And the Inter-Class Separability is given by

$$I_{cpP} = \sum_i \sum_{(i,j) \in P_{k2}(c_i)} \|W_{AV}^T x_i - W_{AV}^T x_j\|^2 \quad (18)$$

$$= 2 W_{AV}^T X_{AV} (D_{AV}^P - S_{AV}^P) * W_{AV}^T W_{AV}$$

$c_i$  is the emotion of class  $i$ ,  $P_{k2}(c_i)$  is the set of  $K_2$  nearest pairs and  $S_{AV}$  is given by

$$S_{AVij}^P = \begin{cases} 1 & \text{if } (i,j) \in P_{k2}(c_i) \\ 0 & \text{Otherwise} \end{cases} \quad (19)$$

And the objective function is given as follows

$$W_{AV}^{\wedge} = \arg_{W_{AV}} \left\{ \min \left\{ \frac{W_{AV}^T X_{AV} (D^{AV} - S^{AV}) X_{AV}^T W_{AV}}{W_{AV}^T X_{AV} (D_{AV}^P - S_{AV}^P) X_{AV}^T W_{AV}} \right\} \right\} \quad (20)$$

And the optimal solution is given by

$$Y_{AV} = X_{AV}^T W_{AV} \quad (21)$$

$$L_{AV} \cdot Y_{AV} = \lambda L_{AV}^P \cdot \quad (22)$$

Where  $L_{AV} = D^{AV} - S^{AV}$  and  $L_{AV}^P = D_{AV}^P - S_{AV}^P$  are called Laplacian matrices for  $W_{AV}$  and  $W_{AV}^P$

#### E. Proposed CNN Architecture

The proposed CNN architecture consists of four fully connected layers, one flattening layer and two dense layers. All the fully connected layers are interconnected with each other where the output features obtained from each fully connected layer are given as an input to the next fully connected layer. The inputs to the first fully connected layer are audio, video, and multimodal features that are obtained during pre-processing by applying the audio feature, image feature, and feature level fusion extraction techniques described in the above sections. The first fully connected layer consists of convolution and max polling layers, and the representation of the first fully connected layer is given as

$$\text{Out}_{conv1} = \text{Act}(\sum_i L_{AV} * W_{ij}^n) \quad (23)$$

Where  $\text{Out}_{conv1}$  is the output of the convolutional layer,  $\text{Act}$  is the activation function,  $L_{AV}$  is the latent space or latent features obtained after applying feature level fusion, and  $W_{ij}^n$  is the set of weights associated with the convolutional layer

$$\text{Out}_{convf1} = \text{Max polling}\{\text{Out}_{conv1}\} \quad (24)$$

$Out_{convf1}$  is the output obtained from the max polling layer, where the input is  $Out_{conv1}$ , the first convolutional layer output. The output of the first fully connected layer  $Out_{Maxpoll1}$  is given as input to the second fully connected layer, which consists of convolutional, max polling, and dropout layers, and the representation of the second fully connected layer is given as

$$Out_{conv2} = Act(\sum_i Out_{Maxpoll1} * W_{ij}^{2n}) \quad (25)$$

$$Out_{Maxpoll2} = \text{Max polling}\{Out_{conv2}\} \quad (26)$$

$$Out_{conv2f} = Act((Out_{Maxpoll2} * Drop(0.2))) * W^{[2n+1]} \quad (27)$$

$Out_{conv2f}$  is the output of the second fully connected layer,  $Drop(0.2)$  means that 20% of the features are dropped from the output of the max polling layer, and  $W^{[2n+1]}$  are associated weights used.

$Out_{conv2f}$  the output of second fully connected layer, is given as input to the third fully connected layer which consists of the same layers as second fully connected layer and the output of the third fully connected layer is given as

$$Out_{conv3f} = Act((Out_{Maxpoll3} * Drop(0.2))) * W^{[2n+2]} \quad (28)$$

$Out_{conv3f}$  is given as input to the fourth fully connected layer which consists of a convolution and max polling layers and the output is given as

$$Out_{conv4} = Act(\sum_i Out_{conv3f} * W_{ij}^n) \quad (29)$$

$$Out_{conv4f} = \text{Max polling}\{Out_{conv4}\} \quad (30)$$

The output of the fourth fully connected layer is flattened by giving to a flatten layer and the output is represented as

$$\text{Flatten}_{CNN} = \text{Flatten}(a_1 Out_{convf1}, a_2 Out_{convf2}, a_3 Out_{convf3}, a_4 Out_{convf4}) \quad (31)$$

The output of a flattening layer is given to a dense layer and a dropout of 20% is applied to the output obtained from the dense layer. The resultant features are given as input to the next dense layer where the output is classified. Relu activation function is used in the dense layers that are used in between, and a SoftMax activation function is used in the final dense output layer. The representation of the dense, dropout, and final output layers is as follows:

$$Out_{Dense1}^1 = \text{Dense}(Den_N, Act_{Relu}(\text{Flatten}_{CNN})) \quad (32)$$

$$Out_{Drop}^1 = Act(Out_{Dense1}^1 * Drop(0.2)) * W \quad (33)$$

$$Out_F^1 = \text{Dense}(Den_C, Act_{Softmax}(Out_{Drop}^1)) \quad (34)$$

$Out_{Dense1}^1$  is the output of the dense layer,  $Out_{Drop}^1$  is the output of dropout layer  $Out_F^1$  is the final classified output. The architecture of the proposed CNN is given in the Fig. 1.

| Layer (type)                   | Output Shape     | Param # |
|--------------------------------|------------------|---------|
| conv1d (Conv1D)                | (None, 168, 256) | 1824    |
| max_pooling1d (MaxPooling1D)   | (None, 53, 256)  | 0       |

## F. Data Preprocessing

For experimentation, the RAVDESS and CREMAD datasets are used in this paper. The datasets contain data related to audio and video emotions of various actors, and the description of the data is given in the dataset description section of the same module. The features of the video and audio data are obtained by using the image feature extraction and audio feature extraction methods explained above. There is dissimilarity in the number of features obtained from audio and video datasets. There are more features in the resultant dataset of video images when compared to audio files. A dimensionality reduction technique is applied to the image set to reduce the number of features so that the same number of features is present in the audio and video resultant datasets. Finally, a multimodal dataset is obtained by combining the resultant features of audio and video from the respective datasets by using the feature-level fusion technique that was explained in Section D, namely the "Feature Level Fusion" of the same module. The features obtained after applying Feature Level Fusion are given to the proposed CNN Model for Evaluation, and the description of the proposed CNN Model is explained in Section E, named "Proposed CNN Architecture." Fig. 2 gives the workflow of the proposed work done in this paper.

Fig. 2. Workflow of the Proposed Method.

IV. EXPERIMENTATION AND RESULTS

Fig. 3(a) and (b), 3(c) and (d) and 3(e) and (f) represent training and testing accuracy and loss comparisons in audio, video, and multimodal modes on the RAVDESS dataset. Test accuracies of 95.96, 96.28, and 95.07 were observed. On the CREMAD dataset, train and test accuracies and train and test accuracies losses are shown in Fig. 4(a) and (b), 4(c) and (d), and 4(e) and (f) represent training and testing accuracy and loss comparisons in audio, video, and multimodal modes. Test accuracies of 80.70, 97.88, and 69.66 were observed. A detailed description of the results is given in Table II.

(a) Training and Testing Loss of Audio Data in CREMAD Dataset, (b) Training and Testing Accuracy of Audio Data in CREMAD Dataset, (c) Training and Testing Loss of Video Data in CREMAD Dataset, (d) Training and Testing Accuracy of Video Data in CREMAD Dataset, (e) Training and Testing Loss of Multi Modal Data in CREMAD Dataset, (f) Training and Testing Accuracy of Multi Modal Data in CREMAD Dataset.

TABLE II. ACCURACY AND LOSS OF RAVDESS AND CREMAD DATASETS ON DIFFERENT TYPES OF DATA IN THE DATASET

| Name of Dataset | Type of Data | Train Accuracy | Test Accuracy | Train Loss | Test Loss |
|-----------------|--------------|----------------|---------------|------------|-----------|
| RAVDESS         | Audio        | 92.19          | 95.56         | 0.2430     | 0.161     |
|                 | Video        | 96.92          | 96.28         | 0.1716     | 0.173     |
|                 | Multi Modal  | 91.95          | 95.07         | 0.2155     | 0.136     |
| CREMAD          | Audio        | 72.70          | 80.50         | 0.7293     | 0.588     |
|                 | Video        | 95.33          | 97.88         | 0.1978     | 0.151     |
|                 | Multi Modal  | 65.20          | 69.66         | 0.7840     | 0.646     |

Fig. 5(a) and 5(b) represent the confusion matrix/classification report of how the classes are classified during the testing phase on audio data of the RVDSR and CREMAD datasets. It has been observed that an average precision, recall, f1-score and support values of 0.955, 0.954, 0.953 and 540 on RAVDESS, 0.807, 0.806, 0.805 and 744 on CREMAD datasets, respectively. The detailed description of various emotions and their respective performance measure values of RAVDESS and CREMAD audio data is given in Table III.

Fig. 6(a) and 6(b) represent the confusion matrix/classification report of how the classes are classified during the testing phase on video data of the RVDSR and CREMAD datasets. It has been observed that an average precision, recall, f1-score and support values of 0.98, 0.985, 0.985 and 997 on RAVDESS, 0.973, 0.975, 0.975 and 1027 on CREMAD datasets, respectively. The detailed description of various emotions and their respective performance measure values of RAVDESS and CREMAD video data is given in Table IV.

A multi-modal dataset has been obtained by combing the features of audio and video by using the feature level fusion techniques described in the feature level fusion section of the proposed method on the RAVDESS and CREMAD datasets. Fig. 7(a) and 7(b) give the classification report/confusion matrix obtained from the proposed CNN architecture during the evaluation stage. The classification report shows how the six classes, namely angry, disgust, fear, happy, neutral, and sad, are properly classified during their test by the proposed CNN architecture. An average precision of 0.953 & 0.716, recall of 0.953 & 0.7, f1-support of 0.951 & 0.688, and support of 1613 & 2817 were observed by the proposed CNN architecture during the evaluation phase on RAVDESS & CREMAD multimodal. The detailed description of the results is explained in Table V.

V. CONCLUSION AND FUTURE WORK

A multimodal system for emotion recognition was proposed in the current work. Audio and video information are used here. Audio features are obtained by the Mel-Frequency Cepstral Coefficients extraction technique, and all the videos are converted into images and stored in a spatial-temporal space. The image features are extracted by using a Gaussian weighted function. The MFA fusion technique is to fuse the audio and video features, and the resultant features are given to the FERCNN Model for training and evaluation. For experimentation, the RAVDESS and CREMAD datasets, which consist of audio and video data, are used. Test accuracies of 95.07 and 69.66 were obtained on the RAVDSR

and CREMAD datasets in multimodal mode. Even though many multimodal emotional datasets exist, only two of them are considered. An efficient multimodal system that is generic to all types of multimodal emotional databases can be designed, and the maximum multimodal data accuracy on the CREMAD dataset is 69.66%, which can be further improved.

**Abstract**—Hadith serves as a second source of Islamic law for Muslims worldwide, especially in Indonesia, which has the world's most significant Muslim population of 228.68 million people. However, not all Hadith texts have been certified and approved for use, and several falsified Hadiths make it challenging to distinguish between authentic and fabricated Hadiths. In terms of Hadith science, determining the authenticity of a Hadith can be accomplished by examining its Sanad and Matn. Sanad is an essential aspect of the Hadith because it indicates the chain of the Narrator who transmits the Hadith. The research reported in this paper provides an advanced Natural Language Processing (NLP) technique for identifying and authenticating the Narrator of Hadith as a part of Sanad, utilizing Named Entity Recognition (NER) to address the necessity of authenticating the Hadith. The NER technique described in the research adds an extra feed-forward classifier to the last layer of the pre-trained BERT model. In the testing process using Cahya/bert-base-indonesian-1.5G, the proposed solution received an overall F1-score of 99.63 percent. On the Hadith Narrator Identification using other Hadith passages, the final examination yielded a 98.27 percent F1-score.

**Keywords**—Hadith narrator; hadith authentication; natural language processing; named entity recognition; NLP; NER; BERT; BERT fine-tune

## I. INTRODUCTION

Islam is a massive faith globally, with over 2 billion Muslims in 2018, accounting for approximately 29.04% of global society. Indonesia has the most massive Muslim community, with more than 233.38 million Muslims in 2018. Muslims need to refer to Islamic rules in the Holy Qur'an and Hadith as their life guidance. The Holy Al-Qur'an is the absolute revelation from Allah (God of Muslims), while Hadith, notably, is a compilation of quotes that Prophet Mohammed has said. Nevertheless, not all the Hadith text is authenticated and authorized to apply. Several fabricated Hadiths cause many issues in determining between genuine and non-genuine Hadiths. The existence of fabricated Hadiths denigrates and reduces the Hadiths' authority and significantly affects Muslim's entire lives, mainly in belief, law, morals, observance, and others. The worst effect of fabricated Hadiths is the confusion they bring to Muslims and, consequently, corrupt their faith [1]. Therefore, it is vital to investigate to verify the authenticity and originality of the accessed Hadiths.

Hadith verification can employ two principal parameters that possibly recognize the condition of a particular Hadith: (1) the context (the meaning of the Hadith itself) and (2) the narrators (the people who recite the Hadith). Recognizing the narrators' names has a crucial role in authorizing a particular Hadith. For example, the snippet of text from Indonesia's Hadith is below:

Telah menceritakan kepada kami Al Humaidi Abdullah bin Az Zubair dia berkata, Telah menceritakan kepada kami Sufyan yang berkata, bahwa Telah menceritakan kepada kami Yahya bin Sa'id Al Anshari berkata, telah mengabarkan kepada kami Muhammad bin Ibrahim At Taimi, bahwa dia pernah mendengar Alqamah bin Waqash Al Laitsi berkata; saya pernah mendengar Umar bin Al Khaththab diatas mimbar berkata; saya mendengar Rasulullah shallallahu'alaihi wasallam bersabda: "Semua perbuatan tergantung niatnya, dan (balasan) bagi tiap-tiap orang (tergantung) apa yang diniatkan; Barangsiapa niat hijrahnya karena dunia yang ingin digapainya atau karena seorang perempuan yang ingin dinikahinya, maka hijrahnya adalah kepada apa dia diniatkan"

The meaning is:

Has told us Al Humaidi Abdullah bin Az Zubair he said, Has told us Sufyan who said, That has said us Yahya bin Sa'id Al Ansari said, has told us Muhammad bin Ibrahim At Taimi, that he had heard of Alqamah bin Waqash Al Laitsi said; I once heard Umar bin Al Khaththab on the pulpit say; I heard the Prophet sallallaahu'alaihi wasallam say: "All actions depend on the intention, and (retribution) for each person (depending on) what is intended; Whoever intends to emigrate because of the world he wants to achieve or because of a woman he wants to marry, then his hijrah is what is he intended for?"

The example Hadith text above has five narrators (highlighted in gray). The status of the above Hadith, authentic or not, can be assessed by identifying and assessing the worthiness of the five narrators. NER is an NLP role that recognizes and classifies named entities in a provided text. "Named entities" refer to predefined semantic categories such as people, locations, and organizations. NER is theoretically applicable to various domains and languages. Therefore, it is challenging to address NER to identify the Hadith Narrator and authenticate it.

This study proposes semi-supervised BERT (Bidirectional Encoder Representations from Transformers) with an extra feed-forward neural network for Hadith Narrators to execute NER, particularly for Indonesian Hadith texts. In case all of the Hadith Narrators have already been identified using the proposed NER Model. Then it is possible to continue with defining the Hadith authentication. The remainder of the essay is organized as follows: To begin, Section II reviews prior work on NER and Hadith Narrator Identification. Section III substantiates this view by discussing the academic definitions of the NER and BERT and the evaluation factors used. Then, Section IV clarifies the recommended model for this investigation. Section V discusses the findings of this research examination. In the end, Section VI discusses the final findings and future research directions.

## II. RELATED WORK

The implementation of NER is domain and language-dependent. When utilized in other domains, the NER generated for one domain performs poorly [2][3]. The scope of the study reported in this paper is limited to identifying the Hadith Narrator using the NER technique. Specifically, Hadith in the Indonesian language.

The study [4] proposes a new Part of Speech (POS) tag and rule-based narrator name extraction for Malay Hadith text. The result was the creation of the POS tag involving 256 words developed from Hadith text, and the rules were created based on five Narrator chains. Similarly, in [2], the author presents a unique rule-based technique for automatically identifying person-name entities in the Malay Hadith text-domain. The model was developed by manually recognizing the names and mannerisms of 150 Malay Hadith books and then developing rules based on them.

The study [5] created a model of NER for Hadith texts written in English. The proposed model makes use of the Support Vector Machine (SVM), the Maximum Entropy Classifier (ME), as well as the Naive Bayes (NB), and classifier combination methods. The results indicate that the classifiers' combination technique achieves the best performance, with precision, recall, and F-Measure values of 96.9 percent, 93.6 percent, and 95.3 percent, respectively. Another author [6] built a NER-based knowledge extraction framework that employs finite-state transducers (FSTs) – KEFST – to extract the Hadith Narrators from the Urdu Translation Hadith text. KEFST consists of five steps: content extraction, tokenization, part of speech tagging, multi-word detection, and NER. This study achieved a precision, recall, and F-measure sequentially of 68%, 75%, and 72%.

The study [7] constructed NERs for Arabic Hadith texts using three machine learning algorithms: naive Bayes, K-nearest Neighbor, and Decision Tree. During the training phase, the NER model achieved a precision of 90% and a recall of 82%. Evaluating the created model on various corpora demonstrates that it can achieve an accuracy of 80% and a recall of 73%. The author [8] constructed NERs for Arabic Hadith texts using three distinct approaches: rule-based, statistical, and hybrid (rule-based combined with statistical). The statistical methods used are the Log-likelihood Ratio (LLR), Point-wise Mutual Information (PMI), S-cost, R-cost,

and U-cost. LLR outperformed PMI, S-cost, R-cost, and U-cost, capturing 76% of the F-measure. Additionally, the rule-based approach captured 80% of the F-measure. The experimental results indicate that the proposed hybrid method of rule-based and statistical analysis achieved an F-measure of 82 percent, which is a positive outcome compared to the individual approach.

The study [9] used two RNN-based models to recognize and categorize named things in Classical Arabic Hadith text by fine-tuning the pre-trained BERT language model. Additionally, this study investigates alternative designs for the BERT-BGRU/BLSTM-CRF models. The BERT-BGRU-CRF model outperformed the other models with an F-measure of 94.76 percent on the CANERCorpus. Another author [10] developed a novel NER model for Arabic Hadith text extracted from the Sahih Bukhari Urdu translation book. The proposed model extracts entities from Hadith text using Finite State Transducers (FST) and subsequently tags them using Conditional Random Fields (CRF). The model had a precision of 96.44 percent, a recall of 88.77 percent, and an F-Measure of 92.41 percent. Similarly, in [11], the author proposes a new approach for extracting Arabic person names from Arabic Hadith text. This study built NER using N-gram phrase extraction and a simple rules model, and the result showed excellent precision of around 84%.

The work [12] offers a novel NER model for Hadith texts in Indonesia using Support Vector Machines (SVM). The results suggest that the NER model attained the most incredible F-1 score of 0.9 using 140 Hadiths containing 1564 entities for training and 60 Hadiths containing 677 entities for testing. Another study [15] built NER with a Naive Bayes classifier for Indonesian Hadith from nine narrators. The results of experiments involving 258 people's names extracted from 13870 tokens of data from 100 Indonesian hadith texts show that combining all features can achieve 82.63% of the F1-Score. The author [13] built NER for indexing names in the Indonesian Hadith Text. This study employs the Hidden Markov Model (HMM). The values of performance that were obtained using HMM's method are 86%. However, by using cross-validation based on the parameters, the performance values increased by 2%, which means that the performance in this research is quite suitable for 38.102 data hadith.

Although various studies have successfully proved the application of NER on Hadith, there is a dearth of studies that optimize BERT to execute NER in order to detect the Narrator in Indonesian Hadith text automatically.

## III. FUNDAMENTAL THEORY

### A. NER

The NER is an NLP task that identifies text fragments related to a specific named entity and categorizes them according to predefined categories such as a person, location, or organization [14]. Four key lines of progress can be seen in the evolution of NER techniques [15]:

- 1) Rule-based techniques are non-annotated and rely on manually written rules.
- 2) Unsupervised learning methods rely on unsupervised

algorithms in the absence of manually labeled training examples.

3) Feature-based techniques for supervised learning depend on supervised learning techniques that have been carefully engineered with features.

4) Deep-learning techniques automatically locate representations required for classification or detection.

Fig. 1 depicts the progress of the NER approach.

Fig. 1. NER Method's Evolution.

**B. BERT**

A BERT (Bidirectional Encoder Representations from Transformers) is a pre-trained transformer representation that may be fine-tuned to utilize one extra layer of output. BERT enhanced its capacity to create new state-of-the-art outcomes for several assignments, including question answering and sentence categorization, without significantly altering the task-specific architecture [16][17]. Fig. 2 illustrates the BERT architecture.

A feature-based or fine-tuning method might be applied to assign downstream assignments to pre-trained language representations [16]. Fine-tuning is simple, as the transformer's self-attention mechanism enables BERT to perform many downstream assignments on a single text or text pair by swapping the relevant inputs and outputs. Each assignment needs BERT to receive just the assignment-specific inputs and outputs, which fine-tunes all parameters end-to-end.

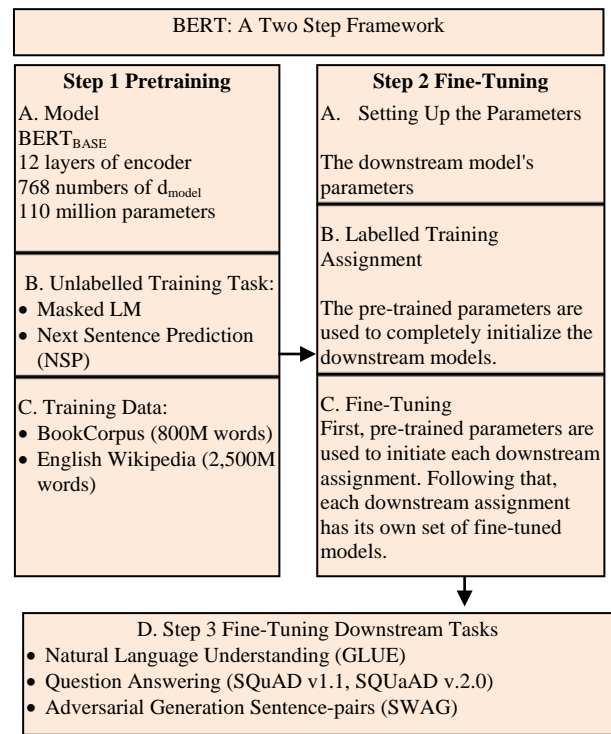

Fig. 2. NER Method's Evolution.

**IV. PRESENTED MODEL**

The methodology used in this investigation is summarized in Fig. 3.

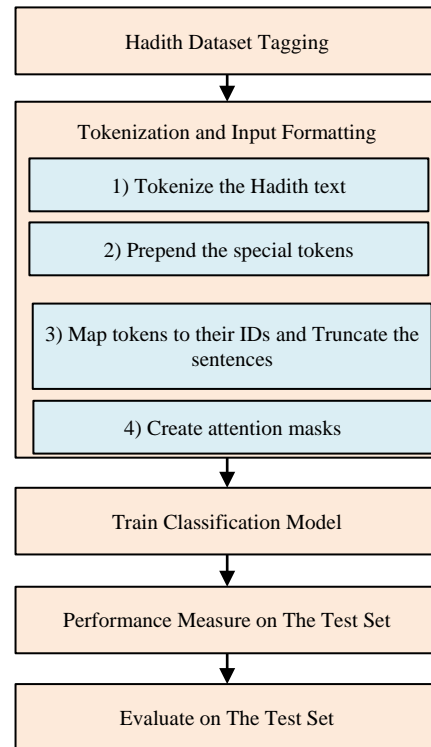

Fig. 3. Proposed Methodology.

TABLE II. SAMPLE OF TOKENS

| WORD        | TOKENS             | WORD         | TOKENS       |
|-------------|--------------------|--------------|--------------|
| dari        | dari               | kami         | kami         |
| abu         | abu                | sesungguhnya | sesungguhnya |
| abdurrahman | abdurrahman        | penciptaan   | penciptaan   |
| bin         | bin                | kalian       | kalian       |
| mas'ud      | mas<br>[UNK]<br>ud | dikumpulkan  | dikumpulkan  |
| ia          | ia                 | dalam        | dalam        |
| berkata     | berkata            | rahim        | rahim        |
| bahwa       | bahwa              | sang         | sang         |
| rasulullah  | rasulullah         | ibu          | ibu          |
| yang        | yang               | selama       | selama       |
| jujur       | jujur              | empat        | empat        |
| dan         | dan                | puluh        | puluh        |
| terpercaya  | terper<br>##caya   | hari         | hari         |
| bersabda    | bersabda           | berupa       | berupa       |
| kepada      | kepada             | sperma       | sperma       |

The number of words that must be tokenized down to the subword level and the final number of tokens for a Hadith text is determined by the used pre-defined BERT. Since the BERT vocabulary for each of the pre-defined BERTs is diverse.

Table III compares the tokenized outcomes of numerous pre-defined BERTs. Most pre-defined BERTs built on the Indonesian language have shorter median token lengths than pre-defined BERTs "bert-base-uncased" built on the general language.

2) *Prepend the special tokens*: Tokenization in BERT entails putting the unique [CLS] token at the beginning of the Hadith text and appending the [SEP] token at the end to indicate the text's beginning and end. This treatment is depicted in Fig. 4 Step C.

3) *Map tokens to their IDs and truncate the sentences*: The word tokens must be mapped to their BERT vocabulary IDs, and all sentences must be made to have the same number of tokens. In order for the GPU to operate on a batch. This process is addressed with some steps, i.e., (1) defining the max sentence length, (2) adding the special [PAD] token to the sentences with the token shorter than the max length, and (3) truncating sentences that are longer than the max length.

The max length adjustment in this study refers to the column max length in Table III, except when employing "bert-base-uncased," in which case the max length is set to 512. Since the limit is derived from the Transformer architecture's positional embeddings, a maximum length must be imposed. Fig. 2 Step D depicts this treatment.

TABLE III. TOKENIZATION RESULTS OF SEVERAL PRE-DEFINED BERT

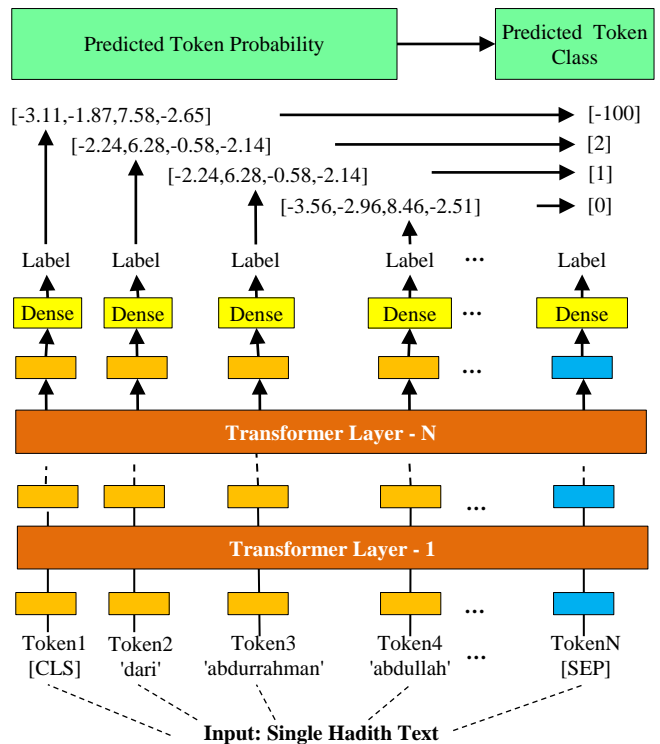

| BERT PRE-TRAINED                | MIN LENGTH | MAX LENGTH | MEDIAN LENGTH |
|---------------------------------|------------|------------|---------------|
| bert-base-uncased               | 90         | 736        | 214           |
| cahya/bert-base-indonesian-1.5G | 50         | 408        | 113           |
| indobenchmark/indobert-base-p1  | 46         | 361        | 104           |
| indobenchmark/indobert-base-p2  | 46         | 361        | 104           |

The max length adjustment in this study refers to the column max length in Table III, except when employing "bert-base-uncased," in which case the max length is set to 512. Since the limit is derived from the Transformer architecture's positional embeddings, a maximum length must be imposed. Fig. 2 Step D depicts this treatment.

4) *Create attention masks*: The final tokenization and formatting process provides the model with an "attention mask" for each sample that identifies and instructs BERT to ignore the [PAD] tokens. This procedure is depicted in Fig. 4 Step E.

C. Classification and Model Training

Thirdly, the classification model must be trained. The proposed model architecture is the BERT with a single linear layer for classifying the entity classes associated with each Narrator token. The proposed model architecture is depicted in Fig. 5.

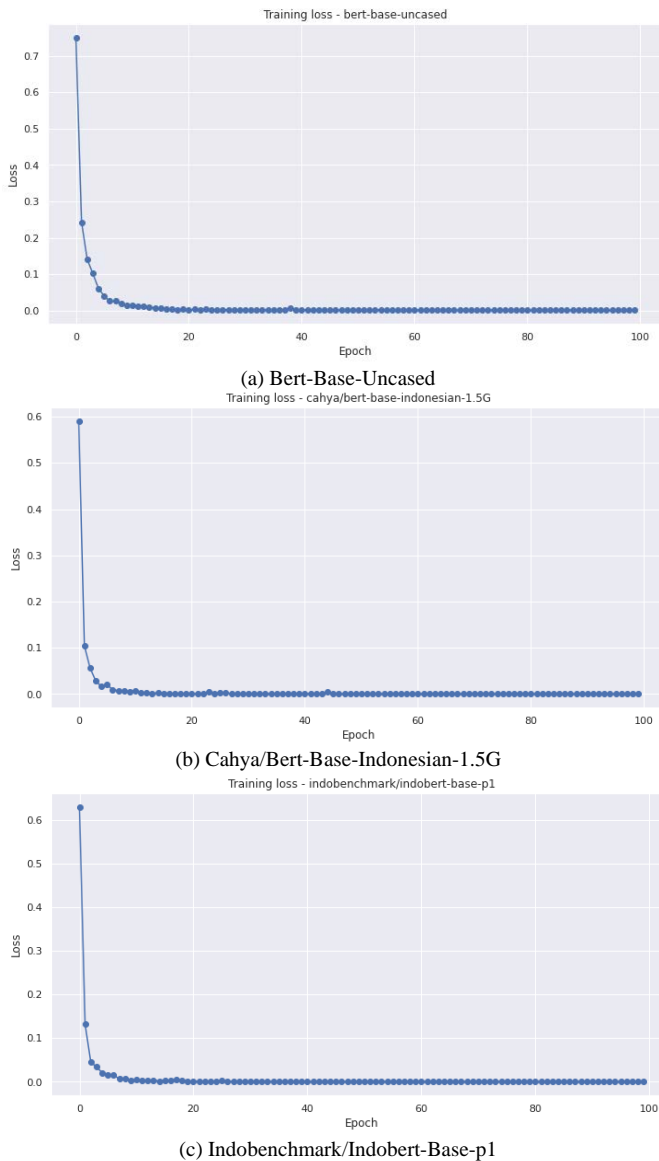

*Dari Abu Abdurrahman Abdullah bin Mas'ud, ia berkata bahwa Rasulullah yang jujur dan terpercaya bersabda kepada kami, "Sesungguhnya, penciptaan kalian dikumpulkan dalam rahim sang ibu selama empat puluh hari berupa sperma..."*

Fig. 5. Classification Model for Hadith Text Tokens.

According to the pre-trained model used, the BERT model employs N-Layer Transformers. The final additional layer will consist of two steps for classifying the token into the token class. Forecast probability of tokens first, followed by the class of tokens. This study examines how four different BERT pre-trained models can be scaled up to become NER models. The NER model is the target model, which was trained using the following parameters:

- Maximum Length : 512
- Number of Batches : 16
- Number of Epochs : 100
- Classification Labels 2 for 'B-Narrator', 0 for 'I-Narrator', and 1 for 'O'.

Fig. 6 depicts the training loss graphics associated with the process of fine-tuning the NER Model.

(d) Indobenchmark/Indobert-Base-p2

Fig. 6. The NER Model's Training Loss During the Training Process.

#### D. Performance Measure

The fourth stage is to evaluate the performance of the test set. The performance of the NER Model is quantified using an F1-Score. The F1-score is a numerical term that denotes the compatible mean of precision and recall. The formula below expresses the precision, recall, and F1-score:

$$Precision = \frac{TP}{TP + FP} \quad (1)$$

$$Recall = \frac{TP}{TP + FN} \quad (2)$$

$$F1 - Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (3)$$

The F1-score result for the NER model constructed on top of four separate BERT pre-trained models is shown in Table IV. Except for the bert-base-uncased model, the general BERT model, the BERT pre-trained model contains options supporting the Indonesian language.

TABLE IV. THE NER MODEL F1-SCORE ON TRAINING PROCESS

| BERT PRE-TRAINED                | F1 score |
|---------------------------------|----------|
| bert-base-uncased               | 99.08%   |
| cahya/bert-base-indonesian-1.5G | 99.63%   |
| indobenchmark/indobert-base-p1  | 99.43%   |
| indobenchmark/indobert-base-p2  | 99.11%   |

#### E. Evaluation

The fifth stage involves the evaluation of the NER model. As shown in Table IV, the NER model's performance was assessed again using an additional forty New Hadith texts. The evaluation conclusions are summarized in Table V. The NER model's assessment results are, on average, 0.28 percent lower than the training results. The sequence, on the other hand, is preserved. Cahya/bert-base-indonesian-1.5G demonstrated the best performance, followed by indobenchmark/indobert-base-p1, indobenchmark/indobert-base-p2, and bert-base-uncased.

Table VI summarizes the results of the NER evaluations of three Hadith passages. On hadith1, hadith2, and hadith 3, texts of assessment, some errors in tagging output were made. For instance, in Hadith 1, "Abu" should be labeled as I-Narrator rather than B-Narrator. On hadith2, the word "Ummu" should be categorized as I-Narrator but tagged as "O", and so forth.

TABLE V. THE NER MODEL F1-SCORE ON EVALUATION PROCESS

| BERT PRE-TRAINED                | F1 score |
|---------------------------------|----------|
| bert-base-uncased               | 98.68%   |
| cahya/bert-base-indonesian-1.5G | 99.27%   |
| indobenchmark/indobert-base-p1  | 99.23%   |
| indobenchmark/indobert-base-p2  | 98.94%   |

TABLE VI. THE NER MODEL EVALUATION SAMPLES

| Input   |           | Expected Output | Bert-base-uncased Output | Cahya/bert-base-indonesian-1.5G |
|---------|-----------|-----------------|--------------------------|---------------------------------|
| Tokens  |           |                 |                          |                                 |
| Hadith1 | Dari      | O               | O                        | O                               |
|         | Amirul    | B-Narrator      | B-Narrator               | B-Narrator                      |
|         | Mukminin  | I-Narrator      | I-Narrator               | I-Narrator                      |
|         | Abu       | I-Narrator      | B-Narrator (False)       | I-Narrator                      |
|         | Hafsh     | I-Narrator      | I-Narrator               | I-Narrator                      |
|         | Umar      | I-Narrator      | I-Narrator               | I-Narrator                      |
|         | bin       | I-Narrator      | I-Narrator               | I-Narrator                      |
|         | Khaththab | I-Narrator      | I-Narrator               | I-Narrator                      |

|         | ...       | ...             | ...                      | ...                             |
| Hadith3 | syubhat   | O               | B-Narrator (False)       | O                               |
|         | yang      | O               | O                        | O                               |
|         | ...       | ...             | ...                      | ...                             |
|         | menjaga   | O               | O                        | O                               |
|         | dirinya   | O               | O                        | O                               |
|         | dari      | O               | O                        | O                               |
|         | halhal    | O               | B-Narrator (False)       | O                               |
|         | syubhat   | O               | B-Narrator (False)       | O                               |

## V. RESULT

As mentioned previously, NER's implementation is domain and language dependent. When a NER developed for one domain is used in another, it performs poorly [4][5]. This study aims to identify the Hadith Narrator using the NER approach. More precisely, Hadith in Indonesian. The results of this study can be compared to those of the previous study, as indicated in Table VII. Most studies on NER measure its performance by utilizing the F1-score. The distribution of each NER Tag cannot be predicted and may have imbalanced data. An F1-score is needed to capture the harmonic mean of precision and recall. The highest F1-score of the proposed NER model indicates a high value for both precision and recall. The proposed NER model achieved 99.27% of the F1-score.

TABLE VII. COMPARISON OF THE NER MODEL'S PERFORMANCE

| Study      | Dataset           | Methods            | F1-Score |
|------------|-------------------|--------------------|----------|
| [5]        | English Hadith    | SVM                | 95.30%   |
| [6]        | Urdu Hadith       | FST                | 72.00%   |
| [7]        | Arabic Hadith     | NB, KNN, DT        | 86.00%   |
| [8]        | Arabic Hadith     | Rule-based and LLR | 82%      |
| [9]        | Arabic Hadith     | BERT               | 94.76%   |
| [10]       | Arabic Hadith     | FST and CRT        | 92.41%   |
| [11]       | Arabic Hadith     | N-Gram             | 84.00%   |
| [12]       | Indonesian Hadith | SVM                | 90.00%   |
| [18]       | Indonesian Hadith | NB                 | 82.63%   |
| [13]       | Indonesian Hadith | HMM                | 86.00%   |
| This study | Indonesian Hadith | BERT fine-tuned    | 99.27%   |

## VI. CONCLUSION AND FUTURE WORK

The BERT is designed and implemented in this research to provide a NER Hadith Narrator identification using an extra feed-forward classifier. Cahya/bert-base-indonesian-1.5G received the highest F1-score of 99.63 percent during the training phase. On the Hadith Narrator Identification using other Hadith passages, the final examination yielded a 98.27 percent F1-score. It suggests that when utilized to identify Hadith Narrators for Indonesian Hadith texts, the suggested NER model in this work performs best.

There are several future avenues that this experiment should take. The first step in developing an experiment dataset is to increase the amount of Hadith texts. This is required since the Hadith contains a range of Sanad and Matn forms. The current study then applies three IOB tags, namely B-Narrator, I-Narrator, and O. These three tags sufficed because all that was required was to determine which words were associated with the Narrator and which were not. Additional study is warranted in light of the Hadith dataset's addition. Other tags must be considered, such as those for Rasulullah, Taraf, and others.

# An Early Intervention Technique for At-Risk Prediction of Higher Education Students in Cloud-based Virtual Learning Environment using Classification Algorithms during COVID-19

Dr.Arul Leena Rose.P.J, Ananthi Claral Mary.T\*

Department of Computer Science

College of Science and Humanities, SRM Institute of Science and Technology  
Chengalpattu, India

**Abstract**—Higher Education is considered vital for societal development. It leads to many benefits including a prosperous career and financial security. Virtual learning through cloud platforms has become fashionable as it is expediency and flexible to students. New student learning models and prediction outcomes can be developed by using these platforms. The appliance of machine learning techniques in identifying students at-risk is a challenging and concerning factor in virtual learning environment. When there are few students, it is easy for identification, but it is impractical on larger number of students. This study included 530 higher education students from various regions in India and the outcomes generated from online survey data were analyzed. The main objective of this research is to predict early identification of students at-risk in cloud virtual learning environment by analyzing their demographic characteristics, previous academic achievement, learning behavior, device type, mode of access, connectivity, self-efficacy, cloud platform usage, readiness and effectiveness in participating online sessions using four machine learning algorithms namely K Nearest Neighbor (KNN), Support Vector Machine (SVM), Linear Discriminant Analysis (LDA) and Random Forest (RF). Predictive system helps to provide solutions to low performance students. It has been implemented on real data of students from higher education who perform various courses in virtual learning environment. Deep analysis is performed to estimate the at-risk students. The experimental results exhibited that random forest achieved higher accuracy of 88.61% compared to other algorithms.

**Keywords**—Prediction; at-risk; machine learning; virtual learning environment; cloud platforms; classification; COVID-19; random forest; student academic performance

## I. INTRODUCTION

During COVID-19 crisis, the entire education system all over the world has shifted towards virtual learning. Online teaching is highly dependent on the successful delivery of the content. Cloud-based Virtual Learning Environment (VLE) is vital component of education in university environments. This interactive platform enables learners to achieve education objectives during pandemic outbreak. The growth of cloud computing technology has brought new opportunities in the field of education as it facilitates effective and efficient learning mechanism. Benefits of cloud computing includes

collaborative learning environment, expense reduction, scalability, shareable content, usability, and global education. This induces the way online learning can be shared and distributed on diverse types of devices and platforms. Some of the biggest organizations including Amazon, Google, Microsoft, and Oracle are selecting the cloud due to its several benefits. Currently, due to the rising of educational institutions every day there exists a gap between industrial requirements and educational institutions. The technological enhancement of cloud computing might fill the gap by rendering free or paid training to the students' using systems that do not require any additional cost. For instance, educators can widen most crucial sections, upload necessary audio/video materials to support contents in cloud-based platforms, etc. However, despite of these advantages, students' learning behaviors and interaction with digital contents is still limited. Hence, this research analyzes at-risk students in cloud-based virtual learning platforms. Early prediction using classification techniques is an efficient and significant way to deliver timely intervention for dropout.

Many researchers have investigated that there are numerous ways of applying machine learning algorithms in education field. One of the vital focuses is to predict at-risk students in VLE by observing diverse student's attributes. Compared with traditional face-to-face education, dropout rates are higher as there was a sudden transformation towards virtual learning. COVID-19 pandemic has led to increase in digitalization and triggered online learning implementation in education sectors. All over the globe, learning sectors are focusing on virtual learning platforms to enhance the procedure of enlightening students. The effectiveness of online medium depends on students. The predominant usage of VLE has helped them to complete their course work examinations. However, evaluating student's results and predicting at-risk students is complex. Personalized assistance must be given to the students at-risk. In this context, this research focuses on identifying exact predictive models to investigate unidentified information regarding students' demographics characteristics, previous academic history, learning behavior, device type, mode of access and connectivity for online classes, self-efficacy, cloud platform usage, readiness, and effectiveness of participation in virtual

\*Corresponding Author

classes. We have examined that these are the appropriate features that makes an impact of student learning and helps in prediction.

Recently, for schools and higher education sectors online learning has emerged as a vital source and will prolong in future. In virtual learning courses, the collaboration between learners and educators is mediated by virtual learning environment. Chatbox helps the students to interact with instructors and take part in the classroom discussions. Machine learning is widely used in education sectors for classroom management, scheduling, etc. It is a method of personalized learning that provides an individualized educational experience to students where they can manage their own learning, at their own pace, make their own decisions about what to learn. In a classroom using personalized learning, students select what they are interested in, and educators fit the curriculum and guidelines to students' interests. Scheduling helps in searching for an optimal and adaptive teaching policy that helps students learn more efficiently. Dynamic scheduling matches students requiring assistance with teachers allocating time. It is regarding designing algorithms that automatically bring out valuable information from the given data. While machine learning has many success stories, there are software available to design and train rich and flexible machine learning systems. The mathematical foundations are important to build complicated machine learning systems. These models can be created by using diverse features of student data. The machine learning algorithms can be used to develop successful classifiers.

## II. LITERATURE REVIEW

Three determinant factors based on technological, organizational, and environmental contexts impact the acceptance of cloud computing in higher education sectors. Survey method was used to collect data from respondents and powerful statistical tool SmartPLS examined the significance of each of these influencers. Results show that factors of compatibility, security, peak management support, authoritarian policy and relative advantage have positive effect [1]. Dataset was chosen from UK Open University, which enclosed students' activity logs, assignment, and final marks, all stored in VLE logs. Feature selection was essential for designing accurate prediction models thereby facilitating students to improve their performance. A predictive model was constructed by the researchers to early forecast students at-risk of dropout. SELogisticRegression and Input-Output Hidden Markov Model (IOHMM) outperformed other baseline models. The overall accuracy of their proposed model is 84% [2]. Almajali & Masadeh ascertained how enabling circumstances, social media, comfort of utilization affect students' opinion for online learning during COVID-19. Their study proved that enabling conditions had a positive impact. Furthermore, they have discussed about the difficulties faced by the students during pandemic like anxiety, lack of device, issues in internet connectivity, etc. Their findings revealed that students who are expertise in utilization of online learning technologies have positive perception towards it [3]. In educational institutions identifying at-risk students was a problematic task. Naive Bayes classifier was selected for the progress of early warning system. Four classification colors

were used to represent the various warning levels namely green for non-at-risk, yellow represents possible at-risk, red for at-risk and black color indicates dropout based on students' grades [4]. The study employs dataset from two academic writing courses in Hong Kong University. Logistic regression and classification trees can be utilized in higher education perspective, but ANN is not appropriate. The research team suggested that accuracy can be improved with other datasets [5]. The researchers have used extremely limited student attributes. Their predictions help to classify the students who are potentially at-risk. This information facilitates tutors to make timely intervention to increase student success. Three machine learning techniques DT, KNN, RF were used. Static attributes namely sexual category, age and previous educational results were excluded [6].

During pandemic contentment of higher education students aspired for learning in virtual modality was forecasted. Students responded that they obtain their classes, seminars, videoconferences using Google Meet and Zoom compared to WebEx and Blackboard. Researchers have concluded that students have better opinion towards online learning, the difficulty do not stretch out in technology usage, but it lies in the teachers' teaching strategy [7]. A tool that allows estimating the hazard of quitting an academic course was proposed. Python programming language was used to implement several machine learning algorithms namely LDA, SVM and RF. LDA and SVM was proved to have utmost performance with a slight superior variance for SVM results. When additional learning requirements feature were introduced, in random forest, the final performance was improved compared to LDA and SVM results. The suggestion for the future development is to have more data regarding student performance by considering the outcome of their activities completed in virtual education environments namely Moodle, Google Classroom and Edmodo [8]. Francis Ofori et al. reviewed the literature and summarized the various machine learning models with their corresponding prediction accuracy. It helps to improve the graduation rates by providing feedbacks to educators and students thereby modifying learning environments. They concluded that most machine learning models dwelled in studying students' performance prediction but failed to identify the best model [9]. Identifying students' at-risk by using eBook interaction logs have employed 13 prediction algorithms. Results revealed that random forest performed better than other algorithms with accuracy 82.3% and kappa 64.7% for raw data, J48 algorithm with accuracy 83.3% and kappa 66.5% performed better with transformed data. Naive Bayes accuracy 81.1% and kappa 62.1% outperformed other algorithms for categorical data [10]. Automated machine learning usage was proposed to improve correctness of prediction percentage depending on the data before commencing of their academic year. This aids students to moderate their risk failure and has achieved the overall accuracy of 75.9% [11]. Perceptions of post graduate students towards responding online learning process have been discussed. Majority of the students used Zoom cloud platform for learning from home activities. Others preferred Google Classroom, Whatsapp and other applications based on the agreement provided by each platform. Few students declared that limitations in technology and usage of

applications hampered the online learning process [12]. The data of 2097 students of higher education were investigated, and the system was trained with Logistic Regression and ANN with four attributes related to student socio-economic and academic details. Results have shown that highest risk of dropping out of students has lowest grade. Comparing to Logistic Regression, ANN has better classification accuracy. However, the accuracy of ANN did not exceed 80% [13].

The researchers developed an early identification system using student performance and administrative data from private and state university. AdaBoost algorithm was used to predict the student dropout. The results revealed that prediction accuracy improves at fourth semester when compared to first semester. The demographic data available at the time of enrollment does not improve prediction accuracy when performance data is available in increasing semesters; this issue must be solved [14]. Khadija Alhumaid focused on the fear of technology usage by students and educators during Covid-19 pandemic. The various fear factors are uncertainty, anxiety, and fear of losing loved ones. Hence m-learning was adopted by the educational institutions, the results of studying and teaching was promising. She has concluded that with the assistance of mobile learning the fear factors can be reduced. It has a high perceived usefulness and perceived ease of use that can decrease the fear and enable the respondents to achieve their classes on time [15]. Reduced Training Vector-SVM was proposed to predict marginal and at-risk students. Analysis revealed that this algorithm can diminish number of training vectors and training time of classifier by at least 60% thereby retaining accurateness. Results represented an overall accuracy of 93.5% [16]. Two open-source datasets namely mathematics and Portuguese was selected for predicting student educational performance. It was identified that prior grade has most impact on finishing grade. Random Forest has gained higher accuracy in mathematics dataset. SVM attained better accuracy than Random Forest in Portuguese dataset [17]. The four main difficulties of students in virtual learning classes were meager internet connection, lack of experience to virtual education applications and tools namely Teams, Padlet, Socrative and Miro, students' restricted English proficiency and difficulty in concentration. Besides, results have proved that online learning is cost effective, as it's not necessary for students to arrive to campus. They had better time management and have utilized digital devices to access online classes. The students get encouraged when they had quizzes established through interactive applications namely Kahoot, Padlet, Micro, Socrative and many other. Lecturers gave more assignments during online learning period than traditional face-face learning [18]. The troubles faced by at-risk students were analyzed in VLE. These predictive models can be used for avoiding student dropouts. Feature engineering was used to enhance performance of predictive models. Experimental results revealed that random forest provides excellent results when compared to other baseline models [19].

Several machine learning algorithms were employed to the dataset to predict low-engagement students in web-centered learning systems from log data of VLE. Kappa and accuracy values were compared for the models. Outcomes proved that J48, decision tree, JRIP, gradient-boosted classifiers revealed

improved results [20]. Predicting students' difficulties in digital design course session were investigated. SVM has achieved 80% performance accuracy compared to other classifiers namely ANN, LR, NBC, DT for predicting student obscurity [21]. Deep long short-term memory model was deployed for students' performance prediction. This model tends to monitor the week-wise pattern of students' interaction and their engagement activities to learn their behavior and generate better outcomes. It outperformed other baseline models namely logistic regression, ANN. It predicted with 90% accuracy of student interaction in VLE [22]. An application was implemented that utilizes academic information of university students and generated classification models by using ANN, ID3 and C4.5. Decision tree built by C4.5 has higher performance measure. Suggestions were given to increase the number of variables and including the institutional and socio-economic variables for further research [23]. The ways to measure fairness in VLE was examined. CGPA was referred as main attribute for student performance prediction. A great underrepresentation of disabled students was determined. This leads to misclassification that disable students were predicted to fail the course. These guidelines must be considered by the researchers [24]. Zulherman analyzed the strength, weakness, opportunities, and threats to Zoom Cloud Meeting, a reliable video platform. The results focused behavioral intention drivers of ZCM usage during crisis are hedonic inspiration and perceived self-efficacy. Influence among these attributes was stronger [25]. Moreover, researchers focused on predicting student's dropout at course level in e-learning course using various machine learning techniques. Five attributes reflecting course activities namely accesses, assignments, tests, exam, and project were considered. Pearson correlation was conducted to identify correlations between independent variables and results. The most appropriate attribute for prediction with high correlation besides project and tests is access that detects students who do not obtain time for accesses that expose them to higher risk. Most adopted algorithms are Logistic Regression, Decision Tree, Naive Bayes Classifier, Support Vector Machine, Random Forest, Neural Network. Results proved that Random Forest classifier obtained best accuracy with 93%, precision reached 86%, F1 score was 91% compared to other classifiers [26]. Researchers have collected real students' data with various information namely personal, economic, and academic records and evaluated by statistics values to find most effective one. They used three prediction algorithms Decision tree, SVM and KNN to detect student dropout. Decision tree reaches better performance for identifying students at high risk. In decision tree they have used J48 technique that represents real dropout groups. Authors have stated that it is vital to evaluate student behavior through multi objective algorithms that assess their skills and emotions [27]. On the other hand, dropout rates are higher in online learning than offline as students must control their own study time without the help of educators. It is vital for professors to assist students in a timely intervention to avoid dropout. Lowering dropout rate is an important challenge for universities. The experiment collected actual log and historical records from Cyber University Learning Management System (LMS) to predict drop-out risk during learning period. They have used four

machine learning algorithms Decision Tree, Random Forest, SVM and Deep Neural Network. Random Forest shows the best performance with 96% accuracy [28].

In previous studies it is evident that predicting student dropout is challenging task. When different machine learning algorithms are employed, it reveals varying prediction accuracy of students' at-risk. It is inexplicit that which algorithm is most excellent for predicting at-risk students in virtual learning environments, and what are the most appropriate features to be considered for various machine learning classifiers, as the determinants of attrition depend on multi-dimensional character. Also, during time of registering for online classes, the student data collected at the university are not sufficient for dropout prediction. In this scenario, our research focuses on several factors namely prior academic achievement, demographic characteristics, learning behavior, device type, access, connectivity, self-efficacy, cloud platform usage, readiness, and effectiveness of participation in online classes through Google Classroom and Zoom cloud platforms. We have not focused on a specific predictive model; instead, we have considered four machine learning algorithms to identify best model.

In the light of the reviewed literature above, cloud computing adoption in higher education institutions have a positive effect. Rest part of paper was organized as follows. Section 3 explains research method that provides a description on real time student dataset, preprocessing, feature extraction and normalization. Section 4 describes machine learning algorithms; Section 5 reveals experimental results. Section 6 draws conclusions and the further research guidelines.

### III. RESEARCH METHODOLOGY

#### A. Research Questions of Inquiry

The intention of this study is to extend an early detection model for finding at-risk students. Machine learning algorithms are implemented on the student's real time dataset collected from various educational institutions, and its accuracy has been analyzed. Within an online learning environment, the system can be globalized to any type of course. Proposed model of research is depicted in Fig. 1. This research aims to respond subsequent questions:

- 1) To build a predictive system to classify the at-risk students of cloud virtual learning platform.
- 2) To estimate model accuracy by means of various machine learning algorithms namely KNN, SVM, LDA and Random Forest.
- 3) To investigate most suited machine learning algorithm for predicting student difficulties based on demographics,

device type, access, connectivity, self-efficacy, cloud platform usage, readiness, and effectiveness of participation in online learning sessions.

#### B. Methodology

A sequence of steps has been adopted prior to the model is organized for assessment and final reporting. Methodological data flow of the complete process is visualized in Fig. 2. Initial step is collecting real data from students, and the data is preprocessed to eliminate missing value, duplications, and outliers. Feature extraction is employed to extract features. Data is normalized and is passed to the four classifiers KNN, SVM, LDA and Random Forest. Classification models have discrete outcome, we need a metric that compares discrete classes in some form. A model's performance can be evaluated using classification metrics and it determines how well or bad the classification is, but each of them evaluates it in a different way. Each classification result is tested with the performance metrics. Finally, the results are visualized.

#### C. Dataset Description

To meet the objective of the study, an electronic survey was conducted to gather real time data from higher education students belonging to various academic institutions throughout India. The instrument used for this research is E-questionnaire. It was chosen as it was considered as an efficient and effective approach. The target population for this study consisted of 530 students enrolled in online courses. The survey was broadly classified into five factors. (1) Demographic characteristics (2) Device type, mode of access, connectivity (3) Self-Efficacy (4) Familiarity with cloud platform usage (5) Readiness and Effectiveness of online learning compared to regular classroom setting. Demographic information of the respondents is presented in Table I, which shows that 66.60% are male respondents, and 33.40% are females between age group of 17 and 45 years. They are from diverse departments namely B.Sc Computer Science (20.38%), B.Com (14.34%), M.C.A (11.32%), B.C.A (11.32%), B.Tech (11.32%), M.sc (15.09%), M.com (4.91%) and BBA (11.32%) degree programmes. Online classes were managed for the students through cloud platforms. We have used free cloud services Google Forms and Google Sheets for collecting and analyzing the data. Conceptually, Self-Efficacy was estimated with 5-point Likert-scale ranging from 1= "Strongly Disagree" to 5= "Strongly Agree". Cloud platform usages are measured using 4-point range from "Not Familiar" to "Very Much Familiar". Readiness is given 4-point range from 1= "Not Ready" to 4= "Very Much Ready" and Effectiveness from 1= "Much Less Effective" to 5= "Much More Effective".

Fig. 1. Proposed Model.

Fig. 2. Conceptual Framework of the Research Model.

TABLE I. SUMMARY OF DEMOGRAPHIC CHARACTERISTICS OF STUDENTS

| Variable                | Label                 | n=530 | %     |
|-------------------------|-----------------------|-------|-------|
| Gender                  | Male                  | 353   | 66.60 |
|                         | Female                | 177   | 33.40 |
| Age                     | 17-19                 | 158   | 29.81 |
|                         | 20-29                 | 370   | 69.81 |
|                         | 30-45                 | 2     | 0.38  |
| Education qualification | B.Sc Computer Science | 108   | 20.38 |
|                         | B.Com                 | 76    | 14.34 |
|                         | M.C.A                 | 60    | 11.32 |
|                         | B.C.A                 | 60    | 11.32 |
|                         | B.Tech                | 60    | 11.32 |
|                         | M.Sc                  | 80    | 15.09 |
|                         | M.Com                 | 26    | 4.91  |
|                         | B.B.A                 | 60    | 11.32 |

#### D. Data Preprocessing

Before evaluation phase of the classification model, the dataset was passed through a preprocessing stage. Initially, we observed that the real time dataset contains fifty-six features with missing data, redundant data, and outliers. Few students have submitted the questionnaire redundantly and missed to fill some data. When a specific value could not be estimated for a data sample, it leads to missing data. They have not provided the correct data that tends to form outliers, as the data plunge outside the range of typical distribution. By preprocessing the data, they were eliminated to maintain the quality of prediction. R4.1.1 statistical software was used as

an experimental tool. Machine learning was conducted using caret package that is a comprehensive framework for constructing machine learning models in R. The model was fed with more students' engagement activities; self-efficacy in online learning tends to learn about the behavioral patterns. The final dataset was exported into a .csv file and it is ready to be trained with different machine learning algorithms and evaluated to select most accurate one. We have used Microsoft Excel for visualizing the outcomes.

#### E. Feature Selection

It is the procedure of choosing optimal number of attributes from a larger dataset, which is the most difficult and challenging task. From this procedure, we come to know the utmost useful set of features for predicting target variable. To diminish computational cost and to increase model performance it is desirable to reduce number of features. To find the top variables, we are attaining improved cross-validated accuracy and data can be used to identify most likely elements to predict at-risk students. Two reliable measures of random forest algorithm namely %IncMSE and IncNodePurity were utilized for feature selection to generate an optimal subset of features. Finally, we have extracted forty-six features for each student with CGPA as the target variable. The selected features by our model render excellent instructions that educators can utilize to offer early assessments to learners prior to closure of course work.

1) %IncMSE: The first measure is %IncMSE which is a highly informative measure of importance. It defines the mean decrease in accuracy or how the prediction gets poorer when the variable alters its value. The variation among original

mean error and randomly permuted mean error is computed and this forms the fundamental idea for measuring important score of variables. For each tree prediction error on test is recorded (Mean Squared Error- MSE). Same process is carried after permuting each predictor variable. Higher the difference, then variable is more important. The general equation is,

$$\text{MSE} = \text{mean} ((\text{actual}_y - \text{predicted}_y)^2)$$

2) *Mean decrease gini (IncNodePurity)*: Depending on the gini impurity index this is a variable importance measure for computing splits in trees. Higher value of mean decrease gini score, higher importance of variable.

#### F. Normalization of Data

3) For machine learning this is a procedure employed as a part of data preparation. Extracted features were originally at various scales. To adjust scales of features to have a standard scale of measure the data was normalized to improve the model accuracy. The formula is given by,

$$\text{Min-Max Normalization: } (x - \min(x)) / (\max(x) - \min(x))$$

### IV. MACHINE LEARNING MODELS

Machine learning is regarding designing algorithms that automatically bring out valuable information from the given data. It is not possible for an “AI” to be trained without data. In every project, classifying and labeling datasets takes most of the time, when it reflects the real time data. The techniques applied to predict the students at risk occur as training and testing phases. To train an algorithm to know how to pertain the concepts, to identify and produce outcomes the training dataset is utilized. When we train a model on dataset, measuring its performance on the same tells how good it is at making predictions on data it has already seen. Training a model on a subset of our data, we can then use the data the model was not trained on to calculate how this would perform on unseen data. These purposefully hold out part of our dataset from training and then use the performance on this held-out dataset as a proxy of our model’s performance in production. The model is constructed on training set and examined on held-out testing set. This allows us to test that our model can generalize to unseen data. 530 students’ academic performance data were randomly divided into two datasets. Training set makes up most total data, around 70% (372 student records). The test data represents 30% (158 student records) that is used to estimate how well our algorithm was qualified with training data. Each technique is presented with data that have not been used during training to observe the classification performance during the testing phase. Before applying classifiers, feature selection methods were implemented using random forest algorithm. CGPA (Cumulative Grade Point Average) indicates the percentage of marks scored by the students. This attribute was used as response or target variable, which logically is the best predictor for course grade. This dependent variable depends on various independent variables namely demographics, previous academic outcomes, learning behaviors, device usage related factors, familiarity of cloud platform usage, self-efficacy, and readiness & effectiveness in participation of

online classes. Based on the CGPA we have calculated the risk category of students. The criteria if  $\text{CGPA} \leq 55$ , classifies the students as “At-Risk”. Else they are considered as “Non-AtRisk” students. We have used the variable Academic Performance as Boolean attribute depending upon CGPA. This attribute indicates class for supervised binary classification task and result of prediction. For our model, a negative outcome means student was not at-risk. A positive outcome defines student was at-risk. Thus, the students are classified into two categories.

For our research we have used supervised machine learning algorithms, as our dataset have labels. We considered K Nearest Neighbor (KNN), Support Vector Machine (SVM), Linear Discriminant Analysis (LDA) and Random Forest (RF) as they are the most preferable algorithms by researchers to resolve related issues. We validated our methodology by supplying appropriate set of estimation measures. We have assessed the performance of different classifiers with model parameters.

#### A. KNN Algorithm

KNN categorizes a new data point into target class, based on similarity of its neighboring data points. We input a dataset of atrisk and non-atrisk students. We train our model to identify students’ performance depending on extracted features.

Choose the number k of neighbors

Compute Euclidian Distance between the data points. It is given by,

$$\text{Euclidian Distance} = \sqrt{(X_2 - X_1)^2 + (Y_2 - Y_1)^2}$$

Select K nearest neighbor.

Count number of data points in each group, among these K neighbors.

Allot new data point to that group for which number of neighbor is maximum.

#### B. SVM

A Support Vector Machine is utilized for classification and regression problems. In our dataset, we have used kernel SVM to conduct non-linear partitioning. The main idea behind this algorithm is,

Find the lines that separate the classes optimally. This dividing line is called a hyperplane.

Find the optimal hyperplane that helps in maximizing the margin between two classes.

Transform it into a higher dimension by employing a kernel function to dataset.

Clearly separate the two groups with a plane with the end goal of maximizing the margin.

Once the data points are separated into dimensions, SVM classifies the two groups.

#### C. LDA

Linear Discriminant Analysis (LDA) considers a data set of observations as input. We require having a categorical

variable to define class and several predictor variables for each observation. Steps involved in this algorithm,

- Compute mean vectors of each class of dependent variable
- Compute with-in class and between-class scatter matrices
- Calculate eigenvalues and eigenvector for scatter matrix within class and between class
- Sort eigenvalues in descending order and select top k.
- Create a new matrix containing eigenvectors that maps to k eigenvalues.
- Obtain linear discriminants by taking the dot product of data and matrix.

#### D. Random Forest

This model extends and integrates multiple decision trees to create a forest. It allows for more correct and constant outcomes as it relies on multitude of trees. Steps involved in this algorithm,

From the dataset having k number of records, n records are taken randomly.

For each sample individual decision trees are constructed.

Each decision tree will generate a result.

Outcome is measured depending on majority of the votes for classification or averaging the output of all trees for regression respectively.

### V. RESULT AND DISCUSSION

In this part of the study, we predicted the at-risk students from their multidimensional characteristics. To answer the research questions, we performed several experiments. The educators can utilize the predictive model to determine students having difficulties. They can deliver relevant materials, increase the student engagement activities, and improve the marks of such candidates in cloud-based learning platforms. They can acquire corrective actions at former stage, to offer supplementary assist to the students at-risk. This is vital to exactly rank the classifiers depending on their prediction potential of at-risk and subsequent decision making.

#### A. Binary Classifier Evaluation Metrics

Model performance in classification problem is assessed through confusion matrix. It represents four numbers in a two-by-two matrix. Each element displays class-wise accuracy. Reason for depicting this is to obtain benefit of our outstanding visual abilities to process more information. The elements of the confusion matrix are used to find three important parameters namely accuracy, sensitivity, and specificity. We implemented our experiment with 10-fold cross validation; each model we constructed has ensued in Kappa and Accuracy. These assessment metrics can be utilized to assess the value of classifiers for ranking various models. This generates True Positive (TP), True Negative (TN), False Positive (FP) and False Negative (FN). Accuracy, specificity, sensitivity is used to enhance experimental results in case of binary classification.

- Accuracy is the ratio between accurate predictions over entire number of instances. It is used to determine number of times classifier is correct. This is given by,

$$\text{Accuracy} = (\text{TP} + \text{TN}) / \text{Total}$$

- Sensitivity (True Positive Rate) refers to proportion of correct positives that are accurately detected as positives by classifier. Formula is,

$$\text{Sensitivity} = \text{TP} / (\text{TP} + \text{FN})$$

- Specificity (True Negative Rate) relates to classifier's ability to find negative results. The equation is,

$$\text{Specificity} = \text{TN} / (\text{TN} + \text{FP})$$

Table II presents results of KNN, SVM, LDA and RF for real-time dataset. The similar data was passed for all these techniques. As the research aims to classify students' at-risk, it is vital to attain better predictive accurateness for unsuccessful learners. Accuracy from Random Forest is 88.61% it is representing good performance based on accuracy, sensitivity and specificity compared to KNN, SVM and LDA. Fig. 3 visualizes the classification accuracy, sensitivity and specificity obtained using various classifiers. The output shows our model accuracy for test set. The figure clearly depicts that Random Forest algorithm outperformed the other machine learning techniques KNN, SVM and LDA for identifying at-risk students.

TABLE II. EXPERIMENTAL RESULTS OF REAL-TIME DATASET FOR PREDICTING STUDENT'S AT-RISK USING VARIOUS CLASSIFIERS

| Classifier | Accuracy | Sensitivity | Specificity |
|------------|----------|-------------|-------------|
| KNN        | 79.11    | 97.66       | 31.32       |
| SVM        | 84.18    | 96.09       | 33.33       |
| LDA        | 82.28    | 92.97       | 36.67       |
| RF         | 88.61    | 96.09       | 56.67       |

Fig. 3. Visualization Results of Different Classifier for Real-Time Student Dataset.

### B. ROC Curves

When we are evaluating classifier performance it is the dominant visualization tool. Performance metrics helps generate an aggregate perspective of a model's performance. For binary classification problems, receiver operating characteristic (ROC) curves can be very informative. It illustrates true positive rate as a function of false positive rate, hence prompting sensitivity of classifier. We partition predictions into positive and negative classes for purpose of obtaining ROC measurements namely specificity and sensitivity normally used on ROC curve axis. For our real-world dataset, if we are classifying whether a student is at-risk or non-atrisk, it is significantly better to categorize a small number of additional non-atrisk students as at-risk and avoid classifying any at-risk as non-at-risk students. We would choose threshold that reduces false-negative rate, increase true-positive rate, and rest us at the top of the ROC plot. This gives an observation of overall performance of the classifier. Fig. 4 visualizes column-wise area under ROC curve (AUC) for KNN, SVM, LDA and RF. For classification models, another performance metric is AUC. This is measure of capability of classifier to differentiate among classes and is

utilized as a summary of ROC curve. The classification performance is enhanced when this area is larger. For evaluating and comparing models this is an extensively used option.

An ROC curve gives us a more nuanced view of how a model's performance changes as we make predictions conservative. Table III illustrates the results of ROC curve for various machine learning algorithms. After observing ROC curves of each classifier, it's clear that Random Forest algorithm has the highest statistic of ROC 76.38%. Classification models often use the area under the curve (AUC) to represent performance. It delivers an agreement measure of performance across all possible classification thresholds. Fig. 5 illustrates the highest Area Under Curve that corresponds to random forest algorithm. Higher AUC depicts classifier has outstanding performance to differentiate among positive and negative classes. From these series of experiments, it is apparent that in overall random forest algorithm can be used to detect the students regarded at-risk in cloud-based virtual learning environment based on multidimensional variants.

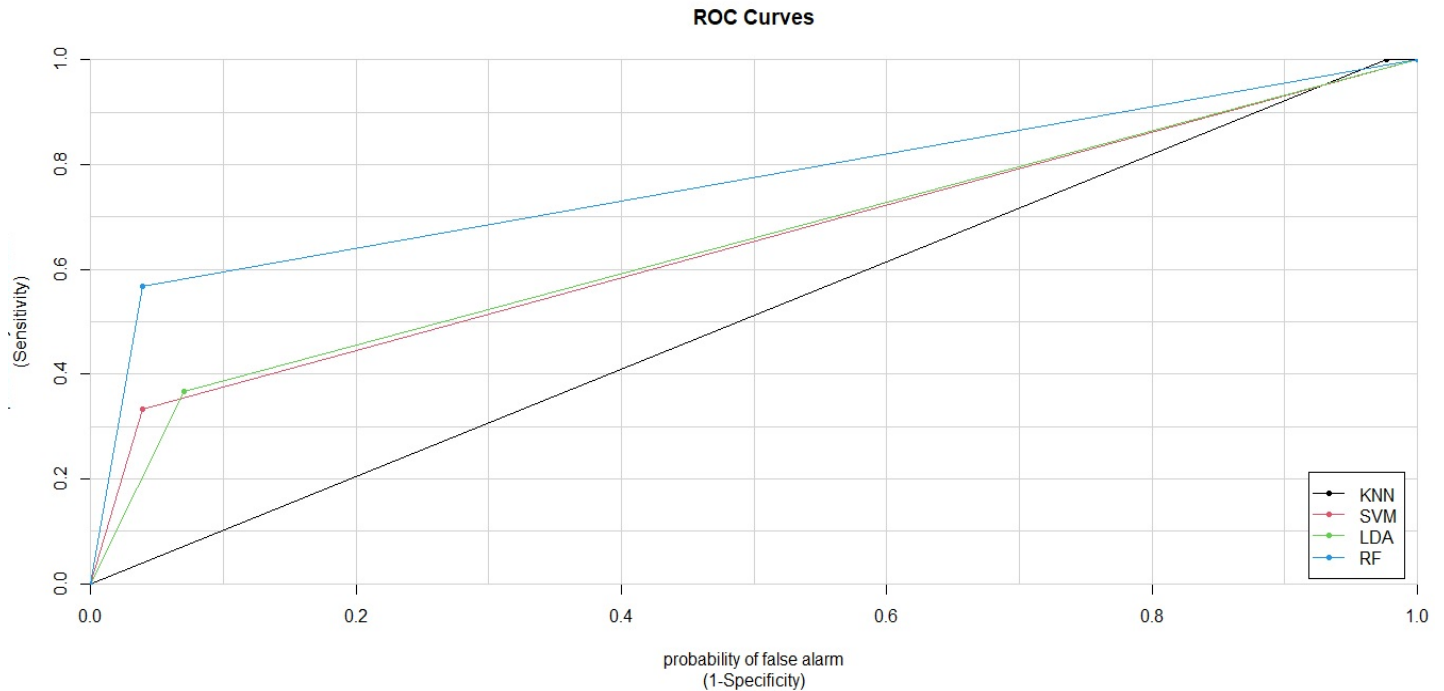

Fig. 4. Column-Wise Area Under ROC Curve (AUC) of Classifiers for Students' At-Risk Prediction.

TABLE III. COMPARATIVE RESULTS OF RECEIVER OPERATOR CHARACTERISTIC (ROC) CURVES FOR KNN, SVM, LDA AND RF

| Classifier | ROC Curve Statistic |
|------------|---------------------|
| KNN        | 51.17               |
| SVM        | 64.71               |
| LDA        | 64.82               |
| RF         | 76.38               |

## VI. CONCLUSION AND FUTURE WORK

As there is a sudden shift away from the traditional classroom in many parts of the globe, the adoption of virtual learning is more effective during the COVID-19 crisis. The students are in diverse geographical locations, the cloud platforms have empowered them to learn in their own comfort zone. They had an opportunity to participate in an interactive and collaborative learning environment. The instructors can upload and share the course material in cloud platforms. The students can access the materials from their own individual portal that enables them as independent learners. By applying machine learning algorithms in cloud platforms progress of the students can be tracked hence the learning gaps can be identified. This research work focuses on implementing students' outcome based early prediction model. We employed different machine learning approaches namely KNN, SVM, LDA and RF to detect at-risk students. The lower academic results decrease self-confidence of the learners and depletion of valuable educating efforts. These students always have an intention of dropping out from college. To solve the problem of drop out, this system helps the higher education institutions to classify the risky students at earlier stage. The amount of data generations depends on the students' multivariate characteristics for the courses enrolled in online classes. This was used to create the machine learning model that resourcefully utilizes this data, hence forth bring outcomes that can be used additional in students' wellbeing in terms of their performance and personal growth. The versatility of these systems also helps the teachers to take potential efforts towards the risky students. A sequence of experiments has been managed to identify the most excellent model.

Comparing to the existing research and results, current research revealed that the most promising random forest

algorithm achieved high accuracy with 88.61% and outperformed other binary classification models. These algorithms were used to classify the students' at-risk in VLE by considering their multideterminant characteristics. The outcomes from this model can profoundly help educators, to upgrade their existing teaching methodologies and the implementation of new techniques facilitates the students to pay additional attention in their studies. This data-driven study can support VLE administrators, instructors, and course co-coordinators in the articulation of effective virtual learning structure that can bestow to process of decision-making. This early intervention technique that was implemented in virtual learning environment motivates the students to have high academic scores.

Depending on our results machine learning is highly recommended to be integrated with cloud platforms. It gives an insight into real-time situations that allows the higher educational institutions to forecast future outcomes. In further research, we plan to deploy predictive model in cloud computing platform by means of helping the educators to progress the performance of unprepared students and for automating the decision-making process.

**Abstract**—In recent years, real-time and big data aroused and received a lot of attention due to the spread of embedded systems in almost everything in life. This has led to many challenges that need to be solved to enhance and improve systems that work on big real-time data. Apache Storm is a system used for computing and analyzing big real-time data of distributed systems. This paper aims to develop a scheduler to improve the scheduling of the applications represented by topologies on the Storm cluster. The proposed scheduler is hybridization between the scheduling algorithms of A3 Storm and the Workload scheduler. Its objective is to minimize the communication between tasks while balancing the workload on all cluster machines. The proposed scheduler is compared with the A3 Storm and Fischer and Bernstein's scheduling algorithm. The comparison has been made using four different topologies. The experimental results show that our proposed scheduler outperforms the two other schedulers in throughput and complete latency.

**Keywords**—Real-time; big data; apache storm; scheduling

## I. INTRODUCTION

Real-time applications such as IoT sensors, climate, and healthcare produce a large amount of continuous real-time data. The nature of this type of data is overgrowing where it can reach quintillions of bytes every day. This extreme and rapid growth of data leads to the term “big data” [1]. 5Vs features usually characterize big data; volume, variety, velocity, veracity, and value. Volume refers to the massive amount of data [2]. Variety means that there are different types of data that cause complexity. The rate at which the data is produced and transferred is the velocity, and it must be analyzed in real-time. Veracity is the precision level of data. Finally, the value is the valuable information derived from the data [1] [3]. Generally, the “big data” processing can be done through two processing techniques; batch and stream processing on high-performance computing resources [4]. Batch processing works on data that is previously stored. At the same time, stream processing refers to processing a large amount of data in real time. Big Data needs specified applications for processing the data, such as Hadoop for batch processing and Apache Storm, S4, Spark, and Flink for real-time streaming applications [4].

Real-time refers to the concept of time quantity, which implies the necessity for a real-time clock to measure it [5]. The real-time tasks are classified into three different cases: hard real-time, firm real-time, and soft real-time. The constraint in hard real-time tasks is to create results within

specific time constraints or cause disastrous results. Firm real-time tasks also have to create the results before the specified time constraints, or the results will be invaluable. Soft real-time tasks have no time limitation, the results could be generated at any time, and it will be beneficial and acceptable [5] [6].

Now-a-days, the processing of streaming data is gaining more attention due to its sensitive cases. Thus, many researchers have tried to enhance the scheduling techniques to handle this huge amount of data and increase performance of processing (i.e., decreases the latency, increase the throughput, balance the network load, etc.). Most of the researchers' algorithm achieved those performance objectives. The relevant algorithms some of them achieved increment in the throughput, some achieved network load enhancement, others achieved decrement in latency, etc. Real-time scheduling for streaming data needs continuous improvements to get better results with better performance. So the issue here is to propose an algorithm that increases the performance of the processing of streaming data in using Apache Storm.

The main idea of the proposed algorithm is to reduce the communication between executors. The scheduler collects information during runtime then it creates a schedule using graph partitioning technique that partition the communication graph [7] [8]. At the end, the collected communication between executors during runtime is used and the pairs of most communicating executors are assigned to the same slot. This will achieve workload balance; improve resource utilization, high throughput with more reduced load on network.

The paper contribution is as follows:

- 1) We proposed a hybrid between two algorithms, the Workload scheduling algorithm and the A3 Storm algorithm, which improves the performance of the Apache Storm. This scheduler maximizes the throughput and minimizes the latency as the communication network load is reduced.
- 2) The scheduler is based on graph partitioning; its objective is workload balance and inter-executor communication.
- 3) Four topologies evaluate the scheduler, and the metrics of throughput and latency are collected as results.
- 4) A comparison is made against two alternative schedulers to find which has better results when running the topologies on them.

This paper is organized as follows. In Section 2, we introduce an overview of the Storm and its scheduling. The related work is shown in Section 3. Section 4 discusses the state-of-the-art scheduling algorithms. The proposed algorithm is discussed in Section 5. Section 6 discusses the results with comparison to the state-of-the-art algorithms. Section 7 is the conclusion.

## II. OVERVIEW ON APACHE STORM

Apache Storm is a widely used real-time processing framework due to its capabilities of carrying out analytics on data streams with high throughput. Storm is an open-source real-time processing framework that contains several components: Topology, Nimbus, Slave, and zookeeper. [9]. Topology is considered the main component in Storm; it is a directed acyclic graph (DAG) that consists of spout and bolts [9] [10]. The spout is the primary source of a stream, and the bolt is the processing unit of the topology which handles the stream of data. Storm is deployed on a cluster that follows a master-slave model. The master is called the Nimbus node, which is responsible for organizing the topology and analyzing it [11][10]. It also distributes the tasks among the supervisor nodes and monitors any failure occurrence on them (i.e., if one of the supervisors fails, it redistributes the work among the remaining supervisors). The slave is any supervisor node. Storm can have one or more supervisors, and each supervisor can have one or more workers, which helps execute the tasks assigned by the supervisor. The worker also can have one or more executors which are responsible for running and executing the tasks. In the end, the task carries out the actual processing of the data (i.e., the tasks can be spouts or bolts). Also, Storm contains the zookeeper, which coordinates the work between the Nimbus and supervisors and saves their state (i.e., in case of Nimbus failure, it will restart from its last state as it is saved in zookeeper). Fig. 1 depicts the components of the Storm cluster.

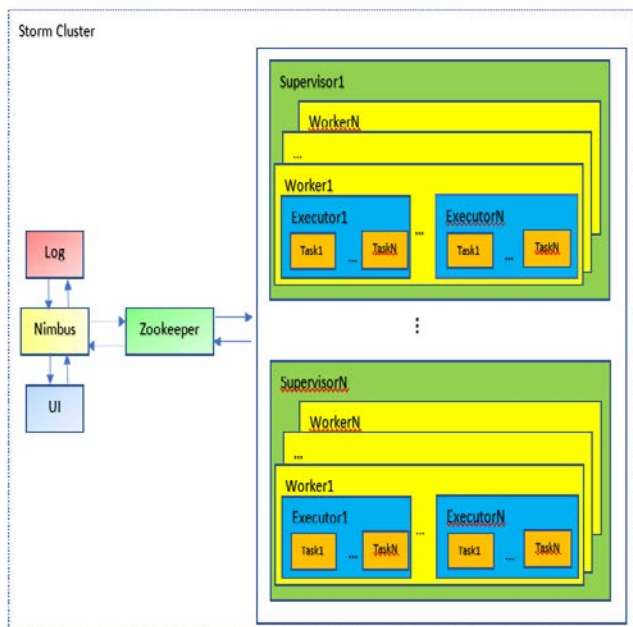

Fig. 1. Storm Cluster.

A default scheduler performs the standard scheduling process in Storm existed in Nimbus called EvenScheduler. This scheduler goes through two main phases; the first is assigning the executors to the workers, and the second is allocating the workers to the slots. EvenScheduler works based on round-robin strategy as follows [3]:

It iterates through the executors of the topology and allocates every executor evenly to the workers based on a round-robin algorithm.

The workers are allocated and assigned evenly to the supervisors, considering the available slots in each supervisor.

## III. RELATED WORK

One of the main benefits of Storm is that it is an open-source framework that allows creating custom schedulers that can meet the needs of the users and data. The default scheduler in Storm has some drawbacks which need to be improved. For instance, it evenly assigns the tasks to the cluster slots, but it does not consider the inter-node and inter-slot communication. Thus, the traffic may negatively influence the throughput and performance of the processing. Recently, many researchers have proposed enhanced scheduling algorithms that can improve the performance of Storm.

Aniello L. et al. [3] have proposed two scheduling algorithms, offline and online. The offline scheduling algorithm is based on the topology structure and how its components are interconnected with each other. It used the round-robin algorithm to assign slots to nodes. The online scheduling algorithm was based on monitoring the communication and the performance of the system at run time. It monitored the traffic of exchanged tuples between executors, sorted the executors in descending order according to the communication patterns, and assigned the most communicating executors in the same slot. Then the communication pairs of workers are iterated in descending order and assigned to the nodes. This algorithm reduced the inter-node traffic and communication, which affected the network load and the throughput.

Xu J. et al. [12] have developed a traffic-aware online scheduling algorithm that can reduce the inter-node and inter-process traffic by monitoring the traffic and workload information during runtime. It expedites the data processing by using the traffic-aware online algorithm for assigning executors. It also enables fine-grained control over worker node consolidation to obtain better performance while using fewer worker nodes.

In the same context, Peng B. et al. [11] have presented a resource-aware scheduling algorithm to improve resource utilization and reduce network latency. This algorithm is based on assigning the task according to an improved breadth-first traversal algorithm. It allocates the node ports that conform to the resource constraints and the network distance requirement.

Fischer L. and Bernstein A. [8] have proposed a workload scheduling based on the graph partitioning technique. It works during runtime and collects the behavior of communication of the topologies that are running. Then it partitions the communication graph to produce the schedule using software

called METIS graph partitioning. METIS uses a multilevel graph bisection. It makes a miniature version of the graph by coarsening it and collapsing the nodes and edges. Then it partitions the resulting small graph before un-coarsening it to its first form. It adapts the partition at each step of the un-coarsening to consider the newly un-collapsed edges and vertices. This scheduler improves resource utilization, reduces the network load, and increases the throughput.

Another direction is presented by Li C. et al. [13]. They have developed a Storm topology dynamic optimization strategy (STDO-TOC) as a real-time scheduling algorithm. The STDO-TOC uses bolts capacity and analyzes the message queue congestion degree to alter the performance parameters during runtime. If the topology bottlenecks are found, they are automatically removed. This leads to optimizing the topology dynamically.

Another resource-efficient algorithm for streaming application scheduling D-Storm has been presented in Liu X. and Buyya R. [14]. D-Storm tracks the streaming tasks during runtime to collect resources and communications and use them in the scheduling process to pack the communicating tasks compactly. This strategy of tight scheduling reduces resource utilization and inter-node communication.

Muhammad A. et al. [15] have developed a topology-based resource-aware scheduling algorithm called Top Storm. It is based on finding the most communicating executors and putting them closer to each other to reduce the number of nodes used to execute topology. Top-Storm is considered a topology-based as it looks at the DAG of the topology to find the connections between the executors. Also, it is resource-aware as the assigning of executors is made based on the computation power of nodes.

An enhanced version of Top Storm called A3 Storm has been developed by Muhammad A. and Aleem M. [4]. It works offline by finding the most communicating executors from the DAG of the topology and putting them closer to each other, and assigning them to the nodes according to the most powerful one. At the same time, it can work online by using traffic beside the topology structure. It reads the inter executor traffic, sorts it into descending order, and then assigns it to the most influential nodes. This scheduler improves resource utilization and increases the throughput of the topology. Finally, Table I displays a brief review of the above-mentioned scheduling algorithms.

#### IV. PRELIMINARIES

##### A. Workload Scheduler

The workload scheduler is the standard storm topology. It has two types of views, logical view, and physical view. The logical view,  $T = (N, C)$ , consists of  $N$  spouts and bolts connected with  $C$  number of connections. While the physical view of storm topology is represented by graph  $G = (V, E)$ , where  $V$  represents the vertices, and  $E$  represents the edges of the graph. A set of task instances represents the spout and bolts  $v_i \in V$ , and  $|v_i| = d_i$  represents the degree of parallelism of each component, spout, or bolt. Every two sets of vertices  $V$  are connected by one edge  $E$ . Generally, the graph is weighted as follows [8]:

- The vertex weights are represented by the sum of the number of all released and received tuples.
- The edge weights are the number of messages released from any of the spout or bolt instances.

The main idea in graph partitioning is to partition the vertices into equal partitions to reduce the edges' number connecting the vertices of different partitions based on the k-way partitioning method. To clarify the k-way partitioning, if a given graph  $G = (V, E)$ , the vertices will be partitioned into  $M$  number of partitions  $P$ , where  $M$  is equal to the supervisor machines number in the cluster. Where  $\cup_{m=1}^M P_m = V$  and  $\cap_{m=1}^M P_m = \emptyset$ . [8] [16].

The communication between partitions can be represented as a matrix. If there is a task  $\tau_u$  and partition  $P_a$ . To check if the task  $\tau_u$  is assigned to the partition  $P_a$ :

$$M_{\tau_u, P_a} = \begin{cases} 1, & \text{if the task } \tau_u \text{ is assigned to the partition } P_a. \\ 0, & \text{if the task } \tau_u \text{ is not on the partition } P_a. \end{cases} \quad (1)$$

Then the communication between the nodes in the communication graph can be represented as follows in (2) [8]:

$$C_{\tau_u, \tau_v} = \sum_{a=1}^P \sum_{b=1}^P M_{\tau_u, P_a} \times M_{\tau_v, P_b} \quad (2)$$

Where  $M$  is the total number of partitions.

According to (2), the formula of the node's communications can be summarized as follows:

$$C_{\tau_u, \tau_v} = \begin{cases} 1, & \text{if task } \tau_u \text{ and task } \tau_v \text{ are on different partitions} \\ 0, & \text{if task } \tau_u \text{ and task } \tau_v \text{ are on the same partitions} \end{cases} \quad (3)$$

Finally, the cost function of the partitioned graph  $G$ , which is partitioned into  $M$  partitions, can be defined as follows [8]:

$$cost(G, M) = \sum_{u=1}^{|V|} \sum_{v=1}^{|V|} C_{\tau_u, \tau_v} \times e_{u,v} \quad (4)$$

where  $|V|$  is the total number of vertices of the graph and  $e_{u,v}$  represents the edge weights.

This partitioning algorithm aims to optimize the costs for the partitions. In this algorithm, there is another constraint: the partitions should be balanced for the workload. The load balance factor  $L_{im}$  is defined as below [8]:

$$L_{im}(G, M) = \max(P_i / AP) \quad (5)$$

where  $P_i$  is the sum of weights of all vertices in partition  $i$ , and  $AP$  is the average weight of partition over all partitions.

The workload scheduler uses METIS as software for graph partitioning, which is used for partitioning a graph into equal partitions [16]. The partitioning process includes three main phases: coarsening, partitioning, and un-coarsening.

Initially, the coarsening phase reduces the size of the graph by combining a set of vertices into one single vertex. The weight of this single vertex must be equal to the sum of weights of all vertices combined in it.

Then the partitioning phase is done on the coarsest graph to receive balanced partitions with respect to the workload.

Finally, the un-coarsening phase is used to return to the original graph and refine the resulting partitions.

To assign the partitions, their number must be equal to the number of machines in the cluster. Each partition will be assigned to one supervisor, and its tasks will be assigned to the slots. Finally, the executors in each partition are assigned to slots in a round-robin manner [7]. A flowchart of the workload scheduler is illustrated in Fig. 2.

##### B. A3 Storm Scheduler

A3 Storm scheduler is a topology, traffic, and resource-aware scheduler. It can find the connections between the executors by considering the DAG of topology, so it is considered a topology-aware scheduler. It also puts inter-executor communication into consideration, so it is a traffic-aware scheduler. Finally, it performs the physical mapping according to the computation power of nodes; thus, it also resources aware scheduler [4].

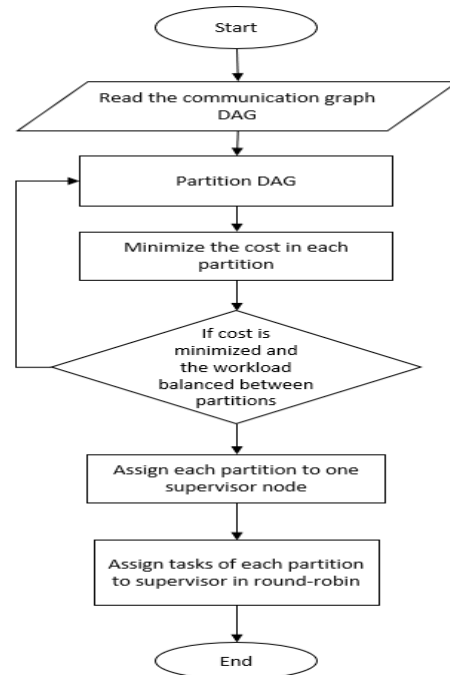

Fig. 2. Workload Scheduler Flowchart.

In general, the A3 Storm scheduler follows two steps: (1) Assignment of Executors, either by using the DAG or the traffic of topology. In this step, the scheduler initially gets the number of worker processes and the inter-executor traffic for executors unassigned from the traffic log. Then the executor assignment process begins by sorting the executors in descending order according to the inter-executor traffic; after that placing the most communicating executors as close as possible to each other. (2) Assignment of Slot; in this step, the created groups of the highest communicating executors are assigned slots. Then these slots are assigned to nodes which are sorted in descending order according to the most computationally powerful node calculated by (6) and (7). [4] [15].

$$Computation_{power} = \alpha \times (Speed) + (1 - \alpha) \times RAM \quad (6)$$

$$Speed = no. of. Cores \times no. of. Sockets \times frequency \times no. of. Flops \quad (7)$$

Where,  $\alpha$  is an adjustment factor equal 0.8.

#### V. FORMULATION OF THE BALANCE WORKLOAD STORM SCHEDULER ALGORITHM

The proposed algorithm hybridizes the Workload scheduler [8] and the A3 Storm scheduler [4]. As mentioned before, the Workload scheduler aims to reduce the network utilization by reducing the inter-node communication to increase the overall throughput and balance the workload among all available machines in the cluster. At the same time, the objective of the A3 Storm scheduler is to reduce the inter-node traffic, increase the throughput, and improve resource utilization.

The proposed algorithm of Balance Scheduling on Storm (BSS) is based on combining both the Workload scheduler and A3 Storm to enhance the performance of the Workload scheduler in increasing the data throughput and reducing the time latency. The main idea of the BSS is to apply the methodology of workload scheduler to monitor the metrics of Storm, collect the data of the communication graph during runtime, partition the graph, and balance the workload among the available machines in the cluster. Then, we have replaced the last step in the Workload scheduler (i.e., assigning each partition to one node and assigning tasks to slots in a round-robin strategy) by the A3 storm first phase (i.e., monitoring the communication between tasks). Therefore, after assigning the partitions to the nodes, the tasks will be assigned to the slots according to their inter-executor communication, which means that the most communicating executors will be assigned to the same slot, which will reduce the network communication between slots and in result this will reduce the latency and increase the throughput.

##### A. The Proposed Algorithm of Balance Scheduling on Storm (BSS)

The proposed algorithm of Balance Scheduling on Storm is based mainly on managing the execution of the topology. Its input and output are the unassigned topologies and the executor to node assignment, respectively. The phases of the proposed BSS algorithm can be concluded as follows:

1) The scheduler collects information about the topology, where it gets the number of worker processes (slots) required to execute the topology. Then it obtains the inter-executor connection of the unassigned executors and the number of the unassigned executors.

2) Calculating the maximum number of executors required per slot by (8):

$$e_{es} = \frac{total\_number\_of\_executors}{total\_number\_of\_slots\_required\_by\_topology} \quad (8)$$

3) Finding the available nodes in the cluster.

4) Partitioning the vertices of the graph into equal partitions using the k-way partitioning method, where the number of partitions should be equal to the number of the topology workers.

5) Sorting the nodes where the nodes with no workers are put at the beginning, and the partially busy nodes are put at the end. In this stage, the scheduler has to ensure that the number of nodes is not smaller than the number of partitions.

6) Sorting the tasks in each pair in descending order according to their inter-executor traffic.

7) Assigning tasks to the slots, where the most communicating tasks are assigned to the same slot until it reaches the maximum number of tasks assigned to it. Then assigning the next task to the next slot and so on until all partition tasks are assigned to the slots of the node. The pseudo-code of the proposed algorithm of Balance Scheduling on Storm is shown in Algorithm 1.

---

**Algorithm (1): Balance Scheduling on Storm**

---

```
1. function Schedule (U);
Input: Unassigned Topologies U
Output: Node-Executor assignment
2. for each topology  $u_i \in U$  do
3.    $n = u_i.numOfWorkers$ ;
// get the number of worker processes
4.    $e_{un} = u_i.UnassignedExecutors()$ ;
// get the list of Inter-Executor for unassigned executors
5.    $e_{total} = e_{un}.Count()$ ;
6.    $e_{es} = ceil(e_{total}/n)$ 

7.   Nodes = cluster.getAvailableNodes();
8.   partition_file = graph.part(Nodes);
// partition = number of workers
9.   Nodes.sort();
// Nodes that have no worker are put at the beginning and
partially busy nodes are put at the end
10.   $slots_{as} = 0$ ;
11.  if Nodes.size() >= partition.size() do
12.    Foreach  $n \in Nodes$  do
13.      Foreach  $tasks \in partition.tasks$  do
14.        tasks.sort("Desc");
// task pairs are sorted in descending order according to the
InterExecutor traffic
15.    While tasks != null
16.      For each task  $\in tasks$ 
17.        If Count <=  $e_{es}$ 
18.          mapExecutorToSlot( $slots_{as}$ , task);
// Assign most communicating task pairs to the same slot;
19.        Count ++;
```

---

```
20.      End If
21.      slotsas ++;
22.      End for
23.      End While
24.      End for
25.      End for
26.      end If
27.      End for
28.      End
```

Also, all the utilized notations and functions in the algorithm are described in Table II.

## VI. EXPERIMENTS AND RESULTS

The experimental study is done on the Apache Storm cluster, which has a Nimbus node, Zookeeper node, and two supervisor nodes having three and four slots, respectively. The configuration of the first supervisor is as follows; it has Ubuntu 20.0.1 LTS 64-bit installed on it with GNOME version 3.36.3, with “10.6 GB” memory, Intel@CoreTM i7-4810MQ CPU @ “2.80GHz × 2” processor, and “536.9 GB” disk capacity. The second supervisor has Ubuntu 14.04 LTS with OS type 64-bit with “9.5 GB” memory, Intel@CoreTM i7-4810MQ CPU @ “2.80GHz” processor, and disk capacity “21.7 GB”. Both of the supervisors have 1000 Mb/s network connectivity speed. Each supervisor has Apache Storm 1.1.1, Apache Zookeeper 3.5.7, and Java Open JDK 13. The proposed algorithm of BSS is compared with the default Workload scheduler and the A3 Storm [4] on four benchmark topologies:

1) *SOL topology* [17]: It has a chain-like structure. It has a spout and a set of bolts. It loads its data directly from the data source. Random messages are used to create sentences with words’ lengths specified by the user. It consists of one spout and a user-defined number of bolts. This topology aims to trace the network’s performance, so it is better to keep the computation as minimum as possible.

2) *Rolling count topology* [17]: It applies rolling counts of incoming terms. By the term rolling, it uses a sliding window to trace the statistics of a term until the current window

compared to the one in previous. A rolling count tuple per term is emitted by reaching the end of each time window, and it consists of the term. The term’s rolling count is a metric that points at how this term is trending now and the actual duration of the sliding window. The term can be emitted from more than one node, so a bolt must join and rank the terms. So, it consists of a spout that directly loads the data from the data source, a bolt that splits the sentences, and a rolling count bolt that uses field grouping to count the terms and group them to emit the ranks of each term.

3) *Word count topology* [18]: The spout emits streams of sentences and sends them to a bolt that splits these sentences into words and emits them to another bolt that, using field grouping, can count how many times each word has occurred. Field grouping means that based on the value of the word, the same word must always go to the same instance so that it can be counted.

4) *Spike detection topology* [18]: The spout receives a stream of data from sensors and emits them to bolts to monitor the occurrences of values that have spikes. Spout emits this stream to a bolt named Moving Average, which gets the data grouped according to the IDs of the device. When a new stream of data is received, the bolt aggregates the new values of a device to the list of values of the same device and emits new events consisting of the device ID, its current value, and its values moving average. These emitted events go to another bolt named Spike Detection, as it detects if there is a spike in the current event or not.

## B. Results and Discussion

To evaluate the performance of the proposed BSS algorithm, we consider two performance metrics:

1) *Throughput*: represents the number of tuples processed per unit time [18].

2) *Complete Latency*: is the average time a tuple takes to be entirely processed by the topology [18].

The experiment has been done by applying the proposed BSS, Workload scheduler, and A3 Storm scheduler, the four benchmark topologies mentioned above. Each algorithm has been run three times to get the average results for the three compared algorithms.

3) *SOL topology results*: SOL is generated with one spout and two bolts. The required number of workers is two, and the number of executors and tasks equals a value of nine. The results are depicted in Table III.

As shown in Table III, the Balance scheduling Storm algorithm achieved the highest value of throughput, which was “4059.67 tuples/second” at the second 240. In comparison, the most negligible value of throughput was “15.33 tuples/second” and achieved by the Workload scheduler after “60 seconds”. It is also obvious that the BSS had the best results for the throughput than the two other algorithms till “600 seconds”. At the “660 seconds” and “720 seconds” the A3 Storm showed better throughput results than the BSS and the Workload scheduler algorithms, then starting from the second 780, the

BSS returned to give high throughput than the two other schedulers. Regarding the latency, it is found that the best complete latency was “63.833 milliseconds” for the BSS the first “60 seconds”, while the worst complete latency value was 949, which is recorded by the Workload scheduler after “120 seconds”. The BSS gave the best latency results during the overall execution except at the second 180; the Workload scheduler gave the best latency. Finally, by looking at the average in Table III, it is obvious that the BSS gave better average results in terms of throughput and complete latency.

TABLE III. SOL TOPOLOGY EVALUATION RESULTS

| Time (sec.) | Throughput (tuples/sec.) |                |                  | Complete Latency (Millisecond) |          |                  |

| 720         | 1410                     | <b>1926</b>    | 1804.67          | 484.20                         | 349.80   | <b>184.33</b>    |
| 780         | 2086.33                  | 2044.33        | <b>2781.33</b>   | 445.93                         | 315.27   | <b>181.33</b>    |
| 840         | 1769                     | 2419.33        | <b>3689.33</b>   | 419.10                         | 291.93   | <b>168.97</b>    |
| 900         | 2123.67                  | 2206.67        | <b>2959</b>      | 382.53                         | 276.97   | <b>162.23</b>    |
| Average     | 1043.11                  | 1803.8         | 2487.98          | 497.54                         | 534.2    | 238.973          |

According to the reported results, it is clear that the BSS outperforms both workload scheduler and A3 Storm in both throughput and complete latency according to the overall average values. In contrast, the Workload scheduler and A3 Storm are recorded the worst average on throughput and the complete latency, respectively. Fig. 3 and Fig. 4 depict the comparison between the three algorithms' throughput and complete-time latency results.

4) *Rolling count topology results:* Rolling Count topology is generated on one spout and two bolts with four workers and 26 executors and tasks. The experiments using the three compared schedulers are presented in Table IV and depicted in Fig. 5 and Fig. 6.

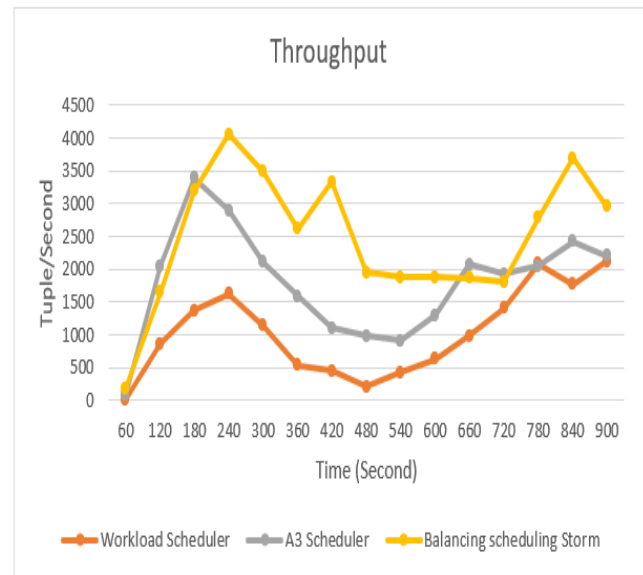

Fig. 3. Throughput Comparison Result between Three Schedulers for SOL.

Fig. 4. Complete Latency Comparison Result between Three Schedulers for SOL.

Table IV shows that the BSS has the highest average of throughput, and the A3 Storm has the least average value of throughput. The best value reached of the throughput was “24627.33 tuples/second” at the second 900 by the BSS. During the overall execution the BSS showed better results for throughput. But only at “240 seconds” and “480 seconds”, the

BSS gave lower results and the Workload scheduler showed higher results than the BSS. For the complete latency values, the results showed that the BSS has a minor average of complete latency. In comparison, the Workload scheduler has the highest value of the average complete latency. The least value recorded was “310.48 milliseconds” for the BSS at the second 900, and the highest value was for the A3 Storm “1844.03 milliseconds” at the second 600. Furthermore, as displayed in Table IV, at the first “60 seconds,” both the Workload scheduler and A3 Storm could not finish any data processing, and their recorded throughput was zero. While the BSS processed the data in this limited time and produced “43.67 tuples/second”. At the end of the Table IV, it is shown that the BSS had the best average results for the throughput and complete latency.

Fig. 5. Complete Latency Comparison Result between Three Schedulers for Rolling Count.

Fig. 6. Throughput Comparison Result between Three Schedulers for Rolling Count.

5) *Word count topology results*: This topology is executed using two workers with one spout and two bolts. It also contains 13 executors and tasks for the “3.8 GB” dataset size.

| 780         | 19160                    | 16323.67 | <b>27318.33</b>  | <b>35.57</b>                   | 109.1    | 48.47            |
| 840         | 18233                    | 16929.67 | <b>29635.67</b>  | <b>35.53</b>                   | 105.03   | 49.4             |
| 900         | 18468                    | 21994.67 | <b>30709.67</b>  | <b>35.4</b>                    | 99.73    | 50.63            |
| Average     | 20329.31                 | 14881.98 | <b>28263.33</b>  | 62.3                           | 119.96   | <b>57.48</b>     |

Table V shows that the BSS recorded the highest throughput, while the A3 Storm recorded Storm the least. The BSS has reached the maximum value of throughput, which is “33584.33 tuples/second” after “720 seconds,” and the A3 Storm has the least value of throughput, which is “344.67 tuples/second” after “60 seconds”. Regarding the complete latency, the experiments' results showed that the least complete latency value was “35.4 milliseconds” by the Workload scheduler after “900 seconds” of execution. But in contrast, the Workload scheduler recorded the highest value of complete latency, which was “296.67 milliseconds” after the first “60 seconds”. For the BSS, the reported average complete latency value was the least. From the comparison presented in Fig. 7 and Fig. 8, it is obvious that the Balancing Scheduling storm enhanced the system's performance.

Fig. 7. Complete Latency Comparison Result between Three Schedulers for Word Count Topology.

Fig. 8. Throughput Comparison Result between Three Schedulers for Word Count Topology.

6) *Real-time spike detection topology evaluation*: Other experiments are carried out based on the real-time spike detection topology described in the Intel Lab Data [19]. The data set presented here is collected from 54 sensors in the Intel Berkeley Research lab. The data set included about two million readings gathered from these sensors. The topology has been deployed with a dataset about “11 GB” size generated by the repetition of the data presented in Intel Lab Data [19]. The recorded results after running the three schedulers are recorded in Table VI, and the comparison between these results are depicted in Fig. 9 and Fig. 10 are gained.

TABLE VI. SPIKE DETECTION TOPOLOGY EVALUATION RESULTS

| Time (sec.) | Throughput (tuples/sec.) |                |                  | Complete Latency (Millisecond) |               |                  |
|-------------|--------------------------|----------------|------------------|--------------------------------|---------------|------------------|
|             | Workload scheduler       | A3 Storm       | The proposed BSS | Workload scheduler             | A3 Storm      | The proposed BSS |

| 780         | 1141.67                  | 1643.33        | <b>1747.33</b>   | 784.31                         | 504.56        | <b>461.25</b>    |
| 840         | 1486.67                  | 1553.33        | <b>1889.33</b>   | 786.86                         | 503.45        | <b>444.81</b>    |
| 900         | 2056.67                  | 1630           | <b>2269.33</b>   | 709.07                         | 501.22        | <b>427.87</b>    |
| Average     | 1072.93                  | 1323.91        | <b>1672.13</b>   | 847.51                         | 537.07        | <b>531.53</b>    |

Table VI shows the comparison results between the three algorithms in terms of throughput and complete latency. The Balancing Scheduling Storm has the maximum value of the average throughput. In contrast, the Workload scheduler has the minimum value. The best result of the throughput is “2311.33 tuples/second”, which was reached by the Balancing scheduling storm after “420 seconds”. The smallest value was “0 tuples/second,” which was reached by the A3 Storm after “60 seconds”. The next worst value of throughput was “5.33 tuples/second” at the first “60 seconds” and was reached by the Workload scheduler.

Also, the latency results are described in Table VI. The worst latency value was for the Workload scheduler at the first minute; it was “1866.24 millisecond”. The best value was for the Balancing Scheduling storm after “15 minutes” it reached the value of “427.87 milliseconds”. And by looking at the end of the Table VI, it is obvious that the BSS had the best average results in both terms, the throughput and the complete latency.

Fig. 10. Throughput Comparison Result between Three Schedulers for Spike Detection Topology.

## VII. CONCLUSION AND FUTURE WORK

In this paper, the Balance Scheduling on Storm (BSS) scheduler is proposed. It is a hybrid scheduling algorithm based on two existing scheduling algorithms: the Workload scheduler and the A3 Storm. It takes balancing the workload between the cluster nodes while minimizing the communication network between them and the inter-executor traffic. This proposed algorithm has been compared with the two existing schedulers using two metrics, throughput, and complete latency metrics. The BSS algorithm has shown better performance. The results show high throughput more than the other two algorithms and less latency. This has improved the performance of the system.

The comparison done in this paper used two essential metrics: throughput and complete latency. In future work, an enhancement in the performance will be carried out for other metrics, such as the amount of memory and resources used to give better performance and enhancement than the already given performance in this thesis. The comparison can be done with more scheduling algorithms than the two algorithms already compared with. New research could enhance the number of resources and the amount of memory and their usage instead of the balanced scheduling. The experiments would take place on more topologies to check their suitability and performance.

# Extract Concept using Subtitles in MOOC

Aarika Kawtar\*, Habib Benlahmar, Mohamed Amine Naji, Elfilali Sanaa, Zouheir Banou  
Laboratory of Information Technology and Modeling, Hassan II University of Casablanca, Faculty of Sciences  
Casablanca, Morocco

**Abstract**—Massive open online courses (MOOCs) are a variety of courses offered through the online mode, paid or unpaid and has evolved as an excellent learning resource for students. The structure of the course design is mainly linear where there are a few video lectures provided by either professors of several universities, or people with expertise in the particular subject. They are usually graded on a weekly basis through quizzes or peer-graded assignments. The objective of this paper is to extract the concepts taught in the videos from the subtitles, which could later be used to enhance recommendations of the learners using their clickstream data. The teachers could also use this to see the demand for their courses. Evaluate two keyword extraction methods, which are BERT and LDA using different Coursera courses. The experimental results show that BERT outperforms LDA in terms of Coherence.

**Keywords**—LDA; BERT; topic coherence; overlap coefficient

## I. INTRODUCTION

One of the most profitable and in demand businesses in today's world are those of Massive open online courses (MOOC). Not only do they offer a vast range of lectures on almost all the topics be it the medical field, or some complex lessons on coding, but can also be easily accessible by everyone sitting at home [1]. These platforms have attracted a large number of people, which sums up to nearly 10 million participants from all over the world. Coursera, Udemy and EdX are some of the classic examples of MOOC [2]. The format of these platforms is similar, where professors or trained people share video lectures covering a particular topic. They use different methods of teaching like using powerpoint presentations, whiteboard or even the electronic boards. Some platforms invest a lot in making their videos interesting and visually appealing, hence they incorporate graphics and colorful animations. This helps in drawing more attention from the learners, especially the younger crowds. The lectures are usually grouped into few modules and a set of modules makes up a course. The module system helps the learner keep track of their progress and also have a better understanding of the pre requisites. The teachers find the module systems easier as it is easier to set assignments and other assessment related work. Each module usually runs for a week, however, it totally depends on the viewers' interests. Weekly deadlines are set, which are flexible. This means that an ideal schedule is provided, which if followed thoroughly can benefit an average learner. However, it is their choice ultimately on how much time they want to spend on it, it could be earlier than the target date of even later. At the end of each module, there is an assessment held. There are several ways in which one is assessed to see how much of the course they have grasped. Some of these assessment techniques are quizzes, projects and peer-graded assignments. Few courses even have cutoffs to be

cleared at the end of module assessment. Failure to complete this successfully would not permit the learner to proceed to the next module or it might not consider the module as complete [3]. Upon course completion, the learner receives a certificate of completion from the institute offering it and it can be considered as a legitimate proof of knowledge acquired, and can be updated in resumes and professional profiles. Courses that have strict assessments do not provide the certificates until all the quizzes have been cleared with the minimum required cutoff and all the peer graded assignments have been checked by the required number of co learners. The legitimacy of MOOC has gone so far that nowadays, universities offer these courses as electives as proper curriculum courses with college credits awarded on their completion. The college provides these courses and has their own assessment methods, however, the students have to complete these courses through the platform in order to receive the assigned number of credits. These courses can be free, but mostly they have to be purchased. Another alternative provided by MOOC is that some courses can be audited for free but do not provide completion certificates hence the purpose is solely for acquiring knowledge.

MOOC provides a form of social learning where interactions constantly take place between learners and the teachers. It paves way for mass learning and personalised comprehension. Even though there is no face-to-face communication taking place, these platforms have been successfully been able to break the barriers of any type of communication hindered otherwise [4]. There are different ways one can engage themselves with the platforms. Learners and teachers can both participate in forum and discussions, helping fellow learners and students. Some even start taking lectures of their own. Others work on in video editing, as mentioned earlier, adding good graphical depictions of what is being explained or colourful animations. There is a lot work that has to be dealt in the back end of the sites or apps belonging to these platforms. A large group of people also contributes by providing constructive feedback and suggests improvements. These are constantly monitored and taken note of in order to improve the user interface of their platforms and attract more learners to purchase their products. These learning methods are completely different from the physical mode of learning and open a wide door of new opportunities to explore [5]. Hence, we can say that the most important factor which determines the success of these MOOCs is the engagement of the students, however not a lot of research has been carried out on how the student engagement affects the platforms. All MOOC platforms primarily run on how much they have been used and a decline in student engagement can give a massive blow to these businesses. It is of utmost importance that the

\*Corresponding Author

engagement is always constantly monitored and changes being continuously implemented in order to keep them high [6]. The discussion forums play a vital role in checking engagement, along with website visits, registrations, clicks etc. However, it is not an easy task to keep track of the engagement as there are so many parameters that have to be taken into consideration while doing the analysis. Some of them are course enrollments, course completion, discussion forums, etc. [7].

These courses come with their own set of disadvantages. Though they attract a large number of student registrations, recent studies have shown that only a small fraction of these students complete their courses [8]. According to statistics provided by Coursera, almost 75% of the courses enrolled by students have not been completed [9]. Another problem is that these platforms do not come with keyphrases and it is going to be a laborious task to identify them manually and will take up a lot of time. This means that one cannot search for courses based on particular topics. There are a variety of topics mentioned in each video, but there is no way of keeping track of these. It is important to do so as it can help recommending better courses to those who show interest in topics. Topic based searches can be made than course-based searches and it will be easier for the learner to choose their apt course based on how much do the topics cover in the course line up with their topics of interest.

Keyphrases are important and significant expressions consisting a collection of words. They give us the contents of the data, or even sometimes summarize it [10]. There have been several algorithms developed to extract keywords from scripts, notes etc. These are used in data mining like clustering of documents, providing recommendations and formulation of queries [11], [12]. Bidirectional Encoder Representations from Transformers (BERT) is one of the models that can be used for keyphrase extraction. This model is used to make sequential recommendations based on past data. The distinctive feature of this method is that it can incorporate context from both sides, unlike other sequential predictors, which only do it from left to right [13]. Latent Dirichlet allocation (LDA) model is a probabilistic modeling algorithm. It is commonly used to identify the topics in a collection of texts. It is usually used in image retrieval and face recognition technologies [14], [15].

Instructors face problems in analyzing each student's level of understanding in order to improve the quality of courses or to provide referral systems. Although the number of students enrolling in courses has increased, very few of them actually complete the course. Therefore, it is necessary to track learner journey data to know what interests them. The goal of this paper is to extract the concepts taught in the videos from the subtitles, which could then be used to improve the learners' recommendations using their path data. Instructors could also use this to learn about the demand for their courses.

In this paper, we have attempted to extract concepts from the subtitles of video lectures of courses offered by Coursera using BERT and LDA models for key phrase extraction. A comparison is made between the results obtained by both.

The paper is organized as follows. In Section 2, we review related work on concept extraction.

Section 3 is devoted to the context of our experimental study, detailing the dataset collected from the Coursera MOOC videos and the models (LDA and BERT) that we will use for this study.

In Section 4, we show our proposed algorithms for concept extraction from the sub-titling of the experimental results which show a better concept extraction. In section 5 we end with a conclusion that shows the results of our work.

## II. RELATED WORK

In our study, we have tried to automatically extract keyphrases from the subtitles of the videos. In general, there are two ways in which these extractions are carried out [16]. The first approach is supervised, where there is binary segregation of each word into either keyphrase or not a keyphrase [17]. The second approach is unsupervised. In this approach, the words are ranked based on what the algorithm asks it to do, for example probability of occurrence, or even usage in the course. Some commonly used machine learning algorithms are Naïve Bayes and support vector machines [18].

Yi-fang et al developed an algorithm called KIP algorithm. In this algorithm the extracted words were first examined and scored on the basis of three factors. The first factor was their frequency in the text. This means they checked how frequently the word occurred in the text. Second parameter considered was their specificity. This means there is a check on how specific or unique the words are to the course provided. This information is also gathered by checking on the neighborhood data. Last parameter taken into consideration is its contents, as in the words that are related to the examined word. The words are arranged in order of their scores. The words that obtain high scores are later categorized as keyphrases [12]. Another similar type of work can be seen in Xiaojun et al's paper used information from the neighborhood documents to get more data and then this data was graphically represented along with the data of the document where keywords need to be extracted. These data were compared and the keyphrase were extracted accordingly [10]. A very similar study to ours was found in the works of Raga et al. They used this method to navigate to the exact part of the video, or access a video segment by just searching for the keyword. They considered factors like statistical and visual features while implementing the algorithm [19]. A model called Text Rank was developed by Rada and Paul where they took a graphical approach to rank the words [20]. The TPR (Topical Page Rank) approach is another one proposed by Liu et al where first the segregation occurs based on various topics and then the TPR algorithm is individually run on each one [18]. Some other algorithms were developed based on using deep learning [21], frequency of occurrence of words [22], word embedding vectors and graphical ranking [23].

Our study draws inspiration from all these works, but still manages to stand apart as we aim on increasing engagement by giving personalised recommendations to learners based on their search history or clickstream data. To ensure this, keyphrases have been extracted from the subtitles using two algorithms and the best of these two on experiments could be used to develop better recommendation systems. Elaborating on that, these keyphrases can be used to match with the learner's

interests thus giving better course recommendations. The teachers can also benefit from this study. The clickstream data allows teachers to know which topics are more in demand and will encourage them to record lectures covering those topics. This will help the algorithm detect their courses and recommend it to the learners. They can also gauge the learner engagement and see which part of their courses attract more attention.

### III. METHODOLOGY

#### A. Datasets

The study will use the dataset called "MOOC DATA". This dataset has been derived from the subtitles of the course videos from Coursera platform. All the words are split up into individual components and these could further be sent into algorithms for keyphrase extraction. This dataset consists of a total of four folders named:

- "CSEN" – Computer Science in English
- "CSZH"- Computer Science in Chinese
- "EcoEN"- Economy in English
- "EcoZH"- Economy in Chinese

The statistics of the four datasets are listed in Table I, where #courses, #videos, are the total number of courses, videos, in each dataset.

TABLE I. DATASET STATISTICS

| Dataset | Domain           | Language | #courses | #video |
|---------|------------------|----------|----------|--------|
| CSEN    | Computer Science | English  | 18       | 2,849  |
| EcoEN   | Economics        | English  | 5        | 381    |
| CSZH    | Computer Science | Chinese  | 8        | 690    |
| EcoZH   | Economics        | Chinese  | 8        | 455    |

However, for the sake of better understanding and better research, only the "CSEN" folder was used for the study. This folder contained two JSON files, one of these files was called "candidates" and the other one was called "captions". Again, since the aim of our study only deals with the subtitles of the videos, only the caption file was utilized. This table contained the video captions of 18 computer courses; the size of this file is 216 MB. Table II shows how the subtitles were sliced and stored.

The first column is usually ignored as it is the serial numbers. The second column is the Course ID. This is a unique code, which is used to identify the particular course. For the course we considered (Computer Science with English), the course id is 1. The column next to this is the text. It consists of the script of the subtitles and is called transcript. This script is so precise that it also has details like parts of the video where there is music. That's what makes the process of keyword extraction challenging. The music is used way too many times; the system might mistake it to be a keyphrase while we know it is just the background music being referred. Hence it is important that all these unwanted parameters are taken care of

at the initial stages and the algorithm is not affected due to them. The column next to it is the tagged column. Here, we see that every word has been sliced up (including the music). The 3 gram model is used to carry out this process. For example, the first row shows that the text has been separated into tags like.

"MUSIC", "Today", "we", "re" and so on. Again, on running models, the music words should not be considered for keyphrase extraction. The last column is video id which is the unique number given to the video in a course, and is used to refer to a particular course. The course is the same while the videos from which the words were extracted from were different. Our study uses the first 5 videos from the course with course id 1. This dataset will run through two models and a comparison will be drawn regarding which is the better one to consider for keyphrase extraction.

#### B. Pre-Processing

Pre-processing is the process where the raw data received is converted into a form that is comprehensible and useful. It is extremely crucial to ensure that data pre-processing has been done before carrying out any analytical task [24] [25]. This helps in having a dataset of good quality. Process used to split the text or segmenting a text to words, meaningful parts or phrases is called tokenization. In this process, punctuations, whitespaces and other non- alphanumeric characters are not considered, all characters are converted to lowercase and stopwords (conjunctions, articles, etc.) are removed [26].

Before proceeding, there is another concept that needs to be looked upon, which is an n-gram. An n-gram (or Q gram) is basically a sliced part of a longer string consisting of n characters. They are usually obtained from a sample text or some form of speech [27]. It could be words, phrases, letters sometimes even syllables. It is a very efficient means of implementation. On conversion in n-grams the string gets embedded into a vector and is further compared with other data of similar type. Its consistency and distribution can be measured too [28]. An n-gram model is a probabilistic language model, where it is used to make predictions of the items succeeding it in the form of a sequence known as an (n-1)- order Markov model. These models find their extensive usage in computational linguistics, communication theory and data compression. There are two major advantages of using thesen-gram models and algorithms. One of them is simplicity, the model is comparatively simpler to operate and execute than its other counterparts. Secondly, its scalability is a boon. At higher n values, this model is able to store more contexts with a space- time tradeoff which has been understood well. This allows the smaller experiments to efficiently expand.

In our study data has been obtained beforehand from the dataset in order to run it with various algorithms. The words from the video subtitles have been sliced out into different words. Each of these go through the algorithm to obtain results on whether it is a keyword or not. That is decided based on other data like how frequently the word is used or its significance in the text. This process will help identify the key topics covered in the course. The data was retained from the dataset, however, unnecessary information like the tagged column and stopwords were eliminated altogether and n-grams were generated.

### C. Models used

1) **BERT**: Bidirectional Encoder Representations from Transformers (commonly known as BERT) is a machine learning model that is used for language representation [28]. These models are pre-trained and they force the model to study the semantic data in between and withing the sentences. Unlike other similar models which only function from left to right, BERT works from both directions i.e. it is bidirectional, just as its name says [29]. This algorithm takes the final hidden state of the first token and uses it to represent the entire sequence for tasks which require classification of texts. When BERT is incorporating with another output layer, there is an advantage of minimal number of parameters being necessary to be learnt from scratch [30]. There is a particular format that any input data needs to fulfill if it has to undergo the BERT model. A special token which consists of the special classification embedding called [CLS] is put prior to every sentence to fulfill this criterion. Another special token that is used is the [SEP]. It is placed at the end of each and every sentence in order to make a clear separation between the segments [26]. BERT also relieves the problem of masked language model (MLM), where it randomly covers some of the input and expects the algorithm to predict it based on the date of the surrounding words. The next sentence prediction (NSP) is also used. Fine-tuning techniques are of various kinds based on how much of the architecture needs to be trained [31]. Basically, it is a sequential predictor. Google uses BERT to enhance its search predictions. In our first study, we have taken the data from the dataset and run it with BERT model [35].

For BERT analysis the probability analysis can be represented using the following language model by Equation (1) [36]:

$$P(w_1, w_2, \dots, w_T) = \prod_{t=1}^T P(w_t | w_1, w_2, \dots, w_{t-1}) \quad [36] \quad (1)$$

Where  $w_1, w_2, \dots$  are the different individual entities of which we need to find the probability distribution and  $T$  is the total number of entities. In our case, this is the probability distribution of each word in the subtitle file.

2) **LDA**: The Latent Dirichlet Allocation (or LDA) is a probabilistic model. The main aim of this model is to represent documents as different topics and each of these topics are characterised by a distribution over words [32]. The assumption made here is that every course has a set of topics already and the text (subtitles in our case) have relevant information to summarise these topics and hence, they can be grouped under them. The algorithm tells us the similarities in the data by grouping them into common topics [14]. It gives us a distribution of the word usage and when we search for a particular word, it refers to this distribution [33]. Supervised Machine Learning algorithms are used to run the model. This approach is used as a solution to a lot of problems related to topic identification, face recognition, web spam classification

and entity resolution [34]. The second part of our study deals with LDA.

To find the normal probability density function using the LDA method, the formula is given by Equation (2) [37]:

$$P(X|\pi_i) = \frac{1}{(2\pi)^{\frac{p}{2}} |\Sigma|^{\frac{1}{2}}} \exp \left[ -\frac{1}{2} (X - \mu_i)' \Sigma^{-1} (X - \mu_i) \right] \quad [37] \quad (2)$$

Where,

$\pi_i$  – Probability density function

$x$  – Multivariable normal

$\mu_i$  – Mean vector

$\Sigma$  – Variance-covariance matrix.

This can be used if all the matrices for all the populations are homogenous. The decision rule of the LDA algorithm is based on the Linear score function, which is defined by Equation (3):

$$S_i^L(x) = -\frac{1}{2} \mu_i' \Sigma^{-1} \mu_i + \mu_i' \Sigma^{-1} X + \log P(\pi_i) \quad [38] \quad (3)$$

Where following substitutions are made:

$$d_{i0} = -\frac{1}{2} \mu_i' \Sigma^{-1} \mu_i \quad ; \quad d_{ij} = j\text{th element of } \mu_i' \Sigma^{-1}$$

$d_i^L(X)$  is the linear discriminant function (4) i.e.

$$d_i^L(X) = d_{i0} + \sum_{j=1}^p d_{ij} x_j \quad (4)$$

Therefore we get Equation (5) [38],

$$S_i^L(x) = d_i^L(X) + \log P(\pi_i) \quad [38] \quad (5)$$

## IV. EXPERIMENT AND RESULTS

### A. BERT

BERT analysis was first carried out on the preprocessed data. There was a restriction put on the number of concepts that could be extracted to only 3 concepts per line. The n-gram set for each concept was between 1 and 3. Fig. 1 depicts the results obtained.

Fig. 2 shows the coherence and the average overlap of the topics when the data was processed through the BERT model. 20 topics were given to derive BERT's selected keywords. The topic coherence graph shows linear increase upto topics, which is also followed by a linear increase, but the slope gets reduced. The average topic overlap graph shows a steep linear decrease initially up to 2 topics, after which the slope reduces. Finally after 3 topics, the line almost flattens out. Both the graphs overlap at a point in the earlier stages. The ideal number of topics is 4.

### B. LDA

The second studies were carried out using the LDA model. Again, concepts per line were restricted to 3 and the n-gram was set between 1 and 3. Fig. 3 gives us the results obtained.

Fig. 3. The Concept Extracted from Subtitles with BERT.

Fig. 4 gives us an insight of the results for the same. A graph containing coherence, average overlap of topics was plotted where 20 topics were given to derive the LDA selected keywords. The graph of Topic Coherence shows a peculiar trend. It remains constant throughout and shows no variations at all. The average topic overlap shows a slight decreasing linear trend up to 2 topics, then it remains constant and above 3 topics there is a further linear slight decrease. The overall overlap decrease is very small. Unlike what we observed in the graph of BERT analysis, in this graph we do not see any intersection of the two parameters.

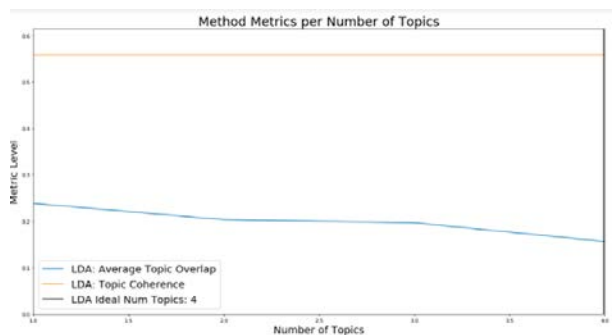

Fig. 4. LDA Coherence Score with Overlap Coefficient.

### C. BERT v/s LDA

In order to draw comparisons with both the studies, the following parameters were considered.

1) *Overlap coefficient*: It is the measure of similarity that is used to track the amount of overlap between two finite sets. In other words, we can say that it is the intersection of two sets. Our studies showed the average overlaps of the topics in LDA to be higher than that of BERT analysis.

2) *Topic coherence*: It measures the total score of a single topic by measuring the degree of semantic similarity between the high scoring words of the topic. The consistency of the concepts by BERT was found to be higher than that of LDA.

As consistency is the more prioritised factor, overall, it can be concluded that BERT is the better model to use for keyphrase extraction of video subtitles in MOOC than LDA as it gives us clearer information about the topic coherence.

### V. CONCLUSION AND FUTURE PROSPECTS

Our studies show that BERT was a better model that could be implemented in order to extract keyphrases from the video subtitles from MOOC videos. The MOOC industry is booming and will continue to do so in the future. It is important to ensure that the course completion rate is high. Now that one can identify the key topics in a course using BERT model, further programming can be done to link these results with the search history of the learner. When any of the key topics are searched, these courses should show up and similar courses be recommended. This will ensure that the learner finds exactly what they are looking for thus motivating them to complete the course and enjoy it. This also helps give them personalised recommendations. As mentioned earlier, the teachers recording the courses also will vastly benefit from this. They can check the engagement of the students in their courses, or have an idea about which part of their video is watched more or gets more demand. They can also use this data to record lectures accordingly so that their courses appear on the top of the recommendations.

**Abstract**—Now-a-days, coronary heart disease is one of the deadliest diseases in the world. An unfavorable lifestyle, lack of physical activity, and consuming tobacco are the causes of coronary heart disease aside from genetic inheritance. Sometimes the patient does not know whether he has abnormalities in heart function or not. Therefore, this study proposes a system that can detect heart abnormalities through the iris, known as the Iridology method. The system is designed automatically in the iris detection to the classification results. Feature extraction using five characteristics is applied to the Gray Level Co-occurrence Matrix (GLCM) method. The classification process uses the Support Vector Machine (SVM) with linear kernel variation, Polynomial, and Gaussian to obtain the best accuracy in the system. From the system simulation results, the use of the Gaussian kernel can be relied on in the classification of iris conditions with an accuracy rate of 91%, then the Polynomial kernel accuracy reaches 89%, and the linear kernel accuracy reaches 87%. This study has succeeded in detecting heart conditions through the iris by dividing the iris into normal iris and abnormal iris.

**Keywords**—Iris; iridology; coronary heart; circle hough transform; gray level co-occurrence matrix; support vector machine

## I. INTRODUCTION

Coronary heart disease is the number one cause of death worldwide. According to data from the World Health Organization (WHO), there are 17 million people in the world who die from coronary heart disease. In Indonesia, coronary heart disease is the highest cause of death after stroke, with a mortality rate of 12.9% in 2014 [1]. Every year there are 1.9 million people die of coronary heart disease due to consuming tobacco [2]. An unhealthy lifestyle and lack of physical activity are the leading causes of coronary heart disease [3]. The death rate is higher among the older age population [4]. Consuming foods high in carbohydrates or fat and obesity are factors that cause constriction of blood vessels in the heart.

Examination to determine coronary heart disease will be advised by checking with an Electrocardiogram (EKG), which uses electricity to determine heart rhythm. The use of echocardiography is also sometimes done to see the part, pump function, and valve function of the heart. Taking some

actions to check the current heart condition costs quite a bit so that a person will be reluctant to examine his heart condition.

Early prevention can be done to reduce the risk of coronary heart disease, namely by consuming enough fruits and vegetables every day [5], exercising or doing physical activities regularly in daily life, and do not consume tobacco [1].

Nowadays, technology to detect heart conditions from an early stage has been carried out by scientists in the medical field and computing technology. One of them is knowing the heart condition through the eye's iris, which is directly connected to the brain [6]. The brain is a human organ that receives 15% of blood flow from the heart and accounts for 20% of oxygen consumption in the body, making it susceptible to vascularization in the human brain [7].

The iris is one of the unique organs in the human body. Iris is usually used as electronic security or biometric identification system [8,9]. Nowadays, the research on the iris in the medical field is increasingly widespread and is being seriously studied by experts. Iris can provide information about the condition of human organs, known as the Iridology method.

Iridology is based on the analysis of one of the most complex tissue structures contained in the iris. This method can determine the condition of organs and systems in the body from the marks on the iris. Iridology cannot diagnose a disease but instead helps to identify existing or any potential problems in a particular organ [10]. According to Iridologists, the condition of the overall organ is reflected on the surface of the iris [11]. In healthcare practitioners, the iris is used to determine the systemic health, innate strengths, or weaknesses of an individual's personality [12]. Image processing and data mining processing techniques have been used as disease diagnosis tools in biomedical applications. There are parameters in improving the quality of the iris diagnosis technique, especially by using iris images by focusing on the PRISMA-ScR guidelines [13]. Based on this statement, the research obtained 89.63% classification accuracy of diabetic patients with iris diagnosis [14]. Heydari M. and Teimouri M. have also conducted a test on type 2 diabetic patients and obtained the highest accuracy rate of 97.44% using Artificial

\*Corresponding Author

Neural Networks in Iran. Young-WoolLim and Young-BaelPark [11] have also conducted a study to examine the relationship between the iris and the characteristics differences of each individual. The results show that iris parameters can be used more definitely related to characteristics than functional changes. Research conducted by M. Gopalan and Gopal S. Pollai stated that iridology could be used to determine the health of humans organs contained in the character of the iris [12], Recognition of the iris identifies biometrics and can diagnose the presence of cholesterol in the blood [15]. Iris is used in providing information of human's physical condition to determine vehicle driver fatigue by detecting the behavior of the iris that has been carried out by [16], with an accuracy of 80%. Research by [17] has diagnosed the heart with the iris using Principal Component Analysis (PCA) and has achieved 80% success using the SVM classification. The use of the GLCM method was also carried out by [18] by using four characteristics of feature extraction with an accuracy rate of 85.6%.

Previous studies have used the iris as an early diagnosis in detecting abnormal conditions in human organs. The use of different methods leads to different results in identification accuracy. The GLCM method using six characteristics of feature extraction has not been carried out until now. So this is a new scope for in-depth research to be carried out in the identification process. Separating the iris from the rest of the

eye is carried out automatically using CHT by utilizing circle edge detection, an important part of the identification system designed in this paper.

In this study, iris samples were collected from healthy individuals and patients with coronary heart disease to explore new directions and methodologies in diagnosing coronary heart disease with computer imaging and machine learning techniques. The determination of the iris section has been carried out automatically using the Hough transformation method, which is considered more efficient in reading multiple iris samples [19]. Gray Level Co-occurrence Matrix as a texture extraction method was chosen in this study because of its ability to perform feature extraction in grayscale images properly [20]. The selection of GLCM as a feature extraction method is based on previous research that has not tested the condition of the heart through the iris using the six characteristics of GLCM. The GLCM method is considered to be better at reading images with grayscale values to obtain accurate results. Determination of the iris that reflects normal and abnormal heart conditions is carried out using the Support Vector Machine as a classification method. The SVM method can separate data into classes with linear solutions in high dimensions [21]. So that the final results of this study can help provide information on normal heart conditions and heart conditions with abnormal conditions through the iridology method. The system design flow can be shown in Fig. 1.

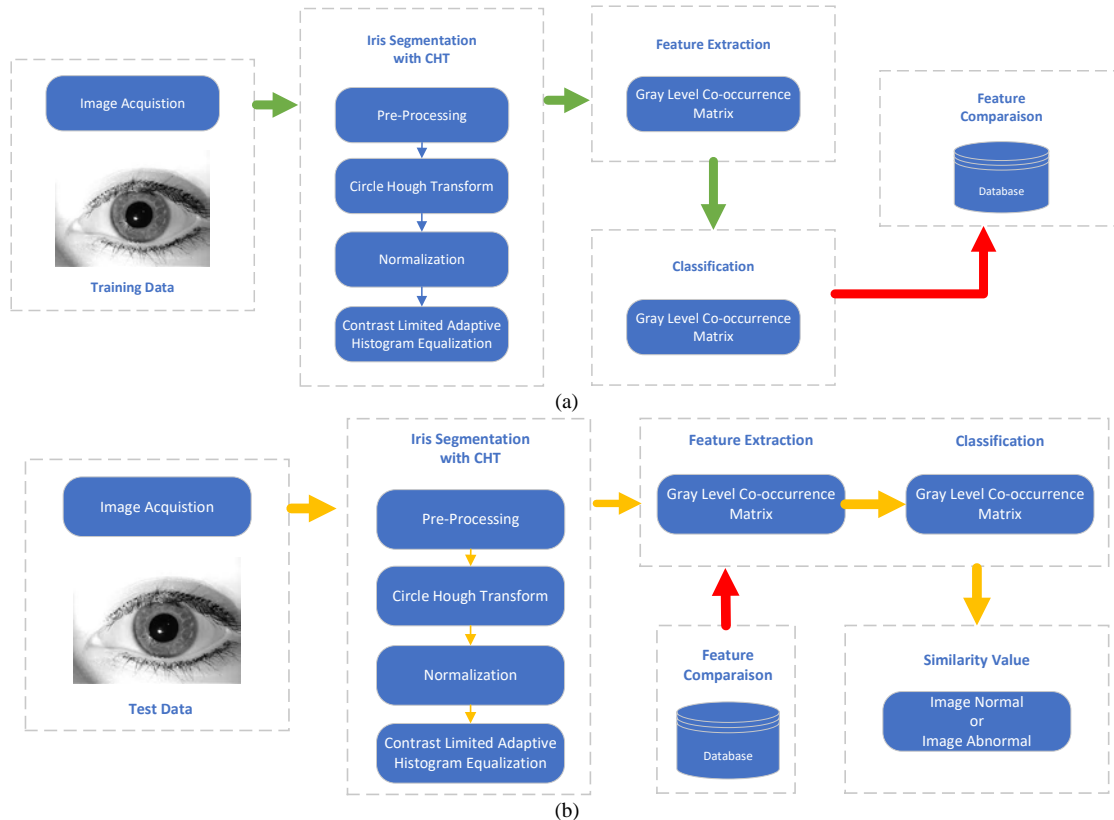

Fig. 1. Shows the Flow of the Designed System; a) the flow of Training on the Recognition System; b) Test Flow on the Recognition System.

## II. RESEARCH METHOD

### A. Iridology

Iridology is known as a diagnostic method using the human iris. In the medical world, the iris can interpret the condition of the human organs [22]. Iridology divides the iris into 60 parts, and each part represents the condition or function of its organs. The right iris will reflect the condition of the right organs of the body, and vice versa, where the left iris will reflect the condition of the left organs [23].

Dr. Bernard Jensen has created a chart that describes each part of the 60 sectors into an image that is mirrored in a circular image like a clock and is divided into sectors according to the part of the iris that reflects the organ. The chart has been described according to the division in the left eye and right eye [10], [24].

Fig. 2. Left Iris and Right Iris Iridology Chart [10].

We can see in Fig. 2, the position of the heart is on the left side of the iris. The location of the heart is reflected through the left iris, which is shown in the iris zone 02.00 – 03.15.

### B. Pre-Processing

The image captured through a digital camera has an RGB (Red, Green, Blue) format, so it is necessary to do a pre-processing process. In the preprocessing the iris image will be converted from an RGB image to a Greyscale image. Grayscale images have a simpler color value with a color intensity of 0 – 255 pixel thus shortening the computation time. The next step is to cut the unused part outside the iris, leaving a part that is close to the iris. Then, The eye image will

be resized so that the entire image has the same pixel size when it enters the extraction process [25].

Fig. 3. Image Pre-Processing Process.

Fig. 3 shows the pre-processing chart. The resized image will be processed into the CHT method to obtain the iris and eliminate the pupil area.

### C. Circle Hough Transform

Images that have gone through the RGB to Grayscale conversion process will be separated between the iris and other objects that are not used, especially the pupil. The CHT method is used to determine the iris part automatically without human assistance in determining the coordinates of the iris. CHT can detect circles in the iris image and know between the outer iris and the outer pupil.

$$(x - a)^2 + (y - b)^2 = r^2 \quad (1)$$

Equation 1 describes the center circle  $(a, b)$  and has a radius of  $r$ . With  $(x, y)$  is a pixel at the edge of the circle, en it can be represented in the form of a circle as [26]:

$$\begin{cases} x = a + r \cos \theta \\ y = b + r \sin \theta \end{cases} \quad (2)$$

Fig. 4 describes the CHT method that is implemented into the iris image. The iris image at point (a) has RGB format, which needs to be converted into a greyscale format. The histogram in the grayscale image shows high values in several white areas of objects that occur from light reflections and black colors that have values from the middle pupil of the iris.

Fig. 4. CHT Process in Detecting Circles on the Iris; a) Iris Image in RGB Format is Converted into Grayscale Format along with Histogram Values; b) Circle Detection Process with CHT; c) the Results of the CHT Process.

Then the image at point b is an image display in determining the point of the circumference of the pupil and iris ring. If a part of the noise is not circular in this process, it will be removed. The image is then given a thickening process on the line to determine the circle in the image. Furthermore, the part that has been detected as a circle will be combined with the initial RGB image and generate an image like point c.

The CHT algorithm is used to separate the iris from the pupil and sclera. This automatic determination is carried out using edge detection in the form of a circle with a diameter value to determine the inner circle and outer circle of the iris. Edge detection is carried out to find objects with a diameter of less than 3 mm for the object removal process. Then the system will detect a circle with a diameter of more than 3 mm with a shape close to a perfect circle that is selected as the inner iris circle. In determining the outline of the outer iris circle, the system looks for the diameter of the circle measuring 12 mm. Determination of the diameter of the circle is adjusted to the process of taking pictures using constant light so that the images in each data taken to have the same size.

#### D. Normalization

The texture in the image has coordinates that represent the dimensions of the iris image, such as pupil dilation [27]. The iris image segmentation method aims to normalize the image in a different form but still has the exact resolution [28]. The iris can be modeled by two non-concentric circles and different textures within an iris circle. The center of the pupil can be used as a reference point for the circle on the iris [8]. A radial line runs through the area in the iris, known as radial resolution. Since the pupil is elastic to the iris, it is necessary to rescaling the reference point. The scaling equation is calculated based on the angle around the iris circle, with the equation:

$$r' = \sqrt{a\beta^2 - a - r_i^2} + \sqrt{a\beta} \quad (3)$$

where,

$$a = o_x^2 + o_y^2 \quad (4)$$

$$\beta = \cos(\pi - \arctan\left(\frac{o_y}{o_x}\right) - \theta) \quad (5)$$

$r'$  is the distance between the pupil and the iris, while  $\theta$  is the edge angle based on the radius of the iris.  $o_x$  and  $o_y$  is the displacement from the center of the pupil to the displacement of the center of the iris [29].

The Iris image that has a circular shape needs to be normalized based on the angle. The circular iris will be formed into a 2D array with horizontal dimensions at angles and vertical dimensions at radial. The circular iris will be formed into a 2D array with horizontal dimensions at angles and vertical dimensions at radial so that it will produce a rectangular or polar image shape as shown in Fig. 5 [30, 31].

Fig. 5. Area of Circle to Rectangle Transformation of Daugman Model; a) Daugman Model; b) The Implementation Result of Iris Image.

#### E. Contrast Limited Adaptive Histogram Equalization (CLAHE)

CLAHE is a method to improve image quality by limiting the histogram value [32]. In this study, the CLAHE method is used to increase image intensity so that there will be a lot of detail that can be improved on the image. The results of using CLAHE are shown in Fig. 6.

Fig. 6. Results of using the CLAHE Method on Polar Iris Images.

#### F. Region of Interest

The process of diagnosing the heart through the iris requires certain parts so that it does not require the whole to be processed. According to Iridology, the iris that reflects the heart is on the left iris, as shown in the sector 02.00 – 03.15 according to Fig. 1.

Region of Interest (ROI) is a process where we only need a specific part of the image to be processed. These sections will be cropped, leaving only the heart's reflection in the iris of the left, as shown in Fig. 7.

Fig. 7. Application of ROI of the Heart on the Iris Image.

G. Gray Level Co-occurrence Matrix (GLCM)

GLCM is a texture analysis technique on images with a gray level. GLCM has a relationship between 2 neighboring pixels, which is determined by the intensity of gray, a certain distance, and angle. The equation for GLCM is shown below [33]:

$$G_{(\Delta x, \Delta y)}(a, b) = \sum_{i=1}^P \sum_{j=1}^Q 1\{I(i, j) = a\} \text{ and } 1\{I(+\Delta x, j + \Delta y) = b\} \quad (6)$$

$I(i, j)$  is the gray value of the column (i) and row (j) pixels,  $(a, b)$  is a gray value that occurs at the same time as the calculation of  $G_{(\Delta x, \Delta y)}(a, b)$ . Then,  $1\{I(+\Delta x, j + \Delta y) = b\}$  is the indicator of  $\Delta x$  as a direction from  $x$  and  $\Delta y$  as a direction of  $y$  which is determined by the distance of the  $x$  and  $y$ .  $P$  and  $Q$  shows the rows and columns of the corresponding image. There are 4 angles used in GLCM,  $0^\circ, 45^\circ, 90^\circ$  and  $135^\circ$ , described in Fig. 8.

The illustration in Fig. 9 is the use of GLCM for image pixels. Point a shows the use of distances that have a value of  $d = 1$  with 4 different directions where  $d$  is the distance between pixels. Point b shows the GLCM Usage calculation on an image with  $\theta = 0^\circ$  and the distance between pixels is 1.

Fig. 9. GLCM Angle Illustration; a) is an Illustration of the use of  $\theta = 0^\circ, 45^\circ, 90^\circ, 135^\circ$  dan  $d = 1$ ; b) GLCM Usage Calculations for Images with  $\theta = 0^\circ$  and  $d = 1$ .

The image that has been calculated for certain distances and angles will then be transposed to the values obtained, and then the GLCM matrix values are added to the transpose results. The results will be normalized using the following equation:

$$GLCM_{Norm} = \frac{GLCM_{value}}{\sum_i^N GLCM_{value}} \quad (7)$$

where,

$GLCM_{value}$  = value of each pixel

The normalization results can be used to determine the texture characteristics of the image by obtaining information, such as Contrast, Dissimilarity, Homogeneity, Angular Second Moment (ASM), Energy and Correlation. The function of the contrast characteristic is the calculation of the difference in intensity between adjacent pixels in the entire image. Dissimilarity is the process of measuring the difference in a texture with a significant value if it is random, and vice versa will have a small value if it is uniform. Homogeneity functions to show the homogeneity of intensity variations in the image. ASM is a uniformity measurement process that produces a high value if the pixel values are similar to each other and vice versa will have a low value if the pixel values are different. Energy is used to measure the concentration of intensity pairs in the matrix, and Correlation is a linearity measurement of several pixel pairs. The equation to obtain each characteristic is shown in Table I [34]:

Fig. 8. Illustration of 4-Way Angle GLCM.

TABLE I. CHARACTERISTIC EQUATIONS ON GLCM

| Texture Characteristics of GLCM | Equation                                                                                                                                                                                                                                                                     |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Contrast                        | $\sum_{a,b=0}^{level-1} P_{a,b}(a-b)^2$                                                                                                                                                                                                                                      |
| Dissimilarity                   | $\sum_{a,b=0}^{level-1} P_{a,b} a-b $                                                                                                                                                                                                                                        |
| Homogeneity                     | $\sum_{a,b=0}^{level-1} \frac{P_{a,b}}{1+(a-b)^2}$                                                                                                                                                                                                                           |
| ASM                             | $\sum_{a,b=0}^{level-1} P_{a,b}^2$                                                                                                                                                                                                                                           |
| Energy                          | $\sqrt{\sum_{a,b=0}^{level-1} P_{a,b}^2}$                                                                                                                                                                                                                                    |
| Correlation                     | $\sum_{a,b=0}^{level-1} P_{a,b} \left[ \frac{(a-\mu_a)(b-\mu_b)}{\sqrt{(\sigma_a^2)(\sigma_b^2)}} \right]$ $\mu_a = \sum_a a \sum_b P_{ab}$ $\mu_b = \sum_b b \sum_a P_{ab}$ $\sigma_a^2 = \sum_a (a-\mu_a)^2 \sum_b P_{ab}$ $\sigma_b^2 = \sum_b (b-\mu_b)^2 \sum_a P_{ab}$ |

where,

$a, b$  = Pixel coordinates on the matrix

$level$  = The range of grayscale value between 0-255 ( $level = 256$ )

$P_{a,b}$  = value of coordinat pixel  $a, b$  on matrix GLCM

#### H. Support Vector Machine

Support Vector machine is one of the supervised machine learning that is commonly used in classification and regression analysis. SVM was widely introduced by Vapnik in the late 90s [35]. SVM can separate data by forming a hyperplane, maximizing margins and dividing data into different classes. The kernel function in SVM can separate data by looking for a hyperplane as a separator between data and finding the best hyperplane to put data in each class [36].

Fig. 10. Illustration of Class -1 and Class -2 Separated by Hyperplane; a) Several Alternative Lines of Discrimination; b) Hyperplane with the Best Margin.

Fig. 10 shows two different classes between class -1 in red and class +1 in yellow. Fig. 5(a) shows classes -1 and +1 separated by several hyperplanes as differentiator classes. The difference can be obtained by measuring the hyperplane margin and finding the maximum point. Margin is the distance between hyperplanes with the closest pattern of each data class. The pattern that has the closest value is also called the support vector. Fig. 5(b) is two classes of data separated by the best hyperplane, where the hyperplane line is located in the middle between the support vector pattern owned by class -1 and class +1.

SVM as a classification method has two essential aspects: the first aspect is finding a hyperplane that can optimally separate two classes. The second aspect is the transformation of linearly inseparable classifications into separable ones [35].

Vector learning input and class  $(x_i, y_i)$ , where  $i = 1, 2, \dots$  with  $x_i \in R^n$  and  $y \in \{1, -1\}$ . In solving problems using linear separation, hyperplane can define boundaries between classes -1 and +1 with the calculation representation as follows. [37]:

$$\min_{\omega, b, \xi} \frac{1}{2} \omega^T \omega + C \sum_{i=1}^l \xi_i \quad (8)$$

towards subject,

$$y_i(\omega^T \phi(x_i) + b) \geq 1 - \xi_i; \xi_i \geq 0 \quad (9)$$

Solving for classes that cannot be solved linearly, then vector  $x_i$  mapped into a higher dimension using the function  $\phi$  so that they can be separated linearly. Furthermore, SVM can define a hyperplane that separates linearly with a maximum margin of higher dimensional space. The SVM error parameter is known as  $C > 0$ .  $K(x_i, x_j) = \phi(x_i)^T \phi(x_j)$  known as the Kernel function, shown in Table II [38].

TABLE II. SVM KERNEL EQUATION

| Kernel Name | Equation                                                                       |
|-------------|--------------------------------------------------------------------------------|
| Linear      | $K(x_i, x_j) = x_i^T x_j$                                                      |
| Polynomial  | $K(x_i, x_j) = (\gamma x_i^T x_j + r)^d, \gamma > 0$                           |
| Gaussian    | $K(x_i, x_j) = \exp\left(-\frac{\ x_i - x_j\ ^2}{2\gamma^2}\right) \gamma > 0$ |

### III. RESULTS AND ANALYSIS

In this study, system training was carried out using 75 normal iris data and 75 abnormal iris data. Normal iris data is the iris of people who have no history of heart disease; on the contrary for abnormal iris data is the iris of people who have heart disease.

Fig. 11 shows the training data using linear, polynomial, and gaussian kernel variations. Iris data in training can be separated according to normal (red) and abnormal (blue) classes. The results of linear kernel training separate the data into each class with an even distribution of data. The difference in the polynomial kernel training where the data has been separated and more centralized. The results of the training using the Gaussian Kernel resulted in a tighter grouping than using the two previous kernels. The results of the training are able to separate between classes according to existing characteristics, which can help in the classification of test data and affect the level of recognition accuracy. The further apart the hyperplane in the SVM that separates the classes, the higher the accuracy.

Tests were carried out on 50 normal iris data and 50 abnormal iris data. The data that has gone through the region of interest process is the iris data which reflects the heart. Then this section will be extracted using the GLCM method. The characteristics used in GLCM are Contrast, Dissimilarity,

Homogeneity, Energy, and Correlation. The use of angle variations in the test is carried out to obtain optimal results. For example, Fig. 12 results from GLCM feature extraction at an angle with a distance of 1.

Taking five types of texture characteristics on iris data is needed to obtain more detailed information in training and testing. Normal and abnormal iris data have different characteristic values. The data can be classified into the appropriate class classification using SVM with three kernels: Linear, Polynomial, and Gaussian.

Simulation testing for variations angle in GLCM  $0^\circ$ ,  $45^\circ$ ,  $90^\circ$  and  $135^\circ$  with the SVM kernel variation is shown in Fig. 13. By using angle  $0^\circ$  the highest level of accuracy is obtained by using the Gaussian kernel which reaches 94%, linear kernel reaches 90% and Polynomial kernel 88%. The use of  $45^\circ$  obtained the highest accuracy rate with 88% Gaussian kernel, 86% polynomial kernel and 82% linear kernel. Then, for angel  $90^\circ$  the highest level of accuracy is achieved by Gaussian and Linear kernels which reach 92% and polynomial kernels which reach 88%. Meanwhile, with angle  $135^\circ$  the highest level of accuracy is achieved by 92% polynomial kernel, 90% Gaussian kernel and linear kernel which reaches 84%. From these data, it can be seen that the angle  $0^\circ$  and  $90^\circ$  has an average classification accuracy level of 90.67% at a distance of 1.

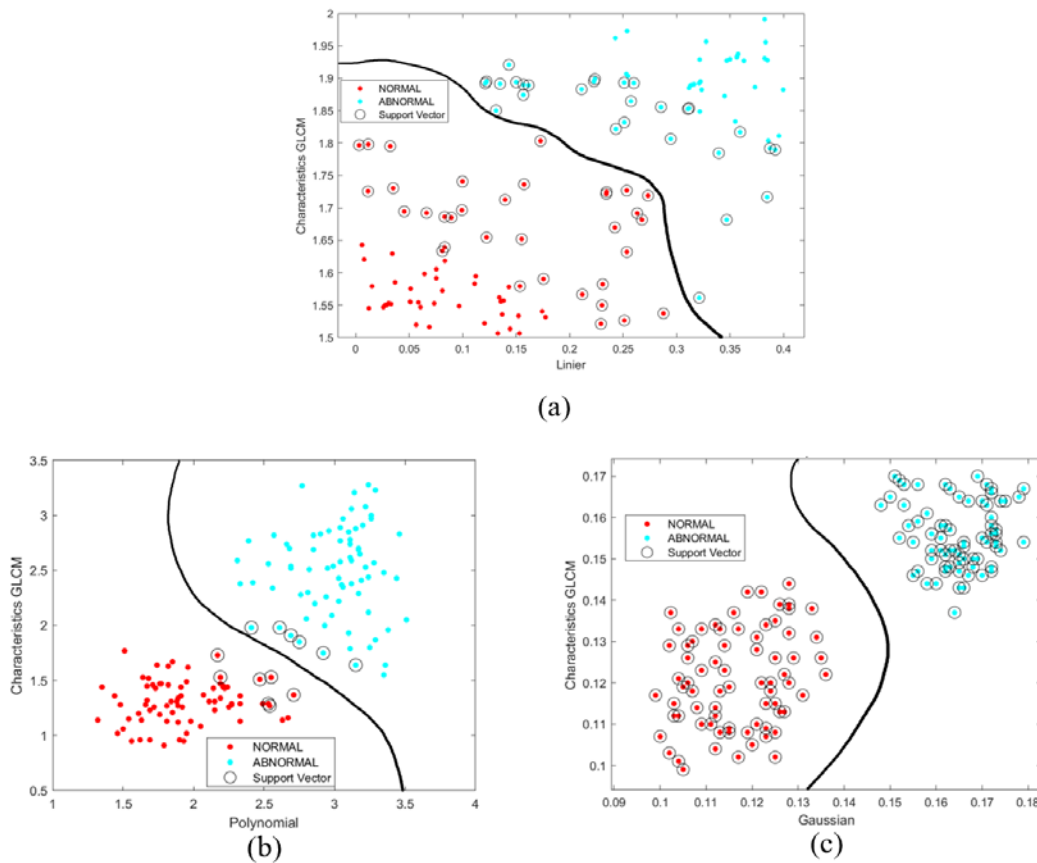

Fig. 11. Results of Training using Kernel Variations; a) Linear kernel; b) Polynomial kernel; c) Gaussian kernel.

Fig. 12. GLCM Characteristic Value using Angle 0° and d = 1 on Normal and Abnormal Iris Data.

Fig. 13. The Results of the Test with Variations of the GLCM Angle on the Variation of the SVM Kernel.

TABLE III. THE AVERAGE LEVEL OF ANGLE ACCURACY ON THE VARIATION OF THE SVM KERNEL

| SVM Classifiers | Training Time (s) | Accuracy Percentage |
|-----------------|-------------------|---------------------|
| Linier          | 381.73            | 87%                 |
| Polynomial      | 422.28            | 89%                 |
| Gaussian        | 583.09            | 91%                 |

From Table III, it can be concluded that the average for each angle variation using different SVM kernels has better performance in the classification process. By testing 100 normal and abnormal iris data, a high degree of accuracy was obtained. The use of linear SVM obtained an accuracy rate of 87%, then the use of polynomials obtained 89%. While the use of the kernel with the highest accuracy reaching 91%, was obtained using Gaussian.

Simulation tests with the Gaussian kernel proved to be superior in iris image classification. The Gaussian kernel

considers the probability of the density function of the standard deviation, squared, and variance. Gaussian can add data space into a higher dimensional vector to determine the intersection of hyperplanes more accurately. With flexible limiting performance, the Gaussian kernel can obtain a higher accuracy level than Linear and Polynomial kernels.

It is proven that normal and abnormal iris conditions can be identified using GLCM feature extraction and a classification process using the Gaussian method on the iris image. Identification is made to assist in providing an early diagnosis of heart conditions through the iris using the iridology method.

#### IV. CONCLUSION

This study has proposed a new method to determine the condition of the heart through the iris using the SVM classification with variations of the linear kernel, polynomial kernel, and Gaussian kernel. The use of GLCM characteristics as feature extraction has an essential role in the classification process. The main contribution in this study is not only limited to determining heart health conditions through the iris but also contributes to the automatic processing of the iris with CHT. The proposed system in determining the heart condition automatically is to optimize the classification by using angle  $0^\circ$  and  $90^\circ$  on GLCM with SVM classification on the Gaussian kernel to obtain a high level of accuracy. In ongoing research, the iris database can be added to improve the classification to make it more accurate. Different extraction methods can be used to get the results of image extraction with a smaller size so that it can increase the system's speed in iris identification.

**Abstract**—This paper investigates the effect of data reduction methods in the performance of Wireless Sensor Network (WSN) using a variety of real-time datasets. The simulation tests are carried out in MATLAB for several methods of reducing the quantity of sent data. These approaches are Data Reduction based - Neural Network Fitting (NNF), Neural Network Time Series (NNTS), Linear Regression with Multiple Variables (LRMV), Data Reduction based – “An Efficient Data Collection and Dissemination (EDCD2)” and Data Reduction based – Fast Independent Component Analysis (FICA). The selected algorithms NNF, NNST, EDCD2, LRMV, and FICA are evaluated using real-time datasets. The performance indicators included are energy consumption, data accuracy, and data reduction percentage. The research results show that the selected algorithm helps to reduce the amount of data transferred and consumed energy, but each algorithm performs differently depending on the dataset used.

**Keywords**—Data reduction algorithms; WSN; energy consumption; accuracy; neural network; independent component analysis

## I. INTRODUCTION

In this paper, Wireless Sensor Network (WSN) is a network that collects data from spatially isolated sensors. Sensor nodes are used to monitor and record environmental variables, such as sound, pollution level, humidity, temperature, and wind, and then send the sensed data to the base station [1][2]. The sensor node in the WSNs application is powered by a battery with limited-service life [3]. Furthermore, sensor nodes with multivariable sensors can have an impact on battery life because the node must support additional data transmission, causing the battery to drain faster than a sensor node with a single sensor [4]. Therefore, many researchers have been proposed various approaches to reduce the amount of transmitted data at the sensor node level, which will help in prolonging the battery lifetime. For example, in WSN, the spatial and temporal correlation between the generated traffic can be used to reduce the energy consumption of continuous sensor data acquisition. Spatial-temporal correlation is used in dual prediction (DP) and data compression (DC) techniques to reduce the number of transmissions to save energy and bandwidth. In [5], the author has used these two technologies as part of a two-stage data reduction scheme. The DP

technology reduces traffic between cluster nodes and cluster heads, while the DC scheme reduces traffic between cluster heads and sink nodes.

In [6], the author proposed a data-aware energy-saving technology. The essential correlation between continuous measurements of sensor nodes and the similarity of data trends between adjacent sensor nodes are used to reduce data transmissions. The forecast-based data collection framework reduces time data redundancy. “Autoregressive Integrated Moving Average (ARIMA)” model was used to predict data. The proposed model was implemented in the Cluster head (CH) node.

In [7], the author proposed a novel technique for secure data prediction in WSN by using a Time Series Trust Model (TSTM) based on the Toeplitz matrix and a trust-based autoregressive process (TAR). The author proposed an adaptive data reduction method (AM-DR) in [8]. AM-DR is based on a convex combination of two decoupled Least-Mean-Square (LMS) window filters of different widths for predicting the next readings at both the source and sink nodes.

In [9], the authors have evaluated the performance of several methods based on computational intelligence to decrease the amount of the payload of every packets sent from the sensor node to the base station. These approaches are data reduction based on “artificial neural networks (DR-ANN)”; independent component analysis (DR-ICA) and deep learning regression methods called DR-GDMLR”.

In [10], two multivariate data reduction methods for adaptive thresholds were proposed a Principal Component Analysis Based (PCA-B) –and multiple linear regression Based (MLR-B). PCA-B is a multivariate data reduction method. It uses “Candid Covariance-free Incremental PCA (CCIPCA)” with an adaptive threshold and to reach a high reduction ratio the number of Principal Components (PCs) assigned to “1”. Another method to decrease the amount of payload sensed data is named MLR-B, which it using multiple linear regression (MLR) model. The authors used an adaptive threshold to retrain the model. According to [10], after updating the reference parameters of the model, the size of the transmitted data is greater than or equal to the size of the payload data without being reduced. This means that the sensor node needs

more power during the update phase, than the required power during the phase of reduction. The article recommends a new indicator for evaluating the performance of data reduction models, which it considering the number of repeating of updating the parameters reference of the model. A novel simple scheme called “Adaptive Real-Time Payload Data Reduction Scheme (APRS)” is proposed in [4]. APRS purposes is to decrease the size of the transferred payload of the sensor nodes. Further details on approaches of data reduction for sensor nodes are defined in [11]. In this study, effect of data reduction approaches on WSN performance is investigated using a set of real-time datasets. Simulation tests are performed in MATLAB for different approaches to decrease the amount of transferred payload data. The selected algorithms NNF, NNST, EDCD2, LRMV, and FICA are evaluated using real-time data sets. The performance indicators included are energy consumption, data accuracy, and data reduction percentage.

The organization of the article is as follows: Section I presents the introduction and related work of this study and the main contributions. The selected data reduction algorithms are described in Section II. Section III explores the real-time datasets used in this study. Section IV describes the performance metrics used in this study to evaluate the algorithms. Section V presents the study simulation and results. Lastly, Section VI concludes the outcome of the study.

## II. SELECTED DATA REDUCTION ALGORITHMS

### A. Data Reduction based - Neural Network Fitting (NNF) Algorithm

The NNF model provided by MathWorks [12], helps in solving a data fitting problem using a two-layer feed-forward network. It helps in selecting the data, partitioning it into training, validation, and testing sets, defining the network architecture, and training the network.

In this section, the application of the NNF model to reduce the size of data transferred is described in detail. Fig. 1 represents the block diagram of WSN data reduction based on the NNF algorithm with a general structure. In the training phase, first select the sensor  $S1(t)$  with the highest correlation attribute as the input data of the NNF model and the other sensor features  $S2(t)$  and  $S3(t)$  as the output target of the NNF. The main objective in training NNF is to predict the values  $PS2(t)$  and  $PS3(t)$  from a single input sensor  $S1(t)$  during the reduction phase. As mentioned earlier, NNF is used to decrease the size of the transmitted data by the sensor node.

Fig. 1. General Block Diagram of NNF Algorithm.

The detailed description of the data reduction based NNF algorithm is stated by means of the following pseudocode.

#### NNF Model

```

1 Input: Inputs, targets
2 Output: Net // NNF Model with
3 Begin:
4 // Phase I : Create a Fitting Network //
5 Set Hidden Layer Size ← 10
6 Set net ← Call FITNET (Hidden Layer Size)
7 Select InputOutput Pre-Post-Processing-Functions// n=1, m=2
8 Set net.Inputs{n}.process-Fcns←'removeconstantrows','mapminmax'
9 Set net.outputs{m}.process-Fcns←'removeconstantrows','mapminmax'
10 // Phase II : Setup Division of Data for Training, Validation, Testing //
11 Set TrainRatio, ValRatio and TestRatio ← {70,15,15}
12 Assign the training function // "Levenberg-Marquardt backpropagation
13 Select a Performance_Function// ""
14 Set NETPERFORMFCN ← 'mse'; % Mean squared error
15 Phase III // Network -Train
16 Set [net,tr] ← Call TRAIN(net,inputs,targets)
17 End

```

#### NNF algorithm

```

1 Input: S1(t), S2(t), S3(t) // Sensor value for S1 // real-time data
2 Output: PS2(t), PS3(t)
3 Begin:
4 Call NNF Model
5 For i=1 to M do // M is the number of samples
6 Send S1(i) → BS // Send vaule of the sensor 1 To BS
7 // At BS //
8 Estimate [ PS2(i), PS3(i) ] ← NNF(S1(i)) // Estimated data by NNF
9 // Calculate error // This step for check the performance of the algorithm
10 Err2(i) ← ABS( PS2(i) – S2(i) )
11 Err3(i) ← ABS( PS3(i) – S3(i) )
12 End
13 End

```

### B. Data Reduction based - Neural Network Time Series (NNTS) Algorithm

The prediction model NNTS provides by MathWorks [12]. NNTS is a type of dynamic filtering, that uses past-values of one or more-time series to predict future values. Dynamic neural networks containing tapped delay lines are used for nonlinear filtering and prediction.

This section describes in detail the NNTS algorithm used to reduce the amount of data transmitted. Fig. 2 represents the block diagram of WSN data reduction based on the NNTS algorithm with a general structure. In the training phase, first select the sensor  $S1(t)$  with a high correlation attribute as the input data of the NNTS model and the other sensor features  $S2(t)$  and  $S3(t)$  as the output target of NNTS. The main objective in training NNTS is to predict the values  $PS2(t)$  and  $PS3(t)$  from a single input sensor  $S1(t)$  during the reduction phase, where  $S1(t-1)$  and  $S1(t-2)$  are the last two received values of sensor  $S1(t)$ . As mentioned earlier, NNTS is used to decrease the size of the transmitted data by the sensor node.

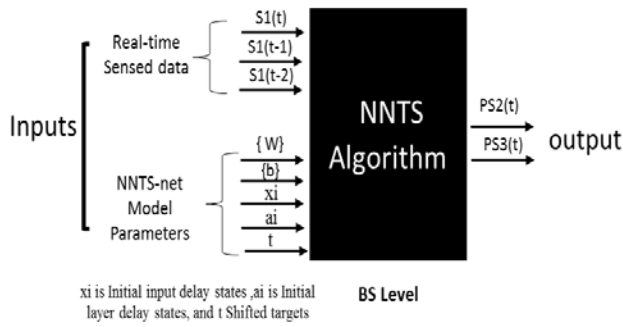

Fig. 2. General Block Diagram of NNTS Algorithm.

The detailed description of the data reduction based NNTS algorithm is given in the following pseudocode.

// Training NNTS Model//

```

1  Input: Inputs,Targets
2  Output: Net // NNTS Model
3  Begin:
4  // Phase I : InputOutput TimeSeries Problem with a Time Delay
   Neural Network//
5  Convert data_to_standard NNet cell array form using Tonndata_Fun
6  Set X ← Tonndata (Inputs,false,false)
7  Set T ← Tonndata (Targets, false, false)
8  Create a Time Delay Network
9  Set Input_Delays ← 1:2
10 Set Hidden_LayerSize ← 10
11 Assign the trainingfunction //” Levenberg-Marquardt backpropagation”
12 TrainFcn ← 'trainlm'
13 Set net ← Call Timedelaynet(InputDelays,HiddenLayerSize,TrainFcn)
14 Select Input_Output Pre-Post-ProcessingFunctions//
15 Set net_inputs .process_Fcns←'removeconstantrows','mapminmax'
16 Set net_outputs .Process_Fcns←'removeconstantrows','mapminmax'
17 Prepare TrainingData using Prepartet_Fun
18 Set [x,xi,ai,t] ← Prepares(net,X,T) // x is Shifted inputs, xi is Initial
   inputdelay states ,ai is Initial_layer_ delay_states, and t Shifted
   targets
19 // Phase II: Setup Division of Data for Training, Validation,
   Testing//
20 Set Train_Ratio, Val_Ratio and Test_Ratio ← {70, 15, 15}
21 Select a Performanc_ Function//
22 Set NET_PERFORMFCN ← 'mse'; % Mean squared error
23 Phase III // Train the Network
24 Set [net,tr] ← Call TRAINFUN (net,x,t,xi,ai)
25 End

```

NNTS algorithm

```

1  Input: S1(t), S2(t), S3(t) // Sensor values // real-time data
2  Output: PS2(t), PS3(t)
3  Begin:
4  Call NNTS Model
5  For i=1 to M do // M is the number of samples
6  Send S1(i) → BS // Send vaule of the sensor 1 To BS
7  // At BS //
8  Set xi ← ([S1(i-1), S1(i-2)])// The recent two received values of the
   sensor 1
9  Determine PS2(i), PS3(i) ← NNTS(S1(i), xi,ai) // Estimated data
   by NNTS
10 // Calculate error // This step for check the performance of the
   algorithm
11 Err2(i) ← ABS( PS2(i) – S2(i))
12 Err3(i) ← ABS( PS3(i) – S3(i))
13 End for
14 End Algorithm

```

C. Data Reduction based – Linear Regression with Multiple Variables (LRMV) Algorithm

In statistics, linear regression is a linear approach to modeling the relationship between a scalar response and one or more explanatory variables (also referred to as dependent and independent variables). The theoretical concept of using linear regression with multiple variables was explained in detail by Ng, Andrew in [13].

In this section, the application of the LRMV algorithm to reduce the amount of data transferred is described in detail. Fig. 3 represents the block diagram of WSN data reduction based on the LRMV algorithm with a general structure, where the sensor S1(t) is assigned as the dependent variable of the LRMV model, and the other sensor features S2(t) and S3(t) are assigned as the predictor/independent variables of LRMV during the training phase. The aim of training LRMV is to predict the PS1(t) value from multiple sensors S2(t) and S3(t) during the reduction phase. The LRMV parameters are theta (θ), mean (mu), and standard deviation (SSDV). As mentioned earlier, LRMV the size of the transmitted data by the sensor node.

Fig. 3. General Block Diagram of LRMV Algorithm.

The detailed description of the data reduction based LRMV algorithm is stated in the following pseudocode.

```

// Training LRMV Model//
1  Input: Training data // Sensed data S1, S2, S3// Features
2  Output: theta -  $\theta$ , Mean -  $\mu$  and standard deviation - SSDV // LRMV
3  Model parameters
4  Begin
5  // Phase I: Load Data and Initialize Variables //
6  Load Sensor dataset // S1, S2, S3
7  Set X  $\leftarrow$  [S2 S3]
8  Set Y  $\leftarrow$  S1//
9  // Set Initialize Variables //
10 Set M  $\leftarrow$  Number of training samples//
11 Set D  $\leftarrow$  Number of features//
12 Initialize  $\theta \leftarrow$  ZEROS(D+1,1); // Initialize thetas to zero.
13 Initialize Number_itr  $\leftarrow$  N; // Set the number of repetitions for gradient
    descent.
14 Initialize  $\alpha \leftarrow$  0.5; // Set alpha Learning rate
15 // Phase II: // Calculate Theta from Normal Equation// data
    processing
16 Set XNormEqn  $\leftarrow$  [ones(M,1) X]
17 Calculate thetaNormEqn  $\leftarrow$  Call NormalEquation(XNormEqn,Y)
18 //Phase III // Feature Normalization//
19 Normalizing Features for gradient descent
20 Calculate [X,  $\mu$ , stddev]  $\leftarrow$  Call featureNormalize(X)
21 Calculating  $\beta$  via gradient descent
22  $\theta \leftarrow$  Call gradientDescent(X,  $\theta$ , Y,  $\alpha$ , Number_itr)
23 End

```

**LRMV algorithm**

```

1  Input: S1(t), S2(t), S3(t) // Sensor values // real-time data
2  Output: PS1(t)
3  Begin:
4  [ $\theta$ ,  $\mu$ , stddev]  $\leftarrow$  Call LRMV Model
5  For i=1 to M do // M is the number of samples
6  Send S2(i), S3(i)  $\rightarrow$  BS // Send vaule of the two sensors 2,3 To BS
7  // At BS //
8  Set X  $\leftarrow$  ([S1(i), S2(i)])// The recent received values of the sensor 2 and
    3
9  Determine PS1(i)  $\leftarrow$  LRMV_Prediction_Fun (X,  $\theta$ ,  $\mu$ , stddev) //
    Estimated data by LRMV Prediction Fun
10 // Calculate error // This step for check the performance of the
    algorithm
11 Err1(i)  $\leftarrow$  ABS( PS1(i) - S1(i))
12 End for
13 End

```

**D. Data Reduction based –EDCD2 Algorithm**

EDCD2 is a scheme to bring up-to-date measured data to the BS [14]. EDCCD2 was used to decrease the number of transferred packets from nodes (multiple sensors). It should be noted that there are two versions of EDCCD, EDCCD1, and EDCCD2 for sensor nodes with one and multiple sensors, respectively.

Fig. 4. General Block Diagram of EDCCD2 Algorithm.

In this section, the application of the EDCCD2 to reduce the size of data transferred is described in detail. Fig. 4 shows the block diagram of WSN data reduction based on the EDCCD2 algorithm with a general structure. The basic idea of EDCCD2 is to avoid transmitting the sensed data if the value of the relative difference between the currently sensed data  $S(t)$  and the last transmitted data  $S(t-1)$  is smaller than the threshold value  $\beta$  for all sensors of the same node, otherwise, the sensed data  $S(t)$  will be transmitted to the BS. The detailed description of the EDCCD2 algorithm based on data reduction is given in the following pseudocode.

```

//EDCCD2//
1  Inputs:
    Si(t), Si(t - 1) for each sensor Si and  $\beta$ .
2  Output: Ds
3  Begin:
4  For i = 1: n Do // i=1, 2,...n ;
5  Set Si(t - 1)  $\leftarrow$  last measuring value transmitted by the sensor Si
6  Read: the sensor value (SVi) at t time
7  Set Si(t)  $\leftarrow$  (SVi)
8  //Calculate the relative differences (Rf)
9  Rf = Abs (S(t) - S(t - 1)) / (S(t) + S(t - 1))  $\times$  0.5)
10 If Rf >  $\beta$  Then
11 Set SSi  $\leftarrow$  1
12 Else: Set SSi  $\leftarrow$  0
13 End if
14 End For
15 // Recalculate the node data size (Ds)
16 Set Ds  $\leftarrow$  0;
17 For i = 1: n Do
18 Ds = (Ds + (SVi  $\times$  SSi))
19 End For
20 // The decision to send data
21 If Ds = 0 Then
22 RFtransmit (Off) // no update / no send
23 Else: RFtransmit (On) // update(send)
24 End If
25 End Algorithm

```

**E. Data Reduction based – Fast Independent Component Analysis (FICA) Algorithm**

Fast Independent Component Analysis (FICA) is an efficient and popular algorithm for independent component analysis developed by Aapo Hyvaerinen at Helsinki University of Technology. [15][16]. Like most FICA algorithms, FICA searches for an orthogonal rotation of the previously whitened data through a fixed-point iteration scheme that make the most of a measure of the non-Gaussian distribution of the rotated components.

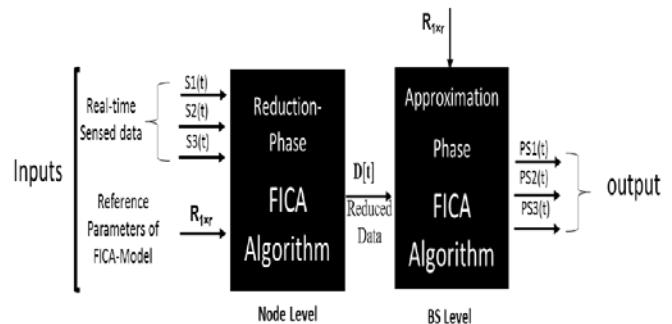

Fig. 5. General Block Diagram of FICA Algorithm.

This section provides a detailed description of the FICA algorithm to reduce the amount of data transferred. Fig. 5 shows the block diagram of WSN data reduction based on the FICA algorithm with a general structure consisting of two phases, namely the reduction phase at the sensor node level and the approximation phase at the BS level. The main objective of training the FICA model is to determine the reference parameters  $R_{(1 \times r)}$ , which are then stored on the sensor node and the same copy is stored on BS. At the node level, the new data  $S1(t)$ ,  $S2(t)$ , and  $S3(t)$  acquired in real-time are reduced by applying the FICA algorithm before transmission and then the reduced data  $D(t)$  is sent to BS. After that, the originally acquired data  $PS1(t)$ ,  $PS2(t)$ , and  $PS3(t)$  are estimated by the approximation phase at BS by applying FICA with the same reference parameters  $R(1 \times r)$  used to reduce the node-level data. As mentioned earlier, FICA is used to reduce the packet size of the sensor node. The detailed description of the data reduction-based FICA algorithm is given in the following pseudocode

**// FICA**

- 1 **Inputs:** Training data  $\bar{S}_{m \times n}[T] // S1, S2, S3$
- 2 **Output:**  $D(t)$
- 3 **Begin:**
- 4 **Load** the training data  $\bar{S}_{m \times n}[T]$ .
- 5 **Apply** FICA ( $\bar{S}_{m \times n}[T]$ ) and calculate the eigenvector array  $R_{n \times r}$ . Then, decreases the eigenvector array to  $R_{1 \times r}$ , and preserved a copy at the node and transfers one copy to the BS.
- 6 Standardizes the current measured data  $\bar{S}_{1 \times n}[t]$ , then decreases it before transferring via the following Equation:
 
$$D_{1 \times r}[t] = \bar{S}_{1 \times n}[t] \times R_{1 \times r}$$
- 7 **Send** the diminished data  $D_{1 \times r}[t]$  to the BS.
- 8 **Approximations** data at BS by applying
 
$$\hat{S}_{1 \times n}[t] = D_{1 \times r}[t] \times R_{r \times n}$$
- 9 **End Algorithm**

**III. REAL-TIME DATASETS**

The considered algorithms are evaluated on different benchmark real-time datasets, as described in the following subsections. It's important to note that, usually only part of the data from specific nodes of these datasets are used to assess the performance of current data reduction methods in WSN [17][18][19][20][11][21][22][23]. The reason is that most data reduction methods focus on reducing the amount of transferred data without considering how this data is forwarded to the CH /BS. In other words, they assume that the sensor nodes can directly transmit the sensed data to the CH /BS. The selected algorithms NNF, NNST, EDCD2, LRMV, and FICA are evaluated on real-time datasets as shown below:

**A. Data I-AirQ**

Data I- Air Quality (AirQ) is a WSN data set, including air pressure, humidity and temperature sensors. These sensor data have been collected by 56 sensor nodes in year 2017 at Krakow, Poland. For more information, see the main source [24]. Fig. 6 shows the structure of Data1- AirQ. In addition, some samples of sensors value provided in Tables I to V.

Fig. 6. Structure of Data1- AirQ.

TABLE I. SOME DATA SAMPLES OF NODE1 – DATA1- AIRQ

| Sample | Temperature | Humidity | Pressure |
|--------|-------------|----------|----------|
| 1      | 6           | 92       | 101906   |
| 2      | 6           | 92       | 101869   |
| 3      | 5           | 94       | 101837   |
| 4      | 5           | 92       | 101834   |
| 5      | 4           | 94       | 101832   |
| 6      | 5           | 94       | 101833   |
| 7      | 9           | 78       | 101842   |
| 8      | 11          | 66       | 101831   |
| 9      | 15          | 50       | 101798   |
| 10     | 17          | 42       | 101745   |

TABLE II. SOME DATA SAMPLES OF NODE2 – DATA1- AIRQ

| Sample | Temperature | Humidity | Pressure |
|--------|-------------|----------|----------|
| 1      | 15          | 90       | 101514   |
| 2      | 15          | 90       | 101516   |
| 3      | 15          | 90       | 101530   |

B. Data 2-ARHO

Data2- American River Hydrologic Observatory (ARHO) is a WSNs data set, including soil temperature, relative humidity, snow depth sensors, etc. These sensor data have been collected by 130 spatially distributed sensor nodes in the river basin of the United States. Period: the water year 2014 to the water year 2017. For more information, see the main source [25]. Fig. 7 shows the structure of Data 2- ARHO, also some examples of sensor values for all used nodes in Tables VI to X.

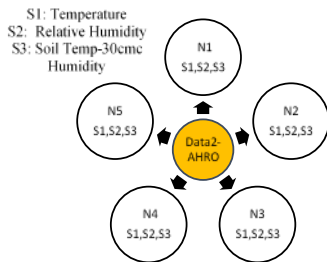

Fig. 7. Structure of Data-2 ARHO.

TABLE VI. SOME DATA SAMPLES OF NODE1 – DATA2- ARHO

| Sample | Temperature (°C) | Relative Humidity (%) | Soil Temp-30cmc |
|--------|------------------|-----------------------|-----------------|
| 1      | 13.2             | 38.462                | 11.5            |
| 2      | 12.52            | 39.867                | 11.6            |
| 3      | 12.01            | 40.756                | 11.6            |
| 4      | 11.45            | 42.309                | 11.7            |
| 5      | 11.04            | 43.095                | 11.8            |

C. Data 3- GSB

Data3- “Grand St. Bernard (GSB)” is WSN data set, which it was gathered by deployed 23 sensors to observe the measurement characteristics of the environmental in the “Grand Saint Bernard Pass” between Switzerland and Italy. The sensors are relative humidity, surface temperature, and ambient temperature [26]. Fig. 8 shows the structure of Data 3- GSB. Some examples of the sensor values of all the nodes used can be found in Tables XI to XV.

Fig. 8. Structure of Data-3 GSB.

TABLE XI. SOME TEMPERATURE SENSOR DATA SAMPLES OF NODE1\_ DATA 3- GSB

| Sample | A. Temperature (°C) | Relative Humidity (%) | S. Temperature (°C) |
|--------|---------------------|-----------------------|---------------------|
| 1      | 12.915              | 51.7785               | 12.881              |

D. Data 4- Intel

Data4- “Intel Berkeley Research Lab (IBRL)” is a WSN data-set, which it was gathered by deployed 54 Mica2Dot sensor nodes at “Intel’s research Lab”, University of Berkeley. The wireless network consisted of. The WSN includes various sensors: voltage, temperature, light, and humidity [27]. Fig. 9 shows the structure of Data 4- Intel, also some examples of sensor values for all the nodes used in Tables VI to XX.

Fig. 9. Structure of Data4-Intel.

TABLE XVI. SOME TEMPERATURE SENSOR DATA SAMPLES OF NODE1\_ DATA4-INTEL

| Sample | Temperature (°C) | Relative Humidity (%) | Light (Lux) | Voltage (V) |
|--------|------------------|-----------------------|-------------|-------------|
| 1      | 19.9884          | 37.0933               | 45.08       | 2.034       |
| 2      | 19.9884          | 37.0933               | 45.08       | 2.6996      |

#### IV. PERFORMANCE METRICS

##### A. Accuracy

Accuracy is the overall average of absolute error for all selected nodes from the same dataset as defined below:

$$Accuracy = \frac{\sum_{k=1}^L AEPN(k)}{L} \quad (1)$$

$$AEPN(k) = \frac{\sum_{i=1}^N |AEPS(i)|}{N}, \quad (2)$$

$$AEPS(i) = \frac{\sum_{j=1}^M |SV(j) - RV(j)|}{M} \quad (3)$$

Where  $K = \{1, 2, \dots, L\}$ ,  $L$  is the number of nodes.,  $AEPN$  is the average of absolute error for all samples transmitted by the node ( $k$ ),  $SV$  is the sensor value at the sensor node,  $RV$  is the received value at  $BS$ , and  $AEPS(i)$  is the mean Absolute error for sensor ( $i$ ),  $i = \{1, 2, \dots, N\}$ ,  $N$  is the number of sensors,  $M$  is the number of samples transmitted by the node ( $k$ ).

##### B. Data Reduction Ratio %

$$DR\% = \left(1 - \frac{Sd_{redc}}{Sd_{Lenght}}\right) \times 100 \quad (4)$$

where  $DR$  is the ratio of the reduced data,  $Sd_{redc}$  is the size of transferred data after reduction and  $Sd_{Lenght}$  is the size of the unreduced transmission samples.

##### C. Total Energy Consumption

$$TE_{Directly} = D_s \times N_{of\ S} \times C_E PByte \quad (5)$$

$$TE_{DR} = RD_S \times N_{of\ S} \times C_E PByte \quad (6)$$

Where:  $TE_{Directly}$  is the Total Energy consumed in case of the Direct transmission,  $D_s$  is the mean Data size,  $N_{of\ S}$  is the mean Number of Samples,  $C_E PByte$  is the mean Cost Energy Per Byte,  $RD_S$  is the mean Data Reduction.

#### V. SIMULATION AND RESULTS

Fig. 10 shows the accuracy of the applied algorithms ED CD2, FICA, NNF, NNTS, and LRMV for all selected nodes N1, N2, N5 from the DATA1-AIRQ dataset. From the results, the ED CD2 algorithm has the best accuracy compared to the other algorithms FICA, NNF, NNTS, and LRMV. The reason for this is the average total absolute error which has the lowest value of 5.48 when ED CD2 is used for all nodes. Moreover, the algorithms FICA and LRMV have the worst performance in terms of accuracy, and the average absolute errors are 62.30 and 20.13, respectively. Table A1, Table A2, Table A3, Table A5 (see Appendix) showed the average of absolute error for all samples transmitted by the nodes (N1-N5) of the applied algorithms ED CD2, FICA, NNF, NNTS, and LRMV, respectively.

Fig. 10. Accuracy of Applying Various Algorithms for all Selected Nodes from DATA1-AIRQ.

Fig. 11 shows the accuracy of the applied algorithms EDCD2, FICA, NNF, NNTS, and LRMV for all selected nodes N1, N2, N5 from the DATA2-ARHO dataset. From the results, the EDCD2 algorithm has the best accuracy compared to the other algorithms FICA, NNF, NNTS, and LRMV. The reason for this is the average total absolute error which has the lowest value of 0.199 when EDCD2 is used for all nodes. Moreover, NNTS and NNF algorithms have the worst performance in terms of accuracy, and the average absolute errors are 5.38 and 5.62, respectively. In summary, EDCD2 is a threshold-based data reduction algorithm. EDCD2 transmits measurement data only when the relative difference between the current measurement data and the last transmitted data is larger than the threshold value.

Fig. 12 shows the accuracy of the applied EDCD2, FICA, NNF, NNTS, and LRMV algorithms for all selected nodes N1, N2, N5 from the DATA3-GSB dataset. From the results, the EDCD2 algorithm has been shown to have the best accuracy compared with the other algorithms, FICA, NNF, NNTS, and LRMV. The reason is related to the overall average absolute error, which is the lowest value of 0.30 for applied EDCD2 for all nodes. Furthermore, the FICA and NNF algorithms have the worst performance in terms of accuracy, and the average absolute errors are 3.84 and 1.34, respectively.

Fig. 11. Accuracy of Applying Various Algorithms for all Selected Nodes from DATA2-ARHO.

Fig. 12. Accuracy of Applying Various Algorithms for all Selected Nodes from DATA3-GSB.

Fig. 13 shows the accuracy of the applied algorithms EDCD2, FICA, NNF, NNTS, and LRMV for all selected nodes N1, N2, N5 from the DATA4-INTEL dataset. From the results, the NNF algorithm has the best accuracy compared to the other algorithms EDCD2, FICA, NNTS and LRMV. The reason for this is the average total absolute error which has the lowest value of 1.01 when NNF is used for all nodes. Moreover, the algorithms FICA and LRMV have the worst performance in terms of accuracy, and the average absolute errors are 28.68 and 1.54, respectively.

Fig. 13. Accuracy of Applying Various Algorithms for all Selected Nodes from DATA4-INTEL.

Fig. 14 shows the average of data reduction ratio percentage for applying various algorithms for different datasets. The studied algorithms are EDCD2, FICA, NNF, NNTS, and LRMV. The selected datasets are Data1-AirQ, Data2-ARHO, Data3-GSB, and Data4\_Intel. From these results, the average data reduction percentage for applied EDCD2, FICA, NNF, NNTS, and LRMV algorithms through a real-time dataset named Data1-AirQ is 33%, 33%, 67%, 67%, and 33%, respectively. It is noted that the NNF and NNTS algorithms have the highest data reduction. By referring to Fig. 10 both algorithms, NNF and NNTS, have acceptable accuracy and the lowest error has been shown by applying EDCD2. In the same way, the average data reduction percentage for applied NNF, NNTS, EDCD2, LRMV, and FICA algorithms through a real-time dataset named Data2-ARHO is 67%, 67%, 56%, 33%, and 67%, respectively. Although NNF and NNTS algorithms achieved the highest data reduction ratio, both NNF and NNTS have the highest error and worst performance in terms of accuracy as shown in Fig. 11 The average data

reduction percentage for applied NNF, NNTS, EDCD2, LRMV, and FICA algorithms through a real-time dataset named Data3-GSB is 67%, 67%, 67%, 33%, and 33%, respectively. It is noted that the NNF, NNTS and EDCD2 algorithms have the highest data reduction, by referring to Fig. 12 the lowest error has been shown by applying EDCD2. FICA showed the worst performance in terms of accuracy, with the highest errors. The average data reduction percentage

for applied NNF, NNTS, EDCD2, LRMV, and FICA algorithms through a real-time dataset named Data4\_Intel is 50%, 50%, 83%, 25%, and 75%, respectively. It is worth noting that the EDCD2 algorithm achieves the highest data reduction. By referring to Fig. 14, Tables XXI, XXII both NNF, NNTS, EDCD2, and LRMV algorithms have acceptable accuracy, and the highest error has been shown by applying FICA.

Fig. 14. Average of Data Reduction Ratio % for Applying Various Algorithms for Different Datasets.

TABLE XXI. TOTAL ENERGY CONSUMPTION BY APPLYING THE SELECTED ALGORITHMS VS WITHOUT ALGORITHMS

|             | NNF     | NNTS    | EDCD2    | LRMV    | FICA    | Without algorithm |
|-------------|---------|---------|----------|---------|---------|-------------------|

| Data4_Intel | 50% | 50%  | 83%   | 25%  | 75%  |

## VI. CONCLUSION

The impact of data reduction methods on WSN performance is investigated in this paper, using a set of real-time datasets. Simulation tests are performed in MATLAB for different methods to reduce the amount of data sent. The selected algorithms NNF, NNST, EDCD2, LRMV, and FICA are evaluated using real-time data sets. The performance metrics measured are energy consumption, data accuracy, and percentage of data reduction. The results of the study show that the selected algorithm helps to reduce the amount of transmitted data and energy consumption, and each algorithm performs differently depending on the dataset used.

## ACKNOWLEDGMENT

“The writers would like to thank University Polyethnic of Bucharest (UPB) for their support to carry out this study.”

# A Global Survey of Technological Resources and Datasets on COVID-19

Manoj Muniswamaiah, Tilak Agerwala, Charles C. Tappert  
Seidenberg School of CSIS, Pace University, White Plains, New York

**Abstract**—The application and successful utilization of technological resources in developing solutions to health, safety, and economic issues caused by COVID-19 indicate the importance of technology in curbing COVID-19. Also, the medical field has had to race against time to develop and distribute the COVID-19 vaccine. This endeavour became successful with the vaccines created and approved in less than a year, a feat in medical history. Currently, much work is being done on data collection, where all significant factors impacting the disease are recorded. These factors include confirmed cases, death rates, vaccine rates, hospitalization data, and geographic regions affected by the pandemic. Continued research and use of technological resources are highly recommendable—the paper surveys list of packages, applications and datasets used to analyse COVID-19.

**Keywords**—Vaccination; hospitalization; confirmed cases; datasets; data science; COVID-19

## I. INTRODUCTION

COVID-19 pandemic has affected the world; data is being collected by agencies, organizations, institutions, and other bodies that are keen on providing insights [391]. Data collection includes conducting case surveillance to gather data on demographics, clinical factors, epidemiologic characteristics, illness course, care, and history on exposure and contact. This data is needed to assess where, when, and

who are most affected by the pandemic. The data available on COVID-19 is used by researchers in the medical field in evaluating different aspects of the virus. Statistical analysis tools estimate factors concerning the virus infectiousness obtained in growth rate and doubling time. Epidemiological models are used to group individuals based on their demographic data and apply mathematical formulas to find virus characteristics. Using machine learning, the time series prediction model is proposed to obtain the curve and forecast the epidemic's tendencies.

As a part of tackling the pandemic, different institutions, governments, organizations, and individuals have developed and adopted technological resources to manage the pandemic and support adherence to containment measures. Most of the technologies developed have utilized R programming, Python, Java, Kotlin, JavaScript, among other resources. Mobile applications were developed to help in contact tracing, notifications, and alerts to users if they interacted with a person infected. Dashboards have been used in visualizing COVID-19 cases across the world. This paper presents a survey of the technological resources and datasets been used by industry and academia to combat COVID-19.

Table I provide the name of the application; the details of the developer, institution, or academia; the summary of the application, its web link, and codebase link.

TABLE I. TECHNOLOGICAL RESOURCES SUMMARY TABLE

| Application                                 | Developer/industry/ Academia/University details | Application summary                                                                                                                                                                                                                                                                 | Application weblink                                                                                                                 | Application code base link                                                                                                    | References  |

| Modeling COVID-19 Spread vs Healthcare Capacity          | Developed by Dr. Alison Hill from Johns Hopkins University                                                                                                                                                                                  | This application utilizes the epidemiological model based on the classic SEIR model to define the Covid-19 spread and clinical progression. The application provides different infection trajectories, clinical interventions to curb transmission, and a comparison to the current healthcare capacity. | <a href="https://alhill.shinyapps.io/COVID19seir/">https://alhill.shinyapps.io/COVID19seir/</a> [8]                                        | <a href="https://github.com/alsnhll/SEIR_COVID19">https://github.com/alsnhll/SEIR_COVID19</a> [9]                                                                              | [3] [8] [9]    |
| COVID-19 Data Visualization Platform                     | Developed by Shubhram Pandey.                                                                                                                                                                                                               | This is a shiny app that provides an elaborate visualization of the impact of Covid-19 across the globe. The application also applies natural language processing from Twitter to provide sentiment analysis.                                                                                            | <a href="https://shubhrampandey.shinyapps.io/coronaVirusViz/">https://shubhrampandey.shinyapps.io/coronaVirusViz/</a> [10]                 | <a href="https://github.com/shubhrampandey/coronaVirus-dataViz">https://github.com/shubhrampandey/coronaVirus-dataViz</a> [11]                                                 | [3] [10] [11]  |
| Coronavirus 10-day forecast                              | This application was developed by Spatial Ecology and Evolution Lab (SpEEL) from the University of Melbourne.                                                                                                                               | It is a shiny app that provides a ten-day forecast of likely coronavirus cases by country, giving individuals a sense of how the Covid-19 is spreading or progressing.                                                                                                                                   | <a href="https://covid19forecast.science.unimelb.edu.au/">https://covid19forecast.science.unimelb.edu.au/</a> [12]                         | <a href="https://github.com/benflips/nCovForecast">https://github.com/benflips/nCovForecast</a> [13]                                                                           | [3] [12] [13]  |
| Coronavirus (COVID-19) across the world                  | This application was developed by Anisa Dhana.                                                                                                                                                                                              | It is a shiny app that uses a map visualization of cases confirmed to monitor the spread of Covid-19 across the world and graphs to visualize the growth of the disease.                                                                                                                                 | <a href="https://dash.data-scienceplus.com/covid19/">https://dash.data-scienceplus.com/covid19/</a> [14]                                   | <a href="https://github.com/CSSEGISandData/COVID-19">https://github.com/CSSEGISandData/COVID-19</a> [15]                                                                       | [16] [14] [15] |
| COVID-19 outbreak                                        | Dr. Thibaut Fabacher developed this application in collaboration with the department of Public Health of the Strasbourg University Hospital and the Laboratory of Biostatistics and Medical Informatics of the Strasbourg Medicine Faculty. | The application displays an interactive map that indicates the worldwide monitoring of Covid-19 infection. The main area of focus of the app is on the evolution of the number of Covid-19 cases per country for a given period.                                                                         | <a href="https://thibautfabacher.shinyapps.io/covid-19/">https://thibautfabacher.shinyapps.io/covid-19/</a> [17]                           | <a href="https://github.com/DrFabacher/Corona">https://github.com/DrFabacher/Corona</a> [18]                                                                                   | [3] [17] [18]  |
| Corona trajectories                                      | This application was developed by André Calero Valdez, from RWTH Aachen University.                                                                                                                                                         | The application uses two graphs to compare the number of confirmed cases and the deaths from Covid-19 with the country's trajectories. The application also allows users to compare the case number and growth rate of the Covid-19 pandemic per country using a table.                                  | <a href="https://andrevalerovaldez.shinyapps.io/CovidTimeSeriesTest/">https://andrevalerovaldez.shinyapps.io/CovidTimeSeriesTest/</a> [19] | <a href="https://github.com/Sumidu/covid19shiny">https://github.com/Sumidu/covid19shiny</a> [20]                                                                               | [3] [19] [20]  |
| Flatten the curve                                        | Tinu Schneider developed                                                                                                                                                                                                                    | this application.<br>In an interactive way, the app illustrates the different scenarios behind the #FlattenTheCurve message.                                                                                                                                                                             | <a href="https://tinu.shinyapps.io/Flatten_the_Curve/">https://tinu.shinyapps.io/Flatten_the_Curve/</a> [21]                               | <a href="https://github.com/tinuschneider/Flatten_the_Curve">https://github.com/tinuschneider/Flatten_the_Curve</a> [22]                                                       | [3] [21] [22]  |
| Explore the Spread of Covid-19                           | Joachim Gassen developed this application,                                                                                                                                                                                                  | The application allows users to visualize confirmed, recovered cases and reported deaths for several countries via one summary graph.                                                                                                                                                                    | <a href="https://jgassen.shinyapps.io/tidyCovid19/">https://jgassen.shinyapps.io/tidyCovid19/</a> [23]                                     | <a href="https://statsandr.com/blog/top-resources-on-covid-19-coronavirus/#tidycovid19">https://statsandr.com/blog/top-resources-on-covid-19-coronavirus/#tidycovid19</a> [24] | [3] [23] [24]  |
| COVID-19                                                 | Sebastian Engel-Wolf developed the application                                                                                                                                                                                              | The application visualizes elegantly collected Covid-19 data, including the confirmed cases, Maximum time of exponential growth in a row, deaths, populations, and Confirmed cases on 100,000 inhabitants, exponential growth, and the population.                                                       | <a href="https://sebastianwolf.shinyapps.io/Corona-Shiny/">https://sebastianwolf.shinyapps.io/Corona-Shiny/</a> [25]                       | <a href="https://github.com/zappingseb/coronashiny">https://github.com/zappingseb/coronashiny</a> [26]                                                                         | [3] [25] [26]  |
| Simulation tool. COVID-19 epidemic in Togo - West Africa | Dr. Kankoé Sallah developed this application.                                                                                                                                                                                               | Uses SEIR metapopulation model with mobility between catchment areas to describe the country-level spread of COVID-19 and the impact of interventions in Togo, West Africa.                                                                                                                              | <a href="https://c2m-africa.shinyapps.io/togo-covid-shiny/">https://c2m-africa.shinyapps.io/togo-covid-shiny/</a> [27]                     |                                                                                                                                                                                | [3] [27]       |
| Animating                                                | Nathan Chaney                                                                                                                                                                                                                               | This application indicates a map animation of                                                                                                                                                                                                                                                            |                                                                                                                                            | <a href="https://www.nathanchaney.com/">https://www.nathanchaney.com/</a>                                                                                                      | [30] [29]      |

|                                                                      |                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                    |                                                                                                                                                                                                                  |                |

| COVID-19 hotspots over time                                          | developed this application                                                                                                                | new Covid-19 cases in the U.S.A measured in a 7-day rolling average.                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                    | <a href="#">com/</a> [29]                                                                                                                                                                                        |                |
| Covid-19-prediction                                                  | This application was developed by Manuel Oviedo and Manuel Febrero of Modesty research group of the University of Santiago de Compostela. | The application is a shiny app that provides a 5-day horizon prediction growth rate of Covid-19 using the evolution during the past 15-day growth rate. The prediction is performed using three functional regression models fitted and estimated on available data. Apart from the prediction values, the app provides an interactive table and plot for the expected number of accumulated cases and new daily confirmed and death cases.                  | <a href="http://modesty.us.es:3838/covid19prediction/">http://modesty.us.es:3838/covid19prediction/</a> [33]                       | <a href="https://github.com/armimpdm/Covid-19-prediction">https://github.com/armimpdm/Covid-19-prediction</a> [34]                                                                                               | [3] [33] [34]  |
| Healthcare worker deaths from novel Coronavirus (COVID-19) in the US | Jonathan Gross developed this application                                                                                                 | The application is a shiny app that visualizes the U.S. health workers' deaths from Covid-19 reported on media outlets or news. The application is developed using R code with a map on the main page using Leaflet with tabs for additional graphs, including time series, histograms, and bar charts.                                                                                                                                                      | <a href="https://jontheepi.shinyapps.io/hcwcoronavirus/">https://jontheepi.shinyapps.io/hcwcoronavirus/</a> [35]                   | <a href="https://github.com/jontheepi/hcwcoronavirus">https://github.com/jontheepi/hcwcoronavirus</a> [36]                                                                                                       | [3] [35] [36]  |
| Covid-19 Hospitalizations in Belgium                                 | Jean-Michel Bodart developed this application                                                                                             | The dashboard indicates the hospitalizations related to Covid-19 in Belgium by province and region.                                                                                                                                                                                                                                                                                                                                                          | <a href="https://rpubs.com/JMBodart/Covid19-hosp-be">https://rpubs.com/JMBodart/Covid19-hosp-be</a> [37]                           | <a href="https://github.com/jmbo1190/Covid19">https://github.com/jmbo1190/Covid19</a> [38]                                                                                                                       | [3] [37] [38]  |
| Covidminer                                                           | This shiny app was developed by the Rensselaer Institute for Data Exploration and Applications                                            | The application indicates the regional differences in determinants, medications, and outcome of the Covid-19 pandemic across the United but with a specific focus on New York.                                                                                                                                                                                                                                                                               | <a href="https://covidminer.idea.rpi.edu/">https://covidminer.idea.rpi.edu/</a> [39]                                               | <a href="https://github.com/TheRensselaerIDEA/COVIDMINER">https://github.com/TheRensselaerIDEA/COVIDMINER</a> [40]                                                                                               | [41] [39] [40] |
| COVID-19 Canada Data Explorer                                        | Petr Baranovskiy developed this application.                                                                                              | The application is a shiny app that analyses the official covid-19 dataset from the government of Canada and outputs the several indicators associated with the Covid-19 pandemic in the country.                                                                                                                                                                                                                                                            | <a href="https://dataentusiast.ca/apps/covid-ca/">https://dataentusiast.ca/apps/covid-ca/</a> [42]                                 | <a href="https://milano-r.github.io/erum2020-covid-contest/petr-baranovskiy-covid-ca-data-explorer.html">https://milano-r.github.io/erum2020-covid-contest/petr-baranovskiy-covid-ca-data-explorer.html</a> [43] | [3] [42][43]   |
| PAGTAGNA: Philippine COVID-19 Case Forecasting Web Application       | This application was developed by Jamal Kay Rogers and Yvonne Grace Arandela.                                                             | It is a shiny app that provides a 5-day forecast of Covid-19 cases in the Philippines include the confirmed new cases of infections, confirmed deaths, and recovery rate. Apart from forecasting, the application utilizes plots to visualize the disease's ten-day forecasts and the accumulated and confirmed data. The data used in this application is obtained from the Johns Hopkins University Center for Systems Science and Engineering (JHU CSSE). | <a href="https://jamalrogers.app.shinyapps.io/tforecast/">https://jamalrogers.app.shinyapps.io/tforecast/</a> [44]                 | <a href="https://github.com/fsmosca/COVID-19-PH-dataset">https://github.com/fsmosca/COVID-19-PH-dataset</a> [45]                                                                                                 | [3] [44] [45]  |
| COVID-19 Case & Death Report Number Corrector                        | Matt Maciejewski developed this application.                                                                                              | This shiny application is developed and aligned to make corrections of underreported Covid-19 cases and death. The application applies a multiplicative estimator for total deaths and cases regarding the base country to perform this role.                                                                                                                                                                                                                | <a href="https://pharmhax.shinyapps.io/covid-corrector-shiny/">https://pharmhax.shinyapps.io/covid-corrector-shiny/</a> [46]       | <a href="https://github.com/pharmhax/covid19-corrector">https://github.com/pharmhax/covid19-corrector</a> [47]                                                                                                   | [48] [46] [47] |
| COVID19 forecast                                                     | Carlos Catania developed this application                                                                                                 | This application applies the SEIR model to forecast the spread of Covid 19 in various European and South American countries.                                                                                                                                                                                                                                                                                                                                 | <a href="https://harpomaxx.shinyapps.io/covid19/">https://harpomaxx.shinyapps.io/covid19/</a> [49]                                 | <a href="https://github.com/harpomaxx/COVID19">https://github.com/harpomaxx/COVID19</a> [50]                                                                                                                     | [3] [49] [50]  |
| Trafford Covid-19 monitor                                            | This is a shiny application developed by Trafford Data Lab                                                                                | The application provides trends in confirmed coronavirus cases in Trafford.                                                                                                                                                                                                                                                                                                                                                                                  | <a href="https://trafforddatalab.shinyapps.io/trafford-covid-19/">https://trafforddatalab.shinyapps.io/trafford-covid-19/</a> [54] | <a href="https://github.com/traffordDataLab/trafford-covid-19">https://github.com/traffordDataLab/trafford-covid-19</a> [55]                                                                                     | [53] [54] [55] |
| Covid-19 Bulletin Board                                              | Wei Su developed this application                                                                                                         | The dashboard indicates the real-time Covid-19 visualization of the various covid-19 indicators in Japan, including the confirmed cases, hospital discharge and deaths, positive confirmed, and PCR test.                                                                                                                                                                                                                                                    | <a href="https://covid-2019.live/en/">https://covid-2019.live/en/</a> [56]                                                         | <a href="https://github.com/swsoyee/2019-ncov-japan">https://github.com/swsoyee/2019-ncov-japan</a> [57]                                                                                                         | [3] [56] [57]  |
| Covid-19 Statistics                                                  | Carl Sansaçon developed this                                                                                                              | It is a WordPress plugin that applies the R {ggplot2} graphics with ARIMA forecast and                                                                                                                                                                                                                                                                                                                                                                       | <a href="http://moduloinfo.ca/wordpress/">http://moduloinfo.ca/wordpress/</a> [58]                                                 | <a href="https://plugins.trac.wordpress.org/browser/covid-19-">https://plugins.trac.wordpress.org/browser/covid-19-</a>                                                                                          | [3] [58] [59]  |

|                                                                          |                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                            |                                                                                                                                                                          |                          |

| Displayer                                                                | application                                                                                                        | PHP coding to display or visualize the confirmed new cases of Covid-19 infection, deaths, and recovered cases in various countries. The data used in this application is sourced from the COVID-19 Data Repository by the Centre for Systems Science and Engineering (CSSE) at Johns Hopkins University.                                                                                                                                                                                                                                                                  |                                                                                                                            | <a href="#">statistics-displayer/</a> [59]                                                                                                                               |                          |
| CoronaMapper                                                             | This application was developed by Peter Gruber and Paolo Montemurro supported by OxyLabs.                          | The application visualizes the four-day average growth indicator of Covid-19 to indicate how the disease evolves after filtering out the noise. The visualizations are both interactive and intuitive.                                                                                                                                                                                                                                                                                                                                                                    | <a href="http://coronamapper.com/">http://coronamapper.com/</a> [60]                                                       | <a href="https://github.com/JayWelsch/coronamapper">https://github.com/JayWelsch/coronamapper</a> [61]                                                                   | [3] [60] [61]            |
| CoronaDash                                                               | This is a shiny app developed by Peter Laurinec.                                                                   | This application applies visualization and data mining techniques in R to compare Covid-19 statistics for different countries. The Covid-19 statistics displayed are obtained by using exponential smoothing model to extrapolate total confirmed cases; creating death trajectories; using dendrogram and table of clusters averages to create a multidimensional clustering; developing aggregated views of the entire world; and applying hierarchical clustering to compare the Covid-19 case between countries.                                                      | <a href="https://petolau.shinyapps.io/coronadash/">https://petolau.shinyapps.io/coronadash/</a> [62]                       | <a href="https://github.com/PetoLau/CoronaDash">https://github.com/PetoLau/CoronaDash</a> [63]                                                                           | [3] [62] [63]            |
| Covidfrance                                                              | This is a shiny app developed by Guillaume Pressiat                                                                | The application indicates the changes in the number of Covid-19 deaths and recoveries, hospitalization, and intensive care units by the department in France                                                                                                                                                                                                                                                                                                                                                                                                              | <a href="https://guillaumepressiat.shinyapps.io/covidfrance/">https://guillaumepressiat.shinyapps.io/covidfrance/</a> [64] | <a href="https://gist.github.com/GuilLaumePressiat/0e3658624e42f763e3e6a67df92bc6c5">https://gist.github.com/GuilLaumePressiat/0e3658624e42f763e3e6a67df92bc6c5</a> [65] | [3] [64] [65]            |
| COVID-19 Tracker                                                         | Dr Magda Bucholc developed this application from Ulster University                                                 | The application reports the number of reported Covid-19 cases at the local government district in Northern Ireland and county level across Ireland based on gender and growth rate.                                                                                                                                                                                                                                                                                                                                                                                       | <a href="https://nicovidtracker.org/">https://nicovidtracker.org/</a> [66]                                                 | <a href="https://github.com/YouGov-Data/covid-19-tracker">https://github.com/YouGov-Data/covid-19-tracker</a> [67]                                                       | [68] [66] [67]           |
| WHO COVID-19 Explorer                                                    | This application was developed by the World Health Organization (WHO)                                              | This application provides timely updated data visualizations of Covid-19 cases, including confirmed cases and deaths by region and country.                                                                                                                                                                                                                                                                                                                                                                                                                               | <a href="https://worldhealthorg.shinyapps.io/covid/">https://worldhealthorg.shinyapps.io/covid/</a> [71]                   | <a href="https://github.com/WorldHealthOrganization/app">https://github.com/WorldHealthOrganization/app</a> [72]                                                         | [3] [71] [72]            |
| COVID-19 Scenario Analysis Tool                                          | The MRC Centre developed this application for Global Infectious Disease Analysis from the Imperial College London. | This application applies the squire R package to illustrate the Covid-19 pandemic trajectories, R_t & R_eff measures, and healthcare demand for different countries over time.                                                                                                                                                                                                                                                                                                                                                                                            | <a href="https://www.covid-sim.org/v6.20210915/">https://www.covid-sim.org/v6.20210915/</a> [73]                           | <a href="https://github.com/mrc-ide/squire">https://github.com/mrc-ide/squire</a> [74]                                                                                   | [3] [73] [74]            |
| Coronavirus Package                                                      | Rami Krispin developed this R package                                                                              | This package provides a clean dataset of the Covid-19 pandemic and analytics, including the daily summary of the pandemic cases by state. The dataset is collected from the John Hopkins database.                                                                                                                                                                                                                                                                                                                                                                        |                                                                                                                            | <a href="https://ramikrispin.github.io/coronavirus/">https://ramikrispin.github.io/coronavirus/</a> [75]                                                                 | [3] [75]                 |
| District Health Information Software (DHIS2)                             | The University of Oslo developed this application                                                                  | The District Health Information Software has specific digital packages for Covid-19 that support the pandemic's surveillance and response activities.                                                                                                                                                                                                                                                                                                                                                                                                                     | <a href="https://www.dhis2.org/">https://www.dhis2.org/</a> [76]                                                           | <a href="https://github.com/dhis2/dhis2-covid19-doc">https://github.com/dhis2/dhis2-covid19-doc</a> [79]                                                                 | [80] [76] [77] [78] [79] |
| Surveillance , Outbreak Response Management and Analysis System (SORMAS) | Helmholtz Centre for Infection Research developed this system.                                                     | The system performs the Covid-19 specific functions that are classified into aggregates and case-based functions. The aggregate functions include line listing, import, and export of data in CSV format; standard reporting of covid-19 cases including confirmed cases, deaths, and recoveries; and statistical analysis based on the reports provided by charts, maps, and graphs. The case-based functions include contact tracing, laboratory sample management, port of entry reporting, vaccination campaign, follow-up visit, and enrolling and tracing patients. | <a href="https://sormas.org/">https://sormas.org/</a> [81]                                                                 | <a href="https://github.com/hzi-braunschweig/SORMAS-Project">https://github.com/hzi-braunschweig/SORMAS-Project</a> [82]                                                 | [80] [81] [82]           |

|                                                          |                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                          |                                                                                                                                                                    |                     |
|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| Go.Data                                                  | This application was developed by WHO in collaboration with partners in the Global Outbreak Alert and Response Network (GOARN).                                                                                                                                                                                                                                                  | Since the outbreak of Covid-19 began, metadata packages have been prepared that match the most recent WHO Surveillance Guidance, including uniformity with all core metadata gathered as part of WHO Case Reporting Forms transmitted to COVID-MART / X-MART on a daily and weekly basis. If requested, this allows for streamlined IDSR reporting for countries. Other expanded metadata packages, such as the COVID First Few Hundred Cases (FFX) Protocol and the Unity Studies for HealthCare Workers, are available for countries conducting more extensive data collection or research inquiries. | <a href="https://www.who.int/godata">https://www.who.int/godata</a> [83]                                                 | <a href="https://github.com/godata-who/godata">https://github.com/godata-who/godata</a> [84]                                                                       | [80] [83] [84]      |
| Epi Info                                                 | This application was developed by Centres for Disease Control and Prevention (CDC)                                                                                                                                                                                                                                                                                               | The Covid-19 specific functions include the development of COVID-19 Case Surveillance Forms that are customized for country, region, and local requirements. Epi Info is also applied in Covid-19 outbreak investigations, the development of small to mid-sized disease surveillance systems, the analysis, visualization, and reporting (AVR) components of larger systems, and continuing education in epidemiology and public health analytic methods at public health schools around the world.                                                                                                    | <a href="https://www.cdc.gov/epiinfo/support/downloads.html">https://www.cdc.gov/epiinfo/support/downloads.html</a> [85] | <a href="https://github.com/Epi-Info/Epi-Info-Community-Edition">https://github.com/Epi-Info/Epi-Info-Community-Edition</a> [86]                                   | [80] [85] [86]      |
| Open Data Kit (ODK)                                      | This application was developed by Get ODK, an organization majoring in data collection.                                                                                                                                                                                                                                                                                          | ODK software is being employed in the COVID-19 response for disease surveillance, fast diagnostics, and vaccine trials.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | <a href="https://getodk.org/software/">https://getodk.org/software/</a> [87]                                             | <a href="https://github.com/getodk/collect">https://github.com/getodk/collect</a> [88]                                                                             | [80] [87] [88]      |
| CommCare                                                 | This software was developed by Dimagi, a firm providing digital data solutions                                                                                                                                                                                                                                                                                                   | Dimagi created a set of pre-built COVID-19 template applications to help organizations and governments with their continuing COVID-19 response operations.                                                                                                                                                                                                                                                                                                                                                                                                                                              | <a href="https://www.dimagi.com/covid-19/">https://www.dimagi.com/covid-19/</a> [89]                                     | <a href="https://github.com/dimagi/commcare-hq">https://github.com/dimagi/commcare-hq</a> [90]                                                                     | [80] [89] [90]      |

| The Oxford Covid-19 Government Response Tracker (OxCGRT) | This application was developed by the Blavatnik School of Government.                                                                                                                                  | The Oxford Covid-19 Government Response Tracker (OxCGRT) compiles systematic data on policy responses taken by countries to combat COVID-19. Since January 1, 2020, the various policy reactions have tracked over 180 nations and are categorized into 23 indicators, such as school closures, travel restrictions, and vaccination policies. These policies are scored on a scale to represent the magnitude of government intervention, and the results are compiled into a set of policy indices. The data can improve attempts to combat the epidemic by allowing decision-makers and citizens to understand government responses uniformly. | <a href="https://www.bsg.ox.ac.uk/research/research-projects/covid-19-government-response-tracker">https://www.bsg.ox.ac.uk/research/research-projects/covid-19-government-response-tracker</a> [96]                              | <a href="https://github.com/OxCGRT/covid-policy-tracker">https://github.com/OxCGRT/covid-policy-tracker</a> [97]        | [98] [96][97]           |
| COVID-19 Situazione Italia                               | This application was developed by the Department of Civil Protection (Dipartimento della Protezione Civile) Angelo Borrelli, Italy.                                                                    | This application provides updated Covid-19 data and visualizations for Italy, including new confirmed infections, total confirmed infections, new confirmed deaths, total confirmed deaths, and recovered cases. The data and visualizations are provided for the whole country and the regions.                                                                                                                                                                                                                                                                                                                                                  | <a href="http://arcg.is/C1unv">http://arcg.is/C1unv</a>                                                                                                                                                                           | <a href="https://github.com/pcm-dpc/COVID-19">https://github.com/pcm-dpc/COVID-19</a> [99]                              | [3] [99]                |
| Covid Mobile data                                        | This application was developed by COVID19 Mobility Task Force of the World Bank                                                                                                                        | The application uses the data from Mobile Network Operators (MNOs) to perform analytics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                                                                                                                                                                                   | <a href="https://github.com/worldbank/covid-mobile-data">https://github.com/worldbank/covid-mobile-data</a> [100]       | [3] [100]               |
| Radar Covid-19                                           | The Government of Spain developed this application                                                                                                                                                     | This application was designed to prevent the spread of Covid-19. The application anonymizes users if they have had any contact in the last 14 days with someone infected with Covid-19 via low-power Bluetooth technology.                                                                                                                                                                                                                                                                                                                                                                                                                        | <a href="https://radarcovid.gob.es/">https://radarcovid.gob.es/</a> [101]                                                                                                                                                         | <a href="https://github.com/RadarCOVID/radar-covid-android">https://github.com/RadarCOVID/radar-covid-android</a> [103] | [104] [101] [102],[103] |
| CovidSafe                                                | The University of Washington developed this application.                                                                                                                                               | The application was developed to help prevent the spread of Covid-19 by alerting users about highly relevant public health announcements, exposure to COVID-19 and to assist contact tracing without compromising users' privacy.                                                                                                                                                                                                                                                                                                                                                                                                                 | <a href="https://covidsafe.csis.washington.edu/">https://covidsafe.csis.washington.edu/</a> [105]                                                                                                                                 | <a href="https://github.com/CovidSafe">https://github.com/CovidSafe</a> [106]                                           | [3] [105] [106]         |
| Covid Alert                                              | Volunteers originally developed COVID Alert. The Canadian Digital Service is currently developing its repository.                                                                                      | This application was developed to slow down Covid-19 infections in Canada. The app notifies users if someone they were near in the past 14 days tells the app they tested positive.                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <a href="https://www.canada.ca/en/public-health/services/diseases/coronavirus-disease-covid-19/covid-alert.html">https://www.canada.ca/en/public-health/services/diseases/coronavirus-disease-covid-19/covid-alert.html</a> [107] | <a href="https://github.com/cds-snc/covid-alert-app">https://github.com/cds-snc/covid-alert-app</a> [109]               | [110] [107] [108] [109] |
| erouska-android                                          | A team of volunteers initially developed this application. The application is currently developed and maintained by the Ministry of Health in collaboration with the National Agency for Communication | To combat the COVID-19 epidemic, the app alerts users at risk of spreading the virus. The software delivers guidance on how to minimize the spread of the epidemic based on the user's history of exposure to other potentially contagious users.                                                                                                                                                                                                                                                                                                                                                                                                 | <a href="https://erouska.cz/">https://erouska.cz/</a> [111]                                                                                                                                                                       | <a href="https://github.com/covid19cz/erouska-android">https://github.com/covid19cz/erouska-android</a> [112]           | [113] [111] [112]       |

|                          |                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                                     |                                                                                                                           |                            |

| COVID-19 Dashboard       | Johns Hopkins University Centre developed this application for Systems Science and Engineering.                                    | This is the data repository for the Johns Hopkins University Centre for Systems Science and Engineering's 2019 Novel Coronavirus Visual Dashboard (JHU CSSE). The ESRI Living Atlas Team and the Johns Hopkins University Applied Physics Lab have also contributed to this project (JHU APL).                                                                      | <a href="https://www.arcgis.com/apps/opsdashboards/index.html#/bda7594740fd40299423467b48e9ecf6">https://www.arcgis.com/apps/opsdashboards/index.html#/bda7594740fd40299423467b48e9ecf6</a> [114]                                                                                                   | <a href="https://github.com/sidbannet/COVID-19_analysis">https://github.com/sidbannet/COVID-19_analysis</a> [116]         | [98] [114]<br>[115] [116]  |
| Corona-Warn-App          | This application was developed as an open-source app by SAP and Deutsche Telekom under the directive by the government of Germany. | The Corona-Warn-App was developed with the goal of preventing the spread of Covid-19. The app serves as a digital complement to distancing, hygiene, and wearing masks. Additionally, it provides a functionality to add a user's digital vaccination certificate to prove their vaccination status.                                                                | <a href="https://www.coronawarn.app/en/">https://www.coronawarn.app/en/</a> [117]                                                                                                                                                                                                                   | <a href="https://github.com/coronawarn-app/cwa-app-android">https://github.com/coronawarn-app/cwa-app-android</a> [118]   | [119] [117]<br>[118]       |
| TraceTogether            | The Singapore Government Technology Agency developed this application.                                                             | Through community-driven contact tracing, TraceTogether supports Singapore's efforts to combat the spread of COVID-19. One can use the app to see or display their COVID Health Status based on their immunization and test results.                                                                                                                                | <a href="https://www.tracetgether.gov.sg/">https://www.tracetgether.gov.sg/</a> [120]                                                                                                                                                                                                               | <a href="https://github.com/OpenTrace-Community">https://github.com/OpenTrace-Community</a> [121]                         | [122] [120]<br>[121]       |
| NZ COVID Tracer          | The New Zealand Ministry of Health developed this application                                                                      | The app helps contact tracing go faster by creating a private digital diary of the places you visit. Users Scan the official QR codes wherever they see them and add manual entries for their visits to other places.                                                                                                                                               | <a href="https://www.health.govt.nz/our-work/diseases-and-conditions/covid-19-novel-coronavirus/covid-19-resources-and-tools/nz-covid-tracer-app">https://www.health.govt.nz/our-work/diseases-and-conditions/covid-19-novel-coronavirus/covid-19-resources-and-tools/nz-covid-tracer-app</a> [123] | <a href="https://github.com/minhealthnz/nz-covid-tracer-app">https://github.com/minhealthnz/nz-covid-tracer-app</a> [125] | [126] [123]<br>[124] [125] |
| VigilantGantry           | This an automated contactless gantry system developed by GovTech's Data Science and Artificial Intelligence Division (DSAD)        | VigilantGantry is an open-source implementation of an AI-driven automated temperature screening gantry that improves the rate of contactless screening by augmenting existing thermal systems. VigilantGantry is excellent for automatically scanning high-traffic sites for symptomatic COVID-19 patients. It helps ground crews keep on the lookout for COVID-19. |                                                                                                                                                                                                                                                                                                     | <a href="https://github.com/dsaigo/vsg/vigilantgantry">https://github.com/dsaigo/vsg/vigilantgantry</a> [127]             | [128] [127]                |
| lancet-covid-19-database | Developed by Lancet                                                                                                                | The Lancet COVID-19 Database gives users access to the most up-to-date information on COVID-19, such as cases, deaths, recoveries, testing, and other useful indicators for tracking the pandemic's spread and response.                                                                                                                                            |                                                                                                                                                                                                                                                                                                     | <a href="https://github.com/sdsna/lancet-covid-19-database">https://github.com/sdsna/lancet-covid-19-database</a> [130]   | [131] [130]                |
| Covid19Canada            | SDSN developed this application                                                                                                    | This shiny app provides a forecast of Covid-19 cases and Covid-19 information in Canada, including the confirmed new cases of infections, confirmed deaths, and recovery rate. Apart from forecasting, the application utilizes plots to visualize the disease's ten-day forecasts and the accumulated and confirmed data.                                          | <a href="https://artbd.shinyapps.io/covid19canada/">https://artbd.shinyapps.io/covid19canada/</a> [132]                                                                                                                                                                                             | <a href="https://github.com/ccodwg/Covid19Canada">https://github.com/ccodwg/Covid19Canada</a> [133]                       | [3] [132] [133]            |
| COVI-ML                  | This respiratory was developed by the Quebec Artificial Intelligence Institute                                                     | COVI-ML is the Risk model training code for the Covid-19 tracing application. Its repository provides models, infrastructure, and datasets for training deep-learning-based predictors of COVID-19 infectiousness as used in Proactive Contact Tracing.                                                                                                             |                                                                                                                                                                                                                                                                                                     | <a href="https://github.com/milaiqia/COVI-ML">https://github.com/milaiqia/COVI-ML</a> [134]                               | [3][134]                   |

| Covid-19 model               | Imperial College London developed this application/code.                                                                                                                                                                                         | This code was applied in modeling estimated deaths and infections for COVID-19 from the study "Estimating the effects of non-pharmaceutical interventions on COVID-19 in Europe "done by Flaxman et al. (2020) [136]                                                                   |                                                                                                                                                                                                                                                           | <a href="https://github.com/ImperialCollegeLondon/covid19model">https://github.com/ImperialCollegeLondon/covid19model</a> [135]   | [136] [135]            |
| The COVID Tracking Project   | Alexis Madrigal created this project through a collaborative volunteer-run effort to track the ongoing COVID-19 pandemic                                                                                                                         | This project collects and publishes data required to understand the COVID-19 outbreak in the United States. All 50 states, five territories, and the District of Columbia participate in the Covid tracking project, which will collect data on COVID-19 testing and patient outcomes. | <a href="https://covidtracking.com/">https://covidtracking.com/</a> [137]                                                                                                                                                                                 | <a href="https://github.com/COVID19Tracking">https://github.com/COVID19Tracking</a> [138]                                         | [139] [137] [138]      |
| Covidmx                      | Covidmx was developed by Federico Garza                                                                                                                                                                                                          | The API was developed to handle Covid-19 open data provided by the Mexican Dirección General de Epidemiología.                                                                                                                                                                         |                                                                                                                                                                                                                                                           | <a href="https://github.com/FedericoGarza/covidmx">https://github.com/FedericoGarza/covidmx</a> [140]                             | [141] [140]            |
| Covid19-Scenarios            | Neherlab developed this tool                                                                                                                                                                                                                     | The Covid-19 Scenarios provide Models of generating trajectories for COVID-19 outbreak and hospital demand. The functioning of this tool is based on the SIR model, which simulates a COVID19 outbreak.                                                                                | <a href="https://covid19-scenarios.org/">https://covid19-scenarios.org/</a> [142]                                                                                                                                                                         | <a href="https://github.com/neherlab/covid19_scenarios">https://github.com/neherlab/covid19_scenarios</a> [143]                   | [3] [142] [143]        |
| covid-chest-imaging-database | This database was developed by NHSX and the British Society of Thoracic Imaging (BSTI). NHSX is a joint unit of National Health Service (NHS) England and the Department of Health and Social Care, supporting local NHS and care organizations. | The database was developed with a respiratory containing tooling related to the NHSX National COVID-19 Chest Image Database (NCCID) to promote research projects in response to the COVID-19 pandemic.                                                                                 |                                                                                                                                                                                                                                                           | <a href="https://github.com/nhsx/covid-chest-imaging-database">https://github.com/nhsx/covid-chest-imaging-database</a> [144]     | [145] [144]            |
| Covid-pass-verifier          | This is an application developed by NHSX                                                                                                                                                                                                         | The COVID Pass Verifier app is the official NHS COVID Pass Verifier for England and Wales. The app is a safe and secure way to check if someone has been appropriately vaccinated against COVID-19, has had a negative test, or has recovered from COVID-19.                           | <a href="https://www.nhs.uk/covid-19-response/nhs-covid-pass-verifier-app/international-covid-pass-verifier-app-user-guide/">https://www.nhs.uk/covid-19-response/nhs-covid-pass-verifier-app/international-covid-pass-verifier-app-user-guide/</a> [146] | <a href="https://github.com/nhsx/covid-pass-verifier">https://github.com/nhsx/covid-pass-verifier</a> [148]                       | [145] [146] [147][148] |
| Covasim                      | The Institute for Disease Modelling developed this simulator                                                                                                                                                                                     | Covasim is a stochastic agent-based simulator for performing COVID-19 analyses.                                                                                                                                                                                                        |                                                                                                                                                                                                                                                           | <a href="https://github.com/InstituteforDiseaseModeling/covasim">https://github.com/InstituteforDiseaseModeling/covasim</a> [149] | [150] [149]            |
| covid-19 Dashboard           | Greg Rafferty developed Covid-19 dashboard                                                                                                                                                                                                       | This is a web dashboard developed to monitor the COVID-19 pandemic. The data used is obtained from Johns Hopkins Center for Systems Science and Engineering.                                                                                                                           | <a href="https://covid-19-raffg.herokuapp.com/">https://covid-19-raffg.herokuapp.com/</a> [151]                                                                                                                                                           | <a href="https://github.com/raffg/covid-19">https://github.com/raffg/covid-19</a> [152]                                           | [3] [152] [151]        |
| Covid-19 R/Python scripts    | Developed by QuKunLa; a Laboratory of Immunogenomics and Precision Medicine, University of Science and Technology of China                                                                                                                       | These are R/Python scripts to analyze single-cell RNA-sequence data from COVID-19 patients.                                                                                                                                                                                            |                                                                                                                                                                                                                                                           | <a href="https://github.com/QuKunLab/COVID-19">https://github.com/QuKunLab/COVID-19</a> [153]                                     | [3] [153]              |
| COVID-19-CT-CXR              | COVID-19-CT-CXR was developed by Peng et al. and Intramural Research Programs of the                                                                                                                                                             | This is a public database of COVID-19 CXR and CT images, which are automatically extracted from COVID-19-relevant articles from the PubMed Central Open Access (PMC-OA)                                                                                                                |                                                                                                                                                                                                                                                           | <a href="https://github.com/ncbi-nlp/COVID-19-CT-CXR">https://github.com/ncbi-nlp/COVID-19-CT-CXR</a> [154]                       | [155] [154]            |

|                                          |                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                         |                                                                                                                                               |                   |

## II. CONCLUSION

The summary tables (Tables I and II) present the technological resources and datasets used in tackling covid-19. Most of the data collected with COVID-19 related to hospitalizations, vaccinations, government response measures, deaths, confirmed reported cases, as well as restrictions and policies are used in aiding the pandemic. The R resources have mainly been used to develop Shiny apps and dashboards. Java, Kotlin, and Perl resources have been used in developing Android and iOS applications for contact tracing, disease surveillance, fast diagnostics, and notifying users anonymously if they have had any contact with someone who has been infected with COVID-19 via low-power bluetooth technology [28][31][32][51][52][69][129]. Based on the benefits of utilizing these resources, continued research and application of technological resources are highly recommendable [70].

# A Comparison between Online and Offline Health Seeking Information using Social Networks for Patients with Chronic Health Conditions

Dr Andrew Kear<sup>1</sup>

Faculty of Media and Communication  
Bournemouth University, UK

Simon Talbot<sup>2</sup>

Welspect Healthcare  
UK

**Abstract**—The patient is now better connected with other patients just like the consumer is now better connected with other consumers in particular through the growing adoption of social media and online peer to peer communities. These relationships which become collaborative have either positive or indeed negative consequences that may either endorse or have implications for a firm's products [32]. The aim of this research was to gain an understanding of the impact social media has on patient influence on healthcare provision especially in relation to information seeking and clinical product choice. It compares a group of patients who are predominantly online information seekers with a group who are predominantly offline information seekers. Bias will be eliminated by utilising probability sampling techniques in order to be able to perform statistical analysis on the results obtained. This study capitalises on having access to approximately 8000+ Direct to Patient consumers who are currently receiving devices for the management of their bladder problems. The intention of this research project is to gain an understanding of how two way online interactions have developed between patients with similar chronic medical conditions and how firms can use online social media to improve their relationship with patients. The key research question of this paper is: Have online social media tools affected demand for healthcare intermediation in patients, who experience chronic medical conditions and reflect a need to become better informed. The findings of this pre-Covid research were that, for patient groups that had chronic conditions, there was a positive relationship between time spent in developed peer to peer communities, are more trusting of online information and spend more time online.

**Keywords**—Component; social media; healthcare; peer to peer networks; patient networks; pre-Covid

## I. INTRODUCTION

The digital revolution through information technology has had an empowering influence on interactions between consumers (the end users) and consumers, and consumers and the marketplace. Social media has allowed instant reach to and sharing of information [14] and Social media penetration world-wide is continuously on the uptrend to move to over 3 billion by 2021 (Statista.com) [34]. Social media interactions offer a medium to be used by patients with informational, emotional, and social support pertaining to their issues [42]. This can offer both valuable information and in some cases misleading information. Consumers, in this case patients, have an increasingly loud voice and identity as online social peer to

peer groups form, 9 members of those groups or communities interact with each other [29] and social networks have now become a major component of popular culture [4]. Users of member communities are potentially open to influences, especially from other members within these communities. To search for other patients (consumers) knowledge and experiences [1] remains a key driver in this context. Individuals who never meet face to face today develop an identity and presence within member communities spanning across the globe. Facebook allowed patients to follow health-related pages. YouTube and Twitter are the next two widely used social media platforms. Patients are also able to participate in disease-specific group discussions [2] In a McKinsey survey (2011) involving 4261 respondents 67% of Healthcare companies use at least one social technology tool [16]. Now most businesses, social causes, political movements, public figures and governments' attempt to harness the power of social network sites such as Facebook due to the level of exposure and influence it offers [4]. Thus the benefits of adopting social media for the firm are clear and it is proposed that the patient-provider relationship is enhanced across all age groups (Ybarra & Suman, 2008). One of the key challenges faced by firms, according to a 2012 McKinsey survey, is a lack of quality detailed customer data, for example consumer interests or attitudes [5]. This in turn means that marketing decisions have to be based on known or 'comfortable' data such as internal sales data. This McKinsey survey concluded that less than 20% of marketing decisions are based on external quantitative and qualitative data such as consumer insights, these insights were described as difficult to obtain due to the fact that they are not readily available to the firm [5].

Information seeking is linked to decision making. Roxane Divol [28], in her article entitled 'Demystifying Social Media' describes the consumer decision journey as consisting of 5 stages: 'Consider, evaluate, purchase, experience then advocate' [28]. This stage process has resemblances with the search, experience, and credence model that has been studied in on line shopping [11]. The author in [28] in her paper argues that it is much easier to interact with the consumer at each of the five decision making stages through social media, compared with a more traditional paid media marketing strategy. This means that a social media marketing strategy brings undoubted benefits such as access to the consumer at each stage of the decision making journey. However social

marketing is of course not without its risks. Online communities such as blogs and peer to peer user groups can campaign for unproven or untested treatments. One example is a new untested surgical treatment for Multiple Sclerosis being 'advocated' by an online Canadian community group [10]. Today most clinicians take a positive view of the information found through online searches that patients bring to their clinics [36].

According to [38] 'patients are acquiring more power in the health care supply chain and their preferences are influencing manufacturers, physicians and hospitals' [36]. Therefore patients have influence over prescribed products they receive and have power over which products will appear on formularies in future. Online health information has now grown to become one of the most important information sources for people [17]. Pharmaceutical companies meanwhile provide product information that increases request rates [24]. Patients with chronic health conditions carry out regular searching for information relating to new treatments, nutritional advice and alternative therapies. Patients use both online communities and chat rooms. Today the adoption of online health information seeking behaviour is creating a more informed patient. This greater transparency of information does create issues. For instance, the large number of products potentially creates confusion amongst clinicians which in turn leads to examples of products being unnecessarily or inappropriately prescribed. A key tactic amongst newly formed Clinical Commissioning Groups is to develop what is known as a 'formulary', essentially this is a list limiting the prescription of products. These formularies limit the availability of some of these devices, based on criteria such as clinical or cost effectiveness.

Key questions arise as to differences between online and offline health seeking behaviours and their implications for health care provision. If a proven difference exists between online and off-line information seeking behaviours, especially in the context of patients with long term chronic illnesses, then this would have significant implications for the understanding of consumer behaviour. It would either imply that the patient had already 'decided' before they consulted with a clinician or at least would suggest that there are external influences on choice of treatment that the patient receives from their clinician. A further thing to note is that there are many benefits to researching illness and chronic illnesses beyond that of metaphor [33].

The factors influencing peer to peer communities can be grouped into the following categories:

**Healthcare Professionals** - Declining appointment times are typical; many patients are less satisfied with information and support obtained from clinicians [3]. Poor communication with physicians and the patient physician relationship may drive users to seek online channels for healthcare information [40]. Diffusing health information has a negative effect on frequency of health care/doctor visits [36].

**Behavioural Factors** - Online healthcare Information seeking behaviour is associated with healthier people [3]. Perceived poor health status positively affects both frequency and diversity of search for online health information [40].

Chronic disease sufferers whose condition worsens may look for health information online more often overtime and therefore have less doctor visits [36].

It is noteworthy that offline conversations also take place. A study that was conducted by [31] and discusses information seeking in women before visiting their GP and found that depending on whether these conversations were with 'kin' or 'friends', a difference in frequency of GP visits was noted. Essentially the conversations taking place within kinship networks were more intense and resulted in increased GP consultations [31]. The translation of this research to the social media era could be indicative of differing behaviour amongst diverse social groups that transcends the technology. However it does not always follow that patients who have increased healthcare information needs will seek more doctor visits as highlighted by [36].

[25] suggested that the internet is a key influence in changing the balance of 'power' between healthcare professionals and the public. The patient is becoming more knowledgeable and involved in health care decision-making and this is contributing to the de-professionalising of medicine [25]. This professional practice has often related to knowledgeability or expertise. [3] Highlights paternalistic attitudes of some doctors and nurses and the fact that the internet has created a digital divide providing an opportunity for educated, wealthier people to seek alternative healthcare opinions [3]. In particular the use of social networking has also grown from 5% of all adults in 2005, to 50% of all adults by 2011 [43]. According to a health research Institute survey in 2012 one-third of consumers are now using social media for 'health related matters'; preferring community sites over sponsored sites [17]. This implies that patients do not necessarily have to be in poor health to be motivated enough to seek healthcare information. According to the [20] Survey, 39% of consumers who have a broadband connection at home reported that they had used the internet in the last week for 'finding health information', this figure has increased by 3% since 2011. Finding health information was highlighted as having the most marked increase since last year indicating a growing trend towards the use of the internet for this purpose [20]. Similarly according to the 'Pew Internet and American Life Project' research, 35% of Americans say that at one time or another they have gone online specifically to try to find out what medical condition they or someone else might have. People are increasingly using 'ask a doctor' sites, for example 8% of internet users say they have in the last 12 months posted a health related question online [35]. This research adds further strength to the argument that the internet has increasingly become a compliment to formal healthcare information provision. However a consideration remains that is the law of e-healthcare attrition [6]. In addition some issues remain in relation to the authenticity verification by online health information seekers [8] in addition to the perceived credibility of the internet varied because expertise and trustworthiness were sometimes difficult to determine [12]. Additional consideration is that of the challenge to the authority of the expert causing a perceived deterioration in the physician-patient relationship [19].

This literature review captures two themes. First 'Increased healthcare information seeking behaviour will positively influence the patient's healthcare choices'. Several authors have contributed to the idea that patients do have influence over their healthcare choices [13], [36] including compliance with the advice. The question arises as to whether online information seeking has the same influence on patients with chronic health conditions and furthermore how known demographic factors such as gender, age and health status are influencing this.

The second theme captured by the literature review is 'Are patients seeking healthcare information online becoming more demanding of their healthcare compared with patients seeking healthcare information offline?' [10] discussed how social media messages can spread rapidly and influence demand. It is undetermined whether people seek more clinical appointments as a consequence [31], [36]. The other outcome of patients becoming more self efficacious is a possible reduction in reliance on expert intermediaries, and a consequent reduction in requests for healthcare appointments. A, dynamic Intermediation-Disintermediation-Apomediation (D.I.D.A) model has been proposed for this process [7]. The key question is whether online healthcare information searches are simply meeting a demand for personal understanding of the situation they are in, or if information seeking drives patients to seek more doctor appointments to obtain specific treatments.

The following objectives have therefore been developed for this research.

- 1) To find out which social networks most often used by patients with chronic health conditions.
- 2) To evaluate how patients with chronic health conditions utilise online healthcare information.
- 3) To find out how healthcare companies can better engage with patients who live with chronic health conditions.
- 4) To determine demographic differences in adoption of online social media tools used by patients with chronic health conditions.

## II. METHODOLOGY

The patient population studied in this research project consists of a sample from 8000+ patients who have a chronic health condition. Approximately 11% of these patients are cared for by another individual, either their parent or spouse. A survey was conducted in 2013 as part of a Direct to Patient prescription service audit; this was a requirement by the Department of Health. The resulting patient demographic profile was obtained based on this survey; there were 258 respondents.

The survey indicates that nearly 2/3 of the patients are over 65 years of age. One key factor that determines the degree of internet usage and adoption is age. This might suggest that these patients are relatively low social network users. One-third of the patients in this survey were female, and according to [36] being female increases your likelihood for online seeking of health information. However [41] found that being middle aged was associated with increased internet use in the

context of health care [41]. Taken together this research suggests that the population under study will have a good mix of online and off-line information seekers.

The analysis that follows uses correlation coefficients to test the relationship between two variables [18]. These variables are either positively or negatively correlated and correlations can range in their strength from weak to strong. For this research project weak correlations are taken as below 0.35 (positively or negatively) and correlations above 0.65 (positive or negative) are taken as strong (see, for example, [18]). Correlation analysis explores the extent to which two variables are related to each other without assuming causality. The purpose of performing a correlation is to enable a prediction about one variable based on what is known about another variable; if two variables are strongly correlated then a prediction of the movement of one can be based on the other [18].

For this research project the chosen method will need to produce results that are highly replicable if an understanding is to be gained about a wider chronic long term patient population and their behaviours. To be able to make management decisions relating to the findings of this research a statistical approach will be needed [30]. Hence the quantitative approach will be chosen. The requirement for a large and relatively easy to reach sample frame further supports the quantitative approach; as the 8000+ patient database allows for a relatively large patient sample to be taken. Therefore the quantitative research method represents the most opportunistic and practicable method. For this research project the probability sampling method that will be chosen is systematic sampling because this is simpler to implement. From the database of 8000+ patients an initial sampling frame will be selected consisting of patients with chronic conditions only. This excludes short term patients and allows for a systematic sampling method to select a more manageable sample before conducting a survey.

Focusing on a specific disease or condition can produce patients that are not representative of the population. This is because not everyone with a condition has consulted a doctor or specialist about their condition. This might be an important consideration in the context of this research project because patients who seek online or offline healthcare information before seeing the clinician may satisfy their information needs and therefore choose not to see the doctor or specialist. The sample here will only include chronic or long term patients that have consulted with a doctor or specialist thus introducing a degree of bias. Both time and cost constraints prohibit being able to sample patients who have not visited clinicians, as discussed already.

## III. ANALYSIS AND FINDINGS

The 8000+ database was screened for respondents who were greater than 16 years old and who had ordered products recently meaning that they were current users. Each of the respondents was checked to ensure that they were long-term users by showing that their date of first registration, on the database, was greater than 12 months. This process produced a sampling frame containing 3,767 records.

Using a stratified sampling technique, where every 6<sup>th</sup> patient was selected, a sample of approximately 628 subjects was produced and then targeted with the questionnaire. One hundred and forty five questionnaires were completed with an additional 13 responses which were deemed incomplete. The overall response rate was 25%.

The majority of the sample was from the 55+ age brackets with 25% aged between 55 and 64 and 52% aged 65+. Table I shows the percentage split of the research sample in comparison with the DOH sample. The gender split across each of the age bands was also fairly evenly split except for the 65+ age band which was male dominated, possibly reflecting disease specific demographic trends such as prostate related conditions in older males.

There was some general hypothesis tested using correlation analysis and t Test for independent samples. regarding age, self-efficacy and time within this study.

The following are the hypothesis, results and related discussion thereof.

Hypothesis H1A: Age has a positive effect on health information seeking behaviour online

This was tested against high seeking versus low seeking health information. The correlation analysis suggested that there was a negative correlation between age and health information seeking behaviour meaning that as age increased online information seeking decreased. The t-test performed in this analysis suggested that there was not a significant difference ( $p = 0.068$ ) between those patients classified as high information seekers and those classified as low information seekers online. There was not enough evidence to reject the null hypothesis. As such this was a non-significant finding.

According to [3] age, education and wealth were all associated with increased Internet use. Age was a key factor that discriminated between online and off-line information seekers [3]. The internet adoption rate for 65+ year old patients, the group most represented in this research sample, was twice the level found by the Office for National Statistics (20% vs 10%) [21]. This suggests that patients with chronic health conditions are more likely to use the internet compared to the general population. This did not seem to overcome the negative correlation with age. [31] described a measure of demand as an increase in clinical consultations. What therefore is a true measure of demand? The measure for demand must depend on what outcomes patients expect as a result of healthcare information seeking. This research project repeated [31] work with kinship (off-line) versus friendship networks being compared. However as the number of online general Internet users is so high in this research project (see Fig. 3) it is difficult to screen for 'off-line only' users. The 'Non Significant Finding' therefore may not be a surprise. One of the limitations of this research project was that these patients had already received a diagnosis and treatment. This made measures for of demand for (increased GP consultations) difficult to draw from this cohort.

Hypothesis H1<sub>B</sub>: Increased patient self-efficacy is associated with increased demand for healthcare.

TABLE I. RESEARCH SAMPLE OF AGE SPLIT

| Age Split (yrs) | Research sample | DOH sample |
|-----------------|-----------------|------------|
| 16-24           | 2%              | 2%         |
| 25-34           | 4%              | 2%         |
| 35-44           | 7%              | 3%         |
| 45-54           | 9%              | 9%         |
| 55-64           | 25%             | 20%        |
| 65+             | 52%             | 64%        |

This was tested against high versus low demand for healthcare. According to the correlation analysis matrix reported self-efficacy was only linked to age, being negatively correlated ( $p = 0.397$ ). This means that as patients get older their self-efficacy decreases. Whilst there was a good sample size here there was not enough evidence to reject the null hypothesis. The result was therefore not significant.

The key issue with demand for health care is that increasing demand may lead to increase in self-efficacy and this means that patients are less likely to seek health care professional opinions [7]. The findings from this research project suggest that age is negatively correlated with self-efficacy and online information searching; this implies that a younger age group are more likely to search online for health information and take charge of their own health care decisions. This research project concurs with the conclusion in. The author in [3] found in their study that age is negatively correlated with online health information seeking and self-efficacy.

The following hypothesis tests the reported relationship between time on line and demand for healthcare.

Hypothesis: There is a positive relationship between time spent online and demand for healthcare.

This was tested against patients either spending a low amount of time or a high amount of time. Time spent online and demand for health care was supported both by the correlation matrix analysis and by the t test ( $p = 0.011$ ) (one tailed) that was conducted on this research sample. There was evidence to reject the null hypothesis. There was a positive correlation observed between time spent online and demand for health care. Hypothesis H1c also confirmed that there may be a causal link between time spent online and demand for healthcare. This was a significant finding at the 5% level.

## Section 2 Offline and online networks by type

The following hypotheses were used to test the differences between use of two online and two offline forms of information seeking. The following diagram (Fig. 1) maps the two dimensions of on-line and off-line and the amount of active participation. It shows the four possible outcomes from the combination of these two dimensions.

The following represents the hypothesis D, E, F, G, H, and I, the results and the related discussions.

Hypothesis: Patients seeking healthcare information online are more demanding than patients seeking healthcare information offline.

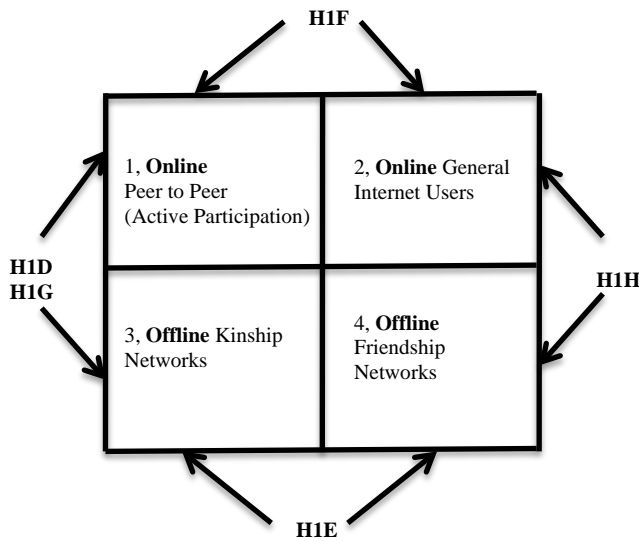

Fig. 1. Offline and Online Networks by Type.

Further exploring demand for healthcare when patients seek healthcare information online using the Chi squared test indicated that there is a statistically significant effect (Chi Squared Test Result:  $p = 0.023$ ) on health care demand compared to patients seeking healthcare information offline. As already discussed the only correlation found with online healthcare information seeking through the correlation matrix analysis was with age where a negative correlation was noted. There was evidence to reject the null hypothesis. This was a significant finding.

This is a significant result and concurs with the results obtained in previous studies [36], [13]. [36] found that searching for healthcare information online has a positive, relatively large and statistically significant effect on demand for healthcare and [13] found that online searches resulted in specific demands for cancer treatments. However this result does not rule out the possibility that patients who seek healthcare information offline are simply less interested in healthcare and those who utilise online methods are more interested.

Hypothesis H1<sub>E</sub>: Increased healthcare information seeking behaviour within online peer to peer patient networks results in increased demand for healthcare, compared with offline 'Kinship' based networks.

The Chi squared test result confirmed that there was no significant difference between online peer to peer networks and offline kinship networks. From this result offline kinship and online peer-to-peer networks cannot be distinguished and have a similar effect on demand for healthcare (Chi Squared Test Result:  $p = 0.487$ ). It is noteworthy that the balance between high and low demand was about equal whereas the split between high and low GP consultation rates in the research sample was 0.62:1 Overall there was not enough evidence to reject the null hypothesis. This was a Non-significant finding.

Hypothesis H1<sub>F</sub>: Patients taking part in offline 'kinship' based networks are more demanding than patients taking part in offline 'friendship' based networks.

The correlation matrix analysis, discussed already, concluded that there was no correlation ( $p = 0.500$ ) between the tested factors with demand for health care. There was no difference observed between off-line kinship and off-line friendship networks. This was a surprise as this test was a repeat of the research done by [31]. It can only be concluded that either the sample size was inadequate to show a statistically significant difference or there is an effect associated with long term chronic conditions which was not evident in the research conducted by [31] and her team. Overall there was not enough evidence to reject the null hypothesis. This was a Non-significant finding.

Hypothesis H1<sub>G</sub>: Patients taking part in online peer to peer networks are more demanding than patients who don't participate in online networks.

The correlation matrix highlighted sharing and engaging online, in other words participating in peer to peer networks, as being positively correlated (Chi Squared Test Result: P value = 0.723) to online information seeking. However a more detailed Chi Squared test did not find a relationship. There was not enough evidence to reject the null hypothesis. This was a Non-significant finding.

Hypothesis H1<sub>H</sub>: The use of non-participatory online networks results in greater demand for healthcare compared with offline friendship based networks.

Chi Squared Test Result: P value = 0.909. The Chi squared test used to compare non-participatory online networks with off-line friendship based networks showed that there was not a statistically significant difference between these two network types. This may be an expected result if there was no 'internet effect' on demand for healthcare when comparing two similar networks whether they be online or offline. A better understanding of the 'internet effect' can be gained by contrasting this result with hypothesis H1<sub>E</sub> which similarly attempted to measure whether there was an 'internet effect' or whether there was a 'social network effect' on demand for healthcare. There was not enough evidence to reject the null hypothesis. This was a Non-significant finding.

Hypothesis H1<sub>I</sub>: The use of social media tools increases demand for specific treatments compared to offline networks.

The Chi squared test was used to establish whether social media tools increase demand for specific treatments. A comparison was made between two cohorts; one that adopted social media tools and one that did not. Whilst there was no significant difference found (Chi Squared Test Result: P value = 0.894), it could be seen that the cohort that adopted online tools within this research project was small for both high and low demand ( $n = 10$  and  $n = 11$  respectively). There was not enough evidence to reject the null hypothesis. This was a Non-significant finding.

Demand for specific treatments as a result of using social media tools represents a significant opportunity for commercial companies. The author in [13] highlighted that this was indeed the case for patients with colon cancer (S. W. Gray, et al., 2009). This research project specifically examined the demand effect for patients with chronic conditions - hypothesis H1<sub>A</sub> above. The measure for demand in this instance, GP consultations, was appropriate as patients who want specific treatments as a result of searching for information online would need to see their clinician. The null hypothesis was accepted. This implies that this patient group are not demanding specific treatments as a result of online searches. The author in [37] in his comparison of online with offline information seeking in older patients and suggests that healthcare decisions based on information obtained 'offline' are more probable in this patient group [37]. Unlike the colon cancer study [13], this patient group was older and perhaps seeking healthcare information offline is more appropriate. This research project explored offline kinship and friendship networks to see if there was a link between offline information searches and healthcare demand (Hypothesis H1<sub>D</sub>), however none was found for this research sample. It is therefore not possible to confirm either [13] or [37] research findings for patients with chronic conditions. This may be that the number of active participants in peer to peer networks in this survey was low as discussed in the limitations of this research.

#### Discussion of findings

Hypothesis H1<sub>D</sub> looked at online versus off-line information seeking and its effect on demand. Based on hypothesis H1<sub>D</sub> this research project supports the idea that utilising the internet compared to offline methods for seeking healthcare information does have a significant effect on demand for healthcare. The result from this research project suggests that some patients seek healthcare information online and in particular younger patients gain a degree of self-efficacy which potentially results in these patients seeking more GP appointments. According to [26], "internet users are more likely to expect they could obtain reliable information about health conditions compared to non internet users" [26]. This result supports the case for a higher degree of motivation amongst online information seekers to seek healthcare information and then do something with that information, for example seeking a clinician appointment. This confirms the results obtained by [36] in that searching for healthcare information online has a positive, relatively large and statistically significant effect on demand for healthcare [36].

Taking Hypothesis H1<sub>E</sub> as a non-significant result; implies that kinship and online peer-to-peer patient communities have no significant difference in the way they act in the context of demand for healthcare. The results from hypothesis H1<sub>E</sub>, non-significant result, when combined with Hypothesis H1<sub>E</sub> infers that there is no 'social network affect' on demand for healthcare, whether that be peer-to-peer or kinship based.

Hypothesis H1<sub>E</sub> was intended to repeat of the work done by [31]. However in comparing the kinship and the friendship networks this hypothesis did not show a statistically significant (off-line) effect.

This again raises the question as to the validity of demand as measured by GP consultation rates. Another explanation is that perhaps patients seeking information online in this research project simply want to explore their current acute condition, a condition that is unrelated to their underlying chronic condition. Overall, however, this research project found no evidence to support peer-to-peer or kinship based influence on demand for healthcare. This concurs with a review [9] which failed to find robust evidence for the benefits of virtual communities about health outcomes [9].

The remaining tests covered by hypotheses H1<sub>F</sub>, H1<sub>G</sub>, and H1<sub>H</sub> resulted in non-significant results. Therefore it is not possible to accept any difference in these methods of information seeking. In particular it is not possible to find a difference between the use of peer to peer networks and general internet searches in increasing demand for health services. This lack of significance is a challenge to the development of the use of peer to peer sites in this context. The following test therefore investigates the demand for specific treatments in the use of social media.

The table (Table II) highlights the summary outcomes of the correlation analysis. What follows is a detailed discussion on the results.

#### Results for Research Objective 1:

To find out which social networks most often used by patients with chronic health conditions.

TABLE II. SUMMARY RESPONSE FROM THE CORRELATION ANALYSIS

| Factor                      | Correlation                              | Pearson's Correlation Coefficient | Strength of Correlation | Sig. (p value) |
|-----------------------------|------------------------------------------|-----------------------------------|-------------------------|----------------|
| Age                         | <i>Self-Efficacy</i>                     | -0.437                            | Moderate                | P = 0.014*     |
|                             | <i>Online Information Seeking</i>        | -0.414                            | Moderate                | P = 0.021*     |
| Online Info Seeking         | <i>Time Spent Online</i>                 | 0.386                             | Moderate                | P = 0.032*     |
|                             | <i>Sharing Health Information Online</i> | 0.404                             | Moderate                | P = 0.024*     |
|                             | <i>Engaging With Others Online</i>       | 0.371                             | Moderate                | P = 0.041*     |
| Offline Info Seeking        | <i>Sharing Health Information Online</i> | -0.556                            | Moderate/Strong         | P = 0.001**    |
|                             | <i>Engaging With Others Online</i>       | -0.523                            | Moderate                | P = 0.002*     |
| Sharing Health Info Online  | <i>Offline Social Networks</i>           | -0.367                            | Moderate/Weak           | P = 0.043*     |
| Engaging With Others Online | <i>Offline Social Networks</i>           | -0.404                            | Moderate                | P = 0.024*     |

From the research sample the respondents could be attributed to each of four categories that are online P2P users, Online general users, Offline Kinship, Offline friendship networks and Offline social networks were easy to identify. However it was difficult to establish whether respondents using ‘offline’ networks ever used the internet for health purposes. Some patients inevitably do and this is reflected by a large ‘online general users’ group.

Referring to section 2.4 and the D.I.D.A. model it was noted that patients who were empowered, ie had a high degree of self-efficacy, may demand more healthcare. According to the D.I.D.A. model if the patient has a positive experience with ‘apomediary’ websites, their knowledge or self-efficacy will increase and the patient will feel more empowered. Consequently their reliance on clinical experts will decrease. Table III highlights websites that respondents in this research project described as ‘favourites’ and therefore have the potential to act as apomediary websites. Of note is that this research uncovered that very few patients (just over 5%) said they regularly visited a ‘favourite’ health website.

Apomediary websites are used to enable patients to become both more self efficacious and autonomous meaning that they depend less on clinicians, known as intermediaries in the Eysenbach’s D.I.D.A. model [7]. The principals of the D.I.D.A. model mean that clinicians today are gatekeepers to treatment whereas previously they were also gatekeepers for information. This information is now being made available online. As internet adoption increases and healthcare information seeking becomes more prevalent so then does the empowering force of the internet on the demand for specific treatments.

Summary Response: Evidence to support adoption of both online and offline networks, however scanty evidence to support adoption of favourite or ‘apomediary’ websites.

TABLE III. LIST OF ‘APOMEDIARY’ WEBSITES

| Website                                                                                                                                         | Description                                    | Number Cited |

Results for Research Objective 2:

To evaluate how patients with chronic health conditions utilise online healthcare information.

It was concluded from hypothesis H1<sub>F</sub> and H1<sub>G</sub> that patients who spend significant time on the internet experience an increase in demand for healthcare. Seeking information online made patients more demanding than patients who seek healthcare information offline. This objective, however, seeks to understand how patients with chronic health conditions use online healthcare information; i.e. does it lead to specific requests for treatment or is it used to comment on other patients’ health situation?

Fig. 2, highlights the extent patients with chronic conditions seek healthcare information online and offline. In this research project there was a 60:40 split between online and offline information seekers in favour of online information seekers.

Patients with chronic conditions, approximately 19%, view other patients’ experiences through online communities, and approximately half of this group will either share their own health experience or comment on others health experiences through these communities. See Fig. 3:

Disclosure of new treatments, such as a possible cure for multiple sclerosis, can drive popularity of social media; it follows that like-minded consumers come together and potentially influence other patients through viral marketing [10]. [4] found that social networking provides ‘social incentives’ meaning that there is a motivation for patients partaking in the sharing of information and engaging with others online [4].

Summary Response: A relatively small but significant proportion of patients view, share and engage online with other patients though patient led communities.

Objective 3

To find out how healthcare companies can better engage with patients who live with chronic health conditions.

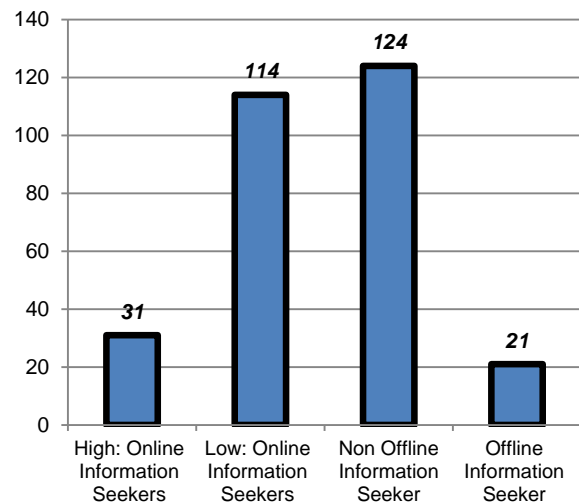

Fig. 2. Online and Offline Information Split by Level.

Fig. 3. Viewing, Sharing and Engaging Online.

Companies operating in health care could influence consumer behaviour in several ways based on the findings within this research project. Patients or consumers are potentially most open to influence if they are high internet users, or prefer to take part in peer to peer interactions online with other like-minded patients rather than sharing their symptoms within offline kinship based networks. It is known from this research that patients who use online search methods demand more healthcare than patients who adopt offline methods. It is also known that the more time a patient spends online the more demanding the patient becomes. Patient forums are popular with some patients and indeed these forums or communities encourage patients to spend more time online. Whilst this research project failed to show a correlation with peer to peer networks and demand for healthcare; a relationship between time spent online and P2P network usage was shown to exist, see Table IV.

Patients using P2P communities spend more time online. This may be a consequence, albeit not proven in this research project, that patients who use these networks may be more demanding of healthcare as a result of the time spent online. If healthcare companies encourage patients to utilise P2P communities via their own websites then this may encourage increased time spent online and consequently encourage an increase in demand for healthcare e.g. demanding specific treatments.

TABLE IV. PEER TO PEER USAGE ACCORDING TO TIME SPENT ONLINE

| Actual Result            | P2P non user | P2P User | Total | Exp. Result              | P2P non user | P2P User | Total |
|--------------------------|--------------|----------|-------|--------------------------|--------------|----------|-------|
| Time Spent Online = High | 11           | 9        | 20    | Time Spent Online = High | 16           | 4        | 20    |
| Time Spent online = low  | 101          | 18       | 119   | Time Spent online = low  | 96           | 23       | 119   |
| Total                    | 112          | 27       | 139   | Total                    | 112          | 27       | 139   |

Chi Squared Test Result: P value = 0.0018\*

\* significant at 1% level

Summary Response: Evidence to support the link between P2P network usage and time spent online but insufficient causal evidence to support P2P network usage and increase demand for healthcare.

Objective 4

To determine demographic differences in adoption of online social media tools used by patients with chronic health conditions.

TABLE V. GENDER SPECIFIC INTERNET ADOPTION RATES

| Gender | High Internet Adoption (n) | Low Internet Adoption (n) | Percentage High Adoption |
|--------|----------------------------|---------------------------|--------------------------|
| Female | 12                         | 43                        | 22%                      |
| Male   | 19                         | 68                        | 22%                      |
| Total  | 31                         | 111                       | 22%                      |

The table (Table V) highlights the fact that there were no gender differences in internet adoption rates in this research sample. The author in [15] found that females were more likely to use the internet for health related information than males and were more likely to belong to patient support groups [15]. This effect was not observed in this research project, possibly a reflection of the smaller size of the female segment.

TABLE VI. GENDER SPECIFIC SELF EFFICACY I.E SEEKING DISEASE AND TREATMENT INFORMATION

| Statistical Comparison     | Variable               | Comparison | Sample Size | Mean | Variance | P value one tailed |
|----------------------------|------------------------|------------|-------------|------|----------|--------------------|
| t Test independent samples | Gender & Self Efficacy | Female     | n = 55      | 3.51 | 0.82     | p = 0.063          |
|                            |                        | Male       | n = 87      | 3.10 | 1.26     |                    |

This table (Table VI) illustrates gender specific differences in self-efficacy, known to be a key factor in demanding more healthcare information and potentially asking the GP for specific treatments. Statistically there are no gender specific effects for self-efficacy.

Summary Response: There was evidence to support increased internet adoption rates according to defined age bands, indicating that being unwell increases likelihood of internet use compared to the general population. There were no gender differences noted.

Research Question

Have online social media tools affected demand for healthcare in patients who experience chronic medical conditions?

This research project provides evidence to support the idea that searching for healthcare information and spending more time online has positive effects on demand for healthcare amongst patients who live with chronic medical conditions. Patients who have chronic conditions spend more time online than the general population. Patients who take part in online peer to peer communities are more trusting of healthcare

information obtained in an online setting. There was a causal link between time spent online and Peer to Peer network adoption. Spending time online was shown to have a positive effect on demand for healthcare. This research project also highlighted that younger patients are likely to become more self-efficacious and this potentially translates into a greater autonomy relating to their healthcare treatment decisions. In future these younger patients will age and replace the older generations with their social networking preferences. These patients will spend increasing time on peer to peer communities and as a consequence their demand for healthcare in general for treatments specifically will increase. The patients of the future will therefore depend less on their doctor for healthcare or product information and see the doctor as simply a gatekeeper for accessing treatments. The doctors of the future will experience patients who are more demanding, not necessarily for health information but for specific treatments.

TABLE VII. OVERVIEW OF HYPOTHESIS, TEST TYPE, P VALUES AND OUTCOME

| Hyp             | Detail                                                                                                                                                                                                          | Statistical Comparison     | P value   | Null Hypothesis Accepted or Rejected |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|-----------|--------------------------------------|
| H1 <sub>A</sub> | Age has a positive effect on health information seeking behaviour online                                                                                                                                        | t Test independent samples | p = 0.068 | Accepted                             |
| H1 <sub>B</sub> | Increased patient Self Efficacy is associated with increased demand for healthcare                                                                                                                              | Linear Regression          | p = 0.397 | Accepted                             |
| H1 <sub>C</sub> | Patients taking part in increased healthcare information seeking behaviour within online peer to peer patient networks seek more GP consultations compared with patients using offline 'Kinship' based networks | Chi Squared Test           | p = 0.487 | Accepted                             |
| H1 <sub>D</sub> | Patients taking part in offline 'kinship' based networks are more demanding than patients taking part in offline 'friendship' based networks                                                                    | Chi Squared Test           | p = 0.500 | Accepted                             |
| H1 <sub>E</sub> | Patients taking part in online peer to peer networks are more demanding than patients who don't participate in online networks                                                                                  | Chi Squared Test           | p = 0.728 | Accepted                             |

|                 |                                                                                                                                       |                            |            |          |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------|----------------------------|------------|----------|
| H1 <sub>F</sub> | There is a positive relationship between time spent online and demand for Healthcare                                                  | t Test independent samples | p = 0.011* | Rejected |
| H1 <sub>G</sub> | Patients seeking healthcare information online are more demanding than patients seeking healthcare information offline                | Chi Squared Test           | p = 0.023* | Rejected |
| H1 <sub>H</sub> | The use of non-participatory online networks results in greater demand for healthcare compared with offline friendship based networks | Chi Squared Test           | p = 0.909  | Accepted |
| H1 <sub>I</sub> | The use of social media tools increases demand for specific treatments compared to offline networks                                   | Chi Squared Test           | p = 0.894  | Accepted |

\* significance at 5% level

The table (Table VII) highlights the hypotheses tested, the test, result and the outcome pertaining to the acceptance or rejection of the hypotheses.

#### IV. LIMITATIONS OF RESEARCH

The sample targeted represented patients that all had chronic long term conditions. This was identified by them being on treatment for a significant length of time; unfortunately this also meant that these patients were not recently started on treatment. Therefore the possibility exists that these patients might have referred to health conditions that were not related to their primary diagnosis when completing this questionnaire. This could have affected their interpretation of the questions which would have a negative effect on the validity of the results obtained.

The literature clearly suggested that there were differences in demand noticed as a result of the use of social media tools. However there remains the possibility that patients may perceive to have their demand for healthcare satisfied through their online search for healthcare information. Thus resulting; however, in a decrease in essential GP consultation, a key outcome of demand. However there is a significant likelihood that misinformation and mis-diagnosis can result in further complications due to the reduction of GP consultations.

For companies in healthcare that currently have no social media policy, any patients registered on the company's Direct To Patient service, would find very limited information on products through social media. In contrast other manufacturers in the healthcare sector that do have a social media policy may be at an advantage. Potentially this creates a bias in so much that patients who are familiar with social media tools may 'prefer' products from manufacturers who have a social media policy. This introduces a potential bias in this study whereby

the testing of patients from other healthcare Direct To Patient Services with social media provision was not undertaken.

## V. CONCLUSION

1) *The changing doctor-patient relationship:* From this research paper the link between age and sharing and engaging online was unproven. Age was however negatively correlated with online information seeking behaviour and self-efficacy. This implies that the younger patient is taking more control of their health and seeking more information online, a trend that is likely to increase as these young patients become old patients.

2) *The patient as the new decision maker:* More than ever before it is possible to listen to the consumers' voice through either producer or community led communities and acting on their feedback. Involving the patient in the product or healthcare decision making process serves to not only add value but can improve healthcare outcomes especially patient compliance. In an attempt to overcome poor compliance it has been suggested that patient involvement through the concordance model would achieve greater self-efficacy [39]. A concordance between the expert and the patient requires the mutual adoption of the treatment regime. This mutuality often requires a positive efficacious embrace of the adopted solution. The consequence of this is that patients often are now much more demanding of their healthcare professional; appointment times are however increasing due to Covid and demands upon healthcare professionals are ever more stretched meaning that the burden of responsibility for patient knowledge and healthcare choices falls increasingly upon the patient [3]. The key here being that the patient can contribute more, regarding symptoms that can better inform the GP to enable more accurate diagnosis. As already discussed self-efficacy is negatively correlated with age but was not shown to be related to demand for healthcare in this research project. The issue of measuring demand was discussed and a further understanding of outcomes expected as a result of online searches is needed.

3) *A model for seeking Health information:* Eysenbach's D.I.D.A. model explored the idea of relying on apomediarities [7]. These may be specific 'one stop shop' websites or peer to peer networks. It was apparent from this research project that patients taking part in patient peer to peer communities either online or offline were no more demanding in terms of GP consultation requests. There was no 'network effect' observed offline which contradicted [31] work. It can be concluded that modern day healthcare information seekers behave differently to the kinship of friendship networks observed by [31].

4) *Healthcare information seeking increases demand for health care:* Spending more time online, from this research project, was shown to have a positive effect on demand for healthcare. It was also demonstrated that patients seeking healthcare information online were more demanding than patients who seek healthcare information offline, meaning that patients who spend time online and seek healthcare

information are likely to seek more GP consultations. However whilst these patients are consulting more with their GP they are not, according to this research, demanding specific treatments.

## Recommendations

Concerning the patient population in this study; patients who experience ongoing changes in their treatments as a result of their condition (e.g. MS patients - whose condition evolves over time) may have been a better group of respondents to judge the effectiveness of social media and its influence. Given the difficulties in determining demand for healthcare inherent in this research project, a re-examination of the research philosophy is suggested. The chosen philosophy was positivism as this emphasised the value of predicting outcomes of the research so that these variables might be controlled in future. According to [36] at the root of the positivist research philosophy is the law of cause and effect [36].

Examples of cause and effect in this research project are:

- 1) Social networks 'cause' an increase in healthcare information seeking behaviour - the 'effect'
- 2) Age 'causes' increase in healthcare information seeking behaviour - the 'effect'
- 3) Spending time online 'causes' an increase in demand for healthcare - the 'effect'

Essentially, and as discussed previously, assumptions were made about what causes demand and what 'demand' is in the context of healthcare. Therefore a better way of determining the factors or 'causes' that are likely to predict the outcome, the 'effect' is needed. According to [36] greater organisational or online market complexity, with the online/offline environment, would lead towards an interpretivist approach [36]. Referring to interpretivism makes it necessary to conduct research in the online environment in order to understand what is going on among the markets 'social actors'; people who play a part on the stage of online and offline information seeking. Building on the correlation analysis the demand for healthcare could be further explored using an interpretivist approach to better understand what patients with chronic conditions are looking for.

This research project represents a snapshot in time of people's current internet adoption rates. Therefore as age and usage of technology increases in future, the age correlation is expected to become less negative meaning that patients across all levels will have greater self-efficacy in their online searching behaviours. This means that the younger patient with a chronic condition will, if they stay with the company's Healthcare's DTP service, become the next older patient generation and as such be more accustomed to using online search tools.

The author in [23] suggests that a stronger bond between producer led and customer (the patient) led community interactions will better enable both an understanding and adaptation of the marketing message. The findings from this research project suggest that peer to peer communities are more trusting of online information and spend more time

online; typically these patient groups are patients with chronic conditions. These patient led communities represent an opportunity to augment the traditional direct marketing interface which represents a producer: customer interaction. This may take the form of directing patients to the company's own website which may not contain traditional marketing or product related information but rather contains the resources required for the patient to begin to see the company website as a 'one stop shop' or favourite website, known as an apomediary website. This would provide the patient with the patient networks and information needed to help the patient form positive impressions of the website, and the company that produced it. Ultimately the patient will express a preference for the company's products once they visit their GP.

## VI. FUTURE RESEARCH

From this research project it is clear that more work would need to be done to corroborate the motivation patients have for seeking healthcare information online and how this translates into more demand for healthcare. Thus:

Establishing the motives for healthcare information seeking through a qualitative analysis and structured interviews would prove insightful.

Exploring the extent to which patients with chronic conditions depend on the internet and social media tools would also prove invaluable.

This research project looked at patients who had already received their primary diagnosis. What happens to patients before that diagnosis? Is it possible that patients who were prolific internet users prior to receiving their initial diagnosis and once established on treatment their internet usage waned? This research project was unable to establish internet and social media tool usage prior to the patients receiving treatments.

It is well known that an established friend on Facebook follows an 'offline to online' trend with people making friends offline first and then later adding them online [27]. Does the same 'offline to online' affect exist with patients who have long term conditions such as spinal cord injury? For example do these patients later connect online with other patients met 'offline' within spinal cord units?

According to [22] Social psychologists make a distinction between different attitude levels with the deepest being referred to as personality, followed by values then attitudes with the most superficial being referred to as opinions [22]; establishing the effect of the patients' personality on social media usage, for example the degree of extroversion or introversion. Could this be a motivation to experiment with seeking online health information rather than utilizing established offline methods? Conversely introversion is associated with a greater dependence on Facebook for communicating with and establishing friends (Orr et al.,2009); could the same influence exist with patients with chronic conditions?

It would be valuable to establish a long term view of how patients with chronic conditions use social media tools post

Covid, particularly as this study was pre-Covid. This research project took a cross sectional view on social media adoption. A longitudinal study could follow the patient's use of social media tools from before diagnosis to a time period where the patient was established in terms of both their condition and treatment. This would give invaluable insights into the patient's use of social media tools.

This research project only looked at patients with long term conditions; it would also be helpful to consider patients with short term acute conditions to establish differences in motivations for seeking healthcare information and support.

An underlying tenet of this study was that use of social media tools affects demand for healthcare. It was assumed that demand could only be in the form of seeking clinician appointments or specifically asking for treatments. Additional needs affecting demand may also exist particularly with patients using peer to peer networks.

# Predicting Cyber-Attack using Cyber Situational Awareness: The Case of Independent Power Producers (IPPs)

Akwetey Henry Matey<sup>1</sup>, Paul Danquah<sup>2</sup>, Godfred Yaw Koi-Akrofi<sup>3</sup>  
Department of I.T. Studies, University of Professional Studies, Accra (UPSA), Ghana<sup>1,3</sup>  
Department of I.T. Heritage Christian College, Accra, Ghana<sup>2</sup>

**Abstract**—The increasing critical dependencies on Internet-of-Things (IoT) have raised security concerns; its application on the critical infrastructures (CIs) for power generation has come under massive cyber-attack over the years. Prior research efforts to understand cybersecurity from Cyber Situational Awareness (CSA) perspective fail to critically consider the various Cyber Situational Awareness (CSA) security vulnerabilities from a human behavioural perspective in line with the CI. This study evaluates CSA elements to predict cyber-attacks in the power generation sector. Data for this research article was collected from IPPs using the survey method. The analysis method was employed through Partial Least Squares Structural Equation Modeling (PLS-SEM) to assess the proposed model. The results revealed negative effects on people and cyber-attack, but significant in predicting cyber-attacks. The study also indicated that information handling is significant and positively influences cyber-attack. The study also reveals no mediation effect between the association of People and Attack and Information and Attack. It could result from an effective cyber security control implemented by the IPPs. Finally, the study also shows no sign of network infrastructure cyber-attack predictions. The reasons could be because managers of IPPs had adequate access policies and security measures in place.

**Keywords**—Internet of things; cyber situational awareness; critical infrastructures; power generation; cyber-attack; cyber security; human behavioural and independent power producers

## I. INTRODUCTION

The massive application of IoT on the electrical grid opened up a huge opportunity to utilize previously untapped processing power to offload custom applications directly to other devices. These transformations are not achievable without experiencing some form of security vulnerabilities on the grid ([1], [2]), even though deploying these business applications on the grid will increase the overall robustness of the grid and reduce communication overhead. A recent attack in 2016 on the Ukrainian power grid was an advanced form of hacking the CI by the Russians extending their intrusion to increase control using the “Crash Override”. A related attack occurred in March 2016, compromising the command-and-control (C&C) system on the New York Dam with a cellular phone. The Stuxnet attack also created awareness of potential cyber threats on power generation companies[3], impacting the grid's reliability [4]. According to [5], various

forms of cyber-attack concerning the grid are man-made manipulation. Raikuma, et al [6], have indicated the need to avoid such incidents due to the ripple effects of a power system shutdown. The growing investment of human capital and financial resources injected into CI protection shows the extent to which industry players and the research community understand CI challenges. The increased investment in the sector calls for the need to evaluate cyber situational awareness (CSA) from a human behaviour perspective since the critical infrastructure (CI) falls within a dynamic changing environment. CSA can assist in comprehensively investigating an approach to the ongoing debates relating to cyber security. Cyber awareness for cyber defence generally requires perception, understanding and projection. CSA creates room for predictions in line with an action sequence and effectively plans for new cyber-attacks trends. Hence, the need to identify activities of interest to maintain awareness of a new paradigm in cyber defence. According to Franke and Brynielsson [7], CSA is comparable to insider informants leaking information on an imminent attack. Prior studies had also revealed a range of cyber incidents stemming from minor employee mistakes, misinformation on controls, and highly coordinated, well-planned attack on the critical infrastructure ([1], [8]–[10]). Johnson and Banfield [11] revealed that current cybersecurity defences cannot match the sophistication of embedded technologies attacks capabilities. Hence, the need to evaluate cyber situational awareness (CSA) from human behaviours perspective to predict, detect, and prevent cyber-attack vulnerabilities in a dynamic power generation environment. The concept of cyber situational awareness can be situated based on the insight of individual abilities to distinguish and assess current and future effects in terms of how situations evolve from an attacker's perspective to understand and restrict cyber vulnerabilities [12]. Prior research has made an immense contribution in applying various technologies to support critical cyber incidents. Yet, today's cybersecurity challenges in the power generation sector are increasing and becoming more sophisticated and alarming than we think in the power sector ([5], [13], [14]). The introduction of intelligent information technology equipment such as the Internet of things (IoT) devices and other industrial control systems (ICS) enabled the power generation grid to become more effective and intelligent ([3], [15], [16]). Fig. 1 depicts a visual overview of a possible cyber-attack on the generation and distribution section of the power grid.

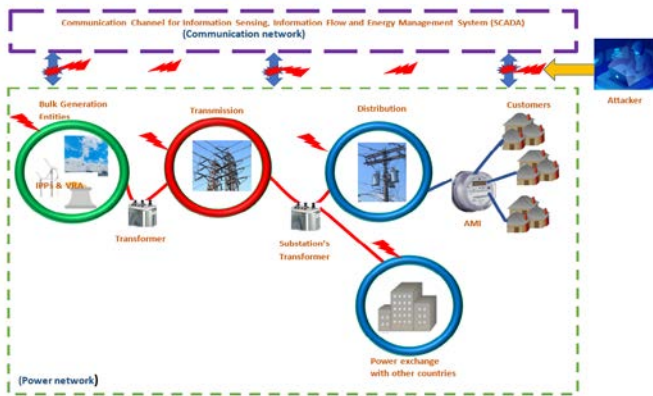

Fig. 1. Smart Grid Perspective in Ghana Source: Authors' Construction (2021).

Based on the above discussion, this current study seeks to establish how CSA elements (Network, Information and People) influence cyber-attacks in the power generation environment in perspective. Digital trust links people, data, and networks [17]. The specific objectives of this study are therefore to:

- 1) Evaluate how staff perceives potential cyber threats in their working environment.
- 2) Evaluate information vulnerabilities and how they influence cyber Attack.
- 3) Assess how cyber situational awareness network vulnerabilities contribute to cyber Attack.

## II. LITERATURE REVIEW

### A. Theoretical Review

Endsley [18] gave three (3) levels of indication to assist in forming a mental model of having a more comprehensive view of an operational environment, as shown in Fig. 2.

In our effort to evaluate cyber situational awareness from human behaviour in an IPPs environment, the authors consider the base of the variable in the conceptual framework in line with the considerations in Table I and Fig. 3.

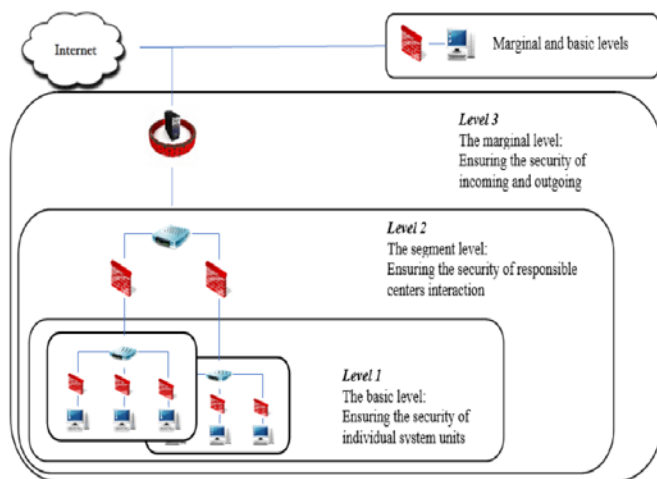

Fig. 2. A Model for Understanding Operational Situation by Endsley.

TABLE I. SHOWS THE MAP OF AUTHORS CONSIDERATIONS AND ENDSLEY

| Focus | Endsley                                   | Authors Considerations                                                                                                  |
|-------|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| 1     | Security of individual systems            | Security from human behavioural in context interacting with the system of the IPPs                                      |
| 2     | Security of Centre's                      | Security from the perspective of the IPPs Grid Network                                                                  |
| 3     | Security concerning incoming and outgoing | protection from human behavioural in context when dealing with sensitive and confidential pieces of information of IPPs |

Fig. 3. A Proposed Conceptual Framework Source: Authors' Construction (2021).

The basis for each of the hypotheses used in this study is explained below.

### B. People

In 2019 the Worldwide Threat Assessment by the U.S. indicated that hackers, hacktivists, and insiders pose significant cyber threats to the grid. According to [19], a variation of threat actors pose substantial cybersecurity threats to the electric grid; these actors support grid operations. Ramamurthy and Jain [16] also indicated the difficulty in managing the workforce transformation, which is likely to be the most worrying complication of IoT implementations. Cyberattacks at varying levels of criticality on nations businesses and organizations with an internet presence primarily contribute to human-centric activities [20]. Some persons may work as a team to make decisions and carry out actions [18]. In the work of [21], internal employees working on the grid due to untrained employees or unhappy employees who have hatefulness for other consumers or the service providers also contribute to cyber-attack activities, therefore, seeking to evaluate the vulnerabilities. These factors are considered based on social networking, operating procedure maintenance, and security-related issues, such as user elicitation of information on cyber threats on CI networks, person-to-person interactions challenges concerning user control, and whether or not users strictly adhere to cyber security protocols. Based on the preceding, we propose the following hypothesis.

(H1): Operational staff's cyber security vulnerabilities positively influence cyber-attacks.

(H1.1): Vulnerabilities from operational staff effect of network activities positively influence cyber attacks.

### C. Information

In conceptualizing cyber situational awareness, there is the need to stress the practical concept that conveys security-

relevant information that supports the decision-making process [7]. In context, we refer to the logical data flow between network nodes, such as the IoT devices and other intermediary devices, which mandate is to temporarily collect and transmit some form of data emanating from CI activities. A recent report [19] indicated that a critical protection assessment action required to address cybersecurity risks facing the electric grid is Data security and Information protection processes and procedures. Due to power generation system vulnerabilities to cyberattacks against practical state estimation, Zhang [22] develops a comprehensive situational awareness framework for distribution system information on monitoring and controlling state estimation components, cyber-attack detection information, fault location, and voltage control information. Frequently, receiving devices generate information obtained from different devices sources and determine its reliability. Nonconformities between the essential information and possible vulnerabilities areas in the grid can be recognized from emerging information's nature [23]. The constructs objective is to evaluate vulnerabilities and their ramifications on the grid.

- The authors measured how individuals apply cyber security controls when dealing with sensitive and confidential information.
- Whether they had ever experienced information leakages or sensitive information received from the grid comes with inaccuracies.
- If there are restrictions on remote access and finally to enquire if there had been pieces of evidence of frequent misleading information been to receive on their systems.

(H2): The Information handling from operational staff positively influences cyber-attack.

(H2.1): The effect of network activities on information handling influences the cyber Attack.

#### D. Network

The communication network and the electrical grid play a significant role in generating and transmitting power to either a sub-station or a customer. Hence, identifying various network vulnerabilities impact assessments will provide knowledge of future impact projection. Prior studies have discussed different techniques to improve cyber situational awareness [7], [24], [25], mainly for analyzing the trends in network traffic. With the evolution of grid networks, there are increasing security threats due to the expanding volume of data transmitted on the grid. Some of these specific cyber incidents on the grid network, as indicated by ([26]–[28]) in their recent study. Because Cyber situation awareness empowers cybersecurity experts to detect and fully understand and anticipate incoming threats, however, our thorough review of the literature revealed no previous studies on how the human behavioural concept can apply in this context. To assess cyber situational awareness of the grid network vulnerabilities and how these vulnerabilities can influence cyber-attacks. Per these constructs, our goal is to evaluate

vulnerabilities and their implications for the grid. Concerning the measurement of network vulnerabilities from a human behavioural perspective, authors seek to:

- Enquire whether or not individuals can access the grid network with their devices.
- Find evidence of unauthorized persons accessing the grid network remotely.
- Find the frequency of change of network access policies.
- Enquire if there is evidence of unauthorized IT staff accessing the network remotely.
- Finally, enquire if users can access social media applications on the network.

H3. Negative human behavioural activities on the network positively influence cyber-attacks.

#### E. Cyber Situational Awareness

The military is where situational awareness first appears. Situational awareness aims to identify events, causes, consequences, and future projections [18]. It also considers the status and attributes of elements by assessing the present situation and predicting future outcomes based on previous understanding and acquaintance [29]. It becomes possible through the acquisition of data, conception, and synthesis to enable decision-makers to resolve problems with the massive deployment of IoT devices in the power generation sector; for data, acquisition to continuously monitor various sub-systems of the entire power generation system Infrastructure. Therefore, Cyber Situation Awareness (CSA) extends Situation Awareness (SA) to the power generation cyber domain. Hence, we can access fist hand information and seek indications from an attacker's perspective, estimate the impact, to anticipate their actions. Research has carefully refined cyber situational awareness predominantly in the CI ([22], [30], [31]). However, a careful study of the literature did not reveal any prior studies investigating how the Cyber Situation Awareness elements (people, information, and networks) concept can apply in human behaviours from IPPs operational environment. Because according to Michael, et al [32], CSA is the degree to which individuals within a team possess the CSA required in carrying out their responsibilities. We believe cyber vulnerabilities could occur due to various duties discharged by the operational staff of IPPs hence, evaluating human behaviours in the power generation sector. These vulnerabilities can occur in any of the layers; physical layer, information layer, and the human layers in the CI [33]. Also see Appendix.

#### F. Cyber-Attack

Cyber-attack issues relating to the smart grid and its impact on the IPPs are increasingly problematic and threatening to a developed and developing economy. In terms of business and human privacy and even national security, the current grid Infrastructure uncertainties manifest due to the power generation sector's Internet of things (IoT). Its cyber security issues have become a significant subject of debate

globally. Krishnan, et al [34] indicate evidence of price cap and bid price manipulation and subsequent Attack on the generation unit. Memories of a cyber attack in New York in March 2016 affected the Dam control system with a cellular modem. Such attacks can lead to incapacitating the practical function of the electric grid in line with communication between systems or equipment on the grid network ([8], [15], [35]). It can also harm the effective grid functioning ([1], [36], [37]). Recent studies in the area reveal various cyber-attacks such as False data injection attacks ([27], [38], [39]), Denial-of-service attacks identified by ([40], [41]), Distributed Denial of Service attack indicated by [42], Man-in-the-middle attack [6], Malware Attack by ([43], [44]), State Estimation attack [45], and Price manipulation and Misrepresentation of values attack[1] Coordinated ([10], [43]), etc.

### G. Related Work

The new paradigm of human-centric warfare on cybersecurity is wealth looking into because insider threats can be disruptive and equally malicious as an attack from outside an organization [20]. Cyber situational awareness gives insight into understanding an impending phenomenon [46]. Since many sectors in the economy are primarily dependent on Critical infrastructures (CI) [11], where information is sent and received for processing to predict possible future threats and adequately plan the power generation environment. According to Nekha and Dorosh [23], the critical aspect of cyber situational awareness can timely deal with an emerging threat model. Hence, critically examine elements such as people, information, and networks in the context of cyber situational awareness within the operational environment of the independent power producers (IPPs) in perspective. The growing adoption of high IoT devices connected to the Internet and the use of the global positioning system to harmonize grid operations contributes to grid vulnerabilities [19]. Current studies in the sectors focus on the cyber-physical aspect of the grid; [47] examine the multi-stage attacks using WannaCry ransomware. The study of [48] accesses the vulnerability with the local power trading. Sharafeev et al [1] develop an algorithm to monitor electrical power systems (EPS) cyber-attacks. A framework for assessing critical infrastructure in an attack was created by Akhtar, et al [49]. Sarangan, et al [50] Analyzed cyber-attacks of the power grid in considering the ill-effects of increasing renewable penetration [39]. Develop a systematic two-stage approach for detecting false data injection (FDI). Roy and Debbarma [27] also Proposed a cyber-attack detection and mitigation platform which uses forecasted data. Raikuma, et al [6] also demonstrate the impact of the man-in-the-middle attack, which exploits vulnerabilities in the Generic Object-Oriented Substation Event (GOOSE). Prior related research work was sort of giving indications of lack of effort to explore vulnerabilities from Human Behavioral perspective particularly, in the power generation sector. Hence our current study seeks to critically evaluate and access the cyber vulnerabilities within the IPPs using cyber situational awareness.

Based on the above reviews, we propose five (5) hypotheses, as follows:

Fig. 4. Conceptual Framework.

Based on the above research hypotheses, the influence of cyber situational awareness on People, Information, and Network cyberattacks is present in Fig. 4.

## III. RESEARCH DESIGN AND METHODOLOGY

### A. Research Design

The approach of our current study is purely quantitative. We sort to use this approach because it involves an empirical investigation of the social phenomena of Cyber Attacks from Human Behavioral in the context of the IPPs. Therefore, the employs quantitative data using the survey method to collect and gather the information required for the analysis.

### B. Data Collection

Questionnaires were administered purposively to a sample of selected units of the IPPs staff who are directly involved in the organization's day-to-day grid operations from March to May 2021. We sort to use questionnaire because of anonymity among respondents and its low-cost implication. The questionnaire consists of four (4) parts: Demographic factor, People, Information, and Network. The questionnaire design is founded on [51] conceptual framework using a Likert scale from (One)1 for strongly disagree to (Five) 5 for strongly agree.

### C. Population and Sampling Procedures

The population studied is GRIDco and five (5) IPPs in Ghana that is actively operating with GRIDco in the power generation sector to assess Cyber Attacks on the electrical grid from human behaviour in context. Our estimated sample frame is 300, based on the various units within the IPPs: Supervisory Control and Data Acquisition (SCADA) Unit, Telecommunication Unit, and the Management Information Systems (MIS). The sampling method employed was probability sampling (random sampling). Choice of employees was at random within the various IPPs units selected to answer the questions

### D. Sample Size Calculation

Our Sample size is calculated based on Yamane 1967 formula with 95 per cent confidence level plus or minus 5 per cent confidence intervals using the formula  $n = \frac{N}{1+N(e)^2}$  where  $n$ = is the sample size  $N$  =is the population,

and  $e$  is the error margin. Although a sample size of 171 is obtained per our calculation from the estimated population of 300. Meanwhile, the Actual sample size used for the analysis is based on the number of respondents, which is (238) was used for the study because, with most research, a large sample size gives more reliable results than smaller samples.

IV. ANALYSIS AND RESULTS

The PLS-SEM approach seeks to support evaluating patterns of causality of target constructs in the structural model. It also provides more detailed statistical associations supporting variables included in a model. Authors' employees' PLS-SEM in the study since it allows relatively more minor samples than other statistical software like Amos and Lisrel. PLS-SEM does not enforce stringent assumptions on data distribution [52]. 238 is the valid responses received, which forms the basis of data analysis; 86.1% were males, while 13.9% were from females (see Table 2) on demographic of respondents. Using the two-step approach to evaluating structural equation models as suggested by [53], we began examining the measurement model to assess the instrument's reliability and validity. We then looked at the structural model based on the hypotheses proposed in this study.

A. Measurement Model

Following our measurement model assessment, we identified four(4) items (AK2, C5, C6, and C15) is removed from the study as a result of their low loadings, which is less than 0.600as recommended by ([54], [55]). In assessing the reliability of the constructs for our measurement Models, we used Cronbach's alpha and composite reliability measures to test the model's internal consistency. Hence Cronbach's alpha and composite reliability for each construct are adequate, as indicated in Table III. Composite reliability should be higher than 0.6 and 0.70 ([56]–[58]). With indicator factor loadings surpassing 0.5, Nunnally [58] and Hair, et al [59] recommended that the Average Variance Extracted for each variable should exceed 0.5 [56] to assess convergent validity [59]. Indications of convergent instrument validity are present

in Table III. Hence, convergent validity is suitable since the AVE values exceed 0.500 [60]. We strictly adhere to the Fornell–Larcker criterion in reporting the discriminant validity, which posits that AVE for each latent construct should be higher than the construct's highest squared correlation with any other latent construct [56].

Additionally, the loadings of each indicator should be greater than all its cross-loadings [53]. An inspection of indicator cross-loadings in Table III shows that all indicators load their highest on their respective construct. No Indicator loads higher on other constructs than on its intended construct. Evident in Table 4 shows that the square root of the AVEs for each construct is greater than the cross-correlation for different constructs. Based on these results is the established discriminant validity of the instrument. We also measured Discriminant validity using the Heterotrait-Monotrait Ratio of correlation(HTMT) criterion by [61], [62], see Table V below.

TABLE II. DEMOGRAPHY OF RESPONDENTS

| ATTRIBUTE           | CATEGORIES                 | PERCENTAGE (%) |
|---------------------|----------------------------|----------------|
| Gender              | Male                       | 86.1           |
|                     | Female                     | 13.9           |
| Age                 | 18 -30                     | 0.8            |
|                     | 31-40                      | 12.6           |
|                     | 41-50                      | 19.7           |
|                     | 51-60                      | 37.8           |
|                     | 61+                        | 29             |

### B. Structural Model

In this section, overall explanatory power, Amount of variance explained by the independent variables, the degree of strength of each path is assessed. To estimate path significance, we applied bootstrap. We also assess the quality of the structural model with the coefficient of determination ( $R^2$ ) and standardized root mean square residual (SRMR) ([63] [64]). Our structural model results are present in Fig. 5 and Table 6. Regarding our (H1), The result shows even though people have a negative influence in predicting cyber-attack plays a significant role for an attack to occur ( $\beta = -0.435$ ;  $p = 0.000$ ). (H1.1) However, the mediation effect of network activities from people to attack does not have a negative relationship and plays no significant role in predicting cyber-attack within the grid. ( $\beta = -0.008$ ;  $p = 0.643$ ). (H2) our results reveal that information handling is significant and positively influences cyber-attack predictions within the grid. ( $\beta = 0.296$ ;  $p = 0.020$ ). Meanwhile, (H2.1) information handling positively affects network activities within the grid and significantly influences cyber-attacks ( $\beta = -0.949$ ;  $p = 0.000$ ). (H3) was found to have network activities positively affect predicting cyber-attack but not significant ( $\beta = 0.123$ ;  $p = 0.300$ ). Hence in this study, we did not find support for H3 and H1.1, as indicated in table 6 below. According to [62], the predictive validity of variance is a criterion for determining a model's prediction accuracy. Hence the coefficient of determination ( $R^2$ ) is the output of regression value as variance proportion in endogenous variable predicted by exogenous variable.

$R^2$  values range from 0 to 1; A higher value is said to have a higher level of  $R^2$  of .75 is substantial, .50 is moderate, and .25 is considered as weak ([65], [66]).

This study shows Attack (0.396, being Moderate) and Network with (0.901, substantial) value. In conclusion, the  $R^2$  indicates a sufficient level of  $R^2$  (see Table VI) and Fig. 5.

The authors performed analysis to assess the mediation role of the Network between People and Attack. The study results in (Table VII) reveal that the total effect of People on Attacks, even though negative is significant (H1.1:  $\beta = -0.436$ ,  $p = 0.000$ ). With the introduction of the mediator variable Network, the impact of People on Attack gives negative effect but significant ( $\beta = -0.435$ ,  $p = 0.000$ ). The indirect impact of people on Attacks through networks is insignificant ( $\beta = 0.116$ ,  $p = 0.318$ ), which indicates no mediations effect between the association of People and attacks.

Finally, assessing the mediation role of the Network between Information and Attack. Our results in (Table VII) also show that the total effect of Information on Attacks has a positive impact and is significant (H2.1:  $\beta = 0.413$ ,  $p = 0.000$ ). By introducing the mediator variable Network, the information effect on the Attack shows a positive impact and is significant ( $\beta = 0.296$ ,  $p = 0.022$ ). The indirect implications of Information on Attacks through networks have a positive effect and are insignificant ( $\beta = -0.001$ ,  $p = 0.768$ ), which indicates no mediations effect between the association of Information and Attack.

TABLE VI. PATH COEFFICIENTS AND THEIR SIGNIFICANCE

| Hypotheses | Path                   | Standardized path coefficient | T Statistics | P Values | Result        |
|------------|------------------------|-------------------------------|--------------|----------|---------------|
| H1         | PEOPLE -> ATTACK       | -0.435                        | 5.704        | 0.000    | Supported     |
| H1.1       | PEOPLE -> NETWORK      | -0.008                        | 0.463        | 0.643    | Not Supported |
| H2         | INFORMATION -> ATTACK  | 0.296                         | 2.330        | 0.020    | Supported     |
| H2.1       | INFORMATION -> NETWORK | 0.949                         | 91.394       | 0.000    | Supported     |
| H3         | NETWORK -> ATTACK      | 0.123                         | 1.037        | 0.300    | Not Supported |
|            |                        | <b>R<sup>2</sup></b>          |              |          |               |
|            | ATTACK                 | 0.396                         |              |          |               |
|            | NETWORK                | 0.901                         |              |          |               |

Notes: SRMR= 0.155; ns-not significant.

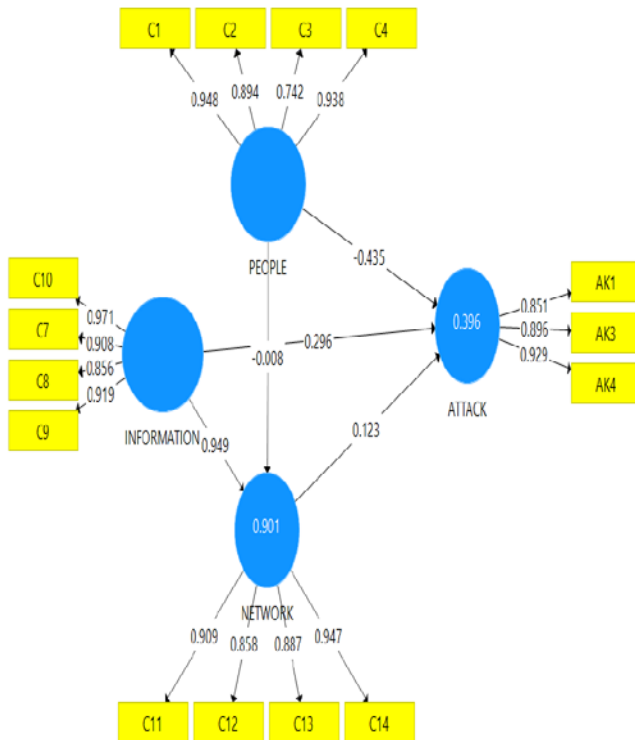

Fig. 5. PLS Results for Structural Model.

C. Effect Size ( $f^2$ )

Effect size is a concept to measure how strong the relationship of an indicator or the effect of exogenous constructs to endogenous constructs is. It examines changes in  $R^2$  value when an exogenous construct is detached from the model. An effect size of .02 has a minor influence, a value of .15 has a medium effect, and a value of .35 has a significant impact. [66]. Hence the current study revealed four correlational effect sizes. C15 with a value of 0.018 as a small effect, AK2 and C6 also gave indications of values of 0.264 and 0.543, respectively, having an effect size of the medium impact. C5 recorded the most significant effect sizes with the value of 0.617.

V. IMPLICATIONS OF THE STUDY

CSA aims to improve the quality of appropriateness of concerted decision-making concerning the protection of the electrical grid. Invalidating our hypothesis, although (H1) posited there is a negative effect of people in predicting cyber-attack, it also plays a significant role for an attack to occur in the operational environment of the IPPs. Therefore, consider

cyber security measures to ensure operational staff knows potential external cyber threats. Ensuring that the grid and its sub-systems are fully protected, prohibiting personal devices from accessing and transmitting information on the grid. Finally, steps must be taken to monitor users' grid activities strictly. Hypothesis (H1.1) indicates no mediation effect between the association of People and attacks. Explaining that, irrespective of users' activities such as personal devices, remote access to the network by I.T and Non-I.T staff can prevent an attack on the electrical grid network with the proper security controls. Frequent changes in network access security policies (H2) suggest that information handling is significant and positively influences cyber-attack. Therefore, lack of CSA from the perspective of information accessibility and distribution concerning cyber security controls will distort confidential and sensitive information; hence the need to ensure the information on the grid activities is well-coordinated and accessible to only specific users within the operational environment. The mediation effect of H2.1 indicates no mediations effect between the association of Information and Attack. Reasons could be due to an effective cyber security control is implemented by the IPPs. Information from the grid received with inaccuracies is attributed to frequent updates of security policies in the context of perspective network access. (H3) reveals no sign of cyber-attack predictions. It indicates that the grid infrastructure network managers have put adequate security measures. Such as frequent network access policies, hence irrespective of who performs activities on the network do not translate into any negative impact on the grid network.

VI. CONCLUSION

Over the years, the power generation and distribution sectors have seen an increase in the number of independent power producers in the electricity market. This sector of power generation has advanced its operations with the intervention of internet of things (IoT) technology and other electronic equipment making the entire grid network susceptible to attack [1], [67], [68]. From the literature perspective, very little is known about user behaviour concerning cyber vulnerabilities in the sector. Bradley [69] insider threats are the most expensive threats challenging to address threats to people, information, and technology in the business environment. In this regard, our research helps to improve the understanding of user behaviour in the context of Ghana's electricity generation sector. From the context of cyber situational awareness (CSA), authors sort to (1) evaluate how the operational staff of IPPs perceive cyber vulnerabilities within their operational environment, (2) evaluate the information vulnerabilities that seeks to influence cyber-attack and finally (3) assess network

vulnerabilities that contribute to cyber-attack on the electrical grid. Our findings show that People's construct negatively predicts cyber-attack but plays a significant role in attacking the electrical grid. The authors also realized no mediation effect from people and attack network activities, probably because of constant security controls measures such as frequent update network access policies. Meanwhile, authors also realized that information handling is significant and positively influences cyber-attack, which calls for well-coordinated cyber security controls on the grid activities in line with confidential and sensitive information in the operational environment of IPPs. In addition, there was no indication of mediations effect from network activities between the association of Information and Attack. Such development can be to adequate security measures being put in place to ensure information from the grid are received devoid of errors. Finally, managers of IPPs infrastructure networks seem to have suitable security measures concerning the network activities. Hence irrespective of the numerous activities on the network cannot easily translate into any negative cyber-attack impact on the grid network.

APPENDIX 1

Instrument: Cyber Situational Awareness(Csa)

SECTION A: DEMOGRAPHIC (Please tick appropriately)

1) Please indicate your gender:

Male [ ]

Female [ ]

2) Please indicate your age category:

18 -30 [ ]

31-40 [ ]

41-50 [ ]

51-60 [ ]

61 [ ]

3) Please indicate your highest category:

- Diploma
- HND
- First degree
- Postgraduate degree
- Professional qualification
- Masters
- PhD

4) Please indicate your years of experience on the job:

- 1-5
- 6-10
- 11-15
- 16-20
- 21 and above

SECTION B: Please tick appropriately

| Please tick the correct numeric response to each question |                                                                                                      | 1= Strongly Disagree, 2=Disagree, 3=Neutral, 4= Agree, 5= Strongly Agree |   |   |   |   |
|-----------------------------------------------------------|------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|---|---|---|---|
|                                                           | <b>People</b>                                                                                        | 1                                                                        | 2 | 3 | 4 | 5 |

**Abstract**—The compressor system is caused by the surge, which is an instability occurrence in most gas-process and oil industries. These issues are solved by using a recycle valve that avoids the surge and provides higher mass flow in the compressor system. An advanced controller-based anti-surge control mechanism is a need in the compressor system to improve the stability and surge issues. In this manuscript, an efficient, Neural-network predictive controller (NNPC) based variable speed compressor recycle system is modeled with an anti-surge control mechanism. When the mass flow is deficient, the recycle system is introduced, acts as a safety system, and feeds the compressed gas back to the upstream system. The different controllers like Proportional Integral Derivative (PID) controller, Fuzzy logic controller (FLC), and Neuro-fuzzy controller (NFC) based anti-surge control mechanism are also used in Compressor recycle system to compare the stability and performance metrics with NNPC. The NNPC based compressor system provides a better operating position and dynamic response with less error than other controllers-based compressor systems.

**Keywords**—Anti-surge; fuzzy logic controller (FLC); neuro-fuzzy controller (NFC); compressors; neural-network

## I. INTRODUCTION

The centrifugal Compressor is used in most industries like oil, aero-space, and gas-plant to increase pressure and oil production. The gas compressors are generally divided into four types: Axial-flow, centrifugal, rotary, and Reciprocating-type. The rotary and Reciprocating-type compressors reduce the gas volume's occupancy and later apply the higher Pressure to discharge the gas. The axial and centrifugal compressors act as turbo-compressor with continuous flow [1-2]. The Axial compressors with rotating stall and surge are presented with theoretical and mathematical concepts by Greitzer et al. [3]. The non-dimensional parameter (B) factors define whether the Compressor is in surge or rotating stall conditions. If the 'B' factor is lower, then a rotating stall will occur, which causes the instabilities by reducing the mass flow by rising the Pressure.

Similarly, a surge will occur with the mass flow and pressure oscillations if the 'B' factor is higher. The spool dynamics are introduced in the 'B' parameter to improve the speed control [4]. The Full-range Surge and rotating-stall avoidance by Badmus et al. are presented in the compressor system. The model uses open-loop feed-forward and closed-loop feedback control mechanisms in the throttle valve area to control the Pressure and mass flow. These control mechanisms are scheduled and use in rotating stall and surge avoidance [5]. The calculation of operating location between surge and the stable condition is necessary to avoid the surge in Compressor. To counteract the surge, the invariant coordinate system is introduced by changing molecular weight [6]. Gravdahl et al. present the drive-torque actuation system to regulate the active surge in the centrifugal Compressor. The active surge stabilization utilizing control law [7] causes the throttle line to appear left to the surge line.

In contrast, the compressor system for active surge control is presented by bohagen et al. using drive torque as a control input. The desired operating point stabilization is achieved with static and dynamic feedback mechanisms [8]. The Fuzzy logic-based surge control mechanism [9] is introduced for the Moore-Greitzer model with constant speed in the compressor system, stabilizing the different operating conditions and extending the stable line next to the surge line. The active surge control with variable speed mechanism [10] in centrifugal Compressor is designed to analyze the different performance metrics with better improvement than the Gravdahl et al. [1] work. The Contribution of the research work is organized as follows:

- The complete variable speed-based Compressor system with a recycling loop is modeled to ensure higher mass flow and avoid the surge.
- The Neural-network predictive controller (NNPC) based anti-surge control mechanism is modeled for the Compressor recycle system to improve stability and prevent active surges.

- The different controllers like PID controller, Fuzzy logic controller (FLC), and Neuro-fuzzy controller (NFC) are also modeled in anti-surge control mechanism to analyze the stability and performance comparison.

In this manuscript, an efficient Compressor recycle system with an anti-surge control mechanism using NNPC is modeled and compared with other controllers to evaluate performance metrics. The manuscript is organized as follows: Section II explains the Compressor-based system's current works for different applications. The simple compressor system with mathematical expressions is described in Section III. The Compressor recycle system with an anti-surge control mechanism using other controllers is explained in Section IV. The results and discussion is carried out in Section V. Section VI concludes the overall work with performance improvement and also suggest the future scope.

## II. RELATED WORK

This section analyzes the recent works on Compressor based systems for different application requirements. Budinis et al. [11-12] describe the Centrifugal compressor's control mechanism using a Model predictive controller (MPC), which can control the Compressor's Pressure during surge operation. The hot and cold recycle line is configured with an anti-surge control mechanism to analyze the performance metrics and power consumption. Cortinovis et al. [13-14] present the Linearize MPC-based centrifugal gas compressor system with an anti-surge and process control mechanism. These mechanisms are adopted in safe and electric-driven applications with improved surge 11% by maintaining distance and 50% reduction in process control time (settling). Sheng et al. [15] describe the Throttle and closed-coupled Valve (CCV) actuators based Compressor system for the instability control mechanism. The double actuators scheme is introduced to improve the control performance in CCV by tuning the B-parameter in the Throttle valve. Gritli et al. [16] present the Electronic throttle valve (ETV) optimization using a genetic algorithm (GA) by tuning the PID-based Fuzzy factors. The GA with PID-based FLC provides better disturbance rejection and trajectory tracking points than other conventional ETV approaches. Azeem et al. [17] present the ETV with FLC based super-twisting-Sliding mode control (STSMC) scheme. The STSMC scheme improves the controller's dynamic performance in ETV without compromising the tracking accuracy and stability features. Saeed et al. [18] present the Hybrid electric vehicles (HEVs) speed control mechanism using different controllers. The state observer controller (OBC) and linear quadratic regulator (LQR) based scheme provide better dynamic control response than the conventional PID Controller scheme in HEV.

The Neuro-Fuzzy controller (NFC) based Grid-connected gas turbine is modeled by Iqbal et al. [19] to improve the transient response and maintain stable operations. Liying et al. [20] present the non-linear compensation control mechanism using a PID controller for ETV to analyze the response time and performance. Zaibari et al. [21] explain the constant-speed-based centrifugal Compressor using Tube-MPC to control the surge instability. The Adaptive fuzzy logic with MPC acts as

an anti-surge controller to avoid the surge and improve the robustness against the mass flow and pressure-based disturbances. Khsheem et al. [22] present the Surge compressor system with an active control mechanism. The PID controller controls the surge line and provides the dynamic response to use in the control valve. Guan et al. [23] present the centrifugal compressor surge control mechanism. The work analyzes the variable –tip clearance mechanism is introduced to control the surge and analyzes the compressor performance. The Surge control with different speeds and also with different throttle opening sizes are analyzed with simulation results. Aribi et al. [24] present the Recycle compressor system for active surge control using a hybrid adaptive controller. The PID with auto tuning Fuzzy interface system (FIS) controls the operating points under the Surge line at different speeds. The artificial neural network (ANN) based Centrifugal compressor is modeled by Ebrahimi et al. [25] to predict operational parameters.

## III. COMPRESSOR MODEL

The surge control and instabilities are the main issues in any of the axial and centrifugal compressors. In this work, variable-speed Centrifugal-based Compressor is discussed. The overview of the Compressor system is represented in Fig. 1. It mainly contains a Torque drive, Compressor with duct, Plenum, and Throttle valve. The Compressor model produces the mass and Pressure using torque drive and plenum units. The Throttle valve delivers the mass throttle value and feedback to the Plenum unit and Compressor mass flow.

When the mass is applied to the Plenum unit, which produces the Pressure, it is represented in Equation (1). The momentum applied on the Compressor with duct produces the mass flow is described in Equation (2). The torque drive delivers the angular speed using the angular momentum feature represented in Equation (3). The work was initially presented by Gravdahl et al. [1], and it is extended by Fink et al. [2]. The Pressure, mass flow, and speed is represented in Equation (1-3) as follows:

$$\dot{P}_p = \frac{a_p^2}{V_p} (m - m_t) \quad (1)$$

$$\dot{m} = \frac{A}{L} (\psi_c(m, \omega) P_{01} - P_p) \quad (2)$$

$$\dot{\omega} = \frac{1}{J} (\tau_d - \tau_c) \quad (3)$$

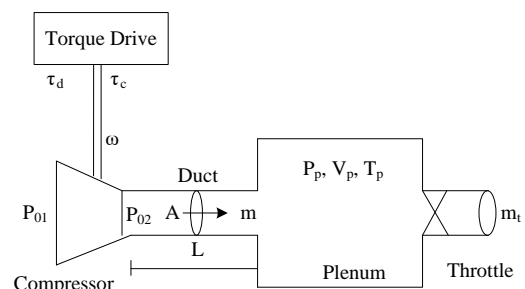

Fig. 1. An Overview of the Compressor System.

The above Equations (1-3) uses few of the notations as follows: where  $\dot{m}$  is mass flow,  $\dot{P}_p$  is Plenum Pressure,  $\omega$  is Torque speed of the impeller,  $V_p$  is Plenum Volume,  $a_p$  Plenum's speed of the gas,  $m_t$  is Throttle's mass flow,  $A$  is the cross-sectional area of the duct,  $L$  is the length of the duct,  $P_{01}$  is the Pressure (Ambient),  $\psi_c$  is Compressor Characteristic,  $J$  represents the moment of inertia of torque,  $\tau_d$  is Torque drive, and  $\tau_c$  is impeller blades torque.

The predicting surge is possible using Equations (1-3) and is one-dimensional in centrifugal compressors. When Compressor is in the deep surge point, and the impeller blade's torque is represented in Equation (4) as follows:

$$\tau_c = |m| r_2^2 \mu \omega \quad (4)$$

The Compressor system is used to determine the pressure ratio using  $\psi_c$ . The compressor characteristic is expressed in Equation (5) as follows [1]:

$$\psi_c(m, \omega) = \left( 1 + \frac{\mu r_2^2 \omega^2 - \frac{1}{2} r_1^2 (\omega - \alpha m)^2 - k_f m^2}{a_p T_1} \right)^{\frac{k}{k-1}} \quad (5)$$

The throttle mass flow is represented in Equation (6) as follows:

$$m_t = \tanh(\zeta(P_p - P_{01})) A_t \sqrt{(P_p - P_{01}) \tanh(\zeta(P_p - P_{01}))} \quad (6)$$

The above Equations (4-6) uses a few of the notations as follows:  $r_1$  is inducer radius, and  $r_2$  is impeller exit radius,  $\mu$  is flow co-efficient,  $k$  is heat capacity ratio,  $T_1$  is inlet temperature,  $A_t$  is Orifice Opening area, and  $\zeta$  is zeta ( $\gg 1$ ). The Compressor characteristic provides the performance metrics of the Compressor using mass flow and Pressure. When the mass flow decreases, the Pressure will increase until its instability point, Then Surge or rotating stall problems arise in the compressor system.

#### IV. COMPRESSOR WITH ANTI-SURGE CONTROL USING DIFFERENT CONTROLLERS

The oscillations, stalls/surge, and lower pressure rises will always affect the centrifugal Compressor's performance. The operating point is always far away from the surge line (SL), which is the best option at low pressure and high mass flow conditions. But the efficiency of the Compressor always lacks in this region. So for better efficiency, the Pressure will rise at its highest, which is close to the SL. Surge avoidance is also known as an anti-surge control mechanism. Most commonly, the recycle valves are used to avoid the surge in industry applications. The Compressor Recycle system based Anti-surge Control Mechanism using different Controllers is represented in Fig. 2.

Using an anti-surge control mechanism, the Compressor recycle system contains a Suction unit, Compressor with duct, Torque drive unit, Plenum and recycle valve units. The feed flow mechanism is essential to analyze the compressor system performance if the feed flow value is high or too low, which

affects the operating point and speed features in the compressor system. Suppose the pressure  $P_1$  value is too high in the suction unit, which fails to operate in the compressor system. The Suction unit with Pressure ( $P_1$ ), and Volume1 ( $V_1$ ), are part of the upstream piping operation. Similarly, The Plenum unit with Pressure ( $P_2$ ), and Volume2 ( $V_2$ ), are part of the downstream piping operation. The modeling of the Compressor recycle system is represented in Fig. 3.

The amount of feed flow ( $m_f$ ) with mass applied on the Suction unit, which generates the Pressure ( $P_1$ ) and is represented in Equation (7). The mass flow is used on the Plenum unit, which produces the Pressure ( $P_2$ ) and is represented in Equation (8). The momentum applied to the Compressor creates the mass flow ( $m$ ), described in Equation (9). The throttle mass flow of the compressor recycle system is represented in Equation (10) as follows:

$$\dot{P}_1 = \frac{a_p^2}{V_1} (m_f - m_r - m) \quad (7)$$

$$\dot{P}_2 = \frac{a_p^2}{V_2} (m - m_t - m_r) \quad (8)$$

$$\dot{m} = \frac{A}{L} (\psi_c(m, \omega) P_1 - P_2) \quad (9)$$

$$m_t = \tanh(\zeta(P_2 - P_{01})) C_t \sqrt{(P_2 - P_{01}) \tanh(\zeta(P_2 - P_{01}))} \Big|_{\zeta \gg 0} \quad (10)$$

The feed flow mechanism is dependent more on the type of Compressor used and is not constant while performing the simulation process. The feed flow ( $m_f$ ) operation is represented in Equation (11), and recycle flow ( $m_r$ ) operation is described in Equation (12) and are as follows:

$$m_f = C_f \sqrt{P_{01u} - P_1} \quad (11)$$

$$m_r = C_r \sqrt{P_2 - P_1} \quad (12)$$

$C_f$  and  $C_r$  are coefficients of Feed flow and recycle flow, respectively;  $P_{01u}$  is upstream ambient Pressure.

The Anti-Surge Control mechanism using PID Controller with different Controllers like Fuzzy logic controller (FLC), Neuro-fuzzy Controller (NFC), and Neutral network Predictive Controller (NNPC) are represented in Fig. 4. In this work, the PID controller is used as the industry standard and other controllers to analyze the anti-surge control operations. The Compressor system produces the mass flow ( $m$ ) and compressor characteristic ( $\psi_c$ ) outputs and inputs the anti-surge mechanism. The different controller's output ( $asc_{in}$ ) is input the recycle value unit. The Surge control line (SCL) is considered along with the surge line (SL), which is linear and horizontal to the surge margin. The compressor characteristic SCL with the mass flow is represented in Equation (13) as follows:

$$\psi_{scl}(m) = im + j \quad (13)$$

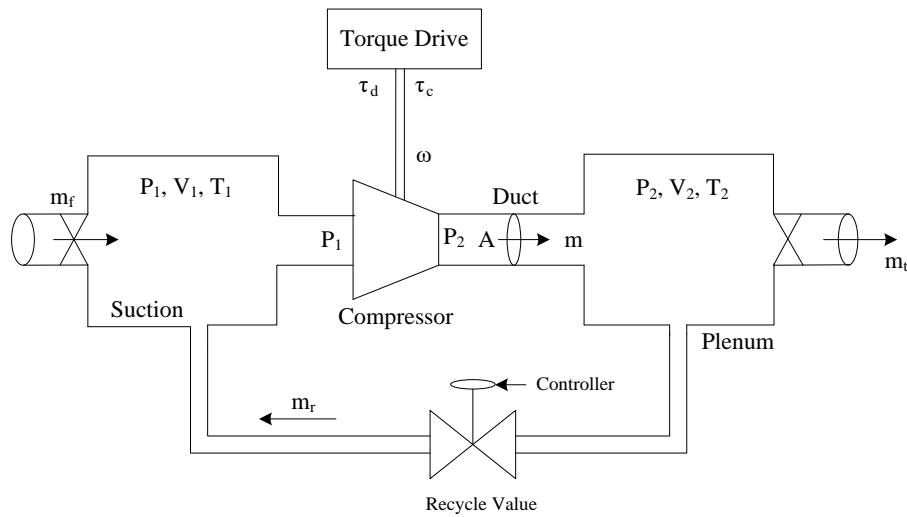

Fig. 2. Compressor Recycle System based Anti-surge Control Mechanism in using different Controllers.

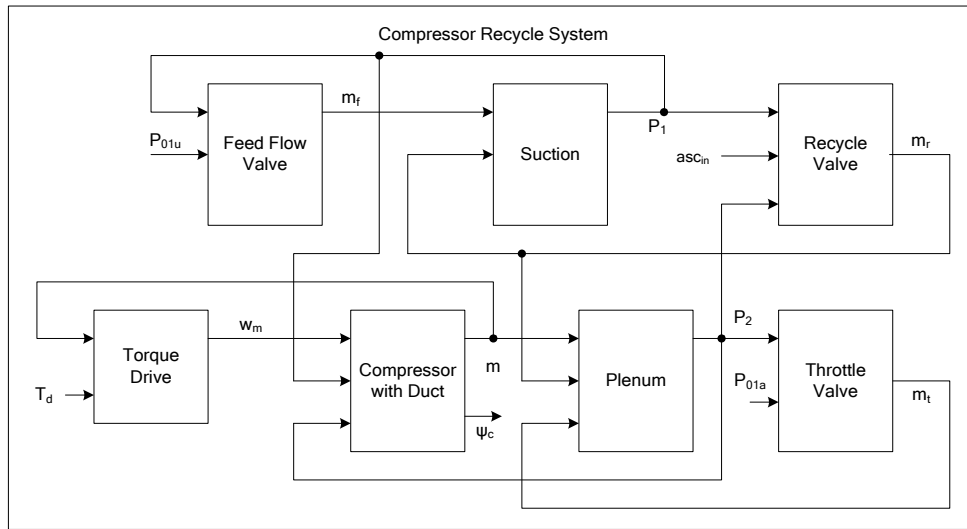

Fig. 3. Modeling of the Compressor Recycle System.

Fig. 4. Anti-Surge Control Mechanism using different Controllers.

Where  $i$  and  $j$  are the coefficients for SCL, when the operating point (OP) is right to the SCL, the control mechanism is not activated.

Only when the operating point (OP) is left to the SCL, the control mechanism is activated. The PID controller and other controllers (FLC/ NFC/NNPC) are used to getting the OP back to the right, with its controlling mechanism. To analyze the controlling mechanism, first, find the distance ( $d_i$ ), as the difference (horizontal) between the SCL and OP, which is represented in Equation (14) as follows:

$$d_i = m - m_{scl}(\psi_c) \quad (14)$$

The OP is calculated using mass ( $m$ ) and  $\psi_c$ . The  $\Psi_{scl}$  ( $m$ ) is same as  $\psi_c$ , when Pressure rises and consider the inverse of Equation (13) to calculate the  $m_{scl}(\psi_c)$ , which is represented in Equation (15) as follows:

$$m_{scl}(\psi_c) = \frac{\psi_c - j}{i} \quad (15)$$

Use Equation (15) to calculate the distance value in Equation (14). The error value is calculated based on the horizontal distance using OP and SCL. When the distance value is +ve, the error value ( $E_r$ ) is set to zero, and no need to perform any controlling operation, and the OP is located to the right position of SCL. When the distance value is -ve, its +ve value is used to calculate the error value ( $E_r$ ) using controlling operation. The error value ( $E_r$ ) calculation is represented in Equation (16) as follows:

$$E_r = \begin{cases} 0 & d_i > 0 \\ -d_i & else \end{cases} \quad (16)$$

This error value ( $E_r$ ) is input to the PID controller and it is represented in Equation (17) as follows:

$$O_{pid} = K_p E_r + K_i \int_0^t E_r dt \quad (17)$$

Where  $K_p$  and  $K_i$  are the proportional gain and integral gain of the PID controller, the PID Controller output ( $O_{pid}$ ) is used directly to control the flow percentage in recycling valve for the anti-surge control mechanism. To improve the anti-surge control with OP, a different controlling mechanism is introduced.

#### A. Fuzzy Logic Controller (FLC)

The Fuzzy logic Controller (FLC) provides a better dynamic response than the conventional PID controllers and is used in most industrial control applications. The FLC mainly contains five blocks: the Compressor recycle system: Fuzzification, De-fuzzification, database (Knowledge base), Ruleset, and evaluation process. The Fuzzification converts absolute (crisp) data into Fuzzy (linguistic) data. The PID controller output is input to the fuzzification process as crisp data and produces the fuzzy data. These fuzzy data values are considered as Fuzzy-sets in FLC. The membership functions analyze these fuzzy sets and estimate whether they are low, high, or oversized. The evaluation process provides the decision to control and study the fuzzy rules stored in the rule base. The FLC process performance is analyzed by rule base. The de-fuzzification process converts back the Fuzzy data into crisp data. The Knowledge-based is used to store the membership functions of both the Fuzzification and de-fuzzification processes. The evaluation of fuzzy rules is done by basic fuzzy sets with AND, OR, and NOT operations. The de-fuzzification output is the final FLC output and is processed in Compressor recycle system. The function of the Fuzzy logic process with the Compressor recycle system is represented in Fig. 5.

The Mamdani Fuzzy interface system (FIS) is used to create the FLC. The two fuzzy variables are used in the FLC: one is PID output ( $O_{pid}$ ), and another is Change in PID output ( $CO_{pid} = O_{pid}(i) - O_{pid}(i-1)$ ). Where  $i$  value is set to 1 to 3.

Fig. 6. Operation of NFC.

The two Fuzzy inputs ( $O_{pid}$  and  $CO_{pid}$ ) and FLC output ( $O_{flc}$ ) are normalized to the display range [0 to 0.6] using fuzzy set membership functions for the given universe of discourse. The Fuzzy Input and output use the triangular-shaped membership functions. The Three fuzzy variables are used as  $O_{pid}$  and  $CO_{pid}$ , which includes Negative Big (NB), Zero (ZO), and Positive Big (PB). Human knowledge is used to create the decision logic for fuzzy rule sets. The Fuzzy rule set for Compressor recycle system is tabulated in Table I. The fuzzy variables like NB are in the range of [-0.3 to 0.3], ZO is in the field of [0 to 0.6], and PB is in the range of [0.3 to 0.6]. The nine- rules are used in the fuzzy inputs ( $O_{pid}$  and  $CO_{pid}$ ) with three fuzzy variables. The rule set converts these two fuzzy inputs into single FLC output using the centroid technique in the de-fuzzification process.

#### B. Neuro-Fuzzy Controller (NFC)

The FLC is extended with NFC using an Artificial Neuro-fuzzy interface system (ANFIS). The NFC automatically realizes the FIS using Neural networks (NNs). The NFC provides a conversion mechanism (Crisp to fuzzy and vice-versa) efficiently. The NFC uses the NN to optimize the FIS using the ANFIS system. The operation of the NFC is represented in Fig. 6. The NN has a learning skill set and is capable of training and testing the FIS in NFC. The NFC uses two inputs like PID controller output ( $O_{pid}$ ) and change in PID controller output ( $CO_{pid}$ ) for training. Once the training data is loaded in NFC, generate the FIS using grid partition using the Gaussian membership function. The seven MF's are considered with constant output in NFC.

Next, Train the FIS using the hybrid optimization method. The error tolerance is set to 3 epochs to complete the ANFIS training. Lastly, test the training data to analyze the NFC output.

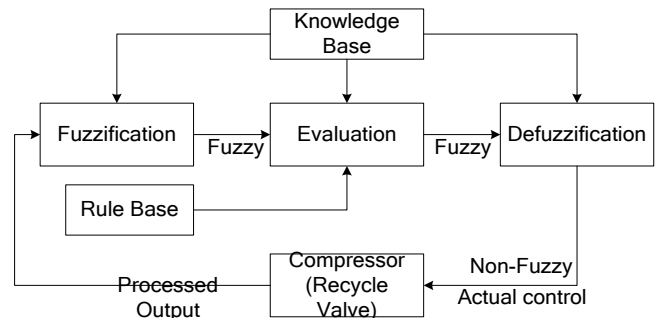

Fig. 5. Fuzzy Logic Process with Compressor Recycle System.

TABLE I. THE FUZZY RULE SET FOR COMPRESSOR RECYCLE SYSTEM

| E/CE | NB | ZO | PB |
|------|----|----|----|
| NB   | NB | NB | ZO |
| ZO   | NB | ZO | PB |
| PB   | ZO | PB | PB |

### C. Neutral Network Predictive Controller (NNPC)

The NNPC mainly contains the NN model, Optimization unit, and Compressor recycle system. The NNPC predicts the future performance of the Compressor recycle system using the NN model. The NNPC Based Compressor recycle system for the anti-surge controlling mechanism is represented in Fig. 7. The NNPC is used to calculate the NN model input ( $m$ ) and further optimize the Compressor recycle system's performance over a defined time horizon.

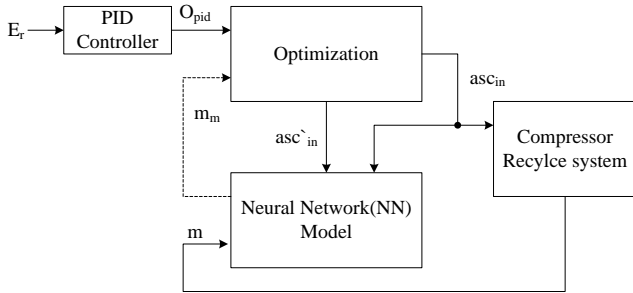

Fig. 7. NNPC based Compressor Recycle System for Anti-surge Control.

The NNPC first identifies the Compressor recycle system (plant) and then uses this model to predict the future performance using a controlling mechanism. In the first stage, the NN model is trained by a predictive control mechanism to analyze the dynamics of the Compressor recycle system. The NN training signal is generated by calculating the predictive error between the NN mode output and Compressor recycle system output. The NN model [26] uses the previous inputs (Optimization) and the previous compressor system's output to analyze the Compressor recycle system's output values. In the second stage, the optimization algorithm [27-28] is used for precision and to calculate the control signal. This control signal minimizes the below Equation's (18) performance over a defined time horizon.

$$J = \sum_{j=N_1}^{N_2} (O_{pid}(t+j) - m_m(t+j))^2 + \rho \sum_{j=1}^{N_u} (asc'_{in}(t+j-1) - asc'_{in}(t+j-2))^2 \quad (18)$$

Where  $asc'_{in}$  is a temporary control signal,  $O_{pid}$  is PID controller's output acts as a desired response,  $m_m$  is the response of NN model,  $\rho$  is used to calculate the performance index's sum with squares of control increments.  $N_1$ ,  $N_2$ , and  $N_u$  values define cost and control horizon.

The  $J$  value is minimized using the optimization unit by calculating the  $asc'_{in}$  and inputting the  $asc_{in}$  to the Compressor recycle system. The Recycle valve output is represented after the anti-surge controlling mechanism using NNPC controller is described in Equation (19) as follows:

$$m_r = O_{pid} \cdot asc_{in} \cdot \sqrt{P_2 - P_1} \quad (19)$$

The NNPC uses four input layers, five hidden layers, and 1-output layer for training the data. The 100 training samples with a sample interval of one second are selected for training the data in the NN training tool. The NNPC obtains the six iterations (epoch) with 8.44e-6 performance and six validation checks while training the data.

### V. RESULTS AND DISCUSSION

The Compressor recycle system with an anti-surge control mechanism using a PID controller with different controllers is presented in this section. The Simulation results of NNPC based compressor recycle system are introduced and compared with other controllers like PID controller, FLC, and NFC to realize the performance metrics. The NNPC based Compressor recycle system is simulated with the following assumption. The mass flow ( $m$ ) and compressor speed ( $\omega$ ) is set to zero initially; two volumes of Pressure ( $V_1$  and  $V_2$ ) are defined as ambient. The higher mass flow will be obtained by opening the recycle valve. When more mass flow occurs, the operating point (OP) positions are shifted to the right position in  $\psi c$ . The simulation results of the Compressor recycle system are represented in Fig. 8. The compressor output mass flow ( $m$ ), throttle valve output ( $m_t$ ), recycles valve output ( $m_r$ ), and feed flow valve output ( $m_f$ ) is represented on the left-hand side. The torque drive's speed ( $\omega$ ), suction pressure ( $P_1$ ), and Plenum pressure ( $P_2$ ) are presented on the right side of Fig. 8.

Fig. 8. Simulation Results of Compressor Recycle System.

The mass flow is set to zero initially and varied based on speed, Throttle, and feed flow response. The throttle output (mt) is changed based on plenum pressure ( $P_2$ ) and ambient condition ( $P_{01a}$ ). The recycle output is not activated until the controller responds and varies based on NNPC controlling mechanism. The feed flow ( $m_f$ ) is zero initially and increases to some extent and gradually decreases, which indicates the system enters into surge line (SL). When the feed flow ( $m_f$ ) output is steady, the OP's are shifted from SL to SCL. The torque drive provides 3000 rad/s—speed output ( $\omega$ ) after the controller response. The two pressures ( $P_1$  and  $P_2$ ) outputs are decreased eventually and reach steady-state after NNPC response.

The operating point (OP) position and SL and SCL using different controllers in the Compressor recycle system is represented in Fig. 9. The current OP position is identified using other controllers (PID, FLC, NFC, and NNPC) and

compared with SL and SCL. The SL and SCL are defined initially and perform the simulation of the Compressor recycle system using different controllers to obtain the OP's position.

The SL and SCL are linear and defined with i and j values using Equation (15). The OP is in the left position during the initialization of the Compressor recycle system. Later shifted to the right next to the SCL and moving around it. The OP is very near to SL and turns back to SCL using PID Controller, whereas, in FLC and NFC, The OP is flat and back to SCL. In contrast, The NNPC provides a better OP position, and OP is located next to the SCL. So, the NNPC provides a better OP position than PID, FLC, and NFC in Compressor recycle system.

The different controller's output response for Compressor recycle system is represented in Fig. 10. The output response of all the controllers is initially zero and later varied based on the controlling mechanism in Compressor recycle system.

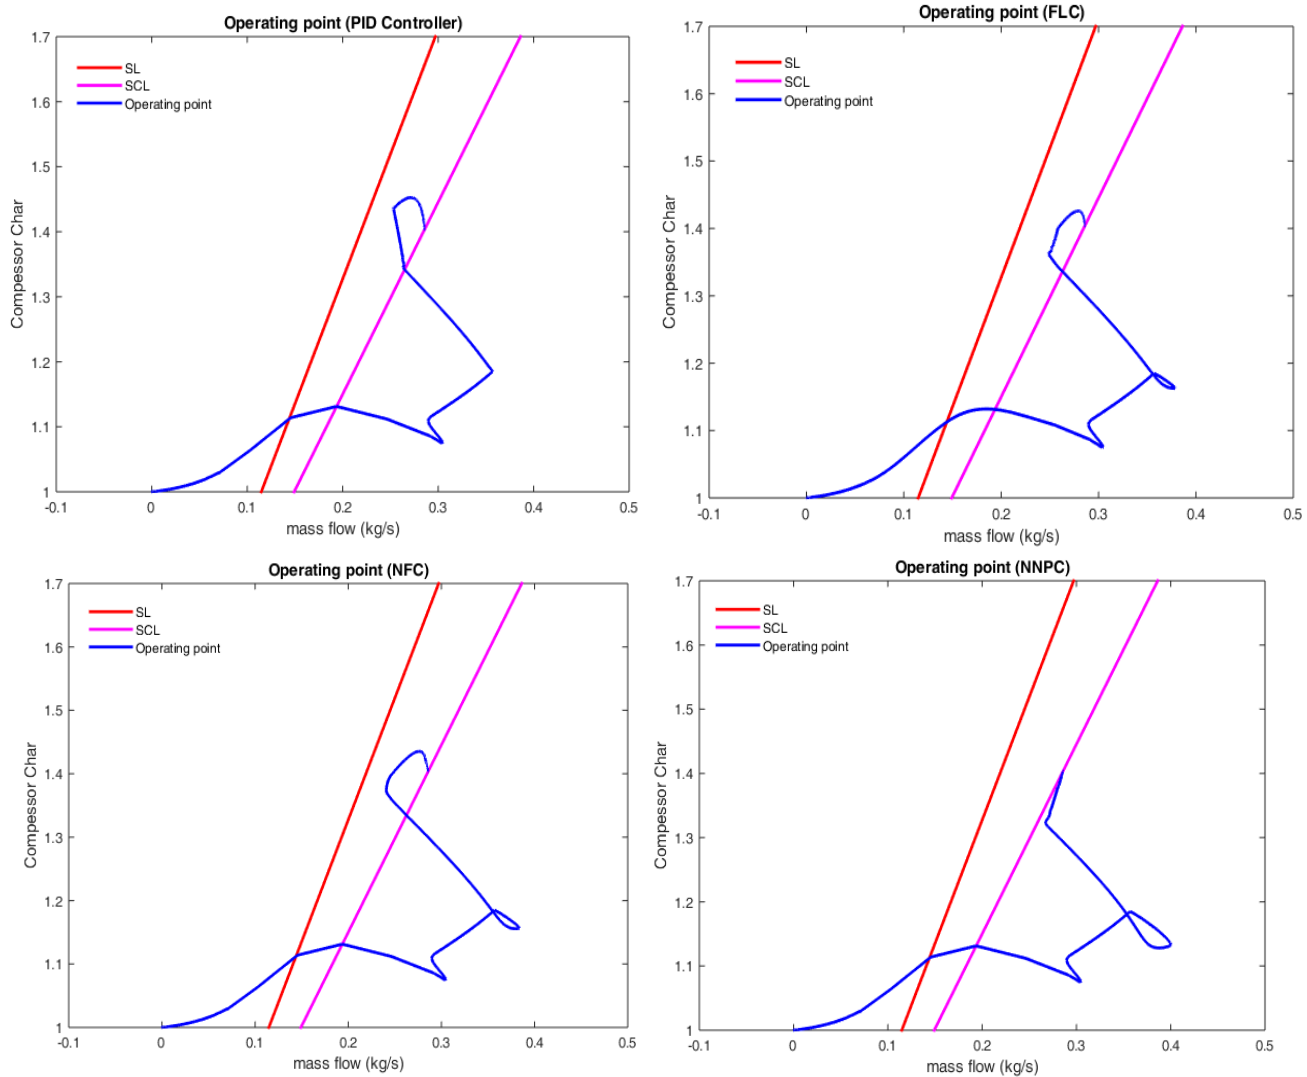

Fig. 9. Different Controller's Operating Points Position in Compressor Recycle System.

Fig. 10. Dynamic Response of different Controllers for Compressor Recycle System.

The FLC takes more time to provide the output response, whereas NNPC takes less time to provide output response than PID and NFC. The dynamic output response values of different controllers concerning time for the Compressor recycle system are represented in Fig. 11. The output response of the PID controller takes a rise time of 0.976 sec, settled at 4.27 sec with an overshoot (%) of 0.263 sec. Similarly, the FLC controller takes a rise time of 1.905 sec, settled at 3.87 sec with an overshoot (%) time of 0.077 sec. The NFC takes 0.1112 for rising time, settled at 0.236 sec with overshoot (%) time of zero. In contrast, the output response of the NNPC takes a rise time of 0.013 sec, settled at 0.2369 sec with an overshoot (%) of zero. Overall, the NNPC provides a better dynamic output response with less rise time, settled early, and zero overshoot time than PID, FLC, and NFC.

The error analysis of different controllers for the Compressor recycle system is represented in Fig. 12. The error analysis includes Integral Square Error (ISE), Integral Absolute Error (IAE), and integral time absolute error (ITAE) parameters. The error response of the NNPC based Compressor recycle system improves 14.49 % in ISE, 51.9 % in IAE, and 95.6 % in ITAE than the PID-based Compressor recycle system. Similarly, the 4.83 % in ISE, 34.8 % in IAE, and 91.04 % in ITAE are improved compared to FLC. Compared to NFC, the 11.86 % in ISE, 34.92 % in IAE and 95.53 % in ITAE are improved in NNPC based compressor recycle system.

Fig. 12. Error Calculation of different Controllers for Compressors Recycle System.

## VI. CONCLUSION AND FUTURE WORK

In this manuscript, an efficient NNPC based anti-surge control mechanism is modeled for variable-speed centrifugal Compressor recycle system. The NNPC provides higher mass flow in the recycle valve to the compressor system and avoids the surge with better stabilization. The Compressor is working at a more increased mass flow with low Pressure to avoid the surge. The simulation results of NNPC based Compressor recycle systems like mass flow, speed, and Pressure waveforms are discussed. The operating point's position with the Surge line and surge control line for different controllers is represented. The NNPC based mechanism provides dynamic response than PID, FLC, and NFC controller-based mechanisms. The dynamic responses (Rise time, settling time, and % overshoot time) of the NNPC based Compressor recycle system reduces the ISE of 14.49%, 4.83%, and 11.86% in PID, FLC, and NFC based Compressor recycle system. Similarly, NNPC also reduces the IAE and ITAE values than PID, FLC, and NFC-based controller mechanisms. In future, incorporate the proposed work with real-time gas plants to realize the performance metrics. Also extend the recycle system with new approach to analyze the stability of the compressor system.

**Abstract**—Applications, such as Internet of Things, deal with huge amount of transmitted, processed and stored images that required a high computing capability. Therefore, there is a need a computing architecture that contribute in increasing the throughput by exploiting modern technologies in both spatial and temporal parallelisms. This paper conducts a parallel quad-engine cybersecurity architecture with new configuration to increase the throughput. using DE1-SoC and Neek FPGA boards and HDL. In this architecture, each engine operates with 600MHz maximum frequency. Each image is divided into four parts of equal size and each part processed by single engine concurrently to achieve spatial parallelism. Internally, engine is handling image's part in temporal parallelism and deep pipelining abstraction applied in every engine by dividing it to sub modules to execute different tasks concurrently. All data processed in engines is encrypted via AES algorithm that implemented as a significant part of engine architecture. The obtained results increased the throughput by four times, with 153,600Mbps, that make this computing architecture efficient and suitable for fast applications such as IoT and cybersecurity level of processing.

**Keywords**—Field programmable gate array (FPGA); spatial parallelism; cybersecurity; throughput component

## I. INTRODUCTION

Data processing and transfer and store have grown dramatically in the last year because they are used in different applications via different communication networks. This growth requires an exploitation of modern technologies to enhance and increase this processing in a parallelism manner to achieve high throughput. Various algorithms and devices introduced by researchers to achieve this goal in both software and hardware implementations by exploit the available modern techniques and possibilities in temporal and spatial parallel processing [1]. Gaining high productivity requires devices that are reconfigurable, work in real-time, efficient, low power consumption, and the ability to perform parallel processing features. One of the candidates' approaches to spatial parallel processing is field-programmable gate arrays (FPGAs), whose features meet this. So, one can take advantages of FPGAs to implement a platform to achieve efficient parallelism for real time processing applications [2].

At the same time, much of the data, which are transferred through cyberspace, include confidential or personal information, so it has become a target for hackers and adversaries to access, change, or damage them. Therefore, it is necessary to use techniques that maintain the confidentiality and integrity of these data. One efficient way to achieve this is

cryptography, in which various algorithms that vary in their security are proposed. An algorithm of cryptography, which has not yet been found a way to break it, is the AES algorithm [3]. However, the AES algorithm has high computational power to achieve its operations because of the large number of rounds that are used, and the need for more time to encrypt the data [4,5].

To obtain faster and more efficient computation power to encrypt massive data with high throughput, the AES algorithm must be implemented in a parallel manner. Therefore, the FPGA is a candidate approach to hardware implementation of the AES algorithm to ensure data protection, high-speed encryption rate, and high throughput.

This paper focuses on hardware architecture implementation on FPGA that based on true spatial and temporal parallelism using quad engines for cybersecurity. This architecture works through partition each image into four parts and distributes these parts to multiple engines that can process data in temporal and spatial parallelism the image parts concurrently.

The paper is organized to include a survey related work that has been conducted by some academic and researchers in Section II. Section III includes a detail description of the proposed architecture. Section IV contains the implementation results. It includes a new architecture to improve the performance in terms of the operating frequency and throughput of the AES algorithm. The results of the simulation and a comparison with previous studies are presented in Section V. Section VI presents the conclusions of the study.

## II. RELATED WORK

Different approaches have been proposed to enhance hardware implementation to obtain more image processing performance. The widespread deployment of field-programmable gate arrays (FPGAs) has enabled multi-processing in real-time processing applications, which has accelerated massive spatial parallel applications. Throughput increasing is one of the important criteria in measuring the efficiency of the used technique. To achieve this, there is a need to make use of spatial parallelism and duplicate processing units that execute simultaneously. This can done by divide the main task into several subtasks, each subtask is executed one processing elements [5]. Combining the FPGA features with spatial parallelism will help to decrease the complexity, cost, and power consumption and increase the throughput of the proposed systems. In [6], a design and

simulation was proposed to enhance the images using VHDL language using Xilinx Virtex- 2 Pro FPGA and MATLAB. In [7], the AES algorithm was implemented using Xilinx's Virtex-E and Virtex-II devices to achieve faster FPGA – based implementation. The obtained experimental results were throughput of 17.80 Gbps on a Virtex-II with a clock frequency of 139.1 MHz and 10750 slices were used.

The Altera FLEX FPGA family utility was used in [8] to execute different types of algorithms that deal with the image as a whole image instead of dealing with pixels values individually. For image encryption, Chang et al. al in 2009 implemented the AES algorithm on an FPGA using a Virtex22 device. The core of the AES was 32 bits, and it occupied 104 slices. The throughput of implementation was 794 Mbps and the efficiency was 7.93 Mb/slice [9]. In 2010, Kumar and Purohit implemented a 128-bit AES algorithm on an FPGA using a Xilinx Spartan 3 device to achieve high speed using low-cost devices [10].

In [11], Manoj and Manjula implemented an AES 128 bit using a Xilinx Spartan 6 device, 8-bit input (data pixels), and unrolled them to 128 bits. The throughput of encryption was 252.132 Mb/s, and the efficiency was 0.53 Mb/slice. In [12], Karimian, Rashidi, and Farmani implemented a 128-bit AES algorithm using an Altea Stratix device, achieving a throughput of 617 MB/s and an efficiency of 0.76 Mb/slice. In [13], the throughput obtained from implemented a 128-bit AES using a Xilinx Spartan was 3.40 GB/s and efficiency of 5.43 Mb/slice. In [14], some algorithms for image enhancement were implemented using the Spartan3E FPGA kit to obtain high-performance digital signal processing applications. MATLAB, Xilinx ISE, Verilog HDL, and ModelSim were used for this implementation. In [15], Xilinx 14.2 software for 2D and 3D image enhancement was used to design and develop algorithms to enhance the size of image pixels. In [16], the image enhancement and DE noising process was introduced using point processing methods by using a partial dynamic reconfiguration of the FPGA to decrease the requirement of resources and increase the performance. In [17], image enhancement approaches were introduced to enhance grayscale images by adopting a custom hardware processor on an FPGA. The implementation depended on the use of filters and the VERILOG hardware description language. The achieved image enhancement of these approaches used neighborhood processing operations in the spatial domain using parallel processing.

In [18], Rahimunnisa et al. the proposed structure is implemented in a Virtex-6 XC6VLX75T FPGA device, which gave a throughput of 37.1 Gb/s with a maximum frequency of 505.5 MHz in [19], Groth implemented AES encryption on a Xilinx Kintex27 FPGA for application data of the biometric image. The implementation throughput was 40 GB/s with an efficiency of 5.27 Mb/slice and a powerful performance of 286 GB/w. In [20], techniques to perform task-level out-of-order execution were proposed and implemented using the Xilinx Virtex-5 FPGA device to improve flexibility. The implementation results showed a better efficiency in terms of performance and resource usage. In [21], AES was implemented on FPGA; the obtained experimental results were a throughput of 113.5 GB/s on a Spartan-6 device. In [22], the

focus was on exploring the features of FPGA parallelism to process image applications in spatial parallelism for real-time image processing. They used board DE2-115 as a vehicle project, while the VHDL hardware description language was used as the hardware design of the system. The operating frequency was 1GHz, and the system could be reconfigured to implement several algorithms using the same hardware. In [23]. In [24] architecture was conducted to optimize parallel processing and implement this architecture on FPGA. It improved the consumption of the power by 90% in compared with others. Its throughput was 1.34 GB/s at a 131.16 MHz operating frequency for processing images with a size of  $512 \times 512$ .

Presented two pipelined algorithms for effective processing time reduction using pipelined and parallel techniques to process the AES encryption algorithm using FPGA. Xilinx "Spartan-3A/3AN FPGA Starter Kit was used in the implementation of algorithms. The results showed that parallel implementation was good.

### III. PROPOSED HARDWARE PARALLELISM QUAD-ENGINE ARCHITECTURE

The introduced architecture aims increasing the operating frequency and throughput, while decrease the power dissipation, area, and latency by exploiting a quad-engine with true parallelism. Each engine operates with 64 bits and a frequency of 600 MHz.

This section provides the structure of the proposed architecture and the mechanism for performing true parallelism quad-engine cybersecurity. The architecture in the spatial domain begins with the top-level design of the proposed architecture, as shown in Fig. 1.

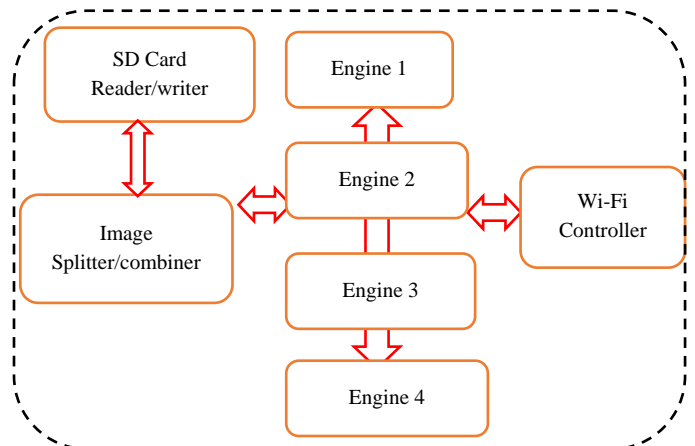

Fig. 1. System Top Level Design and Implementation True Parallelism Quad-Engine Cybersecurity Architecture.

#### A. Hardware Components

To implement the proposed approach, the following components are used:

- SD Card: used Micro SD card interface to read and store images.
- FPGA board: DE1-SoC board and NEEK board with the same TLD are used.

- Wi-Fi controller: Wi-Fi controller in DE1 as (Server) and Wi-Fi controller in NEEK board as (Client) to transfer the image between the two boards.

### B. Software Component

The VHDL, synthesized by Altera Quartus II and simulated using Modelsim are used to implement the architecture.

### C. The Proposed Algorithm

The design steps of the algorithm take traditional AES and apply it to an FPGA platform to exploit spatial and temporal parallelism to increase throughput of cybersecurity encryption/decryption processing.

Input: Images need encryption

Output: Encrypted message.

- Read four images each time and stores them on an SD card.
- Split each image spatially into equal four parts. Each part is represented by a matrix and takes a number of two digits, where the first digit is part number and the second digit is image number, (for image 1, the parts number are 11, 21, 31 and 41), Fig. 2.
- Make cycle shifting to the image parts. The shifting amount depends on the image number, as in Fig. 3.
- Sent each one of the four parts independently to one of the four-engine in the encryption/decryption unit, each engine will encrypt 1/4 image using AES 128-bit block.
- In each engine, a deep pipelining is used by divide it into sub modules to process different task.
- After encrypt the image parts, they are merged to create the encrypted image.

The cycle shifting of image parts is done as follow:

- Engine 1, will send the first part of all 4 images (11, 12, 13 and 14).
- Engine 2, will rotate (as a ring counter) forth index in this image 2 to become the first part (24, 21, 22 and 23), cycle shift by 1.
- Engine 3, will rotate again to start with the next index in image 3, cycle shift by 2.
- Engine 4, will rotate again to start with the next index in image 4, cycle shift by 3.

To decrypt the image, the encryption steps are executing in reverse order.

The architecture processes four parts at the same time, using spatial and temporal parallelism, where each engine processes one part from each image with 600MHz and 64 bits. The input images used in this approach can have different colors or grays of any size. The WIFI controller controls the transfer between the DE1-SoC board and NEEK board. It is necessary for the two boards to have the same TLD.

Fig. 2. Quad Sub Image.

Fig. 3. Shifting Sub Image.

The throughput, number of bits processed per unit time, is measured using the following equations, specified in Mbps or Gbps.

$$\text{Throughput} = (F_{\max} * 4 * \text{No. of bits processed}) \quad (1)$$

Where  $F_{\max}$  represent the maximum frequency and in the proposed design, taking 600 MHz for  $F_{\max}$ , No. of bits equals to 64 bit, whereas, the 4 represents the number of used engine.

### IV. IMPLEMENTATION

The proposed architecture was used to implement the traditional AES algorithm as an application to encrypt four image at the same time.. To encrypt these images the DE1\_Soc, Neek board FPGA device, and Wi-Fi (server and client) are connected together. The Altera Quartus Prime18.1 tool used for the synthesis. These images may have different types of colors or gray of any size.

First, the images were read, as shown in Fig. 4. After reading the image will be doing splitting process, each image was split into four sub-images. Fig. 5 illustrates the sequence of quad sub image 1, 2, 4, and 5.

Then perform the cycle shifting for parts of each image independently, Fig. 5.

Fig. 4. Input Image.

Fig. 6. Split each Image into 4 Sub-Images.

Fig. 5. Step 1 Split Image to Sub Images.

Fig. 7. Split Image Step to Sub Images.

Now, each part is transferred to a separate engine for execution, which performed in a pipelining manner, temporal parallelism. The engine consists of the necessary operation of an encryption/decryption unit. Each engine operates at 600 MHz, and each sub-image part is encrypted by one engine. The four sub-image encryption was performed simultaneously, as shown in Fig. 6.

In Fig. 6 to 10 shows images of real-time execution on FPGA that are highlighted on the LCD touch screen of the NEEK board. VHDL is used to write the design code, in addition to use Altera Quartus II for synthesized. Fig. 6 shows the sub-images of the four image parts after the splitting process is performed.

Each part of the image is sent independently to one of engines, and then a new part of new image following it. Sub images are reordered and sent to make the system more secure.

Fig. 8. Real Live Implementation of First Splitting on NEEK Board.

Fig. 9. Real Live Encryption of Images Splitting on NEEK Board.

Fig. 10. Real Live Implementation of Second Splitting on NEEK Board.

Table I includes the details Altera Quartus utilization and Table II includes performance comparisons with other works.

TABLE I. SUMMARY OF DEVICE UTILIZATION USING ALTERA QUARTUS

| Resources           | Available                | Used    | Utilization |
|---------------------|--------------------------|---------|-------------|
| Total Logic Element | 25K logic elements (LEs) | 19,351  | 77.4%       |
| Dedicated Register  | 50                       | 43      | 86%         |
| Memory Bits         | 66 M9K                   | 428,133 | 68%         |

TABLE II. PERFORMANCE COMPARISON

| Reference        | FPGA Device             | Throughput   |
|------------------|-------------------------|--------------|
| Our architecture | The DE1_Soc, Neek board | 153,600Mbps  |
| [7]              | Virtex-II               | 17.8 Gbps    |
| [9]              | Virtex 22               | 794 Mbps     |
| [11]             | Xilinx Spartan 6        | 252.132 Mbps |
| [12]             | Altera Statix           | 617 Mbps     |
| [18]             | Virtex 6                | 37.1 Gbps    |
| [21]             | Spartan 6               | 113 Gbps     |
| [23]             | Spartan 3A/3AN          | 1.34 Gbps    |

The obtained results showed the increasing in the throughput by four times, the throughput rate becomes 153,600Mbps that make this introduced architecture efficient and suitable for fast applications Area utilization was specified with respect to the number of slices used in Altera FPGAs. Additionally, four look-up tables (LUTs) and eight storage elements exist in each slice of the Altera FPGA.

## V. CONCLUSION

This study demonstrates the architecture ability to perform the AES algorithm in spatial and temporal parallelisms. To implement this project, several Altera® Nios II Embedded Evaluation Kit and Cyclone III Edition features were harnessed, such as switch inputs and the LCD touch screen alongside the LEDs. Each of the four engines operates with maximum 600 MHz clock frequency, and the implementation results throughput rate is 153,600Mbps. These results make this introduced architecture efficient and suitable for fast image processing, such as using complex cyber security algorithms for secure information.

## ACKNOWLEDGMENT

I would like to thank my supervisors Dr. Amiza Amir and Dr. Muataz Hameed, UniMAP staff, my family, and everyone who supported me to make this work.

**Abstract**—Cotton is a very important crop, as India leads it in terms of production in the world; and also that a vast number of manpower is engaged in farming as well as post-harvest processing and management of different derivatives of it. Weather is crucial for the productivity of the crop. The challenges of climate change; availability of limited land and water for farming; lack of knowledge for good cultivation practices and judicious use of agricultural inputs with farmers are critical hindrances for improving productivity. This requires thorough research on land preparation and use, how to improve fertility of soil, good agronomic practices in lieu of variable climatic conditions, etc. All the talukas of the three districts of North Gujarat where cotton is cultivated have been selected purposively for this study. The effect of soil type, soil pH, soil organic carbon, phosphorous, potassium, precipitation and temperature were selected as independent factors. The yield of cotton crop has positive correlation with the selected parameters. The data sets were applied for analytical process to WEKA. The difference between average of predicted and actual yields of all talukas for high rainfall year 2013 was only 1.55 per cent. The difference between actual and predicted yield for the low temperature year (2015) in different talukas of all talukas was only 0.44 per cent.

## I. INTRODUCTION

One of the great challenges of agricultural development is to guarantee food security. Simultaneously, securing fiber requirement is also one of the necessities of human being. Cotton is an important crop for world's poor. Cotton is grown commercially in more than 80 different countries, mostly in the longitudinal band between 37°N and 32°S.

Cotton is especially adapted to semi-arid and arid environments, where it is either grown as rain-fed or with irrigation. About 53 per cent of the world's cotton growth areas benefit from full or supplementary irrigation. Cotton has certain resilience to high temperatures and drought due to its vertical tap root. The crop is, however, sensitive to water availability, particularly at the stage of flowering and boll formation. Rising temperatures favor development of the cotton plant, unless day temperatures exceed 32° C.

Climate change will affect the cotton crop in numerous ways in different areas. Temperatures are expected to increase all over India. Rainfall intensity during monsoons may become a prevalent problem. Higher temperatures in already hot areas

may hinder cotton development and fruit formation. Rain-fed cotton production may suffer from higher climate variability leading to periods of drought or flooding. With respect to the production level, cotton has limited capacity to respond to heat stress, through 'compensatory growth'. Its vertical tap root also provides resilience against spells of drought, but also makes it vulnerable to water-logging.

Cotton is a natural plant fiber which grows around the seed of the cotton plant. Fibers are used in the textile industry. First, the cotton fiber is obtained from the cotton plant and then spun into yarn. Further, the cotton yarn is woven or knitted into fabric. The use of cotton has a long tradition in the clothing industry due to its desirable characteristics. The value of world cotton production in 2017-18, was around US\$50 billion. Cotton is a driver of economic development and is of critical importance to the economies of developing and least developed countries. Cotton connects people to markets and provides economic opportunities on the frontiers of the world economy.

Of course, there are many factors that affect prediction of cotton. However, crop yield prediction is extremely challenging due to numerous complex factors which affect cotton crop at different growth stages (a short list is as per Annexure 1). It is very difficult to have a site specific measurement of each of these factors and to evaluate their combined effect on cotton production. As such, the current study was planned to look at the effect of the key seven parameters and their contribution to production.

## II. BACKGROUND

Cotton is one of the major cash crops grown in India. The productivity of this crop can be improved dramatically if correct agro-technologies are adhered. The yield gap of research farms or potential of a variety and that of average harvest at farmers' fields is very high.

Cotton is a crucial component of the Indian economy as her textile industry is predominantly cotton based. India is one of the biggest producers and also exporter of cotton fabric. Cotton cultivation is a well-established practice in India. Gujarat, Maharashtra, Telangana, Andhra Pradesh and Karnataka are the major cotton producer states in India. Indian textile industry contributes to around 5 percent to the nation's gross domestic product (GDP), 14 percent to industrial production and 11 percent to total export earnings. After agriculture, textile industry is the second largest employer of over 510 lakh people directly and 680 lakh people indirectly.

The challenges of climate change; availability of limited land and water for farming; lack of knowledge for good cultivation practices and judicious use of agricultural inputs with farmers are critical hindrances for improving productivity. This requires thorough research on land preparation and use, how to improve fertility of soil, good agronomic practices in lieu of variable climatic conditions, etc. The analytical issues, till yesterday, were been handled by applying different statistical tools. However, using tools of data mining and other diagnostic approaches are becoming more useful in making decisions regarding production practices and also prediction of yields [4].

The comprehensive approach, which comprises of various technologies and methods, for example, statistics, Data Mining, Visual Data Mining (VDM), information handling, Data Warehousing (DW), Online Analytical Processing (OLAP) and different frameworks, was considered to be a useful approach. It can also help in better crop predictions based on historical data.

#### A. Role of DM in Agriculture

An accurate estimate of crop production and risk helps the country in planning supply chain decision like production scheduling. Business such as seeds, fertilizers, agrochemicals and agricultural machinery industries plan production and marketing activities based on crop production estimates [9], [14]. These are helpful for the farmers and the government in decision making namely:

- 1) It helps farmers in providing the crop yield record with a forecast, so as to reduce the risk of crop management.
- 2) It helps the government in making policies for crop insurance and supply chain operations.

In large data sets, data mining is the computational process for discovering new patterns. Data mining provides major advantage in agriculture for disease detection, problem prediction and for optimizing inputs like pesticides, irrigation, fertilizers, etc. With advancement in technological applications in agriculture, a lot of information is made available. Hence, data mining techniques in agriculture is used for pattern reorganization and crop health detection. Reliable and timely estimates of crop production are important for taking various decisions for marketing, pricing, storage, distribution and import-export. The crop yields primarily depend on diseases, pests, climatic conditions, time of harvest, etc. As such, these predictions are very useful for agriculture domains. Data mining techniques are used not only for quantifying requirements of inputs and timely executing various agricultural operations but also for pre-harvest forecasting for crop yields. Data mining is also called as knowledge discovery database (KDD).

Data mining tasks can be classified into two categories:

- Descriptive data mining.
- Predictive data mining.

Descriptive data mining tasks characterize the general properties of the data in the database while predictive data mining is used to predict the direct values based on patterns

determined from known results. Prediction involves using some variables or fields in the database to predict unknown or future values of other variables of interest. As far as data mining technique is concern, in most of the cases, predictive data mining approach is used. Predictive data mining technique is used to predict future crop, weather forecasting, pesticides and fertilizers to be used, revenue to be generated and so on. [4].

### III. SURVEY OF LITERATURE

Many research studies have focused on the importance of data mining to be used as a tool for analysis of big data of agriculture for meaningful conclusions [1], [2].

Ashok Kumar and N. Kannathasan dealt with various data mining procedures that can be utilized in farming. Their examination suggested that a correlation of various data mining strategies could deliver a productive calculation for soil grouping [3].

M. C. Geetha researched Data Mining Techniques in Agriculture and argued that information mining in agriculture is quite useful to forecast the productivity and production of crops. She talked about various information-digging applications for tackling distinctive farming related issues [8].

Ruß G. utilized information got from three fields of Germany. Researcher utilized regression methods on farming yield information and reasoned that help vector regression can fill in as a superior reference demonstrates for yield expectation. Likewise, the model parameters which have been built upon one informational index can be utilized for different techniques on selected agriculture data [12].

S. Veenadhari, B. Misra, and C. Singh endeavored to aggregate the examination discoveries of various scientists who took a shot at harvest profitability information. The machine learning approach of coordinating software engineering with farming will help in gauge farm yields adequately [13].

A study by Ekasingh B. S. Ngamsomsuke K. Letcher R. A. & Spate J.M. has analyzed how data mining may be applied for the purposes of crop production [7]. Majority of earlier researchers including Dunstan D. (2009) who used data mining as a supportive tool with statistical analysis, have focused on crop yield management and its' quality evaluation [6].

Raorane A.A. and Kulkarni R.V. (2012) talked about different data mining strategies, as a result of use of data mining methods; an effective production system can be derived that can take care of complex farming issues [11].

Ramesh Vamanan and K. Ramar (2011) presumed that the Data Mining method (Naïve Bayes Classifier) when connected to a farming soil profile may enhance the confirmation of legitimate soil profile, substantial examples and profile classification are contrasted with standard statistical investigation strategies [10].

### IV. MATERIALS AND METHODOLOGY

#### A. Data Acquisition

The focal point of this research was to look at the effect of temperature, rainfall and soil parameters (namely soil type, Soil

pH, Carbon, phosphorus, and potassium) on the cotton yields for different farming locales in the study area.

For the present research, 27 talukas of the three districts of Gujarat State were taken. The soil parameter data were retrieved from the Soil Health Card data of Government of Gujarat routed through Anand Agricultural University, District Anand, Gujarat State. The production data were collected from the Department of Agriculture, Government of Gujarat, by approaching them personally and also by random access to farmers for verification of the information. The data of rainfall and temperature were collected from the Sardarkrushinagar Dantiwada Agricultural University, SKNagar, District Banaskantha, Gujarat State.

In the present study, the rainfall, temperature and five soil parameters were considered as independent factors and their effect on cotton productivity was analyzed. As a consequence, instances of cotton yield were examined against these datasets. The average rainfall, temperature and selected soil parameters of the ten years for each of the 21 talukas in the three districts were obtained from a secondary database. These data sets of ten years (from 2006 to 2015) were analyzed. The dataset was structured and combined to be managed in excel spreadsheet as talukas, average rainfall, maximum and minimum temperature, soil parameters, and cotton yield.

#### B. Analytical Procedure

To conduct different research experiments and calculations WEKA, Revolution R and SPSS have been used. Initially the data was collected and maintained in Microsoft Excel. Further, data transformation and other calculations were done in software like SPSS and Microsoft Excel. The total datasets was classified and kept in different folders; and further that ordered into the rainfall, temperature, and soil variation (pH, Carbon, Phosphorous, and Potassium) and yield. Different algorithms were tested in WEKA software to check and decide the most suitable among all algorithms and evaluate output with other datasets. These data were used in WEKA and R software for dept. analysis and experiments.

#### C. The Activity Experiments

The following examinations were done iteratively for calculating the impact of the climatic factors on cotton yield:

- 1) Rainfall and soil type relationship in view of the cotton crop.
- 2) Effect of nutritional variations of soil on cotton yield.

Further the data were restructured from the perspective of having sufficient depth and substance to be believable before initiating the processing. The lateral development happened because attributes were included from other data collection. Both the reduction and extension add up to the pre-preparing of the dataset and incorporation and delineation of outliers through Exploratory Visual Data Mining (EVDM) of the mapped information.

The compiled data were administered to techniques of combination, categorization, accumulation and statistical projection to locate elite method and related best fit design. In the auxiliary investigation through OLAP appraised for

association in the data sets. Examination of these outcomes were taken up and concluded accordingly.

At last, the two assortments of outcomes were combined and arranged diagrammatically to decide a general example that gave both a minute and apparent context of data. The datasets were then examined through a progression of tests which included cross classifications, correlation, sequencing, time series analysis and regression. The outcomes of these tests were then investigated and delineated in detail.

As a result of this study, recommendations for getting good cotton crop yields by managing the agronomical and other practices in lieu of the difficult weather and soil conditions were made for north Gujarat farming area.

#### D. Data Analysis

The information utilized in this investigation had diverse attributions and was comprised of five separate however related substances. The majority of the datasets were in connection with North Gujarat, India.

In the current research, different data were used with varied reasoning. As referred in Section 3.3, the different datasets comprised of temperature, soil type, rainfall and soil parameters were used. Different data sets were obtained either from secondary source of data namely Department of Agriculture, Government of Gujarat; Anand Agricultural University, Anand and Sardarkrushinagar Dantiwada Agricultural University, Sardarkrushinagar, Gujarat, India. The counter verification of these data and obtaining few other data were done by personal deliberation with scientists and farmers. All the datasets were fitted explicitly for the cotton crop production areas of the selected locale of the study.

The data extraction and pertinence involved using a number of software tools that represented an admixture of retrieving, pre-processing, scrutiny, data mining and revelation of temperature, soil type, rainfall, and soil parameters' data. The process was alienated into five fundamental stages namely data collection, pre-processing, handling, data examination and processing.

Different crop have their critical and optimum climatic requirements, for example, the increasing temperature may affect agriculture by reducing the productivity on different crops in different seasons. The analysis of climatology at the region level is most useful for the solution of practical agricultural problems. Temperature has a complex relationship to the development of plant at different growth stage.

#### E. Basic Model Process Flow

The entire information extraction and analysis process is demonstrated graphically in Fig. 1 below. It framed the initial segment of research in anticipation of the data collection, data preparation, data modeling and data storage in the protected investigations.

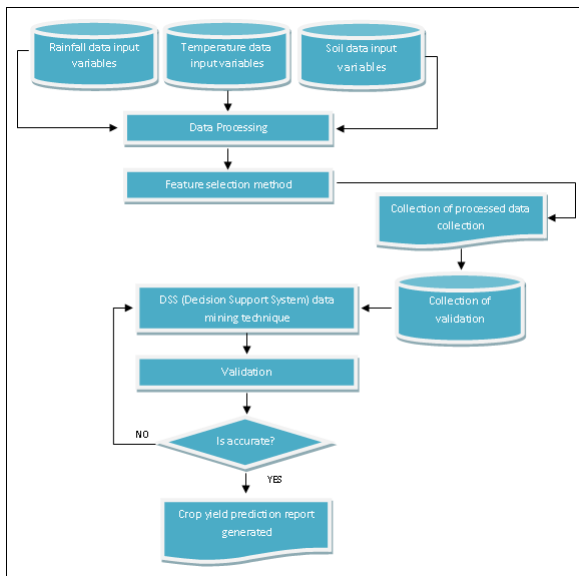

Fig. 1. Basic Model of Process Flow.

### F. Analytical Procedure

To conduct different research experiments and calculations WEKA, Revolution R and SPSS have been used. Initially the data was collected and maintained in Microsoft Excel. Further, data transformation and other calculations were done in software like SPSS and Microsoft Excel. The total datasets was classified and kept in different folders; and further that ordered into the rainfall, temperature, and soil variation (pH, Carbon, Phosphorous, and Potassium) and yield. Different algorithms were tested in WEKA software to check and decide the most suitable among all algorithms and evaluate output with other datasets. These data were used in WEKA and R software for dept. analysis and experiments.

- The Activity Experiments

The following examinations were done iteratively for calculating the impact of the climatic factors on cotton yield:

- 1) Rainfall and soil type relationship in view of the cotton crop.
- 2) Impact of rainfall on cotton yield.
- 3) Impact of temperature on cotton yield.
- 4) Combined effect of rainfall and temperature on cotton yield.
- 5) Effect of nutritional variations of soil on cotton yield.

As a result of this study, recommendations for getting good cotton crop yields by managing the agronomical and other practices in lieu of the difficult weather and soil conditions were made for north Gujarat farming area.

## V. RESULTS AND DISCUSSION

### A. Taluka Wise Yield Prediction for Low and High Rainfall Years

The data sets of low and high rainfall years (2009 and 2013 respectively) were applied for analytical process to WEKA. The datasets used and calculations made in WEKA are given in Table I.

TABLE I. WEKA PREDICTION FOR YEAR 2009 AND 2013

| Taluka      | LR 2009         |              | HR 2013         |              |
|-------------|-----------------|--------------|-----------------|--------------|
|             | Predicted Yield | Actual Yield | Predicted Yield | Actual Yield |
| AMIRGHADH   | 649.52          | 488          | 627.46          | 598          |
| BECHARAJI   | 481.23          | 584          | 620.87          | 568          |
| BHABHAR     | 500.49          | 526          | 564.92          | 523          |
| DANTA       | 401.41          | 456          | 392.28          | 395          |
| DANTIWADA   | 440.27          | 556          | 610.46          | 630          |
| DEESA       | 657.96          | 621          | 615.55          | 630          |
| DHANERA     | 599.29          | 578          | 647.30          | 615          |
| DIYODAR     | 594.51          | 543          | 645.93          | 599          |
| HIMATNAGAR  | 386.82          | 599          | 605.44          | 617          |
| IDAR        | 737.05          | 636          | 557.37          | 601          |
| KADI        | 427.99          | 500          | 613.31          | 594          |
| KANKARAJ    | 514.21          | 513          | 619.88          | 597          |
| KHEDBHRAMHA | 373.41          | 408          | 435.85          | 451          |
| KHERALU     | 211.74          | 300          | 370.83          | 350          |
| MAHESANA    | 579.97          | 548          | 645.34          | 602          |
| PALANPUR    | 604.30          | 623          | 627.25          | 645          |
| POSHINA     | 475.79          | 348          | 375.57          | 303          |
| PRANTIJI    | 508.20          | 615          | 573.36          | 536          |
| SATALASANA  | 289.91          | 296          | 369.98          | 366          |
| TALOD       | 535.21          | 642          | 537.68          | 566          |
| UNJHA       | 365.22          | 311          | 387.25          | 369          |
| VADALI      | 494.03          | 598          | 633.98          | 565          |
| VADGAAM     | 384.59          | 508          | 352.14          | 439          |
| VADNAGAR    | 601.71          | 578          | 576.96          | 754          |
| VIJAPUR     | 543.93          | 721          | 721.76          | 685          |
| VIJAYNAGAR  | 448.53          | 568          | 539.17          | 495          |
| VISNAGAR    | 597.04          | 654          | 632.21          | 684          |

The difference between actual and predicted yield for the low rainfall year (2009) in different talukas varied greatly. It is obvious that the maximum difference in predicted and actual yield was observed for Poshina taluka as 36.72 per cent, followed by Amirghadh taluka (33.10 per cent) and Unjha taluka (17.43 per cent). The average difference between maximum value of predicted yield and actual yield was 36.72 per cent. The average difference between minimum value of predicted yield and actual yield was -35.42 per cent. However, the difference between average of predicted and actual yields of all talukas was only -5.39 per cent.

The difference between actual and predicted yield for the high rainfall year (2013) in different talukas varied greatly. It is obvious that the maximum difference in predicted and actual yield was observed for Poshina taluka as 23.95 per cent, followed by Vadali taluka (12.21 per cent) and Becharaji taluka (9.31 per cent). The average difference between maximum value of predicted yield and actual yield was 23.95 per cent. The average difference between minimum value of predicted yield and actual yield was -23.48 per cent. However, the difference between average of predicted and actual yields of all talukas was only 1.55 per cent.

### B. Taluka Wise Yield Prediction for Low and High Temperature Years

The difference between actual and predicted yield for the low temperature year (2015) in different talukas varied greatly.

It is obvious that the maximum difference in predicted and actual yield was observed for Becharaji taluka as 18.03 per cent, followed by Vadnagar taluka (17.01 per cent) and Satlasana taluka (16.27 per cent). The average difference between maximum value of predicted yield and actual yield was 18.03 per cent. The average difference between minimum value of predicted yield and actual yield was -29.24 per cent. However, the difference between average of predicted and actual yields of all talukas was only 0.44 per cent.

The difference between actual and predicted yield for the high temperature year (2010) [5] in different talukas varied greatly. It is obvious that the maximum difference in predicted and actual yield was observed for Talod taluka as 34.88 per cent, followed by Prantij taluka (26.02 per cent) and Vijaynagar taluka (25.05 per cent). The average difference between maximum value of predicted yield and actual yield was 34.88 per cent. The average difference between minimum value of predicted yield and actual yield was -38.34 per cent. However, the difference between average of predicted and actual yields of all talukas was only -1.87 per cent.

The data sets of high and low temperature years (2010 and 2015 respectively) were applied for analytical process to WEKA. The datasets used and calculations made in WEKA are given in Table II.

TABLE II. WEKA PREDICTION FOR YEAR 2010 AND 2015

| Taluka      | HT 2010         |              | LT 2015         |              |
|-------------|-----------------|--------------|-----------------|--------------|
|             | Predicted Yield | Actual Yield | Predicted Yield | Actual Yield |
| AMIRGHADH   | 502.43          | 564          | 629.09          | 752          |
| BECHARAJI   | 558.29          | 528          | 634.99          | 538          |
| BHABHAR     | 490.08          | 547          | 544.97          | 518          |
| DANTA       | 388.33          | 383          | 394.86          | 558          |
| DANTIWADA   | 578.35          | 485          | 665.49          | 621          |
| DEESA       | 631.26          | 606          | 613.14          | 589          |
| DHANERA     | 555.71          | 560          | 640.64          | 604          |
| DIYODAR     | 534.43          | 630          | 595.15          | 592          |
| HIMATNAGAR  | 659.87          | 575          | 638.67          | 623          |
| IDAR        | 404.08          | 513          | 608.32          | 627          |
| KADI        | 498.56          | 537          | 560.68          | 540          |
| KANKARAJ    | 394.64          | 640          | 590.18          | 640          |
| KHEDBHRAMHA | 464.23          | 451          | 440.14          | 434          |
| KHERALU     | 278.17          | 320          | 361.47          | 330          |
| MAHESANA    | 539.36          | 574          | 616.16          | 603          |
| PALANPUR    | 520.94          | 630          | 640.54          | 733          |
| POSHINA     | 345.32          | 388          | 378.34          | 368          |
| PRANTIJ     | 626.34          | 497          | 594.32          | 652          |
| SATALASANA  | 303.52          | 315          | 377.89          | 325          |
| TALOD       | 698.69          | 518          | 587.47          | 620          |
| UNJHA       | 300.64          | 334          | 378.01          | 350          |
| VADALI      | 594.92          | 526          | 618.91          | 629          |
| VADGAAM     | 278.92          | 364          | 486.74          | 540          |
| VADNAGAR    | 583.01          | 670          | 772.29          | 660          |
| VIJAPUR     | 753.58          | 694          | 700.61          | 666          |
| VIJAYNAGAR  | 573.98          | 459          | 542.80          | 589          |
| VISNAGAR    | 640.13          | 674          | 702.45          | 673          |

## VI. DISCUSSION

Prediction of yield of a crop is very difficult; as it is the sum of complex interrelationship of many factors. The water affects a lot on cotton crop production. Though the farmers have no control on precipitation; although if having facilities of irrigation; timely irrigation, method of irrigation, quantity of irrigation and other irrigation management issues plays very important role in cotton crop production. Even delaying irrigation by one or two days in a peak season alters the effect of insect and pest infestation on the crop. In the current research, the data mining classification function of Gaussian Processes showed strong positive correlation between the average annual rainfall and cotton crop yield for the selected 27 talukas.

If real time outputs of this information are communicated to farmers for improving their crop management, it can really contribute to sustainable as well as improved production.

## VII. CONCLUSION

Data mining is the process of finding the useful outcomes from the large data sets. During this work, the time series forecasting package have been used for regression approach of Gaussian Processes for yield prediction. The Gaussian Processes algorithm using with parameters like year, crop yield, temperature, rainfall and the five soil parameters are considered within the model development.

Another important factor for cotton crop production is temperature. Temperature in air and soil; difference in day and night temperature; sudden changes in temperature; etc affects the productivity. The hot winds, at a particular growth period are harmful for and at a different growth period is useful for production. When temperatures become too hot, fertilization may be compromised, leading to fewer seeds produced per boll, smaller boll masses, and ultimately, lint yield reductions [15]. Temperature affects cotton crop in a complex way on the production of the crop. However, the results of this study shows very strong and positive correlation between air temperature (minimum and maximum) on cotton crop yield.

The soil parameters, variety, farmers' management abilities and their socio-economic capabilities, etc all independently as well as their interactive effects decides the production of cotton. The yield was directly associated with improved soil water relations resulting from the cropping and tillage treatments. Application of varying levels of fertilizer in combination with bio-fertilizer positively influences to cotton yield as they improve the availability of NPK to the crop. The soil parameters including soil pH, SOC, P & K have positive correlation with cotton crop production. As the soil type in the entire operational area was identical (sandy loam type – Goradu type), its' correlation with cotton crop yields could not be assessed.

If real time outputs of this information are communicated to farmers for improving their crop management, it can really contribute to sustainable as well as improved production.

## VIII. WAY FORWARD

Forecasts of production include imbedded assumptions about farmers' reactions to changes in output prices, input

ANNEXURE I

prices, weather forecasts, labor availability, input availability, storage capacity, marketing opportunities, food security, and changes in technology, government policies and other innumerable factors. Forecasts of consumption are really forecasts of textile mill managers' choices in response to the welter of price information, resource constraints and government policies they face, etc.

Nevertheless, even though human behavior is highly variable and unanticipated policy shocks are common, with great advances in technology improvement in forecasts has not been. Perhaps this is because the information we are getting faster is actually degrading in quality. In other words, the statistics on which forecasts are based are becoming less accurate, thus undermining the value of getting those statistics more easily.

The following are some of the more frequent types of information that can be derived from the basic data:

A. Air temperature

- 1) Temperature probabilities;
- 2) Chilling hours;
- 3) Degree-days;
- 4) Hours or days above or below selected temperatures;
- 5) Interdiurnal variability;
- 6) Maximum and minimum temperature statistics;
- 7) Growing season statistics, that is, dates when threshold temperature values for the growth of various kinds of crops begin and end.

B. Precipitation

- 1) Probability of a specified amount during a period;
- 2) Number of days with specified amounts of precipitation;
- 3) Probabilities of thundershowers;
- 4) Duration and amount of snow cover;
- 5) Dates on which snow cover begins and ends;
- 6) Probability of extreme precipitation amounts.

C. Wind

- 1) Windrose;
- 2) Maximum wind, average wind speed;
- 3) Diurnal variation;
- 4) Hours of wind less than selected speed.

D. Sky cover, sunshine, radiation

- 1) Per cent possible sunshine;
- 2) Number of clear, partly cloudy, cloudy days;
- 3) Amounts of global and net radiation.

E. Humidity

- 1) Probability of a specified relative humidity;
- 2) Duration of a specified threshold of humidity.

F. Free water evaporation

- 1) Total amount;
- 2) Diurnal variation of evaporation;
- 3) Relative dryness of air;
- 4) Evapotranspiration.

G. Dew

- 1) Duration and amount of dew;
- 2) Diurnal variation of dew;
- 3) Association of dew with vegetative wetting;
- 4) Probability of dew formation based on the season.

H. Soil temperature

- 1) Mean and standard deviation at standard depth;
- 2) Depth of frost penetration;
- 3) Probability of occurrence of specified temperatures at standard depths;
- 4) Dates when threshold values of temperature (germination, vegetation) are reached.

*I. Weather hazards or extreme events*

- 1) Frost;
- 2) Cold wave;
- 3) Hail;
- 4) Heatwave;
- 5) Drought;
- 6) Cyclones;
- 7) Flood;
- 8) Rare sunshine;
- 9) Waterlogging.

*J. Agrometeorological observations*

- 1) Soil moisture at regular depths;
- 2) Plant growth observations;
- 3) Plant population;
- 4) Phenological events;
- 5) Leaf area index;
- 6) Above-ground biomass;
- 7) Crop canopy temperature;
- 8) Leaf temperature;
- 9) Crop root length.

# Data Analysis of Coronavirus CoVID-19: Study of Spread and Vaccination in European Countries

Hela Turki, Kais Khrouf  
Jouf University, Sakaka  
Saudi Arabia

**Abstract**—Humanity has gone since a long time through several pandemics, such as: H1N1 in 2009 and also Spanish flu in 1917. In December 2019, the health authorities of China detected unexplained cases of pneumonia. The WHO World Health Organization has declared the apparition of CoVID-19 (novel Coronavirus) that caused a global pandemic in 2020. In data analysis, multiple approaches and diverse techniques were used to extract useful information from multiple heterogeneous sources and to discover knowledge and new information for decision-making; it is used in different business and science domains. In this context, we propose to use the multidimensional analysis techniques based on two concepts: fact (subject of analysis) and dimensions (axes of analyses). This technique allows decision makers to observe data from various heterogeneous sources and analyze them according several viewpoints or perspectives. More precisely, we propose a multidimensional model for analyzing the Coronavirus CoVID-19 data (spread and vaccination in European countries). This model is based on constellation schema that contains several facts surrounded by common dimensions.

**Keywords**—Multidimensional model; constellation schema; coronavirus covid-19; vaccination; European countries

## I. INTRODUCTION

Since December 2019, the new cases of pneumonia were detected in Wuhan City (Hubei Province of China). This novel virus caused the new infectious respiratory disease, called Covid-19 by the World Health Organization (WHO) [19] (Pandemic in 2020 with millions of deaths around the world). The fight against this global pandemic is causing cancellations of sporting and cultural events, the implementation of containment measures and the closure of the borders by many countries, etc. It also has effects in terms of social and economic instability [14].

In order to slow the contagion of this new virus, several studies were proposed in the literature [12][15][16][17], especially about the spread of the Coronavirus [13]; statistics are announced every day by the countries and databases have been established to store this data. In this paper, we propose to use the Multidimensional Analysis techniques in order to analyze the spread of Coronavirus Covid-19 and the evolution of vaccination in European Countries. This technique allows decision makers to observe data from various sources and analyze them according to several viewpoints. A multidimensional model is composed into two concepts: Dimension and Fact. Dimensions contain a set of unique values in order to categorize a particular theme (Countries, Dates,

etc.). Fact is a subject of analysis and it is described by a set of measures.

This paper presents a new approach based on the use of multidimensional techniques on Coronavirus Covid-19 data and the user-defined constraints based on colors in order to highlight relevant information.

This paper is organized as follows. Section 2 presents the literature review for spreading of Coronavirus Covid-19 (Works about data analysis). Then, we present the phase of data preparation (Extraction, Cleaning, Transformation and Loading of Data). In Section 4, we propose a data warehouse schema for storing the prepared data. The next section describes the multidimensional model we propose for analyzing the spread and the vaccination of Coronavirus Covid-19 data. Finally, we present the phase of implementation for European countries and then Conclusion.

## II. LITERATURE REVIEW

Since the appearance of the Coronavirus Covid-19, several studies have focused on the spread of the virus (Medical [13] or Data Analysis aspects [18]).

The objective of [1] is to examine the correlation between pollution and climate data and the Covid-19 pandemic. They propose a data warehouse and data cubes built on data from the regions of Lombardy and Puglia (Italia). Their results show that the Covid-19 pandemic is spreading significantly in regions characterized by the absence of rain and wind.

In [2], the authors study the relationship between new cases of Coronavirus Covid-19 and the Multidimensional Poverty Index (MPI) in the city of Manizales (Colombia). The results of the exploration indicate that in the communes of greater poverty the density of cases per Covid-19 is greater; the relation exists between these two parameters.

Internet of Things (IoT) is an interconnection of Internet and physical devices. These devices are record, monitor and respond. The use of IoT with smart sensors to measure and record the body temperature of individuals can help to identify the infected and to maintain social distance. The authors of [3] propose an IoT architecture in order to minimize the spreading of Covid-19.

In [4], the authors study the evolution of cases and deaths of Covid-19 compared to the population of Brazilian cities. The results show that in the short term small towns are proportionately more affected by Covid-19 during the initial

spread of the disease. In the long term, large cities begin to have a higher incidence of cases and deaths.

The authors of [5] propose an interactive visualization using the concept of Tableau [6] for analyzing data of Covid-19. A Tableau is used to show the personalized and the most important data (dashboards and worksheets). They consider that data analysis can be very fast with Tableau and Visualizations (several visualizations in a single view).

The author of [7] presents a data analysis of Covid-19 in cities of China, by using datasets. He uses a correlation matrix for the phase of data preparation (to summarize data). He uses Python libraries Matplotlib and Seaborn for visualizing data.

In this paper, we propose a multidimensional model based on Constellation Model in order to study the spread of Coronavirus Covid-19 in European countries and the evolution of vaccination, according to several dimensions. The first stage concerns the data preparation (presented in next section).

### III. DATA PREPARATION

Data preparation is the process of several steps (gathering, combining and structuring data) in order to analyze them in business intelligence and data visualization applications. Fig.1 presents the process we propose for data preparation: Data extraction, Data cleaning, Data transformation and Data loading.

#### A. First Step: Data Collection

In this paper, the data used was extracted from [20]. The period of analysis is between 01/01/2021 and 30/09/2021. We mainly use the following files:

The first file concerns data on testing for Covid-19 by week and country and contains the following data: Country name and code, Week of year, Level (national or sub-national), Region code and name, Number of new confirmed cases, Population, Testing rate per 100000 population, Positivity rate and Source.

The second file concerns data on Covid-19 vaccination and contains the following data: Week of year, Country code, Population denominators for target groups, Number of doses received, Number of first dose vaccine, Number of individuals refusing the first vaccine dose, Number of second dose vaccine, Number of doses where the type of dose was not specified, Region, Target group, Name of vaccine and Population.

Fig. 1. Data Preparation.

#### B. Second Step: Data Cleaning

In this step, we removed unnecessary data:

- Source and Level from the first file.
- Population denominators for target groups and Target group from the second file.

We also add the following data in order to perform analyzes at several levels of granularity:

- Month, Trimester and Year for the week of year.
- Zone for countries: we distinguish four zones: Eastern Europe, Western Europe, Northern Europe and Southern Europe (cf. Table I).
- Continent: In this study, we focus on Europe.

TABLE I. ZONES OF EUROPE

| Zones           | Countries                                                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------|
| Eastern Europe  | Belarus, Bulgaria, Czech, Hungary<br>Poland, Moldova, Romania, Russia, Slovakia, Ukraine                                    |
| Western Europe  | Austria, Belgium, France, Germany<br>Liechtenstein, Luxembourg, Monaco<br>Netherlands, Switzerland.                         |
| Northern Europe | Denmark, Estonia, Finland, Iceland<br>Ireland, Latvia, Lithuania, Norway,<br>Sweden, United Kingdom.                        |
| Southern Europe | Albania, Andorra, Bosnia & Herzegovina, Croatia,<br>Greece, Italy, Malta, Portugal, Serbia, Slovenia<br>Spain and Macedonia |

#### C. Third Step: Data Transformation

In this phase, we merged the following data from the two files: Country code, Year of week, Region and Population.

The result after cleaning and merging data is a new file that contains:

- Week of year, Month, Trimester and Year.
- Country Name and Code, Population, Region code and Name.
- Number of new confirmed cases, Testing rate per 100000 population and Positivity rate.
- Number of doses received, Number of first dose vaccine, Number of individuals refusing the first vaccine dose, Number of second dose vaccine, Number of doses where the type of dose was not specified and Name of vaccine.

#### D. Four Step: Data Loading

After data is retrieved, extracted and transformed, it is then loaded into a storage system (a data warehouse); it involves sorting, checking integrity, and building indices and partition.

After the initial load, the data warehouse needs to be updated by the incremental changes in the data sources.

#### IV. DATA WAREHOUSING

Data storage is keeping data in a secure location that the user can easily access. An operational database handles frequent daily changes due to the transactions that take place by the company. However, a data warehouse provides consolidated data in multidimensional form. [8].

A data warehouse is constructed by heterogeneous data from multiple sources in order to support analytical reporting and decision making [11]. Indeed, it focuses on modeling and analysis of data to help decision-makers. The data in the warehouse must be subject oriented, integrated and non-volatile.

The data warehouse possesses consolidated historical data in order to organize, use and analyze this data to take strategic decisions. The main objective of data warehouses is to transform heterogeneous data into a form suitable for analysis.

In this step, we propose a schema of data warehouse (cf. Fig. 2) by using the class diagram of UML (Unified Modeling Language) that contains six classes: Date, Zone, Country, Region, Testing and Vaccine.

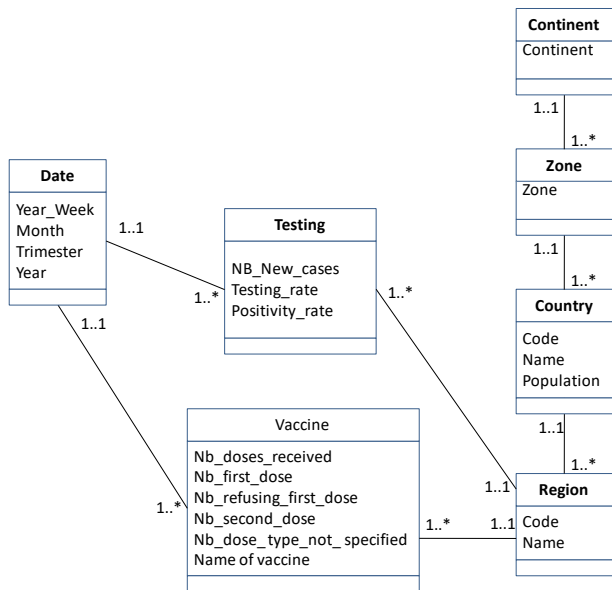

Fig. 2. Data Warehouse for Testing and Vaccination.

#### V. DATA ANALYSIS: MULTIDIMENSIONAL SCHEMA

A data warehouse provides Online Analytical Processing (OLAP) tools that present an interactive analysis of data in a multidimensional view. The results of these OLAP tools are generally Data Cubes, defined by dimensions (described by attributes and hierarchies) and facts (described by measures) [9].

- A dimension is a structure that describes a subject in order to help decision-makers answer business questions (Example: product, store, and date).
- An attribute describes a summary level or characteristic of a dimension (Example: Year).

- A hierarchy classifies a dimension into several levels of granularity (Example: Date can be decomposed into Date→Month→Year).
- A fact presents a subject that models a set of events (Examples: sales, purchases); it has dynamic properties (numeric attributes).
- A measure is a numerical property of quantitative aspect that is relevant to analysis (Example: quantity, number\_of\_customers).

Schema represents a logical description of a database, data warehouse, XML document [10], etc. If a database generally uses relational model, a data warehouse can use Star, Snowflake or Constellation schemas.

- Star Schema: Each dimension is represented by only one-dimension table and the fact table at the center that contains the keys of all dimensions.
- Snowflake Schema: Some dimension tables are normalized.
- Fact Constellation Schema: It contains multiple fact tables connected by common dimensions. Table II presents the components of multidimensional schema we propose.

TABLE II. COMPONENTS OF MULTIDIMENSIONAL SCHEMA

| Concept                                                                     | Description                                                                                                        |
|-----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Constellation C</b><br>$C = (F ; D_i)$                                   | $F$ is a set of facts.<br>$D_i$ is a set of dimensions.                                                            |
| <b>Fact F</b><br>$F = (NameFct ; M_i)$                                      | $NameFct$ is the fact name of $F$ .<br>$M_i$ is a list of measures.                                                |
| <b>Dimension <math>D_i</math></b><br>$D_i = (NameDim_i ; Att_j ; Hierar_k)$ | $NameDim_i$ is the dimension name.<br>$Att_j$ is the list of attributes.<br>$Hierar_k$ is the list of hierarchies. |

Fig. 3 presents the proposed multidimensional model that contains two facts (Testing and Vaccine) surrounded by two dimensions (D\_Date, D\_Region). D\_Date is decomposed into the hierarchy H1 (Week→Month→Trimester→Year). D\_Region is decomposed into the hierarchy H2 (Region→Country→Zone→Continent).

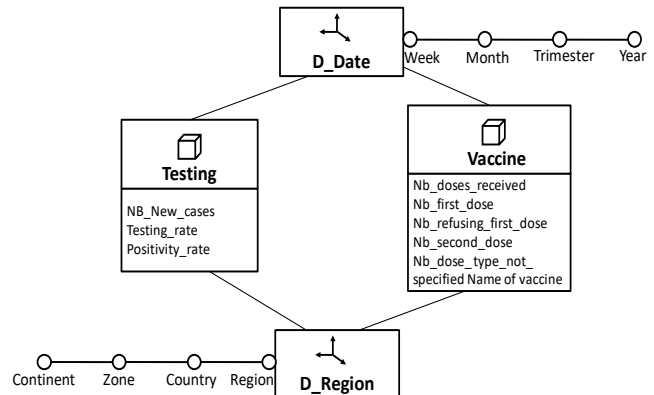

Fig. 3. Multidimensional Schema.

## VI. IMPLEMENTATION AND DISCUSSIONS

The data used for analysis in this paper was extracted from [20]. The analysis period is between 01/01/2021 and 30/09/2021. In this section, we present several examples of multidimensional queries for analyzing data about spreading of Coronavirus Covid-19 and vaccination.

The first query concerns the average of positivity rate by Zone and Trimester. Table III presents the result of this query.

Example 1:

|                                 |
|---------------------------------|
| Dimension 1: Zone               |
| Dimension 2: Trimester          |
| Fact: Average (Positivity_rate) |

TABLE III. AVERAGE OF POSITIVITY RATE BY ZONE AND TRIMESTER

|                 | T1-2021 | T2-2021 | T3-2021 |
|-----------------|---------|---------|---------|
| Eastern Europe  | 18,29   | 9,43    | 0,71    |
| Northern Europe | 3,34    | 2,00    | 1,81    |
| Southern Europe | 7,73    | 3,87    | 4,19    |
| Western Europe  | 5,29    | 3,78    | 2,79    |

We note that the positivity rate is very high for the zone of Eastern Europe during the first two trimesters of 2021. In order to analyze more this multidimensional table, we propose to apply the Drill-down Operator that fragments data into smaller parts. It can be done by descending from a level to another in the hierarchy. Example: For Dimension 1, we can visualize data by passing from Zone to Country (cf. Table IV).

Example 2:

|                                 |
|---------------------------------|
| Dimension 1: Country            |
| Dimension 2: Trimester          |
| Fact: Average (Test_Positivity) |

TABLE IV. AVERAGE OF POSITIVITY RATE BY COUNTRY AND TRIMESTER

|             | T1-2021 | T2-2021 | T3-2021 |
|-------------|---------|---------|---------|
| Austria     | 2,22    | 0,40    | 0,18    |
| Belgium     | 5,74    | 5,65    | 3,27    |
| Bulgaria    | 13,01   | 8,41    | 3,04    |
| Croatia     | 10,34   | 11,83   | 1,98    |
| Cyprus      | 1,13    | 0,72    | 0,99    |
| Czechia     | 11,93   | 0,94    | 0,22    |
| Denmark     | 0,52    | 0,15    | 0,41    |
| Estonia     | 14,93   | 6,98    | 4,44    |
| Finland     | 2,66    | 1,28    | 2,46    |
| France      | 6,68    | 4,91    | 3,98    |
| Germany     | 6,96    | 6,38    | 3,88    |
| Greece      | 3,63    | 0,87    | 1,54    |
| Hungary     | 14,78   | 8,50    | 1,10    |
| Iceland     | 0,38    | 0,26    | 1,56    |
| Ireland     | 7,70    | 2,45    | 5,88    |
| Italy       | 6,90    | 3,54    | 2,16    |
| Latvia      | 6,61    | 3,45    | 0,93    |
| Lithuania   | 8,83    | 4,35    | 3,55    |
| Luxembourg  | 1,92    | 1,43    | 1,42    |
| Malta       | 6,06    | 1,19    | 2,94    |
| Netherlands | 9,46    | 8,13    | 4,07    |
| Norway      | 1,38    | 1,44    | 1,40    |
| Poland      | 18,82   | 10,86   | 0,52    |
| Portugal    | 6,79    | 1,11    | 2,68    |
| Romania     | 13,53   | 5,61    | 1,47    |
| Slovakia    | 46,43   | 8,03    | 0,70    |
| Slovenia    | 6,06    | 1,93    | 0,95    |
| Spain       | 8,81    | 4,96    | 9,34    |
| Sweden      | 11,76   | 8,25    | 3,60    |

For analyzing the number of cases compared to population by Country and Month for Western Europe, we propose the following query. In this example, We add constraints on the measure of the multidimensional table based on colors ( $\leq 2\%$ : Green;  $\leq 3\%$ : Orange;  $> 4\%$ : Red) in order to highlight the most important values (cf. Table V).

Example 3:

|                                                           |
|-----------------------------------------------------------|
| Dimension 1: Month                                        |
| Dimension 2: Country                                      |
| Dimension 3: Zone {Western Europe}                        |
| Fact: (Number_Cases/Population)*1000                      |
| { $\leq 2\%$ : Green; $\leq 3\%$ : Orange; $> 4\%$ : Red} |

TABLE V. NUMBER OF CASES BY MONTH AND COUNTRY FOR WESTERN EUROPE

| Western Europe |         |         |        |         |            |             |
|----------------|---------|---------|--------|---------|------------|-------------|
|                | Austria | Belgium | France | Germany | Luxembourg | Netherlands |
| janv-21        | 1,38    | 1,30    | 1,74   | 1,34    | 1,50       | 2,30        |
| févr-21        | 1,24    | 1,34    | 1,98   | 0,68    | 1,90       | 1,54        |
| mars-21        | 2,10    | 2,28    | 2,17   | 1,01    | 2,13       | 2,35        |
| avr-21         | 1,93    | 2,37    | 2,77   | 1,55    | 2,17       | 3,00        |
| mai-21         | 0,92    | 1,65    | 1,01   | 1,06    | 1,36       | 2,37        |
| juin-21        | 0,23    | 0,71    | 0,67   | 0,21    | 0,36       | 0,76        |
| juil-21        | 0,12    | 0,52    | 0,60   | 0,07    | 0,90       | 1,71        |
| août-21        | 0,43    | 1,16    | 3,19   | 0,23    | 0,73       | 1,49        |

VII. CONCLUSION

Multidimensional analysis techniques have been used to visualize data from several perspectives, in order to help decision-makers exploring data according to several granularities and so make appropriate decisions.

In this paper, we propose a data warehouse for storing data about spreading of Coronavirus Covid-19 and vaccination in European countries. We present a multidimensional model based on constellation schema in order to deduce new knowledge. The user can add constraints or criteria on multidimensional tables based on colors in order to highlight the most important values.

This paper presents a new approach based on the use of multidimensional techniques on Coronavirus Covid-19 data and the user-defined constraints based on colors in order to highlight relevant information.

For future work, we plan to study the impact of vaccination on the spread of the Coronavirus Covid-19 by integrating statistical tools into multidimensional tables.

# Design of Low Cost Bio-impedance Measuring Instrument

Rajesh Birok, Rajiv Kapoor

Dept. of Electronics & Communication Engineering  
Delhi Technological University Delhi, India

**Abstract**—It is a well-established fact that the electrical bio-impedance of a part of the human body can provide valuable information regarding physiological parameters of the human body, if the signal is correctly detected and interpreted. Accordingly, an efficient low-cost bio-electrical impedance measuring instrument was developed, implemented, and tested in this study. Primarily, it is based upon the low-cost component-level approach so that it can be easily used by researchers and investigators in the specific domain. The measurement setup of instrument was tested on adult human subjects to obtain the impedance signal of the forearm which is under investigation in this case. However, depending on the illness or activity under examination, the instrument can be used on any other part of the body. The current injected by the instrument is within the safe limits and the gain of the biomedical instrumentation amplifier is highly reasonable. The technique is easy and user-friendly, and it does not necessitate any special training, therefore it can be effectively used to collect bio-impedance data and interpret the findings for medical diagnostics. Moreover, in this paper, several existing methods and associated approaches have been extensively explored, with in-depth coverage of their working principles, implementations, merits, and disadvantages, as well as focused on other technical aspects. Lastly, the paper also deliberates upon the present status, future challenges and scope of various other possible bio-impedance methods and techniques.

**Keywords**—Noninvasive; bio-electrical; Impedance; bio-impedance; bio-medical; instrumentation

## I. INTRODUCTION

Extensive research is going on in the field of Bio-Medical Instrumentation. Researchers and investigators in this field are striving hard to find out new ways and methods for diagnosis and measurement of health parameters for the welfare of the mankind. There are two types of techniques for measuring biomedical signals namely non-invasive and invasive techniques. Non-invasive techniques are more suitable than the invasive ones if sufficient accuracy can be achieved using them. Whether, it is animal and plant cells or tissues, these are always made up of three-dimensional arrangement of cells and tissues. Therefore, human body is a complex biological structure and system, which is also made up of billions of cells and tissues arranged in 3-D formation [1]. The biological cells and tissues of both animals and plants floats in ECF which is known as Extra-Cellular Fluids. This ECF comprises Intra-Cellular Fluids (ICF) and Cell Membranes (CM) which may be with or without cell wall. When biological cells and tissues are subjected to the external electrical stimulus they respond and produces a complex bio-electrical impedance or simply known as bio-impedance. This bio-impedance is highly frequencydependent [2], [3].

Accordingly, frequency response of bio-impedance of cells and tissues of humans is greatly affected by physiological and physiochemical composition and structure of these cells and tissues. Moreover, it also changes from person to person. As a result, learning about cell and tissue anatomy and physiology through biological cell and tissue bio-impedance analysis will be a valuable resource. Therefore, it has been found that studying complex bio-impedance of biological cell and tissues is a useful method for non-invasive physiological and pathological investigations. As we know that the bio-electrical impedance of a biological cells or tissues is dependent on the signal frequency, however, multifrequency application may also be used for non-invasive diagnostics and medical investigations, so as to determine their physiological or pathological behavior or even properties. There are numerous Non-invasive bio-impedance techniques such as BIA (Bio-Impedance Analysis), EIT (Electrical Impedance Tomography), IPG (Impedance Plethysmography), ICG (Impedance Cardiography), etc. The bio-impedance measurement technique proposed in this research paper, is a low-cost, efficient, and effective non-invasive diagnostic technique.

## II. LITERATURE SURVEY

Impedance offered by a living tissue is known as bio-impedance. The broad variability of Cole parameters makes it difficult to use bio-impedance to distinguish animal and plant tissues. [4] defines a novel electronic procedure for distinguishing fruit or vegetable tissue. This system uses a custom-built electrode pair to compute bio-impedance and Cole parameters covering a wide range of frequencies from 1 Hz to 1 MHz [4]. However, impedance of human cell and tissue consists of resistive and capacitive components [5], [6]. It's determined by injecting an alternating current in the cell or tissue and then measuring the output voltage across it. The Linear Time-Varying (LTV) bio-impedance is measured with a specified precision using stepped-sine excitations, as given in [7], but it is susceptible to temporal distortions affecting the data, which limits the device's temporal bandwidth and sets the data accuracy. Current source and voltage sensing circuit are the essential blocks in the instrument. Several authors have successfully designed current sources operating up to few hundreds of kHz [8]. Paul Annus et.al. [9] have systematically analyzed the design of a current source using transfer function approach and they have measured the load impedance using load in loop method or configuration. The voltage sensing circuit consists of amplifier, demodulator and low pass filter. The use of instrumentation amplifier for bio-impedance measurements has been analyzed by Areny and Webster [10]. The measurement technique has been used in a

number of applications such as calculating Total Body Water (TBW), calculating Intracellular Fluid (ICF) and extracellular fluid (ECF) [6] Electrical Cardiometry [11], Skin Water Content, Impedance Imaging (Tomography), Ablation Monitoring and measurement of Respiration Rate [12]. The technique also has the potential to be used in biometrics [13]. Body Composition Assessment, Transthoracic Impedance Pneumography, Electrical Impedance Tomography (EIT), and Skin Conductance are examples of bio-impedance applications that are described and analysed in [14]. [15] looked into the possibility of non-invasively tracking blood glucose levels using bio-impedance data, which would allow for more regular testing and better diabetes management and monitoring. The bio-impedance measurement is not a new technique in biomedical diagnostic techniques but research is still going on to make this technique a standard procedure for diagnosis of a particular disease. For this purpose, it is required that a large amount of data be collected for a particular disease, for a particular environmental society and analysis to be done, correlating the disease with the signal recorded. To attain this objective, we have designed a low-cost instrument using common analog signal processing blocks, which gives an accurate recording of the bio-impedance signal.

### III. BACKGROUND

#### A. Basics and Origin of Bio-impedance

Bio-impedance is a passive electrical property that describes a biological cell or tissue's ability to obstruct (oppose) the flow of electrical current through it. The reaction to electrical excitation (current or potential) applied to biological tissue is used to determine bio-impedance. The same or other electrodes applies the excitation signal and picks up the reaction in bio-impedance measurements, then charge conversion takes place from electronic to ionic charge and vice versa [7]. Simply, the ratio of voltage (V) to alternating current (I) is known as electrical impedance (Z). Since, Direct Current (DC) is quite hazardous to humans, therefore, it is never used for any experimentation on humans. In fact, Alternating Current (AC) is more preferable choice for such type of applications. The calculated or observed bio-impedance (Z) is highly influenced by the Resistive (R), Capacitive (C), and Inductive (L) parts of the cells and tissues. The bio-impedance (Z) is given by using the modulus  $|Z|$  and the phase change. Since, bio-impedance (Z) is a complex function or parameter, therefore its Resistance (R) is the real part and whereas, the Capacitive Reactance ( $X_c$ ) is the imaginary part. As the ICF, CM, and ECF are made of dissimilar materials with nonidentical electrical properties, therefore every cell and tissue components react differently to the applied AC signal. As we know that ICF and ECF are made up of ionic solution which is highly conducting in nature, thus it provides low resistance path to the applied AC signal [16]. The CM are composed of lipid bilayers which are electrically nonconducting and inserted between two layers of conducting proteins. This sandwiched structure, produces a capacitive reactance ( $X_c$ ) to the applied AC signal [17], [18]. Due to this, biological cells and tissues produces a complex bio-impedance (Z) which can be considered as overall response to an applied AC signal [2], [3]. Thus, bio-impedance (Z) is a complex function depends upon cell and tissue composition and structure, health of person and applied AC signal frequency. Moreover, it also changes with measurement direction,

from one subject to the other subject and even within the tissue itself.

The human body composition comprises, water (64%), protein (20%), fat (10%), and minerals (5%) and starch (1%). The human body mass is mainly due to O (65%), C (18%), and H (8%). The majority of muscles are made up of protein whereas, majority of bones are made up of minerals [19]. The bio-impedance is proportional to Total Body Water (TBW), which contains Intra-Cellular Water (ICW) and Extra-Cellular Water (ECW). Body water, body fat, and body muscle have different impedance values according to the amount of presence of water in these. Thus applied AC signal pass through paths that contain more water as it provides high conductivity [20]. The physiological, morphological, pathological settings and also applied AC signal frequency, all these affect and influence cells and tissues and their electrical properties [21], [22]. The biological cells and tissues may have active (endogenous) or passive (exogenous) electrical properties, depending on the type of source of applied AC signal. The bio-electric signals from the heart known as electrocardiograph (ECG), signals from the brain known as electroencephalograph (EEG), whereas electromyograph (EMG) signals from the muscles are few examples of active properties (bio-electricity) produced by ionic activities within cells and tissues (typical of nerve cells). Passive properties are generated by simulating them with an external electrical excitation source [23], [24].

The extracellular fluids surround all cells with membranes in biological tissues. The main constituents of Extra-Cellular Fluid (ECF) are fluid component of the blood known as plasma and the other one is Interstitial Fluid (IF) which surrounds all cells that are not in blood. The extracellular space is the part of a multicellular organism outside the cells, whereas intracellular space is within the organism's cells. The cell membranes separate extracellular spaces and intracellular space thus producing two electrically conducting compartments known as extracellular media and intracellular media. The resistive pathways are provided by ECF and intracellular fluids (ICF). Due to its insulating design and structure, the lipid bilayer cell membrane is very-very thin measuring approximately 6-7 nm. This lipid bilayer cell membrane is semi-permeable, due to which it has a high capacitance and which produces capacitive reactance [25], [26], [27]. Although biological cells and tissues may have inductive properties, inductance is much lower at low frequencies than resistance and reactance, so it is often overlooked [28]. Thus, biological cells or tissue's complex bio-impedance is the contributions from both frequency-dependent capacitance and conductance [21], [29], [30], [31], [32], [33]. Bio-electrical impedance often differs from one tissue to the next, as well as from one subject to the next. The complex bio-electrical impedance is affected by changes in cell and tissue composition and structure, and even health condition or status of the subject [5], [6].

#### B. Frequency Response of Bio-impedance

The anatomical, physiological, and pathological state of biological cells and tissues determine the bio-impedance frequency response. Therefore, the bio-impedance study can provide much more information related to the anatomy and physiology of a cell or tissue. Since the bio-impedance response is a variable of signal frequency, therefore bio-impedance analysis

with multifrequency inputs can give detailed cell or tissue attributes information, that can help greatly in cell or tissue specifications. Furthermore, the applied ac signal frequency also drastically affects it [2], [3]. Thus, the bio-impedance of cells or tissues and their frequency response is greatly affected not only by the composition and structure of these cells and tissues in the given physiological and physiochemical setting but also by the applied signal frequency. The few bio-impedance analysis techniques which makes use of lumped estimation of the bio-impedance values of the cell or tissue samples are BIA, IPG, and ICG etc. Bio-Electrochemical Impedance Spectroscopy (EIS) measures and analyses bio-impedance at different frequencies. Thus, EIS provides not only a lumped approximation of the cell or tissue sample's bio-impedance values at relatively higher frequency (generally 50 kHz), but also the details required to have better understanding of the many complex bio-electrical phenomena such as dielectric dispersions and relaxation.

The bio-impedance measurement can be broadly divided into two categories, namely, "single-tone" signals and "multi-tone" signals measurements. The analysis of "single-tone" signals is very straightforward, but measurements take longer, whereas use of a multi-tone signal allows for simultaneous coverage of the entire frequency spectrum. However, use of a multi-tone signal may result in an algorithm which can be more complex for analysis purpose [34]. Moreover, especially the dielectric properties of the object determine the required frequency range for bio-impedance measurements, which typically spans 3 to 4 decades in the kHz to MHz range. In general, wider range of frequencies improves fitting accuracy but at the cost of complicating measurements. Furthermore, (SNR) of measured signals also effects the fitting accuracy [35].

### C. Types of Electrode Configurations

When an alternating current is used in bio-impedance testing, the electrode displays a frequency-dependent Electrode Polarisation Impedance (EPI) at the contact point with the tissue or solution as the case may be. Any change in the electrode material that is in contact with the tissue or solution also affects the magnitude and as well as the phase of the electrode impedance. As a result, the total calculated impedance of the system is equal to the sum of the EPI and impedance of the tissue/solution [25]. Finally, the impedance depends upon type of electrode used, electrode material used, the applied signal amplitude and also on its size, shape and structure [36]. In order to measure bio-impedance, we need at least two electrodes for the electrical current to pass through the closed circuit [25]. Therefore, bio-impedance measurements are performed with two or four electrodes. In both methods, the red coloured electrodes depicted in Fig. 1 are known as input or excitation electrodes. Basically, these are the current or driving electrodes. On the other hand, blue coloured electrodes also depicted in Fig.1 are known as voltage/sensing or output electrodes used to determine output signal which is frequency dependent. It should be observed that bio-impedance measurements can be inaccurate due to factors such as movement and improper electrode placement [36]. Bio-impedance measurements are typically done with gel electrodes to minimise electrode-skin impedance. The usability of dry electrodes is studied in [37] because this type of electrode

is not suitable in many measurement environments. For bio-impedance measurement, there are two kinds of electrode configurations. According to its name the two-electrode system or setup depicted in Fig.1(a) for measurement of impedance makes use of two electrodes only. Thus, the current signal injection or current-carrying as well as voltage measurement or voltage pickup are done with the same electrodes. For unipolar measurements, electrode configuration with quite large and small electrodes can also be used [38].

The two-electrode technique suffers from contact impedance due to polarisation impedance at the electrodes' surfaces and the measured signal also covers the contact impedance due to voltage drop [25]. While, analysing the measured signal, the polarisation impedance should be considered and removed in the output signal [39], [40]. Overall, the results obtained using this method are interesting, however they do not provide an accurate signal on the electrode's surface [41]. In four electrode configuration or setup, two independent pair of electrodes are used for current injection and detecting changes in voltage or voltage measurements [39], [42]. In this system, the input that is constant amplitude current signal is injected using the outer electrodes. These electrodes are also known as current or driving electrodes depicted in red colour in Fig.1(b). The output voltage signal produced which is frequency dependent is measured at two points within the current electrode. These electrodes are also known as voltage or sensing electrodes depicted in blue colour in Fig. 1(b). In this configuration, as the distance between electrode pairs was increased, the magnitude of the measured impedance decreased [25], [43]. A number of factors influence the effect of electrode polarisation impedance which includes electrode content, size, measuring frequency, sample impedance, and so on. The main advantage of four electrode configuration over its counterpart two electrode configuration is that the voltage or sensing electrodes do not carry current, due to this it eliminates polarisation impedance. Thus, at the connecting surface of electrode with tissue or electrolyte the influence of contact impedance is greatly decreased. Therefore, use of this method is a common and popular practice to lower the effect of EPI [44]. Furthermore, four electrode configuration measurements are more sensitive and accurate.

## IV. PROPOSED METHOD

The instrument designed consists of power supply, current source, voltage sensing unit and data acquisition system (DAS). Fig.2 depicts the general block diagram of the measuring instrument. The current source circuit is used to generate a sinusoidal current of amplitude in the range of 600  $\mu$ A- 800  $\mu$ A and a frequency of 50 kHz [4]. The voltage sensing unit is used to amplify and remove the high frequency components from the signal sensed by voltage sensing electrodes. The signal is then given to the data acquisition system. The contact surface dimensions of all test electrodes are the same, and the carrier is a circular printed circuit board. To compare the electrodes' characteristics, the electrode-skin impedances are measured under a variety of signal frequencies, contact durations, contact pressures, positioning positions, and subjects. All measurements are often done with silver/silver chloride (Ag/AgCl) dry gel electrodes for contrast. [37] The instrument has four Ag/AgCl electrodes, two on the outside and two on the inside,

Fig. 1. Bio-impedance Measurement using: (a) Two- Electrode Method, (b) Four-electrode Method.

which are used as current electrodes and voltage electrodes, respectively. This type of arrangement is known as a tetra polar arrangement. Such an arrangement has been implemented by J. J. Wang et.al. [45] to use forearm impedance plethysmography for monitoring cardiac pumping function.

#### A. Waveform Generation

This is the first stage of the instrument and also the most critical one. All the parameters for this stage are very important as far as subject's safety and the output of the device is concerned. As this is the first stage any noise added at this stage will get amplified in the subsequent stages. A good waveform generator should have a single frequency output with very low value of total harmonic distortion and should have a very low frequency drift. A Wein bridge oscillator can be used to generate a sinusoidal waveform [46]. The oscillator is designed for a frequency of 50 kHz as this frequency is widely accepted in clinical use as a standard [47]. Among all types of voltage source generators, an oscillator produces the output with the most stable frequency as compared to other sources. Wein bridge oscillator is implemented using an op-amp, which gives a stable output with a single frequency for a particular combination of resistors and capacitors. Proper limiter circuit is also used in the circuit to keep the poles of the oscillator on the imaginary axis. One major problem with using Wein bridge oscillator is that the instrument designed cannot be used for bio-impedance spectroscopy.

A comparator, integrator and wave shaping circuit can be used to generate square, triangular and sinusoidal waveform of variable frequency [48]. The comparator and integrator circuit used together generate square and triangular waveforms. Triangular waveform is shaped using a shaping circuit to generate sinusoidal waveform. The maximum frequency achieved by this circuit using 741 op-amp is 26 kHz. This method can be used for excitation in lower frequency range but lower frequencies are not used in bio-impedance spectroscopy as electrodes get polarized at lower frequencies. It has also been observed during our laboratory experiments that there was no biomodulation obtained in the output signal when a current of frequency less than 20 kHz was injected into human body. The instrument designed uses a monolithic integrated circuit ICL8038, to produce high accuracy sine, square and triangular waveforms [49]. The frequency can be selected externally from 10 kHz to 100 kHz using a potentiometer. The output of ICL8038 is stable over a wide range of temperature and supply variations. The total harmonic distortion for ICL8038 varies

from 1% to 2% depending on the model selected.

#### B. V To I Convertor

The current driver is one of the most important sub circuit for the measurements of bio-impedance. The current driver can easily work over a fairly wide range of impedance and frequency. The main requirements of a current driver are high output impedance, short phase delay and minimal harmonic distortion. Depending on whether they are open loop or closed loop, these are categorized into two groups. The features of each design are described [50].

The voltage waveform generated using 8038 is converted into current, which is injected into human body. The current generated is within the safe limits ( $600\mu\text{A}$ -  $800\mu\text{A}$ ). The V to I converter is intended to run in the frequency range of 10-100 kHz.

The main requirement for a current source is that it should supply a constant amount of current irrespective of the impedance of the load connected to it. When the output impedance of the current source is much greater than the load impedance then the current through the load is maintained constant regardless of the load value. F. Seoane et.al have analyzed Howland circuit as V to I converter [51]. In this instrument Howland circuit with buffer is used for voltage to current conversion. Fig. 3 is the circuit diagram for voltage to current converter. The buffer stage increases the output impedance of the V to I converter. The input impedance of the circuit is around 20 k $\Omega$ . Fig. 4 depicts the simulation results for circuit of Fig.-3. The resistance {R} in the Fig. 3 represents the load to which current would be injected. The human body impedance is in the range 1 k $\Omega$  - 3 k $\Omega$ . In simulation the resistance {R} is varied from 0.1k to 5k in steps of 100  $\Omega$ . It is verified using the simulation results that the current through the load is almost constant (10  $\mu\text{A}$  variation) irrespective of the load resistance.

#### C. Instrumentation Amplifier

The voltage sensed from the section of human body is in range of millivolts. The input signal is amplified using a difference amplifier. A single op-amp can also be used as a difference amplifier but due to its low input impedance it cannot be used. The input impedance of the single op-amp difference amplifier can be increased by introducing a buffer at each of the inputs of the amplifier and instead of using a unity gain follower one can also have some gain from the first

Fig. 2. General Block Diagram of Measuring Instrument.

Fig. 3. Circuit Diagram for Voltage to Current Converter.

Fig. 4. Variation of Current Through {R} with Respect to Change in Value of Load Resistance, y-axis is the Current Through the Load and x-axis is the Impedance of the Load Connected to the V to I Converter.

stage. This leads to the circuit of instrumentation amplifier as shown in Fig. 5. The instrumentation amplifier has high CMRR and high input impedance and has been very effectively used in biomedical applications such as EEG and ECG.

The analysis for instrumentation amplifier has been given by Adel S. Sedra and Kenneth C. Smith [1] and its use as a biopotential amplifier has been analyzed by Nagel J.H [52]. The gain for the instrumentation amplifier is given below.

$$\text{gain} = \frac{R_4}{R_3} \left( 1 + \frac{R_2}{R_1} \right) \quad (1)$$

The signal from the electrodes is given as input to the instrumentation amplifier through its two terminals. The gain of the amplifier is 26.44 dB. The first two op-amps are used for gain and the third operational amplifier is used for common mode rejection. In the circuit designed  $R_4=R_3$  and  $R_2/R_1$  is equal to 20. The amplifier's input impedance is equal to the input impedance of the operational amplifier. Frequency response analysis of the instrumentation amplifier depicts that the phase and gain are constant in the desired frequency range. Fig. 6 depicts the frequency response of the instrumentation amplifier in which the continuous plot is the magnitude plot and dotted plot is the phase plot.

#### D. Demodulator

The signal obtained from the human body is an amplitude modulated signal, where the carrier is the current waveform that we have introduced into the human body. In this case the high frequency carrier is a sinusoidal waveform with a frequency of 50 kHz and the modulating bio-impedance signal is low frequency signal with frequency components less than 50 Hz. Webster and Tompkins [53] have suggested use of full wave rectifier for demodulation. The modulating signal can be extracted using a simple envelope detector circuit as shown in Fig. 7. Asynchronous demodulation has been used so that square and triangular waveform excitation can also be used in addition to the sinusoidal waveform.

For the first cycle diode is forward biased and it charges the capacitor to the first peak value. The charging time constant should be such that the capacitor voltage follows the input signal.

$$\tau \text{ charging} \ll \frac{1}{f_c} \quad (2)$$

where  $f_c$  is the frequency of the carrier. The charging times constant depends on source resistance  $R_s$ , forward bias diode resistance  $r_d$  and capacitance  $C_1$ .

$$\tau \text{ charging} = ((R_s + r_d + R_2) \parallel R_1) C_1 \quad (3)$$

$$R_s + r_d + R_2 \ll R_1 \quad (4)$$

$$\therefore \tau \text{ charging} = (R_s + r_d + R_2) C_1$$

When the input signal drops, diode becomes reverse bias (as capacitor is charged to a higher voltage) and the capacitor voltage remains at the initial level. During this time (when diode is reverse bias) the capacitor discharges through the resistor  $R_1$ .

$$\tau \text{ discharging} = R_1 C_1 \quad (5)$$

The discharging time constant should be large so that the capacitor discharges slowly but it should not be so large that it is unable to trace the low frequency modulating signal. The discharging time constant should follow the following relation:

$$\frac{1}{B} \gg \tau \text{ discharging} \gg \frac{1}{f_c} \quad (6)$$

Where B is the bandwidth of the low frequency bio-impedance signals. For the calculation of the values of resistances and capacitance, value of B is taken equal to 50 Hz. The diode used in the circuit is forward biased when the incoming voltage is greater than 0.7V, therefore the low voltage signals cannot be detected. Taking into account this problem related to cut off voltage of diode, a precision diode [46] is used in this circuit in place of normal diode. A precision diode is an operational amplifier with a diode in the negative feedback followed by a diode whose anode is connected at the output pin of the op-amp. The cutoff voltage for a precision diode is approximately equal to zero volts. Fig. 8 is the circuit for precision diode. The output of the demodulator is given to the low pass filter stage through a buffer. Improved output buffering and peak detector gain greater than unity is achieved with an output voltage follower. This leads to circuit of precision envelope detector in Fig. 9. The precision envelope detector is much more accurate than the simple envelope detector as the voltages below 0.7V are also detected by this circuit. Droop due to detector diode leakage can be removed through the use of bootstrapping feedback that holds detector diode bias at zero when the diode is not conducting.

#### E. Low Pass Filter

The signal from the demodulator contains high frequency components, which needs to be filtered out before the signal is given as input to the analog to digital converter of data acquisition. Here, an antialiasing filter is used as a Low Pass Filter (LPF). Accordingly, a second order Chebyshev LPF with a cutoff frequency of 40 Hz is used. Chebyshev filters differ from Butterworth filters in that they have a roll-off which is steeper and more ripple in passband (type I) or stopband (type II). Chebyshev filters have the property of minimizing the difference between real filter characteristics and the idealized one over the desired filter range, but with passband ripples. The LPF output is given to data acquisition system implemented using Arduino uno board.

#### F. Assumptions, Measurement Protocol and Data Acquisition

According to the BIA assumptions, the human body can be considered as a homogenous conductor having cylindrical dimensions (Fig. 10). In which bio-impedance is directly proportional to 'L' and inversely proportional to 'A', where 'L' is the cylinder's length and 'A' is the cylinder's base cross-sectional area (Fig. 10).

BIA formulation processes typically make the following assumptions for ease of calculation, though in practice the human body varies from these assumptions:

- The human body is considered as cylindrical.
- The cylindrical shape is defined by its height and weight.

Fig. 7. Circuit Diagram of Simple Envelope Detector.

Fig. 8. Precision Detector.

Fig. 9. Precision Envelope Detector.

Fig. 10. The Human Body's Impedance when it is Modelled as a Homogeneous Conductor with Cylindrical Volume.

- Homogeneous and evenly distributed body composition is considered.
- The body compositions have no individual differences or variations.
- The environment parameters like temperature, other physiological parameters such as body heat or stress are assumed to be constant.

The cell membranes produce capacitive reactance due to the capacitive nature and caused by a selectively applied AC signal allows current to pass through these cell membranes using current paths largely depends upon the signal frequency (Fig. 10). The cell membranes are penetrated by current with high frequency. Thus, the current penetrates ECFs, CMs and ICFs. The low frequency current passes through ECF only as the cell membrane reactance prevents its flow through it. The BIA technique can be used to determine the (TBW) which is nothing but combination of ECW and ICW. However, it should be done at a particular frequency of the applied AC signal.

The instrument designed was tested on patients at St. Joseph hospital, Ghaziabad, India. Verbal prior approval for the study was taken telephonically from the concerned authorities. Twenty-five adult human subjects (aged 25-60 years) participated in this study. The general test setup for BIA is shown in Fig. 11. However, in our study it differed little bit for the ease of the subjects. They were made to rest in supine position for about ten to fifteen minutes. Then, Ag/AgCl electrodes were put their right and left forearms. Volunteers were told to lie down straight and remain still during measurement.

## V. RESULTS

The test setup used to validate the instrument is similar to the setup used in impedance plethysmography for the cardiac output measurement. In general, impedance is a measure of resistance. Plethysmography has become the gold standard for measuring changes in blood volume in any part of the body based on electrical impedance changes [54]. It is also being used in the diagnosis of peripheral vascular diseases. In impedance plethysmography, values of instantaneous impedance ( $Z$ ), basal impedance ( $Z_0$ ), which is an average of calculated bio-impedance values and derivative of impedance with respect to time ( $dZ/dt$ ) is used to calculate cardiac output parameters. Since the technique is a standard procedure, the values of basal impedance measured by this technique can be used to validate the instrument designed. The output of the demodulator is essentially the basal impedance of the section across which electrodes have been applied. The basal impedance values of forearm given in literature, [55] are used to validate the output signal of the instrument designed.

The output voltage signal of three sets of volunteers has been displayed in Fig. 12. The slight variations in the voltage values depict the variations in impedance ( $Z_0$ ). The basal impedance is calculated using the constant voltage level. The calculated value of basal impedance and its comparison with values of basal impedance in literature has been shown in Table I. The comparison in Table I shows that the values measured from the output of the instrument is in accordance with that of standard technique, which validates the design of the instrument.

## VI. CONCLUSION

A simple low cost bio-impedance measuring instrument has been designed using common electronic blocks. The results have been validated and have been found to be accurate and reliable. Each block of the instrument has been tested using simulation and verified experimentally. The method and device developed fulfills required specifications and can be used in clinical examinations. Bio-impedance measurement techniques can prove very useful for first hand diagnosis. The major problem for using this technique for diagnosis is that its results are not standardized. By standardized one means that just by looking the graph or using its results one can say whether the results correspond to a normal person or a patient suffering from a disease. A large amount of analysis has to be done for a particular application on bio-impedance signals to enable the doctors to rely on results produced by bio-impedance analysis. The standardization of bio-impedance values for human body may be difficult due to variable ambient conditions, eating habits, lifestyle and anthropological background. So intensive and extensive research and in-depth analysis is required to be carried out towards normalization and standardization of the bio-impedance values.

Researchers in the field of bio-impedance have discovered that multifrequency bio-impedance analysis (BIA) is one of their main interests [56]. A group of researchers are exploring instrumentation and designing more advanced instrumentation. In the future, investigation and research can be carried out for Bluetooth-enabled wireless instrumentation for BIA techniques. Moreover, in future studies Bluetooth-enabled wireless instrumentation for Electrochemical Impedance Spectroscopy (EIS) techniques could be investigated. To improve cardiac health monitoring and to have potential transthoracic parameter assessment; ICG along with a bio-impedance tool with multi-frequency features can be used. Furthermore, in an ambulatory or long-term monitoring requirement in the Intensive Care Unit (ICU) bio-impedance based ICG can be used. However, if future research on Bio-impedance calculation and BIA can overcome these challenges, it can be implemented more appropriately than other commonly used and popular imaging methods in specific medical diagnostic applications especially related to the imaging of brain, breast, abdominal and whole body, etc.

Bio-impedance technology is becoming more prevalent as a result of an increasing number of healthcare monitoring applications. The study presented has a wide range of implications, including the ability to improve bio-impedance studies and healthcare devices that use bio-impedance technology [7]. Bio-impedance spectroscopy measures the bio-impedance of cells and tissues covering fairly good frequency range. Physiological testing and health-monitoring systems benefit greatly from this method. Devices must be compact, wearable, or even implantable for a wide variety of applications. As a result, the next generation of bio-impedance sensing systems must be designed to save energy and resources [34]. It's critical to consider the application as well as the type of cell or tissue culture to be monitored when selecting a bio-impedance measurement technique [57]. As a result, choosing the right electrode configuration is crucial. Future research should focus on the electrodes and the bio-impedance measurement method [57]. Overall, this paper describes a low-cost, bio-electrical impedance

measurement system that has been successfully developed and tested and can be used effectively and efficiently for non-invasive health monitoring. The paper also discussed some of the most important technological aspects and limitations of bio-impedance calculation and study. Finally, in this paper the theoretical dimensions, operating principles, implementations, benefits, disadvantages, and current research status, upcoming developments, and bottlenecks in bio-impedance analysis and calculation all have been covered in great detail.

## STATEMENTS & DECLARATIONS

### FUNDING

The authors hereby declare that no funds, grants, or other support in any form were received during the preparation of this manuscript.

### COMPETING INTERESTS

The authors have no relevant financial or non-financial interests to disclose.

### AUTHOR'S CONTRIBUTION

All authors contributed almost equally for material preparation, data collection and analysis to the said study related to conception and design of bio-impedance measuring instrument. Moreover, all authors read and approved the final manuscript.

### ETHICS APPROVAL

Being an observational study only, it did not require any formal ethical approval. However, verbal consent from the competent authority obtained telephonically.

### CONSENT TO PARTICIPATE

No such Informed consent was required for this observational study, however individual participants if any were informed verbally.

### CONSENT TO PUBLISH

As no figure in the manuscript depicts human participants, therefore no such consent for publication of the images of the human research participants is required.

Jeddah, 21589, Saudi Arabia

**Abstract**—A considerable amount of research has been developed lately to analyze social media with the intention of understanding and exploiting the available information. Recently, irony has took a significant role in human communication as it has been increasingly used in many social media platforms. In Natural Language Processing (NLP), irony recognition is an important yet difficult problem to solve. It is considered to be a complex linguistic phenomenon in which people means the opposite of what they literally say. Due to its significance, it becomes essential to analyze and detect irony in subjective texts to improve the analysis tools to classify people opinion automatically. This paper explores how deep learning methods can be employed to the detection of irony in Arabic language with the help of Word2vec term representations that converts words to vectors. We applied two different deep learning models; Convolutional Neural Network (CNN) and Bidirectional Long Short-Term Memory (BiLSTM). We tested our frameworks with a manually annotated datasets that was collected using Tweet Scraper. The best result was achieved by the CNN model with an F1 score of 0.87.

**Keywords**—Verbal irony; natural language processing; machine learning; automatic irony detection

## I. INTRODUCTION

Sentiment analysis is known as the extraction and interpretation of opinions expressed in a text written in a natural language on a certain subject [1]. Recently, sentiment analysis and opinion mining became extremely popular due to the increase of social network usage, which led to produce a huge number of texts. Researchers and many organizations became more interested in analyzing such a text type in order to understand human communication better. Hence, irony is a sophisticated form of sentiment expression where people express their opinions in a certain way [2]. Therefore, it has become an important topic in NLP as it flips the polarity of the posts.

According to Cambridge dictionary<sup>1</sup>, irony is described as a figure of speech that means the opposite of what people really say in a way of being humorous. For example, "I love going to the dentist!". Irony can be either situational or verbal. Situational event occurs when naturally expecting something to happen but the opposite take place [3]. While verbal irony is when individuals express words that represent the opposite of what they actually feel and that is the focus of the existing studies in irony detection. Sarcasm is another term that often occur along with Irony. There exists a lack of conformity in the relationships between irony and sarcasm. Some researchers [4]

[5] define sarcasm as a type of irony in which it is directed at an individual, with the purpose to mock. While others [6], [7] see them as a distinct phenomenon and consider sarcasm differ from irony in which sarcasm include an element of ridicule that irony has not.

In our regular everyday communication, we meet people who like to use irony in the conversation. In most cases, we can detect irony depending on the tone, context, facial expressions, and the person's character. However, when ironic posts in social media are in question, recognizing the irony becomes more challenging and complex due to its ambiguous nature, the missing intonation of the person who writes the message, restricted length of the words, the informal language, the use of hashtags, and the context is not always clear.

Irony has been studied by many research fields such as psychology [8], linguistics education [9], and computational science. It is used widely as an indirect negation in order to achieve different communication goals in many situations such as criticizing, make fun of people, and manipulate answers to upsetting questions.

In recent years, social media have become a part of people's everyday modern life. It enables them to share their opinions on different topics along with other matters. Therefore, the appearance of irony in social networks such as microblogs has greatly increased. For this reason, one of the primary motivations behind this research is detecting real intention behind posts accurately and understanding how people feel regarding specific matters can be useful for many applications. It can help in correctly identifying security issues such as threatening posts by verifying whether the threat words are literal or not. Also, it can be helpful in distinguishing figurative language devices that are used in the different social media platforms, product reviews, feedback, etc., and recognizing the ironic negative reviews/post that being misinterpreted as positive. In general, any tool that aims to extract the meaning of a post effectively can benefit from such a property.

Existing work on detecting irony in Arabic language have mainly focused on classical machine learning [10], [11], [12]. While recent research on detecting irony in English language, such as [13], [14], and [15], applied neural network approaches. Hence, the importance of this research lies on adopting neural network techniques to improve recognizing irony in Arabic texts. To the best of our knowledge, there is only one experiment [12] on detecting irony in Arabic using a neural model, namely BiLSTM. Therefore, we propose a framework that learns irony using a convolutional neural network (CNN).

<sup>1</sup><https://dictionary.cambridge.org/>

In addition, we experimented with Bidirectional Long Short-Term Memory (BiLSTM) as well. The approach we applied outperformed the state of the art. The main contributions of this research can be summarized as follows:

- 1) A manually annotated ironic Arabic dataset.
- 2) We believe that this is the first work on using CNN for irony detection in Arabic texts.

This paper is structured as follows: Section 2 presents a brief literature review on irony detection; Section 3 discusses the approach including data generation process, feature extraction, and the proposed method; Section 4 dedicated to the results; lastly, Section 5 concludes the paper.

## II. RELATED WORK

The interest in adopting neural networks to detect irony on social media has been increased. Classical methods, e.g. SVM, depend on feature engineering and manually convert texts into feature vectors prior to the classification task. In contrast, neural networks approaches can automatically grasp the representations of input texts with different levels of abstraction and then use the gained knowledge to perform the classification task. Several deep learning-based methods have been reported for the field of automatic irony detection. One of the early work was by Poria et al. [16] who proposed an architecture based on a pre-trained convolutional neural network to detect sarcasm on balanced and unbalanced datasets. Sentiment, emotion and personality features were extracted and applied to the system. The balanced datasets achieved the highest f1 score of 0.97. Ghosh et al. [17] applied a semantic neural network model to detect sarcasm over social media content. The architectures are composed of two CNN layers followed by two long short-term memory (LSTM) layers and a deep neural network (DNN) layer. The evaluation of the model achieved an F-score of .92. Ilić et al. [18] proposed a deep neural network model that depends on character-level word representations extracted using the Embeddings from Language Models (ELMo). ELMo is a contextualized representation method that uses vectors extracted from BiLSTM. They tested their system on seven datasets obtained from three different data sources. The results yield 0.87 F-score using Twitter dataset. Authors noted that annotating data manually is necessary in order to improve the performance results. Furthermore, transfer learning approaches, i.e., applying the knowledge of an already trained model to a new task, became very popular in many problems including irony detection in recent research. Potamias et al. [14] proposed a transformer based architecture that builds on the pre-trained RoBERTa model and integrated with a recurrent convolutional neural network (RCNN) that uses non-hand crafted features as they argue that overly trained deep learning approach does not need engineered feature step. They used several benchmark datasets that contain ironic, sarcastic, and figurative expressions. The highest performance of the hybrid neural system achieved f1 score of 0.90 by the sarcastic Riloff's dataset [19]. As for Zhang et al. [20], they focused on finding implicit incongruity without depending on explicit incongruity expressions. They used three transfer learning-based techniques to enhance the attention mechanism of RNNs. The applied attention-based Bi-LSTM achieved higher outcomes on the hashtag-labeled corpus compared to

the human-labeled one. The authors discuss that manually-labeled dataset is considerably more difficult than the hashtag-based dataset and that human annotated dataset results in a more accurate prediction for irony in real applications. Gonzalez et al. [21] used a Transformer Encoder (TE) architecture on two corpora; English and Spanish languages. They applied two TE models with and without the sine-cosine positional information: TE-Pos and TE-NoPos. As a result, TE-NoPos outperformed the TE-Pos system. They also studied the affect of the transformer architecture's multi-head self-attention processes on the irony detection topic. Wu et al. [13] proposed a framework based on four layers of BiLSTM with three dense layers. they combined three tasks which includes finding the missing irony hashtags, classifying ironic or non-ironic and detecting the irony types. The system is concatenated with the sentiment and sentence embedding features that improved the performance by achieving an f1 score of 0.70 and 0.49. Huang et al. [22] considered three deep learning models; Convolutions Neural Network (CNN), Recurrent Neural Network (RNN), and Attentive RNN. The Attentive RNN outperformed other models by achieving F1 score of 0.89. They discussed how attention mechanism improved the irony detection performance. Khalifa and Hussein [12] implemented an ensemble of 8 models based on biLSTM network with TF-IDF, topic modeling and word and character counts features on an Arabic tweets. The ensemble achieved the F1 score of 0.82. Golazizian et al [15] employed a bidirectional LSTM (BiLSTM) network to detect irony in Persian language. They used emoji prediction to construct a pre-trained model that include an attention layer that improved the performance. They reached an accuracy of 83.1. Ren et al. [23] employed two context-augmented neural network methods on Twitter dataset to recognize sarcastic signs from contextual data. Baruah et al. [24] used BiLSTM and BERT transformer based architecture to detect sarcasm in Twitter texts. They applied historical conversational features such as response only and response with varied number of utterances from the dialogue. The F-score of 0.74 was achieved using the BERT classifier. A recent study by Razali et al. [25] which used CNN to extract lexical and contextual features. They chose FastText as word embedding technique. Authors claim that manually extracted contextual features improves the overall accuracy.

## III. APPROACH

### A. Data Generation

A critical challenge for automated irony detection is the availability and quality of a set of ironic examples in order to train a model. This step is performed in three stages shown in Fig. 1.

### B. Data Collection

For the ironic data, we initially collected 12700 Arabic tweets using Tweet Scraper [26]. We gathered the data using the following hashtags: #irony, #Sarcasm, #بتدقيق، #تهكم، #تريقه، #أيروني، #سخرية، #استهزاء

As for the non-ironic datasets, we decided to use a random sample of an existed Arabic sentiment corpus [27].

Fig. 1. Data Generation Stages.

### C. Preprocessing of Data

This step is considered as an essential task in sentiment analysis. The goal of preprocessing is to remove corrupt and irrelevant information from raw text. The stream of data we gathered from Twitter is noisy as it has lots of retweets, social interaction, etc. Hence, tweet preprocessing is essential in order to eliminate noisy data that are not useful to the task. We performed some basic text preprocessing listed below:

- 1) Remove metadata: time and ID.
- 2) Remove usernames, mentions, and RTT.
- 3) Remove all numbers.
- 4) Remove redundant texts.
- 5) Remove punctuation.
- 6) Remove foreign characters.
- 7) Remove emojis.
- 8) Remove hashtags.
- 9) Remove repeated characters.
- 10) Remove diacritics (shaddah, fatha, tanwin, damma, kasra, and sukoon)
- 11) Remove tweets that contain URLs or images as their existence could be required to identify any figurative language present in the texts.
- 12) Replace emoticon with its corresponding meaning.
- 13) Use NLTK stopwords
- 14) Normalize some Arabic letters:

- ا إلى ا
- ي to ي
- ء to ئ و
- ك to ك
- ه to ه

### D. Data Annotation

To deal with the problem of [28] that tweets include hashtags are biased and noisy, we manually labelled Both datasets by two Arabic speakers. However, it is considered a time-consuming process. Three main guidelines were given to the annotators:

1- The tweet is ironic if the literal word is opposite to the intended.

2-The tweet is ironic if it was written in a context other than the common context of communication with the aim of negatively mocking sayings, ideas, beliefs or objects.

3- Otherwise, the text is not ironic.

After including the tweets that both annotators agreed on as ironic and non-ironic, the total amount of data are 5620 ironic and 5620 non ironic tweets (Table I). This qualitative analysis revealed that despite having irony-related hashtags, many tweets turned to be not ironic, which shows the significance of manual corpus annotations.

TABLE I. DATASET SUMMARY

| Label        | Number of Tweets |
|--------------|------------------|
| Ironic       | 5620             |
| Non-ironic   | 5620             |
| Total: 11240 |                  |

### E. Features Extraction

We adopted a simple feature extraction technique, which is (pre-trained) word embedding. Word embedding is a form of terms representation for text analysis in which When two words have the same meaning, they are represented in a vector space by similar vectors that are near together. Otherwise, if the terms have different meanings, then the real-valued vectors are far from each other.

To construct such an embedding, Word2Vec [29] is one of the popular techniques. There exist two different methods to learn the embedding: Skip Gram and Continuous Bag of Words (CBOW) (Fig. 2). The CBOW model takes in context words as an input and try to predict the target word equivalent to the context. on the contrary, skip gram tries to predict the surrounding words given a target word which is the opposite of what the CBOW model does. For the purpose of this work, we applied the pre-trained Arabic word embedding model AraVec 3.0 [30], which provides various pre-trained Arabic words. It has a total of 12 distinct word embedding models extracted from various Arabic content domains, which are Twitter, World Wide Web (WWW) pages, and Wikipedia. Moreover, we used Twitter SkipGram 300D-embeddings as according to [29], Skip Gram works good with small dataset and is able to represent uncommon terms. For our neural network model, the embedding vectors are utilized to instate the weights of the embedding layer. Then, it is linked with the remainder of the layers in the system.

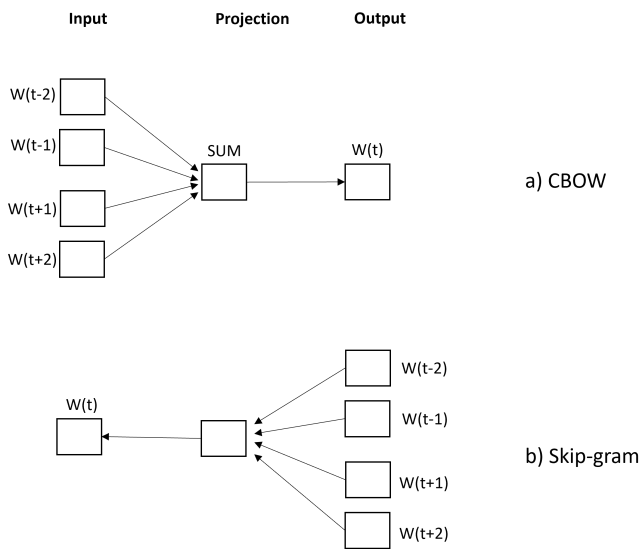

Fig. 2. CBOw and Skip-gram.

F. Methods

1) Convolutional Neural Network (CNN): We adopted a basic CNN architecture, similar to [31], to extract local features from each utterance found in the training dataset by using word vectors that are captured from the pre-trained Word2Vec model. Fig. 3 represents the various layers that are applied to perform the convolution function on the dataset. The Keras library was used to implement the embedding layer. We configured three parameters, which are:

- input\_dim: describes the size of the vocabulary in the data text; it is composed as 30462.
- output\_dim: represents the dimension of the dense embedding; it is configured as 300.
- input\_length: identifies the length of the maximum document; it is composed as 41.

Once we obtained the suitable word vectors from the skip-gram model, the neural network takes the output features as inputs and applies two convolutional layers to the features to learn context information of the words. The convolution operation is described as formula (1).

$$C_i = f(W.X + b) \tag{1}$$

where  $C$  is the convolution output that is created from a window of words  $X$ ,  $W$  is the convolution matrix,  $f$  is the activation function and  $b$  is a bias term.

The two convolution layers have kernel sizes of 4 and 5 to look at sequences of the word embeddings. Each layer consists of 100 filtered outputs. Furthermore, a ReLu activation was applied to the outputs of the convolutional layers followed by a maxpooling layer that takes the highest element from the rectified feature. It minimizes the dimensionality of the feature map and helps capture the key feature. The maxpooling operation (P), as expressed in Equation 3, is done for feature selection that nominates the significant features suitable to

Fig. 3. The Architecture of our CNN.

various hidden layers.

$$C = (c_1, c_2 \dots c_n) \tag{2}$$

$$P_i = \max(C) \tag{3}$$

$$S(x) = \frac{1}{1 + e^{-x}} \tag{4}$$

Next, the output is sent to a layer that flattens the matrices. Finally, the result is a fully connected layer having the outputs of the sigmoid function (Equation 4), that determines whether a sentence is ironic or not, along with the binary cross entropy loss function, which is a good option for binary classification. The model was trained using “Adam” learning rate method.

2) Bidirectional Long Short-Term Memory (BiLSTM): RNN is excellent for sequence learning, but it struggles with long-range dependency due to exploding gradient. On the other hand, LSTM has the capability to learn those long-range dependencies. Bi-LSTM is a variant of LSTM that contains two LSTMs to capture the input information in a forward and backwards directions. In other words, it allows in any point in time to preserve information from both past and future. Given a document,

$$D = (x_1, x_2, \dots, x_n)$$

Bi-LSTM model results with a set of hidden state vectors  $h_t$  for the document sequence. Furthermore, Bi-LSTM combines the forward LSTM (Equation 5) and the backward LSTM (Equation 6).

$$\vec{h}_t = LSTM(x_t, \vec{h}_{t-1}) \quad (5)$$

$$\overleftarrow{h}_t = LSTM(x_t, \overleftarrow{h}_{t+1}) \quad (6)$$

The architecture of our model consists of one Bi-LSTM layer followed by a dropout layer to occupy most of the parameters by ignoring neurons during the training of particular set of units, which is chosen randomly. Next, the model flattens the input data into a 1-dimensional array for inputting to the dense layers. Lastly, two fully connected layers were applied where the first layer contains 32 neurons and the second fully connected layer, which also represents the output layer, contains 2 neurons with the ReLU and Sigmoid activation functions used respectively.

### G. Hyperparameters Setting

There are various important hyperparameters in our systems, and we tune their values using the development corpus. The tuned values of our models hyperparameters are summarized in Table II and Table III.

TABLE II. TUNED VALUES OF THE CNN HYPERPARAMETERS

| Hyperparameter                 | Value               |
|--------------------------------|---------------------|
| Kernel size                    | 4 and 5             |
| Number of filters              | 100                 |
| Maxpooling size                | 2                   |
| Learning rate (adam optimizer) | 0.0001              |
| Loss function                  | Binary crossentropy |
| Batch size                     | 100                 |

TABLE III. TUNED VALUES OF THE BiLSTM HYPERPARAMETERS

| Hyperparameter          | Value               |
|-------------------------|---------------------|
| BiLSTM number of layers | 1                   |
| Number of hidden units  | 128                 |
| Dropout rate            | 0.2                 |
| Optimizer (adam)        | 0.0001              |
| Loss function           | Binary crossentropy |

Using the proper learning rate and setting the correct learning value is critical for enhancing the weights and offsets of the neural model. The low value may cause long training time while its high value could lead to network instability. After several experiments, we set the learning value to 0.0001.

Batch size is another key hyperparameter in neural networks. It defines the number of training examples a neural network can process before resetting the model internal parameters. If the value of batch size too low, then it could slow down

the training process. On the contrary, if the value is too high, it may needs more memory and decrease the generalization capability. Therefore, we started with a small batch value and then increased the value to 64 and 100 in order to use less memory and achieve a durable system.

Neural networks model has the ability of learning complex connections between their inputs and outputs. Yet, some of these relations could be affected by the sampling noise. Hence, the connections will be shown during the training phase but will not occur in the real test data. This problem may cause overfitting and that decreases the classifier's accurate prediction and lead to a poor performance. Therefore, we applied two methods for the purpose of avoiding overfitting in our proposed model. First, we employed early stopping function which refer to stopping the training iterations before the learner passes the point where the model's capability to generalize can decrease as it starts to over-train, thus overfit the training data. Second, we used dropout which is a regularization method of neural networks developed by [32]. It refers to randomly ignore units along with their relationships from the neural network during training process. This stops units from co-adapting too much.

## IV. RESULTS

In this section, we explore the performances of our deep learning models trained with word2vec (skipgram). Table IV shows the performance results of our proposed models. We used the accuracy, recall, precision, and F1 score as performance metrics. These scores are defined as follows [33]:

$$Precision = \frac{TP}{TP + FP} \quad (7)$$

$$Recall = \frac{TP}{TP + FN} \quad (8)$$

$$F1 = \frac{2 * Precision * Recall}{Precision + Recall} \quad (9)$$

$$Accuracy = \frac{TP + TF}{TP + TF + FP + FN} \quad (10)$$

Where TP referred to True Positives, FP is the number of False Positives, FN is False Negatives, and TN is True Negatives. The predicted values are described as positive and negative, while the real values are described as true and false. Recall measure how much out of all the positives were predicted correctly, whereas precision measures how many are actually positive. F-score helps in measuring both recall and precision at the same time. Finally, accuracy measures the overall classifier correctness.

At first, we tried to apply one CNN layer which resulted with 0.86 F1 score. However, the two-layer CNNs slightly improved the performance of the classifier and achieved F1 score of 0.87. We also experimented with BiLSTM and reached 0.86 F1 score, while the results achieved by [12] using BiLSTM model is 0.83. Our scores outperformed the classical and neural approaches used in irony detection in the Arabic language shared task [34]. In spite of the fact that performance of various work existed vary since different datasets have

TABLE IV. RESULTS OF OUR CNN MODELS AGAINST OTHER MODELS

| Model           | Accuracy | Precision | Recall | F1          |
|-----------------|----------|-----------|--------|-------------|
| CNN- One Layer  | 0.86     | 0.90      | 0.83   | 0.86        |
| CNN- Two Layers | 0.87     | 0.90      | 0.84   | <b>0.87</b> |
| BiLSTM          | 0.87     | 0.88      | 0.85   | 0.86        |
| BiLSTM [12]     | -        | -         | -      | 0.83        |

different data distributions, our experiment suggests that the manual annotation improves the learning and prediction tasks. Also, fine tuning the pre-trained vectors and the model play a role in improving the overall results.

Based on the literature [14] [22] [17] [24] [25], CNN's are useful at finding local and position-invariant features whereas BiLSTM are good when classification is specified by a long range semantic relationships and dependency. In our experiment, CNN worked better than BiLSTM in detecting irony since such a sentiment is commonly determined by some key phrases. The output of each convolution layer will let off when a pattern is detected regardless of their position. Changing the size of the kernels and concatenating the received outputs allowed to discover patterns of multiples sizes (4 and 5).

## V. CONCLUSION AND FUTURE WORK

Irony detection research has grown remarkably in recent years. In this paper, we presented an approach based on pre-trained word embedding called AraVec, to address the problem of detecting irony in Arabic tweets. We adopted a basic CNN architecture which found to be very effective for irony detection in Arabic language. The experiment reveals that the method we used performs well with two convolutional layers and even outperform an existing technique. The CNN model achieved F1 score of 0.87. We also experimented with BiLSTM and the results reached 0.86 F1 score. For future work, we plan to extend the extraction of meaningful features, such as sentiment and contextual clues, in order to find the optimal features. Additionally, we can experiment with combined CNNs and RNNs to gain the characteristics of both methods for enhancing the classification performance.

# Analysis about Benefits of Software-Defined Wide Area Network: A New Alternative for WAN Connectivity

Catherine Janiré Mena Diaz, Laberiano Andrade-Arenas, Javier Gustavo Utrilla Arellano, Miguel Angel Cano Lengua  
Facultad de Ingeniería de Sistemas e Informática  
Universidad Tecnológica del Perú  
Lima, Perú

**Abstract**—This article is based on conducting research to analyze the benefits of emerging trends in communications and networking technology, such as software-defined wide area networks. Using Waterfall as a methodology, the main objective is to carry out a technical comparison at the design and configuration level, creating a virtual environment that simulates traditional and SDWAN (Software-Defined Wide Area Network) infrastructures. The results obtained verify that the benefits of SDWAN maintain business continuity, anticipate situations in which the infrastructure can act intelligently, optimize connectivity while maintaining security, and provide improvements in the management of the entire infrastructure. People will be able to see the results obtained between both technologies and validate the benefits that SDWAN offers.

**Keywords**—*Networking technology; connectivity; SDWAN; wide area network; waterfall*

## I. INTRODUCTION

Nowadays, for many companies, communications are a vital part of the business continuity, however, in this process the infrastructure and technology that carry out this activity goes unnoticed.

All companies that provide services need to maintain an agile data transmission, as well as an infrastructure that supports it. In turn, connectivity between the company's headquarter, branch offices and data center is a very important aspect because it is necessary to provide services to its customers continuously and with high availability. For this reason, most companies opt to use private networks that are deployed and managed by external service providers, however, today a new technology is being used called SDWAN to communicate all the company's sites. This technology provides a significant change on networking because it delivers innovation in the way it operates, adds a return of investment in medium term and several benefits that makes more companies dare to invest in it [1].

This research work aims to present SDWAN as a new technological alternative for WAN connectivity between multiple sites, because traditionally for 15 years it has been using traditional WAN or known as Multiprotocol Label Switching (MPLS) in Peru. MPLS is known in the technological field as the most popular communication protocol and used by service providers to connect multiple locations of their customers. SDWAN is a relatively new technology in the world since it

is only about 3 years since it became more widely known and it is being adopted by more companies every year.

It is necessary to emphasize that in Peru there are many companies that do not dare to make technological changes or renovations due to a lack of knowledge or rejection of change. Therefore, this research focuses on the benefits that SDWAN technology can bring, for this purpose, the operational benefits at the deployment level of software-defined network solutions for WAN connectivity are analyzed. In addition to the technical benefits at the scalability level and the economic benefits of the software-defined networking solution. Likewise, as support for the research, laboratory tests are carried out that provide technical results in which the benefits that this technology brings in comparison with traditional WAN technology are manifested, not only at a theoretical level, but also at practical level.

This article has the objective to analyze the benefits at the operational, technical, economic level and the comparison between the traditional technology and SDWAN.

## II. LITERATURE REVIEW

According to the growing demand of users towards companies for the use of their services; the use of the internet and the need to maintain connectivity have been fundamental factors in order to deploy applications and meet the expectations of its customers. It can be said that any company that provides services needs to maintain an agile data transmission, as well as an infrastructure that supports it. Nowadays companies are not only looking for availability, reliability and performance so that they can provide connectivity between their sites. Now they are also looking for scalability [2]; for that is inevitable to speak of wide area networks (WAN) when it comes to transmitting data or information. In turn, connectivity, between the sites that a company may have, is a very important issue because it is necessary to provide services to its customers continuously and with high availability. Most companies choose to use private networks that are deployed and managed by external service providers. However, today a new technology is being used to communicate the headquarters of a company, called software-defined wide area networks. This technology provides a change in the use of traditional networks because it delivers innovation in the way it operates, adds a share of cost and benefit in the medium term that makes more companies dare to invest in it

[3]. Finally, it removes the prominence of service providers since it provides greater autonomy to clients to be able to manage their networks [1].

One characteristic that SDWAN has is that it uses three planes: the data plane, which contributes to making communication between sites easier, since a logical infrastructure is created which will work on a physical infrastructure and will allow to transfer data from origin to destinations in a fluid way; the control plane will carry out the control of the configurations of the devices connected to the network, such as policies, routing information, accesses [1]; the orchestration plan that provides a business policy and security framework.

One of the advantages in the use of SDWAN in wide area networks, is that it allows the configuration and management of connections between branches of a company is simple and also flexible, easy to control and supervise, which in the medium and long term results in reducing operating costs [4]. This type of network emerge as a solution to face the different deficiencies that traditional networks present [5], because they facilitate bandwidth management and prioritize data traffic in WAN networks that can also be done in traditional networks, but which requires more effort.

Another advantage that SDWAN networks have is the management, control and configuration of the company's networks from a centralized web platform. This allows changes that are applied to different network connections to take effect immediately. In the centralized platform it will be possible to visualize in a unified way parameters such as the data consumption of the interfaces, latencies of the links, use of the bandwidth by IP, the available bandwidth and other statistics that allow optimal monitoring and control of the network status [4]. It also mentions that in traditional wide area networks to be able to update a network successfully, it is usually necessary to configure the devices manually, which is time consuming and prone to errors compared to an SDWAN type network, in which everything is executed from the centralized platform. Likewise, the platform makes it possible to differentiate the types of traffic that are used by clients or by the companies that manage this platform. These types of traffic are: video traffic, voice traffic, data traffic, and management traffic. Each of them has a prioritization over the other which is defined as follows: video over voice, voice over data and data on administration.

Thus, in a comparison of scenarios to measure and verify the effectiveness of software-defined networks, a simulation was carried out, for which they created a virtual scenario and implemented an SDWAN network. Which allows to establish communication between 2 data centers that use software-defined network technology and in whose tests voice information was transmitted over IP. As a result of the tests carried out, it was evidenced that by configuring the traffic prioritization policies, it is possible to guarantee that the bandwidth quality of service works at an adequate level, in addition to only using a low percentage of CPU load, which translates into efficient network management [5].

In another investigation, 2 scenarios are compared. The first corresponds to a network configured with classic IP / MPLS using manual routing policies and the second scenario uses a software-defined WAN network, for both scenarios the same number of routers and links are used. In the first scenario,

manual routing policies were configured in which low or high latency routes were established. When a router needs to establish communication with another and requests a low latency, the communication will be sent on those links configured with low latency. If at any time the latency of these links increases, the communication will be sent through the same route, as the configuration establishes it. While, in the second scenario, in which a software-defined WAN network is used, the network controller is the one in charge of continuously measuring the status of the links and dynamically defining which route should be used to send the communication [6], as it is programmed in such a way that it has a complete view of the network topology.

In another investigation similar to the one mentioned in the previous paragraph, they evaluated the performance of implementing a software-defined WAN network in an enterprise. In this investigation, they communicated two branches to their headquarters through two Internet / Broadband connections. In the simulation, 2 performance metrics are considered, which are the service time and the percentage of lost packets. The configuration established as the delay time is 10ms and a loss of 2 packets per second (pps). During the simulation, an increase in the delay time was induced, to cause packet losses. When the SDWAN controller detects that the configuration parameters have been exceeded, it automatically establishes a route change for sending the packets, so that it does not affect the quality of service (QoS) [7]. Another investigation refers to the traffic routing associated with applications and administration and how these can be optimized by means of a module added to the controller [8].

Another point to consider in the use of SDWAN technology is that it can work with several connection links, through which traffic is routed through a WAN network making use of load balancing [9], which allows to improve and manage the traffic of the network in the different links [10].

On the other hand, examples of the use of SDWAN in the banking sector are presented. In 2017, there was a drop of 8,800 ATMs in India. Because the satellite connections had a disconnection due to a failure in the satellite leaving many ATMs unusable. This resulted in customers being unable to make transfers or transactions until the failure that cost approximately 600 to 900 billion was resolved. As a lesson learned, it was decided to bet on making viable a project in which important points are considered such as having a connection in contingency in case the main link falls and that is cost effective for the banks. In such a way that it adapts to the existing environment at a technical and cost level, as well as the investment and expected performance, appropriate to the services and the architecture [11]. For this reason, a plan was deployed in the cities of Java and Bali (Indonesia) that in a period of 3.5 years provided satisfactory results and in that same period of time many other companies began to invest in wide area networks defined by software.

The example above explains how SDWAN operates in this specific scenario. Provide the feasibility of having a connection as a contingency in case the satellite connection has any failure. The redundant connection can work in an active / active or active / available way, in either case the objective is to keep the WAN connection secure. The secondary or contingency medium that was chosen in this scenario was 4G / LTE. For

this reason, SDWAN can benefit companies that have many locations and that need to keep their WAN connection always active, in addition, with the TCAC it is demonstrated in an agile way that indicates feasibility and that it can be cost effective.

It is also important to mention that software-defined wide area networks are a relatively new technology and for that reason many companies have not yet chosen to use it. For example, in India, 75% of business customers want to start using these kinds of new solutions; however, only 5% of customers risk making the change, even though it has been shown that this type of network generates great benefits [12], which allows companies to have lower operating costs, higher performance and a robust deployment of software-defined wide area networks. With this technology it can be said that the bottlenecks to transfer information will no longer exist.

Additionally, when comparing traditional WAN networks with SDWAN, the latter are notably superior because in addition to providing centralized control, they allow defining network policies based on profiles and managing data traffic without the need for individual configurations [4]. Also, by massively coupling similar configuration profiles to a set of computers, which would help facilitate the tasks of network administrators because they could manage tasks jointly making more efficient use of work times.

Finally, it is necessary to take into account that security is another outstanding feature in SDWAN because it is present during connectivity, traffic management, additional security services, deployment, visibility and compliance with what is configured [13]. In addition, security is necessary for any company and from the point of view of service providers, security is an essential requirement to be able to implement their projects, although there are different architectures, designs and brands [14].

Based on what was read, it concludes that software-defined WAN networks represent a viable solution to address the difficulties that arise in a traditional WAN network. In addition, it allows to ensure the quality of service through efficient management of network resources, which allows improving network performance, availability and security. Another point to highlight is the reduction of costs in infrastructure and human resources, especially since this technology is simple to administer, which allows a staff with basic knowledge of networks to create offices and perform agile configurations, which shows us that the difficulty in managing networks is significantly reduced, making this type of technology become the next generation network.

### III. METHODOLOGY

The methodology used in this research is Waterfall (see Fig. 1) because the research activities are distributed in phases which are developed sequentially. It is important to mention that a phase cannot be started if the previous one has not been completed. That is why the Scrum framework is not used [15] [16] [17] [18].

#### A. Phase 1 - Start

1) *Project Scope*: Functional requirements: It is necessary to keep in mind that the focus of this research is associated with

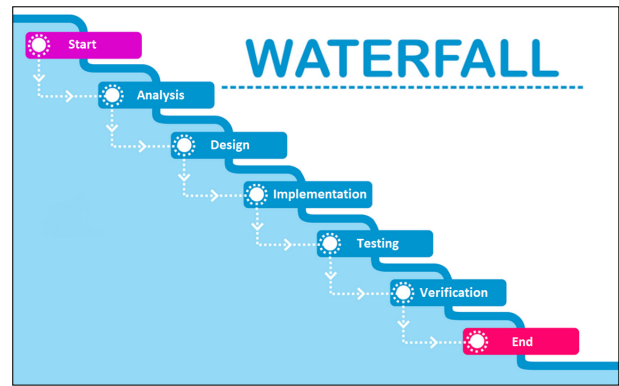

Fig. 1. Implementation Methodology.

the quantitative part, therefore, a laboratory will be executed that will provide results associated with parameters, for this it is necessary to cover certain technical requirements at the software and hardware level to be able to carry out the laboratory.

To perform the deployment for both the traditional environment and the SDWAN environment, PNETLAB tool will be used. This software is a virtual machine that can be provisioned on a VMWare Workstation. The advantage of this technology is that it is not necessary to invest to buy physical devices to be able to emulate the hardware and software.

The laboratory is going to use virtualized devices that are associated with one of the best-known brands in the network and communications environment. Cisco was the chosen brand because its software can be executed in a virtualized environment and also its entire platform is supported and maintained, thus providing reliability for laboratory development. Table I and Table II specify hardware requirements for traditional WAN and SDWAN environments. The hardware and software requirements for the server are detailed in Tables III and IV.

TABLE I. HARDWARE REQUIREMENTS SDWAN

| Device   | Quantity | CPU | Memory | Total CPU | Total Memory |
|----------|----------|-----|--------|-----------|--------------|
| vBond    | 1        | 1   | 1      | 1         | 1            |
| vManage  | 1        | 4   | 16     | 4         | 16           |

- Testing scopes
- Work breakdown structure
- Topological diagrams
- Gantt diagram
- Polls
- Survey results
- Results of internet quotes
- Laboratory results

B. Phase 2 - Analysis

1) Traditional Architecture:

Traditional WAN technology is connection-oriented, meaning that its main purpose is to carry information from a source to a destination. In addition, the main weaknesses of the traditional WAN are its manual configuration, its reactive response to incidents, it is oriented to the use of physical components to function and it is not compatible with other programming tools.

Currently, the traditional WAN architecture can cover the different ways of getting from one point to another either by LTE, MPLS, internet or satellite, however, it does not provide dynamism when connecting a point of origin to destination.

Fig. 2 illustrates communication in a traditional WAN environment. It should be noted that communication in a company has the priority of using an MPLS network, in which the components are configured manually. For LTE, internet and satellite, private communications called VPNs are created, which remain manual settings.

2) SDWAN Architecture: For SDWAN, communication is not only based on communicating a point of origin to a destination, but also provides greater benefits such as the automation of configurations, virtual machines can be used and it is compatible with APIs, for this reason it is programmable. In addition, it uses a graphical interface to be able to visualize the health status and settings in a centralized way. Also, it is not oriented to the connection, but to the business need, for example, when a device has two links and one of them is congested, SDWAN has the ability to use a connection that is less congested.

Some of the strengths of SDWAN is that an additional layer of security can be added for information processing and the

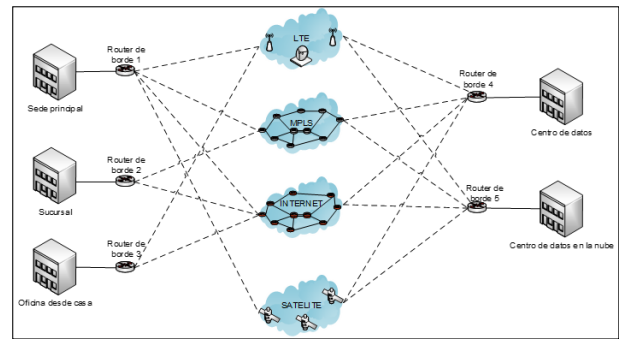

Fig. 2. Traditional WAN Architecture.

provisioning that is given to the equipment is done from a web interface, it is not necessary to configure the equipment onsite, it just requires access to internet and also it needs to be configured with a minimum administration parameters. In addition, it provides analytics on traffic use, applications, users and devices. This makes it a tool that gives companies visibility on bandwidth usage.

Fig. 3 illustrates the communication that occurs between vEdge devices, that are associated with a dynamic communication between any other, also, for each connection a secure and private tunnel is created while the communication is established. The only thing they need is to have ip connectivity between them. The intelligence at the routing level is provided by the vSmart controllers. In addition, you can see the communication between the different premises that, unlike the traditional WAN, is dynamic and provides flexibility when configuring because templates are used and are applied in an automated way.

Fig. 3. Cisco SD WAN Architecture.

3) Risks: It is necessary to bear in mind that unexpected events can occur even in a controlled environment, in this case a virtual environment that is simulated by a tool. These risks can be found at the hardware level, software level, or even human error. The most important risks to consider for the development of the laboratory implementation are detailed below.

- Risk 1: Bugs
  - Description: Error caused by SDWAN software code

- Cause: Defective software
  - Consequence: Malfunction in some of the SD-WAN services
  - Probability: Low
  - Impact: High
  - Risk Level: Considerable
  - Control: Use the latest recommended version
- Risk 2: Performance
    - Description: Server saturation for virtual environment emulation
    - Cause: Limited server resources
    - Consequence: Slow use of virtualized computers services
    - Probability: Low
    - Impact: High
    - Risk Level: Considerable
    - Control: Run one virtual environment at a time
  - Risk 3: Human error
    - Description: Error in the configuration of virtualized machines
    - Cause: Disorder in virtual machine configuration
    - Consequence: Lack of connectivity or malfunction in virtualized communication equipment
    - Probability: Medium
    - Impact: Medium
    - Risk Level: Considerable
    - Control: Review the equipment configurations so that a double check is performed

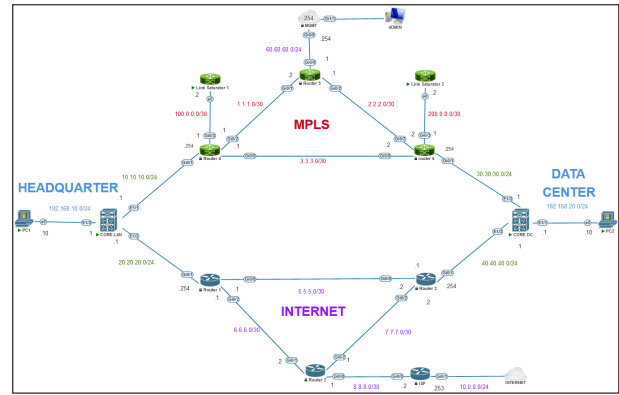

Fig. 4. WAN Topology.

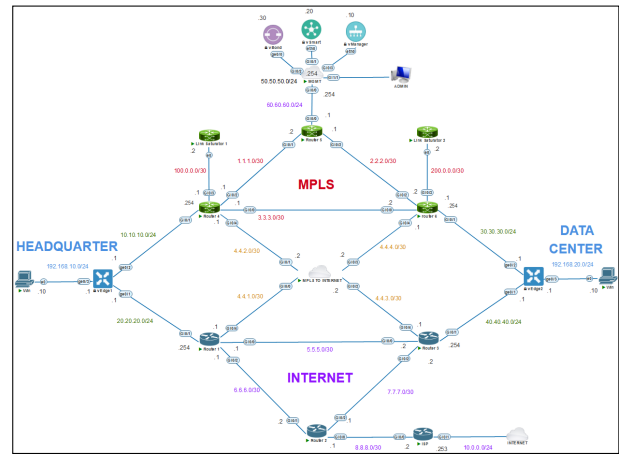

Fig. 5. SDWAN Topology.

### C. Phase 3 - Design

In this phase, a topology is created for traditional WAN and SDWAN environments. Each of the environments will have similar parts as their own technology. It is necessary to keep in mind that the topology for both is logical and physical and also it is oriented for a technical purpose.

A well known design was used in WAN Traditional topology; for SDWAN design MPLS and Internet must have at least a connection between them in order to communicate servers network to Internet interface for vedges.

1) *Technical Scope for Laboratory*: For MPLS and Internet dynamyc routing protocols were used. For practical purpose, OSPF was used.

2) *WAN Traditional Topology* : The connection must be made from Headqueaters to Data center using MPLS and Internet as backup only with MPLS's link is down (see Fig. 4).

3) *SDWAN Topology* : The connection must be made from Headqueaters to Data center using MPLS as a priority and Internet as backup with latency is high (see Fig. 5).

4) *Work Breakdown Structure* : These are the activities used for the laboratory (see Fig. 6).

### D. Phase 4 - Implementation

In the next section shows aspects at the IP addressing level that will be used to run the laboratory and optimize communication between the different communication devices.

1) *Traditional WAN Environment* : The Table V consider the devices shown in Fig. 4.

2) *SDWAN Environment* : The Table VI consider the devics shown in Fig. 5.

## IV. RESULTS AND DISCUSSIONS

### A. Phase 5 - Testing

1) *Testing Traditional WAN*: The tests are based on evaluating two scenarios, one without saturation and the other with saturation in order to evaluate the behavior of a traditional WAN network. The objective of these tests is to validate that the current technology is connection oriented and does not have an intelligence that adapts to changes in the network and can make routing decisions that benefit more stable connectivity in case of intermittences or saturation.

All tests performed consider the path to the MPLS as a routing priority because it is a dedicated network for the client, however, this network in many occasions in a real scenario is

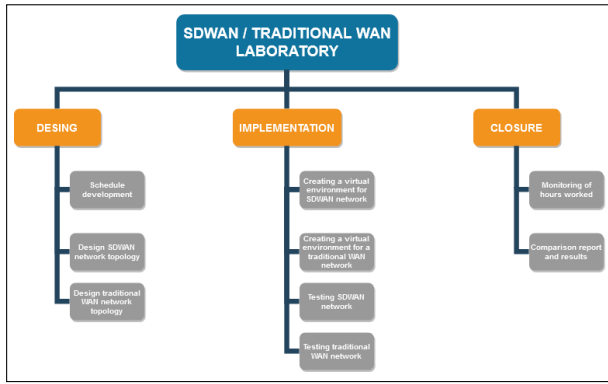

Fig. 6. Work Breakdown Structure.

TABLE V. TRADITIONAL WAN ENVIRONMENT IP ADDRESSING

| HOSTNAME         | LOCATION    | IP/MASK          | GATEWAY      |
|------------------|-------------|------------------|--------------|
| Computer 1       | Headquarter | 192.168.10.10/24 | 192.168.10.1 |
| Computer 2       | Data Center | 192.168.20.10/24 | 192.168.20.1 |
| Link Saturator 1 | Mpls        | 100.0.0.2/30     | 100.0.0.1    |
| Link Saturator 2 | Mpls        | 200.0.0.2/30     | 200.0.0.1    |
| Router 1         | Mpls        | 5.5.5.1/30       |              |
|                  |             | 6.6.6.1/30       |              |
|                  |             | 20.20.20.254/24  |              |
| Router 2         | Mpls        | 6.6.6.2/30       |              |
|                  |             | 7.7.7.1/30       |              |
|                  |             | 8.8.8.1/30       |              |
| Router 3         | Mpls        | 5.5.5.2/30       |              |
|                  |             | 7.7.7.2/30       |              |
|                  |             | 40.40.40.254/24  |              |
| Router 4         | Internet    | 1.1.1.1/30       |              |
|                  |             | 3.3.3.1/30       |              |
|                  |             | 10.10.10.254/24  |              |
| Router 5         | Internet    | 100.0.0.1/30     |              |
|                  |             | 1.1.1.2/30       |              |
|                  |             | 60.60.60.1/24    |              |

|                  |             | 192.168.10.1/24  |              |
|                  |             | 30.30.30.1/24    |              |
| ISP              | Internet    | 40.40.40.1/24    |              |
|                  |             | 192.168.20.1/24  |              |
| INTERNET         | Internet    | 8.8.8.2/30       |              |
| ADMIN            | Internet    | 10.0.0.253/24    | 10.0.0.1     |
| MGMT             | Internet    | 10.0.0.1/24      | 192.168.1.1  |
|                  |             | 10.0.0.10/24     | 10.0.0.1     |
|                  |             | 50.50.50.254/24  |              |
|                  |             | 60.60.60.1/30    |              |

also subject to congestion or falls, therefore, a situation will be created in which it is stressed or congested by a lot of traffic.

a) *No link saturation* : Fig. 7 and Fig. 8 shows the Netscantools application after having taken the capture of information for 100 seconds without saturation.

For these tests, ping, latency and jitter and traceability tests have been considered. These tests refer to the hops between devices from a point of origin to a destination. Likewise, Netscantools provides information both at a graphic and textual level, this is very important because it gives visibility of the times that exist while the information goes from one point to another (see Fig. 9).

TABLE VI. SDWAN ENVIRONMENT IP ADDRESSING

| HOSTNAME         | LOCATION    | IP/MASK          | GATEWAY      |
|------------------|-------------|------------------|--------------|
| Computer 1       | Headquarter | 192.168.10.10/24 | 192.168.10.1 |
| Computer 2       | Data Center | 192.168.20.10/24 | 192.168.20.1 |
| Link Saturator 1 | Mpls        | 100.0.0.2/30     | 100.0.0.1    |
| Link Saturator 2 | Mpls        | 200.0.0.2/30     | 200.0.0.1    |
| Router 1         | Mpls        | 5.5.5.1/30       |              |
|                  |             | 6.6.6.1/30       |              |
|                  |             | 20.20.20.254/24  |              |
| Router 2         | Mpls        | 6.6.6.2/30       |              |

|                  |             | 50.50.50.254/24  |              |
|                  |             | 60.60.60.1/30    |              |

Fig. 7. Test Results without Saturation, no Link Saturation.

b) *With link saturation*: For this part, it was considered an additional program that generates traffic and allows to simulate congestion or saturation in the MPLS network. Fig. 10 show the program that was used to generate traffic on the network.

Fig. 11 and Fig. 12 show the results of the Netscantools application after running the test for 100 seconds with saturation. Fig. 13 shows the last traceroute of the tests.

Fig. 8. Closeup of the Results, no Link Saturation.

Fig. 9. Five Trace Information.

Fig. 10. Saturation Program Configuration.

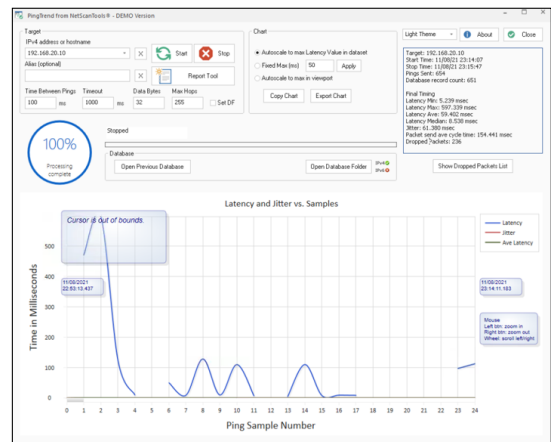

Fig. 11. Test Results of the Netscantools Application with Saturation.

2) *Testing SDWAN*: In this case, two scenarios will also be evaluated, one without saturation and one with saturation in order to find. These tests will validate that the new software-defined network technology allows automatic changes in the network to make routing decisions that benefit more stable connectivity in case of intermittences or saturation of the links.

a) *No link saturation* : Fig. 14 shows the Netscantools application capture with the resulting information after running the test for 100 seconds without saturation.

Fig. 15 correspond to the graph obtained during the execution time of the test. The values obtained allow to validate that there are minimal changes in the communication speed. It is necessary to take into account that the times are considered in milliseconds.

As in the traditional WAN laboratory, traceability tests have also been considered, which refer to the number of computers through which the information passes from a point of origin to a destination. The tests will be executed in 5 consecutive times, leaving a lapse of 5 seconds between each one. Fig. 16 shows the last traceroute of the tests run.

b) *With link saturation* : Fig. 17 and Fig. 18 are the result after having run the tests for 100 seconds with saturation. Fig. 19 shows the last traceroute of the tests.

3) *Traditional WAN Lab Results* :

a) *Latency*: The following tables compare the results at the latency level obtained in the traces of the tests executed with and without saturation of the links. Table VII compares

latency level with and without saturation. Table VIII and Table IX show the minimum and maximum values obtained in the tests and Table X compares the average values.

TABLE VII. COMPARISON OF THE LEVEL OF LATENCY WITH AND WITHOUT SATURATION WAN

| Hop | IP            | Without Sat. (ms) | With Sat. (ms) | Difference (ms) |
|-----|---------------|-------------------|----------------|-----------------|
| 0   | 192.168.10.10 | 0.379             | 0.281          | -0.10           |
| 1   | 192.168.10.1  | 1.392             | 1.707          | 0.32            |

4) SDWAN Lab Results:

a) Latency: The following tables compare the results at the latency level obtained in the traces of the tests executed with and without saturation of the links. Table XII compares latency level with and without saturation. Table XIII and Table XIV show the minimum and maximum values obtained in the tests and Table XV compares the average values.

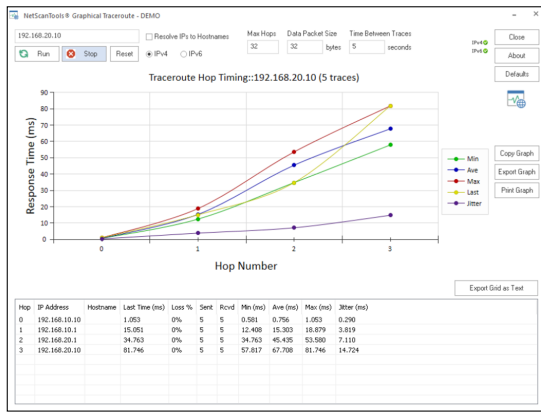

Fig. 16. Last Trace Graph of the Test Run.

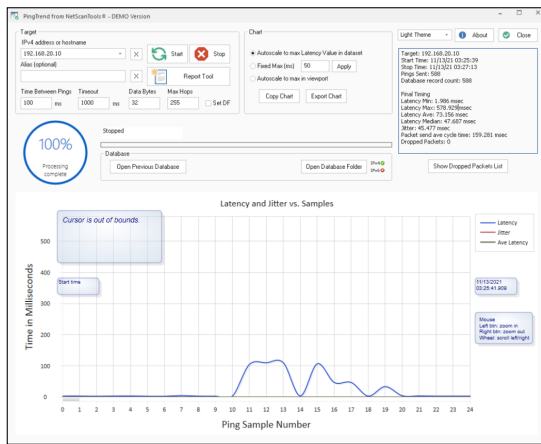

Fig. 17. Test Results with Saturation.

TABLE XII. TRACE COMPARISON WITHOUT AND WITH SATURATION IN MILLISECONDS SDWAN

| Hop | IP            | Final Trace (ms) | Final Trace (ms) | Difference (ms) |

b) *Jitter*: Table XVI compares the results of jitter level obtained in the traces of the tests with and without saturation of the links.

TABLE XVI. COMPARISON OF JITTER WITHOUT AND WITH SATURATION IN MILLISECONDS SDWAN ENVIRONMENT

| Hop | IP            | Without Sat Jitter (ms) | With Sat. Jitter(ms) | Difference (ms) |
|-----|---------------|-------------------------|----------------------|-----------------|
| 0   | 192.168.10.10 | 0.28                    | 0.29                 | 0.01            |
| 1   | 192.168.10.1  | 1.091                   | 3.819                | 2.73            |
| 2   | 192.168.20.1  | 1.336                   | 7.11                 | 5.77            |
| 3   | 192.168.20.10 | 1.054                   | 14.724               | 13.67           |

B. Phase 6 - Evaluation

1) *Technical Comparison:* In the next section, the following tables represent the crossing of information between saturation tests of both technologies, also there is a difference in the number of hops, in SDWAN there a less because the connection is by tunneling.

a) *Design:* A big difference between both designs is that SDWAN needs to have servers hosted and Internet and MPLS must have a connection in order to get those servers. In the other hand, for traditional WAN, since each device will be managed independently.

b) *Configuration:* The configuration in the initial phase for SDWAN is executed by command line because it is necessary to assign some parameters for its registration and synchronization with the solution servers. The rest of the configurations are made from a graphical interface. In the other hand, for traditional WAN, 100% of the configurations are made in command lines and additionally the validations are done in the same way. It is important to mention that this can be done initially onsite and then it could be managed remotely.

c) *Latency:* In the results, it can be seen that for traditional WAN technology there is a higher rate of slowness in the response when there is saturation, whereas for SDWAN there is a certain increase in latency, but it is not so considerable (see Table XVII). The important thing is that the connectivity service in general would not be affected and users could perceive a certain slowness, but not disconnections that is a great benefit for SDWAN.

TABLE XVII. LATENCY COMPARISON BETWEEN SDWAN AND TRADITIONAL WAN

|                 | Hop | IP            | Without Saturation | With Saturation  | Difference (ms) |
|-----------------|-----|---------------|--------------------|------------------|-----------------|
|                 |     |               | Final trace (ms)   | Final trace (ms) |                 |
| Traditional WAN | 0   | 192.168.10.10 | 0.379              | 0.281            | -0.10           |
|                 | 1   | 192.168.10.1  | 1.392              | 1.707            | 0.32            |
|                 | 2   | 10.10.10.254  | 2.693              | 790.459          | 787.77          |
|                 | 3   | 3.3.3.2       | 3.768              | 2540.401         | 2536.63         |
|                 | 4   | 30.30.30.1    | 4.892              | 5.298            | 0.41            |
| SDWAN           | 0   | 192.168.10.10 | 8.479              | 8.162            | -0.32           |
|                 | 1   | 192.168.10.1  | 0.575              | 1.053            | 0.48            |
|                 | 2   | 192.168.20.1  | 1.702              | 15.051           | 13.35           |
|                 | 3   | 192.168.20.10 | 4.111              | 34.763           | 30.65           |
|                 | 3   | 192.168.20.10 | 3.65               | 81.746           | 78.10           |

d) *Jitter:* SDWAN has better values because it can switch links in a smart way and this allows the communication to have better performance and quality (see Table XVIII).

TABLE XVIII. JITTER COMPARISON BETWEEN SDWAN AND TRADITIONAL WAN

|                 | Hop | IP            | Wlthout Saturation | With Saturation | Difference (ms) |
|-----------------|-----|---------------|--------------------|-----------------|-----------------|
|                 |     |               | Jitter (ms)        | Jitter (ms)     |                 |
| Traditional WAN | 0   | 192.168.10.10 | 0.552              | 0.798           | 0.25            |
|                 | 1   | 192.168.10.1  | 0.527              | 1.086           | 0.56            |
|                 | 2   | 10.10.10.254  | 1.453              | 609.051         | 607.60          |

|                 | 4   | 30.30.30.1    | 2.592              | 59.992          | 57.40           |
| SDWAN           | 0   | 192.168.10.10 | 1.176              | 182.506         | 181.33          |
|                 | 1   | 192.168.10.1  | 0.28               | 0.29            | 0.01            |
|                 | 2   | 192.168.20.1  | 1.091              | 3.819           | 2.73            |
|                 | 3   | 192.168.20.10 | 1.336              | 7.11            | 5.77            |
|                 | 3   | 192.168.20.10 | 1.054              | 14.724          | 13.67           |

V. CONCLUSIONS AND FUTURE WORK

SDWAN is a technology that improves capabilities and characteristics over traditional technology in different aspects such as automatization, hardware agnostic , programmable, web interface interaction, business-oriented, cloud-based, secure, scalable and provides analytics. SDWAN networks allow branch offices to have greater communication availability with data centers by prioritizing critical traffic using different types of parameters such as delay or jitter. The result of the tests executed in a virtual environment validates the great benefits at the level of agility and scalability that the solution brings because it was shown that SDWAN was much more effective than the traditional WAN to continue communication despite the fact that the network was congested. It is concluded that SDWAN offers many technical benefits that in the end of the day will keep smart communications and save cost for companies. The next step is to investigate about the return on investment and comparison between the different SDWAN brands that exist in the market so that it can enrich the research presented in this document.

# Data Recovery Approach for Fault-Tolerant IoT Node

Perigisetty Vedavalli, Deepak Ch  
School of Electronics and  
Communication Engineering  
VIT-AP University  
Amaravathi, Andhrapradesh, India 522237

**Abstract**—Internet of Things (IoT) has a wide range of applications in many sectors like industries, health care, homes, militarily, and agriculture. Especially IoT-based safety and critical applications must be more securable and reliable. Such type of applications needs to be operated continuously even in the presence of errors and faults. In safety and critical IoT applications maintaining data reliability and security is the critical task. IoT suffers from node failures due to limited resources and the nature of deployment which results in data loss consequently. This paper proposes a Data Recovery Approach for Fault Tolerant (DRAFT) IoT node algorithm, which is fully distributed, data replication and recovery implemented through redundant local database storage of other nodes in the network. DRAFT ensures high data availability even in the presence of node failures to preserve the data. When an IoT node fails in any cluster in the network data can be retrieved through redundant storage with the help of neighbor nodes in the cluster. The proposed algorithm is simulated for 100-150 IoT nodes which enhances 5% of network lifetime, and throughput. The performance metrics such as Mean Time to Data Loss (MTDL), throughput, Network lifetime, and reliability are computed and results are found to be improved.

## I. INTRODUCTION

IoT provides an integration of multiple controllers, IoT nodes, servers, and gateways which contains embedded technologies to be logically connected and enables them to sense and interact to the real world and also among themselves. It is attainable for them to gather data from a wide range of existing structures. The accuracy of the IoT network is diminished, when the transmission data is faulty which leads to cause for inappropriate actions. So, it is critical to enhancing the ability of the IoT network to detect and recover the faulty node's data. Difficulties of detecting incorrect data and the quality of data have been studied extensively [1]. Fault tolerance is an important aspect for ensuring the high reliability and availability of the IoT network. Due to resource-constrained devices, there may be a lot of chances to occur failures in the network. Hence traditional networking technologies cannot handle IoT requirements effectively [2]. According to the survey, 48% of IoT projects may fail due to data failures and security. Data failures include missing files, corrupt files, and data blocks, and inconsistent files [3].

Capturing the data quality levels is more effective to estimate the device's quality and their produced data. Data quality estimation mechanism depends on three stages[4],

data reliability, device availability, and overall quality of data. Sensors are small devices with limited resources like memory space, battery, and processing power. These resource-constrained nodes pose multiple challenges for network designers' accurate usage of scarce resources. In certain times IoT applications need to be deployed in harsh environments [5]. In such IoT applications, nodes are prone to failures due to various reasons, such as hardware failure, battery depletion, and external events. Complex IoT applications with the help of various techniques require effective data management [6]. IoT is a complex heterogeneous network, maintaining high reliability is one of the major concerns. IoT networks should be more reliable for safety and critical applications, with the help of heuristic binary decision diagrams can able to access the link failures that occur due to data loss in community structures [7].

IoT applications help the industries to bring a competitive edge on their competitors. Even due to sharing data, security, device faults, and data manipulation between the various smart devices which becomes a serious concern to many industries, these interrupt the workflow of industries. IoT network comprises many sensing nodes, so the network needs to collect and process an enormous amount of external environment data. Enhancing the fault tolerance and reliability can be achieved by adding redundant bits to the original data at the information level is necessary for an IoT network. By employing the Reduced Variable Neighborhood Search (RVNS) algorithm the IoT network can enhance the processing speed and reliable transmission of data [8]. Generally, sensor data validation includes mainly two steps, those are data faults detection and data reconciliation. There is no perfect tool or method for this process.

In [9] various faulty data detection and correction methods and tools are discussed. In an IoT network, each sensor node works with a limited power source and when the sensor stops working the network cannot process data that they received this may affect the prediction of network health and reliability which leads to network failure. When this situation happens RAID structures are very useful for maintaining the redundant copies of data. This paper focuses on data management with the help of a particular RAID-like technique in the cluster for achieving fault tolerance with additional communication costs.

The remaining paper is organized as Section 2 recent data replication and recovery methods in IoT, Section 3 is about the implementation of a DRAFT algorithm in the IoT network. Section 4 is discussed about performance evaluation for DRAFT Algorithm and finally, section 5 draws conclusion

and possible future directions of work.

## II. RELATED WORK

IoT requires efficient data collection, generation, and presentation through wireless sensor nodes. Due to limited energy resources, sensor nodes are unreliable, which may lead to the loss of valuable data. In IoT, data replication is a promising method for data management. In [10] data replication algorithms for IoT nodes classification, analysis, and comparison are presented. Data replication techniques include query balancing, data availability, system robustness, and data retrieval Resilient data-centric storage algorithm is utilized by [11] to illustrate the tiny database systems for easy data retrieving. It is specially designed for low-powered IoT sensor nodes. A Distributed Hash Table(DHT) is used for storing the redundant data into the node.

The redundant storage of data assures the information available in case of source failure. A greedy replication-based distributed storage algorithm is proposed in [12], if a node in the network fails then the data can be retrieved through neighbor donor nodes. IoT sensor nodes data is stored in distributed mini data centers in a decentralized manner cloud rather than single cloud storage. In those data storage areas, each IoT data item has predetermined redundant data copies. This problem has been formulated with the help of a complex-linear programming model and heuristic algorithms are proposed in [13]. These algorithms are helping to improve the latency of reading and writing operations.

A multi-dimensional data storage algorithm is implemented within a single node [14], which can create to handle querying, indexing, storing, and ingestion of huge amounts of data. A distributed MDDS offers high ingestion rates, fault tolerance, and horizontal scaling when compared to Relational database management systems (RDBMS). To assure high data availability in the IoT network during the node failure distributed hop by hop data replication (DRAW) technique is proposed in [15]. This algorithm helps to identify the best replica node for maintaining a redundant copy. For selecting the replica node this technique applies a series of conditions like availability of the memory in the device, the number of hops, degree of replication, previous replicas of the data items, and common neighbors of the devices.

Data availability during the failures can be achieved through data replication algorithms. In [16] bridged replication control algorithm (BRC) is proposed for smart logistics. BRC creates temporary replication access when the link failure occurred through the bridge token. BRC provides efficient data management for smart networks. By maintaining redundant data components in multiple storage locations can achieve high fault tolerance. An adaptive data replication algorithm is proposed [17], and incorporated at the gateway level.

IoT network is deployed with many sensor nodes, in this context energy of the sensor nodes is depleted during data transmission. An adjustable data replication algorithm based on virtual grid technology is implemented in [18]. This scheme helps to enhance the lifetime and performance of the sensor nodes. A dynamic sink node will determine the communication link depending on the selected beacon and continuously develop a replica node across the query node

to create a balance between the rate of energy consumption and the overhead in the network. Data recovery is one of the essential features of an IoT network. These networks may face some issues due to sensing and connection errors which result in incorrectly received data [19]. By incorporating probability matrix factorization at the cluster level can recover the missing data through neighbor nodes in the cluster.

In [20] a convolution neural network has been utilized for generating data recovery algorithms. For restoring the data which mainly includes two steps, all sensed collected for the training process to the networks and data recovery has been initiated with the help of a trained generator. An redundant residue number system algorithm [21], Max-flow algorithm fault tolerant [22], Device pairing algorithm [23], Finding Least connected points algorithm [24], Least connected neighbour algorithm [25] are the few fault-tolerant algorithms have been studied. The above-listed literature algorithms in Table I were presented with a minimum of 10 to a maximum of 100 nodes. This work was analyzed properly to extend the existing algorithms works towards 150 IoT nodes with network lifetime, MTTDL, Reliability, and throughput of the network.

## III. IMPLEMENTATION OF A DRAFT ALGORITHM IN THE IOT NETWORK

Safety and critical industrial IoT applications such as IoT based nuclear radiation monitoring systems require more data availability and high fault tolerance during data loss. Thus protecting sensed data through redundant storage can significantly improve the system performance. Let us consider 'n' clusters with 'N' static nodes are randomly deployed in a sensing field. Each node has a unique ID, 'i' where  $i=1,2,3,\dots,P$ . Each node 'i' has fixed memory space 'k', to hold data and parity items. The memory space is partitioned into two units based on the RAID5 structure, one is for storing data and another unit is for parity storage. RAID is a well-proportioned technology that creates improved storage reliability and functions by block-level striping with parity in the node storage area. At

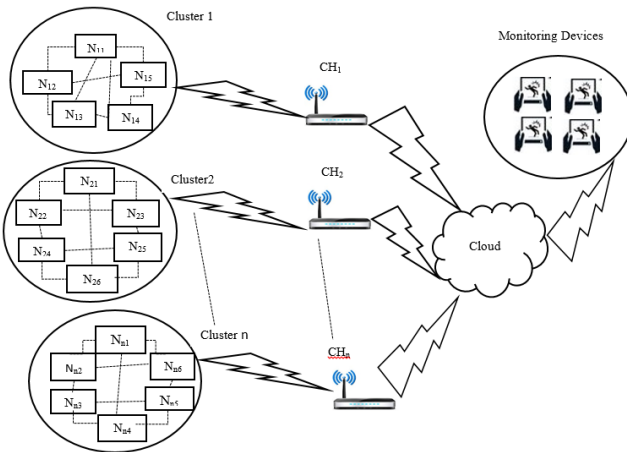

Fig. 1. Cluster Based Multi-Node IoT Architecture.

regular intervals, all the nodes detect environmental factors and produce sensing data  $D_i$ . The effective capacity for storing the sensing information is  $(k-1)/k$  of its total storage 'k'.  $1/k$  storage space is utilized for storing redundant information. Each node preserves a Direct Neighbor Node(DNN) attribute list ' $N_{Att}$ '. Every sensor node in the network can produce data and updates in the data unit as well as parity unit, with the help of all DNN in the cluster, and the node failure is denoted as  $N_F$ . To implement the DRAFT algorithm, a few assumptions have been made regarding the cluster-based multi-node IoT architecture as follows

- Assume that each cluster has at least five nodes.
- All nodes are having identical significance and storage space.
- All the nodes are having similar computation resources and initial energy supply.

To follow these steps the architecture is built as shown in Fig. 1. The basic architecture of IoT nodes consists of five elements they are controller, sensing element, battery, local storage, and network connectivity. The local storage of the node is partitioned into two parts. A DRAFT algorithm is invoked at each node and its storage unit is partitioned into two units based RAID5 mechanism. The inputs of the algorithm are no. of clusters 'n', storage space 'k', Data items  $D_i$ ,  $1/k$  parity unit,  $(k-1)/k$  data unit space, DNN attribute table  $N_{Att}$ . As the outputs of the algorithm create a node ID, and generate the parity based on DNN, data recovery from the DNN, MTTDL, throughput, network lifetime, and reliability. For every round, if any node data loss occurs can be retrieved through the DNN of that particular node in the cluster. A node collects new data samples continuously, and that data only updates its  $D_i$  section, but it also transmits a copy of the newly detected data to all of its direct neighbors, allowing them to update their  $P_i$  sections by computing the parity from the received data. The procedural steps for DRAFT Algorithm in IoT network as follows:

### DRAFT Algorithm

#### Step1 Input declaration

**Input:** Number of clusters  $n$ , Data item  $D_i$ , storage space  $k$ , DNN attribute table  $N_{Att}$

#### Step2 Output declaration

**Output:** Parity generation, data recovery if any data loss occurs, MTTDL, Network Lifetime, throughput, and reliability.

#### Step3 Node structure

Algorithm defnode (node id, cluster id, Data  $D_i$ , parity  $P_i$ )

begin

$C_{id}$  = Cluster id

$N_{id}$  = Node id

$D_i$  = Data of  $i$ th node

$P_i$  = Parity of  $i$ th node

end

#### Step4 Storage unit structure

Algorithm DRAFT ( $n$ ,  $k$ , DNN)

def node

Data unit =  $(k-1)/k$

Parity unit =  $1/k$

update  $D_i$ ,  $N_{att}$ ,  $P_i$

#### Step5 Initialize the first round

Node  $i$  transmitted data to cluster head  $i$

if ( $D_i$  of  $N_i = D_i$  of  $C_i$ )

transmit ACK

{

initialize next round

}

Else (error detection=true)

Transmits NACK

{

For each node in cluster A data recovery

$$DL_{iA} = \sum_{j=1}^n D_{jA}$$

$P_i = \text{XOR}(\text{DNN data of } i^{\text{th}} \text{ node})$

Data Recovered successfully

transmit ACK

}

#### Step6 Network lifetime extraction

Network lifetime

{

$P_v = (1 - p)^{N_d}$

}

#### Step7 MTTDL

{

MTTDL =  $\int_0^{\infty} P(S_0(t)) + P(S_1(t)) + P(S_2(t)) dt$

$$MTTDL = \frac{H(x)}{V(x)}$$

Where as

$H(x) = (\mu_D + k\lambda_0 + (k-1)\lambda_1)(\alpha_1 + (k-1)\beta_1) + (k\lambda_0 + (k-1)\lambda_1)(\mu_D + \lambda_2 + (k-1)\lambda_1)$

$V(x) = (k\lambda_0(k-1)\lambda_1(\alpha_1 + \lambda_2 + (\mu_D(k-1)\lambda_1)(k-1)(\lambda_1 + \beta_1))$

{

if  $\mu_D \rightarrow \infty$

{

$MTTDL = \frac{\alpha_1 + k\lambda_0 + (k-1)(\lambda_1 + \beta_1)}{k\lambda_0(k-1)(\lambda_1 + \beta_1)}$

}

if  $\mu_D \rightarrow 0$

$$MTTDL = \frac{1}{k\lambda_0} + \frac{1}{(k-1)\lambda_1}$$

**Step8 Reliability extraction**

$P(S_0(t)) + P(S_1(t)) + P(S_2(t)) + P(S_F(t)) = 1$   
 For each cluster A in N {

$$\frac{\partial P(S_0(t))}{\partial t} = -k\lambda_0 P(S_0(t)) + \alpha_1 P(S_2(t))$$

$$\frac{\partial P(S_1(t))}{\partial t} = k\lambda_0 P(S_0(t)) - (\mu_D + (k-1)\lambda_1)P_1(t) + \lambda_2 P(S_2(t))$$

$$\frac{\partial P(S_2(t))}{\partial t} = \mu_D P(S_1(t)) - (\alpha_1 + \lambda_2 + (k-1)(\lambda_1 + \beta_1))P(S_2(t))$$

$$\frac{\partial P(S_F(t))}{\partial t} = (k-1)\lambda_1 P(S_1(t)) + (k-1)(\lambda_1 + \beta_1)P(S_2(t))$$

**Step9 Throughput**

if  $D_i$  of  $N_i = D_R$   
 {  
 Successful recovery  
 }  
 else  
 {  
 Unrecoverable data  
 }  
 Repeat  
 End

Parity is computed by XORing all the inputs in a bit-wise manner. If there are more than one boolean inputs, XOR returns true when the two inputs are different. A parity scheme is one of the common approaches for error detection. Cluster1 is grouped with five nodes each node is connected with three nodes. If any node failure causes the neighbor nodes will help to retrieve the data of that failed node by using redundant information. Data storage in  $D_i$  and  $P_i$  and recovery is represented in Fig. 2 topology. Here defining the following relations for nodes with their corresponding neighbors,

$$P_1 = D_1 \oplus D_2 \oplus D_3 \oplus D_5 \quad (1)$$

$$P_2 = D_1 \oplus D_4 \oplus D_3 \oplus D_2 \quad (2)$$

$$P_3 = D_1 \oplus D_4 \oplus D_5 \oplus D_3 \quad (3)$$

$$P_4 = D_2 \oplus D_3 \oplus D_5 \oplus D_4 \quad (4)$$

$$P_5 = D_1 \oplus D_4 \oplus D_3 \oplus D_5 \quad (5)$$

By using the above equations 1 to 5, the pi will store the information in cluster 1, similarly, all the clusters in the network the parity unit will update based on the DNN of the particular node in the network. Di unit will update the sensing data into it.

Using parity can easily rebuild the lost data inputs by conducting XOR of all the remaining values and former output values. Assume that node2 fails the data recovery of the node2

Fig. 2. Representation of Cluster1 Data Storing and Communication Process.

TABLE II. DATA RECOVERY PATTERNS OF CLUSTER1 FOR ROUND1 AND ROUND2

| Cluster1          |          |                |                            |                                             |
|-------------------|----------|----------------|----------------------------|---------------------------------------------|
| Transmission Data | Parity   | Receiving Data | Faulty Data Identification | Data Recovery                               |
| D1 = 100          | P1 = 111 | 100            | ACK                        | No error                                    |
| D2 = 101          | P2 = 101 | 111            | NACK                       | error occurred, Recovery initiated, D2= 101 |
| D3 = 111          | P3 = 001 | 111            | ACK                        | No error                                    |
| D4 = 011          | P4 = 000 | 011            | ACK                        | No error                                    |
| D5 = 001          | P5 = 001 | 001            | ACK                        | No error                                    |
| D1 = 101          | P1 = 100 | 101            | ACK                        | No error                                    |
| D2 = 101          | P2 = 011 | 101            | ACK                        | No error                                    |
| D3 = 111          | P3 = 101 | 111            | ACK                        | No error                                    |
| D4 = 100          | P4 = 101 | 100            | ACK                        | No error                                    |
| D5 = 011          | P5 = 101 | 001            | NACK                       | error occurred, Recovery initiated, D5= 011 |

will get with the help of redundant information stored and its corresponding neighbors, Identified that if D2 and D5 at round1 and round2 instances then data recovery has been done with the help of all DNN and parity of the failed node in that cluster which is represented in Table II. Hence the data is proved that fault recovery has been made using a DRAFT algorithm. IoT network is grouped with 'n' no. of clusters, each cluster consists of  $n \geq 5$  nodes. Each node has four states they are normal state, degraded state, recovery state, and failed state. The reliability of the network and MTTDL of the node has been derived with the help of the following state diagram Fig. 3.

Let us consider the nonzero time of node replacement, the failure rate of a node is normal in degraded and rebuild states.  $S_0$  is the normal state, in this state all the nodes in the cluster are operable and data in every node is available. From this state, the node can pass to state  $S_1$  with the rate of  $k_0$  (Failure of any node).

$S_1$  is a degraded state, in this state one of the nodes in the cluster has been failed and waiting for a replacement and the remaining k-1 nodes are operable and data can be available. From this state, the node can move to either state F with the failure rate  $(k-1)\lambda_0$  (failure of another operable node) or  $S_2$  with the repair rate of  $D$ .

$S_2$  is the recovery state, in this state the failed node is replaced and the recovery process has been started, the remaining k-1

Fig. 3. Reliability State Graph Model for An IoT Cluster.

nodes are operable and data is available. From this state, the node can move to either state0 with the rate of  $\alpha_1$  (successfully data recovery completed) or to  $S_1$  with the failure rate  $\lambda_2$  (failure of the node during the data recovery process) or to  $S_F$  with the rate of  $(k-1)\lambda_1$  (failure of one of the operable nodes) or with the rate of  $(k-1)\beta_1$  (read error on one of the operable nodes during data recovery process).  $S_F$  is the failed state data of the node that are non-recoverable and unavailable. Let us present the state diagram based on the above transitions.

Where as

- $\lambda_0$  is the failure rate of the node in a cluster.
- $\lambda_1$  is the failure rate of the node in case of data unavailability of the node which is operable.
- $\lambda_2$  is the failure rate of the replaced node during the data recovery.
- $\mu_D$  repair rate of the faulty node.
- $\alpha_1$  is the success rate of data recovery.
- $\beta_1$  rate of reading errors on the operable nodes during the data recovery.

The above state diagram is solved with the help of Kolmogorov-Chapman differential equations which are analyzed as follows:

Initially the probabilities of state  $S_0$  is  $P(S_0(t)) = 1$ , the remaining states probability which is equals to zero, hence  $P(S_1(t)) = P(S_2(t)) = P(S_F(t)) = 0$ .

$$P(S_0(t)) + P(S_1(t)) + P(S_2(t)) + P(S_F(t)) = 1 \quad (6)$$

$$\frac{\partial P(S_0(t))}{\partial t} = -k\lambda_0 P(S_0(t)) + \alpha_1 P(S_2(t)) \quad (7)$$

$$\frac{\partial P(S_1(t))}{\partial t} = k\lambda_0 P(S_0(t)) - (\mu_D + (k-1)\lambda_1) P(S_1(t)) + \lambda_2 P(S_2(t)) \quad (8)$$

$$\frac{\partial P(S_2(t))}{\partial t} = \mu_D P(S_1(t)) - (\alpha_1 + \lambda_2 + (k-1)(\lambda_1 + \beta_1)) P(S_2(t)) \quad (9)$$

$$\frac{\partial P(S_F(t))}{\partial t} = (k-1)\lambda_1 P(S_1(t)) + (k-1)(\lambda_1 + \beta_1) P(S_2(t)) \quad (10)$$

The reliability shows that only from state 0-2, the cluster will be in operational mode, and the data is also available. To derive the formula for mean time to data loss (MTTDL) for the cluster, considering the cluster will be staying at state0 – state2 and taking into that initial state of the cluster is state0 for calculating the MTTDL as follows:

$$MTTDL = \int_0^{\infty} P(S_0(t)) + P(S_1(t)) + P(S_2(t)) dt \quad (11)$$

By substituting the above values 7,8,9 and 10 in 11 we get,

$$MTTDL = \frac{H(x)}{V(x)} \quad (12)$$

Where as

$$H(x) = (\mu_D + k\lambda_0 + (k-1)\lambda_1)(\alpha_1 + (k-1)\beta_1) + (k\lambda_0 + (k-1)\lambda_1)(\mu_D + \lambda_2 + (k-1)\lambda_1)$$

$$V(x) = (k\lambda_0(k-1)\lambda_1(\alpha_1 + \lambda_2 + (\mu_D(k-1)\lambda_1)(k-1)(\lambda_1 + \beta_1)))$$

If the faulty node replacement rate  $\mu_D \rightarrow \infty$  then the simplified formula for MTTDL is

$$MTTDL = \frac{\alpha_1 + k\lambda_0 + (k-1)(\lambda_1 + \beta_1)}{k\lambda_0(k-1)(\lambda_1 + \beta_1)} \quad (13)$$

If the faulty node replacement rate  $\mu_D \rightarrow 0$  then the simplified formula is

$$MTTDL = \frac{1}{k\lambda_0} + \frac{1}{(k-1)\lambda_1} \quad (15)$$

Meantime to data loss occurs on the unavailability of data and failure of node capacity. MTTDL is decreasing when the node failure rate in the network has been increased.

#### IV. PERFORMANCE EVALUATION FOR DRAFT ALGORITHM

This section presents the simulation setup, performance metrics, comparison of performance analysis with and without the DRAFT algorithm incorporated into the network.

##### A. Simulation Setup

The proposed DRAFT algorithm has been executed in CUPCARBON. The simulation setup consists of 150 sensor nodes with 27 clusters and is randomly deployed in a 200 X 200m square region. Assuming that all sensor nodes are to be homogeneous resources and characteristics. Each node data size is 100 to 2000 units and generates the data items periodically. Every node in the cluster maintains a DNN attribute table which holds MAC address, neighbors list, node id and the storage space of each node learned through continuous resource management messages broadcast by every 10s. Each round simulation time is set to be 600s. Fault-tolerant system parameters are listed in the following Table III.

TABLE III. FAULT-TOLERANT SYSTEM PARAMETERS

| Fault-tolerant system parameters |                   |
|----------------------------------|-------------------|
| No. of Nodes                     | 100-150 Nodes     |

B. Performance Metrics

The impact of the DRAFT algorithm on an IoT network is analyzed through the following performance metrics.

1) *Network Lifetime*: In the simulation, the average Network lifetime of the IoT network with and without the DRAFT algorithm has been evaluated. This algorithm recovers the data when node failure occurs in the network. Considering ‘p’ is the probability of node failure that a node fails in one round. Assuming that the probability of a node failure for each round should vary from 0.1% to 0.5% as an increment. The total no. of deployed nodes in a cluster is ‘Ni’ and the communication range is ‘X’. For without recovery scheme, in around at least a single node failure probability is  $P_f$  and is  $1 - (1 - p)^{Nd}$  (Bernoulli’s trails) whereas Nd is the network density and considering as a standard value. In the case of with recovery scheme, ‘R’ is the recovery candidate, and there are two requirements to recover the data, first, the recovery candidate must be alive and the second is all of its direct neighbors should be alive. The probability of R is  $P_v = (1 - p)^{Nd}$  whereas  $P_v$  is the probability of a recovery candidate. The

Fig. 4. Analysis of Network Lifetime with Respect to Node Failure Probability.

network lifetime of the proposed recovery scheme is more as compared to the without DRAFT algorithm as clearly shown in Fig. 4. When the probability of node failure is increased automatically the network lifetime is dropped for both with and without recovery scheme.

2) *Throughput*: Throughput is defined as the amount of data transmitted successfully from one node to another node in the network within a period. When the probability of the node failure decreases then the throughput of the network increases gradually as shown in Fig. 5. If there is a node failure occurs the data has been transmitted successfully because of the DRAFT algorithm. The throughput has improved double times with the recovery scheme as compared to the without recovery scheme.

Fig. 5. Throughput with Respect to Probability Node Failure.

3) *MTTDL*: Meantime to data loss is the average time that causes data loss in the node. Data loss is occurred due to error situations in the networks. Backup and data recovery methods are helping to recover data or to avoid data loss in the IoT networks. If failure of any node in the cluster,

Fig. 6. Simulation Result of Mean Time to Data Loss.

MTTDL is decreased by increasing the recovery rate of the data. This will help to improve the network reliability and data availability in the network. The simulation results in Fig. 7 show the best recovery rate when the DRAFT algorithm has been incorporated into the network.

4) *Reliability*: Reliability is the capacity of the network to work during the presence of node failures concerning time. Here the time considering as the normalized time which means scaling the time within the range of 0 to 1. For an IoT network

Fig. 7. Observations for Data Reliability in IoT Network.

at t = 0, the reliability is approximately high, with respect to time the network reliability is gradually decreasing which is shown in Fig. 6. The reliability mainly depends on the failure rate and repair rate of the node, and data recovery of the node.

## V. CONCLUSION AND FUTURE WORK

The proposed DRAFT algorithm is most suitable for IoT-based safety and critical applications. It is implemented with the concept of the RAID5 storage mechanism used for soft computing. Hence, this scheme can be easily incorporated with other IoT algorithms. By conducting a series of experiments the data reliability achieved as 85%. The throughput and network lifetime of the proposed algorithm are enhanced 5% as compared with the existing algorithms. The complete data recovery simulation is carried out which ensures reliable data transmission. In real scenario the data can be dropped due to noise, environmental factors, and data collisions. This paper presented analysis and simulation of simultaneous single IoT node failure in a cluster for the mentioned scenarios. This algorithm can be carry forward for the future multi-node data failures and data transmission reliability.

# An Enhanced Traffic Split Routing Heuristic for Layer 2 and Layer 1 Services

Ahlem Harchay, Abdelwahed Berguiga, Ayman Massaoudi  
Department of Computer Science  
Jouf University, Sakakah  
Saudi Arabia

**Abstract**—Virtual Private Networks (VPNs) have now taken an important place in computer and communication networks. A virtual private network is the extension of a private network that encompasses links through shared or public networks, such as the Internet. A VPN is a transmission network service for businesses with two or more remote locations. It offers a range of access speeds and options depending on the needs of each site. This service supports voice, data and video and is fully managed by the service provider, including routing equipment installed at the customer's premises. According to its characteristics, VPN has widely deployed on "COVID-19" offering extensive services to connect roaming employees to their corporate networks and have access to all the company information and applications. Hence, VPN focuses on two important issues such as security and Quality-of-Service. This latter has a direct relationship with network performance such as delay, bandwidth, throughput, and jitter. Traditionally, Internet Service Providers (ISPs) accommodate static point-to-point resource demand, named, Layer 1 VPN (L1VPN). The primary disadvantage of L1VPN is that the data plane connectivity does not guarantee control plane connectivity. Layer 2 VPN is designed to provide end-to-end layer 2 connection by transporting layer 2 frames between distributed sites. An L2VPN is suitable for supporting heterogeneous higher-level protocols. In this paper we propose an enhanced routing protocol based on Traffic Split Routing (TSR) and Shortest Path Routing (SPR) algorithms. Simulation results show that our proposed scheme outperforms the Shortest Path Routing (SPR) in term of network resources. Indeed, 72% of network links are used by the Enhanced Traffic Split Routing compared to Shortest Path Routing (SPR) which only used 44% of the network links.

**Keywords**—Virtual private network; enhanced traffic split routing; quality of service; shortest path routing; layer 1 VPN; layer 2 VPN

## I. INTRODUCTION

Computing, and networks in particular, have changed a lot over the past twenty years. The flow of information and the emergence of new technologies have increased considerably [1]. It is now possible to exchange substantial data of all types as well as to transmit voice and video over computer networks [2].

Indeed, with a modern economy based on new information and communication technologies, most companies use a set of means for the implementation of a reliable and flexible computer network [3]. This network allows corporate users to share resources such as printers, files and data. As a result, the need for remote connection to corporate resources has become common. Remote applications thus become the main tool of

the company's information system. The question that may arise then is how to ensure access within a structure sometimes spread over large geographical distances? In concrete terms, how can a branch of a company access data located on a server in the headquarters several thousand kilometers away?

Virtual private networks (VPNs) have been set up to respond to this type of problem and takes an important place in computer and communication networks. As pointed out by [4], a VPN is the extension of a private network that encompasses links through shared or public networks, such as the Internet.

It offers a range of access speeds and options depending on the needs of each site. This service supports voice, data and video and is fully managed by the service provider, including routing equipment installed at the customer's premises [5]. Indeed, the damaged caused by "COVID-19" on global economy leads company networks on looking for VPN solutions to establish a private communication to the corporate intranet while traveling from home.

Both service providers and customers are starting to realize the benefits of VPN solutions. New applications such as voice, telemedicine and video on demand make it possible to envisage an increase in productivity and a reduction in costs. However, VPNs are not only interested in extending LANs at a lower cost, but also in the use of specific services or functions ensuring quality of service (QoS) and security of exchanges [6] [7]. Indeed, the notion of quality of service makes it possible to formalize the requirements for each type of service in terms of performance criteria: bandwidth, end-to-end transmission delay, packet loss rate, jitter, etc. Each service may have different quality requirements.

Services such as voice or video impose very strong constraints on the quality of transmission: transmission delays or data loss must not degrade communication or the broadcasting of a video stream. In order to support real-time and multimedia applications on virtual private networks, it is necessary to develop routing algorithms which take QoS parameters into account. Routing algorithms with QoS must be adaptive and flexible for efficient management of resources in the network [8]. In practice, routing with QoS has not worked well.

The objective of routing is to determine a route (i.e. a set of links to be traversed), respecting certain constraints, to establish a connection from a source node to a destination node. The purpose of a routing algorithm is to allow the calculation of the route between those two nodes within the meaning of a certain criterion?

The remainder of the paper is organized as follows. The next section will focused on different algorithms such as Waxman and Brite algorithms. Section 3 highlights the approach proposed in this work. Then, an analysis of the performance of our prototype system implemented using simulation model will be described in Section 4. In Section 5, numerical results are presented to show the effectiveness of the proposed algorithm. Lastly, the conclusion and future work are outlined in Section 6.

## II. LITERATURE REVIEW

VPNs allow remote users, partners and providers to access certain parts of their networks (intranets). They also allow the deployment of many types of applications such as real-time voice or video, critical business management software or interactive applications [9] [10]. Originally, companies using VPN solutions used "layer 1" services such as "leased lines" (and referred to as layer 1 VPN, L1VPN). Leased lines are dedicated connections that a telecom operator operates directly between two customer sites, providing a permanent connection at a determined speed. Although leased lines offer users the confidentiality and reliability of transferred data, they suffer from a lack of flexibility compared to other types of layer 2 solutions such as Frame Relay, ATM, L2TP, L2F or also more recently Carrier/Metro Ethernet.

However, as mentioned in [11] [12], this type of VPN is characterized by its prolificity in singular domain and the lack the Quality of Service (QoS) during the inter-domain routing which lead to inhibit its scalability and flexibility. Another issue with L1VPN is the inter-configuration of a customer on another Service provider network as the policies are distinctives. This can be solved using the address mapping mechanism, unfortunately , this latter is not well-defined in standard specifications [13].

In fact, "layer 2" VPN services (or also layer 2 VPN, L2VPN) have allowed service providers to offer their customers a connection similar to that offered by leased lines. On the other hand, with L2VPN it is no longer necessary to have a dedicated leased line for each network interconnection. The clients share a single physical line and each has its own logical channels to send its traffic [14]. Layer 2 VPN services are attractive to the service operator because they do not require the operator to participate in the design and configuration of layers 2/3 of the customers' LAN. Also, the management and maintenance of the control plan are carried out by the customer and they are transparent to the operator's network [15] [16].

The major problem with L2VPN is security. Unlike L1VPN where each customer has their own private line, a layer 2 VPN is deployed on a shared network infrastructure that can be managed by national and international network service providers. As a result, several companies disagree that their data should be transferred through shared, unsecured tunnels [17]. One solution would be to offer a layer 3 or L3VPN VPN service. Security is usually provided by a combination of tunneling and encryption methods. The best known is the one that implements the IPSec (IP Security) protocol. IPSec is a "layer 3" security protocol. It is based on the IP protocol and offers tunneling and security features, including encryption, authentication and key management [18]. In this

work, a random generator graph named "Brite" is used [19]. The BRITE topology generator assigns each link with a delay based on its physical distance. The algorithm can be described as follows [20]:

- Firstly, we specify the number of nodes on the networks.
- For a link creation between two nodes  $u$  and  $v$  we define the probability  $P(u, v)$  :

$$P(u, v) = \beta \exp \frac{-d(u, v)}{L\alpha} \quad (1)$$

Where,

- $d(u, v)$ : the distance separating from node  $u$  to node  $v$ ;
- $L$ : the maximum distance between node  $u$  and node  $v$ ;
- $\alpha$  and  $\beta$ : These two constant parameters are defined in the interval (0.1).

When the constant  $\alpha$  is decreased, we noticed that the link's density on the network is increased. Based on the link probability  $(u, v)$  a link is added or not between  $u$  and  $v$ . In a shortest path tree problem, we consider a directed graph  $G = (V, E)$ , where  $V$  represents the set of nodes and  $E$  the set of links. Each edge has a weight  $P_i$ . A path  $C = \langle e_1, e_2, \dots, e_n \rangle$  has a weight which represents the sum of the weights of the edges constituting the path. The shortest path from a vertex  $d$  to a vertex  $a$  is the minimum weight path that connects  $d$  to  $a$  [21].

The two algorithms Bellman-Ford and Dijkstra described in [22] are two well known shortest path algorithms. Shacham [23] proposed a maximum bandwidth tree algorithm to distribute data hierarchically. It uses an algorithm close to Dijkstra to calculate the maximum bandwidth of a single path to all destinations.

The principle of this algorithm is as follows:

- 1) Determine the maximum bandwidth paths available between the different nodes.
- 2) Sort the receivers according to their reception capacities.
- 3) Add recipients to the maximum bandwidth tree one by one.

This hierarchical distribution approach gives for each individual receiver the rate at which it will receive data from the source. The bandwidth will then be allocated appropriately.

## III. PROPOSED ALGORITHM

As aforementioned, there are many issues on deploying Dijkstra and Bellman-Ford for routing protocols using two or more constraints. Dijkstra as well Bellman-ford are deployed where we using one constraint and offer good paths. However, when we need the formation of a balanced system when distributing the load this is not guarantee by Dijkstra and Bellman-ford which use an order of priority in the constraint's choice.

Our proposed scheme, named Enhanced Traffic Split Routing (E-TSR), is based on algorithm Traffic Split Routing (TSR) [24] [25] which offer a good objective on load balancing inside a network. Enhanced Traffic Split Routing try to distribute homogeneously the traffic on the network and offer a balanced sharing of traffic. Indeed, with E-TSR, the maximum possible of links are used to balance the traffic on the network.

We present in what follows, *algorithm 1*, the heuristic of traffic distribution used which is an enhanced algorithm based on [24] [25]. To begin, it is interesting to note that is not always optimal to use the shortest path between a pair of nodes "i" and "j". Accordingly, we will use a model of an M/M/1 queue. Suppose that between two nodes "i" and "j" we have two paths: the shortest path of length "n" and another longer path of length  $m > n$ .

To begin with, we assume that we have a first path calculated by the shortest path algorithm. This path links a source "i" to a destination "j" and uses "n" links. We assume that each link in the path from "i" to "j" is modeled by an independent M/M/1 queue (*Kleinrock independence assumption*) as illustrated on Fig. 1.

Now suppose that the traffic is shared between the path with "n" hops and that of "m" hops. Consider the following variables:

$\rho$ : use of the link,  
when all the traffic is offered to the first path only (the shortest path) we have the average residence time on a link:

$$T = \frac{1}{\mu - \lambda} \quad (2)$$

Therefore, the use of the link

$$\rho = \frac{\lambda}{\mu} \quad (3)$$

Since this path is composed of "n" independent links, the average residence time in the path is modeled by the following formula:

$$T_1 = n \times T = \frac{n}{\mu - \lambda} \quad (4)$$

Fig. 1. Shorter Path Versus Sharing of Traffic Through Disjointed Paths.

If we share the traffic between the two paths; the first made up of "n" hops and the second of "m" hops, we have the variables:

- $\lambda_1$ : the arrival rate for path 1

- $\lambda_2$ : the arrival rate for path 2

So, the average residence time across the two paths is:

$$T_2 = \frac{\lambda_1}{\lambda} \frac{n}{\mu - \lambda_1} + \frac{\lambda_2}{\lambda} \frac{n}{\mu - \lambda_2} \quad (5)$$

If we find cases where  $T_1 < T_2$  then we can state that the shortest path does not give precisely the best delay. We can say that:

$$T_1 \leq T_2 \Leftrightarrow \frac{\rho_1}{1 - \rho_1} + \frac{m}{n} \frac{\rho_2}{1 - \rho_2} \leq \frac{\rho}{1 - \rho} \quad (6)$$

Where,

$$\rho_1 = \frac{\lambda_1}{\mu} \quad (7)$$

$$\rho_2 = \frac{\lambda_2}{\mu} \quad (8)$$

$$\rho \geq \rho_1 \quad (9)$$

$$\rho \geq \rho_2 \quad (10)$$

$$\rho = \rho_1 + \rho_2 \quad (11)$$

In the case where  $m < n$ , then the inequality 6 gives us:

$$m \leq \frac{n(1 - \rho_2)}{(1 - \rho_1)(1 - \rho)} \quad (12)$$

The inequality 12 shows that the number of hops in the path should be small and not greater than a certain constant. Additionally, this inequality clarifies that when the shorter path is overloaded (maximum link utilization), using another longer path to route traffic can be useful in order to reduce the wait time. Moreover, we can deduce that the number of hops in the longest path decreases when the load offered to this path ( $\rho_2$ ) increases. In particular, in the case where the traffic is distributed between the shortest path and the longest one ( $\rho_1 = \rho_2$ ), it suffices to have  $m < n/((1 - \rho))$  to reduce the waiting time by traffic distribution. For example, if  $\rho = 80\%$ , then we must have  $m < 5n$ . That is, the number of hops in the longest path should not exceed 5 times the number of hops in the shortest path.

#### IV. RESULT AND DISCUSSION

This section is devoted to evaluating the performance and quality of services resulting from the Enhanced Traffic Split Routing (E-TSR) algorithm by comparing the results with those obtained with Traffic Split Routing (TSR) [25] and the Shortest Path Routing (SPR). In order to be able to evaluate these three algorithms, various simulations were carried out using the NS-2 simulation platform [26].

To begin, we attempt to give an overview of different parameters related to evaluate the performance of our proposed scheme. Then, we will present more closely the NS-2 tool as

**Algorithm 1** Enhanced Traffic distribution heuristic

**Input** :  $L_s$  the number of times a link  $S$  appears in a VPN tree

- 1: **procedure** HEURISTIC PROCEDURE
- 2:      $L_s \leftarrow 0$  :Definition of a link Variable
- 3:      $n \leftarrow 0$  :Definition of the number of nodes on the network
- 4:     *loop*: waiting for a new Virtual Private Network connection demand from any network's node
- 5:     Complete (or Generate) a path (tree) coupling all the new Virtual Private Network and avoiding links whose  $L_s > n$
- 6:     **if** path is icomplete **then**
- 7:          $n \leftarrow n + 1$  and **goto** step 5
- 8:     **else**
- 9:          $L_s \leftarrow L_s \log(L_s) + 1$  for all the links of the new generated tree and **goto** step 3.
- 10:    **end if**
- 11: **end procedure**

well as the network model used to perform different scenarios to be simulated under NS-2.

The rest of this section will highlights the QoS parameters used to evaluate the three heuristics: the enhanced traffic distribution (TSR, Traffic Split Routing), the traffic distribution (TSR, Traffic Split Routing), and the shortest path (SPR, Shortest Path Routing). All the simulation parameters are given in Table I. Our simulations are performed using the

TABLE I. SIMULATION PARAMETERS

| Parameters                               | Values       |
|------------------------------------------|--------------|
| Simulator name                           | NS-2         |
| Node's number                            | 24 nodes     |
| Tree's link capacity                     | 100 Mb/s     |
| Transmission delay                       | 10 ms        |
| Source's number of the generic tree      | 4-24 nodes   |
| Simulation Time                          | 2000 seconds |
| Application type used on the simulations | FTP          |
| Packet size                              | 1 KB         |

NS-2 network simulator. For accuracy and compliance, all simulations are performed Twenty times for each scenario. All simulations are performed to study the behavior of the three routing algorithms; E-TSR, TSR, and SPR. All simulations are generated with different random number seeds and the results are averaged over all the outcomes. Fig. 2, Fig. 3, and Fig. 4 illustrate an example of network scenario used in performance study for the three heuristics E-TSR, TSR, and SPR.

Fig. 4 illustrates the scenario using Shortest Path traffic algorithm. From this figure, we suppose that the traffic is sent from node 2 to the destination node 4. We see that the node named 6 used as a Steiner node and all traffic is focused on the shortest path (from node 2 to node 6, and from node 6 to node 4). On the other hand, Fig. 2 illustrates the scenario of the Enhanced Traffic Split Routing. From this Figure we can see that the traffic is shared equitably between different paths. Indeed, the traffic sent from node 2 and has as destination node 4 has taking different paths (from node 2 to node 6, from node 2 to node 7, etc.). with this approach, we can see that we use maximum links on the network.

*A. Average Reception Data Rate*

Fig. 5 illustrates the average data rate reception of the three algorithms, E-TSR, TSR and SPR. As we can see, the Fig. 5 shows the average data rate as a function of the number

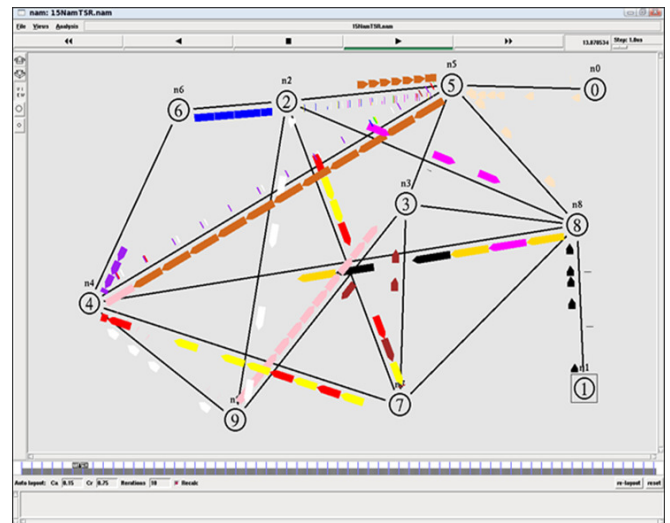

Fig. 2. Enhanced TSR Traffic.

Fig. 3. TSR Traffic.

of source VPNs. Indeed, in the case of 6 source VPNs we have 5.9 Mbps with E-TSR heuristic, 5.58 Mbps with TSR heuristic while the average throughput with SPR is 5.23 Mbps.

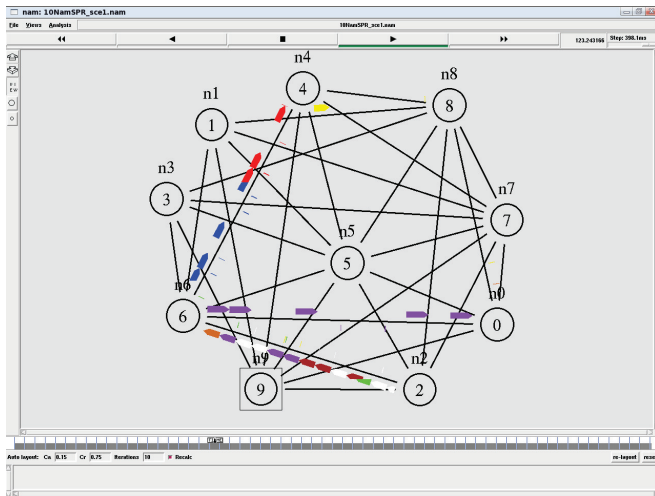

Fig. 4. SPR Traffic.

subsequently, with 16 source VPNs, the average throughput with E-TSR is equal to 5.35 Mbps while it is equal to 3.93 Mbps with SPR algorithm. We see also that the gap on the average data rate increase with the number of source VPNs and the E-TSR algorithm offer good throughput compared to TSR and SPR algorithms. This is due to algorithm properties. Indeed, with SPR, all the traffic is focused on the shortest path while with E-TSR the traffic is divided between the maximum number of links on the network. Moreover, the use of maximum links allowed networks to offer a higher throughput especially for networks with large traffic, unlike to shortest path algorithm which focused only on some links (shortest link) which lead to some links to become overloaded, leaving others unused. This had an influence on the flow and then on the error rate.

Fig. 5. Average Data Rate Reception.

### B. Packet Loss Rate

Fig. 6 illustrates the packet loss rate as a function of number of source VPNs for each routing technique E-TSR, TSR and SPR. As shown in this figure, with low number of source VPNs average error rate with E-TSR and TSR become more frequent due to the fact that the routing techniques must search new link every time there is a new source VPN. It can be noticed that when the number of VPN sources increases

to 12 sources, SPR and E-TSR have almost the average error rate,  $9.6 \times 10^{-4}$  and  $11.5 \times 10^{-4}$ , respectively.

This rate increases to reach  $43 \times 10^{-4}$  packets loss with SPR routing technique,  $30 \times 10^{-4}$  packets lost with TSR routing technique, and  $27 \times 10^{-4}$  packets lost with E-TSR routing heuristic for 24 source VPNs.

Furthermore, as the number of source VPNs increase, the gap between SPR, TSR, and E-TSR increases and as we can see E-TSR provides less packet error rate. Indeed, with a shortest path routing technique all the traffic takes the same path which lead to a huge traffic on some links and then more error rate. However, with distributed traffic routing technique the traffic flow is sent over the network moderately over all links.

Furthermore, using a traffic distributed technique, packet have low chance to enter on overloaded queues, thus dropping packets will minimized and rejecting packets will be decreased. On the other site, with shortest path routing technique, there is a high probability the traffic takes the same path leading to a queue overload and then increase rejected packets.

Fig. 6. Average Packet Loss Rate.

### C. Average End-to-end Delay

In this section we examine the mean delay to send a packet from one source to a destination. This delay is given according to the number of source VPNs on the network. Fig. 7 shows that the delay of three heuristics E-TSR, TSR, and SPR increases linearly with the number of source VPNs.

Moreover, Enhanced Traffic Split Routing algorithm exhibit a brief variation on delay compared to the Shortest Path Routing Algorithm. From Fig. 7 we remark that SPR has a delay around of 30 ms with 6 source VPNs. By increasing the number of source VPNs we see that E-TSR offer less end-to-end delay compared to TSR and SPR. In fact, E-TSR and TSR look increase on logarithmic fashion compared to SPR.

It is clear to see that in the case of 16 source VPNs the average end-to-end delay is equal to 25.32 ms for E-TSR algorithm whereas it is equal to 27 ms for TSR algorithm, and 39 ms for SPR algorithm. Table II gives an overview of the measured values related to the mean delay for three routing algorithms. The gap on the end-to-end delay increases as number of source VPN increase. Our observations, for instances imply that when the network deploy a traffic distributed technique offer more chance of using a less queue memory which means packets

TABLE II. GAP MEAN DELAY

| # VPNS | Mean delay SPR (ms) | Mean delay TSR (ms) | Mean delay E-TSR (ms) |
|--------|---------------------|---------------------|-----------------------|
| 4      | 24                  | 25                  | 23                    |
| 6      | 30                  | 26                  | 23.56                 |
| 8      | 34                  | 26                  | 23.58                 |
| 10     | 36                  | 26                  | 23.99                 |
| 12     | 37                  | 26                  | 24                    |
| 14     | 39                  | 26                  | 24.12                 |
| 16     | 39                  | 27                  | 25.32                 |
| 18     | 40                  | 27                  | 25.64                 |
| 20     | 40                  | 27                  | 25.87                 |
| 22     | 41                  | 27                  | 25.9                  |
| 24     | 41                  | 28                  | 26                    |

sent on different links have more chance of going through small queues and therefore a small delay variation as shown on Fig. 8.

Fig. 7. Mean Delay.

Fig. 8. Flow of Sent Data.

## V. CONCLUSION AND FUTURE WORK

In this paper, we proposed an enhanced traffic split routing algorithm. Such algorithm is compared with shortest path algorithm. Simulations were performed using NS-2 to analyze the functionality and performance of the proposed algorithm in terms of average data rate, packet loss rate, and average end-to-end delay.

The results show that Enhanced Traffic Splitting Routing algorithm provides least values on packet loss rate and average end-to-end delay compared to Shortest Path Routing and legacy Traffic Splitting Routing algorithm.

Also, simulation results show that TSR provides better performance in term of average data rate. So, it is concluded that enhanced traffic split routing algorithm has the capability

to provide better low packet loss rate and data rate by using 72% of network links compared to shortest path routing algorithm which uses only 44% of network links.

As a future work, we plan to design and implement the proposal experimentally in order to study these factors practically and exploring the potential of utilizing enhanced traffic split routing on real-time multimedia and VoIP applications.

**Abstract**—Nowadays, connected devices are growing exponentially; their produced data traffic has increased unprecedentedly. Information systems security and cybersecurity are critical because data typically contain sensitive personal information, requiring high data protection. An authentication system manages and controls access to this data allowing the system to ensure the legitimacy of the access request. Most of the current identification and authentication systems are based on a centralized architecture. However, some concepts as Cloud computing and Blockchain use respectively distributed and decentralized architectures. Users without a central server will own platforms and applications of the next generation of Internet and Web3. This paper proposes AuSDiDe, a new authentication system for the distributed and decentralized structure. This solution aims to divide and share keys toward different and distributed nodes. The main objective of AuSDiDe is to securely store and manage passwords, private keys, and authentication based on the Shamir secret sharing algorithm. This new proposal significantly reinforces data protection in information security.

**Keywords**—Shamir's secret sharing; authentication system; decentralized; distributed; blockchain

## I. INTRODUCTION

Currently, the number of connected machines is growing exponentially. This is explained by several factors such as the use of social networks, streaming and sharing videos, online services (payment, purchases, etc.), connected objects, cryptocurrency [1].

The world has never been digitized as it is today. Digitization of different services, the use of cryptocurrency, IoT, etc. Moreover, the Covid-19 pandemic has given a boost to digitization, paving the way for new opportunities for growth, competitiveness and inclusion. The global data traffic has increased at an unprecedented rate over the last decade. There are various challenges and issues associated with this data.

Among these challenges, security and privacy have been considered as important issues since data often involves different types of sensitive personal information, e.g., addresses, personal preference, banking details, governmental data, financial, medical, military, or NFT's - Non-fungible token. Putting the data on the Net and on the Cloud [2] makes them vulnerable. This requires more vigilance from the administrators and owner of this data. To put more reliable and secure means to protect and secure the data against malicious people

and botnets. It is necessary to choose the security criteria to be taken into account. Commonly used security criteria are availability, integrity, and confidentiality, but it may be relevant to add others such as proof, control, anonymity, reliability. The scale of needs will be determined according to these security criteria. Information systems security and cybersecurity ensure data protection. An authentication system manages and controls access to this data [3]. Fig. 1, 2, and 3 show a centralized, decentralized, and distributed organizational structure.

Fig. 1. Centralized Organizational Structure.

In Fig. 1, server systems with one or more slave nodes directly linked to a central server are centralized systems. In many companies, this is the most frequent sort of system.

In Fig. 2, every node in a decentralized system makes its own choice. The sum of the individual node choices determines the system's ultimate behavior. It is worth noting that the request is not received and responded to by a single organization structure.

A distributed system shown in Fig. 3 comprises a group of loosely coupled processors that are linked together via a communication network. A distributed system may consist of computational and diverse nodes connected by a communication network. Any node's total resources should be visible and freely available to other nodes. The choice of a load sharing or global planning technique is an important aspect of a distributed system's design configuration.

The advantage of the proposed approach, on the contrary

Fig. 2. Decentralized Organizational Structure.

Fig. 3. Distributed Organizational Structure.

to most traditional secret sharing schemes, is that the shares are distributed and decentralized. This study presents a novel authentication scheme for the distributed (Fig. 3) and decentralized (Fig. 2) structure. This method aims to split and share keys across several remote nodes.

Most of the current identification and authentication systems are based on centralized architecture [4], today it is necessary to think about new methods and structures in order to strengthen the authentication and to be compatible with the new architectures.

There are some concepts like Cloud computing [5] and Blockchain [6] use respectively distributed and decentralized architectures [7] as shown in Fig. 2 and 3. For example, in the next generation Internet, the platforms and applications built on the Web3 will be owned by users, without a central server [8]. In order to remedy these limitations and security concerns, this paper presents a new approach, focused on the authentication systems, key and password management.

In Docker, integrity comes from trust, i.e. the user decides to retrieve a Docker image from the Docker hub, which is a set of community images. Docker security relates to threats and attacks that challenge security based on confidentiality, integrity, and availability of services. The application system must function flawlessly during the expected use ranges and guarantee access to the services and resources installed with

the expected response time. Basic Docker provides functionality to have high availability, Docker Swarm, an orchestrator that allows you to manage your cluster of containers. Indeed, the security of the information system is considered one of the primary issues to be established. Each organization must define a security policy to succumb to its needs and protect these resources and their trade secrets.

In order to increase the level of security [9], a new authentication mechanism is introduced. This authentication mechanism for distributed and decentralized structures is based on Shamir's secret sharing.

Hadoop is a big data processing paradigm that can efficiently address the issues of big data because of its distributed storage and parallel processing properties, as well as other benefits such as open source. The proposal is considered as the last method to guarantee the robustness of any key management system is to divide the keys into various bits, as recommended in the Split Keys approach. In this approach, no one individual has access to the real key; instead, the key must be used by a group of people. The system suggested in this paper splits and distributes keys to distinct and scattered nodes in all clusters.

AuSDiDe a new proposed architecture to securely manage passwords, private key and authentication. Shamir's algorithm is used to share secret information

The main purpose of this system is to split the secret key into parts, giving each server its own shared key, where some or all of the parts are needed in order to rebuild a passphrase that gives access to the secret.

The remainder of the paper is laid out as follows. First a review of the related work realized in this topic is presented. Then a presentation of the architecture of an authentication system. After the implementation results are displayed. The conclusions and future work are presented in the last Section.

## II. RELATED WORK

Nowadays, there are many proposals for securing and managing authentication systems. The proposed system reinforces security, prevents certain attacks such as man in the middle, identity theft, and adapts to new distributed and decentralized architectures.

To improve the security of keys used for encryption, [10] proposes a threshold secret sharing system employing Newton division difference interpolating polynomial in a distributed Cloud context.

The study [11] proposes a system that employs secure multiparty computation (SMPC) protocols with Shamir secret sharing for password- and iris-based authentication.

Hashing may not be able to hide data as effective in post quantum era [12], an authentication protocol which will use Shamir's secret sharing method to authenticate with server is proposed. A novel approach based on blockchain technology [13], digital signatures and threshold ElGamal Cryptosystem to address the problem of single point of failure.

The authors in [14] provide a viable way for protecting the traditional password-based authentication system since this

sort of authentication is often required. They suggest a way for sharing a secret based on Shamir's well-known (k, n) threshold approach.

In [15], the authors discuss a new approach for managing the secrets in a decentralised way by leveraging decentralised identity concepts such as verifiable credential technologies, password-authenticated key exchange protocols and multi-party computation.

Another approach were developed in [16] who introduce PASSAT is a practical method that enhances the security assurance provided by today's cloud architecture without needing any modifications or collaboration from cloud service providers. PASSAT is a cloud-invisible program that enables users to safely and effectively save and retrieve their files on public cloud storage with a single master password.

### III. SHAMIR'S SECRET SHARING

Authentication for a computer system is a process that allows the system to verify the legitimacy of the access request. The system then assigns this entity the identity data for this session. Access to the resources of an information system by an entity is broken down into three sub-processes, authentication, identification and access control [17].

Cryptography is one of the disciplines of cryptology focusing on protecting messages ensuring confidentiality, authenticity and integrity by often using secrets or keys. Shamir's Secret Sharing is an example of this cryptographic algorithm [18].

#### A. Distributed Scenario

A distributed system is a computer environment in which numerous nodes on a network are used to distribute different components [7].

Because distributed networks are formed up of equal, interconnected nodes, data ownership, and computing resources are dispersed equitably throughout the network. These nodes divided up the work and coordinated their efforts to finish the assignment more quickly than if it had been assigned to a single node. Compared to decentralized networks, distributed networks are more scalable.

A node in a distributed network may fail on its own without impacting the rest of the system. It is more difficult to change information on a distributed network since data is spread equitably throughout the whole network [7].

#### B. Decentralized

Decentralization is defined by the distribution of powers. Scaling decentralized networks is simple. Instead of depending on a single central node, a decentralized network spreads information processing among numerous nodes [7]. Even if one of the master nodes fails, the remaining servers can continue to offer data access to users, and the network as a whole will keep running. Because information kept on the network is spread across numerous points rather than via a single one, decentralized networks provide a higher level of consumer privacy [19]. Furthermore, user requests are often completed faster when using a decentralized network. Fig. 4 shows the nodes of the AuSDiDe node's topology.

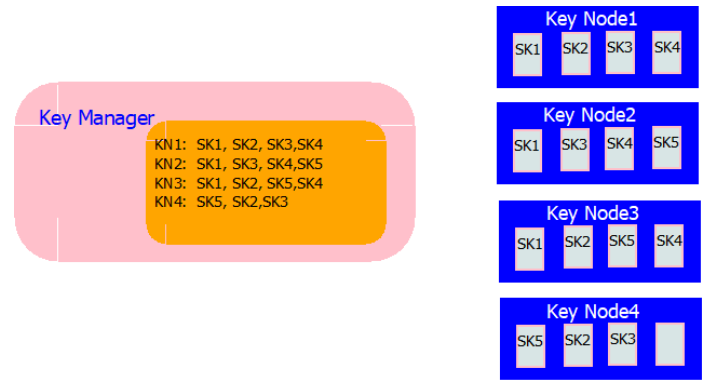

Fig. 4. AuSDiDe Nodes.

Fig. 5 details a schematic diagram of the general AuSDiDe architecture used for Distributed and Decentralized Structure Based on Shamir's Secret Sharing.

#### C. Shamir's Secret-Sharing Scheme

Shamir's Insider Information Adi Shamir is the creator of sharing. A secret is split into pieces in a kind of dispersed secret [18]. Each participant has their own shared key, where some or all the parts are needed to reconstruct a passphrase. Shamir's secret sharing or key sharing, is a process which a private encryption key is split into separate fragments. Every fragment is useless, unless it is sufficiently assembled to reconstitute the original key [7].

It is not necessary that all the participants reconstitute the access password. This is why the threshold scheme is sometimes used where a number  $k$  of the parts is sufficient for rebuild the original secret [20].

In Shamir's secret-sharing arrangement, there are  $n$  shareholders [21].  $U_i = \{U_1, U_2, \dots, U_n\}$  and a mutually trusted dealer  $D$ .

The dealer  $D$  produces a  $(t-1)$  degree polynomial  $f(x) \in Z_p$ , where  $P$  is a prime integer, to divide the secret  $S$  into  $n$  shares.  $S = f(0)$  is the shared secret, and before sending the  $(x_i, y_i)$  to the shareholder  $U_i$  the dealer calculates the secret-sharing shares as  $y_i = f(x_i)$  for  $x_i \neq 0$ .

When regenerating the secret, at least  $t$  shares  $(x_i, y_i)$  are required to recover the polynomial  $f'(x)$ , allowing each shareholder to get the secret  $S = f'(0)$ . The approach is comprised of two algorithms: secret reconstruction and share generation [21]:

For share generation, the  $(t-1)$  degree polynomial is defined as:

$$f(x_i) = a_0 + a_1x^1 + ax^2 + \dots + a_{t-1}x^{t-1}, (mod p) \quad (1)$$

and  $a_i \in Z_p$ , for  $0 \leq i \leq t-1, a_{t-1} \neq 0$ , the secret  $S = f(0) = a_0$ .

In  $a(t, n)$  secret-sharing system,  $n$  points are randomly chosen as  $x_i : 1 \leq i \leq n$ , and  $x_i \neq 0 \in Z_p$ , the

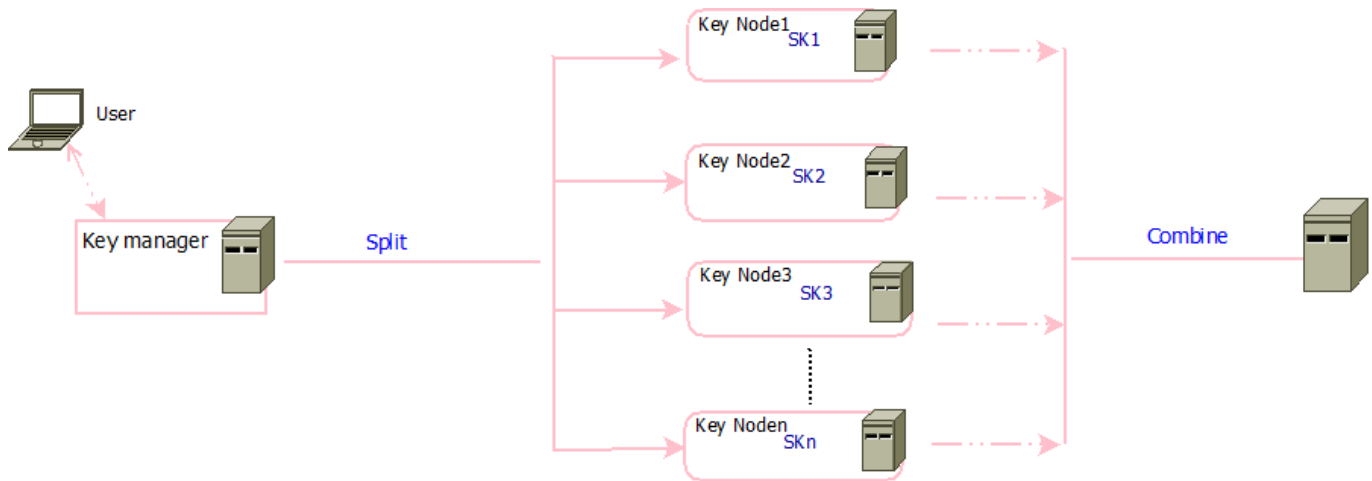

Fig. 5. Architecture AuSDiDe.

dealer calculates  $y_i = f(x)$  and transmits  $s_i = (x_i, y_i)$  to shareholders  $U_i$ .

For a secret reconstruction [18], supposing that  $t$  shareholders  $U_1, U_2, \dots, U_t$ . Each shareholder  $U_i$  gives a share  $s_i$  to the other stockholders. After that, if a shareholder possesses  $m$  shares  $s_1, s_2, \dots, s_m$ , he may retrieve  $f'(x)$  using the Lagrange interpolation polynomial as [21]:

$$f'(x) = \sum_{i=1}^t s_i \prod_{j=1, j \neq i}^t \frac{x_j - x}{x_j - x_i}, (mod p) \quad (2)$$

The secret  $S$  will be computed as:

$$f'(0) = \sum_{i=1}^t s_i \prod_{j=1, j \neq i}^t \frac{x_j}{x_j - x_i}, (mod p) \quad (3)$$

#### IV. AUSDiDE GENERAL ARCHITECTURE

The AuSDiDE is introduced to enhance security and been developed to increase the level of security. This system takes into consideration those architectures: distributed and centralized.

AuSDiDe is composed of nodes playing different exclusive roles between them. Hacking and attacking servers should be difficult. Getting a key will not be enough to encrypt the passphrase, you need to get all shared keys. It will be complicated, given the number of servers.

The AuSDiDe is composed of two main Node as shown in Fig. 4: Key Manager – the master and Key Node – the slave. One of the machines is the master, called Key Manager: This machine contains all names and key parts, like a phone book.

All other machines are Key Node. They store the different shared secret key. The key Manager knows where the keys are, which part of the key and on which key Manager are registered.

The key manager will be dividing the secret into several parts –  $(n, k)$  key parts after having defined the threshold  $k$ . As illustrated in Fig. 5, this task called split operation.

The threshold represents the minimum number of parties necessary to reconstitute the passphrase and unlock access to the secret. This task called combine operation.

#### V. IMPLEMENTATION

In this section, the implementation of the AuSDiDe is presented. The created cluster is composed of different servers, playing different exclusive roles. For this operation, the docker [22] and Hadoop framework [23] are used.

##### A. Docker Security Advantages

Docker's most widely used containerization technique can raise the degree of security if used correctly (in comparison to running applications directly on the host). On the other hand, misconfigurations might result in a reduction in security or even the introduction of new vulnerabilities. Docker gives the ability to automate the deployment of applications into Containers [24]. Docker offers an additional layer of deployment engine on top of a Container environment where programs are virtualized and executed. Docker is meant to offer a speedy and lightweight environment in which code may be executed quickly and an additional facility of the competent work process to remove the code from the computer for testing before production [24]. You may certainly start with a docker with a basic configuration system, a docker binary with a Linux kernel. Docker has four major internal components: Docker Server and Client, Docker Registries, Docker Images, and Containers. A Docker image is used to generate a Docker container [22]. Containers store all of the components needed for a program, allowing it to execute in isolation. Assume there is an image of Ubuntu OS with MongoDB server; when executed with the docker run command, a container is produced, and MongoDB server is operating on Ubuntu OS [22].

##### B. Benefits and Advantages of Hadoop

The Apache Hadoop project creates open-source software for scalable, distributed computing. The software library is a framework that enables the distributed processing of massive

data volumes across computer clusters by using basic programming techniques [23]. It is intended to grow from a single server to thousands of computers, providing local computing and storage.

Rather than relying on hardware to provide high availability, the library is intended to identify and manage failures at the application layer, allowing a highly available service to be delivered on top of a cluster of machines that may all fail [23]. Therefore, it is widely used today to store, analyze, and manipulate huge amounts of data: Hadoop is a standard for Big Data processing. Hadoop refers to its ecosystem and all software such as Apache Spark, Cloudera Impala, Sqoop, etc.

The Experimental Architecture of AuSDiDe Implementation is illustrated in Fig. 6.

Fig. 6. Experimental Architecture of AuSDiDe Implementation.

The three containers represent a Key Manager and three Key nodes utilizing a Docker image. We use throughout the implementation three containers, representing respectively a Key Manager and three Key Nodes using docker image [24], as shown in Fig. 6.

The result of this execution shows how the split operation at the Key Manager was able to divide and share the shared keys SK1, SK2 and SK3 and store them to the different Key Node1, Key Node2 and Key Node3.

For the inverse operation i.e combine operation, the threshold equal two, representing the minimum number of parties necessary to reconstitute the passphrase and unlock access to the secret. It can be SK1 and SK2; SK2 and SK3 or SK1 and SK3.

## VI. DISCUSSION

Several considerations must be taken to determine the authentication system adapted for new architectures. The future of internet (for example web 3.0) implement a decentralized architecture, all machines can play the role of master and slave at the same time. For example, Peer-to-peer (P2P) is a model of computer network structured in a decentralized way [25], the communications between nodes with equal responsibility. In

the world network, nodes are identified by a logical IP address. To maintain anonymity in a network, it is better to use private or public key addresses. These different constraints have been well studied for the development of the AusDiDe solution.

## VII. CONCLUSION

This paper proposes a new approach focused on authentication systems, private keys, and password management. This solution presents a new way of thinking about authentication systems and sensitive data security. These will be adapted to future generation Internet, e.g., web3. The implementation of AuSDiDe clearly shows better security and an obstacle for malicious attacks. The AuSDiDe system divides and shares keys toward different and distributed nodes in all clusters. Hacking requires obtaining all the shared keys, making it difficult for hackers. As continuity to this work and to enhance the AuSDiDe functionality, the artificial intelligence concept will develop an intelligent AuSDiDe system operating in decentralized and hybrid architecture as Blockchain. Towards a framework for a smart AuSDiDe with a learning system to anticipate intrusions and anomalies in order to reinforce security.

**Abstract**—The extraction of high-quality keywords and summarising documents at a high level has become more difficult in current research due to technological advancements and the exponential expansion of textual data and digital sources. Extracting high-quality keywords and summarising the documents at a high-level need to use features for the keyphrase extraction, becoming more popular. A new unsupervised keyphrase concentrated area (KCA) identification approach is proposed in this study as a feature of keyphrase extraction: corpus, domain and language independent; document length-free; utilized by both supervised and unsupervised techniques. In the proposed system, there are three phases: data pre-processing, data processing, and KCA identification. The system employs various text pre-processing methods before transferring the acquired datasets to the data processing step. The pre-processed data is subsequently used during the data processing step. The statistical approaches, curve plotting, and curve fitting technique are applied in the KCA identification step. The proposed system is then tested and evaluated using benchmark datasets collected from various sources. To demonstrate our proposed approach's effectiveness, merits, and significance, we compared it with other proposed techniques. The experimental results on eleven (11) datasets show that the proposed approach effectively recognizes the KCA from articles as well as significantly enhances the current keyphrase extraction methods based on various text sizes, languages, and domains.

**Keywords**—Keyphrase concentrated area; KCA identification; feature extraction; data processing; keyphrase extraction; curve fitting

## I. INTRODUCTION

The continuous development of the information age and exponential growth of textual information makes it even more challenging to handle this large amount of information [1]. Before the emergence of technology, this information could be processed by humans, which was very time-consuming. Furthermore, due to the inconsistencies between the amount of data and manual data processing skills, it is challenging to

complete this vast information, leading to automated keyphrase extraction systems that utilise computers' extensive computational capability to substitute manual labour [2], [3].

The goal of automated keyword/keyphrase extraction techniques is to extract high-quality keys from documents. In general, Keyphrase offers a high level of description, summary, and characterization of documents, which is crucial for many aspects of Natural Language Processing, such as articles categorization, classification, and clustering [3]. They are, nevertheless, used in a wide range of Digital Information Processing applications, including Digital Content Management, Information Retrieval [3], [4], Contextual Advertising [5], and Recommender System [6]. It also offers a wide range of practical uses, including media searches, search engines, digital libraries, legal and geographic information retrieval [7].

Various keyphrase extraction methods have been developed to support the aforementioned applications [8], [9], [7], [10], [11], [12]. Domain-specific strategies [9], for example, need knowledge of the application domain, whereas linguistic approaches [9] demand language proficiency. They cannot solve problems in other disciplines or languages as a result. Supervised techniques need a lot of unusual train data to extract the quality keyphrases. Owing to their vast number of complicated operations, unsupervised machine learning methods are computationally costly, and they perform badly due to their inability to identify cohesiveness among several words that make up a keyword [7], [13], [14], [15]. Feature extraction is essential for those keyphrase extraction methods that want high-quality keyphrases. It's the process of obtaining characteristics (sometimes referred to as features) that distinguish keywords from other terms [16]. These features also impact the performance of various supervised and un-supervised keyword/keyphrase extraction methods. It is demonstrated that from the previous debate, the feature extraction of keyphrases remains an essential research topic for the study.

Therefore, this article proposes an unsupervised new Keyphrase Concentrated Area identification technique with ensuing significant contributions:

- The proposed technique, which is corpus-independent, can be applied to any text and any corpus.
- KCA identification's a domain- and language-agnostic method that relies on little statistical knowledge.
- The proposed method can be used as a keyphrase feature in both supervised and unsupervised approaches.
- It's a document length-free refers to the fact that there are no requirements for the minimum length of a document that a keyphrase must-have.
- Eleven datasets have been used to test and assess the effectiveness of the proposed method.

The remainder of this paper is organised as follows. Section II outlines the various methodologies, including their benefits and drawbacks, and so emphasises the need for a new strategy to be proposed. The suggested technique is then discussed in depth in Section III. The setup of the experiments is detailed in Section IV, which contains corpus data, evaluation measures, and implementation details. In Section V, all of the obtained findings are plotted and analysed, and Section VI brings this article to a close.

## II. RELATED WORK

This section will discuss similar strategies because the proposed technique is a novel approach for extracting keyphrase features. Most keyphrase extraction techniques are categorized into two groups such as supervised and unsupervised, based on the training datasets [4]. Feature extraction is used in both ways. Below, we'll go over the main points of both of these groups' approaches.

### A. Supervised Methods

The keyphrase extraction technique is counted as a binary classification problem [1] using this method from articles, with a proportion of candidate keyphrases categorised as keyphrases and non-keyphrase. Methods for solving the classification problem include support vector machines, Decision trees, Naive Bayes [3], Neural networks [17], [18], and C4.5 [19]. The prominent techniques are examined in detail in the subsequence that adopts this method.

As a feature, Key Extraction Algorithm (KEA) [20] uses TFxIDF and the first presence location. It utilises descriptive approaches for identifying candidate keyphrases, estimating feature values for each candidate and predicting and determining candidates' good keyphrases using the Naive Bayes algorithm. However, KEA depends on the training dataset, and if the training dataset does not match the documents, it may produce poor results.

As a feature, Genitor Extractor (GenEx) [1] assigns first occurrence position, term frequency (TF), and keyphrase length. The most well-known key extraction approach is established on a collection of parametrized heuristic rules that employ genetic algorithms to retain their efficacy across diverse domains, and it is based on a C-4.5 decision-making process. It does not use

the Term Frequency-Inverse Document Frequency technique (TF-IDF).

Unlike the GenEx and KEA methods, the Hult system [1] allows the extracted keys to be as long as they want to be. The four characteristics it utilises are part of speech (POS) tag, n-grams, noun phrase (NP) chunks, first occurrence position, and TF. Unfortunately, no association exists between the various POS tag features. The system doesn't test on KEA or GenEx corpus, and the stated recall value is poor.

The Maui Algorithm [21], based on the KEA system, is an automatic generic topical indexing algorithm. It adds data from Wikipedia to expand the KEA system. However, one of this algorithm's flaws is its lack of assessment abilities.

The position of a term, its first occurrence; phrases; informativeness; keywords; and the length of the candidate term as a feature are all used by HUMB [22]. In a variety of data sets, the HUMB system has produced positive results. HUMB, on the other hand, has only used scientific papers.

The Document Phrase Maximality (DPM)-index, first position, TF, TFxIDF, IDF, first sentence, average sentence length, head frequency, substrings frequencies sum, and five other new features are (18 statistical features) used by DPM-index [23]. Without external knowledge or document structural elements, this system's results have improved significantly compared to other keyphrase extraction systems.

Citation-enhanced Keyphrase Extraction (CeKE) [24] utilize the following keyphrase features such as TFxIDF, relative Pos, inCited, POS, first position, inCiting, TF-IDF-Over, firstPosUnder, citation TF-IDF. They can improve keyphrase extraction and add keyphrase features. (CeKE + keys) the model outperforms other systems [1].

Keyphrase Extraction (KeyEx) Method [25] finds a large number of possible candidate keyphrases and build a classification model for key extraction using supervised learning methods. Experiments conducted by the author revealed that the KeyEx system has effectively improved the extracted keyphrase's quality. In addition, their strategy beats existing sequential pattern mining methods.

### B. Unsupervised Methods

The keyphrase extraction scheme is a ranking issue that is solved without prior knowledge. These methods can be classified as statistical or graph-based [1]. The following sections go over the most important techniques used by both groups in sufficient detail.

PageRank [26] is a graph-based algorithm that uses random walks as its foundation. It is, however, appropriate for raking web and social media pages but not for extracting keyphrase from formal documents. PageRank extension known as PositionRank [14] was discovered to improve performance, which scores word by taking into account all of its positions and its frequency, and thus determines its rank. This technique, however, poorly performs because it ignores topical coverage and diversity.

TextRank [27] uses Parts of Speech (POS) as an internal feature, with several limitations, including the inability to

capture cohesiveness, resulting in sub-optimal results. TopicRank [28] is another keyphrase extraction technique that overcomes TextRank's limitations. The noun phrases in the document are extracted and clustered into topics by TopicRank. Furthermore, it has an issue with error propagation. The lengthening of TextRank is SingleRank [29]. It correctly pulls only noun phrases from the records, not keyphrases, by collecting ranked words. However, it does not always filter out low-scoring words and gives longer keys higher scores, but non-significant keys are included in the ranking process.

MultipartiteRank [15] is a technique for resolving the TopicRank error propagation problem. However, it suffers from clustering error, making selecting the most representative candidates challenging. Tree-based Keyphrase Extraction Technique (TeKET) [7] is a renowned unsupervised keyphrase extraction method that is language and domain-independent and needs only rudimentary statistical knowledge. Though it outperforms some other keyphrase extraction techniques, it has some disadvantages, such as tremendous flexibility.

The most common statistical method is named TF-IDF [30]. Although TF-IDF is simple to implement, computing Inverse Document Frequency (IDF) takes a long time and requires a lot of computing power when dealing with a large dataset. The KP-Miner [31] program is used to solve the problem of single-term preference. Although KP-Miner exceeds TF-IDF, it still has some drawbacks, including degrading the global ranking performance if the number of records increases. It's also computationally expensive because it relies on TF-IDF.

Yet Another Keyword Extractor (YAKE) [10] is another popular technique for removing the IDF problem by calculating the weighting score of a keyphrase using five features/attributes: as term position, casing, term relatedness to context, term frequency normalization, and term distinct sentence. However, because it uses the N-grams technique to generate candidate keys, its computational complexity grows linearly with N-grams.

According to the previous discussions, both supervised and unsupervised keyphrase extraction techniques have several drawbacks that prevent them from achieving better results. Therefore, this paper proposes a new unsupervised KCA identification technique as a keyphrases feature that will significantly decrease the specified flaws as well as extract high-quality keywords from academic articles.

### III. METHODOLOGY

The whole approach of keyphrase concentrated area identification utilizing the proposed method is divided into three major stages: *i*) Data preprocessing, *ii*) Data processing, and *iii*) KCA identification (see Fig. 1). In the subsequent sections, the proposed strategy is illustrated in detail.

#### A. Data Pre-processing

It is an important stage in the development of our proposed technique. Initially, the proposed approach gathered eleven datasets (having 9006 papers) covering three languages (Portuguese, English, and Spanish), different disciplines (such as chemistry, physics, computer science, and others). Containing

four different kinds of papers (news, abstracts, full articles, and M.Sc/Ph.D. Thesis) ranging from 75 tokens to 8000 tokens per document) [32]. Every dataset has two kinds of file names, like keys and docsutf8, including the same articles/documents. Visit Section IV-A for more information.

After that, the suggested method extracts the docsutf8 files (which include various vital articles as text files) as well as the keys files independently (containing different essential keys known as text files). Afterward, read these two files and save them respectively as document ( $\delta$ ) and keys ( $\chi$ ). After receiving the documents and keys, they must normalize the data, which entails four steps: Convert the document to lower case; Eliminate the irrelevant numbers by employing regular expressions); Remove all punctuation marks; Remove blank spaces (using the strip() function to remove leading and to end spaces) [33]. After that, The splitting technique is applied on keys files to compute the keyphrase learned as GoldKey ( $\gamma$ ) founded on Newline ( $\backslash n$ ) method. At that moment, in our proposed approach, the length of text or document is split into ten (10) and twenty (20) regions.

#### B. Data Processing

This is a crucial step after pre-processing the data. During this step, the proposed system uses the first appearance to locate (*Loc*) of each ( $\gamma$ ) of ( $\chi$ ) from the ( $\delta$ ). Save the *Loc* of  $\gamma$  in the proper region of the  $\delta$  if located in the  $\delta$ . Note that the *Loc* is stored on two-dimensional (2D) array in which column is the ( $\delta$ ) region's number and row is the ( $\gamma$ )'s number. If the  $\gamma$  is not located, research the  $\delta$  for the next  $\gamma$  of  $\chi$ . This procedure will repeat until  $\gamma$  has completed the  $\chi$  file for a single dataset document. The same procedure will continue for all datasets.

#### C. KCA Identification

It is an important and final phase after data processing. The output of the data processing phase is applied to this phase to find the concentration area of the keyphrases. This phase consists of the three significant steps: *i*) Average value calculation, *ii*) Curve plotting, and *iii*) Curve fitting technique that describes the following sections.

*a) Average Value Calculation:* To begin, for a single document/text, compute the Average (Avg) value of every region and save it in a new 2D array whose row is the number of records in a particular dataset and column is the text/document regions like as before. Afterwards, the process will resume until every document for a specific dataset has been completed. Calculate the average value of every region/portion for every record in a particular dataset and save this average value in another new 2D array whose row is the entire dataset and column is the same as before. After that, the Avg calculation will resume until every dataset has been completed [3]. Definitely, for all datasets, compute the Avg value of all regions.

*b) Curve Plotting (CP):* CP is a graphical presentation approach for a dataset. It's possible to read plotted values as known functions of unknown variables using this method. In data analysis and statistics it is pretty useful. CP is used to understand our proposed method's keyphrases concentration region/area. Because of this, the Avg value of each dataset is plotted alongside the Avg value of the whole dataset.

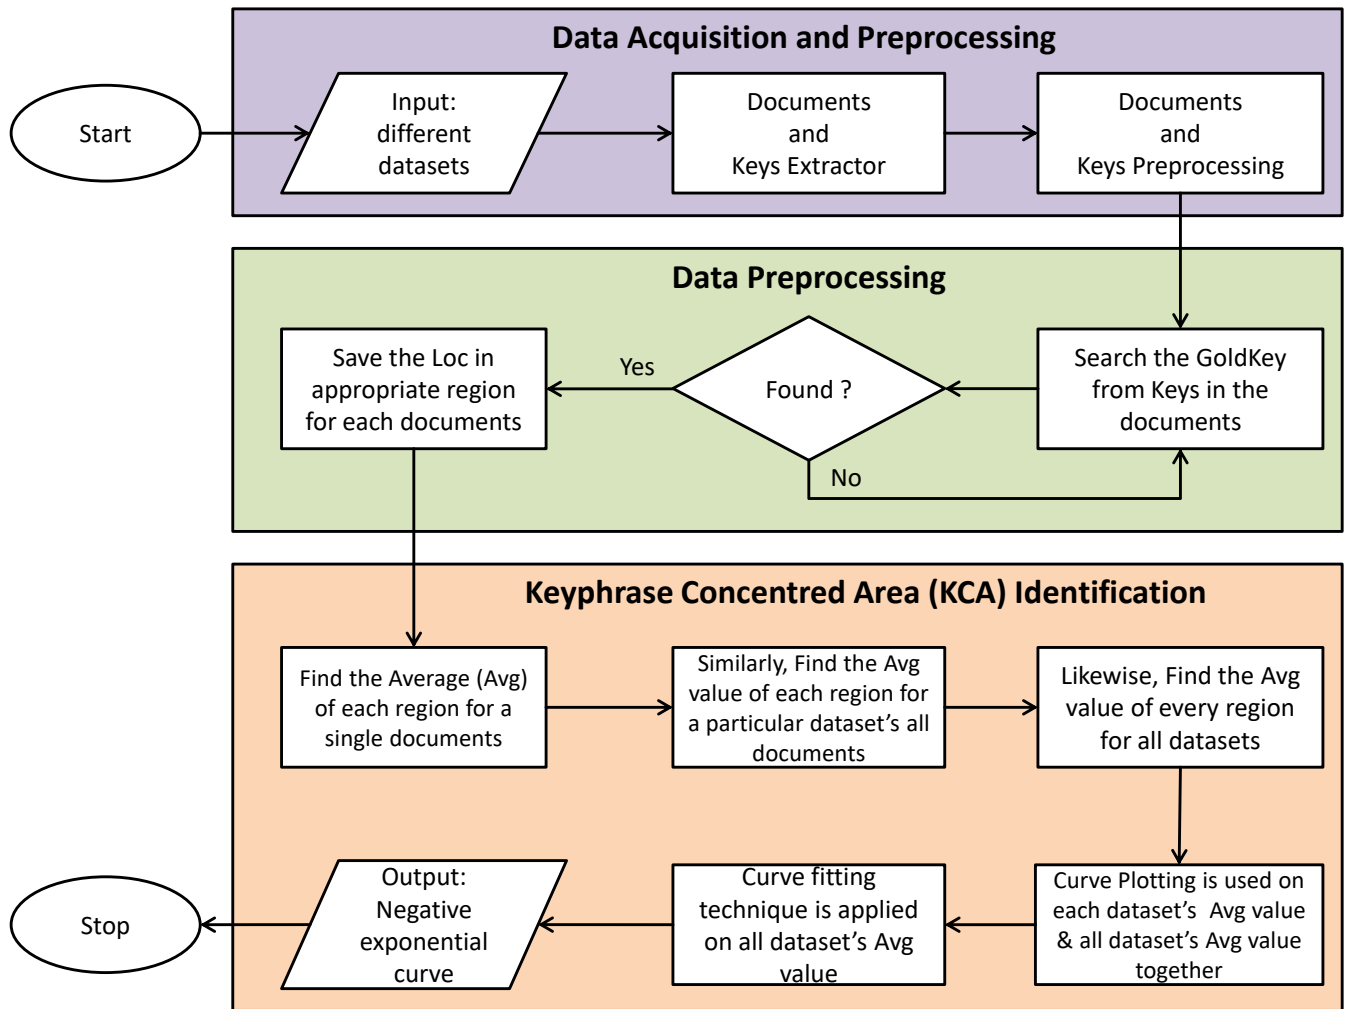

Fig. 1. The Proposed Technique's Flow Diagram for KCA Identification.

c) *Curve Fitting Technique (CFT)*: It is a helpful method for analysing linear, polynomial, and nonlinear curves. It is most likely the process of producing the best-fitting curve or mathematical function for a constrained set of data points. CFT is used to identify the critical concentration region/area in our proposed approach. As a result, CFT is applied on the Avg value of all datasets, resulting in a negative exponential curve for the proposed approach.

#### IV. EXPERIMENTAL SETUP

Our proposed method clearly stated that the experimental setting introduces corpus/dataset details, implementation details, and evaluation metrics, presented in the following section. Afterwards, the outcomes are explained in Section V.

##### A. Corpus Details

our proposed approach has tested on 11 datasets/corpus to evaluate the performance. How the proposed approach behaves under many datasets was our another ambition to understand. Standard gatherings such as Inspec [32], SemEval2010 [34], 110-PT-BN-KP [35], Nguyen2007 [36],

PubMed [32], Schutz2008 [37], catic [38], kdd [39], wicc [38], www [39], and theses100 [32] are used in our proposed approach. A quick summary is given in the preceding section III-A, and a statistical review of all datasets is given in Table I. Every corpus is explained in detail in the following sections.

**Inspec** [32] contains 2000 abstracts and 28220 gold keys from computer science articles published from 1998 to 2002. There are two sets of keywords in each document: controlled keywords, selected manually from the Inspec vocabulary, and uncontrolled keywords, which the editors liberally allocate.

**WWW** [39] and **KDD** [39] are the tiniest datasets (on an Avg of 84 and 75 tokens per document). The collection of those datasets (like Inspec) is based on abstracts of papers published between 2004 and 2014 at the ACM Conference and the World Wide Web(WWW) Conference on Knowledge Discovery in Databases (KDD). There are 1,330 and 755 documents in each and 6405 and 3093 goldkeys.

**SemEval2010** [34] is one of the famous standard datasets, which contains 244 whole scientific articles extracted from the ACM Library. The papers range in length from 6 to 8 pages

TABLE I. A STATISTICAL DATASETS SUMMARY FOR THE ANALYSIS OF PRESENT AND ABSENT GOLDKEYS

| Dataset      | Language | Type of Doc    | Domain        | #Docs | #Gold Keys | #Present Goldkey | #Absent Goldkey | Absent Goldkey per doc(%) | Present Goldkey per doc(%) |

and cover four distinct areas of computer science: information search and retrieval, Distributed artificial intelligence, Distributed Systems, and Social and behavioural sciences. Every paper has a set of keyphrases assigned by the author as well as by professional editors.

**Nguyen2007** [36]: There are 209 scientific conference papers and 2507 gold keys in this dataset. Three articles were provided to student volunteers to read, and the goldkeys were handed out manually. Each document has twelve(12) goldkeys on Avg.

Both **Schutz2008** [37] and **PubMed** [32] are corpuses compiled from a PubMed Central full-text paper that cites over 26 million online books of life science journals from MIDLINE. Schutz2008 is made up of 1,231 articles chosen from PubMed Central, whereas PubMed is made up of 500 articles chosen from identical sources. The authors' Schutz2008 keyword is hidden in the paper and employed as goldkeys, yielding 45.26 goldkeys per document. The gold keyword in PubMed is Medical Subject Headings (MeSH), which is a controlled vocabulary glossary utilised to index articles, occurring in 14.24 goldkeys in each document.

**Theses100** [32] corpus comprises of hundred(100) complete Masters and PhD thesis from University of Waikato, New Zealand. These domains are relatively dissimilar, departing from computer science, chemistry, economics, philosophy, psychology, history, etc. It has 6.67 goldkeys per document, on Avg.

**110-PT-BN-KP** [35] is a Television(TV) Broadcast News(BN) corpus including 110 transcripts from eight(8) broadcast news programmes from the European Portuguese ALERT BN corpus, including finance, sports, politics, and others theme. Goldkeys were created by having a tagger remove all keywords that contained document content summaries, yielding 24.44 goldkeys per document.

**Cacic** [38] consists of 888 scientific publications from 2005 to 2013. It also comprises the minor number 3.82 goldkeys in each document, on Avg. The **Wicc** [38] dataset made up of

TABLE II. CONFUSION MATRIX

|                 |          | Actual Class Positive | Actual Class Negative |
|-----------------|----------|-----------------------|-----------------------|
| Predicted Class | Positive | $T_P$                 | $F_N$                 |
|                 | Negative | $F_P$                 | $T_N$                 |

1,640 scientific papers published from 1999 to 2012, with an Avg of 3.57 goldkeys in each document.

### B. Evaluation Metrics

*Accuracy, error rate, recall, precision, F<sub>1</sub>-score*, and other significant and relevant metrics are routinely used to measure the performance of a system. To evaluate the performance of our proposed approach, we employ accuracy data and a confusion matrix (shown in Table II). The accuracy measure is generally defined as the percentage of correct predictions out of the total number of patterns analysed. The following equation (1) represents *accuracy*.

$$Accuracy = \frac{T_P + T_N}{T_P + F_P + T_N + F_N} \quad (1)$$

Here, True Positive ( $T_P$ ) and True Negative ( $T_N$ ) denote the number of positive and negative keyphrases accurately classified, respectively. On the other hand, False Positive ( $F_P$ ) and False Negative ( $F_N$ ) represent the number of positive and negative keywords that were wrongly classified.

### C. Implementation Details

Python 3.6 and the Spyder-IDE are used to implement the proposed method. It is a high-level and object-oriented programming language that is easy to learn and utilise. It has a data structure that is user-friendly, versatile, and supported by numerous libraries. It increases productivity, is interpreted, dynamically typed, and is free and open-source. It is applied in big data, Cloud Computing, and Machine Learning, etc.

Fig. 2. The Avg Number of Goldkeys are Present and Absent in Each Document for All Datasets.

Following that, the machine is outfitted with an Intel Core i7 processor, RAM-12GB, a SATA-connected solid state drive (SSD), and the Windows 10 operating system [3].

## V. RESULTS AND DISCUSSION

This section includes a full examination of the experiment outcomes. The proposed system divides the text or documents length into twenty (20) and ten (10) regions to identify the Keyphrases Concentrated Area (KCA). When more than twenty regions are raised, the first region produces significantly less goldkey than twenty regions. Similarly, if the number of regions is lowered to less than 10, the first region has significantly more goldkey than ten regions. Our proposed technique aims to locate the KCA in documents/articles; thus, instead of expanding or lowering the regions, the system is examined for all types of text lengths as ten and twenty regions. This section is divided into two phases described in the following section: *i)* Result Analyses, and *ii)* Comparison of Proposed Systems.

### A. Results Analysis

The proposed system's performance is evaluated in this phase using the following criteria: *i)* Dataset Analysis, *ii)* Plotting Analysis, and *iii)* Curve Fitting Analysis, are the three types of results analysis.

*a) Dataset Analysis:* The proposed system has been tested on eleven (11) datasets (detail in section IV-A) to judge the performance of the proposed technique. Afterwards, the proposed system determines how many documents, number of goldkeys, present and absent goldkeys, as well as present and absent goldkeys in each article in (%) exist in every dataset provided in Table I based on the analysis of the datasets. The Avg number of goldkeys present and absent per document are examined for each dataset, exhibited in Fig. 2. Likewise, the Avg number of goldkeys absent and present in percentage(%) of each document for all datasets is displayed in Fig. 3. According to our findings, 65.70% of goldkeys per document are present on Avg across all datasets, while 34.30% are absent.

Fig. 3. The Avg Number of Goldkeys are Absent and Present in Percentage per Document for all Datasets.

Fig. 4. The Plotting Analysis of KCA Identification by Considering 1st Appearance Keyphrases for 20 Regions.

*b) Plotting Analysis:* According to the previous discussion, Since the Avg of 65.70% of goldkeys is present per document for each dataset, all the results in this work have been predicated on 65.70% of present goldkeys. The first appearance keyphrases in a document are considered in our proposed method, and the text length is divided into twenty(20) and ten(10) regions. The proposed method then plots the eleven (11) dataset's values and Avg value of all datasets together based on each region of articles. Fig. 4 shows the analysis of first appearance keyphrases in each region for KCA identification when the text length is divided into twenty(20) regions. Similarly, Fig. 5 shows the analysis of first appearance keyphrases in each region for KCA identification when the text length is divided into ten(10) areas/regions. Since all dataset curves together are negative exponential, it is confirmed that the maximum goldkeys/keyphrases are found in 1st region, then 2nd region of the articles, and so forth, as shown in Fig. 4 and Fig. 5.

*c) Curve Fitting Analysis:* After completing the plotting analysis, the Avg value of entire datasets is applied in this analysis of our proposed system. Afterwards, the system attempts to discover the first fitted curve and then the negative exponential equation for each region's Avg value. In Fig. 6, the

Fig. 5. The Plotting Analysis of KCA Identification by Considering 1st Appearance Keyphrases for 10 Regions.

Fig. 7. The Curve Fitting Analysis of KCA Identification by Considering the Text Length as 10 Regions.

Fig. 6. The Curve Fitting Analysis of KCA Identification by Considering the Text Length as 20 Regions.

analysis of the curve fitting technique for KCA identification in each region is shown, with the text length divided into twenty (20) parts/regions, yielding the negative exponential equation expressed as follows (2) where  $p = 1.05$ ,  $q = 1.25$ , and  $r = 0.01$ . Similarly, KCA identification from this analysis for the length of text as ten (10) regions or portion is displayed in Fig. 7 and also gives the similar equation which is negative exponential in where  $p = 2.47$ ,  $q = 1.85$ , and  $r = 0.02$ . Since the fitted curves are found in negative exponential from the curve fitting analysis, It is demonstrated that most of the keyphrases are concentrated in the 1st portion of the documents, and next to the 2nd region of documents and so on, that are exhibited in Fig. 6 and Fig. 7.

$$y = p * e^{-qx} + r \quad (2)$$

### B. Comparison of Proposed Systems

Since KCA is a new technique with no existing policies, the proposed method does not compare with other techniques. The proposed system compares our two proposed approaches

considering the length of the documents as ten (10) regions and twenty (20) regions for KCA identification shown in the following Table III. Both proposed systems are employed 11 datasets for comparison. From Table III, in ten (10) regions, more keyphrases concentrated in 1st region (62.09%) than twenty (20) regions (48.37%) of the documents/articles. Similarly, in ten (10) regions, more keyphrases concentrated in 1st two regions combine (73.70%) than twenty (20) regions (62.08%) of the documents/articles. Afterwards, the ten(10) regions approach provides more keyphrases concentration in the 1st three regions combined (79.97%) than twenty (20) regions (69.48%). Finally, we can say that our proposed technique for ten (10) regions provide more keyphrase concentration than twenty (20) regions in 1st regions, then 2nd region, and so on. The KCA in an article is proven from these two approaches.

## VI. CONCLUSION

The extraction of features for the keyphrase extraction approach has evolved into a critical component in a wide range of computer science applications. A new unsupervised approach termed Keyphrases Concentrated Area identification as feature of keyphrase extraction is presented in this paper. It is domain and language independent, needs little statistical expertise, and does not need the use of train data. The proposed technique starts with data pre-processing, processing, and KCA identification (average calculation, plotting analysis, and curve-fitting analysis).The proposed approach effectively recognises the KCA from texts/articles and creates a negative exponential equation, showing that the first region of the document/article contains more keyphrases than the rest of the articles.

In comparison to the suggested two techniques, the system tested on 11 datasets and produced a superior result based on the 65.70 per cent existing goldkey. Taking use of the more statistical elements discussed in this research, we want to develop a strong keyphrase extraction approach in the future. Moreover, when multiple manually specified keywords are not found in the page, there are some limitations in resolving the missing goldkeys/keywords issue.

TABLE III. COMPARE OUR PROPOSED TWO APPROACHES FOR KCA IDENTIFICATION

| Articles Regions    | Keyphrase concentrated in 1st region(%) | Keyphrase concentrated in 1st two regions combine (%) | Keyphrase concentrated in 1st three regions combine (%) | Negative Exponential ( $p * e^{-q * x} + r$ ) |
|---------------------|-----------------------------------------|-------------------------------------------------------|---------------------------------------------------------|-----------------------------------------------|
| Ten (10) Regions    | 62.09%                                  | 73.70%                                                | 79.97%                                                  | p=2.47, q=1.85, r=0.02                        |
| Twenty (20) Regions | 48.37%                                  | 62.08%                                                | 69.48%                                                  | p=1.05, q=1.25, r=0.01                        |

# Transfer Learning based Performance Comparison of the Pre-Trained Deep Neural Networks

Jayapalan Senthil Kumar, Syahid Anuar, Noor Hafizah Hassan  
Razak Faculty of Technology and Informatics  
Universiti Teknologi Malaysia (UTM)  
54100 Kuala Lumpur, Malaysia

**Abstract**—Deep learning has grown tremendously in recent years, having a substantial impact on practically every discipline. Transfer learning allows us to transfer the knowledge of a model that has been formerly trained for a particular task to a new model that is attempting to solve a related but not identical problem. Specific layers of a pre-trained model must be retrained while the others must remain unmodified to adapt it to a new task effectively. There are typical issues in selecting the layers to be enabled for training and layers to be frozen, setting hyperparameter values, and all these concerns have a substantial effect on training capabilities as well as classification performance. The principal aim of this study is to compare the network performance of the selected pre-trained models based on transfer learning to help the selection of a suitable model for image classification. To accomplish the goal, we examined the performance of five pre-trained networks, such as SqueezeNet, GoogleNet, ShuffleNet, Darknet-53, and Inception-V3 with different Epochs, Learning Rates, and Mini-Batch Sizes to compare and evaluate the network's performance using confusion matrix. Based on the experimental findings, Inception-V3 has achieved the highest accuracy of 96.98%, as well as other evaluation metrics, including precision, sensitivity, specificity, and f1-score of 92.63%, 92.46%, 98.12%, and 92.49%, respectively.

**Keywords**—Transfer learning; deep neural networks; image classification; Convolutional Neural Network (CNN) models

## I. INTRODUCTION

The primary evolution of neural networks was stimulated by the desire to design a process that could imitate the human brain. The ability of conventional machine-learning approaches to explore natural data in its natural form was limited. Deep learning enables computational models with several processing layers to learn and represent data at multiple levels of abstraction, simulating how the brain receives and analyses multi-modal information, and so implicitly capturing intricate data structures [1]. A convolutional neural network (CNN) is one of the most popular deep learning models. It uses deep convolutional networks and non-linearity to discover local and spatial features, and patterns directly from raw data. As a result, a CNN learns features from data automatically, eliminating the necessity to manually extract them [2]. Image classification is a vital phenomenon in computer vision and other computer vision approaches, such as localisation, detection, and segmentation are built on top of it [3]. Deep neural networks (DNN) have recently been popular in the deep learning community for solving real-world issues, but the deep networks may face obstacles and hurdles throughout the training process, such as exploding/vanishing gradients and degradation [4]. The deep architecture presents the dedicated

concern of training a CNN from scratch, which needs massive computational power, a long training time, and a substantial amount of training data. The specificity of features rises as we progress from lower-level CNN layers to higher-level layers, until the last classification layer becomes profoundly task specific. The image features extracted by the lower-level CNN layers can be used to retrain the model for a completely different task, avoiding the need to start over [5]. In this case, all of the layers of a pre-trained CNN model can be employed as fixed feature extractors, with the exception of the final classification layer. Using the knowledge gained from earlier training, the final layer can be customised and retrained for a new task. When the depth of a network goes beyond the limit, it endures the degradation problem, which results in a decline in accuracy [6]. The internal covariate shift, which is the variation in the dissemination of the input data to a layer during training, is another matter of concern.

Transfer learning is a machine learning technique in which knowledge gained from one type of problem is applied to another similar task or domain [7]. CNN models are normally trained either from scratch or by applying transfer learning. Training from scratch involves a substantial amount of data to learn millions of parameters. Because a sufficiently labelled dataset is required for many applications, CNNs rarely train from scratch. Instead, a large-scale dataset is commonly used to pre-train a CNN, which is subsequently used as a fixed feature extractor or as an initialisation for other particular tasks [2]. The initial few layers of CNN models are trained to recognise task features. In the first layer, pre-trained models learn simple patterns like shapes and diagonals, then combine these components in successive layers to learn multipart features [8]. The models create meaningful constructs in the final layer by exploiting patterns learned from earlier layers. The final few layers of the trained network can be replaced and retrained with new layers for the target activity during transfer learning. Although fine tuned learning experimental studies need some learning, they are still much quicker than learning from the scratch [9], [6].

### A. Pre-Trained Deep Learning Architectures

The promotion of artificial neural networks (ANNs) is the deep neural network (DNN), which comprises numerous hidden layers between the input and output layers. A DNN is capable of expressing an object well through its deep architectures and excels at modelling complex nonlinear relationships [10]. In recent times, CNNs have played a critical role in image classification and object detection. In 1998

TABLE I. SUMMARY OF SELECTED PRE-TRAINED CNN MODELS

| Pre-Trained Models | Time | Depth | Layers | Image Input Size | Parameters |
|--------------------|------|-------|--------|------------------|------------|
| SqueezeNet [19]    | 2016 | 18    | 68     | 227-by-227       | 1.24 M     |
| GoogleNet [20]     | 2014 | 22    | 144    | 224-by-224       | 7.0 M      |
| ShuffleNet [21]    | 2018 | 50    | 173    | 224-by-224       | 1.4 M      |
| Darknet-53 [22]    | 2018 | 53    | 184    | 256-by-256       | 41.6 M     |
| Inception-V3 [23]  | 2016 | 48    | 315    | 299-by-299       | 23.9 M     |

LeCun et al. [11] proposed the first multilayer CNN, which is a convolutional network with seven levels that is simple to use, called LeNet-5. The layers of CNNs have become significantly deeper as GPU technology continues to advance. From 1998 to 2018, a number of CNN frameworks were developed, including LeNet [12], AlexNet [13], VGG 16 and VGG 19 [14], ResNet's Inception ResNet [15], ResNeXt, and other frameworks including PolyNet [16], DenseNet [17]. Transfer learning at a deep level instead of utilising traditional machine learning approaches that benefit from handcrafted features, CNN learns the most representative features from raw data automatically [18]. A variety of CNN architecture modifications with a rapid growth in the number of layers have recently been demonstrated. In this study, five pre-trained models, namely SqueezeNet, GoogleNet, ShuffleNet, Darknet-53, and Inception-v3 have been selected for the performance comparison and a brief summary is provided in Table I.

A system designer must incorporate their judgment and substantial feature engineering to resolve the question of what needs to be transferred. The challenge on how knowledge should be conveyed through is model selection and how to supplement it to enhance prediction performance [11]. When selecting a network to apply to a problem, different aspects of pre-trained models are important to consider. Network accuracy, speed, and size are the most important considerations. Choosing a network is usually a compromise between these factors. The primary goal of this study is to compare the network performance of the selected pre-trained models based on accuracy, speed, and size to help the selection of a suitable model for image classification.

The rest of the paper is organised as follows. In Section II, we give a description of the related works. In Section III, the methodology is described in detail together with the transfer learning steps used in MATLAB. In Section IV, the experimental results are shown, followed by the performance evaluation and performance comparison of the pre-trained deep neural networks. Finally, in Section V, we provide the conclusions and future work.

## II. RELATED WORK

In several disciplines, traditional machine learning algorithms have been widely accepted. Deep learning as well as image processing techniques have been used. With the introduction of transfer learning as a new learning framework [24], by fine-tuning pre-trained CNN models that have already been trained on ImageNet, similar results can now be obtained on deep learning applications. These models require a smaller number of training examples than developed models, which necessitate a significant amount of effort to acquire a big number

of training instances [25]. Transfer learning has been used in a variety of fields, including agriculture, where it has been used to identify weeds, classify land cover, identify plants, count fruits, and classify crop types. Transfer learning has become increasingly important in medical image processing, while pre-trained deep neural networks have made significant advances in the medical field, including the use of magnetic resonance imaging (MRI) scans, computerised tomography (CT) scans, and electrocardiograms (ECs) to detect life-threatening diseases, such as heart disease, cancer, and brain tumours. Shakil Ahmed et. al. [8] developed a transfer learning-based framework, which was tested against two well-known CNN models, Inception-V3 and VGG-16, using the Kimia Path24 dataset, which was created specifically for the classification and retrieval of histopathological images. Muhammed Talo [26] did the same kind of study with the same Kimia Path24 dataset. ResNet-50 and DenseNet-161, however, were used as well-known pre-trained CNN models. Rishav Singh et. al [11] presented a framework based on the concept of transfer learning to address and focus efforts on histopathology and unbalanced image classification, employing the widely used VGG-19 as a base model.

Samuel Kumaresan et. al. [18], suggested employing transfer learning to overcome the issue of a small dataset of welding defect X-ray pictures. They used two large pre-trained convolutional neural networks, VGG16 and ResNet50, to extract features from weld defect radiograph images that can be used to classify 14 different types of weld defects. The goal for Edna Chebet Too et. al. [6] was to fine-tune and explore the deep convolutional neural network for image-based plant disease classification. The models VGG 16, Inception V4, ResNet with 50, 101, and 152 layers, and DenseNet with 121 layers were assessed in an empirical comparison of the deep learning architectures. Jianping Ju et. al. [27] in an effort to address the actual demand for jujube fault detection, introduced a jujube sorting model in small data sets based on convolutional neural networks and transfer learning using the SE-ResNet50-TL and SE-ResNet50-CL models. Triplet loss function and Center loss function were used to replace SoftMax loss function and embedded SE module for the dry red date defect detection. Alper et. al. [28] recommended a new CNN architecture for the hazelnut variety classification and the model was compared with four pre-trained models: VGG16, VGG19, InceptionV3, and ResNet50. In recent years, the difficulty of layer selection when using transfer learning with fine-tuning has received substantial attention. With the widespread adoption of deep learning techniques, transfer learning with fine-tuning appeared to be the ultimate approach for transferring knowledge, allowing scientists and professionals to apply such deep learning methods more quickly to a variety of domain problems [29].

## III. METHODOLOGY

Classification has been an effective mission, and it is important in the subject of computer vision, which seeks to classify images into predefined classes automatically. Prior to the boom of deep learning approaches, a lot of effort was invested into constructing scale-invariant features, feature representations, and image classification classifiers [30]. These well-crafted qualities, on the other hand, work against objects in natural images with complex scenes, varying colour, texture, and illumination, as well as constantly changing positions

and view parameters. Researchers have been working on sophisticated ways to increase image classification accuracy for decades. When the large-scale image dataset ImageNet was formed in 2009, Feifei Li [31] created the great-leap-forward advancement of image classification. The information about dataset, learning environment, gradient, learning rate, epoch, and mini-batch size employed in MATLAB, and the steps of transfer learning used in this study are explained under the methodology in the subsequent sections.

#### A. Dataset

The CIFAR-10 [32] dataset has 32 x 32 colour images that are divided into ten classes, each with 5,000 training images and 1,000 test images. Among the ten classes, five classes have been selected for the experimental process. From the training dataset, 3,000 training images are selected for each of the five classes, which includes the list as shown below:

Selected Classes = ('bird', 'cat', 'deer', 'dog', 'horse');

The most widely used split ratios are 70:30; 80:20; 65:35; 60:40 etc., in which the sample size suits the nature of the problem and the architecture implemented. There is no fixed law for dividing training and test datasets when it comes to data splitting. Some scholars have traditionally used the 70:30 ratio to differentiate the datasets. As most widely used in MATLAB, the training set of images is split into training set and validation set by the 70:30 ratio.

```
[imdsTrain, imdsValidation] = splitEachLabel(imds, 0.7);
```

Besides that, image augmentation could be used at random on the training datasets with distinct values to help expand the dataset, preventing the network from overfitting and capturing the exact features of the training images. The following settings for image augmentation have been chosen, as indicated in most of the MATLAB examples: horizontal reflection, horizontal and vertical translation in the range [-30 30] pixels, and horizontal and vertical scaling in the range [0.9 1.1] with a random rate.

#### B. Learning of the Pre-Trained Networks

- Environment – The networks are implemented in MATLAB R2021a. The size of input images is adjusted to match the layers of various models.
- Stochastic Gradient Descent with Momentum (SGDM) – Gradient descent [10] is a popular neural network optimisation approach that can tackle a variety of trivial issues. When the training dataset is huge, however, the simple gradient descent method may use a lot of processing resources, making the convergence process slow. Simultaneously, because the gradient descent approach considers all of the training data for each calculation, it may result in overfitting. To resolve this challenging dispute, SGDM has been considered in this study. Momentum [33] is a commonly used acceleration technique in the gradient descent method whereby the convergence process can be accelerated.
- Learning Rate (LR) – When it comes to CNN training, LR is a crucial parameter. The LR is frequently

decreased by a factor of 0.1 or 0.5. In this study, fixed learning rates of LR-0.001 and LR-0.0001 have been chosen instead of reducing the LR by each epoch.

- Epoch – The complete pass of the training algorithm across the entire training set is referred to as an epoch. In this study, the selected epoch values are 10, 20, 30.
- Mini Batch Size – A mini-batch is a subset of the training set that is utilised to calculate the loss function's gradient and update the weights. Two batch sizes are selected as part of the experimentation process: 32 and 64.

#### C. Transfer Learning Flow in MATLAB

CNN's unique qualities, such as incremental feature extraction in subsequent layers, make it possible to use parts of a pre-trained model for a completely new task without retraining the entire network [34], [35]. The fundamental idea is to use the initial layers from a pre-trained model and just retrain the last few layers on new images. Transfer learning can be implemented by replacing the output layer with a new classifier and then, selecting one of the two approaches:

- Fixed feature extraction by freezing the initial layers or other layers of the convolutional base.
- Fine-tuning the weights and other parameters to retrain one or more convolution layers.

The entire experimentation process of image classification with the dataset CIFAR-10 has been done with MATLAB. The CIFAR-10 dataset is downloaded and provided as input data to the pre-trained model. Prior to loading the data, the entire dataset is divided into three main datasets comprising the training, validation, and testing datasets. To get good performance, deep neural networks require a vast amount of training data. Image augmentation, such as reflection, translation, and scaling, are used to increase the performance of deep networks in order to develop an effective image classifier with little training data. The pre-trained network is loaded, and the final layers are replaced with a new classification layer and a fully connected or convolutional layer. To fine-tune the model, the initial layers of each network are frozen and other parameters like the pool size, stride etc., are updated. The freezing layers are chosen according to the depth, size, and number of layers of the pre-trained network. Afterwards, the training process is initiated, followed by the classification of the validation, and test images. Finally, the classification accuracy is computed and performance of the networks are evaluated using confusion matrix. The transfer learning steps are illustrated in Fig. 1 which is then followed by the detailed steps performed in MATLAB to implement the entire transfer learning process.

First, training and validation sets are used to perform the training process to make sure that we have the best possible training model in the study. By checking the accuracy and loss of training and validation sets, we will be able to control the model's performance during training. Thus, the best possible model can be obtained by fine-tuning at the end of the training process. The results are evaluated by using the test set and these procedures were applied for each of the five models used in the study. All parameters are used in the same way for each model and the models used were evaluated using confusion

**Confusion Matrix**

- 15) `cm = confusionmat(trueLabels, predictedLabels);`
- 16) `cm_chart = confusionchart(trueLabels, predictedLabels);`

**Reset GPU**

matrix to find out the performance of the classifier. The performance evaluation used in the study and the comparison on the performance of different models are presented in Table VIII and Table IX in the following section.

**IV. RESULT AND DISCUSSION**

The whole experimental process was carried out with a laptop and the experimental setup including the hardware, software, and its specifications are mentioned in Table II.

**A. Experimental Results**

In the training process, each iteration involves a gradient estimation and a network parameter update. Training can be tracked in MATLAB to determine how quickly the network's accuracy improves, as well as if the network attempts to overfit the training data. Following the completion of the training, the results can be inspected to see the finalised validation accuracy and to discover how the training was proceeded by plotting the key metrics, which include training accuracy, validation

such as Table III-SqueezeNet, Table IV-GoogleNet, Table V-ShuffleNet, Table VI-Darknet-53 and Table VII-Inception-V3, including the hyperparameters such as mini-batch size, learning rate (LR), epoch as well as the validation accuracy and testing accuracy with the elapsed time to complete the training progress. The experimental findings made it possible to emphasise the following outcomes,

- Epoch-30 was chosen for further comparison based on the experimental findings, and the results were quite promising.
- When it comes to mini batch sizes, batch 32 has shown to be more promising than batch 64. Also, with Darknet-53, batch 64 displayed an error due to a lack of RAM (out of memory); hence batch 32 was chosen for further evaluation and comparison.
- With the exception of Darknet-53, LR-0.001 yielded favourable results when compared to LR-0.0001. For the subsequent studies, LR-0.001 findings were chosen for the other four networks, and LR-0.0001 results for Darknet-53.
- Out of the five pre-trained networks, Inception-V3 produced the best results, with the most layers, while SqueezeNet produced the unpleasant results, with the

fewest layers.

**B. Performance Evaluation using Confusion Matrix**

The ratio between the number of right predictions made and the total number of predictions produced is known as classification accuracy [18]. The learning performance of the pre-trained deep neural networks is assessed using a standard confusion matrix method. A confusion matrix is a summary of classification problem prediction outcomes. It provides insight into correct and incorrect classifications, as well as the types of errors made, for each specific class. In image classification, the confusion matrix is primarily used to compare the classification to the actual measurement value in order to intuitively and accurately describe the accuracy of model classification [36]. The confusion matrix can be used to directly identify the performance of deep CNN models, and the evaluation metrics are listed below:

$$ACC = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

where ACC stands for accuracy, which is defined as the percentage of correctly classified samples when a measured value is compared to a known value.

$$PREC = \frac{TP}{TP + FP} \quad (2)$$

where PREC is the precision used to determine the model’s ability to correctly classify positive values.

$$SENS = \frac{TP}{TP + FN} \quad (3)$$

where SENS is the sensitivity, also known as recall, which is the frequency with which the model correctly predicts positive values. It’s used to figure out how well the model can predict positive values.

$$SPEC = \frac{TP}{TN + FP} \quad (4)$$

where SPEC denotes the specificity with which the model’s ability to predict negative values.

$$F1 - Score = \frac{2 * PREC * SENS}{PREC + SENS} \quad (5)$$

whereas the harmonic mean of the precision and sensitivity is the F1-score, also known as the balanced F-score or F-measure.

In MATLAB, the predicted class is represented by the rows, while the true class is represented by the columns. The diagonal cells relate to accurately classified observations. The off-diagonal cells correspond to observations that were inaccurately classified. The number of accurately and inaccurately classified observations for each predicted class are displayed as percentages of the total number of observations in the respective predicted class in a column-normalized column summary. The number of accurately and inaccurately classified observations for each true class are displayed as percentages of the total number of observations for that true class in a row-normalized row summary.

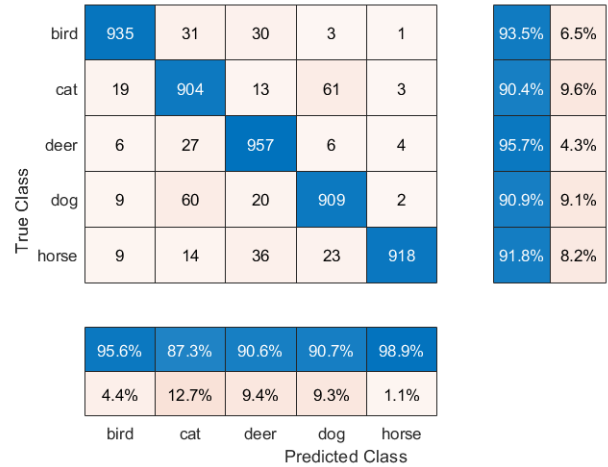

Fig. 4. Confusion Matrix of Inception-v3 - LR-0.001.

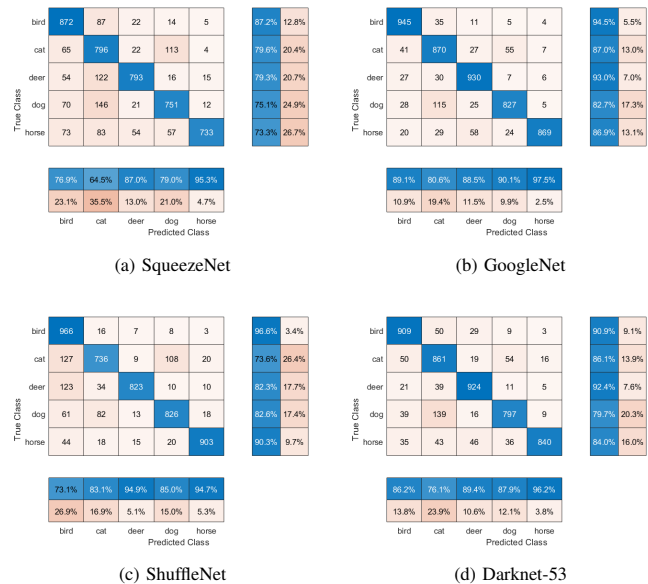

Fig. 5. Confusion Matrices for LR-0.001|Batch-32.

The Fig. 4 demonstrates the confusion matrix for the pre-trained network Inception-V3 and the Fig. 5 represents the confusion matrices for networks such as (a) SqueezeNet, (b) GoogleNet, (c) ShuffleNet and (d) Darknet-53 for the mini-batch 32 and LR-0.001. The Fig. 6 describes the confusion matrix for the pre-trained network Darknet-53 and the Fig. 7 represents the confusion matrices for networks such as (a) SqueezeNet, (b) GoogleNet, (c) ShuffleNet and (d) Inception-V3 for the mini-batch 32 and LR-0.0001. When it came to learning rates, among the selected five pre-trained networks LR-0.0001 was outperformed by LR-0.001. Under LR-0.001, almost all of the networks performed well in classifying the images and prediction, however under LR-0.0001, most of the networks struggled to predict the positive values. Based on the confusion matrices, the following inferences were discovered,

Fig. 6. Confusion Matrix of Darknet-53 - LR-0.0001.

Fig. 7. Confusion Matrices for LR-0.0001|Batch-32.

- In terms of LR – 0.001, Inception-V3 outperformed the rest of the pre-trained networks in the model’s ability to predict positive values followed by GoogleNet and Darknet-53. With Inception-V3, all five classes were correctly classified with an overall accuracy of above 90%. Among the classes deer class made the highest score whereas 957 out of 1000 images were classified correctly. When it comes to prediction, the horse class scored high of correctly predicting 98.9% of the positive values. For all the five classes, GoogleNet scored 80% or higher, with the horse class getting the highest prediction score, predicting 97.5% of positive values. Darknet-53 scored the highest among the networks a prediction score of 96.2% in the horse class but got a very least score of only 76.1% in the cat class. ShuffleNet had a mediocre

| ShuffleNet                    | 93.02        | 82.76        | 82.54        | 95.63        | 82.57        |
| <b>Darknet-53</b>             | <b>94.70</b> | <b>88.29</b> | <b>86.76</b> | <b>96.69</b> | <b>86.70</b> |
| Inception-V3                  | 93.54        | 84.55        | 83.86        | 95.96        | 83.91        |

performance, scoring 94.7% in the horse class and a very low prediction score of 73.1% in the bird class. SqueezeNet had the lowest classification performance of all the networks, with a prediction score of 95.3% in the horse category and 64.5% in the cat category.

- In terms of LR – 0.0001, Darknet-53 outperformed the rest of the pre-trained networks in the model’s ability to predict positive values followed by Inception-V3 and GoogleNet. If compared with LR 0.001, Darknet-53 scored the maximum classification accuracy under LR 0.0001 with the highest score of 97% among all the networks. With prediction, scored the highest of 98.9% in horse class and 75.9% in cat class. The bird class received the highest classification score of 93% in Inception-V3, with 930 out of 1000 images correctly classified, whereas the model struggled to predict the positive values of the bird class, accounting for 77.1%. In GoogleNet among the five classes, horse class got the highest prediction score of 91.1% and cat class got the lowest score of 81.7%. ShuffleNet had an average classification compared to other networks whereas horse class got the highest prediction score of 91.5% and cat class got the lowest score of 76.1%. SqueezeNet had the lowest performance among all other networks with the lowest prediction score of 66.0% for the bird class whereas got the highest score of 90.7% for the horse class.

The results of the classification metrics evaluation of the five pre-trained networks for both the Learning Rates of 0.001 and 0.0001 are summarized in Table VIII. According to the evaluation results it is evident that the networks performed well on the LR-0.001 in compared to LR-0.0001 except for Darknet-53. Darknet-53, in compared to the other four networks, showed promising results with a LR-0.0001, whilst the other networks’ performances were on the decline.

### C. Pre-Trained Networks Performance Comparison

The performance comparison of the five pre-trained networks, encompassing both LR, is shown in Table IX. Based on the performance comparison of the pre-trained networks, Inception-V3 has achieved the highest accuracy of 96.98%, as well as other metrics such as precision, sensitivity, specificity,

TABLE IX. PERFORMANCE COMPARISON OF THE PRE-TRAINED NETWORKS

| Pre-Trained Models  | ACC (%)      | PREC (%)     | SENS (%)     | SPEC (%)     | F1-Score (%) |
|---------------------|--------------|--------------|--------------|--------------|--------------|
| SqueezeNet          | 91.56        | 80.53        | 78.90        | 94.73        | 79.16        |
| GoogleNet           | 95.53        | 89.16        | 88.82        | 97.21        | 88.85        |
| ShuffleNet          | 94.03        | 86.15        | 85.08        | 96.27        | 85.13        |
| Darknet-53          | 94.70        | 88.29        | 86.76        | 96.69        | 86.70        |
| <b>Inception-V3</b> | <b>96.98</b> | <b>92.63</b> | <b>92.46</b> | <b>98.12</b> | <b>92.49</b> |

and f1-score. The other networks produced somewhat lower results than Inception-V3, but altogether, all five pre-trained networks attained an accuracy of 90% or higher.

Transfer learning using a pre-trained CNN model is a better option for classification with the availability of only small datasets. In many of the previous studies, different pre-trained CNN models were compared using medical images and other relevant datasets. The results showed that the performance of the pre-trained models were mainly based on the dataset. With the limited computing resources, only five classes of the benchmark CIFAR-10 dataset are selected, but still managed to accomplish the aim of this study in the selection of a suitable model for image classification, Inception-V3. Even though one of the CNN model darknet-53 produced an error (out of memory) over batch-64, the current study shows that pre-trained networks with the highest number of layers (Darknet-53 and Inception-V3) provided the maximum scores in the prediction of classes with best accuracy. The current study proves that transfer learning can be useful for various computer vision problems, especially for the ones with small datasets. With the availability of proper datasets, deep CNN models have the capabilities to take medical imaging technology further, providing a higher level of automation in medical imaging, including image processing and analysis.

## V. CONCLUSIONS

In this study, we experimented with the performance of five pre-trained networks, such as SqueezeNet, GoogleNet, ShuffleNet, Darknet-53, and Inception-V3 with different epochs, learning rates, and mini-batch sizes. We performed the entire training process in MATLAB R2021a where we can view the complete network architecture of the CNN models, which helped us in the selection of freezing the initial layers. The final layers of the pre-trained CNN models are replaced either with a fully connected layer or convolutional layer and a new classifier replacing the classification layer. The initial layers are frozen to keep the weights intact and after the training, each model was evaluated using a confusion matrix. The experimental findings show that each pre-trained network produced different results with different hyper-parameters in the prediction of positive values. The results demonstrate that all the five pre-trained networks yielded promising results over the mini batch size-32, and epoch-30. In terms of LR, Darknet-53 delivered impressive results with LR-0.0001, achieving a maximum accuracy of 94.70%. Overall, the Inception-V3 model with LR-0.001 achieved the highest accuracy of 96.98%, as well as other evaluation metrics including precision, sensitivity, specificity, and f1-score of 92.63%, 92.46%, 98.12%, and 92.49%, respectively.

## VI. FUTURE WORK

We presented a transfer learning-based performance comparison between the selected five pre-trained networks in this study. The freezing of network layers was selected based on the network depth, size, and number of layers. Only the initial layers were frozen; however, different sets of layers can be frozen. In the future, focus will be given to freeze multiple set of layers and to compare the results of frozen and non-frozen layers of the pre-trained networks. For further evaluation and comparison, different datasets and other pre-trained deep neural networks can also be explored.

## ACKNOWLEDGMENT

The authors are grateful to Universiti Teknologi Malaysia (UTM) for supporting the work with cost center number Q.K130000.2656.17J22.

**Abstract**—In recent years, augmented reality is playing an important role in the world of mobile technology, since it is a way to facilitate the teaching-learning processes, this easy teaching-learning process generates a great contribution in companies, either creating opportunities or changing the way in which companies approach and interact with their end customers, this can mean a remarkable growth of the organization, that is why in this work an augmented reality prototype has been made using the methodology Scrum at the University of Sciences and Humanities of Lima-Peru, but with a focus on the nursing career. Knowing that the problem is the limited learning that students acquire in the classrooms, for which, we want to make use of augmented reality, so that this improves the form of education that is provided to university students. The result obtained, from developing the case study, was an augmented reality prototype for the improvement of education at the University of Sciences and Humanities of Lima-Peru, which shows a virtual model (it depends on the image shown), able to interact with the user, making it attractive and motivating for the student, this prototype was achieved, using Unity (3D development platform, Vuforia (augmented reality software development kit), Microsoft Visual Studio (integrated development environment), the Scrum Methodology (Scrum Pillars, Product Backlog, Product Backlog Estimation, Speed, Backlog Prioritization and Sprint Planning) and the C# Language (C Sharp).

**Keywords**—Augmented reality; teaching; education; scrum; unity

## I. INTRODUCTION

The use of the increased reality, in the world, is one of the most modern technologies, because it is considered to be a technique that offers privileges in education, giving a high potential to this, making the learning more attractive to the students. According to the [1] that is carried out, using the increased reality, the project offers the opportunity to work with the students, to motivate them and administer them knowledge through the improvement of the teaching of the real world, with a series of virtual objects within this, creating this year, learning experiences. According to this, [2], communications between teachers and students, which, when performing activities together, serves teachers to study as students acquire knowledge in the classroom, but only, providing them with a limited vision of learning, so this study, makes a useful contribution to existing knowledge.

Likewise, in research [3], about learning, it was more likely more than 70% of students identified learning experience, as a preferred method of learning. And the research [4] has shown how it is better learned and participating in "real" tasks in practice, instead of teaching theory, this can be developed through the teaching of cognitive processes such as perception, attention, memory, and thought. This is the case, that learning [5] experience requires a repetitive process, whereby ideas are applied and tested as feedback is received for improvement. According to China [6], reports in its studies on the use of increased reality tools to develop the oral competition of students in language learning, where data was collected, recorded oral presentations, observations, and comments from students.

These results revealed, which, with the use of the augmented reality tool, obtained a higher score, which when they have not augmented reality tools, these increased reality tools, showed students a facility in learning. In Peru [7], There is a problem with education, that is why the incorporation of augmented reality is an alternative for the improvement of some concepts, in the way that teachers teach students, to generate, susceptible to use new technologies in the field of teaching, giving positive results, since the increased reality, as a complement to teaching, will be beneficial. Therefore, the importance of this work lies in the fact that, slowly, but steadily, they allow augmented reality to be established among education professionals as a strategy that can transform the education of students.

All this was done through the use of the Scrum methodology, where the Pillars of Scrum were used so that the methodology is effective at the time of implementation, the Product Backlog where the user stories were placed, Estimating the Product Backlog where each story was scored of user, Velocity where it was established how many sprints were carried out, Backlog Prioritization where the user stories were ordered by priority and Sprint Planning where the development of each sprint was planned to develop the augmented reality prototype.

The objective of this work is to make a prototype of augmented reality under the Scrum methodology to carry out a pilot with the Nursing career.

Section II explains the literature review, Section III the methodology, Section IV the results and discussions, and

finally Section V explains the conclusions and future work.

## II. LITERATURE REVIEW

This section explains the fundamental material for the preparation of this paper.

### A. Background

A survey on augmented reality is approached, it tells us about the progress that augmented reality has had, showing us that augmented reality is compatible with many technologies [8]. It also shows us successful designs and applications of augmented reality in education, architecture and marketing aspects, in addition to dealing with important topics based on augmented reality such as augmented reality screen technologies (sensory screens), augmented reality development tools (Software frameworks, development tools and creation tools), augmented reality interaction technologies (Browsers and interfaces), interface patterns and evaluations of virtual reality systems (Methods).

This article [9] provides us with a wide range of various software development kits (SDKs) related to augmented reality, such as Metaio, Vuforia, D' Fusion, Wikitude, ARToolKit and AR-media; In order to compare them (by license, by platform, by markers and by the ability to superimpose) according to the qualities that each one of them has, it also shows us the differences between virtual reality and augmented reality, where its details are detailed. more relevant differences so that the reader can differentiate them quickly, in addition this article emphasizes the fact that mixed reality is the sum of augmented reality with virtual reality, and finally shows us how augmented reality works, teaching it in a bold way so that in this way its operation can be fully understood.

As for learning, this article [10] presents augmented reality focused on education, says augmented reality can be found in different areas, but in itself it will be more focused on education, provoked and thus generating unique environments; it also shows the uses, advantages, characteristics and effectiveness of augmented reality; He tells us about the analysis they made of augmented reality, following classifications such as countries, subject matter, type of augmented reality and research methods. To conclude, it infers us that there are numerous educational applications regarding augmented reality and that they are used in classrooms as well as abroad.

Another field in medicine, this article [11] mentions augmented reality but applied to surgery, it mentions that augmented reality can give efficiency and safety in surgical training; It also shows a scheme with basic principles of augmented reality as a basis for the reader to understand clearly and concisely "What is augmented reality?", this article mentions that the augmented reality system provides data in real time to the surgeon, Emphasizing the projection of augmented reality that can be given through the screen of computers, tablets, projectors, cameras and smart glasses, the article ends by making it clear that augmented reality is capable of revolutionizing the field of surgery.

To finish the background of the literature review section, the following article [12] will be addressed based on a survey on the applications of augmented reality, this article gives us

to understand that augmented reality is capable of improving human perception by mixing objects physical of artificial ones; It also gives us an apex of the initial applications that augmented reality addressed, these being medicine, manufacturing and repair, annotation and visualization, robot route planning, military applications and finally entertainment, as well as those initial applications Over time applications such as tourism, architecture, cultural heritage (Museums) and education were added; To finish this article, mention that augmented reality is related to miniaturization.

### B. Related Work

In this article [13], the use of mixed reality for the development of an Augmented Paper Map (APM) system was observed, the two authors who developed this article report Scrum, as the methodology that helped them to achieve the objectives of their article, explaining a bit about the roles and artifacts that were useful for the application of this methodology, they also express the design philosophy they used, which is that the design is user-centered, so that in this way the final product complies with the needs of these (Users), and thus achieve the greatest satisfaction with the minimum effort on the part of the user. It also tells us about the activities that they had to develop and carry out during the course of the article, as well as the exploration, analysis and evaluations that they had to develop for the development of the Augmented Paper Map (APM) system.

The mention of games is observed, it tells us drastically how the game is encompassed in the lives of human beings, it also mentions mixed reality but in the approach of games [14], it tells us like the previous article the use of Scrum , but focusing on the MVCE architecture (Model-View-Controller-Environment), which is nothing more than the MVC architecture (Model-View-Controller), but adding an "Environment" component. It also highlights the design of a mixed reality, but based on the independence of the device, the adaptive presentations and the updates of the context with respect to the game, as well as its philosophy of design centered on the user, which achieves a better experience for the game. (User) only with minimal effort.

As the clear examples of the application of the Scrum methodology, now there is a combination of the Scrum methodology with the extreme programming methodology (XP), which is focused on virtual reality. This article [15] shows us the use of a video game engine known as Unity, the Scrum plus XP combination to use it as a methodology as mentioned before and the objective of the article, which is the creation of virtual reality for the training of technicians and industrial operators. They focus on using virtual reality as an economical alternative to using and damaging expensive industrial equipment, so their objective is focused on two scenarios: instrument recognition activity (HART Device) and training activity (Installation, connection, basic and advanced settings).

Virtual reality focused on agile development, this article [16] shows the explanation of the use of the Scrum methodology, as well as the explanation of the use of the extreme programming methodology (XP), the principles of the agile manifesto are also covered, the life cycle of Scrum and extreme

programming (XP), the systems developed based on virtual reality, the application of agile methodologies in virtual reality and to finish they propose a process of development of virtual reality systems based on eight activities main (Definition of user stories, architectural peak, elucidation of interactivity requirements, iteration planning, peak, development, integration tests and customer tests).

### III. METHODOLOGY

In this section, the methodology that was carried out was explained, in the augmented reality prototype using Unity, the Scrum methodology was carried out, for the improvement of education at the University of Sciences and Humanities in Lima-Peru, thus achieving the objectives, with support of this methodology [17] that is shown in Fig. 1.

Fig. 1. Scrum Agile Methodology for the Augmented Reality Prototype.

As mentioned the prototype was made in Unity, which is a 3D development platform, to develop a variety of simulations, in games (developers of games), AEC (architecture, engineering, and construction), cars, and cinematographies [18]. And it is used, Vuforia (augmented reality software development kit), which is, one of the most popular to introduce the increased reality, Vuforia (augmented reality software development kit) uses vision technology to recognize and track images in real-time.

The increased reality based on Vuforia (augmented reality software development kit), takes the display of the device screen, as a "medium" to connect it to the world of the increased reality. What it does, is to show the images of the real world in the Camera of the corresponding device, adding the virtual objects 3D, in the images of the real world, what it does, that is a combination, of a feeling of immersion towards the world of the increased reality, also, to develop the programming in the prototype will be used the Microsoft Visual Studio integrated development environment, using programming language C# (C Sharp) [19].

#### A. Scrum

Scrum won't tell you exactly what to do, what it means, that can be done differently, as your merits, that is why the "power" is in us, to adapt it to a specific situation, and is here, where everything starts.

1) *Pillars of Scrum:* In the Fig. 2 the three pillars (transparency, inspection, and adaptation) that sustains SCRUM, the first pillar, the transparency, gives a clear vision to all the interested parties of the project, customers, users, sponsors, investor, among others. It tells us that clear agreements must

be reached on what must be delivered or informed to the interested parties, being thus, trancing and sincere, of "how much has been advanced?", "What is it will be achieved?" and "What will not be achieved?". Inspection, the second pillar, is where the project checks, to know if the established goals are being fulfilled and if there are problems or any deviation, to be able to correct them at the time.

In Scrum there are meetings such as the diary scrum (it is done when starting the day), or the retrospective (checking at the end of each sprint), this is done to know "What has been done?", "What problems have been?" and "What is going to do today?" That's why it can be said that in Scrum if there is a "constant inspection". Adaptation, the third pillar, means those that change is welcome, and this is so, to be able to minimize the problems that are generated in the future so that in this way, continue to provide the maximum value to the client, to the business, and/or to what is developing [20].

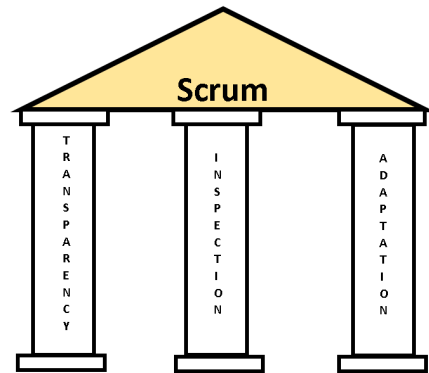

Fig. 2. The Three Pillars of Scrum.

2) *Project Charter:* Table I shows the Project Charter, which describes the objectives to be achieved in the project, it is here, where it is defined that the agile methodology is used., specifying the acceptance criteria for this one. In this Project Charter, the following questions are answered (Who?, What?, Where?, When?, Why? and how?), And is it here, where you can use the tool known as "Elevator Pitch", to perform the Project Charter [21].

TABLE I. PROJECT CHARTER

| For             | Target customer                   |
|-----------------|-----------------------------------|
| Who             | Need (Opportunity or problem)     |
| He              | Product / Service name            |
| What is it      | Product Category                  |
| For             | Key benefits / Reasons to buy it  |
| Is not equal to | Main competencies or alternatives |
| We              | Definition                        |

3) *Product Backlog:* Fig. 3 shows us the backlog prioritized, this is achieved, when performing meetings with the owner of the product, and thus generate the stories of users and prioritized (functionalities, epic, user stories), in addition to focusing on business terms, you are to be built in a short time, conducting valuable features for customers [22].

Fig. 3. Product Backlog.

4) *Estimating the Product Backlog:* Fig. 4 shows us how it would be an estimate of the Product Backlog, indicating its story points (sp), stories, must be reasonable, and these estimates can be generated with various tools, such as the size of your shirts, analogous estimate, Delphi and/or Planning Poker [23].

Fig. 4. Estimating the Product Backlog.

5) *Velocity:* In Scrum the speed is used, to define how many Sprints have, and this is, in function to speed, which is the stories of stories (necessary effort, with which the user stories were estimated) that a development team performs in each sprint. This speed may vary in each sprint, as shown in Fig. 5, wherein the chart of columns grouped in 3D, observed that the speed varies or changes by Sprint [24].

Fig. 5. Estimate Sprint Velocity.

6) *Backlog Prioritization:* In Fig. 6, the map of the story is displayed, which serves to prioritize the Product Backlog, the structure of this is the same as that of the Road Map, where its columns are the software or project modules, and where the first row is the backbone (most importantly, if this is not done. No system), the second row is the walking skeleton (Minimum viable product, which means, the most valuable functionality for the user, and the one that will give it to the system), and the following rows range from the most important user stories, at least important [25].

Fig. 6. Map of the Story.

7) *Sprint Planning:* In Fig. 7, it is observed that the structure of the Road Map [26], is the same as that of the map of the story, this is the map of the story sorted by delivery (Sprint set) or by Sprint (1 to 4 weeks), according to one establishes it, and is used to plan the Sprint. After performing the sprint planning, the user stories of the Sprint are selected to work, you are user stories will be developed, in a format of user stories, already established by the person in charge, as shown in Fig. 8, which has fields such as, the developer, the estimated time, the description of the user story, tests, tasks and finally the prototype; this format may vary [27].

Fig. 7. Road Map.

| USER STORY           |               |
|----------------------|---------------|
| Number:              | Story name:   |
| User:                | Estimate:     |
| Developer:           |               |
| Description:         |               |
| Acceptance criteria: |               |
| Tests:               | Define tasks: |
| Prototype            |               |
|                      |               |

Fig. 8. User Story Format.

## B. Tools and Programming Language to Develop the Prototype

In this section, it was detailed, the tools to be used to develop the prototype of increased reality focused on improving teaching at the Universidad de Ciencias y Humanidades, as well as the programming languages to be used.

1) *Unity*: Unity is a 3D development platform, which gives us everything we need to be able to develop a variety of functionalities, such as simulating the laws of physics, adding animations, adding sounds and programming; This platform supports the C# (C sharp) programming language, in addition to having an Assets (resource) library known as the Asset Store of Unity, where you can find textures, animations and models ready to use in Unity [28].

2) *Vuforia*: To introduce the augmented reality, Vuforia (augmented reality software development kit) was used, since this uses vision technology to recognize and track the images in real-time, taking the display of the screen of the devices as a "medium" to connect it with the world of the increased reality. Vuforia (augmented reality software development kit). It serves us to generate a license key, which will help us load the database created in Vuforia (augmented reality software development kit) in Unity, to generate the augmented reality [29].

3) *Microsoft Visual Studio*: It is an integrated development environment (IDE) that supports several programming languages (C++, C#, Visual Basic .Net, F#, Java, Python, Ruby and PHP), this IDE gives developers the ability to create websites (Collection of web pages); Knowing that this IDE includes the C# (C Sharp) programming language, this is beneficial for this article, since the C# (C Sharp) programming language was used for the development of the augmented reality prototype [30].

4) *C#*: For the development of this augmented reality prototype, the programming language C# (C Sharp) was used, this programming language C# (C Sharp) can be used in several integrated development environments (IDE), such as Microsoft Visual Studio, SharpDevelop, QuickSharp, xacc.ide, MonoDevelop, and Xamarin Studio (XS); Since this programming language is compatible with Unity, this was the one that was used to give interactions of the "models" with the user, to achieve a kind of "communication" between the prototype and the user [31].

## C. Development of the Methodology

According to the methodology mentioned above, and the processes that were detailed in it, the development of the prototype will be implemented, based on the increased reality for the teaching of the courses of certain professional schools of the Universidad de Ciencias y Humanidades.

1) *Product Backlog*: In this section can observe the user stories that were developed to develop the prototype:

- User Story 1: As the director, I want to visualize a model that is related to a university course to be able to better explain the class.
- User Story 2: As the director I want to visualize multimedia content that is related to a university course to convey knowledge to students.

- User Story 3: As the director I want the prototype to be used in smartphones to have quick access to it.
- User Story 4: As the director I want the prototype to be interactive with the user to improve the education process.

2) *Estimating the Product Backlog*: To estimate the stories of users who were placed on the product stack (Product Backlog), a technique known as planning poker is going to be used, but not the planning poker is known as such, but a variant of it is, which works with the Fibonacci Sequence, which will be explained below. The Planning Poker has about eight "cards" (1/2, 1, 2, 3, 5, 6, 7,  $\infty$ ), without counting the "card" of doubt and rest, while the variance of the planning poker that goes from hand with the Fibonacci Sequence works with ten "cards" (0, 1/2, 1, 2, 3, 5, 8, 13, 21,  $\infty$ ), which will help us give you a "score", to each user story. The user's stories were beginning to be story through story (necessary effort), using the variation of Planning Poker, who works with the Fibonacci Sequence, was taken as a reference The user story that it is less than to make, making a "score" of "2" story points (necessary effort) and thus continue to find the estimates of the remaining user stories.

3) *Determination of Speed*: Here it is defined, how many sprints will be done, for this, first a "10" speed was determined, without forgetting, that each Sprint has user stories and these are in turn, they have "activities", and these "activities" are expressed in time (hours), which cannot exceed 4 weeks, since that deals with the agile methodologies, which each Sprint is completed from 1 to 4 weeks. After that, the sum of the story points was divided (necessary effort) of the user stories that were placed in the Product Backlog, between the certain speed which originated us "2.8", but when rounding it gives us "3", which means that for the prototype of this work have "3 Sprint". At the beginning of the first sprint, it was started with a speed of "10", which has a sum of "13" story points (necessary effort), and then, as it was advanced in the Sprint, this speed was changing, reaching the second Sprint, with a speed of "7", and with a sum of points of story (necessary effort) of "7", already in the last of the Sprint, the third Sprint, the speed was maintained in "7", and with a total amount of story points (necessary effort) " 8 ".

4) *Prioritizing the Backlog*: In this section, the backlog is prioritized, depending on the value given to the business, this is where, use the tool known as the map of the story, to generate the prioritization of the backlog. This map of the story, gives us an overview of "What is to do first?", and "What is to do after?". In the development of the map of story, it began, with the backbone that is the first "row" of the map of story, where it was placed, the essential user stories (as the director I want to visualize a model that is related to a course of the university to be able to better explain the class, as the director I want to visualize a multimedia content that is related to a course of the university to transmit knowledge to the students), to give improvement to education, then on the second "row", that of the walking skeleton was placed, the user story that gives the most valuable functionality for the user (as the director I want the prototype to be interactive with the user to improve the process of education), to end this section, in the last "row" remained the remaining user stories, ordered more important,

unless important (as the director I want the prototype to be used in smartphones to have quick access to it).

5) *Sprint Planning*: To plan the Sprint, the technique known as road map was used, as mentioned, in the methodology of this work, could be said that the path of the product, is originated from the map of the story. To start with this, the map of the story is taken, and starts to choose from, that user stories that was planned by Sprint.

6) *Sprint Backlog*:

- Sprint 1: In the first Sprint, as mentioned in the section of the speed determination, it was started with a "10" speed, making the user stories corresponding to this (as the director I want to visualize a model that is related to a course of the university to be able to better explain the class), for which, Unity is used, which is a 3D development platform, and Vuforia (augmented reality software development kit), to introduce the augmented reality, to which you ensemble the renovated reality, since this, uses vision technology to recognize and track the images in real-time, taking the visualization of the screen of the devices as "Medium" to connect it with the world of the increased reality, finally for this Sprint used web platforms used as free3d, to find and download 3D models, and find and download 3D models. In the first Sprint, in summary, what was done, was that the virtual 3 "objects" were added, to the 3D development unit platform, modifying the "object", since some of the components of the "object", not use it, it should be highlighted, that this modification was done in Unity, and the result of this, can observe it in Fig. 9.

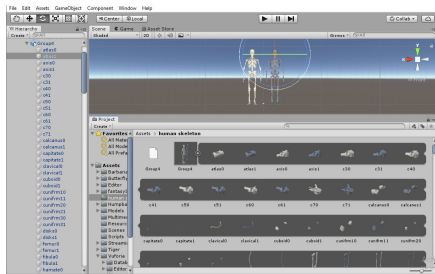

Fig. 9. Sprint 1 - User Story 1.

- Sprint 2: In the second Sprint, as mentioned in the section of the determination of the speed, it was begun with a "7" speed, making the user stories corresponding to this (as director I want to visualize a multimedia content that is related to a course of the university to convey knowledge to students, as director I want the prototype to be used in smartphones to have quick access to it), for which, Unity, Vuforia (augmented reality software development kit) was used and videos. To start with the second Sprint, in summary, what was done, was that the videos were added to 3D objects that can be created in Unity, the result of this can be seen, in Fig. 10, also, Unity (3D development platform) was used, so that the prototype can be used in smartphones, as can observe, in Fig. 11.

Fig. 10. Sprint 2 - User Story 2.

Fig. 11. Sprint 2 - User Story 3.

- Sprint 3: In the third and last sprint, as mentioned in the section of the determination of the speed, it remained with a speed of "7", making the user stories corresponding to this (as the director I want the prototype to be interactive with the user to improve the process of education), for which, Unity, Vuforia (augmented reality software development kit) was used, videos and the Microsoft Visual Studio integrated development environment. In the third, and last sprint, in summary, what was done, was that the Microsoft Visual Studio development environment was used to program, using programming language C# (C sharp), added this, to videos and models, to achieve that both the video and the model are interactive with the user, the result of this, can observe it in Fig. 12.

7) *Sprint Review*: This meeting was made at the end of each Sprint, to check how the objectives are being developed, it is meeting one hour by Sprint. Here what was done is to review the progress to reach the prototype, identified what was achieved, as well as what was not achieved, and is here where the operation of the end is shown in the Sprint.

8) *Sprint Retrospective*: This meeting, was made to give improvements to the following Sprint as it was moving forward, it should be noted, that this meeting was held after the Sprint Review with a duration of an hour, and is here where some questions were made ("worked on the last Sprint?", "What will be improved in the following Sprint?" and "What problems have been had in the progress of the development of the prototype?"), and at the end of the recommendations, the improvement was given to the following Sprint.

Fig. 12. Sprint 3 - User Story 4.

#### D. Testing

This section shows the survey administration software known as Google Forms, which can be seen in Fig. 13, where a survey was carried out among the students of the Faculty of Health Sciences of the Professional School of Nursing, in the It shows four short answer questions which are "What is your opinion about virtual reality?", "Would you like to visualize through the Smartphone 'objects' in 3D dimension?", "Are you likely to use this application?" and "Does its implementation seem correct?"; as well as a box question which is "For what course would you like this application?" This survey is key to the objective proposed in this paper, since the implementation of the prototype is focused on improving the teaching of the University of Sciences and Humanities, therefore, the opinion of the students cannot go unnoticed, since These are the ones that will handle the application, since this "application" is still a prototype, this does not evade the importance of the student's perception of virtual reality, because in the end it is for the student to feel satisfied with this implementation versus education, and thus goal-focused improvement is achieved.

Here is the before and after obtained from the Human Anatomy course, as shown in Table II, in the question "From traditional to automated", "From normal teaching to remote teaching" and "Contribution to the nursing career".

TABLE II. BASE LINE (BEFORE - AFTER)

| Before human anatomy course                | After human anatomy course                                            |
|--------------------------------------------|-----------------------------------------------------------------------|
| Traditional                                | Automated                                                             |
| Normal Teaching                            | Remote Teaching                                                       |
| Contribute to the nursing career community | Contribute to the nursing career community in these times of pandemic |

#### IV. RESULT AND DISCUSSION

In this section, the results of the case study should be shown, such as that of the Scrum methodology, used in this work.

Fig. 13. Student Survey.

#### A. About the Survey

The survey carried out previously establishes specific questions, which can be observed in this subsection, but with the difference that the results obtained from each question asked in the survey are shown here, as shown in Table III, in the question "What is your opinion on virtual reality?" can observe a 48.1% knowledge about virtual reality by nursing students, while a higher number still do not know its meaning, in the question "Would you like to visualize 'objects' in 3D dimension through your Smartphone?" a low percentage of "37.8%" is established in the question "Are you likely to use this app?" A high interest in the application is observed since they find it curious to see how this prototype would perform in education, in "For which course would you like this application?", have varied percentages, since it is in a box question, these Results are respectively set to the boxes of question 4 shown in Fig. 13 and to finish a large number of students are observed who consider the implementation of this prototype correct.

The results of a survey carried out in the organization towards the General Manager, Coordinators, School Directors and the Dean are also observed, as shown in Table IV, in

TABLE III. SURVEY RESPONSE

| Questions                                                                      | Answers                                 |
|--------------------------------------------------------------------------------|-----------------------------------------|
| What is your opinion on virtual reality?                                       | 48.1 %                                  |
| Would you like to visualize 'objects' in 3D dimension through your Smartphone? | 37.8 %                                  |
| Are you likely to use this app?                                                | 89.9 %                                  |
| For which course would you like this application?                              | 95.7 %, 85.4 %, 80.2 %, 86.5 % y 86.1 % |
| Does its implementation seem correct to you?                                   | 94.3 %                                  |

the question "Are you satisfied with the scrum methodology carried out in the prototype?", Where a 65% acceptance is observed; in the question "Would you recommend using the scrum methodology for other projects?", where a 75% acceptance is observed; and to finish in the question "Do you think that Scrum methodology is better than the traditional methodology used in the university?", an 80% acceptance is observed.

TABLE IV. ORGANIZATION SURVEY

| Questions                                                                                              | Answers |
|--------------------------------------------------------------------------------------------------------|---------|
| Are you satisfied with the scrum methodology carried out in the prototype?                             | 65 %    |
| Would you recommend using the scrum methodology for other projects?                                    | 75 %    |
| Do you think that Scrum methodology is better than the traditional methodology used in the university? | 80 %    |

### B. About the Case Study

In the case of study, which deals with the development of the prototype of augmented reality, for the improvement of the teaching of certain courses of the professional schools of the University of Sciences and Humanities of Lima-Peru, was developed based on the Scrum methodology [32], which helped, on the process of development of the prototype as a "guide", since we showed the way for which it should advance for this development, this path can be observed and read in section 3 (case study) of this work, the 3D development platform was also used, the Unity [33], this being a good platform for the proposed in this work since the prototype was developed, thanks to this platform, as shown in Fig. 9, Fig. 10, Fig. 11 and Fig. 12 of point 6 (Sprint Backlog) of the SCRUM subsection belonging to the case of study, where it is observed, that in each of the Sprint it was vital, use the 3D replacement platform, for which, it could be said, that this platform is the center, of everything that was used, for the goal of this work, it should be noted that this 3D development platform, Unity, has a shop known as "Asset Store of Unity" to download models, textures and animations, and thus facilitate the process of development of the prototype, since if we find the model we require, it can be imported, and use it at the time, another platform, which was used, were the web platforms such as free3d, to find and download 3D

models, it was used, because in this, it is easier to find models that are required, since unlike "Asset Store of Unity", this is organized by categories (architecture, vehicles, characters, aircraft, furniture, electronics, animals, plants, weapons, sports, food and anatomy), it should be noted that as it is a model already created, Unity was used to modify it to the convenience of the prototype, as shown in Fig. 9, where a model containing two human skeletons, that of the left of an approximate color to the Black Squeeze is observed, which resembles the color of the bone, which we will need and the one of the right of the grayish blue color, which we will not need, so, we have to modify in Unity, this model that contains two human skeletons, also for the development of the prototype, was used, Vuforia (augmented reality software development kit) [34], to introduce the augmented reality, as it was mentioned, in the development of the study case, this is perfect for recognizing and tracking the images in real time, taking the display as "medium", to connect it with the world of the augmented reality, this can be seen in Fig. 12, where Vuforia (augmented reality software development kit) is doing their work, by recognizing and tracking in real time, the "Human Skeleton" image (behind the model), and connect it with the model of human skeleton, thus generating the augmented reality, which is key to this prototype, since the "essence" of this work, is the creation of a prototype of augmented reality, Vuforia (augmented reality software development kit) was used, since its handling is easy, apart from providing us with a database, where the images that will be tracked, to generate the augmented reality, and finally, for the development of the prototype, the Microsoft Visual Studio integrated development environment was used, in order to be programmed in C# language (C sharp), since it was wanted, that the prototype has interactions with the user. All mentioned in this subsection of "Results and Discussions", was made, to achieve good control and result in the development of the prototype.

### C. About the Methodology

The method of scrum [35], was very helpful, as we guide us, in the development of the prototype, to start, helped us to focus requirements, thanks to user stories, also, to estimate these stories, to know what the user's stories that are found to make them more, as those that were easier to develop, they also helped us, namely what amount of effort necessary we could do by Sprint, this became known, thanks to the determination of the speed; And thanks to the prioritization part of this methodology, where the story map was used, it was possible to know which user stories are more important for the prototype and which stories are less important, on the other hand, the path or route of the product was also used to know how much sprint, and which user stories are going to be done by sprint, and at the end of each sprint was made a review to see if the objectives were achieved, as well as, At the end of each sprint review, the feedback was used for continuous improvement.

- Benefits: The benefits offered by the Scrum methodology are varied [36], since when deciding to make the prototype using an agile methodology, it allows us to have a finished "product" in less time than when choosing a traditional methodology, that's why, here, we are dealing with specific things, which strengthened the development of the prototype, that's why we

will start with the speed, which made us know, how much effort was invested per sprint, but this, depending on the performance, that is giving the sprint. Also, thanks to the Scrum methodology, the development of the prototype could be divided into parts, thus generating a "finished product" by sprint. On the other hand, another benefits of the scrum methodology is the sprint review, as this helps us to verify the achievement of the goal, identifying what was achieved, as well as what was not achieved, and finally, the feedback sprint, offered by the scrum methodology, is good, as this allows us to make improvements towards the following sprint.

- Comparison: If compare the scrum methodology, with the methodology RUP (rational unified process) [37], can say, that the methodology RUP (rational unified process), is rigid, meaning that if the customer wants a change, it is very difficult to make it, since you follow the plan until the end of the project development, whereas in the Scrum, this is possible, because, scrum is flexible to change, another comparison, you can make, The reason for this is that, in the methodology RUP (rational unified process), the project is conceived as one, while in scrum the project is divided into parts. It can also be said that in the methodology, the deliverable is at the end of the entire project development, while in scrum the delivery is constant [38]. This comparison of Scrum and RUP can be seen in Table V.

TABLE V. SCRUM VS TRADITIONAL METHODOLOGY RUP

| SCRUM                                      | RUP                                                        |
|--------------------------------------------|------------------------------------------------------------|
| Accept changes                             | Resists changes                                            |
| Its development is flexible                | Its development is rigid                                   |
| The client is part of the development team | Customer communicates with development team                |
| Client available throughout the project    | Client available at the beginning of the project           |
| Value is delivered to the customer early   | Value is delivered to the client at the end of the project |

## V. CONCLUSION AND FUTURE WORK

This augmented reality prototype has been developed satisfactorily, and thus this will help to improve the teaching in the Universidad de Ciencias y Humanidades, since this augmented reality prototype, by teaching through cognitive processes, is suitable for courses in biology, human anatomy, human physiology, microbiology, and parasitology, belonging to the professional school of nursing. The tools used for the development of this prototype were efficient and valuable, both in the use of the 3d development platform, in the ability to introduce augmented reality, and in the interactions of the "models" with the users. And the methodology used, the scrum, was very efficient, for the development of the prototype, being the scrum processes, key, to achieve the goal set, and thus ensure the development of the prototype. In future research, a menu system could be implemented for the prototype, which has options, so that the users, can know, how the prototype is used, which will show the scanned images, and thus, achieve a better understanding with the user.

**Abstract**—The growth of the number of e-commerce users and the items being sold become both opportunities and challenges for e-commerce marketplaces. As the existence of the long-tail phenomenon, the marketplaces need to pay attention to the high number of rarely sold items. The failure to sell these products would be a threat for some B2C e-commerce companies that apply a non-consignment sale system because the products cannot be returned to the manufacturer. Thus, it is important for the marketplace to boost the promotion of long-tail products. The objective of this study is to adapt the graph-based technique to build the recommendation system for long-tail products. The set of products, customers, and categories are represented as nodes in the tripartite graph. The *Absorbing Time* and *Hitting Time* algorithms are employed together with the *Markov Random Walker* to traverse the nodes in the graph. We find that using *Absorbing Time* achieves better accuracy than the *Hitting Time* for recommending long-tail products.

**Keywords**—Long tail; recommender system; tripartite graph; random walker; hitting time; absorbing time

## I. INTRODUCTION

Promotion becomes one of the success factors in product marketing [1], i.e. the better the promotion, the more people recognize the products being promoted, and the higher chance for those products being sold. On the other hand, the wrong strategy in promoting products could also cause difficulty or even failure in selling specific products [2]. In general, e-commerce companies tend to recommend popular products to customers. Those products would remain popular and the not recommended products would be less exposed by customers. The high number of unpopular products would be harmful to some B2C (Business-to-Consumer) e-commerce companies that apply the non-consignment sale system. These e-commerce companies have already paid the products from the manufacturer to be sold to the customers. The products will not be returned even though the companies are unable to sell them. The more unpopular products are unsold, the higher the cost would be due to the damage risk or the inventory cost for storing such products.

The long-tail phenomenon is a condition when the unpopular (niche) products dominate the total sales [3]. Long-tail products are also interpreted as the less popular products among customers [4]. Even though the sales volume of each product was not so high, the total number of products dominate the total sales [2]. The ratio between long-tail products and popular products is following the 80/20 principle or Pareto rules. The 80% of total revenue is obtained from 20% of total products, i.e., the popular ones. By increasing the sales volume

of the remaining 80% of the total products (the long tail), the total revenue could be increased significantly.

A recommendation system is one of the important tools for marketing strategy. It is useful in dealing with the information overload issue as the variation of the products increases. Many studies in the recommendation systems for the e-commerce domain have been conducted [5], [6], [7], [8], [9]. Studies in this area are usually focused on the behavior or characteristics of the "known" products or "the shopping history" of customers. The common objective is to recommend the most suitable products based on transaction history. By its ability to capture customers' preferences, it is easier to recommend such suitable products for them. And for the customers, it will be easier to determine which to purchase and where to buy. On the other hand, since the recommendation commonly brings popular products up, these products become more competitive among many business owners [4]. Thus gaining profit from such products could be more challenging. On contrary, the less popular products are less noticed by many sellers so they could bring more profit if it is successfully sold [10], [4].

The characteristic of the data being used in a recommendation system is suitable to be represented in a graph. In every domain of the recommendation system, it is possible to represent the entities, such as users, items, movies, foods, images, books, as the nodes (vertices) of a graph. Meanwhile, any relations between entities can be represented as the edges. Many studies about graph-based recommendation systems have been conducted for different problems to be solved. A graph structure was owned by mostly recommendation system and also it raises many potential exploration and development through graph learning [11]. One common graph representation is a bipartite graph, for example, to capture the relationship between a set of users and a set of items. A study by [12] used this kind of representation to apply collaborative filtering based on user similarity and item similarity. A bipartite graph was also used by [2] to solve the long-tail problem through a random walker that is adopted in this study. The other example with different graph representation but also employed the random walker is a study by [13]. It solves the cold start problem through a trust network by applying trust-based and item-based collaborative filtering.

Now recalling the non-consignment sale system applied to some B2C e-commerce companies, besides capturing customers' preferences, it is also important to take the unpopular products out to the customers. The motivation behind this study is to find the recommended products, which not only focus on the more popular products but also those which

are less exposed by customers but still in the customers' preference area. Adopting previous studies, a tripartite graph representation is used to draw the relation between users, items, and categories. Since customers nodes are only connected to product nodes that they have ever purchased, then to make them exposed by the long-tail products, the *Markov Random Walker* combined with *Hitting Time* or *Absorbing Time* is employed to find the unpopular yet suitable products to be recommended to the users. In addition, as the product categories are available at different levels, this study also tries to figure out whether the different category level being used affects the recommendation results. More specifically, studies about the recommendation system for long-tail products are presented in Section 2 followed by the detail about tripartite graph implementation in Section 3. Section 4 consists of the experimental result and its analysis, and the conclusion would be presented in the last section.

## II. RELATED WORK

Studies to deal with the long-tail problem have been widely conducted. A study in [14] tries to analyze and solve the long-tail problems on the traditional recommendation system (i.e. collaborative filtering) on an e-commerce platform. By capturing the users' information and behavior together with the systems' behavior, several models are established involving Gradient Boosting Decision Tree, Logistic Regression, and user entropy-based LDA. This study shows that it is possible to recommend long-tail products while maintaining the quality of the recommendation.

A similar conclusion was also obtained from a study in [15] to enhance the collaborative filtering such that it considers mining the long-tail items in the recommendation process. This study was conducted on the sales of alcoholic beverages (RateBeer). A matrix factorization was established based on personal experience to generate the user experience level. The top  $N$  recommendation is then obtained from the experience level together with the consideration of items' popularity. This study captured a phenomenon where the customers with lower experience levels tend to purchase popular products more, and vice versa: those with higher experience levels, tend to purchase the unpopular ones. The problem of this study happened for new customers. The recommendation was either not relevant or only focused on the popular products.

Specific to deal with the cold-start problem and long-tail problem, a study by using social data (Flickr, BlogCatalog, YouTube, HetRec11-LastFM) conducted in [10] first decompose the overall products into the low-rank (short-head) products and the sparse part (long-tail) products. These two groups were trained independently and the final recommendation from each group was merged then became the recommended products for the new users. But basically, this study focuses more on resolving the cold start problem while 'introducing' some items from the long-tail category in the recommendation. Experimenting on a similar domain, especially related to movie viewers data (through MovieLens and Last.fm), a study by [16] developed CORE (Cosine Pattern-based Recommender). This system allows product recommendation based on either the popular products (based on those which have been rated by a user) or the niche products (based on the *cosine* pattern. This

study reported that the accuracy of the recommendation will be decreased when comes to dense data.

Other studies in recommendation system studies employ the graph representation. Specific for the long-tail problem in a movie data set, a study in [2] initiate the use of a bipartite graph to represent the user-item relation. *Markov Random Walker* was implemented to calculate the *Hitting Time*, *Absorbing Time*, and *Absorbing Cost* which were used to determine the ranking of the product recommendations. The performance of *Absorbing Cost* outperformed the other two on various measurement metrics used due to the characteristic of the *Absorbing Cost* that considers customer interests/preferences when giving a recommendation. This is suitable if all products are similar as in movie data because it is easier to recommend a movie to customers who have a specific interest in a particular genre compared to customers who have an interest in several genres.

Adopting the bipartite graph approach in [2], a study in [17] added latent information (i.e genre node) as a link between the customer node and the recommended product node such that the graph representation became a tripartite graph. By this improvement, it is possible to traverse from a user node  $x$  to the item node  $y$  that is not directly connected through the intermediate genre node  $z$  that might be indirectly connected to  $y$  (for example through the intermediate node). The result shows its ability to 'pick' the recommended items from the region that is suitable to the users' taste. A study in [4] makes an improvement in determining the latent information by using a single category. This study was also proposed a new approach to calculate the weight between product and category nodes to avoid the misleading caused by the use of direct average rating, namely the Bayesian averages. It shows the recall and the diversity score improvement compared to the former study in [17]. In both of these studies, the *Hitting Time* and *Absorbing Cost* was employed based on their performance in the study by [2].

Compared to the movie data (MovieLens) used by [17] and [4], the domain of this study (e-commerce data from B2C company) owns similar components. Both data own set of users, items (i.e. movies vs products), and category (i.e. genres vs products' categories) such that it is possible to build the tripartite graph representation. This study then adopts the approach used by [17] and [4] to build the tripartite graph-based recommendation system that employs the *random walker* to promote the long-tail item to the user. However, the characteristic of e-commerce data is different from the movie data, so this work differs from the former at some points. The first one is when customers often purchase products from certain categories than the other, it does not always imply that the category is preferable to the other. For example, because a customer often purchases snacks on e-commerce, this does not imply that the customer does not interested to purchase clothes or electronic devices. This is probably the customer prefers to buy clothes or electronic devices on offline stores rather than from e-commerce. This is surely different from movie data where the preference to watch movies for a specific genre generally implies the preference to the respective genre. From this condition, having information about what a customer often purchased from e-commerce is not too useful for the recommendation process, so that *Absorbing Cost* that works

by considering such information to make a recommendation is not suitable to be applied on e-commerce data. Thus, even though [2] mentioned that *Absorbing Cost* could recommend better than *Hitting Time* and *Absorbing Time*, this study try the other way –to not include the *Absorbing Cost*. The second point is that latent information in the movie data (genre) is very different from the latent information in e-commerce data (category). The main difference is that movie genres have the same level, while the product categories are divided into general categories (top-level) to the most specific category (leaf-level). Since the relation (as well as the weight) between items and different levels of the category might be different, the use of different levels of product categories could be one thing to be elaborated on, whether or not it affects the result of the recommendations.

### III. TRIPARTITE GRAPH RECOMMENDATION SYSTEM

#### A. Graph Representation

This study employs a tripartite graph, i.e. a graph  $G = \{V, E\}$  which its node set  $V$  is partitioned into three disjoint node subsets  $V_1, V_2$ , and  $V_3$  such that  $V = V_1 \cup V_2 \cup V_3$  and for each  $(u, v) \in E$ , if  $u \in V_i$  and  $v \in V_j$ , then  $i \neq j$  [18]. The graph representation utilized in this study would be an in-directed graph since a relationship between two nodes implies the reverse relationship. There are three types of nodes such as the *user* nodes representing the customers, *item* nodes representing the products, and *category* nodes representing the categories. The relationship between nodes is represented as weighted edges. There are also three types of edges connecting nodes from different types, they are the *user-item* edges, *item-category* edges, and the *user-category* edges.

Illustration of a tripartite graph representation is presented in Fig. 1. The blue, red, and green nodes represent the group of user or customer nodes, category nodes, and the item or product nodes, respectively. The label for user nodes was taken from the customers' username, while the product category label represents the product category name, and the item nodes use the brand name of the products as their label. In Fig. 1 each edge connecting nodes in the different groups represent different relationships. For example, the user node labeled "agustini24" has a pair of edges with opposite directions that are connected to the "Home Living" node. These edges represent that "agustini24" purchased products belonging to the "Home Living" category, and vice versa, the products belonging to the "Home Living" category were purchased by a user with the username "agustini24". Similar relations are also applied for the other edges connecting nodes from different groups of nodes. The rest of this subsection discusses detailed information about edge representation.

1) *User-Item Edges*: These edges connecting the *user* nodes with the *item* nodes. The weight of this edge is 1 if a customer has given a rating to a product, and 0 otherwise. To avoid the density of the graph, edges whose weight is 0 are removed.

2) *Item-Category Edges*: These edges connect the *item* nodes to *category* nodes. This type of edge uses the average rating value from all customers for a product in a specific category as the weight. It is computed from the average rating for a product  $i$  (denoted by  $i_{avg}$ ) divided by the total number

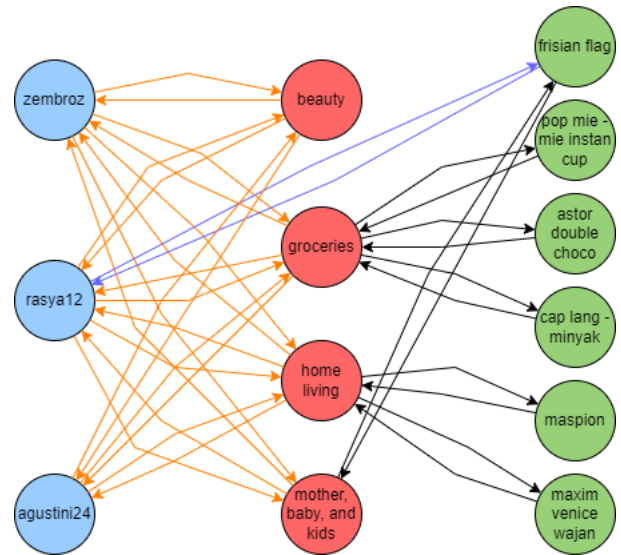

Fig. 1. An Illustration of the Tripartite Graph.

of categories connected to the product  $i$  (denoted by  $|C|$ ). The formula is presented as

$$w_{i,cat} = \frac{i_{avg}}{|C|} \quad (1)$$

3) *User-Category Edges*: These last group of edges exist between the *user* and *category* nodes. These node connect *user* node to more *item* node with shorter paths. The weight is computed by using *Bayesian Average*

$$w_{u,cat} = \frac{avg\_votes_u \times avg\_rating_u + votes_{u,cat} \times rating_{u,cat}}{avg\_votes_u + votes_{u,cat}} \quad (2)$$

for edges connecting *user* node  $u$  and *category* node  $cat$ . The value of  $avg\_votes_u$  is obtained by calculating the number of products bought by customer  $u$  in category  $cat$  divided by the total number of categories. The value of  $avg\_rating_u$  is calculated by dividing the total ratings from customer  $u$  for all products with the total number of categories. The  $votes_{u,cat}$  denotes the number of products in category  $cat$  that has been purchased by customers  $u$ . And the last,  $rating_{u,cat}$  denotes the average ratings from customer  $u$  in a category.

#### B. Product Recommendation

This section contains an explanation about how to get the recommended long-tail product for certain customers by traversing the tripartite graph. The long-tail products are determined based on the average number of customers that give ratings to the whole product in the data set. A product is then labeled as long-tail if the number of customers that give a rating to it is below the average.

1) *Markov Random Walker*: A *random walk* is formed from a graph traversal such that given a starting node  $a$ , we choose an adjacent node  $b$  to be visited at random (usually based on predefined transition probability), then choose the

next random node  $c$  to be visited from  $b$  and so on until certain steps [19], [11]. On a weighted graph, it forms a Markov Chain with the transition matrix consisting of the probability value of the movements between node  $i$  and  $j$  such that

$$p_{i,j} = \frac{w_{i,j}}{d_i} \quad (3)$$

where  $w_{i,j}$  denotes the weight between node  $i$  to node  $j$  while  $d_i$  is the total weight of node  $i$  to all of its adjacent nodes [20]. In this study,  $p_{i,j}$  refers to the probability of the *random walker* arrives at a product node  $j$  from a customer node  $i$  as the time  $t$  increases. The transition matrix (which is then denoted as  $M_S$ ) is also called as a *stochastic matrix* since the sums of each row equals to 1.

In the matrix representation of a graph, the dot product of a matrix by itself for  $n$  times results in the availability of paths with length  $n$  between each pair of nodes. Related to this study, from a given *user* node, an iterative process is done by the *random walker* to find the suitable long-tail *item* node. This process is equivalent to the dot product of the *stochastic matrix*  $M_S$  by itself for  $t$  times which represents a *random walker* probability traverse from node  $i$  to node  $j$  in time  $t (\geq 1)$ . As the time  $t$  increases, the elements in this *stochastic matrix* converge such that no change in their value or the changes are very small. However, according to [17], it is better to use a small value of  $t$  since as it grows higher, the *random walker* tends to visit the popular nodes. Thus in this study,  $t = 2, 3, \dots, 7$  are used since after  $t = 7$ , the ability of the system to recommend the long-tail products was decreased [4].

2) *Hitting Time*: As stated in [2], *Hitting Time* (denoted as  $H(q|j)$ ) is defined as the expected number of steps that is needed by a *random walker* to move from an *item* node  $j$  to *user* query node  $q$  with  $j \neq q$ . The value of *Hitting Time* is obtained from

$$H(q|j) = \frac{\pi_j}{p_{q,j} \cdot \pi_q} \quad (4)$$

where  $\pi_j$  and  $\pi_q$  are the *stationary probability* for node  $j$  and node  $q$  respectively. Meanwhile,  $p_{q,j}$  represents the weight of edge connecting node  $q$  and node  $j$ , i.e. the movement probability between node  $q$  and node  $j$ . The smaller the value of  $H(q|j)$  denotes the more relevant node  $q$  and  $j$  and that only a few users have rated item  $j$ . This conclusion comes from the following information.

- Consider the fact the value of *stationary probability* stays constant for all nodes, the value of the *Hitting Time* is inversely proportional to  $p_{q,j}$ . This means that the higher the value of  $p_{q,j}$  which denotes the more relevant node  $q$  and  $j$ , then the lower the *Hitting Time* value will be obtained.
- The *stationary probability* of a node is proportional to the number of customers that give a rating to the product. This means that the lower the *stationary probability* of a product, then it belongs to the long-tail product because it is only rated by a few customers.

**Algorithm 1.** Recommendation by using Hitting Time

---

**Input:**

A tripartite graph  $G = (V, E)$   
A customer node  $q \in V$   
Time  $t$  for how long the *random walker* traverse the nodes

**Recommendation\_By\_HT( $G, q, t$ ):**

- 1) define a subgraph  $G' = (V', E')$
  - 2) for each node  $j \in V$  that has not been rated by customer  $q$ :
  - 3) include node  $j$  as the member of  $V'$  in  $G'$
  - 4) include edge  $(q, j) \in E$  as the member of  $E'$  in  $G'$
  - 5) create a stochastic transition matrix  $M_S$  from  $G'$
  - 6) for each node  $j$  in subgraph  $G'$ :
  - 7) calculate the stationary probability ( $\pi_j$ )
  - 8) perform dot products:  $(M_S)^t$  represents the random walk length  $t$
  - 9) for each node  $j$  in subgraph  $G'$ :
  - 10) calculate the *Hitting Time* value  $H(q|j) = \frac{\pi_j}{p_{q,j} \pi_q}$
  - 11) sort the *Hitting Time* value for all node  $j$  in ascending order, except node  $q$
- 

Algorithm 1 presents the steps to recommend the unpopular products (i.e. the long-tail products) based on the *Hitting Time* value. This algorithm intuitively tries to find the product nodes which has never been purchased by a customer but have higher similarity to those that have been purchased by the customer.

3) *Absorbing Time*: As the comparison of *Hitting Time*, the *Absorbing Time* is implemented regarding the study by [2]. It explains that *Absorbing Time* is suitable for data in which the number of customer nodes is far higher than the product nodes. Within this condition, the number of average rating for each product is higher than the number of average rating for each customer. Thus this information should be more useful for the recommendation process. *Absorbing Time* that is denoted by  $AT(S|i)$  is defined as the expected number of steps before a *random walker* that is started from node  $i$  is absorbed by  $S$ . While the set  $S$  denotes the *Absorbing Nodes*, i.e. set of nodes  $S \subseteq V$  in a graph  $G = (V, E)$  for which the *random walker* stops when any node in  $S$  is reached for the first time.

$$AT(S|i) = \begin{cases} 0 & , i \in S \\ 1 + \sum_{j=1}^n p_{i,j} \cdot AT(S|j) & , i \notin S \end{cases} \quad (5)$$

calculates the value of *Absorbing Time*. It can be seen that  $AT(S|i)$  would be 0 whenever the current node is one of the *Absorbing Node*, i.e those which are directly connected to the customer node. While a recursive calculation is performed from the source node (the customer node) to one of the *Absorbing Node*. This approach is similar to the one that uses *Hitting Time*, to find the less popular products (i.e. those belonging to the long-tail) and recommend products that are similar to what a customer has already purchased and rated. The difference is in its traversal route. By using *Absorbing Time*, the *random walker* traverses through the unpopular nodes until it arrives at a node that represents the popular one. The detail of the recommendation process through *Absorbing Time* is presented in Algorithm 2.

#### IV. DATA AND EVALUATION

##### A. Data Set

This study adopts the approaches from previous studies [14], [17] by employing the tripartite graph representation to build the recommendation model for a B2C e-commerce

**Algorithm 2.** Recommendation by using Absorbing Time

**Input:**

A tripartite graph  $G = (V, E)$

A customer node  $q \in V$

Time  $t$  for how long the *random walker* traverse the nodes

**Recommendation\_By\_AT( $G, q, t$ ):**

- 1) define a subgraph  $G' = (V', E')$
- 2) define  $S \subseteq V'$  and  $S' \subseteq V'$  such that  $V' = S \cup S'$
- 3) for each product  $i$  that has been rated by customer  $q$ :
- 4) include node  $i$  as the member of  $S$
- 5) include edge  $(q, i) \in E$  as the member of  $E'$
- 6) for each product  $j$  that has not been rated by customer  $q$ :
- 7) include node  $j$  as the member of  $S'$
- 8) create a stochastic transition matrix  $M_S$  from  $G' = (S \cup S', E')$
- 9) perform dot products  $(M_S)^t$  represents the random walk length  $t$
- 10) for each node  $i$  in subgraph  $G'$ , calculate the *Absorbing Time* value:
- 11) if node  $i \in S$  then:
- 12)  $AT(S|i) = 0$
- 13) else:
- 14)  $AT(S|i) = 1 + \sum_{j=1}^n p_{i,j} \cdot AT(S|j)$
- 15) sort the *Absorbing Time* value in ascending order for all node in  $S'$

$$Recall@N = \frac{\sum hit@N}{|L|} \quad (6)$$

2) *Evaluation on Products Diversity*: The purpose of this measurement is to identify the recommendation performance in term of a variety of products, whether the recommendation covers both the popular and unpopular products or only focus on the popular ones. The higher the diversity value, the more different types of products would be recommended to customers.

The value of *Diversity* is obtained from the comparison of the number of unique products being recommended by the system and the maximum amount of the recommendation. The amount of the recommendation is calculated from the multiplication of the desired number of top recommendations with the number of customers involved in the experiment. The formula for *Diversity* score is presented in Equation (7).

$$Diversity = \frac{|\bigcup_{u \in U} R_u|}{|I|} \quad (7)$$

3) *Evaluation on Long-Tail Products*: The last evaluation utilizes the *Long Tail* measurement. This metric determines whether the recommendation system successfully recommends long-tail products. Rather than using the average rating as conducted in [2] which could lead to the misleading implication, this metric is modified by considering the average number of customers who give a rating of a product. For example, product A is purchased by five people and all of them give 1 rating. Product B is only purchased by one person and the given rating is 5. If the *Long Tail* score is calculated using the average value, then product A will be considered as a long-tail product while product B is the popular product. Equation 8 presents the equation for calculating the *Long Tail* score. The notation  $|L|$  denotes the number of tests, while  $rating(i)$  denotes the number of customers who give a rating on product- $i$ .

$$LongTail = \frac{\sum_{i=1}^n rating(i)}{|L|} \quad (8)$$

TABLE I. GRAPH DATA SET DESCRIPTION

| The Number of               | 1st-level Category | 3rd-level Category |
|-----------------------------|--------------------|--------------------|
| Total nodes                 | 63,068             | 3,011,244          |
| Category nodes              | 21                 | 626                |
| Product/item nodes          | 20,000             | 20,000             |
| Customer/user nodes         | 43,047             | 43,047             |
| user-item edges             | 80,000             | 80,000             |
| item-category edges         | 469,036            | 1,123,096          |
| user-category edges         | 1,808,148          | 1,808,148          |
| Average degree of each node | 37                 | 47                 |

company. One of the differences is that in this domain, the product category has several levels. Thus, there are two types of data set being used in this study, differentiated based on the level of the category as summarized in Table I. There are in total 63,068 nodes that are connected to the 1-st level category nodes and 3,011,244 nodes connected to the 3-rd level category nodes. The objective of this differentiation is to identify the effect of the specialization (by using the 3rd-level category) and generalization (by using the 1st-level category) in the latent information for the recommendation result.

**B. Evaluation Metrics**

This study uses three metrics to evaluate the performance of the recommendation system adopting from [2]. These metrics evolved the evaluation of the accuracy, diversity, and exposure of the long-tail products. For each of these criteria, the comparison of *Hitting Time* and *Absorbing Time* performance are evaluated.

1) *Evaluation on Accuracy*: This metric use *Recall@N* that measures the accuracy of the recommendation result for each algorithm (*Hitting Time* and *Absorbing Time*). It evaluates how far the algorithm could recommend the long-tail products.

Given a collection of products consisting of the combination of customers' favorite products and other randomly chosen products, the recommendation system would recommend top  $N$  recommendations. If a customers' favorite product is included in the top  $N$  recommendation, the value of *hit@N* would be 1 and 0 otherwise. The notation  $|L|$  represents the number of tests case, i.e. the total instances of long-tail products that are tested their membership to the top  $N$  recommendations. The formula for this metric is given in Equation (6).

**V. RESULT AND ANALYSIS**

Starting by entering a username of a customer into the system, a set of  $N$  products are generated as the recommended products for the customer, following Algorithm 1 (by using *Hitting Time*) and Algorithm 2 (by using *Absorbing Time*) separately. Each Algorithm is run by using two types of data set described in Subsection IV-A combined with a specific value of  $N$  (the number of products to be recommended) and  $t$  (the length of time needed by the *random walker*). The evaluation is conducted through the observation of the accuracy, diversity, and long-tail measurement.

**A. Evaluation on Accuracy**

The aim of this experiment is to identify the accuracy of the utilization of *Hitting Time* and *Absorbing Time* in different types of category levels, i.e the use of 1-st level category vs 3-rd level category. In general, the value of *Recall@N* is increasing with the increase of the number of products ( $N$ ),

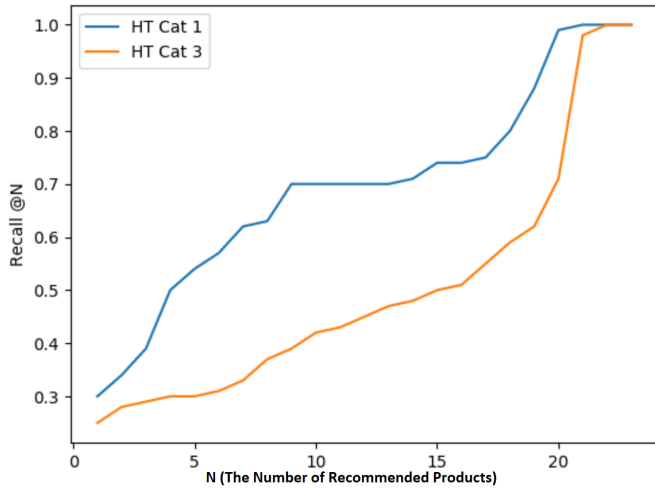

Fig. 2. The Accuracy (Recall@N) Value of using the Hitting Time.

but different combinations of the algorithm and category level being used lead to different results.

Fig. 2 present the accuracy comparison by using different level of category in the implementation of *Hitting Time*. This result shows that the accuracy of using the general category (1st-level category) is better than the specific one. This is caused by the condition that the 1st-level category has a smaller number of *user-category* edges. This situation produces a higher rating average on each of these edges that drives to the higher probability value in the transition matrix. Thus, the *random walker* traverses the graph faster to reach the nodes around the customer query node, especially when the nodes are in the same category.

Fig. 3 presents the comparison of accuracy in different category levels by using *Absorbing Time*. If the use of *Hitting Time* resulting better accuracy when it is combined with the use of data from the 1st-level category, *Absorbing Time* performs better in its combination with the data from the 3rd-level category. This difference is affected by the working principle of both algorithms in determining the source and target nodes to be traversed by the *random walk* and the different characteristics of the connectivity in each level of category.

Regardless of the level of category data, both results presented in Fig. 2 and 3 shows that the curve of the *Absorbing Time* is higher than the *Hitting Time*. This implies that the implementation of *Absorbing Time* has a better performance in terms of its accuracy. Since *Absorbing Time* would run better in a graph with a shorter path between nodes, this condition is consistent with the fact that the data set consisting more customer nodes than the product nodes. Therefore, the connectivity between product nodes has a shorter path.

### B. Evaluation on Diversity

In term of diversity, Fig. 4 shows the diversity comparison in top  $N$  recommendation ( $N = 5, 10, 15, 20$ ). This figure shows that the implementation of *Absorbing Time* tends to

Fig. 3. The Accuracy (Recall@N) of using the Absorbing Time.

Fig. 4. The Comparison of Diversity Value by using *Hitting Time* and *Absorbing Time*.

be better than the *Hitting Time* in the small number of  $N$ . Moreover, the use of specific category data (i.e. 3rd-level) yields better diversity in both algorithms. From Fig. 4, it can be said that the greater value of  $N$ , the lower the diversity value would be obtained (for both approaches). However, this diversity value does not guarantee the quality (accuracy) of the recommendation because the accuracy is inversely proportional to diversity. Moreover, as summarized in [17] that the higher diversity value reflects the high probability of the long-tail products to appear in the recommendation. Thus, the *Hitting Time* algorithm produces the more diverse products, and probably captures the long-tails better than *Absorbing Time* algorithm, but might not be better in terms of accuracy.

TABLE II. THE LONG TAIL COMPARISON BY USING *Hitting Time* AND *Absorbing Time*

| Top N Recommendation | Hitting Time | Absorbing Time |
|----------------------|--------------|----------------|
| 5                    | 362.01       | 347.13         |
| 10                   | 366.18       | 333.19         |
| 15                   | 330.87       | 330.57         |
| 20                   | 327.01       | 322.01         |

### C. Evaluation on Long Tail

This evaluation calculates the average number of customers who give a rate to a product in each of the top recommendation levels. The lower average value denotes the better long-tail products recommendation. As presented in Table II, the value by using *Absorbing Time* implementation is slightly lower than the *Hitting Time*. This indicates that the more recommended products generated by the implementation of *Absorbing Time* come from the long-tail products. Compared to the result on diversity evaluation that *Hitting Time* probably has the more long-tail products to be recommended, from the result of the long-tail evaluation, it is not valid. Though the long-tail values between both algorithms are slightly different, the *Absorbing Time* performs better. Thus, as the aim of the long tail measurement is to identify whether the recommendation system correctly recommends more long-tail products, it is confirmed for the use of *Absorbing Time*.

## VI. CONCLUSION

This study focus to solve the long-tail problem specifically for B2C e-commerce domain using a tripartite graph representation. Markov random walker is employed to traverse the graph based on *Hitting Time* and *Absorbing Time* algorithm in order to recommend the products for the customers. The experimental result shows that *Absorbing Time* algorithm yields better accuracy than the *Hitting Time*. The use of this method also slightly generates more long-tail products to be recommended. In terms of diversity, the *Hitting Time* algorithm provides slightly more diverse recommended products. In addition, specialization and generalization on the product category levels as the latent information are observed. The experimental result shows that there is a difference in using generalized vs specialized category levels. *Absorbing Time* perform better in recommendation accuracy combined with the 3-rd level category, and in terms of diversity, the use of this specialized category level for both approaches shows the more diverse recommended products. This experiment shows that to deal with the problem of long-tail in the e-commerce domain, it is possible to make a recommendation by involving the products from the long-tail groups. The diversity score implies that the use of the more specific categories generates the more varied products to be recommended to the users. Through the implementation of the tripartite graph, either *Hitting Time* and *Absorbing Time* approach for graph traversal are considerably to be implemented in B2C companies.

# Machine Learning Applied to Prevention and Mental Health Care in Peru

Edwin Kcomt Ponce, Melissa Flores Cruz, Laberiano Andrade-Arenas  
Facultad de Ciencias e Ingeniería  
Universidad de Ciencias y Humanidades  
Lima, Perú

**Abstract**—The present research aims to develop an application that allows the early and timely detection of signs of problems in the mental health of citizens. Agile methodology was used, with its SCRUM framework developing its four steps. In addition, technological tools such as artificial intelligence, mobile applications, social networks and the python programming language were used. Also using SQL Server, Android Studio and the Marvel applications, the latter for the design of the prototypes, through the method of sentiment analysis and machine learning, in order to create a mobile application that is as accurate as possible in its results. For this, several types of algorithm were evaluated, managing to select the most appropriate one since it works based on information collected through the social networks Facebook and Twitter. The result that was obtained was the application that uses machine learning to prevent and take care of mental health in Peru, thus benefiting the citizens of society.

**Keywords**—Artificial intelligence; machine learning; mental health; scrum; sentiment analysis

## I. INTRODUCTION

The current global health emergency caused by the SARS-CoV-2 virus has left behind countless deaths and confirmed cases due to the high level of contagion of the disease. Since then, the countries have focused their efforts mainly on controlling and taking the necessary preventive measures to avoid an increase in the number of infections by implementing public health policies [1]. At the same time, various academic articles regarding the coronavirus have been disseminated, the vast majority focusing on epidemiological, genetic and clinical aspects. However, know that the pandemic caused by COVID-19 [2], also brought uneasiness and negative thoughts in the general population that have been spreading since then threatening mental health.

Peru has been one of the countries most affected by the pandemic. Thus, the population had to respect the restrictions established by the governments of the day, remaining long periods of confinement, which in the short or long term represents a potential psychosocial impact on children, adolescents and adults. Due to a radical change in their way of life and the stressful environments caused by the pandemic, as a consequence, concern about the consequences arises not only on physical and mental health [3]. In a survey conducted during the current juncture of 546 people [4], the result was that 69.2% of the participants showed changes in behavior and emotions as well as high levels of stress (47.2%).

In addition to all the above and before the start of the pandemic, in Peru it is estimated that 1 in 5 individuals shows signs of a significant mental problem each year. In the last

4 decades, various initiatives have been promoted but these have not been sustainable, it is not until the approval of Law 29889 that a series of innovations in the provision of services take place in the period 2013-2018. All this has made it possible to implement more than a hundred new mental health care facilities [5]. However, everything is still subject to the commitment of the authorities, the gradual increase in public financing and joint national and international strategies.

In addition, a study of burden by disease category carried out in the country already revealed that mental and behavioral disorders were at the top of the list. It is estimated that approximately 20% of the adult and older population suffer from mental health problems, especially depression, anxiety and alcohol dependence. In addition to the above, 20% of boys and girls suffer from behavioral and emotional disorders; these antecedents are the consequence of an insufficient supply of mental health services by the state. The resources are still insufficient to manage to address the previous problems such as the new ones caused by psychosocial stress [6], linked to exposure to a possible contagion, insecurity and prolonged confinement.

Faced with this pandemic and the various challenges it poses in health matters, the College of Psychologists of Peru consider that in the face of this new reality it is important to be able to adapt to the changes and challenges country is going through. In this sense, they state that the use of technologies represents an opportunity to update knowledge with new learning and various challenges that promote research [7]. Therefore, in order to face mental health problems, it is important to promote mental health research because the country is at risk of continuing to increase the burden of disease from psychiatric institutions. So the need arises for this area to be included in the priorities of health research in Peru [8], the latter being recently ratified by the Ministry of Health for the period 2019-2023.

It is for these reasons that it is important to offer support to contribute and improve the efficiency of mental health plans promoted by the competent institutions. Thus, achieving to offer innovative ways of attending to mental health in the country through the use of technology, thus reinforcing the still fragile efforts to provide a service in conditions to the population. In this way, the effectiveness of the care of our professionals was increased, lightening the load of the functions they perform for better performance.

The objective of this work is to implement an app for the prevention and care of mental health in the country through the

use of artificial intelligence. This app can be downloaded to any Smartphone which gives greater accessibility to the service since nowadays everyone has a mobile device. The purpose is to quickly anticipate possible reactions caused by mental illnesses and disorders, the application by means of the activity record in messaging services and / or social networks allow knowing the current situation of the user. If any risky behavior is detected, an alert notification was sent to 1 or more trusted persons. In addition, it was possible to know the mood on a daily basis, which is very important for a person with mental health problems, the latter was possible through a rating scale that have to be marked at the beginning of the day, which allows better monitoring and follow-up user.

## II. LITERATURE REVIEW

In carrying out the research work, the subject of artificial intelligence was addressed and how this technology applied to health generates significant contributions to improve the precision and effectiveness of diagnoses and treatments of diseases. It focus mainly on mental health in the country, becoming a very helpful support for the work of specialized medical personnel.

According to the author [9], comments that suicide as a mental health problem is increasing worldwide with a figure of approx. 800,000 deaths per year added to a subjective suicide risk assessment process which limits its efficacy and accuracy. Due to this, suicide detection strategies are focusing on the use of artificial intelligence for the optimization of suicide risk prediction and behavior management. The methodology use was based on articles published between the years 1990 to 2019 and how artificial intelligence has had a positive impact on the care and monitoring of mental health. In addition, artificial intelligence has been used to support the clinical management of suicide, demonstrating the advantages of incorporating this technology. Ideal for use in remote locations with limited access to mental health care. The author concludes based on the observed benefits artificial intelligence has a proven advantage for suicide prediction and mental health care.

On the other hand the author [10], confirming that existing mental disorders have been even more affected by the current global situation caused by COVID-19 increasing mental health problems. To better understand the role of artificial intelligence in their research, the methodology used was based on a review of 253 articles. In the analysis of his framework, he consisted in deriving ideas, concepts and knowledge that was integrated into the development of his project. The results obtained were mainly the possible applications of telepsychiatry and artificial intelligence as well as characteristics and models of artificial intelligence in mental health. Finally, they conclude that even these new technologies cannot be fully adopted in the field of mental health care, they consider that health professionals must choose the most appropriate tools. Based on various aspects, a balance must be found between conventional care and technology-based care, which was achieved progressively.

It also coincides that in order to assess and treat the sequelae of mental health and possible psychiatric comorbidities, it is important to optimize patient care [11]. To ensure the efficient use of limited resources, artificial intelligence can help to achieve this. It considers for its methodology the use of

artificial intelligence applications that include validations based on clinical trials. As a result, it is evident that most artificial intelligence applications use simulated data sets that limit the rate and restrict its applicability in a clinical population and in a real world environment. In conclusion, however, more up-to-date and innovative test designs can generate better data sets that are generalizable to the entire world population. The acquisition of large volumes of data is of the utmost importance as they are vital to guarantee that the applications allow to obtain greater precision in the results, especially when they are used as part of a diagnosis or clinical treatment.

The objective of the study was a preliminary evaluation of real-world data to verify the effectiveness of a mental well-being mobile application that interacts through text with users with symptoms of depression [12]. The methodology put into use for this case was to observe a group of anonymous users who installed the application. The study used a mixed methods approach to evaluate the impact and levels of user participation. Quantitative analysis measured the impact of the app by comparing the average improvement in depression symptoms among users. The results obtained were the average improvement in the participants' state of mind, and 67.7% considered the application experience useful and encouraging. The effectiveness and levels of user participation were concluded as promising; however, these first findings have yet to be validated in much larger samples and over longer periods of time.

In addition to the aforementioned, he agrees that the current situation has aggravated various existing problems in the field of health and has focused on knowing a list of factors that could show a predisposition to a mental disorder [13]. For its methodology, a survey was conducted of 17,764 adults of different age groups, genders and economic status through statistical analysis and Bayesian network inference. Key factors that affected the mental health of the participants were identified during the pandemic, the integration of Bayesian networks with classic machine learning approaches allowed generating an effective model of the prevalence level of mental health. It was also recognized who were more prone to mental disorders and causes that cause mental pressure, with the aforementioned it was prefixed with a precision of approx. 80% that people are more mentally vulnerable. As a conclusion, it was determined that factors influence mental health problems during the pandemic and what activities help to keep at bay from disorders that may affect, confirming that caring for people with a history of mental illness seems to be more important during this time.

Finally, after what has been stated by the various authors mentioned, consider that the use of artificial intelligence is of utmost importance and is relevant for a faster, more efficient and optimal work with regard to mental health as it shows great advantages that serve as support health professionals in their work, reducing the workload which not only help better decision-making, but also ensures better care and more accurate results in diagnoses and treatments as well as monitoring and supervision of the patient until recovery.

## III. METHODOLOGY

Next proceed to describe the methods and tools used for this research work.

### A. SCRUM Methodology

This framework implies a process management to tackle complex projects that require dynamic environments, so they demand speed of results and flexibility. It is an agile work methodology that has several objectives and that allows to accelerate processes, act quickly on possible changes and make periodic deliveries of work.

1) *Beginning*: In this first phase, the respective roles are identified and assigned, who was the Scrum Master and the Stakeholders [14]; the members of the work teams are defined according to their abilities and contributions to the project.

2) *Planning and Estimation*: In this second phase, the user stories are created, the sprint backlog [15], also be carried out taking into account the estimate for their correct implementation of each one of them [16].

3) *Implementation*: In this third phase, the respective prototypes are designed, taking into account the requirements of each of the stories raised.

4) *Reviews and Retrospectives*: In this fourth phase, the respective review of the Sprint is carried out by the team, in an activity that allows the inspection and adaptation of the product, the most important thing is the conversation by the team to understand the situation and receive feedback [17]. In Fig. 1 observe the order of the processes for the Scrum methodology.

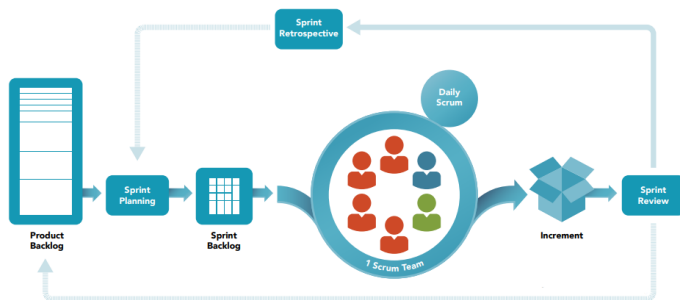

Fig. 1. Scrum Methodology Flow.

### B. Technological Tools

The technologies used for this research work guarantee an optimal development of the mobile application based on the knowledge of the members, managing to finish it according to the specifications and in the established time.

1) *Artificial Intelligence*: This technology seeks to provide software with the capacity for learning based on data, with the latter patterns and opportunities arise through which performance tests are carried out to measure efficiency based on the percentage of errors and successes. The present research project opts for machine learning as it is not linear since it adapts through learning to new cases or situations, even not needing constant supervision. In Fig. 2 can see the steps of machine learning.

Fig. 2. Flow Diagram of the Machine Learning Modeling Process.

2) *Mobile Apps*: Refer to programs designed for exclusive use on mobile devices, generally smartphones, which allows the user access to various services and functions, both professional, entertainment, educational, among others, facilitating the development of their activities.

3) *Social Networks*: Social networks are communities made up of various people and organizations that relate to each other through internet access, allowing immediate communication between users, sharing information and leisure activities. For the present work, take advantage of the messaging service that these communities provide, serving as the basis for the analysis of the individual's behavior and considering the massive use of these tools. Table I shows the results of a survey carried out by IPSOS [18], confirming the high percentage of use of social networks in the country.

TABLE I. USE OF SOCIAL NETWORKS IN PERU 2020

| Estimated Users | Population | Most used social networks                                   |
|-----------------|------------|-------------------------------------------------------------|
| 13.2 Millions   | 78%        | Facebook, WhatsApp, YouTube, Instagram, Messenger, Twitter. |

4) *Python*: It is a high-level programming language that manages to process all kinds of data structures, whether text or numeric. It has taken the characteristics of its predecessors, it is free software, that is to say, open source and allows it to be used and distributed freely even for commercial use. It is accessible, simple and multiplatform, for this project it represents a great advantage due to its wide library, selection of frameworks and its simplicity in syntax.

### C. System Requirements

The programs necessary for an adequate development environment are considered for this project, allowing the realization and implementation of the app correctly.

1) *SQL Server*: is a relational database management system (RDBMS). It supports a wide variety of transaction processing, business intelligence, and analytical applications in corporate IT environments.

2) *Android Studio*: is a development platform that allows you to build mobile applications exclusively for Android operating systems, as well as various tools that allow you to develop an app that is stable on the target devices.

3) *Marvel App*: is an online tool to make layout and prototypes of both web pages and applications on mobile devices.

#### IV. CASE STUDY

##### A. Planning

This project is made up of several stages where various advances are made that must be completed in a certain time. These stages begin with the definition of user stories that allow identifying the system requirements. The project has 10 user stories with an approximate time of 15 weeks for the stories to be finalized. In Table II can see the description of each story, which allows to better understand the functions that the app has.

TABLE II. USER HISTORY

| History No. | Description                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| H1          | As an administrator I want the application to show a friendly and intuitive interface so that it is easy to use and allows the user to register.                                                                               |
| H2          | As an administrator, I want the application to ask the user to mark their state of mind on a daily basis.                                                                                                                      |
| H3          | As an administrator, I want the application to be able to collect information from social networks and messaging services used by the user.                                                                                    |
| H4          | As administrator I want the application to send a daily report to the email of the assigned medical specialist.                                                                                                                |
| H5          | As an administrator, I want the app to display a questionnaire on the cell phone screen that the user must fill out on a mandatory basis in order to better control their mental health.                                       |
| H6          | As a user, I want to be able to register the contact details of trusted people.                                                                                                                                                |
| H7          | As a user, I want the application to show me information related to emotional well-being when entering the app.                                                                                                                |
| H8          | As an administrator, I want the application to send an alert notification to the user's trusted persons in case risky behavior is detected.                                                                                    |
| H9          | As an administrator, I want the application interface design to be made based on colors and sounds that transmit calm and stimulate positive emotions in the user.                                                             |
| H10         | As an administrator, I want the application to show the user motivational and / or informative messages as a preventive function in case indications of possible risky behaviors are detected without having to enter the app. |

##### B. Estimate

For this phase, the user stories that have been previously defined are organized through the product backlog allowing to have fixed goals and meet the established deadlines. The estimations are made by means of the planning poker technique where the team is in charge of assigning a number (Fibonacci series) to each user story to be able to classify them through previous agreements. As can be seen in Table III in the estimation column, the team determines the effort involved in developing each function and requirement raised based on history 6 since its development is the one with the least difficulty.

To define the priority of user stories, take into account the effort and difficulty that their respective development, operation and execution may require, as well as the importance and relevance that it supposes for the present project.

The development of the project is divided into three sprints, with the first sprint obtaining a total of 8 story points, being

TABLE III. PRODUCT BACKLOG

| History No. | Estimate | PRIORITY | Sprint |
|-------------|----------|----------|--------|
| H3          | 5        | 1        | 3      |
| H4          | 5        | 2        | 3      |
| H10         | 8        | 3        | 3      |
| H8          | 8        | 4        | 2      |
| H5          | 3        | 5        | 2      |
| H6          | 1        | 6        | 2      |
| H2          | 2        | 7        | 2      |
| H1          | 2        | 8        | 1      |
| H7          | 3        | 9        | 1      |
| H9          | 3        | 10       | 1      |

the one that requires the lowest speed, which allows the team to integrate and gain greater confidence in the process and progress of the sprint in question. The second and third sprints receive 14 and 18 points respectively and although the points have increased, the team is already able to organize and communicate much better, which allows a greater understanding and minimizes errors when working as a team. In Fig. 3, see in a graph the sprints already organized and with their respective story points.

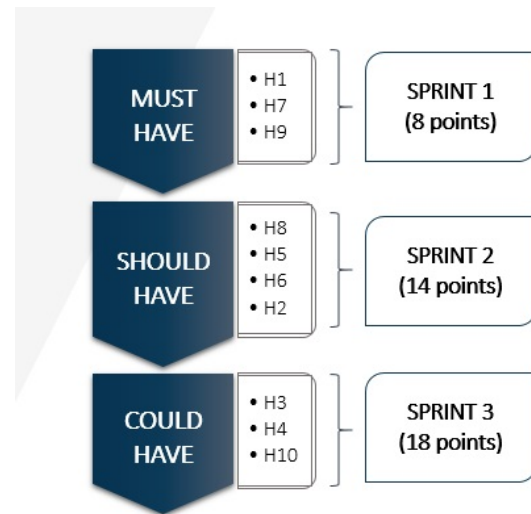

Fig. 3. Story Points and Number of Sprints.

##### C. Implementation and Development

In this phase, the process to develop the mobile application is detailed using the technologies and procedures proposed. The modeling of the Machine Learning software is carried out, in addition [19], at this stage make the choice of the algorithm for learning the artificial intelligence software.

1) *Sentiment Analysis*: It is a process that analyzes opinions, behavior and impressions of users, basically it consists of extracting valuable information after having evaluated attitudes and emotions behind a series of words, focusing on the lexicon that expresses feelings. It has a generally commercial use with applications in marketing, politics, services, companies, surveys, brand positioning, etc. For the present project [20], this method is used for the analysis of data in social networks because the latter have gone from being simple means of

communication to means of critical thoughts and / or opinion, allowing the content to be classified into two categories: positive and negative.

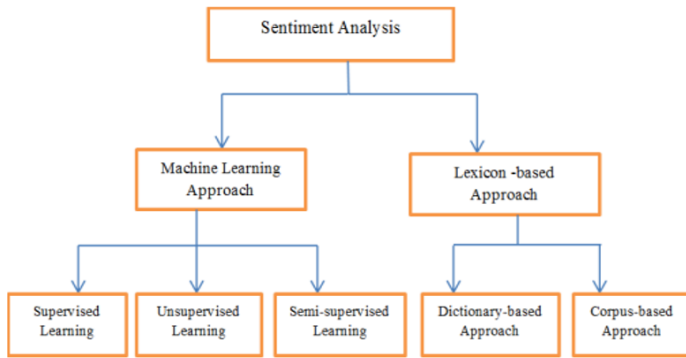

Fig. 4. Methods for Sentiment Analysis [21].

In Fig. 4, observe the two methods that can be used for the process and development of sentiment analysis, for the present work the alternative of an automatic learning model is chosen to achieve better precision and accuracy of the results.

2) *Supervised Learning*: Machine learning is divided into 2 types of methods for the application of the project, supervised learning is chosen since it is the most recommended for jobs that require the use of classification and [22], allowing developers to more accurately identify the processes of intelligence software artificial and at the same time have a better control of the training material for the learning process.

3) *Datasets*: The data set is divided into two parts, the first data is used for tests and the rest as training, the latter being used to achieve Machine Learning modeling that gives the most exact results possible and with the least margin of error.

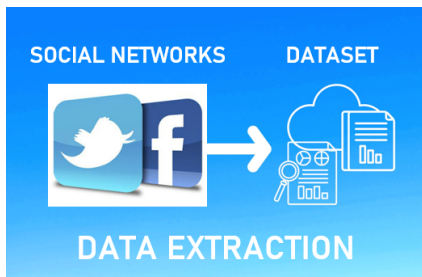

Fig. 5. The Data Extracted, Publications and Content Shared in a Public Way.

In Fig. 5, Facebook and Twitter are considered as social networks of reference for the extraction of data from the present project. To obtain the necessary data, the API that the platforms offer for developers is used. The results obtained from the model [23], are compared with information based on the medical history of patients who have presented disorders related to depression and anxiety.

4) *Data Preprocessing*: The set of training and testing data for the algorithm is previously subjected to a series of techniques and procedures that allow cleaning and reducing

certain characteristics of the texts that are irrelevant for processing. The purpose of this phase is to normalize the data by converting the text into vectors for the classification process and facilitating sentiment analysis using Machine Learning.

a) *Filter*:

In some cases the data may contain special characters that denote admiration, questions or some reference to web pages or tagging. These characters must be removed obtaining a clean data set for vector representation and model classification.

b) *Tokenization*:

It allows to divide the sentences into smaller parts called tokens, which are used for later stages of the processing, facilitating the use of the data. For the project, a token is equivalent to a word.

c) *Anonymity of Personal Information*:

The identity of the authors of social media posts must be kept anonymous so as not to expose users without their consent.

d) *Remove Stop-Words*:

In natural language there are many words that are used frequently and that by themselves do not keep any meaning. In the Spanish language these words are usually articles, conjunctions and pronouns.

Fig. 6. Architecture for the Dataset Collection Process for the Testing and Training of the Machine Learning Model.

5) *Algorithm*: For this project, the Support Vector Machines classification algorithm is chosen, due to its advantage and ability to work with large databases in addition to performing text classification very well because it can handle large functions and in turn demonstrate robustness when the set of data is small and is distributed in a large area, for those reasons it has given reliable results in past research.

In Fig. 6, the process from when the data are obtained to their respective classification and modeling with the chosen algorithm is graphically represented. As mentioned in [24] correct data processing can make the difference between a model with lower or higher performance. This project takes these procedures into consideration to guarantee a model that is as accurate and precise as possible.

In Fig. 7, see a graph that represents the operation of the algorithm, dividing classes, that is, cases versus non-cases, based on a line called the hyperplane. The hyperplane

Fig. 7. Graphic Representation of the Algorithm Used Support Vector Machines [25].

Fig. 8. First and Second Prototype.

is created based on the greatest possible distance from the closest neighboring predictor data points between the classes [25]. More complex data that cannot be separated into two dimensions can be raised to a higher dimension through a process called kernelling.

## V. RESULT AND DISCUSSION

### A. Design and Prototypes

The designs are evidenced based on the sprints and user stories, each one is described to understand in greater detail the functions that are implemented in the mobile platform.

1) *First Sprint:* This sprint focuses mainly on the user interface and menu section, in Fig. 8 can see on the left the prototype that shows the options to be able to register and log in to the application, the use of sober colors is considered in the realization of the prototypes so that they can transmit calm stimulating positive emotions to the user.

In the prototype on the right note the data that the user is required to register and create an account, in turn it has a section where you fill in the data of trusted people or close contacts.

2) *Second Sprint:* This sprint focuses on the part of mental health care of the user, in Fig. 9 the alert message sent to the trusted person or close contact of the user is shown, in this way preventive measures are reinforced and maintained an alert to any risky behavior that can be detected by the app based on the data obtained from the activity on the smartphone.

In the following figure, a form appears on the user's screen that must be filled out monthly in order to have greater control over the behaviors, moods or behaviors that the user may manifest, said screen appear without the need for the user. Once entered into the app, the questions allow to detect symptoms related to depression or anxiety. In addition, an interface appears to the user at the beginning of his day, he must fill it with a mandatory character to know her state of mind, this screen appear daily.

Fig. 9. Third and Fourth Prototype.

3) *Third Sprint:* This sprint is related to the collection of information based on the user's interactions with their social networks and messaging services. In Fig. 10 observe the report that it generates monthly to be sent to the health specialist or medical center where the information was evaluated and allows the user's diagnosis and treatment to be further adapted.

### B. Mobile App

Once the model has been completed and put to the test, the application must now obtain the permissions to access the mobile device and begin to collect data on the user's activities through the use of their social networks and messaging applications. In Fig. 11, see graphically the steps that the application follows once it is installed on the mobile device and launched.

The information already being stored is examined by the artificial intelligence program and is responsible for comparing patterns through a database that determine indications or possible changes in the user's behavior and that may pose a

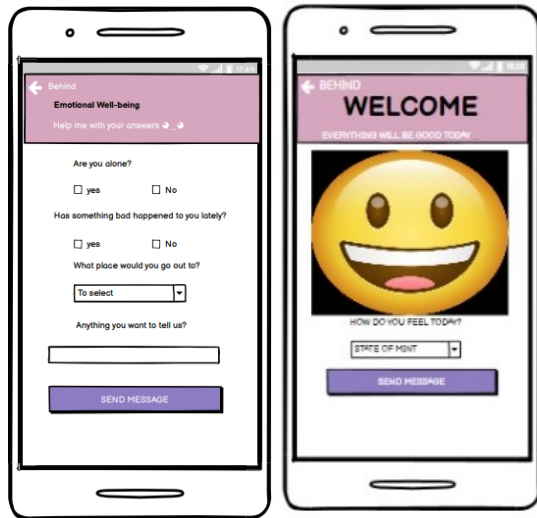

Fig. 10. Fifth and Sixth Prototype.

Fig. 13. Bar Graph Comparing the Performance of the Algorithm Proposed in [26].

In Fig. 13, the Super Vector Machines (SVM) algorithm stands out for the results obtained in precision and F-score (accuracy) obtaining 0.95% and 0.92% respectively, demonstrating good performance to predict users that may present problems of mental health. In addition, the good result of the algorithm is recognized in the face of this type of problem.

#### D. Mental Health in Peru

Mental health problems in the country have increased with the current situation, according to data from INFOSALUD telephone line authorized by the state for citizens who want psychosocial support, it is confirmed that the first 2 places of the most made calls are related to mental health problems where anxiety and depression occupy second place only in the months of April to May 2020 with a total of 3144 calls [27].

Fig. 11. Flow Chart of the Mobile Application.

risk to this or their environment. In case a risky behavior is detected, an alert notification is sent to trusted people who have been registered by the user in the application, being relatives or the assigned health specialist. In Fig. 12, observe the architecture of the app and the processes it carries out communicating through internet access to notify in case the algorithm detects unusual behavior on the part of the user.

#### C. Algorithm Performance

The present work proposes an application for the care and prevention of mental health, mainly focused on depression and anxiety disorders that have worsened even more with the current pandemic. On [26], the good performance of the algorithm chosen for this project is verified, where 3 aspects are taken into consideration: precision, sensitivity and F-score.

Fig. 14. Ipsos Survey 2020 [28].

In Fig. 14, a survey recently carried out by the IPSOS pollster is shown where 37% of those interviewed consider that one of the biggest problems facing the population is mental health.

The survey was carried out during the pandemic period, so the responses of the interviewees reflect the reality of a large part of the population that not only considers to have been affected by the economic situation but also psychologically

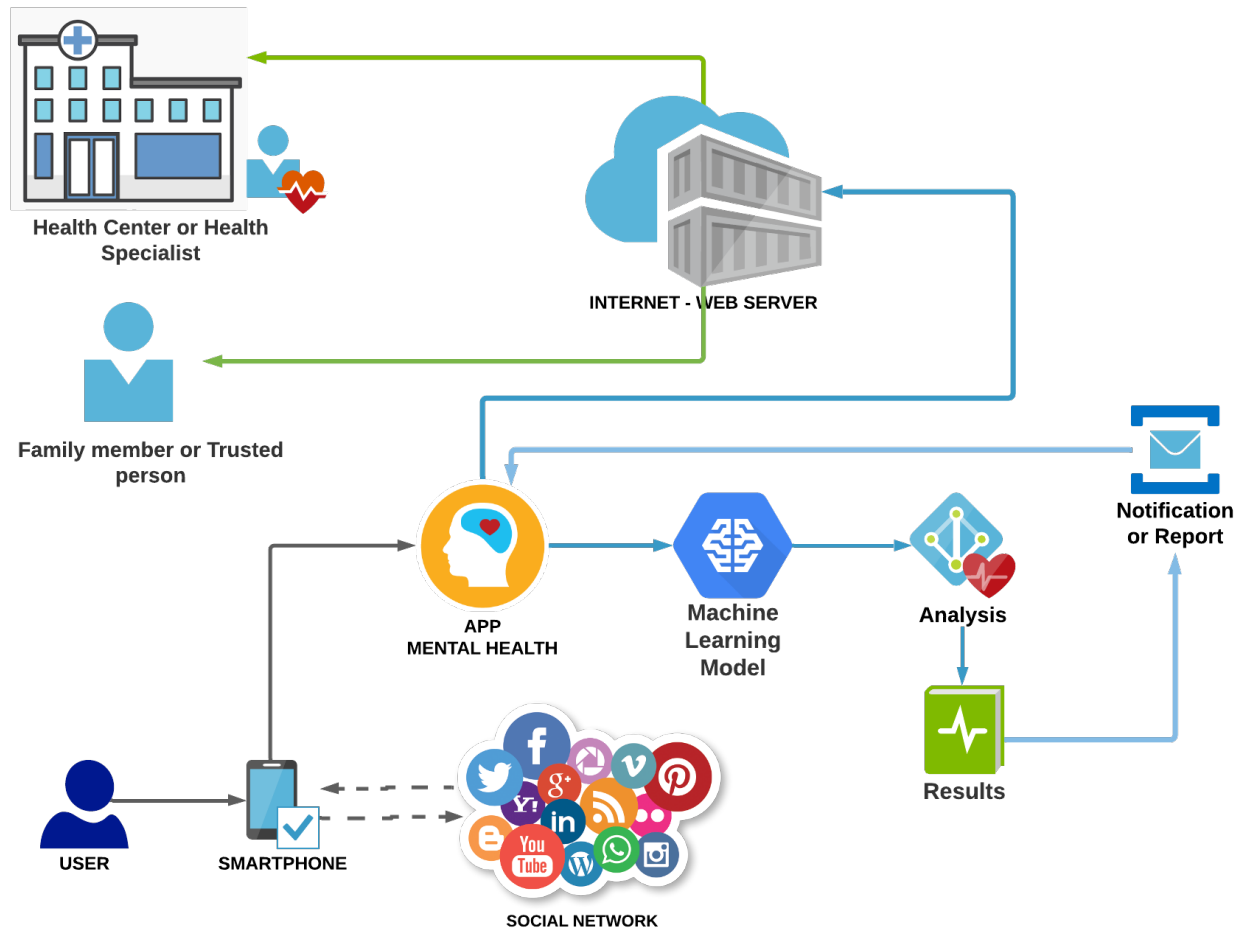

Fig. 12. Mobile Application Architecture.

by the long period of quarantine that still exists lives in the country, added to the fear and concern of being infected with the Covid-19 virus.

The results of this project favor to reduce the psychological effects caused by quarantine for this reason, the development of an application that serves as support to specialized health personnel turns out to be a support that generates a positive impact for both doctors and patients. In this way, access to personalized care is facilitated and appropriate preventive measures can be taken in the event of warning signs that may manifest as risk behaviors that are induced by mental health problems.

## VI. CONCLUSION AND FUTURE WORK

The research concludes that the application of Machine Learning allowed effective and efficient monitoring of mental health care and prevention through better control of user behavior through the use of social networks, even allowing the appropriate measures to be taken. for behaviors that indicate possible harm to your mental health. In addition, the scrum methodology allowed making suitable prototypes to be able to prevent health and thus benefit citizens. For future work, it is

recommended to continue increasing the data for the training of the Machine Learning model, allowing it to be more robust with information related to more mental health diseases and expanding its predictive capacity. This project has only been limited to exploring results considering an ideal environment for data collection, it is also recommended to improve the processing in cases where the data may not be objective, such as cases of sarcasm, spelling errors and spam in the content written by the users.

## ACKNOWLEDGMENT

The research that was carried out was supported by the University of Sciences and Humanities and its research institute.

**Abstract**—Establishing patient-specific finite element analysis (FEA) models for computational fluid dynamics (CFD) of double stenosed artery models involves time and effort, restricting physicians' ability to respond quickly in time-critical medical applications. Such issues might be addressed by training deep learning (DL) models to learn and predict blood flow characteristics using a dataset generated by CFD simulations of simplified double stenosed artery models with different configurations. When blood flow patterns are compared through an actual double stenosed artery model, derived from IVUS imaging, it is revealed that the sinusoidal approximation of stenosed neck geometry, which has been widely used in previous research works, fails to effectively represent the effects of a real constriction. As a result, a novel geometric representation of the constricted neck is proposed which, in terms of a generalized simplified model, outperforms the former assumption. The sequential change in artery lumen diameter and flow parameters along the length of the vessel presented opportunities for the use of LSTM and GRU DL models. However, with the small dataset of short lengths of doubly constricted blood arteries, the basic neural network model outperforms the specialized RNNs for most flow properties. LSTM, on the other hand, performs better for predicting flow properties with large fluctuations, such as varying blood pressure over the length of the vessels. Despite having good overall accuracies in training and testing across all the properties for the vessels in the dataset, the GRU model underperforms for an individual vessel flow prediction in all cases. The results also point to the need of individually optimized hyperparameters for each property in any model rather than aiming to achieve overall good performance across all outputs with a single set of hyperparameters.

**Keywords**—Double stenosed artery; CFD; neural network; LSTM; GRU

## I. INTRODUCTION

Cardiovascular diseases (CVDs) are the most common causes of death around the world. Heart attacks are typically sudden occurrences caused by the narrowing and blockage of blood vessels<sup>1</sup>. A stenosed artery refers to the narrowing of a blood vessel caused by the deposition of atherosclerotic plaque on the inner walls of the arterial lumen [2, 3]. These cholesterol

and fatty deposits lead to a swollen and inflamed inner arterial wall which restricts the flow of oxygenated blood cells, nutrients, and other essential substances from reaching the heart muscles [4, 5]. Cholesterol have been shown to accelerate the formation of plaque in arteries, eventually obstructing the bloodstream and altering hemodynamics [6]. When the plaque ruptures, the accumulated fatty acids, platelets, and dead cells may coagulate, resulting in thrombosis formation [7]. In the case of a coronary or cerebral artery, the blood clot may have fatal consequences since it will also cut off the blood flow to the cerebral region of the brain or the myocardial heart wall [8]. The likelihood of developing thrombosis is highly dependent on the thickness of the plaque, the characteristics of infected blood, and blood pressure [9].

Numerous studies observed pulsing flow behavior and constant dampening of its oscillations, which they attributed to the flexibility of blood vessels [10]. Coronary artery disorder is critical in hemodynamics because it alters the flow pattern, resulting in variations in the wall pressure and shear stress of the arteries. As a result, health researchers must determine the flow velocity and amount of shear stress in arteries. A substantial part of the published research [11] focused on the physiological origins of the disease as they relate to blood vessels. However, few have made strides in understanding the underlying physics of the illness in order to better understand the cause and, as a result, paving the way to less invasive and more long-term treatments. Medical imaging can be utilized to visualize the areas of fatty deposits inside artery walls, but it is not capable of providing numerical data in the same way that computational fluid dynamics (CFD) simulations are capable of providing. According to Kompatsiaris et al. [12] and Liu et al. [13], computational simulations can offer an in-depth evaluation of flow resistance owing to wall shear stress ( $WSS$ ) on blood vessel walls, blood flow rates, and pressure changes. CFD results generated by modeling vessels in the relevant regions may be compared to the reliability of mathematical data. It is possible to develop a less invasive dependable method for medical diagnosis by integrating physician expertise with data derived from realistic computational fluid dynamics models. Owing to the vessel's small dimensions, in vitro, and in vivo flow field experiments are not representative and accurate. Thus, with improved software development and computer

<sup>1</sup><https://www.who.int/news-room/fact-sheets/detail/cardiovascular-diseases-cvds>

efficiency, CFD may replace such experimental approaches. CFD has been already used in several studies involving blood flow through vessels. Fazlay et al. [14] used CFD to show that following a double stenosed region in an artery, blood flow is hampered significantly at maximum systolic velocity and acceleration. Jianhuang et al. [15] coupled transient blood flow with elastic artery to evaluate unsteady flow characteristics along its length using computational fluid dynamics. Mukesh et al. [1] used an in-house CFD solver to verify and simulate blood flow via a stenosed artery. Mehdi et al. [17] compared several turbulent models from blood flow through vessels and concluded that inaccuracies are introduced by assuming the flow to be laminar.

Setting up patient-specific finite element analysis (FEA) models for CFD takes time and effort, limiting quick response to physicians in time-sensitive medical applications. As such, Liang et al. [18] created deep learning (DL) algorithm to predict aortic stress distributions. The DL model was developed to use FEA data and directly produce aortic wall stress distributions, skipping the FEA calculation step entirely. Arzani et al. [19] proposed a Physics-informed neural networks framework for predicting near-wall blood flow and wall shear stress from sparse velocity data concentrated in an interest region. Gao et al. [20] proposed a deep neural network approach that allows machines to recognize fractional flow reserve values directly from static coronary CT angiography images. Such progressions in computer science open up new horizons for further development. For instance, if the diameters of the stenosed aortic vessel are considered at regular intervals, a special kind of artificial neural network called recurrent neural network (RNN) can be implemented. RNN's internal memory allows them to comprehend sequential data. Their ability to retain crucial details about the preceding step, such as aortic diameter, could enable them to predict occurrences in the next step such as *WSS*, blood pressure or flow velocity more accurately. Previously RNN has been successfully implemented for malware classification [21], 3D shape generation [22], traffic forecasting [23], and speech enhancement [24]. While former research works explored various aspects of blood flow through arteries and investigated the predictive capabilities of several DL models, they overlooked such sequential trends in the variation of aortic diameter that occurs within the vessels. As such, it is unclear what effects these specialized RNNs might have on the fast prediction of blood flow characteristics through the arteries. A double stenosed artery is of particular interest in this study since it not only provides wide variations in aortic diameters within a short length but also poses serious health hazards within the human body, so much so that stenting might be required. Thus predicting the flow within them quickly might aid medical researchers with stent improvements and deployment. However, there are several hurdles that must be addressed before such analysis can be performed. As a result, the paper is divided into the following sections in order to discuss them further:

- Section II explains the computational fluid dynamics simulations.
- Section III describes the deep learning models utilized in this study.
- Section IV demonstrates the data source and the organization of the dataset.

- Section V presents the hyperparameters that were fine-tuned in this study.
- Section VI discusses the results obtained.
- Section VII presents the conclusion that can be drawn from the findings.

## II. COMPUTATIONAL FLUID DYNAMICS SIMULATIONS

Several data are necessary to construct a dataset in order to implement artificial intelligence (Ai). The lack of sufficient medical data on blood flow patterns in doubly stenosed arteries necessitates the use of computational approaches to generate the data. This allows for the exploration and visualization of the variations in blood flow behavior induced by several combinations of stenosis at varying distances apart. This section describes the processes used to set up CFD simulations and compares a couple of simplified models to identify which one best depicts the real flow characteristics, using an actual double stenosed artery model as a reference.

### A. Governing Equations

If the Navier–Stokes equation is interpreted as the sum of an average and an oscillating component for each variable, then the continuity and Reynolds averaged Navier–Stokes equations (RANS) are as follows:

$$\frac{\partial \bar{u}_i}{\partial x_i} = 0 \quad (1)$$

$$\frac{D\bar{u}_i}{Dt} = -\frac{1}{\rho} \frac{\partial \bar{P}}{\partial x_i} + \frac{\partial}{\partial x_j} \left( \frac{\mu + \mu_T}{\rho} \left( \frac{\partial \bar{u}_i}{\partial x_j} + \frac{\partial \bar{u}_j}{\partial x_i} \right) \right) \quad (2)$$

where  $\mu$  represents the summation of laminar  $\mu_0$  and turbulent  $\mu_T$  viscosities:

$$\mu = \mu_0 + \mu_T \quad (3)$$

For  $K$ - $\varepsilon$  standard turbulence model,  $\mu_T$  is computed as:

$$\mu_T = \rho c_\rho \frac{K^2}{\varepsilon} \quad (4)$$

where  $K$  represents the turbulence kinetic energy and  $\varepsilon$  denotes the rate of turbulence dissipation.

A straight double stenosed artery can be simply modeled as a tube with a diameter  $D$  with stenosed necks  $S_1$  and  $S_2$  separated by a distance of  $L$ . The degree of obstruction of the stenosed regions can be expressed as follows:

$$\%S = \frac{D-d}{D} \times 100\% \quad (5)$$

where  $d$  is the lumen diameters at neck  $S$ . The fraction of lumen opening at the neck then can be addressed as:

$$\text{Fraction of lumen opening} = 1 - \%S/100 \quad (6)$$

### B. Simulation Setup

Solidworks is used to model the arteries for this study. The blood vessels are assumed to be rigid with the no-slip condition at the arterial wall. Ansys Fluent software is used to set up the simulation and solve the RANS equations utilizing the finite volume method (FVM). The second-order upwind scheme was employed to spatially discretize the governing equations and the SIMPLE method was used to manage the pressure-velocity decoupling [16]. Blood is considered to be an incompressible fluid with a density of  $1050 \text{ kg/m}^3$  and a viscosity of  $0.0033 \text{ Pa}\cdot\text{s}$  [17]. The inlet flow velocities are obtained from the velocity profile presented by Fazlay et al. [14]. The authors pointed out five particular velocities from the waveform:  $0.21 \text{ m/s}$ ,  $0.33 \text{ m/s}$ ,  $0.28 \text{ m/s}$ ,  $0.14 \text{ m/s}$ , and  $0.09 \text{ m/s}$  at maximum systolic acceleration, systolic velocity, systolic deceleration, diastolic velocity, and at minimum systolic velocity respectively. Due to the presence of plasma, platelets, and suspended cells, blood has the characteristics of non-Newtonian fluid [16]. However, numerous previous CFD research treated blood as a Newtonian fluid [14, 17, 25]. In fact, Ku et al. [26] observed that for Reynolds numbers ( $Re$ ) ranging from 110 to 850 in big arteries, the non-Newtonian impact of blood is insignificant. As such, blood is deemed Newtonian in this analysis since  $Re$  stays within this range. The simulations are carried out with a time step of  $0.0001 \text{ s}$  and a mesh element size of  $0.112 \text{ mm}$ .

Fig. 1 shows the velocity profile for the sinusoidal stenosed artery model presented by Fazlay et al. [14] at a distance equal to the vessel's diameter  $D$  away from the stenosed neck using the aforementioned blood flow characteristics and the  $K-\epsilon$  standard turbulence model. The velocity curve closely matches the velocity profile of the model suggested by Mehdi et al. [17] and has a good agreement with the experimental results of Ahmed and Giddens [27]. As a result, further simulations are performed using this particular turbulence model.

Fig. 1. Validation Test Comparing Velocity Profile of Present Simulation with Simulation Result of Mehdi et al. and Experimental Results of Ahmed and Giddens at a Distance Equal to the Vessel's Diameter  $D$  Away from the Stenosed Neck.

### C. Modeling Double Stenosed Artery

Fig. 2 illustrates the modeling of a straight section of an actual doubled stenosed artery obtained via intravascular ultrasound (IVUS) imaging using a  $3 \text{ fr}$  catheter and a  $1 \text{ mm}$  guidewire, with a pullback rate of  $1 \text{ mm/s}$ . It has an average non-stenosed hydraulic diameter of approximately  $4 \text{ mm}$ , with  $40.25\%$  and  $32\%$  stenosis situated  $10 \text{ mm}$  apart. Fig. 3 shows two simplified representations of the actual artery with similar stenoses. Unlike the sinusoidal equation-generated model [14] for a similar configuration, the actual model exhibits a gradual decrease in lumen diameter, as visible from Fig. 4, while Fig. 4 illustrates the variation in blood flow patterns through them. This simplification has a significant effect on the flow characteristics of blood. As demonstrated by Fig. 4, the steep sinusoidal stenosed edges exhibit a wide variation in average velocity ( $V_{avg}$ ), wall shear stress ( $WSS$ ), and pressure from those obtained from the actual model simulation for input velocity of  $0.3 \text{ m/s}$ . As such, a more representative model is required. Fig. 3 presents another model denoted as the splined model. This model features a  $25\%$  stenosis region  $5 \text{ mm}$  upstream and  $5 \text{ mm}$  downstream of the main stenosed neck. When such circular cross-sections are joined with spline guidelines, the simplified model captures the actual model's naturally formed gradual stenosis characteristics. This results in a  $WSS$  curve that is more similar to that of the actual artery model as can be seen in Fig. 4. The  $V_{avg}$  curve also shows a similar trend but is visibly higher due to the absence of surface irregularities to retard the flow as in the actual model. On the other hand, both simplified models fail to represent the actual model's pressure fluctuations effectively, especially at the diverging sections following the stenosed necks.

Fig. 2. Modeling of an Actual Double Stenosed Artery from IVUS Images. For Clarity, Only a Few IVUS Images are Shown.

Fig. 5 illustrates the aforementioned flow characteristics visually. The graphic clearly illustrates the influence of naturally produced uneven surfaces on the actual model. Initially, the blood pressure is rather high in all three models. As the blood reaches the first stenosed neck, the pressure gradually drops to or below zero. According to Bernoulli's principle, the decrease in pressure induces an increase in flow velocity in the stenosed region, as also visible from the figure. This results in a significant rise in  $WSS$  at the constriction site. According to the

Fig. 3. Comparison Between the Sinusoidal and Splined Representation of Stenosed Neck Geometry in a Simplified Model of the Actual Double Stenosed Artery.

continuity equation, when blood travels further into the first diverging section, the increase in the cross-sectional area results in a reduction in flow velocity. As a consequence, pressure rises and  $WSS$  falls. As the blood approaches the next stenosed neck, the velocity increases again but to a lower magnitude due to less constriction there. The pressure decreases once again, along with a slight rise in  $WSS$ . Further downstream, the velocity attains equilibrium, and both pressure and  $WSS$  approach near-zero values. Although not perfect, Fig. 4 and Fig. 5 indicate that the splined model would be a better match than the sinusoidal model for the artificial intelligence (Ai) implementation in the next section. Such is the cost of creating a generalized simplified model without being patient-specific. From these discussions, it is also apparent that the progressive change in the cross-sectional diameter of the stenosed aortic vessel gradually affects blood flow characteristics. This enables the generation of a sequential dataset by taking into account the diameters and flow properties at regular intervals along the length of the blood vessel. The mesh independence test, as illustrated in Fig. 6, demonstrates that changing the mesh element size has a minor influence on the flow characteristics of blood through the splined double stenosed artery model. Between  $0.099\text{ mm}$  and  $0.112\text{ mm}$ , the variation in simulation results is significantly less. As such, it is more reasonable to adopt a mesh element size of roughly  $0.112\text{ mm}$  throughout this study to achieve high CFD simulation accuracy without being too computationally expensive.

### III. DEEP LEARNING MODELS

A recurrent neural network (RNN) is a special kind of Ai network with internal memory that enables it to comprehend sequential data. However, the basic RNN is afflicted by a phenomenon known as vanishing gradient [28]. Long short-term memory (LSTM) and gated recurrent units (GRU) are special kinds of RNN networks developed to mitigate the problem. Their capacity to retain crucial details from the preceding step, such as aortic diameter, would allow them to effectively forecast occurrences in the following step, such as wall shear stress ( $WSS$ ), average velocity ( $V_{avg}$ ) of blood, and pressure. Three techniques are employed in this study to

Fig. 4. Comparison of Flow Characteristics Through the Actual and Simplified Double Stenosed Artery Models.

predict these flow properties: Gated Recurrent Unit (GRU), Long short-term memory (LSTM), and Neural Network (NN) models. All three models used inlet velocity and percentage lumen openings at eleven locations along the  $50\text{ mm}$  long blood artery at regular  $5\text{ mm}$  intervals to predict the blood

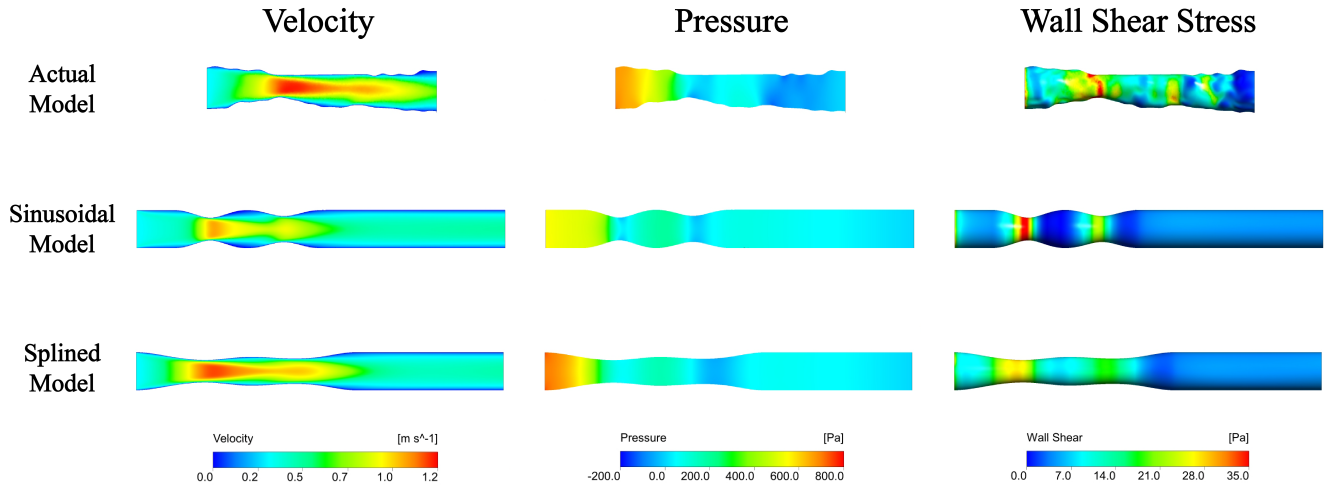

Fig. 5. Visualization of Flow Properties Through the Actual and Simplified Double Stenosed Artery Models.

Fig. 6. Mesh Independence Test with Various Sizes of Mesh Elements.

flow characteristics at those positions. This section highlights each of the three deep learning models.

#### A. Gated Recurrent Unit Model

Gated Recurrent Unit (GRU) [29] is a special kind of recurrent neural network that consists of an update gate and a reset gate. GRU's update gate determines how much data from previous units must be passed on. The update gate computes  $z_t$  for time step  $t$  using the formula:

$$z_t = \sigma(W_z \cdot [h_{t-1}, x_t]) \quad (7)$$

where  $z_t$  is update gate output at the current timestamp,  $W_z$  is weight matrix at update gate,  $h_{t-1}$  information from previous units, and  $x_t$  is input at the current unit.

The model used the reset gate to determine how much information from previous units should be erased. This is

calculated using the following formula:

$$r_t = \sigma(W_r \cdot [h_{t-1}, x_t]) \quad (8)$$

where  $r_t$  is reset gate output at current timestamp,  $W_r$  is weight matrix at reset gate,  $h_{t-1}$  information from previous units, and  $x_t$  is input at the current unit. The relevant data from earlier units were stored in the current memory content using this formula:

$$\tilde{h}_t = \tanh(W \cdot [r_t * h_{t-1}, x_t]) \quad (9)$$

where  $h_t$  is current memory content,  $W$  is weight at current unit,  $r_t$  is reset gate output at current timestamp,  $h_{t-1}$  is information from previous units, and  $x_t$  is input at the current unit.

Final memory at the current unit was a vector that stored and conveyed the current unit's final information to the next layer. This was computed using the following formula:

$$h_t = (1 - z_t) * h_{t-1} + z_t \tilde{h}_t \quad (10)$$

where  $h_t$  is final memory at the current unit,  $z_t$  is update gate output at current timestamp,  $h_{t-1}$  is information from previous units, and  $h_t$  is current memory content.

#### B. Long Short-term Memory Model

Another sort of RNN is the Long short-term memory (LSTM) [30]. In contrast to the GRU, the LSTM contains three gates: the forget gate, the update gate, and the output gate. The LSTM gates' formulae are as follows:

$$i_t = \sigma(W_i [h_{t-1}, x_t] + b_i) \quad (11)$$

$$f_t = \sigma(W_f [h_{t-1}, x_t] + b_f) \quad (12)$$

$$o_t = \sigma(W_o [h_{t-1}, x_t] + b_o) \quad (13)$$

where  $i_t$  represents input gate,  $f_t$  represents forget gate,  $o_t$  represents output gate,  $\sigma$  represents sigmoid function,  $W_x$  represents weight of the respective gate( $x$ ) neurons,  $h_{t-1}$  represents output of previous LSTM block at timestamp  $t - 1$ ,  $x_t$  represents input at current timestamp and  $b_x$  represents biases for the respective gates( $x$ ).

Both GRU and LSTM models utilized the many-to-many combination, with an 11 node dense layer as the output, to predict the  $V_{avg}$ ,  $WSS$ , or blood pressure at the eleven positions, taking the aforementioned inputs. These models are depicted in Fig. 7. The hyperparameters of these models were varied in order to maximize the prediction accuracies across all three flow properties.

Fig. 7. Illustration of LSTM / GRU Ai Models in Many-to-Many Configuration.

### C. Neural Network Model

The other aspect of the present study is the neural network (NN) as shown in Fig. 8. It is defined as a collection of algorithms that are capable of correctly recognizing the underlying connections between a set of data via a method that replicates the way the human brain works. They are not limited to sequential data and are composed of nodes with assigned weights. Through the forward and backward propagation processes using labeled data, the network is able to fine-tune the weights to make accurate predictions. It also, applied the same inputs as the previous two models to predict the same flow features. The hyperparameters were also varied for this model to improve its accuracy.

## IV. DATASET

Since the present study involves a newly proposed doubled stenosed artery model, a dataset of CFD simulation results relating to it is unavailable. As such, a custom dataset containing 180 data points was constructed. To create the dataset, several configurations of fractions of lumen opening at each stenosed neck, gaps between them, and inlet velocities, as previously mentioned in the simulation setup section, were used. In particular, stenosis severity levels of 25%, 50%, and 75% were applied at individual necks, with 10 mm, 15 mm, 20 mm, and 25 mm spacing between them. 90% of the total data were utilized for training, while the remaining 10% was

Fig. 8. Illustration of Neural Network (NN) Ai Model.

used for validation. A different test set containing 18 datapoints was also constructed using configurations that were absent in the main dataset, such as different inlet velocities and stenosis severity levels of 70%, 60%, 40%, 30%, etc. Due to the lack of additional IVUS images with similar double stenosis conditions, the blood vessel employed is a generalized form of a patient-specific actual model. Overcoming such hurdles, as well as including CFD simulations of curved vessels in the future could make the dataset even more beneficial.

## V. HYPERPARAMETERS

In order to improve the accuracy of these three models, several hyperparameters were tuned. Table I summarizes the ranges of the parameters varied. Firstly, different units for the LSTM / GRU models and different numbers of hidden layers (HL), containing 12 nodes in each, for the NN model were tested to determine the conditions that performed well for predicting all three flow properties. Subsequently, the number of epochs and the learning rates were optimized to maximize the accuracies of the deep learning models. Other parameters such as the loss function, activation functions, and optimizer were kept uniform in all models to provide a fair comparison. Initially, min-max normalization was used to ensure that all of the data in the dataset was within the range of 0 to 1.

To compute the loss, each model utilized the Mean squared error (MSE) function which is represented by the formula:

$$L(y, \hat{y}) = \frac{1}{N} \sum_{i=0}^N (y - \hat{y}_i)^2 \quad (14)$$

where  $\hat{y}$  is the predicted value,  $N$  is the number of data points, and  $y$  is the observed value. MSE in particular can penalize large errors more than smaller ones, making it a good choice for achieving multiple accurate predictions. Each dense layer utilized the sigmoid activation function, which produces a probabilistic output that exists exclusively between 0 and 1, following the equation:

$$\phi(z) = \frac{1}{1 + e^{-z}} \quad (15)$$

For its capability of achieving excellent results quickly and effectively, the Adam [31] optimizer was implemented in all of the models.

TABLE I. HYPERPARAMETERS ADAPTED IN DIFFERENT MODELS

## VI. RESULT AND DISCUSSION

Training and testing accuracies were used to assess the three suggested Deep Learning approaches. These accuracies indicated the degree to which each model could correctly predict  $V_{avg}$ ,  $WSS$ , or blood pressure during testing or training. The variance in the accuracies for varying the number of units in the GRU and LSTM models, as well as for different the number of hidden layers in the NN model is represented in Table II. In these cases, the number of epochs and learning rate were kept constant at 100000 and 0.0001 respectively. Owing to a small dataset, the LSTM model with 84 units overall performed well across all flow properties for both training and test sets, as visible in the table. In contrast, the GRU model did well throughout both sets with only 48 units. Extending the units beyond these ideal values seems to degrade the efficacy of both models. On the other hand, the NN model shows an overall decreased effectiveness in predicting the flow properties for both sets as compared to the other two models with the same number of epochs and learning rate. Nonetheless, testing with different numbers of hidden layers reveals that the smaller number of data prefers a shallower architecture with 2 intermediate layers only, having good accuracies on most occasions. Pressure values in the dataset were either very large or very small at certain points along the length of the vessel, as also visible from Fig. 4. As a consequence, when these numbers were normalized, tiny values were transformed to near-zero values, while bigger values were changed to near-one values. As such, each model only needed to learn either of these two extreme quantities at certain locations, leading to much higher accuracies for both training and test sets.

To further tune the hyperparameters and improve the accuracies of the models, the number of epochs was varied from

50000 to 200000 while keeping the learning rate constant at 0.0001. Based on the previous evaluations, the number of units for LSTM, GRU, and the number of hidden layers for the NN model is set to 84, 48, and 2 respectively. The results of these evaluations are reported in Table III. It can be seen that for the LSTM model, the highest accuracy for  $V_{avg}$  is obtained at 200000 epochs, whereas pressure achieves the greatest accuracy at 150000 epochs. The predicting effectiveness for  $WSS$  remains unchanged from 100000 to 200000 epochs. However, the average testing accuracies across three properties are much lower above and below 100000 epochs, indicating the model cannot generalize well in those ranges. The GRU on average also performs very well at 100000 epochs using both sets of data. The training dataset for the NN model clearly prefers the higher epochs but the peak average test set accuracy at 150000 epochs indicates non generalizing effect beyond this value.

Finally, the learning rates of each model are tuned, setting the other hyperparameters to their predetermined optimum values. The results of these investigations are shown in Table IV. The table suggests that LSTM performs very well in predicting the flow properties for learning rate in between 0.01 to 0.0001, whereas GRU is most accurate for a rate of 0.001. NN model on the other hand prefers a learning rate between 0.001 and 0.0001. In certain cases the larger learning rate overshoots, destabilizes the training process, and fails to reach optimum accuracy, for example, NN for predicting pressure of the flow. It also tends to overfit the data from both LSTM and NN models. Too small learning rate isn't beneficial either since it also lowers the overall accuracies of all the models across the three flow properties. Although not the most accurate in every instance, a learning rate of 0.001 that can generalize well is preferred by all three models to reasonably predict each of the flow properties from both datasets.

Fig. 9 compares the predicted flow characteristics obtained with the optimized hyperparameters to the CFD simulation results obtained with the real and splined models for the identical configuration with 40.25% and 32% stenosis located 10 mm apart. In the case of average velocity, the LSTM model overestimates, while the GRU model underestimates, and therefore fails to effectively estimate the flow pattern. On the other hand, the NN model is far more accurate at forecasting flow velocity patterns and is comparable to the simulation results achieved with the splined model. Again, for  $WSS$ , the NN models perform well and closely track the simulation outcomes. Interestingly, the prediction imperfections put the LSTM model's  $WSS$  pattern prediction closer to the actual model's simulation outcomes without even training on that model. Nevertheless, both LSTM and GRU models fail to predict the  $WSS$  pattern entirely. Then again, the LSTM model performs much better at predicting pressure fluctuations, while the GRU model's simplicity prevents it from learning the pressure changes effectively from the small dataset. Unlike the other two properties, the NN model seems to be less capable of comprehending flow pressure variation. Thus, Fig. 9 further demonstrates that tuning the hyperparameters to generalize the models for predicting all flow properties leads to their overall diminished performance. As such, although more effort is necessary, optimizing the models based on each of the flow characteristics individually would be more beneficial. Additionally, the graphic illustrates the NN model's supremacy

TABLE II. ACCURACIES ACHIEVED BY DIFFERENT MODELS BY VARYING THE NUMBER OF UNITS FOR THE GRU AND LSTM MODEL AND CHANGING THE NUMBER OF HIDDEN LAYERS FOR THE NEURAL NETWORK MODEL

| Model | Units/HL | Epoch  | Learning Rate | Training  |        |          | Testing   |        |          |

in predicting short lengths of sequential data from a small dataset.

## VII. CONCLUSION

The present study explored the faithfulness of simplified models' flow characteristics to that of the actual model derived from IVUS imaging. The model with a sinusoidal representation of stenosed geometry, which has been widely used in earlier research, entirely fails to portray the actual model's fluctuations in flow property patterns. Although not fully perfect, owing to non-circular cross-sections of the actual model, the newly proposed splined model stands out as a better representation for the construction of a database with various percentage stenoses with varying gaps between them,

for implementation of artificial intelligence. The sequential nature of the input and subsequently the flow properties opened up opportunities for specialized RNNs to be implemented. As it turns out, the short lengths of the vessel and small dataset prefer a simpler, less sophisticated conventional neural network model with shallow architecture for efficiently predicting most flow parameters, such as average velocity and wall shear stress. On the other hand, the considerable variation in pressure along the short length of the vessel favors the computationally expensive LSTM model with a large number of units. The simpler GRU model, although generalized well in terms of over accuracies across both training and test sets, fails to generate better predictions than the other two Ai models for any individual double stenosed artery. This highlights the fact that

Fig. 9. Comparison Between Predicted Flow Characteristics with Optimized Hyperparameters and Simulated Results of Actual and Splined Artery Models.

instead of aiming to achieve overall good performance across all outputs with a single set of hyperparameters, each property needs to be addressed and models optimized individually. The major limitation of this study has been its small dataset. With more CFD simulations featuring stenosis configurations in

between those used in this training dataset, as well as with more inlet blood flow velocities within the relevant range it might be possible to improve the efficiencies of the Ai models. Future work on this subject might involve simulating and forecasting flow characteristics for curved vessels in order to make it an even better representation of the arteries naturally found in the human body. In addition, new Ai models might be developed to generate images directly from input fraction lumen opening data in order to better analyze blood flow patterns through double stenosed arteries. Such advancements, as well as the current findings, would allow medical researchers to swiftly estimate the severity of blood flow obstructions through constricted arteries, thereby assisting in stent development and deployment.

#### DECLARATION OF COMPETING INTEREST

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

#### ACKNOWLEDGMENT

The authors would like to express their gratitude to Dr. Md. Habibur Rahman, Associate Professor and Senior Consultant Cardiologist at National Heart Foundation Hospital & Research Institute, for providing medical expertise and IVUS imaging for this study.

**Abstract**—There are many different programming languages and each programming language has its own structure or way of writing the code, it becomes difficult to learn and frequently switch between different programming languages. Due to this reason, a person working with multiple programming languages needs to look at documentations frequently which costs time and effort. In the past few years, there have been significant increase in the amount of papers published on this topic, each providing a unique solution to this problem. Many of these papers are based on applying NLP concepts in unique configuration to get the desired results. Some have used AI along with NLP to train the system to generate source-code in specific language, and some have trained the AI directly without pre-processing the dataset with NLP. All of these papers face two problems: a lack of proper dataset for this particular application and each paper can convert natural language into only one specified programming language source-code. This proposed system shows that a language independent solution is a feasible alternate for writing source-code without having full knowledge about a programming language. The proposed system uses Natural Language Processing to convert Natural Language into programming language-independent pseudo code using custom Named Entity Recognition and save it in XML (eXtensible Markup Language) format which is an intermediate step. Then, using traditional programming, this system converts the generated pseudo code into programming language-dependent source-code. In this paper, another novel method has been proposed to create dataset from scratch using predefined structure that is filled with predefined keywords creating unique combination of training dataset.

**Keywords**—*Natural Language Processing (NLP); Natural Language Interface (NLI); Entity Recognition (ER); Artificial Intelligence (AI); source code generation; pseudocode generation*

## I. INTRODUCTION

Source-code is a list of human-readable instructions written in particular programming language. The aim of source-code is to check for precise specification, format and rules so that it can be interpreted into machine language [1]. Therefore, source-codes are the fundamentals of a computer program. It is usually written by a programmer or developer that has some training and knowledge of the programming language. There are many independent languages and each has its own distinctive way to writing instructions.

Natural Language Interface (NLI) provides a different input method in which users can interact with computer using spoken human language, like English instead of using a graphical user interface (GUI), command line interface (CLI) or computer languages like C and Python [2]. NLI enables the computer

to recognize and understand the flow of human language by providing an abstract layer that connects computers to users [3]. It enables users to enter their search queries in natural language which can be in either spoken audio or written text. The goal for most natural language systems is to make the system easier to use and to provide an interface that decrease the training time required for users.

The proposed system aims to generate source code of various programming languages like python and C using natural language as input. Making use of NLI to generate source-code can help beginners understand the language well. It can also help professionals to increase their working speed as uncommon and easy problems can be solved without going through documentation of that programming language.

As writing source-code is becoming more widespread and complicated, it is becoming an essential to automate writing simpler source-code by AIs to save time in writing, learning and understanding source-code. With Natural Language Processing (NLP) getting better and simple with each year and the demand for writing new and complex source code is increasing every year, it was inevitable for these two fields to join. There are many natural language interfaces that connect NLP with databases but not many programs that connect NLP with computer languages. Creating an Natural Language Interface that helps programmers to create source code will reduce the time it takes for them to write source code as they will refer to complex documentation less frequently and will reduce the bar to enter the world of programming language.

## II. LITERARY STUDY

### A. Different Natural Language Interface Approaches

Review of different approaches in natural language interfaces to databases [4] published by Reshma E. U. and Remya P. C. explores some Natural Language Interfaces to Databases (NLIDB) trends in 2017. They found that current NLIDB system consists of following types: 'Pattern matching' (i.e. Using manually defined rules), 'Syntax based system' (i.e. Creating parse tree and mapping it to database), 'Semantic grammar system' (i.e. Passing user input with hard wired semantic grammar and then creating parse tree which will be mapped to database) or 'Intermediate representation system' (i.e. it first translates the natural language input into intermediate logical query and then, it translates intermediate logical query into database query language.

There are many such systems that follow the same techniques and patterns with minor changes, namely, "IQS - Intelligent Querying System using Natural Language Processing" [5] and "MyNLIDB: A Natural Language Interface to Database" [6].

The advantages of these NLIDBs are that the users does not need to learn any artificial language, no need for spending time on training, simple and easy to use, are better for some questions and have high fault tolerance.

The disadvantages of these systems are that they deal with small amount of natural language i.e. can recognize limited set of words, errors and failures are not properly handled, ambiguity i.e. one word having many unrelated meaning can cause the query to change its meaning and finally users may not construct the query using recommended or pre-programmed words.

### B. Natural Language Query to SQL

In the paper "Formation of SQL from Natural Language Query using NLP" M. Uma et. al. [7] used the following techniques to extract information from natural language.

First, they extracted 'attribute' using Parts Of Speech (POS) tags. They used tokens next to a proper noun (i.e. NNP tag in NLTK Library). To search for 'date' they used regular expression (RegEx) to extract it using common writing formats. To extract 'fares' they used lemmatized word 'fare' and finally they used RegEx again for extracting train names.

This system is very rigid and can only perform SQL tasks on predefined database. But, we can use these methods to tag our own data to give to an AI model

### C. Conversion of Natural Language Query to SQL Query

In the paper titled "Conversion of Natural Language Query to SQL Query" by Abhilasha Kate et. al. [8] they first performed "Tokenization" on their input sentence and remove the stop words, then those tokens would be passed onto "Lexical analysis" which will replace all the words with their dictionary counterpart. This is the step where the natural language starts to look like a SQL sentence. Lastly, "Semantic Analysis" is performed which will replace natural sentence (e.g. less than or equal to) to their symbol counterparts (i.e.  $\leq$ ).

The given system has a shortcoming in lexical analysis phase as all the keywords needs to be known beforehand to be able to match those keywords with dictionary.

### D. Language to Code

The paper titled "Language to Code with Open Source Software" [9] published by Lei Tang, Xiaoguang Mao and Zhuo Zhang uses an encoder-decoder technique to automatically train NLP to generate source-code. They first converted the natural language descriptions into word-embeddings and fed it into the encoder to generate coding vector. Then the decoder maps this vector back into the desired code. They used LSTM neural network to train their model. Due to the labor-intensive nature of generating dataset they used a previously proposed method by Gu Xiaodong et.al in the paper "Deep code search" [10]. In this paper they proposed a unique method

to create training dataset i.e. they used comments from a Java program and its attached code snippet from open source Java projects as the dataset.

Even though this technique covers many complicated code scenarios, this technique is limited by the programming language it generates (here they can only generate Java source-code). To generate source-code in other programming languages, we need to create another database from scratch which is a lengthy and tedious task. From this system we can adopt the training methods they used with the databases tagging techniques they used.

### E. Natural Language Database Query Interface

"A Simple Guide to Implement Data Retrieval through Natural Language Database Query Interface (NLDQ)" [11] published by Tameem Ahmad and Nesar Ahmad uses a straight forward approach to convert a natural language statement to database query. They first used "Tokenizer" to divide the input into individual tokens or words. They then used "Parsing" to create a parse tree with its related POS (parts-Of-Speech) tags. After this they used "Syntactic Comparison" to check if any keywords that appeared in the input is already available in the database as either a direct match or a alias of it. Lastly, in "SQL Generator" they used static templates that can be used as fill-in-the-blanks to choose the correct template and fill all the related fields labeled in previous steps.

The main advantage of this type of system is that it is easy to make any new changes that the client requests. But the downsides are that this is a very rigid system that is tied to a particular database. Although, we won't tie our system with templates, but each programming language uses a predefined format (i.e. main function, indentation, parentheses "}", etc.) which we can add to our system.

### F. Modified Co-occurrence Matrix Technique

Anuradha Mohite and Varunakshi Bhojane [12] proposed a updated way to find co-occurrence matrix formulation in the paper titled "Natural Language Interface to Database Using Modified Co-occurrence Matrix Technique". They first parsed the input to create POS (i.e. Parts Of Speech) tags and parse tree. They then used modified Hyperspace Analogue to Language (HAL) matrix to find tokens related to nouns. Using cosine-similarity they get a table with nouns associated with different POS and using this technique they identified the WHERE clause in SQL (Structured Query Language).

With the hardest part of the query now identified they used stemming technique to convert all words into their common roots and then used semantic mapping to find words such as min, max, avg,  $\geq$ , etc. Once these word are identified they used bi-gram algorithm to find correct attribute and table name from the database and create the final query to be displayed to user along with its output. "Natural Language to Structured Query Language using Elasticsearch for descriptive columns" [13] uses similar approach with changes made in word embeddings.

Their clever use of POS tag pair such as "numeric value-noun pair" or "proper noun-noun pair" to find where clause in SQL can help us to identify inconsistent attributes such as names of variables and functions in our system.

### G. Pseudocode to Source-code

Teduh Dirgahayu et.al. [14] proposed a method to automatically convert pseudocode to Source-code. In this method, the pseudocode is first translated to an intermediate model then to source-code. The intermediate model consists of a parse tree that is created with the help of a tool called ANTLR. This represents pseudocode in a more structured and language independent way. Then language dependent tool for generating source-code is created.

The main shortcoming of this method is that the pseudocode which is in the form of XML needs to be created manually. This manual pseudocode and source-code must comply to their respective grammars (i.e. metamodels). The XML intermediate model must comply to a XML schema.

### H. An XML-based Pseudo-code Online Editing and Conversion System

Liu Haowen et.al in their paper "An XML-based Pseudo-code Online Editing and Conversion System" [15] introduced an innovative way to convert pseudo code into source-code. They first convert the input pseudo code into an XML (eXtensive Markup Language) format using DOM4J package available in Java programming language. From there, using the same DOM4J package, they converted the pseudo code in XML format into Java source-code. In doing so, they also created XML tags for pseudo code which we can use in our system as a reference.

The reason to choose XML is that it is a cross-platform language i.e. they can be used in any software and in any operating system making this system independent of any programming language.

### I. Pseudocode to Source-code using NLP

Ayad Tareq Imam et.al [16] proposed a unique way to convert pseudocode to source-code i.e. using NLP. The problem with this method is that it presents a complex solution to a simple problem. As seen in previous 2 papers [14] & [15], the same output can be achieved with simple one-to-one mapping.

### J. Generating Source-code without NLP

Till here we have studied ways to generate structured code like SQL queries (due to lack of source-code generation) using NLP techniques. There are other papers that can generate proper source-code but they bypass the NLP requirements and directly train their models to generate source-code from training data.

Some such papers are "DeepCoder" [17], "Text2App" [18], "Generating Pseudo-Code from Source Code Using Deep Learning" [19], "Incorporating External Knowledge through Pre-training for Natural Language to Code Generation" [20], "In-IDE Code Generation from Natural Language" [21] and "Programming with a Differentiable Forth Interpreter" [22].

All these papers faces a problem of lack of source-code datasets. Some uses premade dataset, many generate their own. Another problem they face is all these papers generate source-code in one specific programming language

Fig. 1. History of NLP Concepts.

### K. History of Various Concepts of NLP

Fig. 1 lists the papers where important concepts have been introduced in history of NLP with the importance of the paper. These concepts have been used in our system. The Long Short-Term Memory (LSTM) neural network [23] has not been mentioned explicitly in our system but we used this neural network to train our various NLP models.

Some may argue that the NLP as a field began when Warren Weaver mentioned using of modern computing devices to translate from one language to another in his memorandum [24] in 1949 and the rest is history.

1) *Parts of Speech*: Noam Chomsky in 1956 [25] introduced the concept that grammar of a language can be viewed as a theory of the structure of this language and is based on certain finite set of observations. It introduced the finite-state language for NLP that we called today as Parts Of Speech (POS).

2) *Stemming Algorithm*: The stemming algorithm which converts all the redundant words to its common "stem" was published in 1968 by Julie Beth Lovins [26]. Surprisingly its main purpose was not for NLP purposes but for retrieving huge amount of data from databases (back then data transfers were a lot slower).

3) *Porter-Stemming Algorithm*: The famous porter-stemming algorithm was easy to find as it is in public repository online. This was developed to further improve the efficiency of the information retrieval systems of the various stemming algorithms available at that time [27].

4) *The Viterbi Algorithm*: Although, Viterbi algorithm was originally proposed to calculate the error bounds in convolutional codes [28] as just a proof of concept, David Forney Jr. [29] in his paper "The Viterbi Algorithm" modified this algorithm for NLP purposes. Till this date we use this algorithm alongside with Hidden Markov Model to predict the POS tag of a word with probability even though an AI solution exists.

5) *Named Entity Recognition (NER)*: "Nymble: a High-Performance Learning Name-finder" published by Daniel Bikel et.al. [30] was the first to introduce a Named-Entity Recognition system using slightly modified Hidden Markov Model. It performs at or above the 90% accuracy level, often considered "near-human performance".

Observing all those systems, we came to conclusion that there is a lack of NLP system where a natural language is converted into a source-code (all those systems converted natural language into database queries). Also, those systems that do convert to natural language does not allow customizations (i.e. adding custom keywords to recognize) as a feature.

Our project intends to introduce a novel method that helps the programmers in developing source-code and increasing their speed and efficiency.

### III. PROBLEM STATEMENT

The project intends to introduce a novel method that helps the programmers in developing source-code increasing their speed and efficiency.

- An interface to take natural language as input.
- An option to select programming language on the interface (initially python).
- Convert natural language into pseudo code using NLP (using intent recognition and entity recognition).
- Convert pseudo code into source-code (using traditional programming).
- Output the source-code onto the interface.

### IV. PROBLEM DEFINITION

For a programmer, the ability to learn a programming language's commands and functions on the fly is crucial to the time they spend on creating a source-code. No matter the skill of the programmer, there are always cases where they have to tackle uncommon features present in a programming language which they have not seen before. To solve those uncommon and unseen features they refer documentation of

that programming language and then learn from it which requires time.

The programmers can define the problem in natural languages easily, the problem lies in remembering the exact keywords and parameters. By providing a Natural Language Interface we can shorten the time the programmer takes to search through documentations. It can also help to reduce the skill and experience required to write complicated source-code which heavily depends on using functions.

### V. PROPOSED WORK

- 1) A python based interface to input English natural language and an option to choose target programming language.
- 2) Gather training data from the internet. The data will be simple beginner's problem statements from various sites for variety.
- 3) Provide "Parts Of Speech" (POS) tags to each word.
- 4) Train "Intent Classification" to recognize different operations such as "addition", "multiplication", "variable declaration", "print statement", etc.
- 5) Train "Entity Recognition" to recognize various data types of variables.
- 6) Identify variable names through POS if they are present in the input.
- 7) Write a function for each "intent" and extract information like number of variables, their type and name if it is present and other information if required.
- 8) Convert the extracted information into a pseudo code in a XML format.
- 9) Read that XML file and convert it into source-code through python.
- 10) Save the source-code into a file.
- 11) Display the file into the interface.

### VI. LIBRARIES REQUIRED

#### A. Tkinter

Tkinter is the standard GUI library for Python. Tkinter provides a fast and easy way to create GUI applications [31]. Tkinter provides various controls, such as buttons, labels and text boxes used in a GUI application. These controls are commonly called widgets.

#### B. NLTK vs SpaCy

NLTK (Natural Language Toolkit) [32], spaCy [33] and Stanford's CoreNLP [34] are all similar libraries that provide off-the-shelf functions for NLP. As we are using "python" programming language for creating a demo, we need to list all pros and cons on NLTK and spaCy libraries as those support the python language, coreNLP does not (it only supports Java). Table I lists the differences between NLTK and spaCy libraries.

The paper titled "Using Natural Language Processing to Detect Privacy Violations in Online Contracts" by P. Silva et.al. [35] and another paper titled "Extractive Automatic Text Summarization using SpaCy in Python & NLP" [36] made comparison between spaCy, coreNLP and NLTK and came to conclusion that coreNLP has the best performance in terms of precision, recall and F1 score followed by spaCy and lastly NLTK.

TABLE I. NLTK LIBRARY VS SPACY LIBRARY

| NLTK                                                                                                                  | SpaCy                                                                                                                                                                             |
|-----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NLTK (Natural Language Toolkit) library was released in 2001.                                                         | SpaCy library was released in February 2015.                                                                                                                                      |
| NLTK library is only supported in "python" programming language.                                                      | SpaCy is supported in number of programming languages like "R", "ruby", "cpp", "java script", ".net", "python", etc.                                                              |
| NLTK has a lot of algorithms as compared to spaCy which is helpful in learning and research applications.             | SpaCy has a small group of algorithms that they regularly update, which is critical in industry usage.                                                                            |
| As it is not updated regularly, the algorithms provided by NLTK are comparatively slower than spaCy.                  | With their regular update to latest techniques spaCy is significantly faster than NLTK.                                                                                           |
| NLTK incorporates several languages.                                                                                  | SpaCy have statistical models for seven languages including English, German, Spanish, French, Portuguese, Italian, and Dutch, It also braces "named entities" for multi-language. |
| NLTK is string processing library. It takes input as strings and provides output as string or lists of strings.       | SpaCy uses object-oriented approach. It takes input in string but return the output in objects.                                                                                   |
| NLTK does not support word vectors.                                                                                   | SpaCy has support for word vectors.                                                                                                                                               |
| NLTK tries to break the text into sentences. It just returns the words itself, no extra information is given with it. | SpaCy builds a semantic tree for individual sentence as higher a potent approach, returns more information.                                                                       |
| NLTK has inferior precision, recall and F1 score than spaCy.                                                          | SpaCy has better precision, recall and F1 score than NLTK.                                                                                                                        |

### C. Regex

Although spaCy provides "Pattern Matcher" functionality to its toolbox which is similar to regex, a regular expression or regex can be used in some limitations of spaCy's pattern matcher.

A regex defines a set of strings that lets you check if a particular string is present in a large text [37]. The most common usage of regex is to alert system administrators if an error appeared in log files. Another example would be to extract phone numbers, email addresses from a large database. It is commonly used where fixed pattern appears.

To find a email address that has the format "someone@somedomain.sometopleveldomain" (eg. john@gmail.com) we use the regex "[a-zA-Z0-9+@][a-zA-Z0-9-]+.[a-zA-Z0-9-]+]" to find emails in plethora of texts.

## VII. WORKING MODEL

The main goal of our system is to convert "Natural Language" statements into source-code. It is able to handle one line statements as input and can generate 3-5 lines source-code depending on the input given.

Fig. 2 shows the working of our system when the system has been deployed at the client side. It is a step-wise working model which defines the processes from user input to showing output to the user and all the other steps in-between. In this figure, the light-blue nodes denotes the generation of files. For example, the node "Pseudo code statement/command" denotes saving the .xml file in log folder. The white nodes denotes processing.

### A. NLP Translator

The first step in this process is to get the user input. The input has to be in English natural language and has to describe

the programming problem. Once the input is received the "NLP Translator" uses a trained NLP model to break down the input and extract important information from it. In this process, the first thing applied is "Tokenizer" to split the input into individual tokens or words, then entity extractor identifies important keywords like equals sign, condition statements, etc. Next, the "Intent Identifier" identifies what kind of operation does the user wants to perform like "addition", branching, etc. Lastly, POS is used to identify the variable name, its value (if present) and function/program name.

### B. Post Processor

Once all the input has been identified, it's time to convert the extracted information into a pseudo code, this is done is "Post Processing" step. It first arranges the input in specific order that resembles a pseudo code, adds extra information if missing and the using XML parsers converts the pseudo code into XML. After this we are left with pseudo code file that is easier to read by both humans and computers thanks to the XML format.

### C. Rule Based Translator and Its Post Processor

Rule Based Translator is an easier step that reads the pseudo code line by line and converts the keywords from universally understood to language specific format. The post processor adds extra features to the syntactical code like parenthesis "{ }", indentation, semi-comma ";", etc. The output is then saved on disk and displayed to the user on the interface.

## VIII. ALGORITHM

Algorithm given in Fig. 3 is a coarse-grain view of the proposed system that gives the basic steps needed to implement this system.

We first start by creating an interface that can get input and provide output. Second step is to search for a dataset. Since, we did not find any we created the dataset from scratch. The method of which is defined further ahead.

Next is to create a Named Entity Recognition or NER model. To create a NER model we first need to provide Parts Of Speech or POS tags which then be used by NER model to identify various entities.

Once the system is trained we then start extracting information from it. The first information we extract is variables, their name, datatype, scope and value. After which "operations" are identified and all the variables associated with it are processed i.e. each individual part of the operation is identified (for example, in the statement "add var1 and var2", add is the type of operation, var1 and var2 are the two variables associated with it).

The extracted information is then parsed into XML format and a pseudocode file is generated. Then this XML pseudocode file is read again by the system and is converted into source-code. This source-code is saved on the user's system and displayed on the interface.

## IX. SYSTEM DESIGN

Fig. 4 is a detailed view of the proposed system that explains the steps needed to create this system.

Fig. 2. NLI-GSC Working Model.

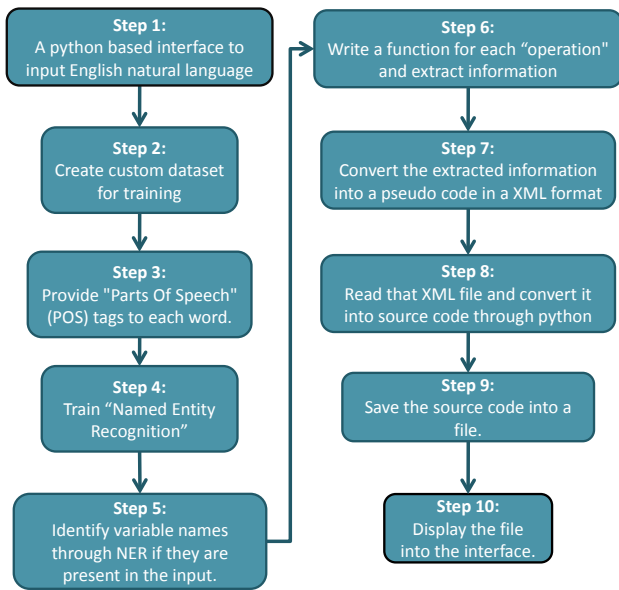

Fig. 3. Algorithm of NLI-GSC System.

A. Data Generation

There are not many NLP datasets, if any, that address the programming aspects that we can use. Generating data manually for an AI system is very tedious and time-consuming process as it requires a minimum of hundreds of data to provide any acceptable results. Hence, due to these reasons we have developed an automated system that can create its own dataset.

As seen in Fig. 4 & 5, we first define "nutrients" tokens i.e. variations of similar word. For example, "DATATYPE" is a nutrient containing integer, int, float, str, string, etc. We then define "seed" sentences. Seed sentences are made up of combinations of "nutrients". An example of seed sentence is "COMMAND DATATYPE VARIABLE" which when expanded will result in sentences like "create integer var1", "define float area" and "initialize string text\_1".

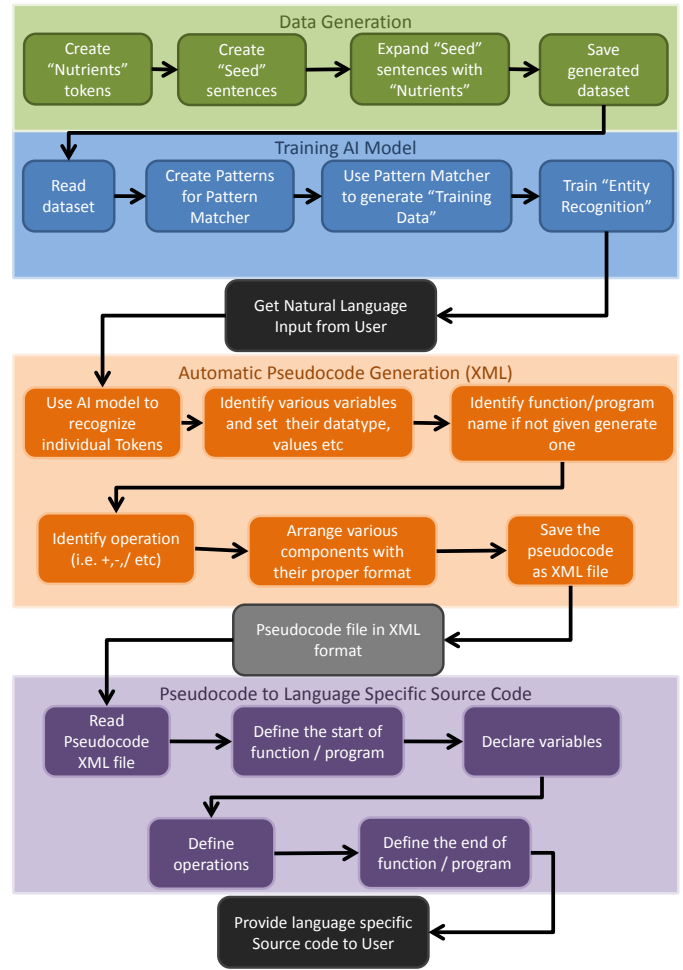

Fig. 4. NLI-GSC System Design.

The next step is to expand the seeds using individual nutrient tokens. This will result in generating all the possible combination of statements for the given format. In our program, we were able to generate 1,565,668 statements from 23 seed statements (each seed's length ranging from 3-6 nutrient

tokens) and 19 individual nutrient tokens. Since, 1.5 mil is too much of a dataset, we have reduced it with the ratio 1:20 resulting in getting a final dataset of 78,284 statements.

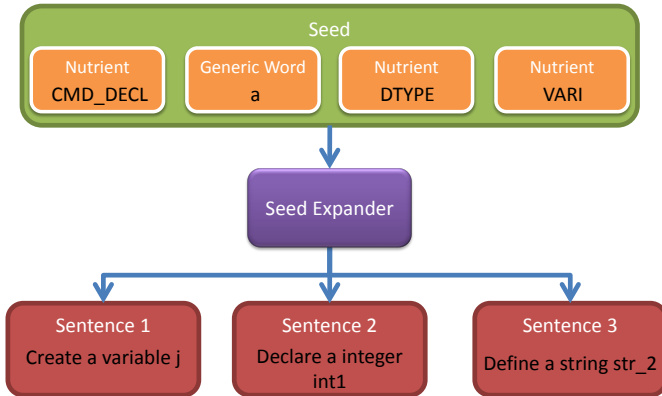

Fig. 5. Data Generation Process.

### B. Training AI Model

For training of the AI model, we used "spaCy" library [33]. Unlike its NLTK counterpart which focuses on academics and learning, spaCy is built for industrial uses and production.

We used Named Entity Recognition (NER) as our model to tag words that may belong to certain instruction. For example, the word "int" will tell NER model that it belongs to "datatype" while words like "addition", "sub", "\*" will be recognized as "operations".

In training in the AI model, we first need to create a dataset from data which we have achieved using spaCy's "Pattern Matcher". Since, we can control which words appear in the data in Data Generation phase, we can easily use pattern matcher to find a word or sequence of words to tag it. Once all the relevant words are tagged and a training dataset is created we can proceed to train it. Again, we used spaCy standard libraries to train. We used 3 epochs with batch size = 100 and got the final training loss of 1.95.

### C. Automatic Pseudocode Generation

When the user inputs their natural language query, our system automatically converts it to pseudocode and saves it in XML format. The process is as follows.

After the user has given their input, the system uses NER model trained in previous step to identify various tags examples can be seen in Fig. 6 and 7. Once the tokens have been recognized, we lemmatize them for easy recognition. We lemmatize all the types of tokens inside the tags except variables tag, since they are user given names. We process them based on the tags it has been assigned.

The variables are assigned names (if none is given it will automatically generate based on datatype), datatypes (If none is given, it will first try to get it from another variable in the input if not it will be assigned as string.), scope (local or global) and values (if they are given). If the program recognizes that it does not require any variables it will skip this step.

The input is recognized as either a function or a program and then the name of the function/program is recognized if the user has mentioned it in the query. A name is automatically generated based on available tags if the user has not mentioned the name explicitly. Once an operation tag is detected it will take all the variables associated and arrange them in specific pattern (i.e.  $ans = var1 + var2$ );).

Finally, all the components will be arranged by the order of appearance. First, the program/function will be declared with a proper indentation, then variables will be declared and then operations will be written and lastly if the language demands, the program/function will end (For example, some program requires "}" to end them ). All this will then be parsed to XML file and saved on the desired location.

### D. Pseudocode to Language Specific Source-code

Once the pseudocode file is ready, the only thing left to do is to convert it into a programming language. Using techniques that convert XML to program [14] [15], we can easily convert pseudocode to source-code. An automatic pseudocode generation is independent in creating a language specific source-code. Hence, we can- create the output of any programming language by creating a new file.

It's a simple process that reads the XML from top to bottom and depending on the tag encountered it will use a specific format to fill in the blanks.

## X. RESULTS

Our system produces multiple outputs before reaching the final source-code output. Below are the outputs according to the order they are generated.

### A. Generating Data for Training

As explained in Section IX-A, seed statements are used to generate input data that is later used to train the NLP model. Table II lists all the seed statements used in the system along with some sample output it generates. This output is unlabelled text data that acts as raw dataset.

TABLE II: Seed Statements along with Example Uoutput

| Seed No. | Seed Statement                                                               | Example Output                                        |
|----------|------------------------------------------------------------------------------|-------------------------------------------------------|

Table III depicts time taken for each seed statement to generate their respective statements, their individual time and the amount of raw statements it generates. The full seed statements can be seen in Table II. It can observe that statements that have large number of nutrients takes more time to execute and generate more statements compared to ones that have small number of nutrients.

### B. Varying NLP Hyper-parameters

While training this NLP models, there were various hyper-parameters like learning rate, batch size, dropout rate, total epochs, etc. Changing those hyper-parameters resulted in different loss and execution time. In Table IV, shows various effects of changing those hyper-parameters.

The first column is kept as the base for benchmark as this is giving the best possible loss value along with relatively fast training time. The other columns shows gradual changes in various parameters, the changed parameters are shown as **bold** while the unchanged parameters (compared to first column) are normal.

TABLE III. TIME TAKEN TO GENERATE INPUT DATA STATEMENTS FROM SEED STATEMENT ALONG WITH THE AMOUNT EACH STATEMENT GENERATES

| Seed No. | Individual Time | Cumulative Time | No. of Statements Generated |
|----------|-----------------|-----------------|-----------------------------|
| 1        | 0.049s          | 0.049s          | 15288                       |
| 2        | 0.022s          | 0.073s          | 7176                        |
| 3        | 0.438s          | 0.512s          | 174096                      |

C. Input Statement

We used the below 2 statements to demonstrate the output of our system during various stages of the system. These are the example of inputs that the user might use during its production phase.

Statement 1:

define variable text1 = 'please enter value'

Statement 2:

create a function to add a and local number num\_1 = 15

and b

D. NER System Output

Fig. 6 and 7 are the outputs given by the NER model. Each word (token) is bundled with original word given by the user and tag assigned by the NER model. In the left is the word/token and in the right is tag assigned.

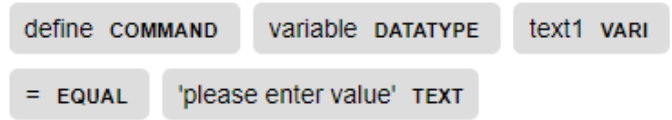

Fig. 6. NER Model Output of Statement 1.

Fig. 7. NER Model Output of Statement 2.

E. Pseudocode Output

Pseudocode file generated by our system is shown below in listings 1 and 2.

```

1 <?xml version="1.0" ?>
2 <root>
3   <statement value="define variable text1 = 'please
4     enter value'"/>
5   <program type="program" name="define_variable">
6     <variables>
7       <variable name="text1" datatype="variable"
8         value="'please enter value'"/>
9     </variables>
10  </program>
11 </root>

```

Listing 1: Pseudocode output of statement 1

```

1 <?xml version="1.0" ?>
2 <root>
3   <statement value="create a function to add a and
4     local number
5     num_1 = 15 and b"/>
6   <program type="function" name="create_function">
7     <variables>
8       <variable name="a" datatype="number"/>
9       <variable name="num_1" scope="local"
10        datatype="number" value="15"/>
11       <variable name="b" datatype="number"/>
12     </variables>
13     <add variable1="a" variable2="num_1" variable3
14       = "b"/>
15   </program>
16 </root>

```

Listing 2: Pseudocode output of statement 2

F. Final Source-code

The source-code is the final output generated. This is the only output visible to the user. Listings 3 and 4 shows the output code.

```
1 def main():
2     variable text1 = 'please enter value'
3
4 if __name__ == "__main__":
5     main()
```

Listing 3: Source-code output of statement 1

```
1 def create_function():
2     number a
3     number num_1 = 15
4     number b
5
6     answer = a + num_1 + b
7
8 create_function()
```

Listing 4: Source-code output of statement 2

The final results as obtained in our program that is made using python can be seen in Fig. 8, 9, 10 and 11.

## XI. FUTURE WORK

One of the ways we can further improve on this project is to create support for more programming languages. Currently we have only implemented support for python and C. We can also add support for new common functions like date, time, string operations, etc. Loops like "for", "while" and "do while" are also left out due to its complexity and time constraints which can be expanded later.

Our approach serves as the basic idea that allows the development of systems that are more complex in terms of keyword detection and contains more functionalities like loops and branching by adding additional NLP elements like dependency parsing and Semantic parsing.

## XII. CONCLUSION

This proposal shows that a language-independent solution is a feasible alternate for writing source-code without having full knowledge about a programming language.

Using XML based pseudo code as an intermediate step makes this method as programming language-independent which solves the major drawbacks in existing research that comes with a rigid commitment to only one programming language. The next step, which is converting XML based pseudo code into language-dependent source-code is dependent on premade language format which is modifiable by anyone, making this approach module based approach. If a person wishes to convert the natural language into some other programming language, they simply need to duplicate the premade language format and fill it with their desired programming language keywords.

Another challenge faced in this area which is program based NLP is that, there is not many datasets available in this particular sub-field which severely limits the research capabilities and keeps this sub-field from growing forward. Although not ideal, our dataset generation system provides an automated approach to create thousands of data that can be used in an AI system as a training dataset.

One way this system can be used is with ticket based programming, where the programmers get their tasks in the

form of tickets in their mail. The system can be used as a suggestion system where the mail is analyzed and a suggested solution is provided to the programmer. Another use is to pair this system with voice recognition and let the programmer write simple source-code only through speech making their hands free for writing other more complex code.

**Abstract**—Social media platforms allow users to share thoughts, experiences, and beliefs. These platforms represent a rich resource for natural language processing techniques to make inferences in the context of cognitive psychology. Some inaccurate and biased thinking patterns are defined as cognitive distortions. Detecting these distortions helps users restructure how to perceive thoughts in a healthier way. This paper proposed a machine learning-based approach to improve cognitive distortions' classification of the Arabic content over Twitter. One of the challenges that face this task is the text shortness, which results in a sparsity of co-occurrence patterns and a lack of context information (semantic features). The proposed approach enriches text representation by defining the latent topics within tweets. Although classification is a supervised learning concept, the enrichment step uses unsupervised learning. The proposed algorithm utilizes a transformer-based topic modeling (BERTopic). It employs two types of document representations and performs averaging and concatenation to produce contextual topic embeddings. A comparative analysis of F1-score, precision, recall, and accuracy is presented. The experimental results demonstrate that our enriched representation outperformed the baseline models by different rates. These encouraging results suggest that using latent topic distribution, obtained from the BERTopic technique, can improve the classifier's ability to distinguish between different CD categories.

**Keywords**—Arabic tweets; cognitive distortions' classification; machine learning; social media; supervised learning; unsupervised learning; transformers; BERTopic; topic modeling

## I. INTRODUCTION

Researchers attempt to understand the psychological well-being of users by analyzing the published social media content [1], [2]. This content may hold negative, and inaccurate conclusions called cognitive distortions (CDs). Research showed that CDs could be detected in social media [3]. In cognitive psychology, CDs are biased perspectives, patterns, and beliefs that have been reinforced over the years [4]. Usually, individuals diagnosed with depression express higher levels of distorted thinking than others [5], which affect the content they share.

Moreover, CDs can lead to poor behavior and chronic anxiety and are related to symptoms of depression [6]. Examples of these categories are overgeneralization, emotional reasoning, and catastrophizing. Until being diagnosed, a CD can be so problematic to change. Machine learning (ML) and natural language processing (NLP) can improve mental health care by defining CDs within a text. Classifying CDs can be beneficial to the therapy process in two ways. It helps in replacing these inaccurate thoughts and evaluating the improvement over time.

While many previous works with CDs showed promising results with detecting CD, they faced disappointing results with the multi-class CD classification [7], [4], [8]. This work aims to improve the classification task by dealing with the text shortness problem. In general, many classification tasks working with short text fails to achieve high performance according to the sparse representation of the textual data [9], [10], [11]. Extra contextual information can be deployed to overcome the sparse representation and make the data more related, comprehensively expressed, and expand the efficiency of classifiers to handle unseen data.

Contextual topic modeling (TM) can provide extra latent information and identify semantically similar groups in the corpus. The topic-based embeddings can learn global semantics from the entire corpus [12], which provides the features with an opportunity to become more representative.

Also, while analyzing textual cognitive distortions, we noticed that individuals mostly use a common CD when expressing their thoughts about a specific topic or domain. For example, catastrophizing is highly related to relations, self-image terms, and academic achievement. General terms like life, humans, country and government are mostly related to over-generalizing and labeling. This observation encouraged us to utilize TM as extra contextual information in CD classification.

The TM algorithm used in this work is a transformer-based algorithm that utilizes the pre-trained knowledge in the modeling process to provide a topic distribution. So, our primary contribution in this paper is using the state-of-the-art transformer-based TM algorithm to enrich the CD representations and improve its classification task by exploring potential semantically meaningful categories in the data.

The remainder of the paper is structured as follows. In Section II, a summary of related work is presented. Section III overviews some background. Section IV presents the design and methodology used in the research, while the experimental results are analyzed in Section V. Finally, Section VI discuss conclusions.

## II. RELATED WORK

The proposed approach utilizes the TM algorithm to overcome the shortness of social media text to improve CD classifications. Accordingly, this research is related to three main topics; CD classification, short text classification, and TM in text classification.

| [8]  | Proved the possibility of detecting cognitive distortions (binary classification) automatically from personal blogs with relatively good accuracy (73.0%).                                                                                                                                                          | Experiments showed a poor performance in multi-class classification, which was justified by the limited size of individual posts and the overall dataset.                                                                                                                                                                                                           |

Researchers applied ML and NLP to look for mental health and cognitive psychology inferences. Many attempts were made to detect and classify a defined set of cognitive distortions in the English language. Table I summarizes a sample of this studies and describes the related advantages and limitations. Most of the proposed work in Table I couldn't classify CD efficiently. Besides, datasets were collected from different resources, and most of them are not publicly available. The proposed approach creates a dataset by crawling social media to overcome this constraint. Also, we utilized the pre-trained bidirectional encoder representations from transformers (BERT) model to improve classification performance.

The limited number of words in tweets leads to sparse co-occurrence patterns, making the classification task more challenging. To tackle the feature sparseness, works in the literature choose between two main approaches; either represent texts in a lower-dimensional space [9] or add external, implicit, and valuable information to enhance the data representation on the feature space [10], [11]. The second method works on enriching the representation of a short text using additional knowledge or semantics [15]. These semantics could be derived internally [16], or from an external resource, such as a collection of longer documents in a similar domain, or a huge resource such as Wikipedia and WordNet [16], [17], [18]. While the mentioned approaches require additional datasets to enrich the text representation, the proposed approach analyzes the topic distribution within the same dataset.

TM methods have been used to improve text classification in the literature. Anantharaman et al. [19] surveyed a set of TM algorithms for classifying short text and large text (document). Results suggested that the latent semantic analysis method (LSA) is the best for short text classification tasks, while latent dirichlet allocation (LDA) performs better on document classification. In addition, Albalawi et al. [20] investigated TM methods by comparing five frequently used methods. Methods were applied to short textual social data to show their capabilities in defining key and meaningful topics. Their study indicates that TM can overcome the noisy data contained in a short text. Also, an efficient application by Phan et al. [21] classified short medical text by exploiting the

hidden topics in large-scale data collections (Wikipedia and MEDLINE datasets).

Furthermore, Dai et al. [22] extended the bag-of-words representation and introduced a new feature space by using a hierarchical clustering algorithm. Yajian et al. [23] worked on extending the short text to a reasonably long one. In their approach, weighted synonyms and related words are generated for every word by the Word2vec and LDA model.

Most proposed approaches use traditional TM algorithms, such as LDA, a word co-occurrence-based method that only works efficiently with long text. However, the previous methods improved the classification results to some extent but still leave considerable space for improvement.

The proposed approach considers the shortness of social media text in CD classification, which (to the best of our knowledge) is not explored in the literature. The novelty of this approach is based on employing a BERT-based model (BERTopic) for the TM, which provides a better contextual representation. The BERTopic model was employed previously for Arabic text modeling in [24]. It showed a better performance than non-negative matrix factorization (NMF) and LDA.

### III. BACKGROUND

#### A. Cognitive Distortions

Social media textual content represents a rich resource for natural language processing techniques to make inferences in cognitive psychology. Machine learning approaches can be applied to learn the distorted thinking patterns to perform CD detection and classification. Table II shows the five considered CDs used in this work.

#### B. Term Frequency-Inverse Document Frequency

One of the weighting methods for feature-based representation is term frequency-inverse document frequency (TF-IDF). It provides a weight for each word. A TF-IDF value is determined by the relative frequency of a word in a specific text and the inverse proportion of the word over the entire corpus, which reflects how relevant a word is to a particular

TABLE II. COGNITIVE DISTORTION AND THEIR DEFINITIONS

| Cognitive distortion | Definition                                                                           |
|----------------------|--------------------------------------------------------------------------------------|
| Inflexibility        | "Having rigid beliefs about how things or people must or ought to be [25].           |
| Over-generalizing    | Creation negative conclusions without full evidence [5].                             |
| Labeling             | To describe self or others negatively without giving credit to counterevidence [25]. |
| Emotional reasoning  | Depend on feelings as a source of facts [5].                                         |
| Catastrophizing      | Enlarging negative statements or events into disasters [25].                         |

text. The TF-IDF is given by the equation 1. Where the weight of the word  $i$  in the text (document)  $j$  is  $w_{ij}$ .  $N$  is the number of documents, and  $tf_{ij}$  is the frequency of the word  $i$  in the document  $j$ , and  $df_i$  is the number of documents that contain the word  $i$  [26].

$$W_{ij} = tf_{ij} * \log \frac{N}{df_i} \quad (1)$$

### C. Topic Modeling with BERT

Topic modeling (TM) is an analytical unsupervised learning model that discovers topics distribution in a corpus. In this context, a topic can be defined as a repeated pattern of terms [27]. Mainly, the TM algorithm provides two distributions; document-topic and topic-term.

Recently, a transformer-based algorithm was deployed for TM called BERTopic [28]. The algorithm uses three primary phases to produce a topic's distribution for a set of documents. First, it creates sentence embedding. Second, it creates clusters of semantically similar sentences. The last step includes creating topic representation with c-TF-IDF. Each step will be elaborated on in the methodology section.

The usual TF-IDF equation defines the importance of a word between different documents. Differently, the class-based TF-IDF (c-TF-IDF) [28] defines the importance of a word within a class (topic). It treats all documents in a single class as a single document. Equation (2) finds the c-TF-IDF of each word, where  $W_{ic}$  is the weight of word  $i$  in class  $c$ . The frequency of word  $i$  in class  $c$  is  $tf_{ic}$ .  $A$  is the average number of a word per class, and  $f_i$  is the frequency of word  $i$  across all classes.

$$W_{ic} = tf_{ic} \times \log\left(1 + \frac{A}{f_i}\right) \quad (2)$$

Essentially, the BERTopic technique utilized two Algorithms; UMAP and HDBSCAN. Uniform manifold approximation and projection (UMAP) [29] is an algorithm for non-linear dimension reduction that combines manifold learning and topological data analysis. The algorithm optimizes a low-dimensional graph to be structurally similar to the original graph. While HDBSCAN algorithm [30] is a hierarchical clustering algorithm that stands for hierarchical density-based spatial clustering of applications with noise. The algorithm first transforms the space according to the density or sparsity of the data to provide a distance-weighted graph, and then it creates the minimum spanning tree for this graph. The algorithm also represents the connected components by a cluster hierarchy

then condenses them based on the minimum cluster size parameter. Finally, it extracts clusters from the condensed tree.

## IV. METHODOLOGY

In general, usual text mining methods have some limitations in classifying short texts. The limitations are related to the sparsity of co-occurrence patterns in short texts, and the lack of context information (semantic features) [31]. A common method to overcome these limitations is to enrich the texts with additional information to make data more related and extend the classifiers' coverage to perform better in future data [21]. The additional information can be directly attached to the textual representation. After that, the standard classification is performed.

The proposed approach in this paper contains two phases; the enrichment phase and the classification phase. Two main steps are performed in the enrichment phase; the first step is acquiring the additional information, while the second step combines them with the original data representation.

In this work, the additional information source is the output of a TM algorithm (described briefly in the background section). The algorithm generates probability distributions of the hidden topics in the corpus. BERTopic [28] is used as a TM technique, where it takes advantage of BERT embeddings. The BERTopic technique produces the distribution of topics within a document  $d$ . Later, this distribution (BERTopic ( $doc_d$ )) is combined with text embedding.

Fig. 1 shows an overview of the proposed approach that uses BERTopic processes to enrich the document representation with the hidden topic distribution. The following steps summarize the BERTopic processes:

- 1) Generate embeddings for tweets to provide numerical vector representations, where each tweet is considered a single document. This step is based on a pre-trained deep bidirectional transformer. This type of embedding is very powerful for language understanding and can capture the semantic relations between words.
- 2) Reduce the dimensionality of the embedding vectors to create a lower-dimensional embedding of tweets by using the UMAP algorithm [29]. The algorithm preserves the local and global structure in lower dimensionality. Cosine-similarity is used as a distance metric to measure distances between data points.
- 3) Perform clustering using HDBSCAN [30] to find highly similar text in the semantic space that produces a single topic. Defining the number of topics in this stage is a crucial decision. It is supposed to be reasonable and compatible with the dataset size and topics-related words. The generated topics can be too fine-grained, which results in a massive number of topics. Also, it can dismiss important details by defining a small number of clusters. In BERTopic, the algorithm infers the ideal number from the data itself. This step applies iterative merging for the most similar topics. Cosine

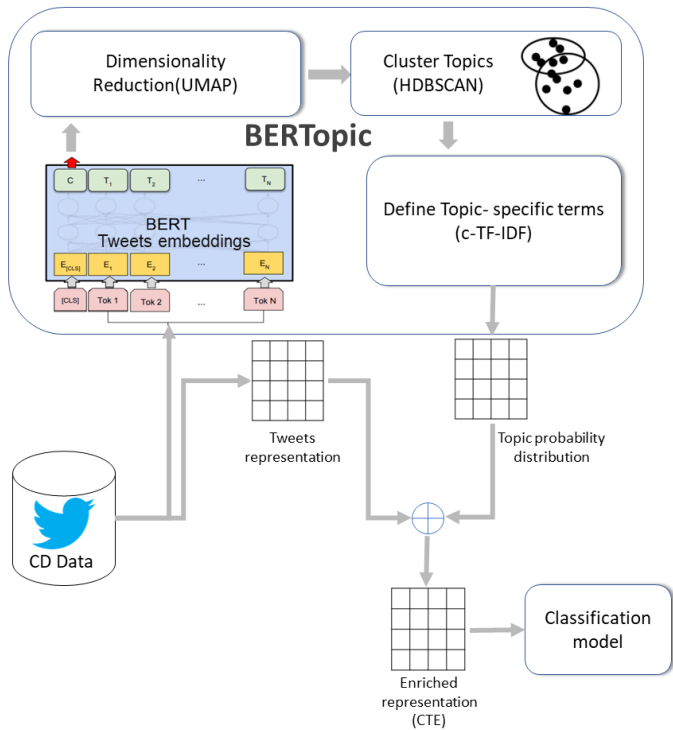

Fig. 1. A Graphical Representation of the TM Enrichment Approach for CD Classification.

similarity between c-TF-IDF vectors is utilized in this process.

- 4) Define the essential words in a topic according to the c-TF-IDF equation. Words with a high score are more representative of the topic. Accordingly, every tweet is related to a set of topics with different probabilities. In this step, BERTopic generates a topic distribution vector for each tweet,  $Pr(topic | tweet)$ . A graphical representation map for this process is shown in Fig. 2.

The previous processes produce topic distribution for each document as  $BERTopic(doc_d)$ . Then, the distribution is used in Algorithm 1 to produce the final contextual topic embedding (CTE) for each document. Mainly, the algorithm uses two types of document representations; topic distribution and word embedding. Then, it performs averaging and concatenation. The nested for (line 2-4) creates word embeddings for each word in a document  $d$  using the word2vec model, while line 5 constructs document embeddings. All word vectors in document  $d$  are averaged to produce a single vector in the same embedding space.

Combining BERTopic distribution and word2vec representation keeps the semantic information and creates contextual topic representation. The topic representation and the word embedding are composed in line 6 to produce CTE for a given document ( $d$ ), where  $\oplus$  represents the arithmetic concatenation operator. We use "featureUnion" function<sup>1</sup> in Python to

<sup>1</sup><https://scikit-learn.org/stable/modules/generated/sklearn.pipeline.FeatureUnion.html>

perform the concatenation.

---

**Algorithm 1:** Generate Contextual Topic Embedding

---

**input :**  $M$ : Maximum sequence of words,  
 $D$ : Number of documents,  
 $doc_d = \{w_1, \dots, w_M\}$ .  
 $BERTopic(doc_d)$

**output:**  $CTE(doc_d)$

- 1 **for**  $d \in \{1, \dots, D\}$  **do**
- 2     **for**  $n \in \{1, \dots, M\}$  **do**
- 3         | Embedding( $w_{dn}$ )= word2vec( $w_{dn}$ )
- 4     **end**
- 5     Embedding( $doc_d$ )= Avg(Embedding( $w_{d1}$ ),...,Embedding( $w_{dm}$ ))
- 6      $CTE(doc_d)$ =Embedding( $doc_d$ ) $\oplus$  BERTopic ( $doc_d$ )
- 7 **end**

---

The next step is feeding the enriched representation  $CTE(doc_d)$  to different classifiers and evaluating the results. Because this approach uses hidden topic knowledge of the corpus as the primary source of enrichment, its effectiveness is corpus-dependent.

## V. EXPERIMENTAL RESULTS AND DISCUSSION

The dataset was collected by crawling Twitter data. First, a translated version of the cognitive distortion scale [32] was utilized. Volunteers were asked to express distorted thoughts they had. The initial responses were used to define a keyword list for each category. Keywords were defined as the top frequent and influential words in the responses. For example, one of the CD patterns is inflexibility. The related seed words were: (لازم / يجب / لابد / واجب / مفروض) / (محتّم / المفترض), which mean: (obligatory / must / must / obligatory / obligatory / unavoidable / supposed) respectively. The defined seed words were used for crawling Twitter by streaming API in June 2021.

Tweets were labeled by two reliable annotators who work in the psychotherapy domain. The annotators labeled the data independently of one another. Inter annotator agreement (IAA) was calculated to evaluate the annotation quality. Cohen's kappa coefficient between annotators was 0.817, which indicates an almost perfect agreement according to Kappa's interpretations [33]. We only considered texts that both annotators labeled with the same label (9250).

We excluded the noise usually found in a social media text. The preprocessing operation included removing Arabic diacritics, Arabic and English punctuations, stop words, emojis, and non-Arabic characters. Also, The Arabic letters were normalized, where we replaced letters with different shapes with one of its defined shapes. "Alef" (آ, إ, أ) into ا, and "Ta Marbouta" (ة) into (o). In addition, we removed tweets-related noise like users' mentions, usernames, hashtags, and Twitter handles (@user), RT, <>. The last stage in the preprocessing is stemming, which removes any suffixes, prefixes, or infixes from words. This step reduces the derived or inflected words

| XGBoost  | 0.8789   | 0.8782   | 1         | 0.8797 | 0.9823                        | 0.9823   | 0.9823    | 0.9823 |
| Bagging  | 0.7760   | 0.7798   | 1         | 0.7771 | 0.9710                        | 0.9709   | 0.9709    | 0.9709 |
| Stacking | 0.9280   | 0.9297   | 1         | 0.9270 | 0.9710                        | 0.9813   | 0.9710    | 0.9710 |

Fig. 4. F1-score Comparison between Classifiers that used Word2vec only and Classifiers that Utilized the Enriched Features (CTE).

into their related stems and relates all the variations into one stem. We used Tashaphyne<sup>2</sup>, an Arabic light stemmer tool.

All experiments were applied by splitting data randomly into 75% (6,940 tweets) for training and 25% (2,310 tweets) for testing. Ten runs were performed for each experiment, and we reported the average results to overcome the performance variation problem. We used the NVIDIA Tesla K80 GPU provided on the Google colaboratory notebook.

The word2vec representation and BERTopic [28] algorithm are employed in this approach. We applied the BERTopic algorithm on the preprocessed CD dataset using Python’s ”bertopic” library. Arabert model [34] was used as a pre-trained language model. Each term in the corpus contributes differently to each topic. Fig. 3 shows the bar charts of the first six topics with a subset of the most contributing terms according to the c-TF-IDF scores.

We reduced the number of topics by starting from the least frequent topic and merging topics as long as the similarity exceeds 0.915, the threshold suggested in the BERTopic documentation. The number of topics was reduced from 70 topics to 47. Afterward, the resulting topic distributions for tweets in the dataset were concatenated to the word2vec representation.

The resulting enriched features are fed into six classifiers.

Table III demonstrates the results of four performance metrics; macro-accuracy, macro-precision, macro-recall, and macro-F1. Also, Fig. 4 shows F1-scores of classification using enriched features approach compared with classification using word2vec features. According to Fig. 4, the performance of the proposed approach improved all the classification results. DT and bagging results boosted the most. These encouraging results suggest that using latent topic distribution, obtained from BERTopic, can improve the classifier’s ability to distinguish between different CD categories. The baseline classifiers could not fully capture the relations of a CD category and a subset of topics due to the shortness of tweets. On the contrary, the enriched features emphasized these relations.

## VI. CONCLUSION

The constant evolution in natural language processing and machine learning has made it possible to address different cognitive distortions in a text. This paper suggests an approach for enriching short textual representations to improve cognitive distortions’ classification of the Arabic context over Twitter. The enrichment approach considers the shortness of social media text and the sparsity of word co-occurrence patterns, which (to the best of our knowledge) is not explored in the literature. It also utilizes a transformer-based topic modeling algorithm (BERTopic) that employs a pre-trained language model (AraBERT). For evaluation, various

<sup>2</sup><https://pypi.org/project/Tashaphyne/>

classifiers were used; DT, k-NN, SVM, RF, XGBoost, stacking and bagging. Experimental results showed that the proposed approach improved the performance of the defined classifiers with different rates using an Arabic CD dataset. We will study other TM approaches with advanced feature representations and embeddings for future work. In addition, CD data from other sources and languages can be tested to examine the generality of the proposed approach. As a recommendation for other researchers, we encourage examining transformer-based topic modeling to empower different supervised tasks in NLP. Also, it is good practice to define an approximation for topics' granularity in different domains.

**Abstract**—Cloud computing allows a pool of resources, such as storage, computation power, communication bandwidth, to be shared and accessed by many users from different locations. High dependency on sharing resources among different cloud users allows some attacker to hide and commit crimes using cloud resources and as a result, cloud computing forensics become essential. Many solutions and frameworks for cloud computing forensics have been developed to deal with cloud based crimes. However, many problems and issues face the proposed solutions and frameworks. In this paper, a new framework for cloud computing forensics is proposed to enhance the investigation process performance and accuracy by adding a new stage to conventional stages. This new stage includes the implementation of a new way for matching based on the LSH algorithm. The proposed framework evaluation results show an improvement for matching and accurate cluster retrieval through the collection process.

**Keywords**—Cloud computing forensics; genetic clustering algorithms; genetic dynamic clustering; forensics framework; digital forensics

## I. INTRODUCTION

Digital forensics is a science which is defined by many researchers, see [31][20], as a science of retrieving, examining, and analysing digital evidences collected from digital devices. A Digital evidence, according to [20], is defined as the information and data of investigative value that is stored on, received, or transmitted by a digital device. The goal of digital forensics is to detect and extract the evidences, analyze the collected evidences and preserve related ones in a format that can be presented in a court [24][18].

Cloud computing is one of the most popular technologies since different users and companies around the world are rapidly becoming more dependent on cloud computing. This means that millions or even billions of files have been uploaded to cloud computing resources. Security of resources over the cloud is a challenging issue that has to be addressed [43] [3]. Fog computing is similar to cloud computing but closer to the user which also has many security concerns [2]

Cloud computing forensics refers to one of the digital forensics branches This branch has gained popularity from the importance of today's cloud computing. Many researchers describe cloud computing forensics as an application for digital forensics for cloud computing resources to investigate the crimes that occurred in cloud computing resources. Text files and textual information represent a very high percentage of types of evidence, particularly in cloud computing [20].

Accordingly, and due to the extra high volume of data stored on the cloud, an enhanced solution is needed to handle textual evidence by extracting and encouraging the handling of textual evidence.

In recent years, the number of digital crimes that involve internet and computer has grown, which has encouraged a lot of companies to include measures in their products to assist law enforcement in using digital evidences to determine the perpetrators, methods used, timing, and victims of computer crimes. The process of applying digital forensics in the huge volume of files which stored in cloud computing resources is very hard. Therefore, the idea of clustering has been applied to facilitate the investigation process. Clustering is the process of grouping objects or documents related to each other in the same group. This is important in the investigation process, since the investigator needs to search for all documents in the storage space to define if there are any documents related to the original file [17].

This paper presents a new approach to cloud computing forensics, which solves some of existing problems and challenges. The proposed solution consists of two main parts. The contribution of this paper can be summarized in the following points:

- A pre-investigation stage has been added to the standard forensics stages as part of the propose Cluster Based Investigation Framework (CBIF). Through this stage, a new hierarchical clustering algorithm capable of handling all types of evidence is added.
- Genetic Based Dynamic Clustering Algorithm (GB-DCA) has been developed to divide a dataset into suitable number of clusters in cloud storage.
- A new search and matching technique based on using a locality-sensitive hashing algorithm has (LSH) to enhance the accuracy of the matching process.
- Additionally, the proposed idea can match parts of the files based on the concept of hierarchical matching and examining process.

This paper is organized as follows. Section 2 brings forth the related work. Section 3 presents a brief description of cloud computing and cloud forensics. Section 4 illustrates the proposed idea and foremost step of the proposed solution. Section 5 details the experimental implementation and results from the discussion. We conclude with Section 6.

## II. RELATED WORK

In the field of digital forensics, some frameworks have been suggested as a general frameworks while others were proposed for lower levels of digital forensics branches. Example of frameworks that are suggested as generic framework for digital forensics is an integrated digital forensics process model [41], which is a standard framework for digital forensics and can apply to all branches of digital forensics. This framework contains all standard stages of digital forensics with some changes in the level of combining evidence collection and the preservation stage into a single stage to make sure the identified evidence does not change through the collection stage.

Another model proposed as a generic framework is the integrated framework for digital forensics [48], where the proposed model is a standard model that helps the investigators to follow a uniform approach in digital forensics. The model contains all conventional stages of digital forensics. This framework is classified as a simple framework based on [31]. And other models that fall under general framework such as the model suggested through [40], [8], [32], and [7].

On the level of the computer forensics branch, many frameworks were suggested, such as the computer forensics investigation approach to evidence in cyber-crime [13], which aims to define a new approach to solve and enhance the stage of computer forensics examination. The model meets Italian legislation and could probably be used in other countries.

Numerous frameworks and solutions have been proposed in other digital forensics branches [31], [47]. One instance includes the frameworks and solutions proposed in the IoT forensics branch, which refer to one of the digital forensics branches, such as the one in [13]. The idea of the proposed system relates to using Block-Chain through the investigation process to improve the collection stage's security level and credibility.

The model proposed in [21] refers to a new model for reviewing and investigating cyber attacks, where digital

other framework was proposed in [37], which refers to a new framework for mobile forensics, since a lot of crimes was applied on the resources of mobile devices, specially with rapid development of wireless network and smart mobile. The idea that proposed here refers to depends on the clustering process to facilitate the investigation as all.

The model proposed in [6] refers to the first framework, which contains various safety principles proposed by the ISO standard. Another framework for investigating crimes committed in IoT devices is the IoT forensics framework for the smart environment [39]. The proposed model was specified to investigate the crimes committed in a smart environment, where the proposed model is a lightweight model that is well equipped to be compatible with IoT resources. Moreover, this model can classify as a generic model for all IoT crimes with a high level of privacy based on the principles mentioned for this point.

Other frameworks and solutions proposed in the other branches of digital forensics include the framework and solutions proposed to investigate the crimes committed in a cloud

computing environment. One of these frameworks is presented in [26], where the main contribution for the proposed model is defining the difference between the evidence collection stage and the preservation stage, since many frameworks are merged between the two stages. In [42], a new framework for cloud computing with a fundamental change in the stages of conventional frameworks is illustrated. The change affects the proposed model of the identification and collection stages, and the rest of the stages did not change. The science of the proposed framework focuses on the first two stages. Additionally, an open cloud forensics model is also an example of a framework proposed for cloud computing forensics [51]. The framework consists of primary stages of digital forensics with an update on the levels of preservation and collection. The model merges between these two stages in a single stage to make sure that the evidence does not change through the collection stage, and merges between the analysis stage and examination stage in a new stage called the organization stage.

One solution proposed for the cloud forensics process is to secure logging as a service for cloud forensics [50]. The idea of this solution is to introduce secure logging as a service that allows the cloud service provider to store virtual machine logs and to provide access for the investigators while preserving the privacy for the tenant of the cloud. In [35], the goal of the proposed model is to provide as much information about each record, such as when any trigger occurs, as when a new record is added or deleted.

When the cloud computing environment contains multiple tenants for its resources, the privacy and security of evidence are essential. One of the proposed solutions to deal with this problem is presented in [5], where the idea of the proposed solution is to use a third party to check and evaluate data collected by investigators. Another solution to solve the multi-tenant problem is proposed in [4], where the idea depends on upholding the confidentiality and integrity for evidence that used through the investigation process.

Yet an additional issue facing the investigation process in cloud computing is the data gathering challenge, which faces the acquisition stage of the investigation process, because the data is distributed amongst different servers which ultimately decrease the performance of the investigation process. Specific frameworks and solutions have been proposed to deal with this problem, such as the framework proposed by Adams [44], which suggested a new cloud forensics model which consists of a planning stage, on-site survey stage, and acquisition stage. This applies to deal with the process of acquisition without any further intervention.

Numerous frameworks and approaches have been suggested to investigate crimes committed in computer networks. Frameworks that scales for a large-scale environment are called dynamic network forensics and have a specific property for investigation such as the framework presented in [25], which investigates the crimes that occur in network infrastructure. The framework contains the standard stages of any digital forensic framework with additional stages to enhance the investigation process, such as the evidence reduction stage, which can enhance the accuracy of the investigation process. Graphic network forensics have many frameworks are specialized for graphics-based network forensics crimes [49], [28], [38]. Many approaches and solutions have been proposed to

investigate soft-computing crimes specific to network analysis and monitoring. The systems proposed in this field are tailored to the environment that includes many attacks, because this type of network forensics can analyze the data collected and identify relevant attacks [9], [36].

Numerous researchers identified cloud computing forensics [14], as an application for digital forensics in cloud computing as a subset of network forensics. NIST framework [29], defines it as an application of science to the identification, examination, and analysis of data while preserving the integrity of data and maintaining the chain of custody for the data through the investigation process. Any information or data stored or extracted from digital devices can be evidence or part of the evidence; these pieces of evidence are analyzed through the investigation process.

The goal of digital and cloud investigation is to ensure that the collected evidence is admissible in a court of law and to maintain that the chain of custody is essential and documented, and is thus stored throughout the entire investigation process [16]. The chain of custody is the process of recording and storing digital evidence as well as managing historical history to protect the custody chain from any alteration or modification or damage by any unauthorized user, and so, a high level of care is required.

The investigation of crimes occurring in the cloud computing environment is faced with many issues. These issue can be summarized through the Table I as follow

Based on the issues mentioned above, a solution for cloud computing forensics is required, as many of the proposed frameworks do not provide a general solution to the aforementioned problems. The solution suggested in this article aims to avoid all the above mentioned significant issues. The proposed solution can be applied in all branches of digital forensics in addition to cloud computing, such as applying the proposed solution in computer forensics, cloud forensics, network forensics, database forensics, and all others.

TABLE I. KEY ISSUE THAT FACES CLOUD COMPUTING FORENSICS PROCESS.

| Key Issue Description                   | The Reason of Key Issue                                                                                                                                                                                                                                                                        |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Searching for Candidate Files           | Cloud computing contains a considerable amount of massively distributed information from different users, which makes the searching for evidence a laborious process                                                                                                                           |
| Privacy of users documents              | Cloud computing contains a considerable amount of massively distributed information from different users, which makes the searching for evidence a laborious process.                                                                                                                          |
| Time Needs for locating the target file | Searching for the target file or any of its pieces is time-consuming, based on the massive amount of files in the data center. On that basis, a new matching technique is required to improve the efficiency and accuracy of the matching process for evidence.                                |
| The Integrity of users data             | In conventional ways, the investigator must check all files to check whether or not they relate to the target file, which may violate all data in the storage center if the investigator is a criminal. A technique is required to check only those files that are related to the target file. |

### III. PROPOSED IDEA

The idea of the proposed solution focuses on resolving shortcomings and problems that face previous related solutions such as these related to the used conventional clustering algorithm in [17] [33]. The solution which proposed in [17] depends on using conventional versions of k-means and k-medoid clustering algorithms during the pre-investigation stage to enhance the accuracy of investigation process. While in [33] the approach suggested is based on the usage of the hierarchical clustering algorithm in the pre-investigation process to enhance the investigation’s accuracy and performance.

Another weak-point faces the previous suggested frameworks is related to the privacy of users’ data through the investigation process. This is because many of proposed framework does not proposed any solution for the privacy problem [1] and [34].

The proposed framework consists of all stages of a conventional framework for digital investigation, with additional stages to achieve enhancement goals. The pre-investigation stage is essential and was added in the proposed framework to enhance the investigation process from in regards with the performance, accuracy, and security. The proposed solution consists of a set of stages as follows:

- Pre-investigation stage: this stage reduces the amount of information submitted to the investigator. The stage can improve the accuracy and efficiency of the investigation process.
- Evidence collection stage: in this stage the investigator is responsible for collecting and transferring to the investigator side only those clusters identified in the preceding stage which are related to the target files.
- Matching stage: conventional matching, such as sequential and carving based matching, is usually used in related framework found in the literature [1]. LSH based matching is suggested in the proposed framework in order to improve the matching process accuracy and efficiency.
- Analysis and presentation stage: in this stage the investigator is responsible for the analysis of the evidence gathered and finalizing the report to be presented in front of the court. .5

The improvement introduced in CBIF framework relates to the addition of the pre-investigation stage and to the improvement of the efficiency and accuracy of the investigation process

Fig. 1. Main Stages for the Cluster based Investigation Framework(CBIF).

by introducing the LSH based matching. Detailed discussion of each of the CBIF enhanced points will be presented in the subsections below.

**A. Hierarchical Clustering used in the Pre-Investigation Stage**

The objective of the hierarchical clustering algorithm used in the suggested idea is to improve the investigation process by enhancing the crime-related matching and related data collection within proper clusters. The idea of hierarchical clustering algorithm merges between a static clustering algorithm based on a genetic algorithm [23][27][30], and a dynamic clustering algorithm using an evolutionary algorithm [44][38].

Fig. 1 illustrates how the proposed hierarchical clustering algorithm operates. The algorithm starts by applying a genetic-based static clustering algorithm (GBSCA) to divide the storage center into a set of clusters based on files data-type. The storage center in Fig. 2 is divided into four main clusters; one for audio files, one for video files, one for text files and documents, and one for executable files. Afterward, another clustering round process is applied to each of the clusters formed. The second-level clustering algorithm is a genetic-based dynamic clustering algorithm (GBDCA). The objective of this second round is to divide each cluster generated into a suitable number of sub-clusters. The execution of all steps in Fig. 2 is the responsibility of the cloud service providers.

The evaluation metric which is used in the evaluation process refers to the Sum Square Error(SSE), whereas the equation for this evaluation metric is as follows.

$$SSE = \sum_{i=1}^k \sum_{j=1}^{|c_i|} D(c_j - f_i)^2 \dots (1)$$

In Equation (1) D refers to the Euclidean distance between Centroid file Cj and a specific file fi. The value of SSE must be minimized as much as possible.

**B. Genetic based Dynamic Clustering Algorithm (GBDCA)**

Dynamic clustering algorithm refers to a clustering strategy used to divide the storage center into a set of clusters [24], which is different from the conventional clustering algorithm. The goal of a dynamic clustering algorithm in CBIF is to divide the storage center into a proper number of clusters. Dynamic clustering algorithm consists of a set of iterations; the

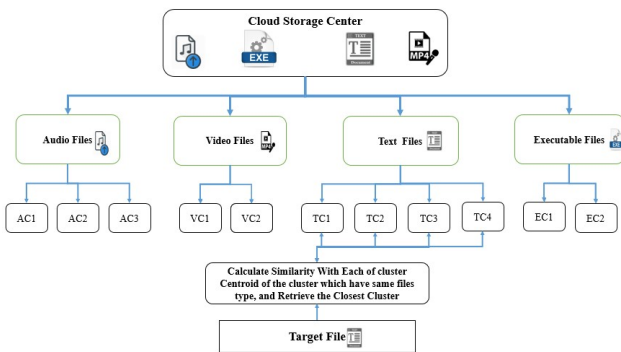

Fig. 2. The Main Steps of the Pre-investigation Step of the Proposed Idea to Divide the Cloud Storage Center into a Suitable Number of Clusters.

maximum number of iterations is defined before the algorithm is started. The iterations begin with an arbitrarily small number of clusters; at each iteration the number of clusters increases by one until the maximum number of iterations is reached. The number of clusters used is evaluated, based on two fitness functions, the internal fitness evaluation, and external fitness evaluation that is measured in each iteration.

The goal of the internal loop is to select the best centroid file which achieves the highest fitness value based on the SSE equation. fitness is achieved based on specific centroid files being compared with the best fitness value.

The results of applying the genetic-based dynamic clustering, as the second level in the hierarchical clustering algorithm, is getting the most suitable set of clusters based on the reported best fitness function of the external loop. The flowchart below shows the main stages of the GBDC algorithm.

The flowchart in Fig. 3 represents the main stages of the dynamic clustering algorithm, which can facilitate the investigation process by dividing the files into a suitable number of clusters. This means that the cluster which achieves a high level of similarity to the target file will contain all the files actually related to the target file indicated by low intra-distance which means high similarity between files in the same cluster. The equation for the ratio between inter-distance, i.e. the differences between files in different clusters, to intra-distance, which is proposed in [12] is mentioned in equation (2). This equation represents the external fitness function proposed in GBDCA, which is responsible for selecting the optimal number of clusters for the files in the original data set. The output of the external fitness evaluation helps in descending on the best number of related clusters:

$$R = \frac{InterDistance}{K - 1} * \frac{IntraDistance}{n - K} \quad (1)$$

...(2)

In equation (2), “R” refers to the ratio between the inter-distance and intra-distance, “K” refers to the maximum number of clusters that are allowed in a solution, and “n” refers to the number of data instances, e.g. number of files. In the Algorithm 1, the similarity between data centers and all files in the cloud

            Break;
Return T;
Return T1;

```

storage center is determined using Euclidean distance, see [19], based on the following equation.

$$D = \sqrt{\sum(C_{jr}, fir)^2} \dots (3)$$

Where D refers to the distance or the similarity between files. Two fitness functions are used through clustering based on genetic, internal fitness, and external fitness. The internal fitness function allows for the selection best centroid data item based on equation (1). The external fitness function has to do with the decision on the proper number of clusters based on the out come of equation (2).

As a summary of the actions and steps of the pre-investigation stage, it starts by dividing the storage center into a set of clusters based on the data types of the files. Afterward, another level of clustering round using genetic-based dynamic clustering, divides the generated clusters from static clustering step into a set of sub-clusters, which produces a set of small clusters for each of the first round's clusters.

The next step in the proposed idea is to start the investigation process by retrieving the cluster that is highly similar to the tampered file based on ranking the clusters according to the similarity achieved through the internal loop of the genetic-based dynamic clustering using equations (1) and (3). Then comes the step of matching and finding the file or files related to the target file. The outcome of the pre-investigation step is to define the clusters that are very similar to the target file. The pre-investigation step can improve the performance and accuracy of the investigation process.

*C. The LSH Algorithm Applied for the Matching and Examination Stage*

Another step in the process of improving the matching and searching for evidence in cloud computing forensics depends on using the Locality Sensitive Hashing (LSH) algorithm. The LSH algorithm consists of three steps. The first step is the shingling step, which is responsible for building the shingle matrix of two dimensions. The second step is the implementation of the Min-hashing algorithm; this step is responsible for the compression of the shingle matrix. The last step is the implementation of the LSH algorithm [24], which is an enhanced matching algorithm that is implemented on the signature matrices generated to identify similar files in the previous step. LSH algorithm can improve the accuracy and efficiency of the investigation process based on reducing the size of the shingle matrix extracted from the original data. Fig. 4 shows the main stages of the LSH algorithm, where the steps begin after retrieving the clusters linked to the tampered file.

The following steps present detailed information on the improved examination and matching steps based on the LSH algorithm.

1) *Shingling Step:* The initial step of the LSH algorithm implementation is the extraction of shingles for each file of the retrieved cluster data, and developing a two-dimensional shingle matrix for all extracted files' shingles. The shingle matrix shown in Table II represents an example of a shingle matrix extracted from the files of the cluster. In the Table, a Shingle matrix ID in a row exists in documents, specified in column, where the flag bit is set.

Table II displays the shingle matrix structure. The shingle matrix building step is the initial step in the LSH algorithm procedure. All documents contents must be transformed into

Fig. 4. Main Steps of Applying the LSH Algorithm to Enhance the Investigation Process in Cloud Computing

TABLE II. AN EXAMPLE OF A SHINGLE MATRIX EXTRACTED FOR A SET OF TEXT FILES

| Shingle ID | First Document | Second Document | Third Document |
|------------|----------------|-----------------|----------------|
| Shingle 1  | 1              | 0               | 0              |
| Shingle 2  | 0              | 1               | 0              |

| shingle 4  | 1              | 0               | 0              |
| Shingle 5  | 0              | 1               | 0              |
| Shingle 6  | 0              | 0               | 1              |
| Shingle 7  | 1              | 1               | 0              |
| Shingle 8  | 0              | 0               | 1              |
| Shingle 9  | 1              | 1               | 0              |
| Shingle 10 | 0              | 0               | 1              |
| Shingle 11 | 1              | 1               | 0              |
| Shingle 12 | 0              | 0               | 1              |
| Shingle 13 | 1              | 1               | 1              |
| Shingle 14 | 1              | 1               | 0              |
| Shingle 15 | 0              | 0               | 1              |

shingles that are added into a shingle matrix which represents the files in the cloud storage center.

The process of extracting shingles from documents is called the shingling extraction step where each document is represented by a string of characters. Shingles extraction is the process of creating a set of k-shingles for a document to be any sub string of length k found. As an example of the shingle extraction step, assuming the original document containing a, b, c, d, e, f, g, h, and k is 3 then some possible shingles are a, b, c, b, c, d, c, d, e, d, e, f, e, f, g, and f, g, h. The similarity of documents is measured based on the degree of overlapping between these shingles. Increasing the number of shingles overlapped between two files means that the two files are more similar to each other [11].

The similarity between documents is measured using Jaccard similarity metric [45], which depends on the degree of overlapping between shingles. matrix. The equation used to calculate Jaccard similarity is as follows

$$Sim(File1, File2) = \frac{|File1 \cap File2|}{|File1 \cup File2|}$$

... (4) By increasing the intersection ratio between the two files, the degree of similarity would increase. Based on this, the degree of similarity between the two files will increase when the amount of intersected characters or features between the two files is increased.

2) *The Step of Compression using Min-hashing Algorithm* : The signature matrix which is built through the first step of the pre-investigation stage will be usually very large due to the huge volume of files stored in cloud computing storage space. Accordingly, it is very complicated to handle the shingle matrix for the recovered clusters. Therefore, further processing is needed, which could be very time consuming to use the conventional method for performing the searching and matching steps.

It is necessary to compress the shingle matrix in a specific way while keeping the distance between the files in the original matrix. One of the best solutions is the Min-hashing algorithm, which can compress the shingle matrix into a small matrix called signature matrix "M". The most important feature of this algorithm is that it keeps the similarity of the underlying sets of shingles in the compressed version.

Min-hashing algorithm allows for the generating of a permutation list, which contains random numbers in the range from 1 to the number of shingles. The result of the Min-hashing process is stored in a signature matrix, where its rows are the Min-hashing value, and the column of the signature matrix is the file name. The number of permutation lists determines the accuracy of the signature matrix. Each permutation list produces a row in the signature matrix. Fig. 5 shows an example of the main step of converting the shingle matrix for a set of files into a signature matrix using 4 Min-hashing functions (4 permutation lists). The similarity between doc1 and doc3 in the shingle matrix is very close to the similarity between h(doc1) and h(doc2) in a signature matrix.

The pseudo code shown in Algorithm 1 contains the steps of min-hashing starting from the step of generation of a permutation list and all steps of compression for the shingle matrix until the production of the signature matrix and signature list. For more details on how to calculate the signature matrix out of the permutation lists please refer to [15].

3) *Locality Sensitive Hashing (LSH)*: The last step after creating the signature matrix from the shingle matrix is applying locality-sensitive hashing to the produced signature matrix. LSH step is very helpful in dealing with parts of a file in order to discover criminal acts rather than dealing with the whole file imposed by other techniques. In the matching and examination forensic stage, we suggest to use LSH algorithm to enhance the investigation process based on the following factors:

- 1) The conventional way of matching byte-to-byte takes significantly long time carry out especially on the cloud.
- 2) High degree of accuracy in the matching process can be obtained. This aspect is essential and useful in a cloud computing environment since it contains a huge volume of files.
- 3) The LSH algorithm can handle all cases of the matching process, such as if the file was removed, partially modified, or fully updated.

Locality-sensitive hashing mainly depends on the division of the signature matrix from the shingle matrix into several bands. Specific hash function F(x) is used for each band of a signature matrix. The result of the hashing step maps to a specific bucket in a bucket list. Each column in the signature matrix is hashed multiple times based on splitting the column into band sets, and each band is hashed using a specific, preferably different, hashing function.

The Signature list will also be hashed multiple times based on splitting it into bands and hashing each band using a same hash function that has been used for that band over the signature matrix. The bands with the same data will be hashed and mapped to the same bucket [22]. This means that the files which are shared in the bucket are exactly identical.

The flowchart in Fig. 6 shows the key steps of the LSH algorithm which are used in CBIF as the step of matching began by dividing the signature matrix into a specific number of bands. In order to determine that a set of files match, specific threshold has to be defined to determine which of the candidate set of files have contributed in creating the targeted document. The threshold in CBIF will be changed based on the corresponding results as shown in the flowchart in Fig. 6.

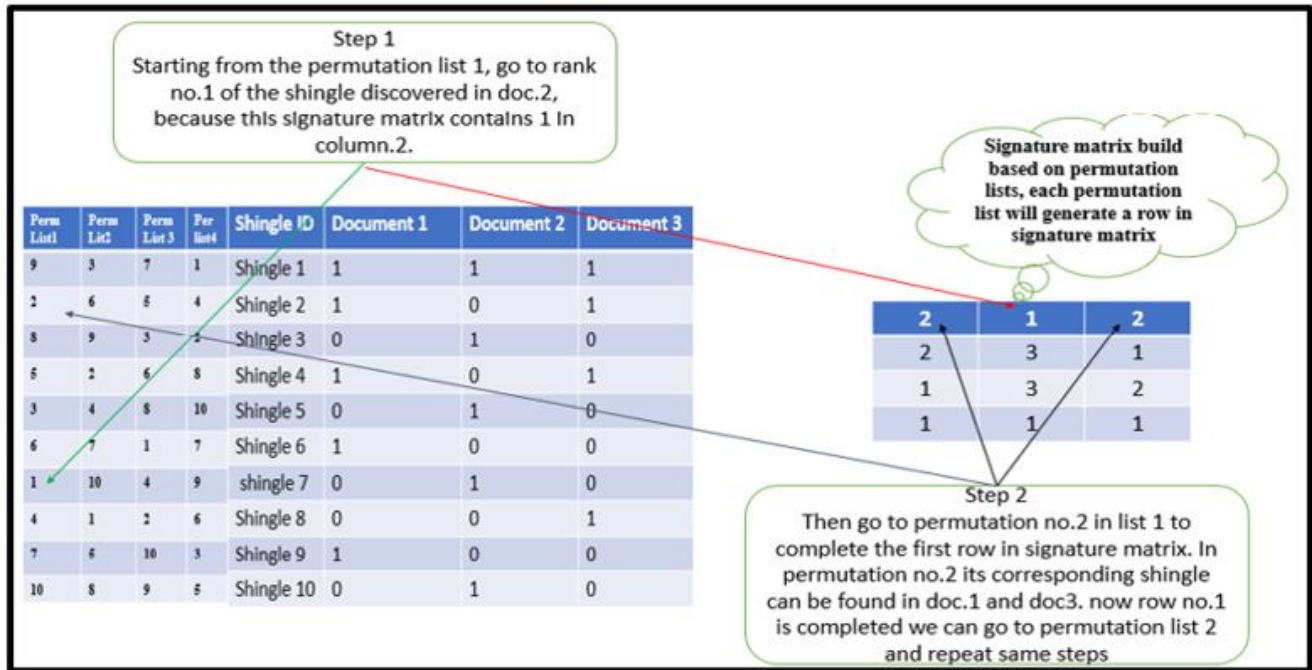

Fig. 5. Main Steps of Building a Signature Matrix from the Shingle Matrix.

```

Algorithm 2: Pseudo code for the main steps of Min-hashing algorithm
Start Define shingle Matrix M(S);
Define shingle List L(x);
Define LP;
Define T;
Define T1;
Define P[size];
Fill T with zeros;
Fill T1 with zeros;
Define I;
Generate permutation lists randomly;
for P = 0; P < P.length; P++ do
  for I = 0; I < size; I++ do
    Find the row which contains number i in permutation list;
    Let R in M(S) = I;
    for C = I; C < File - Count; C++ do
      if R[C] = 1 then
        T[P][C] = i
        rowT[P][C] contains no - zeros Break;
  for P = 1; P <= P.length; P++ do
    for I = 1; I <= LP; I++ do
      Find the row which contains number I in permutation list if rowT1[P][I] contains no zeros then
        T1[P][I] = i;
        rowT1[P][I] contains no zeros Break;
Return T, T1;
    
```

If there are no two files shared in a number of buckets based on the given threshold, the threshold's value will be reduced until it reaches zero. Therefore, it can be concluded that no file matches fully or partially the targeted file. Fig. 7 shows an example of how to apply LSH algorithm in the matching system to identify the set of matching documents.

#### IV. EXPERIMENTS IMPLEMENTATION AND RESULTS DISCUSSION

Two main experiments have been implemented throughout this research paper. The first one has to do with the implementation and evaluation of the clustering algorithm which makes use of CBIF. The second experiment has to do with the implementation and evaluation of LSH algorithm. All the experiments were implemented with Java Programming language using Net-Beans 8.1 on a PC with 64-bit Windows 10 operating system, and an Intel core i7-6500u CPU with 32GB of RAM.

##### A. Testing and Evaluation of Clustering Algorithm

To define the performance of the genetic-based dynamic clustering algorithm used through the second level of clustering, an implementation of the algorithm over ten, real and artificial data-sets obtained from UCI [10] was performed. The data-sets used in this experiment have various numbers of features ranging between '3' to '13' features. It contains various numbers of clusters ranging from '2' to '6' clusters. A set of experiments have been designed to measure the accuracy and performance of GBDCA before being used in CBIF. Each experiment has been applied over the data-sets mentioned in Table III. GBDCA has been compared with K-means clustering algorithm which we have been also implemented to measure its accuracy and performance.

Table III represents the number of clusters resulted from running each of the two clustering algorithms. The number of clusters achieved by each algorithm is compared with the original number of clusters for each data-set, and represented as the Error Rate. The results shown in Table III is the average value of ten experiment runs applied for each data-set. The main objective of these experiments and the comparison between GBDCA and K-means algorithms were to prove that GBDCA is the better than K-means and can be used in the investigation process to enhance the forensics process of digital devices. The genetic based dynamic clustering algorithm depends on using the Inter/Intra ratio, as an external fitness function.

$$POE = \frac{ABS(OriginalNo - AchievedNo)}{Originalnumber} * 100$$

... (5) In the equation above, the POE refers to the percentage of error, ABS refers to the absolute value, which is calculated for the difference between the original number (OriginalNo.) of clusters for each algorithm and the average number of clusters achieved by the experiments applied on a specific data-set (AchievedNo.). Table IV shows the error rate for each competitive algorithm for the different data-set.

TABLE IV. ERRORS PERCENTAGE FOR EACH COMPETITIVE CLUSTERING ALGORITHM BASED ON THE RESULTS ILLUSTRATED IN TABLE 2

| Dataset Description | Genetic Error Rate | CRO Error Rate | Kmeand Error Rate | Min Error Rate |
|---------------------|--------------------|----------------|-------------------|----------------|
| E. coli DS          | 10%                | 14.67%         | 44.67%            | 10%-GA         |
| IRIS DS             | 14.44%             | 21.11%         | 41.1%             | 14.44%-GA      |
| Seed DS             | 12.22%             | 18%            | 37.78%            | 12.22%-GA      |
| Balance DS          | 7.78%              | 12%            | 36.6%             | 7.78%-GA       |
| Blood DS            | 25%                | 30%            | 46.67%            | 25%-GA         |
| Wine DS             | 6.67%              | 16%            | 18.89%            | 6.67%-GA       |
| Hepatitis DS        | 38.33%             | 42%            | 53.33%            | 38.33%-GA      |
| Vertebral DS        | 36.67              | 47             | 53.33%            | 36.67%-GA      |
| Breast Cancer       | 18.33%             | 28%            | 51.7%             | 18.33%-GA      |
| Glass DS            | 16.11%             | 6%             | 18.9%             | 6%-CRO         |
| Average Results     | 19%                | 23%            | 40%               | 19%-GA         |

Table IV allows us to determine which is the best algorithm to be used through the step of dynamic clustering in the proposed hierarchical clustering algorithm. The average percentage of error rate achieved by the dynamic clustering-based genetic algorithm is 19%, and the percentage of error achieved by the dynamic conventional k-means algorithm is 40%. The results shown in Table 3 can be interpreted as a recommendation to use a genetic-based dynamic clustering algorithm in our solution, given the low percentage rate in comparison with the K-means algorithm.

### B. Experimental Implementation for the LSH Algorithm

Several tests have been performed to determine the accuracy and reliability of CBIF and different data set sizes have been used. Furthermore, various structures for the tampered file were designed and used to test the proposed solution through a set of experiments. The data set used in our experiments is the Reuters data set consisting of 21000 files [46]. The experiments are divided into four main categories based on the structure of the tampered file used. Each category of experiments consists of 10 runs and the average value was calculated. In each run, the variables that controls the structure of tampered file were different. The details about the structures of tampered file will be shown in detail just before discussing the results of that experiment. The Reuters files were divided into sets and the series of experiments were applied to each of these sets; the size of these sets will be addressed below. The matching accuracy based on equation (5) has also been calculated.

The data set used in these experiments is divided into clusters based on the dynamic clustering algorithm decision proposed in the hierarchical clustering step. In most cases, the number of clusters achieved was 6 clusters. The files were distributed over the clusters based on the level of similarity between cluster centroid files and all other files.

1) *Tampered File Description:* The tampered file used in the experiments to evaluate the accuracy and efficacy of the CBIF has many structures, as follows.

- Structure-One: The first structure for the tampered file

consists of three random files from three random clusters. File "A", from a random cluster "A", is involved with 10% of the tampered file content. Random file "B", from another random cluster "B", is involved with 20% of the tampered file content. Finally, 70% of the tampered file creation process is from random file "C", which belongs to yet another cluster "C". The files and clusters "A", "B", and "C" are random in that they may vary from experiment to experiment. This also applies for the next structures. see Fig. 8A.

- Structure-Two: The second structure for the tampered file consists of three random files from three random clusters with different participation rates with 20%, 30%, and 50% for random files A, B, and C from random clusters A, B, and c respectively. Fig. 8B shows the percentage of participation for each file in the tampered file content data
- Structure-Three: Another structure for the tampered file was used that consists of two random files from two random clusters. Random file "A", from random cluster "A", is involved with 40% of the tampered file content, while random file "B", from random cluster "B", is involved with 60% of the tampered file content. Third part of Fig. 8C shows the percentage of participation for each file in the tampered file content.
- Structure-Four: The last structure of the tampered file used consists of two random files "A" and "B" from two random clusters "A" and "B" where each file is involved with 50% of the tampered file as shown in Fig. 8D.

2) *Experimental Implementation for LSH Based Framework Using Different Tampered File's Structures* : Multiple experiments were conducted based on the above mentioned tampered file structures. Each experiment was replicated sixty times with random file selected randomly from a different cluster each time. The AMA is the average results for '60' of the repeated experiments. Each experiment has different variable values for the structure of the tampered file. The purpose of repeating the experiments '60' times is to test CBIF's performance and reliability in order to deal with all cases of file creation being tampered with. The purpose of repeating the experiments is to test the CBIF's ability to recognize the original files in all cases of manipulated files.

For example, in the experiment defined for Structure-One of the tampered file structure, Cluster A can be randomly selected as Cluster '2', and File X can be randomly selected to be File '5', meaning that the tampered file has 10% of its content taken randomly from File number '5' in Cluster '2'. Cluster B can be cluster '4' and File Y can be File '1', this means that the randomly selected File '1' in Cluster '4' has participated with 20% of that tampered file content. Finally, Cluster C can be cluster '5' and File Z can be File '2', meaning that from Cluster '5' we have randomly selected File '2', which contributes to 70% of that same tampered file's content. Fig.9 consists of 4 main sub-figures A,B,C, and D, whereas each sub-figure of Fig. 9 is specified for an experiment based on a specific tampered file structure.

The Average Matching Accuracy (AMA) is a metric that we have used to measure the accuracy of the matching process

and is calculated based on the percentage of matching between the tampered file and the original files which participated in the tampered file content. The equation which was used to calculate AMA between the tampered files and original files is equation (6). In this equation the Avg-Matching(Bx, ..., By) refers to the average results of matching between the tampered file and all clusters participating with a certain percentage of the tampered file's construction. As an example, if equation (6) was used to calculate the average accuracy for a cluster involved with 50% of the tampered file content, then in this case, the AvgMatching(F.1, F.2, ..., F.n) is the average result of matching between the tampered file and the "n" files F.1, ..., F.n that are involved with 50% of the tampered file content. Here "n" is the number of runs the experiment has been repeated which is in our case equals 60.

$$AMA = 100 - \frac{ABS(AvgMatching(Bx, \dots, By) * 100 - Actualmatchingpercentage)}{ActualmatchingPercentage} * 100 \dots (6)$$

The results in Fig. 9 show how accurate CBIF is for the matching process, and presents how the AMA for the results of matching is close to the actual ratio of participation in all matching results.

Details of each result shown in Fig. 9 will be thoroughly explored next before comparing CBIF with other rival algorithms. The purpose of this is to reduce the complexity of discussing this comparison into two simpler phase. In the first phase we discuss the results obtained for CBIF and in the second phase we compare these results with results obtained for other protocols.

- **First Experiment**

The tampered file used through the first experiment was built according to Structure-One of the tampered file structures shown in Fig. 9A, which consists of three files.

Fig. 9-A consists of three columns where each column shows the average matching ratio between the tampered file and the original files in a specific cluster based on the percentage of participation in the tampered file content. The figure show the participation results of three clusters, thus we have three columns, since the participation ratios of other clusters were negligible and thus are not shown in the figure.

The average accuracy of matching between the tampered files and original files which were involved in 10% of tampered file contents is 76.78%, the average accuracy of matching with the files involved in 20% of tampered file contents is 94.44%, and the average result of matching with the files participating in 70% of the content is 87.71%.

The conclusion that can be drawn from Fig. 9A is that CBIF's has the ability to deal with the case when the target file in the investigation process was mixed with other files. This indicates that the file that the investigator was searching for and modified at a certain rate was found at a high accuracy rate.

- **Second Experiment**

Another experiment was conducted based on the second structure of the tampered file that was referred to in Fig. 9B. This figure consists of three columns, each column is specified for the AMA between

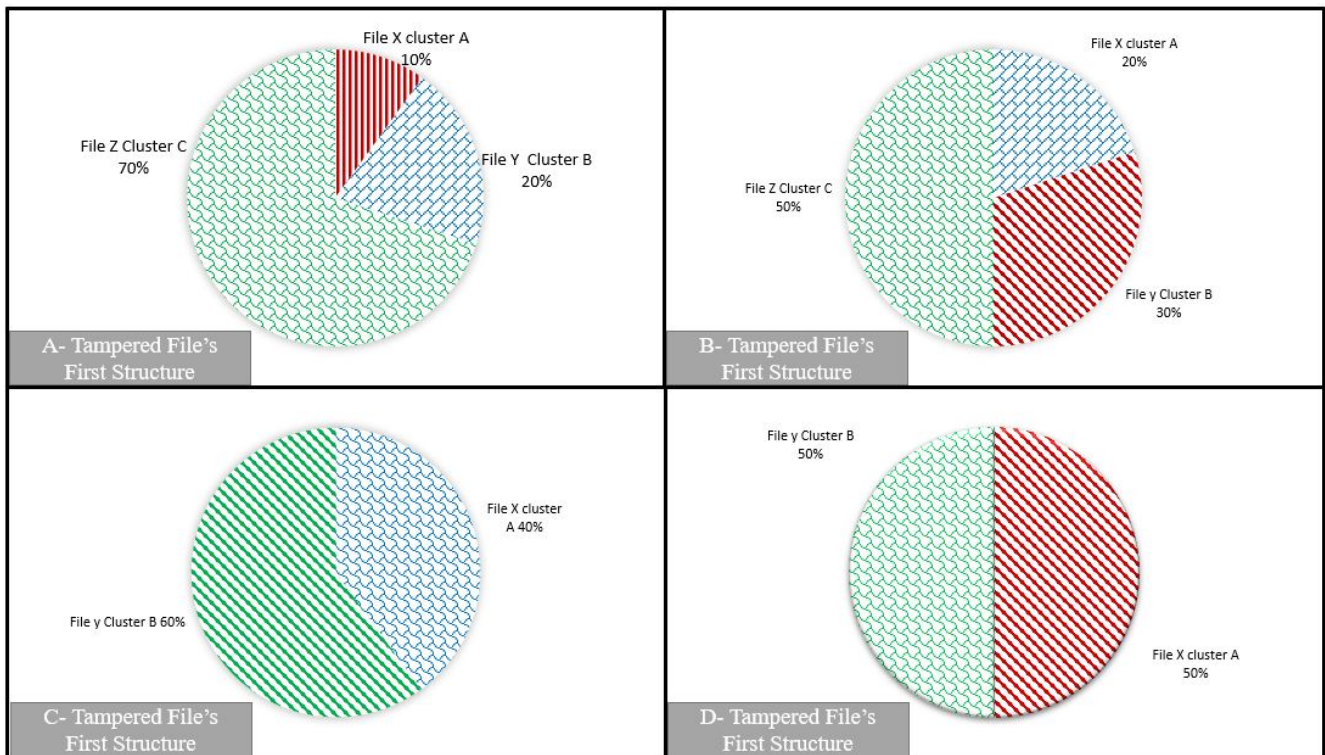

Fig. 8. Key Structures of Tampered File Content which were used by Experimental Implementation.

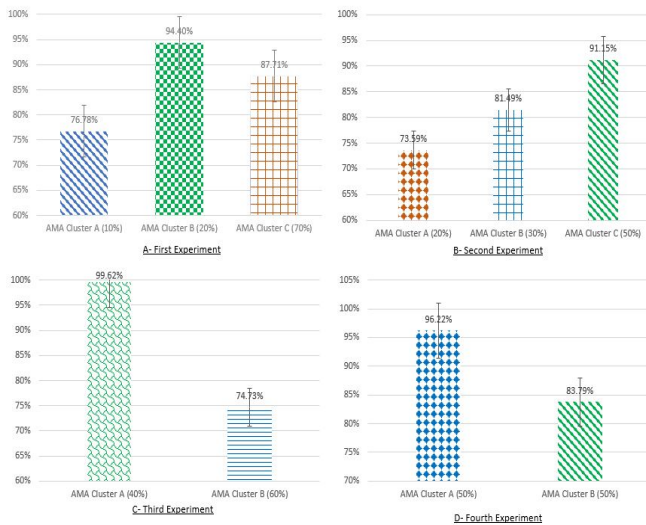

Fig. 9. Results for Set of Experiments based on Different Structures for Tampered Files.

tampered file and each of the original files which were involved in the creation process of the tampered file.

The files that participated in the tampered file's content creation achieves a high level of similarity if compared with other files, such that the accuracy of matching that was shown in Fig.9B depends on

the values of actual matching results. The conclusion that can be drawn on the basis of the results shown in Fig.9B is that the proposed CBIF succeeds in retrieving the right files with a higher matching level than the other files in the storage space.

- Third Experiment The third experiments was applied based on the third structure of the tampered file mentioned earlier in Fig. 9C. This figure consists of two columns, each column represents the average accuracy of matching between the tampered files and original files which were involved in the construction process of the tampered file. The results shown in Fig. 9C represents the extent of accuracy and reliability of CBIF to deal with the third case of tampered file content mentioned earlier. This gives a strong argument for the benefits and importance of using the proposed CBIF.
- Fourth Experiment. The last experiment was applied based on the structure of the tampered file mentioned in Fig. 9D. The results shown in Fig. 9D illustrate the AMA for this experiment which consists of two bars, each bar shows the average accuracy of matching with each original file involved in creating the tampered file. The results shown in Fig. 9D show the accuracy of CBIF in retrieving the correct files which actually participated in the contents of the manipulated file.

3) Comparisons between the Proposed Solution and Related Cluster-based Solutions: Two of the related solutions have been implemented and compared with the proposed CBIF.

The purpose of this comparison is to demonstrate matching accuracy level of CBIF relative other similar techniques. The first competitive solution relies on using the traditional k-means clustering algorithm [10]. The idea of the solution revolves around applying the k-means clustering algorithm in the investigation process to divide the documents in the storage center into groups and to focus on the group which is most similar to the target file. The second competitive solution is to use a k-medoid clustering algorithm to enhance the investigation process with respect to accuracy and performance [17]. Both solutions have been implemented and used with the data-set which was used to test CBIF. The structure of the tampered file which was used through the experiments of testing the competitive solutions is the same as the structure which mentioned earlier to test the proposed CBIF. All of experiments have been run 60 times. The average accuracy of matching for all experiments have been applied using equation 6 . The results for the experiments are as follows:

- Comparison between CBIF, a K-means based solution, and a k-medoid based solution using the first structure of the tampered file

Fig. 10A shows the AMA for the three solutions based on structure-One of the tampered file. The figure consists of three groups of bars, each group contains three bars. Each bar refers to the average accuracy of matching between the tampered file and other files, exist in a specific cluster, using one of the three compared solutions. The first group which represents the AMA between the tampered file and a clustered file which participated in 10% of the tampered file content. CBIF has achieved higher AMA than the results obtained by the other solutions for the first tampered file structure.

The AMA of the file which participated with 70% of tampered file content is greater in CBIF, close to 88%, compared to the other solutions, almost 75% and 65% for k-means and k-medoid, respectively. This demonstrates the ability of CBIF in improving the matching accuracy which is better than similar solutions. This helps in finding the correct file that actually participated in the contents of the tampered file.

Another important enhancement of CBIF is related to the rank of the original files which participated in the tampered file's content. The files that were already involved in creating the file that was tampered with, in most experiments, have the highest degree of similarity with the tampered file. On the other hand, only in 72% of the total experiments did the original files that participated in the composition of the manipulated file obtain the highest similarity with the tampered file, which means that the original files did not get the highest similarity in a 28% of experiments.

- Comparison based on the second structure of the tampered file  
Other experiments have been designed and implemented for the related solutions to show how CBIF solution performs. AMA has been calculated for the 60 runs of experiment for each solution. The summary

of these experiments can be shown in Fig. 10B. Results shown in Fig. 10B represent the AMA of the competitive solutions to retrieve the original participated files. CBIF achieved an accuracy level that is, also in this experiment, higher than other two competitive solutions for all participated files, as can be seen in the results shown in group three of Fig. 10B.

The AMA achieved by CBIF is 91.15%, whereas the average accuracy achieved by the k-means based solution is close to 75%, and the average accuracy of matching achieved by the k-medoid based solution is close to 67%. This indicates the gap in the performance between CBIF solution and the other related solutions. This point is important to encourage the prefer the usage of the CBIF in investigation process over the other rival solutions.

Another significant improvement accomplished by CBIF is the ranking of files based on the degree of similarity with the tampered file. File ranking here indicate the ability of the solution to rank the actual original files that have participated in the tampered file as the top ones. For example assume that file A and B have participated in creating a tampered file T with a certain percentage from each one. A solution that gives the highest percentages to files A and B, regardless of the accuracy results for each one, is assumed to reach 100% ranking accuracy. While a solution that gives a percentage for another file, e.g. file C, that is higher than A or B gets a lower ranking accuracy.

In the experiments that are based on the Structure-One of the tampered file, using a solution based on k-means and a solution based on k-medoid, the files involved with the tampered file content do not reach the highest degree of similarity with the tampered file in some of the experiments. In the solution that depends on the k-medoid clustering algorithm, the ranking accuracy was close to 77% while in the solution that depends on the conventional k-means clustering algorithm, 80% was the ranking accuracy. CBIF has achieved 95% to 100% ranking accuracy in all of the experiments and for all tampered file structures.

- Comparison based on Structure-Three of the tampered file.  
Third part of Fig. 10C shows the results for the experimental implementation of competitive solutions based on Structure-Three of the tampered file mentioned earlier. For the 60 experimental runs, the average accuracy was calculated. The average level of accuracy obtained by CBIF was higher than the average accuracy achieved by the competitive solutions in the matching process with the files that participated in 40% of the tampered file contents. Although the difference is less than the case with 40% participation, CBIF achieved higher accuracy also for the 60% participation results. Additionally, for the ranking accuracy, in the k-means based solution 86% of all experiments. In the k-medoid based solution is 84% of all experiments.
- Comparison between the CBIF and other competitive solutions based on the Structure-Four of the tampered file

The results shown in last part of Fig. 10D represent the average accuracy of matching for the three competitive solutions to enhance the investigation process. CBIF achieves higher AMA in both clusters, which has participated with 50% of the tampered file, than the other compared solutions. Moreover, k-medoid based solution, shows ranking accuracy as 86% while solutions based on k-means results in 90% ranking accuracy which is much less than what CBIF has achieved.

To conclude, from the section of comparisons between the proposed CBIF and other rival solutions, it can be inferred that the proposed solution improves the average matching accuracy for the investigation process in all cases and for all of the files structures involved. This point is important in the forensics process, as many of the crimes are hidden based on mixing the original file with other files. Moreover, the point of enhancement in the accuracy of matching is what all frameworks and solutions are looking for to achieve; the results shown in the above figure indicate a noticeable improvement on average matching accuracy in most cases. This is supported by the results of ranking accuracy which prove that CBIF outperforms K-means and K-mediod algorithms in all the conducted experiments.

4) Comparison between CBIF and Related Solution on the Basis of Execution Time: Another comparison is between the competitive solutions based on the execution time for each algorithm. The comparison is based on the size of the data-set used. The execution time was measured for applying the three solutions for the 2000 file, 4000 file, 8000 file, 16000 file, and 21000 file data-sets. The results for the execution time are shown in Table V. The results in Table V refers to the time needed for the investigation to find a file similar to the target file. k-medoid clustering algorithm needs less time than k-means based investigation process which in turn takes less than proposed CBIF. This slight extra is justified by the higher average matching accuracy achieved by CBIF.

TABLE V. RESULTS FOR THE EVALUATION PROCESS OF THE PROPOSED DYNAMIC CLUSTERING ALGORITHM

| No.Files in a data-set | Execution time for CBIF in seconds | Execution time For k-means based investigation in seconds | Execution time for k-medoid in seconds |
|------------------------|------------------------------------|-----------------------------------------------------------|----------------------------------------|
| 1000                   | 189.2                              | 150.388                                                   | 135.9                                  |
| 2000                   | 238.7                              | 215.9                                                     | 182.6                                  |
| 4000                   | 1972.15                            | 1213                                                      | 600.356                                |
| 8000                   | 4370.16                            | 4222.11                                                   | 3446.462                               |
| 16000                  | 12325.2                            | 11863.5                                                   | 10695                                  |
| 21000                  | 18735.5                            | 17962                                                     | 16818.5                                |

## V. CONCLUSION

Many frameworks and solutions have been proposed in the field of cloud computing forensics. Each of these frameworks have specific drawbacks and weak points in certain stages of the investigation process. In the paper, CBIF is proposed to focused on a specific issue of cloud computing forensics; namely, the performance and accuracy of the investigation process. CBIF adds a new stage called the pre-investigation stage, which is responsible for filtering and grouping the evidence and files in the cloud storage center into a set of groups based on using a hierarchical clustering approach. This stage enhances the average accuracy of the matching process by dividing the storage center into sets of groups.

The results achieved from the experimental implementation shows how the proposed CBIF enhances the average accuracy when compared with the related solutions, the k-means based solution and the k-medoid based solution. CBIF achieved higher accuracy matching levels and ranking accuracy than the competing solutions in most of the experiments.

The proposed CBIF solution can be enhanced in the future by enhancing the LSH step of current solution by changing the technique of selecting band size.

**Abstract**—The development of big data in the era of data explosion and the growing demand for micro-servers in place of traditional servers to adapt to lightweight tasks in recent years has put into question how to integrate and make use of these two important domains. During the same era, CPU performance growth has reached a certain maturity. In order to surpass these issues and to reach high performances computing, a new trend now is to use multiple processing units or heterogeneous components in micro-servers to reduce computational complexity. The implementation of Big Data processing algorithms using embedded heterogeneous architectures rises a new challenges due to constraints of the used architecture-based system on chip which require a special attention and imposed new demands to our works. In this article, we focus on using embedded FPGA accelerator to give a solution to this problem. Precisely, we will attempt to prototype a micro-server for the processing of big data on FPGA and compare its performances with a high-end GPGPU using existing benchmarks. The implementation on the FPGA is done using a High-Level Synthesis based-OpenCL (HLS) instead of the traditional description language. The obtained results shows that FPGA is an interesting alternative and can be a promising platform to design a micro-server when it comes to process a hug amount of data, in particular with the emerging technologies for FPGA programming using HLS approach and by adopting the OpenCL optimization strategies.

**Keywords**—Arria 10 FPGA (Field Programmable Gate Arrays); GPGPU (General Purpose Graphics Processing Unit) ; big data; parallel computing; (HLS) High-Level Synthesis

## I. INTRODUCTION

BIG data, produced from online transactions, emails, videos, audios, picture, posts, search interrogation, medical records, social networking interface and science applications, has become one of the most important domain in the information technology industry [1]. According to IBM (2015), around 2.5 nonillion (10 to the power of 30) bytes of data is created every day. The overwhelmingly large amount of data leads to challenges including storage, analysis and fetch. To define the properties of big data, Doug Laney (2001) has proposed the 3Vs (Volume, Variety, Velocity) [2]. In current hypercompetitive industry environment, several challenges related to big data processing are imposed on the companies, which include to meet with the need for speed, to understand the data, to address

the data quality, to display significant results and to distinguish the outliers. There is growing interest in FPGA (Field Programmable Gate Array) as a solution. FPGA has always been considered as the generation of integrated circuit that could replace ASIC (application specific integrated circuit). Able to be fully reconfigured by user, an FPGA is commonly claimed higher performance, shorter time to market, lower cost, high reliability, less needs for long-term maintenance. Being reprogrammable results is the main difference between an FPGA and an x86 processor: the FPGA does not waste compute cycles doing unnecessary processing. In other words, FPGA excels for doing one simple and repetitive task like pattern matching. This great advantage of FPGA has catalyzed investigations on its potential usage in big data processing. One of the most important assets of FPGA is its exceptional ability in the computation of finegrained tasks in clock-cycle basis. This ability is extremely interesting especially regarding Big Data management. However, this high-potential acceleration constrains drastically the possibilities of implementation. After having chosen the FPGA design, the aim is to reproduce this precise organization of the blocks matrix using OpenCL code and the IntelFPGA OpenCL SDK, which generates a board organization and the full setups given an OpenCL code. In this article, we investigate the challenges for speeding up Big Data algorithms and provide a roadmap for further improvement. Ultimately, our aim is seamless integration of FPGAs to build a micro-server for Big Data processing. Many recent research has been conducted to strengthen the niche of FPGA in big data business [3], [4], [5]. However, the current available tool sets to build FPGAs are still complex. On the other hand, GPUs are leveraged well with the implementation of CUDA language. Besides, GPUs where instructions are executed in fixed instruction set are more flexible; they are also more adapted for floating point arithmetic.

The paper is organised as follow: Section II present the related work and our contribution, Section III presents our methodology applied for performance evaluation. In Section IV, we will give a description of the test benchmarks implemented in our work. Section V presents the hardware specification as well as the software tools and the adopted parallel programming technology. In Section VI we will present

the algorithms implementation as well as the performance evaluation. Section VII gives a holistic overview and conclude the work

## II. RELATED WORK AND CONTRIBUTION

Authors in [6] presented an FPGA-Accelerated Big Data implementation. The proposed system is based on the popular Apache Spark framework on the software side, and on an OpenCAPI-based POWER9 platform with Xilinx VU37P FPGA on the hardware side. Their system is able to generate a high-performing FPGA circuit from very high-level code descriptions in Spark.

The work in [7] present a case study of accelerating Apache Spark using re-configurable architecture. The authors proposed a framework to integrate FPGA accelerator into a Spark cluster. The Spark tasks are accelerated on the FPGA using Python. The performance results are evaluated with a case study of 2D FFT algorithm acceleration. The obtained results showed that FPGA based Spark implementation acquires 1.79x speedup than a conventional CPU implementation.

The author in [8] proposed the use of distributed databases and high-performance computing architecture in order to exploit multiple re-configurable computing and application specific processing. The proposed a 4-layer general architecture for smart agriculture, which is able to collect, store and process data from IoT nodes, integrate external data from other sources and allows efficient treatments of data coming from several sources with a cloud high-performance heterogeneous architecture.

A collaborated research team from George Mason University and University of California, guided by Netshatpour [3] has discovered a significant speedup with respect to K-means, KNN, SVM and Naive Bayes while implementing the mentioned machine learning algorithms in a Hadoop Platform with Intel Atom C2758 and Xeon E5 as master nodes and several Xilinx Zynq devices as slave nodes.

Besides, [4] have presented an FPGA-based hardware accelerator platform for big data matrix processing. A comparison of performance has been conducted between an Intel I7-4770 CPU (3.4GHz) and an FPGA of the model VC707 (125 MHz). Furthermore, a recent research published by the University of Science and Technology of China [5] has presented a software-defined operating system framework for FPGA based accelerator with the implementation on Xilinx Zynq FPGA.

On the other hand, ITRS Semiconductor roadmap foresees that hundreds of processors would be the base for the next generation embedded multicore designs. Recently, Microsoft in 2015 collaborated with Bing to investigate the use of FPGA. The project, also known as Project Catapult, has showed an improvement of nearly a factor of two of the operations per second in a critical component of Bing search engine [9].

With the demand for high speed network and computing, speed and parallel algorithms have become essential tools for development. Many of these operations were performed by a general purpose processor. But now days due to the availability of FPGAs, many researchers try to implement various algorithms on FPGAs more efficiently. FPGAs are often used

TABLE I. PERFORMANCE METRICS

| Metrics used for FPGA and GPU | Additional metrics for FPGA |
|-------------------------------|-----------------------------|
| Execution time                | % of DSP blocks             |
| Memory bandwidth              | % Logic Elements            |
| -                             | % of Memory Block           |

as hardware accelerators. Our work aims to implement big data benchmarks and to compare the performance of GPUs and FPGAs when it comes to big data processing. The main idea of our targets is to construct a scaled up platform of FPGA-based micro-server for big data processing. To date, among all the current research and works in the state of the art, none of them targets the application of FPGA in big data processing. To our knowledge, this is the first work to evaluate and optimize big data algorithms on a dedicated architecture by adopting the high level synthesis approach.

## III. PERFORMANCE EVALUATION METHODOLOGY

### A. Performance Metrics

The FPGA and the GPU we plan to use does not have the same I/O maximum speed, which will result in a comparison error if the slowest computing unit is limited by its I/O maximum bandwidth. Therefore, for each algorithm and each implementation, we plan to save the different metrics during the computing of the same series of test files on the two components. These metrics will then be compared by being put into charts and analysed.

For the GPU: We use Nvvp which is a built-in tool of Nsight to evaluate the performance of GPU. This tool allows us to measure the running time and the throughput of each function implemented, hence, allows us to know which parts of the code can be improved. For FPGA: Assuming that there is still no benchmark available regarding FPGA for the algorithms we decided to propose our own implementation. There is no implicit way of evaluating their performances precisely. Therefore, our study is based on a data-processing speed comparison between an FPGA and a GPU, the last being already used for massive parallel computing. The performances of our algorithms will also be verified by the IntelFPGA SDK for OpenCL, which includes an optimization report. The Table I gives some important metrics evaluated in our results.

### B. Multiobjective Optimization and Pareto Optimality

FPGA programming is about finding algorithms that optimize some aspects of the performance regarding different limited resources. Therefore, there is no unique solution to those problems, and the optimal computation depends on the factors that we want to optimize. No single FPGA implementation for all benchmarks can be an optimal  $\langle P, E, A \rangle$  with P for Performance, E for Energy and A for Chip Area [10]. Therefore, with  $N$  benchmarks each being potentially individually implemented Pareto like with numerous configurations the automatic optimization variations on concurrency E against A is needed.

TABLE II. EXECUTION OUTPUT AND DATASET STATISTICS

|                                 |             |
|---------------------------------|-------------|
| Average path distance           | 3.692507    |
| Network diameter                | 8           |
| Global efficiency               | 0.306578    |
| Clustering coefficient          | 0.632353    |
| Transitivity                    | % 0.000073  |
| Betweenness centrality          | 4051.734470 |
| Closeness centrality            | 0.261441    |
| Degree Distribution             | 0.023026    |
| Pearson correlation coefficient | -1.536665   |

### C. Graph Measures Results

The implemented big data algorithms were tested on the Stanford Large Network Dataset Collection provided by SNAP (Stanford Network Analysis Project) [11]. We have executed our algorithms on the dataset consisting of <circles> (and <friends lists>) from Facebook, which can be represented by an undirected graph of 4039 vertices and 88234 edges. Table II represent the execution outputs of the created graph. We have implemented the graph using C language and produce the algorithms to measure the dataset statistics: the Average path distance, Network diameter, Global efficiency, Clustering coefficient, Transitivity, Betweenness centrality, Closeness centrality, Degree distribution and Pearson correlation coefficient.

### D. Test-bed Setup

To evaluate the OpenCL FPGA implementation, we used a host computer, operating at 2.5 GHz under CentOS Linux 7.0 with a 32 GB RAM, with FPGA board mounted on the PCIe slot. We used the De5a-Net board embedding the IntelFPGA Arria 10, Fig. 1 shows the test-bed setup.

## IV. ALGORITHM DESCRIPTION

### A. K-means

K-means is a popularly-used algorithm for clustering. The aim of clustering is to divide the given set of data  $X$  composed of  $n$  points into partition  $\{C_i\}_{1 < i < k}$  such that points in each subset are similar to each other; otherwise, points from different groups are dissimilar [12]. The similarity is defined by a distance function; therefore, clustering task is able to be interpreted quantitatively as minimizing the cost function desired by user, which is normally formulated as below:

$$e_k(X, C) = \sum_{i=1}^n \min(D(x_i, c_j)) \quad (1)$$

where  $c_j$  is the center of subset  $C_j$

For K-means, we set the distance  $D(x, y)$  by the square of Euclidean distance  $\|x - y\|^2$  (this is not a metric, because it does not have triangular inequality property). Hence, K-means cost function is defined by:

$$e_k(X, C) = \sum_{i=1}^n \min_{1 < k < j} \|x_i - c_j\|^2 \quad (2)$$

Given a set of data points, a clustering algorithm aims to the similarity which is defined using distance measure. In our

work, the Euclidean distance is utilized. Basically, we start by choosing  $K$  points called centroids randomly among the given points then form  $K$  clusters, each of which contains a centroid and the points that accept this centroid as the nearest one. We gradually update these centroids by calculating the center of mass in each group. This algorithm terminates when the number of iterations exceeds a chosen number or the change after each iteration is less than a chosen threshold

1) *Lloyds heuristic algorithm for Kmeans*: The Lloyds heuristic algorithm [13] for clustering high-dimensional data is usually described by 4 steps. Firstly, stop condition is defined as following: algorithm terminates after exceeding a number of loops or whenever the difference of  $e_k(X; C)$  between two consecutive loops is less than a real positive threshold  $r$  given.

- Step 1: Initialize  $k$  temporary centroids. Start loop of  $N$  iterations:
- Step 2: For each  $x$  in given data set, search for the nearest centroid  $c$  from  $x$  and assign  $x$  to this cluster.
- Step 3: For each cluster  $C_i$ , calculate the new centroid of  $C_i$  by following formula :

$$c_i = \frac{1}{C_i} \sum_{x \in C_i} x \quad (3)$$

- Step 4: Calculate the new value of  $e_k(X; C)$ , then the difference  $\Delta = e_k(X; C)^{new} - e_k(X; C)^{old}$ . If  $\Delta$  is smaller than  $r$ , return the contemporary assignment and end the loop.

### 2) Initialization Method:

a) *Method 1 (Forgy [14])*: : Choose arbitrarily  $k$  points from data set, this method gives us no guarantee about how close the cost function will be to the global minimum. Therefore, to increase the chance to get well-accepted result, we repeat this initialization  $l$  times and pick out which gives the best output.

b) *Method 2 (K-means++)*: : This method guarantees that:

$$E[e_k] \in 8(2 + \ln k)e$$

where  $e$  is the global minimum, hence allows us to control the performance of heuristic algorithm.

---

#### Algorithm 1 K-means++

---

Choose  $c_1$  uniformly from data set:  $C \leftarrow \{c_1\}$

**for**  $i = 2$  **to**  $k$  **do**

    Choose  $c_i = x \in X$  with the probability

$$p(x) = \frac{D^2(x, C_{++})}{\sum D^2(y, C_{++})}$$

$C \leftarrow C \cup c_i$

**end**

---

### B. Sorting Network

One of the commonly used operations in high speed data processing is data sorting. A sorting network consists of two types of items: comparators and wires. The wires are

Fig. 1. Test-bed Architecture (DE5aNet board).

thought of as running from left to right, carrying values (one per wire) that traverse the network all at the same time. Each comparator connects two wires. When a pair of values, traveling through a pair of wires, encounter a comparator, the comparator swaps the values if and only if the top wire value is greater than the bottom wire value. Sorting networks differ from general comparison sorts in that they are not capable of handling arbitrarily large inputs, and in that their sequence of comparisons is set in advance, regardless of the outcome of previous comparisons. This independence of comparison sequences is useful for parallel execution and for implementation in hardware. Some well-known methods to construct a sorting network can be listed such as Batcher odd-even merge sort [15], bitonic sort [16], Shell sort [17] and the Pairwise sorting network [18], whose depth efficiency is  $O(\log^2(n))$ . Basically, the sequential sorting algorithm requires at least  $n \log n$  comparisons. To boost the performance on treating massive volume of data, some specified algorithms are chosen to be parallelized depending on their characteristics (data dependency, device architecture, methods of communication, network topology, etc.). The most commonly used sorting algorithm is Bubble sorting. For efficient and reduced operations implementation of sorting, [15] proposed a technique of sorting using sorting networks.

1) *Bitonic Sort Algorithm:* The bitonic sort [19] is a divide and-conquer comparison sort usually implemented with recursion. Keys are first ordered into bitonic sequences and are then sorted using a bitonic merger. The number of comparators required can be reduced by a factor of  $\log^2(N)$  by combining the perfect shuffle with bitonic sorting. This sort fits the SIMD (single instruction multiple data) model because it is readily implemented in hardware using a parallel sorting network. Given sufficient hardware, this sort is capable of achieving  $O(\log^2(N))$  performance. A sequential, recursive version of the bitonic sort with running time  $O(N \log^2(N))$  is used on the microprocessor. The FPGA implementation uses a visualized, parallel sorting network. Both implementations sort in-place and require the input key quantity to be a power of 2; however, on the FPGA, we were able to use the same SIMD controller to schedule keys for an eight input sorting network

Fig. 2. Bitonic Sorting Network Illustration .

and a four input sorting network simultaneously. This allowed the use of all six memory banks. Bitonic sortings goal is to sort a bitonic sequence (a sequence  $(a_n)$  is called bitonic if and only if there exist an unique index  $i$  such that for all integer  $m$ , if  $a_m; a_{m+1}; \dots; a_{m+i}$  are monotonically increasing (or decreasing), then  $a_{m+i+1}; \dots; a_{m+2i}$  must be monotonically decreasing (or increasing)), which is easy to be parallelized and applied on hardware or software. For an arbitrary sequence, we can sort the first half of sequence in increasing order and the other in decreasing order, this transforms the sequence into a bitonic sequence in order to apply bitonic sort. For each  $i$  from 1 to  $n = 2$ , match two elements  $x_i$  and  $x_{i+n/2}$  into a pair and swap them to form a pair in order (min; max). Consequently, we obtain two bitonic sequences whose lengths are a half of the given one (bitonic property is invariant by step 1) and also every element in the first half is smaller than every the second half. Apply recursively this procedure to each of two sub sequences until the length of sequence is less than 2.

### C. Correlation Algorithms

Correlation algorithms such as Pearson [20] and Spearman [21] measure the dependence between variables. Popular applications may include calculating the relationship between age and number of hours spent watching TV, or the relationship between product sales and temperature. Assuming that comparisons and simple operations are both done in time  $O(1)$ , Pearson and Spearman correlations are done respectively in time  $O(n)$  and  $O(n \log(n))$ . The Pearson correlation coefficient is given by the formula (4), assuming that  $a$  and  $b$  are

two zero-mean real valued random variables.

$$\rho(a, b) = \frac{E(a, b)}{\sigma_a, \sigma_b} \quad (4)$$

where  $E(a, b)$  is the cross-correlation between  $a$  and  $b$ , and  $\sigma_a^2 = E(a^2)$  and  $\sigma_b^2 = E(b^2)$  are the variance of  $a$  and  $b$  respectively. It is more convenient to work with the squared Pearson correlation coefficient given by (5)

$$\rho^2(a, b) = \frac{E^2(a, b)}{\sigma_a^2, \sigma_b^2} \quad (5)$$

The squared Pearson correlation coefficient give an insight about the strength of the linear relationship between two random variables. When  $\rho^2(a, b) = 0$ , then two random variables  $a$  and  $b$  are uncorrelated. When the value of  $\rho^2(a, b)$  is near to 1, then  $a$  and  $b$  are said to be correlated. The squared Pearson correlation coefficient detects only linear dependencies between the two variables  $a$  and  $b$ . Indeed, If  $a$  and  $b$  are independent, then  $\rho^2(a, b) = 0$ , but the converse is not true. The Pearson correlation coefficient  $\rho_p$  is defined according to equation 6:

$$\rho_p = \frac{\sum_{i=1}^N a_i, b_i}{\sqrt{\sum_{i=1}^N a_i^2 \sum_{i=1}^N b_i^2}} \quad (6)$$

The Spearman correlation coefficient  $\rho_s$  is calculated in the same manner as  $\rho_p$ , except that  $\rho_s$  is calculated after both  $a$  and  $b$  have been rank transformed to values between 1 and  $N$  (Equation 7). When calculating  $\rho_s$ , a fractional ranking is used, which means that the mean rank is assigned in case of ties. For example, suppose that the two smallest numbers of  $a$  are equal, then they will be both ranked as  $1.5 (\frac{1+2}{2})$ . A mean centering is first performed (by subtracting  $N/2 + 1/2$  from each of the two ranked vectors).

$$\rho_s = \frac{\sum_{i=1}^N a_{i,r}, b_{i,r}}{\sqrt{\sum_{i=1}^N a_{i,r}^2 \sum_{i=1}^N b_{i,r}^2}} \quad (7)$$

## V. HARDWARE SPECIFICATION

### A. Field Programmable Gate Arrays

1) *Arria 10 Architecture:* As a dedicated architecture, We used the Arria 10 FPGA as a target platform for our algorithm implementation Fig. 3. Arria 10 is one of the latest chip produced by IntelFPGA delivering the highest performance at 20 nm. Arria 10 FPGA is a low power embedded architecture up to 40% lower power than previous FPGAs generation. It allows up to 1500 GB/s floating-point operation with DSP blocks. The system clock is 100 MHz. The chip also includes a Dual-Core ARM operating at 1.5 GHz. Table III shows the available resources in terms of logic elements, DSP and memory blocks of the Arria 10 FPGA.

2) *High Level Synthesis:* The Arria 10 FPGA programming is done using OpenCL based High Level synthesis [22]. This is to achieve an efficient and fast parallel implementation of the algorithm on FPGA. OpenCL (Open Computing Language) is the first open, royalty-free, unified programming model for accelerating algorithms on heterogeneous systems. Based on

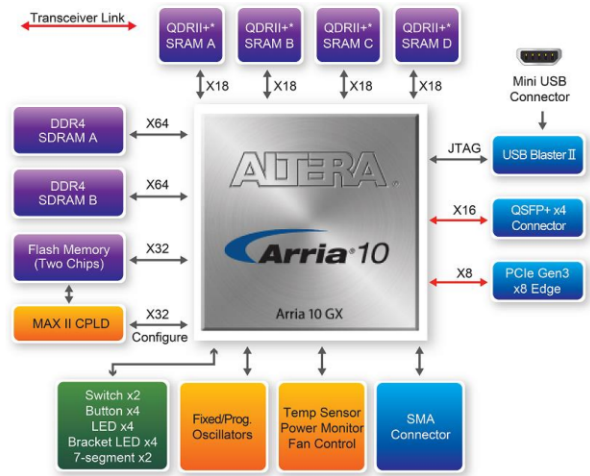

Fig. 3. Arria 10 Architecture .

C (C99), it supports four kinds of processing units: CPU, GPU, FPGA and DSP (digital signal processors). The real asset of this language is to use different units at the same time, processing them in parallel, and using each one of them for what it is the best. However, because of the total differences in processing algorithms between the different sorts of units, an OpenCL code has to be optimized for each device. The IntelFPGA SDK for OpenCL allows avoiding the traditional hardware FPGA development, which is too complicated for the use when it comes to high performance computing, in order to achieve a much faster and higher level software development flow. It includes multiple optimizations and can produce deep reports of the compilation and the code optimization. The IntelFPGA SDK for OpenCL requires the Quartus Prime (Pro version for Arria 10 board), also known as Quartus II, to function optimally. Fig. 4 shows the compilation process of OpenCL code for FPGA.

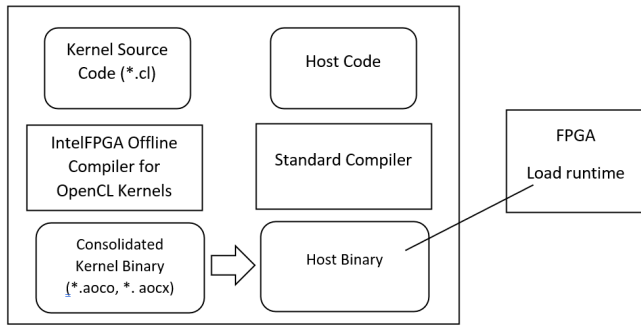

Fig. 4. The Flowchart of Compilation Process of the FPGA .

3) *Quartus TCL Scripting*: The Quartus II development software provides the scripting environment, particularly Tcl (tool command language) scripting. We use scripting support, to achieve custom analysis, automation and reproducibility. Custom analysis allows to build test procedures into the script and change design processing based on the test results. Scripts can automate design flows to perform on the computer and easily archive and restore projects. Reproducibility ensures that scripts use the same project setup and assignments for every compilation.

### B. General Purpose Graphical Processing Unit GPGPU

1) *GPU Architecture*: In our work, we used the Nvidia GPU Quadro K2200 (Table IV). This GPU uses the first generation of Maxwell architecture released by Nvidia in February 2014 (the newest and second generation was released in September 2014). Maxwell introduces an all-new design for the Streaming Multiprocessor (SM) called SMM that dramatically improves energy efficiency compared to its predecessor Kepler. SMM uses a quadrant-based design with four 32-core processing blocks each with a dedicated warp scheduler capable of dispatching two instructions per clock. Each SMM provides eight texture units, one polymorph engine (geometry processing for graphics), and dedicated register file and shared memory. Maxwell improves on Kepler by separating shared memory from L1 cache, providing a dedicated 64KB shared memory in each SMM (for Quadro K2200). It provides native shared memory atomic operations for 32-bit integers and native shared memory 32-bit and 64-bit compare-and-swap (CAS), which can be used to implement other atomic functions.

2) *Programming the GPGPU*: CUDA is a parallel computing platform and application programming interface (API) model created by Nvidia. It allows software developers to use a CUDA-enabled graphics processing unit (GPU) for general purpose processing an approach known as GPGPU. The CUDA platform is a software layer that gives direct access to the GPU virtual instruction set and parallel computational elements. The CUDA platform is designed to work with programming languages such as C, C++ and Fortran. Quadro K2200 uses the version CUDA 5.0. We are using Nsight Eclipse Edition (CUDA SDK 6.0) for algorithm implementation. This is a full-featured IDE powered by the Eclipse platform that provides an all-in-one integrated environment to edit, build, debug and profile CUDA-C applications.

## VI. ALGORITHM IMPLEMENTATION AND PERFORMANCE EVALUATION

### A. FPGA Design and OpenCL Optimization

The conception of the design is a crucial step in the development process. We dispose of four types of blocks (Logic blocks, Memory blocks, Logic Register and Digital Signal Processing Blocks). Each one is able to perform a particular list of actions. Given these four sorts of blocks and their amount on the board, the aim is to associate to each one of them simple and statics instructions to do and to link them in a network. For instance, if we want to compute the sum of four 64-bytes integers  $i_1$ ,  $i_2$ ,  $i_3$  and  $i_4$ , we chose to dedicate:

- One Logic Blocks programmed to do the summation of  $i_1$  and  $i_2$ , then send the data directly to the third block.
- One Logic Blocks programmed to do the summation of  $i_3$  and  $i_4$ , then send the data directly to the third block.
- One Logic block programmed to do the summation of the two previous results

On this example, we see an important characteristic of FPGA: the temporary variable of summation doesnt have to be stored, so there is no need for write/read operations, reducing the total amount of clock-cycles. If we want to be able to compute a new set of data every clock-cycle, the path taken by the data has to be the same regardless of the data themselves, even though we increase the number of comparison or assignment.

OpenCL is a language developed in order to support multi-platform computing. Considering the deep differences between computing units (CPU,GPU), the same OpenCL code is implemented highly differently on different platforms on a hardware level. Therefore, even though an OpenCL code for GPU will work on other platforms, it will only be optimized for GPU, and will certainly be highly inefficient if run on other computing units. It is the same for FPGAs: multiple valid implementations are inefficient, and there are multiple ways of coding that have to be promoted or avoided.

The first coding optimization specific to IntelFPGA OpenCL is the command `#pragma unroll` that has to be put in the OpenCL kernel file. Used before a loop, this command is read by the compiler, that process what is called the unrolling of the loop. On a hardware level, each iteration of a nonunrolled loop is by default done by the same area of the computing unit. The process of unrolling by a factor N consists in replicating the hardware  $(N - 1)$  time in order to be able to compute N iteration of the loop at the same time. If it seems efficient to unroll the loops, it is important to notice that the factor of the unroll has to be defined during the synthesis step, and cant be changed during the computation. Moreover, the hardware resources being limited, before unrolling it is important to be sure that the concerned loop results in a bottleneck of the overall computing process. It is useless to unroll a loop more than the number of iterations, and difficult to unroll it if the number of iterations is not easy to determine. It is important to underline the differences between the two kinds of parallelization that we have presented: the loop unrolling is a hardware-parallelization, whereas the ability

TABLE IV. SPECIFICATIONS FOR THE QUADRO K2200

|                 | Processing Power<br>(GFLOPS)                           | Memory Clock<br>(MHz) | Memory    |                   |          |                     |
|-----------------|--------------------------------------------------------|-----------------------|-----------|-------------------|----------|---------------------|
|                 |                                                        |                       | Size (MB) | Bandwidth<br>GB/s | Bus type | Bus width<br>(bits) |
| Quadro<br>K2200 | 1280 (Single<br>precision)<br>40 (double<br>precision) | 1250 (5000)           | 4096      | 80                | GDDR5    | 128                 |

of computing a new set of data every clock-cycle is a time-parallelization. Their combination can theoretically lead to drastic computing acceleration.

In order to simplify the unrolling process, it is important to avoid nested loops as much as possible. A nested loop is a loop called in another loop. The more loops inside a loop there are, the harder it is to unroll them. Therefore, an OpenCL code should promote one, maximum two loop levels with explicit amount of iterations. For these reasons, the OpenCL kernel for our algorithms are implemented with only two levels of loops having an explicit amount of iterations.

Another optimization possible to perform is the balance of reducing a set of data using an associative operation. For instance, if you want to add a set of  $N$  integers, the usual loop unrolled will use  $N-1$  Logic Blocks. However, by doing a tree summation, the number of blocks can be reduced to  $N/2$ . This optimization can be managed by the compiler, even for more complex operations. Moreover, if the overall computation tree implies non-associative operations, the compiler can identify parts of the computation tree that can be balanced and balance them. Because of the difficulty in identifying such parts, the compiler proposes this optimization as an option. It is to the programmer to understand if this auto-balancing function is relevant, or to balance manually by modifying the code when the compiler cant extract the balancing. Many other constrains and way of coding are to consider when producing OpenCL code for FPGA, like the impossibility to use pointer to pointer parameter in the kernel functions, or the simplicity of indexes when arrays are called. In order to show the efficiency of OpenCL kernel optimization, we have implemented two version of Summary Statistics algorithm: Optimized (Algorithm 2 ) and unoptimized (Algorithm 3) kernels. This algorithm calculate the column-wise min, max, mean, variance, count, and number of non-zeros in a given dataset. (assuming each simple is done in  $O(1)$ , all these statistics share the same complexity of  $O(n)$ ).

Table V shows the estimated resource usage before kernel optimization. The problem reported by the optimization report is that too many kernels attempted to access the same variable at the same time (hereby is the variable sum), but there is only limited amount of access possible on the same variable each clockcycle. Therefore, the blocks that try to access have to wait, blocking the overall process and retarding it by  $N$  clock-cycle. An efficient way to avoid this problem is to use a shift-register with the size  $N$ , the maximum encountered late. The amount of clock-cycle is revealed by the optimizer.

Table VI shows the estimated resource usage after kernel optimization. The kernel optimization has improved the computation speed. The processing time is divide by a factor  $N$ , which is the number of clock-cycles that were lost because

TABLE V. ESTIMATED RESOURCE USAGE SUMMARY (UNOPTIMIZED SUMMARY STATISTICS)

| Resource                  | usage |
|---------------------------|-------|
| Logic utilization         | 16%   |
| Dedicated Logic registers | 8%    |
| Memory blocks             | 28%   |
| DSP blocks                | 4%    |

of blocking access. The IntelFPGA optimization report ensure to identify the most important bottlenecks and processes that slow down the computing and increase the number of clock-cycles taken by an overall computation. These optimizations strategy are adopted for the other algorithm in order to achieve an efficient parallel implementation with less resources usages.

### Algorithm 3 Unoptimized OpenCL kernel

```
__kernel void summarystat (__global float *A,
unsigned int size, __global float*rep, __global
int*non_zero)
```

```
min = A[0]; max = A[0]; sum = 0.0f; sqsum = 0.0f;
nonzero_count = 0;
```

```
#pragma unroll
for (i = 1; i < size; i++) do
    x = A[i];
    sum += x;
    sqsum += x * x;
    if x ≠ 0 then
        | nonzero_count ++
    end
    if x < min then
        | min = x
    end
    if x > max then
        | max = min
    end
end
```

```
rep[0] =max;
rep[1] =min;
rep[2] =sum/size;
rep[3] =sqsum/size - (sum/size)2;
*non_zero = nonzero_count;
```

### B. OpenCL Implementations of Bitonic Sort Algorithm

If we consider a regular optimal sorting algorithms like the Quick sort, which has a  $O(n \log(n))$  complexity in term of

**Algorithm 2** Optimized OpenCL Kernel

```
__kernel void summarystat_optimized(__global
float *restrict A, unsigned int size, __global
float*restrict rep, __global int*restrict non_zero)
min_temp = A[0]; max_temp = A[0]; min_rep = min_temp;
max_rep = max_temp; sum = 0.0f; sqsum = 0.0f;
nonzero_count = 0;
```

```
float shift_reg_x_s[N + 1]; float shift_reg_sqx[N + 1];
float shift_reg_min[N + 1]; float shift_reg_max[N + 1];
int shift_reg_non_zero[N + 1];
for (i = 0; i < N + 1; i++) do
    shift_reg_x_s[i]=0;
    shift_reg_sqx[i]=0;
    shift_reg_min[i]=min_temp;
    shift_reg_max[i]=max_temp;
    shift_reg_non_zero[i]=0;
```

```
end
for (i = 0; i < size; i++) do
    x= A[i]; shift_reg_x_s[N]= shift_reg_x_s[0] + x;
    shift_reg_sqx[N] = shift_reg_sqx[0] + x * x; if x <
    shift_reg_min[0] then
        | shift_reg_min[N]=x
    end
    else
        | shift_reg_min[N] = shift_reg_min[0]
    end
    if x < shift_reg_max[0] then
        | shift_reg_max[N]=shift_reg_max[0]
    end
    else
        | shift_reg_max[N] = x
    end
    if x ≠ 0 then
        | shift_reg_non_zero[N] = shift_reg_non_zero[0] + 1
    end
    #pragma unroll for (j = 0; j < size; j++) do
        shift_reg_x_s[j]= shift_reg_x_s[j + 1]
        shift_reg_sqx[j]= shift_reg_sqx[j + 1]
        shift_reg_min[j]= shift_reg_min[j + 1]
        shift_reg_max[j]= shift_reg_max[j + 1]
        shift_reg_non_zero[j]= shift_reg_non_zero[j + 1]
    end
end
#pragma unroll for (j = 0; j < size; j++) do
    sum +=shift_reg_x_s[j]; sqsum += shift_reg_sqx[j];
    nonzero_count += shift_reg_non_zero[j]; if min_rep >
    shift_reg_min[j] then
        | min_rep = shift_reg_min[j]
    end
    if max_rep > shift_reg_max[j] then
        | max_rep = shift_reg_max[j]
    end
end
rep[0] = max_rep; rep[1] = min_rep; rep[2]= sum/size;
rep[3]=sqsum/size - (sum/size)2; *non_zero = nonzero_count;
```

TABLE VI. ESTIMATED RESOURCE USAGE SUMMARY (OPTIMIZED SUMMARY STATISTICS).

| Resource                  | usage |
|---------------------------|-------|
| Logic utilization         | 8%    |
| Dedicated Logic registers | 4%    |
| Memory blocks             | 10%   |
| DSP blocks                | 1%    |

Fig. 5. Execution time of the Sort Algorithm for Many Input Sizes.

comparisons, it seems impossible to find a fixed organization of blocks that applies the algorithm to any input data. Whereas sorting networks, like Bitonic Sort present a complexity of  $O(n \log^2(n))$ , seems highly optimized for FPGA, because they use a fixed data path. For the Bitonic sort algorithms, we configure the logic blocks to have two input and two output: the first one returning the max of the two input and the second one returning the minimum of these two. With these sorting networks, each new list to sort is computed every  $p$  clock cycles,  $p$  being the number of clock-cycle taken by logic block to return the max and min of the two inputs. In order to achieve a parallel implementation of Bitonic sort we divide the dataset into multiple threads (one thread occupies at least one data). For each step of bitonic sort as we can notice in Fig. 2, all of comparing operations are executed simultaneously on available threads. Fig. 5 shows the performance evaluation of sort implementation on the GPU and FPGA. We run the GPU and FPGA implementation to sort a set of different float ranging from  $2^{10}$  to  $2^{24}$ . The obtained results shows the parallel computing power of the FPGA. For even large number of sorted float ( $2^{24}$ ) the FPGA implementation is always efficient compared to the GPU implementation which need more then 1 second to process ( $2^{24}$ ) floats.

**C. OpenCL Implementations of K-means Algorithm**

K-means has the difference of data independence from Bitonic Sort. In fact, to find the nearest centroid from one point, we can assign each points from data set onto available threads and perform the calculation and comparison; on the other hand, new centroids calculation needs data from the membership matrix, this step can be parallelized by assigning

Fig. 6. K-mean GPU Result of Clustering 125000 2D-points into 10 Clusters.

Fig. 7. K-mean FPGA Result of Clustering 125000 3D-points into 15 Clusters .

each cluster to a thread and carrying out the calculation separately for each of them. However in this implementation, we let the host device take the task sequentially. For K-mean implementation, the test data is generated by the Spark benchmark. Firstly, we tested the algorithm on small dimensional data (2D and 3D) in order to test the output. Then the algorithm is tested on 10 and 100 dimension points sets. Finally, we tested on high dimensional data (500D). The size of data ranged from 12500 to 125000 points for small dimensional sets and up to 31250 points on high dimensional sets (up to 300MB). Figures Fig. 6 and Fig. 7 shows respectively the GPU and FPGA results of the k-mean implementation. Each red point is the visualization of a point in the given data set and each green point is a centroid found by the heuristics. The obtained results confirm the functional validation about clustering. Indeed, the cost function (sum of square of the distance from each point to the centroid of the cluster containing it) is shown to decrease after each iteration.

Table VII shows the performance evaluation of k-mean implementation on the GPU and FPGA. The running time to cluster 125000 3D points is 380 ms for the GPU implementation and 33 ms for the FPGA implementation. For 31250 500D points is 12 seconds on the GPU and 158 ms on the FPGA. The occupancy achieved is 98.8 percent in the first measurement and 49.5 percent (over the theoretical 50 percent) in the second. This shows that the occupancy is well controlled. The GPU

TABLE VII. GPU AND FPGA K-MEAN EXECUTION TIME

| Execution Times |              |              |
|-----------------|--------------|--------------|
| Platform        | 125 000 (3D) | 31250 (500D) |
| GPU             | 380 (ms)     | 12 (s)       |
| FPGA            | 33 (ms)      | 158 (ms)     |

implementation is far from real time performances. Indeed, the choice of block and grid size strongly affects the efficiency. For example, if the block size is reduced from (256 x 1 x 1) to (64 x 1 x 1), the time to find the centroids for the 125000 3D point set goes down from 380 ms to 250 ms. This can be explained by the use of synchronization in each block. By contrast, if the block size is increased from (61 x 1 x 1) to (1024 x 1 x 1) the running time on the data set of 31250 500D points goes down significantly from 12 seconds to 1.9 seconds. This can be explained by the large size of shared memory in each block. In the GPU implementation, the low DRAM utilization may come from the non-coalesced access to memory. Reducing this can also result in the better performance. The FPGA implementation is shown to outperform the GPU one. Only 158 ms is needed to cluster a very high dimensional data (500D).

#### D. OpenCL Implementations of Correlation Algorithms

The Pearson Correlation Algorithm was implemented using two reductions to find the mean of both input vectors, followed by the computation of the covariance of both entries and each one of the standard deviations. The final result is given by  $cov(X; Y) / (\sigma_X * \sigma_Y)$ . To calculate the Spearman coefficient we need to calculate the Pearson coefficient of the ranks. For the computation of the ranks, we first sort both samples by the values of the first one and calculate the ranks for the first sample by using a simple kernel that for each position in the sample that has an element different from the next one, goes back and counts all the occurrences of that element and then finally fills all the position with that same value with the mean of the ranks. This part of the code is not very parallelizable and can run in  $O(n)$  if all the elements in the initial sample are the same, opposed to  $O(1)$  with all elements different from one another [23]. But since in normal samples with float values this is unlikely to happen the approach works well. Then we sort again the first, the second and the ranks of the first by the values of the second sample, calculate now the ranks of the second sample using the same method and now that we got both ranks array, we use the Pearson Correlation Coefficient algorithm in this data to find the Spearman Correlation Coefficient. For measuring the execution time of both correlation algorithms, we first generated 5 input files for different sizes of samples, then we ran each one of those input files and took the mean of the execution times for each one of the 5 input files. Fig. 8, Fig. 9 shows the performance evaluation respectively of the Pearson and Spearman Correlation algorithm implementation on the GPU and FPGA. We test both implementation using a number of elements in sample ranging from  $2^{10}$  to  $2^{24}$ . For a high number of elements  $2^{24}$  the GPU process the pearson correlation algorithm in 1 seconds and the Spearman algorithm in 5.5 seconds. For the same number of elements, the FPGA implementation process the pearson and spearman correlation in 90 ms and 400 ms respectively. The processing time of the correlation algorithms on the FPGA implementation

has been decreased by a factor x12 compared to the GPU implementation.

Fig. 8. Execution Time of the Pearson Algorithm for Many Input Sizes .

Fig. 9. Execution Time of the Spearman Algorithm for Many Input Sizes .

### E. Synthetic Results

Our work adopted the high level synthesis for FPGA implementation using OpenCL. Despite of the advantage of high level programming, its use is still limited. The Intel offline compiler takes a lot of time in order to generate the hardware configuration files (aocx) (duration of compilation hours for more complex function and if more optimization are requested from the compiler). However, we can achieve higher acceleration using OpenCL, which provides better memory management. We can freely access the local, global and constant memory in the OpenCL kernel. This allows us to better manage the data transmission and data structure. In addition, the FPGA is considered as the generation of integrated circuit claimed higher performance and reliability, and the emerging high level software tools make it easily accessible to the community. The encouraging results we obtained on the FPGA in term of acceleration performance, demonstrates that a dedicated architecture can be used to prototype a micro-server for big data that operates under real-time constraints.

As a future work, we intend to achieve a full embedded implementation for Big Data algorithms on FPGA using the integrated ARM processor of the Arria 10 SoC.

## VII. CONCLUSION

In this work, we have implemented and optimized three algorithms: Bitonic Sorting network, K-means, Spearman and Pearson correlation. The purpose behind this implementation is to prototype a micro-server for processing big data algorithms on both GPU and FPGA and compare their performance. We have implemented and quantitatively evaluated the execution times of some of the most important algorithms for big data. We present performance results on a heterogeneous architectures: high-end CPU-GPU and a dedicated CPU-FPGA architecture. The choice of using dedicated architecture was made principally because the big data algorithms can be massively parallelized. This property is exploited by using a dedicated FPGA-based architecture as a target platform for an efficient embedded micro-server. The performance of the optimized algorithms on the FPGA show a promising prospect of utilizing them in solving real-world problems.

King Faisal University Al-Ahsa 31982  
Saudi Arabia

**Abstract**—Cyber-attacks on IT domain infrastructure directly affect the security of businesses' operational processes, potentially leading to system failure. Some industries have a high risk than others due to the sensitivity of their data, including the transportation industry, which has recently moved from traditional data management to digitalization. This study aims to identify the main cyber threats in the transportation sector by analyzing related works and highlighting the main countermeasures used to respond to such threats as well as enhance overall cybersecurity. This paper presents a comprehensive cybersecurity risk assessment for the transportation companies, identifying the most common attacks and proposing methods to minimize risk as much as possible. A risk assessment analysis was prepared by industry experts that included previous cyberattack scenarios. The results of our paper identified the most critical attacks on the transportation company's booking system and recommended suitable countermeasures to minimize the risk of those attacks.

**Keywords**—Cyber-attacks; cyber-security; risk assessment; countermeasures

## I. INTRODUCTION

### A. Background

Cyber-security attacks are considered one of the hot topics in the field of information security and can result in huge losses to organizations if not carefully handled. Cybersecurity attacks usually result from several factors related to threats, human errors or insufficient knowledge [1]. Cybersecurity relates to technologies, processes, practices, and information assets, aiming to protect against any damage or unauthorized access caused by cyberattacks [2]. Cyberattacks on information systems, in particular, directly affect the operational processes that support businesses, potentially leading to corporate paralysis. Some industries are at more risk than others due to their highly sensitive data, one of which is the transportation industry, which has recently moved from traditional data management to digitalization. This transition has raised concerns about cybersecurity and necessitated proper risk assessments due to their importance in protecting critical infrastructure; for instance, cyberattacks on aircraft, which are considered essential transportation, can impact safety-of-flight systems and/or the systems supporting the airlines' business [3]. Cyber threats often take advantage of the increased complexity of infrastructure systems, placing critical industries' security at risk [4]. A physical cyber threat not only harms the integrity of the IPs but may also disrupt production processes and cause serious damage to various systems [5]. To

understand cyberattacks, it is important to dig deeply and identify their main causes. Spreading awareness and proper knowledge about cyberattacks and providing sufficient training can reduce the damage they cause. This is often difficult to accomplish because cybersecurity behaviors do not necessarily come naturally, and people need support and encouragement to develop and adopt them [1]. As technology becomes increasingly present in daily life, cybercrime, and cybersecurity tools and techniques require innovative solutions at all organizational levels [4].

Transportation systems, in particular, offer major services that can be put at risk by an absence of real awareness, and neglecting the proper assessment of vulnerabilities can lead to major damage [6]. Cyberattacks on transportation technologies are usually unexpected and require considerable effort to classify the threats, identify impacted assets, develop proper countermeasures, and engage IT teams throughout the process. However, transportation systems vary in their ability to handle threats and in the ways in which organizations prioritize their assets when a risk is identified. This paper discusses how risks to booking systems in the transportation industry are assessed at times of risk and presents a comprehensive cybersecurity risk assessment of information systems in a transportation company to identify the most common threats and recommend methods for minimizing risks as much as possible. A risk assessment report was prepared by industry experts that included previous cyberattack scenarios. This paper aims to answer the following questions:

What are the common types of cyberattacks on transportation systems?

What are the main techniques used to identify vulnerabilities in transportation systems?

What are the main risks and countermeasures used to mitigate these risks?

### B. Motivation

Understanding the nature of cyberattacks and their main causes can enhance the overall cybersecurity of an organization. A cyber threat may disrupt production processes and cause serious damage to various systems [5]. Identifying the root cause of such problems can help organizations solve them at a deep level and avoid future attacks rather than relying on temporary prevention solutions. Information systems generally contain critical data that businesses place a high priority on protecting. Some industries, such as the

transportation industry, hold more sensitive data than others; hence, their risks from cyberattacks are huge and can directly impact operational processes. It is therefore vital for them to identify the main causes of cyberattacks and the main practices they should adopt to protect sensitive data from exposure. Cybersecurity for transportation systems has been affected by the dynamic nature of the technology used within the industry. Cybersecurity guidelines have been developed for transportation systems, especially in the past few years, to ensure cybersecurity and raise awareness of its importance [6].

### C. Cybersecurity

The main reasons for cybersecurity failures are human error and insufficient knowledge [1]. According to [2], cybersecurity is central to all technologies, standards, and procedures developed to protect infrastructure elements against serious cyberattacks. Some cyberattacks cause major harm to system users, sometimes unintentionally [7]. In other words, cybersecurity protects property rights in an infrastructure context if an attack occurs. Furthermore, cybersecurity is concerned with related issues such as access, extraction, manipulation, or modification of property [8], protecting property against the harm that can be caused by an attack [7]. To maintain a secure environment, effective cybersecurity behaviors must be identified and promoted to raise awareness among users from different backgrounds. Both human and technological aspects of information systems need to be clearly identified to maintain a strong cybersecurity environment [1].

1) *Cybersecurity in information systems:* Today’s technology allows for easy, rapid communication across different systems, particularly in domains such as teleworking and m-commerce, which have grown rapidly [9]. Moreover, information and communication technology (ICT) applications have increased dramatically and cyberattacks have spread easily across such applications [10]. The more sensitive the data is, the greater attention needs to be paid. Sensitive data can be vital for businesses because they use it to make critical decisions; major problems can result from cyberattacks that place data at risk of exposure. Protecting infrastructure is a major priority for preventing unauthorized access that can lead to data misuse or corruption. Both individuals and organizations can suffer hugely from data exposure [11].

Recently, cyberattacks have increased due to advances in the technologies used in most information systems. Consequently, most organizations need to invest in cybersecurity and employee training to raise awareness of the importance of securing systems and their sensitive information [12]. One approach to protecting information systems was suggested by [13], which suggested that integrating information systems across organizational environments can improve cybersecurity. The researchers suggested and tested three hypotheses to investigate whether integration is positively related to cybersecurity countermeasures (see Table I).

Although [14] suggested considering all ICS features, the researchers proposed a targeted multilevel Bayesian network for identifying attacks, the functional level of attacks, and

incident models. This dynamic cybersecurity risk assessment approach can help assess the risks caused by unknown attacks (see Fig. 1).

Study [10] evaluated power supply reliability using Stackelberg Security Game (SSG) strategies to assign defense resources to various cyber-threat targets. This paper discussed how to benefit from the intrusion tolerance capability of SCADA systems that provide buffer periods before the failure of substations. The overall goal was to improve network strength in the face of cyber threat events. Different cyber threat scenarios were tested to assess intrusion tolerance capabilities, and the authors designed an insurance premium principle to provide incentives for enhancing intrusion tolerance capability.

Study [5] conducted a literature review to identify the impact of cyberattacks on total productive maintenance in smart manufacturing systems. Cyberattacks can directly affect manufacturing equipment and, hence, the services provided, including maintenance services. This paper highlighted major physical cyberattacks and proposed countermeasures to reduce the negative impact of such attacks. The authors identified different challenges in enhancing equipment effectiveness in light of current cybersecurity threats in the manufacturing industry.

TABLE I. HYPOTHESES AND EVIDENCE SUMMARY [12]

| Hypotheses                                                                                                                            | Findings  | Evidence                                                                                                                                                                                |
|---------------------------------------------------------------------------------------------------------------------------------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| H1. The greater the integration of IS, the greater the investment in countermeasures.                                                 | Supported | IS integration causes fewer weak points, reducing the possible impact of breaks.                                                                                                        |
| H2. H1 will be more powerful when considering external IS integration rather than internal IS integration.                            | Supported | Weak points in external IS integration involve greater risk exposure because of greater uncertainty.                                                                                    |
| H3. Organizations tend to use self-protective controls more often in highly volatile environments than in less volatile environments. | Supported | Although the impact may not be strong, volatile environments can impact the three aspects of vulnerability. This means that the addressing of weak points must highlight these aspects. |

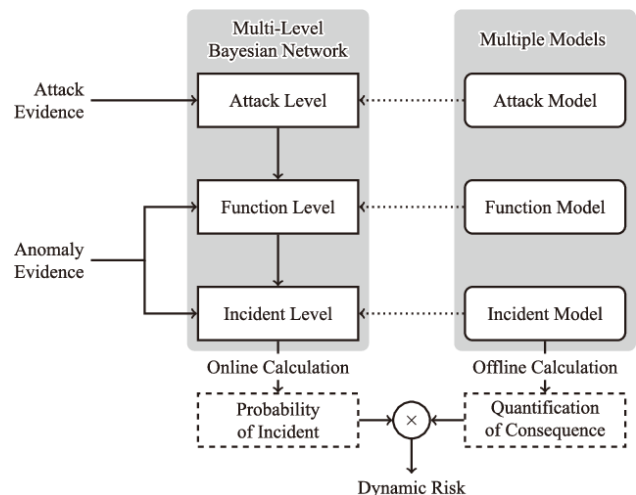

Fig. 1. Architecture of the Dynamic ICS Cybersecurity Approach.

According to study [15], attack graphs are essential for identifying the variables involved in an attack and reducing their impact on networks. This research introduced a cyberattack path method that used restrictions and an in-depth search to successfully produce attack graphs according to the interests of users. The researchers used real data from a maritime supply chain to ensure the validity of the proposed method.

In [16], the author identified the effects of cyberattacks on general systems. As cyberattacks continue to develop, it is becoming more difficult to identify the nature of the attacks; therefore, there is a great need for smart risk assessment. This research proposed the use of a fuzzy inference (FIS) model to produce risk assessment outputs, which relied on four risk factors—vulnerability, threat, likelihood, and impact—to identify risks targeting a system entity and suggest possible solutions for them. A summary of related work is provided in Table II.

2) *Cybersecurity threats in the transportation industry:* The transportation industry needs to distinguish between operations systems and business systems to provide the right protection for each [6]. Over the years, the industry has shifted from traditional business to e-business, and this shift has expanded technologies and their features [2]. According to [11], 80 % of assets in transportation infrastructure are being digitalized. In recent years, many attacks have been made on transportation, which has increased the need for cybersecurity protection guidelines [6], and some factors are critical for ensuring the effectiveness of overall cybersecurity, such as PCS systems, knowledge about cyber threats, and communication between private corporations and public agencies [17]. In the air transportation domain, cybersecurity tends to focus greatly on protecting the operational and technical aspects of businesses; hence, fast adaption to a rapidly changing risk environment is vital, and the framework of technical and operational systems should be redesigned based on continuous risk analysis and simulations [18]. The rapidly changing nature of the transportation industry makes it important to focus on cybersecurity to protect valuable assets and protect the business from harmful threats.

Study [18] was conducted to address the increase in cyberattacks, the impact of which could critically affect civil

aviation functions. The huge increase in technologies and integrated connectivity tools can expose air traffic management (ATM) to major risk, despite its high value as an asset. This study evaluated cybersecurity difficulties in ATM to develop a threat model that included likely risks. It also included an overall framework that required full collaboration between entities to identify threats and protect systems from attacks.

Study [19] asserted that the port industry is experiencing a transformation in connectivity between ports, where most functions are being digitalized. This necessitates focusing on cybersecurity to protect major infrastructure against advanced attacks and maximize the use of new technologies with minimum risk of affecting valuable business assets.

Study [11] highlighted the importance of data-driven functions that many business aspects depend on, such as operations, maintenance, planning, and decision-making. To ensure the smooth operation of all functions relating to railways, data should be strongly secured against cyberattacks and unauthorized access to avoid major losses. This paper identified possible challenges, impacts, threats, vulnerabilities, and methods for managing risks and protecting railway infrastructure data, particularly in an e-maintenance context.

Study [6] used a case study to raise awareness of the cybersecurity attacks that affect the transportation field. It developed an attack–fault tree for the mentioned case study as proof of concept for integrated risk analysis. The overall purpose was to help companies understand that no attacks targeting critical technological systems should be ignored, and potential risks should be analyzed.

The author in [3] proposed a new system for gathering, managing, and reporting aircraft failures. The motivation behind this paper was the great expansion in connectivity and communication infrastructure that is affecting aircraft. The increase in mobile computing device use among individuals has allowed for external connectivity increments as well as providing internet access for passengers, involving a greater risk of aircraft cyberattacks that can affect other critical systems supporting the business. The proposed system can help identify such attacks, hence reducing their impact. A summary of related work in the transportation domain is provided in Table III.

| <p><b>Risk assessment enhancement (previous approaches)</b></p> | <ul style="list-style-type: none"> <li>▪ Component burnout and exhaustion of processing power.</li> <li>▪ Simulating and forecasting real-time load to ensure system frequency during an attack.</li> </ul>                                           | <ul style="list-style-type: none"> <li>▪ IDS to observe network and system activities.</li> <li>▪ An anomaly detection system (ADS) to gather data from a system and compare them with normal values (reports produced in cases of deviation)..</li> </ul>                                                                                     | <ul style="list-style-type: none"> <li>▪ Use of overall equipment effectiveness (OEE), which is considered a major KPI for measuring the effectiveness of TPM in a system. The OEE of a system is calculated using the input of three components: <ul style="list-style-type: none"> <li>- breakdowns (availability)</li> <li>- small stops (performance)</li> <li>- defects (quality)</li> </ul> </li> <li>▪ Each component can be impacted by a cyberattack.</li> <li>▪ <math>OEE = \text{availability} * \text{performance} * \text{quality}</math></li> </ul> | <ul style="list-style-type: none"> <li>▪ To deal with the uncertainty factor when gathering data, the fuzzy set theory can help in making decisions about various alternatives. Despite its ability to deal with fuzziness, only a few studies have used fuzzy set theory to handle risk uncertainty, although it is highly recommended for improving the use of this theory for critical risk assessment.</li> <li>▪ Existing models without human intervention.</li> </ul>                                                                                | <ul style="list-style-type: none"> <li>▪ MulVal network security analyzer to target bugs within network configurations.</li> <li>▪ TVA tool for topological network-based analysis.</li> <li>▪ A graph model based on a specific language to simulate attack scenarios using various methods.</li> <li>▪ An intrusion detection system to generate graphs for attacks.</li> <li>▪ NuSMV model for allocating vulnerabilities and producing attack graphs.</li> </ul> |
| <p><b>Proposed Contribution/ Recommendation</b></p>             | <p>A Stackelberg Security game model to allocate defense resources, unknown to the attacker. Encouraging investment in defense resource coverage to improve the intrusion tolerance capability of SCADA systems and protect them against failure.</p> | <p>The proposed solution is capable of measuring cybersecurity risks of ICSs in a A short-term multimodal-based cybersecurity risk assessment approach with the ability to produce cybersecurity risk values by calculating the probabilities of risks and quantifying the impacts of different possible incidents caused by cyberattacks.</p> | <p>Acquiring an agile maintenance system and considering both mean time between failures (MTBF) and mean time to repair (MTTR), relying on a short repair time. A proposed plan for system recovery, enabling repairs to be performed as quickly as possible.</p>                                                                                                                                                                                                                                                                                                 | <p>The proposed solution senses a weak item and moves it to a risk assessment model, which then determines the items for the spatial computation methods and passes them to the next model for approval. Approval suggests the end of the process. However, if an item is not approved, it will be moved to other models for vulnerability estimation using fuzzy theory. Information will be displayed to interested parties, enabling them to decide mitigating actions. The process starts again, relying on human judgment to decrease uncertainty.</p> | <ul style="list-style-type: none"> <li>• The proposed method identifies specific paths in a certain network to enhance risk assessment. These paths are unique, such as: <ul style="list-style-type: none"> <li>○ attacker capability</li> <li>○ attacker location</li> <li>○ propagation length</li> <li>○ maximum length</li> <li>○ entry points</li> <li>○ target points</li> </ul> </li> </ul>                                                                   |

## II. CASE STUDY: RISK ASSESSMENT

### A. Scenario

Daily DDoS attacks against company systems are a great concern for IT managers; however, the previous severe DDoS attack, which was repeated twice, resulted in approximately four hours of total downtime, was extremely intense, and aimed to fully disrupt the company's booking services, which could have had a significant financial impact. IT leaders directed the cybersecurity team to immediately conduct a risk assessment of these cyberattacks and provide feedback for decision-making. A risk analysis report was prepared using various cybersecurity risk management methodologies to overcome the above-mentioned issues, and the general scenario related to "the risk associated with cyberattacks against the availability of the booking system." [22-26].

### B. Risk Assessment

The company follows a combined approach to risk assessment, which is managed by the Cybersecurity Department and the IT Governance, Risk, & Audit (GRA) Department. Their goal is to ensure the management of information technology and security risks [27-32].

1) *Asset identification*: To identify the assets related to the system, system functions were first had identified [32-38]. The scope of the risk assessment was the company's booking system, represented by an application that provides reservation and ticketing services to various transport sectors through the company's digital channels (see Table IV). List of the most common risks and their corresponding controls targeting booking systems is shown in Table V.

2) *Threat and vulnerability identification*: Table VI contains the most common threat types targeting web-based systems and their threat communities. Due to the high level of data sensitivity, vulnerabilities were derived from study [20], which highlighted the most common vulnerabilities of Web-based systems but did not necessarily reflect the actual company's data [39-40].

Vulnerabilities can be divided into two classes. The first class includes vulnerabilities that affect a host or only a service running on it:

- host crash.
- performance fault.
- host infection.

The second class includes vulnerabilities that affect only a single service:

- inaccessible service.
- corrupted service.

3) *Techniques to identify vulnerabilities*: Companies use various techniques to identify vulnerabilities in their systems, and this paper identifies the set of techniques used by transportation companies; for instance, the network security team scans the system a number of times daily, and firewalls and scanners are in place to detect spikes in incoming traffic. Additionally, a DDoS protection service is in place to protect the system. The IT Security team conducts regular exercises to identify vulnerabilities using various technologies, including system vulnerability scans, penetration testing, Web application assessments, and network mapping. Furthermore, the IT team conducts special system scans for indicators of compromise upon requests from the NCA. The company also has monitoring, incident response, and forensics teams working closely with security business partners to cover various areas, such as system logs and audit reports.

### C. Minimizing Risks

The chosen risk was based on the two previous high-DDoS incidents that affected the transportation company's system. Management direction played a critical role in selecting what type of risk to manage (see Table VII).

1) *Threat community profile*: Each threat was known to have its own community profile and could have different initiating factors or triggers. Below are common factors relating to cybersecurity attacks (particularly regarding DDoS; see Table VIII).

TABLE IV. ASSET IDENTIFICATION AND CORRESPONDING VALUES

| System functions                                                                                                                                                                                                                                                                                                                                      | System elements                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Related department                                                                                                                                                                                                     | Number of employees | Assets                                                                                                                                                                                                       | Value                                                                                                                                                                                                                                                                                                                        |

TABLE VII. THE SELECTED RISK

| Asset at Risk  | Threat Community | Type | Effect       |
|----------------|------------------|------|--------------|
| Booking system | Cyber criminals  | DDoS | Availability |

TABLE VIII. DDoS COMMUNITY PROFILE

| Factor                                   | Value                                           |
|------------------------------------------|-------------------------------------------------|
| Motive                                   | Financial disruption.                           |
| Primary intent                           | Illegal activities to maximize profit.          |
| Sponsorship                              | Non-state or illegal gangs.                     |
| Preferred general target characteristics | Easy financial gains via remote means.          |
| Preferred targets                        | Financial services and retail organizations.    |
| Capability                               | Professional, skilled, and well-funded hackers. |
| Personal risk tolerance                  | Relatively high, without being exposed.         |
| Concern for collateral damage            | Prefer to keep their identities hidden.         |

D. Likelihood Estimation

Threat event frequency (TEF) was used to estimate the likelihood of a threat, indicating the probable frequency within a given timeframe that a threat would result in loss (see Table IX).

TABLE IX. THREAT EVENT FREQUENCY (TEF) FOR A DDoS ATTACK

| TCom            | Threat Type | TEF Min                     | TEF ML                        | TEF Max                         |
|-----------------|-------------|-----------------------------|-------------------------------|---------------------------------|
| Cyber criminals | DDoS        | 365 (per year)<br>1 (daily) | 1,825 (per year)<br>5 (daily) | 10,220 (per year)<br>28 (daily) |

TCom: Threat community (source)

TEF Min: Minimum threat event frequency (attack frequency)

TEF ML: Most likely threat event frequency (attack frequency)

TEF Max: Maximum threat event frequency (attack frequency)

Similarly, loss-even frequency (LEF) was calculated to indicate the probable frequency within a given timeframe of a loss being expected to occur (see Table X).

TABLE X. LOSS EVENT FREQUENCY (LEF) FOR A DDoS ATTACK

| TCom            | Threat Type | LEF Min    | LEF ML       | LEF Max      |
|-----------------|-------------|------------|--------------|--------------|
| Cyber criminals | DDoS        | 1 per year | 2 (per year) | 4 (per year) |

1) *Likelihood scale for the identified risk:* According to the previously identified incident, the likelihood of a DDoS attack being successful was 2 (as per the previous incident). Table XI was used to derive the loss event frequency (likelihood) and total risk category to be input into the risk matrix.

2) *Impact identification:* The table below shows the total impacts due to loss of availability. Impact types varied between lost revenue, the cost of hiring an incident response team, and the cost of investigating the crime (i.e., forensics cost; see Table XII).

Table XIII shows the availability impact scale used by the company to identify the severity of an impact for the risk matrix.

TABLE XI. LIKELIHOOD SCALE FOR DDoS RISK

| Score | Rating                   | X | Description                          |
|-------|--------------------------|---|--------------------------------------|
| 4     | Very high (VH)           |   | More than 5 likelihood of occurrence |
| 3     | High (H)                 |   | 4–5 likelihood of occurrence         |
| 2     | Medium (M)               | X | 2–3 likelihood of occurrence         |
| 1     | Very low to unlikely (L) |   | 0–1 likelihood of occurrence         |

TABLE XII. TOTAL IMPACT

| Impact Type                      | Min. (1–2 h downtime) | Most Likely (3–5 h downtime)     | Max. (10 h downtime) |
|----------------------------------|-----------------------|----------------------------------|----------------------|
| Lost revenue                     | 1,050,000             | 2,625,000                        | 5,250,000            |
| Incident response team(internal) | 5,000                 | 7,800                            | 10,000               |
| Forensics (external)             | 50,000                | 56,250                           | 60,000               |
| Total                            | 1,105,000             | 2,689,050 (rounded)<br>2,700,000 | 5,320,000            |

TABLE XIII. AVAILABILITY IMPACT SCALE

| Risk Rating | Impact                                                                                                                                                                                                       |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Low         | <ul style="list-style-type: none"> <li>no significant effect on operations and services</li> <li>asset can be replaced within an acceptable time frame</li> <li>insignificant interruption costs</li> </ul>  |
| Medium      | <ul style="list-style-type: none"> <li>no significant effect on operations and services</li> <li>asset can be replaced within a medium time frame</li> <li>low interruption costs</li> </ul>                 |
| High        | <ul style="list-style-type: none"> <li>effect on individual operations and services</li> <li>critical assets cannot be replaced by manual methods</li> <li>high interruption costs</li> </ul>                |
| Very High   | <ul style="list-style-type: none"> <li>significantly affects multiple operations and services</li> <li>critical assets cannot be replaced by manual methods</li> <li>very high interruption costs</li> </ul> |

According to the scenario provided by the company’s IT team, the DDoS attack was repeated twice, resulting in an approximate downtime of four hours (see Table XIV).

3) *Risk matrix:* The following risk matrix includes two factors: impact and likelihood. Both factors have a rating scale of 1–4, as shown in the previous scaling tables. The IT team identified the likelihood of the risk occurring as stated in the scenario (i.e., twice a year; medium rating = 2), and the teams also measured the loss impact of four hours of total system downtime (very high rating = 4). The risk level was then calculated as the likelihood of risk occurrence \* impact of a loss, resulting in a risk level of eight (see Table XV).

The company’s main risk objective was to protect the organization’s information and technology assets by maintaining confidentiality, integrity, and availability of service effectively with minimum cost and without affecting business operations. The strategy for responding to risks

depended on the individual risk situation and was based on risk assessments and recommendations from decision-makers. As shown in Table XV, the risk level was relatively high and needed to be managed; hence, the transportation company decided to mitigate the risk by applying appropriate countermeasures. A list of countermeasures suggested by IT experts was prepared by the transportation company's IT team (see Fig. 2).

a) Internal controls

Procedures: enhance the DDoS Response Plan with:

- a systems checklist including all assets to ensure advanced threat identification and assessment.
- notifications and escalation procedures for quick recovery.

Training:

- train special teams to extensively monitor traffic and look for abnormalities, including unexplained traffic spikes and visits from suspect IP addresses and geolocations.
- create additional response teams to minimize the impact of attacks.

TABLE XIV. IMPACT SCALE FOR A DDoS ATTACK

| Score | Rating    | X | Description               |
|-------|-----------|---|---------------------------|
| 4     | Very high | X | More than 3 h downtime    |
| 3     | High      |   | 1–3 h downtime            |
| 2     | Medium    |   | 30 min–1 h downtime       |
| 1     | Low       |   | Less than 30 min downtime |

TABLE XV. DDoS RISK MATRIX

|            |   |   |   |    |    |
|------------|---|---|---|----|----|
| Likelihood | 4 | 4 | 8 | 12 | 16 |
|            | 3 | 3 | 6 | 9  | 12 |
|            | 2 | 2 | 4 | 6  | 8  |
|            | 1 | 1 | 2 | 4  | 5  |

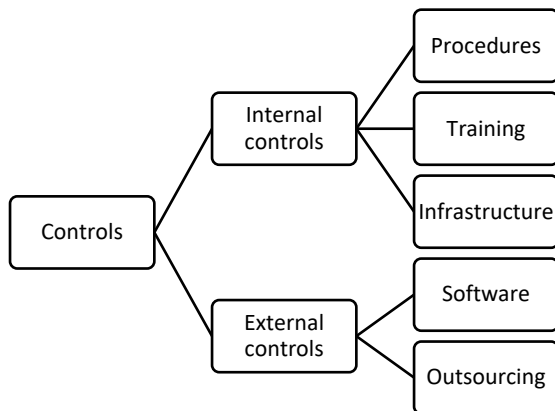

Fig. 2. List of Suggested Countermeasures.

Infrastructure:

- create redundant network (FW/IPS) resources so that, if one server is attacked, the others can handle extra network traffic.

b) External controls

Software:

- purchase threat intelligence software to monitor social media and the dark Web for threats, suspicious conversations, and boasts that may hint at an incoming attack.

Outsourcing:

- use third-party DDoS testing (i.e., pen testing) to simulate attacks against IT infrastructure so that the company can be prepared for any real threats.
- Use DDoS-as-a-service to provide improved flexibility for environments that combine in-house and third-party resources, or cloud and dedicated server hosting.
- outsource DDoS prevention to cloud-based service providers operated by software engineers whose job consists of monitoring the Web for the latest DDoS tactics. For decision-makers to choose between countermeasures for mitigating DDoS attacks, IT experts used the following scale to evaluate the effectiveness of each control.

Each control had a corresponding estimated cost and effectiveness rating (see Table XVI and XVII). The following criteria were used to choose the appropriate controls:

- If the control will reduce the risk more than needed, a less expensive alternative should be used.
- If the control will cost more than the risk reduction provided, an alternative should be used.
- If the control does not sufficiently reduce the risk, either more or different controls should be used.
- If the control provides sufficient risk reduction and is the most cost-effective option, use it.

TABLE XVI. CONTROL EFFECTIVENESS SCALE

| Risk Rating             | Impact                                                                                                                                                                                    |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ineffective             | <ul style="list-style-type: none"> <li>• poor control design</li> <li>• significant control gaps</li> <li>• does not treat root causes</li> <li>• does not operate effectively</li> </ul> |
| Partially effective     | <ul style="list-style-type: none"> <li>• satisfies control design needs</li> <li>• partially treats the root causes of the risk</li> <li>• not very effective</li> </ul>                  |
| Substantially effective | <ul style="list-style-type: none"> <li>• designed correctly</li> <li>• treats most of the root causes of the risk</li> <li>• requires improvements to operate effectively</li> </ul>      |
| Fully effective         | <ul style="list-style-type: none"> <li>• well designed</li> <li>• addresses and treats all root causes</li> <li>• effective and reliable at all times</li> </ul>                          |

TABLE XVII. ESTIMATED COST FOR EACH CONTROL

| # | Control                                            | Estimated Cost | Effectiveness           |
|---|----------------------------------------------------|----------------|-------------------------|
| 1 | Enhance the DDoS response plan                     | 10,000         | Ineffective             |
| 2 | Train special teams                                | 30,000         | Partially effective     |
| 3 | Create additional response teams                   | 45,000         | Partially effective     |
| 4 | Use third-party DDoS testing                       | 75,000         | Substantially effective |
| 5 | Purchase threat intelligence software              | 100,000        | Substantially effective |
| 6 | Create redundant network resources                 | 200,000        | Substantially effective |
| 7 | DDoS-as-a-service provision                        | 350,000        | Fully effective         |
| 8 | Outsource DDoS prevention to a cloud-based service | 500,000        | Fully effective         |

c) Suggested controls for implementation: A cost-benefit analysis was conducted to identify the most appropriate controls and provide the greatest benefit to the company given the available resources. Two selected controls were recommended for implementation based on a cost-benefit analysis performed to justify why decision-makers should implement them (see Table XVIII).

TABLE XVIII. SUGGESTED CONTROLS FOR IMPLEMENTATION

| #          | Control                            | Estimated Cost | Effectiveness           |
|------------|------------------------------------|----------------|-------------------------|
| 3          | Create additional response teams   | 45,000         | Partially effective     |
| 6          | Create redundant network resources | 200,000        | Substantially effective |
| Total Cost |                                    | 245,000        | Substantially effective |

E. Cost-Benefit Analysis

The selected controls minimized the likelihood of a DDoS risk occurring twice to 0 or 1 (very low rating = 1), while the impact of DDoS was reduced from a total downtime of three hours to a medium impact (30 min–1 h), with a score of 2 (see Tables XIX and XX).

TABLE XIX. LIKELIHOOD OF A RISK AFTER IMPLEMENTING SELECTED COUNTERMEASURES

| Score | Rating                   | X | Description                  |
|-------|--------------------------|---|------------------------------|
| 4     | Very high (VH)           |   | More than 5                  |
| 3     | High (H)                 |   | 4–5 likelihood of occurrence |
| 2     | Medium (M)               |   | 2–3 likelihood of occurrence |
| 1     | Very low to unlikely (L) | X | 0–1 likelihood of occurrence |

TABLE XX. IMPACT OF THE RISK AFTER IMPLEMENTING THE SELECTED COUNTERMEASURES

| Score | Rating    | X | Description               |
|-------|-----------|---|---------------------------|
| 4     | Very high |   | More than 3 h downtime    |
| 3     | High      |   | 1-3 h downtime            |
| 2     | Medium    | X | 30 min–1 h downtime       |
| 1     | Low       |   | Less than 30 min downtime |

As shown in the risk level matrix (see Table XXI), the new risk level was calculated as the likelihood of risk occurrence \* impact of a loss, resulting in a residual risk level of two.

TABLE XXI. RESIDUAL RISK AFTER IMPLEMENTING CONTROLS

|            |   |   |    |    |
|------------|---|---|----|----|
|            | 4 | 8 | 12 | 16 |
| Likelihood | 3 | 6 | 9  | 12 |
|            | 2 | 4 | 6  | 8  |
|            | 1 | 2 | 4  | 5  |
|            |   | 1 | 2  | 3  |

III. CONCLUSION

As shown in the case study scenario, the risk assessment identified the most critical attacks on the transportation company’s booking system and provided suitable countermeasures to minimize the risk of attacks. The risk level decreased from eight to two, indicating the effectiveness of the selected countermeasures. Risk assessment was extremely useful for assessing potential risks and suggesting useful controls. Moreover, the two identified DDoS attacks were mitigated by implementing suitable controls, and recommendations were made to analyze and monitor incidents and increase the company’s preparedness for another wave of DDoS or other attacks.

# ASM-ROBOT: A Cyber-Physical Home Automation Controller with Memristive Reconfigurable State Machine

Kennedy Chinedu Okafor<sup>1</sup>, Omowunmi Mary Longe<sup>2</sup>

Dept. of Mechatronics Engineering, Federal University of Technology, Owerri, Nigeria<sup>1</sup>  
Electrical and Electronic Engineering Science, University of Johannesburg, South Africa<sup>1,2</sup>

**Abstract**—In the next 5 to 10 years, digital Artificial Intelligence with Machine Circuit Learning Algorithms (MCLA) will become the mainstream in complex automated robots. Its power concerns, ethical perspectives, including the issues of digital sensing, actuation, mobility, efficient process-computation, and wireless communication will require advanced neuromorphic process variable controls. Existing home automated robots lack memristic associative memory. This work presents Cyber-Physical Home Automation System (CPHAS) using Memristive Reconfigurable Algorithmic State Machine (MRASM) chart. A process control architecture that supports Concurrent Wireless Data Streams and Power-Transfer (CWDSPT) is developed. Unlike legacy systems with power-splitting (PS) and time-switching (TS) controls, the MRASM-ROBOT explores granular wireless signal controls through unmodulated high-power continuous wave (CW). This transmits infinite process variables using Orthogonal Space-Time Block Code (OSTBC) for interference reduction. The CWDSPT transmitter and receiver circuit design for signal processing are implemented with complexity noise-error reduction during telemetry data decoding. Received signals are error-buffered while gathering control variables' status. Transceiver Memristive neuromorphic circuits are introduced for computational acceleration in the design. Hardware circuit design is tested for system reliability considering the derived schematic models for all process variables. Under small range space diversity, the system demonstrated significant memory stabilization at the synchronous iteration of the synaptic circuitry.

**Keywords**—Cloud computing; cyber-physical systems; complex robot; computational science; IoT; machine learning

## I. INTRODUCTION

### A. Background

Memristive Reconfigurable Algorithmic State Machine Robot (MRASM-ROBOT) is a novel intelligent automation approach that provides support for the control of converged appliances using localized space diversity. The concept is very useful for providing security to both localized and remote homeowners. It exploits associative memory which has a structured memory unit for storing identified data both at the edge and cloud control levels respectively. The system uses access by data content (content addressable memory), and address by memory location (associative memory).

Memristive neuromorphic circuits can be constructed with associative memory for infinite process variables such as

temperature, smoke, flames, gases, humidity, and water, among others. Modern-day hardware modules can easily be implemented using Memristive reconfigurable memory systems. This is found in neuromorphic robots and other complex systems [1]. The application areas are very huge, thereby creating demands for location-independent automation processes. Smart Internet of Things (IoT) is often used in this regard due to space diversity considerations. In such cases, IoT RF technology (such as ATMEL Smart-SAM25 module) with the CWDSPT technique can be adapted to provide effective monitoring and control of both on-premises and remote processes. With heightened security challenges as well as domestic havoc at homes and offices, such an automated security system becomes very handy [1], [2].

Existing home automation approaches fail to account for space diversity sensitivity. Also, process variable coordination in various application contexts is unpredictable. In most legacy systems, their efficiency often involves a high cost, especially when using remote network services. There is a need for an automated security system that is optimized for high efficiency in controlling home appliances at short-range communication. Smart Energy Audit Systems (SEACS) have been proposed which largely depends on IoTs via near field communication (NFC) [2]. Hand-gesture-based control Robots have been implemented for real-time interactive control systems targeted at household appliances [3]. Home automation systems for anomaly classification using unsupervised probabilistic associations for sensing and event tracing in smart homes are trending [4], [5], and [6].

Recently, researchers are making efforts to drive biological neural networks and map with memristive neuromorphic models to customize AI-based Robots [7], [8], [9]. Similarly, memristive neuromorphic models have been applied in most computing acceleration designs [10], [11], [12]. In classical literature such as social psychology, the capacity to learn and recall the relationship-map existing among unconnected variables is referred to as associative memory [13]. This could be declarative in its structure or episodic [14] in its application contexts.

Various attributes of complex radio frequency (RF) robots such as real-time withdrawal reflex, classical eyeblink, etc., can occur via a complex learning process in associative memory. In this case, a conditioned reflex can be established between conditioned stimulus (CS) and system state-response.

Low range RF memristive neuromorphic circuits can be leveraged as a Pavlov associative memory (PAM) or a withdrawal reflex [15], [16]. Max-input-feedback adaptive-learning rule has been applied to train the neuromorphic circuit while adapting it to PAM [17]. Some designs explore microcontrollers, and signal conditioners such as A/D converter to synthesize memristor features in a robot. In this case, the memristor can be used as a synaptic/ neuromorphic circuit, to model PAM [18]. Though finite state machine is not new, however, it can be employed to assist an unsupervised  $k$ -means logic intelligence while monitoring and detecting abnormal conditions.

### B. Advantages of Memristive Control Design Technique

- Offers bifurcation analysis involving two or more parameters and predict the linear stability boundaries.
- Similar to biological synapses, dendrites, and neurons, the memristive technique with neuromorphic computing offers another layer to AI at a physical level.
- The memristive method offers insights into non-linear systems by extending the capabilities of resistors, Capacitors, and Inductors.
- The Memristive approach provides optimal control in circuit diversity.

Existing works on memristive systems focused on high-density filters or FPGAs volatile memory, crossbar latches, neural networks, modeling of neural synapses, nonlinear oscillators, and filters. Very little work has been done field of Memristive reconfigurable state machine and space diversity control signaling.

### C. Research Contributions

This work presents a novel control strategy for process variable transceiver modules in smart homes designs. The system allows for the optimization of errorless information decoding. The other contributions in this research include:

- Derive a standardized remote-controlled automation architecture adapted for process aggregation dynamics.
- To evaluate the IoT-gateway transmission and receiver behavior for a low bit error rate under the influence of Multipath Rayleigh Channel Space Vector (MRCSV) and White Gaussian noise (AWGN).
- To show the impact of space diversity on received signal using optimal OSTBC-combiner block (CB).
- To demonstrate MRASM-ROBOT use case scenario for bit error response at scale.

The rest of the paper is organized as follows. Section II presents related works. Section III presents the methodology. Section IV presents the smart automation engine (SAE). Section V presents the feedback scheduling algorithm, Section VI focused on space diversity control. Section VII discussed the experimental results, while Section VIII concludes the work.

## II. RELATED WORK

Mostly, there are challenges regarding the coordination of control states and the collection of telemetry data for smart home analytics. The absence of MRASM-CWDSPT affects the accuracy of data communication on the home server. This leads to under-utilization and lower efficiency. In this section, closely related literatures on two important elements were studied namely: CWDSPT Space diversity and automated/smart homes without neuromorphic circuits.

### A. CWDSPT Space Diversity

Concurrent Wireless Data Streams and Power-Transfer is an emerging area with great prospects especially with 5G rollout in Africa. In most works, spatial diversity (SD) is introduced in transmissions systems to mitigate the effect of multipath fading [19]. In lengthy links over extremely reflective surfaces like water bodies where a non-diversity link can't deliver high availability, SD is needed. It is used in multiple antennas that have similar characteristics involving real physical separation from each other. There have been several works on space diversity, but the work in [20] used a concave-convex procedure (CCCP) scheme to maximize the minimum rate of IoT nodes' private streams. This was done via the allocation of transmit power and adjustment of power-splitting ratios at the IoT edge nodes.

A similar work [21], discussed spatially modulated space-time block code (HRSM-STBC) developed for two active antennas. To optimize space diversity schemes, extensive discussions on wireless power transfer (WPT) capabilities were presented in [22]. The work [23] investigated a wireless power transfer (DWPT) tool for developing wireless power transfer (WPT) systems and its related parameters. In [24], the authors proposed a radial-flux rotational wireless power transfer (RF-R-WPT) system with a rotor state identification function for devices mounted on a rotating shaft. In [25], the authors focused on the systematic review of metamaterials and meta surfaces for wireless power transfer (WPT) and wireless energy harvesting (WEH) [26].

In [27], the authors leveraged Wireless power transfer (WPT) systems due to their security, convenience, and flexibility to propose a control strategy referred to as periodic energy control (PEC) in WPT. So far, current literature on wireless information power transfer and space diversity has not been explored in Cyber-physical home automation. Its applications in MRASM-ROBOT will be very novel and useful too.

### B. Neuromorphic State Machine (NSM)

The authors [28], developed an inverter-based memristive neuromorphic RF switch on the microstrip line with good performance up to 5GHz. Their design explored conductive bridging random access memory (CBRAM) scheme in which the switch uses metal-insulator-metal (MIM) structure, Copper/Nafion/Au majorly. In [29], the authors focused on inverter-based memristor crossbar neural networks. The work [30] investigated the impacts associated with the computing accuracy of analog memristive circuits for neuromorphic applications. In [31], the security application of memristive crossbar physical unclonable function was investigated for

resource optimization. The work [32] investigated neuromorphic computational system models using the spine technique. This is used to improve system lifetime in mapping machine learning workloads. The work in [33] focused on the optimization of Memristive Crossbar Arrays. In [34], the authors investigated memristance variations capture synaptic weight variations. The authors [35], [36] proposed the Pavlov associative memory process otherwise known as multi-functional memristive Pavlov associative memory circuit. The work [37] proposed a weight optimization scheme that combines quantization and Bayesian inference for memristor-based neuromorphic computing system (NCS).

In cases of Mixed-signal analog/digital neuromorphic circuits, there has been the characterization of such circuits using ultra-low power consumption, real-time processing abilities, and low-latency response times [38]. In this case, neuromorphic processors are used as the neuromorphic agent. The work [39] discussed a new neuro-inspired, hardware-friendly readout stage for the liquid state machine (LSM) using neuromorphic VLSI implementation. The work [40] discussed a neuromorphic computational scheme known as the prefrontal cortex (PFC). The work is equally looked at as mixed-signal analog/digital neuromorphic implementation. Authors [41] highlighted that memristive circuits can trigger the associative memory processes while retaining the design parameters.

There are other types of memristive circuits without any clear synaptic and neuron circuits. Hence, with a modified memristive circuit, the memristive neuromorphic models can be employed to enhance computational efficiency in deployment contexts.

Considering the memristive neuromorphic circuits used for computation acceleration, the work [42], [43], [44], showed that the synaptic circuit is required to represent process variable weights in binary form. The works equally highlighted that various synaptic circuits can be designed to utilize neuromorphic circuits. At the implementation level, Field programmable gate arrays (FPGAs) have been used to provide neuromorphic reconfigurable characteristics while enabling flexible schematic designs for various applications [44], [45], [46], [47]. Interestingly, various control circuit topologies designated for process variables in existing designs lack the functionality of MRASM states. Also, the design of memristive neuromorphic circuits must replicate the process of learning, with high retention for conditional state-based signals.

Therefore, the gap in NSM is that low-end cyber-physical applications cannot fit into the design complexity due the memory stabilization issues. However, the use of associative memory can help in the design of Cyberphysical robots that learns and remembers the relationship between unrelated things. Such reconfigurable NSM can be useful in the design of intelligent RF systems.

### C. Summary of Related Works (Automated Home)

The use of NSM to drive space diversity intelligent systems is novel. In this section, the summary current related efforts on automated/smart home without NSM. In [48], the authors proposed Open-source home automation systems which lacked a detailed implementation framework. In the work [49], the

authors proposed home energy management systems (HEMS). The design supports end-users by allowing for demand-side management and automation. In [50], the authors developed a secured but lightweight three-factor driven privacy-preserving authentication model specifically for IoT-enabled smart home environments. The authors [51], presented a scheme that automates home appliances in three modes viz: local, web, and app-based automation. These were achieved with a low-cost microcontroller, a web page with support for remote applications. The work [52] presented an improved robots index model used to optimize the robust level of home energy local network (HELN) while considering its numerous household appliances. In [53], a novel proximity service model for smart home automation is proposed. Their work uses wireless networks and native Internet connectivity. The work [54] discussed an asynchronous electrooculography (EOG)-based human-machine interface (HMI) for smart home environmental control. The work [55] focused on a machine-learning-based approach to assessing activity quality in smart homes based on automation assessment. The work [56] highlighted an efficient implementation approach using IoT for real-time monitoring of routine activities in homes.

So far, the future of ubiquitous home networks will rely on sensors to aggregate various environmental data variables [57]. This work has similar baseline design attributes with robotic smart homes based on stabilized feedback Episodic memory (SF-EM) [58], stewards robot smart homes [59], humanoid defense smart homes [60], Indoor autonomous robots [61], and Smart home activities IoT [62]. These similarities are highlighted below [63], [64], [65]:

- Process automation through task allocation.
- Lightweight process variable control.
- Layered integrations with NSM.

The identified gaps/limitations are found below:

- Absence of space diversity characterization under multipath fading channels.
- Absence of NSM for hardware analytics.
- Though most systems have complex design topologies.
- Absence of CPS process variable control using the associative-memory based on the reconfigurable memristive neuromorphic scheme.
- The absence of multipath fading channel optimization for memory stabilization is novel.

### D. Summary of Contributions

The generalized smart home systems are anticipated to provide custom-based services, especially to home users thereby reducing human efforts. Unfortunately, the legacy computational knowledge-driven algorithms for learning and reasoning do not completely orchestrate unpredictable changes in these homes. In this work, the service provisioning demand seeks to handle: i.) remote learning and reasoning process control algorithms, and ii) Edge layer integration of smart endpoints. To fix these issues, the contributions of this work are as follows.

- 1) Develop an associative-memory-induced reconfigurable memristive neuromorphic for memory stabilization.
- 2) Introduce a logical feedback mechanism for behavioral learning from the state machine.
- 3) Complete a set of space diversity optimization for memory service guarantee from multipath fading errors.

### III. METHODOLOGY

The physical design topology of the smart automation engine (SAE) is shown in Fig. 1. This depicts the design symmetry of MRASM-ROBOT enabled with machine learning automation and CWDSPT. The implementation of the smart automation/security system is based component layered approach and its subsystems were implemented as a stand-alone system for ease of reconfiguration. The optimally controlled process variables modeled are temperature states, room lighting, overhead tank, as well as house security.

The design can protect the occupants from life-threatening hazards. This is achieved by getting inputs from sensors placed at different locations throughout the house/deployment environment. Application program interfaces (API) are used for remote communications.

The inputs are then fed into the Arduino MKR1000 Wi-Fi process controller (PCon) through which these different aspects of the house are controlled. Essentially, communication happens in a short-range transmission distance of 100 to 100mW. This class 1 range uses the RF ISM bands (2.402GHz-2.48GHz).

The objective function (OF) is the infinite process maximization with constraint variables such as link capacity, channel effects, resource availability, and cost function. These are responsible for the smart automation engine (SAE). This further incorporates static real feedback looping for dynamic stability, having an optimal algorithm with low-bit error signaling. These functionalities are implemented to monitor and control devices that drain energy while securely protecting the home facility. As shown in Fig. 1, there are two major parts viz.

- Automation module. This controls the lights, inductive load, and cooling systems (HVACs) in and around the house thereby saving energy. Also, it has the following sub-systems namely – the process controller, level converter, GSM modem, smart green power supply unit, the input interface (sensor subcircuit), control system, and the output Interface such as APIs.
- Associative-memory-induced scheme i.e., memristive reconfigurable state machine attributes.

A brief explanation of the resilient transmitter, RF-wireless communication channel (i.e., transmitter/receiver) for the proposed MRASM-CWDSPT is presented via the component modeling technique. Also, the details proposed CWDSPT, (i.e., DC-biased orthogonal frequency-division multiplexing (DC-biased OFDM) in the IoT controller is equally presented below.

Let's define the following process variables as follows:

$API_{g_m} = API\ gateway$

$SGg_{v_\alpha} = smaoke\ signal\ conditioner\ API\ communication$

$WT_{Cm_\beta} = water\ signal\ conditioner\ API\ communication$

$TM_{Cm_\beta} = Temperature\ signal\ controller\ API\ communication$

$LG_{as_\mu} = Light\ intensity\ siganl\ controller\ API\ communication$

The sink controller functions include Smoke, water, temperature, and light intensity.

#### A. Memristive Reconfigurable Neuromorphic Circuit Model

In this section, the component modeling technique was introduced to build the MRASM-Robotic subsystem. This involves process variable synaptic modeling. First, a neuron circuit refers to the schematic baseline unit used to implement a functional neuromorphic system for MRASM-Robotic. It connects more than one synaptic subcircuit interface module depicted in Fig. 1.

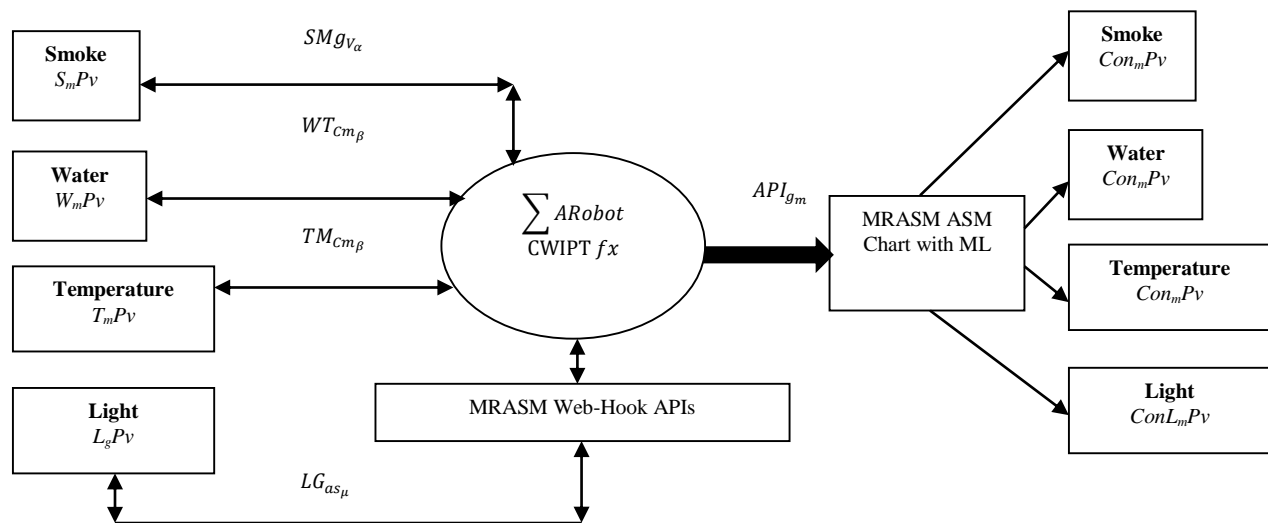

Fig. 1. MRASM-ROBOT Process Model for Memory Stabilization.

Second, there are three major parts in the neuron circuit: 1) MRASM-Robotic selection circuitry; 2) MRASM-Robotic synaptic circuitry, and 3) MRASM-Robotic neuron circuitry.

In the design implementation, the MRASM-Robotic neuron circuitry has two input voltage levels/signals, MVanalog and MVdigital. The former depicts the analog signal estimated at 1–5 V. The latter refers to the binary digital signal where the voltages of logic 1 and logic 0 are represented as 5 and 0 V respectively. Voltage thresholds of pMOS transistors and nMOS transistors in MRASM-Robot are fixed at  $-0.6$  V and  $0.6$  V, respectively.  $T_1$  and  $T_2$  pMOS are used for the selection circuitry.

Now, let's define the computational core of the MRASM-Robot which orchestrates both the input and output subsystems in Fig. 1. The process variables (smoke, water, temperature, light signals) modeled in the design include the overhead tank water level sensor module ( $W_mPv$  in Fig. 2a), a Smoke detection module ( $S_mPv$  in Fig. 2b), temperature control system ( $T_mPv$  in Fig. 2c), and motion-controlled lighting ( $L_gPv$  in Fig. 2d.).

Using digital comparators shown in Fig. 2a-d, the work estimated appropriate voltages at the output of the comparator. The water resistance was determined experimentally by using a neural network digital ohmmeter (NNDM). A resistance of approximately between  $100\text{ k}\Omega$  and  $120\text{ k}\Omega$  was obtained using various samples of water. The resistance of  $100\text{ k}\Omega$  was taken to be the water resistance using voltage divider models while accounting for tolerance consideration.

A tamper-proof was introduced to monitor open circuit situations or when the sensor goes bad. This is included since if the sensor goes bad without being detected, lives and properties may be lost. The system consists of an additional length of wire connected along with the smoke sensor. This drives the transistor to saturation and diode  $D_1$  then conducts. When there is a tamper or if the sensor goes bad, this condition is sensed by the processing unit. From Fig. 2c, ideally, the input of an Op-amp has almost infinite resistance. This then forces the  $V_{cc}$  to be dropped across  $R_{30}$  and  $R_{31}$ . Since the output of LM35 is between  $0\text{ V}$  to  $1\text{ V}$  ( $10\text{ mV}/^\circ\text{C}$  to be precise). To allow power drop across  $R_{31}$ , the value was arbitrarily chosen as  $1\text{ M}\Omega$ . This is well shown in Fig. 2c.

Furthermore, the use of empirical data from machine learning computations is currently investigated in Fig. 1. This is to show the extent of metrics performance between the Memristic control strategy and the traditional models using quantified datasets. Also, The adjusting/changing memristor states are done by changing the resistance value over time during switching of control state variables.

### B. Motion Controlled Lighting

For the LDR section, various experimental trials were carried out. It was noticed that in a dark environment, the LDR will have a resistance of  $10\text{ k}\Omega$ , thus allowing  $2.5\text{ V}$  to drop across LDR as shown in Fig. 2d. That means that the voltage drop across  $R_{49} = 2.5\text{ V}$ . The essence of this sensing arrangement is to create a path across which blockage will obstruct the transmitted rays and the receiving phototransistor, resulting in an open circuit. Anybody entering or leaving the

room as a result of crossing this path creates such a situation and will be detected.

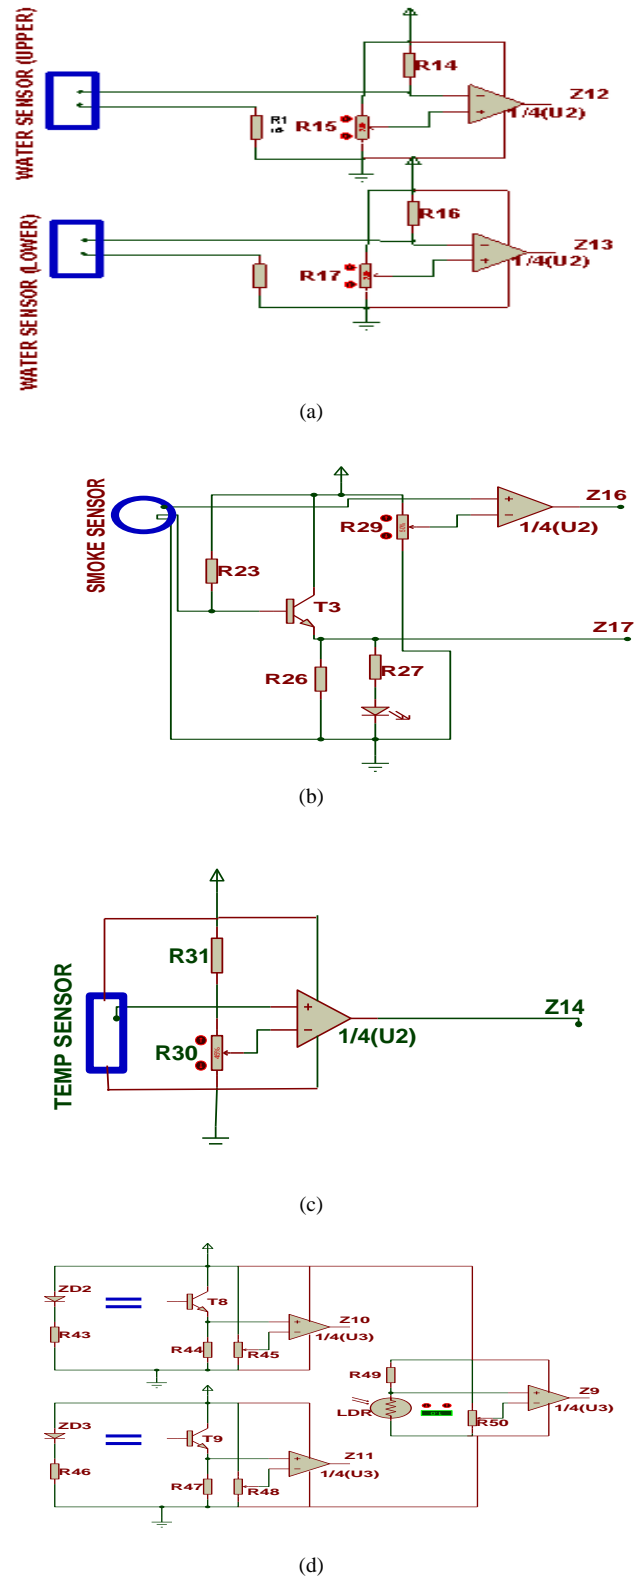

Fig. 2. (a) MRASM Overhead Tank Sensor, (b). MRASM Smoke Detection Module, (c): MRASM Temperature Sensor, (d). MRASM Motion-controlled Light.

### C. Pass-worded Locking System

Push switches are used like keypads for security controls. A switch is used with a resistor as shown in Fig. 3. The value of the resistor selected is 10 kΩ resistor. When the switch is 'open' the 10 kΩ resistor connects the microcontroller input pin down to 0 V, which gives an off (logic level 0) 0 V signal to the microcontroller input pin. When the switch is activated, the input pin is connected to the positive battery supply (V+). This provides an on (logic level 1) signal to the PCon. It is a 4x4 matrix keypad requiring eight Input/Output ports for interfacing. Rows are connected to peripheral Input/Output (PIO) pins configured as an output. Columns are connected to PIO pins configured as input with interrupts. In this configuration, four pull-up resistors must be added to apply a high level on the corresponding input pins. The corresponding hexadecimal value of the pressed key is sent on four LEDs.

Fig. 3. MRASM-ROBOT Keypad Interface.

## IV. SMART AUTOMATION ENGINE

In this Section, MRASM-ROBOT was improved with feedback scheduling at the controller level. PIDs algorithm was added for dynamic stability and process controls. The IoT space diversity model for reliable data stream/message delivery is developed. This uses a two-way transceiver communication for memory stabilization. Static real-time scheduling for the automation processes in MRASM-ROBOT was introduced. Also, the design optimization algorithm and implementation emulations, among others were achieved via proofs-of-concept. These components comprise the smart automation engine for MRASM-ROBOT.

### A. Design Description

- Considering the block diagram of the smart automation engine (SAE) in Fig. 1, three layers were identified viz. core, access/automation layer, and aggregation layers. Recall that the process controller is the major component in the core speed redundancy layer, while automation devices in the access layer are interconnected through the ports of the process controller. The MRASM-Robot automation shown in Fig. 4 has the model specifications briefly discussed. There are six process variables in the access layer. These include Water Level Signal ( $P_{v1\_WLS}$ ), Temperature Control Signal ( $P_{v2\_TCS}$ ), Smoke Signal ( $P_{v3\_SKS}$ ), Motion Detection Signal ( $P_{v4\_MDS}$ ), = Keypad Signal ( $P_{v5\_KPS}$ ). These are all interconnected as in Fig 4. In programming script,  $P_{v1}$ ,  $P_{v2}$ ,  $P_{v3}$ ,  $P_{v4}$ ,  $P_{v5}$  denotes Water Level Signal (WLS), Temperature Control Signal (TCS), Smoke Signal (SKS), Motion

Detection Signal (MDS), and Keypad Signal (KPS) among others. These are all connected to the Process Controller (PCon).

- The process controller uses the optimization algorithm in the aggregation layer to recursively monitor and control the devices without a drop in their stability.
- The MRASM-ROBOT output interface is modeled to report recurrent processes on the system display dashboard or sink. Commands instruction is given to dashboard then execute any predefined task such as initialization, reset, setting the cursor position, controlling the display, etc. The data register stores the data to be displayed on the dashboard. The data is the ASCII value of the character to be displayed on the dashboard.

### B. Smart Automation MRASM Chart

In the MRAM automation system, the derived chart was designed which controls the process variables shown in Fig. 4 using wireless signaling (i.e. CWDSPT). The MRASM chart design is essentially is a finite state machine design scheme used to represent diagrams of process logic regulation in the PCon. The MRASM technique comprises these steps:

- 1) Create pseudocode for the desired operation of MRASM on the controller.
- 2) Translate the pseudocode into an MRASM chart.
- 3) Derive the datapath from the MRASM chart.
- 4) Create a detailed MRASM chart based on the Datapath.
- 5) Create the control logic from the MRASM chart.

The outcome of the above steps resulted in Fig. 5 showing the PCon MRASM logic box for the smart automation system. Fig. 5 shows the PCon MRASM logic box for the smart automation system. Fig. 6 shows the design flowchart.

For the model, let the process variables be represented in the MRASM chart State Transition Table presented in Table I with various variables defined below:

$P_{v1\_WLS}$  = Water Level Signal;  $P_{v2\_TCS}$  = Temperature Control Signal;  $P_{v3\_SKS}$  = Smoke Signal;  $P_{v4\_MDS}$  = Motion Detection Signal;  $P_{v5\_KPS}$  = Keypad Signal

PSN = Present State Name; PSC = Present State Code; NSN = Next State Name; NSC = Next State Code.

Fig. 4. MRASM-ROBOT Input Interfaces for  $P_{v1}$ ,  $P_{v2}$ ,  $P_{v3}$ ,  $P_{v4}$ ,  $P_{v5}$ , &  $P_{vn}$ .

TABLE I. MEMRISTIVE RECONFIGURABLE STATE MACHINE TRANSITION

Fig. 5. MRASM Process Controller Block.

C. MRASM Design Description

As depicted in Table I, the design chart for MRASM smart automation security control was further characterized using schematics capture C++ scripting. Test case values are derived from optimal system response conditions. The input interface to the PCon is made up of the input qualifiers. The qualifiers are the comparator output from the different sensor modules at the access layer. As shown in Fig. 6, these include the water level signal (P<sub>v1</sub>\_WLS), smoke signal (P<sub>v3</sub>\_SKS), temperature control signal (P<sub>v2</sub>\_TCS), the motion detection signal (P<sub>v4</sub>\_MDS), and the keypad signal (P<sub>v5</sub>\_KPS). Whenever any of the qualifiers changes its state, either from logic 1 to logic 0 or from logic 0 to logic 1; there is an event at the output interface. For instance, in link path L1 to L4, when the input qualifier, water level signal (WLS) changes its state from logic 0 to logic 1 (L1-L2), Relay1 (the relay that turns on the pumping

machine) is energized and the water pump turns on. As long as it stays on in 1, the water pump will keep on pumping water. But once it changes its state from 1 to 0 (L3-L4), Relay1 is de-energized and the water pump turns off.

The link path L5 to L8 depicts what happens in the temperature channel and how the microcontroller reacts to it. When the temperature exceeds the preset value or goes below the preset value, the signal from the temperature module changes from logic 0 to logic1 (L5-L6), Relay 2 is energized and the air conditioner turns on. On the other hand, when the signal goes from 1 to 0 (L7-L8), the relay is de-energized and the air conditioner turns off. The L9-L12 depicts what happens in the smoke channel how the microcontroller reacts to it and what happens at the output interface. When there is a smoke occurrence, the signal from the smoke channel (one of the input qualifiers), changes from logic 0 to 1 L9-L10, the Buzzer is energized and turned on. For as long as the signal remains in logic 1, the buzzer will be sounding, but when a signal goes from logic 1 to 0 (L11-L12), the buzzer is de-energized and therefore stops sounding.

The link path L13-L16 depicts what happens in the motion-controlled light module and how the microcontroller reacts to it. When motion is detected and there is insufficient light, the signal from this module changes from logic 0 to 1, L13-L14, the relay known as RL3 is energized and the light turns on. As long as the person is in the room, the light will be on. But once the person leaves, that is, when the person is no longer sensed, the signal changes from logic 1 to 0, L15-L16 RL3 is de-energized and the light turns off.

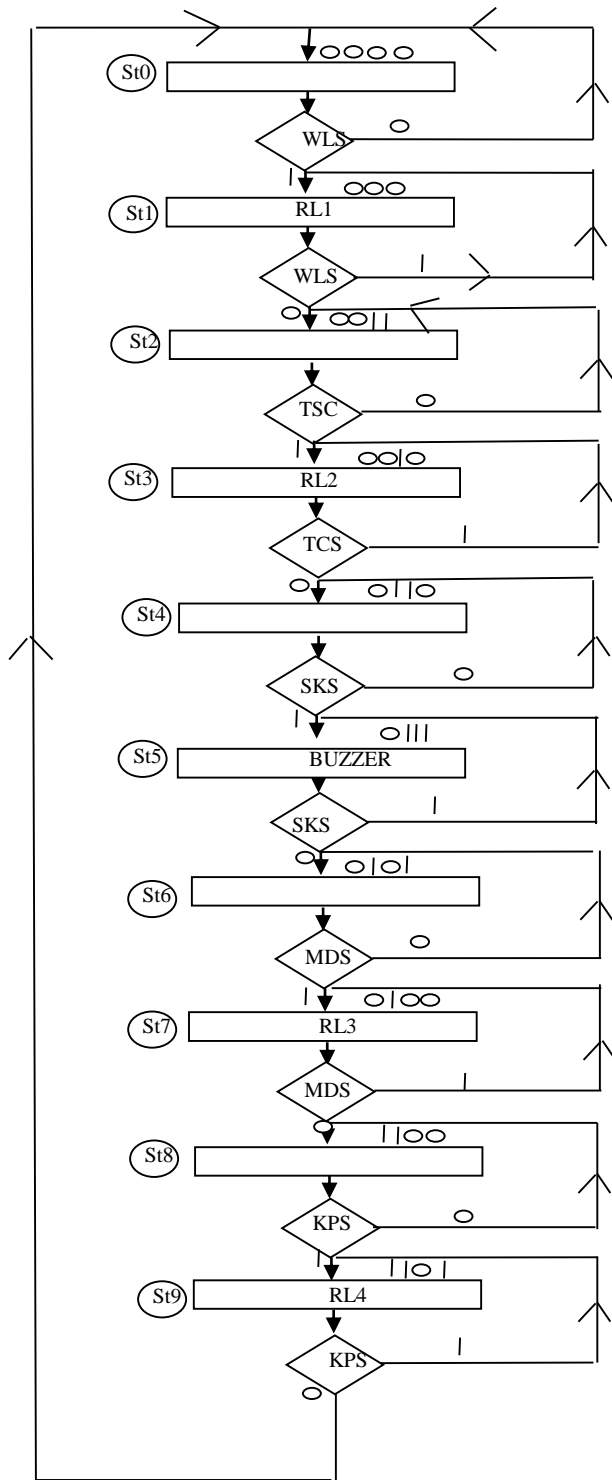

Fig. 6. MRASM Design Chart for Smart Automation and Security Design System.

The link path L17-L20 depicts what happens when the keypad is pressed. When pressed and the input code is correct, L17-L18, the signal from here changes from logic 0 to 1, the relay known as RL4 is energized and the door opens. Once the door is shut, the signal changes from logic 1 to 0, L19-L20. With the MRASM Chart and the corresponding, STT table, the system, home automation, and security system were developed

in the prototype design. The keypad signal ( $P_{v5\_KPS}$ ) goes into the PCon through port 3 pins 1 to 8 of the controller chip. The motion detection signal ( $P_{v4\_MDS}$ ) goes into the PCon through port 3 pins 12, 13, 14. The water level signal ( $P_{v1\_WLS}$ ) goes into the PCon through port 3 pins 15 and 16. The temperature control signal ( $P_{v2\_TCS}$ ) goes into the PCon through pins 17. While the smoke signal ( $P_{v3\_SKS}$ ) goes in through pins 22 and 23. Fig. 7 shows the neuromorphic/schematic implementation described above.

## V. FEEDBACK SCHEDULING ALGORITHM

### A. Dynamic Stability Control

Dynamic stability was introduced using digital real-time scheduler architecture in Fig. 8. This is implemented in Algorithm I, and II. The scheduler links the internal feedback control loop structures synchronously. Also, it sets the error margin for the scheduler, observes the error deviation state, and dynamically adjusts the infinite process variables for stable optimization. Algorithm II shows the temperature optimization algorithm. The AC, lights, pumps, and other processes are continuously monitored for efficient power management. At each instance, a control API communication is triggered for remote transmission.

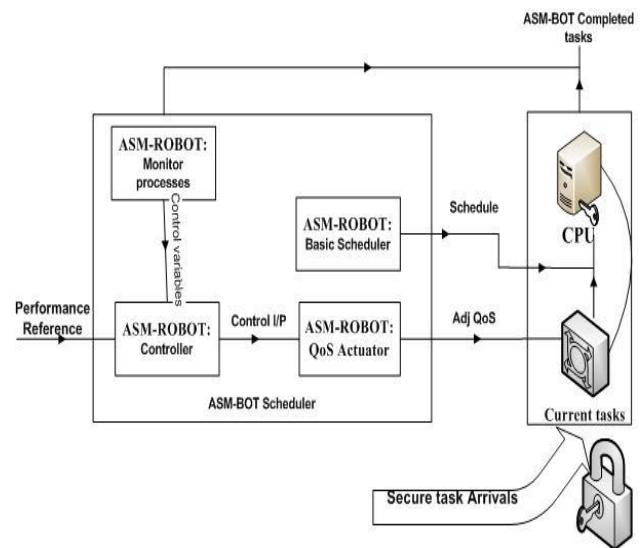

Fig. 8. MRASM-BOT Scheduler Architecture.

Internally, the deadline, estimated execution time, actual execution time, and baseline tasks are processed once the performance reference is set via initialization procedures. The MRASM-BOT captures the infinite process variables in the system and feeds samples to the controller. The controller makes comparisons between the performance reference and the controlled variables to ascertain immediate errors, and compute any error differential. The QoS actuator smartly adjusts the computed utilization at each sample scenario. The algorithm I demonstrate the optimization controls.

---

In the neuromorphic automation model, once the message is sent, the message is received by SMSC (SMS controller). This then reaches an appropriate device/interface. Recall that the process controller (*PCon*) interface for SMS in Algorithm I provides a path for transmitting control signals in full-duplex mode.

A simple algorithm for IoT-SMS communication in the smart automation model is given in Algorithm II.

---

**Algorithm II.** IoT SMS Event Stream

**Input:** Set PID Gains (x, y, z) // gain service provisioning  
Set feedback static scheduling

**Output:** Keypad, Smoke, Temperature, Roomlight, etc  
Set Pcon ON() // Set controller\_Monitor Active

*Do forever*  
*Begin* ()  
Step 1: Start  
Step 2: Process Controller Event initialization  
Step 3: Get Hardware Software  
Step 4: Poll SMS from AT Command for the Event  
Step 5: *If* abnormal condition at access layer sensor node, *then* go to step6 else, go to step1  
Step 6: Send SMS to mobile phone < Notify end-user >  
Step 7: Decode && Receive SMS based on Low BER  
Step 7: Check SMS pattern  
Step 8: Check Control device for own status  
Step 9: Take Corrective Action  
Step 10: Go to step1  
*Endif*  
End  
*end return*

**B. Reconfigurable Associative-Memory**

Recall from Table I, the memristive neuromorphic scenario is derived completely for all the machine states. The neuron circuitries with associative-memory-based reconfigurable neuromorphic (AMBRN) structure are implemented. In this case, learning and forgetting with associative memory dynamically reconfigures the circuit schematics. For this MRASM design, the design structure and its use-case are shown in Fig. 9.

Fig. 9. Neuromorphic System Structure.

In Fig. 9, the AMBRN system has the following entities: 1) Machine learning subsystem block for speeding up process controls; 2) associative memory mimicking subsystem; 3) synaptic circuit block, 4) control circuits. The technique of mimicking the associative learning and the remembrance processes between conditioned and unconditioned process variable signals achieves the activation function. The remembrance process allows the control circuits to activate or deactivate links to the synaptic circuits. These synaptic circuits implement ML optimization in the robot, though this is currently under investigation. It realizes the associative memory network for dynamic responses.

## VI. SPACE DIVERSITY CONTROL MODEL

### A. IoT RF Modulation Construction

In this research, an investigation into the design properties of IoT RF transceiver was carried out in [66] leading to the model for computing error performance by measurements in Fig. 10. The model accounts for:

- Receiver sensitivity with different error measures (BER, Error SNR).
- Modulator frequency and phase error.
- Timing error deviation of the IoT RF transceiver.

Considering Fig. 10, the MRASM digital modulation process encodes data stream information from the sensed sources and makes it suitable for transmission. The modulation technique transports available data stream message/signal via radio channel. Best transmission quality on an optimal radio spectrum is leveraged.

Let's now, consider the SMS message from the robot as:

$$\psi(t) = \beta \cos(\omega t + \theta) \rightarrow \text{Channel} \quad (1)$$

Where  $\psi(t)$  = data streams,  $\beta \cos(\omega t + \theta)$  is the modulation. It is key to note that modulation is achieved via amplitude ( $A = \beta$ ) variation, phase  $\theta$ , high-frequency carrier ( $\omega t$ ) per the amplitude of the data streams signal. Also, Complexity Minimum Shift Keying (CMSK) is used for IoT RF optimization. The reason is that it offers a uniform envelope, optimal spectral efficiency, excellent bit error rate.

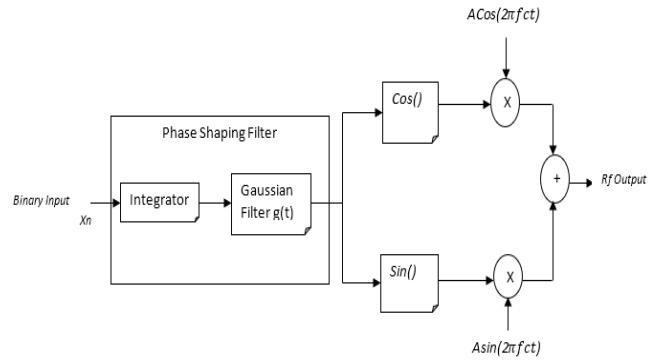

Fig. 10. MRASM IoT Modulation.

In context, the mathematical model for the modulated function  $X(t)$  is shown in (2).

$$x(t) = \text{Cos}(2\pi f_c + \phi(t)) \quad (2)$$

$$\phi(t) = 2\pi h \int_{-\infty}^{\infty} \sum_{k=-\infty}^{\infty} a_s s(\tau - kT) d\tau \quad (3)$$

### B. IoT GSMK Modulator

In the RF diversity design for MRASM-ROBOT in Fig. 10, complex IoT GSMK modulator/demodulator was used which has a Gaussian frequency shaping filter and key parameters from orthogonal space-time block code (OSTBC) transmission [66], sideband modulation [67], continuous phase modulation [68], GFSK Receiver [69], GSMK Pulse [70]. The scheme offers a continuous phase modulation (CPM) signal and has a modulation index  $h = 1/2$ . This means that the continuous phase shift function  $\theta(t)$  will have the complex baseband structure shown in (4).

$$\tau_{transmit}(t) = \beta \exp \sum_n^1 x_n \phi(t - nT) + \phi_0 \quad (4)$$

Where  $T$  is bit period,  $\beta$  is amplitude,  $X_n = \pm$  is the structural binary symbols,  $\phi_0$  is the random initial phase and  $\phi(t)$  is the phase shift function.

The unmodulated continuous-wave technique employed is robust and is not affected by signal fading and interference. Its spectral efficiency is optimal with slower/smooth phase changes. From Fig. 9, the IoT modulation signal is obtained through modulation and infusion of two quadrature carriers having frequency  $F_c$ . Phase changes are smoothed with a filter whose Gaussian impulse response is given by (5):

$$g(t) = \frac{1}{2T} Q \left( 2 \left( \pi B \frac{t - \frac{T}{2}}{\sqrt{\ln 2}} \right) \right) - Q \left( 2\pi B \frac{t + \frac{T}{2}}{\sqrt{\ln 2}} \right) \quad (5)$$

Where  $Q(t)$  is the Q-function given by (6):

$$Q(t) = \int_t^{\infty} \frac{1}{2\pi} \exp\left(-\frac{r^2}{2}\right) dr \quad (6)$$

and the phase shift function  $Q(t)$  in (1) is given by (7):

$$\phi(t) = \int_{-\infty}^t g(t) dt \quad (7)$$

In all, the IoT bandwidth and interference resistance parameters are controlled within space diversity by combination. The IoT modulation interface is shown in Fig. 11a. The source Bernoulli input is fed into the IoT RF

transmitter comprising convolutional encoding, data framing, interleaving, data burst, and cyclic redundancy checks (CRC). Also, its differential encoder with GMSK modulator is optimized for resilient transmission of process variables. The RF channel is constructed using additional white Gaussian noise (AWGN) and the Multipath Rayleigh fading. These were introduced for BER testing.

Similarly, the receiver the demodulation is derived from a decoder that has an isolated matched-filter, cyclic redundancy check, decoder, GMSK demodulation, differential-decoder, and reshape-optimizer. The receiver interface terminates with a BER/Error estimator sink.

In this work, BER is processed additive mapping, i.e., including source generated data with the demodulator output. Using GMSK modulation and demodulation processes in Fig. 11a leads to a stable but sensitive system. Form Fig. 10, the base BER is 0.03846 (i.e. less than 1). Hence, the system space diversity achieves absolute reliability as a transceiver unit.

In the MRASM-ROBOT, complex multiple-input multiple-output (MIMO) deployment especially in Rayleigh fading, can be determined.

Let's consider a complex IoT MIMO scenario with  $N_s$  Transmit antenna and  $N_d$  receive antennas, where  $N_s N_d \in \mathbb{Z}^+$ ,  $N_d > N_s$ , and  $N_d$  and  $N_s$  use huge values. The OSTB transmission for complex constellations in  $N_d * N_s$  MIMO system is derived from [66]. The MRASM-ROBOT channel matrix  $H \in \mathbb{C}^{N_d * N_s}$  can be computed from (8).

$$Y = HC + W \tag{8}$$

where  $C$  is the is code matrix, transmitted from transmitter and  $W$  is additive white Gaussian noise (AWGN) noise matrix.

By transforming (8) such that IoT OSTBC receiver combiner interface is shown in Fig. 11(b). The orthogonal code matrices  $C$ , decoder design are derived from [66]. The results for OSTBC are discussed later in Section VII.

Again, let's consider a single-IoT RF diversity design for which the signal received in (8) is the sum of the expected data stream signal and noise ( $W = n$ ) given by:

$$X = hu(t) + n \tag{9}$$

Where  $C = u(t)$  denotes IoT transmitted power signal.  $H = h$  denotes channel matrix with signal power.  $n$  the noise. The signal power sent out over a period,  $T_s$ , at nth element is given by (10).

$$P = \frac{1}{T_s} \int_0^{T_s} |h_n(t)|^2 |u(t)|^2 dt = |h_n(t)|^2 \frac{1}{T_s} \int_0^{T_s} |u(t)|^2 dt = |h_n(t)|^2, \tag{10}$$

Assuming slow fading due to small distance  $< 50m$ , the term  $|h_n(t)|^2$  will be kept constant for a period with an integral unit power  $E$ .

By letting  $E\{|h_n(t)|^2\} = \sigma^2$ , the instantaneous SNR at the  $n$ -th element ( $\gamma_n$ ) is given by (11).

$$\gamma_n = \frac{|h_n|^2}{\sigma^2} \tag{11}$$

The instantaneous SNR under channel matrix  $h_n$  is estimated such that noise power is obtained over a relatively short period  $T$ .

Given that Rayleigh fading is still possible over short-range, hence,  $h_n = [h_n]e^{j\angle h_n}$ , where  $\angle h_n$  is constant in  $(0, 2\pi)$ .  $[h_n]$  still has Rayleigh pdf, such that  $|h_n|^2$  and ( $\gamma_n$ ) has an exponential pdf given by (12).

$$[h_n] \sim \frac{2[h_n]}{P_0} e^{-|h_n|^2/P_0} \tag{12}$$

$$\gamma_n \sim \frac{1}{\Gamma} e^{-\gamma_n/\Gamma} \tag{13}$$

$$\Gamma = E\{\gamma_n\} = \frac{E\{|h_n|^2\}}{\sigma^2} = \frac{P_0}{\sigma^2} \tag{14}$$

Therefore, the instantaneous SNR at individual RF elements is exponentially distributed and  $r$  denotes the average SNR at each IoT element. This is also the SNR of a single element IoT RF antenna, i.e., the SNR with zero arrays. Hence,  $r$  is now the baseline for IoT RF SNR enhancement Fig. 11(b).

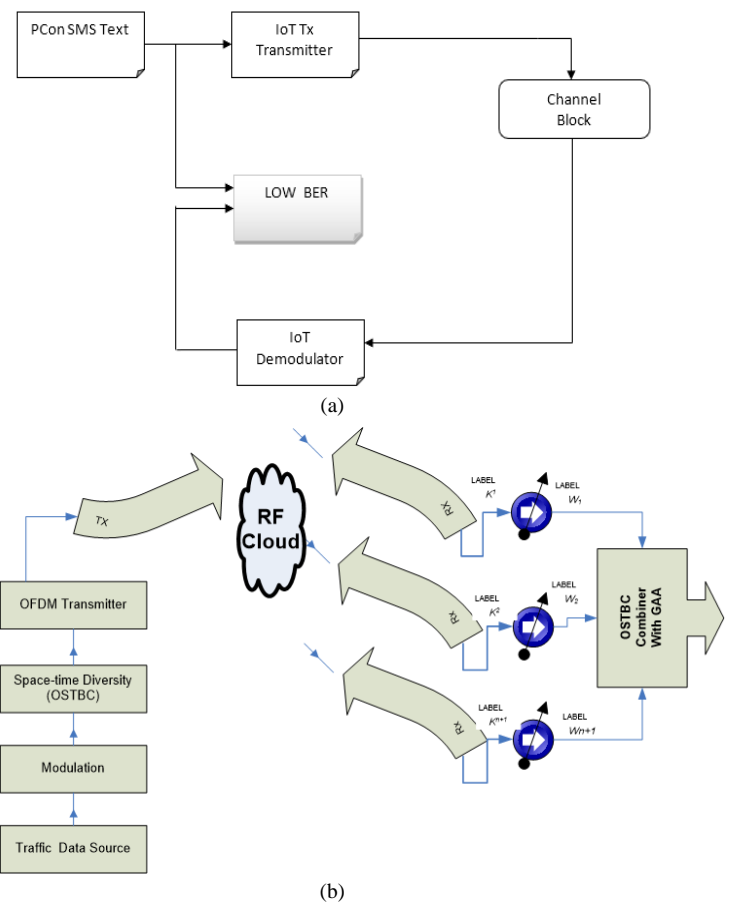

Fig. 11. (a) IoT Modulation Interface Model., (b). IoT OSTBC Receiver Combiner.

## VII. EXPERIMENTAL RESULTS

### A. MRASM-ROBOT Transmitter-Receiver Analysis

In this section, the experimental results to verify the proposed MRASM for the neuron control variables using space diversity theorems are presented. A brief discussion on the performance of the IoT CWDSPT scheme is highlighted. As a first step, C++ scripts was used to implement the control logic while MATLAB tool generated the plots. The implementation of the final version of the MRASM-ROBOT is currently undergoing packaging as a commercial off-the-shelf derivative.

For the IoT module, the receiver circuit is mapped at the carrier frequency  $FC = 2.4\text{GHz}$ . These schematics depict both embedded transmitter and receiver circuitry of the IoT module respectively. In Fig. 12a, the MRASM-ROBOT depicts the smart home automation and security system in an off-mode scenario. In Fig. 12b, the MRASM-ROBOT depicts the smart home automation and security system in the ON mode scenario.

### B. OSTBC Optimization Response

Recall in Section VI, the IoT GSMK Modulator was introduced. For process variables, the CWDSPT are affected by Multipath fading effects especially IoT RF interface that works with channel interference and AWGN. This paper introduced an enhanced layer 2 protocol called OSTBC. It is based on orthogonal frequency division multiplexing (OFDM) to suppress and enhance traffic frame delivery in the MRASM design. The OSTBC strategy in the receiver diversity block regulates efficient throughput by suppressing channel effects and recovering the transmitted signals.

Fig. 12 shows the error low pass filtering effect for noise reduction at receiving node while Fig. 13 shows the declining probability bit error rate (BER) under channel noise effect. These plots show the optimal capacity of the IoT CWDSPT scheme. This is because signal transmission and reception from other modules are achieved seamlessly.

The implication is that the MRASM-Robot supports process variable manipulation while reducing both the RF interference level (MRCSV) and (AWGN) for optimal performance.

Fig. 12. MRASM-ROBOT Error Deviation with IoT Nodes.

Based on data generated, the relationship model using the modulation technique for BER is depicted in Table II. BER graph was obtained considering the AWGN channel and multipath fading. The GSMK modulation technique in the AWGN channel has good performance as shown in Fig. 12. When the robot was placed in the Multipath Rayleigh channel, an increasing value of Doppler shift (Hz) is shown to be acceptable. The implication is that the system will perform poorly as the coverage distance of the robot RF terminal is increased. Moreover, the system performs average well since the BER is quite low for such short-range communication distance. The results for BER vs. SNR are summarized in Table III.

TABLE II. SIMULATION SPECIFICATION [71]

| Simulation Parameters    | Specifications                     |
|--------------------------|------------------------------------|
| Scenario                 | Macro-Cell, 7-Nodes B's (21Sector) |
| Bs-2-Bs Distance         | 2800m (Large), 100m & 10m          |
| Cell Radius              | 933m                               |
| Propagation Model        | OSTBC Space diversity              |
| Channel Profile          | Multipath fading +AWGN             |
| Modulation               | OFDM bank                          |
| Channel bandwidth        | 3.5MHz                             |
| OFDM Symbols per burst   | 2                                  |
| Cyclic Prefix Factor (G) | 1/8                                |
| Receiver Type            | OFDM Receiver                      |
| Max.Doppler Shift (Hz)   | 0.5                                |

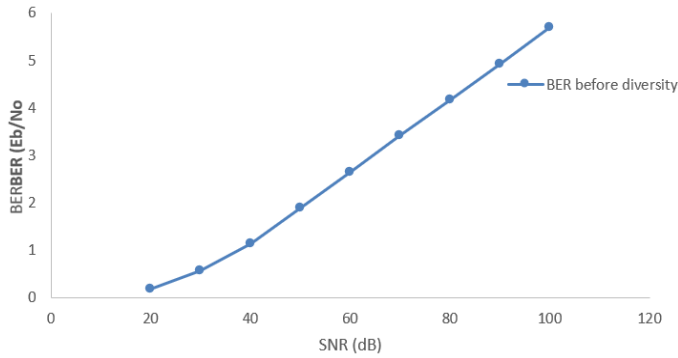

Fig. 14. MRASM-ROBOT BER before Diversity with IoT Nodes.

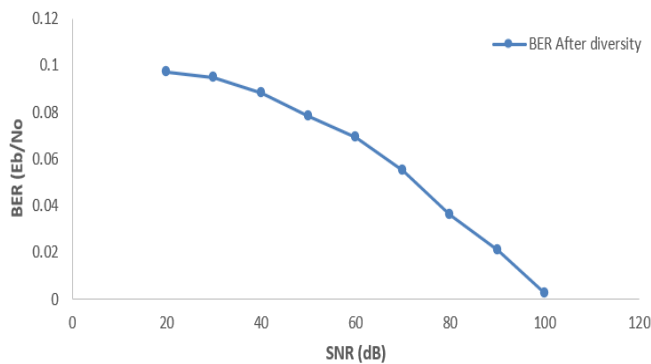

Fig. 15. MRASM-ROBOT BER after Diversity with IoT Nodes.

MRASM-ROBOT MIMO module is investigated for spatial diversity analysis since the robot communicates from a source to a sink always. The additive noise is varied with SNR. Space diversity analysis was carried out in Fig. 14 depicting ER before diversity and Fig. 1 denoting BER after diversity. Fig. 15 increases the reliability of the MRASM-ROBOT MIMO module. A second MRASM-ROBOT MIMO module (i.e., the IoT diversity antenna) below the first (i.e., the primary antenna) at each location of the MRASM-ROBOT having MIMO module will increase reliable connectivity.

Fig. 16, 17, 18, 19, and 20 shows that with the space diversity, the model will scale gracefully while offering better performance than the multipath fading schemes.

Under concurrent wireless data streams and power transfer, various space diversity simulation runs were executed and obtained polar graphs with different scenarios of CWDSPT (optimized and un-optimized). The analysis considered multipath channel fading effects in IoT RF interfaces. In the receiver diversity, with the channel interruptions, the plot no

OSTBC combiner is shown in Fig. 18 and 20. This leads to multipath fading channel issues and there is no memory stabilization since the OSTBC combiner block is absent. Fig. 19 and 21 depict highly optimized memory stabilization for the MRASM-ROBOT process variables. The optimization scenarios reflect the parametric sensitivities highlighted in Table III.

### C. CyberPhysical Home Automation Demonstration

Fig. 22 shows the MRASM-ROBOT demonstration (use case) for home automation and security control using the MK1000 controller. The different input interfaces for the access layer can be distinctly seen in Fig. 22. For the input/output Interface, the motion-controlled light is shown inside the simulated house. On sensing entrance, LDR inside the house checks for the ambient light. If it is not enough, the light comes on. Also, the counter is incremented, and the LCDs the number of persons inside the house. The purpose of the counter is to know when the room is no longer occupied so that the light will be turned off. Also, the Smoke occurrence scenario is captured while the simulated air conditioner is shown inside the system. In this case, the preset temperature is 22°C. Once the temperature reaches 22°C, the controller displays a high temperature and the air conditioner comes on. The temperature of the room is maintained at 22°C which can run in concurrent IoT Fog designs in complex environments [71], [72].

In Fig. 22, the output of the various neuron circuit linking the  $1, \dots, n+1$  input synaptic circuits is demonstrated on the virtual terminal. For a neuron circuitry having  $n$  input signal states, this will yield  $n+1$  synaptic output circuits corresponding to the input signal states. The various light conditions are monitored and controlled by the synaptic circuits. At the production settings, the smart home security module is implemented with a secured message digest 5 (MD5) password lock. If the input password is wrong on three trials, the controller will sound an alarm and the IoT module will send the message “security threat” to a dedicated number. In terms of the control system, the main control houses the RF triggered control system. It acts as a link between the input interface, control algorithm, and output interfaces. To verify, the design, different test plans were used and each sub-unit was tested before testing the entire system for validations. A temperature of 22°C was injected into the system while the module output changes from zero to 1.

So far, the proposed MRASM-ROBOT uses Cyber-physical attributes such as diversity to propagate the process variables. Considering the low range coverage distance in Table IV, the proposed system offers relatively better BER, SNR, and high reconfigurability compared with existing works that leveraged OSTBC and HRSM-STBC. This is very

significant in IoT-powered neuromorphic robots. The CWDSPT signaling can then fix the complexity error reduction for telemetry data decoding.

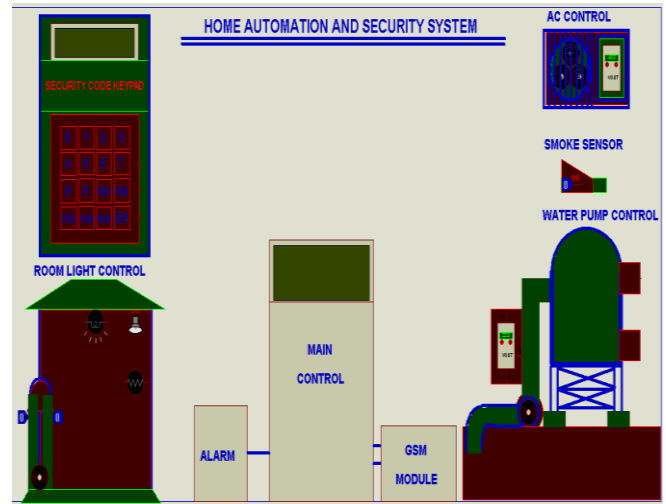

Fig. 20. MRASM-ROBOT (OFF Mode Scenario).

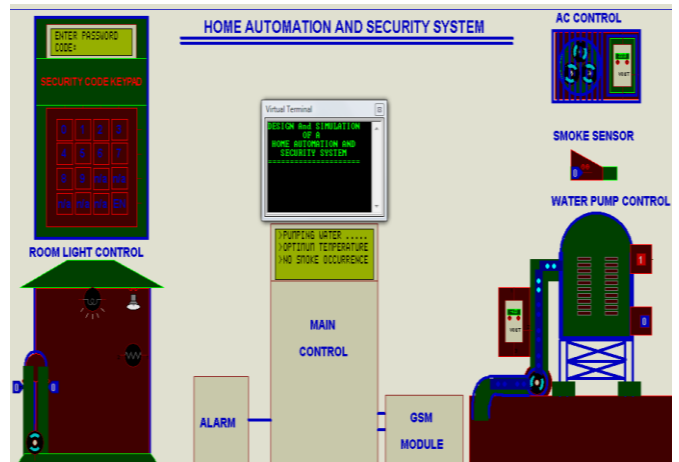

Fig. 21. MRASM-ROBOT (ON Mode Scenario).

Fig. 22. MRASM-ROBOT Neuron Circuit Control.

TABLE IV. DIVERSITY COMPARISON

| Schemes        | BER        | SNR   | Reconfigurability |
|----------------|------------|-------|-------------------|
| HRSM-STBC [21] | $10^{-5}$  | 5.7dB | High              |
| OSTBC [66]     | $10^{-10}$ | 15dB  | Moderate          |
| MRASM-ROBOT    | $9^{-2}$   | 4dB   | Very High         |

### VIII. CONCLUSION

This paper has presented MRASM-ROBOT as a smart home automation system for both security challenged and process-driven environments. The reconfigurable memristive control strategy was used in the synaptic schematics. Dynamic stability with an error-free feedback control loop was realized for design architecture. The CWDSPT was introduced and tested with the OSTBC-CB space diversity scheme. For the process variables, control signals are transmitted with unmodulated high-power continuous wave (CW) for interference minimization. The design offered lower bit error rates leading to minimal error deviation for short distances.

The integration of IoT transmitter and receiver circuit for the device-to-device communication was implemented considering space diversity link reliability. Hence, CWDSPT signaling was optimized for telemetry data decoding within the deployment domain. The work showed the optimization polar plots with the OSTBC-CB for memory stabilization.

Future work will focus on the use of FPGA, containerization, machine learning, and cloud provisioning to address massive scalability concerns under RF antenna diversity. Also, process variable automation such as light systems, air conditioners, overhead tanks, security doors, among others, will be managed with containers.
